This must option must be matched with one of the options $ifThen, $ifThenE or $ifThenI. For an example, see section Conditional Compilation with $ifThen and $else.

See also $ifThen and section Conditional Compilation.

$eolCom (!!!)

Syntax:

$eolCom char[char]

This option redefines and activates the end-of-line comment symbol, which may be one character or a sequence of two characters. By default, this is initialized to !!, but is not active. The option $onEolCom is used to activate the end-of-line comments. If $eolCom is used, $onEolCom is set automatically.

Example:

$eolCom //
Set i /1*2/ ;    // set declaration
Parameter a(i) ;  // parameter declaration

Here the character sequence // serves as the end-of-line-comment indicator.
Attention

It is not allowed to reset the end-of-line comment symbol to the current end-of-line comment symbol. This would cause an compilation error as in the following example:

```
$eolCom //
$eolCom //
```

Some end of line character settings can cause confusion. The widely used end of line character sequence `//` is also legal GAMS syntax in `put` statement to indicate two line breaks:

```
file fx; put fx;
put 'first line' // 'second line' //;
$eolCom //
put 'third line' // 'fourth line';
```

results in a put file with the following content:

```
first line
second line
third line
```

This can also confuse syntax highlighting in editors (or on this web page). Other popular end of line characters like `#` and `@` are also used as GAMS syntax, see [Controlling the Cursor On a Page](#).

See also section [Comments](#) for more about comments in GAMS.

**$error**

**Syntax:**

```
$error [text]
```

This option will issue a compilation error and will continue with the next line.

**Example:**

```
$if not exist myfile
$error File myfile not found - will continue anyway
```

Note that the first line checks if the file `myfile` exists. If the file does not exist, it will generate an error with the comment `File myfile not found - will continue anyway` and then the compilation will continue with the next line.

See also `$abort`, `$exit`, `$terminate`, and `$stop`.

**$escape**

**Syntax:**

```
$escape character
```
This option allows users to work with text sequences containing % without substitution.

This causes all subsequent commands of the form %symbol% to not have parameter substitution done for them. As a consequence, no parameter substitutions are performed in GAMS statements (mostly useful in display and put statements) and the outcome of such statements where %symbol% is used is just %symbol%.

Note that the effect of the option $escape may be reversed with the option $escape %.

Example:

```gams
$set tt DOIT
file it; put it;

display "first %tt%";
display "second %&tt%&";
put "display one ", "%system.date%" /;
put "display two " "%&system.date%&"/;

$escape &
display "third %tt%";
display "fourth %&tt%&";
put "display third ", "%system.date%" /;
put "display fourth " "%&system.date%&"/;

$escape %
display "fifth %tt%";
display "sixth %&tt%&";
put "display fifth ", "%system.date%" /;
put "display sixth " "%&system.date%&"/;
```

The output generated by the display statements follows:

```
---- 6 first DOIT
---- 7 second %&tt%&
---- 12 third DOIT
---- 13 fourth %tt%
---- 18 fifth DOIT
---- 19 sixth %&tt%&
```

The file it.put will contain the following lines:

```
display one 08/10/17
display two %&system.date%&
display third 08/10/17
display fourth %system.date%
display fifth 08/10/17
display sixth %&system.date%&
```

Note that this option was introduced to facilitate writing GAMS code (or command.com/cmd.exe batch scripts) from GAMS including unsubstituted compile-time variables. Text can also be written at compile-time without parameter substitution via option $on/offEchoV and at run-time via $on/offPutV.
Note

In GAMS the escape character follows the character (%) that needs to be escaped. In many other languages the escape character precedes the to be escaped character.

$eval

Syntax:

$eval VARNAME expression

This option evaluates a numerical expression at compile time and places it into a scoped compile-time variable. In turn the option $ifE may be used to do numeric testing on the value of this variable.

VARNAME is the name of a compile-time variable and expression is an expression that consists of constants, functions, operators and other compile-time variables with numerical values. Note that no whitespace is allowed in the expression which can be overcome by additional parentheses.

Example:

$eval b1 ifthen(uniform(0,1)<0.5,0,1)
$eval b2 ifthen(uniform(0,1)<0.5,0,1)
$eval b3 (%b1%)xor(%b2%)
$log b1=%b1% b2=%b2% b1 xor b2=%b3%

The first two lines use the uniform function to generate a random number between 0 and 1 and assign 0 if this number is less than 0.5 otherwise 1 via the ifthen function to the scoped compile-time variable b1 and b1. In the third line we apply the logical xor operator to b1 and b2 and store the result in b3. The parentheses are required because the more natural expression %b1% xor %b2% contains spaces. In the forth line we print the values and result to the log.

b1=1 b2=1 b1 xor b2=0

The expression are evaluated using IEEE nonstop arithmetic, so no evaluation errors are triggered as demonstrated in the following example:

$eval OneDividedByZero 1/0
$log 1/0=%OneDividedByZero%

This produces the following log:

1/0=+INF

The $eval and related dollar control options give access to a reduced set of GAMS functions: abs, card, ceil, cos, errorlevel, exp, fact, floor, frac, gamsrelease, gamsversion, gday, gdow, ghour, gleap, gmillsec, gminute, gmonth, gsecond, gyear, ifthen, jdate, jnow, jobhandle, jobkill, jobstatus, jobterminate, jstart, jtime, log, log10, log2, max, min, mod, numcores, pi, power, round, sameas, sign, sin, sleep, sqrt, sqrt, tan, trunc, and uniform. The available operators are: +, -, *, /, ** and even ^ (integer power) which is not available in regular GAMS expression and requires the use of the function ipower. The comparison relations are <, >, <=, >=, <>, and =. The logical operators are not, and, or, xor, imp, and eqv.

The expression also allows the use of dollar on the right. In the following example we replace the ifthen function by a dollar one the right:
Moreover, the `$eval` has access to data available at compile time. The expression can access the value of scalars and for other symbols we can use the `card` function to access the cardinality (at this point) of the symbol. Here is an example:

```gams
Scalar ac 'Avogadro constant' / 6.0221409e+23 /
$eval log_ac round(log10(ac))
$log round(log10(ac))=%log_ac%
Set d / d0*d%log_ac% /
$eval card_d card(d)
$log card(d)=%card_d%
```

Access to individual records of symbols is not possible. The embedded code facility allows access to symbol records at compile time.

The user has the possibility to hide some of the GAMS functions by symbols with the same name. In this case, the GAMS function can still be accessed, but needs to be prefixed with `system`. as in the following example:

```gams
Scalar pi /3/;
$eval myPi pi
$eval GAMSPi system.pi
$log myPi = %myPi%
$log GAMSPi = %GAMSPi%
```

This is the resulting output in the log:

```plaintext
myPi = 3
GAMSPi = 3.14159265358979
```

See also `$eval.Set`, `$evalGlobal`, `$evalLocal`, `$ifE`, and `$set`.

$eval.Set

**Syntax:**

```
```

This option evaluates an attribute of a GAMS set at compile time and places it into a scoped compile-time variable. `VARNAME` is the name of a compile-time variable and `SETID` is the identifier of a GAMS set. The following attributes are allowed in this context:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[First OR Last]TE</td>
<td>Explanatory text of the first or last element of the set SETID</td>
</tr>
<tr>
<td>[First OR Last]TL</td>
<td>Label of the first or last element of the set SETID</td>
</tr>
<tr>
<td>[First OR Last]TN</td>
<td>Set identifier with with element labels of the first or last element of the set SETID</td>
</tr>
<tr>
<td>TS</td>
<td>Explanatory text of the set SETID. This is also the default, if no attribute is specified</td>
</tr>
</tbody>
</table>
Note

- **First??** and ?? are synonyms in the table above. It always accesses the first element of the referenced set.
- **Last??** always accesses the last element of the referenced set.
- For **Singleton Sets** First??, Last?? and ?? are synonyms.

**Example:**

Singleton Set h Greeting / Hello , 'Welcome' /
Set p Person / Mr.President , 'Male'
Mrs.Chancellor , 'Female' /

$eval.Set X h.TE
$log %X%
$eval.Set X p.lastTL
$log %X%
$eval.Set X p.FirstTN
$log %X%

This will generate the following in the log:

Welcome
Mrs.Chancellor
p('Mr','President')

See also $eval, $evalGlobal.Set, $evalLocal.Set, and $set.

$evalGlobal

**Syntax:**

$evalGlobal VARNAME expression

This option evaluates a numerical expression at compile time and places it into a global compile-time variable. The syntax and behavior otherwise is identical to $eval.

$evalGlobal.Set

**Syntax:**

This option evaluates an attribute of a GAMS set at compile time and places it into a global compile-time variable. The syntax and behavior otherwise is identical to $eval.Set.

$evalLocal

**Syntax:**

$evalLocal VARNAME expression

This option evaluates a numerical expression at compile time and places it into a local compile-time variable. The syntax and behavior otherwise is identical to $eval.

$evalLocal.Set

**Syntax:**
$evalLocal.Set VARNAME SETID[.][First|Last]TE[.][First|Last]TL[.][First|Last]TN|TS

This option evaluates an attribute of a GAMS set at compile time and places it into a local compile-time variable. The syntax and behavior otherwise is identical to $eval.Set.

$exit

Syntax:

$exit

This option will cause the compiler to exit (stop reading) from the current file. This is equivalent to having reached the end of file.

Example:

Scalar a ;
a = 5 ;
display a ;
$exit
a = a+5 ;
display a ;

Note that the lines following the option $exit will not be compiled.

Observe that there is a difference to the dollar control option $stop. If there is only one input file, $stop and $exit will have the same effect. If the option $exit occurs within an include file, it acts like an end-of-file on the include file. However, if the option $stop occurs within an include file, GAMS will stop reading all input.

See also $abort, $error, $terminate, and $stop.

$expose

Syntax:

$expose all | ident1 ident2 ...

This option removes all privacy restrictions from identifiers.

With explicit identifiers the privacy restrictions are removed only for the listed identifiers and with all the restrictions are removed for all identifiers. The privacy restrictions may be set with the dollar control options $hide or $protect. Note that a special license file is needed for this feature to work and that the expose only takes effect in subsequent restart files. For further information, see chapter Secure Work Files.

$funcLibIn

Syntax:

$FuncLibIn InternalLibName ExternalLibName

This makes extrinsic function libraries available to a model. InternalLibName is the internal name of the library in the GAMS code and ExternalLibName is the name of the shared library in the file system. See Using Function Libraries for more information.

$gdxIn

Syntax:
$gdxIn [GDXFileName]

This option is used in a sequence to load specified items from a GDX file. Here GDXFileName denotes the name of the GDX file (with or without the extension .gdx) and the command opens the specified GDX file for reading. The use of $gdxIn without a file name closes the currently open GDX file. The command is used in conjunction with the option $load or one of its variants.

Example:

set i,j; parameters a(i), b(j), d(i,j), f;
$gdxIn mydata.gdx
$load i j a b d f
$gdxIn

See also $load, and $gdxOut.

$gdxLoad

Syntax:

$gdxLoad GDXFileName [sym1[,] sym2=gdxSym2[,] sym3=[=]gdxSym3[.dimI][,] ...]

This option loads symbols from a specified GDX file. It basically combines $gdxIn and $load in one call. This can be particularly useful for $[bat|lib]include files when you want to be sure, to not interfere with potentially previously opened GDX files. For example, a $load after a "$gdxLoad" will still load the symbols from the GDX file opened before:

$gdxIn A.gdx
$load a b c
$gdxLoad B.gdx d
* The following $load gets the symbols e, f, and g from GDX file A.gdx
$load e f g

See also $[on][off]Filtered, $[on][off]Multi, and $onMultiR.

$gdxOut

Syntax:

$gdxOut [GDXFileName]

This option is used in a sequence to unload specified items to a GDX file at compile time. Here GDXFileName denotes the name of the GDX file (with or without the extension GDX) and the command opens the specified GDX file for writing. The use of $gdxOut without a file name closes the currently open output GDX file and initiates the actual writing of the sequence of symbols. The command is used in conjunction with the dollar control option $unLoad.

Example:

set i /i1*i3/; parameters a(i) /i1 3, i2 87, i3 1/;
$gdxOut mydata.gdx
$unLoad i a
$gdxOut

See also $unLoad, and $gdxIn.

$gdxUnload
Syntax:

$gdxUnload GDXFileName [sym1[, sym2=gdxSym2[, ...]]

This option unloads symbols from a specified GDX file. It basically combines $gdxOut and $unload in one call. This can be particularly useful for $batlibinclude files when you want to be sure, to not interfere with potentially previously opened GDX files. For example, a $unload after a "$gdxUnload" will still unload the symbols to the GDX file opened before:

$gdxOut A.gdx
$unload a b c
$gdxUnload B.gdx d
* The following $unload puts the symbols e, f, and g into GDX file A.gdx
$unload e f g

$goto

Syntax:

$goto id
$label id

This option will cause GAMS to search for a line starting with $label id and then continue reading from there. This option can be used to skip over or repeat sections of the input files. In $batinclude files the target labels or label arguments can be passed as parameters because of the manner in which parameter substitution occurs in such files. In order to avoid infinite loops, jumps to the same label are restricted to a maximum of 100 times by default. This maximum may be changed with the option $maxGoto.

Example:

Scalar a ;
a = 5;
display a ;
$goto next
a = a+5 ;
display a ;
$label next
a = a+10 ;
display a ;

Note that GAMS will continue from line $label next after reading line $goto next. Observe that all lines in between are ignored. Therefore the final value of a in the example above will be 15.

Attention

The lines $goto and $label have to be in the same file. If the target label is not found in the current file an error will be issued.

See also $label, $maxGoto.

$hidden

Syntax:

$hidden text
A line starting with this option will be ignored and will not be echoed to the listing file. This
option is used to enter information only relevant to the person manipulating the file.

Example:

$hidden You need to edit the following lines if you want to:
$hidden
$hidden  1. Change form a to b
$hidden  2. Expand the set

The lines above serve as comments to the person who wrote the file. However, these comments
will not be visible in the listing file and are therefore hidden from view.

Note

This option is particularly useful when the input file is encrypted.

$hiddenCall

Syntax:

$hiddenCall [=}command

This option does the same as $call but the statement is neither shown on the log nor the
listing file.

$hiddenCall.Async[NC]

Syntax:

$hiddenCall.Async[NC] command

This option does the same as $call.Async[NC] but the statement is neither shown on the log
nor the listing file.

$hiddenCall.checkErrorLevel

Syntax:

$hiddenCall.checkErrorLevel [=}command

This option does the same as $call.checkErrorLevel but the statement is neither shown on the
log nor the listing file.

$hide

Syntax:

$hide all | ident1 ident2 ...

This option hides identifiers so they cannot be displayed or computed, but they may still be
used in model calculations (i.e. commands when the solve statement is executed).

With explicit identifiers the listed identifiers are hidden and with all all identifiers are hidden.
These restrictions may be removed with the dollar control options expose or purge. Note that
a special license file is needed for this feature to work.

For further information, see chapter Secure Work Files.
$\textit{if}$

\textbf{Syntax:}

\texttt{$\textit{if}$ [not] conditional\_expression new\_input\_line}

This dollar control option provides the greatest amount of control over conditional processing of the input file(s).

For more information on the \texttt{conditional\_expression} allowed, details on the \texttt{new\_input\_line} and examples, see section \textit{Conditional Compilation} below.

See also $\textit{ifE}$, $\textit{ifI}$, $\textit{ifThen}$.

$\textit{ifE}$

\textbf{Syntax:}

\texttt{$\textit{ifE}$ [not] conditional\_expression new\_input\_line}

This dollar control option does the same as the option $\textit{if}$ but allows constant expression evaluation. The \texttt{conditional\_expression} may take two different forms:

\begin{align*}
\text{expr1} &= \text{expr2} & \text{TRUE} & \text{if } (\text{expr1}-\text{expr2})/(1+\text{abs(}\text{expr2})) < 1\text{e-12} \\
\text{expr} &= \text{TRUE} & \text{if } \text{expr1} < 0
\end{align*}

\textbf{Example:}

Scalar \texttt{a};
\begin{align*}
&$\textit{ifE} \ (\log2(16)^2)=16 \quad a=0; \ \text{display a;} \\
&$\textit{ifE} \ \log2(16)^2 == 16 \quad a=1; \ \text{display a;} \\
&$\textit{ifE} \ \text{NOT round}(\log2(16)^2-16) \quad a=2; \ \text{display a;} \\
&$\textit{ifE} \ \text{round}(\log2(16)^2-16) \quad a=3; \ \text{display a;} \\
&$\textit{ifE} \ \text{round}(\log2(16)^2-17) \quad a=4; \ \text{display a;}
\end{align*}

This will create the following output:

\begin{align*}
{\text{----}} & \quad 3 \text{ PARAMETER a} & \quad = \quad 1.000 \\
{\text{----}} & \quad 4 \text{ PARAMETER a} & \quad = \quad 2.000 \\
{\text{----}} & \quad 6 \text{ PARAMETER a} & \quad = \quad 4.000
\end{align*}

See also $\textit{if}$ and section \textit{Conditional Compilation}.

$\textit{ifI}$

\textbf{Syntax:}

\texttt{$\textit{ifI}$ [not] conditional\_expression new\_input\_line}

This option is working like the option $\textit{if}$. The only difference is that $\textit{if}$ makes comparisons involving text in a case sensitive fashion while $\textit{ifI}$ is case insensitive.

See also $\textit{if}$ and section \textit{Conditional Compilation}.

$\textit{ifThen}$

\textbf{Syntax:}

\texttt{$\textit{ifThen}$ [not] conditional\_expression new\_input\_line}

This option is working like the option $\textit{if}$. The only difference is that $\textit{if}$ makes comparisons involving text in a case sensitive fashion while $\textit{ifThen}$ is case insensitive.

See also $\textit{if}$ and section \textit{Conditional Compilation}. 
$ifThen[E|I] \ cond
... 
{ $elsif[E|I] \ cond
... 
} 
[ $else 
... 
] 
$endif

This option is a form of the option $if that controls whether a number of statements are active. The syntax for the condition is generally the same as for the option $if. Like $if, it is case sensitive. Often it is followed by one or more of the following dollar control options: $else, $elsif, $elsifI, $elsifE. The option $ifThen must be matched with the option $endif that marks the end of the construct. An example is given in section Conditional Compilation with $ifThen and $else.

Note that users may add a tag to the $ifThen and $endif. For example, $ifThen.tagOne has to match with $endif.tagOne.

Example:

$ifThen.one \ x == y 
display "it1";
$elsif.one \ a == a 
display "it2";
$ifThen.two \ c == c 
display "it3";
$endif.two
$elsif.one \ b == b 
display "it4";
$endif.one

The resulting listing file will contain the following lines:

---- 2 it2
---- 4 it3

Note that the first condition (x == y) is obviously not true and the fourth condition (b == b) is not tested because the second condition (a == a) was already true.

See also $if, $ifThen, $ifThenI, $else, $elsif and section Conditional Compilation.

$ifThenE

Syntax:

$ifThen[E|I] \ cond
... 
{ $elsif[E|I] \ cond
... 
} 
[ $else 
... 
] 
$endif

This option does the same as the option $ifThen but evaluates numerical values of the control variables.

See also $ifThen and section Conditional Compilation.
$ifThenI

Syntax:

$ifThen[E|I] cond
...
{ $elseif[E|I] cond
...
}
[ $else
...
] $endif

This option does the same as the option $ifThen but it is case insensitive.

See also $ifThen and section Conditional Compilation.

$include

Syntax:

$include external_file

This option inserts the contents of a specified text file at the location of the call. Note that text files that have been compressed with Posix utility gzip or have been encrypted with tool ENDECRYPT are also allowed. External_file is the name of the file that is included. It can be quoted or unquoted. Note that include files may be nested.

The include file names are processed in the same way like the input file. The names are expanded using the working directory. If the file cannot be found and no extension is given, the standard GAMS input extension is tried. However, if an incomplete path is given, the file name is completed using the include directory. By default, the library include directory is set to the working directory. The default directory search path may be extended with the command line parameter InputDir.

Note that the start of the include file is marked and the include file is echoed to the echo print in the listing file. This reference to the include file may be omitted by using the option $offInclude.

Example:

$include myfile
$include "myfile"

Both statements above are equivalent and the search order for the include file is as follows:

1. myfile in current working directory
2. myfile.gms in current working directory
3. myfile and myfile.gms (in that order) in directories specified by the command line parameter InputDir.
Attention

The current settings of the dollar control options are passed on to the lower level include files. However, the dollar control options set in the lower level include file are passed on to the parent file only if the option $onGlobal is set.

Note that details on the compilation output of include files are given in section The Include File Summary.

See also $batInclude, $libInclude, $sysInclude.

$inlineCom (/ * */)

Syntax:

$inlineCom char[char] char[char]

This option redefines and activates the in-line comment symbols. These symbols are placed at the beginning and the end of the in-line comment and are one character or a two character sequence at the beginning and the end. By default, the system is initialized to '/*' and '*/*', but is not active. The option $onInline is used to activate the in-line comments. If $inlineCom is used, $onInline is set automatically.

Example:

$inlineCom {{ }}
Set {{ this is an inline comment }} i / 1*2 /;

Note that the character pairs {{ }} serve as the indicator for in-line comments.

Attention

It is not allowed to reset the option $inlineCom to the current symbol for in-line comments. This would cause a compilation error as in the following example:

$inlinecom {{ }}
$inlinecom {{ }}

Note

The option $onNestCom enables the use of nested comments.

See also section Comments.

$kill

Syntax:

$kill ident {ident}

This option removes all data for the identifiers ident, only the type and dimension are retained (this means that these identifiers will be declared but not defined anymore). Note that only the data of the following data types may be removed: sets, parameters, variables and equations. Note further that the data removal is carried out during compile time and not when the GAMS program executes.

Example:
Set i / 1*20 /;
Scalar a /2/;
$kill i a

Note that the effect of the third line above is that all data from \(a\) and \(i\) is removed, so the set \(i\) and the scalar \(a\) are declared, but not initialized or assigned to. Note that after \(i\) and \(a\) have been killed, a display statement for them will trigger an error. However, new data may be assigned to identifiers that were previously killed. Thus the following statements are valid if appended to the code above:

Set i / i1 *i3 /;
a = 7;

Observe that this option needs to be distinguished from the dollar control option $clear, that resets the data to the default values.

$label

Syntax:

$goto id
$label id

This option marks a line to be jumped to by a dollar control option $goto. Any number of labels may be used in files and not all of them need to be referenced. Re-declaration of a label identifier will not generate an error and only the first occurrence encountered by the GAMS compiler will be used for future $goto references.

Example:

Scalar a ;
a = 5 ;
display a ;
$goto next
a = a+5 ;
display a ;
$label next
a = a+10 ;
display a ;

When GAMS reaches the line $goto next, it continues from the line $label next. All lines in between are ignored. Therefore in the example above, the final value of \(a\) is 15.

Attention

If several dollar control options appear in one line and label is one of them, then label must be listed first.

See also $goto, $maxGoto.

$libInclude

Syntax:

$libInclude external_file {arg}
This option is mostly equivalent to the option $batInclude. However, if an incomplete path is given, the file name is completed using the library include directory. By default, the library include directory is set to the directory inclib in the GAMS standard locations. Note that the list of default directories searched may be prepended with the command line parameter libIncDir.

Example:

$libInclude abc x y

This call will first look for the include file inclib/abc in the standard locations. If this file does not exist there GAMS will look for the file inclib/abc.gms in the standard locations. The arguments x and y are passed on to the include file and are interpreted as explained in the detailed description of the option $batInclude.

See also $include, $batInclude, $sysInclude.

$lines

Syntax:

$lines n

This option starts a new page in the listing file if less than n lines are available on the current page.

Example:

$hidden Never split the first few lines of the following table
$lines 5
Table io(i,j) Transaction matrix
...
;

This will ensure that if there are less than five lines available on the current page in the listing file before the next statement (in this case, the table statement) is echoed to it, the contents of this statement are echoed to a new page.

$load

Syntax:

$load [sym1[,] sym2=gdxSym2[,] sym3<=[=]gdxSym3[,].dimI][,] ...]

This option is preceded and succeeded by the option $gdxIn that open the GDX file for reading. The option $load loads specified items from the GDX file. Note that more than one instance of $load may occur. A listing of the GDX file contents will be created if the option $load is not followed by arguments.

Examples

Consider the following example, where transsol is the GDX file of the transportation model [TRANSPORT]

$gdxIn transsol
$load
Sets i, j; Parameters a(i), b(j), d(i,j), f;
$load i j a b d f
$gdxIn
A comma between the symbols is optional. The follow example works identically:

```gams
$gdxIn transsol
$load
Sets i, j; Parameters a(i), b(j), d(i,j), f;
$load i, j, a, b, d, f
$gdxIn
```

The `$load` without any arguments produces a table of contents of the GDX container in the listing file:

```
Content of GDX C:\Users\default\Documents\gamsdir\projdir\transsol.gdx
5 UELs

<table>
<thead>
<tr>
<th>Number</th>
<th>Type</th>
<th>Dim</th>
<th>Count</th>
<th>Name</th>

</tbody>
</table>
```

Symbols may be loaded with new names with the following syntax: `$load i=gdx_i j=j.gdx`. The universal set may be loaded using `$load uni=*`.

```gams
$gdxIn transsol
Sets i, jj, uni; Parameters a(i), bb(jj), d(i,jj), f;
$load i jj=j uni=* a bb=b d f
$gdxIn
display uni;
```

This results in a display of all used labels:

```
---- 5 SET uni
Seattle , San-Diego, New-York , Chicago , Topeka
```

The syntax `sym<=[=]GDXSym.[dimI]` allows to load a one dimensional set from a symbol in the GDX file that has even a higher dimensionality. GAMS tries to find the set `sym` as a domain in the symbol `GDXSym` and uses the labels from this index position (with `<` the first domain set from the right and with `<=` from the left). If no domain information is stored in the GDX file or the domain information does not match the suffix `.dimI` allows to pick a fixed index position.

In the following we work with a GDX file created by the following code:

```gams
set i / i1*i3 /, ii(i,i) / i1.i2, i2.i3 /;
execute_unloadDI 'ii', i, ii;
```

Now use use this GDX file to load the first and second index from `ii`:

```gams
set i, ii;
$gdxIn ii
* Load first index from ii as i
$load i<=ii i1<ii.dimI
display i, ii;
```
the display lists all labels from the first index of ii:

```
---- 5 SET i Domain loaded from ii position 1
 i1, i2
---- 5 SET i1 Domain loaded from ii position 1
 i1, i2
```

Now we match from the right and get the second index of ii:

```
set i, i2;
$gdxIn ii
* Load second index from ii as i
$load i<ii i2<ii.dim2
display i, i2;
```

The resulting listing file will contain the following lines:

```
---- 5 SET i Domain loaded from ii position 2
 i2, i3
---- 5 SET i2 Domain loaded from ii position 2
 i2, i3
```

This type of projection loading can be useful to extract the domain sets from a single parameter that is stored in a GDX file:

```
set i,j,k; parameter data(i,j,k);
$gdxIn data
$load i<data.dim1 j<data.dim2 k<data.dim3 data
```

Attention

Loading an item that was already initialized will cause a compilation error.

For example, the following code snippet will cause a compilation error:

```
Set j / 1*5 /;
$gdxIn transsol
$load j
$gdxIn
```

Note that GAMS offers variants of `$load` that do not cause a compilation error in such a case: `$loadM` and `$loadR`.

**$loadDC**

**Syntax:**

```
$loadDC [sym1[, sym2=gdxSym2[, sym3<=[=]gdxSym3[.dim1][,] ...]]
```

This option is an alternative form of `$load`. It performs domain checking when items are loaded. Any domain violations will be reported and flagged as compilation errors. This is basically the opposite of `$loadFiltered`. All other features are the same as discussed under `$load`.

**Example:** Consider the following example where `transsol` is the GDX file of the transportation model `[TRNSPORT]`. 
Set i, j;
Parameter b(i), a(j);
$gdxIn transsol
$load i b
$loadDC j a
$gdxIn

Note that in contrast to the example above, the parameter a is indexed over the set i and the parameter b is indexed over the set j in the file transsol. While $load i b does not generate an error and b is just empty, the option $loadDC j a triggers a domain violation error because in transsol a is indexed over i and produces a list of errors in the listing file:

---  LOAD  a = 3:a
**** Unique domain errors for symbol a
  Dim  Elements
   1  seattle, san-diego

   5  $loadDC j a
****  $649

$loadDCM

Syntax:

$loadDCM [sym1[, sym2=gdxSym2[, sym3<=[=]gdxSym3[, dim1][,] ...]]

This option combines the functionality of merging as in $loadM and domain checking as in $loadDC.

Example:

Consider the following example where transsol is the GDX file of the transportation model [TRANSPORT].

Set i, uni 'all labels';
Parameter abFail(i), ab(uni) 'capacity and demand';
$gdxIn transsol
$load i abFail=a
$loadDCM abFail=b
$loadDCM uni=i uni=j ab=a ab=b
$gdxIn
display uni, ab;

Here we try to merge parameters a and b together into one parameter. The first attempt (to merge it into parameter abFail) would fail because of line 5 and result into a domain violation report as described with dollar control option $loadDC. In the second attempt we first merge the sets i and j into set uni and then merge the parameters a and b into ab. If one comments line 5 the resulting display looks as follows:

---  8 SET uni all labels
    seattle, san-diego, new-york, chicago, topeka

---  8 PARAMETER ab capacity and demand
    seattle 350.000, san-diego 600.000, new-york 325.000
    chicago 300.000, topeka 275.000

$loadDCR

Syntax:
$\text{loadDCR} \ [\text{sym1[,] sym2=gdxSym2[,] sym3=[=]gdxSym3[.dimI[,] \ldots]}$

This option combines the functionality of replacing data as in $\text{loadR}$ and domain checking as in $\text{loadDC}$.

Example:

Consider the following example where transsol is the GDX file of the transportation model [TRNSPORT].

Set uni 'all labels';
Parameter ab(uni) 'capacity and demand';
$\text{gdxIn transsol}$
$\text{loadM uni=i uni=j ab=a}$
$\text{loadDCR ab=b}$
$\text{gdxIn}$
display uni, ab;

Here we try to read twice into the parameter $ab$. First GDX symbol $a$ and $b$ are read into $ab$. GDX symbol $b$ is read with replace and hence the parameter $ab$ contains the elements of $b$ only.

$\text{loadFiltered}$

Syntax:

$\text{loadFiltered} \ [\text{sym1[,] sym2=gdxSym2[,] sym3=[=]gdxSym3[.dimI[,] \ldots]}$

This option is an alternative form of $\text{load}$, in particular, it works like $\text{load}$ while $\text{SonFiltered}$ is set. That means, when items are loaded, domain violations are not flagged as compilation errors, but items violating the domain definition are just filtered out. This is basically the opposite of $\text{loadDC}$. All other features are the same as discussed under $\text{load}$.

Example: Consider the following example where transsol is the GDX file of the transportation model [TRNSPORT].

Set i / seattle /
    j / new-york, chicago /;
Parameter a(i), b(j);
$\text{gdxIn transsol}$
$\text{loadFiltered a}$
$\text{loadDC} \ b$
$\text{gdxIn}$

While $\text{loadFiltered a}$ does not generate an error, but just ignores the data that does not match the defined domain, $\text{loadDC} \ b$ triggers a domain violation error.

See also $\text{loadFilteredM}$ and $\text{loadFilteredR}$.

$\text{loadFilteredM}$

Syntax:

$\text{loadFilteredM} \ [\text{sym1[,] sym2=gdxSym2[,] sym3=[=]gdxSym3[.dimI[,] \ldots]}$
This option combines the functionality of \textit{merging} as in \texttt{$loadM} and domain filtering as in \texttt{$loadFilterd}.

\textbf{Example:}

Consider the following example where \texttt{transsol} is the GDX file of the transportation model [\texttt{TRNSPORT}].

\begin{verbatim}
Set i, uni 'all labels';
Parameter abFilter(i), ab(uni) 'capacity and demand';
$gdxIn transsol
$load i abFilter=a
$loadFilteredM abFilter=b
$loadFilteredM uni=i uni=j ab=a ab=b
$gdxIn
Display uni, ab, abFilter;
\end{verbatim}

Here we try to merge parameters \texttt{a} and \texttt{b} together into one parameter. The first attempt (to merge it into parameter \texttt{abFilter}) does not add anything, since the elements in \texttt{b} do not match the defined domain \texttt{i} (compare \texttt{$loadFilterd}). In the second attempt we first merge the sets \texttt{i} and \texttt{j} into set \texttt{uni} and then merge the parameters \texttt{a} and \texttt{b} into \texttt{ab}. The \texttt{Display} statement produces the following output:

\begin{verbatim}
---- 31 SET uni all labels
  seattle, san-diego, new-york, chicago, topeka

---- 31 PARAMETER ab capacity and demand
  seattle 350.000, san-diego 600.000, new-york 325.000, chicago 300.000, topeka

---- 31 PARAMETER abFilter capacity of plant i in cases
  seattle 350.000, san-diego 600.000
\end{verbatim}

\texttt{$loadFilteredR}

\textbf{Syntax:}

\texttt{$loadFilteredR [sym1[,] sym2=gdxSym2[,] sym3=[\texttt{=}gdxSym3[].dimI][][,] \ldots]}

This option combines the functionality of \textit{replacing} data as in \texttt{$loadR} and domain filtering as in \texttt{$loadFilterd}.

\textbf{Example:}

Consider the following example where \texttt{transsol} is the GDX file of the transportation model [\texttt{TRNSPORT}].

\begin{verbatim}
Set uni 'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadFilteredM uni=i uni=j ab=a
$loadFilteredR ab=b
$gdxIn
Display uni, ab;
\end{verbatim}
Here we try to read twice into the parameter ab. First GDX symbol a and b are read into ab. GDX symbol b is read with replace and hence the parameter ab contains the elements of b only:

---- 31 SET uni all labels
seattle, san-diego, new-york, chicago, topeka

---- 31 PARAMETER ab capacity and demand
new-york 325.000, chicago 300.000, topeka 275.000

$loadM
Syntax:
$loadM [sym1[, sym2=gdxSym2[, sym3<=[gdxSym3[dimI][,] ...]]]

This option is an alternative form of $load. Instead of replacing an item or causing a symbol redefined error if the item was already initialized it merges the contents. Records that would result in domain violations will be ignored.

Example:
Consider the following example where transsol is the GDX file of the transportation model [TRNSPORT].

Set i, uni 'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadM uni=i uni=j ab=a ab=b
$gdxIn
display uni, ab;

Here we merge parameters a and b together into one parameter ab. We first merge the sets i and j into set uni and then merge the parameters a and b into ab. The resulting display looks as follows:

---- 6 SET uni all labels
seattle, san-diego, new-york, chicago, topeka

---- 6 PARAMETER ab capacity and demand
seattle 350.000, san-diego 600.000, new-york 325.000
chicago 300.000, topeka 275.000

$loadR
Syntax:
$loadR [sym1[, sym2=gdxSym2[, sym3<=[gdxSym3[dimI][,] ...]]]

This option is a variant of the option $load. With $loadR we can have multiple loads into the same symbols and the data stored in GAMS will be replaced with the one from the GDX container.

Example:
Consider the following example, where transsol is the GDX file of the transportation model [TRNSPORT]:

--- 31 SET uni all labels
seattle, san-diego, new-york, chicago, topeka

--- 31 PARAMETER ab capacity and demand
new-york 325.000, chicago 300.000, topeka 275.000

$loadM
Sets i / 1*3 /  
  j / 1*2 /;
$gdxIn transsol
$loadR i j
$gdxIn
display i, j;

The resulting listing file will contain the following lines:

---- 6 SET i canning plants
Seattle , San-Diego

---- 6 SET j markets
New-York, Chicago , Topeka

$log

Syntax:

$log text

This option will send a message text to the log file. Recall that by default, the log file is the console. The default log file may be reset with the command line parameters logOption and logFile.

Attention

• Leading blanks are ignored when the text is written out to the log file as a result of using the $log option.
• All special % symbols will be substituted before the text passed through the $log option is sent to the log file.

Example:

$log
$log The following message will be written to the log file
$log with leading blanks ignored. All special % symbols will
$log be substituted before this text is sent to the log file.
$log This was line %system.incLine% of file %system.incName%
$log

The log file that results by running the lines above will contain the following lines:

The following message will be written to the log file
with leading blanks ignored. All special % symbols will
be substituted before this text is sent to the log file.
This was line 5 of file C:\tmp\logTest.gms

Note that %system.incLine% is replaced by 5 which is the line number where the string replacement was requested. Note further that %system.incName% is substituted with the name of the file completed with the absolute path. Observe that the leading blanks on the second line of the example are ignored.

$macro

Syntax:

$macro name(arg1,arg2,arg3,...) macro_body
This option defines a macro in GAMS. Here \texttt{name} is the name of the macro, \texttt{arg1, arg2, arg3, ...} are the arguments and \texttt{macro body} defines what the macro should do. The macro names follow the rules for identifiers. The macro \texttt{name} cannot be used for other symbols. For further details and examples, see section Macros in GAMS below.

\texttt{\$maxCol \hspace{1em} (80001)}

\textbf{Syntax:}

\texttt{\$maxCol \hspace{0.5em} n}

This option restricts the valid range of input columns at the \textit{right} margin. Note that all input after column \texttt{n} is treated as comment, therefore it is ignored.

\textbf{Example:}

\texttt{\$maxCol 30}
\texttt{Set \hspace{1em} i / vienna, rome /; \hspace{1em} set definition}
\texttt{Scalar \hspace{0.5em} a / 2.3 /; \hspace{0.5em} scalar definition}

Observe that the text strings \texttt{set definition} and \texttt{scalar definition} are treated as comments and are ignored since they begin on or after column 31.

Any changes in the margins via \texttt{\$maxCol} or \texttt{\$minCol} will be reported in the listing file with the message that gives the valid range of input columns. For example, the dollar control option \texttt{\$minCol 20 \hspace{1em} \$maxCol 110} will trigger the following message:

\textbf{NEW MARGINS: 20–110}

\textbf{Note}

\begin{itemize}
  \item GAMS requires that the right margin set by \texttt{\$maxCol} is greater than 15.
  \item GAMS requires that the right margin set by \texttt{\$maxCol} is greater than the left margin set by \texttt{\$minCol}.
\end{itemize}

See also \texttt{\$on/offMargin} and section Comments.

\texttt{\$maxGoto 100}

\textbf{Syntax:}

\texttt{\$maxGoto \hspace{0.5em} n}

This option sets the maximum number of jumps to the same label and is used in the context of the options \texttt{\$goto} and \texttt{\$label}. Once the maximum number is reached a compilation error is triggered. Such a limit has been implemented to avoid infinite loops at compile time.

\textbf{Example:}

\texttt{Scalar \hspace{0.5em} a / 1 /;}
\texttt{\$maxGoto 5}
\texttt{\$label label1}
\texttt{a = a+10;}
\texttt{display a ;}
\texttt{\$goto label1}

Note that a compilation error is triggered if \texttt{\$goto label1} is called for the fifth time.

\texttt{\$minCol \hspace{1em} (1)
Syntax:

$\text{minCol } n$

This option restricts the valid range of input columns at the left margin. Note that all input before column $n$ is treated as comment, therefore it is ignored.

Example:

$\text{minCol 30}$

\begin{verbatim}
Set definition     Set  i / vienna, rome /;
Scalar definition  Scalar a / 2.3    /;
\end{verbatim}

Observe that the text strings set definition and scalar definition are treated as comments and are ignored since they are placed before column 30.

Any changes in the margins via the option $\text{maxCol}$ or $\text{minCol}$ will be reported in the listing file with the message that gives the valid range of input columns. For example, the dollar control option $\text{minCol 20 maxCol 110}$ will trigger the message:

NEW MARGINS: 20-110

Attention

GAMS requires that the left margin set by the option $\text{minCol}$ is smaller than the right margin set by the option $\text{maxCol}$.

See also $\text{on/offMargin}$ and section Comments.

$\text{[on][off]CheckErrorLevel (offCheckErrorLevel)}$

Syntax:

$\text{onCheckErrorLevel}$

$\text{offCheckErrorLevel}$

If the option $\text{onCheckErrorLevel}$ is active, the errorLevel is checked implicitly after $\text{call}$ and $\text{hiddenCall}$. A compilation error is triggered and the compilation is aborted if it is not 0. With $\text{offCheckErrorLevel}$, this is not done, but one can do it explicitly. So, with $\text{onCheckErrorLevel}$ $\text{call}$ behaves like $\text{call.checkErrorLevel}$ and $\text{hiddenCall}$ behaves like $\text{hiddenCall.checkErrorLevel}$.

$\text{[on][off]Delim (offDelim)}$

Syntax:

$\text{onDelim}$

$\text{offDelim}$

This option controls whether data in table statements may be entered in delimited format. As delimiter one can use ",", ",", or "TAB".

Example:
Sets  plant 'plant locations'  / NEWYORK, CHICAGO, LOSANGELES /  
       market 'demands'       / MIAMI, HOUSTON, PORTLAND    /;

Table dist(plant,market)  
$onDelim  
   ,MIAMI,HOUSTON,PORTLAND  
NEWYORK,1300,1800,1100  
CHICAGO,2200,1300,700  
LOSANGELES,3700,2400,2500  
$offDelim  
;  

Display dist;  

The resulting listing file will contain the following output:  

---- 12 PARAMETER dist  

<table>
<thead>
<tr>
<th></th>
<th>MIAMI</th>
<th>HOUSTON</th>
<th>PORTLAND</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEWYORK</td>
<td>1300.000</td>
<td>1800.000</td>
<td>1100.000</td>
</tr>
<tr>
<td>CHICAGO</td>
<td>2200.000</td>
<td>1300.000</td>
<td>700.000</td>
</tr>
<tr>
<td>LOSANGELES</td>
<td>3700.000</td>
<td>2400.000</td>
<td>2500.000</td>
</tr>
</tbody>
</table>

$[on][off]Digit  ($onDigit)  

Syntax:  

$onDigit  
$offDigit  

Historically, GAMS has run on widely different platforms where even the floating-point arithmetic varied. To ensure the precision specified in the GAMS input didn't exceed what could be stored and computed with as GAMS ran, we limited the precision (i.e. the number of significant digits used for numbers) that could be specified in the GAMS source. This limit could be relaxed by using the $offDigit control.  

Modern computers all support IEEE double-precision arithmetic, and GAMS uses this internally. It's a well-accepted and familiar standard, and the current behavior - to convert the decimal value in the GAMS source into the nearest double-precision value, regardless of the number of digits in the GAMS source - is what is generally expected. There is a limit (currently 40) on the number of digits treated as potentially significant: digits beyond this point are quietly treated as zero.  

The $offDigit control remains useful for changing how GAMS handles numbers with very large or small magnitude. With $onDigit, GAMS throws compiler warnings/errors for these values. With $offDigit, GAMS quietly converts them to UNDF or EPS, respectively.  

Example:  

scalar aboveTheLimit / 222e299 /;  
scalar tiny / 1.0e-275 /;  
scalar tinier / 1.0e-285 /;  
$offdigit  
scalar uberTheLimit / 222e299 /;  
scalar klein / 1.0e-275 /;  
scalar kleiner / 1.0e-285 /;
The resulting listing file will contain the following lines:

```
1 scalar aboveTheLimit / 222e299 /;
**** $106
2 scalar tiny / 1.0e-275 /;
**** $595
3 scalar tinier / 1.0e-285 /;
**** $594
5 scalar uberTheLimit / 222e299 /;
6 scalar klein / 1.0e-275 /;
7 scalar kleiner / 1.0e-285 /;
```

Error Messages

```
106 abs(number) out of range
abs(number) must be less than 1E300
   $offdigit can be used to replace large numbers with UNDF
594 Exponent very very small - rejected
   $offdigit can be used to replace with EPS
595 Exponent very small
   $offdigit can be used to quietly accept very small values
```

```
$[on][off]Dollar  ($offDollar)

Syntax:

$onDollar
$offDollar

This option controls the echoing of dollar control option lines in the listing file.

Example:

```
$hidden This line will not be displayed
$onDollar
$hidden This line will be displayed
$offDollar
$hidden This line will not be displayed
```

The compilation output of the resulting listing file will contain the following lines:

```
2  $onDollar
3  $hidden This line will be displayed
```

Note that all lines between the option $onDollar and the option $offDollar are echoed in the listing file. Note further that the effect of this option is immediate: the line $onDollar is echoed in the listing file, while the line $offDollar is not.

```
$[on][off]DotL ($offDotL)

Syntax:

$onDotL
$offDotL
```
This option activates or deactivates the automatic addition of the attribute .L to variables on the right-hand side of assignments and in put statement. It is most useful in the context of macros. For further information, see section Macros in GAMS below.

Example:

Consider the following code snippet which can be added to the end if the `TRNSPORT` model:

```gams
$onDotL
file fx; put fx;
loop((i,j),
   put / x(i,j)
);
$offDotL
file fx; put fx;
loop((i,j),
   put / x(i,j)
);
```

This is the generated output:

```
50.00
300.00
0.00
275.00
0.00
275.00
x('seattle','new-york')
x('seattle','chicago')
x('seattle','topeka')
x('san-diego','new-york')
x('san-diego','chicago')
x('san-diego','topeka')
```

First, we see the level for each x record. After setting `$offDotL` we are back at the default which means, that the .tn attribute is used implicitly.

$[on][off]DotScale ($offDotScale)

Syntax:

```
$onDotScale
$offDotScale
```

This option activates or deactivates the automatic addition of the attribute .Scale to variables and equations on the right-hand side of assignments and in put statements. As with on/offDotL It is most useful in the context of macros. For further information, see section Macros in GAMS below.

$[on][off]Echo[S][V][.tag]

Syntax:
This option is used to send one or more lines of text to an file external_file. The text and the file name may be quoted or unquoted. The external file is not closed until the end of the compilation or when the option $call$ or any variant of the option $include$ is encountered. Note that the redirection symbols $>$ and $>>$ have the usual meaning: $>$ creates a new file and writes to it or - in case there exists already a file with the respective name - overwrites the existing file and $>>$ appends to a file. Note further that parameter substitutions are permitted with $onEcho$. The option $onEcho$ has two more variants: $onEchoS$ and $onEchoV$. $onEchoS$ allows parameter substitutions like $onEcho$, so it is just a synonym which makes it more obvious that parameter substitution is allowed with the appended S. The option $onEchoV$ does not allow parameter substitutions but writes the text verbatim.

Example:

```
$set it TEST
$onEchoS > externalfile1.txt
send %it% to external file
line 2 to send
$offEcho

$onEchoV > externalfile2.txt
send %it% to external file
line 2 to send
$offEcho
```

The externalfile1.txt will contain the following lines:

```
send TEST to external file
line 2 to send
```

The externalfile2.txt will contain these lines:

```
send %it% to external file
line 2 to send
```

Observe that in the first case %it% is substituted with TEST, but in the second case there is no substitution.

Note that by default the external file will be placed in the current working directory if there is no path specified.

One may add a tag to the $onEcho[S|V]$ and $offEcho$. This allows to use nested echo blocks like this:

```
$onEcho.outer > outerFile.gms
$onEcho.inner > innerFile.txt
Line 1 of text
Line 2 of text
$offEcho.inner
$offEcho.outer
```

The resulting file outerFile.gms looks like this:
4.41 Dollar Control Options

$onEcho.inner > innerFile.txt
Line 1 of text
Line 2 of text
$offEcho.inner

See also options $echo, and $echoN.

$[on][off]ECImplicitLoad  ($onECImplicitLoad)

Syntax:

$onECImplicitLoad
$offECImplicitLoad

This option enables or disables the implicit loading of symbols set in embedded code sections, which are not loaded explicitly with $offEmbeddedCode.

Example:

Set i(*);

$offECImplicitLoad
$onEmbeddedCode Python:
i = ['a','b']
print(i)
gams.set("i", i)
$offEmbeddedCode

This will result in a compilation error, since i is set in the embedded code block (by gams.set("i", i)), but not loaded with $offEmbeddedCode. If $onECImplicitLoad would be active, $offEmbeddedCode would be treated like $offEmbeddedCode i here.

See also ECImplicitLoad.

$[on][off]Embedded  ($offEmbedded)

Syntax:

$onEmbedded
$offEmbedded

This option enables or disables the use of embedded values in parameter and set data statements. If enabled, the explanatory text for set elements is concatenated with blank separators. For parameters, the embedded values get multiplied.

Example:

Set k / a,b /
   l / a /;
Set   i(k,l) / a.a 'aaaa cccc dddd'
      b.a 'bbbb cccc dddd' /;
Parameter m(k,l) / a.a 12
      b.a 24 /;
$onEmbedded
Set   j(k,l) / (a aaaa, b bbbb).(a cccc) dddd /;
Parameter n(k,l) / (a 1, b 2) .(a 3) 4 /;
Note that the explanatory text of the set elements in $i$ and $j$ as well as the values of the parameters $m$ and $n$ are identical.

$\text{on/offEmbeddedCode[S|V][.tag]}$

Syntax:

$\text{onEmbeddedCode[S|V][.tag]} \text{Connect|Python: [arguments]}
\begin{align*}
\text{Embedded code} \\
\{\text{Embedded code}\}
\end{align*}

$\text{offEmbeddedCode[.tag]} \{\text{symbol}<[=]\text{embSymbol[.dimX]}\}

This option is used to execute one or more lines of embedded code (e.g. Python code) while GAMS stays alive. The embedded code has access to GAMS symbols and can read and change them.

Note that parameter substitutions are permitted with $\text{onEmbeddedCode}$. The option $\text{onEmbeddedCode}$ has two more variants: $\text{onEmbeddedCodeS}$ and $\text{onEmbeddedCodeV}$. $\text{onEmbeddedCodeS}$ allows parameter substitutions like $\text{onEmbeddedCode}$, so it is just a synonym which makes it more obvious that parameter substitution is allowed with the appended $S$. The option $\text{onEmbeddedCodeV}$ does not allow parameter substitutions but passes the code verbatim to the embedded code engine. The optional arguments given to $\text{onEmbeddedCode[S|V]}$ can be accessed in the Python code.

$\text{offEmbeddedCode}$ can be followed by a GAMS symbol or a list of GAMS symbols. If GAMS symbols are specified they get updated in the GAMS database after the embedded code got executed. The syntax $\text{symbol}<[=]\text{embSymbol[.dimX]}$ allows to load a one dimensional set from a symbol which was set in the embedded code that has even a higher dimensionality (here we call $<[=]$ the projection operator). GAMS tries to find the set symbol as a domain in the symbol embSymbol and uses the labels from this index position (with $<$ the first domain set from the right and with $<=$ from the left). If no domain information is stored in the GDX file or the domain information does not match the suffix .dimX allows to pick a fixed index position ($X$ needs to be replaced by the desired index position).

One may add a tag to the $\text{onEmbeddedCode[S|V]}$ and $\text{offEmbeddedCode}$. For example, $\text{onEmbeddedCode.tagOne}$ would match with $\text{offEmbeddedCode.tagOne}$.

Example:

    country
city
mccCountry(cc,country<) Mapping between country and related elements in set cc
mccCity(cc,city<) Mapping between city and related elements in set cc;

$\text{onEmbeddedCode Python:}$
mccCountry = []
mccCity = []
for cc in gams.get("cc"):  
r = str.split(cc, " - ", 1)  
mccCountry.append((cc,r[0]))  
mccCity.append((cc,r[1]))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
$\text{offEmbeddedCode mccCountry mccCity}$

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry, mccCity;
The data definition of the sets country and city happen while loading the set mccCountry and mccCity implicitly because of the implicit set definition in declarations of mccCountry and mccCity. Also note, that the list of output symbols does not need to be explicitly specified (for most embedded code engines). Performing the actual write in the embedded code (here via gams.set) is sufficient to signal GAMS to load the symbols. Providing an explicit list of symbols can be required (for embedded code engines without implicit loading) and be advantageous for code readability even for embedded code engines that support this. With the dollar control option $offECImplicitLoad providing an explicit list of output symbols can be enforced and setting symbols inside the embedded code not in the explicit list will lead to compilation errors.

The program above will result in the following listing file:

```
----  25 SET country
 Spain , USA , Germany, France
----  25 SET city
 Berlin, Bilbao, Cordoba, Madrid
 New York, Washington DC, Paris, Houston
 Munich, Lille, Seville, Bonn
Toulouse

----  25 SET mccCountry
 France - Paris .France
 France - Lille .France
 France - Toulouse .France
 Spain - Madrid .Spain
 Spain - Cordoba .Spain
 Spain - Seville .Spain
 Spain - Bilbao .Spain
 USA - Washington DC .USA
 USA - Houston .USA
 USA - New York .USA
 Germany - Berlin .Germany
 Germany - Munich .Germany
 Germany - Bonn .Germany

----  25 SET mccCity
 France - Paris .Paris
 France - Lille .Lille
 France - Toulouse .Toulouse
 Spain - Madrid .Madrid
 Spain - Cordoba .Cordoba
 Spain - Seville .Seville
 Spain - Bilbao .Bilbao
 USA - Washington DC .Washington DC
 USA - Houston .Houston
 USA - New York .New York
 Germany - Berlin .Berlin
 Germany - Munich .Munich
 Germany - Bonn .Bonn
```

Using the projection operator on the $offEmbeddedCode line the same task could be done like this:

```
Set cc / "France - Paris", "France - Lille", "France - Toulouse"
   "Spain - Madrid", "Spain - Cordoba", "Spain - Seville", "Spain - Bilbao"
   "USA - Washington DC", "USA - Houston", "USA - New York",
```
"Germany - Berlin", "Germany - Munich", "Germany - Bonn" /
country
city
mccCountry(cc,country)  Mapping between country and related elements in set cc
mccCity(cc,city)  Mapping between city and related elements in set cc;

$onEmbeddedCode Python:
mccCountry = []
mccCity = []
for cc in gams.get("cc"):
r = str.split(cc, " - ", 1)
mccCountry.append((cc,r[0]))
mccCity.append((cc,r[1]))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
$offEmbeddedCode
country<mccCountry city<mccCity

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry, mccCity;

Please note that due to implicit output symbol loading, see \$offECImplicitLoad, the symbols
mccCountry and mccCity are not only used to define country and city but are also loaded
into GAMS because the embedded code uses gams.set to write to these symbols.

See also chapter Embedded Code Facility for more details.

$[on][off]Empty  ($onEmpty)

Syntax:

$onEmpty
$offEmpty

Setting $onEmpty allows empty data statements for list or table formats. Note that by default,
empty data statements will cause a compilation error.

Example:

Set    i   / 1,2,3 /;
Set    j(i) / /;
Parameter x(i)  "empty parameter" / /;
Table    y(i,i)  "headers only"
    1    2    3
;
$onEmpty
Set    k(i) / /;
Parameter xx(i)  "empty parameter" / /;
Table    yy(i,i)  "headers only"
    1    2    3
;

The resulting listing file will contain the following lines:
Set i / 1,2,3 /;
Set j(i) / /;
**** $460
Parameter x(i) "empty parameter" / /;
**** $460
Table y(i,i) "headers only"
 1 2 3
;
**** $462
Set k(i) / /;
Parameter xx(i) "empty parameter" / /;
Table yy(i,i) "headers only"
 1 2 3
;

Error Messages

460 Empty data statements not allowed. You may want to use $ON/OFFEMPTY
462 The row section in the previous table is missing

Empty data statements are most likely to occur when data is being entered into the GAMS model by an external program. This problem may be overcome with the option $onEmpty.

Note

The empty data statement may only be used with symbols which have a known dimension. If the dimension is also derived from the data, the option $phantom should be used to generate 'phantom' set elements.

The option $onEmpty in conjunction with the option $onMulti and the save and restart feature may be used to set up a model and add data later.

$[on][off]End   ($offEnd)

Syntax:

$onEnd
$offEnd

This option offers an alternative syntax for flow control statements. The option $onEnd causes the following words to be regarded as keywords: do, endLoop, endIf, endFor and endWhile. They are used to close the language constructs loop, if, for and while respectively.

Example:

Note

The standard syntax is given as an end-of-line comment.

Set i / 1*3 /;
Scalar cond / 0 /;
Parameter a(i) / 1 1.23, 2 2.65, 3 1.34/;
$solCom //
$onEnd

loop i do
  // loop (i,
display a;
  // display a;
endLoop;

if (cond) then
    display a;
else
    a(i) = a(i)/2;
    display a;
endIf;

for cond = 1 to 5 do
    a(i) = 2 * a(i);
endFor;

while cond > 3 do
    a(i) = a(i) / 2;
    cond = cond-1;
endWhile;

Observe that the alternative syntax is more in line with the syntax used in some of the popular programming languages.

Attention

Setting the option $onEnd will make the alternative syntax valid, and at the same time it will make the standard syntax invalid. Therefore the two forms of the syntax will never be valid simultaneously.

$[on][off]EolCom ($offEolCom)

Syntax:

$_onEolCom$
$_offEolCom$

This option acts as a switch to control the use of end-of-line comments. Note that by default, the end-of-line comment symbol is set to !! but the processing is disabled.

Example:

$_onEolCom$
Set i /1*2/ ; !! set declaration
Parameter a(i) ; !! parameter declaration

Observe that after the option $_onEolCom$ has been specified, comments may be entered on the same line as GAMS code.

Note

The option $_eolCom$ automatically sets $_onEolCom$.

See also section Comments.

$[on][off]Eps ($offEps)

Syntax:
$onEps
$offEps

This option is used to interpret zero values as EPS when non-scalar parameters, variable attributes, or equation attributes are defined or loaded (e.g. from GDX or embedded code) at compile time. This can for example be useful if the value of zero is overloaded with existence interpolation.

See option zeroToEps for the execution-time equivalent.

Example 1:

Consider the following example where zero values are defined for a one dimensional parameter, once under $onEps and $offEps.

Set i / one, two, three, four /;
Parameter a(i) /
$onEps
  one 0
$offEps
  two 0
  three EPS /;
Display a ;

The outcome generated by the display statement follows:

---- 8 PARAMETER a
one     EPS, three EPS

Note that only those entries specifically entered as 0 are treated as EPS.

Example 2:

Consider the following example where zero values are loaded from a GDX file, once under $offEps (default) and $onEps (derived from test library model [ZEROTOEPS1]).

Set s,t;
Parameter p(s<,t<)
  pOnEps(s,t);
$gdxIn zeropar.gdx
$onText
P looks like this:
  t1   t2   t3
s1 0  0.843267
s2 0.224053 0.349831 0
s3 0  5
$offText
$load p
$onEps
$load pOnEps=p
display p, pOnEps;

The outcome generated by the display statement follows:
--- 15 PARAMETER p

<table>
<thead>
<tr>
<th></th>
<th>t1</th>
<th>t2</th>
<th>t3</th>
</tr>
</thead>
<tbody>
<tr>
<td>s1</td>
<td>0.843</td>
<td></td>
<td></td>
</tr>
<tr>
<td>s2</td>
<td>0.224</td>
<td>0.350</td>
<td></td>
</tr>
<tr>
<td>s3</td>
<td>5.000</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

--- 15 PARAMETER pOnEps

<table>
<thead>
<tr>
<th></th>
<th>t1</th>
<th>t2</th>
<th>t3</th>
</tr>
</thead>
<tbody>
<tr>
<td>s1</td>
<td>EPS</td>
<td>0.843</td>
<td></td>
</tr>
<tr>
<td>s2</td>
<td>0.224</td>
<td>0.350</td>
<td>EPS</td>
</tr>
<tr>
<td>s3</td>
<td>EPS</td>
<td>5.000</td>
<td></td>
</tr>
</tbody>
</table>

Example 3:

Consider the following example where zero values are loaded from embedded Python code, once under $offEps (default) and $onEps (derived from test library model [ZERO TO EPS1]).

Set s / s1*s3 /;
Parameter pEC(s)
  pECOnEps(s);
$onEmbeddedCode Python:
p = [(s1',1), (s3',0)]
gams.set('pEC',p)
$offEmbeddedCode pEC
$onEps
$onEmbeddedCode Python:
p = [(s1',1), (s3',0)]
gams.set('pECOnEps',p)
$offEmbeddedCode pECOnEps
display pEC, pECOnEps;

The outcome generated by the display statement follows:

--- 14 PARAMETER pEC

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
</table>
s1 1.000 |

--- 14 PARAMETER pECOnEps

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
</table>
s1 1.000, s3 EPS |

$[on][off]EpsToZero  ($offEpsToZero)

Syntax:

$onEpsToZero
$offEpsToZero
This option is used to write EPS values as zero when parameters, or variable and equation levels get written to GDX at compile time.

See option EpsToZero for the execution-time equivalent.

**Example:**

Usually GAMS squeezes out 0 values when writing to GDX. To get them written anyway, one can define them as EPS (e.g. by using $onEps) and set $onEpsToZero:

```plaintext
Set i / zero, one, two /;
$onEps
Parameter a(i) / zero 0
      one 1
      two 2 /;

$onEpsToZero
.gdxUnload 'zero.gdx' a
```

$[on][off]Expand ($offExpand)

**Syntax:**

$onExpand
$offExpand

This option changes the processing of macros that appear in the arguments of a macro call. The default operation is not to expand macros in the arguments. The switch $onExpand enables the recognition and expansion of macros in the macro argument list and $offExpand will restore the default behavior.

**Example:**

```plaintext
variable x(*,*);
$macro f(i) sum(q, x(i,q))
$macro equ(x) equation equ_&x; equ_&x.. &x =e= 0;
equ(f(i))
```

The macro expansion of the code above will result in an equation definition that reads as follows:

```plaintext
equation equ_f(I); equ_f(i).. f(i) =e= 0;
```

If we compile the code under $onExpand the argument f(i) is expanded before the macro equ() gets expanding resulting in the following (incorrect) code:

```plaintext
equation equ_sum(q, x(i,q)); equ_sum(q, x(i,q)).. sum(q, x(i,q)) =e= 0;
```

For further information, see section **Macros in GAMS** below.

$[on][off]ExternalInput ($offExternalInput)

**Syntax:**

$onExternalInput
$offExternalInput

$onExternalInput and $offExternalInput mark the beginning and end of a well defined section in which data is loaded implicitly from an external data source, namely from a GDX file specified by the command line parameter IDCGDXInput.
Note

- If none of the command line parameters `IDCGDXInput`, `IDCGenerateGDXInput`, `IDCJSON`, `IDCGenerateJSON`, or `IDCGenerateGDX` is set, nothing - but a few checks for consistency - will happen by setting `$onExternalInput` and `$offExternalInput`.
- If at least one of the before mentioned command line parameters is set, an additional license check will be triggered: Without the MIRO Connector License not more than 5 indexed symbols can be declared as external input or external output.

For symbols, which are declared, while `$onExternalInput` is active, data in data statements of the declaration is ignored. Instead, the data is loaded from the GDX file specified by `IDCGDXInput`. Also for those symbols, if they are referenced with `$load` or `$offEmbeddedCode` while `$onExternalInput` is active, the data is loaded from the GDX file specified by `IDCGDXInput` instead of the defined data source and symbol renaming as well as the projection operator are ignored in this case.

In addition, the following dollar control options are ignored, while `$onExternalInput` is active and `IDCGDXInput` is set:

- `$batInclude`
- `$call`
- `$call.Async[NC]`
- `$call.checkErrorLevel`
- `$gdxIn`
- `$hiddenCall`
- `$hiddenCall.Async[NC]`
- `$hiddenCall.checkErrorLevel`
- `$include`
- `$libInclude`
- `$onEmbeddedCode[S|V]` (including the following embedded code until `$offEmbeddedCode` is hit)
- `$sysInclude`

Example:

Let's look at a modified version of the simple example presented here:

Set
  i 'canning plants'
  j 'markets';

$onExternalInput
$call mdb2gms l=Sample.accdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
Parameter d(i<j) 'distance in thousands of miles' /
$include distances.inc
/;
$offExternalInput

display d;

Without setting a command line parameter, this runs in the same way as described in the other chapter, so by default, setting `$onExternalInput` and `$offExternalInput` does not make much of a difference. Now, let's run it with `IDCGDXInput` being set to `transsol`, which is a GDX file generated by running the transportation model `[TRNSPORT]`. There will be some new messages in the log:
First, we notice, that the file *transsol.gdx* will be opened for input. This happens implicitly with `$onExternalInput`. Then, both the `$call` as well as the `$include` lines were ignored, since we do not want to query the data source explicitly defined in the model, but the GDX file defined by IDCGDXInput. Note, that the data statement in the declaration of $d$ is actually empty when we ignore the `$include` statement. While `$onExternalInput` this does not lead to an error, but behaves as if `$onEmpty` was set. Looking at the output of the `display` statement in the lst file, one can see that the expected data was loaded:

```
----  13 PARAMETER d distance in thousands of miles

new-york  2.500  1.700  1.800
seattle    2.500  1.700  1.800
san-diego  2.500  1.800  1.400
```

If any of the options IDCGDXInput, IDCGDXOutput, IDCJSON or their Generate versions, e.g. IDCGenerateGDXInput, has been set, a MIRO connector license is required. See also `$[on][off]ExternalOutput`.

### `$[on][off]ExternalOutput` ($offExternalOutput)

**Syntax:**

```
$onExternalOutput
$offExternalOutput
```

$onExternalOutput and $offExternalOutput mark the beginning and end of a well defined section in which data is written implicitly to an external data file, namely to a GDX file specified by the command line parameter IDCGDXOutput or IDCGenerateGDXOutput.

**Note**

- If none of the command line parameters IDCGDXOutput, IDCGenerateGDXOutput, IDCJSON, IDCGenerateJSON, or IDCGenerateGDX is set, nothing - but a few checks for consistency - will happen by setting $onExternalOutput and $offExternalOutput.
- If at least one of the before mentioned command line parameters is set, an additional license check will be triggered: Without the MIRO Connector License not more than 5 indexed symbols can be declared as external output or external input.

**Example:**

This is a slightly modified code snippet of the transportation model [TRNSPORT]:

```
...$onExternalOutput
Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;
Variable
   x(i,j) 'shipment quantities in cases'
```
$offExternalOutput
z 'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
$onExternalOutput
cost 'define objective function'
$offExternalOutput
supply(i) 'observe supply limit at plant i'
demand(j) 'satisfy demand at market j';

Without setting a command line parameter, this runs in the same way as the original model, so by default, setting $onExternalOutput and $offExternalOutput does not make much of a difference. Now, let's run it with IDCGDXOutput being set to transOut.gdx. This generates the file transOut.gdx with the following content:

<table>
<thead>
<tr>
<th>Entry</th>
<th>Name</th>
<th>Type</th>
<th>Dim</th>
<th>Records</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>c</td>
<td>Parameter</td>
<td>2</td>
<td>6</td>
<td>transport cost in ...</td>
</tr>
<tr>
<td>2</td>
<td>x</td>
<td>Variable</td>
<td>2</td>
<td>5</td>
<td>shipment quantity</td>
</tr>
</tbody>
</table>

So, this implicit generation of the output file is basically equivalent to the following explicit statement:

execute_unload 'transOut.gdx', c, x, cost;

If any of the options IDCGDXInput, IDCGDXOutput, IDCJSON or their Generate versions, e.g. IDCGenerateGDXInput, has been set, a MIRO connector license is required.

See also $[on][off]ExternalInput.

$[on][off]Filtered  ($onFiltered)

Syntax:

$onFiltered
$offFiltered

This dollar control option controls how GAMS loads data from GDX with gdxLoad, $load, $loadR, and $loadM. With $onFiltered the $load* calls behave like $loadFiltered* calls. With $offFiltered the $load* calls behave like $loadDC* calls. This dollar control option also controls how GAMS loads symbols on the $offEmbeddedCode line. With $onFiltered data is read filtered while $offFiltered triggers a domain check of the data. The gams.set Python function allows to overwrite the setting of this dollar control option with the argument domCheck=DomainCheckType.CHECKED or domCheck=DomainCheckType.FILTERED.

$[on][off]Global  ($offGlobal)

Syntax:
When an include file is inserted, it inherits the dollar control options from the higher level file. However, the dollar control option settings specified in the include file do not affect the higher level file. This convention is common among most scripting languages or command processing shells. In some cases, it may be desirable to break this convention. This option allows an include file to change the options of the parent file as well.

Example:

```plaintext
$include 'inc.inc'
$hidden after first call to include file
$onGlobal
$include 'inc.inc'
$hidden after second call to include file
```

The file `inc.inc` contains the following lines:

```plaintext
$onDollar
$hidden text inside include file
```

The the echo print of the resulting listing file follows:

```
INCLUDE D:\GAMS\INC.INC
2 $onDollar
3 $hidden text inside include file
#include D:\GAMS\INC.INC
7 $onDollar
8 $hidden text inside include file
9 $hidden after second call to include file
```

Note that the dollar control option `$onDollar` inside the include file does not affect the parent file until `$onGlobal` is set. The text following the option `$hidden` is then echoed to the listing file.

$[on][off]IDCProtect  ($onIDCProtect)

Syntax:

```plaintext
$onIDCProtect
$offIDCProtect
```

This controls if symbols which are declared as external input can be changed at execution time. With `$onIDCProtect` external input symbols are protected from being changed; `$offIDCProtect` allows it.

The initial state of this can be set with the command line parameter `IDCProtect`.

$[on][off]Include  ($onInclude)

Syntax:

```plaintext
$onInclude
$offInclude
```
This option controls the listing of the expanded include file name in the listing file.

**Example:**

```
$include 'inc.inc'
$offInclude
$include 'inc.inc'
```

We assume that the file `inc.inc` contains the following lines:

```
$onDollar
$hidden Text inside include file
```

The resulting listing file will contain the following lines:

```
INCLUDE C:\tmp\inc.inc
2 $onDollar
3 $hidden Text inside include file
6 $onDollar
7 $hidden Text inside include file
```

Note that the include file name is echoed the first time the include file is used. However, the include file name is not echoed after `$offInclude` has been set. Also, the include file summary and the creation of an **Expanded Include File** is suppressed if `$offInclude` is set.

**$[on][off]Inline**  (**$offInline**)  

**Syntax:**

```
$onInline
$offInline
```

This option acts as switch to control the use of in-line comments. Note that by default, the in-line comment symbols are set to the two character pairs `/*` and `*/` but the processing is disabled. In-line comments may span several lines till the end-of-comment characters are encountered.

**Example:**

```
$onInline
Set i /* The default comment symbols are now
active. These comments can continue
  to additional lines till the closing
  comments are found. */ /i*i3 /;
```

Note

- The option `$inlineCom` automatically sets `$onInline`.
- *Nested* in-line comments are illegal unless the option `$onNestCom` is set.

See also section **Comments**.

**$[on][off]Listing**  (**$onListing**)  

**Syntax:**

```
```
This option controls the echoing of input lines to the compilation output of the listing file. Note that suppressed input lines do not generate entries in the symbol and reference sections that appear at the end of the compilation output. Lines with errors will always be listed.

Example:

```plaintext
Set i /0234*0237/
    j /a,b,c/ ;
Table x(i,j) "very long table"
    a b c
    0234 1 2 3
$offListing
    0235 4 5 6
    0236 5 6 7
$onListing
    0237 1 1 1
; 
```

The resulting listing file will contain the following lines:

```plaintext
1 Set i /0234*0237/
2    j /a,b,c/ ;
3 Table x(i,j) very long table
4    a b c
5 0234 1 2 3
10 0237 1 1 1
```

Note that the lines in the source file between the options `$offListing` and `$onListing` are not echoed to the listing file.

Note

For some projects the listing file can become huge and can take significant time to be written. This time can be saved by setting `$offListing` at the beginning of the input file and `$onListing` just before the parts one is interested in, or not at all, if one does not look at the listing file anyway.

$[on][off]Local ($onLocal)

Syntax:

$onLocal
$offLocal

The suffix `.local` attached to the name of a controlling set will use an *implicit alias* within the scope of the indexed operation or on the left-hand side of an assignment statement. This feature is particularly useful in the context of nested macros.

Example:

```plaintext
Set i /1*3/; alias(i,j);
Parameter xxx(i,j) / 1.1 1, 2.2 2, 3.3 3, 1.3 13, 3.1 31 /;
display xxx;

Parameter p(i);
p(i.local) = sum(j, xxx(i,j));
display p;
```
Note that in the assignment statement the set \( i \) on the right-hand side is controlled by \( i\.local \) on the left-hand side. Thus we have the following values for the two parameters:

\[
\begin{array}{ccc}
1 & 2 & 3 \\
1 & 1.000 & 13.000 \\
2 & 2.000 & \\
3 & 31.000 & 3.000 \\
\end{array}
\]

\[
\begin{array}{ccc}
1 & 2 & 3 \\
1 & 1.000 & 13.000 \\
2 & 2.000 & 3.000 \\
\end{array}
\]

In the example above, the suffix \( .local \) appeared one time on the left-hand side. The option \$onLocal \ allows the suffix \( .local \) to appear more than one time attached to the same symbol. Consider the following example that extends the example above:

Parameter \( g(i,i) \);
\( g(i\.local-1,i\.local) = xxx(i,i) \);
display \( g \);

Note that in the assignment statement of \( g \) the suffix \( .local \) attached to the set \( i \) appears two times on the left-hand side. The question arises whether the reference to the set \( i \) on the right-hand side refers to the first or the second instance of \( .local \) on the left-hand side. The assignment statement may alternatively be written in the following way using an explicit alias statement:

\[
\text{alias } (i,i1,i2);
\]
\( g(i1-1,i2) = xxx(i2,i2) \);

display \( g \);

Thus it becomes clear that the symbol on the right-hand side refers to the controlling index that enters last (here the second one). The output generated by the display statement follows:

\[
\begin{array}{ccc}
1 & 2 & 3 \\
1 & 1.000 & 2.000 & 3.000 \\
2 & 1.000 & 2.000 & 3.000 \\
\end{array}
\]

Observe that the multiple use of the suffix \( .local \) on the same symbol is considered an error with the option \$offLocal \.

Note that it is also allowed to combine the original index with an index suffixed with \( .local \). Consider the following alternative formulation:

\( g(i\.local-1,i) = xxx(i,i) \);

Note that in this case the index suffixed with \( .local \) takes precedence and the reference of \( i \) on the right-hand side refers to the index \( i\.local \) even though \( i \) is entered last. Observe that this statement even works with \$offLocal \ as the suffix \( .local \) appears only once.

See also section Macros in GAMS below.

\$[on][off]Log \ ($onLog$)

Syntax:

\$onLog
\$offLog
This option acts as a switch that controls logging information about the line number and memory consumption during compilation. This is scoped like the option $on/offListing applying only to included files and any subsequent included files but reverting to the setting $onLog in the parent files (if it was not changed there as well).

Example:

```
Set i /i1*i20000000/;
$include inc.inc
Set l /l1*l12000000000/;
```

The file inc.inc looks like this:

```
Set j /j1*j20000000000/;
$offLog
Set k /k1*k20000000000/;
```

The generated log will contain the following lines:

```
--- test.gms(1) 1602 Mb 5 secs
--- test.gms(2) 1602 Mb
--- inc.inc(1) 3122 Mb 6 secs
--- test.gms(3) 6161 Mb 14 secs
```

Note that the first line of both the parent and the include file got logged, but not the third line of the include file, after $offLog was set. The last line of the parent file got logged again.

$[on][off]Macro ($onMacro)

**Syntax:**

```
$onMacro
$offMacro
```

Enables or disables the expansion of macros defined by $macro.

**Example:**

```
$macro oneoverit(y) 1/y
$offMacro
y = oneoverit(x1);
display y;
```

causes an error because the macro oneoverit in line 3 can not be expanded.

$[on][off]Margin ($offMargin)

**Syntax:**

```
$onMargin
$offMargin
```

This option controls margin marking, that means if margins set by the options $minCol and $maxCol, should be marked in the lst file.

**Example:**
Now we have set i "plant" / US, UK /; This defines i
turned on the scalar x / 3.145 /; A scalar example.
margin marking. parameter a, b;
Define some
parameters.

The lst file will contain this:

2  Now we have | Set   i "plant" / US, UK /; | This defines i
3  turned on the | Scalar x / 3.145 /; | A scalar example.
4  margin marking. | Parameter a, b; | Define some
5                                   | parameters.

Note that any statements between columns 1 and 19 and any input beyond column 52 are
treated as comments. These margins are marked with | on the left and right.

See also section Comments.

$[on][off]Multi ($offMulti)

Syntax:

$onMulti
$offMulti

This option controls multiple data statements or tables. By default, GAMS does not allow
data statements to be redefined. If this option is activated the second or subsequent data
statements are merged with entries of the previous ones. Note that all multiple data statements
are performed before any other statement is executed.

Note

• There is also $onMultiR, which behaves similarly, but replaces existing data instead
  of merging into it. Compare the example here and there to see the difference.
• When $onMulti is active $load behaves like a $loadM.
• The initial state of this dollar control option can be set through the command line
  parameter multi.

Example:

Consider the following slice of code. The list after the end of line comment describes the
complete content of the symbol x after the data statement has been processed:

$eolCom //
set i / i1*i10 /;
parameter x(i) / i1*i3 1 / // /i1 1,i2 1,i3 1/
$onMulti
parameter x(i) / i7*i9 2 / // /i1 1,i2 1,i3 1,i7 2,i8 2,i9 2/
parameter x(i) / i2*i6 3 / // /i1 1,i2 3,13 3,14 3,15 3,16 3,17 2,i8 2,i9 2/
parameter x(i) / i3*i5 0 / // /i1 1,i2 3,16 3,17 2,i8 2,i9 2/
$offMulti
display x;

Note that the repeated parameter statements would have resulted in a compilation error
without the presence of the option $onMulti. The result of the display statement in the listing
file follows:
4.41 Dollar Control Options

---

8 PARAMETER x

1 1.000, 2 3.000, 6 3.000, 7 2.000, 8 2.000, 9 2.000

Note that \textit{x(\textquoteleft{i1\textquoteleft})} is assigned the value of 1 with the first data and is not affected by any of the subsequent data statements. \textit{x(\textquoteleft{i3\textquoteleft})} on the other hand is reset to 3 by the third data statement and wiped out with 0 in the fourth data statement.

\textbf{Attention}

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Dollar control options and data initialization are both done in the first pass and assignments in the second, irrespective of their relative locations. This is an issue particularly with the option \texttt{$onMulti} since it allows data initializations to be performed more than once. See section GAMS Compile Time and Execution Time Phase for details.

Consider the following example:

Scalar a /12/;
a=a+1;
\texttt{$onMulti}
Scalar a /20/;
display a;

Note that the two \texttt{scalar} data initialization statements and the option \texttt{$onMulti} are processed before the assignment statement \texttt{a=a+1}. As a result, the final value of \texttt{a} will be 21. The output of the display statement follows:

---

5 PARAMETER a = 21.000

Observe that the option \texttt{$onEmpty} in conjunction with the option \texttt{$onMulti} and the save and restart feature may be used to set up a model and add data later. See example in section Advanced Separation of Model and Data for details.

\texttt{$onMultiR/onMulti (\texttt{$offMulti})}

\textbf{Syntax:}

\texttt{$onMultiR}
\texttt{$offMulti}

This option controls multiple data statements or tables. By default, GAMS does not allow data statements to be redefined. If this option is activated the second or subsequent data statements replace the previous ones. Note that all multiple data statements are performed before any other statement is executed.

\textbf{Note}

- There is also \texttt{$onMulti}, which behaves similarly, but \textit{merges} into existing data instead of replacing it. Compare the example here and there to see the difference.
- In contrast to \texttt{$onMulti}, \texttt{$onMultiR} also allows to redefine an equation and a macro.
- The initial state of this dollar control option can be set through the command line parameter \texttt{multi}.

\textbf{Example:}

Consider the following slice of code. The list after the end of line comment describes the complete content of the symbol \textit{x} after the data statement has been processed:
Note that the repeated parameter statements would have resulted in a compilation error without the presence of the option $onMultiR. The result of the display statement in the listing file follows:

```
---- 9 PARAMETER x
      ( ALL       0.000 )
```

Note

- When using a redefinition with $onMultiR to remove elements from a set, which was used as domain of another symbol, also the dependent symbol gets reduced. This can happen through data statements, but also with $clear and $load/$loadDC.
- When $onMultiR is active $load behaves like a $loadR.

Example:

```
Set i /i1*i5/;
Parameter p(i) /#i 3/;
$onMultiR
Set i /i3*i6/;
Display p;
```

Looking at the output from the Display statement one can see, that the entries for i1 and i2 were removed by the second definition of i:

```
---- 7 PARAMETER p
i3 3.000,  i4 3.000,  i5 3.000
```

Attention

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Dollar control options and data initialization are both done in the first pass and assignments in the second, irrespective of their relative locations. This is an issue particularly with the option $onMultiR since it allows data initializations to be performed more than once. See section GAMS Compile Time and Execution Time Phase for details.

Consider the following example:

```
Scalar a /12/;
a=a+1;
$onMultiR
Scalar a /20/;
Display a;
```
Note that the two scalar data initialization statements and the option $onMultiR are processed before the assignment statement a=a+1. As a result, the final value of a will be 21. The output of the display statement follows:

```plaintext
---- 5 PARAMETER a = 21.000
```

Observe that the option $onEmpty in conjunction with the option $onMultiR and the save and restart feature may be used to set up a model and add data later. See example in section Advanced Separation of Model and Data for details.

### $[on][off]$NestCom  ($offNestCom$)

**Syntax:**

```plaintext
$onNestCom
$offNestCom
```

This option controls nested in-line comments. It makes sure that the open-comment and close-comment characters match.

**Example:**

```plaintext
$inlineCom { } onNestCom
{ nesting is now possible in comments { braces have to match } }
```

See also $inlineCom, $onInLine and section Comments.

### $[on][off]$Order  ($onOrder$)

**Syntax:**

```plaintext
$onOrder
$offOrder
```

Lag and lead operations and the ord function require the referenced set to be ordered and constant. In some special cases users might want to use those operations on dynamic and/or unordered sets. The option $on/offOrder has been added to locally relax the default requirements. The use of this option comes with a price, the system will not be able to diagnose odd and incorrect formulations and data sets.

**Example:**

```plaintext
Parameter p(t2);
$offOrder
p(t2) = ord(t2);
display t2,p;
```

Without the $offOrder the compilation of the line p(t2) = ord(t2); would have triggered a compilation error. The ordinal numbers assigned here are probably not what one expects. The element 1987 gets ordinal number 1 although it seems to be last last in the set. The ordinal numbers are assigned in the order the set is stored internally in GAMS. This order is also used when displaying the set t2:
---- 6 SET t2
---- 6 PARAMETER p
1987 1.000, 1983 2.000, 1984 3.000, 1985 4.000, 1986 5.000

$[on][off]Put[S][V][.tag]

Syntax:

File myputfile;
put myputfile;
$onPut[S|V][.tag]
{text}
$offPut[.tag]

The pair $onPut - $offPut causes a block of text to be placed in a put file at run-time. The is one of the few dollar control options that operate at run time. The $ in the first column usually indicates action at compile time.

Note that parameter substitutions are not permitted with $onPut. The option $onPut has two more variants: $onPutS and $onPutV. $onPutS allows parameter substitutions while the option $onPutV does not allow parameter substitutions, like $onPut, so it is just a synonym which makes it more obvious that the text is written verbatim with the appended V.

Example:

$set it TEST
File myputfile;
put myputfile;
$onPutS
Line 1 of text "%it%"
Line 2 of text %it%
$offPut

This code generates the put file myputfile.put with the following content:

Line 1 of text "TEST"
Line 2 of text TEST

Note that the compile-time variable %it% was replaced by TEST. However, if the option $onPutV is used instead, then %it% will not be substituted:

$set it TEST
File myputfile
put myputfile
$onPutV
Line 1 of text "%it%"
Line 2 of text %it%
$offPut

The resulting file myputfile.put will contain the following lines:

Line 1 of text "%it%"
Line 2 of text %it%
One may add a tag to the $onPut[S][V]$ and $offPut$. This allows to use nested put blocks like this:

```gams
File myputfile / outer.gms /;
put myputfile;
$onPut.outer
File myputfile;
put myputfile;
$onPut.inner
Line 1 of text
Line 2 of text
$offPut.inner
$offPut.outer
```

The resulting file `outer.gms` looks like this:

```gams
File myputfile;
put myputfile;
$onPut.inner
Line 1 of text
Line 2 of text
$offPut.inner
```

`$[on]offUpper ($offUpper)`

**Syntax:**

```gams
$onUpper
$offUpper
```

GAMS code echoed to the listing file is written in upper case after `$onUpper`. The default of mixed code echoing is restored with `$offUpper`.

**Note**

The default case of the echo print can be set using the command line option `case`.

**Example:**

```gams
Set
  i 'Canning plants' / seattle, san-diego /
  j 'Markets' / new-york, chicago, topeka /;
$onupper
Parameter
  a(i) 'Capacity of plant i in cases'
  / seattle 350
  san-diego 600 /
$offupper
  b(j) 'Demand at market j in cases'
  / new-york 325
  chicago 300
  topeka 275 /;
```

The generated listing file looks like this:
Set
  i 'Canning plants' / seattle, san-diego /
  j 'Markets' / new-york, chicago, topeka /;

PARAMETER
  A(I) 'CAPACITY OF PLANT I IN CASES'
    / SEATTLE 350
    SAN-DIEGO 600 /

  b(j) 'Demand at market j in cases'
    / new-york 325
    chicago 300
    topeka 275 /;

$[on][off]Recurse ($offRecurse)

Syntax:

$onRecurse
$offRecurse

This option controls whether it is permitted for a file to include itself.

Example:

The following GAMS program result in a recursive inclusion of the program itself:

$onRecurse
$include "%gams.input%"

Note that the maximum include nesting level is 40 and if it is exceeded an error is triggered.

In the following example that prints a string and then the reverse string the nesting level is less that 40 and one get some kind of recursion at compile time:

$onEchoV > reverse.gms
$ifthene %1=%3+1
  put ' ';
$ exit
$endif
loop(map(chars,code)$(code.val=ord("%2",%1)), put chars.tl:0);
$eval posPlus1 %1+1
$batInclude reverse %posPlus1% %2 %3
loop(map(chars,code)$(code.val=ord("%2",%1)), put chars.tl:0);
$offEcho

set chars / A*Z /, code / 65*90 /, map(chars,code) / #chars:#code /;
file fx /''/; put fx;
$onRecurse
$batInclude reverse 1 RACECAR 7
put /;
$batInclude reverse 1 LAGER 5

The log will print the following lines:
4.41 Dollar Control Options

--- Starting execution: elapsed 0:00:00.067
RACECAR RACECAR
LAGER REGAL
*** Status: Normal completion

$[on][off]StrictSingleton ($onStrictSingleton)

Syntax:

$onStrictSingleton
$offStrictSingleton

If the option $onStrictSingleton is active, a compilation error is triggered if a data statement for a singleton set contains more than one element. After activating the option $offStrictSingleton GAMS will take the first element of a singleton set that was declared with multiple elements as the valid element, the other elements are disregarded and there is no error. The option to control this behavior at runtime is strictSingleton.

Example:

The first element is not always the one that appears in the data statement first as the following example shows:

```gams
set i /1,2/
$offStrictSingleton
singleton set ii(i) /2,1/;
display ii;
```

The set ii contains the element 1 because it is the first in the GAMS label order as the display statements shows:

```gams
---- 4 SET ii

1
```

$[on][off]SuffixDLVars  ($onSuffixDLVars)

Syntax:

$onSuffixDLVars
$offSuffixDLVars

This option controls if it is allowed to use suffixes on variables with limited domains in a model. By default this is not allowed but this can be changed by setting $onSuffixDLVars.

Example:

```gams
Set n / n1*n100 /
   t / t1*t10 /
   sub(n,t) / #n:#t /;
Variable z, x(n,t);
Equation obj;

x.up(n,t) = uniformInt(7,13);
obj.. z =e= sum((n,t),x(n,t)/x.up(n,t));
Model m / all, x(sub) /;
Solve m min z use lp;
```
This causes the following error by default:

*** Problem in Model Generation: Variable "x" appears with suffix "Up".
*** Error at line 12: Cannot use domain limited variables with suffix in model - use $onSuffixDLVars

The purpose is to make the user aware of the fact, the she uses x.l, which would also be affected by the domain restriction of x(sub) in the model statement. So, if the user made sure, that this is all intended, setting $onSuffixDLVars before the solve statements overcomes this error. Though, with the example given here, this would actually lead to a "division by zero" error, since some x.up were excluded leaving a 0 as divisor.

See also related command line parameter SuffixDLVars.

$[on][off]SymList  ($offSymList)

Syntax:

$onSymList
$offSymList

This option controls whether the symbol listing map appears in the compilation output of the listing file. The symbol listing map contains the complete listing of all symbols that have been defined and their explanatory text. The entries are in alphabetical order and grouped by symbol type.

Example:

The symbol listing map generated by running [TRNSPORT] with $onSymList is as follows:

Symbol Listing

SETS

i   canning plants
j   markets

PARAMETERS

a   capacity of plant i in cases
b   demand at market j in cases
c   transport cost in thousands of dollars per case
d   distance in thousands of miles
f   freight in dollars per case per thousand miles

VARIABLES

x   shipment quantities in cases
z   total transportation costs in thousands of dollars

EQUATIONS

cost   define objective function
demand satisfy demand at market j
supply observe supply limit at plant i

MODELS

transport
This serves as a simple description of the symbols used in a model and may be used in reports and other documentation. For further information, see section The Symbol Listing Map.

$[on][off]$SymXRef  ($offSymXRef$)

Syntax:

$onSymXRef
$offSymXRef

This option controls the following:

- Collection of cross references for symbols like sets, parameters, variables, acronyms, equations, models and put files.
- Symbol cross reference report of all collected symbols in the compilation output of the listing file. For details, see section The Symbol Reference Map.
- Listing of all referenced symbols and their explanatory text by symbol type in listing file. This listing may also be activated with the option $onSymList$.

Example:

$onSymXRef
Set i / 1*6 /, k;
$offSymXRef
Set j(i) "will not show" / 1*3 /;
$onSymXRef
k('1') = yes;

The resulting listing file will contain the following symbol reference map and symbol listing map:

<table>
<thead>
<tr>
<th>SYMBOL</th>
<th>TYPE</th>
<th>REFERENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>i</td>
<td>SET</td>
<td>declared</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 defined</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2</td>
</tr>
<tr>
<td>k</td>
<td>SET</td>
<td>declared</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 assigned</td>
</tr>
<tr>
<td></td>
<td></td>
<td>6</td>
</tr>
</tbody>
</table>

SETS

i
k

Note that the set j does not appear in these listings because the listing was deactivated with the option $offSymXRef$ in line 3 of the code above.

$[on][off]$Text

Syntax:

$onText
$offText

The pair $onText - $offText encloses comment lines. Line numbers in the compiler listing are suppressed to mark skipped lines.

Example:
* Standard comment line
$onText
Everything here is a comment until we encounter the closing $offText like the one below
$offText
* Another standard comment line

The echo print of the resulting listing file will contain the following lines:

```
1  * Standard comment line
   Everything here is a comment
   until we encounter the closing $offText
   like the one below
7  * Another standard comment line
```

Attention
GAMS requires that every $onText has a matching $offText and vice versa.

See also section Comments.

$[on][off]UElList ($offUElList)

Syntax:

```
$onUElList
$offUElList
```

This option controls the complete listing of all set elements that have been entered in the compilation output of the listing file. For details see section The Unique Element Listing Map.

Example:

The unique element listing in the listing file generated by running the model [TRNSPORT] with $onUElList follows:

Unique Element Listing

Unique Elements in Entry Order

1 seattle san-diego new-york chicago topeka

Unique Elements in Sorted Order

1 chicago new-york san-diego seattle topeka

Note that the sorted order is not the same as the entry order. For more information, see section Ordered and Unordered Sets.

$[on][off]UElXRef ($offUElXRef)

Syntax:

```
$onUElXRef
$offUElXRef
```

This option controls the collection and listing of cross references of set elements in the compilation output. For more information, see section The Unique Element Listing Map.

Example:

Set i "set declaration" / one, two, three /, k(i);
$onUElXRef
k('one') = yes;
$offUElXRef
k('two') = yes;
$onUElXRef
k('three') = yes;

The resulting listing file will contain the following unique element reference report:

Unique Element Listing

ELEMENT REFERENCES

one index 3
three index 7

Note that the element two does not appear in this listing because the listing was deactivated with the option $offUElXRef in line 4 of the code above.

$[on][off]UNDF  ($offUNDF)

Syntax:

$onUNDF
$offUNDF

This option controls the use of the special value UNDF which indicates a result is undefined. For details see section Extended Range Arithmetic. By default, UNDF is not permitted to be used in assignments. This may be changed with the option $onUNDF.

Example:

Scalar x;
$onUNDF
x = UNDF;
Display x;

The output of the display statement follows:

---- 4 PARAMETER x = UNDF

Note that an error would have been triggered without the use of $onUNDF. The option $offUNDF will return the system to the default, where UNDF may not be used in assignments.

$[on][off]Uni  ($offUni)

Syntax:

$onUni
$offUni
This controls whether the compiler checks the referential integrity (see section Domain Checking) of the code. This is an essential part of good GAMS programming and it is highly recommend to declare symbols with proper domains. With the universe as a domain the compiler does not help the user with easy-to-make mistakes, like swapping indexes, \texttt{a(i,j)} versus \texttt{a(j,i)}. By default something like this would generate an error, if \texttt{a} was declared as \texttt{a(i,j)}. Such an error could be ignored, by setting \$onUni, which can be useful in few situations, when accessing a symbol with a set that is not the domain or a subset of the domain. For example, we could read data of a union of sets that already exist. We could use the universe as the domain for that symbol, but perhaps we need to protect the referential integrity of this symbol too.

**Example:**

```gams
Set fruit / apple, pear /
    veggie / carrot, pea /
    produce / #fruit, #veggie /;
Parameter produceCalories(produce) "per 100g" / apple 52, pear 57, carrot 41, pea 81 /
    fc(fruit) "calories per 100g"
    vc(veggie) "calories per 100g";
$onUni
fc(fruit) = produceCalories(fruit);
vc(veggie) = produceCalories(veggie);
$offUni
display fc, vc;
```

So when assigning \texttt{fc} we only access \texttt{produceCalories} with \texttt{fruit}. We could reverse the order of declaration of \texttt{fruit, veggie} and \texttt{produce} and use a proper subdomain, but sometimes data flow and input don't allow that.

**Attention**

When the GAMS compiler operates under \$onUni it treats all symbols as being declared over the universe. So all domain checking is gone. We can set elements in a symbols that normally can't be entered. This can also lead to strange effects:

```gams
set i / 1*2 /
    j / a,b /;
parameter pi(i);
$onuni
pi(j) = 1;
$offuni
* We will see elements from j in pi
display pi;
* The following should only clear the i-elements from pi, but it clears the
* entire symbol, because GAMS knows it's doing this to the entire domain and
* takes a shortcut.
p(i) = no;
display pi;
```

**$[on][off]Verbatim**

**Syntax:**

```
$onVerbatim
$offVerbatim
```

These options are used in conjunction with the GAMS command line parameter DumpOpt to suppress the input preprocessing for input lines that are copied to the dmp file. This feature is mainly used to maintain different versions of related models in a central environment.
Note

- The options $on/offVerbatim are only recognized for DumpOpt $\geq 10$ and apply only to lines in the file between the two options
- If $onVerbatim$ is active, DumpOpt = 11 behaves like DumpOpt = 21 (comments are kept)

Observe that the use of the options $goto$ and $on/offVerbatim$ are incompatible and may produce unexpected results.

Example:

```plaintext
$set f 123
$log %f%
$onVerbatim
$log %f%
$offVerbatim
$log %f%

The corresponding dmp file will contain the following lines:

$log 123
$onVerbatim
$log %f%
$offVerbatim
$log 123

See also command line parameter DumpOpt.
```

$[on][off]Warning  ($offWarning)

Syntax:

```
$onWarning
$offWarning
```

This option acts as a switch for data domain checking. In some cases it may be useful to accept domain errors in data statements that are imported from other systems and report warnings instead of errors. Data will be accepted and stored, even though it is outside the domain.

Attention

- This switch effects three types of domain errors usually referred to as error numbers 116, 170 and 171, see example below.
- This may have serious side affects and we recommend to exercise great care when using this feature.

Example:

```plaintext
Set i / one, two, three /
$onWarning
   j(i) / four, five /
   k / zero /;
Parameter x(i) "Messsed up Data" / one 1.0, five 2.0 /;
x('six') = 6;
x(j) = 10;
x('two') = x('seven');
j(k) = yes;
$offWarning
display i,j,x;
```
Note that the set \( j \), although specified as a subset of \( i \), contains elements not belonging to its domain. Similarly, the parameter \( x \) contains data elements outside the domain of \( i \). The skeleton listing file that results from running this code follows:

```plaintext
1 Set i / one, two, three /;
3     j(i) / four, five /
**** $170 $170
4 k / zero /;
5 Parameter x(i) "Messied up Data" / one 1.0, five 2.0 /;
**** $170
6 x('six') = 6; x(j) = 10; x('two') = x('seven');
**** $116,170
7 j(k) = yes;
**** $171
9 display i,j,x;
```

Error Messages

116 Label is unknown
170 Domain violation for element
171 Domain violation for set

**** 0 ERROR(S) 7 WARNING(S)

Execution

---- 9 SET i
one, two, three

---- 9 SET j
four, five, zero

---- 9 PARAMETER x Messied up Data
one 1.000, four 10.000, five 10.000, six 6.000

Observe that the domain violations are marked like normal compilation errors but are only treated as warnings and it is permitted to execute the code.

For an introduction to domain checking in GAMS, see section Domain Checking.

\$phantom id

Syntax:

\$phantom id

This option is used to designate id as a phantom set element. Syntactically, a phantom element is handled like any other set element. Semantically, however, it is handled like it does not exist. This is sometimes used to specify a data template that initializes the phantom records to default values.

Example:
$\text{phantom null}
\text{Set } i / \text{null } /
\qquad j / \text{a, b, null } /;
display i,j;

The output generated by the display statement is shown below:

\begin{verbatim}
---- 4 SET i
   ( EMPTY )
---- 4 SET j
   a, b
\end{verbatim}

Note that null does not appear in the listing file.

Attention

Statements that assign values to phantom labels are ignored.

Consider the following extension to the previous example:

$\text{Parameter } p(j) / \text{a 1, null 23 } /;
display p;

The output generated by the display statement is shown below:

\begin{verbatim}
---- 6 PARAMETER p
   a 1.000
\end{verbatim}

The system attribute system.empty is an implicitly defined phantom element. The following code works even without specifying $\text{phantom}$:

$\text{Set } i / \text{system.empty } /
\qquad j / \text{a, b, system.empty } /;
display i,j;

Another way to specify empty data statements makes use of on/offEmpty. The following example produces the same data as the data statement with the phantom label. In contrast to the example we $\text{phantom}$ we need to provide the dimensionality of the symbol $i$ explicitly via the $(*)$:

$\text{onEmpty}
\text{Set } i(*) / /
\qquad j / \text{a, b } /;
display i,j;

\$\text{prefixPath}

\text{Syntax:}

\$\text{prefixPath directoryPath}

This option augments the search path in PATH environment variable. The effect is that the text directoryPath is added to the beginning of the search path.

\text{Example:}
The log contains the following two relevant lines:

```
C:\Windows\system32;C:\Windows;C:\Windows\System32\Wbem;C:\Windows\System32\WindowsPowerShell\v1\Interacti
C:\somewhereelse\anotherpath;C:\Windows\system32;C:\Windows;C:\Windows\System32\Wbem;C:\Windows\System32\Window
```

The option `setEnv` and `%sysEnv.VARNAME%` allow to modify system environment variables but the length of the environment variable value is limited in GAMS to 255 characters. The `PATH` environment variable is often much longer and therefore this special `$prefixPath` option exists.

This works on all platforms but the path separator depends on the operating system (`;` for Windows and `:` for Unix).

### $protect

**Syntax:**

```
$protect all | ident1 ident2 ...
```

This option creates a privacy setting: it freezes all values of identifiers with the result that modifications are no longer allowed but the parameters may still be used in model calculation (for example, equation definitions). Here `ident1` and `ident2` are specific GAMS identifiers previously defined in the program and the keyword `all` denotes all identifiers.

Note that this option is mainly used in the context of **secure work files**. The privacy restrictions may be removed with the options `$expose` or `$purge`.

### $purge

**Syntax:**

```
$purge all | ident1 ident2 ...
```

This option removes the identifiers and all associated data in a privacy setting. With explicit identifiers the listed identifiers are removed, and with `all` all identifiers are removed.

Note that this option is used in the context of **secure work files**. A special license file is needed for this feature to work, the removal only takes effect in the restart files.

### $remark

**Syntax:**

```
$remark text
```

This option performs a parameter substitution and writes a comment `text` to the compilation output of the listing file. Note that the line numbers of the comment are suppressed.

**Example:**

```
$set it TEST
$remark Write %it% to the listing file
```

The resulting listing file will contain the following line:
Write TEST to the listing file

$scratchFileName

Syntax:

$scratchFileName VARNAME [fileStem]

This option establishes or redefines the content of a scoped compile-time variable that is accessible in the code where the command appears and all code included therein. Here VARNAME is any user chosen variable name; fileStem is optional and used to built the name for a file in the scratch directory with a scratch extension (unless an extension is set explicitly). If it is omitted, the system will make up a random file name.

So,

$scratchFileName fn abc

is equivalent to

$set fn %gams.scrDir%abc.%gams.scrExt%

Example:

* Set fileStem explicitly
$scratchFileName fn1 abc
$log %fn1%

* Omit fileStem
$scratchFileName fn2
$log %fn2%

The log will show:

C:\Data\tmp\225a\abc.dat
C:\Data\tmp\__sFN__-0_313342928588555.dat

See also $set and section Compile-Time Variables.

$set

Syntax:

$set VARNAME text

This option establishes or redefines contents of a scoped compile-time variable that is accessible in the code where the command appears and all code included therein. Here VARNAME is any user chosen variable name; text is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that scoped compile-time variables may be destroyed (removed from the program) with the option $drop.

Note that in contrast to the option $eval the option $set does not evaluate the expression at compile time.

Note that GAMS allows scoped, local and global compile-time variables to be defined with the same name and therefore in some cases needs to prioritize. When referencing a compile-time variable via %VARNAME% a local variable hides scoped and global variables and a scoped variable hides the global variable as the following example demonstrates.

Example:
\$setLocal myvar this is a local variable
\$set myvar this is a scoped variable
\$setGlobal myvar this is a global variable
\$log %myvar%
\$droplocal myvar
\$log %myvar%
\$drop myvar
\$log %myvar%

The log will look as follows:

this is a local variable
this is a scoped variable
this is a global variable

If one wants to set a compile-time variable in an include file that is visible to the program after the $include one need to use $setglobal:

\$onEchoV > setvar.gms
\$setArgs varname varvalue
\$setglobal %varname% %varvalue%
\$offEcho
\$batInclude setvar MYVAR one
\$log %MYVAR%

The log will show

one

An inventory of all defined compile-time variables and their type (local, scoped, and global) is available with the option $show.

See also $setGlobal, $setLocal, and section Compile-Time Variables.

$setArgs

Syntax:

$setArgs id1 id2 id3 ...

With this option parameters that may be substituted are defined as GAMS compile-time variables. Note that $setArgs may only be used in external files that are included with the option $batInclude, $libInclude, and $sysInclude.

Example:

Scalar a /2/, b /4/, c /5/;
\$batInclude test3 a b c

The file test3.gms contains the following lines:

Scalar x;
x = %1 + %2 * %3 ;
display x;
$setArgs aa bb cc
x = %aa% - %bb% * %cc% ;
display x;
x = %1 + %2 * %3 ;
display x;
The option $setArgs$ allows the batInclude file to use the more descriptive compile-time variables $%aa%$ instead of $%1$, $%bb%$ instead of $%2$ and $%cc%$ instead of $%3$. Note that the use of $%1$, $%2$ etc. is still allowed. The program listing looks as follows:

```plaintext
1 Scalar a /2/, b /4/, c /5/;
BATINCLUDE C:\Users\default\Documents\gams\projdir\test3.gms
3 Scalar x;
4 x = a + b * c ;
5 display x;
7 x = a - b * c ;
8 display x;
9 x = a + b * c ;
10 display x;
```

and the output generated by the display statements follows:

```
---- 5 PARAMETER x = 22.000
---- 8 PARAMETER x = -18.000
---- 10 PARAMETER x = 22.000
```

See also $set$, $batInclude$.

$setComps$

Syntax:

```
$setComps perioddelimstring id1 id2 id3 ...
```

This option establishes or redefines compile-time variables so they contain the components of a period delimited string.

Here `perioddelimstring` is any period delimited string like the set specification of a multi-dimensional parameter, `id1` is the name of a scoped compile-time variable that will contain the name of the set element in the first position, `id2` is the name of a scoped compile-time variable that will contain the name of the set element in the second position and `id3` is the name of a scoped compile-time variable that will contain the name of the set element in the third position. The items may be recombined back into the original filename string by using $%id1%.%id2%.%id3%$.

Example:

```
$setComps period.delim.string id1 id2 id3
$log id1=%id1%
$log id2=%id2%
$log id3=%id3%
$set name %id1%.%id2%.%id3%
$log name=%name%
```

The resulting log file will contain the following lines:

```
id1=period
id2=delim
id3=string
name=period.delim.string"
```

See also $set$. 

$setDDList[.Cont]$
Syntax:

\>$setDDList\Cont id1 id2 \ldots$
\>$setDDList \quad id3 id4 id5 \ldots$

This option causes GAMS to look for misspelled or undefined double dash GAMS parameters.

**Example**: Consider the following example where three double dash GAMS parameters are defined on the command line:

```
> gams mymodel.gms --one=11 --two=22 --three=33 --four=44
```

The corresponding GAMS file follows:

```
$log \%one\%
$log \%two\%
$setDDList three
$log \%three\%
$log \%four\%
```

Note that the option `$setDDList three` checks if all double dash parameters have been used so far except for three. An error is triggered because four has not been used so far, the log file will contain the following:

```
*** 1 double dash variables not referenced
   --four=44
```

$setDDList\Cont$ can be used to define a list of parameters to be checked over multiple lines. So, the following two examples do the same thing:

```
$setDDList one two three four
$setDDList\Cont one
$setDDList\Cont two three
$setDDList four
```

Note

$setDDList\Cont$ does not do anything without a $setDDList$ statement.

See also section Double Dash Parameters.

**$setEnv**

Syntax:

```
$setEnv \ VARNAME \ value
```

This option defines an operating system environment variable. Here \VARNAME\ is a user chosen environment variable name and value may contain text or a number. Note that system environment variables are destroyed (removed from the program) with the option `$dropEnv` or when GAMS terminates.

**Example:**
The following output is echoed to the log file:

--- Starting compilation
this is very silly
this is very silly

See also $dropEnv and section Environment Variables in GAMS.

$setGlobal

Syntax:

$setGlobal VARNAME text

This option establishes or redefines contents of a global compile-time variable that is accessible in the code where the command appears and all code included therein and all parent files. Here VARNAME is any user chosen variable name; text is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that global compile-time variables may be destroyed (removed from the program) with the option $dropGlobal.

The difference between local, scoped, and global compile-time variable is explained with the option $set.

See also $set, $setLocal, $dropGlobal and section Compile-Time Variables.

$setLocal

Syntax:

$setLocal VARNAME text

This option establishes or redefines contents of a local compile-time variable that is accessible only in the code module (source file) where it is defined. Here VARNAME is any user chosen variable name; text is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that local compile-time variables may be destroyed (removed from the program) with the option $dropLocal.

The difference between local, scoped, and global compile-time variable is explained with the option $set.

See also $set, $setGlobal, $dropLocal and section Compile-Time Variables.

$setNames

Syntax:

$setNames file filepath filename fileextension
This option establishes or redefines three scoped compile-time variables so they contain the
drive subdirectory, filename and extension of a file named with full path. Here file is any
filename, filepath is the name of a scoped compile-time variable that will contain the name
of the subdirectory where the file is located, filename is the name of a scoped compile-time
variable that will contain the root name of the file and fileextension is the name of a scoped
compile-time variable that will contain the extension of the file.

Example:

```
$setNames "%gams.input%" filepath filename fileextension
$set name %filepath%%filename%%fileextension%
$log %name%
```

The log will show

```
C:\Users\default\Documents\gamside\projdir\ Untitled_1 .gms
```

Note that file is separated into its three components placing C:\Users\default\Documents\gamside\projdir\ into filepath, Untitled_1 into filename and .gms into fileextension. The three items may
be recombined back into the original filename by using %filepath%%filename%%fileextension%
as shown in the example.

If the file is missing a path, name, or extension the corresponding variable is defined but
remains empty as demonstrated in the following example:

```
$onEchoV > showfileparts.gms
$setNames "%1" filepath filename fileextension
$log path=%filepath%
$log name=%filename%
$log ext=%fileextension%
$offEcho
$batInclude showfileparts "C:\tmp\"
$batInclude showfileparts "Untitled_1"
$batInclude showfileparts "Untitled_1.gms"
$batInclude showfileparts "Untitled_1.gms.txt"
```

The log shows:

```
--- Untitled_1.gms(7) 2 Mb
path=C:\tmp\name=
    ext=
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(8) 2 Mb
    path=
    name=Untitled_1
    ext=.
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(9) 2 Mb
    path=
    name=Untitled_1
    ext=.gms
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(10) 2 Mb
    path=
    name=Untitled_1
    ext=.txt
```
Note that if a file contains multiple . the last one will be assigned to the fileextension as shown in the example with Untitled_1.gms.txt.

$shift

Syntax:

$shift

This option is similar to the command.com/cmd.exe shift operator (see \url{en.wikipedia.org/wiki/COMMAND.COM::Batch}). It shifts the order of all parameters passed once to the left. This effectively drops the lowest numbered parameter in the list.

Example:

Scalar a, b, c ; a = 1 ;
$batInclude inc.inc a b c
display a, b, c ;

The batch include file inc.inc follows:

%2 = %1 + 1 ;
$shift
%2 = %1 + 1 ;

The resulting listing file will contains the following echo print:

1 Scalar a, b, c ; a = 1 ;
BATINCLUDE C:\Users\default\Documents\gamsdir\projdir\inc.inc
3 b = a + 1 ;
5 c = b + 1 ;
6 display a, b, c ;

Note that in the first statement in the include file, %1 is the first argument in the $batInclude call and in this case it is interpreted as a. %2 is the second argument in the $batInclude call and is interpreted as b. This leads to the overall assignment being interpreted as b=a+1. The dollar control option $shift shifts the arguments to the left. As a result, %1 is interpreted as b, and %2 is interpreted as c. This leads to the second assignment being interpreted as c=b+1.

Therefore the outcome generated by the display statement in the input file is as follows:

---- 6 PARAMETER a = 1.000
       PARAMETER b = 2.000
       PARAMETER c = 3.000

See also $batInclude.

$show

Syntax:

$show

This option causes current values of the compile-time variables plus a list of the macros and active input and include files to be shown in the compilation output, where "active" means, that $show was either directly in that file or that file is a parent that includes the file with $show.

Example:
$set it 1
$setLocal yy
$setGlobal gg what
$include myinclude
$macro addx(x) x+x
$show

The file myinclude.gms follows:

$set inincs
$setLocal inincsl
$setGlobal inincsg
$macro multx(x) x*x
$show

The resulting listing file will contain the following environment reports in the compilation output:

---- Begin of Active File List
Level Type Line Filename
----------------------------------
1 INCLUDE 5 C:\Users\default\Documents\gamside\projdir\myinclude.gms
0 INPUT 4 C:\Users\default\Documents\gamside\projdir\Untitled_1.gms
---- End of Active File List

---- Begin of Compile-time Variable List
Level SetVal Type Text
----------------------------------
1 inincsl LOCAL
1 inincs SCOPED
0 yy LOCAL
0 it SCOPED 1
0 gg GLOBAL what
0 inincsg GLOBAL
---- End of Compile-time Variable List

---- Begin of Macro List
$macro multx(x) x*x
---- End of Macro List

and

---- Begin of Active File List
Level Type Line Filename
----------------------------------
0 INPUT 6 C:\Users\default\Documents\gamside\projdir\Untitled_1.gms
---- End of Active File List

---- Begin of Compile-time Variable List
Level SetVal Type Text
----------------------------------
0 yy LOCAL
0 it SCOPED 1
0 gg GLOBAL what
0 inincsg GLOBAL
---- End of Compile-time Variable List

---- Begin of Macro List
$macro multx(x) x*x
$macro addx(x) x+x
---- End of Macro List
4.41 Dollar Control Options

Note that only the macros and the item defined with the option $setGlobal in the included file carries over.

If one needs only parts of this report, the dollar control options $showFiles, $showMacros and $showVariables can be used.

See also section Compile-Time Variables.

$showFiles

Syntax:

$showFiles

This option prints the active files to the lst file as described at $show.

$showMacros

Syntax:

$showMacros

This option prints a list of macros to the lst file as described at $show.

$showVariables

Syntax:

$showVariables

This option prints a list current values of the compile-time variables to the lst file as described at $show.

$single

Syntax:

$single

The lines following this option will be echoed single spaced in the compilation output. Note that this is the default. The option is only useful as a switch to deactivate the option $double.

Example:

Set i / 1*2 / ;
Scalar a / 1 / ;
$double
Set j / 10*15 / ;
Scalar b / 2 / ;
$single
Set k / 5*10 / ;
Scalar c / 3 / ;

The echo print in the resulting listing file will look as follows:
$splitOption

Syntax:

$splitOption KEYVALPAIR optname optvalue

Establishes or redefines two scoped compile-time variables so they contain the name and value of an option key/value pair specified in various formats. KEYVALPAIR is a string formatted as -opt=val or -opt val (instead of - one can also use /). optname is the name of a scoped compile-time variable that will contain the name of the option and optvalue is the name of a scoped compile-time variable that will contain the value of the option. This is useful in particular in combination with batInclude files.

Example:

$onechoV > myinclude.gms
* Default values for named arguments
$setGlobal a1 1
$setGlobal a2 2
$setGlobal a3 nothing
$setLabel positionalArgs
$splitOption "%1" key val
$ if x%key%==x $goto FinishProcessNamedArguments
$ ifThenI.NamedArguments %key%==a1
$ setGlobal a1 %val%
$ elseIfI.NamedArguments %key%==a2
$ setGlobal a2 %val%
$ elseIfI.NamedArguments %key%==a3
$ setGlobal a3 %val%
$ else.NamedArguments
$ error Unknown named argument "%key%"
$ endIf.NamedArguments
$ shift
$goto ProcessNamedArguments
$setLabel FinishProcessNamedArguments
$setGlobal positionalArgs %1 %2 %3
$offEcho
$batInclude myinclude "-a3=some things" -a2=3.14 i j k
$log Using named arguments a1:%a1% a2:%a2% a3:%a3% positionalArgs:%positionalArgs%<

Now when calling this piece of code as a batInclude one can specify optionally some named arguments (in any order) right after the name of the batInclude file and before the positional arguments as demonstrated by the log output:
Using named arguments a1:>1< a2:>3.14< a3:>some things< positionalArgs:>i j k<

stars (****)

Syntax:

\$stars char[char][char][char]

This option is used to redefine the **** marker in the GAMS listing file. By default, important lines like those that denote errors and the solver and model status are prefixed with ****. A new marker consists of one to four characters.

Example:

\$stars *###*
garbage

The resulting listing file follows:

2 garbage
### $140
### $36,299 UNEXPECTED END OF FILE (1)

Error Messages
36 '=' or '..' or ':=' or '$=' operator expected
rest of statement ignored
140 Unknown symbol
299 Unexpected end of file

$sTitle

Syntax:

$sTitle text

This option sets the subtitle in the page header of the listing file to text. Note that the next output line will appear on a new page in the listing file.

Example:

$sTitle Data tables for input/output

See also $title.

$stop

Syntax:

$stop [text]

This option stops program compilation without creating an error. Note there is a difference to the option $exit. If there is only one input file, $stop and $exit will have the same effect. In an include file the option $exit acts like an end-of file on the include file. However, the option $stop in an include file will cause GAMS to stop reading all input but continue the execution phase of the so far compiled program. The text followed by $stop is ignored.

Example:
$ifthen not set EXPORTEXCEL
  $ stop No export to Excel
$else
  $ call gdxxrw ...
$endif

See also $abort, $error, $exit, and $terminate.

$sysInclude

The syntax of this dollar control option is equivalent to the syntax of $batinclude:

Syntax:

$sysinclude external_file arg1 arg2 ...

However, if an incomplete path is given, the file name is completed using the system include directory. By default, the system include directory is set to the GAMS system directory. Note that the default directory may be reset with the command line parameter sysIncDir.

Example:

The only relevant include file in the GAMS system directory is mpsgeset for MPSGE models, see for example [HARMGE]:

$sysInclude mpsgeset KAMIYA

Note that this call will first look for the include file [GAMS System Directory]/mpsgeset. If this file does not exist, it will looks for [GAMS System Directory]/mpsgeset.gms. The argument KAMIYA is passed on to the include file and are interpreted as explained for the dollar control option $batInclude.

Consider the following example:

$sysInclude C:\Users\default\Documents\mpsgeset KAMIYA

This call will first look specifically for the include file C:\Users\default\Documents\mpsgeset and next for C:\Users\default\Documents\mpsgeset.gms.

See also $batInclude.

$terminate

Syntax:

$terminate [text]

This option terminates compilation and also does not execution to program compiled so far without giving an error.

Example:

$if set JUSTTERMINATE $terminate

See also $abort, $error, $exit, and $stop.

$title

Syntax:
$title text

This option sets the title in the page header of the listing file to text. Note that the next output line will appear on a new page in the listing file.

Example:

$title Production Planning Model
$sTitle Set Definitions

See also $sTitle.

$unLoad

Syntax:

$unLoad [sym1[, sym2=gdxSym2[, ..., symN]]]

This option unloads specified items to a GDX file. Note that $unLoad must be used in conjunction with the option $gdxOut: $gdxOut must precede $unLoad. More than one option $unload may appear in between. Symbols can be renamed via the sym=GDXSym syntax. A $unLoad without arguments unloads the entire GAMS database into the GDX file.

Example: Consider the following slice of code:

Sets i 'canning plants' / seattle, san-diego /
   j 'markets' / new-york, chicago, topeka / ;

Parameters
   a(i) 'capacity of plant i in cases'
      / seattle 350
      san-diego 600 /
   b(j) 'demand at market j in cases'
      / new-york 325
      chicago 300
      topeka 275 / ;

Table d(i,j) 'distance in thousands of miles'

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

$gdxOut tran
$unLoad i j=k
$unLoad b=dem a=sup
$unLoad d
$gdxout tranX
$unLoad

Note that the last lines will create a file named tran.gdx that contains i, j (now named k) and d and the parameters a and b which are now named dem and sup. The $unLoad in the very last line creates a GDX file tranX.gdx with all symbols (with their original names). The table of content (via $gdxIn and $load without parameters) of these two files looks as follows:
Both listings show domain information for the various symbols but only the file `tranX.gdx` created with `$unLoad` without arguments has consistent or full domain information while `tran.gdx` may have inconsistent or relaxed domain information. Domain matching when loading with the `$load sym<=[=]symGDX`, see `$load` for details, can be used in both cases but can become subtle with the relaxed domain information from `tran.gdx`.

Starting with GAMS 34 the behavior of `$gdxOut` and `$unload` changed compare to previous versions. In order to write consistent domain information and write aliases as such, the actual writing of the symbols to GDX is delayed until the GDX files is about to be closed either through an explicit `$gdxOut` (potentially with another filename) or through the end of the compilation phase. The advantage of the delayed writing is that the compiler can now better analyze the symbols and e.g. write alias symbols as aliases with the aliased set is also written to the GDX file (aliases were always written as sets before GAMS 34).

This new behavior can result in different GDX files. Here are two examples:

```
Set i /1,2,3/; Parameter p(i);
$gdxOut x.gdx
$unload
Parameter p(i) /1 1, 2 2, 3 3/;
```

In the GAMS versions before 34 the export GDX happened when the compiler processed the `$unload` command. At this point the parameter `p` did not have any data yet, so the GDX symbol `p` had no records. With the new behavior, the actual writing happens when the GDX file will be closed. Since there is no explicit close via a `$gdxOut` the GDX file is closed at the end of the compilation phase. By then the compiler has processed the statement `Parameter p(i) /1 1, 2 2, 3 3/;` and has filled `p` with data that will show up in the GDX file. In such a case an explicit `$gdxOut` after the `$unload` helps to get the old behavior back.

```
Set i /1,2,3/; Parameter p(i) / 1 1/;
$gdxOut x.gdx
$unload p=p1
$onmulti
Parameter p(i) / 2 2/;
$unload p=p2
```
In the GAMS versions before 34 the GDX file x.gdx contains two parameters p1 with record 1 1 and p2 with record 1 1, 2 2. With the new behavior the symbols are written again at the end of the compilation phase and by then the parameter p has the records 1 1, 2 2 and will write to GDX the parameters p1 and p2 with the two records each. The only way to accomplish the old behavior in this case is to write p1 and p2 to different GDX files:

Set i /1,2,3/; Parameter p(i) / 1 1/;
$gdxOut x1.gdx
$unload p=p1
$gdxOut x2.gdx
$onMulti
Parameter p(i) / 2 2/;
$unload p=p2

This delayed writing also influence other options like $onEpsToZero. The state of this becomes relevant when the file is actually written, not when a symbol is added to the list of symbols to be exported with $unload. This can be seen in the following example:

Set i / i1*i3 /;
Parameter p1(i) / i1 0, i2 EPS, i3 1 /
  p2(i) / i1 0, i2 EPS, i3 1 /;

$gdxOut out.gdx
$onEpsToZero
$unload p1
$offEpsToZero
$unload p2
$gdxOut

$call.checkErrorLevel gdxdump out.gdx

Here is the output from gdxdump at the end:

Parameter p1(*) /
  'i2' Eps,
  'i3' 1 /

Parameter p2(*) /
  'i2' Eps,
  'i3' 1 /

$use205

Syntax:

$use205

This option sets the GAMS syntax to the syntax of Release 2.05. This is mainly used for backward compatibility. New keywords have been introduced in the GAMS language since Release 2.05. Models developed earlier that use identifiers that have since become keywords will cause errors when run with the latest version of GAMS. This option will allow to run such models.

Example:

$use205
Set if /1.2.3/;
Scalar x ;
The word "if" is a keyword in GAMS that was introduced with the first version of Release 2.25. Setting option $use205 allows "if" to be used as an identifier since it was not a keyword in Release 2.05.

$use225

Syntax:

$use225

This option sets the GAMS syntax to the syntax of the first version of Release 2.25. This is mainly used for backward compatibility. New keywords have been introduced in the GAMS language since the first version of Release 2.25. Models developed earlier that use identifiers that have since become keywords will cause errors when run with the latest version of GAMS. This option will allow to run such models.

Example:

$use225
Set for /1.2.3/;
Scalar x ;

The word "for" is a keyword in GAMS that was introduced with the later versions of Release 2.25. Setting option $use225 allows "for" to be used as an identifier since it was not a keyword in the first version of Release 2.25.

$use999

Syntax:

$use999

This option sets the GAMS syntax to the syntax of the latest version of the compiler. Note that this setting is the default.

Example:

$use225
Set for /1.2.3/;
Scalar x ;
$use999
for (x=1 to 3, display x) ;

Note that the word "for" is used as a set identifier after setting the option $use225 and later the keyword for is used in a looping construct after having set the language syntax to that of the latest version using the option $use999.

$version

Syntax:

$version n

This issues a compilation error if n is greater than the current GAMS version. This can be useful to ensure that a model is run only with new versions of GAMS, because, e.g., a particular feature which did not exist in older versions is needed.

Example:
* With GAMS 24.8.1 the function numCores was added to the system.
* Make sure, that we use this GAMS version or newer.

\$version 24.8

Scalar nc "Number of cores";
nc = numCores;
Display nc;

\$warning

Syntax:

\$warning text

This dollar control option issues a compilation warning to the log and listing but continues
compilation and execution.

Example

\$ifthen not set INPUTFILE
$ set INPUTFILE default.txt
$ warning Using default INPUTFILE "default.txt". Use --INPUTFILE=myfile.txt to overwrite default.
$endif

The GAMS log file will issue a warning:

*** Error 332 in C:\Users\default\Documents\gamsdir\projdir\myinput.gms
   $Warning encountered - see listing for details

with the details in the listing file:

    3 $ warning Using default INPUTFILE "default.txt". Use --INPUTFILE=myfile.txt to overwrite default.
    **** $332

4.41 Dollar Control Options

GAMS offers several dollar control options that facilitate conditional compilation. In this section we will
first introduce the general syntax, present an overview of all relevant options and list the conditional
expressions that may be used to perform tests. Then we will give several examples to illustrate how these
options are used and to demonstrate their power. This section is meant as an introduction to conditional
compilation in GAMS and complements the detailed descriptions of the dollar control options listed in
Table 1 below.

4.41.4 Conditional Compilation

GAMS offers several dollar control options that facilitate conditional compilation. In this section we will
first introduce the general syntax, present an overview of all relevant options and list the conditional
expressions that may be used to perform tests. Then we will give several examples to illustrate how these
options are used and to demonstrate their power. This section is meant as an introduction to conditional
compilation in GAMS and complements the detailed descriptions of the dollar control options listed in
Table 1 below.

4.41.4.1 Conditional Compilation: General Syntax and Overviews

The dollar control option \$if and its variants provide a great amount of control over conditional processing
of the input file(s). The syntax in GAMS is similar to the IF statement of the DOS Batch language:

\$if [not] <conditional expression> new_input_line

The dollar control statement begins with \$if. Note that \$if may be replaced by one of its variants that
are listed in Table 1 below. The operator not is optional and makes it possible to negate the conditional
expression that follows. The conditional expression may take various forms, a complete list is given in
Table 2. The result of the conditional test is used to determine whether to process or not the remainder
of the line, new_input_line, which may be any valid GAMS input line.
Attention

The first non-blank character on the line following the conditional expression is considered to be the first column position of the GAMS input line. Therefore, if the first character encountered is a comment character the remainder of the line is treated as a comment line. Likewise, if the first character encountered is the dollar control character, the line is treated as a dollar control line.

Alternatively, the `new_input_line` may be placed in the next line. The corresponding syntax follows:

$$\texttt{$if \ [\text{not}] \ <\text{conditional expression}>}$

```
new_input_line
```

Note that in this version the space after the conditional expression is left blank. If the conditional is found to be false, either the remainder of the line (if any) will be skipped or the next line will not be processed.

The overviews in Table 1 and Table 2 conclude this subsection. Examples are given in the next subsection.

Table 1: `if` and Related Dollar Control Options

<table>
<thead>
<tr>
<th>Dollar Control Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>if</code></td>
<td>This option is used to do case sensitive comparisons. Several examples are given in the next subsection.</td>
</tr>
<tr>
<td><code>ifE</code></td>
<td>This variant does the same as <code>if</code> but allows numerical constant expression evaluation. For an example, see the detailed description of this option.</td>
</tr>
<tr>
<td><code>ifI</code></td>
<td>This variant is the same as <code>if</code>, but it is case insensitive.</td>
</tr>
<tr>
<td><code>ifThen</code></td>
<td>This variant controls whether a block of statements will be processed or not. It is used to do case sensitive comparisons. Most often it is followed by one or more of the following dollar control options: <code>else</code>, <code>elseIf</code>, <code>elseIfI</code>, <code>elseIfE</code>. The option <code>ifThen</code> must be matched with the option <code>endIf</code> that marks the end of the block. An example is given below.</td>
</tr>
<tr>
<td><code>ifThenE</code></td>
<td>This is a variant of <code>ifThen</code> and is used for numerical comparisons. Like <code>ifThen</code>, it is often followed by the option <code>else</code> or one of its variants and must be matched with the option <code>endIf</code> that marks the end of the construct.</td>
</tr>
<tr>
<td><code>ifThenI</code></td>
<td>This is a variant of <code>ifThen</code> and is used to do case insensitive comparisons. Like <code>ifThen</code>, it is often followed by the option <code>else</code> or one of its variants and must be matched with the option <code>endIf</code> that marks the end of the construct.</td>
</tr>
<tr>
<td><code>endIf</code></td>
<td>This option must be matched with a preceding option <code>ifThen</code>, <code>ifThenE</code> or <code>ifThenI</code> and marks the end of the <code>if - then</code> construct. Note that the option <code>endIf</code> is not followed by a conditional expression, but it may be followed by a <code>new_input_line</code>. This GAMS input is restricted to other dollar control statements. An example is given below.</td>
</tr>
<tr>
<td><code>else</code></td>
<td>This option follows the option <code>ifThen</code>, <code>ifThenE</code> or <code>ifThenI</code>. It is followed by an instruction which is executed if the conditional expression of the matching <code>ifThen</code> statement is not true. Note that therefore this dollar control statement does not contain a conditional expression. An example is given below.</td>
</tr>
<tr>
<td><code>elseIf</code></td>
<td>This option follows the option <code>ifThen</code>, <code>ifThenE</code> or <code>ifThenI</code>. It is followed by another conditional expression and instruction. Note that this option is case sensitive. An example is given below.</td>
</tr>
<tr>
<td><code>elseIfE</code></td>
<td>This is a variant of <code>elseIf</code> that evaluates numerical values.</td>
</tr>
<tr>
<td><code>elseIfI</code></td>
<td>This is a variant of <code>elseIf</code> that is case insensitive.</td>
</tr>
</tbody>

Table 2: Conditional Expressions in Conditional Compilation

<table>
<thead>
<tr>
<th>Conditional Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acrType id</td>
<td>True if id is an acronym.</td>
</tr>
<tr>
<td>decla_OK</td>
<td>True if a declaration statement is permitted in the current line.</td>
</tr>
<tr>
<td></td>
<td>Note that declaration statements are not permitted within programming flow control structures like if statements or loop statements. An example is given below.</td>
</tr>
<tr>
<td>declared id</td>
<td>True if id was declared.</td>
</tr>
<tr>
<td>defined id</td>
<td>True if id was defined. An example is given below.</td>
</tr>
<tr>
<td>dExist directoryname</td>
<td>True if a directory with the name directoryname exists.</td>
</tr>
<tr>
<td>dimension n id</td>
<td>True if id has n dimensions. Note that n may take values from 0 to maximum number of possible indexes (see Dimensions).</td>
</tr>
<tr>
<td>equType id</td>
<td>True if id is an equation.</td>
</tr>
<tr>
<td>errorFree</td>
<td>True if compilation up to this point has been free of errors.</td>
</tr>
<tr>
<td>errorLevel n</td>
<td>True if the return code of a program called via $call is equal to or larger than n. For lists of GAMS return codes, see chapter GAMS Return Codes. An example is given below.</td>
</tr>
<tr>
<td>exist filename</td>
<td>True if a file with the name filename exists in the working directory or an input file directory. If no extension is specified, also filename.gms is checked. An example is given below.</td>
</tr>
<tr>
<td>filType id</td>
<td>True if id is the name of a put file.</td>
</tr>
<tr>
<td>funType id</td>
<td>True if id is a GAMS function.</td>
</tr>
<tr>
<td>gamsVersion n</td>
<td>True if current GAMS version is greater than or equal to n. GAMS versions are referenced with a single number. For example, if it should be tested whether the current GAMS version is 24.7 or newer, n will equal 247. Maintenance version numbers, e.g. 24.7.4 do not count.</td>
</tr>
<tr>
<td>gdxDimension n id</td>
<td>True if id exists in a GDX file previously opened with $gdxIn and has n dimensions. Note that n may take values from 0 to maximum number of possible indexes (see Dimensions).</td>
</tr>
<tr>
<td>gdxEquType id</td>
<td>True if id exists in a GDX file previously opened with $gdxIn and is an equation.</td>
</tr>
<tr>
<td>gdxParType id</td>
<td>True if id exists in a GDX file previously opened with $gdxIn and is a parameter.</td>
</tr>
<tr>
<td>gdxSetType id</td>
<td>True if id exists in a GDX file previously opened with $gdxIn and is a set.</td>
</tr>
<tr>
<td>gdxSymExist id</td>
<td>True if id exists in a GDX file previously opened with $gdxIn.</td>
</tr>
<tr>
<td>gdxVarType id</td>
<td>True if id exists in a GDX file previously opened with $gdxIn and is a variable.</td>
</tr>
<tr>
<td>macType id</td>
<td>True if id is a macro.</td>
</tr>
<tr>
<td>modType id</td>
<td>True if id is a model.</td>
</tr>
<tr>
<td>onState key</td>
<td>True if the state of key is on (i.e. activated by $onKey). An example is given below.</td>
</tr>
<tr>
<td>parType id</td>
<td>True if id is a parameter.</td>
</tr>
<tr>
<td>preType id</td>
<td>True if id is a one of the predefined symbols in GAMS. Details are given below.</td>
</tr>
<tr>
<td>putOpen</td>
<td>True if both a file statement and at least one put statement have been compiled. Note that this does not guarantee that a file will be open at runtime.</td>
</tr>
<tr>
<td>readable id</td>
<td>True if id was correctly initialized, i.e. the symbol has a data statement or appeared on the left-hand side of an assignment statement, and may therefore be used on the right-hand side of an assignment statement. An example is given below.</td>
</tr>
<tr>
<td>Conditional Expression</td>
<td>Description</td>

</tbody>
</table>

### 4.41.4.2 Conditional Compilation: Examples

#### 4.41.4.2.1 File Operation Test
The operator `exist` may be used to test whether a given file name exists. Consider the following example:

```
$if exist myfile.dat $include myfile.dat
```

Observe that the effect of this dollar control statement is that the file `myfile.dat` is included if it exists. Note that the character `$` at the beginning of the option `$include` is the first non-blank character after the conditional expression `exist myfile.dat` and therefore it is treated as the first column position. The statement above may also be written as follows:

```
$if exist myfile.dat
$include myfile.dat
```

#### 4.41.4.2.2 Conditional Compilation and Batch Include Files
In the next example we will illustrate how the option `$if` is used inside a batch include file where parameters are passed through the option `$batInclude` from the parent file:

```
$if not "%1a" == a $goto labelname
$if exist %1 file.ap=1;
```

Note that in the first line the `$if` condition uses the string comparison "%1a" == a to check if the parameter is empty. This test may also be done in the following way: %1 == "". If the parameter is not empty, the option `$goto` is processed.
4.41 Dollar Control Options

Note

The option $label cannot be part of the conditional input line. However, if the option $label appears on the next line, the condition decides once if the label is placed or not and subsequent instances of $goto will find the label without reevaluating the condition.

The second line illustrates the use of standard GAMS statements if the conditional expression is valid. If the file name passed as a parameter through the $batInclude call exists already, the GAMS will execute the $ap=1; statement which will append to the file.

The next example demonstrates how an unknown number of file specifications may be passed on to a batch include file that will include each of them if they exist. The batch include file could look as follows:

```
* Batch Include File - inclproc.gms
  * include and process an unknown number of input files
$label nextfile
  * Quote everything because file name might have blanks
$if exist "%1" $include "%1"
$shift
$if not "%1a" == a $goto nextfile
```

The call to this file in the parent file could take the following form:

```
$batInclude inclproc "file 1.inc" file2.inc file3.inc file4.inc
```

4.41.4.2.3 Testing Whether an Item Has Been Defined

The next example shows how to test if a named item was declared and/or defined.

```
Set i;
$if defined i $log First: set i is defined
$if declared i $log First: set i is declared
Set i /seattle/;
$if defined i $log Second: set i is defined
$if declared i $log Second: set i is declared
```

Note that after the first declaration of i only declared i evaluates to true when after the second declaration with a data statement both defined i and declared i are true.

4.41.4.2.4 Testing the state of a flag set by a dollar control option

The expression onState key tests whether the state of key is on. So the following example could be done with any key available as a $[on|off]Key dollar control option:

```
$if onState listing $log Listing is active at checkpoint 1
$if onState listing $set reactivateListing
$offListing
  * Do something which should not be seen in the listing
$if onState listing $log Listing is active at checkpoint 2
  * Reactivate listing if it was active at the start only
$if set reactivateListing $onListing
$if onState listing $log Listing is active at checkpoint 3
```
4.41.4.2.5 Testing Whether an Item May Be Used in an Assignment  The expression `readable` id tests whether data were assigned to an item and therefore the item may be used on the right-hand side of an assignment statement. Consider the following example:

Scalar f;
$if not readable f $log f cannot be used on the right
Scalar f /1/;
$if readable f $log f can be used on the right
$kill f
$if not readable f $log f cannot be used on the right after clear
f = 1;
$if readable f $log f can be used on the right after assignment

Note that in the first test the set f was declared, but there was no data statement, hence it is not readable. After a declaration with a data statement the test readable f evaluates to TRUE. With $kill we can revert f to a data less state and hence not readable f is TRUE after the "$kill". The assignment statement f = 1; make the scalar f readable again.

4.41.4.2.6 Testing Whether an Identifier May Be Declared  In programming flow control structures, like if statements or loop statements declaration statements are not permitted. The test `decla_ok` may be used to test whether the current environment allows declaration statements. Consider the following example:

$if decla_ok $log declarations are possible
if(1,
$ if not decla_ok $log declarations are not allowed
);

Note that the conditional expression in the both $if tests will evaluate to TRUE. However, the second test of decla_ok itself will be FALSE because it is processed while compiling an if statement, but with the not the entire expression evaluated to TRUE. For more information, see chapter Programming Flow Control Features.

4.41.4.2.7 Comments in the Context of Conditional Compilation  In-line and end-of-line comments are stripped out of the input file before processing the new_input_line. If either of these forms of comments appear, they will be treated as blanks. Consider the following example:

Parameter a ;
a=10 ;
$eolCom // inlineCom /* */
$if exist myfile.dat /* in line comments */ // end of line comments
a = 4 ;
display a;

Note that the comments on line 3 are ignored and the fourth line with the assignment statement will be processed if the conditional expression is true. Hence the outcome generated by the display statement will list a with a value of 4 if the file myfile.dat exists and a value of 10 if the file does not exist.
4.41.4.2.8 Error Level Test  Consider the following example:

\[
\texttt{
$\texttt{call gams mymodel.gms lo=2}$}
\texttt{
$\texttt{if errorlevel 1 $} \texttt{abort one or more errors encountered}$}
\]

Note that the errorlevel is retrieved from the previous system call via \texttt{$call$}. The conditional statement \texttt{errorlevel 1} is true if the returned errorlevel is equal to or larger than 1. In case of calling GAMS this means that something was not quite right with the execution of GAMS (either a compilation or execution error or other more exotic errors, see GAMS return codes. If this is the case, this GAMS program will be aborted immediately at compilation time.

Usually programs return 0 on success and non-zero on failure. The \texttt{if errorlevel 1} checks for strictly positive return codes. There are rare cases with failures and negative return codes (e.g. on Windows if some DLL dependencies of the program can't be resolved). In such a case \texttt{if errorlevel 1} will evaluate to false and not continue with the \texttt{abort} instruction. It might be better to access the program return code via the \texttt{errorLevel} function in the following way:

\[
\texttt{
$\texttt{call gams mymodel.gms lo=2}$}
\texttt{
$\texttt{ifE errorLevel<>0 $} \texttt{abort one or more errors encountered}$}
\]

4.41.4.2.9 Solver Test  The following example illustrates how to check if a solver exists.

\[
\texttt{
$\texttt{if solver ZOOM}$}
\]

Note that the conditional expression is false since the solver named \texttt{ZOOM} does not exists in the GAMS system (anymore).

4.41.4.2.10 Command Line Parameters in String Comparison Tests  Assume we include the following dollar control statements in a GAMS file called \texttt{myfile.gms}:

\[
\texttt{
$\texttt{if not '%gams.ps%'=='' $log Page size set to %gams.ps%}$}
\texttt{
$\texttt{if not '%gams.pw%'=='' $log Page width set to %gams.pw%}$}
\texttt{
$\texttt{if not '%gams.mip%'=='' $log MIP solver default is %gams.mip%}$}
\]

Then we run the program with the following call:

\[
> \texttt{gams myfile pageSize=60 pageWidth=85 mip=cbc}$
\]

Note that we specified values for the command line parameters \texttt{pageSize}, \texttt{pageWidth}, and \texttt{MIP}. We can either use the short or long name on the command line and in the compile-time variable. If we do not specify the option on the command line we will get the default value for option page size and page width. The MIP solver line will not show because \texttt{%gams.mip%} remains empty. The log with option setting on the command line will include the following lines:

\[
\text{Page size set to 60}
\text{Page width set to 85}
\text{MIP solver default is cbc}$
\]

Command line parameters are introduced in chapter The GAMS Call and Command Line Parameters.
4.41.4.2.11 System Attributes in String Comparison Tests

Compile-time system attributes may also be used in string comparison tests. The system attribute that is most useful in this context is .fileSys. It identifies the name of the operating system being used. Consider the following example:

```gams
$ifthen not %gams.logOption%==3
  $ ifi %system.fileSys%==UNIX  $set nullFile > /dev/null
  $ ifi %system.fileSys%==MSNT  $set nullFile > nul
$ if not set nullFile $abort %system.fileSys% not recognized
$else
  $ set nullFile
$endif
$call gamslib trnsport %nullFile%
```

These dollar control statements allow the definition of a NULL file destination that is dependent on the operating system that is being used. Note that the control variable nullFile contains an operating-system-dependent name. This is useful when making an external program that writes to STDOUT quiet in case the GAMS log does not go to STDOUT (logOption=3). This example could also have used the system attribute %system.nullFile% which contains the operating-system-dependent NULL file destination:

```gams
$set nullFile
$if not %gams.logOption%==3 $set nullFile > %system.nullFile%
$call gamslib trnsport %nullFile%
```

System attributes in general are introduced in chapter System Attributes.

4.41.4.2.12 Conditional Compilation with $ifThen and $else

Consider the following example which illustrates the use of $ifThen, $elseif, $else and $endif:

```gams
$set x a
$label test
$ifThen %x% == a $set x 'c' $log $ifThen with x=%x%
$elseif %x% == b $set x 'k' $log $elseif 1 with x=%x%
$elseif %x% == c $set x 'b' $log $elseif 2 with x=%x%
$else $set x 'e' $log $else with x=%x%
$endif $if not %x% == e $goTo test
```

Note that the resulting log file will contain the following lines:

```gams
$ifthen with x=a
$elseif 2 with x=c
$elseif 1 with x=b
$else with x=k
```

Observe that the options $else and $endif are not followed by conditional expressions and the instruction following the option $endif contains a dollar control statement. Moreover, note that the ‘$set x ‘’has the text to be set in quotes. GAMS needs to know where the text ends and the next dollar control option (in this case$log’) starts.
4.41 Dollar Control Options

4.41.4.2.13 Type of Identifiers  The type of a symbol can be retrieved via \$if ...Type. Consider the following example:

```
Set diag / 1*3 /;
Parameter p(diag) / 1 1, 2 4, 3 8 /;
$if setType diag $log diag is a set
$if not varType diag $log diag is not a variable
$if preType diag $log diag is a predefined type
$if parType p $log p is a parameter
$if setType sameAs $log sameAs is a set
$if preType sameAs $log sameAs is a predefined type
```

Note that for predefined symbols more than one type applies (e.g. sameAs is of set and predefined type). Please also note that diag is a set even though there is a predefined symbol named diag but that becomes invisible with a user defined symbols with the same name.

Normally there is no way to get a symbol into the GAMS symbols table without a proper type. However, if the dollar command line parameter multiPass is set to a value larger than zero, then the compiler will just check for some integrity and will try to deduce the symbol type from the context. If it is not able to do so, the symbol type will remain unknown. For example, compiling the following lines with multiPass=1

```
display x;
$if xxxType x $log x is of unknown type
```

result in the line x is of unknown type in the GAMS log.

4.41.5 Macros in GAMS

Macros are widely used in computer science to define and automate structured text replacements. The GAMS macro processors function similarly to the popular C/C++ macro preprocessor. Note that the GAMS macro facility has been inspired by the GAMS-F preprocessor for function definition developed by Michael Ferris, Tom Rutherford and Collin Starkweather, 1998 and 2005. The GAMS macro facility incorporates the major features of the GAMS-F preprocessor into the standard GAMS release as of version 22.9. GAMS macros act like a standard macro when defined. However, their recognition for expansion is GAMS syntax driven.

4.41.5.1 Syntax and Simple Examples

The definition of a macro in GAMS takes the following form:

```
$macro name  macro_body
$macro name(arg1,arg2,arg3,...) macro_body with tokens arg1, ...
```

The dollar symbol $ followed by macro indicate that this line is a macro definition. The name of the macro has to be unique, similar to other GAMS identifiers like sets and parameters. The macro name is immediately followed by a list of replacement arguments arg1, arg2, arg3,... that are enclosed in parentheses. The macro body is not further analyzed after removing leading and trailing spaces.

The recognition and following expansion of macros is directed by GAMS syntax. The tokens in the macro body to be replaced by the actual macro arguments follow the standard GAMS identifier conventions. Consider the following simple example of a macro with one argument:
Here the name of the macro is `reciprocal`, `y` is the argument and the macro body is `1/y`. This macro may be called in GAMS statements as follows:

```gams
$macro reciprocal(y) 1/y
scalar z, x1 /2/, x2 /3/;
z = reciprocal(x1) + reciprocal(x2);
```

As GAMS recognizes `reciprocal(x1)` and `reciprocal(x2)` as macros, the assignment statement will expand to:

```
z = 1/x1 + 1/x2;
```

Note that the macro use cannot be spread over multiple lines. Single line use with more complex arguments as in

```
z = reciprocal(x1+x2);
```

is recognized and will expanded to:

```
z = 1/x1+x2;
```

Note that `z` will be equal to 3.5 in this example as division takes precedence over addition. But breaking the argument of the macro over multiple lines as follows will trigger a macro expansion error:

```
z = reciprocal(x1
+x2);
```

The next example illustrates macros with multiple arguments:

```gams
$macro ratio(x,y) x/y
scalar z, x1 /2/, x2 /3/;
z = ratio(x1,x2);
```

The assignment above will expand to:

```
z= x1/x2;
```

Note that the macro definition may extend over several lines with the symbol `\` acting as a continuation string. Consider the following example:

```gams
$macro myxor(a,b) (a or b) \
            and (not a or not b)
scalar z;
z = myxor(1,0);
display z;
```

```
4.41 Dollar Control Options

The z assignment expands to

\[ z = (x_1 \text{ or } x_2) \text{ and } (\text{not } x_1 \text{ or } \text{not } x_2); \]

Note that although the macro has been defined over two lines, the expansion happens by combining the lines after stripping leading white spaces of the second line as demonstrated in the next example (because and has a higher precedence than or we can omit the parenthesis):

```gams
$macro myxor(a,b) not a and b \\
    or a and not b
scalar z;
z = myxor(1,0);
display z;
```

The z assignment expands to this:

\[ z = \text{not } 1 \text{ and } 0 \text{ or } 1 \text{ and } \text{not } 0; \]

The &, explained in more detail in the next section can be used to preserve (some of the) leading white spaces (but not the line breaks) if that is desired:

```gams
$macro myxor(a,b) not a and b \\
& or a and not b
```

4.41.5.2 Nested Macros

Macros may be nested. Consider the following example:

```gams
$macro product(a,b) a*b
$macro addup(i,x,z) sum(i,product(x(i),z))
set j / j1*j10 /;
Parameter a1(j) / #j 1 /, z, x1 /5/;
z = addup(j,a1,x1);
```

Observe that the macro product is nested in the macro addup. The assignment will expand to:

\[ z = \text{sum}(j,a1(j) \times x1); \]

Note that nested macros may result in an expansion of infinite length. An example follows.

```gams
$macro a b,a
display a;
```

This will expand into:

display b,b,b,b,b,b,b,b,b,b,b,b,...

In such a case GAMS will eventually refuse to do more substitutions and will issue a compilation error:

732 Too many edits on one single line - possible recursion in macro calls
compilation will be terminated
4.41.5.3 Ampersands in Macro Definitions

The expansion of arguments may be more carefully controlled by the use of ampersands & in the macro body. A single ampersand & is used as a concatenation or separation symbol to indicate tokens that are to be replaced. Consider the following example:

```
$macro f(i) sum(j, x(i,j))
$macro equ(q) equation equ_&q; \ 
equ_&q.. q =e= 0;
set i /i/, j /j/;
variable x(i,j);
equ(f(i))
```

This will expand into:

```
equation equ_f(i);equ_f(i).. sum(j, x(i,j)) =e= 0;
```

Note that without the ampersand notation, GAMS would have recognized only the third occurrence of q and hence the expansion would have been:

```
equation equ_q;equ_q.. sum(j, x(i,j)) =e= 0;
```

Two ampersands && immediately preceding a token will drop the most outer matching single or double quotes of the replacement argument. This makes it possible to include expressions with spaces, commas and unbalanced parentheses. The latter one is something users should really avoid doing. An example follows.

```
$macro d(q) display &&q;
$macro ss(q) &&q)
set i /i/, k /k/;
parameter a1(i) / i 1/, z;
d("here it is", i,k')
d("(zz")
z=ss('sum(i,a1(i)');
z=ss('prod(i,a1(i)');
```

Note that the expressions d contain quotes, spaces and commas and the expression ss has unbalanced parentheses within the quoted parts. In turn these expand to become:

```
display "here it is", i,k;
display "(zz";
z=sum(i,a1(i));
z=prod(i,a1(i));
```
4.41.5.4 Additional Macro Features

Deeply nested macros may require aliased sets in indexed operations like sum and prod. A minor syntax extension allows the implicit use of aliases. The suffix .local on a controlling set will use an implicit alias within the scope of the indexed operation. Consider the following example:

```plaintext
$macro ratio(a,b) a/b
$macro total(q) sum(i,q(i))
set i /i1*i15/;
parameter a(i) / #i 1 /, b(i) / #i 2 /, r(i), asum;
asum = total(a);
r(i) = ratio(total(a), b(i));
```

The assignment statement will expand to:

```plaintext
asum = sum(i,a(i));
r(i) = sum(i,a(i))/b(i);
```

The second line will not compile because the i in the sum is already controlled from the i on the left. The intention was the total macro is to add up the elements of a parameter indexed over i. As in the r(i) assignment the macro might be used in a statement where i is already controlled hence when doing the sum in the macro we want to use an alias of i. If we change the macro definition to

```plaintext
$macro total(q) sum(i.local,q(i))
```

The code works as expected because the i in the sum refers to the i.local and not the outside i.

Note that the the modifier .local is not limited to macros and may be used in any context. For further details and more examples, see the detailed description of the dollar command option $on/offLocal.

Another feature of macros is the implicit use of the suffix .L in report writing and other data manipulation statements. This allows using the same algebra in model definitions and assignment statements. The following code illustrates this feature:

```plaintext
$macro sumIt(i,term) sum(i,term)
cost .. z =e= sumIt((i,j), (c(i,j)*x(i,j))) ;
supply(i) .. sumIt(j, x(i,j)) =l= a(i) ;
demand(j) .. sumIt(i, x(i,j)) =g= b(j) ;
Model transport /all/ ;
solve transport using lp minimizing z ;
Parameter tsupply(i) total demand for report
tdemand(j) total demand for report
$onDotL
tsupply(i)=sumIt(j, x(i,j));
tdemand(j)=sumIt(i, x(i,j));
```
The option \$onDotL enables the implicit suffix .L for variables. This feature was introduced for macros with variables to be used in equation definitions as well as assignment statements. The matching option \$offDotL will disable this feature. Similarly, \$offDotScale will access the .scale suffix of a variable or equation in an assignment statement.

Three more switches are relevant to macros. The option \$show will list any GAMS macros defined. The option \$on/\$offMacro will enable or disable the expansion of macros; the default is \$onMacro. Finally, the option \$on/offExpand will change the processing of macros appearing in the arguments of a macro call. The default operation is not to expand macros in the arguments. The switch \$onExpand enables the recognition and expansion of macros in the macro argument list. The option \$offExpand will restore the default behavior.

Note that macro definitions are preserved in a save/restart file and are available again for a continued compilation.

Summarizing, macros shares the name space of GAMS symbols, like sets, parameters, variables, etc. Macros are recognized and expanded anywhere a proper GAMS identifier may be used. This may be suppressed with the option \$on/offMacro. The body of macros is only used during expansion. Hence, macro definitions are not order dependent. Variables in macro bodies will have an implicit suffix .L when they are used in assignment statements. This GAMS feature needs to be activated with the option \$onDotL.

### 4.41.6 Compressing and Decompressing Files

GAMS provides two dollar control options for compressing and decompressing GAMS input files:

<table>
<thead>
<tr>
<th>Dollar Control Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$compress &lt;source&gt; &lt;target&gt;</td>
<td>The file source is compressed into the packed file target.</td>
</tr>
<tr>
<td>$decompress &lt;source&gt; &lt;target&gt;</td>
<td>The compressed file source is decompressed into the unpacked file target.</td>
</tr>
</tbody>
</table>

**Attention**

Spaces are interpreted as separators between the source and target file names, hence quotes (single or double) have to be used if the file names contain spaces.

Note that GAMS will recognize whether a file is compressed and will processes it accordingly.

**Note**

Like any other GAMS input files, all compressed files are platform-independent.

#### 4.41.6.1 Compressing and Decompressing Files: A Simple Example

We use the well-known transportation model [TRNSPORT] to illustrate. First we copy the model from the GAMS Model Library and then we create a compressed version of the original:

```bash
> gamslib trnsport
> echo \$compress trnsport.gms t1.gms > t2.gms
> gams t2
```
Alternatively, the following code snippet may be used from within a GAMS file:

```
$call 'gamslib trnsport'
$compress trnsport.gms t1.gms
$include t1.gms
```

Note that the compressed input file `t1.gms` can be treated like any other GAMS input file. If it is executed, the listing file will be identical to the listing file of the original input file `trnsport.gms`, since a decompressed input is reported in the echo print. As usual, the parts of the model that are marked with the dollar control option `$on/offListing` will not appear in the echo print.

The compressed file `t1.gms` can be decompressed as follows:

```
> echo $decompress t1.gms t3.gms > t4.gms
> gams t4
```

Alternatively, from within a GAMS file:

```
$decompress t1.gms t3.gms
```

Observe that the decompressed file `t3.gms` is identical to the original file `trnsport.gms`. This can easily be tested with the following command:

```
> diff trnsport.gms t3.gms
```

### 4.41.6.2 Compressing and Decompressing Files: The Model CEFILES

The following more elaborate example is self-explanatory. It is adapted from model `[CEFILES]` and can easily be modified to test the use of compressed files.

```
* --- get model
$call gamslib -q trnsport

* --- compress and run model
$compress trnsport.gms t1.gms
$decompress t1.gms t1.org
$call diff trnsport.gms t1.org > %system.nullFile%
$if errorLevel 1 $abort files trnsport and t1 are different

* --- check to see if we get the same result
$call gams trnsport gdx=trnsport lo=%gams.lo%
$if errorLevel 1 $abort model trnsport failed
$call gams t1 gdx=t1 lo=%gams.lo%
$if errorLevel 1 $abort model t1 failed
$call gdxdiff trnsport t1 %system.reDirLog%
$if errorLevel 1 $abort results for trnsport and t1 are not equal

* --- also works with include files
$echo $include t1.gms > t2.gms
$call gams t2 gdx=t2 lo=%gams.lo%
$if errorLevel 1 $abort model t2 failed
$call gdxdiff trnsport t2 %system.reDirLog%
$if errorLevel 1 $abort results for trnsport and t2 are not equal
$terminate
```
4.41.7 Encrypting Files

When models are distributed to users other than the original developers, issues of privacy, security, data integrity and ownership arise. To address these concerns, secure work files may be used and GAMS input files may be encrypted. Note, that the encryption follows the work file security model and requires special licensing.

Note

Like any other GAMS input files, all compressed and encrypted files are platform-independent.

Encryption is only available if a system is licensed for secure work files. There are two way to encrypt a file: Encryption for a particular user group that is identified by a target license file or for a general wide audience. In the prior case the key for encryption and decryption is extracted from the target license (specified by command line parameter pLicense) while for the latter the key for encryption and decryption is passed to GAMS via the command line parameters encryptKey and decryptKey. Note that once a file has been encrypted it cannot be decrypted any more. GAMS provides the following dollar control option to encrypt an input file:

$encrypt <source> <target>

Here the name of the input file to be encrypted is source and the name of the resulting encrypted file is target.

4.41.7.1 Encrypting Files: A Simple Example

We use again the transportation model [TRNSPORT] to illustrate. First we copy the model from the GAMS Model Library and then we create an encrypted version of the original via a target license:

> gamslib -q trnsport
> echo $encrypt trnsport.gms t1.gms > t2.gms
> gams t2 pLicense=target lo=%gams.logOption%

Note that the first two lines are similar to the directives that we have used to compress the model above. In the third line, the command line parameter pLicense specifies the target or privacy license to be used as a user key for encrypting. Thus the new encrypted file t1.gms is locked to the license key target and it can only be executed with the license file target:

> gams t1 license=target dumpOpt=11

Note that the command line parameter license is used to override the default GAMS license file gamslice.txt that can be located in various system wide and user locations. Note further that the command line parameter dumpOpt is usually used for debugging and maintenance. The value 11 causes a clean copy of the input to be written to the file t1.dmp, where all include files and macros are expanded. Observe that if some lines have been marked with the dollar control options $on/offListing in the original file, then these lines will be suppressed in the file t1.dmp.

An alternative approach to encrypt GAMS source file without a target license is done by the pair of command line parameters encryptKey and decryptKey:
In the third line, the command line parameter encryptKey specifies the encryption key. Thus the new encrypted file is locked and requires this key to successfully decrypt via command line parameter decryptKey:

> gams t1 decryptKey=ThisIsAPasswordSomeoneNeedsToRunTheModel

Any other key will result in a failure with the message Integrity check failed.

Note

Once a file has been encrypted, it cannot be decrypted any more. There is no inverse mechanism to recover the original file from the encrypted file. An attempt to decompress it using decompress will fail.

Observe that decrypting is done on the fly into memory when the GAMS system files are read. GAMS will recognize if a file is just plain text or compressed and/or encrypted and will validate and process the files accordingly.

4.41.7.2 Encrypting Files: The Model ENCRYPT

The following more elaborate example is self-explanatory; it is model [ENCRYPT] from the GAMS Model Library.

$title Input File Encryption Demo (ENCRYPT,SEQ=318)
$onText

Input files can be encrypted with an encryption key. Either the privacy license file mechanism or the command line parameter pair encryptKey/decryptKey can be for managing the password. Similar to compression, we offer an $encrypt utility to lock any file to a specific key. Once a file has been encrypted it can only be read by a gams program that has the matching license file or the matching decryption key. There is no inverse operation possible: you cannot recover the original GAMS file from the encrypted version.

To create an encrypted file, we need a license file which has the security option enabled.

Keywords: GAMS language features, input file encryption
$offText

$if not set MYPLICENSE $set MYPLICENSE "$gams.sysdir%license.txt"
$ifthen not exist "$MYPLICENSE%" $ log *** Target license file "$MYPLICENSE%" does not exist. $ log *** Specify via --MYPLICENSE=... $ log *** Encryption only via en/decryptKey $ drop MYPLICENSE $endif
* --- get model
$onDollar
$call gamslib -q trnsp

$ifthen.MYPLICENSE set MYPLICENSE
* --- encrypt and try to decrypt
$call rm -f t1.gms
$echo $encrypt trnsp.gms t1.gms > s1.gms
$call gams s1 plicense="%MYPLICENSE%" lo=%gams.lo%
$ifE errorLevel<>0 $abort encryption failed

$eolCom //
$if not errorFree $abort pending errors
$decompress t1.gms t1.org // this has to fail
$if errorFree $abort decompress did not fail
$clearError

* --- check for hidden output
$call grep "this is hidden" t3.lst > %system.nullfile%
$if not errorLevel 1 $abort did not hide in listing
$call grep "this is hidden" t3.dmp > %system.nullfile%
$if not errorLevel 1 $abort did not hide in dump file
4.42 The Put Writing Facility

4.42.1 Introduction

While the GDX facility is widely used to exchange bulk GAMS data with other programs the put writing facility allows to generate sophisticated reports in GAMS. The result are external ASCII files that are structured using information that is stored by the GAMS system. The put writing facility offers users numerous ways to control three format layers: the format of the external file that is written to, the format of the pages of the external files and the format of output items. Hence the structure of the put writing facility is more complex and requires more programming than the display statement, but there is much more flexibility and control over the output. The put writing facility generates external files automatically when the GAMS program is executed. The files are written sequentially, a single page at a time. The current page is stored in a buffer, which is automatically written to an external file when the page is full. Thus, the put writing facility has only control over the current page and does not have the ability to go back to alter former pages. However, while a particular page is current, information placed on it may be overwritten or removed at will.

This chapter is organized as follows. We will first introduce the file statement and the put statement, which are at the core of the put writing facility. Then we will present a simple example that will serve as illustration. We will also introduce some widely used features as we comment on the example. The remainder on the chapter will cover in detail the external report files, also called put files, the structure of put file pages and ways to control their format, types of output items and their formatting controls, and the put utility statement, a variant of the put statement that allows to special communication of formatted elements with the outside world. In addition, we will briefly discuss exception handling in the context of put statements and GAMS errors that are specific to put statements. We will conclude the chapter with an elaborate example. Note that put file attributes play a crucial role, since they are used for most formatting controls. A complete list of all file attributes is given in section Put File Attributes.

4.42.2 The Syntax

The basic structure of the put writing facility in its simplest form is as follows:

File file_name {,file_name};
put file_name;
put item {,item};

Note that the first line is a file statement. File statements define one or more external files that will be written to and specify internal names for them. These internal names will be used in the GAMS model to reference the external files when they are written to. The second line is a put statement that assigns the file with the name file_name as the current file. The third line is a put statement that writes one or more items to the current file. Items are any type of output like explanatory text, set labels, parameters, and variable, equation values and model attributes.

Next, we will present more details on the file statement and the put statement in the following two subsections and then we will turn to a first example that will illustrate how the the put writing facility works.
4.42 The Put Writing Facility

4.42.2.1 The File Statement: Defining Put Files

External files that are written to with the put writing facility are called put files. They are defined with a file statement. The syntax for a file statement is as follows:

```
File[s] file_name ["text"] [external_file_name]
    {,file_name ["text"] [external_file_name] } ;
```

The keyword `file` or `files` indicates that this is a file statement. It is followed by the internal name for the put file, `file_name`. The internal file name is a handle for the put file, it is used in the GAMS model to refer to the put file. The optional explanatory text may be used to describe the put file for future reference and to ease readability. The final part of the file statement is the actual name of the put file. Naming the external file is optional. In case it is omitted, by default, GAMS will create a name by appending the extension `.put` to the internal name. Consider the following example:

```
File results;
```

Note that in this statement no external file name is specified. Thus GAMS will create the external file `results.put` in the current working directory. Observe that by default, all put files are stored in the current working directory. There are several ways to specify alternative directories for put files. For details see section Choosing Where Put Files are Saved below.

Note

Multiple put files may be defined with one file statement.

Consider the following example:

```
File    class1
    class2   "this defines a specific external file" /report.txt/
    log      "this defines access to the GAMS log file" /''/;
```

Observe that the internal name of the first file is `class1`. As no external name is specified, GAMS will assign the absolute name `class1.put` to this file. The second file will be referenced in the model with the name `class2` and it corresponds to the external file `report.txt`. The third file is special: the internal name `''` is reserved for writing output to the GAMS log. Note that writing to the GAMS log can be useful to monitor how the solution process of the model is progressing.

For further details on put files, see section Put Files below.
4.42.2.2 The Put Statement

The put statement is at the core of the put writing facility. It has two different functions: it specifies which of the previously defined put files is the current file and it writes output to that file. The syntax for the first function is simple:

\[ \text{put file\_name;} \]

The keyword \text{put} indicates that this is a put statement, \text{file\_name} is the internal name of a put file that was previously defined with a file statement. This put statement has the effect that the specified file is now ready to be written to. Note that this put statement is necessary even if only one put file has been previously defined. For an example of how it is used when output is written to several different files, see the next section.

The basic syntax for a put statement that is used to write output to a file is as follows:

\[ \text{put item \{,item\};} \]

The statement begins with the keyword \text{put} followed by one or more items. Items may be a text (like a quoted text, an explanatory text, the name of a set element), a numerical value (like the value of a parameter, the value of an attribute, the solution status of the model) or a set value (\text{YES} or \text{NO} indicating whether a label is an element of a specific set). These items are discussed in detail in section Output Items below. In addition, GAMS facilitates writing a text block to a put file and including the content of an external file in a put file. For details see sections Text Items: Text Blocks and The Put Utility Statement respectively.

Note that it is also allowed to use only one put statement to assign one file as the current file and write to it. The syntax follows:

\[ \text{put file\_name item \{,item\};} \]

In addition, it is permitted to use just one put statement to write to multiple files sequentially. Thus the most general form of a put statement is as follows:

\[ \text{put file\_name item \{,item\} \{,file\_name item \{,item\}%;} \]

Note that only one file is current at a time. When a file is current, the output items following the name of this file will be written to the file. After this has been completed, the current file is reassigned to the next internal file name in the statement. The last internal file name used in a put statement continues to be the current file until a subsequent put statement uses an internal file name.

Observe that the keyword \text{put} has several variants: putclose, putltl, puthd, putpage and put_utility.
4.42 The Put Writing Facility

4.42.3 A First Example

We will use a small example to introduce the basic features of the put writing facility. The example is based on the well-known transportation model [TRNSPORT]. The following code segment could be placed at the end of the transportation model to create a report:

```gams
File factors /factors.dat/,
     results /results.dat/;
put factors;
put 'Transportation Model Factors' / /
   'Freight cost ', f,
   @1#6, 'Plant capacity'/;
loop(i, put @3, i.tl, @15, a(i)/);
put '/Market demand'/;
loop(j, put @3, j.tl, @15, b(j)/);
put results;
put 'Transportation Model Results' / /;
loop((i,j), put i.tl, @12, j.tl, @24, x.l(i,j):8:4 /);
```

In the first line, the file statement defines the internal file names `factors` and `results` and connects them to the external files `factors.dat` and `results.dat` respectively. These internal file names are used inside the model to reference files which are external to the model.

In the second line, the put statement assigns the file `factors` as the current file, that is the file which is currently available to be written to.

In the third line, the put statement starts the actual writing to the put file. The first item that is written is the quoted text string `Transportation Model Factors`. The item is followed by two slashes. A slash instructs the cursor to move to the first column of the next line. Two slashes have the effect that the cursor is moved to the first column of the second line, thus introducing a blank line.

Attention

Two slashes // are a popular end of line comment character sequence. So an intended blank line can result in a comment in the GAMS code. A safe way to use slashes in put statement is to separate the slashes by a space.

The next item is the string `Freight cost` followed by the value of the scalar `f`. Note that these output items are separated by commas. Blanks and commas serve as delimiters for separating different output items. These delimiters leave the cursor at the next column position in the file following the last item written. In most cases, a blank and a comma may be used interchangeably. However, the comma is the stronger form and will eliminate any ambiguities.

In the fifth line, the code above starts with the instruction @1#6. In the context of put statements, the symbols @ and # serve to reposition the cursor to a specific column and row respectively. Thus in our case, the cursor is repositioned to column 1 of row 6 of the put file. Then another text string is written and a new line is started. The semicolon terminates the put statement. More details on cursor positioning are given in section Controlling the Cursor On a Page.

In line 6, the next put statement is embedded within a loop statement. Note that the set `i` is the looping set. The put statement writes at column position 3 the set label name and at column position 15 the value of the parameter `a(i)` for each element of the set `i`. Observe that set element labels are referenced with the name of the set and the suffix `.tl`. For more information on identifier suffixes, see section Text Items below. Note that the put statement has to be placed within a looping structure, since only one element of the index set may be written with a put statement.
In line 7, the first symbol after the keyword put is a slash, that has the effect that a blank
line is inserted before the text string 'Market demand' is written.

In line 8, we have again a put statement within a loop structure: the values of the parameter b are written in a similar way to those of parameter a in line 6.

After execution, the put file factors.dat will look as follows:

Transportation Model Factors

Freight cost 90.00

Plant capacity
   Seattle 350.00
   San-Diego 600.00

Market demand
   New-York 325.00
   Chicago 300.00
   Topeka 275.00

Note that this output has been formatted using the default file format values. GAMS offers several ways to customize the format, see sections Global Item Formatting Controls and Local Item Formatting Controls below for further information.

In the last three lines of the code above, the file results.dat is made current and the level values associated with the variable x along with their corresponding set element index labels are written line by line. Note that the format of the output results of the variable x is customized by specifying a field width of 8 spaces with 4 of these spaces reserved for decimal places. This is an example of local formatting. The put file results.dat will contain the following lines:

Transportation Model Results

Seattle New-York 50.0000
Seattle Chicago 300.0000
Seattle Topeka 0.0000
San-Diego New-York 275.0000
San-Diego Chicago 0.0000
San-Diego Topeka 275.0000

This small example has demonstrated the main features of the put writing facility. However, its surface has just barely been scratched. In the remainder of this chapter we will describe in detail the many features of the put writing facility. Observe that in section Creating a Report for the Model MEXSS at the end of this chapter we will present a more elaborate report.

4.42.4 Put Files

As mentioned earlier, external files that are written to with the put writing facility are called put files. They are defined with a file statement and are made current with a put statement. Once they are current, they may be written to. By default, put files are saved in the current working directory. In this section we will cover more details on put files. We will discuss ways to specify other directories for put files, introduce the putclose statement, a variant of the put statement that closes the current file, and we will show how to append to an existing external file instead of replacing (overwriting) it. In addition, we will introduce the notion of put file attributes including a list of all attributes.
4.42 The Put Writing Facility

4.42.4.1 Choosing Where Put Files are Saved

Recall that by default, put files are saved in the current working directory. GAMS offers several ways to specify other directories for put files. The easiest way to specify another directory is by including the absolute or relative path in the file statement. Consider the following example:

```
File report / C:\Documents\GAMS\Output\report.dat /;
```

Note that the put file `report.dat` with the internal name `report` will be stored in the directory specified in the file statement instead of the current working directory.

An alternative directory for all put files in a model may be specified with the command line parameter `PutDir`. Assume we wish to write some output from running the well-known transportation model `[TRNSPORT]` to the file `results` defined above. Consider the following GAMS call:

```
> gams trnsport PutDir=c:\output
```

Note that the file `results.put` will be stored in the directory specified in the GAMS call. Observe that storing put files in the directory specified with `PutDir` is applies to all file that are not specified via an absolute file name. For more information on command line parameters, see chapter The GAMS Call and Command Line Parameters. scratchdir as putdir option (`.pdir`) lets GAMS write put files into the scratch directory.

The content of a put file will be sent to the GAMS log file if the put file is specified in the following way:

```
File name / '' /;
```

For example, the following code snippet may be added to the transportation model `[TRNSPORT]`:

```
File name / '' /;
put name ;
put 'instructions that will go to the GAMS log' /;
put 'more instructions that will go to the GAMS log' /
```

As a result, the respective GAMS log will contain the following lines:

```
... instructions that will go to the log file
more instructions that will go to the log file
*** Status: Normal completion
--- Job trnsport.gms Stop 01/25/17 15:46:09 elapsed 0:00:00.320
```
4.42.4.2 The Putclose Statement: Closing a Put File

Recall that the file statement and the put statement are at the core of the put writing facility. The putclose statement is a variant of the put statement, it is used to close a put file. The syntax is as follows:

```
putclose [file_name] {item} {file_name item {item}};
```

If the file_name is missing, putclose will close the current file. Often the putclose statement is used in this simple form. Consider the following example:

```
File report;
put report;
put "This is a report."
putclose;
```

Note that the last line has the effect that the file report.put is closed. The file may be used again later. As usual, it has to be assigned as the current file and then it may be written to. By default, an existing file is overwritten (replaced). Alternatively, it may be appended to. For details see section Writing to an Existing Put File below. The briefest version of the above code is

```
File report; putclose report "This is a report."
```

Closing a put file is useful for example when writing a solver option file from within the GAMS model. Consider the following example, where we will create and close an option file for the solver MINOS.

```
File opt 'Minos option file' / minos.opt /;
put opt 'Iteration limit 500' /
     'Feasibility tolerance 1.0E-7' /
putclose opt;
```

Note that the file minos.opt is closed with a simple putclose statement. This will make the file available to be used by the solver. Observe that the code snippet above has to be placed before the respective solve statement.

Now, the last three lines in the example above may be reduced to two lines in the following way:

```
putclose opt 'Iteration limit 500' /
     'Feasibility tolerance 1.0E-7' /
```

In this formulation, the putclose statement makes the file minos.opt current, writes to it and then closes the file after the last item has been written. Even though this is shorter, many users prefer the first formulation, since it is clearer.

Similarly to the put statement, the putclose statement may also be used to write to several files subsequently. The only difference to the put statement is, that the last current file will be closed after is has been written to.

Observe that GAMS automatically closes the put files of a model when it exits, even without a putclose statement.
4.42.4.3 Writing to an Existing Put File

When the put writing facility is used to write to a file that is not empty, by default, the existing content is overwritten (replaced). However, GAMS provides the option to append to the file instead via the file attribute `append option (.ap)`. Consider the following example:

```gams
File append /append.dat/
  put append;
  put "This is the first line." /;
  putclose;
  append.ap = 1;
  put append;
  put "This is the second line.";
```

Note that the `putclose` statement in line 4 closes the file `append.dat`. The assignment in the next line instructs the put writing facility to append to the file if the file is opened again and written to. Thus the following output is generated:

```
This is the first line.
This is the second line
```

For information on file attributes in general, see section Put File Attributes below.

4.42.4.4 Put File Attributes

Put files have attributes that are mainly used to customize the format of put files, put file pages and output items. Put file attributes are accessed in the following way:

```
file_name.attribute
```

Here `file_name` is the internal name of the put file and `.attribute` is the specific attribute that is to be accessed. We can also access the specific attribute of the current file by `file.attribute`. This useful in particular in `batincludes` that are used for multiple put files. Put file attributes may be used on the left-hand side and right-hand side of assignments. Consider the following example:

```gams
factors.nw = 10;
scalar x; x = factors.nw;
```

In the first line, the attribute `numeric field width (.nw)` of the put file with the internal name `factors` is assigned the value of 10. In the second line, the value of the attribute `.nw` is assigned to a scalar parameter `x`. In addition, put file attributes may be used as output items. For an example, see section Controlling the Cursor with File Attributes below. A complete list of put file attributes is given in Table 1.

**Table 1: Put File Attributes**
<table>
<thead>
<tr>
<th>Put File Attribute</th>
<th>Symbol</th>
<th>Description</th>
<th>Default Value</th>
<th>Optional Values</th>
</tr>
</thead>

<td>---------------</td>
<td>------------------------------------------------------</td>
</tr>
<tr>
<td>Number of decimals</td>
<td>.nd</td>
<td>Sets the number of decimals that are displayed for numeric items. A value of zero entails that fixed-format output will show the number rounded to the nearest integer. For an example, see section Global Item Formatting Controls.</td>
<td>2</td>
<td>Values may be between 0 and 20.</td>
</tr>
<tr>
<td>Numeric justification</td>
<td>.nj</td>
<td>Alignment of numeric output.</td>
<td>1</td>
<td>1: Right, 2: Left, 3: Center</td>
</tr>
<tr>
<td>Numeric round format</td>
<td>.nr</td>
<td>Selects the formatting used for numeric output. For example, one can choose to use scientific notation (i.e. E-format) for all numbers: this is especially useful for numbers so small that they display as only zeros in fixed format with the specified suffix number of decimals (.nd). For more information and an example, see section Global Item Formatting Controls.</td>
<td>1</td>
<td>0: Item is displayed in F or E format to fit given width and decimals. 1: Item is rounded to fit given width and decimals. 2: Item is displayed in E format to fit given width and decimals. 3: Item is rounded to fit given width. 4: Item is displayed in F or E format to fit given width.</td>
</tr>
<tr>
<td>Numeric field width</td>
<td>.nw</td>
<td>Field width of numeric output. For more information, see section Global Item Formatting Controls.</td>
<td>12</td>
<td>Values may be 0 or larger.</td>
</tr>
<tr>
<td>Numeric zero tolerance</td>
<td>.nz</td>
<td>Sets the tolerance level for which a number will be rounded to zero for display purposes. Note that in case this attribute is set to zero, rounding will be determined by the field width.</td>
<td>1.0e-10</td>
<td></td>
</tr>
<tr>
<td>PutDir becomes scratch directory</td>
<td>.pdir</td>
<td>Setting this to nonzero will result in resetting the PutDir to the scratch directory. Since the scratch directory is unknown while parameters are provided, this allows to use the scratch directory as PutDir.</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Put File Attribute</td>
<td>Symbol</td>
<td>Description</td>
<td>Default Value</td>
<td>Optional Values</td>

### 4.42.5 Put File Pages

In this section we will discuss the structure of put file pages, in particular how to write titles and headers. In addition, we will give details on how users may control many aspects of the format of a put file page.

#### 4.42.5.1 Adding Titles and Headers

Titles and headers are widely used when there are sections of a page that remain relatively constant throughout a document. There are three independent writing areas on each page of a put file: the title block, the header block and the main window. The layout of a page is shown in the following diagram.

```
+-----------------+
| Title Block     |
+-----------------+
| Header Block    |
+-----------------+
| Main Window     |
```
Note that the put statement writes to the main window. There are two variants of the put statement that write to the title block and header block respectively: the puttl statement and the puthd statement.

Observe that every page must have an entry in the main window. If a page has no output in its main window, the page will not written, regardless of whether there are output items in the title or header blocks. To force a page that has an empty window out to file, we recommend to simply write something innocuous to the window, like the following:

```
put ''; // space
```

This will initiate the main window of the page and thus the page will be written.

Further, note that the size of any area of a page is based on the number of lines written to it and the total number of lines has to be smaller than the specified page size. A new page is started automatically whenever a page is full. For details on manual pagination, see section The Putpage Statement: Controlling Paging. Each area of a page is maintained independently. For example, we may write to the title block first, then to the header block and then again to the title block. However once we have written to the main window, all subsequent entries to the title and header are written to the next page, not the current page.

4.42.5.1.1 The Puttl Statement: Writing to the Title Block

The puttl (or putTitle which can be used as a synonym) statement is a variant of the put statement that writes to the title block of a page. The syntax is as follows:

```
puttl [file_name] item {item};
```

The keyword puttl indicates that this is a puttl statement. The internal name of the file, file_name, may be omitted if the desired file is already current. Like in the put statement, the content that is written is one or more items, that may be a text string, a numerical value or a set value. For more information on items, see section Output Items below. Consider the following example:

```
puttl factors 'GAMS Put Example';
```

If this line is placed before the put statement that writes to the main window in the example above, then GAMS Put Example will be written to the title block.

Observe that title blocks often contain the name of the model and the number of the put page. Once content is placed in the title block, it will be repeated on every page unless it is modified or deleted. For details on how to write output like the page number to a put file, see section System Suffixes as Output Items below.

Note

If content has already been written to the main window of a page, the items in the puttl statement will appear in the title block starting from the next page. Thus the title has to be written before any entries in the main window if it is to appear on the current page.

Observe that if the title and header blocks contain too many lines given the page size, the page will overflow resulting in a put error.
4.42.5.1.2  The puthd Statement: Writing to the Header Block  Like the puttl statement, the puthd (or putHeader which can be used as a synonym) statement is a variant of the put statement. Puthd statements write to the header block of a page. The syntax is as follows:

```
puthd [file_name] item {item};
```

The keyword puthd indicates that this is a puthd statement. The internal name of the file, file_name, may be omitted if the desired file is already current. Like in the put statement, the content that is written is one or more items. See section Output Items below for more information on items.

Observe that title blocks often contain a disclaimer or an instruction that is meant to be repeated on every page. Once content is placed in the header block, it will be repeated on every page unless it is modified or deleted.

Note

If content has already been written to the main window of a page, the items in the puthd statement will appear in the header block starting from the next page. Thus the header has to be written before any entries in the main window if it is to appear on the current page.

Observe that if the title and header blocks contain too many lines given the page size, the page will overflow resulting in a put error.

4.42.5.1.3  The putclear Statement: Deleting Title and Header Blocks  The putclear (or putfmcl which can be used as a synonym) statement may be used to delete the title and header blocks. The syntax is simple:

```
putclear;
```

If the keyword putclear is inserted after a title and/or header block has been written, but before the main window has been written to, then the title and/or header blocks of the current page will be deleted. If the main window has already been written to, the the title and/or header block of the next page and all subsequent pages will be deleted. Note that if the user wishes to delete either only the title or only the header block, the put file attributes .tlll and .hdll respectively may be set to zero. For more information, see Last Line Control.

4.42.5.2  The putpage Statement: Controlling Paging

A new page is started automatically if the bottom of a page is reached. Alternatively, a new page may be started early using a variant of the put statement: the putpage statement. The syntax is as follows:

```
putpage [file_name] {item};
```

The keyword putpage indicates that this is a putpage statement. In its simplest form, the putpage statement consists of just the keyword. If only the keyword is used, the current page will be terminated. The optional file_name makes the put file with the internal name file_name current. If output items follow, they will be written to the current page and a new page will be made available for the next put statement.

Consider the following example:

```
File example / example.txt /;
putpage example "This text is placed in the main window and the page ends here.";
put "Here starts a new page in the same putfile."
```

Observe that three file attributes are helpful for manual paging: last page (.lp), window size (.ws) and last line (.ll).
4.42 The Put Writing Facility

4.42.5.3 Controlling the Format of a Put File Page

While GAMS established gracious defaults, there are numerous ways to customize the format of a put file page. In this section we will present the put file attributes that facilitate the control of various aspects of page formatting and ways to control the position of the cursor.

4.42.5.3.1 Controlling Page Size, Page Width and Margins

By default, 60 rows (lines) may be written on a put file page. At any point in the program the file attribute page size (.ps) may be used to reset this value. Note that the upper limit is 130. Note further, that a put error will result if the attribute is set to value that is smaller than the number of rows which have already been written to the current page. Observe that the specification of .ps is only effective if the attribute print control (.pc) has a value other than its default value.

By default, 255 characters (columns) may be written to each line of a put file page. Like the page size, the page width may be reset at any point. GAMS provides the file attribute page width (.pw) to do this. Note that the upper limit is 32767. Note further, that a put error will result if the attribute is set to value that is smaller than the number of columns which have already been written to the current page.

By default, put file pages do not have top, bottom and left margins. However, it is easy to specify blank lines for the margins with the file attributes top margin (.tm) and bottom margin (.bm). Note that the lines reserved for the margins are in addition to the value specified for the page size (.ps). Observe that the file attribute .bm is only functional if the value of the file attribute print control (.pc) is set to zero. In addition, the number of empty columns for left margins may be specified with the file attribute left margin (.lm).

4.42.5.3.2 Controlling the Print Format and the Use of Capital and Lower Case Letters

By default, GAMS prints continuous pages. However, the file attribute print control (.pc) offers several alternative options. For a full list, see the respective entry in Table Put File Attributes above. Note in particular that the options 4, 5, 6 and 8 create delimited files, which are useful for importing output to other applications like spreadsheets. For an example, see section Creating a Report for the Model MEXSS.

By default, alphabetic characters are displayed in the case they were inputted. Note that the value of 1 for the file attribute alphabetic case (.case) will display all output in capital letters, regardless of the input, and the value of 2 will result in only lower case letters being displayed.

Assume that we wish a put file report.txt to have pages with 72 characters to a row and 58 lines, ASCII page control characters to be inserted at the end of every page, an additional top margin of 6 lines and all output displayed in upper case. The following assignments will implement these specifications:

```plaintext
File report /report.txt/;
report.pw = 72; report.ps = 58; report.pc = 3;
report.tm = 6; report.case = 1;
```

4.42.5.3.3 Controlling the Cursor On a Page

There are three ways to control the position of the cursor: with cursor control characters, with the system attribute system.tab and with file attributes. In this section we will give details on cursor control characters, while inserting tabs and file attributes that are relevant for cursor control will be discussed in the next two sections.

By default, the cursor is moved to the space immediately following the last character written. GAMS provides the control characters listed in Table 2 to specify another position for the cursor.
Table 2: Cursor Control Characters

Note that the numeric value n that follows the characters # and @ may be any expression or symbol with a numeric value. An example is given below. Note further, that the character @ is commonly used to align columns if the column headings have different widths. For an example, see section Creating a Report for the Model MEXSS. Observe that the character @ may be used to overwrite output items that were written earlier. Consider the following example:

```plaintext
File out /out.dat/;
put out;
put 'Good' @3 'morning everybody!';
```

This code snippet will generate the following output:

```
Good morning everybody!
```

Observe that cursor control characters are also used and discussed in the example at the beginning of this chapter.

4.42.5.3.4 Controlling the Cursor with a System Attribute: Inserting Tabs

The system attribute system.tab may be used to insert tabs. Consider the following example:

```plaintext
File test / test.dat /;
put test;
put "1" system.tab "2" system.tab "3" ;
```

The put file will contain the following line, separating 1, 2, and 3 by tabs.

```
1 2 3
```

4.42.5.3.5 Controlling the Cursor with File Attributes

In addition to cursor control characters and tabs, the position of the cursor may be controlled using the file attributes that will be discussed in this section. These file attributes refer to the current column, the current row and the last line in the title block, the header block and the main window.

Current Cursor Column

As there are three independent writing areas on each put file page, there are three file attributes that refer to the current column. They are listed in Table 3.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#n</td>
<td>Move cursor position to row n of current page.</td>
</tr>
<tr>
<td>@n</td>
<td>Move cursor position to column n of current line.</td>
</tr>
<tr>
<td>/</td>
<td>Move cursor to first column of next line.</td>
</tr>
</tbody>
</table>
Table 3: File Attributes for the Column Position of the Cursor

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.cc</td>
<td>Current cursor column in the main window.</td>
</tr>
<tr>
<td>.hdcc</td>
<td>Current cursor column in the header block</td>
</tr>
<tr>
<td>.tlcc</td>
<td>Current cursor column in the title block</td>
</tr>
</tbody>
</table>

Note that the values for these attributes are numeric and they are updated only at the end of a put statement. Consequently, their values will remain constant during a put statement, even if multiple items or lines are displayed. Observe that the attributes may be used on the left-hand side and on the right-hand side of an assignment statement to set the current column position and return it respectively.

The following example illustrates the updating of the cursor control suffixes and the use of cursor control characters. The example is trivial but instructive:

Scalar lmarg 'left margin' /6/;
File out; put out;
put @(lmarg+2) 'out.cc = ', out.cc:0:0 ' ';
put @out.cc 'x'/ @out.cc 'y'/ @out.cc 'z ';
put 'out.cc = ' out.cc:0:0;

The resulting file out.put will contain the following lines:

```
out.cc = 1  x
      y  out.cc = 23
```

Note that the scalar lmarg is set to a specific value that will be used as an alignment tab. Symbols which hold common alignment values such as margins or tabs are often useful for large structured documents. The first put statement uses the cursor control character @ to relocate the cursor to column 8 where the text item out.cc and the respective value for the file attribute .cc are displayed. Note that the numerical value of the file attribute is formatted locally with the effect that only integers are displayed. We observe that at the start of the first put statement the file attribute out.cc equals 1.

The second put statement illustrates the updating of the cursor control suffixes by writing the letters x, y and z on three different lines. Each is preceded by moving the cursor to the value of the file attribute .cc. Note that at the end of the first put statement the value of out.cc is updated to 20. Hence, out.cc is 20 at the start of the second put statement. As a single put statement is used to write all three letters, the value of out.cc remains constant and thus the letters are written in the same column. At the end of the second put statement the value of out.cc value is updated to 23 (observe that there are two blank spaces after the letter z).

The third put statement writes the current value of the file attribute out.cc, which is the value at the start of the put statement.

Current Cursor Row

As there are three independent writing areas on each put file page, there are three file attributes that refer to the current row. They are listed in Table 4.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.cr</td>
<td>Current cursor row in the main window.</td>
</tr>
<tr>
<td>.hdcr</td>
<td>Current cursor row in the header block</td>
</tr>
<tr>
<td>.tlcr</td>
<td>Current cursor row in the title block</td>
</tr>
</tbody>
</table>
Table 4: File Attributes for the Row Position of the Cursor

Note that the values for these attributes are numeric and they updated only at the end of a put statement. Consequently, their values will remain constant during a put statement regardless of how many rows are displayed. Observe that the attributes may be used on the left-hand side and on the right-hand side of an assignment statement to set the current row and return it respectively. The files attributes for the row position of the cursor behave similarly to those for the column position.

Last Line Control

Like the file attributes for the current column and row position, the file attributes for the last line have three variants, one for each writing area. They are given in Table 5.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.ll</td>
<td>Last line in the main window</td>
</tr>
<tr>
<td>.hdl1</td>
<td>Last line in the header block</td>
</tr>
<tr>
<td>.tll1</td>
<td>Last line in the title block</td>
</tr>
</tbody>
</table>

Table 5: File Attributes for the Last Line

Note that unlike the row and column controls, the last line attributes are updated continuously. Last line attributes are especially useful for modifying the three writing areas of a page. They may be used on the left-hand side and on the right-hand side of an assignment statement to set the current last line and return it respectively. Rows will be deleted if the last line attribute is set to a value that is lower than the current row.

Attention

The file attributes .tll1 and .hdl1 may not hold values applicable to the current page, because when the title or header blocks are modified, they will correspond to the title or header blocks of the next page if the main window has been written to on the current page.

As mentioned above, in addition to determining the last line in a writing area, these file attributes may be used to delete lines within a writing area. In the following example, the header block will be completely deleted by resetting the attribute .hdl1 to zero.

File out;
puthd out 'This header statement will be eliminated';
out.hdl1 = 0;

Note that a header is written initially. However, by changing the attribute .hdl1 to zero, the cursor is reset to the top of the header block. As a result, the header will not be written unless something new is added to the header block.

4.42.6 Output Items

Output items are the items in the put statement that are written to the put file. They may be a text, a numerical value or a set value. In this section we will provide more information on these three types of items. Observe that system suffixes and command line parameters are either text strings or have a numerical value. They may also be used as output items.
4.42.6.1 Text Items

Text items may be a quoted text, an explanatory text of identifiers and labels or names of set elements. In this section we will give details on each of these text items. In addition, text items may be system attributes or command line parameters. For these text items, see sections System Suffixes as Output Items and Command Line Parameters as Output Items respectively. Details on default field widths and alignments for text items and global and local customizing controls are given in section Customizing the Format of Output Items.

4.42.6.1.1 Text Items: Quoted Text The simplest text output item is a quoted text. A quoted text is any combination of characters or numbers set apart by a pair of single (‘) or double (“) quotes with each the items needing to use a matching pair. Thus the following three lines are all exactly equivalent.

```
put 'Run on ' system.date ' using source file ' system.ifile;
put "Run on " system.date " using source file " system.ifile;
put 'Run on ' system.date " using source file " system.ifile;
```

Note that there is a limit on the length of all output items: output items may not exceed the page width. In case this limit is exceeded, a put error will be reported in the listing file. Put errors are introduced and discussed in section Put Errors.

4.42.6.1.2 Text Items: Identifier Attributes Text items like the explanatory text of an identifier, the name of a set element and the explanatory text of a set element are specified with identifier attributes. The identifier attributes are listed in Table 6.

<table>
<thead>
<tr>
<th>Identifier Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanatory text of an identifier</td>
<td>.ts</td>
<td>Displays the descriptive text associated with any identifier (like a set, a parameter, a variable, an equation, a model).</td>
</tr>
<tr>
<td>Name of a set element</td>
<td>.tl</td>
<td>Displays the names of the individual elements of a set. Observe that the put statement must be embedded in a loop statement, where the respective set is the looping set or the set is a singleton set.</td>
</tr>
<tr>
<td>Identifier Attribute</td>
<td>Symbol</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>Explanatory text of a set element</td>
<td>.te(index_list)</td>
<td>Displays the explanatory text associated with a set element. Note that this attribute requires the specification of a driving index. If the set is a simple set, the set name itself will have to be specified as index (see example below). If the set is defined over an index, then the index or a subset of the index may be specified. A special case arises in case users wish to gain access to the explanatory text that appears in the definition of another set (see example below). Observe that if there is no explanatory text for a set element in the set definition, then either the name of the set element (default) or a blank will be displayed, depending on the value of the file attribute text fill (.tf). Note that with .tf=3 even if an explanatory text exists, the name of the element will be displayed. Observe that the put statement must be embedded in a loop statement, where the respective set is the looping set or the set is a singleton set.</td>
</tr>
<tr>
<td>Indexed identifier with label combination</td>
<td>.tn</td>
<td>Displays the name of the identifier with all individual label combinations. Observe that the put statement must be embedded in a loop statement, where the respective index is the looping set or the set is a singleton set. See example below.</td>
</tr>
</tbody>
</table>

**Table 6: Identifier Attributes**

Consider the following example:

Set  
\[
i \text{ master set of sites } / i1 \text{ Seattle, } i2 \text{ Portland } \]  
\[
i3 \text{ San Francisco, } i4 \text{ Los Angeles, } i5 / \]  
\[
j \text{ subset of sites } / i3 * i5 / ; \]

File out; put out i.ts /;  
loop(i, put i.tl, i.te(i) /);

The resulting put file out.put will contain the following output:

```
master set of sites
i1 Seattle
i2 Portland
i3 San Francisco
i4 Los Angeles
i5
```
Note that the explanatory text of the set \( i \) is written first, followed by the label names of the set \( i \) and their respective explanatory texts. Note further that even though the set \( i \) does not have an index (it is a simple set), an index is required for the attribute \( .te \). In this case we specify as index the set itself. Observe that the set element \( i5 \) was defined without an explanatory text. By default, GAMS inserts the name of the element instead. This may be changed by altering the code in the following way:

```gams
put out i.ts /;
out.tf = 0;
loop(i, put i.tl, i.te(i) /);
```

Note that we assign the value of zero to the file attribute text fill (.tf) before the put statement where one of the items refers to the explanatory text of a set element. As a result, a blank will be displayed where the explanatory text of the set element \( i5 \) is supposed to appear:

```
master set of sites
i1    Seattle
i2    Portland
i3    San Francisco
i4    Los Angeles
i5
```

Assume we also wish to display the elements of the set \( j \) and their explanatory texts. We could just adapt the code above for the set \( j \) and add the following two lines:

```gams
put / j.ts /;
loop(j, put j.tl, j.te(j) /);
```

These lines will result in the following output to be appended to the put file:

```
subset of sites
i3
i4
i5
```

Note that the explanatory text associated with the set elements is missing, since there is no explanatory text for the elements in the definition of the set \( j \) and the value of zero for text fill is still valid. However, we may gain access to the explanatory text of the set elements in the definition of the set \( i \) in the following way:

```gams
put / j.ts /;
loop(j, put j.tl, i.te(j) /);
```

Note that the the specification \( i.te(j) \) singles out the explanatory texts of the elements of the set \( i \) that are also elements of the set \( j \). Hence we will obtain the desired output:

```
subset of sites
i3    San Francisco
i4    Los Angeles
i5
```
The following example illustrates the use of the identifier attribute .tn. The model [MEXSS] is a simplified representation of the Mexican steel sector, where five steel plants have to satisfy the demand for steel in three markets. Each steel plant \( i \) has several productive units \( m \) and the capacity of every unit in every plant is specified with the parameter \( k(m,i) \). Assume we wish to write to a put file a list of all nonzero capacities. We could add the following code to the model:

```plaintext
File out /out.dat/;
put out 'Capacity (in metric tons)' / /
loop((m,i)$k(m,i),
   put k.tn(m,i), @30 '=' k(m,i) /;
)
```

Note that we restrict the loop statement with a logical condition to exclude entries of zero. The put file out.dat will contain the following lines:

Observe that a more elaborate report for the model [MEXSS] is given in section Creating a Report for the Model MEXSS at the end of this chapter. The identifier attribute .tn is particularly useful when creating scalar EMP info files.

4.42.6.1.3 Text Items: Text Blocks The easiest way to write blocks of text to a put file is with the dollar control options $onPut and $offPut. Consider the following example:

```plaintext
File fx; put fx;
$onPut
We will write four
lines of text to the put file,

including a blank line.
$offPut
```

The put file fx.put will contain the following lines.

We will write four
lines of text to the put file,

including a blank line.

Note that these dollar control options have a variant that allows the substitution of compile-time variables. For details see the description of $on/offPut.
4.42.6.2 Numeric Items

Numeric items may be values of parameters, variable and equation attributes or model attributes and expressions of such elements. These numeric items will be discussed in this section. In addition, numeric items may be command line parameters. For these numeric items, see section Command Line Parameters as Output Items. Details on default field widths and alignments for numeric items and global and local customizing controls are given in section Customizing the Format of Output Items.

4.42.6.2.1 Numeric Items: Parameters and Functions  In our first example in this chapter, one of the output items was the parameter \( f \). For convenience, we repeat the respective code below:

\[
\text{put 'Freight cost ', f;}
\]

Note that the simple name of the parameter is sufficient. In the same example we also had two parameters that were defined over an index: \( a(i) \) and \( b(i) \). The respective lines of code follow:

\[
\text{loop(i, put @3, i.tl, @15, a(i)/;}
\]

* ...

\[
\text{loop(j, put @3, j.tl, @15, b(j)/;}
\]

Note that indexed parameters must be specified with their index and a put statement with an indexed parameter has to be embedded within a loop structure.

4.42.6.2.2 Numeric Items: Variable and Equation Attributes  Recall that data associated with variables and equations is stored in variable attributes and equation attributes respectively. A full list is given in sections Variable Attributes and Equation Attributes.

Suppose we wish to generate a report with the demand for each market in the transportation model [TRNSPORT], the satisfied demand after solution of the model and the marginal cost of meeting the demand. Recall that the demand data for each market is saved in the parameter \( b(j) \) and the relationship between shipment quantities and demand is encoded in equation \( \text{demand}(j) \). The following code will generate the desired report:

\[
\text{File report /report.dat/; put report;}
\]

\[
\text{loop(j,}
\]

\[
\text{put 'Report for ' j.tl/}
\]

\[
\text{'Demand' @35 b(j):10:0 /}
\]

\[
\text{'Demand satisfied' @35 demand.l(j):10:0 /}
\]

\[
\text{'Marginal Cost of meeting demand' @35 demand.m(j):10:2 /;}
\]

\]

Note that we use three numeric output items: the parameter \( b(j) \), the level value of the equation \( \text{demand}.l(j) \) and the marginal value of the equation \( \text{demand}.m(j) \). Note further, that all three items are indexed over the set \( j \) and thus the put statement has to be placed within a loop statement. Observe that we customize the formatting of the items. For details see section Local Item Formatting Controls. The put file report.dat will contain the following output:
Report for New-York
Demand 325
Demand satisfied 325
Marginal Cost of meeting demand 0.23

Report for Chicago
Demand 300
Demand satisfied 300
Marginal Cost of meeting demand 0.15

Report for Topeka
Demand 275
Demand satisfied 275
Marginal Cost of meeting demand 0.13

4.42.6.3 Numeric Items: Model Attributes GAMS models have many model attributes. An introduction and a complete list is given in section Model Attributes. While in principle all model attributes may be used as output items, the attributes .modelstat and .solvestat with their string valued counter parts .TModStat and .TSolStat are used most frequently. They refer to the model status and solver termination condition after solution respectively. For a complete list of their values, see sections Model Status and Solver Status.

Suppose we wish to generate a report that contains the time it took to execute the solve statement of the transportation model [TRNSPORT], the objective value and the corresponding string valued model and solver status. Recall that the name of the model is transport. The following code will generate the desired report:

File report /report.dat/; put report;
put 'elapsed time in seconds of solve statement : ' transport.etSolve:0 /
   'objective value: : ' transport.objVal:0 /
   'model status: : ' transport.tmodstat /
   'solver status: : ' transport.tsolstat ;

Observe that we customize the formatting of the first two items. For details see section Local Item Formatting Controls. The put file report.dat will contain the following output:

elapsed time in seconds of solve statement : 0.11
objective value: : 153.68
model status: : 1 Optimal
solver status: : 1 Normal Completion

4.42.6.3 Set Value Items

There are only two set values: YES and NO. The set value will be YES if a label is an element of a specific set and NO otherwise. Consider the following example which is adapted from the example in section Text Items: Identifier Attributes above:

Set i master set of sites / i1 Seattle, i2 Portland i3 San Francisco, i4 Los Angeles, i5 /
   j subset of sites / i3 * i5 / ;
File out2 / out2.dat /;
put out2 j.ts /
   out2.tf = 0;
loop(i, put i.tl, j(i), ' ', i.te(i) /);
Note that within the loop structure, the put statement writes each element of the set \( i \), determines whether it is a member of the set \( j \) and displays the respective set value, and adds the explanatory text for the label. Hence the resulting put file \( \text{out2.dat} \) will look as follows:

\[
\begin{align*}
\text{subset of sites} \\
i1 & \quad \text{NO Seattle} \\
i2 & \quad \text{NO Portland} \\
i3 & \quad \text{YES San Francisco} \\
i4 & \quad \text{YES Los Angeles} \\
i5 & \quad \text{YES}
\end{align*}
\]

Observe that the set values in the second column reflect set membership of the set \( j \). Observe further, that the missing explanatory text for label \( i5 \) is displayed as a blank, since the value of the file suffix \text{text fill} (.tf) equals zero.

### 4.42.6.4 System Suffixes as Output Items

System suffixes contain information about a GAMS run, they are introduced and discussed in chapter \text{System Attributes}. System suffixes may be used as output items in the context of put statements. They are accessed in the following two ways:

- \text{system.attribute}
- \%\text{system.attribute}\%

Here \text{system} is a keyword and \text{.suffix} is a specific system suffixes. Note that \text{system.suffix} references the \textit{execution-time} version (which can be of type string or numeric) of the system suffixes and \%\text{system.suffix}\% (which is interpreted by the compiler as part of the input string) references the \textit{compile-time} version. For further details on the difference between execution-time and compile-time system suffixes, see chapter \text{System Attributes}. A complete list of all system suffixes is given in section \text{List of all System Suffixes}, in Table 7 we present a list of the most common system suffixes.

<table>
<thead>
<tr>
<th>System Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.date</td>
<td>Program execution date</td>
</tr>
<tr>
<td>.ifile</td>
<td>Input file name</td>
</tr>
<tr>
<td>.ofile</td>
<td>Output file name</td>
</tr>
<tr>
<td>.rdate</td>
<td>Restart file date</td>
</tr>
<tr>
<td>.rfile</td>
<td>Restart file name</td>
</tr>
<tr>
<td>.sfile</td>
<td>Save file name</td>
</tr>
</tbody>
</table>
| .title           | Title of the model as specified by \\$\text{title}\

**Table 7: A Selection of System Suffixes**

To illustrate how system suffixes are used, assume we wish to include the program execution date, the name of the input (GAMS) file, and the page number of the current put statement in the input file to the report \text{results.dat} in section \text{A First Example} above. We will modify the code in the following way:

```plaintext
File factors /factors.dat/, results /results.dat/;
* ...
put results;
```
puthd 'Program Execution Date:', @26, system.date / 
'Source File:', @26, system.ifile / ;
'Page Number:', @26, system.page / ;
put 'Transportation Model Results' / ;
loop((i,j), put i.tl, @12, j.tl, @24, x.l(i,j):8:4 /);

The file results.dat will then contain the following lines:

Program Execution Date: 01/13/17
Source File: C:\Documents\GAMS\Models\transport.gms
Page Number: 1

Transportation Model Results
Seattle New-York 50.0000
Seattle Chicago 300.0000
Seattle Topeka 0.0000
San-Diego New-York 275.0000
San-Diego Chicago 0.0000
San-Diego Topeka 275.0000

Note that the date is given in the American format: month/day/year and can be reset via the command line parameter DFormat. Also note that including the page number in the header block of a put file will have the effect that the pages of the put file will be numbered. Of course, this is especially useful for longer put files.

It is also possible to read environment variables at execution time in a put context using sysEnv.name as in the following example:

$setEnv hello world
put_utility 'log' / sysEnv.hello;

If the environment variable queried is not defined, the result depends on the value of the command line parameter stringChk.

4.42.6.5 Command Line Parameters as Output Items

Command line parameters may also be used as output items. They are introduced and discussed in chapter The GAMS Call and Command Line Parameters. For an overview of all GAMS command line parameters, see section List of Command Line Parameters. Like system suffixes, command line parameters are referenced in the context of a put statement either compile-time strings or in an execution time version as follows:

put "%gams.parameter%";
put gams.parameter;

Here parameter is a GAMS command line parameter. To illustrate how command line parameters are used, assume we wish to include the page size of the input file, the name of the input file and the name of the restart file in the report results.dat in section A First Example above. We will modify the code in the following way:
File factors /factors.dat/, results /results.dat/ ;
* ... 
put results;
put 'Transportation Model Results'// ;
loop((i,j), put i.tl, @12, j.tl, @24, x.l(i,j):8:4 //);
put / "Page size = %gams.ps%
/ "GAMS input file = %gams.input%"
/ "GAMS restart file = %gams.restart%"

The last three lines of the put file results.dat follow:

Page size = 58
GAMS input file = C:/Documents/GAMS/Models/trnsport.gms
GAMS restart file =

Note that there was no restart file in the GAMS run, thus the value for %gams.restart% is the empty string.

In this example it actually makes no difference if one uses the compile- or execution time version to query the value of a command line parameter. This might be different, when doing the compile and execution phase separately, e.g. when using remote execution. Here is a toy example showing the difference:

$onEchoV > logScrDir.gms
put_utility 'log' / '%gams.scrDir%';
put_utility 'log' / gams.scrDir;
$offEcho

$call gams logScrDir.gms a=c s=1 keep=1
$call gams logScrDir.gms a=e r=1

In the log, one will see that %gams.scrDir% is evaluated in the first run at compile time already, while gams.scrDir is evaluated at execution time in the second run:

--- logScrDir.gms(1) 3 Mb
  C:\Data\tmp\225d\n--- logScrDir.gms(2) 3 Mb
  C:\Data\tmp\225e\n
4.42.6.6 Customizing the Format of Output Items

GAMS provides global and local controls to modify the default format of output items. Global controls are set with file attributes and apply to all output items in a put file that follow the assignment of a file attribute. Local controls are used to change the format of only one specific output item.

4.42.6.6.1 Global Item Formatting Controls The alignment (justification) of the field and the width of the field may be modified for all types of output items. The attributes that control field alignment are listed in Table 8. Note that possible values are 1 (right), 2 (left) and 3 (center).

<table>
<thead>
<tr>
<th>Type of Output Item</th>
<th>Symbol</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text items: set labels</td>
<td>.lj</td>
<td>2: Left</td>
</tr>
<tr>
<td>Text items: quoted and explanatory text</td>
<td>.tj</td>
<td>2: Left</td>
</tr>
<tr>
<td>Numeric values</td>
<td>.nj</td>
<td>1: Right</td>
</tr>
<tr>
<td>Set values</td>
<td>.sj</td>
<td>1: Right</td>
</tr>
</tbody>
</table>
Table 8: File Attributes for Field Alignment

The width of the field is specified with the number of spaces to be allocated. The attributes that control field width are listed in Table 9.

<table>
<thead>
<tr>
<th>Type of Output Item</th>
<th>Symbol</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text items: set labels</td>
<td>lw</td>
<td>12</td>
</tr>
<tr>
<td>Text items: quoted and explanatory text</td>
<td>tw</td>
<td>0</td>
</tr>
<tr>
<td>Numeric values</td>
<td>nw</td>
<td>12</td>
</tr>
<tr>
<td>Set values</td>
<td>sw</td>
<td>12 (maximum 20)</td>
</tr>
</tbody>
</table>

Table 9: File Attributes for Field Width

Note that the value of zero signifies a *variable* field width, matching the exact size of the item being displayed. If a text output item does not fit within the specified field, truncation will occur to the right. For numeric output items, the decimal portion of a number is rounded or scientific notation is used to fit the number within the given field. If a number is still too large, asterisks will replace the value in the output file.

For example, the following assignment will set the field width for numeric items in the file `out.put` globally to 4:

```
out.nw = 4;
```

In addition to field alignment and field width, there are further global controls that apply to numeric output items only. They are given in Table 10.

<table>
<thead>
<tr>
<th>File Attribute</th>
<th>Symbol</th>
<th>Description</th>
<th>Default Value</th>
<th>Optional Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of decimals</td>
<td>nd</td>
<td>Sets the number of decimals that are displayed for numeric items. A value of zero entails that fixed-format output will show the number rounded to the nearest integer.</td>
<td>2</td>
<td>Values may be between 0 and 20.</td>
</tr>
</tbody>
</table>
### File Attributes for Global Format Control Specific to Numeric Items

<table>
<thead>
<tr>
<th>File Attribute</th>
<th>Symbol</th>
<th>Description</th>
<th>Default Value</th>
<th>Optional Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric round format</td>
<td>.nr</td>
<td>Selects the formatting used for numeric output. For example, one can choose to use scientific notation (i.e. E-format) for all numbers: this is especially useful for numbers so small that they display as only zeros in fixed format with the value specified for number of decimals (.nd). The default rounding format will treat small values in this way, but in many situations, it is important to be aware that such small values exist.</td>
<td>1</td>
<td>0: Item is displayed in F or E format to fit given width and decimals. 1: Item is rounded to fit given width and decimals. 2: Item is displayed in E format to fit given width and decimals. 3: Item is rounded to fit given width. 4: Item is displayed in F or E format to fit given width.</td>
</tr>
<tr>
<td>Numeric zero tolerance</td>
<td>.nz</td>
<td>Sets the tolerance level for which a number will be rounded to zero for display purposes. Note that in case this attribute is set to zero, rounding is determined by the field width.</td>
<td>1.0e-10</td>
<td></td>
</tr>
</tbody>
</table>

Table 10: File Attributes for Global Format Control Specific to Numeric Items

Note that numeric items are always formatted to fit within the specified width limit, but their display may use fewer characters. Similarly, for some values of .nr, the number of digits shown is limited by the choice of the .nd parameter, but fewer digits may be shown. At most 17 significant digits are included - this is enough to represent any double-precision value unambiguously, i.e. as a base-10 string that converts back into this same double. With this in mind, any number can be represented fully in E-format using at most 24 digits, e.g. -1.25E+102.

With .nr=0, the formatting routines honor the decimals limit. Values closer to 1 are displayed in fixed format. Values so small they would display only zeros in fixed format are displayed in E-format, as are values too large for the width limit. Formatting with .nr=1 is similar, but small values are shown in fixed format even if they show all zeros. With .nr=2 E-format is used for all values, with the number of trailing digits respecting the decimals limit .nd. The decimals limit is ignored for .nr=3, and fixed format is used unless the value is so large that E-format output is shorter. Finally, .nr=4 is intended to be used with larger output widths, e.g. 18 or 24, in order to show values of all magnitudes in as full a precision as possible: it ignores the decimal limit and uses whatever format allows more significant digits in the specified width.

The following example illustrates the result of different combinations of numeric file attributes. Note that we will use five combinations of the file attributes .nd, .nz, .nr and .nw to display three numerical values.

```bash
Set c suffix combinations / comb1 * comb9 /
```
v value indices / value1 * value5 / ;

<table>
<thead>
<tr>
<th>Table</th>
<th>suffix(c,*) numeric suffix combinations</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>nd nz nr nw</td>
</tr>
<tr>
<td>comb1</td>
<td>3 0 0 12</td>
</tr>
<tr>
<td>comb2</td>
<td>3 1e-5 0 12</td>
</tr>
<tr>
<td>comb3</td>
<td>3 1e-5 1 12</td>
</tr>
<tr>
<td>comb4</td>
<td>8 0 0 10</td>
</tr>
<tr>
<td>comb5</td>
<td>6 1e-5 1 12</td>
</tr>
<tr>
<td>comb6</td>
<td>0 1e-5 1 12</td>
</tr>
<tr>
<td>comb7</td>
<td>10 0 2 18</td>
</tr>
<tr>
<td>comb8</td>
<td>0 0 3 14</td>
</tr>
<tr>
<td>comb9</td>
<td>0 0 4 18</td>
</tr>
</tbody>
</table>

Parameter value(v) test values
/ value1 1.2345678901e14
value2 $\pi$
value3 -0.1234567
value4 0.0001234567
value5 1.234567e-13 / ;

File out; put out;
out.nj=2; out.lw=10; out.cc=11;
loop (v, put v.tl:21);
loop (c,
   out.nd=suffix(c,"nd");
   out.nz=suffix(c,"nz");
   out.nr=suffix(c,"nr");
   out.nw=suffix(c,"nw");
   put / c.tl;
   loop (v,
      put @(ord(v)*21-10), value(v)
   )
);

Observe that we have chosen to align the values to the left. This will enhance readability as the model loops through the suffix combinations that entail different field widths. The resulting output file out.put follows:

<table>
<thead>
<tr>
<th>value1</th>
<th>value2</th>
<th>value3</th>
<th>value4</th>
<th>value5</th>
</tr>
</thead>
<tbody>
<tr>
<td>comb1 1.2345678E+14</td>
<td>3.142</td>
<td>-0.123</td>
<td>1.2345670E-4</td>
<td>1.234567E-13</td>
</tr>
<tr>
<td>comb2 1.2345678E+14</td>
<td>3.142</td>
<td>-0.123</td>
<td>1.2345670E-4</td>
<td>0.000</td>
</tr>
<tr>
<td>comb3 1.2345678E+14</td>
<td>3.142</td>
<td>-0.123</td>
<td>0.000</td>
<td>0.000</td>
</tr>
<tr>
<td>comb4 1.2345678E+14</td>
<td>3.14159265</td>
<td>-0.1234567</td>
<td>0.00012346</td>
<td>1.234567E-13</td>
</tr>
<tr>
<td>comb5 1.2345678E+14</td>
<td>3.141593</td>
<td>-0.123457</td>
<td>0.000123</td>
<td>0.000000</td>
</tr>
<tr>
<td>comb6 1.2345678E+14</td>
<td>3</td>
<td>-0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>comb7 1.2345678901E+14</td>
<td>3.1415926536E+00</td>
<td>-1.2345670000E-01</td>
<td>1.2345670000E-04</td>
<td>1.234567E-13</td>
</tr>
<tr>
<td>comb8 1.23456789E+14</td>
<td>3.141592653590</td>
<td>-0.12345670000</td>
<td>0.00012345670</td>
<td>0.000000</td>
</tr>
<tr>
<td>comb9 123456789010000</td>
<td>3.14159265389739</td>
<td>-0.12345678</td>
<td>1.234567E-4</td>
<td>1.234567E-13</td>
</tr>
</tbody>
</table>

Note that in comb1 the display of values switches to the exponential notation when the value becomes smaller than the number of decimal places allowed. This is a result of .nr=0. Note further, that value4 is greater than the zero tolerance level (.nz), but smaller than the number of decimals allowed (.nd) in both, comb2 and comb3. However, .nr=0 results in the exponential notation in the display of comb2, while .nr=1 has the effect that this small value is rounded to zero. Observe that in comb6 fixed-format is used whenever allowed by the width limit, and in these cases the output is rounded to integer because .nd is
set to zero. With comb7 E-format is used in all cases: a leading space is added for positive values and a minus sign to negative values, and the magnitude is indicated with an explicit plus/minus and two digits (three if necessary). With comb8 we see fixed-format used whenever possible and as many digits (significant or not) as allowed by the width. With comb9 we see only significant digits, with the format chosen to allow the display of as many digits as possible.

### 4.42.6.6.2 Local Item Formatting Controls

The local item formatting controls allow to format specific output items. Note that local formatting overrides global format settings. The syntax is as follows:

```
item:{<>}width:decimals;
```

Here `item` is the output item, followed by a colon, an alignment (justification) symbol, the field width, a colon and the number of decimals to be displayed. Note that the limit on the number of the decimal places is only valid for numeric output. Note further, that if a component of the local formatting feature is omitted, then the respective global formatting settings will be used. The local alignment symbols are listed in Table 11.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Alignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;</td>
<td>Right</td>
</tr>
<tr>
<td>&lt;</td>
<td>Left</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>Center</td>
</tr>
</tbody>
</table>

Table 11: Local Alignment Symbols

Observe that similar to global formatting, a field width of zero means that the field width will be variable, depending on the item to be displayed.

The following example serves as illustration. Observe that we use end-of-line comments to annotate the code.

```
File out; put out;
$eolCom //
Set   i / i1*i3 /;
Parameter d(i) / i1 1426, i2 1347, i3 900 /;
Scalar f / 17.6745 /;
loop(i, put d(i):0:0 /); // default justification and a field width
// of variable size with no decimals
put / 'Right Justified Comment':>50
// 'Center Justified Truncated Comment':<>20;
put / / f:<6:2; // left aligned scalar with 6 spaces for field width
// and two decimals
```

### 4.42.7 The Put Utility Statement

The put utility statement is a variant of the put statement that may be used to execute external programs. The syntax is as follows:
put_utility [file_name] 'command' / 'arguments' {/ 'command' / 'arguments'};

The keyword put_utility and its synonym put_utilities indicate that this is a put_utility statement. The keyword is followed by the internal name of an external file, file_name. Note that file_name may be omitted. It is not required for the put_utility statement but might be used to activate a file to be used with following put statements. Command denotes one of the commands listed in Table 12 below. Commands are followed by a slash and their respective arguments. Observe that a put_utility statement may contain multiple command / argument pairs. An example is given below.

The following simple example illustrates the put_utility statement:

File test / test.txt /;
put test "This is the original file."
put_utility 'ren' / 'test.dat';
putclos "This is the renamed file."

test.ap = 1;
put "Write to the renamed file."

Note that first the put file test.txt with the internal name test is defined, made current and written to. Then the put_utility statement uses the command ren to rename the current put file. The new name is test.dat and the internal name test will from now on reference the new file test.dat. However, the original file test.txt is not deleted. Hence, the code above will create two external files: test.txt and test.dat. The file test.txt will contain the following line:

This is the original file.

The file test.dat will have the following content:

This is the renamed file.
Write to the renamed file.

Note
If Put File Attributes are specified, they are also considered for the put_utility commands and arguments. This could lead to surprising results in some cases, like in this example:

File test / test.txt /;
test.pc = 5;
put test "This is the original file."

put_utility 'ren' / 'test.dat';
putclos "This is the renamed file."

This will trigger the following errors:

*** Error at line 5: Put_Utilities: Unknown request ""ren"
*** Error at line 5: Put_Utilities: Unknown request ""test.dat"

The problem is, that test.pc = 5; puts quotes around non-numeric output, and thus "ren" (including the quotes) is not recognized as command anymore. To overcome this issue test.pc should be set back to default for the ren command like this:
File test / test.txt /;
test.pc = 5;
put test "This is the original file."

test.pc = 2;
put_utility 'ren' / 'test.dat';
test.pc = 5;
putclose "This is the renamed file."

We will present a list of all commands and their arguments in Table 12 and give examples for most commands below.

Table 12: List of Commands and their Arguments

<table>
<thead>
<tr>
<th>Command</th>
<th>Description of Command</th>
<th>Description of Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>assignText</td>
<td>Allows to set the explanatory or label text of a singleton set element. See example below.</td>
<td>Name of singleton set symbol and text.</td>
</tr>
<tr>
<td>click</td>
<td>Adds a clickable file reference to the process window of the IDE. See example below.</td>
<td>File name of the file to which the reference will point.</td>
</tr>
<tr>
<td>dropEnv</td>
<td>Removes an environment variable at execution time.</td>
<td>Name of the environment variable.</td>
</tr>
<tr>
<td>ECArguments</td>
<td>Allows to set the arguments for execution time embedded code execution. See example in section Embedded Code at Execution Time.</td>
<td>Text for the embedded code argument.</td>
</tr>
<tr>
<td>exec</td>
<td>Passes a command to the operating system for execution. GAMS will wait until the command is executed. See example below. Note that the distinction between exec and shell is technical and may be operating system specific. Typically, the ability to use redirect of standard input output and the error console is involved.</td>
<td>Command to be executed with arguments.</td>
</tr>
<tr>
<td>exec.aSync</td>
<td>Passes a command to the operating system for execution. However, GAMS will not wait until the command is executed.</td>
<td>Command to be executed with arguments. Job control is handled identical to jobs spawned via execute.async.</td>
</tr>
<tr>
<td>exec.aSyncNC</td>
<td>Passes a command to the operating system for execution using a different console than the parent process (Windows only). GAMS will not wait until the command is executed, thus using multiple processors is possible. Job control is handled identical to jobs spawned via execute.async.</td>
<td>Command to be executed with arguments.</td>
</tr>
<tr>
<td>exec.checkErrorLevel</td>
<td>Passes a command to the operating system for execution. GAMS will wait until the command is executed, raises an execution error and aborts the execution, if the errorLevel returned is not 0.</td>
<td>Command to be executed with arguments.</td>
</tr>
<tr>
<td>Command</td>
<td>Description of Command</td>
<td>Description of Arguments</td>
</tr>
<tr>
<td>---------</td>
<td>------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>gdxIn</td>
<td>Accesses the GDX file specified in the argument. A subsequent directive <code>execute_load</code> or <code>execute_loadpoint</code> without a specified file name will unload data from the GDX file thus accessed. See example below.</td>
<td>Name of the GDX file that data will be loaded from.</td>
</tr>
<tr>
<td>gdxOut</td>
<td>Creates a new GDX file or accesses an existing GDX file specified in the argument. A subsequent directive <code>execute_unload</code> without a specified file name will write to the GDX file thus created or accessed. Note that if an existing GDX file is accessed, it will be overwritten. See example below.</td>
<td>Name of the GDX file to which data will be unloaded.</td>
</tr>

<td>Sends a message to both, the log file and the listing file. See example below.</td>
<td>Text of message.</td>
</tr>
<tr>
<td>ren</td>
<td>Creates a new external name for the current put file. The internal name will reference the new external file. Any subsequent put statements will write to the new file. See the simple example above and a more complex example below.</td>
<td>External file name.</td>
</tr>
<tr>
<td>save</td>
<td>Writes a save file of the current state of execution.</td>
<td>Name of save file.</td>
</tr>
<tr>
<td>setEnv</td>
<td>Sets an environment variable at execution time.</td>
<td>Name of the environment variable and its value.</td>
</tr>
</tbody>
</table>
4.42 The Put Writing Facility

<table>
<thead>
<tr>
<th>Command</th>
<th>Description of Command</th>
<th>Description of Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>shell</td>
<td>Passes a command to the command shell processor, where it is processed. The processed form of the command is then passed to the operating system for execution. See example below. Note that the distinction between shell and exec is technical and may be operating system specific. Typically, the ability to use redirect of standard input output and the error console is involved.</td>
<td>Command to be executed with arguments.</td>
</tr>
<tr>
<td>shell.checkErrorLevel</td>
<td>Passes a command to the command shell processor, where it is processed. The processed form of the command is then passed to the operating system for execution. GAMS checks the errorLevel returned implicitly, raises an execution error and aborts the execution, if is not 0.</td>
<td>Command to be executed with arguments.</td>
</tr>
<tr>
<td>solver</td>
<td>Selects a solver for a given or all model types (use *) by name. See example below.</td>
<td>Model type or * and solver name.</td>
</tr>
<tr>
<td>title</td>
<td>Changes the title on the DOS window.</td>
<td>New name for window.</td>
</tr>
<tr>
<td>winMsg</td>
<td>Sends a message to a window on a Windows machine. For examples, see models [ASYNNTRP] and [MRW01] in the GAMS Test Library.</td>
<td>Window name and message.</td>
</tr>
</tbody>
</table>

In the remainder of this section we will present examples.

**Exec: Creating Empty Files by Executing External Program touch**

Consider the following example:

```
Set i / 1*3 /;
loop(i, put_utility 'exec' / 'touch ' i.tl:0 '.txt');
```

Note that the command to be executed is `touch`. Thus this code snippet will create three empty files called `1.txt`, `2.txt` and `3.txt`.

**Exec and Ren: Creating Directories and Renaming Files**

Consider the following example:

```
File test / test.txt /; put test;
Set i / i01*i07 /;
loop(i,
    put_utilities 'exec' / 'mkdir ' 'test-':0 i.tl:0;
    put_utilities 'ren' / 'test-':0 i.tl:0 '%system.dirSep%test-':0 i.tl:0 '.txt':0 ;
    put 'this should be ' i.tl );
```

```
Observe that as the loop is executed, the first put_utility statement will create seven subdirectories called test-i01, ..., test-i07. The second put_utility statement will create a text file for each of the new subdirectories. The text file in subdirectory test-i01 is called test-i01.txt, the text file in subdirectory test-i02 is called test-i02.txt, etc. The put statement in the last line will write to each text file. For example, the following line will be generated for the text file test-i01.txt:

this should be i01

Note that at the end of the loop, the external file associated with the internal file name test is the put file test-i07.txt, since this file was the last current put file.

**Inc: Including the Content of a File**

In this example, we first create the external file recall.txt, write to it and close it. Then we create a new external file called report.dat. In a third step we include the content of the first file in the second file.

```plaintext
File recall /recall.txt/;
putclose recall "I am the external content."

File report /report.dat/;
put report "Here we include content from an external file.";
put_utility 'inc' / 'recall.txt' ;
```

Note that the file report.dat will contain the following lines:

Here we include content from an external file.
I am the external content.

**IncMsg, IncLog and IncMsglog: Including the Content of a File to the Log File and Listing file**

In this example, we first create the external file recall.txt, write to it and close it. Then we include the content of recall.txt into the log and listing file.

```plaintext
File recall /recall.txt/;
putclose recall "I am the external content." / "I go over more than one line."

display 'before the include';
put_utility 'incMsg' / 'recall.txt' ;
display 'after the include';
```

The listing file of this model shows the content of recall.txt:

```
---- 4 before the include
*** Start of include of file recall.txt
I am the external content.
I go over more than one line.
*** End of include of file recall.txt
---- 6 after the include
```
Msg, Log and Msglog: Writing to the Log File and Listing file

Consider the following example:

```gams
put_utility 'msg' / 'This message is for the lst file.'
   / 'log' / 'This message is for the log file.'
   / 'msgLog' / 'And this message is for the lst and the log file.' ;
```

Note that the following two lines will be generated in the log file:

This message is for the log file.
And this message is for the lst and the log file.

In addition, the listing file will contain the following two lines just before the report file summary.

This message is for the lst file.
And this message is for the lst and the log file.

Gdxout: Creating GDX Files and Unloading Data to them

Consider the following example:

```gams
Set j / 2005*2007 /;
Scalar random;
loop(j,
   put_utility 'gdxOut' / 'data' j.tl:0;
   random = uniform(0,1);
   execute_unload random;
);
```

This code will create the GDX files `data2005.gdx`, `data2006.gdx` and `data2007.gdx`. Note that each GDX file will contain a value between zero and 1 for the scalar `random`. For example, the file `data2005.gdx` (exported to an ASCII via `gdxdump`) will have the following content:

Scalar random / 0.171747132 /;

Gdxin: Loading Data from GDX Files

Note that the following example is an extension of the previous example that demonstrated the use of the command `gdxout`.

```gams
loop(j,
   put_utility 'gdxIn' / 'data' j.tl:0 ;
   execute_load random;
   display random;
);
```

This code loads the values of the scalar `random` from the GDX files `data2005.gdx`, `data2006.gdx` and `data2007.gdx` and displays them in the listing file of the GAMS input file:
Consider the following example:

Set j / j1*j5 /;
Scalar random;
loop(j,
    random = uniformint(0,100);
    put_utility 'shell' / 'echo ' random:0:0 ' > ' j.tl:0;
);

Observe that the shell script command `echo` outputs an integer between zero and 100 to the files j1, ..., j5.

Assume that there is a file called `sets.html` in our working directory. Consider the following code snippet:

```
put_utility 'click' / 'sets.html' ;
```

If we run this code snippet with the GAMS IDE, the following clickable link will appear in the IDE process window:

```
>>> File sets.html
```

### Solver: Select a solver by name at execution time

The `solver` keyword allows to select a solver at execution time by name. Normally, the option statement `option solver=xpress, lp=cplex;` is used to select the current solver, but in case where you want to programatically change the solver as in this example, this `put_utility` keyword can be useful. Consider the following code snippet which extends the [DICE] model:

```
... 
set slv 'MIP solvers to run' / cplex, gurobi, mosek, scip, xa, xpress /;
parameter rep 'report status, time, objective value, and more';
option bratio=1;
loop(slv,
    put_utility 'solver' / 'mip' / slv.tl:0;
    solve xdice using mip max wnx;
    rep(slv,'sstat') = xdice.solveStat;
    rep(slv,'mstat') = xdice.modelStat;
    rep(slv,'obj') = xdice.objVal;
    rep(slv,'time') = xdice.etSolve;
    rep(slv,'solver id') = xdice.sysIdent;
);
display rep;
```
If we run this code we get a report like this:

```
---- 82 PARAMETER rep report status, time, objective value, and more

<table>
<thead>
<tr>
<th>sstat</th>
<th>mstat</th>
<th>obj</th>
<th>time</th>
<th>solver</th>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>cplex</td>
<td>1.000</td>
<td>1.000</td>
<td>21.000</td>
<td>0.385</td>
<td>10</td>
</tr>
<tr>
<td>cbc</td>
<td>1.000</td>
<td>1.000</td>
<td>21.000</td>
<td>2.547</td>
<td>36</td>
</tr>
<tr>
<td>gurobi</td>
<td>1.000</td>
<td>1.000</td>
<td>21.000</td>
<td>1.077</td>
<td>36</td>
</tr>
<tr>
<td>mosek</td>
<td>1.000</td>
<td>1.000</td>
<td>21.000</td>
<td>2.372</td>
<td>56</td>
</tr>
<tr>
<td>scip</td>
<td>1.000</td>
<td>1.000</td>
<td>21.000</td>
<td>7.346</td>
<td>56</td>
</tr>
<tr>
<td>xa</td>
<td>3.000</td>
<td>8.000</td>
<td>21.000</td>
<td>20.061</td>
<td>80</td>
</tr>
<tr>
<td>xpress</td>
<td>1.000</td>
<td>1.000</td>
<td>21.000</td>
<td>1.460</td>
<td>81</td>
</tr>
</tbody>
</table>
```

If one want's to set a solver for all possible model types (similar to `option solver=xpress;`) specific model type has to be replaced by `*`: `put_utility 'solver' / '*' / 'xpress';`

**AssignText**: Assigns label text to an element of a singleton set

GAMS has no string data type. The explanatory or label text of an element can serve in several situations as a poor man's string type and used in `put` and `put_utility` statements. The example below extends the `TRNSPORT` model and disables flow on a particular connection. The solution point file created by `savePoint` gets renamed to e.g. `sol_seattle_new-york.gdx`. The filename is assembled using the `assigntext` keyword. This has been packaged for better readability in some STRING macros:

```
...$macro STRINGDEF(sym) singleton set sym / sym /
$macro STRING(sym) sym.te(sym)
$macro STRINGASSIGN(sym,text) put_utility 'assignText' / 'sym' / text
$macro STRINGAPPEND(sym,text) put_utility 'assignText' / 'sym' / sym.te(sym) text
alias (i,ii), (j,jj);
transport.savePoint = 1;
STRINGDEF(fname);
loop((ii,jj),
    x.up(ii,jj) = 0;
    solve transport min z using lp;
    x.up(ii,jj) = inf;
    STRINGASSIGN(fname,'sol');
    STRINGAPPEND(fname,'_' ii.tl:0);
    STRINGAPPEND(fname,'_' jj.tl:0 '.gdx');
    put_utility 'shell' / 'mv transport_p.gdx ' STRING(fname);
);```

### 4.42.8 Conditional Put Statements

In GAMS, shorthand notation for conditional statement are `dollar conditions`, as introduced in chapter Conditional Expressions, Assignments and Equations. Dollar conditions may also be used in the context of a `put` statement and its variants. The syntax in its most general form is as follows:

```
put $ logical_condition [file_name] item {item} {file_name item {item}};
```
Note that like all put statements, the conditional put statement begins with the keyword `put`. The keyword is followed by the dollar operator and a logical condition. If the logical condition is `TRUE` the put statement will be executed, otherwise the put statement will be ignored. For details on logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. Observe that the remainder of the conditional put statement is identical to the regular put statement introduced in section The Put Statement.

The following example demonstrates how dollar conditions are used in the context of put statements.

```gams
put$(a > 10) 'Some output items';
```

Note that the quoted text will only be written to the put file if the scalar or variable `a` is greater than 10.

### 4.42.9 Errors Associated with Put Statements

There are two types of errors that may occur when the put writing facility is used: syntax errors and put errors. In this section we will discuss these errors.

#### 4.42.9.1 Syntax Errors in Put Statements

Syntax errors are caused by the incorrect usage of the GAMS language, including unmatched parentheses, undefined identifiers, uncontrolled sets or the incorrect use of a keyword. These errors are detected during program compilation and are always fatal to program execution. For more information on compilation errors, see section Compilation Errors and the tutorials A GAMS Tutorial by Richard E. Rosenthal and Fixing Compilation Errors.

#### 4.42.9.2 Put Errors

Put errors are unique to the put writing facility. They are detected during program execution and are caused when the specifications of file attributes are violated. Typical errors include assigning inappropriate values to file attributes and attempts to write outside a page, like moving the cursor with the cursor control character `@` to a location beyond the page width. Consider the following example:

```gams
File out /out.dat/;
out.pw = 8;
put out "Let's try this.";
```

Note that we specify the page width (`.pw`) to be just 8 characters. However, the quoted text has clearly more than 8 characters. In such a case the GAMS code will be compiled and the log file will report "Normal completion". At the appropriate position in the listing file the following error will be reported:

```
**** PUT ERROR FOR FILE out AT LINE 5: PUT LINE OVERFLOW - LOOK FOR **** ON PUTFILE, YOU CAN RESET .PW UP TO 32767
```

The put file `out.dat` will contain the following line:

`Let'****`

As put errors are not fatal and are not emphasized in the log file, they may be easily overlooked. Especially in large put files, put errors may go undetected. GAMS provides the file attribute `.errors` that facilitates the display of the number of put errors. Consider the following example:

```gams
File out /out.dat/;
out.pw = 8;
put out "Let's try this.";
abort$(out.errors) "Put errors in out: ", out.errors;
```

Users may choose to output the number of put errors in a put file or display statement or even trigger an execution error as in the example above.
4.42 The Put Writing Facility

4.42.10 Creating a Report for the Model MEXSS

We started this chapter with a simple example and we will complete it with a more elaborate example. In this section we will show how the put writing facility may be used to create a report for the model [MEXSS]. The code for the report may be inserted at the end of the original model and is shown below in its entirety.

The model [MEXSS] analyzes the relative efficiency of five different plants for meeting the product requirements of ingot steel in three different markets. The model may be used to identify the major bottlenecks that constrain production in the system of plants. It will find the production levels in the steel mills and shipments from the mills to the markets that will meet the market requirements at least cost. We will create a report for this model that will present details on the available capacities of the productive units at the five plants, the unused capacities and the marginal values of the capacities. This report may be extended to include other data and results and the code may be reused to create new reports if the data in the model is changed. For models that are run periodically, say, weekly or monthly, reusable reports can be invaluable.

We will start the code for the report with defining the put file, setting the file attributes print control and page size and making the the put file current. Then we will specify some global formatting settings. We will continue with writing a title block and finally turn to the core of the report: a table with three subtables. Note that we will use in-line comments to annotate the code. The code follows:

```plaintext
$ compl //
File out /out.dat/;
out.pc=3; out.ps=54; // print control, page size
put out;

* Global Format Settings:
Scalars indent1 indent to first column of units display
       indent2 indent to first column of field labels
       indent3 indent to first column of first numeric field
       textwide wide text / 80 /
       textnarr narrow text / 30 /
out.nr = 0; // numeric round format
out.tw = textwide; // width of text field
out.lw = 11; // width of label field
out.nw = 11; // width of numeric field
out.nd = 2; // number of decimals displayed
indent1 = 3;
indent2 = 30;
indent3 = 27;

* Title Block
puttl 'MEXICO STEEL - SMALL STATIC MODEL':<> /
   system.date:<>/ /;

* Main Window
out.tj = 3; // alignment of text: center
put
   'This report is based on selected data and results from the model'/
   'MEXSS in the GAMS Library. This model analyzes the relative efficiency'/
   'of five different plants in meeting the product requirements for ingot'/
   'steel in three different markets. The model aims to find the pattern '/
   'of production levels in the mills and shipments from the mills to the '/
   'markets that will meet the market requirements at the least cost.' /
```

out.tj = 2; // alignment of text: left
out.tw = textnarr; // width of text field
putpage$(out.ll+card(m)+7 > out.ws); // manual paging

put 'Table 1. Plant Data and Results':0 '/--------'/; // Table 1
out.cc = indent2; // current column
loop(i, put i.tl::<>); // column headings

put / / 'CAPACITY (metric tons)'; // Capacity
loop(m,
    put / @indent1, m.te(m), @indent3; // row headings
    loop(i, put k(m,i)); // numeric values
);

* Header Block with column headings for next page (will be used only if necessary)
puthd 'Table 1 (continued). Plant Data and Results':0 /'----------'/;
out.hdcc = indent2;
loop(i, put i.tl::<>); // column headings
puthd '/';

* Main Window continued
if(out.ll+card(m)+sum((m,p)$b(m,p), 1)+3 > out.ws,
    putpage; // manual paging
    else put / /;
)

put 'UNUSED CAPACITY (metric tons)'; // Unused Capacity
loop(m,
    put / @indent1, m.te(m), @indent3; // row headings
    loop(i, put (k(m,i)-cc.l(m,i))); // numeric values
);

if(out.ll+card(m)+4 > out.ws,
    putpage; // manual paging
    else put / /;
)

put 'MARGINAL VALUE OF CAPACITY' @indent1 '(US$/ton)'; // Marginal Value of Capacity
loop(m,
    put / @indent1, m.te(m), @indent3; // row headings
    loop(i, put abs(cc.m(m,i))); // numeric values
);

Note that we set print control (.pc) to ASCII formfeed. Below we illustrate how to use one of the print control settings that generate a delimited file. Observe that we group all global format parameters and settings near the top of the code. This way of organizing the code will make it easy to modify the structure of the report in the future as needed. Observe further, that the output items in the title block are locally formatted to be center aligned.

In the remainder of the code the actual report is written in the main window. The block of text at the beginning serves as a brief introduction to the report. Note that the core of the report is a table consisting...
of three subtables, where the subtables share the column headings. Before writing the table, we insert a test - the conditional `putpage` statement - to determine whether there is a sufficient number of lines on the current page to accommodate the size of the first subtable. Thus the put writing facility would start a new page if there were not enough rows. We repeat similar tests before the code for the other two subtables. Observe that we insert a header block with the column headings. If a new page had to be started since there were not enough rows for the second or the third subtable, the header block would contain the column headings of the table. (Users might want to experiment by reducing the file attribute `page size (.ps)` to say, 30.) The report that will be generated follows:

**MEXICO STEEL - SMALL STATIC MODEL**

01/31/17

This report is based on selected data and results from the model MEXSS in the GAMS Library. This model analyzes the relative efficiency of five different plants in meeting the product requirements for ingot steel in three different markets. The model aims to find the pattern of production levels in the mills and shipments from the mills to the markets that will meet the market requirements at the least cost.

<td>136.46</td>
<td>138.03</td>
<td>140.00</td>
<td>0.00</td>
<td>94.28</td>
</tr>
</tbody>
</table>

Assume we need the data reported in the first subtable above in a delimited file format in order to import it to other applications, like spreadsheets or databases. Consider the following code:

```plaintext
file out2 / 'out2.csv' /;
```
Note that we set the file attribute page control (.pc) to 5. This means that non-numeric output items will be quoted and each output item will be delimited with commas. Observe that field widths, alignments and horizontal cursor relocations were completely avoided. The put file out2.put will contain the following lines:

```
"capacity (metric tons)","ahmsa","fundidora","sicartsa","hylsa","hylsap"
"blast furnaces",3.25,1.40,1.10,0.00,0.00
"open hearth furnaces",1.50,0.85,0.00,0.00,0.00
"basic oxygen converters",2.07,1.50,1.30,0.00,0.00
"direct reduction units",0.00,0.00,0.00,0.98,1.00
"electric arc furnaces",0.00,0.00,0.00,1.13,0.56
```

While a comma is the most commonly used delimiting character, other delimiters like a blank space (.pc=4) and a tab (.pc=6) may also be used.

For other examples of code that uses the put writing facility, see the various models in the GAMS Model Library.

### 4.43 Solver Usage

For the novice GAMS user, solver usage can be very simple: one runs the model and inspects the listing file to see what the solution is. No knowledge of solver options or solver specific return codes is required. While this is enough for some users, most will quickly find they need some basic knowledge of how to control the solver and interpret the results. Section Controlling a Solver via GAMS Options describes how to set the GAMS options that control a solver. Further, most solvers allow the user to set additional, solver-specific options. These can be set via a solver specific options file, which will be discussed in Section The Solver Options File. However, use of generic GAMS options should be preferred, since a GAMS option setting applies to all solvers and is interpreted by the solvers in a consistent way.

A number of solvers can make use of an initialization of variable and equation values. This will be discussed in Starting Point and Initial Basis.

Further solver specific topics, which are more interesting for advanced users, are discussed in the Sections Solve trace and Branch-and-Cut-and-Heuristic Facility (BCH).

For some hints on how to select a solver, see Choosing an appropriate Solver.
4.43 Solver Usage

4.43.1 Controlling a Solver via GAMS Options

GAMS options can be set on the GAMS command line, e.g.,

$ gams transport iterlim = 100

Additionally, they can be set by an option statement within a GAMS model, e.g.,

option iterlim = 100;

Finally, a model attribute can set a GAMS option for an individual model:

mymodel.iterlim = 100;

The model suffix takes precedence over the option statement, which takes precedence over the command line parameters. If none of these methods is used to set an option, default values apply.

Further, one can unset any model-specific option by assigning it the value \texttt{NA}:

mymodel.iterlim = NA;

Unfortunately, not every option can be set as command line parameter, option statement, and model attribute. We refer to

- Solver-Related Options for the list of solve-related options that can be set via the command line,
- Options that Control Solver-Specific Parameters and Options that Control the Choice of Solver for the list of solve-related options that can be set via the option statement, and
- Model Attributes Mainly Used Before Solve for the list of solve-related model attributes.

4.43.2 The Solver Options File

To specify solver-specific options, it is necessary to use a solver option file. Two things are required to do this: one must create an option file having a proper name, and one must tell the solver to read and use this option file.

To tell a solver to use an option file, one can set the \texttt{optfile} model attribute or the \texttt{optfile} option to a positive value. For example,

model mymodel /all/;
mymodel.optfile = 1;
solve mymodel using nlp maximizing dollars;

The option file takes its name from the solver being used: \texttt{solvername.XYZ}, where \texttt{solvername} is the name of the solver that is specified, and the suffix \texttt{XYZ} depends on the value to which \texttt{optfile} has been set. If its value is 1, the suffix is \texttt{opt}. For example, the option file when calling CONOPT would be called \texttt{conopt.opt}. See the documentation on \texttt{optfile} for more information.

The format of the options file can change marginally from solver to solver. The following illustrates some frequent features of the option file format. However, solvers may vary from this format. Thus, the solver-specific documentation should be checked before using an option file.
• Blank lines in an option file are ignored.
• A comment line might begin with an asterisk (\*) in the first column, is not interpreted by either GAMS or the solver, and is used purely for documentation.
• Each non-comment line contains only one option specification.
• The format for specifying options is as follows:

  keyword(s) [modifier] [value]

The keyword may consist of one or more words and is not case sensitive. The value might be an integer, a real, or a string. Real numbers can be expressed in scientific format, e.g., 1e-6. Note that not all options require modifiers or values.
• Any errors in the spelling of keyword(s) or modifiers will lead to that option being misunderstood and therefore ignored. Errors in the value of an option can result in unpredictable behavior. When detected, errors are either ignored or pushed to a default or limiting value, but not all can or will be detected.

Consider the following CPLEX options file,

* CPLEX options file
  barrier
  crossover 2

The first line begins with an asterisk and therefore contains comments. The first option specifies the use of the barrier algorithm to solve the linear programming problem, while the second option specifies that the crossover option 2 is to be used. Details of these options can be found in Summary of CPLEX Options.

Options can also be defined by generating an options file within the GAMS source code. Consider the following code fragment for using MINOS options file,

```gams
Model m /all/;
Option NLP = MINOS;
* MINOS options file
$onecho > minos.opt
  scale option 2
  completion partial
$offecho
m.OptFile = 1;
Solve m maximizing z using nlp ;
```

The first option sets the scale option to a value of 2. In this case, the keyword 'scale option' consists of two words. In the second line, the 'completion' option is set to 'partial'. Details of these options can be found in Summary of MINOS Options.

### 4.43.2.1 Dot Options

Dot options in a solver option file allow users to associate values to variables and equations using the GAMS name of the variables and equations. The general syntax of a dot option in the option file is as follows:

```
(variable/equation name).optionname (value)
```
Dot options can be specified for **all**, a **block**, a **slice**, and a **single** variable and equation. Please note that a specific dot option may only apply to variables or equations (e.g. the GAMS/Gurobi dot option **prior** applies to variables only). The following example makes the use of the dot option clear.

For example, suppose one has a GAMS declaration:

```gams
Set i /i1*i5/;
Set j /j2*j4/;
Variable v(i,j);
Equation e(i,j);
```

Consider the following lines in an option file with the imaginary option name **dotopt**:

<table>
<thead>
<tr>
<th>Line in option file</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>variables.dotopt 1</td>
<td>Sets the value of all variables to 1</td>
</tr>
<tr>
<td>equations.dotopt 2</td>
<td>Sets the value of all equations to 2</td>
</tr>
<tr>
<td>v.dotopt 3</td>
<td>Sets the value of the variables in block v to 3</td>
</tr>
<tr>
<td>e.dotopt(∗,∗) 4</td>
<td>Sets the value of the equations in block e to 4</td>
</tr>
<tr>
<td>v.dotopt(∗,'j2') 5</td>
<td>Sets the value of the variables v that have j2 in the second index position (slice) to 5</td>
</tr>
<tr>
<td>e.dotopt('i3',∗) 6</td>
<td>Sets the value of the equations e that have i3 in the first index position (slice) to 6</td>
</tr>
<tr>
<td>w.dotopt('i2') 7</td>
<td>Sets the value of the single variables v('i2') to 7</td>
</tr>
<tr>
<td>e.dotopt('i3','j3') 8</td>
<td>Sets the value of the single equations e('i3','i3') to 8</td>
</tr>
</tbody>
</table>

The values of the dot option are applied in correspondence to the sequence in which they appear in the option file. In the current example, the values of **dotopt** for the equation **e** would be as follows:

<table>
<thead>
<tr>
<th>e.dotopt</th>
<th>i1</th>
<th>i2</th>
<th>i3</th>
</tr>
</thead>
<tbody>
<tr>
<td>j2</td>
<td>4</td>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>j3</td>
<td>4</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>j4</td>
<td>4</td>
<td>4</td>
<td>6</td>
</tr>
</tbody>
</table>

### 4.43.3 Starting Point and Initial Basis

#### 4.43.3.1 Starting Point

NLP solvers that search for a locally optimal solution of a NLP require an initial point to start their search. Further, the closer this initial point is to a local optimum, the less effort the solver may have to spend. The latter can also be true for solvers that search for global optimal solutions, such as most LP or MIP solver or global MINLP solvers.

Because of this immense importance of a starting point, GAMS always passes a starting point to a solver. By default, the point passed on by GAMS is given by the level and marginal attributes of variables and equations. If these values have not been set yet, default values are used. This default value is zero, except for variables whose bounds would forbid this value. In this case, the bound closest to zero is used.

In addition to setting these values explicitly in a GAMS model, a user can also load them from a **save file** or a GDx point file via **execute_loadpoint**. The latter may have been generated by running a related model and using option **savepoint**. Further, in models with several solve statements, the solution from...
one solve, if any, is used to initialize the starting point for a succeeding solve. This happens automatically since solutions from a solve statements are also stored in the level and marginal values of variables and equations. Finally, note that model attribute defpoint can be used to force sending the default starting point to a solver.

For some solvers, in particular for MIP or MINLP, an option may have to be set to make use of the starting point. Further, some solvers offer the possibility to make use of a partial starting point or use the starting point as a guide for the search. For details, see the specific solver manuals and look for parameters like mipstart and the use of the GAMS parameter tryint.

### 4.43.3.2 Initial Basis

While for some solvers, the values of a starting point are sufficient to initialize the search, active-set algorithms make use of a different form of starting information. An active-set algorithm tries to identify which constraints are active (or binding) in a feasible or optimal solution, that is, which variables are at one of their bounds and for which equations the activity equals the right-hand-side and the marginal is non-zero. For example, the simplex method for linear programs is an active-set algorithm. The classification of constraints as either active or inactive is closely linked to a basis. Active constraints are called nonbasic and inactive constraints are called basic. A basis that specifies the active and inactive constraints in an optimal solution is called an optimal basis.

Active-set algorithms may start by guessing an initial basis and then iteratively updating this basis until an optimal basis is found. Solution time may be reduced substantially if a good approximation of the optimal basis can be identified and passed on to the solver. Such a user-provided initial basis is called an advanced basis. However, provision of an advanced basis does not always help. For example, the presolving algorithms used in some solvers may cause the advanced basis to be ignored. Further, solvers may perform poorly when the advanced basis provided is worse than what the solver would otherwise have constructed with its own heuristics. Finally, not all algorithms benefit from the provision of an advanced basis: interior-point algorithms are a notable example.

GAMS provides a hint to the solver to suggest whether a basis can or should be extracted from the initial point. The hint is based on the number of rows (aka single equations) with nonzero marginals and the value of the bratio option and is computed internally as:

\[
\text{hint} := (0 == \text{bRatio}) \text{ or } (\text{rowsWithNonzeroMarg} > \text{nRows} \times \text{bratio})
\]

While the setting of the variable level and marginal values is important in specifying an advanced basis, only the marginal values for the rows are relevant in computing the basis hint and in choosing a value for bratio. For example, in a problem with 1000 rows and with the default value of bratio (0.25), GAMS would suggest a basis only if at least 250 nonbasic rows exist.

Note that the default starting point - all marginals zero - is usually not sufficient for the construction of an initial basis. If the automatic transfer of a basis from one solve statement to the next leads to poor behavior in the solver, setting the option bratio to 1 will cause the basis hint to be false and suppress the use of an initial basis. Setting the model attribute defpoint to 1 or 2 will achieve the same result. Conversely, setting bratio to 0 will force the basis hint to be true.

Active-set solvers in GAMS typically use the basis hint value to decide whether to extract (and use) the advanced basis available in the starting point. Details can vary by solver, but typically it works as follows:

- Variables with a zero level value are suggested to be nonbasic if and only if they have a non-zero marginal value.
- Variables with a non-zero level value are suggested to be nonbasic if the level value is equal one of the variable bounds. The marginal values may also be used here: nonbasic variables correspond with non-zero marginal values.
• Equations with non-zero marginal are suggested to be nonbasic. Otherwise, they are suggested to be basic.

Thus, a user can attempt to explicitly provide an initial basis by setting a corresponding starting point. That is, one can set a guess for an initial basis by specifying

• non-zero marginals for equations that are predicted to be active in a solution
• non-zero marginals for variables that are predicted to be at their bound in a solution
• non-zero levels for the variables that are predicted to be non-zero in a solution

4.43.4 Trace Features

Sometimes it might be useful to get certain information about a particular solve statement (or GAMS job) in a compact and customizable format.

• The Trace file facility allows to create files containing information about the "end data" of a GAMS job and the contained solve statements.
• The Solve trace facility can provide more detailed information about the solution progress of a particular solve statement (e.g. objective value of the incumbent solution or the best dual bound every five seconds)

4.43.4.1 Trace File

The trace file contains information about the "end data" of a GAMS job and the contained solve statements. Creation of a trace file can be activated via command line parameter trace (see example below). The trace feature supports several predefined formatting options, that is differently formatted trace files can be created, depending on what output information is desired. The trace file format option can be set via command line parameter traceOpt. The trace file header defines the contained trace records and the associated trace record fields.

Note

• Trace information is appended to existing trace files in the format of the existing trace file. That is, if a previous trace file of the same name already exists, then all new trace data will be appended in the initial format, no matter if the current traceOpt value actually implies a different format.
• Trace file headers can be modified, i.e. the predefined formats can be customized and trace record fields can be added or removed as needed.

4.43.4.1.1 Trace Records A trace file can contain different types of trace records:
<table>
<thead>
<tr>
<th>Trace Record Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>GamsStep</td>
<td>A GamsStep refers to a GAMS execution phase (there are potentially multiple phases of GAMS execution in a single GAMS Job). For example, a trace file created with traceopt=0 for the [TRNSPORT] model, which contains a single solve statement, will contain two GamsSteps, one referring to the GAMS execution phase before the solve statement, the other one referring to the execution phase after the solve statement. Note that this may change depending on the setting of solveLink.</td>
</tr>
<tr>
<td>GamsExit</td>
<td>GamsExit describes the final GamsStep.</td>
</tr>
<tr>
<td>GamsSolve</td>
<td>GamsSolve describes a trace record referring to a solve statement. If a file has multiple solve statements, the corresponding trace file can have multiple GamsSolve trace records.</td>
</tr>
</tbody>
</table>

### 4.43.4.1.2 Trace Record Fields

For every trace record, the trace file can contain multiple fields from the following list.

<table>
<thead>
<tr>
<th>Name of Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CNS</td>
<td>CNS solver.</td>
</tr>
<tr>
<td>ComputerName</td>
<td>Computer name.</td>
</tr>
<tr>
<td>Direction</td>
<td>Direction of optimization: 0=min, 1=max.</td>
</tr>
<tr>
<td>DNLP</td>
<td>DNLP solver.</td>
</tr>
<tr>
<td>EMP</td>
<td>EMP solver.</td>
</tr>
<tr>
<td>ETAlg</td>
<td>Elapsed time it took to execute the solve algorithm (see corresponding model attribute etAlg).</td>
</tr>
<tr>
<td>ETSolve</td>
<td>Elapsed time it took to execute a solve statement in total (see corresponding model attribute etSolve).</td>
</tr>
<tr>
<td>ETSolver</td>
<td>Elapsed time taken by the solver only (see corresponding model attribute etSolver).</td>
</tr>
<tr>
<td>GamsCloseDownTime</td>
<td>The time it takes to close down GAMS (which partly depends on command line parameters) including the time to write the file summary, a GDX file, a (obfuscated) save file, a parameter file.</td>
</tr>
<tr>
<td>GamsCompTime</td>
<td>Time of the GAMS compilation phase.</td>
</tr>
<tr>
<td>GamsElapsedTime</td>
<td>Elapsed time since the start of a GAMS run in seconds.</td>
</tr>
<tr>
<td>GamsElements</td>
<td>Number of labels.</td>
</tr>
<tr>
<td>GamsErrorCount</td>
<td>Number of compilation and execution errors.</td>
</tr>
<tr>
<td>GamsExecTime</td>
<td>GAMS execution time.</td>
</tr>
<tr>
<td>GamsLineNumber</td>
<td>Number of lines. This corresponds to the number of lines in the echo print of the input file.</td>
</tr>
<tr>
<td>GamsReturnCode</td>
<td>GAMS return code.</td>
</tr>
<tr>
<td>GamsStartupTime</td>
<td>The time it takes to start up GAMS including the time to check and dump command line parameters, initialize certain internal data structures, loading a work file, reading a license file.</td>
</tr>
<tr>
<td>GamsSymbols</td>
<td>Number of symbols (also called identifiers) including names of intrinsic functions and predefined symbols.</td>
</tr>
<tr>
<td>GamsTotalTime</td>
<td>Total time of the corresponding trace record. Does only apply for trace records of type GamsStep and GamsExit.</td>
</tr>
<tr>
<td>GamsVersionID</td>
<td>String that contains a GAMS version ID, e.g. WEX282-282 for the Windows 64bit version of GAMS 28.2.</td>
</tr>
<tr>
<td>InputFileName</td>
<td>GAMS model filename.</td>
</tr>
<tr>
<td>JobDate</td>
<td>Day when the job started.</td>
</tr>
<tr>
<td>Name of Field</td>
<td>Meaning</td>
</tr>
<tr>
<td>-----------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>JobTime</td>
<td>Time when the Job started.</td>
</tr>
<tr>
<td>JulianDate</td>
<td>Julian date number with start day/time of job.</td>
</tr>
<tr>
<td>LP</td>
<td>LP solver.</td>
</tr>
<tr>
<td>Marginals</td>
<td>Indicates availability of marginals: 0=no, 1=yes.</td>
</tr>
<tr>
<td>MCP</td>
<td>MCP solver.</td>
</tr>
<tr>
<td>MINLP</td>
<td>MINLP solver.</td>
</tr>
<tr>
<td>MIP</td>
<td>MIP solver.</td>
</tr>
<tr>
<td>MIQCP</td>
<td>MIQCP solver.</td>
</tr>
<tr>
<td>ModelGenerationTime</td>
<td>Model generation time. Refers to the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>modelName</td>
<td>Model name. Refers to the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>ModelStatus</td>
<td>Model status. Refers to the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>ModelType</td>
<td>Model type. Refers to the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>MPEC</td>
<td>MPEC solver.</td>
</tr>
<tr>
<td>NLP</td>
<td>NLP solve.</td>
</tr>
<tr>
<td>NumberOfDiscreteVariables</td>
<td>Number of discrete variables. Refers to the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>NumberOfDomainViolations</td>
<td>Number of domain violations (see also model attribute domUsd).</td>
</tr>
<tr>
<td>NumberOfEquations</td>
<td>Number of equations. Refers to the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>NumberOfInstructions</td>
<td>Length of non-linear code.</td>
</tr>
<tr>
<td>NumberOfIterations</td>
<td>Number of iterations. Refers to the solve of the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>NumberOfNodes</td>
<td>Number of nodes. Refers to the solve of the last model in the part of the program that corresponds to the trace record. Only relevant if some tree search algorithm (e.g. branch-and-bound was used).</td>
</tr>
<tr>
<td>NumberOfNonlinearNonZeros</td>
<td>Number of non-zeroes. Refers to the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>NumberOfNonZeros</td>
<td>Number of variables. Refers to the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>NumberOfVariables</td>
<td>Number of variables. Refers to the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>ObjectiveValue</td>
<td>Objective value. Refers to the solve of the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>ObjectiveValueEstimate</td>
<td>Estimate of the best possible solution for a mixed-integer model (aka best bound). Refers to the solve of the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>OptionFile</td>
<td>Solver option file number. Refers to the solve of the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>Platform</td>
<td>Platform ID, e.g. WEX for the Windows 64bit.</td>
</tr>
<tr>
<td>QCP</td>
<td>QCP solver.</td>
</tr>
<tr>
<td>RMINLP</td>
<td>RMINLP solver.</td>
</tr>
<tr>
<td>RMIP</td>
<td>RMIP solver.</td>
</tr>
<tr>
<td>RMIQCP</td>
<td>RMIQCP solver.</td>
</tr>
<tr>
<td>RMPEC</td>
<td>RMPEC solver.</td>
</tr>
<tr>
<td>SolveLine</td>
<td>Line number of the last solve statement in the part of the program that corresponds to the trace record. This corresponds to the line number in the echo print of the input file.</td>
</tr>
<tr>
<td>Name of Field</td>
<td>Meaning</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SolveNumber</td>
<td>Number of solve statement for a particular model. For example, solve myModelA...; solve myModelB...; solve myModelA...; results in solve numbers 1, 1, 2.</td>
</tr>
<tr>
<td>SolverCalcTime</td>
<td>Time spent in function and derivative calculations (deprecated, see also model attribute resCalc).</td>
</tr>
<tr>
<td>SolverElapsedTime</td>
<td>Elapsed time taken by the solver when solveLink=0 is used (almost identical to model attribute etSolver).</td>
</tr>
<tr>
<td>SolverID</td>
<td>Solver ID number.</td>
</tr>
<tr>
<td>SolverName</td>
<td>Name of the solver. Refers to the solve of the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>SolverReadTime</td>
<td>Time to import model (deprecated, see also model attribute resIn).</td>
</tr>
<tr>
<td>SolverRealTime</td>
<td>Elapsed time taken by the solver when solveLink=0 is used (almost identical to model attribute etSolver).</td>
</tr>
<tr>
<td>SolverSignature</td>
<td>String containing a solver signature, e.g. IBM ILOG CPLEX 28.2.0 r750fa45 Released Aug 19, 2019 WEI x86 64bit/MS Window. Refers to the solver used to solve the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>SolverStatus</td>
<td>Solver Status. Refers to the solve of the last model in the part of the program that corresponds to the trace record.</td>
</tr>
<tr>
<td>SolverTime</td>
<td>Time used to solve the model in seconds reported by the solver (see also model attribute resUsd).</td>
</tr>
<tr>
<td>SolverVersion</td>
<td>Solver Version (see also model attribute sysVer).</td>
</tr>
<tr>
<td>SolverWriteTime</td>
<td>Time to export solution (deprecated, see also model attribute resOut).</td>
</tr>
<tr>
<td>User1</td>
<td>Content of user1 string.</td>
</tr>
<tr>
<td>User2</td>
<td>Content of user2 string.</td>
</tr>
<tr>
<td>User3</td>
<td>Content of user3 string.</td>
</tr>
<tr>
<td>User4</td>
<td>Content of user4 string.</td>
</tr>
<tr>
<td>User5</td>
<td>Content of user5 string.</td>
</tr>
<tr>
<td>UserName</td>
<td>User name.</td>
</tr>
</tbody>
</table>

### 4.43.4.1.3 Trace Report

GAMS can create trace reports from trace files, if started with command line parameter action=gt. The following sequence of commands loads model [TRNSPORT] from the GAMS model library, runs trnsport.gms and creates a tracefile trc.txt, and produces a trace report plus a trace summary from the trace file.

```
$ gamslib trnsport
$ gams trnsport trace=trc.txt
$ gams trc.txt a=gt
```

The trace file trc.txt contains the default trace record fields for the GamsStep and GamsSolve trace records:

- Trace Record Definition
- GamsStep
  - JobDate JobTime InputFileName GAMS GamsVersionID GamsReturnCode GamsErrorCount GamsStartupTime GamsCompTime GamsExecTime GamsCloseDownTime GamsTotalTime
- GamsSolve
  - JobDate JobTime InputFileName ModelType SolverName SolverStatus ModelStatus SolveNumber SolveLine SolveNumber SolveLine
  - NumberOfIterations ModelGenerationTime SolverReadTime SolverCalcTime SolverWriteTime ObjectiveValue
The trace summary trc.sum contains condensed information about the trace records:

Trace Summary with TL=0 for [...]\trc.txt
Trace Records = 3, Error Records = 0, First Date = 09/25/19 07:04:00

The trace report is created in trc.lst and contains detailed information about the trace records from the underlying trace file including a ModelSolveStat matrix that assigns a score from 0 to 9 to all potential combinations of model status and solver status:

[...]
Trace Report for File: [...]\trc.txt

Using ModelSolveStat for TL=0

<table>

GTRACE TIME = 0.000 SECONDS VERID WEX282-282 [...]

The trace report may be particularly interesting, if the underlying trace file contains multiple trace records from different solve statements. In combination with command line parameter traceLevel, it is easy to
filter for GamsSolve trace records with a low ModelSolveStat score, i.e. undesirable combinations of model status and solver status. If we run [TRNSPORT] again with an iteration limit of 0 (remember that the trace information will be appended to the trace file from the example above) and recreate the trace report as follows

```bash
$ gams trnsport trace=trc.txt iterlim=0
$ gams trc.txt a=gt
```

the trace report shows two solve records and the obtained statuses:

```
Total SOLVE records = 2 all return codes

  solvestatus           1 RC=  1 1 Normal Completion
  solvestatus           1 RC=  2 2 Iteration Interrupt
  modelstatus           1 RC=  1 1 Optimal
  modelstatus           1 RC=  6 6 Intermediate Infeasible
```

A look at the ModelSolveStat matrix from the initial example, tells us that a combination of model status 6 (Intermediate Infeasible) in combination with solve status 2 (Iteration Interrupt) results in a score of 5. If we increase the traceLevel to a value greater than or equal to 5 and recreate the trace report again, e.g. via

```bash
$ gams trc.txt a=gt tracelevel=5
```

the ModelSolveStat matrix at the beginning of the trace report changes such that only the scores greater than 5 for accepted combinations of model and solver status are shown

Using ModelSolveStat for TL=5

```
  1  2  3  4  5  6  7  8  9 10 11 12 13
1  9 . . . . . . . . . . . .
2  9  9  9  9  9 .  9 . . .
3  9 . . . . . . . . . . .
4  9 . . . . . . . . . . .
5  9 . . . . . . . . . . .
6 . . . . . . . . . . . .
7  9  9  9  9  9 .  9 . . .
8  9  9  9  9  9 .  9 . . .
9 . . . . . . . . . . . .
10 9 . . . . . . . . . . .
11 . . . . . . . . . . . .
12 . . . . . . . . . . . .
13 . . . . .  6 . . . . .
14 . . . . . . . . . . . .
15 9 . . . . . . . . . . .
16 9 . . . . . . . . . . .
17 9 . . . . . . . . . . .
18 9 . . . . . . . . . . .
19 9 . . . . . . . . . . .
```

and GAMS throws an execution error

```text
--- Starting trace report generation
*** Status: Execution error(s)
```

The trace file facility in combination with the trace report can be particularly useful for automated quality assurance tests where certain expected outcomes should be audited.
4.43.4.2 Solve trace

In order to do accurate performance evaluations it may be useful to obtain more detailed information about a solve than the “end data” that the trace file provides. E.g., for a branch-and-bound based solver, one may want to have intermediate information about the values of primal and dual bounds at the root node and subsequent nodes within the search.

The solve trace option that is implemented in some of the GAMS solver interfaces allows users to output solve information, e.g., primal and dual bounds, for every n nodes or at every time step. For example, the user may be interested in the objective value of the incumbent solution or the best dual bound on the optimal value every 50 nodes and every five seconds of the solve.

Note

The solve trace file format and options may change in a future GAMS release.

The solve trace option is invoked via a GAMS solver options file. Usually, options to specify a filename of the trace file to be created and options to specify time and node intervals are available. Please refer to the GAMS solver manuals for the exact names of these options (search for solvetrace or miptrace).

The solve trace file is written in comma-separated-value (CSV) format, where the entries in each line have the following meaning:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>lineNum</td>
<td>a line index</td>
</tr>
<tr>
<td>seriesID</td>
<td>indicator why the line was written: S = start of search, N = node frequency, T = time frequency, E = end of search</td>
</tr>
<tr>
<td>node</td>
<td>number of enumerated branch-and-bound nodes</td>
</tr>
<tr>
<td>seconds</td>
<td>time since the solving started</td>
</tr>
<tr>
<td>bestFound</td>
<td>primal bound, i.e., objective value of incumbent solution</td>
</tr>
<tr>
<td>bestBound</td>
<td>dual bound, i.e., bound on optimal value</td>
</tr>
</tbody>
</table>

A sample solve trace file including statistics of a GAMS run using the MIP model [DICE] and the solver XPRESS looks as follows:

* miptrace file miptrace.mtr: ID = XPRESS.1 Instance = dice
* fields are lineNum, seriesID, node, seconds, bestFound, bestBound
1, S, 1, 0.078, na, na
2, N, 101, 0.781, 21, 23.9369
3, N, 201, 0.875, 21, 23.5564
4, N, 304, 1.031, 21, 23.5564
5, E, 399, 1.094, 21, 21
* miptrace file miptrace.mtr closed

See also the slides for the presentation Advanced Use of GAMS Solver Links (2013) and the accompanying scripts for some ideas on what to do with the solve trace functionality.

4.43.5 Branch-and-Cut-and-Heuristic Facility (BCH)

Global search algorithms can sometimes significantly benefit from user supplied routines that support the solution process of an hard optimization problem. For example, branch-and-cut solvers (e.g., CPLEX,
Gurobi, SCIP, Xpress) can profit from user-supplied cutting planes or good feasible solutions. GAMS users could supply these as part of the model given to the solver, by adding a set of constraints representing likely to be violated cuts and an initial solution (possibly in combination with GAMS parameters like tryint and solver-specific options like mipstart in CPLEX). However, this does not allow a dynamic interaction between a running solver and user supplied routines that, for example, use a current relaxation solution to construct cutting planes or feasible solutions. The GAMS Branch-and-Cut-and-Heuristic (BCH) facility attempts to automate all major steps necessary to make callbacks that certain solvers provide for such usage available to the GAMS user. This allows GAMS users to apply complex solution strategies without having to have intimate knowledge about the inner workings of a specific solver.

Currently, only two solvers support the BCH facility: CPLEX and SBB. With GAMS/CPLEX, user supplied GAMS programs that implement primal heuristics and cut generation can be used. With SBB, only primal heuristics are possible.

As the name indicates, the BCH facility has been designed with the solving process of a branch-and-cut solver (e.g., CPLEX, Gurobi, SCIP, Xpress) in mind. Such solvers often allow to call a user supplied routine after a node in the branch-and-bound (B&B) tree has been processed. Within that routine, available information like the solution of a relaxation (often an LP or NLP) at that node and the current incumbent, if any, is exported by the BCH facility into a GDX file using the original GAMS namespace. Next, different user supplied GAMS programs can be called, e.g., for finding cuts which are violated by the relaxation solution (cut generator) or to find new incumbents (primal heuristic). These GAMS programs should import the information from the GDX file and do their computations. After termination, the BCH facility resumes control, reads the findings from the GAMS program and passes them to the solver.

A relaxation solution may be exported into a file `bchout.gdx` by the BCH facility. This GDX file does not only contain the variable values as level values (.l), but also variable bounds (.lo and .up). For a B&B solver, these are the local bounds at this node. Hence, they reflect branching decisions made in the B&B tree and bound tightenings that were deduced by the solver. In a similar way, the BCH facility may export an incumbent solution to the GDX file `bchout_i.gdx`. The bounds for the incumbent solution reflect global bounds, i.e., the original bounds, possibly tightened by the solver. GDX files can be imported by the GAMS program using the compile time `$load` or run time `execute_load`.

The BCH facility is activated and controlled by setting certain options in the solvers options file. The precise names and meanings of the options may vary from one solver to another. Therefore, also the corresponding GAMS solver manual should be checked. The options that come with the BCH facility can be used to define the calls of the users GAMS programs, to determine when they should be called, and to overwrite the filenames for the GDX files (to avoid name clashes). General BCH related options are the following:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserGDXIn</td>
<td>The name of the GDX file read back into the solver.</td>
<td>bchin.gdx</td>
</tr>
<tr>
<td>UserGDXName</td>
<td>The name of the GDX file exported from the solver with the solution at the node.</td>
<td>bchout.gdx</td>
</tr>
<tr>
<td>UserGDXNameInc</td>
<td>The name of the GDX file exported from the solver with the incumbent solution.</td>
<td>bchout_i.gdx</td>
</tr>
<tr>
<td>UserGDXPrefix</td>
<td>Prefix to add to UserGDXIn, UserGDXName, and UserGDXNameInc</td>
<td>empty</td>
</tr>
<tr>
<td>UserJobID</td>
<td>Postfix to add to listing and log filenames and to UserGDXIn, UserGDXName, and UserGDXNameInc. Further, --UserJobID is added to calls to users GAMS programs.</td>
<td>empty</td>
</tr>
<tr>
<td>UserKeep</td>
<td>Calls users GAMS programs with gamskeep instead of gams. The use of gamskeep will preserve the scratch directory similar to the command line option keep</td>
<td>0</td>
</tr>
</tbody>
</table>

In the following, the interface for the available callbacks are explained in more detail and corresponding options are listed.
4.43.5.1 Primal Heuristics

In the primal heuristic callback, the user can provide a GAMS program which tries to construct a feasible solution based on the information provided by the solver, e.g., a current relaxation solution and the current incumbent. Thus, the GAMS program could attempt to repair infeasibilities in the relaxation solution or try to improve the incumbent from the solver.

If the GAMS program finds a new solution, it should store it in the level values of variables that correspond to the original variables. For example, if the original model uses binary variable \( \text{open}(i,t) \), then at the end of the GAMS program \( \text{open}.l(i,t) \) should contain a 0 (zero) or a 1 (one). The BCH facility calls the GAMS program and instructs GAMS to store the results in a GDX file at termination. This GDX file is then read in again by the BCH facility and the solution is passed back to the solver. The solver checks this solution for infeasibilities and in case this check is passed and the solution is better than the best known solution, the solver updates it's incumbent.

If the GAMS program cannot find a feasible solution, it can terminate with an execution error triggered by an \texttt{abort} statement to prevent the BCH facility from reading the results from the heuristic run.

BCH parameters to control the primal heuristic call are typically the following:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserHeurFreq</td>
<td>Determines the frequency of the heuristic call.</td>
<td>10</td>
</tr>
<tr>
<td>UserHeurMult</td>
<td>Determines the multiplier for the frequency of the heuristic call.</td>
<td>2</td>
</tr>
<tr>
<td>UserHeurInterval</td>
<td>Determines the interval when to apply the multiplier for the frequency of the heuristic call. For example, for the first 100 (UserHeurInterval) nodes, the solver calls the heuristic every 10th (UserHeurFreq) node. After 100 nodes, the frequency gets multiplied by 10 (UserHeurMult), so that for the next 100 nodes the solver calls the heuristic every 20th node. For nodes 200-300, the heuristic get called every 40th node, for nodes 300-400 every 80th node and after node 400 every 100th node.</td>
<td>100</td>
</tr>
<tr>
<td>UserHeurFirst</td>
<td>For how many of the first nodes the heuristic should be called.</td>
<td>10</td>
</tr>
<tr>
<td>UserHeurObjFirst</td>
<td>Similar to UserHeurFirst, but specifies for how many of the first nodes the heuristic should be called if the optimal value of the current nodes relaxation promises a significant improvement of the current incumbent, i.e., the optimal value of the relaxation at the node has to be closer to the current dual bound than the current primal bound.</td>
<td>solver dependent</td>
</tr>
<tr>
<td>UserHeurNewInt</td>
<td>Whether to calls the heuristic when the solver found a new feasible solution.</td>
<td>no</td>
</tr>
<tr>
<td>UserHeurCall</td>
<td>Arguments to the GAMS call to invoke the heuristic GAMS program.</td>
<td>empty</td>
</tr>
</tbody>
</table>

As an example, for the Oil Pipeline Network Design problem, the BCH options to invoke the primal heuristic in the GAMS program \texttt{bchoil.h.inc} when using GAMS/CPLEX could be

```
userheurcall      bchoil_h.inc mip cplex optcr 0 reslim 10
userheurfirst     5
userheurfreq      20
userheurinterval  1000
```
4.43.5.2 Cutting Planes

In the cut generator callback, the user can provide a GAMS program which tries to find a linear cut (that is, a linear inequality) that is violated by the relaxation solution. The solver would then add these cuts to its cut pool. Typically, it then resolves the relaxation at the node and calls the cut generator again. If no cutting planes are found, the solver will continue, e.g., by processing the next node. Please note that the solver cannot perform validity checks on the provided cuts. Hence, it is possible to cut off areas of the feasible region, including optimal solutions.

Exporting cuts is a little more complicated than a solution because next to the cut coefficients, also the sense and the right-hand-side of the cut inequality needs to be exported. Further, exporting several cuts with one call should be possible. For this purpose, the GAMS program has to define and fill a set cc and parameters `numcuts`, `rhs_c(cc)`, and `sense_c(cc)` appropriately. The set cc is used as a cut index. It can be larger than the number of actually generated cuts.

Note

The elements of the cut index set must form a series of integers starting at 1 (1, 2, 3,...).

Parameter `numcuts` should specify the number of added cuts. `rhs_c(cc)` should store the right-hand-side of each cut. Finally, `sense_c(cc)` should store the sense of each cut, which must be 1 for lower-equal (≤), 2 for equal (=, rather unusual for cuts), and 3 for greater-equal (≥). The corresponding declaration in GAMS code may be

```gams
$set MaxCuts 100
Set cc 'cuts' / 1 * %MaxCuts% /;
Parameters numcuts 'number of cuts to be added' / 0 /
  rhs_c(cc) 'cut rhs'
  sense_c(cc) 'the sense of the cuts';
```

The only thing missing are the cut coefficients. As it should be possible to return more than one cut, using variable attributes like level values is not sufficient. Therefore, for each variable that is part of a cut, a new parameter must be added in the GAMS program. The name of the parameter must be the name of the corresponding variable with an additional `_c` at the end. Further, the parameter must be indexed like the variable, but with the cut index set cc added at the beginning. For example, assume variable `open(i,t)` should be part of a cut. Then the cut coefficients should be stored in a parameter `open_c(cc,i,t)`, e.g.,

```gams
Parameter open_c(cc,i,t) 'coefficients of variable open(i,t) in cut cc';
```

The BCH facility reads all parameters that end in `_c`, takes the base name and looks for a variable with that name and indices and builds up the cut matrix. A cut cannot introduce a new variable into the model. All cuts added to the model are assumed to be global cuts, that is, they need to be valid for the entire problem, not just for the current node.

BCH parameters to control the cut generation call are typically the following:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserCutFreq</td>
<td>Determines the frequency of the cut generator call.</td>
<td>10</td>
</tr>
<tr>
<td>UserCutMult</td>
<td>Determines the multiplier for the frequency of the cut generator call.</td>
<td>2</td>
</tr>
<tr>
<td>UserCutInterval</td>
<td>Determines the interval when to apply the multiplier for the frequency of the cut generator call. See <code>UserHeurInterval</code> for details.</td>
<td>100</td>
</tr>
<tr>
<td>UserCutFirst</td>
<td>Calls the cut generator for the first n nodes.</td>
<td>10</td>
</tr>
<tr>
<td>UserCutNewInt</td>
<td>Whether to call the cut generator if the solver found a new integer feasible solution.</td>
<td>no</td>
</tr>
<tr>
<td>UserCutCall</td>
<td>Arguments to the GAMS call to invoke the cut generator GAMS program.</td>
<td>empty</td>
</tr>
</tbody>
</table>
As an example, for the Oil Pipeline Network Design problem, the BCH options to invoke the cut generator in the GAMS program bchoil_c.inc when using GAMS/CPLEX could be

```
usercutcall  bchoil_c.inc mip cplex
usercutfirst  0
usercutfreq  0
usercutnewint yes
```

### 4.43.5.3 Incumbent Callbacks

The incumbent callbacks can be used to execute a GAMS program when the solver found a new feasible solution that improves the incumbent. Additionally, the incumbent check callback `UserIncbCall` can be used to notify the solver whether the given feasible solution should be accepted by the solver. This allows to implement a filtering mechanism that forces a solver to search for additional solutions even though an optimal solution might have been found already. Furthermore, the callback `UserLazyConCall` allows to add lazy constraints after an incumbent has been found.

The following parameters control the incumbent callbacks:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserIncbCall</td>
<td>Arguments to the GAMS call to invoke the incumbent checking GAMS program. The incumbent is rejected if the GAMS program terminates normally. In case of a compilation or execution error, the incumbent is accepted.</td>
<td>empty</td>
</tr>
<tr>
<td>UserIncbICall</td>
<td>Arguments to the GAMS call to invoke the incumbent reporting GAMS program.</td>
<td>empty</td>
</tr>
<tr>
<td>UserLazyConCall</td>
<td>Arguments to the GAMS call to invoke the lazy constraint adding GAMS program. Lazy constraints that cut off the incumbent are expected (in a format similar to UserCutCall) if the GAMS program terminates normally. In case of a compilation or execution error, the incumbent is accepted.</td>
<td>empty</td>
</tr>
</tbody>
</table>

### 4.43.5.4 Examples

The GAMS model library contains a few examples to show to use the BCH facility:

- **bchtlbas.gms**: Trim Loss Minimization with Heuristic using BCH Facility This model implements a very simple LP/MIP based primal heuristic for the trimloss minimization problem.

- **bchfcnet.gms**: Fixed Cost Network Flow Problem with Cuts using BCH Facility This model implements simple but difficult to separate cuts for a network design problem. The global solver BARON is used to find violated cuts by solving a non-convex MINLP.

- **bchtmknap.gms**: Multi knapsack problem using BCH Facility This model implements simple cover inequalities for the multi-knapsack problem.

- **bchoil.gms**: Oil Pipeline Design Problem using BCH Facility This is the most complex example. It implements three different primal heuristics: an initial heuristic based on a simplified cost structure, a rounding heuristic, and a local branching heuristic. In addition, complex cuts are generated by solving regionalized versions of the original problem.
4.43 Solver Usage

- **dicegrid.gms**: MIP Decomposition and Parallel Grid Submission - DICE Example
  This example uses many of the UserJobID option to rename files, since running multiple jobs in parallel requires the use of different filenames. This example also uses the incumbent reporting call UserIncbCall.

- **solnpool.gms**: Cplex Solution Pool for a Simple Facility Location Problem
  This example uses the incumbent checking call UserIncbCall as an advanced filter for accepting or rejecting solutions found by CPLEX.

### 4.43.6 Choosing an appropriate Solver

For any of the GAMS problem classes (LP, MCP, MINLP, ...), there is no solver that is best on every problem instance. Below, we provide some links to rules of thumb on choosing a solver or solver comparisons.

- M. Bussieck and S. Vigerske, **MINLP Solver Software**.

- H. Mittelmann: **Decision Tree for Optimization Software** and **Benchmarks for Optimization Software**

### 4.43.6.1 Relative Merits of MINOS and CONOPT

#### 4.43.6.1.1 How to choose between MINOS and CONOPT

It is almost impossible to predict how difficult it is to solve a particular model. The best and most reliable way to find out which solver to use is to try out both. However, there are a few rules of thumb:

**CONOPT** is well suited for models with very non-linear constraints. If you experience that MINOS has problems achieving feasibility during the optimization, you should try CONOPT. On the other hand, if your model has few nonlinearities outside the objective function, MINOS and QUADMINOS is probably the best solver.

**CONOPT** is has a fast method for finding a first feasible solution that is particularly well suited for models with few degrees of freedom (this means: the number of variables is approximately the same as the number of constraints - in other words, models that are almost square). In these cases CONOPT is likely to outperform MINOS while for models with many more variables than equations MINOS is probably more suited.

**CONOPT** has a preprocessing step in which recursive equations and variables are solved and removed from the model. If you have a model where many equations can be solved one by one, **CONOPT** will take advantage of this property. Similarly, intermediate variables only used to define objective function terms are eliminated from the model and the constraints are moved into the objective function.

**CONOPT** has many built-in tests (e.g. tests for detecting poor scaling). Many models that can be improved by the modeler are rejected with a constructive message. **CONOPT** is therefore a useful diagnostic tool during model development even if another solver is used for the production runs.
4.43.6.1.2 Why serious NLP modelers should have both MINOS and CONOPT

It is almost impossible to predict how difficult it is to solve a particular model. However, if you have two solvers, you can try both. The overall reliability is increased and the expected solution time will be reduced.

On a test set of 196 large and difficult models, many poorly scaled or without initial values, both MINOS and CONOPT failed on 14 models. However only 4 failed on both MINOS and CONOPT. So the reliability of the combined set of solvers is much better than any individual solver.

Many examples of poorly formulated models were observed on which MINOS failed. CONOPT rejected many of the models, but with diagnostic messages pinpointing the cause of the problem. After incorporating the changes suggested by CONOPT, both MINOS and CONOPT could solve the model. Switching between the two solvers during the initial model building and debugging phase can often provide useful information for improving the model formulation.

4.43.6.1.3 Special Offer for two NLP Solvers

In order to encourage modelers to have two NLP solvers, GAMS offers a 50% discount on the second solver when both MINOS and CONOPT are purchased together.

4.43.6.2 PATH versus MILES

This document describes some of the differences between the MCP solvers PATH and MILES. MILES is a free solver, that comes with the GAMS/BASE module, while PATH is an optional solver, that is charged for separately.

PATH and MILES are two GAMS solvers capable of solving mixed nonlinear complementarity problems (MCP). Both solvers are based on the sequential linear complementarity algorithm, i.e., they both solve a sequence of linear mixed complementarity problems whose solutions typically converge to the solution of the MCP. To solve each of the linear subproblems (major iterations), both codes use a generalization of an algorithm due to Lemke that is based on a sequence of pivots (minor iterations) similar to those generated by the simplex method for linear programming. To do these pivots efficiently, both codes use the same sparse linear algebra package.

As a result of the above similarities, the performance of the two codes is comparable for many "easy" models. Viewed over a broad range of problems, however, PATH is typically faster and more robust than MILES. While both codes solve all the MCP and MPSGE models in GAMSLIB, PATH significantly outperforms MILES on the MCPLIB test collection found at CPNET.

Most sophisticated MCP and MPSGE modelers prefer to use PATH over MILES. PATH has a crashing scheme that allows it to quickly improve the user given starting point before starting to solve the linear subproblems. This frequently speeds up solution time. PATH automatically attempts to fix "singular" models using a technique based on proximal perturbations. In many cases, this enables the linear subproblems to be solved, leading to a model solution. This typically helps modelers at model development time.

PATH has many more solution options to enable it solve difficult models. The code automatically tries useful options on difficult problems using a restart procedure. PATH has a much more sophisticated "globalization" procedure that typically improves speed and robustness. PATH implements a nonmonotone watchdog technique. Stalling is frequently circumvented by allowing larger steps to be taken toward solutions.

PATH has many more diagnostic features that help uncover problems in a model. In particular, singularities in the model, zero rows and columns and several measures of optimality are returned to the user. Theoretically, PATH has better convergence properties than MILES. In particular, new merit functions are known to allow more reliable and faster convergence.
4.44 The Save and Restart Feature

GAMS saves the information provided in input files in intermediate - mostly binary - files, called work files or scratch files. Some of these files are used to exchange information between GAMS and the solvers. They are usually deleted just before a GAMS run is complete. However, these intermediate files may be used to process an input file, save the result and later reload this file and continue with processing another input file. Thus, input files may be processed sequentially through the use of the intermediate files. This is a useful feature that can help to reduce the required time when, e.g., several runs of similar models are being made, all of them sharing an equal large initialization part.

The same process may be described in a different way. Assume a large GAMS program is run and an output file is generated, as usual. Suppose the large program is split in two parts. The first part is run and the resulting work file is saved along with the resulting listing file. Then the second part is run after reading in the data from the work file saved previously and a new listing file is generated for the second part. The content of the two listing files will be the same as the content of the output from the very first run when the large program was processed without interruption. Only the arrangement of the content will slightly differ. Splitting the files makes it possible to interrupt a GAMS task and restart it later without loss of information. Furthermore, changes could be made or errors corrected in the later parts.

Note
- The work file preserves all information (including declarations, values, option settings and dollar control options) known to GAMS at the end of the run.
- The work file is not machine specific and thus is portable between platforms. However, a work file that has been generated with one version of GAMS cannot be used for a restart with an older GAMS version (unless command line parameter forceWork is set).
- Absolute or relative path names (e.g. for put files) that do not exist or have the wrong directory separator may cause execution errors. Moreover, if the code in the work file executes a program that might not exist on another platform (e.g. gdxxrw on Linux) the GAMS execution might also result in execution errors.

This chapter illustrates the basics of the save and restart feature in Section Basic Usage and presents some use cases in Section Use Cases. Preventing unauthorized access to and obfuscating the content of work files is discussed in Sections Secure Work Files and Obfuscated Work Files, respectively. An overview of all command line parameters for saving and restarting in GAMS is given in Section Save and Restart Options (chapter The GAMS Call and Command Line Parameters).

4.44.1 Basic Usage

The mechanism to break up the compilation of a large input file into many components and stages is provided by the command line parameters save and restart.

The following demonstrates saves and restarts with the well known transportation model [TRNSPORT]. First, the code is split into three parts, resulting in the files tranmodel.gms, transolve.gms, and tranreport.gms. The file tranmodel.gms contains the first part of the model up to and including the model statement:

Sets
  i "canning plants" / seattle, san-diego /
  j "markets" / new-york, chicago, topeka / ;

Parameters
  a(i) "capacity of plant i in cases"
  / seattle 350
san-diego 600 /

b(j) "demand at market j in cases"
/ new-york 325
chipago 300
topeka 275 /;

Table d(i,j) "distance in 1000 miles"

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chipago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

Scalar f "freight in dollars/case per 1000 miles" /90/;

Parameter c(i,j) "transport cost in $1000/case";
c(i,j) = f * d(i,j) / 1000;

Variables

x(i,j) "shipment quantities in cases"
z "total transportation costs in 1000$";
Positive Variable x;

Equations

cost "define objective function"
supply(i) "observe supply limit at plant i"
demand(j) "satisfy demand at market j";

cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;
supply(i) .. sum(j, x(i,j)) =l= a(i) ;
demand(j) .. sum(i, x(i,j)) =g= b(j) ;

Model transport /all/ ;

The file transolve.gms contains the solve statement:
solve transport using lp minimizing z;

And the third file, tranreport.gms, contains the display statement:

display x.l, x.m ;

Observe that concatenating the three files (in the right order) results in the original model [TRNSPORT].

4.44.1.1 Saving The Work File

The information in tranmodel.gms may be stored by using the following call to GAMS:

> gams tranmodel save=s1

This command line statement creates the output file tranmodel.lst and the work file s1.g00 in the current working directory.

Note that the command line parameter s is a synonym to save.
4.44.1.2 Restarting from the Work File

Consider the following call:

> gams transolve restart=s1

GAMS reads the work file named s1.g00 and regenerates the information stored in tranmodel.gms. Then transolve.gms is run and the result is as if the a concatenation of tranmodel.gms and transolve.gms had been executed. Note, that the output file tranmodel.lst will contain the echo print of the model and transolve.lst will contain the echo print of the solve statement and all the output generated by the solve.

Note that the command line parameter r is a synonym of restart.

Observe that a restarted run always requires a GAMS input file to continue with. The restart does not alter work files. They may be used repeatedly to continue a particular run many times, possibly with many different continuation input files.

4.44.1.3 A Sequence of Saves and Restarts

In case there are more than two files that should be run sequentially, the second and any other non-final run will have to generate input files for a following restart. Therefore, their workfiles need to be saved.

Following the splitup of model [TRNSPORT] into the three files tranmodel.gms, transolve.gms, and tranreport.gms, a sequence of GAMS calls that would run the whole trnsport model could be as follows:

> gams tranmodel s=s1
> gams transolve r=s1 s=s2
> gams tranreport r=s2

The listing file of tranreport.gms will contain the compilation output with the echo print of the display statement, the final execution summary with the output generated from the display statement and the file summary. The listing files of all three input files together will have the same content as trnsport.lst (generated by a run of trnsport.gms).

Observe that the three files could also have been processed with a sequence of $include file statements. The advantages of using the save and restart feature instead are given in section Use Cases below.

4.44.1.4 Avoiding Common Mistakes

A common mistake that occurs when using the save and restart feature is running GAMS on the same file twice, e.g.,

> gams trnsport s=trans
> gams trnsport r=trans

In this case all the data and equation definitions are repeated, which will cause compilation errors for the second run as in GAMS each data item may be defined only once.

Further, it is the responsibility of the modeler to ensure that the contents of the input file matches that of the work file, although the compiler will issue errors if it detects any inconsistencies, such as references to symbols not previously declared.
4.44.1.5 Prefixing Symbols in the Work File

Assume writing some reporting code that works off a restart file and new symbol names that have not been used in the previous program are required. GAMS offers a convenient and systematic way to achieve this by prefixing all symbols in the work file with a specified string. Consider the following example, again using the transportation model \texttt{[TRNSPORT]}:

> gams trnsport s=prefixed symPrefix=aa_

This solves the model and saves the work file \texttt{prefixed.g00}. The command line parameter \texttt{symPrefix} has the effect that all symbols in the work file are prefixed with \texttt{aa}. For the next step, consider the following simple reporting code, saved in a file called \texttt{report.gms}:

Scalar i / 0 /;
loop(aa_i, i = i+1);
display 'number of canning plants', i;

Note that this code will be run with a restart from the work file \texttt{prefixed.g00}. Therefore, the looping set \texttt{aa_i} is identical to the set \texttt{i} in the model \texttt{[TRANSPORT]}. Since all symbols from the original model have been prefixed, convenient symbol names can be used for reporting purposes. The run of \texttt{report.gms} is achieved by the following call:

> gams report r=prefixed

The resulting listing file contains the following output:

---- 76 number of canning plants
PARAMETER i = 2.000

4.44.2 Use Cases

The basic function of a work file is to preserve information that has been expensive to produce. The following discusses several use cases for work files.

4.44.2.1 Separation of Model and Data

The separation of model and data is one of the core principles of the GAMS modeling paradigm. Using the save and restart feature helps to exploit this separation.

Separation of model and data will be illustrated on the transportation model \texttt{[TRNSPORT]}. First, consider a GAMS file \texttt{transportmodel.gms} which contains only the algebraic representation of the transportation problem, obtained by removing all data and execution statements from \texttt{[TRNSPORT]}. 

---
Sets i canning plants
j markets

Parameters a(i) "capacity of plant i in cases"
b(j) "demand at market j in cases"
c(i,j) "transport cost in 1000$/case"
d(i,j) "distance in 1000 miles"
Scalar f "freight in $/case per 1000 miles"

Variables x(i,j) "shipment quantities in cases"
z "total transportation costs in 1000$"
Positive Variable x

Equations cost "define objective function"
supply(i) "observe supply limit at plant i"
demand(j) "satisfy demand at market j"

\[
\text{cost ..} \quad z = \text{e} = \sum_{i,j} c(i,j) \times x(i,j)
\]
\[
\text{supply(i) ..} \quad \sum_j x(i,j) = \text{l} = a(i)
\]
\[
\text{demand(j) ..} \quad \sum_i x(i,j) = \text{g} = b(j)
\]

Model transport /all/ ;

Second, consider a GAMS file transportdata.gms that contains the data of the model as well as the solve and display statements:

Sets i / seattle, san-diego /
j / new-york, chicago, topeka / ;

Parameters a(i) / seattle 350
san-diego 600 /
b(j) / new-york 325
chicago 300
topeka 275 /
Table d(i,j)
         new-york  chicago  topeka
seattle    2.5     1.7     1.8
san-diego  2.5     1.8     1.4

Scalar f / 90 / ;
c(i,j) = f * d(i,j) / 1000 ;
Solve transport using lp minimizing z ;
Display x.l, x.m ;

The second file (transportdata.gms) cannot be run alone as the definition of model transport is missing. However, one may first run the first file (transportmodel.gms) and save its work file. Then one can restart from this work file to run the second file:

> gams transportmodel.gms s=transmod
> gams transportdata.gms r=transmod
4.44.2.2 Advanced Separation of Model and Data

In the previous example some execution time statements namely the assignment of c, the solve, and the display where performed in the data file. If the model execution logic is more complex we do not want to add this to the data file. Hence we create in this example a restart file from this first file but will only compile, but not execute (see difference between compile and execute phases in section GAMS Compile Time and Execution Time Phase):

```gams
$onEmpty
Sets i(*) canning plants / /  
j(*) markets / /  
Parameters a(i) "capacity of plant i in cases" / /  
b(j) "demand at market j in cases" / /  
c(i,j) "transport cost in 1000$/case" / /  
d(i,j) "distance in 1000 miles" / /  
Scalar f "freight in $/case per 1000 miles" / 0 /;  
c(i,j) = f * d(i,j) / 1000 ;  
Variables x(i,j) "shipment quantities in cases"  
z "total transportation costs in 1000$" ;  
Positive Variable x ;  
Equations cost "define objective function"  
supply(i) "observe supply limit at plant i"  
demand(j) "satisfy demand at market j" ;  
cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;  
supply(i) .. sum(j, x(i,j)) =l= a(i) ;  
demand(j) .. sum(i, x(i,j)) =g= b(j) ;  
Model transport /all/ ;  
Solve transport using lp minimizing z ;  
Display x.l, x.m ;  

Second, we consider a file that contains the data of the model but no other execution time statements. Because we already have empty data statements (/ /) for the data items in the first file, we need to instruct the compiler to allow a second data statement with the real data using $onMulti:

```gams
$onMulti
Sets i / seattle, san-diego /  
j / new-york, chicago, topeka / ;  
Parameters a(i) / seattle 350  
           san-diego 600 /  
b(j) / new-york 325  
           chicago 300  
           topeka 275 /  
Table d(i,j)  
    new-york  | chicago  | topeka  
    seattle   | 2.5      | 1.7     | 1.8  
    san-diego | 2.5      | 1.8     | 1.4  ;
```
Scalar f / 90 / ;
$offMulti

In order to run the model we first compile, but not execute the first model (see command line parameter action=c) and create a save file. Next, we run the second model. This does a continued compilation, it compiles the data statements from the second files and then executes the execution time statements from the first (c(i,j)=..., solve ..., and display ...) and second (here there are none).

> gams transportmodel.gms action=c s=transmod
> gams transportdata.gms r=transmod

4.44.2.3 Generating Concise Listing Files

By default a GAMS listing file has many components, see chapter GAMS Output for details. In case a more concise listing file is needed, the save and restart feature may be used to generate such a file.

Recall the reorganization of the transportation model [TRNSPORT] into a model file trnsportmodel.gms and a data-and-solve file trnsportdata.gms from the previous section. Now consider the addition of two further files. The first one, called trnsportreport.gms, contains post-solution computations for reporting:

Parameter m(*,*), 'movement of commodities in cases';
  m(i,j) = x.l(i,j);
  m('total',j) = sum(i, x.l(i,j));
  m(i,'total') = sum(j, x.l(i,j));
  m('total','total') = sum(j, m('total',j));

The second one, called trnsportdisplay.gms, contains only a display statement:

Option decimals = 0;
Display m;

Using these four files, the following save and restart sequence can be called:

> gams trnsportmodel s=trans1
> gams trnsportdata r=trans1 s=trans2
> gams trnsportreport r=trans2 s=trans3
> gams trnsportdisplay r=trans3

The output file trnsportdisplay.lst is brief. Apart from the echo print, the execution time and the file summary, it contains only the output generated by the display statement:

---- 52 PARAMETER m movement of commodities in cases

new-york    chicago   topeka    total
seattle      50        300       275      350
san-diego    275       300       275      550
total        325       300       275      900

In this way it is possible to create output files that are concise and contain only the information needed, while at the same time the more detailed output is stored in other listing files and may be inspected if needed.
4.44.2.4 Incremental Program Development

GAMS programs are often developed in stages. A typical approach is to start with set statements, tables and data manipulations, then equations are declared and defined, followed by model and solve statements and finally assignments for generating reports. As each piece of the model is built, it should be run and checked for errors by inserting diagnostic display and abort statements. As confidence grows that the parts of the model are correct, it is useful to save the completed parts in a work file. Subsequently, it is possible to work only on the piece under active development by restarting from the saved work file and thus reducing running time and the amount of output produced in each of the development runs.

This approach is especially useful when working on the results report part, since the setup and solution of a model instance is typically dominating the computing time, while the report part has to be run often to get all details of setting up content and layout into a satisfying form. Thus, the model may be generated and solved and the result saved in a work file. One may then restart from the work file while developing the report.

4.44.2.5 Tracking a Sequence of Difficult Solve Statements

In many cases where solves are known to be difficult and expensive, it may be too risky to let GAMS process a job containing many solve statements. The risk is that if one solve does not proceed to normal completion, then the following solve will not be possible or will start from a bad initial point and much time and effort will be wasted.

An alternative is to request one solve at a time and save the work file. By doing so, the output of each solve can be carefully inspected before proceeding. If everything is as expected, the job can be restarted and the next solve be executed. If an error has occurred, the previous solve may be repeated, maybe with a different initial point or modified working limits such as iteration or time limits.

4.44.2.6 What-If Analysis

Many modeling exercises involve a 'what if' analysis, in which a base case is defined and the point of the study is to see how the system changes when circumstances change, either naturally or by design. Often, the effect of many different changes to the base case are considered separately.

The save and restart feature facilitates such analyses. The base case may be saved using a work file and then all desired scenarios may be run separately by restarting from the same work file. Each scenario probably involves only doing some changes to the data (e.g., coefficients in equations or variable bounds), solving the changed model (the solution of the base case will then automatically be used as a starting point), and reporting.

4.44.2.7 The GAMS Runtime License

A GAMS runtime license can be used to restrict users to run an existing model with their own data without the possibility to modify the model itself.

For example, recall the separation of model [TRNSPORT] from Section Separation of Model and Data above into a model file trnsportmodel.gms and a data and solve file trnsportdata.gms. The developer of the model may run trnsportmodel.gms with the command

```gams
> gams trnsportmodel s=trans
```

to generate a work file trans.g00. She then distributes this work file and the data and solve file trnsportdata.gms to endusers. If the endusers have a run-time license for GAMS, they are not able to see the model or change it by adding any new variables or equations, but they can run the model by the command

```gams
> gams trnsportdata r=trans
```

Observe that the endusers have full control of the data, e.g., are able to manipulate the elements of sets or the values of the various parameters.
4.44.3 Secure Work Files

When models are distributed to users other than the original developers or embedded in applications to be deployed by other developers, issues of privacy, security, data integrity and ownership arise. One may have to hide, protect or purge some parts of the model before it can be released. The information to be protected can be of numeric or symbolic nature. Examples include the following:

Privacy

A Social Accounting Matrix supplied by a statistical office is required in a general equilibrium model to be used by the Ministry of Finance. The data from the statistical office needs to be protected for obvious privacy reasons and the model experiments are used to evaluate policy options that are highly confidential. Most of the model structure is public, most of the data however is private and model results need to be transformed in such a way as to prohibit the discovery of the original data.

Security

Components of a model contain proprietary information that describes mathematically a chemical reaction. The associated algebra and some of the data are considered of strategic importance and need to be hidden completely. However, the final model will be used at different locations around the world.

Integrity

Data integrity safeguards are needed to assure the proper functioning of a model. Certain data and symbolic information need to be protected from accidental changes that would compromise the operation of the model.

To address these issues, so called secure work files have been introduced to GAMS. Such a work file behaves like any other work file but it is locked to a specific user’s license file. The content of a secure work file protected against unauthorized access via the GAMS license mechanism.

Attention

A special GAMS license is required to create secure work file, see also Usage. The security features of secure work files are not extended to the solver level. As a consequence, full information about a model instance can be extracted on the GAMS solver level by a user that is authorized to solve the model. See Limitations for more information.

4.44.3.1 An Introductory Example

The well-known transportation model [TRNSPORT] will be used again to illustrate the creation and deployment of a secure work file. Assume one wants to distribute this model but there are concerns about proprietary formulations and data. In addition, one would like to prevent that the user does unintentional modifications to the model. It is assumed that the objective function and the supply constraints are to be hidden from other users and only the demand figures should be allowed to be changed. Data that is not needed any more will be purged as well.

First, a copy of the model from the model library is created, the model is run and a normal work file t1 is created:

> gamslib trnsport
> gams trnsport s=t1
Next, a file t2.gms with access control commands is created,

```
$eolcom //
$protect all // make all symbols read only
$purge  d f // remove items d and f
$hide  cost supply a // make objective invisible
$expose transport b // allow changes to b
```

and a secure work file t2.g00 is created by executing t2.gms with a restart from t1.g00:

```
> gams t2 r=t1 s=t2 plicense=target
```

The newly created work file is secure since the access control commands were activated with the privacy GAMS license option PLicense. This command line parameter specifies the name of the target user's license file. The effect is that the work file t2.g00 can now only be read with the target license file.

The log output will contain the following lines:

```
GAMS Rev 124  Copyright (C) 1987-2001 GAMS Development...
Licensee: Source User Name
         Source Company Name
*** Creating a Secure Restart File for:
***     Target User Name
***     Target Company Name
--- Starting continued compilation
--- T2.GMS(6)  1 Mb
--- Starting execution
*** Status: Normal completion
```

The three lines starting with *** are a recap of the content of the target license file. From now on, the source and the target licenses are 'burned into' this file and all its descendants. One can now send the restart file to the target user or system.

The target user may run the model with new data, add new GAMS statements and create new work files. However, there are two restrictions: some of the symbols are hidden and this model can only be executed using the target license file.

For example, the target user may want to half the demand and compare the original solution with the new one. The following file, called t3.gms, will accomplish this:

```
Parameter rep 'summary report';
rep(i,j,'base') = x.l(i,j);
b(j) = b(j)*0.5;
solve transport minimizing z using lp;
rep(i,j,'half') = x.l(i,j);
display rep;
```

This new file may be executed on the target system, restarting from the work file t2.g00:

```
> gams t3 r=t2
```
The resulting log file will contain the following lines:

GAMS Rev 124 Copyright (C) 1987-2001 GAMS Development...
Licensee: Target User Name
  Target User Company
*** Restarting from a Secure Restart File created by:
***   Source User Name
***   Source Company Name
--- Starting continued compilation
--- T3.GMS(5) 1 Mb
...

Note that the originator/owner of the secure work file is mentioned by name. A similar message will be contained in the listing file:

EXECUTION TIME = 0.000 SECONDS 1.1 Mb WIN201-124

**** Secure Save/Restart File Source:
   Source User Name
   Source Company Name
**** Secure Save/Restart File Target:
   Target User Name
   Target User Company
...

A more detailed inspection of the listing file shows that the hidden variables and equations do not appear in the usual equation and variable listings and the solution print. The hidden items can only be accessed via a public (exposed) model and a solve statement. However, note that the full model instance may still be accessed by the target user, see Limitations.

In the following, secure work files and the access control commands are described in more detail.

4.44.3.2 Usage

Secure work files control access to symbolic and numeric information and can only be read by a specific GAMS user. The initial creation or additions to access control requires a special GAMS license. Saving secure work files without new access controls does not require a special GAMS license. The creation or addition of access control is signaled by the use of the GAMS command line parameter PLicense, which gives the name of a privacy license file. The shortcut PLICENSE=LICENSE sets the privacy license to the current license file. This is convenient when experimenting with access controls.

When a secure work file is written for the first time, the first and second lines of the current license file and the privacy license file are inserted into the work file. This information cannot be changed any more and the original source and the intended target users are locked into the work file.

A secure work file may be used just like any other work file and new work files may be derived from secure files. However, their use is restricted to the target user specified with the command line parameter PLicense. The target user can, if licensed, add access controls to an existing secure file by using the parameter PLICENSE=LICENSE but cannot change the original information about source and target users.

There are four access control commands (ACCs) that are processed during the compilation phase. These commands can be inserted anywhere in the program. They are processed in chronological order and have the following syntax:

$acc ident1 ident2 ...
$acc all

Here ident1 and ident2 are GAMS identifiers previously defined in the program and acc denotes one of the four access control commands:
<table>
<thead>
<tr>
<th>Dollar Control Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>purge</td>
<td>Removes the objects and all data associated.</td>
</tr>
<tr>
<td>hide</td>
<td>Hides the objects but allows them to be used in model calculations.</td>
</tr>
<tr>
<td>protect</td>
<td>The objects cannot be modified but they may be used in model calculations.</td>
</tr>
<tr>
<td>expose</td>
<td>Removes all privacy restrictions, the symbols will be reverted to their original state.</td>
</tr>
</tbody>
</table>

The keyword `all` applies the ACCs to all identifiers defined up to this point in the GAMS source code. Note that ACCs may be changed and redefined within the same GAMS program. However, identifiers inherited from a restart file cannot be changed.

### 4.44.3.3 A Practical Example

This section uses the transportation model `[TRNSPORT]` to show how to hide input data and results from the target user. The target user will be allowed to view percentage changes from an unknown base case only. In addition to the original model, a data initialization and a report model will be introduced.

First, a method to calculate input data is defined. As the GAMS language does not offer the definition of methods (or functions), here a model is used to define algebraically the desired correspondence between the input and output of the method we wish to emulate. Execution of the method will then correspond to solving the model. The model is the following:

```plaintext
$include trnsport.gms

Variable newc(i,j) 'new transport data';
Equation defnewc(i,j) 'definition of new transport data';
defnewc(i,j).. newc(i,j) =e= f*d(i,j)/1000;
Model getc 'compute new transport data' / defnewc /;
Solve getc using cns;
```

By solving model `getc` (see Constrained Nonlinear System (CNS) for details on problem type CNS), the variable `newc(i,j)` will obtain the value of `f*d(i,j)/1000` in the variable level attributes. Thus, `newc.l` corresponds to parameter `c` in the original model.

Next, the objective function of the original model is changed to reflect **economies of scale**. Furthermore, a base case value `basex` is computed for later use in the reporting model:

```plaintext
Scalar beta 'scaling exponent' / 1.1 /;
Equation newcost 'economies of scale objective function';
newcost.. z =e= sum((i,j), newc.l(i,j) * x(i,j)**beta);
Model estrans / newcost, supply, demand /;
solve estrans using nlp minimizing z;
```

Parameter `basex(i,j)` 'base values of x';
`basex(i,j)` = `x.l(i,j)`;

Finally, a method to transform the results of model `estrans` to the relative change with respect to the base case is defined. As for the computation of the input data (`newc`), a model is used to emulate this method:
Variable delta(i,j)  'percentage change from base values';
Equation defdelta(i,j)  'definition of delta';
defdelta(i,j)$basex(i,j).. delta(i,j) =e= 100*(x.l(i,j)-basex(i,j))/basex(i,j);

Model rep / defdelta /;
solve rep using cns;

Assume the GAMS code above has been saved in a file p1.gms. Running GAMS on this file,

> gams p1 s=p1

creates a work file with the name p1.g00.

In the following, some test runs similar to those that are expected to be defined by the target user are made. Three scenarios to be solved in a loop are defined in file u1.gms:

Set   s / one, two, three /;
Parameter sbeta(s) / one 1.25, two 1.5, three 2.0 /
    sf(s) / one 85, two 75, three 50 /;
Parameter report  'summary report';
loop(s,
    beta = sbeta(s);
    f   = sf(s);
    solve getc using cns;
    solve estrans using nlp minimizing z;
    solve rep using cns;
    report(i,j,s) = delta.l(i,j);
    report('','beta',s) = beta;
    report('','f',s) = f;
    report('obj','z',s) = z.l
);

display report;

File u1.gms can be executed with a restart from the work file p1.g00:

> gams u1 r=p1

The display statement generates the following output:

---- 109 PARAMETER report summary report

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle.new-york</td>
<td>-4.050</td>
<td>-6.967</td>
<td>-8.083</td>
</tr>
<tr>
<td>seattle.topeka</td>
<td>233.958</td>
<td>348.468</td>
<td>404.187</td>
</tr>
<tr>
<td>san-diego.new-york</td>
<td>3.605</td>
<td>6.201</td>
<td>7.194</td>
</tr>
<tr>
<td>san-diego.chicago</td>
<td>28.138</td>
<td>40.719</td>
<td>47.228</td>
</tr>
<tr>
<td>.beta</td>
<td>1.250</td>
<td>1.500</td>
<td>2.000</td>
</tr>
<tr>
<td>.f</td>
<td>85.000</td>
<td>75.000</td>
<td>50.000</td>
</tr>
<tr>
<td>obj .z</td>
<td>526.912</td>
<td>1652.963</td>
<td>13988.774</td>
</tr>
</tbody>
</table>
Note that all symbols are still completely exposed. Access controls need to be added to the model p1.gms before it can be made available to the target client. The information to be protected is the original distance matrix and derived information. A recommended procedure is to first hide everything and then enable access to only selected parts of the model. The access control information is collected in the file s1.gms:

```
$hide all
$expose getc estrans rep
$expose i j z delta
$expose f beta a b
```

Using the initial workfile p1, a secure work file s1.g00 is created by executing

```
> gams s1 r=p1 s=s1 plicense=license
```

To test the system from the target user's point of view, the license of the current GAMS system is used also for the target user.

To test the secure work file, problem u1.gms is run again, restarting from the work file s1:

```
> gams u1 r=s1
```

Inspecting the resulting listing file, one observes that equation, variable and solution listings related to the hidden variables are not shown anymore. Any attempt to reference a hidden variable will cause a compilation error.

### 4.44.3.4 Limitations

One of the design goals for secure work files has been to minimize the impact on other components of the GAMS system. Solvers used within a secure environment should work as if called within a normal environment. This implies that certain information about a model can easily be recovered by using solvers like CONVERT or solver options like writelp for CPLEX, writemps for CBC, or gams/interactive for SCIP.

For example, consider the secure work file t2.g00 from Section An Introductory Example. The target user could now reproduce the complete model instance, including the hidden equation supply or the objective function cost by running the following GAMS code, restarting from t2.g00:

```gams
option mip = SCIP;
transport.optfile = 1;
$echo gams/interactive = "display prob quit" > scip.opt
solve transport min z using mip;
```

This produces the log output:
original problem has 6 variables (0 bin, 0 int, 6 cont) and 5 constraints

STATISTICS
  Problem name : r
  Variables : 6 (0 binary, 0 integer, 0 implicit integer, 6 continuous)
  Constraints : 0 initial, 5 maximal

END

...
Note, that the command line parameter action=compile is used to only compile, but not execute, the model. Observe that the name of the regular work file is *named.g00 and the name of obfuscated work file is *obfuscated.g00.

In the next step, the obfuscated work file is moved to a non-secure machine and GAMS is restarted from this work file on an empty GAMS model file. This executes the original model (here *trnsport), but with all names obfuscated. The outcome of this execution is saved in another, still obfuscated, work file *obfuscated.g00.

The work file *obfuscated.g00 is now brought back to a trusted machine. To obtain the results, say the marginal values of the supply equation, in a non-obfuscated form, GAMS is executed again on a model that writes out values of supply.m to a GDX file supply.gdx. This model is restarted from the obfuscated work file *obfuscated.g00, but additionally the originally created non-obfuscated work file *named.g00 is passed in via the command line parameter RestartNamed (short: *rn):

Recall, that the work file *named.g00 resulted from the initial compilation and contains the names from the original namespace. It never left the trusted environment. The effect of combining options *r and *rn is that all content from the obfuscated work file is taken, except for the names of symbols and labels, the explanatory texts, and the listing file titles and subtitles, which are read from the work file specified via *rn.

GAMS automatically performs the following three checks to ensure that the named and obfuscated work files are consistent:

1. The number of labels and symbols must be identical.
2. The size of the string pool must be identical.
3. The first 10 labels point to the same addresses in the string pool.

The first two checks imply that the execution in the obfuscated name space cannot introduce new symbols or labels or even new strings (e.g., from display *this is a new string*). Therefore, the empty GAMS program that was used to execute from the obfuscated work file above can hardly be replaced by any useful code since the obfuscated symbols and labels are not known.
4.45 Embedded Code Facility

4.45.1 Motivation

GAMS uses relational data tables as a basic data structure. With these, GAMS code for parallel assignment and equation definition is compact, elegant, and efficient. However, traditional data structures (arrays, lists, dictionaries, trees, graphs, ...) are not natively or easily available in GAMS. Though it is possible to represent such data structures in GAMS, the GAMS code working with such structures can easily become unwieldy, obfuscating, or inefficient. Also, in the past it was not easy to connect libraries from other systems for special algorithms (e.g. graph algorithms, matrix operations, ...) to GAMS without some data programming knowledge and a deep understanding of internal representation of GAMS data (e.g. the GDX API).

The Embedded Code Facility addresses this need and extends the connectivity of GAMS to other programming languages. It allows the use of external code (e.g. Python) during compile and execution time. GAMS symbols are shared with the external code, so no communication via disk is necessary. It utilizes an API (this API can be found in apifiles/C/api/emlib*.h together with the code for the Python and Connect embedded code library apifiles/C/api/embpyoo.c/h) and additional source code for common tasks so that the user can concentrate on the task at hand and not the mechanics of moving data in and out of GAMS.

4.45.2 Concept

As pointed out in section Motivation, the main idea of the Embedded Code Facility is to enable the use of external code in GAMS and give this code direct in-memory access to the GAMS database (or better: to GAMS symbols, namely sets, parameters, variables, and equations). This can be done by defining sections in the GAMS code which contain no GAMS code, but code written in a defined external code. These sections can be used at both GAMS compile and execution time (compare section GAMS Compile Time and Execution Time Phase). Details about how to do this can be found in the Syntax section.

Note

We will continuously extend this feature to different programming languages. At the moment only Python and Connect are supported.

Also, the system provides some help to develop and debug the external code independent of GAMS first. More about this topic can be found in section Troubleshooting Embedded Python Code.

The communication of the data between the GAMS part of the program and the embedded code part was inspired by the existing interface to GDX in many ways. For example, using dollar control options $on/offMulti, $onMultiR, and $on/offFiltered it is possible to decide if data changed in the embedded code should replace the GAMS data or get merged with it and just like loading data from GDX, one can decide if data from embedded code should change the GAMS database filtered or domain checked.
4.45.3 Simple Example

4.45.3.1 Python

In a very first example we look into some Python code that helps to split some label names that are already present in GAMS. We do this at compile time in order to read the broken up pieces as individual sets (country and city) into GAMS plus some mapping sets (mccCountry and mccCity) between the original labels and the new labels. The compile-time embedded code starts with a $onEmbeddedCode followed by the type of code to expect (Python). The lines between $onEmbeddedCode and $offEmbeddedCode is Python code. We do not want to go into Python details, but the first few lines initialize some empty Python list objects (mccCountry and mccCity) as well as some empty Python set objects. In the Python for loop that follows we iterate over all individual labels of the GAMS set cc. Python gets access to the GAMS set cc via the member function get of the implicitly defined Python object gams. get returns an object that is iterable and can be used in a Python for loop. The type of the records one gets depend on the dimensionality and type of the GAMS symbol. In the loop body we use the Python split function to extract the first (r[0] is country) and second (r[1] is city) part of the label. The three strings cc, r[0], r[1] are used to build up the Python list objects that store the information for the maps mccCountry and mccCity and the Python set objects that store the labels for the new sets country and city. The Python set has the advantage to store a label just once even if we add it multiple times. Python prepares to send items back to GAMS via the gams member function set that can deal with both Python list and Python set objects. The command $offEmbeddedCode is followed by a list (without separating commas) of GAMS symbols that instructs the GAMS compiler to read these symbols back. This list is optional and can be left out. GAMS will import all symbols set by the Python code. The GAMS compiler (without executing execution-time embedded code) does not know which symbols will be implicitly loaded, hence it cannot define symbols. If such a symbol is referenced further down in the compilation process, the compiler will complain with error $141: Symbol declared but no values have been assigned. One can avoid this situation by explicitly list the symbols on the end/pauseEmbeddedCode line.

Another caveat with implicit loading is related to aliases. GAMS does not allow to load data into an alias, so the following code will fail with a compilation error 493 Alias cannot receive data:

Set i(*); Alias (i,j);
$onEmbeddedCode Python:
gams.set('j',['i1','i2','i3'])
$offEmbeddedCode j

By leaving off the symbol j from the $offEmbeddedCode line, the code works fine and actually imports the set i. The gams.set and other write methods in embedded code to an alias symbol, here j, actually fills the aliased set, here i, and hence the implicit load will load the modified symbol i into GAMS.

Implicit loading also needs special consideration in the context of external input. Since embedded code inside an $on/offExternalInput section is not executed if the command line parameter IDCGDXInput has been set, there will be no symbols to be loaded implicitly. So make sure the symbols to load are given explicitly in such a situation.

Note that GAMS syntax is case insensitive while Python is case sensitive. Hence, the strings that represent the GAMS symbol names in the Python code can have any casing (e.g. gams.get("cc") or gams.get("CC")) , while the corresponding Python objects need to have consistent casing throughout the Python code.

The following code presents the entire embeddedSplit example from the GAMS Data Utilities Library:
Set cc / "France - Paris", "France - Lille", "France - Toulouse"
    , "USA - Washington DC", "USA - Houston", "USA - New York",
    , "Germany - Berlin", "Germany - Munich", "Germany - Bonn" /
    country
city
mccCountry(cc,country<) Mapping between country and related elements in set cc
mccCity(cc,city<) Mapping between city and related elements in set cc;
$m onEmbeddedCode Python:
mccCountry = []
mccCity = []
for cc in gams.get("cc"):
r = str.split(cc, " - ", 1)
mccCountry.append((cc,r[0]))
mccCity.append((cc,r[1]))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
$offEmbeddedCode mccCountry mccCity

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry, mccCity;

The display in the listing file looks as follows:

---- 25 SET country
Spain , USA , Germany, France

---- 25 SET city
Berlin , Bilbao , Cordoba , Madrid
New York , Washington DC, Paris , Houston
Munich , Lille , Seville , Bonn
Toulouse

---- 25 SET mccCountry
France - Paris .France
France - Lille .France
France - Toulouse .France
Spain - Madrid .Spain
Spain - Cordoba .Spain
Spain - Seville .Spain
Spain - Bilbao .Spain
USA - Washington DC.USA
USA - Houston .USA
USA - New York .USA
Germany - Berlin .Germany
Germany - Munich .Germany
Germany - Bonn .Germany

---- 25 SET mccCity
France - Paris .Paris
France - Lille .Lille
France - Toulouse .Toulouse
Spain - Madrid .Madrid
Spain - Cordoba .Cordoba
Spain - Seville .Seville
Spain - Bilbao .Bilbao
The second example demonstrates the use of embedded code at execution time. The syntax for the execution time embedded code in this example is identical to the compile time variant with the exception of the keywords that start and end the embedded code section: `embeddedCode` and `endEmbeddedCode`. It is important to understand that the execution of the code happens at GAMS execution time, so e.g. no new labels can be produced and send back to GAMS. In this example we use some Python code to generate a random permutation of set elements of set `i` and store this in a two dimensional set `p`. In this example we do not use a loop to iterate through the elements of a GAMS system but make use of the fact that the Python object returned by `gams.get("i")` is iterable and can in its entirety be stored in the Python list with name `i` with the short and powerful command `i = list(gams.get("i"))`. The permutation of elements in list `p` which is a copy of list `i` is created by the Python statement `random.shuffle(p)`. The following code presents the entire example:

```python
Set i /i1*i10/
  p(i,i) "permutation";

embeddedCode Python:
import random
i = list(gams.get("i"))
p = list(i)
random.shuffle(p)
for idx in range(len(i)):
  p[idx] = (i[idx], p[idx])
gams.set("p", p)
endEmbeddedCode p

option p:0:0:1;
display p;
```

The display in the listing file looks as follows:

```
---- 11 SET p permutation
  i1 .i1
  i2 .i7
  i3 .i5
  i4 .i2
  i5 .i10
  i6 .i6
  i7 .i4
  i8 .i18
  i9 .i18
  i10.i13
```

### 4.45.3.2 Connect

In the following example, we need to process a CSV file that cannot be read directly by GAMS under `$onDelim`. So we instruct `Connect` to read the CSV file into the Connect database and then write to GAMS:
Set dates, stocks;
Parameter stockprice(dates<,stocks<);

$onText
Read a CSV file that looks as follows:

date;symbol;price
2016/01/04;AAPL;105.35
2016/01/04;AXP;67.59
2016/01/04;BA;140.50
...

and can’t be read directly by GAMS under $onDelim because some labels include ‘/’ and are not quoted, use ‘;’ as field separator, and ‘,’ as decimal character.
$offText

$onEmbeddedCode
Connect:
- CSVReader:
  file: stockprice.csv
  name: stockprice
  indexColumns: [1, 2]
  valueColumns: [3]
  fieldSeparator: ‘;’
  decimalSeparator: ‘,’
- GAMSWriter:
  symbols:
  - name: stockprice
$offEmbeddedCode

display stockprice;

We leave the CSV file processing to the CSVReader and then export the stockprice symbol to GAMS. Please note that the symbols written to GAMS by the GAMSWriter do not have to be explicitly listed on the $offEmbeddedCode line, this is optional. Moreover, the Connect agents GAMSReader and GAMSWriter are only available under embedded code.

We might use the data to calculate an optimal portfolio. The share of each stock in this optimal portfolio is represented by the parameter share(stocks) and can be exported to Excel using the PandasExcelWriter. Before exporting to Excel, the data first needs to be transferred from GAMS to Connect using the GAMSReader:

* Continues the code from the previous example

Parameter share(stocks);
* For demonstration we fill share with random numbers
share(stocks) = uniform(0,1);

embeddedCode
Connect:
- GAMSReader:
  symbols:
  - name: share
- PandasExcelWriter:
  file: share.xlsx
  symbols:
  - name: share
    range: Share!A1
endEmbeddedCode
4.45.4 Syntax

This section explains the GAMS functions/keywords which were introduced to enable the Embedded Code Facility. The first subsection deals with the syntax for compile time, the second with the syntax for execution time (compare section GAMS Compile Time and Execution Time Phase).

4.45.4.1 Compile Time

There are three dollar control options to start an embedded code section at compile time:

\[
\begin{align*}
\$onEmbeddedCode[.tag] & \text{[Connect|Python]: [arguments]} \\
\$onEmbeddedCodeS[.tag] & \text{[Connect|Python]: [arguments]} \\
\$onEmbeddedCodeV[.tag] & \text{[Connect|Python]: [arguments]}
\end{align*}
\]

Lines following one of the above statements are passed on to the embedded code engine (e.g. Connect or the Python interpreter) until this dollar control option, which ends the embedded code section at compile time, is hit:

\[
\$offEmbeddedCode[.tag] \{symbol[<=]embSymbol[.dimX]\}
\]

These dollar control options are explained here in more detail. The usage of the optional arguments by the embedded code is explained in the specific embedded code engine section below.

Note

- The optional arguments from the \$onEmbeddedCode[S|V][.tag] statement can be accessed as gams.arguments in the Python code.
- The optional output symbols from the \$offEmbeddedCode[.tag] statement need to be written to by the embedded code.
- More about the specific GAMS Python syntax can be found below.

4.45.4.2 Execution Time

At execution time an embedded code section is started with one of these statements:

\[
\begin{align*}
\text{embeddedCode[.tag]} & \text{[Connect|Python]: [arguments]} \\
\text{embeddedCodeS[.tag]} & \text{[Connect|Python]: [arguments]} \\
\text{embeddedCodeV[.tag]} & \text{[Connect|Python]: [arguments]}
\end{align*}
\]

Similar to the compile time alternatives \$onEmbeddedCode[S|V][.tag], the first two variants are synonyms which allow parameter substitution in the code that follows, while the last variant does not allow this but passes the code verbatim to the embedded code engine. The usage of the optional arguments by the embedded code is explained in the specific embedded code engine section below. The arguments passed to the embedded code engine at execution time can be extended by the put_utility command ECArguments. For example,

\[
\begin{align*}
\text{put\_utility 'ECArguments' / 'world...'}; \\
\text{embeddedCode} & \text{ Python: Hello} \\
\text{gams.printLog(gams.arguments)} \\
\text{endEmbeddedCode}
\end{align*}
\]
prints Hello world....

Lines following one of the statements `embeddedCode[S|V]` are passed on to the embedded code engine (e.g. the Python interpreter) until one of the following two statements, which end the embedded code section at execution time, is hit:

```
endEmbeddedCode[.tag] {output symbols}
pauseEmbeddedCode[.tag] {output symbols}
```

When the optional `tag` suffix (which can be any string) is used to start an embedded code section, the same one has to be used to end/pause that section. Both statements end the embedded code section and switch back to GAMS syntax in the following lines. Also, both statements can be followed by a GAMS symbol or a list of GAMS symbols which would get updated in the GAMS database after the embedded code got executed. If `output symbols` are specified, they need to be written to (e.g. by `gams.set` for embedded Python code) by the embedded code before.

To continue a previously paused embedded code section one of the following statements is used:

```
continueEmbeddedCode [handle]: [arguments]
continueEmbeddedCodeS [handle]: [arguments]
continueEmbeddedCodeV [handle]: [arguments]
```

As seen before, the first two variants are synonyms which allow parameter substitution in the embedded code that follows, while the last variant does not allow this but passes the code verbatim to the interpreter. Again, the usage of the optional `arguments` by the embedded code is explained in the specific embedded code engine section below.

New in these statements is the optional `handle`. If omitted, the last code section that was paused will be continued. However, sometimes one might need to maintain different embedded code sections active in parallel and independent of each other. There is a new function to store a handle of the last embedded code section that was executed which could then later be used to continue a specific paused code section:

```handle = embeddedHandle;
```

What it exactly means to end or pause/continue an embedded code section depends on the embedded code engine and is explained in more detail with the code engine below. Independent of the embedded code engine it is important to note that if GAMS stops and restarts while executing a `solve` statement (with `solveLink=0`) continuing any embedded code section causes the code to fail with the following error message:

```
Error executing "continueEmbeddedCode" section
--- (Hint: "Solve" with SolveLink=0 frees previously initialized embedded libraries):
Error at line 71: No embedded library initialized
```

This happens because under `solveLink=0` the GAMS process terminates when the solver starts up. This causes the loss of the state of the embedded code environment that is linked into the GAMS process as a shared library. Under all other settings of `solveLink` the GAMS process is not stopped and restarted and hence a paused embedded code environment can be continued after the solve statement has carried out.
4.45.5 Python

GAMS and Python complement each other in many different ways. GAMS has a compact but readable syntax for data assignment and equation definition statements. Python is a great scripting language to do more traditional type programming especially string manipulation which is completely missing in GAMS. Moreover, the vast number of packages help solving scientific problems outside the scope of GAMS. In order to open this world to our customers in an easy way, GAMS comes with a Python 3 installation. By default, this installation is used in the Embedded Code Facility for Python and is ready to be used with the GAMS Python API. The Python installation is located in \[GAMS\text{ directory}/GMSPython\]. In contrast to earlier versions this installation comes without the Python package manager \texttt{pip} and therefore is not easily extendable. \texttt{GMSPython} comes with a selection of third party packages and modules that are either required by the APIs of the GAMS Python API collection or that are particularly helpful from within embedded Python code. Those packages are located in \[GAMS\text{ directory}/apifiles/Python/thirdparty\]. Running the \texttt{GMSPython} interpreter like follows will display all available modules:

\[\text{[GAMS directory]}/\text{GMSPython/python -c"help(\textquote{modules})"}\]

The list of redistributed third party packages is subject to constant changes and it is not recommended to rely on their availability. If you need packages that do not come with \texttt{GMSPython}, we recommend that you install your own version of Python and follow a few steps to connect GAMS with your Python installation. It is also possible to install \texttt{pip} for \texttt{GMSPython} using \texttt{get-pip}. While any Python installation should work in combination with GAMS we can recommend the \texttt{Anaconda} or \texttt{Miniconda} Python distributions. These Python distributions work with environments which allow you to have many different Python installations at the same time that don’t get in each other’s way.

During the lifetime of the GAMS process a single Python interpreter is used and the code "lives" in Python’s global scope. This means that objects defined in one embedded Python code section are still there in another embedded Python code section:

\begin{verbatim}
$onEmbeddedCode Python:
s = 'Hello world'
$offEmbeddedCode
$onEmbeddedCode Python:
gams.printLog(s)
$offEmbeddedCode
\end{verbatim}

will produce the following output in the GAMS log:

\begin{verbatim}
--- Starting compilation
--- main.gms(3) 2 Mb
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
--- main.gms(6) 2 Mb
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
Hello world
--- main.gms(7) 2 Mb
\end{verbatim}

If the GAMS process stops and restarts during execution, e.g. because of a solve with \texttt{solveLink=0}, the Python interpreter will be started new. This can cause complications if GAMS is in a sequence of \texttt{pause/continueEmbeddedCode} as discussed above.
4.45.5.1 Interface between GAMS and Python

The Python class `ECGamsDatabase` is the interface between GAMS and Python. An instance of this class is automatically created when an embedded code section is entered and can be accessed using the identifier `gams`. The following methods can be used in order to interact with GAMS:

```python
    gams.get(symbolName, keyType=KeyType.STRING, keyFormat=KeyFormat.AUTO, valueFormat=ValueFormat.AUTO, recordFormat=RecordFormat.AUTO)
```

This method retrieves an iterable object representing the symbol identified with `symbolName`. Typically there are two possibilities to access the records. Iterating using e.g. a `for` loop provides access to the individual records. By calling `list()` on the iterable object, a list containing all the data is created. Several optional parameters can be used in order to modify the format of the retrieved data:

- **keyType**: Determines the data type of the keys. It can be either `KeyType.STRING` (labels) or `KeyType.INT` (label indexes). The default setting is `KeyType.STRING`.
- **keyFormat**: Specifies the representation of the keys. Possible values are as follows:
  - `KeyFormat.TUPLE`: Encapsulate keys in a tuple
  - `KeyFormat.FLAT`: No encapsulation
  - `KeyFormat.SKIP`: Keys are skipped and do not appear in the retrieved data
  - `KeyFormat.AUTO` (default): Depending on the dimension of the GAMS symbol, a default format is applied:
    * Zero dimensional/scalar: `KeyFormat.SKIP`
    * One dimensional: `KeyFormat.FLAT`
    * Multi dimensional: `KeyFormat.TUPLE`
- **valueFormat**: Specifies the representation of the values. Possible values are as follows:
  - `ValueFormat.TUPLE`: Encapsulate values in a tuple
  - `ValueFormat.FLAT`: No encapsulation
  - `ValueFormat.SKIP`: Values are skipped and do not appear in the retrieved data
  - `ValueFormat.AUTO` (default): Depending on the type of the GAMS symbol, a default formats is applied:
    * Set: `ValueFormat.SKIP`
    * Parameter: `ValueFormat.FLAT`
    * Variable/Equation: `ValueFormat.TUPLE`
- **recordFormat** Specifies the encapsulation of records into tuples. Possible values are as follows:
  - `RecordFormat.TUPLE`: Encapsulates every record in a tuple
  - `RecordFormat.FLAT`: No encapsulation. Throws an exception if it can not be applied. It is guaranteed that the length of a retrieved Python list is equal to the number of records of the corresponding GAMS symbol. This principle leads to an incompatibility of `RecordFormat.FLAT` whenever a record consists of more than one item (e.g. multi dimensional symbols, variables and equations which have five numeric values).
  - `RecordFormat.AUTO` (default): Depending on the number of items that represent a record, a default format is applied. If possible this is always `RecordFormat.FLAT`.

GAMS special values `NA`, `INF`, and `-INF` will be mapped to IEEE special values `float('nan')`, `float('inf')`, and `float('-inf')`. GAMS special value `EPS` will be either mapped to 0 or to the small numeric value 4.94066E-324 depending on the setting of flag `gams.epsAsZero`.

The following Python code shows some examples of `gams.get` and illustrates the use of different formats:
Set i / i1 text 1, i2 text 2 /
  j / j1*j2 /

Scalar p0 /3.14/;
Parameter p1(i) / #i 3.14 /
  p2(i,j) / i1.#j 3.14 /
Variable v0 / fx 3.14 /;
equation e1(i) / #i.fx 3.14 /
  e2(i,j) / i1.#j.fx 3.14 /;

$onEmbeddedCode Python:
# scalar parameter
gams.printLog(f"{list(gams.get('p0'))}")               # prints [3.14]
gams.printLog(f"{list(gams.get('p0', recordFormat=RecordFormat.TUPLE))}") # prints [(3.14,)]

# one dimensional parameters:
gams.printLog(f"{list(gams.get('p1'))}")           # prints [('i1', 3.14)]
gams.printLog(f"{list(gams.get('p1', keyFormat=KeyFormat.TUPLE))}") # prints [('i1', (3.14,))]
gams.printLog(f"{list(gams.get('p1', valueFormat=ValueFormat.TUPLE))}") # prints [('i1', (3.14,))]
gams.printLog(f"{list(gams.get('p1', keyFormat=KeyFormat.TUPLE, valueFormat=ValueFormat.TUPLE))}") # prints [('i1', (3.14,))]

# two dimensional parameter:
gams.printLog(f"{list(gams.get('p2'))}")       # prints [('i1', 'j1', 3.14), ('i1', 'j2', 3.14)]
gams.printLog(f"{list(gams.get('p2', keyFormat=KeyFormat.FLAT))}") # prints [('i1', 'j1', 3.14), ('i1', 'j2', 3.14)]

# one dimensional sets:
gams.printLog(f"{list(gams.get('i'))}")      # prints ['i1', 'i2']
gams.printLog(f"{list(gams.get('i', valueFormat=ValueFormat.FLAT))}") # prints [('i1', 'text 1'), ('i2', 'text 2')]

# scalar variables/equations
gams.printLog(f"{list(gams.get('v0'))}")      # prints [(3.14, 0.0, 3.14, 3.14, 1.0)]

# one dimensional variables/equations:
gams.printLog(f"{list(gams.get('e1'))}")       # prints [('i1', (3.14, 0.0, 3.14, 3.14, 1.0))]
gams.printLog(f"{list(gams.get('e1', valueFormat=ValueFormat.FLAT))}") # prints [('i1', (3.14, 0.0, 3.14, 3.14, 1.0))]

# two dimensional variables/equations:
gams.printLog(f"{list(gams.get('e2'))}")       # prints [('i1', 'j1', 3.14, 0.0, 3.14, 3.14, 1.0), ('i1', 'j2', 3.14, 0.0, 3.14, 3.14, 1.0)]

gams.printLog(f"{list(gams.get('e2', keyFormat=KeyFormat.FLAT, valueFormat=ValueFormat.FLAT))}") # prints [('i1', 'j1', 3.14, 0.0, 3.14, 3.14, 1.0), ('i1', 'j2', 3.14, 0.0, 3.14, 3.14, 1.0)]

# using label indexes instead of labels

gams.printLog(f"{list(gams.get('p1', keyType=KeyType.INT))}") # prints [(1, 3.14), (2, 3.14)]
gams.printLog(f"{list(gams.get('i', keyFormat=KeyFormat.TUPLE, valueFormat=ValueFormat.TUPLE, keyType=KeyType.INT))}") # prints [(1, ('text 1',)), (2, ('text 2',))]

$offEmbeddedCode

gams.set(symbolName, data, mergeType=MergeType.DEFAULT, domCheck=DomainCheckType.DEFAULT, mapKeys=mapKeys)

This method sets the data for the GAMS symbol identified with symbolName. The parameter data takes a Python list or set containing items that represent the records of the symbol. It is also possible to pass an instance of a subclass of _GamsSymbol (e.g. GamsParameter or GamsSet) when using the Object-oriented GAMS Python API in an embedded code section. In case of a Python list or set, depending on the type and the dimension of the symbol, different formats can be used in order to specify the data. Different formats cannot be mixed within one list. In general each record needs to be represented as a tuple containing the keys and the value field(s). Keys and/or values can also be enclosed in a tuple. Keys can be entered as labels (string) or label indexes (int). The argument mapKeys...
allows to pass a callable to remap the elements of the key (e.g. turn them explicitly into strings via `mapKeys=str`). Value fields depend on the type of the symbol:

- Parameters: One numerical value
- Sets: explanatory text (optional)
- Variable/Equations: Five numerical values: level, marginal, lower bound, upper bound, scale/prior/stage

IEEE special values `float('nan')`, `float('inf')`, and `float('-inf')` will be remapped to GAMS special values `NA`, `INF`, and `-INF`. The small numeric value `4.94066E-324` will be mapped into GAMS special value `EPS`.

The following Python code gives some examples on different valid formats for different symbol types and dimensions:

```python
Set i / i1 text 1, i2 text 2 /
  j / j1*j2 /
i(i);
Scalar p0;
Parameter p1(i)
p2(i,j);
equation e1(i)
e2(i,j);
$onEmbeddedCode Python:
# scalar parameter
gams.set('p0', [3.14])
gams.set('p0', [(3.14,)])
# one dimensional parameters:
gams.set('p1', [('i1', 3.14), ('i2', 3.14)])
gams.set('p1', [('i1',), (3.14,)], [('i2',), (3.14,)])
gams.set('p1', [('i1', (3.14,)), ('i2', (3.14,))])
gams.set('p1', [('i1',), (3.14,)], [('i2',), (3.14,)])
# two dimensional parameter:
gams.set('p2', [('i1', 'j1', 3.14), ('i1', 'j2', 3.14)])
gams.set('p2', [('i1', 'j1'), (3.14,)], [('i1', 'j2'), (3.14,)])
# one dimensional sets:
gams.set('ii', ['i1', 'i2'])
gams.set('ii', [('i1',), ('i2',)])
# one dimensional sets with explanatory text
gams.set('ii', [('i1', 'text 1'), ('i2', 'text 2')])
gams.set('ii', [('i1',), ('text 1'), ('i2',), ('text 2')])
# one dimensional variables/equations:
gams.set('e1', [('i1', 3.14, 0, 0, 10, 1), ('i2', 3.14, 0, 0, 10, 1)])
gams.set('e1', [('i1', (3.14, 0, 0, 10, 1)), ('i2', (3.14, 0, 0, 10, 1))])
gams.set('e1', [('i1',), (3.14, 0, 0, 10, 1)], [('i2',), (3.14, 0, 0, 10, 1)])
# two dimensional variables/equations:
gams.set('e2', [('i1', 'j1', 3.14, 0, 0, 10, 1), ('i1', 'j2', 3.14, 0, 0, 10, 1)])
gams.set('e2', [('i1', 'j1'), (3.14, 0, 0, 10, 1)], [('i1', 'j2'), (3.14, 0, 0, 10, 1)])
# using label indexes instead of labels
gams.set('p1', [(1, (3.14,)), (2, (3.14,))]) # one dimensional parameter
gams.set('ii', [(1, 'text 1'), (2, 'text 2')]) # one dimensional set
gams.set('e2', [(1, 3, (3.14, 0, 0, 10, 1)), ((4, (3.14, 0, 0, 10, 1)))] # two dimensional variables/equations
$offEmbeddedCode p0 p1 p2 ii e1 e2
The optional parameter mergeType specifies if data in a GAMS symbol is merged (MergeType.MERGE) or replaced (MergeType.REPLACE). If left at MergeType.DEFAULT it depends on the setting of $on/offMulti[R] if GAMS does a merge, replace, or trigger an error during compile time. During execution time MergeType.DEFAULT is the same as MergeType.MERGE.

The optional parameter domCheck specifies if Domain Checking is applied (DomainCheckType.CHECKED) or if records that would cause a domain violation are filtered (DomainCheckType.FILTERED). If left at DomainCheckType.DEFAULT it depends on the setting of $on/offFiltered if GAMS does a filtered load or checks the domains during compile time. During execution time DomainCheckType.DEFAULT is the same as DomainCheckType.FILTERED.

Note

When calling gams.set() in an embedded code section during execution time, new labels that are not known to the current GAMS program can not be added. The attempt will result in an execution error.

\[ \text{gams.getUel(idx)} \]

Returns the label corresponding to the label index idx

\[ \text{gams.mergeUel(label)} \]

Adds label to the GAMS universe if it was unknown and returns the corresponding label index.

Note

When calling gams.mergeUel() in an embedded code section during execution time, new labels that are not known to the current GAMS program can not be added. The attempt will result in an execution error.

\[ \text{gams.getUelCount()} \]

Returns the number of labels.

\[ \text{gams.printLog(msg)} \]

Print msg to log.

\[ \text{gams.arguments} \]

Contains the command line that was passed to the Python interpreter of the embedded code section. The syntax for passing arguments to the Python interpreter can be seen above.

\[ \text{gams.epsAsZero} \]

Flag to read GAMS EPS as 0 (True) or as a small number, \(4.94066 \times 10^{-324}\), when set to False. Default is True.

\[ \text{gams.ws} \]

Property to retrieve an instance of GamsWorkspace that allows to use the Object-oriented GAMS Python API. The instance is created when the property is read for the first time using a temporary working directory. A different working directory can be specified using gams.wsWorkingDir. For debug output, the property gams.debug can be set to a value from DebugLevel.
4.45 Embedded Code Facility

**gams.wsWorkingDir**

Property that can be specified before accessing `gams.ws` for the first time in order to set the working directory. Setting the property after the first call to `gams.ws` will have no effect on the created GamsWorkspace.

**gams.db**

Property to retrieve an instance of `GamsDatabase`. The instance is created when the property is read for the first time and allows to access the GAMS symbols using the methods of the Object-oriented GAMS Python API.

**gams.debug**

Property that can be set to a value from `DebugLevel` for debug output. Default is `DebugLevel.Off` (0). Setting this property affects both the debug output from embedded code and the debug output from the Object-oriented API. The property needs to be changed before accessing `gams.ws` for the first time in order to take effect in the Object-oriented API. Setting the property after the first call to `gams.ws` will have no effect on the GamsWorkspace.

### 4.45.5.2 Using the Object-oriented API

The EGCamsDatabase class provides mechanisms for using the Object-oriented GAMS Python API in an embedded code section. The property `gams.ws` can be used to get an instance of GamsWorkspace. The property `gams.db` allows to access an instance of GamsDatabase that can be used to read and write data from the internal GAMS database like it can be done using `gams.get` and `gams.set` but using the access mechanisms of the GamsDatabase class. In addition to the different reading and writing mechanisms offered by the OO-API other classes like `GamsModelInstance` can be used inside embedded Python code. This combination provides programmatic access to a generated model instance and exchange of update parameters and results between Python and GAMS. The GAMS Library model `embmiex1` gives an example of how to combine embedded Python code and a `GamsModelInstance` which utilized the library include `$libInclude pyEmbMI`.

Moreover, the GAMS Transfer Python API can be combine with the OO-API in the embedded code context as the following example demonstrates:

```python
Set i / i1*i1000 /; alias(i,j);
Parameter a(i,j), aInv(i,j);
a(i,j) = 1 / (ord(i)+ord(j) - 1);
a(i,i) = 1;

import gamstransfer as gt
import numpy as np

m = gt.Container(gams.db)
A = m.data["a"].toDense()
m.data["aInv"].setRecords(np.linalg.inv(A))
m.write(gams.db, ["aInv"]) endEmbeddedCode aInv
```
4.45.5.3 Exchange via Files and Environment Variables

The Python class ECGamsDatabase provides read and write access to GAMS symbols. There are two other communication methods that can be used at GAMS compile time: files and environment variables. At compile time the Python code can produce a text file that can be included into GAMS via $include as in the following example:

```python
$onEmbeddedCode Python: 10
with open('i.txt', 'w') as f:
    for i in range(int(gams.arguments)):
        f.write(f'i{i+1}\n')
$offEmbeddedCode

Set i /
$include i.txt
/;
display i;
```

Here the Python code received the number of elements to write to a text file via the argument after Python:. This text file is then included in the data statement of the GAMS set i. The display in the listing file looks as follows:

```plaintext
---- 20 SET i
i1 , i2 , i3 , i4 , i5 , i6 , i7 , i8 , i9 , i10
```

Python provides many packages to read input files for many different formats and hence can be used to transform such formats to a GAMS compatible input format, as an alternative to providing the data via list objects and the gams.set functionality.

The second alternative to exchange information at compile time are environment variables. GAMS and Python allow to get and set environment variables and hence can be conveniently used to exchange small pieces of information. The following code provides an example where the maximum value of a parameter b is needed to build a set k:

```gams
Set i / i1*i5 /;
Parameter b(i) / i1 2, i2 7, i3 59, i4 2, i5 47 /;
$onEmbeddedCode Python:
import os
os.environ["MAXB"] = str(int(max([b for i,b in gams.get("b")])))
gams.printLog(f'max value in b is {os.environ["MAXB"]}')
$offEmbeddedCode

$if x%sysEnv.MAXB%=x $abort MAXB is not set
Set k "from 0 to max(b)" / 0*%sysEnv.MAXB% /;
$eval CARDK card(k)
$log card(k)=%CARDK%
```

It is important to understand that os.environ is initialized when Python imports the os module. Hence, if we later set an environment variable in GAMS (via $setEnv ABC abc or put_utility "setEnv" / "ABC" / "abc") and access this in some embedded code via os.environ["ABC"], this will not provide the expected value "abc". In such a case the environment variable needs to be accessed via gams.get_env("ABC") (and can be stored in os.environ["ABC"]) as demonstrated by the following code:
4.45 Embedded Code Facility

$onEmbeddedCode Python:
import os
os.environ["TEST"] = 'Hello world'
$offEmbeddedCode
$log TEST=%sysEnv.TEST%
$setEnv ABC abc
$onEmbeddedCode Python:
gams.printLog(f'ABC={os.environ.get("ABC", "ABC not set")}')
gams.printLog(f'ABC={gams.get_env("ABC")}')
$offEmbeddedCode

which produces the following output:

--- Starting compilation
--- main.gms(4) 2 Mb
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
TEST=Hello world
--- main.gms(10) 2 Mb
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
ABC=ABC not set
ABC=abc

Obviously, the set \( k \) can also be filled directly with data from within Python:

Set   i / i1*i5 /;
Parameter b(i) / i1 2, i2 7, i3 59, i4 2, i5 47 /;
Set   k(*) "from 0 to max(b)";

$onEmbeddedCode Python:
kmax = max([b for i,b in gams.get("b")])
gams.set('k',[str(k) for k in range(int(kmax+1))])
$offEmbeddedCode

In both cases the resulting GAMS symbol \( k \) is a set with elements 0 to 59.

Note that the \((*)\) in the declaration of \( k \) is necessary to inform the compiler of dimensionality of the symbol \( k \). GAMS symbol declarations can be done without domain list, so a set \( k \) does not necessarily mean that this is a one dimensional set. The compiler will learn the dimensionality from the use of \( k \). For example, if \( k \) shows up as a domain set in a declaration (parameter \( p(k) \)) it is clear that \( k \) is a one dimensional set. Without knowing the dimensionality \( k \) will not be available with embedded code or exported (at compile-time) to GDX and the following code

Set k;
$onEmbeddedCode Python:
gams.set('k', ['0','1','2'])
$offEmbeddedCode

will fail with compilation error Cannot load/unload symbol with unknown dimension.
4.45.5.4 Encodings

Python 3 expects source code to be encoded in UTF-8 per default. Therefore all embedded Python code has to be encoded in UTF-8 as well. However, this can be customized by adding a comment in the format # coding=<encoding name> or # -*- coding: <encoding name> -*- as first line of an Embedded Python Code section. The encoding can be changed from any Embedded Python Code section and will affect all subsequent sections. So in case of a GAMS source file which is encoded using a non-UTF-8 encoding like cp1252 or others, it is sufficient to change the encoding only once in the very first Embedded Code section. Note that UTF-16 encoding is not supported.

Note
Changing the source code encoding has no effect on the default encoding that is used by the open() function since it uses whatever locale.getpreferredencoding(False) returns. Furthermore the encoding used for stdin/stdout/stderr has to be controlled separately. This can be achieved by setting the environment variable PYTHONIOENCODING.

4.45.5.5 Multiple Independent Python Sessions

At execution time the user has the ability to pause and continue an embedded code segment. As explained at the beginning, the user Python code lives in Python's global scope. Nevertheless, besides some performance aspects one can also allows work with multiple independent Python sessions. Due to some Python module incompatibilities (e.g. numpy) the independent Python sessions have to be enabled with a command line option pyMultInst set to 1. After the pauseEmbeddedCode we can obtain and store the handle of the last embedded code execution via function embeddedHandle. The handle needs to be supplied when we continue the Python session via continueEmbeddedCode. The different Python sessions are fairly separate as shown in the example below. Here we save the GAMS scalar ord(i) in a Python object i five times. The value for i that we store in the five different Python sessions is 1 to 5. In the subsequent loop we activate the Python session with the appropriate handle and print the value of i:

```gams
$if not %sysEnv.GMSPYTHONMULTINST%=1 $abort.noError Start with command line option pyMultInst=1
Set i / i1*i5 /;
Parameter h(i) 'session handle';
loop(i, 
   put_utility 'setEnv' / 'ORDI' / ord(i):0:0;
   embeddedCode Python: 
   i = int(gams.get_env("ORDI"))
   gams.printLog(f'\{i}\n')
   pauseEmbeddedCode
   h(i) = embeddedHandle;
);
loop(i, 
   continueEmbeddedCode h(i):
   gams.printLog(f'\{i}\n')
   endEmbeddedCode
);
```

The GAMS log shows the value of i in the different Python sessions:

```
--- Starting execution: elapsed 0:00:00.002
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
1
--- Initialize embedded library embpycclib64.dll
```
4.45 Embedded Code Facility

--- Execute embedded library embpycclib64.dll
2
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
3
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
4
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
5
--- Execute embedded library embpycclib64.dll
1
--- Execute embedded library embpycclib64.dll
2
--- Execute embedded library embpycclib64.dll
3
--- Execute embedded library embpycclib64.dll
4
--- Execute embedded library embpycclib64.dll
5
*** Status: Normal completion

4.45.5.6 Troubleshooting Embedded Python Code

The GAMS compiler ensures that the number of errors during execution time is minimized. While the logic of the GAMS program might be flawed there is nothing (with a few exceptions) that the GAMS system cannot execute. This is different if we embed foreign code in a GAMS program. The GAMS compiler does not understand the foreign code syntax and just skips over it. Only when the code is executed we will find out if everything works as expected. If the embedded code contains some (Python) syntax errors the Python parser will inform us about this and the message will appear in the GAMS log. For example, the following Python code using the gams.printLog function two times will generate a syntax error:

```plaintext
$onEmbeddedCode Python:
gams.printLog('hello')
gams.printLog('world...')
$offEmbeddedCode
```

The GAMS log will provide some guidance:

```plaintext
--- Execute embedded library libembpycclib64.so
File "<string>", line 7
  gams.printLog('world...')

IndentationError: unexpected indent
Python error! Return code from Python execution: -1
*** Error executing embedded code section:
*** Check log above
```

Moreover, if the Python code raises an exception which is not handled within the code this will also lead to a compilation or execution error in GAMS depending at what phase the embedded code is executed.
embeddedCode Python:
raise Exception('something is wrong')
endEmbeddedCode

will produce the following GAMS log and an execution time error:

--- Initialize embedded library libembpycclib64.so
--- Execute embedded library libembpycclib64.so
Exception from Python (line 0): something is wrong
*** Error at line 1: Error executing "embeddedCode" section: Check log above

Note
It is good practice to raise a Python exception if an error occurs. In any case using `exit()` needs to be avoided since it terminates the executable in an uncontrolled way.

The Python code is executed as part of the GAMS process and GAMS gives control to the Python interpreter when executing the embedded code. So in the worst case if the Python interpreter crashes, the entire GAMS process will crash. Therefore, it is important to be able to test and debug the embedded Python code independent of GAMS. In the following examples we call the Python interpreter executable as part of a GAMS job. In principle this can be tested and debugged completely independent of GAMS where a GDX file represents the content of the GAMS database.

In the first example we mimic the embedded code facility at compile time by exporting the entire GAMS database to a GDX file `debug.gdx`. With `$on/offEcho` we write the embedded code with a few extra lines at the top and bottom surrounded by a `try/except` block and execute the Python interpreter via `$call`. One of the extra lines at the end of the embedded code triggers the creation of a GDX result file `debugOut.gdx` which can be imported in subsequent `$gdxin/$load` commands.

```plaintext
Set i /i1*i10/
   p(i,i) permutation;

$gdxOut debug.gdx
$unload
$gdxOut
$onEcho > debug.py
from gamsemb import *
gams = ECGAMSDatabase(r'\%gams.sysdir%\[:-2\], 'debug.gdx')
try:
   import random
   i = list(gams.get("i"))
   p = list(i)
   random.shuffle(p)
   for idx in range(len(i)):
      p[idx] = (i[idx], p[idx])
   gams.set("p", p)
gmdWriteGDX(gams._gmd,'debugOut.gdx',1);
except Exception as e:
   print(str(e))
$offEcho
$call.checkErrorLevel ="%gams.sysdir%GMSPython/python" debug.py

$gdxIn debugOut.gdx
$loadDC p

Option p:0:0:1;
Display p;
```
In the second example we mimic the embedded code facility at execution time by exporting the entire GAMS database to a GDX file `debug.gdx` via `execute_unload 'debug.gdx';`. We write the embedded code with a few extra lines at the top and bottom surrounded by a try/except block via the `put` facility and execute the Python interpreter via `execute`. Identical to the compile time example, we export the result to the GDX file `debugOut.gdx` which can be imported via the `execute_load` statement.

```plaintext
Set i /i1*i10/
   p(i,i) permutation;
execute_unload 'debug.gdx';
file fpy / 'debug.py' /; put fpy;

$onPutS
from gamsemb import *
gams = ECGAMSDatabase(r'\%gams.sysdir\ %[:2],\'debug.gdx\')
try:
    import random
    i = list(gams.get("i"))
    p = list(i)
    random.shuffle(p)
    for idx in range(len(i)):
        p[idx] = (i[idx], p[idx])
    gams.set("p", p)
    gmdWriteGDX(gams._gmd,'debugOut.gdx',1);
except Exception as e:
    print(str(e))
$offPut
putClose fpy;
execute.checkErrorLevel ="%gams.sysdir%GMSPython/python" debug.py';

execute_load 'debugOut.gdx', p;
Option p:0:0:1;
Display p;
```

### 4.45.5.6.1 Automatic Indentation

All embedded Python code is automatically wrapped in a `try-except` block that requires an indentation (two spaces). While this additional indentation makes no difference for most Python code, it does make a difference when it comes to multi-line strings. Therefore, multi-line strings created with triple quotes (either single or double quotes) are excluded from this rule to avoid unintentional spaces, e.g. when writing to a file:

```plaintext
$onEmbeddedCode Python:
f = open("file.txt", "w")
f.write('''some
 multi
 line
 string
''')
f.close()
$offEmbeddedCode
```

Still, when using the line continuation character (`\`) in combination with strings, one has to be aware of the extra spaces that are added automatically:
This will print *some multi line string* instead of *somemultilinestring* due to the automatically applied indentation.

### 4.45.5.7 Performance Considerations of Embedded Python Code

If the same embedded code section (e.g. in a loop) is executed many times there are a few considerations to be taken into account in order to get the best performance. For this we will experiment with the example from the introduction. We look for a random permutation of a set `i`. In addition we have a cost matrix `c(i,ii)` and we are looking for the least cost permutation. We should just formulate this as matching in a bi-partite graph but in order to demonstrate some performance considerations we will repeatedly call the Python code that provides a random permutation and we will evaluate the cost of the permutation in GAMS and store the value of the cheapest one. Here is the naive implementation using embedded code:

```python
import random
delattr(gams, 'p')
gams.printLog(s)
```

Even though the Python interpreter stays alive the fresh start and end of an embedded code section goes together with the setup and initialization of multiple data structure, including the `gams` object of type `ECGAMSDatabase`. We can avoid the repeated setup and initialization by using `pause` and `continue`:

```python
import random
gams.set('p', [ (i[idx], p[idx]) for idx in range(len(i)) ])
```
embeddedCode Python:
import random
pauseEmbeddedCode

Set iter / 1*100 /
Scalar tcost
    minTCost / +inf /;
loop(iter,
    continueEmbeddedCode:
    i = list(gams.get("i"))
    p = list(i)
    random.shuffle(p)
    gams.set("p", [ (i[idx], p[idx]) for idx in range(len(i)) ])
    pauseEmbeddedCode p
tcost = sum(p, c(p));
    if (tcost < minTCost, minTCost = tcost);
); continueEmbeddedCode:
    pass
endEmbeddedCode
Display minTCost;

The last embedded code execution of the Python pass statement is to clean up and terminate the Python session. Since the amount of data is relatively small, there is little difference in the running time between these variants. The performance impact of independent Python session (command line option pyMultInst) is significant. While the pause/continue code runs at the same speed (roughly 0.2 seconds) independent of the pyMultInst setting, the original code runs much slower (about 6.6 seconds) because every iteration results in a newly created session.

There are other performance considerations. We can actually extract the set i once before the GAMS loop starts. Moreover, we can work with label indexes rather than the labels itself. Indexes are integers and are often faster than labels that are stored as strings. The only difference to the code above is the extraction method of the Python list i by i = list(gams.get("i",keyType=KeyType.INT)).

### 4.45.5.8 Extending GMSPython

While we recommend to use your own Python installation if you need additional packages, there are ways to extend the Python system that comes with GAMS in GMSPython. Here are the steps:

2. Update pip
3. Install additional packages

We highly recommend installing pip and additional packages in the user site (use --user when running get-pip and pip). This is especially important for macOS users. Installing files in the GAMS system directory may interfere with the file notarization and may prevent GAMS from starting properly. Here is a typical dialog for Linux/macOS using curl to download get-pip.py. If you don't have curl or wget, use your web browser for downloading.

```
curl https://bootstrap.pypa.io/get-pip.py -o get-pip.py
/path/to/gams/GMSPython/python get-pip.py --user
"/local/bin/pip install -U pip
"/local/bin/pip install geocoder --user
```
4.45.5.9 Using an External Python 3 Installation

Let's assume you don't want to work with the GAMS distributed GMSPython but you want to connect GAMS with a Python 3 installation of your liking. In order for the Embedded Code Facility to work, you need to make the alternative Python interpreter aware of the required modules provided by GAMS by following the Getting started steps in the Python API tutorial.

In addition to this you need to do one more step to allow GAMS to find your Python installation when executing Embedded Python code: you need to point to the Python dynamic load library or shared object. On Windows this file is called python3X.dll, on Linux libpython3.X.so, and on macOS libpython3.X.dylib. The X stands for the minor version number of Python 3. While embedded code has been built and tested for Python 3.8, chances are that you can also point to other Python 3 libraries. Since the expert level API is required, the set of versions is limited to what GAMS supports (currently GAMS ships these for Python \( \geq 3.6 \)). Limited experiments with the embedded code library for Python 3.8 with Python 3.6, 3.7, and 3.9 libraries were successful. Python 3.10 is not supported yet. You need to set the environment variable GMSPYTHONLIB to point GAMS to the Python library:

- **Windows:**
  ```bash
  set GMSPYTHONLIB=c:\path\to\python\python38.dll
  ```

- **Linux:**
  ```bash
  export GMSPYTHONLIB=/path/to/python/lib/libpython3.8.so
  ```

- **Mac OSX:**
  ```bash
  export GMSPYTHONLIB=/path/to/python/lib/libpython3.8.dylib
  ```

GAMS will extract the Python home from the location of the Python library. In case this extraction does not work (because of an unconventional Python installation), you can instruct GAMS to set the Python home via the additional environment variable GMSPYTHONHOME. Please note, that this environment variable only needs to be set for GAMS Embedded Python code, so it is sufficient to add these variables to the GAMS configuration YAML file.

**Note**
When using environment-based Python distributions like Anaconda or Miniconda, it is not sufficient to set GMSPYTHONLIB (and GMSPYTHONHOME). The environment to be used needs to be activated properly before (e.g. `conda activate myEnv`). Packages like numpy which have been installed using conda (`conda install numpy`) won't work otherwise. In addition to setting GMSPYTHONLIB we therefore recommend to start GAMS itself and also tool like GAMS Studio from an activated conda environment in order to make sure that the environment and all installed packages work as expected.

Although it is recommended to use a self-contained Python installation, it is possible to use a virtual environment instead (e.g. via `venv`). In this case, GMSPYTHONLIB has to be set to the Python library of the installation from which the environment was derived from. In addition, the PYTHONPATH environment variable needs to be set to the site-packages directory of the virtual environment in order to make its packages available. Note that with this setup the site-packages directory of the original Python installation will also be found by GAMS Embedded Python code.

4.45.5.10 Building your own Embedded Python Code Library

Although the Embedded Code Facility and its binary components are part of the GAMS distribution, it is possible to build it manually from source using the following commands. The exact command line might change depending on the compiler and the operating system in use:

- **Windows:**
  ```bash
  ```

- **Linux:**
  ```bash
  ```

- **Mac OSX:**
  ```bash
  ```

Although it is recommended to use a self-contained Python installation, it is possible to use a virtual environment instead (e.g. via `venv`). In this case, GMSPYTHONLIB has to be set to the Python library of the installation from which the environment was derived from. In addition, the PYTHONPATH environment variable needs to be set to the site-packages directory of the virtual environment in order to make its packages available. Note that with this setup the site-packages directory of the original Python installation will also be found by GAMS Embedded Python code.
4.45 Embedded Code Facility

- **Linux:**
  ```bash
cd [GAMS directory]/apifiles/C/api
icl.exe -Feembpycclib64.dll -IC:\path\to\python\include embpyoo.c gmdcc.c gclgms.c -LD -link -nodefaultlib:python38.lib
  ```
- **Mac OS X:**
  ```bash
cd [GAMS directory]/apifiles/C/api
gcc -o libembpycclib64.dylib -dynamiclib -shared -m64 -install_name @rpath/libembpycclib64.dylib embpyoo.c gmdcc.c gclgms.c -lm -ldl
  ```

4.45.6 Connect

The Connect framework gives unified and platform independent access to data exchange with different formats (e.g. CSV and Excel). The instructions how to access the various data sources are given in YAML syntax. These YAML instructions are the code for the embedded Connect code. The embedded Connect code engine will parse the YAML instructions and use Connect agents to act upon the instructions. The agents GAMSReader and GAMSWriter send data back and forth to GAMS. A simple example is given above.

Embedded code Connect is build on top of embedded code Python. Similar considerations (e.g. Python interpreter is loaded once) carry over from Python to Connect. Moreover, the agent PythonCode has access to the object `gams` of type `ECGamsDatabase` which is used for communication of data with GAMS. In contrast to embedded Python code, the code of the agent PythonCode does not execute in the global scope but in a separate block. This means that variables set in the code are not available in another PythonCode section. The following code ends up in the except clause and prints `Cannot access my_i`.

```plaintext
eMBEDDED_CODE
- **PythonCode:**
  ```python
code: |
  my_i = 1
  ```
- **PythonCode:**
  ```python
code: |
  try:
      gams.printLog(f'{my_i}')
  except:
      gams.printLog('Cannot access my_i')
```

END EMBEDDED_CODE

Since Python allows to add attributes to an object at runtime, the `my_i` variable can be added to the `gams` object and hence becomes available in different PythonCode sections and even in different embedded Connect code parts (when pause/continue is used):

```plaintext
eMBEDDED_CODE
- **PythonCode:**
  ```python
code: |
  gams.my_i = 1
  ```
- **PythonCode:**
  ```python
code: |
  gams.printLog(f'{gams.my_i}')
```

PAUSE EMBEDDED_CODE

CONTINUE EMBEDDED_CODE:

- **PythonCode:**
  ```python
code: |
  gams.printLog(f'{gams.my_i}')
```

END EMBEDDED_CODE

Even though embedded code Python and Connect share the same basis, they run in different instantiations of the Python interpreter and hence don't share e.g. the same gams object.
4.45.6.1 Substitutions in Embedded Connect Code

The GAMS compiler has mechanisms to substitute compile-time variables to parameterize GAMS code including embedded code (unless the V, e.g. `$onEmbeddedCodeV`, of embedded code is used). Here is an example how to use double-dash parameters to allow the user to set the CSV file name via the GAMS command line (gams mymodel.gms --csvfilename=mystockprice.csv):

```
$if not set CSVFILENAME $set CSVFILENAME stockprice.csv
$onEmbeddedCode
Connect:
  CSVReader:
  - file: %CSVFILENAME%
    name: stockprice
    indexColumns: [1, 2]
    valueColumns: [3]
  GAMSWriter:
    symbols:
      - name: stockprice
$offEmbeddedCode
```

Not only user defined compile-time variables will be substituted, but also all other compile time variables, e.g. `%gams.scrDir%` or `%system.dirSep%`. Another way to pass substitution instructions down to embedded Connect code are the embedded code arguments:

```
$if not set MYCSVFILENAME $set MYCSVFILENAME stockprice.csv
$onEmbeddedCodeV
Connect: --CSVFILENAME=%MYCSVFILENAME%
  CSVReader:
  - file: %CSVFILENAME%
    name: stockprice
    indexColumns: [1, 2]
    valueColumns: [3]
  GAMSWriter:
    symbols:
      - name: stockprice
$offEmbeddedCode
```

Together with the put_utility command ECArguments that appsends some arbitrary text to the embedded code arguments this can be used to parameterize the embedded Connect code at execution time, e.g. to create files based on label names:

```
Set i /1*5/; Parameter p(i);
loop(i,
  p(i) = uniform(0,1);
  put_utility 'ECArguments' / '--CSVFILENAME=' i.tl:0 '.csv';
  EmbeddedCodeV
Connect:
  GAMSReader:
    symbols:
      - name: p
  CSVWriter:
    name: p
    file: %CSVFILENAME%
endEmbeddedCode
);
```

Please note that while the GAMS command line parameters allow various formats to specify double-dash parameters, the embedded code Connect substitution arguments must be in the form --key=value, so a = character to separate key and value with no spaces. The value might be a (double) quoted string though. Please also note that the embedded code arguments set with put_utility command ECArguments will be applied to any subsequent embedded code section. So one might want to clear the argument by adding a put_utility "ECArguments" / ""; after the relevant embedded code section.
4.46  GAMS Connect

4.46.1  Concept

GAMS Connect is a framework inspired by the concept of a so-called ETL (extract, transform, load) procedure that allows to integrate data from various data sources. The GAMS Connect framework consists of the Connect database and the Connect agents that operate on the Connect database. Via the available Connect interfaces the user passes instructions to call Connect agents for reading data from various file types into the Connect database, transforming data in the Connect database, and writing data from the Connect database to various file types. Instructions are passed in YAML syntax. Note that in contrast to a typical ETL procedure, read, transform and write operations do not need to be strictly separated.

4.46.2  Usage

GAMS Connect is available via the GAMS command line parameters ConnectIn and ConnectOut, via embedded code Connect, and as a standalone command line utility gamsconnect.

Instructions processed by the GAMS Connect interfaces need to be passed in YAML syntax as follows:

```
- <agent name1>:
  <global option1>: <value>
  <global option2>: <value>
  ...
  symbols:
    - <symbol1 option1>: <value>
      <symbol1 option2>: <value>
      ...
    - <symbol2 option1>: <value>
      <symbol2 option2>: <value>
      ...
- <agent name2>:
  ...
```

The user lists the tasks to be performed successively. All tasks begin at the same indentation level starting with a - (a dash and a space) followed by the Connect agent name and a : (a colon). Connect agent options are represented in a simple <option>: <value> form. Please check the documentation of Connect Agents for available options. Some agents can operate on multiple symbols. For these agents there are two types of options:

1. Global: Global options allow to define general settings, e.g. the file name.

2. Symbol: Symbol options allow to define symbol specific settings, e.g. the name of the symbol. Symbol options are defined in a sub-list under the keyword symbols.
Some Connect agent options are of type global and symbol simultaneously, i.e. the user can define a global value for the option but may change the value for some symbols specifically. Note that YAML syntax also supports an abbreviated form for lists and dictionary, e.g. `symbols: [{<symbol1 option1>: <value>, <symbol1 option2>: <value>}, {<symbol2 option1>: <value>, <symbol2 option2>: <value>}]`.

Here is an example that uses embedded Connect code to process instructions:

```plaintext
$onecho > distance.csv
i;j;distance in miles
seattle;new-york;2,5
seattle;chicago;1,7
seattle;topeka;1,8
san-diego;new-york;2,5
san-diego;chicago;1,8
san-diego;topeka;1,4
$offecho

$onecho > capacity.csv
i,capacity in cases
seattle,350.0
san-diego,600.0
$offecho

Set i 'Suppliers', j 'Markets';
Parameter d(i,j) 'Distance', a(i) 'Capacity';
$onEmbeddedCode Connect:
  - CSVReader:
    file: distance.csv
    name: distance
    indexColumns: [1, 2]
    valueColumns: [3]
    fieldSeparator: ' ;'
    decimalSeparator: ','
  - CSVReader:
    file: capacity.csv
    name: capacity
    indexColumns: [1]
    valueColumns: [2]
  - GAMSWriter:
    symbols:
      - name: distance
        newName: d
      - name: capacity
        newName: a
$offEmbeddedCode
```

In this example, we are reading two CSV files `distance.csv` and `capacity.csv` using the `CSVReader`. Then we directly write to symbols in GAMS using the `GAMSWriter`.

Note that even though GAMS is case insensitive, GAMS Connect is case sensitive, i.e., YAML instructions are treated case sensitive. This also includes, e.g., indices in CSV files. Consider the following example where the index `j2` should be substituted by `ABC` when reading the CSV file `y.csv`:

```plaintext
$onecho > y.csv
i1,j1,2.5
```
i1,j2,1.7
i2,j1,1.8
i2,j2,1.4

$offecho

set i,j;
parameter p(i<,j<);

$onEmbeddedCode Connect:
- CSVReader:
  file: y.csv
  name: p
  indexColumns: [1,2]
  valueColumns: [3]
  header: false
  indexSubstitutions: { j2: ABC }
- GAMSWriter:
  writeAll: true
$offEmbeddedCode

display i,j,p;

Since the YAML instructions are treated case sensitive, the index J2 will not be substituted.

<table>
<thead>
<tr>
<th>j1</th>
<th>J2</th>
<th>ABC</th>
</tr>
</thead>
<tbody>
<tr>
<td>i1</td>
<td>2.500</td>
<td>1.700</td>
</tr>
<tr>
<td>i2</td>
<td>1.800</td>
<td>1.400</td>
</tr>
</tbody>
</table>

All instructions provided to the Connect framework are read using UTF-8 encoding (utf-8-sig). This can be customized by adding a comment in the format # coding=<encoding name> or # -*- coding: <encoding name> -*- as first line in the YAML code. Note that UTF-16 encoding is not supported.

### 4.46.3 Connect Agents Summary

Current Connect agents support the following data source formats: CSV, Excel, GDX and SQL. The following Connect agents are available:

<table>
<thead>
<tr>
<th>Connect agent</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSVReader</td>
<td>Allows reading a symbol from a specified CSV file into the Connect database.</td>
</tr>
<tr>
<td>CSVWriter</td>
<td>Allows writing a symbol in the Connect database to a specified CSV file.</td>
</tr>
<tr>
<td>DomainWriter</td>
<td>Allows rewriting the domain information of an existing Connect symbol.</td>
</tr>
<tr>
<td>GAMSReader</td>
<td>Allows reading symbols from the GAMS database into the Connect database.</td>
</tr>
<tr>
<td>GAMSWriter</td>
<td>Allows writing symbols in the Connect database to the GAMS database.</td>
</tr>
<tr>
<td>GDXReader</td>
<td>Allows reading symbols from a specified GDX file into the Connect database.</td>
</tr>
<tr>
<td>GDXWriter</td>
<td>Allows writing symbols in the Connect database to a specified GDX file.</td>
</tr>
<tr>
<td>Options</td>
<td>Allows to set more general options that can affect the Connect database and</td>
</tr>
<tr>
<td></td>
<td>other Connect agents.</td>
</tr>
<tr>
<td>PandasExcelReader</td>
<td>Allows reading symbols from a specified Excel file into the Connect database.</td>
</tr>
<tr>
<td>PandasExcelWriter</td>
<td>Allows writing symbols in the Connect database to a specified Excel file.</td>
</tr>
<tr>
<td>PandasSQLReader</td>
<td>Allows reading symbols from a specified SQL database into the Connect database.</td>
</tr>
<tr>
<td>PandasSQLWriter</td>
<td>Allows writing symbols in the Connect database to a specified SQL database.</td>
</tr>
</tbody>
</table>
### Connect agent Description

<table>
<thead>
<tr>
<th>Connect agent</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Projection</td>
<td>Allows index reordering and projection onto a reduced index space of a GAMS symbol.</td>
</tr>
<tr>
<td>PythonCode</td>
<td>Allows executing arbitrary Python code.</td>
</tr>
<tr>
<td>RawExcelReader</td>
<td>Allows reading unstructured data from a specified Excel file into the Connect database.</td>
</tr>
</tbody>
</table>

### 4.46.4 Getting Started

We introduce the basic functionalities of GAMS Connect agents on some examples.

#### 4.46.4.1 Simple Connect Example with Spreadsheets

The following example is part of GAMS Model Library as model *cta* and shows how to read and write Excel spreadsheets. Here is a code snippet of the first lines:

```plaintext
Set
   i 'rows'
   j 'columns'
   k 'planes';

Parameter
   dat(k<,i<,j<) 'unprotected data table'
   pro(k,i,j)   'information sensitive cells';

* extract data from Excel workbook
$onEmbeddedCode Connect:
  - PandasExcelReader:
    file: cox3.xlsx
    symbols:
      - name: dat
        range: Sheet1!A1
        rowDimension: 2
        columnNameDimension: 1
      - name: pro
        range: Sheet2!A1
        rowDimension: 2
        columnNameDimension: 1
  - GAMSWriter:
    writeAll: True
$offEmbeddedCode

[...]
```

It starts out with the declaration of sets and parameters. With compile-time embedded Connect code, data for the parameters are read from the Excel file *cox3.xlsx* using the Connect agent *PandasExcelReader*. The PandasExcelReader agent allows reading data for multiple symbols that are listed under the keyword *symbols*, here, parameter *dat* and *pro*. For each symbol, the symbol name is given by option *name* and the Excel range by option *range*. The option *rowDimension* defines that the first 2 columns of the data range will be used for the labels. In addition, the option *columnNameDimension* defines that the first row of the data range will be used for the labels. As a last step, all symbols from the Connect database are written to the GAMS database using the Connect agent *GAMSWriter*. The GAMSWriter agent makes
the parameters \texttt{dat} and \texttt{pro} available outside the embedded Connect code. Note that the sets \(i, j\) and \(k\) are defined implicitly through parameter \texttt{dat}.

Finally, after solving the \texttt{cox3c} model with alternative solutions, Connect can be used to export results to Excel:

\[
\text{loop(l$((obj.l - best)/best <= 0.01),}
\]
\[
\text{ll(l) = yes;}
\]
\[
\text{binrep(s,l) = round(b.l(s));}
\]
\[
\text{binrep('','','Obj',l) = obj.l;}
\]
\[
\text{binrep('','','mSec',l) = cox3c.resUsd*1000;}
\]
\[
\text{binrep('','','nodes',l) = cox3c.nodUsd;}
\]
\[
\text{binrep('Comp','Cells','Adjusted',l) = sum((i,j,k)$not s(i,j,k)), 1$round(adjn.l(i,j,k) + adjp.l(i,j,k));}
\]
\[
\text{s\(olve\ cox3c \text{min} \ obj \text{ using \ mip;}\}
\]

This time, we need to use execution-time embedded Connect code. The Connect agent \texttt{GAMSReader} imports the reporting parameter \texttt{binrep} into the Connect database. With the Connect agent \texttt{PandasExcelWriter} we write the parameter into the \texttt{binrep} sheet of the Excel file \texttt{results.xlsx}.

### 4.46.4.2 Simple Connect Example with CSV files

The following example (a modified version of the \texttt{trnsport} model) shows how to read and write CSV files. The full example is part of DataLib as model \texttt{connect03}. Here is a code snippet of the first lines:

\[
\$\text{onEcho} > \text{distance.csv}
\]
\[
i,\text{new-york,chicago,topeka}
\]
\[
\text{seattle,2.5,1.7,1.8}
\]
\[
\text{san-diego,2.5,1.8,1.4}
\]
\[
\$\text{offEcho}
\]
\[
\$\text{onEcho} > \text{capacity.csv}
\]
\[
i,\text{capacity}
\]
\[
\text{seattle,350}
\]
\[
\text{san-diego,600}
\]
\[
\$\text{offEcho}
\]
\[
\$\text{onEcho} > \text{demand.csv}
\]
\[
j,\text{demand}
\]
\[
\text{new-york,325}
\]
\[
\text{chicago,300}
\]
\[
\text{topeka,275}
\]
\[
\$\text{offEcho}
\]
It starts out with the declaration of sets and parameters. With compile-time embedded Connect code, data for the parameters are read from CSV files using the Connect agent CSVReader. The CSVReader agent, for example, reads the CSV file distance.csv and creates the parameter d in the Connect database. The name of the parameter must be given by the option name. Column number 1 is specified as the first domain set using option indexColumns. The valueColumns option is used to specify the column numbers 2, 3 and 4 containing the values. Per default, the first row of the columns specified via valueColumns will be used as the second domain set. The symbolic constant lastCol can be used if the number of index or value columns is unknown. As a last step, all symbols from the Connect database are written to the GAMS database using the Connect agent GAMSWriter. The GAMSWriter agent makes the parameters d, a and b available outside the embedded Connect code. Note that the sets i and j are defined implicitly through parameter d.

Finally, after solving the transport model, Connect can be used to export results to a CSV file:

Model transport / all /;
solve transport using lp minimizing z;

EmbeddedCode Connect:
  - GAMSReader:
    symbols:
      - name: x
  - Projection:
    name: x.l(i,j)
    newName: x_level(i,j)
  - CSVWriter:
    file: shipment_quantities.csv
    name: x_level
    unstack: True
endEmbeddedCode
This time, we need to use execution-time embedded Connect code. The Connect agent \texttt{GAMSReader}
imports variable $x$ into the Connect database. With the Connect agent \texttt{CSVWriter} we write the variable
level to the CSV file \texttt{shipment\_quantities.csv}:

\begin{verbatim}
i_0,new-york,chicago,topeka
seattle,50.0,300.0,0.0
san-diego,275.0,0.0,275.0
\end{verbatim}

Setting the option \texttt{unstack} to \texttt{True} allows to use the last dimension as the header row.

\subsection{Simple Connect Example for SQL}

The following example (a modified version of the \texttt{whouse} model) shows how to read from and write to a
SQL database (sqlite). The full example is part of DataLib as model \texttt{connect04}. Here is a code snippet
of the first lines:

\begin{verbatim}
[...]
Set t 'time in quarters';

Parameter
  price(t) 'selling price ($ per unit)'
  istock(t) 'initial stock   (units)';

Scalar
  storecost 'storage cost ($ per quarter per unit)'
  storecap 'stocking capacity of warehouse (units)';

$onEmbeddedCode Connect:
- PandasSQLReader:
  connection: "sqlite:///whouse.db"
  symbols:
    - name: t
      query: "SELECT * FROM timeTable;"
      type: set
    - name: price
      query: "SELECT * FROM priceTable;"
    - name: istock
      query: "SELECT * FROM iniStockTable;"
    - name: storecost
      query: "SELECT * FROM storeCostTable;"
    - name: storecap
      query: "SELECT * FROM storeCapTable;"
- GAMSWriter:
  writeAll: True
$offEmbeddedCode
[...]
\end{verbatim}

It starts out with the declaration of sets and parameters. With compile-time embedded Connect code, data
for all the symbols are read from the sqlite database \texttt{whouse.db} using the Connect agent \texttt{PandasSQLReader}
by passing the connection url through the option \texttt{connection}. The PandasSQLReader agent, for example,
queries the table \texttt{priceTable} for data and creates the parameter \texttt{price} in the Connect database. The
PandasSQLReader allows reading data for multiple symbols that are listed under the keyword \texttt{symbols}. 

and are fetched through the same connection. For each symbol the name must be given by the option name. The SQL query statement is passed through the option query. The symbol type can be specified using the option type. By default, every symbol is treated as a GAMS parameter. As a last step, all symbols from the Connect database are written to the GAMS database using the Connect agent GAMSWriter. The GAMSWriter agent makes all read in symbols available outside the embedded Connect code.

Further, after solving the warehouse model, Connect can be used to export the results to tables in the SQL database.

```gams
Model swp 'simple warehouse problem' / all /

solve swp minimizing cost using lp;
```

```gams
EmbeddedCode Connect:
  - GAMSReader:
    readAll: True
  - Projection:
    name: stock.l(t)
    newName: stock_level(t)
  - Projection:
    name: sell.l(t)
    newName: sell_level(t)
  - Projection:
    name: buy.l(t)
    newName: buy_level(t)
  - PandasSQLWriter:
    connection: "sqlite:///whouse.db"
    symbols:
      - name: stock_level
        tableName: stock_level
        ifExists: replace
      - name: sell_level
        tableName: sell_level
        ifExists: replace
      - name: buy_level
        tableName: buy_level
        ifExists: replace
endEmbeddedCode
```

Here, we need to use execution-time embedded Connect code. The Connect agent GAMSReader imports all the variables into the Connect database. The PandasSQLWriter agent then writes each symbol to respective tables in the SQL database `whouse.db`. For example the stock level:

```
<table>
<thead>
<tr>
<th>t_0</th>
<th>level</th>
</tr>
</thead>
<tbody>
<tr>
<td>q-1</td>
<td>100.0</td>
</tr>
<tr>
<td>q-2</td>
<td>10.0</td>
</tr>
<tr>
<td>q-3</td>
<td>10.0</td>
</tr>
<tr>
<td>q-4</td>
<td>10.0</td>
</tr>
</tbody>
</table>
```

The ifExists option allows to either append to an extending table or replace it with new data. By default, the value for ifExists is set to fails.
4.46 GAMS Connect

4.46.4.4 Complex Connect Example with Spreadsheets

The following example (inspired by the model \texttt{herves}) reads a 3-dimensional parameter from a spreadsheet that has one row index (\texttt{code}) at the left side of the table and the other row index \texttt{(labId)} at the right of the table. A column index \texttt{(cut)} is at the top of the table. The column index consists of floating-point numbers. The goal it to read the data into GAMS but modify the labels of some sets: Only the first two decimal digits of the elements in \texttt{cut} are significant. Moreover, the \texttt{labId} should be prefixed with an \texttt{L}. A new spreadsheet with the new labels should be written. The layout of the table should remain with the exception of moving the \texttt{labId} column also to the left. Here is a screenshot of the original table:

The following GAMS code uses a separate GAMS program (\texttt{getdata.gms}) to get the raw data from the original spreadsheet. Connect runs inside a compile-time embedded code section and uses the Connect agent \texttt{RawExcelReader} to get the raw Excel data. In some subsequent GAMS code the sets \texttt{rr} and \texttt{cut[Id]} as well as the parameter \texttt{raw} are filled knowing the layout of the table (the code is written in a way that the table can grow). This GAMS program gets executed and instructed to create a GDX file. In a compile-time embedded Connect section the relevant symbols (\texttt{rr, cut, and labdata}) are read from this GDX file. The \texttt{Projection} agent extracts the domain \texttt{labId} from the set \texttt{rr} and some Python code using Connect agent \texttt{PythonCode} makes the label adjustments and sorts the data nicely. The Python code uses the embedded Python methods \texttt{gams.set} to send the data to GAMS, so no GAMSWriter agent is necessary. In the main program at execution-time an embedded Connect code section exports the \texttt{labdata} parameter in the required form (after reading it from GAMS with the GAMSReader agent). Here is a screenshot of the resulting table:

In the remainder of the GAMS code another execution-time embedded Connect code is used to read the data back from the newly created spreadsheet using Connect agent \texttt{PandasExcelReader}. The set \texttt{rr} is created from parameter \texttt{labdata} using the \texttt{Projection} agent and everything is written back to GAMS with Connect agent \texttt{GAMSWriter}. The original data and the data from the newly created spreadsheet are exported to GDX (using \texttt{execute unload}) and compared to verify that the data is identical by calling \texttt{gdxdiff}. The entire code is listed below. This model is part of DataLib as model \texttt{connect01}.

```
Set code, labId, cut, rr(code<,labId);
parameter labdata(code,labid,cut);
$onEcho > getdata.gms
* Symbols for RawExcelReader
alias (u,*); Set s,w,r,c,ws(s,w),vs(s,r,c),vu(s,r,c,u); Parameter vf(s,r,c);
$onEmbeddedCode Connect:
 - RawExcelReader:
    file: labdata.xlsx
 - GAMSWriter:
    writeAll: True
$offEmbeddedCode
* Symbols to be filled
alias (*,code,labId,cut); Parameter raw(code,labid,cut); Set cutId, rr(code,labId)
Set cX(c,cut) 'column index', rX(r,code,labId) 'row index';
Singleton set cLast(c); Scalar lastPos;
loop(ws(s,‘ZAg’),
    lastPos = smax(vu(s,r,c,u), c.pos); cLast(c) = c.pos=lastPos;
    loop(r$(ord(r)>4),
        rX(r,code,labId) $= vu(s,r,’Cl’,code) and vu(s,r,cLast,labId));
    loop(c$(ord(c)>1 and not cLast(c)),
        cX(c,cut) $= vu(s,’R4′,c,cut));
    loop((rX(r,code,labId),cX(c,cut)),
        raw(code,labId,cut) = vf(s,r,c))
    loop(cX(c,cut),
        cutId(cut) = yes)
);
```
option rr(Intent); $offEcho
$call.checkErrorLevel gams getdata.gms lo=%gams.lo% gdx=getdata.gdx
$onEmbeddedCode
Connect:
- GDXReader:
  file: getdata.gdx
  symbols: [ {name: rr}, {name: raw}, {name: cutId, newName: cut} ]
- Projection:
  name: rr(code, labid)
  newName: labid(labid)
- PythonCode:
  code: |
    gams.set('labid', sorted(['L'+t[0] for t in connect.container.data['labid'].records.values], key=lambda t: int(t[1:])))
    gams.set('rr', sorted([(t[0], 'L'+t[1]) for t in connect.container.data['rr'].records.values], key=lambda t: int(t[0])))
    # Trim elements of set Cut to two decimal places
    gams.set('cut', sorted(['{:2f}'.format(float(t[0])) for t in connect.container.data['cut'].records.values], key=float))
    gams.set('labdata', [(t[0], 'L'+t[1], '{:.2f}'.format(float(t[2])), t[-1]) for t in connect.container.data['raw'].records.values])
$offEmbeddedCode
execute_unload 'labdata.gdx', labdata, cut, rr;

* Reintroduce 0 (zeros)
labdata(rr, cut) = labdata(rr, cut) + eps;
execute 'rm -f labdatanew.xlsx';
* Write new workbook with good table
EmbeddedCode
Connect:
- GAMSReader:
  symbols: [ {name: labdata} ]
- PandasExcelWriter:
  file: labdatanew.xlsx
  symbols:
    - name: labdata
      rowDimension: 2
      range: ZAg!A4
endEmbeddedCode
option clear=rr, clear=labdata;

EmbeddedCode
Connect:
- PandasExcelReader:
  file: labdatanew.xlsx
  symbols:
    - name: labdata
      rowDimension: 2
      columnDimension: 1
      range: ZAg!A4
- Projection:
  name: labdata(code, labid, cut)
  newName: rr(code, labid)
  asSet: True
- GAMSWriter:
  writeAll: True
endEmbeddedCode
execute_unload 'labdatanew.gdx', labdata, cut, rr;
execute.checkErrorLevel 'gdxdiff labdata.gdx labdatanew.gdx > %system.NullFile%';

4.46.4.5 Complex Connect Example with CSV Files

The following example shows how to read and write CSV files in Connect. It starts out with defining some data (stockprice) in a table statement in GAMS. With compile-time embedded Connect code utilizing the GAMSReader agent to bring this data into Connect and exporting it as a CSV file with agent CSVWriter. The GDXWriter agent also creates a GDX file with the data which is then used in a subsequent call to feed gdxdump that produces the same CSV file as CSVWriter. The text comparison tool diff is used to compare the two CSV files. The CSV file look as follows:

```
"date_0","AAPL","GOOG","MMM","MSFT","WMT"
"2012-20-11",12.124061,314.008026,60.966354,21.068886,46.991535
"2112-20-11",12.139372,311.741516,60.731037,20.850344,47.150307
"2212-20-11",12.203673,313.674286,61.467381,20.890808,46.991535
"2312-20-11",12.350039,315.387848,62.401108,21.068886,47.626663
"2712-20-11",12.448025,318.929565,62.461876,21.076981,47.499634
"2812-20-11",12.328911,318.656009,61.604042,20.899805,47.420238
"2912-20-11",12.404848,320.000549,62.332813,21.060795,47.626663
"3012-20-11",12.401172,321.744019,62.044331,21.012224,47.444057
```

In remainder of the example this CSV file is read back via the Connect agent CSVReader. The code also utilizes the tool csv2gdx to read the CSV file into a GDX file. The code compares the results of both methods. Csv2gdx also creates sets with the index elements as Dim1, Dim2, ... Therefore, Connect utilizes the Projection agent to extract the index sets date and symbol from the parameter stockprice as sets Dim1 and Dim2. The Connect agent GDXWriter creates a GDX file of the Connect database which then can be compared with the GDX file created by csv2gdx. The GDX comparison tool gdxdiff is used to compare the two GDX files. The entire code is listed below. This model is part of DataLib as model connect02.

```gams
Set date,symbol;
Table stockprice(date<,symbol<)
    AAPL  GOOG  MMM  MSFT  WMT
2012-20-11 12.124061  314.008026  60.966354  21.068886  46.991535
2112-20-11 12.139372  311.741516  60.731037  20.850344  47.150307
2212-20-11 12.203673  313.674286  61.467381  20.890808  46.991535
2312-20-11 12.350039  315.387848  62.401108  21.068886  47.626663
2712-20-11 12.448025  318.929565  62.461876  21.076981  47.499634

4.46.5 Connect Agents

4.46.5.1 CSVReader

The CSVReader allows reading a symbol from a specified CSV file into the Connect database. Its implementation is based on the pandas.DataFrame class and its I/O API method read_csv.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>autoColumn</td>
<td>None</td>

</tr>
</tbody>
</table>
**Option** | **Default** | **Description**
---|---|---
readCSVArguments | None | Dictionary containing keyword arguments for the `pandas.read_csv` method.
skipRows | None | Specify the rows to skip or the number of rows to skip.
stack | inferred | Stacks the column names to index.
textColumns | None | Specify columns to get the set element text from.
textSubstitutions | None | Dictionary used for substitutions in the text columns.
thousandsSeparator | None | Specify a thousands separator.
trace | inherited | Specify the trace level for debugging output.
valueColumns | None | Specify columns to get the values from.
valueSubstitutions | None | Dictionary used for substitutions in the value columns.

Detailed description of the options:

**autoColumn = string** (optional)

Generate automatic column names. The `autoColumn` string is used as the prefix for the column label numbers. This option overrides the use of a `header` or `names`. However, if there is a header row, one must skip the row by enabling `header` or using `skipRows`.

**autoRow = string** (optional)

Generate automatic row labels. The `autoRow` string is used as the prefix for the row label numbers. The generated unique elements will be used in the first index position shifting other elements to the right. Using `autoRow` can be helpful when there are no labels that can be used as unique elements but also to store entries that would be a duplicate entry without a unique row label.

**decimalSeparator = string** (default=`.`)

Specify a decimal separator. [. (period), , (comma)]

**fieldSeparator = string** (default=`,`)

Specify a field separator. [, (comma), ; (SemiColon), \t (Tab)]

**file = string** (required)

Specify a CSV file path.

**header = boolean** (optional)

Indicate if the first row in the CSV file should be used as the column names in the `DataFrame`. Default behavior is to infer the column names: if no `names` are passed the behavior is identical to `header=True` and column names are inferred from the first line of data, if column names are passed explicitly then the behavior is identical to `header=False`. Explicitly pass `header=True` to be able to replace existing names. Note that missing column names are filled with `Unnamed: n` (where `n` is the nth column (zero based) in the DataFrame). Hence, reading the CSV file:

```
,i1,1,2
,i2,3,4
,j1,5,6
```

results in the following 2-dimensional parameter:
indexColumns = list or string (optional)

Specify columns to use as the row labels. The columns can either be given as column positions or column names. Column positions can be represented as an integer, a list of integers or a string. For example: indexColumns: [1, 2, 3, 4, 6] or indexColumns: "1:4, 6". The symbolic constant lastCol can be used with the string representation: "2:lastCol". Note that the usage of lastCol requires header: True or names given. Column names can be represented as a list of strings. For example: indexColumns: ["i1","i2"]. Note that indexColumns and valueColumns/textColumns and must either be given as positions or names not both.

By default the pandas.read_csv method interprets the following indices as NaN: "", ".N/A", ".N/A", ".-1.#IND", ".-1.#QNAN", ".-NaN", ".-nan", ".1.#IND", ".1.#QNAN", ".<NA>", ".N/A", ".NA", ".NULL", ".NaN", ".n/a", ".nan", ".null". The default can be changed by specifying pandas.read_csv arguments keep_default_na and na_value via readCSVArguments. Rows with indices that are interpreted as NaN will be dropped automatically. The indexSubstitutions option allows to remap NaN entries in the index columns.

indexSubstitutions = dictionary (optional)

Dictionary used for substitutions in the index columns. Each key in indexSubstitutions is replaced by its corresponding value. This option allows arbitrary replacements in the index columns of the DataFrame including stacked column names. Consider the following CSV file:

```
i1,j1,2.5
i1,,1.7
i2,j1,1.8
i2,,1.4
```

Reading this data into a 2-dimensional parameter results in a parameter with NaN entries dropped:

```
j1
i1  2.500
i2  1.800
```

By specifying indexSubstitutions: { .nan: j2 } we can substitute NaN entries by j2:

```
j1         j2
i1  2.500   1.700
i2  1.800   1.400
```

name = string (required)

Specify a symbol name for the Connect database. Note that each symbol in the Connect database must have a unique name.

names = list (optional)

List of column names to use. If the file contains a header row, then you should explicitly pass header=True to override the column names. Duplicates in this list are not allowed.
quoting = integer (default=0)

Control field quoting behavior. Use QUOTE_MINIMAL (0), QUOTE_ALL (1),
QUOTE_NONNUMERIC (2) or QUOTE_NONE (3). QUOTE_NONNUMERIC (2) in-
structs the reader to convert all non-quoted fields to type float. QUOTE_NONE (3) instructs
reader to perform no special processing of quote characters.

readCSVArguments = dictionary (optional)

Dictionary containing keyword arguments for the pandas.read_csv method. Not all argu-
ments of that method are exposed through the YAML interface of the CSVReader agent. By
specifying toCSVArguments, it is possible to pass arguments directly to the pandas.read_csv
method that is used by the CSVReader agent.

skipRows = list or integer (optional)

Specify the rows to skip (list) or the number of rows to skip (integer). For example: skipRows:
[1, 3] or skipRows: 5.

stack = boolean (optional)

Stacks the column names to index. Defaults to True if there is more than one value/text
column, otherwise False. Note that missing column names are filled withUnnamed: n (where
n is the nth column (zero based) in the DataFrame).

textColumns = list or string (optional)

Specify columns to get the set element text from. The columns can be given as column
positions or column names. Column positions can be represented as a integer, a list of
integers or a string. For example: textColumns: 1, textColumns: [1, 2, 3, 4, 6] or
textColumns: "1:4, 6". The symbolic constant lastCol can be used with the string
representation: "2:lastCol". Note that the usage of lastCol requires header: True or
names given. Column names can be represented as a list of strings. For example: textColumns:
["i1", "i2"]. Note that textColumns and indexColumns must either be given as positions
or names not both.

By default the pandas.read_csv method interprets the following text as NaN: ", ", ",N/A",
"#N/A", "#NA", ""-1.#IND", "-1.#QNAN", "-NaN", "-nan", "1.#IND", "1.#QNAN",
"<NA>"", "N/A", "NA", "NULL", "NaN", "n/a", "nan", "null". The default can be
changed by specifying pandas.read_csv arguments keep_default_na and na_value via
readCSVArguments. Rows with texts that are interpreted as NaN will be dropped auto-
matically. The textSubstitutions option allows to remap NaN entries in the text columns.

textSubstitutions = dictionary (optional)

Dictionary used for substitutions in the text columns. Each key in textSubstitutions is
replaced by its corresponding value. While it is possible to make arbitrary replacements
this is especially useful for controlling sparse/dense reading. The default reading behavior is
sparse since rows with text that is interpreted as NaN are dropped automatically. Consider the
following CSV file:

i1,text1
i2,
i3,text3

thousandsSeparator = string (optional)

Specify a thousands separator.
trace = integer (optional)

Specify the trace level for debugging output. For \texttt{trace} > 1 some scalar debugging output will be written to the log. For \texttt{trace} > 2 the intermediate data frames will be written abbreviated to the log. For \texttt{trace} > 3 the intermediate data frames will be written entirely to the log (potentially large output). If \texttt{trace} has not been set, the \texttt{trace} value, set by the \texttt{Options} agent, will be used.

valueColumns = list or string (optional)

Specify columns to get the values from. The columns can be given as column positions or column names. Column positions can be represented as an integer, a list of integers or a string. For example: \texttt{valueColumns: 1, valueColumns: [1, 2, 3, 4, 6] or valueColumns: "1:4, 6"}. The symbolic constant \texttt{lastCol} can be used with the string representation: "2:lastCol". Note that the usage of \texttt{lastCol} requires \texttt{header: True} or \texttt{names} given. Column names can be represented as a list of strings. For example: \texttt{valueColumns: ["i1","i2"]}. Note that \texttt{valueColumns} and \texttt{indexColumns} must either be given as positions or names not both.

By default the \texttt{pandas.read.csv} method interprets the following values as NaN: ",", ",#N/A", ",#N/A N/A", ",#NA", ",-1.#IND", ",-1.#QNAN", ",-NaN", ",-nan", ",1.#IND", ",1.#QNAN", ",<NA>\", ",N/A\", ",NA\", ",NULL\", ",NaN\", ",n/a\", ",nan\", ",null\". The default can be changed by specifying \texttt{pandas.read.csv} arguments \texttt{keep_default_na} and \texttt{na_value} via \texttt{readCSVArguments}. Rows with values that are interpreted as NaN will be dropped automatically. Changing the default of values that are interpreted as NaN is useful if, e.g., "NA" values should not be dropped but interpreted as GAMS special value NA. Moreover, the \texttt{valueSubstitutions} option allows to remap NaN entries in the value columns.

valueSubstitutions = dictionary (optional)

Dictionary used for substitutions in the value columns. Each key in \texttt{valueSubstitutions} is replaced by its corresponding value. While it is possible to make arbitrary replacements this is especially useful for controlling sparse/dense reading. All NaN entries are removed automatically by default which results in a sparse reading behavior. Consider the following CSV file:

\begin{verbatim}
  i1,j1,
i1,j2,1.7
i2,j1,
i2,j2,1.4
\end{verbatim}

Reading this data into a 2-dimensional parameter results in a sparse parameter with all NaN entries removed:

\begin{verbatim}
  j2
  i1 1.700
  i2 1.400
\end{verbatim}

By specifying \texttt{valueSubstitutions: { .nan: eps } we get a dense representation where all NaN entries are replaced by GAMS special value EPS:

\begin{verbatim}
  j1   j2
  i1   EPS 1.700
  i2   EPS 1.400
\end{verbatim}
Beside $\texttt{eps}$ there are the following other GAMS special values that can be used by specifying their string representation: $\texttt{inf}$, $-\texttt{inf}$, $\texttt{eps}$, $\texttt{na}$, and $\texttt{undef}$. See the GAMS Transfer documentation for more information.

Reading this data into a 1-dimensional set results in a sparse set in which all NaN entries (those that do not have any set element text) are removed:

'\texttt{i1}' 'text 1',
'\texttt{i3}' 'text 3'

By specifying textSubstitutions: \{ .nan: '' \} we get a dense representation:

'\texttt{i1}' 'text 1',
'\texttt{i2}',
'\texttt{i3}' 'text 3'

It is also possible to use textSubstitutions in order to interpret the set element text. Let's assume we have the following CSV file:

,.j1,j2,j3
i1,Y,Y,Y
i2,Y,Y,N
i3,0,Y,Y

Reading this data into a 2-dimensional set results in a dense set:

'\texttt{i1}'.\'j1' Y,
'\texttt{i1}'.\'j2' Y,
'\texttt{i1}'.\'j3' Y,
'\texttt{i2}'.\'j1' Y,
'\texttt{i2}'.\'j2' Y,
'\texttt{i2}'.\'j3' N,
'\texttt{i3}'.\'j1' 0,
'\texttt{i3}'.\'j2' Y,
'\texttt{i3}'.\'j3' Y

By specifying textSubstitutions: \{ 'N': .nan, '0': .nan \} we replace all occurrences of N and 0 by NaN which gets dropped automatically:

'\texttt{i1}'.\'j1' Y,
'\texttt{i1}'.\'j2' Y,
'\texttt{i1}'.\'j3' Y,
'\texttt{i2}'.\'j1' Y,
'\texttt{i2}'.\'j2' Y,
'\texttt{i3}'.\'j2' Y,
'\texttt{i3}'.\'j3' Y

### 4.46.5.2 CSVWriter

The CSVWriter allows writing a symbol in the Connect database to a specified CSV file.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>decimalSeparator</td>
<td>. (period)</td>
<td>Specify a decimal separator.</td>
</tr>

<td>Specify a field separator.</td>
</tr>
<tr>
<td>header</td>
<td>True</td>
<td>Indicate if the header will be written.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>name</td>
<td>None</td>
<td>Specify the name of the symbol in the Connect database.</td>
</tr>
<tr>
<td>quoting</td>
<td>0</td>
<td>Control field quoting behavior.</td>
</tr>
<tr>
<td>setHeader</td>
<td>None</td>
<td>Specify a string that will be used as the header.</td>
</tr>
<tr>
<td>skipElementText</td>
<td>False</td>
<td>Indicate if the set element text will be skipped.</td>
</tr>
<tr>
<td>toCSVArguments</td>
<td>None</td>
<td>Dictionary containing keyword arguments for the pandas.to_csv method.</td>
</tr>
<tr>
<td>trace</td>
<td>inherited</td>
<td>Specify the trace level for debugging output.</td>
</tr>
<tr>
<td>unstack</td>
<td>False</td>
<td>Indicate if the last dimension will be used as a header row.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**decimalSeparator = string (default=.)**

Specify a decimal separator. [ . (period), , (comma)]

**file = string (required)**

Specify a CSV file path.

**fieldSeparator = string (default=,)**

Specify a field separator. [ , (comma), ; (SemiColon), \t (Tab)]

**header = boolean (default=True)**

Indicate if the header will be written.

**name = string (required)**

Specify the name of the symbol in the Connect database.

**quoting = integer (default=0)**

Control field quoting behavior. Use QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3). QUOTE_MINIMAL (0) instructs the writer to only quote those fields which contain special characters such as fieldSeparator. QUOTE_ALL (1) instructs the writer to quote all fields. QUOTE_NONNUMERIC (2) instructs the writer to quote all non-numeric fields. QUOTE_NONE (3) instructs the writer to never quote fields.

**setHeader = string (optional)**

Specify a string that will be used as the header. If an empty header is desired, the string can be empty.

**skipElementText = boolean (default=False)**

Indicate if the set element text will be skipped. If False, the set element text will be written in the last column of the CSV file.

**toCSVArguments = dictionary (optional)**

Dictionary containing keyword arguments for the pandas.to_csv method. Not all arguments of that method are exposed through the YAML interface of the CSVWriter agent. By specifying toCSVArguments, it is possible to pass arguments directly to the pandas.to_csv method that is used by the CSVWriter agent.

**trace = integer (optional)**

Specify the trace level for debugging output. For trace > 1 some scalar debugging output will be written to the log. For trace > 2 the intermediate data frames will be written abbreviated to the log. For trace > 3 the intermediate data frames will be written entirely to the log (potentially large output). If trace has not been set, the trace value, set by the Options agent, will be used.

**unstack = boolean (default=False)**

Indicate if the last dimension will be used as a header row.
4.46.5.3 DomainWriter

The DomainWriter agent allows to rewrite domain information for existing Connect symbols and helps dealing with domain violations.

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dropDomainViolations</td>
<td>global/symbol</td>
<td>False</td>
<td>Indicate how to deal with domain violations.</td>
</tr>
<tr>
<td>name</td>
<td>symbol</td>
<td>None</td>
<td>Specify the name of the symbol in the Connect database.</td>
</tr>
<tr>
<td>trace</td>
<td>global</td>
<td>inherited</td>
<td>Specify the trace level for debugging output.</td>
</tr>
<tr>
<td>writeAll</td>
<td>global</td>
<td>False</td>
<td>Indicate if all symbols in the Connect database will be treated with the global dropDomainViolations setting.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**dropDomainViolations** = boolean (global)/string (symbol) (default=False)

The Connect symbols might have some domain violations. This agent allows to drop these domain violations so a write to GAMS or GDX works properly. Setting the global dropDomainViolations: True together with writeAll: True will drop all domain violations from all Connect symbols. The symbols section allows to also drop domain violations. In the symbols section the dropDomainViolations attribute need a string value. Possible string values are before, after, "True", and "False". If the attribute has not been set for the symbol, the attribute is inherited from the global attribute. The value before means that domain violations are dropped before a new domain is applied, see attribute name. The value after means that domain violations are dropped after a new domain is applied. The value "True" means that domain violations are dropped before and after a new domain is applied. "False" means to not drop domain violations.

**name** = string (required)

Specify a symbol name with index space for the Connect database. name requires the format symname(i1,i2,...,iN). The list of indices needs to coincide with the names of the actual GAMS domain sets for a regular domain. A relaxed domain is set if the index is quoted. For example name: x(i,’j’) means that for the first index a regular domain with domain set i is established, while for the second index the universal domain * is used and a relaxed domain name j is set.

**trace** = integer (optional)

Specify the trace level for debugging output. For trace > 1 some scalar debugging output will be written to the log. For trace > 2 the intermediate data frames will be written abbreviated to the log. For trace > 3 the intermediate data frames will be written entirely to the log (potentially large output). If trace has not been set, the trace value, set by the Options agent, will be used.

**writeAll** = boolean (default=False)

Indicate if all symbols in the Connect database will be treated according to global attribute dropDomainViolations.

4.46.5.4 GAMSReader

The GAMSReader allows reading symbols from the GAMS database into the Connect database. Without GAMS context (e.g. when running the gamsconnect script from the command line) this agent is not available and its execution will result in an exception.
<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>symbol</td>
<td>None</td>
<td>Specify the name of the symbol in the GAMS database.</td>
</tr>
<tr>
<td>newName</td>
<td>symbol</td>
<td>None</td>
<td>Specify a new name for the symbol in the Connect database.</td>
</tr>
<tr>
<td>readAll</td>
<td>global</td>
<td>False</td>
<td>Indicate if all symbols in the GAMS database will be read into the Connect database.</td>
</tr>
<tr>
<td>trace</td>
<td>global</td>
<td>inherited</td>
<td>Specify the trace level for debugging output.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**name = string (required)**

Specify the name of the symbol in the GAMS database.

**newName = string (optional)**

Specify a new name for the symbol in the Connect database. Each symbol in the Connect database must have a unique name.

**readAll = boolean (default=True)**

Indicate if all symbols in the GAMS database will be read into the Connect database. If True, read all symbols into the Connect database and ignore symbol options.

**trace = integer (optional)**

Specify the trace level for debugging output. For trace > 1 some scalar debugging output will be written to the log. For trace > 2 the intermediate data frames will be written abbreviated to the log. For trace > 3 the intermediate data frames will be written entirely to the log (potentially large output). If trace has not been set, the trace value, set by the Options agent, will be used.

### 4.46.5.5 GAMSWriter

The GAMSWriter allows writing symbols in the Connect database to the GAMS database. Without GAMS context (e.g. when running the `gamsconnect` script from the command line) and as part of the `connectOut` command line option this agent is not available and its execution will result in an exception.
Detailed description of the options:

\( \text{domainCheckType} = \text{string} \) (default=\text{default})

Specify if Domain Checking is applied (\text{checked}) or if records that would cause a domain violation are filtered (\text{filtered}). If left at \text{default} it depends on the setting of \$on/offFiltered if GAMS does a filtered load or checks the domains during compile time. During execution time \text{default} is the same as \text{filtered}.

\( \text{duplicateRecords} = \text{string} \) (default=\text{all})

The Connect container can hold multiple records even for the same indexes. This is only a problem when exchanging the data with GAMS (and GDX). The attribute determines how the agent deals with duplicate records. With the default of \text{all} the GAMSWriter will fail in case duplicate records exist. With \text{first} the first record will be written to GAMS, with \text{last} the last record written to GAMS. With \text{none} none of the duplicate records will be written to GAMS. Note that the agent currently deals with duplicate records in a case sensitive way.

\( \text{mergeType} = \text{string} \) (default=\text{default})

Specify if data in a GAMS symbol is merged (\text{merge}) or replaced (\text{replace}). If left at \text{default} it depends on the setting of \$on/offMulti\{R\} if GAMS does a merge, replace, or triggers an error during compile time. During execution time \text{default} is the same as \text{merge}.

\( \text{name} = \text{string} \) (required)

Specify the name of the symbol in the Connect database.

\( \text{newName} = \text{string} \) (optional)

Specify a new name for the symbol in the GAMS database. Note, each symbol in the GAMS database must have a unique name.

\( \text{trace} = \text{integer} \) (optional)

Specify the trace level for debugging output. For \text{trace} \geq 1 some scalar debugging output will be written to the log. For \text{trace} > 2 the intermediate data frames will be written abbreviated to the log. For \text{trace} > 3 the intermediate data frames will be written entirely to the log (potentially large output). If \text{trace} has not been set, the \text{trace} value, set by the Options agent, will be used.

\( \text{writeAll} = \text{boolean} \) (default=\text{False})

Indicate if all symbols in the Connect database will be written to the GAMS database. If \text{True}, write all symbols to the GAMS database and ignore symbol options.

### 4.46.5.6 GDXReader

The GDXReader allows reading symbols from a specified GDX file into the Connect database.

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>global</td>
<td>None</td>
<td>Specify a GDX file path.</td>
</tr>
<tr>
<td>name</td>
<td>symbol</td>
<td>None</td>
<td>Specify the name of the symbol in the GDX file.</td>
</tr>
<tr>
<td>newName</td>
<td>symbol</td>
<td>None</td>
<td>Specify a new name for the symbol in the Connect database.</td>
</tr>
<tr>
<td>readAll</td>
<td>global</td>
<td>\text{False}</td>
<td>Indicate if all symbols in the GDX file will be read into the Connect database.</td>
</tr>
<tr>
<td>trace</td>
<td>global</td>
<td>inherited</td>
<td>Specify the trace level for debugging output.</td>
</tr>
</tbody>
</table>
Detailed description of the options:

**file = string (required)**

Specify a GDX file path.

**name = string (required)**

Specify the name of the symbol in the GDX file.

**newName = string (optional)**

Specify a new name for the symbol in the Connect database. Each symbol in the Connect database must have a unique name.

**readAll = boolean (default=False)**

Indicate if all symbols in the GDX file will be read into the Connect database. If True, read all symbols into the Connect database and ignore symbol options.

**trace = integer (optional)**

Specify the trace level for debugging output. For trace > 1 some scalar debugging output will be written to the log. For trace > 2 the intermediate data frames will be written abbreviated to the log. For trace > 3 the intermediate data frames will be written entirely to the log (potentially large output). If trace has not been set, the trace value, set by the Options agent, will be used.

### 4.46.5.7 GDXWriter

The GDXWriter allows writing symbols in the Connect database to a specified GDX file.

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>duplicateRecords</td>
<td>global/symbol</td>
<td>all</td>
<td>Specify how to deal with duplicate records.</td>
</tr>
<tr>
<td>file</td>
<td>global</td>
<td>None</td>
<td>Specify a GDX file path.</td>
</tr>
<tr>
<td>name</td>
<td>symbol</td>
<td>None</td>
<td>Specify the name of the symbol in the Connect database.</td>
</tr>
<tr>
<td>newName</td>
<td>symbol</td>
<td>None</td>
<td>Specify a new name for the symbol in the GDX file.</td>
</tr>
<tr>
<td>trace</td>
<td>global</td>
<td>inherited</td>
<td>Specify the trace level for debugging output.</td>
</tr>
<tr>
<td>writeAll</td>
<td>global</td>
<td>False</td>
<td>Indicate if all symbols in the Connect database will be written to the GDX file.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**duplicateRecords = string (default=all)**

The Connect container can hold multiple records even for the same indexes. This is only a problem when exchanging the data with GDX (and GAMS). The attribute determines how the agent deals with duplicate records. With the default of all the GDXWriter will fail in case duplicate records exist. With **first** the first record will be written to GDX, with **last** the last record written to GDX. With **none** none of the duplicate records will be written to GDX. Note that the agent currently deals with duplicate records in a case sensitive way.

**file = string (required)**
Specify a GDX file path.

**name = string (required)**

Specify the name of the symbol in the Connect database.

**newName = string (optional)**

Specify a new name for the symbol in the GDX file. Note, each symbol in the GDX file must have a unique name.

**trace = integer (optional)**

Specify the trace level for debugging output. For \( \text{trace} > 1 \) some scalar debugging output will be written to the log. For \( \text{trace} > 2 \) the intermediate data frames will be written abbreviated to the log. For \( \text{trace} > 3 \) the intermediate data frames will be written entirely to the log (potentially large output). If \( \text{trace} \) has not been set, the \( \text{trace} \) value, set by the Options agent, will be used.

**writeAll = boolean (default=False)**

Indicate if all symbols in the Connect database will be written to the GDX file. If \text{True}, write all symbols to the GDX file and ignore symbol options.

### 4.46.5.8 Options

The Options agent allows to set more general options that can affect the Connect database and other Connect agents. More specifically, the value of an option set via the Options agent can be inherited as a default value to Connect agents that utilize the considered option.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>caseSensitiveLookup</td>
<td>True</td>
<td>Specify how to lookup symbols specified by attribute name and others in the Connect database.</td>
</tr>
<tr>
<td>debug</td>
<td>0</td>
<td>If set to &gt;0 a full trace is written to stdout in case of an exception.</td>
</tr>
<tr>
<td>trace</td>
<td>0</td>
<td>Specify the trace level for debugging output.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**caseSensitiveLookup = boolean (default=True)**

Specify how to lookup symbols in the Connect database. Unlike GAMS, Connect uses case sensitive symbol names hence one needs to pay attention to symbol name casing when the symbol name is specified in an agent description, e.g. via the \text{name} attribute. If the caseSensitiveLookup attribute is set \text{False} Connect will also find symbols if their names match in an case-insensitive way. If multiple symbols with same lower case name exist in the Connect database, the symbol that matches exactly is found. If none of the symbols match exactly, then one of symbols is found but it is unclear which one. For example, symbols ABC and abc exist in the Connect database. If \text{name}: ABC is given symbol ABC will be used, but if \text{name}: aBc is given either abc or ABC is returned. Multiple symbols with the same lower-case name should be avoided, they cause problems e.g. when writing to GAMS or GDX with attribute writeAll: \text{True}.

**debug = integer (default=0)**
A Connect error triggers an exception. By default only the exception message is provided to the user. In case the `debug` attribute is set to an integer larger than 0, a full trace with the calling stack is printed to stdout.

\[
\text{trace} = \text{integer} \ (\text{default}=0)
\]

Specify the trace level for debugging output. A trace level of 0 (default) means no debugging output. For `trace > 0` the Connect database will write some scalar debugging output to the log. The debugging output of Connect agents depends on their implementation of `trace`, please refer to the corresponding documentation.

### 4.46.5.9 PandasExcelReader

The PandasExcelReader agent allows to read symbols from an Excel file into the Connect database. Its implementation is based on the `pandas.DataFrame` class and its I/O API method `read_excel`. The PandasExcelReader primarily aims to read spreadsheets that have been written by its counterpart - the PandasExcelWriter.

<table>
<thead>
<tr>

<td>Control the symbol type.</td>
</tr>
<tr>
<td><code>valueSubstitutions</code></td>
<td>symbol</td>
<td>None</td>
<td>Dictionary used for mapping in the <code>value</code> column of the <code>DataFrame</code>.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**columnDimension = integer (default=1)**

Column dimension: the number of rows in the data range that will be used to define the labels for columns. The first `columnDimension` rows of the data range will be used for labels.

**drop = string (optional)**

Specify a string for dropping each row containing it in one of its labels. The specified string is interpreted as a regular expression.

**excelFileArguments = dictionary (optional)**

Dictionary containing keyword arguments for the `pandas.ExcelFile` constructor.
4.46 GAMS Connect

file = string (required)

Specify an Excel file path.

multiColumnBlankRow = boolean (default=True)

For symbols where more than one dimension is in the columns, i.e. \( \text{columnDimension} > 1 \) the PandasExcelReader expects a blank row before the data starts. This is also the shape the PandasExcelWriter writes:

If multiColumnBlankRow is set to False, the PandasExcelReader expects for table with \( \text{columnDimension} > 1 \) that this blank line is missing. This works properly with the exception of the following corner case:

together with the following Connect instructions

- PandasExcelReader:
  - file: myfile.xlsx
  - symbols:
    - name: s
      rowDimension: 1
      columnDimension: 2
      range: B2:E6
      type: set
      multiColumnBlankRow: False
      valueSubstitutions: { .nan: '' } # read dense

one would expect that the Connect database contains a set with the following elements \( k_1^*k_3.(i_1.j_1,i_2.j_2,i_3.j_3) \) but Pandas interprets the row 4 (because it is entirely blank) as the row with the index name. Hence the data starts in row 5 and the Connect database is missing the \( k_1 \) records: \( k_2^*k_3.(i_1.j_1,i_2.j_2,i_3.j_3) \). In such a case one either needs the blank row between column indexes and data or manages to have this row not entirely empty (which can even be done outside the specified Excel range).

name = string (required)

Specify a symbol name for the Connect database. Note that each symbol in the Connect database must have a unique name.

range = string (required)

Specify the Excel range of a symbol using the format sheet!range. range can be either a single cell also known as open range (north-west corner like B2) or a full range (north-west and south-east corner like B2:D4). For symbols with \( \text{columnDimension}=0 \) and/or \( \text{rowDimension}=0 \), the ending row and/or ending column or the open range can be deduced and is used to restrict the data area.

readExcelArguments = dictionary (optional)

Dictionary containing keyword arguments for the pandas.read_excel method. Not all arguments of that method are exposed through the YAML interface of the PandasExcelReader agent. By specifying readExcelArguments, it is possible to pass arguments directly to the pandas.read_excel method that is used by the PandasExcelReader agent.

rowDimension = integer (default=1)

Row dimension: the number of columns in the data range that will be used to define the labels for the rows. The first \( \text{rowDimension} \) columns of the data range will be used for the labels.
trace = integer (optional)

Specify the trace level for debugging output. For trace > 1 some scalar debugging output will be written to the log. For trace > 2 the intermediate data frames will be written abbreviated to the log. For trace > 3 the intermediate data frames will be written entirely to the log (potentially large output). If trace has not been set, the trace value, set by the Options agent, will be used.

type = string (default=par)

Control the symbol type. Supported symbol types are par for parameters and set for sets.

valueSubstitutions = dictionary (optional)

Dictionary used for mapping in the value column of the DataFrame. Each key in valueSubstitutions is replaced by its corresponding value. The replacement is only performed on the value column of the DataFrame which is the numerical value in case of a GAMS parameter and the set element text in case of a GAMS set. While it is possible to make arbitrary replacements this is especially useful for controlling sparse/dense reading. All NaN entries are removed automatically by default which results in a sparse reading behavior. Let's assume we have the following spreadsheet:

Reading this data into a 2-dimensional parameter results in a sparse parameter in which all NaN entries are removed:

'\text{i1}'.'\text{j1}' 2.5,
'\text{i1}'.'\text{j2}' 1.7,
'\text{i2}'.'\text{j2}' 1.8,
'\text{i2}'.'\text{j3}' 1.4

By specifying valueSubstitutions: \{ .\text{nan}: \text{eps} \} we get a dense representation in which all NaN entries are replaced by GAMS special value EPS:

'\text{i1}'.'\text{j1}' 2.5,
'\text{i1}'.'\text{j2}' 1.7,
'\text{i1}'.'\text{j3}' Eps,
'\text{i2}'.'\text{j1}' Eps,
'\text{i2}'.'\text{j2}' 1.8,
'\text{i2}'.'\text{j3}' 1.4

Beside eps there are the following other GAMS special values that can be used by specifying their string representation: inf, -inf, eps, na, and undef. See the GAMS Transfer documentation for more information.

Let's assume we have data representing a GAMS set:

Reading this data into a 1-dimensional set results in a sparse set in which all NaN entries (those that do not have any set element text) are removed:

'\text{i1}' 'text 1',
'\text{i3}' 'text 3'

By specifying valueSubstitutions: \{ .\text{nan}: '' \} we get a dense representation:

'\text{i1}' 'text 1',
'\text{i2}',
'\text{i3}' 'text 3'
It is also possible to use `valueSubstitutions` in order to interpret the set element text. Let’s assume we have the following Excel data:

Reading this data into a 2-dimensional set results in a dense set:

```
'i1'.'j1' No,
'i1'.'j2' Y,
'i1'.'j3' Y,
'i2'.'j1' Y,
'i2'.'j2' Y,
'i2'.'j3' Y,
'i3'.'j1' Y,
'i3'.'j2' Y,
'i3'.'j3' N
```

By specifying `valueSubstitutions: { 'N': .nan, 'No': .nan }` we replace all occurrences of `N` and `No` by `nan` which gets dropped automatically. Note that `No` has to be quotes in order not to be interpreted as `False` by the YAML parser:

```
'i1'.'j2' Y,
'i1'.'j3' Y,
'i2'.'j1' Y,
'i2'.'j2' Y,
'i2'.'j3' Y,
'i3'.'j1' Y,
'i3'.'j2' Y
```

### 4.46.5.9.1 Fundamentals of Reading Data with PandasExcelReader

As mentioned at the start of this section, the PandasExcelReader works best with tables written by the PandasExcelWriter with a full range (north-west and south-east corner) specification. Nevertheless, the PandasExcelReader can also process tables not precisely in the format and shape given by PandasExcelWriter and also works with an open range (north-west corner only) specification. While the PandasExcelReader shares some functionality with the tool `gdxxrw` there are also significant differences and this section explains some of the perhaps unexpected behavior of this Connect agent.

- Symbols with `rowDimension=0` and/or `columnDimension=0` have an artificial index in 0-dim index and the range specification need to include this artificial index. For example, if one wants to read a scalar, there are two artificial indexes `rval` and `cval` and the north-west corner starts in the artificial index row and column, i.e. range is `B2` or `B2:C3` in the following example:

  The names of the artificial indexes are irrelevant, they can even be blank. But as a consequence of the artificial indexes, PandasExcelReader cannot read a scalar that is located in row 1 or column A. Similarly, symbols with `dim>0` but either `rowDimension` or `columnDimension` equal to 0 need an artificial index:

  Again, the name of the artificial index is irrelevant, it can even be blank. In both examples, the range starts in north-west corner `B2`. For symbols with `rowDimension>0` and `columnDimension>0` there is no artificial index.

- Tables with more than one index in the columns can be read best if the column headers and the data are separated by a blank line (this is the way PandasExcelWriter writes such tables). The PandasExcelReader attribute `multiColumnBlankRow` allows some control. See the option descriptions for details.

- Blank data is read as `nan` (not a number) and such records are dropped before the data is written to the Connect database. The `valueSubstitutions` attribute of PandasExcelReader allows to remap `nan` to other values. Blank index positions are treated very differently. The behavior depends on multiple factors.
If PandasExcelReader encounters a blank index at the beginning of the rows it fills the index with `nan`. With a blank row index in the middle of the table (i.e. if there was a good label before in this column), PandasExcelReader repeats the previous index of this column. In case of `columnDimension=1` blank column indexes are filled with `Unnamed: n` (where n in the nth column (zero based) in the sheet). Hence the following table is transformed into the following pandas.DataFrame (use PandasExcelReader attribute `trace>2` to print intermediate data frames):

<table>
<thead>
<tr>
<th>j1</th>
<th>j3</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>i2</td>
<td>i2</td>
</tr>
<tr>
<td>2</td>
<td>7</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>5</td>
<td>10</td>
</tr>
<tr>
<td>6</td>
<td>6.0</td>
</tr>
</tbody>
</table>

which arrives after dropping the `nan` values and indexes in the Connect database (here a display as a GAMS parameter) as:

<table>
<thead>
<tr>
<th>j1</th>
<th>j3</th>
</tr>
</thead>
<tbody>
<tr>
<td>i2.i2</td>
<td>2</td>
</tr>
<tr>
<td>i2.i3</td>
<td>3</td>
</tr>
<tr>
<td>i5.i3</td>
<td>5</td>
</tr>
<tr>
<td>i6.i6</td>
<td>6</td>
</tr>
</tbody>
</table>

In case of `columnDimension>1` blank column index at the beginning of the column index are filled with `Unnamed: n_level_k` (where n in the nth column (zero based) in the sheet and k is the column dimension). With a blank column index in the middle of the index columns (i.e. if there was a good label before in this row), PandasExcelReader repeats the previous index but might add a suffix `.1`, `.2`, ... to disambiguate the column names. Hence the following table is transformed into the following pandas.DataFrame (use PandasExcelReader attribute `trace>2` to print intermediate data frames):

<table>
<thead>
<tr>
<th>NaN</th>
<th>NaN</th>
<th>NaN</th>
<th>NaN</th>
</tr>
</thead>
<tbody>
<tr>
<td>i2</td>
<td>i2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>7</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>10</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>6.0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

which arrives after dropping the `nan` values and indexes in the Connect database (here a display as a GAMS parameter) as:

<table>
<thead>
<tr>
<th>NaN</th>
<th>NaN</th>
<th>NaN</th>
<th>NaN</th>
</tr>
</thead>
<tbody>
<tr>
<td>i2.i2</td>
<td>i2.i3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The PandasExcelReader attribute `drop` helps to get rid of unwanted indexes (e.g. `drop: Unnamed` or `drop: "\".\"`). Removing row indexes that result from the continuation of previous indexes is significantly harder. Hence such rows should be entirely empty (then the row is dropped because it has only `nan` values). It is best to avoid empty index rows and columns altogether.

- When one specifies an open range (north-west corner only) the PandasExcelReader will read from this north-west corner all the way to the end of the sheet (press Ctrl-End in Excel to locate the
cursor into the last cell of a sheet). It does not stop at blank row or column indexes as the tool gdxrw does. This aggravates the situation with empty index cells. Hence the following table will result in the following pandas.DataFrame (use PandasExcelReader attribute trace>2 to print intermediate data frames):

<table>
<thead>
<tr>
<th></th>
<th>j1</th>
<th>j2</th>
<th>j3</th>
<th>Unnamed: 5</th>
<th>Unnamed: 6</th>
<th>Unnamed: 7</th>
<th>Unnamed: 8</th>
</tr>
</thead>
<tbody>
<tr>
<td>i1</td>
<td>1.0</td>
<td>2.0</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>i2</td>
<td>NaN</td>
<td>1.0</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>i3</td>
<td>NaN</td>
<td>NaN</td>
<td>1.0</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>i3</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>i3</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>i3</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>999.0</td>
</tr>
</tbody>
</table>

which arrives after dropping the nan values and indexes in the Connect database (here a display as a GAMS parameter) as:

<table>
<thead>
<tr>
<th></th>
<th>j1</th>
<th>j2</th>
<th>j3</th>
<th>Unnamed: 8</th>
</tr>
</thead>
<tbody>
<tr>
<td>i1</td>
<td>1</td>
<td>2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>i2</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>i3</td>
<td></td>
<td>1</td>
<td>999</td>
<td></td>
</tr>
</tbody>
</table>

4.46.5.10 PandasExcelWriter

The PandasExcelWriter agent allows to write symbols from the Connect database to an Excel file. Its implementation is based on the pandas.DataFrame class and its I/O API method to_excel. PandasExcelWriter can write sets, parameters, variables, and equations. If the Excel workbook exists, PandasExcelWriter will attempt to append to the existing workbook.

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>excelWriterArguments</td>
<td>global</td>
<td>None</td>
<td>Dictionary containing keyword arguments for the pandas.ExcelWriter constructor.</td>
</tr>
<tr>
<td>file</td>
<td>global</td>
<td>None</td>
<td>Specify an Excel file path.</td>
</tr>
<tr>
<td>name</td>
<td>symbol</td>
<td>None</td>
<td>Specify the name of the symbol in the Connect database.</td>
</tr>
<tr>
<td>range</td>
<td>symbol</td>
<td>None</td>
<td>Specify the Excel range of a symbol.</td>

<td>inherited</td>
<td>Specify the trace level for debugging output.</td>
</tr>
<tr>
<td>valueSubstitutions</td>
<td>symbol</td>
<td>None</td>
<td>Dictionary used for mapping in the value column of the DataFrame.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**excelWriterArguments = dictionary (optional)**

Dictionary containing keyword arguments for the pandas.ExcelWriter constructor.

**file = string (required)**

Specify an Excel file path.

**name = string (required)**
Specify a symbol name for the Connect database.

range = string (required)

Specify the Excel range of a symbol using the format sheet!range. range can be either a single cell (north-west corner like B2) or a full range (north-west and south-east corner like B2:D4). For writing purposes, the south-east corner is ignored. Please note, that PandasExcelWriter always writes an index in the row and column. So even for a scalar or an indexed symbol with rowDimension=0 or dim-rowDimension=0 there will be some index information in the 0 index. For example, the following Connect script

```
parameter x0 / 3.14 /, x1 / i1 1, i2 2, i3 3 /;
$onEmbeddedCode Connect:
- GAMSReader:
  readAll: True
- PandasExcelWriter:
  file: x.xlsx
  symbols:
  - name: x0
    range: Sheet1!a1
  - name: x1
    rowDimension: 1
    range: Sheet1!d1
  - name: x1
    rowDimension: 0
    range: Sheet1!g1
$offEmbeddedCode
```

creates the following Excel output:

rowDimension = integer (optional)

Row dimension: The first rowDimension index positions of the symbol to be written will be written to the rows. dim-rowDimension index positions will be written into the column headers.

toExcelArguments = dictionary (optional)

Dictionary containing keyword arguments for the pandas.DataFrame.to_excel method. Not all arguments of that method are exposed through the YAML interface of the PandasExcelWriter agent. By specifying toExcelArguments, it is possible to pass arguments directly to the pandas.to_excel method that is used by the PandasExcelWriter agent.

trace = integer (optional)

Specify the trace level for debugging output. For trace > 1 some scalar debugging output will be written to the log. For trace > 2 the intermediate data frames will be written abbreviated to the log. For trace > 3 the intermediate data frames will be written entirely to the log (potentially large output). If trace has not been set, the trace value, set by the Options agent, will be used.

valueSubstitutions = dictionary (optional)

Dictionary used for mapping in the value column of the DataFrame. Each key in valueSubstitutions is replaced by its corresponding value. The replacement is only performed on the value column of the DataFrame which is the numerical value in case of a GAMS parameter, variable or equation and the set element text in case of a GAMS set.

4.46.5.11 PandasSQLReader

The PandasSQLReader agent allows to read symbols from a specified database management system into the Connect database. Its implementation is based on the pandas.DataFrame class and its I/O API method read_sql. The method takes in the SQL query or a SQLAlchemy connectable url.
<table>
<thead>
<tr>

<td>inferred</td>
<td>Specify columns to get the values from.</td>
</tr>
<tr>
<td>valueSubstitutions</td>
<td>symbol</td>
<td>None</td>
<td>Dictionary used for mapping in the value column of the DataFrame.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**connection = string (required)**

Allows to specify the connection string to the database and user credentials in order to access
the database. Specify the absolute path to the database or specify SQLAlchemy connectable
url. Here are some examples:

Microsoft Access:

connection: "access+pyodbc://?odbc_connect=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};DBQ=<absolute//path//to//datafile.accdb(.mdb)>;"

SQL Server:

connection: "mssql://?odbc_connect=DRIVER={SQL Server Native Client 11.0};SERVER=<computerName>\SQLEXPRESS;Trusted_Connection=yes;"

SQLite:

connection: "sqlite:///<absolute//path//to//foo.db>"

Postgres:

connection: "postgresql://scott:tiger@localhost/mydatabase"

**dTypeMap = dict (optional)**

Allows to specify the dType of columns in a dictionary as key: value pairs, i.e. <column>:<dtype>.

**indexSubstitutions = dict (optional)**

Dictionary used for substitutions in the index columns. Each key in indexSubstitutions is
replaced by its corresponding value. This option allows arbitrary replacements in the index columns.

**name = string (required)**
Name of the symbol in the Connect database. The name must be unique for each symbol.

**query** = string (required)

Specify the SQL query which will fetch the desired table from the database system.

**readSQLArguments** = dict (optional)

Dictionary containing keyword arguments for the pandas.read_sql method. Not all arguments of that method are exposed through the YAML interface of the PandasSQLReader agent. By specifying readSQLArguments, it is possible to pass arguments directly to the pandas.read_sql method that is used by the PandasSQLReader agent.

**sqlEngineArguments** = dict (optional)

Dictionary containing keyword arguments for the sqlalchemy.create_engine constructor.

**trace** = integer (optional)

Specify the trace level for debugging output. For trace > 1 some scalar debugging output will be written to the log. For trace > 2 the intermediate arrays and data frames will be written abbreviated to the log. For trace > 3 the intermediate arrays and data frames will be written entirely to the log (potentially large output). If trace has not been set, the trace value, set by the Options agent, will be used.

**type** = string (default=par)

Control the symbol type. Supported symbol types are par for GAMS parameters and set for GAMS sets.

**valueColumns** = list or string (optional)

Specify columns to get the values from. The value columns contain numerical values in case of a GAMS parameter and set element text in case of a GAMS set. The columns are given as column names represented as a list of strings. For example: valueColumns: ["i1", "i2"]. If there is more than one value column specified, the column names are stacked to index automatically. As string one can specify the symbolic constant lastCol (i.e. valueColumns: "lastCol") or an empty string (i.e. valueColumns: "). When lastCol is passed the last column will be treated as a value column and all the other columns will be treated as index columns. When an empty list is passed all columns will be treated as index columns. Specifying an empty list is only valid for symbol type set since symbol type par requires at least one value column. The default for symbol type par is lastCol and the default for symbol type set is an empty string.

**valueSubstitutions** = dict (optional)

Dictionary used for mapping in the value column of the DataFrame. Each key in valueSubstitutions is replaced by its corresponding value. The replacement is only performed on the value column of the DataFrame which is the numerical value in case of a GAMS parameter and the set element text in case of a GAMS set. While it is possible to make arbitrary replacements this is especially useful for controlling sparse/dense reading.

### 4.46.5.12 PandasSQLWriter

The PandasSQLWriter agent allows to write symbols from the Connect database to a specified database management system. Its implementation is based on the pandas.DataFrame class and its I/O API method to_sql.
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection</td>
<td>global</td>
<td>None</td>
<td>Connection string to the database.</td>
</tr>
<tr>

<td>Indicate if the last index column will be used as a header row.</td>
</tr>
<tr>
<td>valueSubstitutions</td>
<td>symbol</td>
<td>None</td>
<td>Dictionary used for mapping in the value column of the <code>DataFrame</code>.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**connection = string (required)**

Allows to specify the connection string to the database and user credentials in order to access the database. Specify the absolute path to the database or specify SQLAlchemy connectable url.

**ifExists = string (default=fail)**

Specify the behavior when a table with the same name exists in the database/schema. Valid values are `fail`, `replace` and `append`.

**name = string (required)**

Specify the name of the symbol in the Connect database.

**schemaName = string (optional)**

Specify the schema name for writing the table to the correct location. In Postgres, by default, it writes to a public schema already present in every database.

**sqlEngineArguments = dict (optional)**

Dictionary containing keyword arguments for the `sqlalchemy.create_engine` constructor.

**tableName = string (required)**

Name of the SQL table/relation in the provided database/schema.

**toSQLArguments = dict (optional)**

Dictionary containing keyword arguments for the `pandas.to_sql` method. Not all arguments of that method are exposed through the YAML interface of the PandasSQLWriter agent. By specifying `toSQLArguments`, it is possible to pass arguments directly to the `pandas.to_sql` method that is used by the PandasSQLWriter agent.
**trace** = integer (optional)

Specify the trace level for debugging output. For trace > 1 some scalar debugging output will be written to the log. For trace > 2 the intermediate arrays and data frames will be written abbreviated to the log. For trace > 3 the intermediate arrays and data frames will be written entirely to the log (potentially large output). If trace has not been set, the trace value, set by the Options agent, will be used.

**unstack** = boolean (default=False)

Indicate if the last index column will be used as a header row.

**valueSubstitutions** = dict (optional)

Dictionary used for mapping in the value column of the DataFrame. Each key in valueSubstitutions is replaced by its corresponding value. The replacement is only performed on the value column of the DataFrame which is the numerical value in case of a GAMS parameter, variable or equation and the set element text in case of a GAMS set.

### 4.46.5.13 Projection

The Projection agent allows index reordering and projection onto a reduced index space of a GAMS symbol. For variables and equations a suffix (\(^\cdot\.l\), \(^\cdot\.m\), \(^\cdot\.lo\), \(^\cdot\.up\), or \(^\cdot\.scale\)) can be extracted and is written to a parameter. Otherwise, the type of the source symbol determines the type of the new symbol, unless asSet is set to True. Variables and equations can be turned into parameters with an extra index containing the labels level, marginal, lower, upper, and scale if the attribute asParameter is set to True. Moreover, if name is a list of scalar symbols of the same type (parameters, variables, or equations), they can be stored in a one-dimensional symbols of the same type with the index label being the name of the scalar symbol.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggregationMethod</td>
<td>first</td>
<td>Specify the aggregation method for the projection.</td>
</tr>
<tr>
<td>asParameter</td>
<td>False</td>
<td>Indicate that variable or equation symbols will be turned into a parameter with an extra index that contains the suffix.</td>
</tr>
<tr>
<td>asSet</td>
<td>False</td>
<td>Indicate that the new symbol is a set independent of the type of the source symbol.</td>
</tr>
<tr>
<td>name</td>
<td>None</td>
<td>Specify a symbol name with index space and potentially suffix for the Connect database.</td>
</tr>
<tr>
<td>newName</td>
<td>None</td>
<td>Specify a new name with index space for the symbol in the Connect database.</td>
</tr>
<tr>
<td>text</td>
<td>None</td>
<td>Element text for resulting sets.</td>
</tr>
<tr>
<td>trace</td>
<td>inherited</td>
<td>Specify the trace level for debugging output.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**aggregationMethod** = string (default=first)

Specify the method to aggregate when at least one index position is projected out. The default is first, meaning that the first record will be stored in the new symbol. For sets, variables, and equations (without a suffix specified) only first and last are meaningful. For parameters, variables, and equations with suffix many other aggregation methods are
available and meaningful: \texttt{mad} (mean absolute deviation), \texttt{max}, \texttt{mean}, \texttt{median}, \texttt{min}, \texttt{prod}, \texttt{sem} (unbiased standard error of the mean), \texttt{sum}, \texttt{std} (standard deviation), \texttt{nunique} (number of distinct elements), \texttt{first}, \texttt{last}. The projection agent is based on pandas DataFrames and more detailed explanations of the aggregation method can be found at the pandas website.

\texttt{asParameter = boolean} (default=\texttt{False})

If the symbol specified by \texttt{name} is a variable or equation and \texttt{asParameter} is set to \texttt{True}, the new symbol (after potential \texttt{aggregationMethod} is applied) will be a parameter with an additional index (at the end of the index list) that contains the suffix labels \texttt{level}, \texttt{marginal}, \texttt{lower}, \texttt{upper}, and \texttt{scale} and the corresponding suffix value.

\texttt{asSet = boolean} (default=\texttt{False})

Usually the type of the source symbol and the use of a suffix with variables and equations determine the type of the target symbol. With \texttt{asSet} set to \texttt{True} the target symbol will be a set.

\texttt{name = string or list of strings} (required)

One either specifies a single symbol name with index space and potentially suffix for the Connect database or a list of symbol names of scalar symbols. In the prior case, \texttt{name} requires the format \texttt{symname[.suffix](i1,i2,...,iN)}. The suffix is only allowed on variable and equation symbols and need to be either \texttt{l}, \texttt{m}, \texttt{lo}, \texttt{up}, or \texttt{scale}. The list of indices does not need to coincide with the names of the actual GAMS domain sets. This index list together with the index list specified for \texttt{newName} is solely intended to establish the index order in the symbol specified by \texttt{newName}. In the latter case (a list of symbol names) the symbols need to be scalar symbols of the same type (parameter, variable, or equation) and a new one-dimensional symbol (of the same type) is created (using \texttt{newName}) that holds the symbol names as labels.

\texttt{newName = string} (required)

Specify a new name with index space for the projected or reordered symbol in the Connect database. Note that each symbol in the Connect database must have a unique name. \texttt{newName} is given as \texttt{symname(i1,i2,...,iN)}. The list of indices does not need to coincide with the names of the actual GAMS domain sets. This index list together with the index list specified for \texttt{name} is solely intended to establish the index order. Hence, the names in the index list need to be unique and only names that are part of the index list specified for \texttt{name} can be used. For example: \texttt{name: p(I,j,k)} and \texttt{newName: q(k,i)}.

\texttt{text = string} (default=\texttt{None})

Control the handling of element text if the resulting symbol is a set. If set to "", the text will be dropped. When left at default (\texttt{None}) and the projected symbol is a set, the element text of the original set will be used. For other symbols types, the text will be dropped. If \texttt{text} is a string, this string will be assigned to all elements. The string can contain \texttt{place holders} \{i1\} that will be replaced with the content of the matching index position. For example, \texttt{text: \"{i2} - {i1}: \{element_text\}\", where \{i1\} and \{i2\} should be index space names in the symbol name with index space (attribute \texttt{name}). \{element_text\} refers to original element text (set) or string representation of a numerical value (parameter or variable/equation with a given suffix) of the source symbol.

\texttt{trace = integer} (optional)

Specify the trace level for debugging output. For \texttt{trace} \textgreater 1 some scalar debugging output will be written to the log. For \texttt{trace} \textgreater 2 the intermediate arrays and data frames will be written abbreviated to the log. For \texttt{trace} \textgreater 3 the intermediate arrays and data frames will be written entirely to the log (potentially large output). If \texttt{trace} has not been set, the \texttt{trace} value, set by the \texttt{Options} agent, will be used.
4.46.14 PythonCode

The PythonCode agent allows to execute arbitrary Python code. From within the code, it is possible to access the GAMS database via `gams.db` (if the PythonCode agent is running in a GAMS context) and the Connect database via `connect.container`. The GAMS database is an instance of `GamsDatabase`, whereas the Connect database is a `GAMS Transfer Container` object. Furthermore there is a predefined `instructions` list that can be filled with tasks that are automatically executed.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>code</td>
<td>None</td>
<td>Python code to be executed.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

code = string (required)

Python code to be executed. The YAML syntax offers the pipe character (|) for specifying multi-line strings:

- PythonCode:
  
  code: |
  print("Print from Python")
  # insert more Python code here

It is possible to generate instructions by appending tasks to the Python `instructions` list. A task is specified by using Python data structures that match the schema of a specific Connect agent. At the end of the Python code, all tasks in the `instructions` list are automatically generated and executed. The following example shows how to fill the `instructions` list with three PandasExcelWriter tasks that write different parameters (p0, p1, p2) into separate Excel workbooks (`data_p0.xlsx`, `data_p1.xlsx`, `data_p2.xlsx`).

- GAMSReader:
  
  readAll: True

- PythonCode:
  
  code: |
  symbols = ['p0', 'p1', 'p2']
  for s in symbols:
    instructions.append(
      {'PandasExcelWriter':
       {'file': 'data_{}.xlsx'.format(s),
        'symbols': [{'name': s, 'rowDimension': connect.container.data[s].dimension, 'range': s+'!A1'}]
      })

Using `gams.db` and `connect.container` allows to access symbols directly. The following example shows how to manually fill a symbol in the GAMS database (`gams.db`) with a symbol from the Connect database (`connect.container`) which would normally be done using the `GAMSWriter` agent.

- GAMSReader:
  
  readAll: True

- PythonCode:
  
  code: |
  connect.container.data['p1'].copy_symbol(gams.db['p2'])
4.46.5.15 RawExcelReader

The RawExcelReader allows reading of unstructured data from a specified Excel file into the Connect database. This reader works similarly compared to the xlsdump tool. It reads the entire spreadsheet and represents its content in a couple of GAMS sets:

- s /s1, s2,.../ (workbook sheets)
- w / Sheet1, Sheet2, ... / (workbook sheets by name)
- ws(s,w) / s1.Sheet1, s2.Sheet2, ... / (workbook map)
- r / r1, r2, ... / (rows)
- c / c1, c2, ... / (columns)
- vs(s,r,c) / s1.r1.c2 "cell text", ... / (cells with explanatory text)
- vu(s,r,c,* / s1.r1.c1."cell text" "cell text", ... (cells with potential GAMS label)

and a parameter vf(s,r,c) / s1.r2.c2 3.14, ... / (cells with numerical values). Cells with a date will be stored in it's string representation in vu and as a Julian date in vf. Cells with a string value will be stored in vs. If the string length exceeds the maximum length allowed for elements text, it will be truncated. Excel offers many other cell value types. RawExcelReader will try to represent the cell value as a number and if this succeeds stores the number in vf. Strings of GAMS special values names INF, EPS, NA, and UNDEF will be also converted to its numerical counterpart. It will also try to represent the cell value as a string and stores this as a label in the fourth position in vu. GAMS labels have a length limitation and hence RawExcelReader automatically shortens the label to fit this limit. RawExcelReader will provide a unique label (ending in ∼n where n is an integer for strings exceeding the label length limit) for each string in the workbook. The full string (if it fits) will be available as the element text of the vu record.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cName</td>
<td>c</td>
<td>Symbol name for columns.</td>
</tr>
<tr>
<td>columnLabel</td>
<td>C</td>
<td>Label for columns.</td>
</tr>
<tr>
<td>file</td>
<td>None</td>
<td>Specify an Excel file path.</td>
</tr>
<tr>
<td>mergedCells</td>
<td>False</td>
<td>Control the handling of empty cells that are part of a merged Excel range.</td>
</tr>
<tr>
<td>rName</td>
<td>r</td>
<td>Symbol name for rows.</td>
</tr>
<tr>
<td>rowLabel</td>
<td>R</td>
<td>Label for rows.</td>
</tr>
<tr>
<td>sheetLabel</td>
<td>S</td>
<td>Label for workbook sheets.</td>
</tr>
<tr>
<td>sName</td>
<td>s</td>
<td>Symbol name for workbook sheets.</td>
</tr>
<tr>
<td>trace</td>
<td>inherited</td>
<td>Specify the trace level for debugging output.</td>
</tr>
<tr>
<td>vfName</td>
<td>vf</td>
<td>Symbol name for cells with a numerical value.</td>
</tr>
<tr>
<td>vsName</td>
<td>vs</td>
<td>Symbol name for cells with an explanatory text.</td>
</tr>
<tr>
<td>vuName</td>
<td>vu</td>
<td>Symbol name for cells with a potential GAMS label.</td>
</tr>
<tr>
<td>wName</td>
<td>w</td>
<td>Symbol name for workbook sheets by name.</td>
</tr>
<tr>
<td>wsName</td>
<td>w</td>
<td>Symbol name for workbook map.</td>
</tr>
</tbody>
</table>

Detailed description of the options:

**cName = string (default=c)**

Control the name of the set of columns.

**columnLabel = string (default=C)**
Control the labels for the set of columns (c).

**file = string** (required)

Specify an Excel file path.

**mergedCells = boolean** (default=\texttt{False})

Control the handling of empty cells that are part of a merged Excel range. If \texttt{False}, the cells are left empty. If \texttt{True}, the merged value is used in all cells. Note that setting this option to \texttt{True} has an impact on performance since the Excel workbook has to be opened in a non-read-only mode that results in non-constant memory consumption (no lazy loading).

**rName = string** (default=\texttt{r})

Control the name of the set of rows.

**rowLabel = string** (default=\texttt{R})

Control the labels for the set of rows (r).

**sheetLabel = string** (default=\texttt{S})

Control the labels for the set of workbook sheet (s).

**sName = string** (default=\texttt{s})

Control the name of the set of workbook sheets.

**trace = integer** (optional)

Specify the trace level for debugging output. For \texttt{trace} > 1 some scalar debugging output will be written to the log. For \texttt{trace} > 2 the cell values and its processing will be written entirely to the log (potentially large output). If \texttt{trace} has not been set, the \texttt{trace} value, set by the \texttt{Options} agent, will be used.

**vfName = string** (default=\texttt{vf})

Control the name of the parameter for cells with a numerical value.

**vsName = string** (default=\texttt{vs})

Control the name of the set for cells with an explanatory text.

**vuName = string** (default=\texttt{vu})

Control the name of the set for cells with a potential GAMS label.

**wName = string** (default=\texttt{w})

Control the name of the set of workbook sheets by name.

**wsName = string** (default=\texttt{ws})

Control the name of the set of the workbook map.
4.46.6 Text Substitutions in YAML File

In many cases one would like to parameterize the text in the Connect instruction file. For example, some of the Connect agents require a file name. Instead of hard coding the file name into the YAML instructions, text substitutions allow to have a place holder for the attribute that is substituted out before giving the instructions to Connect. The place holder in the YAML file uses the syntax `%SOMETEXT%`, similar to the GAMS compile-time variables. For example:

- CSVReader:
  
  file: %MYFILENAME%
  name: distance
  indexColumns: [1, 2]
  valueColumns: [3]

Depending on how Connect runs, the substitution is done in various ways. The section Substitutions in Embedded Connect Code described the substitution mechanisms for embedded Connect code. When Connect is initiated via the command line parameters connectIn or connectOut, the user defined parameter specified by double-dash command line parameters and the given GAMS command line parameters, e.g. `%gams.input%` will be substituted in the YAML file. The list of parameters available for substitution is printed to the GAMS log at the beginning of the job in the section GAMS Parameters defined.

When Connect is initiated via the shell command `gamsconnect` all substitutions need to be specified on the command line:

```
gamsconnect myci.yaml key1=val1 key2=val2 ...
```

`key` can be just `MYFILENAME` or be composed like `gams.Input` or `system.dirSep`.

4.46.7 Use Connect Agents in Custom Python Code

Instead of passing instructions via one of the Connect interfaces, users can execute tasks directly in their Python code by creating an instance of `ConnectDatabase` and calling method `.exec_task(task)`. The `task` argument is expected to be a Python dictionary of form:

```python
{
    '<agent name>':,
    {
        '<global option1>': <value>,
        '<global option2>': <value>,
        ...
        'symbols':
        [
            {<symbol1 option1>':<value>,
             '<symbol1 option2>': <value>,
             '
             ...
            },
            {<symbol2 option1>':<value>,
             '<symbol2 option2>': <value>,
             ...
            },
            ...
        ]
    }
}
```
Users can either construct the Python dictionary themselves or let YAML create the dictionary from a YAML script. The following example creates an instance of ConnectDatabase and executes two tasks: First, the CSV file `stockprice.csv` is read into the Connect database and second, the symbol `stockprice` is written to the GAMS database. In this example, the tasks are directly specified as Python dictionaries.

```
Set dates, stocks;
Parameter stockprice(dates<,stocks<);

$onEcho > stockprice.csv
date;symbol;price
2016/01/04;AAPL;105,35
2016/01/04;AXP;67,59
2016/01/04;BA;140,50
$offEcho

$onEmbeddedCode Python:
from gams_connect.connectdatabase import ConnectDatabase
cdb = ConnectDatabase(gams._system_directory, gams)
cdb.exec_task({'CSVReader': {'file': 'stockprice.csv', 'name': 'stockprice', 'indexColumns': [1, 2], 'valueColumns': [3], 'fieldSeparator': ';', 'decimalSeparator': ','}})
cdb.exec_task({'GAMSWriter': {'symbols': [{'name': 'stockprice'}]}})
$offEmbeddedCode

display stockprice;
```

We can also construct the Python dictionaries by using YAML:

```
Set dates, stocks;
Parameter stockprice(dates<,stocks<);

$onEcho > stockprice.csv
date;symbol;price
2016/01/04;AAPL;105,35
2016/01/04;AXP;67,59
2016/01/04;BA;140,50
$offEcho

$onEmbeddedCode Python:
import yaml
from gams_connect.connectdatabase import ConnectDatabase
cdb = ConnectDatabase(gams._system_directory, gams)
inst = yaml.safe_load(''
- CSVReader:
  - file: stockprice.csv
    name: stockprice
    indexColumns: [1, 2]
    valueColumns: [3]
    fieldSeparator: ';'
    decimalSeparator: ','
- GAMSWriter:
  - name: stockprice
''
)
for task in inst:
    cdb.exec_Task(task)
```

Here YAML creates a list of dictionaries (i.e. a list of tasks) from the given YAML script.

### 4.46.8 Command Line Utility gamsconnect

The GAMS system directory contains the utility `gamsconnect` to run Connect instructions directly from the command line. On Windows the utility has the callable extension `.cmd`. This script wraps the Python script `connectdriver.py` by calling the Python interpreter that ships with GAMS. `gamsconnect` operates as the other Connect drivers on a YAML instruction file. The agents `GAMSReader` and `GAMSWriter` are not available from `gamsconnect` and will trigger an exception. Substitutions can be passed to `gamsconnect` via command line arguments as `key=value`, e.g. `filename=myfile.csv` and even `gams.scrdir=/tmp/`. `gamsconnect` is called like this:

```
gamsconnect <YAMLFile> [key1=value1 [key2=value2 [key3=value3 [...]]]]
```

### 4.47 Extrinsic Functions

#### 4.47.1 Introduction

Mathematical functions play an important role in the GAMS language, especially for nonlinear models. Like other programming languages, GAMS provides a number of built-in or intrinsic functions. GAMS is used in an extremely diverse set of application areas and this creates frequent requests for the addition of new and often sophisticated and specialized functions. There is a trade-off between satisfying these requests and avoiding complexity not needed by most users. The GAMS Function Library Facility provides the means for managing this trade-off, since it allows users to import functions from an external library into a GAMS model. However, these external libraries can currently only provide functionality for the evaluation of functions (incl. their first and second derivatives) in a point. Solvers that need to analyze the algebraic structure of the model instance are therefore not able to work with extrinsic functions. This includes the class of deterministic global solvers, see column "Global" in this table, while, for example, stochastic global solvers can work with extrinsic functions.

In this chapter we will demonstrate how to access functions from an extrinsic function library in a GAMS model and we will describe the extrinsic function libraries that are included in the GAMS distribution. In addition, we will provide some pointers for users who wish to build their own extrinsic function library.

#### 4.47.2 Using Function Libraries

Function libraries are made available to a model with the following compiler directive:

```
$funcLibIn <InternalLibName> <ExternalLibName>
```

Here `InternalLibName` is a handle that will be used to refer to the library inside the model source code. `ExternalLibName` is the file name of the shared library that implements the extrinsic functions. If no path is given, GAMS will look for the library in the directory `extrinsic_functions` in the GAMS standard locations and in the GAMS system directory. To access a library that does not reside in these standard places, the external name should include a relative or absolute path to the location of the library. GAMS will then search for the specified library using the mechanisms specific to the host operating system. When processing the directive `$funcLibIn`, GAMS will validate the library, make the included functions available for use and add a table of the included functions to the listing file.
Note

The function library facility gives users complete control over naming so that potential name conflicts between libraries can be avoided.

Before the individual functions may be used, they have to be declared in the following way:

Function \(<\text{InternalFuncName}> /\langle\text{InternalLibName}\rangle.<\text{FuncName}>;/

Here \text{InternalFuncName} is the name of the individual function that will be used in the GAMS code. The user may choose this internal name freely and thus avoid potential naming conflicts. \text{InternalLibName} is the name of the function library as defined by the \$\text{funcLibIn} directive and \text{FuncName} is the name of the individual function in the external function library. Once functions have been declared in this way they may be used like intrinsic functions.

Consider the following simple example:

\$\text{funcLibIn myLib tricclib}

Function myCos /myLib.Cosine/
    mySin /myLib.Sine/
    myPi /myLib.Pi/;

Scalar d;
  d = myCos(myPi/3);
  display d;

Note that in the first line the external trigonometric library \text{tricclib} is activated and the internal name \text{myLib} is specified for it. Then the functions are declared. Observe that \text{Cosine}, \text{Sine} and \text{Pi} are functions in the trigonometric library. After the library has been loaded and the functions have been declared, the functions may be used as usual. The trigonometric library is discussed in section \text{Example: Trigonometric Library} below.

4.47.3 Libraries that are included in the GAMS Distribution

In this section we will present the libraries that are included in the GAMS distribution: the \text{Fitpack Library}, the \text{Piecewise Polynomial Library}, the \text{Stochastic Library} and the \text{LINDO Sampling Library}. Note that the LINDO Sampling Library is only available for LINDO license holders. In addition, we will provide details on the \text{Mutex Library}.

In the tables that follow, the "Endogenous Classification" (last column) specifies in which models the function may legally appear. In order of least to most restrictive, the choices are \text{any}, \text{DNLP}, \text{NLP}, \text{none}. See section \text{Classification of Models} for details on model types in GAMS. Note well that functions classified as \text{any} are only permitted with exogenous (constant) arguments.

A word on the notation in the tables below: for function arguments, lower case indicates that an endogenous variable is allowed. For details on endogenous variables, see section \text{Functions in Equation Definitions}. Upper case function arguments indicate that a constant is required. Arguments in square brackets may be omitted: the default values used in such cases are specified in the function description provided.
4.47.3.1 The Fitpack Library

FITPACK by Paul Dierckx [43] is a Fortran-based library for one-dimensional and two-dimensional spline interpolations. This library has been repackaged to work with the GAMS Function Library Facility. The model [FITLIB01] from the GAMS Test Library is an example of the use of the library FITPACK inside GAMS.

Note that the supporting points to which the function will be fit need to be stored in a three-dimensional parameter, fitdata, in a GDX file fit.gdx. The first dimension is a function index, the second dimension is the index of the supporting point and the third dimension takes one of the following four values: "w" (weight), "x" (x-value), "y" (y-value) or "z" (z-value).

The FITPACK library is made available with the following directive:

$funcLibIn <InternalLibName> fitfclib

It provides the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>fitFunc(FUNIND,x[,y])</td>
<td>Evaluate spline</td>
<td>DNLP</td>
</tr>
<tr>
<td>fitParam(FUNIND,PARAM[,VALUE])</td>
<td>Read or set parameters</td>
<td>none</td>
</tr>
</tbody>
</table>

The function FitParam may be used to change certain parameters that are used for the evaluation. The following values are defined:

- 1: Smoothing factor (S)
- 2: Degree of spline in direction x (Kx)
- 3: Degree of spline in direction y (Ky)
- 4: Lower bound of function in direction x (LOx)
- 5: Lower bound of function in direction y (LOY)
- 6: Upper bound of function in direction x (UPx)
- 7: Upper bound of function in direction y (UPy)

4.47.3.2 The Piecewise Polynomial Library

The Piecewise Polynomial Library may be used to evaluate piecewise polynomial functions. An example is given in the model [PWPLIB01] in the GAMS Test Library. Note that the functions that are to be evaluated need to be defined and stored in a GDX file. The following code snippet serves as illustration:

* Define two piecewise polynomial functions

Table pepdata(*,* ,*) '1st index: function number, 2nd index: segment number, 3rd index: degree'
<table>
<thead>
<tr>
<th>function</th>
<th>segment</th>
<th>degree</th>
</tr>
</thead>
<tbody>
<tr>
<td>leftBound</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1.1</td>
<td>2.4</td>
<td>-2.7</td>
</tr>
<tr>
<td>1.2</td>
<td>5.6</td>
<td>-4.3</td>
</tr>
<tr>
<td>2.1</td>
<td>0</td>
<td>-6.3333</td>
</tr>
<tr>
<td>2.2</td>
<td>0.3333</td>
<td>1.0370</td>
</tr>
</tbody>
</table>
Write pwp data to gdx file, which will be read by external library (pwpcclib)

```
.gdxout pwp.gdx
$unload pwpdata
.gdxout
```

Observe that on each row of the table `pwpdata` we have the following entries:

- `FuncInd` sets a function index
- `SegInd` defines the index of the segment (or interval) which is described
- `leftBound` gives the lower bound of the segment
- `CoefX` defines the X-th degree coefficient of the polynomial corresponding to this segment

The Piecewise Polynomial Library is made available with the following directive:

```
$funcLibIn <InternalLibName> pwpcclib
```

It provides the following function:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwpFunc(FUNIND,x)</td>
<td>Piecewise polynomials</td>
<td>DNLP</td>
</tr>
</tbody>
</table>

### 4.47.3.3 The Stochastic Library

The Stochastic Library provides random deviates, probability density functions, cumulative density functions and inverse cumulative density functions for certain continuous and discrete distributions. This library is made available with the following directive:

```
$funcLibIn <InternalLibName> stodclib
```

The continuous distributions that are available with this library are the following:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>beta(SHAPE_1,SHAPE_2)</td>
<td>Beta distribution with shape parameters SHAPE_1 and SHAPE_2, see MathWorld</td>
</tr>
<tr>
<td>cauchy(LOCATION,SCALE)</td>
<td>Cauchy distribution with location parameter LOCATION and scale parameter SCALE, see MathWorld</td>
</tr>
<tr>
<td>ChiSquare(DF)</td>
<td>Chi-squared distribution with degrees of freedom DF, see MathWorld</td>
</tr>
<tr>
<td>exponential(LAMBDA)</td>
<td>Exponential distribution with rate of change LAMBDA, see MathWorld</td>
</tr>
<tr>
<td>f(DF_1,DF_2)</td>
<td>F-distribution with degrees of freedom DF_1 and DF_2, see MathWorld</td>
</tr>
</tbody>
</table>
### Distribution Description

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gamma(SHAPE, SCALE)</td>
<td>Gamma distribution with shape parameter SHAPE and scale parameter SCALE, see MathWorld</td>
</tr>
<tr>
<td>gumbel(LOCATION, SCALE)</td>
<td>Gumbel distribution with location parameter LOCATION and scale parameter SCALE, see MathWorld</td>
</tr>
<tr>
<td>invGaussian(MEAN, SHAPE)</td>
<td>Inverse Gaussian distribution with mean MEAN and scaling parameter SHAPE, see MathWorld</td>
</tr>
<tr>
<td>laplace(MEAN, SCALE)</td>
<td>Laplace distribution with mean MEAN and scale parameter SCALE, see MathWorld</td>
</tr>
<tr>
<td>logistic(LOCATION, SCALE)</td>
<td>Logistic distribution with location parameter LOCATION and scale parameter SCALE, see MathWorld</td>
</tr>
<tr>
<td>logNormal(LOCATION, SCALE)</td>
<td>Lognormal distribution with location parameter LOCATION and scale parameter SCALE, see MathWorld</td>
</tr>
<tr>
<td>normal(MEAN, STD_DEV)</td>
<td>Normal distribution with mean MEAN and standard deviation STD_DEV, see MathWorld</td>
</tr>
<tr>
<td>pareto(SCALE, SHAPE)</td>
<td>Pareto distribution with scaling parameter SCALE and shape parameter SHAPE, see MathWorld</td>
</tr>
<tr>
<td>rayleigh(SIGMA)</td>
<td>Rayleigh distribution with parameter SIGMA, see MathWorld</td>
</tr>
<tr>
<td>studentT(DF)</td>
<td>Student’s t-distribution with degrees of freedom DF, see MathWorld</td>
</tr>
<tr>
<td>triangular(LOW, MID, HIGH)</td>
<td>Triangular distribution between LOW and HIGH, where MID is the most probable number, see MathWorld</td>
</tr>
<tr>
<td>uniform(LOW, HIGH)</td>
<td>Uniform distribution between LOW and HIGH, see MathWorld</td>
</tr>
<tr>
<td>weibull(SHAPE, SCALE)</td>
<td>Weibull distribution with shape parameter SHAPE and scaling parameter SCALE, see MathWorld</td>
</tr>
</tbody>
</table>

Further, the following discrete distributions are available:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binomial(N,P)</td>
<td>Binomial distribution with number of trials N and success probability P in each trial, see MathWorld</td>
</tr>
<tr>
<td>geometric(P)</td>
<td>Geometric distribution with success probability P in each trial, see MathWorld</td>
</tr>
<tr>
<td>hyperGeo(TOTAL,GOOD,TRIALS)</td>
<td>Hypergeometric distribution with total number of elements TOTAL, number of good elements GOOD and number of trials TRIALS, see MathWorld</td>
</tr>
<tr>
<td>logarithmic(P-FACTOR)</td>
<td>Logarithmic distribution with parameter P-FACTOR, also called log-series distribution, see MathWorld</td>
</tr>
<tr>
<td>negBinomial(FAILURES,P)</td>
<td>Negative Binomial distribution with FAILURES being the number of failures until the experiment is stopped and success probability P in each trial. The generated random number describes the number of successes until the defined number of failures is reached, see MathWorld</td>
</tr>
<tr>
<td>poisson(LAMBDA)</td>
<td>Poisson distribution with mean LAMBDA, see MathWorld</td>
</tr>
<tr>
<td>uniformInt(LOW,HIGH)</td>
<td>Integer Uniform distribution between LOW and HIGH, see MathWorld</td>
</tr>
</tbody>
</table>

Note that for each distribution the library offers the following four functions, where DistributionName is the name of the distribution as listed in the tables above, parameters are the parameters associated with each distribution, and x is the point at which the function is to be evaluated. Note that x may be an endogenous variable.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif. for Continuous Distributions</th>
<th>End. Classif. for Discrete Distributions</th>
</tr>
</thead>
<tbody>
<tr>
<td>d&lt;DistributionName&gt; &lt;parameters&gt;</td>
<td>Generate a random deviate (sample from the distribution)</td>
<td>none</td>
<td>none</td>
</tr>
<tr>
<td>pdf&lt;DistributionName&gt; &lt;parameters&gt;</td>
<td>Probability density function</td>
<td>DNLP</td>
<td>none</td>
</tr>
<tr>
<td>cdf&lt;DistributionName&gt; &lt;parameters&gt;</td>
<td>Cumulative distribution function</td>
<td>DNLP</td>
<td>none</td>
</tr>
<tr>
<td>icdf&lt;DistributionName&gt; &lt;parameters&gt;</td>
<td>Inverse cumulative distribution function</td>
<td>DNLP</td>
<td>none</td>
</tr>
</tbody>
</table>

For example, the functions for the Normal distribution are

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>dNormal(MEAN, STD_DEV)</td>
<td>Samples a random number from the Normal distribution</td>
<td>none</td>
</tr>
<tr>
<td>pdfNormal(x, MEAN, STD_DEV)</td>
<td>Probability density function for Normal distribution</td>
<td>DNLP</td>
</tr>
<tr>
<td>cdfNormal(x, MEAN, STD_DEV)</td>
<td>Cumulative distribution function for Normal distribution</td>
<td>DNLP</td>
</tr>
<tr>
<td>icdfNormal(x, MEAN, STD_DEV)</td>
<td>Inverse cumulative distribution function for Normal distribution</td>
<td>DNLP</td>
</tr>
</tbody>
</table>

Finally, the seed for the various random number generators can be set by using the following function:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>SetSeed(SEED)</td>
<td>Defines the seed for random number generator</td>
<td>none</td>
</tr>
</tbody>
</table>

In the following example, a sample of size 20 is generated from the Normal, Binomial, Cauchy, and Lognormal distributions each:

```gams
$funcLibIn stolib stodclib
Functions randnorm /stolib.dnormal /
    randbin /stolib.dbinomial /
    randcauchy /stolib.dcauchy /
    randlognorm /stolib.dlognormal /

Set i /i1*i20/;
Set j /norm, binomial, cauchy, lognorm/;
Parameter randx(i,j) "distribution sample";

randx(i,"norm") = randnorm(5,2);
randx(i,"binomial") = randbin(10,0.5);
randx(i,"cauchy") = randcauchy(5,1);
randx(i,"lognorm") = randlognorm(1.2,0.3);
display randx;
```

In the example, first the stochastic library is made available in GAMS, then the functions that will be used from the library are declared, giving them names under which to refer to them in the GAMS model. The output generated by the display statement is the following:
4.47 Extrinsic Functions

4.47.3.4 The LINDO Sampling Library

The LINDO Sampling Library provides samples of random numbers for certain distributions.

It is made available by the following directive:

$\text{funcLibIn InternalLibName lsadclib}$

Observe that a LINDO license is required to use this library.

The following table list the LINDO sampling functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End.</th>
<th>Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>sampleLS &lt;DistributionName&gt;</td>
<td>Creates a sample using the distribution &lt;DistributionName&gt;, according to the distribution parameters, and returns a HANDLE that references the sample, as illustrated in the example below.</td>
<td></td>
<td>none</td>
</tr>
<tr>
<td>getSampleValues(HANDLE)</td>
<td>Retrieves sampling created by the function sampleLS. See example below.</td>
<td></td>
<td>none</td>
</tr>
<tr>
<td>induceCorrelation(CORTYPE)</td>
<td>Induces the correlation that was set with the function setCorrelation before. CORTYPE describes the correlation type: 0 (Pearson), 1 (Kendall) or 2 (Spearman). See example below.</td>
<td></td>
<td>none</td>
</tr>
<tr>
<td>setCorrelation(SAMPLE1,SAMPLE2,COR)</td>
<td>Defines correlation between two samplings. See example below.</td>
<td></td>
<td>none</td>
</tr>
</tbody>
</table>
setSeed(SEED)

Specifies the seed for the random number generator.

setRNG(RNG)

Specifies the random number generator that will be used. Possible values are
-1 (FREE), 0 (SYSTEM), 1 (LINDO1), 2 (LINDO2), 3 (LIN1), 4 (MULT1), 5 (MULT2), and 6 (MERSENNE).

The following tables list the available continuous and discrete distributions, respectively. Note that the parameter SAMSIZE must be specified and describes the size of the sample. However, the parameter VARRED is optional and facilitates choosing a variance reduction method. The values are 0 (meaning "none"), 1 (meaning "Latin Hyper Square") and 2 (meaning "Antithetic"). The default is Latin Hyper Square sampling, it will be used if no variance reduction method is specified.

<table>
<thead>
<tr>
<th>Continuous Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>beta(SHAPE_1,SHAPE_2,SAMSIZE[,VARRED])</td>
<td><strong>Beta distribution</strong> specified by two shape parameters.</td>
</tr>
<tr>
<td>cauchy(LOCATION,SCALE,SAMSIZE[,VARRED])</td>
<td><strong>Cauchy distribution</strong> specified by the location and the scale parameter.</td>
</tr>
<tr>
<td>chisquare(DF,SAMSIZE[,VARRED])</td>
<td><strong>Chi-Squared</strong> distribution specified by degrees of freedom.</td>
</tr>
<tr>
<td>exponential(RATE,SAMSIZE[,VARRED])</td>
<td><strong>Exponential distribution</strong> specified by rate of change.</td>
</tr>
<tr>
<td>f(DF_1,DF_2,SAMSIZE[,VARRED])</td>
<td><strong>F distribution</strong> specified by degrees of freedom. Note that the function sampleLSf uses another version of the F distribution than the function dF from the Stochastic Library.</td>
</tr>
<tr>
<td>gamma(SHAPE,SCALE,SAMSIZE[,VARRED])</td>
<td><strong>Gamma distribution</strong> specified by shape and scale parameter. Note that the function sampleLSgamma(A,B) is equivalent to the function dGamma(B,A) from the Stochastic Library.</td>
</tr>
<tr>
<td>gumbel(LOCATION,SCALE,SAMSIZE[,VARRED])</td>
<td><strong>Gumbel distribution</strong> specified by location and scale parameter.</td>
</tr>
<tr>
<td>laplace(LOCATION,SCALE,SAMSIZE[,VARRED])</td>
<td><strong>Laplace distribution</strong> specified by location and scale parameter.</td>
</tr>
<tr>

<td><strong>Pareto distribution</strong> specified by shape and scale parameter.</td>
</tr>
<tr>
<td>studentt(DF,SAMSIZE[,VARRED])</td>
<td><strong>Student’s t-distribution</strong> specified by degrees of freedom.</td>
</tr>
<tr>
<td>triangular(LOW,MID,HIGH,SAMSIZE[,VARRED])</td>
<td><strong>Triangular distribution</strong> specified by lower and upper limit and mid value.</td>
</tr>
<tr>
<td>uniform(LOW,HIGH,SAMSIZE[,VARRED])</td>
<td><strong>Uniform distribution</strong> specified by the given bounds.</td>
</tr>
</tbody>
</table>
### Continuous Distribution

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>weibull(SCALE,SHAPE,SAMSIZE[,VARRED])</code></td>
<td><strong>Weibull distribution</strong> specified by scale and shape parameter. Note that the function <code>sampleLSweibull(A,B)</code> is equivalent to the function <code>dWeibull(B,A)</code> from the <em>Stochastic Library</em>.</td>
</tr>
</tbody>
</table>

### Discrete Distribution

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>binomial(N,P,SAMSIZE[,VARRED])</code></td>
<td><strong>Binomial distribution</strong> specified by number of trials <code>N</code> and success probability <code>P</code> in each trial.</td>
</tr>
<tr>
<td><code>hypergeo(TOTAL,GOOD,TRIALS,SAMSIZE[,VARRED])</code></td>
<td><strong>Hypergeometric distribution</strong> specified by total number of elements, number of good elements, and number of trials.</td>
</tr>
<tr>
<td><code>logarithmic(P-FACTOR,SAMSIZE[,VARRED])</code></td>
<td><strong>Logarithmic distribution</strong> specified by <code>P</code>-Factor. Note that the function <code>sampleLSlogarithmic</code> uses another version of the logarithmic distribution than <code>dLogarithmic</code> from the <em>Stochastic Library</em>.</td>
</tr>
<tr>
<td><code>negbinomial(SUCC,P,SAMSIZE[,VARRED])</code></td>
<td><strong>Negative Binomial distribution</strong> specified by the number of successes and the probability of success. The generated random number describes the number of failures until the defined number of successes is reached. Note that the function <code>sampleLSnegbinomial(R,P)</code> is equivalent to the function <code>dNegBinomial(R,P-1)</code> from the <em>Stochastic Library</em>.</td>
</tr>
<tr>
<td><code>poisson(MEAN,SAMSIZE[,VARRED])</code></td>
<td><strong>Poisson distribution</strong> specified by mean.</td>
</tr>
</tbody>
</table>

The following example illustrates the use of the sample generator and shows the effect of the functions `setCorrelation` and `induceCorrelation`:

```
$funcLibIn lsalib lsadclib

Functions normalSample / lsalib.SampleLSnormal /
    getSampleVal / lsalib.getSampleValues /
    setCor / lsalib.setCorrelation /
    indCor / lsalib.induceCorrelation /;

Scalars d "dummy"
    h "handle for first sample"
    k "handle for second sample" ;

Set i "sample index" / i01*i12 /;

Parameters sv_h(i) "sample values for handle h"
    sv_k(i) "sample values for handle k";

* generate two handles for 12 samples from normal distribution with mean 5 and std.dev. 2 each
  h = normalSample(5,2,12);
  k = normalSample(5,2,12);

* retrieve sample values from Lindo library
  loop(i, sv_h(i) = getSampleVal(h) );
  loop(i, sv_k(i) = getSampleVal(k) );
```
display sv_h, sv_k;

* set and induce a correlation between samples h and k
  d = setCor(h,k,-1);
  d = indCor(1);

* retrieve sample values again from correlated distribution
  loop(i, sv_h(i) = getSampleVal(h) );
  loop(i, sv_k(i) = getSampleVal(k) );

display sv_h, sv_k;

The resulting output shows that the values of sv_k are reordered according to the desired correlation:

---- 25 PARAMETER sv_h sample values for handle h
  i01 2.079,  i02 6.454,  i03 4.437,  i04 2.747,  i05 5.339,  i06 4.059,  i07 6.311,  i08 7.512,  i09 8.280,  i10 3.380,  i11 4.596,  i12 5.752

---- 25 PARAMETER sv_k sample values for handle k
  i01 5.509,  i02 3.021,  i03 7.550,  i04 6.002,  i05 4.227,  i06 0.704,  i07 3.890,  i08 9.474,  i09 5.084,  i10 4.592,  i11 3.311,  i12 6.442

---- 35 PARAMETER sv_h sample values for handle h
  i01 2.079,  i02 6.454,  i03 4.437,  i04 2.747,  i05 5.339,  i06 4.059,  i07 6.311,  i08 7.512,  i09 8.280,  i10 3.380,  i11 4.596,  i12 5.752

---- 35 PARAMETER sv_k sample values for handle k
  i01 7.550,  i02 3.021,  i03 9.474,  i04 6.442,  i05 4.592,  i06 0.704,  i07 3.890,  i08 6.002,  i09 3.311,  i10 5.084,  i11 4.227,  i12 5.509

4.47.3.5  The Mutex Library

The Mutex Library allows us to work with a process-level mutex - a program object that can be used to synchronize multiple processes. For example, a mutex can be used to coordinate mutually exclusive access to a resource shared between processes and, thus, prevent multiple processes from accessing the shared resource at the same time. A mutex object is created with a unique name and can be acquired or locked by only one process at a time. Each process waits to acquire the lock for (i.e. ownership of) the mutex object before executing the code that accesses the shared resource. After accessing the shared resource, the process releases or unlocks the mutex object and other processes waiting for the mutex can acquire the lock and continue execution.

The Mutex Library may be used to prevent simultaneous access to shared resources when running GAMS programs concurrently and the errors and hard-to-explain behavior that result. Such behavior is not unusual or surprising: GAMS even has some language features to spawn programs asynchronously (e.g. Asynchronous Execution), and these concurrent GAMS programs often share files. Consider the following example where we have two GAMS programs A and B concurrently running a common code that writes a GDX file containing a scalar x:
scalar x;
repeat
  execute_load 'x.gdx', x;
  x = x + 1;
  execute_unload 'x.gdx', x;
until x > 100;

To ensure correct execution of the code, we want to ensure that programs A and B have mutually exclusive access to the GDX file. In addition, we want the load-increment-unload sequence to occur atomically (i.e. no other process reads or writes the GDX file during this sequence). The extrinsic function library mtxcc provides us with some functions to accomplish this and similar tasks:

- **Create(x)**: Creates a mutex with id x in the system. Returns 0 on success and UNDF in case of error.
- **Lock(x)**: Request to acquire or lock a mutex with id x: it returns immediately if the mutex is available, otherwise it waits until the mutex becomes available. Returns 0 on success and UNDF in case of error. Any process waiting in this call will wait forever if the mutex is never unlocked.
- **Unlock(x)**: Unlocks or releases a previously locked mutex with id x. Returns 0 on success and UNDF in case of error. If processes are waiting to acquire a lock on x, one of them will acquire the lock. Note that the lock should be held by the unlocking process: behavior is undefined otherwise.
- **TryLock(x)**: Like Lock, but if the mutex is not available, return 1 immediately instead of waiting.
- **TimedLock(x,y)**: Like Lock, but instead of waiting forever, return 1 after waiting unsuccessfully for y milliseconds.
- **Delete(x)**: Erases a mutex with id x from the system. Returns 0 on success and UNDF in case of error. Note that a process does not need to own the mutex to erase it. If a mutex is deleted and there are remaining processes queued up waiting for the unlock, these processes will wait forever.

Continuing our previous example, we need to make the functions Lock and Unlock available so we can use them to protect the entire loop body by enclosing it in Lock/Unlock calls.

```plaintext
$funcLibIn mtxlib mtxcclib
Function lock / mtxlib.Lock /
  unlock / mtxlib.Unlock /;
scalar x;
repeat
  abort$lock(12345) 'Problems locking mutex';
  execute_load 'x.gdx', x;
  x = x + 1;
  execute_unload 'x.gdx', x;
  abort$unlock(12345) 'Problems unlocking mutex';
until x > 100;
```

Before we can use the mutex, we first have to create it. Also if both programs are done, we need to make sure that the named mutex is erased at the end of the programs, otherwise named mutexes collect in your system and consume resources (memory or disk depending on the implementation). Because the deletion of a named mutex might be forgotten or a program exits while holding the lock to the mutex or another concurrent system uses the same id, it is a good idea to find a unique mutex name, create it once, and erase it at the end as shown in the following complete example:
* generate a unique mutex ID
$eval mtxID round(frac(jnow)*24*60*60*1000)

$onEcho > x.gms
$funcLibIn mtxlib mtxcclib
Function lock / mtxlib.Lock /
   unlock / mtxlib.Unlock /;
scalar x;
repeat
   abort$lock(%mtxID%) 'Problems locking mutex';
   execute_load 'x.gdx', x;
   x = x + 1;
   put_utility 'log' / 'Program %prgID% increased x to ' x:0:0;
   execute_unlock 'x.gdx', x;
   abort$unlock(%mtxID%) 'Problems unlocking mutex';
until x >= 100;
$offEcho
* Initialize x.gdx
scalar x /1/;
$gdxOut x.gdx
$unload x
$gdxOut

$onEcho > create.gms
$funcLibIn mtxlib mtxcclib
Function create / mtxlib.Create /
abort$create(%mtxID%) 'problems creating mutex';
$offEcho
* Create the mutex
$call.checkErrorLevel gams create.gms lo=2

* Asynchronously spawn A and B
$call.async 'gams x.gms --prgID=A fileStem=A'
$eval jhA JobHandle
$call.async 'gams x.gms --prgID=B fileStem=B'
$eval jhB JobHandle

* Wait until both jobs are back
$set statA 0
$set statB 0
$label l1
$eval x sleep(1)
$if not %statA% == 2 $eval statA JobStatus(%jhA%)
$if not %statB% == 2 $eval statB JobStatus(%jhB%)
$if not %statA%%statB% == 22 $goto l1

$onEcho > erase.gms
$funcLibIn mtxlib mtxcclib
Function delete / mtxlib.Delete /;
abort$delete(%mtxID%) 'problems erasing mutex';
$offEcho
* Erase the mutex
$call.checkErrorLevel gams erase.gms lo=2

The log indicates which program updated x and the GDX file x.gdx at what stage:

Program B increased x to 20
Program B increased $x$ to 21
Program A increased $x$ to 22
Program A increased $x$ to 23

Models dicegrid and asyncincbi show more realistic uses for the mtxcc library.

### 4.47.4 Build Your Own Library

This section discusses the creation of a custom extrinsic function library. Before attempting to implement such a library, we suggest to study the example libraries for which source code and test models are available. These libraries are studied below.

**Attention**

Building extrinsic function libraries requires the knowledge of a regular programming language (like C/C++, Fortran, ...) and experience with handling compilers and linkers to build dynamically linked libraries. In some situation, it may be easier to use the simpler GAMS macros or batinclude files to define own functions.

**Note**

Extrinsic functions are limited to 20 scalar arguments and return a scalar value.

An extrinsic function library consists of a specification part and a number of callbacks to evaluate the defined functions at an input point.

The specification part is implemented by a callback `querylibrary`. It returns information about the library itself, available functions, their arguments, endogenous classification, etc. to the GAMS execution system. C, Delphi, or Fortran source code for this callback can be generated automatically by using the Python helper script `ql.py`. The script processes a specification file `*.spec`, which is specified as first argument. The format of this file is documented in the file `tri.spec`. Both `ql.py` and `tri.spec` are contained in the source of the trigonometric library examples in the GAMS test library, obtainable via:

```
$ testlib trilib01
$ unzip trisource.zip
```

If an extrinsic function will be used within equations of a GAMS model, next to the function value evaluation callback, also callbacks that compute first and second derivatives with respect to all endogenous arguments at an input point should be provided. Occasionally, this can be inconvenient. Observe that GAMS can use the function values at points close to the input point to estimate the derivative values using finite differences. However, this method is not as accurate as analytic derivatives and requires a number of function evaluations, thus the convenience comes at a price. The attribute `MaxDerivative` in the specification of a function signals GAMS the highest derivatives this function will provide. For higher order derivatives, GAMS will use finite differences to approximate the derivative values. However, a better alternative is often the use of automatic differentiation when implementing the function evaluation. This is demonstrated in the CPP Library Example, see section Automatic Differentiation for more details.

GAMS offers some support to check the implementation of of derivatives for extrinsic functions via the function suffixes `grad`, `gradn`, `hess` and `hessn`. These function suffixes are defined for intrinsic and extrinsic functions. For example, for an extrinsic function `userfunc`, the gradient evaluation that the user implemented may be called with `userfunc.grad`. Further, an approximation of the gradient by finite differences is available by calling `userfunc.gradn`. Comparing the results of these two calls can often help to check the implementation of the gradient. The same principle applies for the Hessian and the function suffixes `.hess` and `.hessn`. The GAMS options `FDDelta` and `FDOpt` can be used to influence the finite difference calculations. For more details, see model [DERIVTST] in the GAMS Model Library.
4.47.4.1 Example: Trigonometric Library

The Trigonometric Library serves as an example of how to code and build an extrinsic function library. The library is included in the GAMS distribution in binary form. In addition, the source code in C, Delphi, and Fortran is available in the include files of the models [TRILIB01], [TRILIB02] and [TRILIB03] respectively. The library implements the following extrinsic functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>setMode(MODE)</td>
<td>Sets mode globally. Possible values are 0 for radian and 1 for degree. May be overwritten by the optional argument MODE in the functions cosine and sine.</td>
<td>none</td>
</tr>
<tr>
<td>cosine(x[,MODE])</td>
<td>Returns the cosine of the argument x. Note that the argument MODE is optional, default setting: MODE = 0.</td>
<td>NLP</td>
</tr>
<tr>
<td>sine(x[,MODE])</td>
<td>Returns the sine of the argument x. Note that the argument MODE is optional, default setting: MODE = 0.</td>
<td>NLP</td>
</tr>
<tr>
<td>pi</td>
<td>Value of π = 3.141593...</td>
<td>any</td>
</tr>
</tbody>
</table>

The C implementation of this extrinsic function library can be found in the files tricclib.c and tricclibql.c. Together with the API specification file extrfunc.h, these files document the callbacks that need to be implemented by a GAMS extrinsic function library. The file tricclibql.c implements the querylibrary callback, which provides information about the library itself and the extrinsic functions it implements. For example, the information that the function cosine has an endogenous required first argument and an exogenous optional second argument is available from the querylibrary callback. The file tricclibql.c (and also the Delphi and Fortran90 equivalents tridclibql.inc and triifortlibql.f90) has been generated by the script ql.py by processing the specification file tri.spec.

4.47.4.2 Example: The CPP Library

The CPP library serves both as an example of how to use C++ to obtain gradients and Hessians "for free" and as a source of functions based on the multivariate Normal distribution. The library is available in compiled form and as C++ source. Test Library model [CPPLIB00] exercises the process of building a shared library from C++ source and doing some basic tests, while models [CPPLIB01], [CPPLIB02], [CPPLIB03], [CPPLIB04], and [CPPLIB05] are more thorough tests for the CPP library extrinsics shipped with the distribution. These functions are listed and described in the following table. Note that in keeping with the language conventions of statistics, PDF is shorthand for "probability density function" and CDF is shorthand for "cumulative distribution function".

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pdfUVN(x)</td>
<td>PDF of uni-variate Normal distribution, see MathWorld or R</td>
<td>NLP</td>
</tr>
<tr>
<td>cdfUVN(x)</td>
<td>CDF of uni-variate Normal distribution, see MathWorld or R</td>
<td>NLP</td>
</tr>
<tr>
<td>pdfBVN(x,y,r)</td>
<td>PDF of bivariate Normal distribution, see MathWorld or R</td>
<td>NLP</td>
</tr>
<tr>
<td>cdfBVN(x,y,r)</td>
<td>CDF of bivariate Normal distribution, see MathWorld or R</td>
<td>NLP</td>
</tr>
<tr>
<td>pdfTVN(x,y,z,r21,r31,r32)</td>
<td>PDF of trivariate Normal distribution, see MathWorld or R</td>
<td>NLP</td>
</tr>
</tbody>
</table>

4.47.4.2.1 Automatic Differentiation Often, extrinsic functions are created in order to be used with endogenous arguments. In such cases it is necessary to provide first and second derivatives with
4.47 Extrinsic Functions

respect to these arguments in addition to the function values themselves. One way to compute these derivatives is via automatic differentiation techniques (see the article in Wikipedia for details).

Note that with C++ it is possible to overload the usual arithmetic operators (assignment, addition, multiplication, etc.) so that automatic differentiation occurs with little or no change to the function-only source code. This is the technique used to compute the derivatives in the CPP Library. Observe that the Test Library model [CPPLIB00] includes all the source code for the CPP Library and illustrates the steps needed to build the library from this source. The source is a working self-documentation of how the process of automatic differentiation works.

4.47.4.2.2 Multi-Variate Normal Distributions As shown in the table above, the CPP Library implements the PDF and CDF for the univariate, bivariate and trivariate standard Normal distributions. We use the standard Normal (mean of 0, standard deviation of 1) since intrinsic functions are limited to 20 arguments. The functions for the univariate case are included as convenient examples and should give results (nearly) identical to the functions pdfNormal and cdfNormal from the stochastic library. For the multivariate cases, the implementation is based on TVPACK from Alan Genz, with some modifications to allow for proper computation of derivatives. Note that we chose to implement the functions taking correlation coefficients as arguments, not a covariance matrix. The conversion from a covariance matrix to correlation coefficients is straightforward. The following R code describes this conversion. Here the package mnormt is used that computes the multivariate CDF with similar code to Genz:

```r
# start with a mean mu and variance-covariance matrix S1
x <- c(1.0, 3.0, 0.3)  
mu <- c(0.0, 1.0, -1.0)  
S1 <- matrix(c(0.0, 1.0, 1.5, 1.5, 1.0, 0.5, 1.5, 1.5, 9.0), nrow=3, ncol=3)  
v1 <- pmnorm(x=x, mean=mu, varcov=S1)  
  # convert to std normal with 3 correlation coeffs
R <- cov2cor(S1)  
sd <- sqrt(diag(S1))  
xn <- (x-mu) / sd  
v2 <- pmnorm(x=xn, mean=0, varcov=R)
```

Note that for the bivariate case there is one correlation coefficient \( r \). The CDF implementation is not quite accurate to machine precision, it has 14 or 15 digits of accuracy. The trivariate case includes 3 correlation coefficients, the 3 off-diagonal elements from the lower trangle of \( R \) above. The accuracy of the CDF depends on the inputs: it is higher when the correlation is nearly zero and lower as the condition number of \( R \) increases. Typically, an accuracy of \( 10^{-11} \) is all that can be achieved. In both multivariate cases, we recommend to avoid evaluating at or near points where the correlation matrix is degenerate. At nearly degenerate points, the accuracy of the distribution and density functions suffers. As the correlation matrix becomes degenerate, the distribution becomes degenerate too.

4.47.4.3 Remark: Stateful Libraries

While GAMS intrinsic functions are stateless, users may implement stateful extrinsic functions, i.e., functions that have some memory. There are two ways to achieve stateful extrinsic functions:

1. Library initialization (LibInit): at initialization time, the function library reads some data that is required to evaluate the provided functions. An example is the Piecewise Polynomial Library.

2. Previous function calls: function calls that alter the execution of successive function calls. An example is the function SetMode from the Trigonometric Library.

Attention

Altering the state of an extrinsic function library by function evaluation calls is problematic, since different parts of the GAMS system potentially use different instances of the function library.

For example, consider that the function SetMode of the Trigonometric Library is called via SetMode(1) before a solve statement. Unless option solvelink is set to 5, the solver will run in a separate process with a new instance of the function library and therefore will use the default mode, which is zero. Further, if solvelink is set to zero, the GAMS process will terminate in order to execute the solve statement and will restart a new GAMS process after the solve. The restarted GAMS process will load a fresh instance of the extrinsic function library, which has no memory of the value of mode from before the solve statement. This problem is demonstrated in the GAMS Test Library model [TRILIB04].

---
4.47.5 Extrinsic Functions vs. External Equations

In addition to extrinsic functions, GAMS offers another facility to include additional mathematical functions in GAMS: external equations. These equations are denoted by `equation type=x=`. A feasible solution for a model instance must satisfy all internal and external equations. External equations are introduced and discussed in chapter External Equations.

Similar to extrinsic functions, it is the users responsibility to provide routines that evaluates the external equation. Further, both facilities are especially pertinent to nonlinear models.

An overview of some characteristics of extrinsic functions and external equations is given in the following table:

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Extrinsic Function</th>
<th>External Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of arguments</td>
<td>20</td>
<td>No limit</td>
</tr>
<tr>
<td>Available in statements</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Debugging support</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Returns Hessian to solver</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Consider the following example, which demonstrates how an equation $z = \int_{x_1}^{x_2} x \, dx$ may be formulated using either an extrinsic function and an external equation:

* using an extrinsic function
  
  ```gams
  e1.. integralx(x1,x2) =e= z;
  ```

* using an external equation
  
  ```gams
  e1.. 1*x1 + 2*x2 + 3*z =x= 1;
  ```

Note that the function `integralx` is assumed to be a user-defined extrinsic function, probably implemented as $\text{integralx}(x_1, x_2) = \frac{1}{2}(x_2^2 - x_1^2)$.

Note further, that the integers 1 to 3 in the external equation are mapped to indices for variables that are used in external functions inside an external module. The right-hand side of the external equation denotes the external equation number. It is assumed that the user-defined external equation implements the function $(x_1, x_2, z) \mapsto \int_{x_1}^{x_2} x \, dx - z$.

As a simple example for the use of an extrinsic function in a statement, consider the following assignment, which sets the level of variable $y$ to the value of $(\int_0^2 x \, dx)^2$:

```gams
y.l = sqr(integralx(0,2));
```

4.48 External Equations

GAMS provides a number of built-in or intrinsic functions for use in equations. Still, the extremely diverse set of application areas in which GAMS is used can create demand for the addition of new and often sophisticated and specialized functions. There is a trade-off between satisfying these requests and avoiding complexity not needed by most users. The GAMS External Equations Facility provides one means for managing this trade-off, since it allows users to import functions from an external library to define equations in a GAMS model. However, these external libraries can currently only provide functionality for the evaluation of functions (incl. their first derivatives) in a point. Solvers that need to analyze the algebraic structure of the model instance are therefore not able to work with external equations. This includes the class of deterministic global solvers, see column "Global" in this table, while, for example, stochastic global solvers can work with external equations.
Both external equations and extrinsic functions aim to provide possibilities to extend GAMS by user-provided mathematical functions. However, there are fundamental differences in the use and implementation of both. For most situations, extrinsic functions should be preferred over external equations. See also Extrinsic Functions vs. External Equations.

Building external equation libraries requires the knowledge of a regular programming language (like C/C++, FORTRAN, ...) and experience with handling compilers and linkers to build dynamically linked libraries.

The external equation interface is not intended as a way to bypass some of the very useful model checking done by GAMS for models that are solved with NLP solvers. External equations are still assumed to be continuous with accurate and smooth first derivatives. The continuity assumption implies that external equations must have very low noise levels, considerably below the feasibility tolerance used by the solver. The assumption about accurate derivatives implies that derivatives must be computed more accurately than can be done with standard finite differences. If these assumptions are not satisfied, then there is no guarantee that the NLP solver can find a solution that has the mathematical properties of a local optimum, i.e., a solution that satisfies the Karush-Kuhn-Tucker conditions within the standard tolerances used by the solver.

In the following, connecting code written in FORTRAN, C, Delphi, or some other programming language to equations and variables in a GAMS model is described. These GAMS equations will be referred to as external equations and the compiled version of the programming routines will be referred to as the external module that defines the external functions. The form of the external module depends on the operating system that is used. The external module under Windows is a Dynamic Link Library (.dll) and the external module under Unix is a shared object (.so or .dylib). In principle, any language or system may be used to build the DLL or shared object that defines the external module, as long as the interface conventions are not changed.

The GAMS Test Library provides examples of external equations consisting of GAMS models and C, Delphi, Java, and FORTRAN code. For more details, see Section Examples in the GAMS Test Library.

The basic mechanism of external equations is to declare all the equations and variables using the usual GAMS syntax. The interpretation of the external equations is done in a special way. Instead of the usual semantic content, the external equations specify the mapping between the equation and variable names used in GAMS and the function and variable indices used in the external module. This mapping is described in Section Model Interface. The external module may be written in C, FORTRAN, or most other programming languages. Section Programming Interface describes the general definitions for an external module for C, Delphi, and FORTRAN from a programming language perspective. Note that the way the program is compiled and converted into an external module is system and compiler specific. The following Section Implementation gives detailed advice on various aspects of the implementation of the external module.

4.48.1 Examples in the GAMS Test Library

Model [TESTEXEQ] gives an overview of all examples in the GAMS Test Library and may be used to compile and run them. Note that the remainder of this chapter will reference examples that are listed in this model. Further, model [COMPLINK] may be used as a script to compile and link external equation libraries. Note that these models hardcore the path to the Java compiler and libraries and these paths will need to be adapted by the user when running the Java examples.

Observe that regardless of how external libraries are built, the examples (e.g. [EX1]) will by default solve a model without using external equations. To solve the example models with all kinds of different external equation libraries, they may be run with the argument...
Alternatively, only selected libraries may be used by using one or more of the following command line parameters:

--runall=1
--runC=1
--runC_cb=1
--runD=1
--runD_cb=1
--runF=1
--runF_cb=1
--runJ=1

4.48.2 Model Interface

4.48.2.1 External Equation Syntax

External equations that are used to specify the interface to the external module are declared in GAMS like any other equation. The syntax for the external equation definition statement is as follows:

```
eqn_name(index_list)[logical_condition(s)].. expression =x= expression ;
```

Note that the only difference to the usual equation definition is the use of the equation type =x=.

The equations defined by an external module are always interpreted as equality constraints with zero right-hand sides. Thus inequalities have to be converted to equalities by adding explicit slack variables, which will serve as additional external variables. A nonzero right-hand side need to be taken care of in the external equation implementation.

4.48.2.2 Mapping of external equations and variables to indices

Some mappings must be specified to link an external module to a GAMS model. External equations are assumed to be defined in terms of indices $i = 1...m$. These indices must be mapped to GAMS equation names. Similarly, the variables used inside the external functions are assumed to be defined in terms of indices $j = 1...n$. These indices must be mapped to GAMS variable names. Finally, the name of the external module must be specified. Note that GAMS solvers are typically designed for large models and rely on sparsity. The last part of the specification of a set of external equations is therefore the sparsity pattern of the external equations, i.e., which variables appear in which equations.

The value of the constant term of the external equation must be an integer, since the value of the constant maps the row of the GAMS equation to the index (in $1...m$) of the external equation. Several blocks of GAMS equations may be mapped to external equations using the =x= notation. The mapping between GAMS equations of type =x= and indices $1...m$ must be bijective (one-to-one). This means that two GAMS equations may not be mapped into the same external equation index and that there may not be any holes in the list of external equation indices. Although there may be any number of blocks of GAMS external equations, they must all map into and be implemented by one single external module.

The variable part of each external equation defines both the sparsity pattern of the external equation and the mapping from GAMS variables to the indices of the external variables. The variable part must be a sum of terms where each term is an integer times a variable. The existence of the term indicates that the variable involved is used in the external equation and that there is a corresponding derivative. The value of the coefficient defines the index of the external variable (in $1...n$) that the GAMS variable is mapped
to. For example, the term $5 \times Y$ indicates that the external equation depends on the GAMS variable $Y$ and that $Y$ is mapped to the 5th element in the vector of external variables. Clearly, if a variable appears in more than one external equation, then the value of its coefficient must be the same in each case.

Note that several blocks of GAMS variables may be used in external equations. In contrast to equations, where all rows in an equation block are either external or not, some columns in a variable block may be external while others are not. The mapping between GAMS variables that appear in equations of type $=x=$ and external variable indices $1...n$ must be bijective (one-to-one). This means that two GAMS columns may not be mapped into the same external variable index and that there may not be any holes in the list of external variable indices. Although there may be any number of blocks of GAMS variables mapped to external variables, they must all map into one single vector passed to the subroutine in the external module.

Observe that while some GAMS variables are external, there is no syntax provided to mark them as external variables. They may be used in non-external GAMS equations as well as external equations. Indeed, without this capability the model would be separable and the external equations and the functions they map to would be of little use.

Note

- As the coefficients and right-hand sides in the GAMS definition of external equations are interpreted as indices, users are not allowed to scale external equations and variables.
- External equations are treated in a special way, therefore the command line parameter and model attribute HoldFixed will not treat any fixed external variables as constants.

4.48.2.3 Name of external module

The name of the external module in which the external equations are implemented may be defined in a number of ways. By default, the external module is assumed to have the same name as the GAMS model with an extension that is operating system dependent. The extension is .dll for Windows, .dylib for MacOS X, and .so for any other Unix.

A custom name for the external module may be specified with a file statement. In this case the file name has to be listed as an additional item in the model statement. If the library extension is omitted in the file statement, GAMS will add the system-dependent extension automatically. This helps to make the model portable between different operating systems.

Consider the following simple example:

```plaintext
File myextfile / extern /;
Model mymodel / all, myextfile /;
```

When model `mymodel` is solved, GAMS will try to load the an external module file named `extern.so`, `extern.dylib`, or `extern.dll`, depending on the current operating system.

By default, the external module is assumed to be located in the directory external_equations in the GAMS standard locations or in the directory from which GAMS is called. A different location may be specified with an added path in the file statement.
### 4.48.3 Programming Interface

This section discusses C, Delphi, and FORTRAN interfaces to the GAMS external equations facility.

The external equation module need to provide a function called `GEFUNC`. The beginning of the external equation module typically looks as follows:

**C:**
```c
#define GEEXPORT
#include "geheader.h"
GE_API int GE_CALLCONV gefunc(int* icntr, double* x, double* f, double* d, msgcb, t msgcb)
```

The header file `geheader.h` can be found in the `testlib_ml` subdirectory of the GAMS distribution. It defines `GE_API` and `GE_CALLCONV` and the signature of the function `gefunc`. `GE_API` is used to indicate to the compiler whether the function should be exported or imported. Due to defining `GE_EXPORT` before including `geheader.h`, `GE_API` is defined such that the function will be marked for export (`_declspec(dllexport)` on Windows and `_visibility_("default")` with GCC). Further, `GE_CALLCONV` indicates the calling convention that should be used on Windows. Currently, this is defined to be `_stdcall`. On other operating systems, it is empty.

**FORTRAN:**
```fortran
Integer Function gefunc (icntr, x, f, d, msgcb)
C Control Buffer:
   Integer icntr(*)
C Numerical Input and Output:
   Double Precision x(*), f, d(*)
C Message Callback Routine
   External msgcb
```

**Delphi:**
```delphi
uses geheader_d;
Function GeFunc(var Icntr: ticntr;
    var x: tarray;
    var F: double;
    var D: tarray;
    MsgFunc: tMsgCallBack): integer; stdcall;
```

The unit file `geheader_d.pas` can be found in the `testlib_ml` subdirectory of the GAMS distribution.

In the following, the arguments of `GEFUNC` are described in detail.

#### 4.48.3.1 Control vector `icntr`

The array `icntr` is a control vector that is used to pack and communicate control information between GAMS and the external module. Some helpful definitions to work with the `icntr` array are provided by the files `geheader.h` (C), `geheader_d.pas` (Delphi), and `gehelper.f90` (Fortran 90). The array elements are the following:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>icntr[I_Length]</code></td>
<td>Holds the length of array <code>icntr</code> in number of elements. This is provided by GAMS.</td>
</tr>
<tr>
<td><code>icntr[I_Neq]</code></td>
<td>Number of external equation rows seen in the GAMS model. This is provided by GAMS.</td>
</tr>
<tr>
<td><code>icntr[I_Nvar]</code></td>
<td>Number of external variables seen in the GAMS model. This is provided by GAMS.</td>
</tr>
<tr>
<td><code>icntr[I_Nz]</code></td>
<td>Number of nonzero derivatives or Jacobian elements seen in the GAMS model. This is provided by GAMS.</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| icntr[I_Mode] | Current mode of operation. This is provided by GAMS. The following values are possible:  
|              | **DOINIT**: Initialize. This will be the first call of GEFUNC, where initializations needed by the external module may be performed.  
|              | **DOTERM**: Terminate. This will be the last call of GEFUNC, where cleanup tasks needed by the external module may be performed.  
|              | **DOEVAL**: Function evaluation. External equations should be evaluated.  
|              | **DOCONSTDERIV**: Constant Derivatives. Information about constant derivatives should be provided.  
|              | **DOHVPROD**: Hessian-Vector product. The product between the Hessian of an external equation and a vector should be computed. See  
|              | Second Derivatives: Hessian times Vector for details.  |
| icntr[I_Eqno] | Index of the external equation to be evaluated during this call to GEFUNC. This is provided by GAMS in function evaluation mode (icntr[I_Mode]=DOEVAL) and is a number between 1 and icntr[I_Neq], inclusive. Note that the external equation interface allows to communicate information about only one function at a time.  |
| icntr[I_Dofunc] | Flag whether function value should be computed. icntr[I_Dofunc] is provided by GAMS in function evaluation mode (icntr[I_Mode]=DOEVAL). If set to 1, then GEFUNC must return the numerical value of the function indexed by icntr[I_Eqno] in the scalar f.  |
| icntr[I_Dodrv] | Flag whether derivative should be computed. icntr[I_Dodrv] is provided by GAMS in function evaluation mode (icntr[I_Mode]=DOEVAL). If set to 1, then GEFUNC must return the numerical values of the derivatives of the function indexed by icntr[I_Eqno] in the array d.  |
| icntr[I_Newpt] | Flag for new point. icntr[I_Newpt] is provided by GAMS in function evaluation mode (icntr[I_Mode]=DOEVAL). If set to 1, then the point x may be different from the previous call of GEFUNC. If set to 0, then x will not have changed since the previous call.  |
| icntr[I_Debug] | If icntr[I_Debug] is set to a nonzero value by the external equation module, then the functions GEstat and GElog will write all strings to a file called debugext.txt and flush the buffer immediately after writing. The string debugger may be used when a shared object crashes before GAMS has had an opportunity to display the messages. In FORTRAN, the string debugger will use FORTRAN unit icntr[I_Debug]. For more details see Section Message Output.  |
| icntr[I_Getfil] | Flag to request the name of a special directory or file from GAMS. The following values are possible:  
|              | I_Scr: Scratch directory,  
|              | I_Wrk: Working directory,  
|              | I_Sys: GAMS system directory,  
|              | I_Cntr: Control file.  
|              | For more information, see Section Communicating Data to the External Module via Files.  |
| icntr[I_Smode] | Flag for string mode. This is provided by GAMS. For details see Section Communicating Data to the External Module via Files.  |
| icntr[I_ConstDeriv] | Number of constant derivatives. Specifying this number during initialization is optional. For details see Section Constant Derivatives below.  |
| icntr[I_HVProd] | Indicator for use of Hessian-Vector product for second order derivatives. This entry is optional. For details see Section Second Derivatives: Hessian times Vector below.  |

Observe that FORTRAN programmers will have to replace the square brackets [] with parentheses ().
4.48.3.2 Evaluation point x

Argument x is an array with icntr[I_Nvar] elements and is provided by GAMS if GEFUNC is called in function evaluation mode (icntr[I_Mode] = DOEVAL). The individual elements of x will always be between the variable bounds defined in the GAMS model. During initialization and termination calls, x is not defined and the external module must not reference x. C programmers should index this array starting at zero, i.e., the first external variable is referenced as x[0].

4.48.3.3 Function value f

If icntr[I_Mode] = DOEVAL and icntr[I_Dofunc] = 1, then the external module must return the value of the external equation icntr[I_Eqno] in the scalar f. During initialization and termination calls, f must not be referenced.

4.48.3.4 Derivative vector d

If icntr[I_Mode] = DOEVAL and icntr[I_Dodrv] = 1, then the external module must return the values of the derivatives of external function icntr[I_Eqno] with respect to all variables in the array d. The derivative with respect to variable x[i] is returned in d[i]. It is sufficient to set only those positions in d that correspond to variables actually appearing in equation icntr[I_Eqno]. Other positions are not being used by GAMS and may be left undefined. During initialization and termination calls, d must not be referenced.

4.48.3.5 Message callback msgcb

This argument is the address of a message callback routine that can be used to write messages to the status and/or log files of the GAMS process. Its type definition in C is as follows:

```c
typedef void (GENCALLCONV * msgcb_t) (const int* mode, const int* nchars, const char* buf, int len);
```

The argument mode is used to point to an integer which indicates where messages should be written to. This integer can be set to the following values:

- LOGFILE (1): Write the message to the log file only.
- STAFILE (2): Write the message to the status file only.
- LOGFILE | STAFILE (3): Write the message to both the log file and the status file. Observe that the symbol | denotes the bitwise logical OR in C.

The argument nchars points to an integer that specifies the number of bytes contained in the message (excluding the \0-terminator if there is one present). Thus, in C, nchars is typically set to strlen(buf). The argument buf is a pointer to the character array containing the message to be printed. Finally, len is the size or length of the string buf, thus it is typically the same as *nchars.

Calling the message callback msgcb from C is straightforward. Note that the arguments mode, nchars, and buf are all call-by-reference and that addresses, not values, must be used. However, the argument len is call-by-value and *nchars should be passed as its value.

If the implementation is done in Delphi or Visual Basic, observe that pointers of all types are 4-byte quantities on a 32bit system and 8-byte quantities on a 64bit system. Integers are 4 bytes.

Calling this routine from a FORTRAN environment is a bit more complicated due to the different ways that FORTRAN compilers handle strings. The Unix convention - at least the convention observed on all systems for which GAMS is built - is that strings are passed by reference. In addition, the length of the string is passed by value as a hidden 4-byte quantity appended to the end of the argument list. This is the reason for including len as the last argument in msgcb. The argument len facilitates making FORTRAN callbacks in a Unix environment like the following:

```fortran
character*(*) msgbuf
int nchars, charcount
nchars = charcount(msgbuf)
call MSGCB (mode, nchars, msgbuf)
```
4.48 External Equations

4.48.3.6 Return code

The function GEFUNC must return one of the following status codes:

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error occurred.</td>
</tr>
<tr>
<td>1</td>
<td>A function evaluation error was encountered. GAMS should not use the content of f and/or d, but GEFUNC has recovered from the error and is ready to be called at a new point. This status code should only be used in function evaluation mode (icntr[1_Mode]=DOEVAL).</td>
</tr>
<tr>
<td>2</td>
<td>Fatal error. If this value is returned during the initialization call, then GAMS should abort immediately. It may be returned by GEFUNC during the initial call if some initializations did not work correctly, or if some of the size values in icntr had unexpected values. It may also be returned during function evaluation mode (icntr[1_Mode]=DOEVAL) if the external module has experienced problems from which it cannot recover.</td>
</tr>
</tbody>
</table>

4.48.4 Implementation

After describing the function GEFUNC in Section Programming Interface above, this section offers some practical comments on implementing GEFUNC.

4.48.4.1 Compiling and Linking

The examples for GAMS external equations contain a set of GAMS models for compiling the code on various systems using various compilers. Note that the compiler and linker flags shown in these examples should be used to ensure that the modules conform to the interface standard. In addition, the appropriate include file (geheader.h, geheader_d.pas, gehelper.f90) should be used.

4.48.4.2 Initialization Mode

The initialization mode should always check whether the external equations have the expected size: icntr[1_Neq], icntr[1_Nvar] and icntr[1_Nz] have to be tested against fixed expected values or values derived from some external data set.

The initialization mode may be used for several purposes like allocating memory and initializing numerical information or mapping information needed by the function evaluations that will follow. Data can be computed or read from external data sources or it can be derived from calls to an external database. Note that data that is shared with GAMS may be written to a file from GAMS using the put statement and then read in GEFUNC. Note further, that users must close the put file with a putclose statement before the solve statement. Observe that memory used to hold information from one invocation of GEFUNC to the next should be static. For FORTRAN it should either be in a Common block or it should be included in a Save statement.

4.48.4.3 Termination Mode

The termination mode may be used to perform some clean-up tasks like computing statistics, closing files, and returning memory.
4.48.4.4 Evaluation Mode

The bulk of the computational work will usually be in evaluation mode. Observe that GEFUNC only works with one equation at a time. One of the reasons for this choice is that the addressing of derivatives becomes very simple: there is one derivative for each variable and they have the same index in d and x, respectively.

In some applications several functions are naturally evaluated together, for example, because all functions are computed in some joint integration routine. The icntr[I_Newpt] flag is included for these applications. Using this flag, an implementation could evaluate all functions using a common routine when icntr[I_Newpt] equals 1 and saves the function and derivative values. Additionally, it returns the values corresponding to equation icntr[I_Eqno]. In subsequent calls to GEFUNC, icntr[I_Newpt] will likely be zero and the function and derivative values can quickly be extracted from the previously computed (and saved) information.

4.48.4.5 Evaluation Errors

It is good modeling practice to add bounds to the variables in such a way that all nonlinear functions are defined for all values of the variables within the bounds. Most solvers will also guarantee that nonlinear functions are called only when all entries of the vector x are between the bounds. However, it may not be practical to add all the necessary bounds and the implementation of GEFUNC should therefore capture evaluation errors such as division by zero, taking the logarithm of non-positive numbers, overflow in exponentiation, etc. If an equation cannot be evaluated at the given point, function GEFUNC should simply let the solver know about this situation by returning the value 1. The solver may then be able to backtrack to a safe point and continue the optimization from there.

Attention

System-default or user-defined functions that handle evaluation errors (for example, the C library function matherr()) will sometimes not work in the same way inside a DLL or a shared object as they do in a self-contained program or a static library.

4.48.4.6 Message Output

External modules can send messages to the GAMS status file (usually the listing file) and the GAMS log file (usually the screen). Messages to be included in the GAMS status file can be buffered using the GEstat utility routine described below and messages to be included in the GAMS log file can be buffered using the GElog utility routine. Note that it is not possible to open these files for writing in the external module since GAMS or the solver process controls them.

Moreover, messages may be sent to both the status and log file without buffering, using the message callback msgcb. This removes the limit imposed by the size of the message buffer and may also make debugging somewhat simpler, since there is no need to worry about messages that never got flushed from the buffer. As it may be difficult or impossible to use the message callback from some environments, both the buffered and unbuffered techniques are provided.

Note that the two techniques for sending messages (buffered via GEstat and GElog and unbuffered via the message callback msgcb) are complementary. Either one or the other may be used, but if both are used in the same external module, the buffered messages will be printed after the unbuffered messages.
4.48.4.6.1 GEstat: The Utility Routine for Writing Messages to the Status File

GEstat is provided in the appropriate include file (Fortran 90: gehelper.f90, C: geheader.h, Delphi: geheader_d.pas). It is used to communicate messages that should be written to the GAMS status file. The function definition follows:

FORTRAN:

```fortran
subroutine gestat (icntr, line)
C Control Buffer:
    integer icntr(*)
C input parameters:
    character(*) line
C:
    void GEstat(int* icntr, char* line)
Delphi:
    Procedure GeStat(var icntr: ticntr; const s: shortstring);
```

Note that the first argument, `icntr`, must be passed through from the call of the function GEFUNC. The content of the argument `line` (or `s` in Delphi) is packed into the control buffer as one line. When GEFUNC returns, the content of the buffer will be written to the GAMS status file. GEstat may be called several times, each time with one line. Observe that `line` should not be longer than 132 characters and the overall amount of information written in one call to GEFUNC should not exceed 1000 characters. Further, `line` should not contain any special characters such as new-line or tab.

In practice, GEstat is often used with calls like the following:

FORTRAN:

```fortran
call GESTAT (icntr, ' ')
call GESTAT (icntr, '**** External module based on abc.for')
C:
GEstat (icntr, ' ')
GEstat (icntr, '**** External module based on abc.c')
Delphi:
gestat(icntr,' ');
gestat(icntr,'**** External module based on abc.dpr');
```

4.48.4.6.2 GElog: The Utility Routine for Writing Messages to the Log File

Like GEstat, GElog is provided in the appropriate include file. It is used to communicate messages that should be written to the GAMS log file. Note that by default, the log file is the screen. Alternatively, log may be written to a file that is specified with the GAMS command line parameter LogFile. The function definition of GElog follows:

FORTRAN:

```fortran
subroutine gelog ( Icntr, line )
C Control Buffer:
    integer Icntr(*)
C input parameters:
    character(*) line
C:
    void GElog(int* icntr, char* line)
Delphi:
    Procedure GeLog(var icntr: ticntr; const s: shortstring);
```

Note that GElog behaves exactly like GEstat, with the status file replaced by the log file. The content of `line` is written to a buffer that in turn is written to the log file when GEFUNC returns.

Observe that it is not possible to write directly to the screen with some combinations of operating system and compiler. This may also depend on the options or flags that are used to build the external module.

Attention

On some systems writing directly to the screen may cause the external module to crash. Therefore, it is advised not to write to the screen as a method for debugging, unless it is clear that it works. Otherwise the module may continue to crash because of the debugging statements after all other errors have been removed. Writing to a file and flushing the buffer is recommended as a safe alternative.
4.48.4.7 Communicating Data to the External Module via Files

Some external equations will need data from the GAMS program. This data may be passed on via one or more files written using put statements. Usually, such put files will be written in the current directory and the external module will look for them in the current directory. However, if users need to run multiple copies of the same model at the same time, data files should be written in the GAMS scratch directory and the external module should be directed to look for the data files in the scratch directory.

Note that a put file may be defined to be located in the scratch directory with the following file statement in the GAMS model:

File f / '%gams.scrdir%filename' /;

Observe that if the extension .dat is used, GAMS will remove the file from the scratch directory after the run. If another extension is used and the file is not deleted, GAMS will complain about an unexpected file when it cleans up after the run. The external module can receive the name of the scratch directory from GAMS during initialization by setting icntr[I_Getfil] to I_scr and returning immediately. GAMS will then store the name of the scratch directory and length of the name in the communication buffer and call GEFUNC in initialization mode again. Note that GEFUNC will now be called with the sub-mode icntr[I_Smode] set to I_Scr. Then the name may be extracted using the following FORTRAN call:

call GENAME(Icntr, Scrlen, Scrdir)

Here, Scrdir (declared as character(255)) will receive the scratch directory and Scrlen (declared as integer) will receive the actual length of Scrdir. In C, the call takes the following form:

char scratchDir[255];
int scratchDirLen;
scratchDirLen = GEname(icntr, scratchDir, sizeof(scratchDir));

Here the routine will return the number or characters transferred to the buffer scratchDir if successful and the value -1 otherwise. If there is space, a terminating '\0'-byte will be written to scratchDir. If the value returned is equal to sizeof(scratchDir), then the string returned will not be '\0'-terminated and may have been truncated as well.

Observe that it is possible to get other directory or file names by specifying other values in icntr[I_Getfil]. After setting this flag, GEFUNC must always return immediately.

For examples, see models [EX5] and [EXMCP3] and their respective FORTRAN and C source files.

4.48.4.8 Constant Derivatives

Some solvers, like the CONOPT solvers, can take advantage of the knowledge about constant derivatives in equations, which are a result of linear terms. This can be especially useful if an external equation represents an equation like \( Y = f(X) \), where \( Y \) is unbounded, since variable \( Y \) can then be substituted by \( f(X) \).

However, with the external module interface as described so far, the solver cannot know which variables appear linearly in the external equations. An optional extension allows to indicate that some of the relationships are linear. This can be activated by returning the number of constant derivatives in icntr[I_ConstDeriv] during the call of GEFUNC in initialization mode.

If the solver can use this information (not all solvers will), then GEFUNC will be called again repetitively with icntr[I_Mode] set to DOCONSTDERIV, once for each external equation, with its index specified as usual in icntr[I_Eqno]. For each of these calls, values of all constant derivatives must be specified in the array d. The remaining elements of d, both those corresponding to varying derivatives and to zeros, must be left untouched. These special calls will take place after the initialization call and before the first function evaluation call. Note that in these calls other flags like icntr[I_Dofunc] and icntr[I_Dodrv] and the array x will not be defined.

For an example, see model [EX4X] with the corresponding Fortran 90 and C source files ex4xf_cb.f90 and ex4xc_cb.c, respectively. It is instructive to compare these files to the corresponding files without constant derivatives: ex4f_cb.f90 and ex4c_cb.c.
4.48 External Equations

4.48.4.9 Second Derivatives: Hessian times Vector

External modules cannot provide a solver with the Hessian matrix of external equations. However, some solvers have particular options for internally approximating the Hessian. For example, see the hessian_approximation option for IPOPT or hessopt for KNITRO. Further, the solver CONOPT can take advantage of second order information in the form of the product Hessian matrix \( \nabla^2 f(x) \) times a vector \( v \). This special form can be used for external equations by setting \( \text{icntr}[\text{HVprod}] \) to 1 during the call of GEFUNC in initialization mode.

If the solver can use this information (not all solvers will), then GEFUNC may be called with \( \text{icntr}[\text{Mode}] \) set to DOHVPROD to request this operation. \( \text{icntr}[\text{Eqno}] \) will hold the equation number and the array \( x \) will hold the values of the variables \( (x) \) in its first \( \text{icntr}[\text{NVar}] \) positions and a vector \( v \) in the following \( \text{icntr}[\text{Nvar}] \) positions. GEFUNC should evaluate and return \( d = \nabla^2 f(x) v \) for the particular external equation \( f \) at the particular point \( x \). Note that \( d \) (which is otherwise used for the derivative vector) will have been initialized to zero by GAMS.

\( \nabla^2 f(x) v \) will often be needed for several vectors \( v \) at the same point \( x \). Therefore, \( \text{icntr}[\text{Newpt}] \) will be used to indicate changes in \( x \) in the usual way.

Note that model [EX1X] with the corresponding Fortran 90 source file shows how to use both constant and second derivatives.

4.48.4.10 Debugging

Implementing external equations brings a number of new potential error sources which GAMS cannot protect against as well as with pure GAMS models. For example, the argument lists in the C or FORTRAN code may be incorrect or the linking process may create an incorrect external module. There is little GAMS can do to help users with this type of errors. It is recommended to carefully follow the examples and output debug messages during the setup calls, for example using the utility routines GEstat and GElog.

Once the overall setup is correct and GAMS can establish proper communication with the external module, there may still be numerical errors where the function values and the derivatives do not match.

Note that the solver CONOPT will by default call its Function and Derivative Debugger in the initial point, if a model has any external equations. The debugger will check that the functions only depend on the variables that are defined in the sparsity pattern and that derivatives computed by numerical perturbation are consistent with the derivatives computed by the external module. If an error is found, CONOPT will stop immediately with an appropriate message. For examples, see the GAMS Test Library models [ER1], [ER2], and [ER3], which illustrate different types of errors. The respective error messages will appear if CONOPT is used as the NLP solver. Note that comments about the errors may be found in the C or FORTRAN source code.

Observe that several types of errors cannot be detected. Derivatives that are computed in the external module and are returned in positions that were not defined in the sparsity pattern in GAMS will be filtered out by the interface and will therefore not be detected. Similarly, derivatives that should be computed but are forgotten, may inherit values from the same derivatives in another equation computed earlier. Finally, fixed variables cannot be perturbed, thus errors related to these variables will usually not be detected.
4.49 GAMS Return Codes

The most convenient way to embed a GAMS program in a different program (e.g. C#, Java, Python, ...) is the object orient API to GAMS. A much simpler but less powerful way is to make a call to the GAMS executable (gams.exe (Windows) or gams (Unix)) with appropriate parameters from your program. Different languages and operating systems have different ways of accomplishing such a task. A common way to communicate a small piece of information from the GAMS program to the caller program is the exit status or return code (see e.g. https://en.wikipedia.org/wiki/Exit_status). GAMS return codes allow the caller to get some information about the status of the finished GAMS job. Note that return codes do not provide information about a model inside the GAMS job: the model may have been infeasible or may have failed in another way while the return code says all is fine. In fact, there may be multiple solves in a GAMS job, so even conceptually it is not possible to return solution status codes in the return code. The user cannot explicitly set the return code but can trigger action (e.g. abort; stop;) that result in a specific return code (here execution error (3)).

Note
In general, the value of zero for return codes denotes success and non-zero values denote failure.

We first demonstrate how to access return codes from within GAMS with a self-explanatory example and then list all return codes. GAMS has the ability to call other programs via the $call (compile time) and execute (execution time) commands. Naturally, GAMS can call GAMS in a recursive fashion. There are different methods to access the return code of such a sub-GAMS job:

```gams
$onecho > x.gms
set a /1,2,3/;
$offecho
* Compile time access inside to return values
* Example for non-zero return code
$call gams x.gms lo=0 this_causes_a_parameter_error_with_return_code_6=1 > %system.nullfile%
* Check the return code via if [not] errorlevel n
$if not errorlevel 1 $abort expect a errorlevel >= 1
* Access the return code as function value of function errorLevel
$eval MYERRORLEVEL errorLevel
$log %MYERRORLEVEL%
* Example for zero return code
$call gams x.gms lo=0 > %system.nullfile%
* Check the return code via if [not] errorlevel n
$if errorlevel 1 $abort expect a errorlevel <= 0
* Access the return code as function value of function errorLevel
$eval MYERRORLEVEL errorLevel
$log %MYERRORLEVEL%
* Runtime
* Example for non-zero return code
execute 'gams x.gms lo=0 this_causes_a_parameter_error_with_return_code_6=1 > %system.nullfile%';
* Access the return code as function value of function errorLevel
```

scalar myerrorlevel;
myerrorlevel = errorlevel;
display 'should be 6:', myerrorlevel;

* Example for zero return code
execute 'gams x.gms lo=0 > %system.nullfile%';

* Access the return code as function value of function errorLevel
myerrorlevel = errorlevel;
display 'should be 0:', myerrorlevel;

Command line interpreters or shells are a powerful way for job control and can naturally also run GAMS jobs. Here are two examples that demonstrate how to access (actually echo) the return code from GAMS in such environments:

Unix shell (e.g. bash):

```
$ gams mymodel ... 
$ echo $? 
```

Here $? is the environment variable that stores the return code from the last run.

Windows (cmd.exe):

```
C:\tmp> gams mymodel ... 
C:\tmp> echo %errorlevel%
```

Here %errorlevel% is the environment variable that stores the return code from the last run.

Note

On UNIX, return codes are treated modulo 256, so the return code 400 will be 144 on Unix. The return code modulo 256 is given in parenthesis in the table, if different from the return code.

### 4.49.1 List of the Error/Return Codes

The following table gives the list of the GAMS return codes:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal return</td>
</tr>
<tr>
<td>1</td>
<td>Solver is to be called, the system should never return this number</td>
</tr>
<tr>
<td>2</td>
<td>There was a compilation error</td>
</tr>
<tr>
<td>3</td>
<td>There was an execution error</td>
</tr>
<tr>
<td>4</td>
<td>System limits were reached</td>
</tr>
<tr>
<td>5</td>
<td>There was a file error</td>
</tr>
<tr>
<td>6</td>
<td>There was a parameter error</td>
</tr>
<tr>
<td>7</td>
<td>There was a licensing error</td>
</tr>
<tr>
<td>8</td>
<td>There was a GAMS system error</td>
</tr>
<tr>
<td>9</td>
<td>GAMS could not be started</td>
</tr>
<tr>
<td>10</td>
<td>Out of memory</td>
</tr>
<tr>
<td>Return Code</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>11</td>
<td>Out of disk</td>
</tr>
<tr>
<td>109</td>
<td>Could not create process/scratch directory</td>
</tr>
<tr>
<td>110</td>
<td>Too many process/scratch directories</td>
</tr>
<tr>
<td>112</td>
<td>Could not delete the process/scratch directory</td>
</tr>
<tr>
<td>113</td>
<td>Could not write the script <strong>gamsnext</strong></td>
</tr>
<tr>
<td>114</td>
<td>Could not write the <strong>parameter</strong> file</td>
</tr>
<tr>
<td>115</td>
<td>Could not read environment variable</td>
</tr>
<tr>
<td>400 (144)</td>
<td>Could not spawn the GAMS language compiler (<strong>gamscmex</strong>)</td>
</tr>
<tr>
<td>401 (145)</td>
<td>Current directory (<strong>curdir</strong>) does not exist</td>
</tr>
<tr>
<td>402 (146)</td>
<td>Cannot set current directory (<strong>curdir</strong>)</td>
</tr>
<tr>
<td>404 (148)</td>
<td>Blank in system directory (UNIX only)</td>
</tr>
<tr>
<td>405 (149)</td>
<td>Blank in current directory (UNIX only)</td>
</tr>
<tr>
<td>406 (150)</td>
<td>Blank in scratch extension (<strong>scrext</strong>)</td>
</tr>
<tr>
<td>407 (151)</td>
<td>Unexpected <strong>cmexRC</strong></td>
</tr>
<tr>
<td>408 (152)</td>
<td>Could not find the process directory (<strong>procdir</strong>)</td>
</tr>
<tr>
<td>409 (153)</td>
<td>CMEX library not be found (experimental)</td>
</tr>
<tr>
<td>410 (154)</td>
<td>Entry point in CMEX library could not be found (experimental)</td>
</tr>
<tr>
<td>411 (155)</td>
<td>Blank in process directory (UNIX only)</td>
</tr>
<tr>
<td>412 (156)</td>
<td>Blank in scratch directory (UNIX only)</td>
</tr>
<tr>
<td>909 (141)</td>
<td>Cannot add path / unknown UNIX environment / cannot set environment variable</td>
</tr>
<tr>
<td>1000 (232)</td>
<td>Driver error: incorrect command line parameters for <strong>gams</strong></td>
</tr>
<tr>
<td>2000 (208)</td>
<td>Driver error: internal error: cannot install interrupt handler</td>
</tr>
<tr>
<td>3000 (184)</td>
<td>Driver error: problems getting current directory</td>
</tr>
<tr>
<td>4000 (160)</td>
<td>Driver error: internal error: GAMS compile and execute module not found</td>
</tr>
<tr>
<td>5000 (126)</td>
<td>Driver error: internal error: cannot load option handling library</td>
</tr>
</tbody>
</table>

Note that error 3000 is sometimes caused by specifying the current directory in Microsoft UNC format. The return codes smaller than 100 come from the GAMS compiler and execution system (**gamscmex**) while the codes above 100 come from the GAMS driver program (**gams**).

### 4.50 GAMS Data eXchange (GDX)

This document describes the **GDX** (GAMS Data eXchange) facilities available in GAMS. The GDX facilities provide basic functionalities for exchanging GAMS data such as read and write. In addition to these facilities, there are a number of **GDX Tools** for exchanging data between GAMS and other data sources as well as for performing specific operations on a GDX file.

A GDX file is a file that stores the values of one or more GAMS symbols such as sets, parameters variables and equations. GDX files can be used to prepare data for a GAMS model, present results of a GAMS model, store results of the same model using different parameters etc. A GDX file does not store a model formulation or executable statements. Among other usages a GDX file can also be used to prepare data for a GAMS model, pass results of a GAMS model into different programs, and pass results into GAMS from different programs.

GDX files are binary files that are portable between different platforms. They are written using the byte ordering native to the hardware platform they are created on, but can be read on a platform using a different byte ordering. See also **General notes on GDX files**.
4.50.1 Reading a GDX file

Reading a GDX file into a GAMS model can be done during the compile phase or the execution phase.

4.50.1.1 Compile Phase

During compilation, we can use Dollar Control Options to read data from a GDX file. Reading during the compile phase also allows us to define the elements of a set and the subsequent use of such a set as a domain. The following Dollar Control Options are available for reading data from a GDX file into GAMS during compilation of a GAMS model:

- `$gdxin`
- `$load`
- `$loaddc`
- `$loadm`, `$loaddr`, `$loaddcm`, and `$loaddcr`
- `$loadidx`

4.50.1.1.1 `$gdxin` The `$gdxin` command is used in a sequence either to load specified items from a GDX file or to close the specified GDX file. The statement with `$gdxin` can be used in one of the following forms:

$$
gdxin \text{ file\_name} \\
\text{gdxin}
$$

where

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_name</td>
<td>Specify the name of the GDX file (with or without the extension .gdx; read from the current working directory)</td>
</tr>
<tr>
<td></td>
<td>(no file_name) closes the GDX file</td>
</tr>
</tbody>
</table>

See Example 1 - Reading a GDX File and Example 2 - Reading a GDX File on how to use `$gdxin`.

4.50.1.1.2 `$load` The `$load` command loads specified items from a GDX file. The statement containing `$load` is preceded and succeeded by the `$gdxin` statements where

- the preceding `$gdxin` specifies the GDX file name and opens the file.
- the succeeding `$gdxin` closes the GDX file.

The statement with `$load` command can be used in one of the following forms:
$load
$load id=*
$load id1 id2 ... idn
$load id1=gdxid1 id2=gdxid2
$load id1<=gdxid1 id2<=gdxid2.dim3

where:

<table>
<thead>
<tr>
<th>Parameter(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(no identifiers)</td>
<td>Reads all symbols from the gdx file and writes to the listing file</td>
</tr>
<tr>
<td>id=*</td>
<td>Loads all unique elements from the gdx file into set id</td>
</tr>
<tr>
<td>id1 id2 ... idn</td>
<td>Read GAMS symbols id1, id2, ... idn from the GDX file</td>
</tr>
<tr>
<td>id1=gdxid1 id2=gdxid2</td>
<td>Read GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2 in the GDX file</td>
</tr>
<tr>
<td>id1&lt;gdxid1 id2&lt;gdxid2</td>
<td>Reads GAMS one dimensional set id1 and id2 from the GDX parameter or set gdxid1 and gdxid2. Without the dimN suffix, GAMS tries to match the domains from the right (&lt;). If no domain information is available for the GDX symbol, the dimN suffix determines the index position that should be read into the GAMS set. For more details see the Example 4 - Reading a GDX File.</td>
</tr>
<tr>
<td>id1&lt;=gdxid1 id2&lt;=gdxid2</td>
<td>Reads GAMS one dimensional set id1 and id2 from the GDX parameter or set gdxid1 and gdxid2. Without the dimN suffix, GAMS tries to match the domains from the left (&lt;=). If no domain information is available for the GDX symbol, the dimN suffix determines the index position that should be read into the GAMS set. For more details see the Example 4 - Reading a GDX File.</td>
</tr>
</tbody>
</table>

Note

- One can load the level values of a variable into a parameter of the same dimension using the syntax parametername=var.l as follows

  parameter storexlevel(i,j);
  $gdxin tran2
  $load storexlevel=x.l
  $gdxin
  display storexlevel;

- Loading the level values for a variable into the same variable (x=x.l) works but loads everything including bounds, scales, marginals and levels.

See Example 1 - Reading a GDX File and Example 2 - Reading a GDX File on how to use $load.

4.50.1.1.3 $loaddc  The $loaddc command lists all symbols in the GDX file and will cause a compilation error when the data read causes a domain violation. In contrast the $load command simply ignores elements that are not in the domain. See also Compile Phase Reading Data using $load.

The statement with $loaddc can be used in one of the following forms:
$loaddc
$loaddc id=*  
$loaddc id1 id2 ... idn  
$loaddc id1=gdxid1 id2=gdxid2  
$loaddc id1<=gdxid1 id2<=gdxid2.dim3

where:

<table>

</tbody>
</table>

See Example 4 - Reading a GDX File on how to use $loaddc.

4.50.1.1.4 $loadm, $loadr, $loaddcm, and $loaddcr  The $loadm, $loadr, $loaddcm, and $loaddcr are additional forms of the $load and $loaddc directives. The M indicates a merge and the R indicates a full replacement.

The statements with $loadm can be used in one of the following forms:

$loadm
$loadm id1 id2 ... idn  
$loadm id1=gdxid1 id2=gdxid2  
$loadm id1<gdxid1 id2<gdxid2.dim3  
$loadm id1<=gdxid1 id2<=gdxid2.dim3

The statement with $loadr can be used in one of the following forms:

$loadr
$loadr id1 id2 ... idn  
$loadr id1=gdxid1 id2=gdxid2  
$loadr id1<gdxid1 id2<gdxid2.dim3  
$loadr id1<=gdxid1 id2<=gdxid2.dim3
The statement with \$loaddcm can be used in one of the following forms:

\$loaddcm
\$loaddcm id1 id2 ... idn
\$loaddcm id1=gdxid1 id2=gdxid2
\$loaddcm id1<gdxid1 id2<gdxid2.dim3
\$loaddcm id1<=gdxid1 id2<=gdxid2.dim3

The statement with \$loaddcr can be used in one of the following forms:

\$loaddcr
\$loaddcr id1 id2 ... idn
\$loaddcr id1=gdxid1 id2=gdxid2
\$loaddcr id1<gdxid1 id2<gdxid2.dim3
\$loaddcr id1<=gdxid1 id2<=gdxid2.dim3

where:

</tr>
</tbody>
</table>

See Example 4 - Reading a GDX File and \[load8\] examples on how to use \$loadm and \$loaddcm.

4.50.1.1.5 \$loadidx The command \$loadidx read GAMS symbols from the GDX file. Each symbol should have been written using an indexed write.

The statement with \$loadidx can be used in one of the following forms:

\$loadidx
\$loadidx id1 id2 ... idn
\$loadidx id1=gdxid1 id2=gdxid2

where:
4.50 GAMS Data eXchange (GDX)

<table>

</tr>
</tbody>
</table>

See [ldidx01] example on how to use $loadidx.

4.50.1.2 Execution Phase

When reading data from a GDX file during execution phase the data in the GDX file will be the data present in the GDX file at the time that the statement is executed. The results of all prior calculations and the most recent solve for any model will be reflected. The statements to read data from a GDX file during execution phase are:

- execute_load
- execute_loaddc
- execute_loadpoint

4.50.1.2.1 execute_load The `execute_load` statement acts like an assignment statement, except that it does not merge the data read with the current data; it is a full replacement. The same restrictions apply as in an assignment statement: we cannot assign to a set that is used as a domain, or to a set used as a loop control.

Sets defining domains cannot be loaded. However sets that are subsets of existing sets and do not define new elements can be loaded at execution time (Domain defining sets can be loaded can at compile time using $load).

The statement with `execute_load` can be used in one of the following forms:

```plaintext
execute_load 'file_name', id1, id2, ..., idn ;
execute_load 'file_name', id1=gdxid1, id2=gdxid2, ..., id2=gdxid2 ;
execute_load 'file_name', setid=* ;
```

where

<table>
<thead>
<tr>
<th>Parameter(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_name</td>
<td>Specify the name of the GDX file (with or without the extension .gdx; read from the current working directory)</td>
</tr>
<tr>
<td>id1, id2, ..., idn</td>
<td>Read GAMS symbols id1, id2, ..., idn from the GDX file; note that commas are optional</td>
</tr>
<tr>
<td>id1=gdxid1, id2=gdxid2, ..., id2=gdxid2</td>
<td>Read GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2, ..., gdxidn in the GDX file; note that commas are optional</td>
</tr>
</tbody>
</table>
| setid=* | Allow to load the universe of labels from a GDX file into a set. Note, that only labels
Note

- items must be declared with Set, Parameter, Scalar, Variable or Equation statements before
the execute_load appears.
- when loading data domain checking is not enforced so that when an item is resident in a GDX
file for set elements not present in the current file these items are ignored and do not create
errors or cause generation of any messages. The execute_loaddc variant checks to see that the
domains match.

See [load11] and [qp1x] from on how to use execute_load.

4.50.1.2.2 execute_loaddc  With execute_loaddc statement any domain violation will be reported
and flagged as execution error. In contrast, the execute_load statement ignores all domain violations
and loads only data that meets the domain restrictions. In addition to loading data for sets, parameters
and variables, we can load a field of a variable into a parameter.

Warning: when loading a single field, all other fields are reset to their default value.

The statement with execute_loaddc can be used in one of the following forms:

execute_loaddc 'file_name', id1, id2, ..., idn ;
execute_loaddc 'file_name', id1=gdxid1, id2=gdxid2, ..., id2=gdxid2 ;

where

<table>
<thead>
<tr>
<th>Parameter(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_name</td>
<td>Specify the name of the GDX file (with or without the extension .gdx; read from the current working directory)</td>
</tr>
<tr>
<td>id1, id2, ..., idn</td>
<td>Read GAMS symbols id1, id2, ..., idn from the GDX file; note that commas are optional</td>
</tr>
<tr>
<td>id1=gdxid1, id2=gdxid2, ..., id2=gdxid2</td>
<td>Read GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2, ..., gdxidn in the GDX file; note that commas are optional</td>
</tr>
<tr>
<td>setid=*</td>
<td>Allow to load the universe of labels from a GDX file into a set. Note, that only labels known to the GAMS program will be loaded.</td>
</tr>
</tbody>
</table>

See [load7] example on how to use execute_loaddc.

4.50.1.2.3 execute_loadpoint  The execute_loadpoint is similar to execute_load, however, the new
values are merged with the old values.

If no arguments besides the name of the GDX file are given, all variables and equations that match
variables and equations of the calling GAMS programs will be merged with the GDX level and marginal
values. Bounds, scales and priorities will remain unchanged.
If one or more symbols to be loaded are specified explicitly, values for these symbols will be merged. For
variables and equations only the levels and marginals will be merged. To merge other variable or equation
attributes like bounds, scales and priorities, they have to be listed explicitly (e.g. `execute_loadpoint
'file_name', x.lo;` to merge the lower bound of variable x).

The statement with `execute_loadpoint` can be used in one of the following forms:

```
execute_loadpoint 'file_name', id1, id2, ..., idn ;
execute_loadpoint 'file_name', id1=gdxid1, id2=gdxid2, ..., id2=gdxid2 ;
```

where

<table>
<thead>
<tr>
<th>Parameter(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_name</td>
<td>Specify the name of the GDX file (with or without the extension .gdx; read from the current working directory)</td>
</tr>
<tr>
<td>id1, id2, ..., idn</td>
<td>Read GAMS symbols id1, id2, ..., idn from the GDX file; note that commas are optional</td>
</tr>
<tr>
<td>id1=gdxid1, id2=gdxid2</td>
<td>Read GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2 in the GDX file; note that commas are optional</td>
</tr>
</tbody>
</table>

### 4.50.1.3 Example 1 - Reading a GDX File

The file `trnsport.gms` (from `[TRNSPORT]`) has been modified to use the demand data from an
external source. Only the relevant declarations are shown.

The parameter B is read from the GDX file using the name 'demand', and only those elements that are in
the domain j will be used. Values for parameter B that are outside the domain j will be ignored without
generating any error messages.

```
* Example 1
Set
  j  markets / new-york, chicago, topeka / ;
Parameter
  B(j) demand at market j in cases ;
$gdxin demanddata.gdx
$load b=demand
$gdxin
```

### 4.50.1.4 Example 2 - Reading a GDX File

In this example, the set J is also read from the GDX file, and is used as the domain for parameter B. All
elements read for the set J will be used. Values for the parameter B that are outside the domain J will be
ignored. Note that the dimension of set J is set to one by specifying its domain.

```
* Example 2
$gdxin demanddata.gdx
Set
  J(*)  markets;
$load j=markets
Parameter
  B(j) demand at market j in cases ;
$load b=demand
$gdxin
```
4.50.1.5  Example 3 - Reading a GDX File

The $load command without parameters can read a listing of all symbols in a GDX file. The following:

* Example 3
$gdxin transport.gdx
$load

writes the following to the listing file:

Content of GDX C:\XLSFUN\TRANSPORT.GDX

<table>
<thead>
<tr>
<th>Number</th>
<th>Type</th>
<th>Dim</th>
<th>Count</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set</td>
<td>1</td>
<td>2</td>
<td>i</td>
</tr>
<tr>
<td>2</td>

<td>1</td>
<td>3</td>
<td>demand</td>
</tr>
</tbody>
</table>

which lists the items present by Type, Name, Number of sets the item is defined over(Dim), number of elements in the file for this item (Count).

4.50.1.6  Example 4 - Reading a GDX File

Sometimes, a set is implicitly given by the elements of a parameter symbol. For example,

parameter a(i) / seattle 350, san-diego 600 / ;

in transport.gms implicitly defines the set of plants i. GAMS does not allow us to provide domain checked data, if the data for domain sets is unknown. So this code produces a compilation error:

Set i plant;
Parameter a(i) capacity / seattle 350, san-diego 600 /;

When entering data directly in the GAMS source adding the domain sets before the actual parameter declarations is usually not a problem, but when data comes from external sources (e.g. spreadsheets, databases, etc), this often results in an additional query to the database, spreadsheet etc. Nowadays, such data exchange happens mostly via the GD facility. With the domain load capability of the compile time load instructions ($load, $loadDC, $loadR, $loadM, $loadDCM, and $loadDCR) one can project an index position from a parameter or set symbol in the GDX container and load this slice into a one dimensional set. Here is a simple example:
Set i plant;
Parameter a(i) capacity;
$gdxin data
$load i<adata a=adata

This will try to load set elements from the GDX parameter symbol adata into the set i and next load the GDX parameter adata into the GAMS parameter a. The latter one is no problem anymore, since the data for set i is known when loading symbol a. GAMS will use the domain information stored in GDX of parameter adata to identify the index position to project on. If no appropriate domain information can be found in GDX, the GAMS compiler will generate an error. In such case the user can explicitly select an index position (here first index position) from the GDX symbol:

$load i<adata.dim1 a=adata

The automatic index position matching (i.e. no .dimN) using the domain information stored in GDX matches on the name of the set to be loaded and the domain set names stored in GDX for the symbol. The domain in GDX are searched from right to left (start with n=symbol dimension, then n-1, n-2, ...) and stops at the first match. With the projection symbol <, the domain in GDX is searched from left to right. This follows the style of the GAMS run time projection operation:

option sym1<sym2, sym1<=sym2;

Here is an example how to load. The network is defined by the capacity parameter cap contained in a GDX container net.gdx:

parameter cap(n,n) / (1*3).4 5, 4.(5*9) 3 /;

The following code loads the entire node set n of the network as well as the nodes with outgoing (out) and incoming (in) arcs and the capacity c.

set n nodes, out(n), in(n);
parameter c(n,n) capacity;
$gdxin net
$loadM n<=cap n<cap
$loadDC out<cap.dim1 in<cap.dim2 c=cap
display n, out, in;

The listing file looks as follows:

```
---- 6 SET n nodes
  1,  2,  3,  4,  5,  6,  7,  8,  9
---- 6 SET out Domain loaded from cap position 1
  1,  2,  3,  4
---- 6 SET in  Domain loaded from cap position 2
  4,  5,  6,  7,  8,  9
```
There is a potential issue with loading domains from parameters that have a zero value for some record. Since GAMS works with sparse data, it is sometime difficult to distinguish between a record with value zero (0) and the non-existence of a record. This is usually not a problem since we know the domain of a parameter and hence know all potential records. In case of using a parameter to define the domain this represents a source of confusion. Moreover, GDX has the capability of storing true zeros (most GDX tools like gdxxrw have options (Squeeze=Y or N) to either write a true 0 or squeeze the 0s when writing GDX). So in case GDX has a zero record, a domain load from such a parameter will include this record. Here is an example. The spreadsheet Book1.xlsx contains the following data:

The GDX utility GDXXRW with the following command line:

```
gdxxrw Book1.xlsx Squeeze=N par=dat rng=Sheet1!a1 rdim=1
```

reads the Excel data and produces a GDX container Book1.gdx with a one dimensional parameter dat(*) which can be viewed in the GDX browser in the GAMSIDE:

Notice that label a4 is present while label a3 is not part of GDX symbol dat. Without the Squeeze=N (the default is Squeeze=Y) we also would not have seen a4. If we load dat to define the domain (remember we need to use $load i<dat.dim1 since gdxxrw does not write domain information to GDX), we will miss out on a3 but have a4 (assuming Squeeze=N). Please also note that the zero record disappears on regular loading and is turned into an EPS when loading under $OnEps:

```
set i;
parameter a(i);
$gdxin Book1
$load i<dat.dim1 a=dat
display i,a;
parameter a0(i);
$OnEps
$load a0=dat
display a0;
```

This results in a listing file

```
---- 5 SET i Domain loaded from dat position 1
  a1,   a2,   a4
---- 5 PARAMETER a
  a1 5.000,   a2 1.000
---- 9 PARAMETER a0
  a1 5.000,   a2 1.000,   a4  EPS
```

With gdxxrw parameter Squeeze=Y the listing file would look as follows:

```
---- 5 SET i Domain loaded from dat position 1
  a1,   a2
---- 5 PARAMETER a
  a1 5.000,   a2 1.000
---- 9 PARAMETER a0
  a1 5.000,   a2 1.000
```

4.50.1.7 Example 5 - Reading a GDX File

The following statement reads gams element k, d, f, a, b, and x from file trans2.gdx during execution phase:

```gams
execute_loadc 'tran2',k=j,d,f,a=sup,b=dem,x,supply;
```

where k be renamed from j, a be renamed from sup, and b be renamed from dem in the GDX file tran2.gdx.

Suppose there is one element topeka missing from the set definition but the element remains in the GDX file tran2.gdx. As a consequences the listing file contains an error message like:

```
**** GDX ERROR AT LINE 45 - Domain violation when loading from GDX file
**** 1 Domain errors for symbol k
topeka

**** GDX ERROR AT LINE 45 - Domain violation when loading from GDX file
**** 2 Domain errors for symbol d
seattle.topeka
san-diego.topeka
```

and the job is aborted with an execution error.

Note

- domain errors occur whenever set element names are not spelled exactly the same as an element specified in the corresponding set in GAMS flagging alternative spellings or missing elements.
- domain errors do not arise when items are not specified with them set to zero (no entry for a set element leaves to a corresponding value of zero)

4.50.1.8 Inspecting contents of a GDX file

In addition to reading data from a GDX file during compile phase or execution phase there are a few ways to examine the contents of a GDX file.

- Inspecting contents with $load
- Inspecting contents with IDE
- Inspecting contents with GDXDUMP
- Inspecting contents with GDXDIFF

Inspecting contents with $load

The $load command without any parameters will show a listing of all symbols in the GDX file. See Example 3 - Reading a GDX File on how to use $load to get a listing of all symbols.

Inspecting contents with the IDE

The GAMSIDE can be used to view the contents of a GDX file by opening a GDX file with the Open file dialogue. The IDE only recognizes the .gdx file extension of a GDX file. The resultant display gives the names of the items in the GDX file on left hand part of the screen while the right part gives the exact data entries for the item highlighted in the left hand part.

For example, opening a GDX file using the Open file dialogue and and moving the cursor to the set i6 causes the screens, it becomes:

showing the elements in the set as contained within the GDX file. Similarly choosing the object modeistance yields the screen:

showing the data for this item. The data may be reordered via the mouse. For example placing the mouse on the column containing san francisco and dragging the column up yields:

which is the slice of the matrix containing san francisco data. In turn clicking on Brussels yields:
Note

• the columns are sortable in the left hand portion of the display. All one needs to do is to click on the gray boxes (Symbol, Type,...) with the mouse. There is also a search dialog at the bottom that permits one to look for select items.

• a right mouse click allows one to write the contents of any or all items to HTML format.

Inspecting contents with GDXDUMP

The GDXDUMP utility can list the symbols in the file and it also can write sets and parameters formatted as a GAMS data statement.

```
gdxdump gdxfile_name format=choice symb=optional choice
```

where

- the `gdxfile_name` is the name of the GDX file to write data from.
- the output is created to the screen not to a file. One can also write the GDX file contents into a GAMS file using the command:

```
gdxdump gdxfile_name > filetouse.gms
```

- Data for a selected set, parameter, variable or equation (under all three of the output options when a specific item is named using the SYMB option)
- Data for all sets, parameters, variables and equations (Under normal option when the SYMB is not used)
- Data on solution items (variables and equations) formatted in a fashion suitable for import as a basis in another GAMS program where the marginals and levels are output. All of the scalars, sets and parameters (tables) in a GDX file to standard output formatted as a GAMS program with data statements or in CSV format. It skips information for variables and equations.
- Under the format=CSV choice it only creates output when a symbol is selected using the SYMB syntax.
- Under the format=CSV choice when the requested symbol is a variable or an equation one only gets the level values not the marginal, under the other formats one gets all items.
- Under the format=gamsbas choice one gets all variables and equations when the SYMB syntax is not used.

Suppose we wish to write out the GDX file `tran.gdx`, then we would use the command:

```
gdxdump tran
```

See more Examples on inspecting contents with GDXDUMP.

Inspecting contents with GDXDIFF

The GDXDIFF utility can be used to compare two GDX files by creating a third GDX file containing a list of differences between all symbols. In particular for all items with the same name, type and dimension in the two GDX files the differences in numerical values are written to a third GDX file with A summary report written to standard output (ordinarily the LOG file).

This utility can be used either at command line, or by $Call, or execute command.
gdxdiff file1 file2 {diffile} {Eps = value} {RelEps = value} {Field = FieldName} {ID=Identifier}

GDXDIFIFF requires the first two file name parameters,

- File1 Name of the first GDX file
- File2 Name of the second GDX file

The remaining parameters are optional

- Diffile An optional third file name that is the name of the GDX file that contains the differences found in the parameters. If that parameter, is absent the file will be named 'diffile.gdx' and placed in the current directory.
- Eps = value A tolerance that is the maximum amount that two numbers may differ by i.e. given a1 and a2 then abs(a1-a2) is reported as different if it exceeds this tolerance
- RelEps = value A tolerance that is the maximum percentage amount that two numbers may differ by i.e. given a1 and a2 then abs(a1-a2)/max(abs(a1),abs(a2)) is reported as different if it exceeds this tolerance.
- Field = FieldName A field that if specified limits done between the information for variables and equations to specific attributes (Lo, L, Up, M, Scale and Prior)
- ID=Identifier Limits the comparisons to selected items; items not specified will be ignored. Multiple items can be specified as: ID=id1 ID=id2 or ID="id1 id2"

Suppose we wish to compare the GDX files tran.gdx and tran2.gdx, then we would use the command:

```
gdxdiff tran tran2
```

In turn the output to standard output (nominally the terminal screen) appears as follows:

```
Summary of differences:
  d  Data is different
  dem  Keys are different
  sup  Keys are different
supply  Symbol not found in file 1
  x  Symbol not found in file 1
```

and summarizes the differences found. Simultaneously the file diffile.gdx when examined in the IDE contains the following

which reports on the differences found in the two files.

Note

- Some new coding is introduced in the difference GDX file. Namely a new dimension is added to the parameters being compared which can contain 4 entries
  - dif1 indicates that the entry occurs in both files and shows the value found in the first file.
  - dif2 indicates that the entry occurs in both files and shows the value found in the second file.
  - ins1 indicates that the entry only occurs in the first files and shows the value found.
  - ins2 indicates that the entry only occurs in the second file and shows the value found.
- Only named items with the same name, type and dimension will be compared in the diffile.gdx output. Named items that are new or are deleted will only appear in the standard output summary report.

See more Examples on inspecting contents with GDXDIFFF.
4.50.2 Writing a GDX file

Writing of GDX files in a GAMS model can be done during the compile phase or the execution phase. A GDX file can also be written after compilation and execution.

4.50.2.1 Compile Phase

During compilation, we can use a group of Dollar Control Options to write data to a GDX file. Writing during the compilation phase also allows us to define the elements of a set and the subsequent use of such a set as a domain. The following Dollar Control Options are available for writing data to a GDX file into GAMS during compilation of a GAMS model:

- $gdxout
- $unload

4.50.2.1.1 $gdxout

The $gdxout command is used in a sequence either to unload specified items to a GDX file or to close the specified GDX file. The statement with $gdxout can be used in one of the following forms:

```
$gdxout file_name
$gdxout
```

where:

<table>
<thead>
<tr>
<th>Parameter(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_name</td>
<td>Specify the name of the GDX file (with or without the extension .gdx; written to from the current working directory)</td>
</tr>
<tr>
<td></td>
<td>(no file_name) closes the GDX file</td>
</tr>
</tbody>
</table>

See Example 1 - Writing a GDX file and [CompTimeWriteTranspGDX] for examples on how to use $gdxout.

4.50.2.1.2 $unload

The $unload command unloads specified items to the GDX file. The statement containing $unload is preceded and succeeded by the $gdxout statements where

- the preceding $gdxout specifies the GDX file name and opens the file.
- the succeeding $gdxout closes the GDX file.

The statement with $unload command can be used in one of the following forms:

```
$unload
$unload id1 id2 ... idn
$unload id1=gdxid1 id2=gdxid2 ... idn=gdxidn
```

where:
<table>
<thead>
<tr>
<th>Parameter(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(no identifiers)</td>
<td>Write all symbols to the gdx file</td>
</tr>
<tr>
<td>id1 id2 ... idn</td>
<td>Write GAMS symbols id1, id2, ..., idn to the GDX file</td>
</tr>
<tr>
<td>id1=gdxid1 id2=gdxid2 ... idn=gdxidn</td>
<td>Write GAMS symbols id1, id2, ..., idn with corresponding names gdxid1, gdxid2, ..., gdxidn into the GDX file</td>
</tr>
</tbody>
</table>

See Example 1 - Writing a GDX file and [unload1] - [unload9] for examples on how to use $unload. See also [CompTimeWriteTrnsportGDX] example.

### 4.50.2.2 Execution Phase

When writing data to a GDX file during execution phase the data in the GDX file will be the data present in the GDX file at the time that the statement is executed. The results of all prior calculations and the most recent solve for any model will be reflected. The statements to write data to a GDX file during execution phase are

- `execute_unload`
- `execute_unloaddi`
- `execute_unloadidx`
- `savepoint`

#### 4.50.2.2.1 `execute_unload`, `execute_unloaddi`, and `execute_unloadidx`  
The `execute_unload` statement replaces an existing file with that name; it does not add symbols to or replace symbols in an existing GDX file. Without specifying any identifier, all sets, parameters, variables and equations will be written to the GDX file.

The `execute_unloaddi` statement replaces an existing file with that name; it does not add symbols to or replace symbols in an existing GDX file similar to `execute_unload`, but also writes the domains of all unloaded symbols to the same file.

The `execute_unloadidx` statement requires that each symbol written is a parameter; each parameter must have a domain specified for each index position. These domains have the requirement that they are formed using an integer sequence for the UELs that starts at 1 (one). The domain names are changed to indicate the size of each domain. This information is used when reading the data back from the GDX file using `$LoadIDX` during compilation. Using the special domain names, the UELs for the domains can be recovered without writing the domains to the GDX file; see example below.

The statement with `execute_unload` can be used in one of the following forms:

```gams
execute_unload 'file_name' , id1, id2, ..., idn ;
execlineexecute_unload 'file_name' , id1=gdxid1, id2=gdxid2, ... ;
execlineexecute_unload 'file_name' , setid=* ;
execline```

The statement with `execute_unloaddi` can be used in one of the following forms:
The statement with `execute_unloaddidx` can be used in one of the following forms:

```sql
execute_unloaddidx 'file_name', id1, id2, ..., idn;
execute_unloaddidx 'file_name', id1=gdxid1, id2=gdxid2, ... ;
execute_unloaddidx 'file_name', setid=* ;
```

where
### 4.50 GAMS Data eXchange (GDX)

<table>
<thead>
<tr>
<th>Parameter(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_name</td>
<td>Specify the name of the GDX file (with or without the extension .gdx; written to from the current working directory)</td>
</tr>
<tr>
<td>id1, id2, ..., idn</td>
<td>Write GAMS symbols id1, id2, ..., idn into the GDX file</td>
</tr>
<tr>
<td>id1=gdxid1, id2=gdxid2</td>
<td>Write GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2 into the GDX file</td>
</tr>
</tbody>
</table>

**Note**
- when only `file_name` is specified without other parameters all GAMS Symbols will be written into the GDX file `file_name`.
- The GAMS option `gdxUELs` controls which UELs are registered in `file_name`. With option `gdxUELs = squeezed;` (default) only the UELs that are required by the exported symbols are registered while all known UELs are registered if we set option `gdxUELs = full;`. See also [unload10].

See Example 2 - Writing a GDX file and [qp1x] on how to use `execute_unload`. See [unload10] on how to use `execute_unloadidx`. See Example 3 - Writing a GDX file on how to use `execute_unloadidx`.

#### 4.50.2.2.2 Savepoint
A GDX file containing the marginals and levels for all variables and equations at the end of a solve will be created with the command line parameter, model attribute or option statement `Savepoint`. One can save the solution information from the last solve or from every solve. The points that are saved can be used to provide an advanced basis, integer program starting point or NLP starting point.

The basic command line form is:

```plaintext
gams mymodelname Savepoint=number
```

the model attribute form is

```plaintext
modelname.savepoint=number;
```

and the option statement form is

```plaintext
option savepoint=number
```

where

- when number equals 1/3 a point gdx file is saved from the last solution collected in the GAMS model and the file name will be `modelname_p.gdx` where model name is the name of the model identified in the solve statement.
- when number equals 2/4 a point gdx file is saved from the every solve in the GAMS model and the file name will be `modelname_pnn.gdx` where model name is the name of the model identified in the solve statement and nn is the internal number of the solve. Thus if 10 solves occur one will get 10 files named `modelname_p1.gdx` through `modelname_p10.gdx`. 
Note

When solving \textit{asynchronously}, one should keep in mind, that the internal numbers mentioned for \texttt{savepoint=2/4} are generated when submitting the model, not when collecting it. And with \texttt{savepoint=1/3} it is the last solution collected, not the last model submitted that is written to the savepoint.

The following example:

\begin{verbatim}
model firm / all /;
    firm.savepoint=1;;
solve firm using LP maximizing objfun;

saved a point gdx file \texttt{firm.p.gdx}.

and:

model transport /all/ ;
    option savepoint=2;
    set newseattle /s1,s2/;
    parameter datador(newseattle) /s1 350, s2 450/;

    loop(newseattle,
        a("seattle")=datador(newseattle);
        Solve transport using lp minimizing z ;
    );
    Display x.l, x.m ;

saved two point gdx files \texttt{transport.p1.gdx} and \texttt{transport.p2.gdx}.
\end{verbatim}

\subsection*{4.50.2.3 Example 1 - Writing a GDX file}

This example has modified the file \texttt{trnsport.gms} from [TRNSPORT] by adding the following statements after the last line.

\begin{verbatim}
...[TRNSPORT]...

d(i,j)=d(i,j)*10;

$gdxout tran
$unload i j
$unload d
$unload f
$unload b=dem a=sup
$gdxout
\end{verbatim}

This example creates the GDX file \texttt{tran.gdx} containing the data for the sets \texttt{i} and \texttt{j} as well as the parameters \texttt{d}, \texttt{f}, \texttt{a} and \texttt{b} during the compile time, when \texttt{a} and \texttt{b} have been renamed in the GDX file to \texttt{dem} and \texttt{sup}. Also note the parameter \texttt{d} will not have been multiplied by 10 but rather take on their compile time value.

An \texttt{$unload} statement above can specify more than one symbol to be written to a GDX file and the similar result could also be accomplished using:

\begin{verbatim}
...[TRNSPORT]...

d(i,j)=d(i,j)*10;

$gdxout tran
$unload i j d f b=dem a=sup
$gdxout
\end{verbatim}
4.50.2.4 Example 2 - Writing a GDX file

This example has modified from the file trnsport.gms (from [TRNSPORT]) by adding the following statement right after the solve statement.

...[TRNSPORT]...

Solve trnsport using LP minimizing Z;
execute_unload 'results.gdx', i, j, z, x;

After solving the model, the sets i and j and the variables z and x with all the data available after the solve.

4.50.2.5 Example 3 - Writing a GDX file

This example shows the use of the indexed write and read data during execution phase:

Set I /1*100/,
  J /1*50 /
parameter A(I,J) /1.1=11, 1.9=19, 10.1=101/
execute_unloadidx 'data.gdx', A;

Viewing the file data.gdx in the gamside shows the modified domain information:

To read from data.gdx, we use the indexed read:

Set I,J;
parameter A(I,J);
* load the data
$gdxin data.gdx
$loadidx A
$gdxin
* write all symbols so we can inspect in the gamside
$gdxout test.gdx
$unload
$gdxout
execute_unloadidx 'data.gdx', A;

Viewing the file test.gdx in the gamside shows that the domains have been populated:
4.50.2.6 Writing a GDX file after compilation or execution

A GDX file containing all data items resident at the end of the run of a GAMS code can be created using the gdx command line option either via GAMS call at the command line or via the command line parameter box in the IDE. This will cause all sets, parameters, variables and equations to be written to the GDX file.

For example:

```
gams mymodelname gdx=gdxfile_name
```

Or

```
gams mymodelname action=c gdx=gdxfile_name
```

where

- `mymodelname` specifies the name of the GAMS file
- `gdxfile_name` gives the file name and possible path where the GDX file is to be retained. When no path is specified the default directory is the current working directory or project directory in the IDE as seen below.
- `action=c` indicates request to write a GDX file after compilation only
- setting GDX to the string "default" (i.e. `gdx=default`) causes GAMS to create a GDX file with the GAMS file root name and a GDX extension. Thus

```
gams transport gdx=default
```

will cause GAMS to write the gdx file `transport.gdx`.

When the IDE is used, the GDX file creation is invoked by an entry in the upper right hand corner of the IDE screen as illustrated below:

Note

- When this option is used the GDX file is created just at the end of the GAMS execution so the data written will contain the current values for all sets, parameters, variables and equations that are on hand at the end of the GAMS job.
- The GDX data for the variables and equations contains the levels, marginals, lower bounds, upper bounds and scales for each item.
- This yields a file that may be automatically opened in the IDE by doing a mouse click on the highlighted line in the IDE process window.

Using the gdx command line parameter when running the model using the IDE, the process window will show the GDX file name in blue indicating that the file can be opened using a double-click with the mouse. See also Inspecting contents with IDE.
4.50.3 General notes on GDX files

There are several things worth noting about GDX files:

- When working with GDX only one GDX file can be open at a time.
- When reading data from a GDX file, the symbol to be read must be declared before the reading statement appears.
- When the GDX file to be written has the same name as an existing GDX file the existing file will be overwritten. The resultant file will only contain the new data; there is no merge or append option.
- The \$unload command to write a GDX during compile time will only write out data defined in the compilation at the point where the command appears. No results of any solves or calculations done within the current GAMS program will be reported with \$unload. This is not true when using the execute_unload or execute_unloaddi commands.
- Both execute_unload and execute_unloaddi will write out data defined in the execution sequence at the point where the command appears. The results of the most recent solve command and any parameter calculations occurring before the GDX write will be reported.
- Any subsequent execute_unload or execute_unloaddi to a GDX file written earlier will totally overwrite that file so care must be taken to write all wanted information in the last appearing execute_unload or execute_unloaddi.
- A command line GDX write using the gdx=file\_name command line parameter will write out data defined at the end of the execution sequence. The results of the most recent solve and any parameter calculations will be reported.
- When loading data domain checking will not be enforced. When items are resident in the GDX file for set elements that are not present in the current file these items will be ignored. GAMS will not generate any message telling you which items are ignored.
- Options Savepoint and execute_Loadpoint provide a GDX way of saving and loading a basis.
- The contents as they differ between GDX files can be examined with GDXMERGE or GDXDIFF.
- Starting with GAMS version 22.3, gdx files can be written in a compressed format unless the environment variable GDXCOMPRESS is set to zero. A value of 1 indicates compression.
- GDX files from a different GAMS version can possibly be incompatible due to compression among other changes. A current GAMS system can read all older GDX file formats. GDX files can be converted to a compressed format or an older format using GDXCOPY.
- Users can also write their own programs accessing data in a GDX file via the expert-level GDX API using gdxdclib library. The interface and usage for this library is described in a separate document; see gdxioapi.chm or gdxioapi.pdf.

4.50.4 GAMS Data eXchange Tools

A number of GDX based tools and GDX related tools are included in the GAMS distribution and maintained by GAMS. See also Tools Manuals.

- The data exchange tools provide functionality to exchange data between GAMS and other data sources.
- The GDX service tools operate directly on GDX containers.
- Some of Data transformation tools perform very specific data transformation tasks that are either awkward or inefficient to implement in GAMS directly.

Some utilities are available only on specific platform. See Supported Platforms for more details.
4.51 Extended Mathematical Programming (EMP)

Extended Mathematical Programming (EMP) is an extension to algebraic modeling languages that facilitates the automatic reformulation of new model types as models in more established mathematical programming classes, allowing them to be solved by mature solver algorithms. A number of important problem classes can be solved, e.g. Nash games and equilibria, bilevel programs, Disjunctive Programs and Stochastic Programs. EMP is independent of the modeling language used but is currently implemented only in GAMS. The new types of problems modeled with EMP are reformulated, using the GAMS solver JAMS, as well established types of problems, and the reformulated models are passed to a suitable GAMS solver to be solved.

EMP models are defined by information taken from two places: the traditional model definition and a text file containing annotations or additional information. The usual model definition contains variables, constraints and/or functions, and perhaps also an objective or matching information. Additional annotations to specify relationships that don't fit within this traditional definition are taken from the EMP info file. For example, the constraints for two optimizing agents in a competitive game can be specified with traditional algebra, while the structure (who owns what variables and constraints) can be specified in the info file. Together, this allows large, complex models to be specified in a convenient, precise, and flexible way.

This chapter is organized as follows.

- EMP Annotations: the EMP Info File
- Soft Constraints
- Variational Inequalities (VI)
- Quasi-Variational Inequalities (QVI)
- Equilibrium Problems
- Embedded Complementarity Systems
- Equilibrium Problems with Shared Constraints
- Equilibrium Problems with Shared Variables
- Bilevel Programs
- Disjunctive Programming
- Stochastic Programming
- EMP Keywords

Note

- At the end of each section we present and discuss the general syntax that EMP provides to write the annotations for that particular problem type. We use the usual GAMS syntax symbols: [ ] (the enclosed construct is optional), { } (the enclosed construct may be repeated zero or more times) and | (exclusive OR).
- Many EMP model examples are available in the GAMS EMP Library.
4.51 Extended Mathematical Programming (EMP)

4.51.1 EMP Annotations: the EMP Info File

EMP models are defined by both the usual content of a GAMS model and annotations found in a simple text file named emp.info (aka the EMP info file). It is often most convenient to create this file via the GAMS put writing facility. The annotations primarily serve to define the model (e.g. to specify that a variable $u$ is really the dual multiplier for a constraint $g$) but can also specify how a solver should process the model. The annotations make use of EMP keywords to do this.

A simple example will serve as illustration. Consider the following NLP:

$$\begin{align*}
\min_{x,y,z} & -3x + xy \\
\text{s.t.} & x + y \leq 1 \\
& x + y - z = 2 \\
& x, y \geq 0
\end{align*}$$

We will use EMP annotations to automatically generate the first order conditions (KKT conditions) of this NLP and thus reformulate the NLP as an MCP:

Variables $f$, $z$;
Positive Variables $x$, $y$;

Equations $g$, $h$, defobj;

$g.. \quad x + y \leq 1$
$h.. \quad x + y - z = 2$
$defobj.. \quad f =e= -3x + x*y$

Model comp / defobj, g, h /

File info / '%emp.info%' /
putclose info / 'modeltype mcp';
solve comp using EMP minimizing f;

Observe that the model is defined in the usual way and the file emp.info contains just one line: modeltype mcp. The EMP keyword modeltype indicates that the value following the keyword is the model type to be used for the reformulation. In this example the model type is mcp. Here this specification is required: the sole point of our EMP annotations is to generate an MCP and not (as is usually the case) to define the model. Usually, the model algebra and annotations together imply the type of the reformulated model and so no modeltype specification is required or wanted. Finally, note that the model type in the solve statement is EMP: this is typical.

The solver JAMS implements the EMP framework. It processes the model and the annotations, automatically reformulates the original EMP model as a model of a different (more easily solved) type, passes the reformulated model on to an appropriate subsolver, and maps the resulting solution back into the original problem space.

In case users wish to inspect the (scalar) reformulated model, the JAMS option FileName may be used to specify the name of the file containing this model. Adding the following lines before the solve statement in the GAMS code above will cause the MCP reformulation to be saved in the file myReform.gms.

File empopt / 'jams.opt' /
comp.optfile = 1;
putclose empopt / 'FileName myReform.gms';

The listing file will contain some additional information - the EMP Summary - as part of the output for each EMP model solved. We provide details on the EMP summary for each reformulation that we discuss below.
4.51.2 Soft Constraints

In many cases modelers wish to relax certain constraints: violation of these constraints is allowed but is associated with a well-defined penalty. The constraints that are allowed to be violated are called *soft constraints* and the constraints that continue to hold are called *hard constraints*.

In this section we present a mathematical formulation of soft constraints, give an example of how soft constraints can be modeled with GAMS EMP and introduce the EMP annotations specific to soft constraints.

4.51.2.1 Soft Constraints: Mathematical Formulation

A general formulation of a constrained minimization problem is:

\[
\begin{align*}
\text{Min} & \quad f(x) \\
\text{s.t.} & \quad c_i(x) \leq 0, \quad \forall i \in \mathcal{I},
\end{align*}
\]  

(2)

where \( f \) and the functions \( c_i \) are smooth, real-valued functions on a subset of \( \mathbb{R}^n \) and \( \mathcal{I} \) is a finite set of indices. Note that in this problem all feasible solutions must satisfy all constraints \( c_i \).

Now assume that some constraints are allowed to be violated (i.e. made soft), while the remaining constraints continue to hold for all feasible solutions. The soft constraints are associated with a penalty function that is added to the objective function. Since we have a minimization problem, the effect will be a balance or compromise between competing goals: minimizing the objective and minimizing the penalty functions.

\[\text{Note}\]

The penalty terms for soft constraints are *added* to the objective function in a minimization problem and *subtracted* in a maximization problem.

Let \( \mathcal{L} \in \mathcal{I} \) be the set of indices for the soft constraints: this implies \( \mathcal{M} := \mathcal{I} \setminus \mathcal{L} \) is the index set for the hard constraints. Problem (2) becomes:

\[
\begin{align*}
\text{Min} & \quad f(x) + \sum_{i \in \mathcal{L}} w_i g_i(c_i(x)) \\
\text{s.t.} & \quad c_i(x) \leq 0, \quad \forall i \in \mathcal{M},
\end{align*}
\]  

(3)

where the penalty functions \( g_i \) are real-valued functions of \( c_i(x), i \in \mathcal{L} \). As we will see later, EMP has implementations of the following penalty functions: absolute value, least squares, and the maximum of a term and zero. Further, \( w_i \) is a multiplier associated with each penalty term, also called the *weight*. The weights facilitate prioritizing soft constraints: the weight of more important constraints will be greater than the weight of lesser constraints.
4.51.2.2 Soft Constraints with EMP: A Simple Example

The following simple example is adapted from the JAMS solver manual:

\[
\begin{align*}
\text{Min} & & -x_1^2 \\
\text{s.t.} & & \log(x_1) = 1 \\
& & x_2^2 \geq 2 \\
& & 3x_1 + x_2 \leq 5 \\
& & x_1, x_2 \geq 0 
\end{align*}
\]  \hspace{1cm} (4)

This problem can be formulated in GAMS as follows:

Positive Variables x1, x2;
Variables obj;

Equations f0 "objective function", f1, f2, f3;

f0.. obj =e= -sqr(x1);
f1.. log(x1) =e= 1;
f2.. sqr(x2) =g= 2;
f3.. 3*x1 + x2 =l= 5;

Model m /all/;
x1.l = 1; x2.l = 1;
solve m using NLP min obj;

Note that this problem has no feasible solution. Thus we choose to relax the first two constraints by adding a penalty for their violation to the objective function. We also weight the relative importance or priority of the objective and the violations of these two constraints by introducing weights to go with these penalty functions. The resulting problem reads as follows:

\[
\begin{align*}
\text{Min} & & -x_1^2 + 5 \|\log(x_1) - 1\|^2 + 2 \max(x_2^2 - 2, 0) \\
\text{s.t.} & & 3x_1 + x_2 \leq 5 \\
& & x_1, x_2 \geq 0
\end{align*}
\]  \hspace{1cm} (5)

Note that the first constraint is replaced by a least squares penalty of \((\log(x_1) - 1)\) with a weight of 5 and the second constraint by the penalty term \(\max(x_2^2 - 2, 0)\) with a weight of 2. However, the "max" penalty makes the objective function non-smooth. To rectify this, we implement the "max" penalty by introducing a new variable \(v\) that, due to its bounds and the direction of optimization, will take the value \(\max(x_2^2 - 2, 0)\) at the solution. The result is:

\[
\begin{align*}
\text{Min} & & -x_1^2 + 5 \|\log(x_1) - 1\|^2 + 2v \\
\text{s.t.} & & 3x_1 + x_2 \leq 5 \\
& & x_1, x_2 \geq 0 \\
& & v \geq x_2^2 - 2 \\
& & v \geq 0
\end{align*}
\]  \hspace{1cm} (6)

This reformulation could of course be implemented directly in GAMS using standard GAMS syntax, but the EMP solution is easier to create and maintain, to read and understand, and to scale upwards as problem size and complexity increase. For the latter, we can simply add the following EMP annotations and updated solve statement (to specify solution as an EMP) to the GAMS code above:
File soft / ’%emp.info%’ /;
put soft;
$onput
adjustequ
f1 sqr 5
f2 maxz 2
$offput
putclose;
solve m using EMP min obj;

Note that the EMP annotations contain three lines: the first line, containing the EMP keyword adjustequ , indicates that the lines that follow specify soft constraints, i.e. equations to be converted to penalty terms; the second line specifies the name of the first soft constraint f1, the penalty function to use, and - optionally - the weight; and similarly the third line specifies the name of the second soft constraint f2, the penalty function to use, and the weight.

The solver JAMS will use the information in the EMP annotations to automatically reformulate problem (4) as problem (6) and pass it along to an NLP subsolver. The EMP Summary produced by JAMS will contain the following line:

--- EMP Summary
   ...
   Adjusted Constraint = 2
   ...

This output reflects that indeed two constraints were ”adjusted”, i.e. converted to penalty terms in the objective function.

4.51.2.3 EMP Syntax for Soft Constraints

The EMP framework provides the following general syntax to specify constraints that are converted to soft constraints:

\[
\text{AdjustEqu } \text{equ } \text{abs|sqr|maxz } \{\text{weight}\}
\{\text{equ abs|sqr|maxz } \{\text{weight}\}\}
\]

The EMP keyword AdjustEqu indicates that the lines that follow specify equations that are ”adjusted”: they are moved from constraints to penalty terms in the objective function. Equ is the name of the equation to penalize, while the three EMP keywords that follow indicate the penalty function to use. If not specified, the weight used defaults to 1. For an example, see above or the model [SIMPENLP] in the GAMS EMP Model Library.

4.51.3 Variational Inequalities (VI)

Variational inequalities provide a general mathematical framework for many problems arising in optimization. For example, constrained optimization problems like LP and NLP are special cases of VI, and systems of equations and complementarity problems can be cast as VI. Thus VI problems have many applications, including those in transportation networks, signal processing, regression analysis, and game theory.

In this section we present a mathematical formulation of VI, give an example of how VI can be modeled with GAMS EMP, and introduce the EMP annotations specific to VI. Note that to fully and properly understand some of this section, the introduction to MCP provides a useful background.
4.51.3.1 Variational Inequalities: Mathematical Formulation

For a given continuous function \( F: \mathbb{R}^n \to \mathbb{R}^n \) and a fixed closed convex set \( K \subset \mathbb{R}^n \) the variational inequality problem \( VI(F, K) \) is to find a point \( x^* \in K \) such that:

\[
\langle F(x^*), (x - x^*) \rangle \geq 0, \quad \forall x \in K, \tag{7}
\]

where \( \langle \cdot, \cdot \rangle \) denotes the usual inner product.

Observe that the VI generalizes many problem classes:

- If \( F(x) = 0 \) and \( K \equiv \mathbb{R}^n \), the VI is a system of nonlinear equations.
- If \( F(x) = \nabla f(x) \), the VI is a convex optimization problem.
- If \( F(x) = \nabla f(x) \) and \( K = \{ x \mid Ax = b, Hx \leq h \} \), the VI is an NLP.
- If \( F(x) = \nabla f(x) = p \) and \( K = \{ x \mid Ax = b, Hx \leq h \} \), the VI is an LP.
- If the feasible region is a box \( B = \{ x \in \mathbb{R}^n \mid l_i \leq x_i \leq u_i, \text{ for } i = 1, \ldots, n \} \), with \( l_i \leq u_i \) \( l_i \in \mathbb{R} \cup \{-\infty\} \) and \( u_i \in \mathbb{R} \cup \{\infty\} \), the VI is an MCP, where \( x^* \in B \) is a solution of the respective MCP if for each \( i = 1, \ldots, n \) one of the following conditions holds:

\[
\begin{aligned}
F_i(x^*) &= 0 \quad \text{and} \quad l_i \leq x^*_i \leq u_i, \\
F_i(x^*) &> 0 \quad \text{and} \quad x^*_i = l_i, \\
F_i(x^*) &< 0 \quad \text{and} \quad x^*_i = u_i.
\end{aligned} \tag{4.18}
\]

Note that the set \( K \) is frequently defined in the following way:

\[
K = \{ x \mid x \geq 0, h(x) \geq 0 \}. \tag{8}
\]

Further, note that the \( VI(F, K) \) represents a wider range of problems than classical optimization whenever \( F(x) \neq \nabla f(x) \) for some objective function \( f \) (or equivalently, the Jacobian of \( F \) is not symmetric). For example, problems that can be cast as VI include (generalized) Nash games and Nash equilibrium problems, systems of equations, complementarity problems, and fixed-point problems.

4.51.3.2 Variational Inequalities with EMP: A Simple Example

Consider the following simple three dimensional linear example (adapted from Yashtini & Malek (2007) [207]). Let

\[
F(x) = \begin{bmatrix}
22x_1 - 2x_2 + 6x_3 - 4 \\
2x_1 + 2x_2 \\
6x_1 + 2x_3
\end{bmatrix}, \quad K = \{ x \in \mathbb{R}^3 \mid x_1 - x_2 \geq 1, -3x_1 - x_3 \geq -4, 2x_1 + 2x_2 + x_3 = 0, l \leq x \leq u \}, \tag{9}
\]

where \( l = (-6, -6, -6)^T \), \( u = (6, 6, 6)^T \). N.B.: \( F \) is not the gradient of any function \( \mathbb{R}^3 \to \mathbb{R} \). This \( VI(F, K) \) has a unique solution: \( x = (2/3, -1/3, -2/3) \). The problem can be implemented in GAMS with EMP as follows:
Set  i /1*3/;
Variable x(i);

x.lo(i) = -6;

x.up(i) = 6;

Equations F(i), h1, h2, h3;

F(i).. (22*x('1') - 2*x('2') + 6*x('3') - 4)$sameas(i,'1')
+ (2*x('1') + 2*x('2'))$sameas(i,'2')
+ (6*x('1') + 3*x('3'))$sameas(i,'3')

= = 0;

h1.. x('1') - x('2') = = 1;

h2.. -3*x('1') - x('3') = = -4;

h3.. 2*x('1') + 2*x('2') + x('3') = = 0;

Model linVI / F, h1, h2, h3 /;

File annotations /'%emp.info%'/;

put annotations;
putclose 'vi F x h1 h2 h3';

solve linVI using EMP;

Observe that the function $F$ and the constraints $h$ are formulated using standard GAMS syntax. $F$ is implemented as an equation of type $=n=$, which does not imply or enforce any relationship between the left-hand side and the right-hand side. Instead, this relationship is implied by the position of the matching variables (given in the EMP info file) relative to their bounds. The annotations in the EMP info file define the structure of the VI: what functions are matched to what variables, and what constraints serve to define the set $K$. The EMP keyword $vi$ indicates that the model is a VI, that the VI function $F$ is matched to the variable $x$, and that the constraints $h1$ $h2$ $h3$ define the set $K$.

Alternatively, the EMP annotations could be written as follows:

putclose 'vi F x';

Here the equations after the equation-variable pair are omitted. This is acceptable, since by default any equations that are part of the model but are not matched with a variable are automatically used to define the set $K$.

Since VI problems have no objective, the short form of the solve statement is used.

The solver JAMS will reformulate the VI as an MCP and pass this on to an MCP subsolver. The EMP Summary produced by JAMS will contain the following line:

--- EMP Summary
...  
  VI Functions = 3
... 

This output reflects the fact that there were three VI functions in the model above, one for each member of the set $i$.

Note that there are several VI models in the GAMS EMP Library. For example, the models [SIMPLEVI] and [VI_MCP] demonstrate how some models can be specified using either MCP or VI syntax. A simple nonlinear VI is given in model [SIMPLEV12]. As the transportation model is so well known, model [TRANSVI] demonstrates how it can be cast as a VI.
4.51.3.3 EMP Syntax for Variational Inequalities

The general syntax of the EMP annotations used to specify variational inequalities is as follows:

\[
\text{VI } \{\text{var}\} \{ [\text{-}] \text{ equ var} \} \{ [\text{-}] \text{ equ} \}
\]

The EMP keyword \text{VI} indicates that this is a variational inequality specification. The core of the VI specification is the (list of) equation-variable pair(s): the other parts are optional. A pair matches the equation \text{equ} with the variable \text{var}. This indicates that \text{equ} defines part of the VI function \(F\), and that these rows of \(F\) are perpendicular to columns taken from \text{var}. Multiple equation-variable pairs are allowed. The optional variables before the pairs are called \text{preceding variables}. These are variables that appear (and are often defined by) the constraints of the model, but they are not matched explicitly via the VI function \(F\). Instead, they are automatically matched with the zero function. See model [ZEROFUNC] for an example and a more detailed discussion. The optional equations after the equation-variable pairs are called \text{trailing equations}. They define the set \(K\) and may be omitted from the VI specification. By default, any equations that are included in the model but are not matched with a variable are automatically used to define the set \(K\). Even though both preceding variables and trailing equations may be omitted from the VI specification, we recommend to explicitly list them, since this clarifies intentions and eliminates ambiguity.

The \(^{-}\) sign in the syntax above is used to flip (i.e. to reorient or negate) the marked equation, e.g. so that \(x^{\ast\ast}1.5 \leq y\) becomes \(y \geq x^{\ast\ast}1.5\). Flipped equations in EMP behave in the same way as flipped equations in MCP.

Note

More than one VI specification may appear in a model. Often, it makes no difference whether multiple \text{equ-var} pairs are part of the same or separate VI specifications, but this is not the case in general. For an example, see model [SIMPLEVI4].

4.51.4 Quasi-Variational Inequalities (QVI)

Quasi-variational inequalities are a generalization of the variational inequality model: in a VI, the feasible set is fixed, while the QVI allows the feasible set to vary with or be a function of the variables in the model. To avoid repetition, we assume you are already familiar with the theory and notation for VI models. In this section, we present a mathematical formulation of QVI, give an example of how QVI can be modeled with GAMS EMP, and introduce the EMP annotations specific to QVI.

4.51.4.1 Quasi-Variational Inequalities: Mathematical Formulation

For a given continuous function \(F : \mathbb{R}^n \to \mathbb{R}^n\) and a point-to-set mapping \(K(y) : \mathbb{R}^n \to \mathbb{R}^n\), the quasi-variational inequality problem \(QVI(F, K)\) is to find a point \(y^{\ast} \in K\) such that:

\[
\langle F(y^{\ast}), (y - y^{\ast}) \rangle \geq 0, \quad \forall y \in K(y^{\ast}),
\]

(4.19)

where \(\langle \cdot, \cdot \rangle\) denotes the usual inner product.

If the point-to-set mapping \(K(y) : \mathbb{R}^n \to \mathbb{R}^n\) is constant, then the QVI above reduces to a VI. In order to define \(K(x)\) as a function of \(x\) it is convenient to introduce a shadow copy \(x\) of the variable \(y\). It should be understood that we have only one variable that appears in two forms: the variable of interest \(y\) and the parameter variable \(x\). Where \(y\) appears, we have a variable in the usual sense, and we take derivatives wrt this variable when deriving optimality conditions. Where \(x\) appears, we have a constant variable, i.e. we assume it is fixed when deriving optimality conditions. We can now use a function \(g(y, x)\) to define \(K(\cdot)\) and express QVI as: find a point \(y^{\ast} \in K\) (with its associated parameter variable \(x^{\ast}\)) such that:

\[
\langle F(y^{\ast}), (y - y^{\ast}) \rangle \geq 0, \quad \forall y \text{ s.t. } g(y, x) \leq 0.
\]

(4.20)
4.51.4.2 Quasi-Variational Inequalities with EMP: A Simple Example

Consider the following simple two dimensional linear example. Let $y$ be the variable of interest with its parameter variable $x$ and let

$$F(y) = \begin{bmatrix} 2y_1 + \frac{2}{3}y_2 - \frac{100}{22.5} \\ 1.25y_1 + 2y_2 - \frac{100}{22.5} \end{bmatrix}, \quad K(x) = \{y \in \mathbb{R}^2 | y_1 + x_2 \leq 15, x_1 + y_2 \leq 20, 0 \leq y, x \leq 11\}. \quad (4.21)$$

This $QVI(F, K)$ has a solution $y = (10, 5)$. The problem can be implemented in GAMS with EMP as follows:

```gams
set i / 1*2 /;
alias(i,j);
table A(i,j)
  1 2
  1 2 [8/3]
  2 [5/4] 2 ;
parameters
  b(i) / 1 [100/3], 2 22.5 /
  Cy(i,j) / 1.1 1, 2.2 1 /
  Cx(i,j) / 1.2 1, 2.1 1 /
  rhs(i) / 1 15, 2 20 /
; positive variables
  y(j) 'variable of interest, aka decision variable'
  x(j) 'parameter variable shadowing y'
  ; y.up(j) = 11; x.up(j) = 11;
equations
  F(i) 'FOC for agent optimization models'
  g(i) 'define feasible set K(x) for QVI'
  ;
  F(i).. sum{j, A(i,j)*y(j)} - b(i) =N= 0;
  g(i).. sum{j, Cy(i,j)*y(j)} + sum{j, Cx(i,j)*x(j)} =L= rhs(i);
model m / F, g /;
file annotations / '%emp.info%' /;
putclose annotations 'qvi F y x g' ;
solve m using emp;
```

Observe that the function $F$ and the constraints $g$ are formulated using standard GAMS syntax. $F$ is implemented as an equation of type $=n=$, which does not imply or enforce any relationship between the left-hand side and the right-hand side. Instead, this relationship is implied by the position of the matching variables (given in the EMP info file) relative to their bounds. The annotations in the EMP info file define the structure of the QVI: what functions are matched to what variables, and what constraints serve to define the mapping $K(x)$. The EMP keyword $qvi$ indicates that the model is a QVI, that the QVI function $F$ is matched to the variable-of-interest $y$ with its parameter variable $x$, and that the constraints $g$ define the mapping $K(x)$.

Since QVI problems have no objective, the short form of the solve statement is used.

The solver JAMS will reformulate the QVI as an MCP and pass this on to an MCP subsolver. The EMP Summary produced by JAMS will contain the following lines:
--- EMP Summary

...  
VI Functions = 2
QVI Parameters = 2
...

This output reflects the fact that there were two VI functions in the model above, one for each member of the set `i`, and that each of the variables matched to these functions was shadowed by a parameter variable.

Note that there are two QVI models in the GAMS EMP Library, the models [SIMPLEQVII] and [SIMPLEQVII2] (an expanded version of the example shown above).

4.51.4.3 EMP Syntax for Quasi-Variational Inequalities

The general syntax of the EMP annotations used to specify quasi-variational inequalities is as follows:

QVI {0 var [ parameterVar] | [-] equ var [ parameterVar] } { [-] equ}

The EMP keyword `QVI` indicates that this is a quasi-variational inequality specification. All variables and equations included in a QVI must be listed explicitly. First we have the VI functions, their matching variables, and (optionally) the parameter variables shadowing these variables. Note that in a QVI there are no preceding variables as we have in a VI spec:: instead, the implied match to the zero function is indicated by the digit 0 appearing where an equation symbol would otherwise appear. After the function/variable pairs have been listed, the trailing equations (i.e. the equations/constraints defining the mapping `K(·)`) appear.

4.51.5 Equilibrium Problems

While optimization problems have one decision maker that controls all decision variables, equilibrium problems are a collection of optimization problems and variational inequalities, each controlled by a different agent. We typically assume that each variable and each equation is controlled by or belongs to exactly one agent. Variables that are controlled by one agent but appear in the equations of a second agent are regarded as fixed or exogenous variables by that second agent: when taking first-order conditions, the second agent won’t take derivatives wrt these exogenous variables. Later we will relax this assumption and introduce equilibrium problems with shared constraints and shared variables. Note that in this section we will discuss equilibrium problems of the Nash type, i.e. where all agents are on the same level, each assuming the decisions or strategies of the other agents are known and fixed. Equilibrium problems of the Stackelberg type, where there are leaders and followers, are covered in section Bilevel Programs.

We start with the mathematical formulation of an equilibrium problem, next present two examples, and conclude with a description of the EMP annotations for equilibrium problems.
4.51.5.1 Equilibrium Problems: Mathematical Formulation

Consider the following equilibrium problem with \( N \) agents solving minimization problems and one agent solving a variational inequality:

\[
\text{Find } (x^*_1, \ldots, x^*_N, p^*) \text{ satisfying } \begin{align*}
x^*_i &\in \arg \min_{x_i} f_i(x_i, x^*_{-i}) \\
s.t. & \quad g_i(x_i, x^*_{-i}) \leq 0, \text{ for } i = 1, \ldots, N, \\
p^* &\in \text{SOL } (H(p, x^*), K(x^*)), \\
\end{align*}
\]

where \( K(x^*) = \{p \mid w(p, x^*) \leq 0\} \).

Note that \( f_i(x_i, x_{-i}) \) denotes the objective function of the problem of agent \( i \), \( g_i(x_i, x_{-i}) \) are the constraints relating to this optimization problem and \( x_{-i} = (x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_N) \) denotes the decisions of the other agents. Further, \( \text{SOL } (H, K) \) represents the solution set of the variational inequality \( VI(H, K) \).

This problem can be implemented with EMP as follows:

```plaintext
Set i;
Variables obj(i), x(i), p;
Equations deff(i), defg(i), defH, defw;

*Definitions of equations are omitted

Model equil / deff, defg, defH, defw /;

File myinfo /'emp.info'/;
put myinfo 'equilibrium';
loop(i,
   put / 'min', obj(i), x(i), deff(i), defg(i);
);
put 'vi defH p defw' /;
putclose myinfo;

solve equil using EMP;
```

Note that the GAMS variable \( \text{obj}(i) \) holds the value of \( f_i(x) \), \( x(i) \) represents the variable \( x_i \) and \( p \) denotes the variable \( p \), of course. The equations \( \text{deff}(i) \) and \( \text{defg}(i) \) are closed-form definitions of the objective function \( f_i(x) \) and the constraint \( g_i(x) \) respectively. The equation \( \text{defH} \) defines the variational inequality function \( H \) and the equation \( \text{defw} \) defines the set \( K \). The EMP annotations found in the file emp.info specify the equilibrium structure of the model:

```plaintext
equilibrium
min obj('1') x('1') deff('1') defg('1')
...
min obj('N') x('N') deff('N') defg('N')
vi defH p defw
```

The EMP keyword \texttt{equilibrium} indicates that the annotations are for an equilibrium problem. Each of the EMP keywords \texttt{min} begins a new optimization problem (owned by a new agent), where each problem has its own objective variable, decision variables, and equations / constraints. For example, the first agent minimizes \texttt{obj('1')} controls or owns \texttt{x('1')}, and is subject to the constraints \texttt{deff('1')} and \texttt{defg('1')}.

If other variables like \texttt{x('2')} and \texttt{x('3')} appear in \texttt{deff('1')} and \texttt{defg('1')}, they will be treated as exogenous by the first agent. This specification is consistent with the formulation above in (9).

Each agent’s optimization problem can be easily (re)constructed given the EMP annotations. Following the optimization problems of the \( N \) agents we have the VI specification for agent \( p \). The EMP keyword \texttt{vi} is followed by the equation-variable pair \texttt{defH p} defining the VI function \( H \) and the equation \texttt{defw} that defines the feasible set \( K \).

Note that the short form of the solve statement is used for equilibrium problems. Objective variables (if and when they exist) belong to individual agents, not to the model as a whole.
4.51.5.2 Equilibrium Problems with EMP: A Simple Example

Consider the following example from Kim & Ferris (2017) [109]. In this economic equilibrium problem there are three agents: one profit-maximizing producer, one utility-maximizing consumer and a market that determines the price of three commodities based on production and demand. The problem data include a technology matrix \( A \), where the entry \( a_{ij} > 0 \) denotes the output of the commodity \( i \) for each unit of activity of producer \( j \) and \( a_{ij} < 0 \) denotes the respective input. Further, an initial endowment \( b \) and the demand function \( d(p) \) is given, where \( p \) is the price. The consumer maximizes her utility within her budget, which depends on the price \( p \) and the initial endowment \( b \). Let \( y \) represent the activity of the producer, \( x \) represent the demand of the consumer and \( p \) represent the prices of commodities. Then \((y^*, x^*, p^*)\) is a general equilibrium if it satisfies the following:

\[
\begin{align*}
-A^T p^* &\geq 0 \quad \text{No positive profit for each activity} \\
b + A y^* - d(p^*) &\geq 0 \quad \text{No excess demand} \\
p^* \geq 0, y^* &\geq 0 \quad \text{Nonnegativity} \\
-A^T p^* &\perp y^* \quad \text{No activity for earning negative profit and positive activity implies balanced profit} \\
b + A y^* - d(p^*) &\perp p^* \quad \text{Zero price for excess supply and market clearance for positive price}
\end{align*}
\]

The code for the respective model is given below. Note that instead of using the consumer demand function \( d(p) \) in its explicit form, we introduce a utility-maximizing consumer with demand \( x \).

```plaintext
set i 'commodities' /1*3/;
variable u 'consumer utility'; positive variables
   y 'activity of the producer'
x(i) 'Marshallian demand of the consumer'
p(i) 'prices';
parameters
   A(i) 'technology matrix' /1 1, 2 -1, 3 -1/
s(i) 'budget share' /1 0.9, 2 0.1, 3 0/
b(i) 'endowment' /1 0, 2 5, 3 3/;
equations
   profit 'profit of activity'
mkt(i) 'constraint on excess demand'
   udef 'Cobb-Douglas utility function'
   budget 'budget constraint';
   profit.. -sum(i, A(i)*p(i)) =g= 0;
mkt(i).. b(i) + A(i)*y - x(i) =g= 0;
udef.. u =e= sum(i, s(i)*log(x(i)));
budget.. sum(i, p(i)*x(i)) =l= sum(i, p(i)*b(i));
model m /mkt, profit, udef, budget/;
file empinfo '%emp.info%'; putclose empinfo
   'equilibrium' /
      ' max', u, ' x', udef, budget /
      ' vi profit y' /
      ' vi mkt p' /
```

* the second commodity is used as a numeraire
p.fx('2') = 1;
x.l(i) = 1;
solve m using EMP;

Observe that in the EMP annotations the problems of the three agents are specified after the EMP keyword equilibrium: the consumer solves a maximization problem (where the utility \( u \) is maximized) and the activities of the producer and the price-setting market are expressed as VI. As there are three commodities, the first VI actually generates three VI functions, one for each commodity. Thus there are three agents and four VI functions in the equilibrium problem. This is reflected in the EMP Summary in the listing file:

--- EMP Summary
...  
VI Functions = 4
Equilibrium Agent = 3
...  

In the GAMS EMP Library there are several models that have a similar form, e.g. Scarf's activity analysis model [SCARFEMP-DEM] and the simple equilibrium problem [SIMPEQUIL]. The latter demonstrates that there are equilibrium problems where the optimization problems of the individual agents are solvable, but the overall equilibrium problem does not have a solution.

4.5.1.5.3 Equilibrium Problems with EMP: Example with Dual Variables

In many applications equilibrium problems come with a twist: the dual variable associated with a constraint in the problem of one agent appears exogenously in the problem of another agent. The following simple example with two agents is from model [DUALVAR] in the GAMS EMP Library.

Problem of the first agent: Min \( z = v + w \)
\begin{align*}
\text{s.t.} & \quad \sqrt{v + 1} + 2w \geq 2 \quad (\bot \quad u \geq 0) \\
& \quad v, w \geq 0
\end{align*}

Problem of the second agent: VI: 
\( F(y) := y - 4u + 1 \quad (\bot \quad y \text{ free}) \)

N.B.: the variable \( u \) that appears in the problem of the second agent is the dual multiplier (aka shadow price) of the first agent's constraint. This equilibrium problem can be modeled in GAMS with EMP as follows:

positive variables
\( v \) 'belongs to min agent'  
\( w \) 'belongs to min agent'  
\( u \) 'dual of min constraint'  
;  
free variables
\( y \) 'belongs to VI agent'  
\( z \) 'objective var'  
;  
equations
\text{defz} 'objective def'
\text{g} 'constraint for min agent'
The EMP info file contains the EMP keyword equilibrium followed by the specifications for the two agents: a minimization problem for the first agent and a VI for the second agent. The special relationship between the variable u and the equation g is declared via the EMP keyword dualvar followed by the respective variable-equation pair. Recall our usual assumption that each variable and each equation is owned or controlled by exactly one agent. Since variable u is tied to equation g and g is owned by the first agent, variable u is owned by the first agent also.

Besides the number of equilibrium agents and the number of VI functions, the EMP Summary lists the number of dual variable maps:

--- EMP Summary

... Dual Variable Maps = 1 ...

... VI Functions = 1
Equilibrium Agent = 2 ...

Note

Although the example above contained an optimizing agent and a VI agent, dual variables most often occur in equilibrium problems with several optimizing agents.

Other examples with dual variables in the GAMS EMP Library include a formulation of the well-known transportation model as an equilibrium problem [TRANSEQL], Scarf's activity analysis model [SCARFEMP-PRIMAL] and the general equilibrium model [TWO3EMP].
4.51.5.4 EMP Syntax for Equilibrium Problems

The EMP framework provides the following general syntax to specify equilibrium problems:

\[
\begin{align*}
\text{Equilibrium} & \quad \{\text{VIsol \{equ\}}
\{\text{Implicit \{var \text{equ}\}}
\{\text{MAX|MIN \text{obj \{var\} \{-\} \text{equ}}
\{\text{VI \{var\} \{-\} \text{equ var} \{-\} \text{equ}}
\{\text{DualVar \{var [-] \text{equ}\}}
\end{align*}
\]

The EMP keyword \text{Equilibrium} indicates that the specifications that follow define the structure of an equilibrium problem. The \text{MAX}, \text{MIN}, and \text{VI} keywords specify agents in the problem, while the rest of the keywords are optional modifiers used to adjust the structure of the agent models or the meaning of the equations they contain.

\begin{itemize}
  \item \text{Note}: An equilibrium problem must contain at least one agent, i.e. must contain one of the keywords \text{MAX}, \text{MIN}, or \text{VI}.
\end{itemize}

The EMP keyword \text{VIsol} identifies a shared constraint(s) and specifies the MCP reformulation to use for it: see section \text{Equilibrium Problems with Shared Constraints} below for details. The keyword \text{Implicit} identifies a shared variable and its defining constraint: see section \text{Equilibrium Problems with Shared Variables} below for details. The keywords \text{MAX} and \text{MIN} each begin the specification of an optimization agent and are followed by the objective variable \text{obj} and the other variables and equations owned by the agent, as described in the formulation and example above. The keyword \text{VI} begins the specification of a VI agent: see the section on \text{VI} above for details. Finally, the EMP keyword \text{DualVar} specifies that the variable \text{var} is the Lagrange multiplier for the equation \text{equ}. For examples, see sections \text{Equilibrium Problems with EMP: Example with Dual Variables} and \text{Embedded Complementarity Systems}.

The symbol '∗' specifies that the default or automatic assignment of variables to this agent be used, i.e. the set of variables used in the equations owned by this agent but not explicitly or otherwise assigned to another agent. Note that if a variable occurs in equations owned by multiple agents and is not explicitly assigned to any agent, the default assignment is not well defined and using it will be flagged as an error. To avoid confusion and promote clarity, we recommend that modelers use explicit variable lists and avoid the '∗' symbol.

The "-" sign in the syntax above is used to flip (i.e. to reorient or negate) the marked equation, e.g. so that \(x^{1.5} = L = y\) becomes \(y = G = x^{1.5}\). Flipped equations in EMP behave in the same way as flipped equations in MCP.

\begin{itemize}
  \item \text{Note}: When the EMP keyword \text{equilibrium} appears in the EMP annotations, the solve statement takes the short form also used for complementarity problems in GAMS.
\end{itemize}
4.51.6 Embedded Complementarity Systems

Embedded complementarity systems of the following form arise frequently in applications:

$$
\begin{align*}
\text{Min}_x & \quad f(x, y) \\
\text{s.t.} & \quad g(x, y) \leq 0 \quad (\perp \lambda \geq 0) \\
H(x, y, \lambda) & = 0 \quad (\perp y \text{ free})
\end{align*}
$$

(12)

Note that the optimization problem is over the variable $x$ and it is parametrized by the variable $y$. The choice of $y$ is determined by the complementarity relationships represented here by $H$.

From an EMP perspective, there are two ways to annotate a GAMS model to specify the model above: we will describe both below. These approaches provide equivalent additional information that prompts the EMP tool to automatically create the following MCP:

$$
\begin{align*}
0 & = \nabla_x L(x, y, \lambda) \quad \perp x \text{ free} \\
0 & \leq -\nabla_\lambda L(x, y, \lambda) \quad \perp \lambda \geq 0 \\
0 & = H(x, y, \lambda) \quad \perp y \text{ free},
\end{align*}
$$

(13)

where the Lagrangian is defined as

$$L(x, y, \lambda) = f(x, y) + \lambda^T g(x, y).$$

(4.24)

The first approach uses the EMP keywords `dualequ` and `dualvar`, as contained in the model [FERRIS43].

```plaintext
variables obj, x, y;
positive variable lambda;

equations defobj, g, H;

* We omit the equation definitions here.

model ecs /defobj, g, H/;

file empinfo / '%emp.info%'/; putclose empinfo
'dualequ H y' /
'dualvar lambda g' /;

solve ecs using EMP minimizing obj;
```

The external constraint $H$ is expressed as a standard GAMS equation. The long form of the solve statement is used here, which implies the existence of a single optimizing agent that by default owns all equations and variables. The first EMP keyword `dualequ` indicates that the equation $H$ and the variable $y$ do not belong to the optimizing agent: instead, $y$ is treated as an exogenous variable by this agent, and this agent is assumed to know nothing about the functional form of $H$, so that $H$ will not appear in any first-order conditions. Instead, a complementarity relationship between the function defined by $H$ and the variable $y$ is required to exist at optimality. The EMP keyword `dualvar` indicates that the variable $\lambda$ is the dual of the equation $g$. As a result $\lambda$ will be treated exogenously wherever it appears. Given the EMP annotations for this model, JAMS will automatically reformulate the problem as the MCP in (12) and pass this model to an MCP subsolver.

The EMP Summary produced by JAMS contains the following lines:
The second modeling approach recasts the problem above as an equilibrium problem with two agents: the first agent solves a minimization problem and the second agent solves a VI. The algebra in the model remains the same: only the EMP annotations and the solve statement change.

```
putclose empinfo
'equilibrium' /
' min obj x g defobj' /
' vi H y' /
' dualvar lambda g' /

solve ecs using EMP;
```

The EMP keyword **equilibrium** indicates we have an equilibrium problem. The EMP keyword **min** indicates that the first agent solves a minimization problem with the objective variable **obj**, the decision variable **x** and the equations **g** and **defobj**. In contrast to the first approach, where the default (because of the long-form solve statement) is one optimizing agent owning all equations, here we specify the first agent’s minimization model explicitly and from the ground up. As a result it doesn’t contain the equation **H** and we do not use the **dualequ** keyword to take **H** out. Instead, the EMP keyword **vi** specifies that the second agent solves a VI defined by **H** matched with the variable **y**. The **dualvar** keyword functions here as it did in the previous example.

The EMP Summary produced by JAMS contains the following lines:

```
--- EMP Summary
... Dual Variable Maps = 1
... Dual Equation Maps = 0
... VI Functions = 1
... Equilibrium Agent = 2
... Dual Variable Maps = 1
Dual Equation Maps = 1

The EMP Summary produced by JAMS contains the following lines:

--- EMP Summary
... Dual Variable Maps = 1
... Dual Equation Maps = 0
... VI Functions = 1
... Equilibrium Agent = 2
... Other examples of embedded complementarity systems in the GAMS EMP Library include the simple equilibrium problem [SIMPEQUIL2], the equilibrium problem formulation of the well-known transportation model [TRANSECS], the PIES energy equilibrium problem [PIES], the pure exchange model [NEGISHI] and the spatial price equilibrium model [HARK-MONOP].

It’s worthwhile highlighting the differences between the **dualvar** and **dualequ** keywords, as the two are easily and frequently confused. The **dualvar** keyword makes reference to a constraint owned by an optimizing agent. Derivatives of this constraint, multiplied by the variable referenced, appear in the first-order optimality conditions for this agent. The **dualvar** keyword allows us to use this variable or multiplier explicitly (and in a sense exogenously) in the model algebra. In contrast, the **dualequ** keyword indicates that, contrary to what the default is, an equation is not owned by any optimizing agent, so no derivatives of this equation will appear in any FOC or in the reformulated model. The two are similar in that if a variable **x** appears with either **dualvar** or **dualequ**, no derivatives w.r.t. **x** will appear in the model reformulation.

4.51.7 Equilibrium Problems with Shared Constraints

In the equilibrium problems we have discussed so far, each variable and each constraint was owned by a single agent. In this section we relax the assumption that each constraint has to be controlled by a single agent and introduce shared constraints. Shared constraints are constraints that appear in the problems of several agents. They are mainly used to model resources shared among agents. Note that the examples in this section are from Kim & Ferris (2017) [109].

Consider the following example:

\[
\begin{align*}
\text{Find } & (x^*_1, \ldots, x^*_N) \text{ satisfying } \\
& x^*_i \in \arg \min_{x_i} f_i(x_i, x^*_{-i}) \\
& \text{s.t. } g_i(x_i, x^*_{-i}) \leq 0 \\
& h(x_i, x^*_{-i}) \leq 0, \quad \text{for } i = 1, \ldots, N.
\end{align*}
\]

(14)

The constraints \(g_i\) are owned by agent \(i\), while the constraint \(h\) is shared by all agents. This example can be reformulated in two different ways, each with its own EMP annotations and resulting MCP. However, both share the model formulation below:

variables obj(i), x(i);
equations deff(i), defg(i), defh;
model sharedc / deff, defg, defh /;

Observe that the equation \(\text{defh}\) implementing the shared constraint \(h(x) \leq 0\) is not indexed: it exists once, not once per agent. The first way to write the EMP annotations is as follows:

file empinfo / '%emp.info%' /;
put empinfo 'equilibrium' /;
loop(i,
    put 'min', obj(i), x(i), deff(i), defg(i), defh; /;
);
putclose empinfo;

Here the equation \(\text{defh}\) appears in the minimization problem of each agent. As the equation \(\text{defh}\) is not indexed by agent and appears in the problem of each agent, it is easy to see that it is a shared constraint. Given these annotations, the EMP framework aggregates the FOC for each agent to create the following MCP:

\[
F(z) = ((F_i(z)^T)_{i=1}^N)^T, \\
F_i(z) = \begin{bmatrix}
\nabla_x f_i(x) - \nabla_y g_i(x) \lambda_i - \nabla_z h(x) \mu_i \\
g_i(x) \\
h(x)
\end{bmatrix}, \\
z = ((z_i^T)_{i=1}^N)^T, \\
z_i = \begin{bmatrix}
x_i \\
\lambda_i \leq 0 \\
\mu_i \leq 0
\end{bmatrix}, \quad \text{for } i = 1, \ldots, N.
\]

(15)

Note that the equation \(h(\cdot)\) is replicated for each agent and each agent is assigned a separate multiplier \(\mu_i\).
Attention

By default, the solver JAMS does not allow shared constraints. The option SharedEqu needs to be specified in the option file jams.opt if shared constraints are intended, otherwise an error is reported when they are detected. This cautious default helps minimize the number of surprising results.

A full model including the JAMS option file is given below.

The second way to write the EMP annotations uses the EMP keyword VIsol to specify that a variational equilibrium be computed, i.e. a solution where the multipliers \( \mu_i \) are all equal. The VIsol keyword should appear after the EMP keyword equilibrium and before the descriptions of agent models.

\[
\text{put / 'VIsol defh'};
\]

The multipliers to make equal (or, equivalently, the constraints not to replicate) are indicated by the equation name(s) following the keyword VIsol. These constraints appear once in the resulting MCP, not once per agent. The EMP tool creates the following MCP:

\[
\begin{align*}
F(z) &= \left( (F_i(z)^T)^{N_{\text{im}}}, F_h(z)^T \right)^T, \\
F_i(z) &= \begin{bmatrix} \nabla z_i \cdot f_i(x) - \nabla x_i g_i(x) \lambda_i - \nabla x_i h(x) \mu \end{bmatrix}, \\
F_h(z) &= \begin{bmatrix} h(x) \end{bmatrix}, \\
z &= \left( (z_i^T)^{N_{\text{im}}}, z_h^T \right)^T, \\
z_i &= \begin{bmatrix} x_i \end{bmatrix}, \quad \lambda_i \leq 0, \\
z_h &= [\mu \leq 0].
\end{align*}
\]

If there are no constraints \( g_i(x) \), then - assuming a constraint qualification - the equilibrium problem with the shared constraint corresponds exactly to the variational inequality \( VI(F,X) \), where the set \( X = \{ x | h(x) \leq 0 \} \) and \( F(x) = (\nabla x_i f_i(x)^T)^{N_{\text{im}}} \). This corresponds in turn to the solution of the first MCP (with the replicated shared constraints) in case that solution has the property that the multipliers \( \mu_i \) are all equal. This is what gives the latter solution its name variational equilibrium. If the equilibrium problem with the shared constraint has a unique solution, both MCP reformulations will have the same solution. Otherwise, the two MCPs that correspond to the two different EMP annotations may have different solutions.

An example for shared constraints is the pollution of a river basin in Haurie & Krawczyk (1997) [96] and Krawczyk & Uryasev (2000) [111], where the total amount of pollutants that may be dumped in a river is restricted. This implies that the environmental constraints of some pollutant-producing agents are shared. This example can be formulated as follows, where \( i \) is the agent index and \( m \) denotes the number of shared constraints.

Find \((x_1^*, x_2^*, x_3^*)\) satisfying

\[
\begin{align*}
\text{arg min}_{x_i} \quad & (c_1 i + c_2 i x_i) x_i - \left( d_1 - d_2 \left( \sum_{j=1, j \neq i}^3 x_j^* + x_i \right) \right) x_i \\
\text{s.t.} \quad & \sum_{j=1, j \neq i}^3 x_j^* u_{jm} e_j x_i + u_{im} e_i x_i \leq K_m, \\
& \text{for } i = 1, 2, 3, \quad m = 1, 2,
\end{align*}
\]

where \((c, d, e, u, K)\) is the problem data.

Here three agents produce some commodities and aim to maximize their profit. The term \((c_1 i + c_2 i x_i) x_i\) denotes the total cost for each agent \( i \) and the term \((d_1 - d_2 (\sum_{j=1, j \neq i}^3 x_j^* + x_i)) x_i\) represents the revenue for each agent. The amount of pollutants each agent dumps in the river is limited by the two shared constraints. This problem can be implemented in GAMS with EMP as follows:
Sets i / 1*3 / 
m / 1*2 / ;
alias(i,j) ;

Variable  obj(i) ;
Positive Variable x(i) ;

Parameters K(m) / 1 100, 2 100 / 
d1 / 3 / 
d2 / 0.01 / 
e(i) / 1 0.5, 2 0.25, 3 0.75 / ;

Table c(m,i)
   1     2     3
1  0.1  0.12  0.15
2  0.01 0.05  0.01 ;

Table u(i,m)
   1     2
1  6.5  4.583
2  5.0  6.250
3  5.5  3.750 ;

Equations objdef(i)
       cons(m) ;

objdef(i)..  obj(i)  =e=  (c('1',i) + c('2',i)*x(i))*x(i) - (d1 - d2*sum(j, x(j)))*x(i);
cons(m)..  sum(i, u(i,m)*e(i)*x(i)) =l= K(m);

Model m_shared / objdef, cons /;

File empinfo / '%emp.info%' /;
put empinfo 'equilibrium' /;
put 'VIsol cons' /;
loop(i,
    put 'min', obj(i), x(i), objdef(i), 'cons' /;
);
putclose empinfo;

$echo SharedEqu > jams.opt
m_shared.optfile = 1;

solve m_shared using emp;
display x.l, cons.m;

Note that the shared environmental constraints are expressed with the equation cons. In the EMP annotations, we have chosen the formulation with the EMP keyword VIsol. It leads to the solution $x^* = (21.145, 16.028, 2.726)$. Alternatively, we could delete the line with the EMP keyword VIsol and thus prompt the framework to compute the MCP in (15), resulting in the solution $x^* = (0, 6.473, 22.281)$.

### 4.51.8 Equilibrium Problems with Shared Variables

In the last section, we relaxed the restriction that each constraint has to be controlled by a single agent and introduced shared constraints. In this section, we go a step further and allow shared variables. Note that the content of this section is adapted from Kim & Ferris (2017) [109].
First, we introduce the notion of *implicit variables*. In mathematical terms, a variable \( y \) is called an implicit variable if for each value of \( x \) there is at most one value of \( y \) satisfying \((y, x) \in X\). For such implicit variables there exists one and only one function \( g(\cdot) \) such that \((g(x), x) \in X\), where \( g \) is defined over the set \( \{ x \mid \exists y \text{ such that } (y, x) \in X \} \). The set \( X \) is called the *defining constraint* of the variable \( y \): the value of \( y \) is implicitly defined by the value of \( x \) via the defining constraint. In the current implementation, the defining constraint may only be represented as a system of equations and implicit variables must be free variables in GAMS.

*Shared variables* in equilibrium problems are implicit variables that have the same defining constraint for all agents that share the variable. Hence, the defining constraint becomes a shared constraint. Consider the following equilibrium problem with the shared decision variable \( y \) and its defining constraint \( X = \{ (y, x) \mid H(y, x) = 0 \} \):

$$
\begin{align*}
\text{Find} & \quad (y^*, x^*_1, \ldots, x^*_N) \\
\text{arg min} & \quad f_i(y, x_i, x^*_{-i}) \\
\text{s.t.} & \quad H(y, x_i, x^*_{-i}) = 0, \quad \text{for } i = 1, \ldots, N,
\end{align*}
\quad (18)
$$

Note that there are \( N \) agents, \( m \) is the dimension of the variable \( y \) and \( n = \sum n_i \), where \( n_i \) is the dimension of \( x_i \). Assuming we have 4 agents, this example can be implemented in GAMS EMP as follows:

```gams
Set      i / 1*4/;
Variables obj(i), x(i), y;
Equations deff(i), defH;
Model    sharedv / deff, defH /;
File empinfo / '%emp.info%' /;
put empinfo 'equilibrium' /;
put 'implicit y defH' /;
loop (i,
     put 'min', obj(i), x(i), y, deff(i) /;
);
putclose empinfo;
solve sharedv using EMP;
```

In the EMP annotations, the EMP keyword *implicit* is used to declare the implicit variable \( y \) and its defining constraint \( \text{defH} \). Note that the keyword *implicit* must be followed by variable-constraint pairs. If multiple pairs are specified with a single keyword *implicit*, they will be augmented to form a single vector of implicit variables and its defining constraint.

Note

Implicit variables are declared *before* the agent problems are defined.

Observe that the shared variable \( y \) appears in the problem specification for each agent. However, the defining equation \( \text{defH} \) does not appear in each problem specification, since it is assumed to be part of the implicit variable.
4.51.8.1 Reformulation Strategies for Equilibrium Problems with Shared Variables

Like other equilibrium problems, equilibrium problems with shared variables are reformulated as MCPs by the EMP tool. Users can choose between three different reformulation strategies if shared decision variables are involved. In the first strategy, the shared variables are replicated for each agent and the respective KKT conditions are computed, resulting in the following MCP:

\[
F(z) = [(F_i(z)^T)^N_{i=1}, F_h(z)^T]^T, \quad z = [(x_i^T)^N_{i=1}, z_h^T]^T
\]

\[
F_i(z) = \left[\begin{array}{c}
\nabla_x f_i(x, y) - \left(\nabla_x, H(y, x)\right) \mu_i \\
\nabla_y f_i(x, y) - \left(\nabla_y, H(y, x)\right) \mu_i \\
H(y, x)
\end{array}\right], \quad z_i = \begin{bmatrix} x_i \\ \mu_i \end{bmatrix}, \quad z_h = [y].
\]

(19)

Note that in this MCP the constraint \( H \) and the variable \( y \) are replicated \( N \) times. The size of the MCP is \((n + 2mN)\). This reformulation is obtained by specifying the option \( \text{ImplVarModel}=\text{replication} \) in the JAMS options file.

The second reformulation strategy involves switching each shared variable with the multiplier associated with its defining equation. This technique can be applied if all of the following three conditions are met:

1. The defining constraint is given as an equation.
2. The dimension of the range of the defining constraint equals the dimension of the shared variable.
3. The shared variable is a free (unbounded) variable.

The switching strategy uses the fact that in an MCP, the matching between free variables and equations is somewhat arbitrary: it can be re-assigned without changing the solution. Applying this technique, we obtain the following MCP:

\[
F(z) = [(F_i(z)^T)^N_{i=1}, F_h(z)^T]^T, \quad z = [(x_i^T)^N_{i=1}, z_h^T]^T
\]

\[
F_i(z) = \left[\begin{array}{c}
\nabla_x f_i(x, y) - \left(\nabla_x, H(y, x)\right) \mu_i \\
\nabla_y f_i(x, y) - \left(\nabla_y, H(y, x)\right) \mu_i \\
H(y, x)
\end{array}\right], \quad z_i = \begin{bmatrix} x_i \\ \mu_i \end{bmatrix}, \quad z_h = [y].
\]

(20)

Observe that in this MCP, the defining constraint \( H \) and the shared variable \( y \) appear only once. Thus the size of the problem is reduced to \((n + mN + n)\). The EMP framework will use this reformulation if the option \( \text{ImplVarModel}=\text{switching} \) is specified in the JAMS option file. This is currently the default strategy used.

The third strategy is selected by specifying option \( \text{ImplVarModel}=\text{substitution} \) in the JAMS option file. It uses the implicit function theorem to substitute the multipliers \( \mu_i \) by new variables \( \Lambda_i \), where \( \Lambda_i = \nabla_x, H(\nabla_y H)^{-1} \). This technique may be applied when the three conditions of the switching strategy are satisfied, and in addition, the implicit function theorem holds for the defining constraints. The basic idea is to regard the shared variable \( y \) as a function of other non-shared variables and apply the derivative. At each solution to the problem \((y^*, x^*)\), there exists a locally defined implicit function \( h_{x^*}(x) \) such that \( y^* = h_{x^*}(x^*) \) and \( H(h_{x^*}(x), x) = 0 \) for each \( x \) in some neighborhood of \( x^* \). It can be shown that given the implications of the implicit function theorem and the new variables \( \Lambda_i \), the equilibrium problem can be reformulated as the MCP that follows. However, we omit a step-by-step mathematical derivation here, it is given in Kim & Ferris (2017) [109].

\[
F(z) = [(F_i(z)^T)^N_{i=1}, F_h(z)^T]^T, \quad z = [(x_i^T)^N_{i=1}, z_h^T]^T
\]

\[
F_i(z) = \left[\begin{array}{c}
\nabla_x f_i(x, y) - \left(\nabla_y, f_i(x, y)\right) \Lambda_i \\
\nabla_y H(y, x) \Lambda_i - \left(\nabla_x, H(y, x)\right) \Lambda_i \\
H(y, x)
\end{array}\right], \quad z_i = \begin{bmatrix} x_i \\ \Lambda_i \end{bmatrix}, \quad z_h = [y].
\]

(21)
The size of this MCP is \( (n + mn + m) \). It can be significantly reduced if the shared variable is *explicitly* defined, for example, \( H(y, x) = y - h(x) \). In this case, \((\nabla_y H)^{-1}\) is the identity matrix, therefore it is not necessary to introduce the variables \( \Lambda_i \) and the MCP takes the following form:

\[
F(z) = \left[ (F_i(z))_{i=1}^N, F_h(z) \right]^T, \\
F_i(z) = \left[ \nabla x_i f_i(x, y) - \nabla x_i H(y, x) \nabla y f_i(x, y) \right], \\
F_h(z) = \left[ H(y, x) \right], \\
z = \left[ z_i^T \right]_{i=1}^N, z_h^T
\]  

(22)

The size of this MCP is \( (n + m) \), which is a huge decrease compared to the other formulations. Note that the EMP framework detects automatically if the shared variable is explicitly defined and exploits this fact. In the following table an overview of the size of the MCP for the different reformulation techniques is given.

<table>
<thead>
<tr>

</tbody>
</table>

Table 2: Size of the Reformulated MCP For Different Reformulation Techniques

### 4.51.8.2 Equilibrium Problems with Shared Variables: A Simple Example

The following simple example computes a saddle point of the Lagrangian associated with a minimization over \( x \) subject to a single equality constraint with dual multiplier \( y \). The GAMS EMP implementation is from Youngdae Kim. The primal (minimizing) and dual (maximizing) agents share the variable \( L \) containing the value of the Lagrangian, as well as its defining equation \( \text{defL} \):

```gams
set i / 1*2 /;
variables
   L  'Lagrangian function: f(x) - y * h(x)'
   x(i) 'primal variables'
   y  'dual variable'
;
equation defL;
defL..  
   L =e= sum{i, sqr(x(i)-1)} - y*(sum{i, x(i)} - 4);
model m / defL /;
file empinfo / '%emp.info%' /; putclose empinfo
   'equilibrium' /  
   'implicit L defL' /  
   ' min L x' /  
   ' max L y' /  
;
solve m using emp;
```

Note that the variable \( L \) is not indexed and it appears in the optimization problem of each agent. It is declared to be an implicit variable (using the keyword *implicit*) in the first line following the *equilibrium* keyword. Its defining constraint \( \text{defL} \) is listed only once, in this same line: it does not appear in the problem specification of each agent. By modeling the Lagrangian as a shared variable, its defining equation does not have to be replicated for each agent.

For other, more complex examples, both with shared decision variables and with a shared objective variable, see Kim & Ferris 2017 [109].
4.51.9 Bilevel Programs

Bilevel programs are mathematical programs with optimization problems in their constraints. The main problem is called the upper-level problem or the leader and the nested problem is called the lower-level problem or the follower. A simple example is the bilevel programming problem that optimizes an upper-level objective over constraints that include a lower-level optimization problem. A famous example from economics is the Stackelberg game, where there is one leader and many followers. Bilevel programming is used in many areas, for example the design of optimal tax instruments: the tax instrument is modeled in the upper level and the clearing market is modeled in the lower level.

In this section we first present a mathematical formulation of a bilevel program with one follower and introduce the respective EMP annotations. Then we present three examples: a simple first example, an example with a variational inequality as the lower-level problem and an example with multiple followers that form a Nash equilibrium. We conclude the section with a short discussion of the general EMP syntax for bilevel programs.

4.51.9.1 Bilevel Programs: Mathematical Formulation

A bilevel program with one leader and one follower can be expressed as follows:

\[
\begin{align*}
\text{Min}_{x \in X, y} & \quad f(x, y) \\
\text{s.t.} & \quad h(x, y) \leq 0 \\
& \quad y \text{ solves } \text{Min}_{y} g(x, y) \\
& \quad \text{s.t. } k(x, y) \leq 0,
\end{align*}
\]

(23)

where

- \( x \in \mathbb{R}^n \) are the upper-level variables,
- \( y \in \mathbb{R}^m \) are the lower-level variables,
- \( f : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R} \) is the upper-level objective function,
- \( g : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R} \) is the lower-level objective function,
- \( h : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^u \) are the upper-level constraints, and
- \( k : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^l \) are the lower-level constraints.

Note that the upper-level constraints do not bind the lower-level decision maker.

This problem can be implemented with EMP as follows:

Sets i, j ;
Variables x(i), objout, y(i), objin;
Equations deff(x,y), defg(x,y), defh(x,y), defk(x,y);

* Definitions of equations are omitted

Model bilevel / deff, defg, defh, defw /;

$onecho > "%emp.info%"
bilevel x
min objin y defg defk
$offecho

solve bilevel using EMP minimizing objout ;
Note that the variables and equations of the program are defined in GAMS in the usual way. The special bilevel structure of the model is specified in the EMP annotations. The EMP keyword **bilevel** indicates that this is a bilevel problem. The name and direction of the leader’s objective variable is taken from the solve statement, but the other variables owned by the leader are listed after the **bilevel** keyword. The lower-level problem is specified next via the EMP keyword **min**, followed by the follower’s objective variable **objin**. The other variables and the equations of the lower-level problem are listed next. Observe that this is exactly the same syntax that we introduced **above** for specifying optimization problems in the context of equilibrium problems.

The EMP tool reformulates the bilevel problem as a Mathematical Program with Equilibrium Constraints (MPEC) and passes this on to a subsolver (e.g. NLPEC or KNITRO). The reformulation is obtained by replacing the lower-level optimization problem by its KKT conditions, resulting in the following problem:

\[
\begin{align*}
\text{Min}_{x \in X, y, \lambda} & \quad f(x, y) \\
\text{s.t.} & \quad h(x, y) \leq 0 \\
& \quad k(x, y) \leq 0 \\
& \quad \lambda_i \leq 0, \quad i = 1, \ldots, l \\
& \quad \lambda_i k_i(x, y) = 0, \quad i = 1, \ldots, l \\
& \quad \nabla_y \mathcal{L}(x, y, \lambda) = 0,
\end{align*}
\]

where

\[
\mathcal{L}(x, y, \lambda) = g(x, y) + \sum_{i=1}^{l} \lambda_i k_i(x, y)
\]

is the Lagrangian function associated with the lower-level problem.

Note, however, that this reformulation is potentially problematic. KKT conditions require theoretical assumptions (like convexity) to be necessary and sufficient for local optimality. There may be cases where the lower level problem has multiple local solutions, but the modeler is interested in the global solution. Hence the reformulation above may not lead to the global solution, even if a global subsolver is used within the solver NLPEC.

Observe that there are two variations to problem (23) that the EMP framework is equipped to handle: the lower-level problem may be a variational inequality instead of an optimization problem, and there may be multiple lower-level problems (optimizing and/or VI) each behaving in a Nash manner. Examples follow in sections Bilevel Programs with EMP: A VI as Follower and Bilevel Programs with EMP: Multiple Followers respectively.

### 4.51.9.2 Bilevel Programs with EMP: A Simple Example

To illustrate, we use model [BARD851](BARD851) from the GAMS EMP Library. Mathematically, the problem is

\[
\begin{align*}
\text{Min}_{x, y_1, y_2} & \quad (x - 1)^2 + 2y_1^2 - 2x \\
\text{s.t.} & \quad (y_1, y_2) \quad \text{solve} \quad \text{Min}_{y_1, y_2} \quad (2y_1 - 4)^2 + (2y_2 - 1)^2 + xy_1 \\
& \quad \text{s.t.} \quad 4x + 5y_1 + 4x_2 \leq 12 \\
& \quad -4x + 5y_1 + 4x_2 \leq -4 \\
& \quad 4x - 4y_1 + 5x_2 \leq 4 \\
& \quad -4x + 4y_1 + 4x_2 \leq -4 \\
& \quad y_1, y_2 \geq 0
\end{align*}
\]

Note that this problem does not have any upper-level constraints. The GAMS code follows.
Positive Variables x, y1, y2;
Variables         objout, objin;

Equations defout, defin, e1, e2, e3, e4;

\[
defout.. \quad \text{objout} = e= \text{sqr}(x-1) + 2*\text{sqr}(y1) - 2*x; \\
defin.. \quad \text{objin} = e= \text{sqr}(2*y1-4) + \text{sqr}(2*y2-1) + x*y1;
\]
\[
e1.. \quad 4*x + 5*y1 + 4*y2 =l= 12; \\
e2.. \quad -4*x - 5*y1 + 4*y2 =l= -4; \\
e3.. \quad 4*x - 4*y1 + 5*y2 =l= 4; \\
e4.. \quad -4*x + 4*y1 + 5*y2 =l= 4;
\]

Model bard / all /;

$echo bilevel x min objin y1 y2 defin e1 e2 e3 e4 > "%emp.info%"

solve bard use emp min objout;

The leader minimizes the variable objout, as specified in the solve statement. The EMP annotations specify the rest of the bilevel structure: the variable x belongs to the upper-level problem, and there is one lower-level agent or problem with objin minimized over the variables y1 and y2 subject to the constraints or equations defin, e1, e2, e3 and e4.

Alternatively, we could write the EMP annotations as:

$echo bilevel x min objin * defin e1 e2 e3 e4 > "%emp.info%"

Here the lower-level variables are not listed: instead, the '∗' indicates that all variables in the GAMS model not explicitly assigned to any agent are to be assigned to the follower.

The EMP Summary produced by JAMS gives the number of followers in the bilevel program:

--- EMP Summary
   Bilevel Followers = 1

The GAMS EMP Library contains other bilevel examples, including several models bard∗, the engineering models [CCMG74] and [CCMG153], and the simple nonconvex model [MIRRLESS]. The models [JOINTC1] and [JOINTC2] illustrate the interplay of the decision variables of the upper-level and lower-level problems.

4.51.9.3 Bilevel Programs with EMP: A VI as Follower

If the lower-level problem is a variational inequality, problem (23) will take the following form:

\[
\begin{align*}
\text{Min}_{x,y} & \quad f(x,y) \\
\text{s.t.} & \quad h(x,y) \leq 0 \\
& \quad y \text{ solves } VI(F, K(x)),
\end{align*}
\] (26)

where
\( x \in \mathbb{R}^n \) are upper-level variables and \( y \in \mathbb{R}^m \) are lower-level variables, and
\( K(x) \subseteq \mathbb{R}^m \) is a closed convex set, parametrized by \( x \).

Consider the following simple example adapted from [MULTMPEC]:

\[
\begin{align*}
\text{Min}_{w,z} & \quad z \\
\text{s.t.} & \quad e^z + w = 2 \\
& \quad z \geq 1 \\
& \quad w \text{ solves the } VI(F, K), \text{ where } K = \mathbb{R} \text{ and } F = w + z + 3
\end{align*}
\]

This bilevel problem can be modeled with EMP as follows:

variables w, z;
equations h, F;
h.. exp(z) + w =e= 2;
F.. w + z =n= -3;
z.lo = 1;
model bpvi / h, F /;

solve bpvi using emp min z;

Note that in the EMP annotations the lower-level problem is specified as a VI with the VI function \( F \) and the corresponding variable \( w \): for details see section EMP Syntax for Variational Inequalities. The count of VI functions is indicated in the EMP Summary:

--- EMP Summary
...
VI Functions \quad = 1
...  
Bilevel Followers \quad = 1

4.51.9.4 Bilevel Programs with EMP: Multiple Followers

The EMP framework allows multiple followers in a bilevel program. Taking the leader decisions as fixed, these followers behave as the agents in a Nash equilibrium. Consider the engineering example [CCMG71] from the GAMS EMP Library. In this bilevel program there are two followers, both solving minimization problems, specified in the EMP annotations as follows:

...
$onecho > %emp.info%
bilevel x1 x2 x3 x4
  min h1 u1 u2 u3 u4 defh1 e1
  min h2 v1 v2 v3 v4 defh2 e2
$offecho
...

The variables $x_1$, $x_2$, $x_3$ and $x_4$ are owned or controlled by the leader. The first follower minimizes the variable $h_1$ over the variables $u_1$, $u_2$, $u_3$ and $u_4$ subject to the constraint/equation $e_1$. The second follower is defined in a similar way. More details on how to specify optimization subproblems in the EMP annotations are given in section EMP Syntax for Equilibrium Problems.

Observe that in the EMP annotations of the actual model [CCMG71] the following shorthand notation is used:

```
... $onecho > %emp.info%
bilevel x1 x2 x3 x4
min h1 * defh1 e1
min h2 * defh2 e2
$offecho ...
```

The symbol '*\  ' in the problem of the first follower indicates that this agent will optimize over all variables appearing in equations $defh1$ and $e1$ (i.e. the equations it controls) that are not claimed by another agent. In this case, the respective variables are $u_1$, $u_2$, $u_3$ and $u_4$. N.B.: in this example, if a variable appears in the equations for both followers the problem structure is not well defined and an error will result. To avoid confusion and promote clarity, we recommend that modelers explicitly list all the variables in each agent's problem, as shown in the first version of the EMP annotations above.

The number of followers is indicated in the EMP Summary:

```
--- EMP Summary
...
Bilevel Followers   = 2
```

The GAMS EMP Library contains several bilevel problems with several followers, e.g. the well-known transportation model with a variable demand function cast as a bilevel problem with one optimization follower and one VI follower [TRANSBP], a simple example with two VI followers [MULTMPEC], and the spatial equilibrium Stackelberg model [HARK-STACK].

### 4.51.9.5 EMP Syntax for Bilevel Programs

The general syntax that EMP provides to specify bilevel programs in the EMP annotations file `emp.info` is as follows:

```
Bilevel {var}
{MAX|MIN obj {var|*} {[-] equ}}
{VI {var|*} {[-] equ var} {[-] equ}}
{Dualvar {var [-] equ}}
```

A bilevel program is declared with the EMP keyword `bilevel`, followed by the decision variables of the upper-level problem. The other specifications refer to the lower-level problems. These lower-level followers are optional, but at least one follower has to be specified. Optimization problems are defined using the EMP keyword `max` or `min` followed by the objective variable `obj` and the decision variables and the equations that implement the constraints of the problem. Variational inequalities are introduced with the EMP keyword `vi`; details of the specification are given in section EMP Syntax for Variational Inequalities.

The `dualvar` keyword is used in the same way as it is for equilibrium problems.

Note

While the EMP framework allows the symbol '*\  ' to be used to specify an automatically-created list of variables, we recommend against using the '*\  ' in the annotations file. Instead, list all variables explicitly to make the structure of the model clear and unambiguous to both human and machine readers of the EMP info file.
4.51.10 Disjunctive Programming

Disjunctive programming is an alternative modeling approach to mixed integer programming. Both mathematical programs model optimization problems that involve discrete and continuous variables. The advantage of disjunctive programming is that it retains and exploits the inherent logic structure of problems and thus reduces the combinatorics and improves the relaxations by using Boolean variables and disjunction definitions for modeling discrete choices.

Disjunctive programs have many applications, including ordering of tasks in a production process, organizing complex projects in a time saving manner and choosing the optimal route in a circuit.

In this section we first present the mathematical formulation of Generalized Disjunctive Programs (GDPs) and then demonstrate how disjunctive programs are implemented with GAMS EMP using two simple examples. Note that both examples are adapted from the LogMIP 2.0 User’s Manual. At the end of the section we introduce and discuss the syntax for EMP annotations for disjunctive programs.

For information on the development of disjunctive programming in GAMS EMP and its connection to the solver LogMIP, see the respective section in the solver manual of the solver JAMS.

4.51.10.1 Generalized Disjunctive Programs (GDPs)

A GDP has Boolean and continuous variables, algebraic constraints that need to be satisfied regardless of the discrete choices, disjunctions that represent the discrete choices, and logic propositions that contain the logic relationships between the Boolean variables. Mathematically, the general structure of a GDP may be expressed as follows:

\[
\begin{align*}
\text{Min} & \quad f(x) \\
\text{s.t.} & \quad g(x) \leq 0 \\
& \quad \bigvee_{i \in D_k} \left( Y_{ik} \cdot r_{ik}(x) \right) \leq 0, \quad k \in K \\
& \quad \Omega(Y) = \text{True} \\
& \quad L \leq x \leq U, \quad x \in \mathbb{R}^n, \\
& \quad Y_{ik} \in \{\text{True}, \text{False}\}
\end{align*}
\]

(28)

where:

- \( f : \mathbb{R}^n \to \mathbb{R} \) is a function, \( x \) is a vector of continuous variables with bounds \( L \) and \( U \).
- \( g : \mathbb{R}^n \to \mathbb{R}^l \) represents the set of global constraints.
- Each disjunction \( k \in K \) is composed of a number of terms \( i \in D_k \) that are connected by the Boolean operator \( \lor \) (\( \lor \)).
- Each term \( i \in D_k \) consists of a Boolean variable \( Y_{ik} \) and a set of inequalities \( r_{ik}(x) \leq 0, \quad r_{ik} : \mathbb{R}^n \to \mathbb{R}^j \).
- If \( Y_{ik} \) is true, then \( r_{ik}(x) \leq 0 \) is enforced, otherwise these constraints are ignored.
- \( \Omega(Y) = \text{True} \) are logic propositions for the Boolean variables \( Y_{ik} \) expressed in the Conjunctive Normal Form \( \Omega(Y) = \bigwedge_{t=1,2,\ldots,T} \left[ \bigvee_{Y_{jk} \in R_t} (Y_{jk}) \cdot \bigvee_{Y_{jk} \in Q_t} (\neg Y_{jk}) \right] \), where for each clause \( t = 1, \ldots, T \), \( R_t \) is the subset of Boolean variables that are non-negated and \( Q_t \) is the subset of Boolean variables that are negated.

N.B.: we assume that each disjunction is an exclusive-or, so that for each \( k \) exactly one variable \( Y_{ik} \) is true. Put another way, we assume the logic constraints \( \bigvee_{i \in D_k} Y_{ik} \) are contained in \( \Omega(Y) = \text{True} \).

There are three cases of disjunctive programs: the functions \( f, g \) and \( r \) are linear, some of them are nonlinear, but convex, and some of them are nonlinear and nonconvex. Note that currently GAMS EMP facilitates modeling only the first two cases.
4.51.10.2 Disjunctive Programming with EMP: Example with No Algebraic Constraints

Consider the following simple example, that has no algebraic constraints which must be satisfied regardless of the disjunctive choices:

\[
\begin{align*}
\text{Minimize} & \quad c + 2x_1 + x_2 \\
\text{subject to} & \quad \begin{bmatrix}
Y_1 \\
-x_1 + x_2 + 2 \leq 0 \\
c \leq 5
\end{bmatrix} \lor \begin{bmatrix}
Y_2 \\
2 - x_2 \leq 0 \\
c \leq 7
\end{bmatrix} \\
\begin{bmatrix}
Y_3 \\
x_1 - x_2 \leq 0
\end{bmatrix} \lor \begin{bmatrix}
\neg Y_3 \\
x_1 \leq 1
\end{bmatrix}
\end{align*}
\]

Disjunctions

\[
\begin{align*}
Y_1 \land \neg Y_2 & \Rightarrow \neg Y_3 \\
Y_2 & \Rightarrow \neg Y_3 \\
Y_3 & \Rightarrow \neg Y_2
\end{align*}
\]

Logic Propositions (29)

Continuous Variables

\[
\begin{align*}
0 & \leq x_1 \leq 5 \\
0 & \leq x_2 \leq 5 \\
c & \geq 0
\end{align*}
\]

Boolean Variables

\[
Y_j \in \{\text{True, False}\}, \quad j = 1, 2, 3
\]

Observe that there are two disjunctions, each with two terms. In the first disjunction, each term is governed by a different Boolean variable: the first term is active if \(Y_1\) is true and the second term is active if \(Y_2\) is true. In the second disjunction, both terms are governed by the Boolean variable \(Y_3\): the first term applies if \(Y_3\) is true and the second term applies if \(Y_3\) is false.

Note that the logic propositions imply that if \(Y_1\) is true and \(Y_2\) is false, then \(Y_3\) must be false, and that \(Y_2\) and \(Y_3\) cannot both be true.

This example can be implemented in GAMS EMP as follows:

\[
\begin{align*}
\text{Set} \quad & i / 1*2 / \\
& j / 1*3 /; \\
\text{Positive Variables} \quad & x(i), c; \\
\text{Variable} \quad & z; \\
\text{Binary Variables} \quad & y(j); \\
x.\text{up}(i) = 5; \\
c.\text{up} = 7; \\
\text{Equations} \quad & \text{Obj, Eq1, Eq2, Eq3, Eq4, Eq5, Eq6}; \\
\text{Obj..} \quad & z =e= c + 2*x('1') + x('2'); \\
\text{* Equations for Disjunctions} \\
\text{Eq1..} \quad & x('2') - x('1') =l= - 2; \\
\text{Eq2..} \quad & c =l= 5; \\
\text{Eq3..} \quad & x('2') =g= 2; \\
\text{Eq4..} \quad & c =l= 7; \\
\text{Eq5..} \quad & x('1') - x('2') =l= 1; \\
\text{Eq6..} \quad & x('1') =l= 1;
\end{align*}
\]
* Equations for Logic Propositions

Logic Equations LEq1, LEq2, LEq3;

LEq1.. y('1') and not y('2') -> not y('3');
LEq2.. y('2') -> not y('3');
LEq3.. y('3') -> not y('2');

Model small1 / all /;

File emp / '%emp.info%' /;
put emp;
$onput
disjunction y('1') Eq1 Eq2 elseif y('2') Eq3 Eq4
disjunction y('3') Eq5 else Eq6
$offput
putclose;

Option optcr = 0.0;

solve small1 using EMP minimize z;

Note that in this model the Boolean variables $Y_j$ are implemented as GAMS binary variables, the inequalities in the terms of the disjunctions are formulated as GAMS equations, and the logic propositions are expressed as GAMS logic equations. The disjunctive structure of the model is specified in the EMP annotations file emp.info. This file contains two lines (one per disjunction), each starting with the EMP keyword disjunction and specifying the structure and content of its disjunction. In the first line or disjunction, the binary variable $y('1')$ that governs the first term is followed by the two equations contained in this term. The EMP keyword elseif denotes the start of a new term, here governed by the binary variable $y('2')$ listed next and containing the two equations Eq3 and Eq4. Similarly, in the second line, the binary variable $y('3')$ that governs the first term of the second disjunction is followed by the equation Eq5 contained in that term. As the binary variable governing the second term is just the negation of $y('3')$, the keyword else is enough to specify this and is followed by the equation Eq6 of the second term.

Note

Much more complex logical constructs for disjunctions are possible. For details, see section EMP Syntax for Disjunctive Programming below.

Finally, note that the model type in the solve statement is EMP.

Given the annotations in the file emp.info, the solver JAMS reformulates the model as a MIP (Mixed Integer Programming) model and passes it to a subsolver. By default, the convex hull relaxation is used for the reformulation, but users may choose reformulations that use big M or indicator constraints: see section EMP Syntax for Disjunctive Programming for details.

Observe that the listing file will contain some additional information if the model type EMP is used. The EMP Summary and the Disjunction Summary may be particularly useful. The respective listings for our example model follow:

--- EMP Summary
  Logical Constraints = 3
  Disjunctions = 2

--- Disjunction Summary
  Disjunction 1 Term 2 is active
  Disjunction 2 Term 2 is active

Note that the EMP summary lists the number of logic constraints and disjunctions and the disjunction summary reports which terms of the disjunctions are active in the optimal solution.
4.51.10.3 Disjunctive Programming with EMP: Example with No Logic Propositions

Consider the following simple example:

\[
\begin{align*}
\text{Min} & \quad t \\
\text{s.t.} & \quad t \geq x_A + 8 \\
& \quad t \geq x_B + 5 \\
& \quad t \geq x_C + 6 \\
& \quad \left[ Y_1 (x_A - x_C + 5) \right. \\ & \quad \left. - Y_1 (x_C - x_A + 2) \leq 0 \right] \\
& \quad \left[ Y_2 (x_B - x_C + 1) \right. \\ & \quad \left. - Y_2 (x_C - x_B + 6) \leq 0 \right] \\
& \quad \left[ Y_3 (x_A - x_B + 5) \right. \\ & \quad \left. - Y_3 (x_B - x_A) \leq 0 \right] \\
& \quad t, x_A, x_B, x_C \geq 0 \\
& \quad Y_j \in \{\text{True, False}\}, j = 1, 2, 3
\end{align*}
\]

As this example has no logic propositions, the binary variables would not appear in any equations of a GAMS formulation like the one above. As a result, the binary variables would not be part of the model and any EMP annotations file that mentions these variables would be rejected by the EMP solver. To avoid this problem, we can introduce a dummy equation and include it in the EMP model: this ensures that the binary variables will be part of the GAMS model. The respective code follows:

```
set i / A, B, C /  
  j / 1*3 /  
  
positive variables x(i), t;  
binary variables y(j);  
variable z;  

equations obj, alg1, alg2, alg3, 
  d1t1, d1t2, d2t1, d2t2, d3t1, d3t2 
  dummy;  

obj.. z =e= t;  

* common algebraic equations  
alg1.. t =g= x('A') + 8;  
alg2.. t =g= x('B') + 5;  
alg3.. t =g= x('C') + 6;  

* equations for disjunctions  
d1t1.. x('A') - x('C') + 5 =l= 0;  
d1t2.. x('C') - x('A') + 2 =l= 0;  
d2t1.. x('B') - x('C') + 1 =l= 0;  
d2t2.. x('C') - x('B') + 6 =l= 0;  
d3t1.. x('A') - x('C') + 5 =l= 0;  
d3t2.. x('B') - x('C') =l= 0;  

* dummy equation  
dummy.. sum(j, y(j)) =g= 0;  
```
model small2 / all /
file emp / '%emp.info%' /

putclose emp
"disjunction y('1') d1t1 else d1t2" /
"disjunction y('2') d2t1 else d2t2" /
"disjunction y('3') d3t1 else d3t2" /
;
option optcr = 0.0;
solve small2 using EMP minimize z;

Apart from the dummy equation, this formulation is very similar to the formulation in the first example above.

EMP also supports an alternative formulation for models that have no logic equations, a formulation using implicit default binary variables. These variables are denoted in the EMP annotations with the star symbol ‘∗’, which is internally replaced by a default binary variable. Note that this alternative model does not contain any explicit binary variables $Y(j)$ and hence the dummy equation may be omitted, as in the following GAMS code which can be added to the model above:

model small3 'no dummy equation needed' / small2 - dummy /

putclose emp
"disjunction * d1t1 else d1t2" /
"disjunction * d2t1 else d2t2" /
"disjunction * d3t1 else d3t2" /
;
solve small3 using EMP minimize z;

4.51.10.4 EMP Syntax for Disjunctive Programming

The general syntax that EMP provides to write disjunctions to the EMP annotations file emp.info is as follows:

\[\text{Disjunction [chull [chull eps] | bigM [big M value] | indic]}
\[\quad \text{[NOT] var|* [NOT] {equ} {ELSEIF [NOT] var|* [NOT] {equ}} [ELSE [NOT] {equ}]\]

The EMP keyword Disjunction is mandatory, it indicates that what follows is a disjunction. The three constructs that follow are optional and relate to the three possible reformulations: convex hull (chull), big M method (bigM) or indicator constraints (indic). Note that in the the sequencing model [SEQUENCE] all three options are implemented. Note further, that currently, indicator constraints can only be handled by the solvers CPLEX, SCIP and XPRESS.

Note
- By default, the convex hull reformulation method is used.
- A different reformulation method may be used for each disjunction.
Observe that for the convex hull reformulation, the value of the parameter \( \text{epsilon} \) may optionally be specified. This parameter is an upper bound to check for constraint satisfaction, the default value is 0.0001.

Note that for the big M method, the value of \( M \) may optionally be specified. The value of \( M \) should be large enough to relax the constraint, but it should not be too large, to avoid infeasible solutions. The default value is 10000.

Following the EMP keyword disjunction, the first mandatory entry is a specification of the variable that governs the disjunction: \([\text{NOT}] \text{ var}\)\(\ast\). This may be either a binary variable, a negated binary variable or the symbol \(\ast\), that is internally replaced by default binary variables. For an example and more details on the symbol \(\ast\) in this context, see section Disjunctive Programming with EMP: Example with No Logic Propositions. Further, \{equ\} denotes a set of GAMS equation names that must be satisfied if the first disjunction term is selected. The remainder of the syntax is self-explanatory.

Alternatively, the following syntax may be used:

Default \[\text{chull [chull eps]} \mid \text{bigM [big M value]} \mid \text{indic}\]

Disjunction \[\text{NOT} \text{ var}\ast \text{ NOT} \{\text{equ}\} \text{ ELSEIF NOT} \text{ var}\ast \\text{ NOT} \{\text{equ}\} \text{ ELSE NOT} \{\text{equ}\}\]

Note that the first line is optional and serves to specify the reformulation method. The second line is identical to the first formulation of the general syntax where the specification of the reformulation method is omitted. Some users find this alternative syntax clearer, since the specification of the reformulation method and the disjunction are separated.

In addition to the sequencing model \([\text{SEQUENCE}]\) that was already mentioned, the GAMS EMP Library has two other models for disjunctive programming: the manufacturing problem \([\text{FOODEMP}]\) and the job scheduling problem \([\text{MAKESPAN}]\).

### 4.51.11 Stochastic Programming

Stochastic programs are mathematical programs that involve data that is not known with certainty. Deterministic programs are formulated with fixed parameters, whereas real world problems frequently include some uncertain parameters. Often these uncertain parameters follow a probability distribution that is known or can be estimated. Thus stochastic programs approximate unknown data by probability distributions. The goal is to find some policy that is feasible for all (or almost all) the possible data instances and that maximizes the expectation of some function of the decision variables and the random variables. The EMP framework includes an extension for stochastic programming that allows users to model various stochastic problems as deterministic models, while information about the stochastic structure of the problem, like probability distributions for some data, is specified in the EMP annotations. Thus formulating stochastic programs becomes straightforward.

In the remainder of this chapter we discuss the stochastic programming extension of GAMS EMP. We introduce the basics of stochastic programming with EMP using a two-stage stochastic model and then show how the logic can be extended to multi-stage stochastic problems. In most stochastic problems the expected value of the objective is optimized. The EMP framework facilitates optimizing two additional risk measures: Value at Risk (VaR) and Conditional Value at Risk (CVaR). These alternative risk measures are discussed next. Another type of stochastic programming includes constraints that hold only with certain probabilities. These constraints are called chance constraints (or probabilistic constraints), they are the topic of the last section on stochastic programming. At the end of each section we give an overview of the EMP annotations that are specific to each topic: stochastic programming with recourse, additional risk measures, and chance constraints. A summary of all EMP keywords for stochastic programming is given in section GAMS EMP Keywords for Stochastic Programming.
4.51.11.1 Stochastic Programming with Recourse

One way to think about stochastic problems is to require the decision maker to make a decision now and then to minimize the expected costs of the consequences of that decision. This paradigm is called the recourse model. The simplest form of the recourse model has two stages: a decision is made in the first stage, then the realization of the uncertain parameters is revealed at the start of the second stage and recourse actions can be taken given this new information. This simple model can be extended to include more stages. In a multistage problem, a decision is made in the first stage, then some uncertainty is resolved in the second stage and another decision is made based on this new knowledge, then some other uncertainty is resolved and so on. The objective is to minimize the expected costs of the decisions in all stages.

This section is organized as follows. We start with a mathematical formulation of the two-stage stochastic problem with recourse, then show how such problems can be modeled with EMP using a simple example. The uncertain data in this first example follows a discrete distribution, there are just three different scenarios. Continuous distributions are more complex to model. Mostly, they are approximated to discrete distributions by sampling, which is discussed next. The second example illustrates how the modeling approach for a simple two-stage problem can be extended to solve a multi-stage problem. We conclude this section with a description of the EMP annotations for stochastic programs with recourse.

4.51.11.1.1 Two-Stage Stochastic Programs: Mathematical Formulation

The simplest form of a stochastic program is the two-stage stochastic linear program with recourse. In mathematical terms it is defined as follows.

Let \( x \in \mathbb{R}^n \) and \( y \in \mathbb{R}^m \) be two variables and let the set of all realizations of the unknown data be given by \( \Omega \), \( \Omega = \{\omega_1, \ldots, \omega_S\} \subseteq \mathbb{R}^r \), where \( r \) is the number of the random variables representing the uncertain parameters. Then the stochastic program is given by

\[
\begin{align*}
\text{Min}_x & \quad z = c^T x + \mathbb{E}[Q(x, \omega)] \\
\text{s.t.} & \quad A x = b, \quad x \geq 0,
\end{align*}
\]

where \( Q(x, \omega) = \text{Min}_y \) (31)

\[
\begin{align*}
\text{s.t.} & \quad T \omega x + q^T \omega y(\omega) = h, \quad y(\omega) \geq 0, \quad \forall \omega \in \Omega.
\end{align*}
\]

The first two lines define the first-stage problem and the last two lines define the second-stage problem. In the first stage, \( x \) is the decision variable, \( c^T \) represents the cost coefficients of the objective function and \( \mathbb{E}[Q(x, \omega)] \) denotes the expected value of the optimal solution of the second stage problem. In addition, \( A \) denotes the coefficients and \( b \) the right-hand side of the first stage constraints. In the second stage, \( y \) is the decision variable, \( T \) represents the transition matrix, \( W \) the recourse matrix (cost of recourse) and \( h \) the right-hand side of the second stage constraints. Note that all parameters and the decision variable of the second stage are dependent on the specific realization of the stochastic data \( \omega \). The objective variable \( z \) is also a random variable, since it is a function of \( \omega \). As a random variable cannot be optimized, stochastic solvers automatically optimize the expected value of the objective variable \( z \). Note that the EMP framework allows other risk measures to be optimized in addition to the expected value. This is discussed below.

In the first stage, a decision has to be made before the realization of the uncertain data is clear. The optimal solution of the first stage is fixed and only then it will become known which values the uncertain parameters will take. Given the fixed solution of the first stage and the new data, recourse action can be taken in the second stage and the optimal solution determined. Each possible realization of the uncertain data is represented by \( \omega_s \in \Omega \) and is called a scenario. The objective is to find a feasible solution \( x \) that minimizes the total cost, namely the sum of the first-stage costs and the expected second-stage costs.

One of the most common methods to solve a two-stage stochastic LP is to build and solve the deterministic equivalent. Assume that the uncertain parameters follow a (finite) discrete distribution and that each scenario \( \omega_s \) occurs with probability \( P(\omega_s) = p_s \) for all \( s = 1, \ldots, S \) and \( \sum_s p_s = 1 \). Thus \( \mathbb{E}[Q(x, \omega)] = \sum_s p_s Q(x, \omega_s) \).
\[
\sum s_i p_s q^T y_s, \quad \text{where } y_s \text{ denotes the optimal second-stage decision for the scenario } \omega_s. \text{ Then the deterministic equivalent can be expressed as follows:}
\]

\[
c^T x + p_1 q^T y_1 + p_2 q^T y_2 + \ldots + p_S q^T y_S \\
\text{s.t.} \\
Ax + W_1 y_1 \quad = \quad b \\
T_1 x + W_2 y_2 \quad = \quad h_1 \\
\vdots \quad \vdots \\
T_S x + W_S y_S \quad = \quad h_S \\
x \in \mathbb{R}^n \quad y_1 \in \mathbb{R}^m \quad y_2 \in \mathbb{R}^m \quad + \quad W_S y_S \quad = \quad h_S
\]

Note that for stochastic linear programs the deterministic equivalent is just another (potentially very large) linear program.

A GAMS EMP stochastic model has three parts: the core model, EMP annotations and the dictionary, which contains output-handling information. The core model is a deterministic model, where the uncertain data is given as fixed parameters. Often, the expected value of the probability distribution is chosen.

The annotations contain information about the stochastic features of the model: a specification of the random variables and their distributions, details about the stages and possibly directions concerning sampling.

Given the probability distributions of the random variables, the solvers of stochastic programming models create various scenarios and evaluate them. In the dictionary users specify which results from each scenario are to be stored in standard parameters in order to be accessed later. These three parts of a GAMS EMP stochastic model will become much clearer as they are illustrated in the next subsection.

### 4.51.11.1.2 A Simple Example: The News Vendor Problem

Consider the following simple example adapted from the news vendor model [NBSIMPLE]. A news vendor has to decide early in the morning how many newspapers to buy from a distributor on a particular day in order to sell them to his customers. He knows from experience that the demand will be 45 in 70% of all cases, 40 with a probability of 20% and 50 with a probability of 10%. If the demand is less than the number of newspapers he bought in the morning, the left-over newspapers will be stored in an inventory at a cost per unit. If the demand exceeds his expectations and there are more customers than newspapers, then he will have to pay a penalty. He aims to maximize his profit by selling the newspapers at a higher price than he has bought them. Mathematically, the problem can be expressed as follows:

\[
\text{Max}_x \quad Z(x, D) = -cx + E[Q(x, D)], \quad x \geq 0,
\]

where

\[
Q(x, D) = \max_{s,i,l} \quad vs_D - hi_D - pl_D \\
\text{s.t.} \quad x - s_D - i_D = 0 \\
\quad s_D + l_D = D, \quad s_D, i_D, l_D \geq 0
\]

where

- the variable \(x\) denotes the number of newspaper bought in the morning,
- \(c\) is the cost per newspaper,
- \(D\) is a random variable that denotes the uncertain demand; the set of all realizations of \(D\) is given by \(\Omega = \{d_1, d_2, d_3\}\), with \(d_1 = 45\), \(d_2 = 40\) and \(d_3 = 50\), and the respective probabilities \(p_1 = 0.7\), \(p_2 = 0.2\) and \(p_3 = 0.1\),
- the variable \(s\) denotes the number of newspapers that are sold,
\( v \) is the selling price,

- the variable \( i \) denotes the number of newspapers that could not be sold, in case the demand turned out to be less than expected,

- \( h \) is the holding cost in the inventory per unit,

- the variable \( l \) denotes the unsatisfied demand, in case the demand turned out to be higher than expected,

- \( p \) is the penalty per unit of unsatisfied demand.

Note that \( x \) is the first-stage decision variable and the variables \( s \), \( i \) and \( l \) are the second-stage decision variables. The second-stage decision variables are dependent on \( D \). An overview of the stages in this problem is given in the following table:

<table>
<thead>
<tr>
<th>1st Stage Decision Variable</th>
<th>2nd Stage Decision Variable; ( \Omega = { d_1, d_2, d_3 } )</th>
<th>Probabilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x )</td>
<td>( y_{d_1} = (s_{d_1}, l_{d_1}, i_{d_1}) )</td>
<td>Scenario 1: ( p_1 = 0.7 )</td>
</tr>
<tr>
<td>( x )</td>
<td>( y_{d_2} = (s_{d_2}, l_{d_2}, i_{d_2}) )</td>
<td>Scenario 2: ( p_2 = 0.2 )</td>
</tr>
<tr>
<td>( x )</td>
<td>( y_{d_3} = (s_{d_3}, l_{d_3}, i_{d_3}) )</td>
<td>Scenario 3: ( p_3 = 0.1 )</td>
</tr>
</tbody>
</table>

Table 3: Two stages in the News Vendor Problem

Observe that the decision \( x \) has to be made before the realization of the demand \( D \) is known. Given the uncertainty of the demand, we aim to maximize the expected value of the profit, denoted by \( \mathbb{E}[Z(x, D)] \). The expected value of the profit is the profit on average. Note that as we have a finite number of scenarios and their probabilities are known, the expected value of the profit \( \mathbb{E}[Z(x, D)] \) can be expressed as a weighted sum:

\[
\mathbb{E}[Z(x, D)] = -cx + \mathbb{E}[Q(x, D)] - cx + \sum_{k=1}^{3} p_k Q(x, d_k).
\] (34)

Note that in this example there are no first stage equations \( Ax = b \).

The core model is the first part of the respective GAMS EMP model:

```
Variable z "profit";
Positive Variables
  x "units bought"
  i "inventory"
  l "lost sales"
  s "units sold";
Scalars c "purchase costs per unit" / 30 /
p "penalty shortage cost per unit" / 5 /
h "holding cost per leftover unit" / 10 /
v "revenue per unit sold" / 60 /
d "demand, random parameter" / 45 /;
Equations profit "profit to be maximized"
row1 "demand = UnitsSold + LostSales"
row2 "inventory = UnitsBought - UnitsSold";
```
profit..  z =e= v*s - c*x - h*i - p*l;
row1..  d =e= s + l;
row2..  i =e= x - s;

Model nv / all /;

Observe that the model is defined in the usual way. In particular, the demand \(d\) is modeled as a fixed parameter.

The EMP annotations are the second part. Here we specify the stochastic structure:

File emp / '%emp.info%' /;
put emp '* problem %gams.i%'/;
$onput
randvar d discrete 0.7 45 0.2 40 0.1 50
stage 2 i l s d
stage 2 Row1 Row2
$offput
putclose emp;

First, we define the parameter \(d\) to be a random variable using the EMP keyword randvar and we specify the probability distribution. The EMP keyword discrete indicates that \(d\) follows a discrete distribution: with probability 0.7 it takes a value of 45, with probability 0.2 it takes a value of 40, and with probability 0.1 it takes a value of 50.

Note

If the sum of the probabilities of a discrete distribution is smaller or larger than 1, the EMP framework will automatically normalize the probabilities so that the sum equals 1 and a corresponding remark will appear in the log and listing file.

Observe that continuous distributions are also possible, see section Random Variables with Continuous Distributions below for details.

Secondly, we specify which variables and equations belong to stage 2 using the EMP keyword stage. Note that the variables and equations that are not listed in the annotations are automatically assigned to a stage, by default stage 1 (this could be changed using the EMP keyword stageDefault). Only the objective variable (in this case \(Z\)) and the objective equation (profit) are assigned to the highest stage specified instead (stage 2 in this example). Observe that \(Z\) is in fact a random variable since it is a function of the random variable \(D\). As such it cannot be optimized directly, EMP implicitly maximizes the expected value of \(Z\). This might lead to some confusion since the expected value of \(Z\) belongs to stage 1. We show in section Expected Value Revisited how to specify more clearly the fact that we are maximizing \(E(Z)\).

All keywords that can be used in EMP annotations in the context of stochastic programming are introduced in subsequent examples and they are summarized in section GAMS EMP Keywords for Stochastic Programming.

The dictionary with output-handling information and the solve statement are the third part of the model. After solving a stochastic programming model, only the solution of the expected value problem may be accessed via the regular .l and .m fields. The results of the scenarios that were created and evaluated by the stochastic solvers may be stored in standard parameters in the following way:
Set scen "scenarios" / s1*s3 /;
Parameter
  s_d(scen) "demand realization by scenario"
  s_x(scen) "units bought by scenario"
  s_s(scen) "units sold by scenario"
  s_rep(scen,*) "scenario probability" / #scen.prob 0/;

Set dict / scen .scenario.''
  d .randvar .s_d
  s .level .s_s
  x .level .s_x
  '' .opt .s_rep /;

solve nv max z use EMP scenario dict;
display s_d, s_x, s_s, s_rep;

The size of the set scen defines the maximal number of scenarios we are willing to store results for. It does not have to match the number of scenarios that are actually generated in the solution process. Assume that the size of the set scen is \( n \) and \( n \) is smaller than the number of generated scenarios. In this case only the results for the first \( n \) scenarios will be stored. On the other hand, if the size of scen is larger than the number of generated scenarios, then the positions of the surplus elements of scen will be empty in the parameters (e.g. s_d).

The elements of the three-dimensional set dict determine which scenario-dependent values will be stored. The set contains mapping information between the symbols in the model in the first position and the symbols in which scenario solution information is stored in the third position. The type of storing is specified in the second position. The following entries are allowed:

<table>
<thead>
<tr>
<th>Label</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>level</td>
<td>Stores the level values of a scenario solution of a variable or equation.</td>
</tr>
<tr>
<td>marginal</td>
<td>Stores the marginal values of a scenario solution of a variable or equation.</td>
</tr>
<tr>
<td>randvar</td>
<td>Stores the realization of a random variable.</td>
</tr>
<tr>
<td>opt</td>
<td>Stores the probability of each scenario.</td>
</tr>
<tr>
<td>scenario</td>
<td>The symbol in the first position of the tuple is used as the scenario index.</td>
</tr>
</tbody>
</table>

**Table 4** Entries in the second position of the tuples in the scenario dictionary

**Attention**

The first two tuples in the set dict are mandatory, all other elements of the set are optional. If one of the first two tuples is missing, the stochastic model cannot be solved and an error will be generated.

In the example above, we store the realization for each scenario of the random variable d in the parameter s_d, the level values of the variables s and x in the parameters s_s and s_x respectively and the actual probability of each scenario in the parameter s_rep.

**Note**

Storing and retrieving the actual probabilities of the scenarios may be particularly relevant if the probabilities have been normalized such that their sum equals 1.

Finally, the solve statement needs to be adjusted: we use the model type EMP and add scenario dict to indicate that a stochastic problem is to be solved.
Random Variables with Continuous Distributions

Now we assume that the random variable $D$ in the example above has a continuous distribution, say a Normal distribution with mean 45 and standard deviation 10. The structure of the problem remains unchanged, the only difference is that the set $\Omega$, that is the set of all realizations of $D$, contains an infinite number of scenarios. There are various ways of modeling this. For example, a sampling procedure implemented in the solver can be used: a finite number of scenarios is generated to approximate $\Omega$ and thus the problem is converted to a problem with a finite discrete distribution.

We can model a continuous distribution of the random variable in GAMS EMP by changing the annotations in the following way:

```
randvar d normal 45 10
```

Note that currently only the solver LINDO has implemented a sampling procedure for parametric distributions so that it can solve such a problem directly. If the solver DE is used, the sampling can be performed by the LINDO system behind the scenes. More details about sampling are given in the next section. All parametric distributions that can be modeled are listed in Table 5.

**Table 5**: Parametric distributions supported by LINDO

Recall that there are two ways to specify that a specific solver should be used (that is not the default solver for the problem type): with a command line parameter (e.g. `emp=lindo`) and with an option statement (e.g. `option emp = lindo;`).

Examples with random variables that follow parametric distributions include the multistage example below (three random variables with Gamma distributions) and the production model \[\text{PRODSP3}\] in the GAMS EMP Model Library (one random variable that follows a Normal distribution and one random variable that is uniformly distributed).
4.51.11.1.4 Sampling  Currently, only the solver LINDO has the ability to perform sampling for parametric distributions directly. Note that LINDO generates 6 samples by default and users need a LINDO license for sample sizes larger than 10 (smaller sample sizes are included in the demo version, but just for certain distributions). Also, changing the default variance reduction method requires a valid LINDO license. There are three ways to customize sampling: including additional information in the EMP annotations, generating a sample with the LINDO library lsadclib (these two options allow to pass on the samples to other solvers with EMP SP capabilities) and setting various options in the solver LINDO. We discuss each method in more detail in the next three subsections.

4.51.11.1.4.1 Customizing Sampling in the EMP Annotations  The EMP framework provides two keywords to facilitate sampling: sample and setSeed. The keyword sample allows users to specify the size of the sample in the EMP annotations. Consider the following example:

```plaintext
randvar d normal 45 10
sample d 9
```

The second line specifies that the size of the sample of the distribution of the random variable $D$ is 9. Note that currently the LINDO Sampling Library is used for this sampling. If the solver DE is used and a parametric distribution for the random variable is specified, the second line with the keyword sample is mandatory. Otherwise the following error message will appear:

```plaintext
*** Only random variables with sampled continuous distributions supported.
```

In addition to specifying the size of the sample, information about a mathematical variance reduction method may be added in the line that starts with the keyword sample. Variance reduction is a procedure used to increase the precision of the estimated values from the distribution. LINDO provides three methods for reducing the variance: Monte Carlo sampling, Latin Square sampling and Antithetic sampling. We illustrate with an example.

Consider a stochastic model with four random variables: $E$, $F$, $G$ and $H$. Assume that $E$ follows a Normal distribution with mean 23 and standard deviation 5, $F$ follows a Normal distribution with mean 37 and standard deviation 8, $G$ is uniformly distributed on the interval $[0, 1]$ and $H$ is binomially distributed with $n = 100$ and $p = 0.55$. We wish that three variance reduction methods are applied: Antithetic sampling is to be used for $E$ and $F$, Monte Carlo sampling for $G$ and Latin Square sampling for $H$. We insert the following lines in the EMP annotations:

```plaintext
randvar e normal 23 5
randvar f normal 37 8
randvar g uniform 0 1
randvar h binomial 100 0.55
sample e f 10 method1
sample g 12 method2
sample h 8 method3
```

First, the random variables and their distributions are defined. Next, details about the sampling procedures are given. Note that the keyword sample can take more than one random variable if the sample size and the variance reduction method for these random variables are identical. We need to add the following lines before the solve statement to specify the content of method1, method2 and method3 (we assume that the name of the model is nv):

```plaintext
```
If Latin Square sampling should also be used for $E$ and $F$, we would simply change the EMP annotations to replace the label `method1` with the label `method3`. For more details on variance reduction methods, please consult the LINDO manual.

In addition, the EMP keyword `setSeed` may be used to further customize the sampling procedure:

```
setSeed <seed>
```

This line sets the seed (an integer number) for the random number generator of the sampling routines. If `setSeed` is used in the EMP annotations, the seed will be set once before all samples are generated. Please note that `setSeed` only works with a valid LINDO license.

### 4.51.11.4.2 Separating Sampling and Solving

Users may want to sample from a distribution with the LINDO system and solve the model with another solver, say DECIS. This is possible with the sampling routines from the LINDO Sampling Library `lsadclib`. We could solve the news vendor model by first drawing a sample from a Normal distribution with mean 45 and standard deviation 10 and then using the sample in the EMP annotations. The GAMS code for sampling from a Normal distribution where the sample size is 9 follows:

```
$funcLibIn msllib lsadclib

Function setSeed / msllib.setSeed /
   sampleNormal / msllib.sampleLSNormal /
   getSampleValues / msllib.getSampleValues /;

Scalar k;
   k = sampleNormal(45,10,9);

Set g /1*9/; parameter sv1(g);
   loop(g,
      sv1(g) = getSampleValues(k);
   );
   display sv1;
```

The directive in the first line makes the LINDO sampling library available, `msllib` is the internal library name (see also `$funcLibIn` for more information). For further details and a list of the available probability distributions, see section The LINDO Sampling Library.

In the following lines we demonstrate how the sample is used in the EMP annotations:

```
File emp / '%emp.info%' /;
put emp;
   put 'randvar d discrete '; loop(g, put (1/card(g)) ' ' sv1(g) ' ');
$onput
   stage 2 I L S d
   stage 2 Row1 Row2
$offput
putclose emp;
```

Note that the third line states that the random variable $D$ follows a discrete distribution and the probabilities and values are taken from the previously generated sample. The other lines of the annotations remain unchanged.
4.51.11.1.4.3 Sampling Options for the Solver LINDO  There are some customizable sampling options in LINDO. Users could control the number of sampled scenarios by setting any of the following LINDO/SP options in the file LINDO options file lindo.opt:

- `STOC_NSAMPLE_PER_STAGE` - list of sample sizes per stage (starting at stage 2)
- `STOC_NSAMPLE_SPAR` - common sample size per stochastic parameter
- `STOC_NSAMPLE_STAGE` - common sample size per stage

For example, we could insert the following three lines before the solve statement:

```
option emp = lindo;
$echo STOC_NSAMPLE_STAGE = 100 > lindo.opt
nv.optfile = 1;
```

The first line directs GAMS to solve models of the type `emp` with the LINDO solver. The second line writes `STOC_NSAMPLE_STAGE = 100` to the file `lindo.opt`, it communicates to the solver to generate 100 samples per stage. The third line informs GAMS to use the solver option file (i.e. `lindo.opt`).

The following example shows how to use large samples and instruct LINDO to use a Benders decomposition algorithm to tackle the problem:

```
$onecho > lindo.opt
STOC_MAX_NUMSCENS = 1000000
STOC_NSAMPLE_STAGE = 40
STOC_METHOD = 1
$offecho
```

In the second line we ensure that the maximum number of scenarios is large enough. The options in the following lines state the sample size and determine the stochastic method to be used (1 means Nested Benders Decomposition). For further details on LINDO options, please consult the LINDO user manual.

4.51.11.1.5 Multistage Stochastic Programming Example  The modeling principles for two-stage stochastic models can be easily extended to multistage stochastic models. At the beginning of each stage some uncertainty is resolved and recourse decisions or adjustments are made after this information has become available. At the point where decisions are made only outcomes of the current stage and previous stages are available. This logic can be pictured schematically as follows:

```
Make decision \rightarrow \text{Random Variable is realized} \rightarrow \text{Make decision} \\
\text{Stage 1} \rightarrow \cdots \rightarrow \text{Stage 2} \rightarrow \cdots \rightarrow \text{Stage n}
```

Observe that random variables which are realized in stage $k$ are fixed parameters in stage $k + 1$ and following; stage 1 random variables are in fact simply given deterministic values and will create a warning or an error dependent on the solver selected.

Consider an inventory problem. At the end of each week the decision how many hats should be bought in order to satisfy the stochastic demand in the following week must be made. The aim is to maximize the profit. We assume that the stochastic demand can be modeled using a Gamma distribution. The planning horizon is 3 weeks. Before the first week starts an initial purchase decision has to be made and
the goods are stored in the inventory for use in week 1. At this point only the distribution of the demand of the first week is known. During the first week the actual demand is revealed and some items that were stored in the inventory are sold. Some items may be left over; they are stored as the inventory for the second week. In addition, a purchase decision for the second week has to be made given the size of the inventory and the distribution of the demand in the second week. Again, the actual demand is revealed in the course of the second week. The same holds for the third week.

We will model the problem with 4 stages, where the first stage corresponds to the preparation time before the first week, the second stage corresponds to decisions made in the first week, the third stage corresponds to decisions made in the second week and the fourth stage corresponds to decisions made in the third week. Let \( t \) denote the stages. Note that while the stages range from \( t = 1 \) to \( t = 4 \), demand variables are realized only at \( t = 2 \) to \( t = 4 \). Let \( y_t \) be the amount bought and \( i_t \) the amount stored at the end of each stage and let \( s_t \) denote the demand in each week and \( s_t \) the amount sold each week. Note that we denote the demand with a capital \( D_t \) since it is a random variable. Let \( \alpha = 10 \) be the cost per hat bought, \( \beta = 20 \) the revenue per hat sold and \( \delta = 4 \) the storage cost per unit. Further, in the storage facility a maximum of \( \kappa = 5000 \) hats can be stored.

Mathematically, this problem can be expressed as follows:

\[
\begin{align*}
\text{Maximize} & \quad z = -\alpha y_1 - \gamma i_1 + E[ \text{Max} \ eta s_2 (D_2) - \alpha y_2 (D_2) - \delta i_2 (D_2) + \cdots + \\
& \quad E[ \text{Max} \ eta s_4 (D_4) + -\alpha y_4 (D_4) - \delta i_4 (D_4) ] ] \\
\text{subject to} & \quad i_1 = y_1 \\
& \quad i_t - 1 + y_t = s_t + i_t \\
& \quad s_t \leq i_{t-1} \\
& \quad s_t \leq D_t \\
& \quad i_t \leq \kappa \\
& \quad y_1, i_1, s_1, y_t, i_t \geq 0,
\end{align*}
\]

where \( t = 2, \ldots, 4 \) and \( D_t \) follows a Gamma distribution. Note that \( s_t, y_t \) and \( i_t \) depend on the realization of \( D_t \).

As discussed above, the solvers use a sampling procedure to approximate a problem with a continuous random variable by a problem with a discrete distribution. Figure 1 illustrates the stages assuming a sample size of 6 (per stage). Note that this results in a total of \( 6^3 = 216 \) scenarios.

The problem can be modeled with GAMS EMP as follows:

```plaintext
* Core Model
Set t "stages" /1*4/;
Set st(t) "stages where sales occur" /2*4/;
Positive Variables
  y(t) "units to be bought in time period t"
  i(t) "ending inventory in period t"
  s(t) "units sold in time period t"

  s_y(scen,t) "units bought by scenario"
  s_s(scen,t) "units sold by scenario"
  s_i(scen,t) "units stored by scenario";

Set dict /
  scen .scenario.''
  d .randvar .s_d
  s .level .s_s
  y .level .s_y
  i .level .s_i /;

option emp=lindo;
solve inventory max profit using emp scenario dict;
display s_d, s_s, s_y, s_i;

Observe that in the core problem the values of the demand \( d(t) \) are replaced by the expected values of the random variable \( D_t \) which follows a Gamma distribution. Note that as expected, in stage 1 we have only the variables \( y \) and \( i \), but no variables \( s \) and \( d \). Recall that currently only the solver LINDO can solve models with parametric distributions, see sections Random Variables with Continuous Distributions and Sampling for more information.

4.51.11.1.6 EMP Syntax for Stochastic Programs with Recourse

The general syntax of the EMP annotations used to specify stochastic problems with recourse is as follows:

```
[randvar rv discrete prob val {prob val}]
[randvar rv distr par {par}]
[jrandvar rv rv {rv} prob val val {val} {prob val val {val}}]
[setSeed number]
[sample rv1 [rv2 ... rvn] sampleSize [varRedMethod]]
[stage stageNo rv | equ | var {rv | equ | var}]
{stage stageNo rv | equ | var {rv | equ | var}]
[stageDefault stageNo]
```

The first three lines present three ways to specify random variables: a single random variable with a discrete distribution, a single random variable with a parametric distribution and joint random variables with discrete distributions. Note that `randvar`, `jrandvar` and `discrete` are EMP keywords. The distribution of single discrete random variables is defined by pairs of the probability `prob` of an outcome and the corresponding realization `val`, see example above. The distribution of parametric random variables is defined by the name of the distribution `distr` and the respective parameter(s) `par`. An overview of all supported parametric distributions can be found in Table 5. All possible values for `distr` and the related parameters `par` are listed there. The keyword `jrandvar` is used to define discrete random variables that are jointly distributed. At least two random variables must be named. For an example, see the news vendor model [NBDISCJOINT].
At least one random variable must be defined and all three ways to define random variables may appear in the EMP annotations. See the scheduling model [Airlift] for an example with both, a discrete random variable and a continuous random variable.

The keywords setSeed and sample are optional. The seed for the random number generator may be set with setSeed. The random number generator is used for the sampling routines that are called with the keyword sample. If setSeed is used, the seed will be set once before all samples will be generated. The keyword sample is followed by the name of the respective random variable, the sample size (a number) and - optionally - a variance reduction method. Note that the random variable must have been previously declared to follow a parametric distribution. Note further, that the sample size of more than one random variable may be customized simultaneously. Observe that the default sample size is 6. For details on available variance reduction methods, see section Customizing Sampling in the EMP Annotations.

Note
- A valid LINDO license is required to use the keywords setSeed and sample. The keyword sample may be used with a demo or community version of the LINDO license, but it is limited to the Normal and Binomial distributions with a maximum sample size of 10 and the variance reduction method cannot be changed.
- If a parametric distribution is used with any solver but LINDO, the keyword sample is mandatory, see above for details.

With the keyword stage random variables, variables and equations are assigned to their respective stages, where StageNo defines the stage number. Note that the default stage for all random variables, equations and variables is 1, except for the objective equation and variable. The default for those is the highest stage in the problem.

With the keyword stageDefault one can change the default stage to which symbols get assigned if they are not listed with a stage keyword explicitly.

4.51.11.2 Risk Measures with EMP

The literature on stochastic programming usually assumes that the expected value of the objective is optimized. The EMP tool follows this trend and implicitly optimizes the expected value. However, there are other risk measures that could be taken into consideration and that are frequently used in practice, particularly in finance. For example, a fund manager might be more interested in the expected value of the 10% worst cases of the projected wins than in the expected value of the overall distribution. The expected value of a partition of the distribution at one tail is called Conditional Value at Risk. The EMP framework provides special keywords to facilitate optimizing this risk measure. On a more abstract level, risk measures can be understood as mechanisms to evaluate the effects of uncertainty in the underlying system on the outcomes of interest. They can be used to modify the distribution of outcomes.

Using the example of an investor who wishes to balance expected rewards and the risk of loss when she decides how to allocate assets in a portfolio, we explore how stochastic optimization problems involving risk measures can be modeled with EMP. Note that this example is adapted from the stochastic portfolio model [Portfolio]. For simplicity of exposition, we only describe two-stage models here. In the examples that follow, the period \((0, T)\) is the period between investing in a portfolio of assets and return from this portfolio.

We first present the example problem and introduce a new EMP keyword to model the expected value explicitly. Then we introduce and discuss Value at Risk (VaR) and Conditional Value at Risk (CVaR). At the end of this section, we give a summary of the EMP annotations that are specific to risk measures.

Note
- The stochastic extension of EMP facilitates the optimization of a single risk measure or a combination of risk measures (for example, the weighted sum of Expected Value and CVaR). In addition, the modeler can choose to trade off risk measures.
4.51.11.2.1 Expected Value Revisited Suppose an investor has the opportunity to invest a certain amount in three assets. She is given the probability distribution in Table 6 that links each asset with a possible return at time $T$. The question arises how she should allocate her funds between the three assets at time 0 in order to maximize her expected return at time $T$.

**Table 6: Return by scenario**

Mathematically, the problem can be expressed as follows:

$$\begin{align*}
\text{Max} \quad & E[R] \\
\text{s.t} \quad & R = \sum_j w_j v_j \\
& \sum_j w_j = 1 \\
& w_j \geq 0,
\end{align*}$$

(36)

where the variable $R$ denotes the return and is a function of the random variable $v$, $E[R]$ is the expected return, $w_j$ is the weight associated with each asset $j$, and $v_j$ is the return of each asset $j$. The weights can also be interpreted as proportions of the amount to be invested, their sum must equal 1. Note that $w_j$ is the decision variable in this problem. Note further, that $v_j$ is a random variable that depends on which scenario is realized.

We present two different ways to model this problem in GAMS EMP: in the first version the expected value of the return is modeled *implicitly* and in the second version it is modeled *explicitly*. Both models have two stages, in the first stage the weights are chosen without knowing which scenario will be realized, in the second stage the 12 scenarios are taken into account. We start with the part of the code where the data is given. It is named `data.gms` and it will be included in all models in this section.

```
Sets j "assets" / att, gmc, usx /
   s "scenarios" / s1*s12 /;
Table vs(s,j) "scenario returns from assets"
   att  gmc  usx
  s1   1.300 1.225 1.149
  s2   1.103 1.290 1.260
  s3   1.216 1.216 1.419
  s4   0.954 0.728 0.922
  s5   0.929 1.144 1.169
  s6   1.056 1.107 0.965
```
Parameters
\[ v(j) \quad \text{"return from assets"} \]
\[ p(s) \quad \text{"probability'' / #s [1/card(s)]} / \;
\]
\[ v(j) = \sum(s, vs(s,j))/\text{card}(s); \]

The first model is similar to the two-stage example model above, the fact that the expected return is being maximized is not stated explicitly but is only implied:

```
* Core Model
$include data.gms
Variables
  r "value of portfolio under each scenario"
  w(j) "portfolio selection"
Positive Variables
  w;
Equations
  defr "return of portfolio"
  budget "budget constraint'';
  defr.. r =e= sum(j, v(j)*w(j));
  budget.. sum(j, w(j)) =e= 1;
Model portfolio / all /
* EMP Annotations
File emp / '%emp.info%' /;
emp.nd=4;
put emp '* problem %gams.i%''
  / 'stage 2 v r defr'
  / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
  put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx");
putclose emp;
* Dictionary
Parameters
  s_v(s,j) "return from assets by scenario"
  s_r(s) "return from portfolio by scenario'';
Set
  dict / s .scenario.'''
  v .randvar .s_v
  r .level .s_r /
solve portfolio using emp max r scenario dict;
display s_v, s_r;
```

As usual, the core model is defined first and the specifications relating to the stochastic structure of the model are written to the file `emp.info`. Note that the statement `emp.nd=4` ensures that 4 decimal places
are used for the values of the parameter vs. In the first line of the EMP annotations, the variables v and r and the equation defr are assigned to the second stage. Note that the other variables and equations (in this case, the variable w and the equation budget) are automatically assigned to the first stage. In the second line of the annotations, the EMP keyword jrandvar is used to declare that v('att'), v('gmc') and v('usx') are joint random variables, i.e. they are jointly distributed (thus we have 12 scenarios and not 12*12*12=1728 scenarios). The respective probabilities and values are specified with a loop statement. Observe that the syntax of the solve statement suggests that the return r is maximized. However, r is in fact a random variable, since it is a function of random variables, so actually the expected return is maximized.

In the second model we introduce a new variable for the expected return, evr. This new variable is linked to the EMP keyword ExpectedValue in the annotations, thus it is made explicit that the expected value of the return is optimized.

* Core Model
$include data.gms

Variables
   r "value of portfolio under each scenario"
   w(j) "portfolio selection"
   evr "expected value of r"
   obj "objective variable";
Positive Variables

Equations
   defr "return of portfolio"
   budget "budget constraint"
   defobj "objective equation";

   defr.. r =e= sum(j, v(j)*w(j));
   budget.. sum(j, w(j)) =e= 1;
   defobj.. obj =e= evr;

Model portfolio / all /;

* EMP Annotations
File emp / '%emp.info%' /;
emp.nd=4;
put emp '* problem %gams.i%
   / 'ExpectedValue r evr'
   / 'stage 1 obj defobj evr'
   / 'stage 2 v defr r'
   / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
   put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
   s_v(s,j) "return from assets by scenario"
   s_r(s) "return from portfolio by scenario";
Set dict / s .scenario."
   v .randvar .s_v
   r .level .s_r /
solve portfolio using emp max obj scenario dict;
In the EMP annotations, the EMP keyword `ExpectedValue` is followed by the variable `r` and the variable `evr`. In this way the variable `evr` is declared to be the expected value of the (random) variable `r`. Note that the new variables `evr` and `obj` belong to stage 1 and the variable `evr` is maximized (via `obj`). The remainder of the annotations and the code referring to the output-handling information in the dictionary are the same like in the first model. Both models have the same solution. We prefer the second model since the syntax is more explicit and clearer.

Observe that the keyword `ExpectedValue` is particularly useful if users wish to model an objective that is the weighted sum of several risk measures, thus trading-off different risk measures. An example with the weighted sum of the expected value and Value at Risk as objective and an example with the weighted sum of the expected value and Conditional Value at Risk as objective are given below.

4.51.11.2.2 Value at Risk (VaR) The Value at Risk (VaR) is the value of the distribution at a given cut-off point; for example, the value of the standard Normal distribution at the point $x$ such that 95% of the distribution is to the left. In this subsection we introduce the notion of VaR in more detail by developing a mathematical formulation, demonstrating how VaR can be modeled with GAMS EMP using a simple example and showing how to optimize the weighted sum of the expected value and VaR.

4.51.11.2.2.1 VaR: Mathematical Formulation Suppose $G(x, \xi)$ is a real valued function of the decision vector $x$ and a random data vector $\xi$ and that it denotes the loss function of a portfolio of assets. We aim to restrict potential losses and so we choose a portfolio composition such that the loss only exceeds a certain threshold $\gamma$ ($\gamma \in \mathbb{R}$) with a probability smaller or equal to $\alpha$, $\alpha \in (0, 1)$, where $\alpha$ is small. This condition can be modeled as a chance constraint and has the following form:

$$P(G(x, \xi) > \gamma) \leq \alpha \quad (37)$$

It is easy to see that this can be written in the following way:

$$P(G(x, \xi) - \gamma \leq 0) \geq 1 - \alpha. \quad (38)$$

Consider the random variable $Z_x := G(x, \xi) - \gamma$. For a given value of $x$, let $F_Z(z) := P(Z \leq z)$ be the cumulative distribution function of $Z$. Now, the point $x$ satisfies the constraint (37) if and only if $F_Z(0) \geq 1 - \alpha$. This is equivalent to saying that $x$ satisfies the constraint (39) if and only if $F_Z^{-1}(1 - \alpha) \leq 0$.

The (left-side) quantile $F_Z^{-1}(\theta)$ is called Value at Risk. It is denoted by $VaR_\theta(Z)$, i.e.

$$VaR_\theta(Z) = \inf\{t : F_Z(t) \geq \theta\}. \quad (39)$$

Hence constraint (38) can be written in the following equivalent form:

$$VaR_{1-\alpha}(G(x, \xi)) \leq \gamma. \quad (40)$$

Value at Risk as introduced in equation (39) refers to a percentile on the left tail of a distribution. From now on it will be denoted by $VaR_\theta(Z)$. When considering the Value at Risk at the right tail of the distribution, $\theta$ typically equals 0.9 or 0.95, it is denoted by $VaR_\theta(Z)$.

Figure 2 illustrates $VaR_{0.05}(Z)$, where $Z$ is normally distributed with mean $\mu = 0.645$ and standard deviation $\sigma = 1$.

The EMP framework provides the EMP keywords `varlo` and `varup` as a convenient alternative to chance constraints to model Value at Risk.
4.51.11.2.2 VaR with EMP: A Simple Example  

We continue to illustrate with the stochastic portfolio model that we have already used above. Consider that the investor might be interested in a strategy that maximizes the threshold at a certain cutoff, say at 10% on the left tail of the return curve. Mathematically, the problem can be expressed as follows:

\[
\begin{align*}
\text{Max} & \quad \text{VaR}_\theta[R] \\
\text{s.t} & \quad R = \sum_j w_j v_j \\
& \quad \sum_j w_j = 1 \\
& \quad w_j \geq 0,
\end{align*}
\]

where $\text{VaR}_\theta$ is the Value at Risk at the lower $\theta$th percentile.

In the EMP annotations of the corresponding GAMS model we introduce a new variable for VaR ($\text{varr}$), a scalar to specify the percentile we are interested in (theta) and the EMP keyword $\text{varlo}$:

```plaintext
* Core Model
$include data.gms
Variables
r "value of portfolio under each scenario"
w(j) "portfolio selection"
varr "value at risk of r"
obj "objective variable";
Positive Variables
w;
```
Scalar theta "relative volume" / 0.1 /

Equations
defr "return of portfolio"
budget "budget constraint"
defobj "objective equation" ;
defr.. r =e= sum(j, v(j)*w(j));
budget.. sum(j, w(j)) =e= 1;
defobj.. obj =e= varr;

Model portfolio / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%' 
  / 'varlo r varr ' theta 
  / 'stage 1 obj defobj varr' 
  / 'stage 2 r defr v' 
  / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
  put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
  s_v(s,j) "return from assets by scenario"
  s_r(s) "return from portfolio by scenario" ;

Set
  dict / s .scenario."
  v .randvar .s_v
  r .level .s_r /

solve portfolio using emp max obj scenario dict;

The first line in the EMP annotations begins with the EMP keyword varlo. This line specifies that the variable varr is the Value at Risk relating to the random variable r and the scalar theta is the percentile (in range 0 to 1) we consider. The other lines in the annotations are similar to the second model above. Note that the objective equals the Value at Risk at the left tail, denoted by $VaR$. Observe that the EMP keyword varlo specifies VaR at the left tail of the probability distribution. For the right tail of the distribution, the EMP keyword to be used is varup.

Note

- The keyword var is identical to varup which refers to the right tail of the distribution.
- Currently only the solver DE supports the keywords for VaR.

Note further, that it is only appropriate to maximize $VaR_\alpha$ and minimize $VaR_\alpha$.

The implementation of the keywords varlo and varup is based on a mixed integer program similar to that described in section Example with a Single Chance Constraint. Observe that these implementations are likely to be hard and/or time consuming to solve. There is an option that allows users to customize the big M value (default is 1000) in the same manner that we outline below:
Observe that the EMP framework offers an alternative, shorter way to model VaR. There is no additional variable for VaR, hence in the EMP annotations, the EMP keyword \texttt{varlo} is only followed by \texttt{theta} and the objective variable in the solve statement is \texttt{r}. As \texttt{varlo} is specified in the annotations, the risk measure is applied to the objective variable implicitly. The modified EMP annotations and the new solve statement follow.

\begin{verbatim}
File emp / '%emp.info%' /;
put emp '* problem %gams.i%' / 'varlo' 'theta'
   / 'stage 2 r defr v'
   / "jrandvar v('att') v('gmc') v('usx')"
loop(s, put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;
...
solve portfolio using emp max r scenario dict;
\end{verbatim}

Note that this alternative notation is shorter, but it is also opaque, therefore we recommend the first way.

### 4.51.11.2.2.3 Combining VaR and Expected Value

In a variation of the example above, consider an investor who aims to take into account both, the expected return and the Value at Risk of the return at a certain threshold \( \theta \). She combines the two risk measures and uses a scalar (\( \lambda \)) as a weight. A mathematical formulation of the problem reads as follows:

\[
\begin{align*}
\text{Max} & \quad \lambda \mathbb{E}[R] + (1 - \lambda) \text{VaR}_\theta[R] \\
\text{s.t} & \quad R = \sum_j w_j v_j \\
& \quad \sum_j w_j = 1 \\
& \quad w_j \geq 0,
\end{align*}
\]

where \( \mathbb{E}[R] \) is the expected value of the return and \( \text{VaR}_\theta \) is the Value at Risk at the \( \theta \)th percentile.

This problem can be modeled in GAMS EMP as follows:

\begin{verbatim}
* Core Model
$include data.gms
Variables
    r         "value of portfolio under each scenario"
    w(j)      "portfolio selection"
    varr      "value at risk of r"
    evr       "expected value of r"
    obj       "objective variable" ;
Positive Variables
    w ;
Scalars
    theta     "relative volume" / 0.1 /
    lambda    "weight EV versus VaR" / 0.2 /
Equations
\end{verbatim}
defr "return of portfolio"
budget "budget constraint"
defobj "convex combination of both risk measures" ;

defr..  r =e= sum(j, v(j)*w(j));
budget.. sum(j, w(j)) =e= 1;
defobj.. obj =e= lambda*evr + (1-lambda)*varr;

Model portfolio_ext / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%' /
   'ExpectedValue r evr'
   'varlo r varr ' theta
   'stage 2 r defr v'
   'stage 1 defobj obj'
   "jrandvar v('att') v('gmc') v('usx')"
loop(s,
   put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
   s_v(s,j) "return from assets by scenario /s1.att 1/"
   s_r(s) "return from portfolio by scenario" ;

Set dict / s .scenario.''
   v .randvar .s_v
   r .level .s_r /;

solve portfolio_ext using EMP max obj scenario dict;

Note that we introduced a variable for the expected value of the return like in the example above where we modeled the expected return explicitly. Note further, that we added the parameter lambda and we defined the variable obj to be the weighted sum of the expected value of the return evr and the lower VaR varr. Observe that in the EMP annotations both keywords ExpectedValue and varlo are used. The other parts of the model remain unchanged.

4.51.11.2.3 Conditional Value at Risk (CVaR) The Conditional Value at Risk (CVaR) is the expected value of the left or right tail of the distribution; for example, the expected value of the left 5% of the standard Normal distribution. Note that CVaR is also called expected shortfall. In this subsection we introduce and discuss CVaR in more detail by presenting a mathematical formulation, demonstrating how CVaR can be modeled with GAMS EMP using a simple example and showing how to optimize the weighted sum of the expected value and CVaR.

4.51.11.2.3.1 CVaR: Mathematical Formulation \( CVaR_\alpha \) is the expected average return (in a given time period) given that we are in the \( (\alpha \times 100\%) \) left tail of the return distribution, where \( \alpha \in (0, 1) \). In other words, \( CVaR_\alpha \) is a mean of the left tail. For example, if we are interested in the 5% worst cases, i.e. \( \alpha = 0.05 \), \( CVaR_\alpha \) is the conditional expectation of the return, given the return is no greater than VaR.

Let \( \xi \) be a random variable with probability density function \( p(\xi) \), let \( G(\xi) \) be a function of the random variable \( \xi \) denoting the return of a portfolio of assets and let \( \alpha \in (0, 1) \) be a probability. Then the conditional value at risk of \( G(\xi) \) is defined as

\[
CVaR_\alpha(G(\xi)) = \frac{1}{\alpha} \int_{-\infty}^{VaR_\alpha} G(\xi) \cdot p(\xi) d\xi, \tag{43}
\]
where \( VaR_\alpha \) is the value at risk.

### 4.51.11.2.3.2 CVaR with EMP: A Simple Example

In the stochastic portfolio example that we have used throughout this section, the investor might be interested to make sure that in the worst cases she loses as little as possible. Thus she could consider only the worst 10% of possible cases and allocate her funds such that the expected mean return in these cases is maximized. Mathematically, the problem can be expressed as follows:

\[
\begin{align*}
\text{Max} & \quad CVaR_\theta[R] \\
\text{s.t} & \quad R = \sum_j w_j v_j \\
& \quad \sum_j w_j = 1 \\
& \quad w_j \geq 0,
\end{align*}
\]

where \( CVaR_\theta \) is the CVaR at the confidence level \( \theta \) at the left tail of the distribution.

Like in the case of Value at Risk above, we introduce a new variable for CVaR (cvarr), a scalar to specify the percentile we are interested in (theta) and the EMP keyword cvarlo in the EMP annotations:

* Core Model

\$include data.gms

Variables

\begin{align*}
\text{r} & \quad \text{"value of portfolio under each scenario"} \\
\text{w(j)} & \quad \text{"portfolio selection"} \\
\text{cvarr} & \quad \text{"conditional value at risk of r"} \\
\text{obj} & \quad \text{"objective variable"} ;
\end{align*}

Positive Variables

\begin{align*}
\text{w} ;
\end{align*}

Scalar

\begin{align*}
\text{theta} & \quad \text{"relative volume"} / 0.1 / ;
\end{align*}

Equations

\begin{align*}
\text{defr} & \quad \text{"return of portfolio"} \\
\text{budget} & \quad \text{"budget constraint"} \\
\text{defobj} & \quad \text{"objective equation"} ;
\end{align*}

\begin{align*}
\text{defr..} & \quad \text{r} =e= \sum(j, v(j) \cdot w(j)); \\
\text{budget..} & \quad \sum(j, w(j)) =e= 1; \\
\text{defobj..} & \quad \text{obj} =e= \text{cvarr};
\end{align*}

Model portfolio / all /;

* EMP Annotations

\$emp / '%emp.info%' /
put emp '* problem %gams.i%' /
    'cvarlo r cvarr' theta
    / 'stage 1 obj defobj cvarr'
    / 'stage 2 r defr v'
    / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
    put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary

Parameters
s_v(s,j) "return from assets by scenario"
s_r(s) "return from portfolio by scenario";

Set dict / s .scenario.
   v .randvar .s_v
   r .level .s_r /;

solve portfolio using emp max obj scenario dict;

In the EMP annotations, the first line starts with the EMP keyword cvarlo. This line specifies that the variable cvarl is the left-tail CVaR relating to the random variable r and the scalar theta is the fraction (in range 0 to 1) we consider. Like in the previous section, the objective variable, the objective equation and the variable in the objective equation belong to the first stage while the equation that handles the random data and all its variables belong to the second stage. Observe that the objective equals the Conditional Value at Risk.

Note that the keyword cvarlo specifies CVaR at the left tail of the probability distribution. For the right tail of the distribution the keyword to be used is cvarup.

Note
- The EMP keyword cvar is identical to the keyword cvarup.
- Currently only the solver DE supports the keywords for CVaR.

The conditional value at risk denoting the mean of the right tail of the distribution can be denoted by $CVaR$ and is defined as:

$$CVaR_{\alpha}(G(\xi)) = \frac{1}{1-\alpha} \int_{\gamma_{\alpha}}^{\infty} G(\xi) \cdot p(\xi) d\xi.$$ (45)

Observe that it is only appropriate to maximize $CVaR_{\alpha}$ and minimize $CVaR_{\alpha}$. Furthermore, $CVaR_{\alpha}$ is a concave function and so should only be constrained using e.g.

$$CVaR_{\alpha} \geq \gamma$$

and $CVaR_{\alpha}$ is convex, so should only appear in constraints like

$$CVaR_{\alpha} \leq \gamma.$$ 

The EMP framework offers an alternative way to model CVaR. In this alternative formulation, there is no additional variable for CVaR, hence in the EMP annotations, the EMP keyword cvarlo is only followed by theta and the objective variable in the solve statement is r. As cvarlo is specified in the annotations, the risk measure is applied to the objective variable implicitly. The modified EMP annotations and the new solve statement follow.

File emp / '%emp.info%' /
put emp '* problem %gams.i%'
   / 'cvarlo' theta
   / 'stage 2 r defr v'
   / "jrandvar v('att') v('gmc') v('usx')"
loop(s, put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

solve portfolio using emp max r scenario dict;

Note that this alternative notation is shorter, but it is considerably less clear, therefore we recommend the explicit notation of the first model.
4.51.11.2.3.3 Combining CVaR and Expected Value  

In a final variation on the portfolio example, we consider an investor who aims to take into account both, the expected return and the Conditional Value at Risk of the return at a certain threshold \( \theta \). She combines the two risk measures and uses a scalar (\( \lambda \)) to weigh the two summands. A mathematical formulation of the problem reads as follows:

\[
\text{Max} \quad \lambda \mathbb{E}[R] + (1 - \lambda) \text{CVaR}_\theta[R] \\
\text{s.t} \quad R = \sum_j w_j v_j \\
\sum_j w_j = 1 \\
w_j \geq 0, \tag{46}
\]

where \( \mathbb{E}[R] \) is the expected value of the return and \( \text{CVaR}_\theta \) is the CVaR at the confidence level \( \theta \).

This problem can be modeled with GAMS EMP as follows:

* Core Model
$sinclude data.gms$
Variables
\[
\begin{align*}
\text{r} & \quad \text{"value of portfolio under each scenario"} \\
\text{w(j)} & \quad \text{"portfolio selection"} \\
\text{cvarr} & \quad \text{"conditional value at risk of r"} \\
\text{evr} & \quad \text{"expected value of r"} \\
\text{obj} & \quad \text{"objective variable"} \\
\end{align*}
\]
Positive Variables
\[
\text{w} \\
\]
Scalars
\[
\begin{align*}
\text{theta} & \quad \text{"relative volume"} / 0.1 / \\
\text{lambda} & \quad \text{"weight EV versus CVaR"} / 0.2 /; \\
\end{align*}
\]
Equations
\[
\begin{align*}
\text{defr} & \quad \text{"return of portfolio"} \\
\text{budget} & \quad \text{"budget constraint"} \\
\text{defobj} & \quad \text{"convex combination of both risk measures"}; \\
\end{align*}
\]
\[
\begin{align*}
\text{defr..} & \quad \text{r} = \text{e} = \sum(j, v(j) \cdot w(j)); \\
\text{budget..} & \quad \sum(j, w(j)) = \text{e} = 1; \\
\text{defobj..} & \quad \text{obj} = \text{e} = \lambda \text{evr} + (1 - \lambda) \text{cvarr}; \\
\end{align*}
\]
Model portfolio_ext / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
   / 'ExpectedValue r evr'
   / 'cvvarlo r cvarr' theta
   / 'stage 2 r defr v'
   / 'stage 1 defobj obj'
   / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
   put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
\[
\begin{align*}
\text{s_v(s,j)} & \quad \text{"return from assets by scenario"} \\
\text{s_r(s)} & \quad \text{"return from portfolio by scenario"} \\
\end{align*}
\]
Note that apart from the EMP keyword varlo being replaced by cvarlo, the code is identical to the code above, where we maximized the weighted sum of the expected value and VaR. Observe that by decreasing the value of $\lambda$ from 1 to 0 we can explore the results of an increasingly risk averse behavior.

4.51.11.4 EMP Syntax for Risk Measures

The EMP annotations where risk measures are used have the same general syntax like stochastic models with recourse. In addition, the following keywords may be used:

- **ExpectedValue** $rv$ $var$
- **varlo** $[rv]$ $var$ scalar
g - **varup** $[rv]$ $var$ scalar
c - **cvarlo** $[rv]$ $var$ scalar
d - **cvarup** $[rv]$ $var$ scalar

The **EMP keyword Expected Value** is used to state that the variable $var$ is the expected value of the random variable $rv$. Note that the random variable $rv$ must be defined to be a random variable in the EMP annotations.

The EMP keywords varlo, varup, cvarlo and cvarup refer to VaR at the left tail of the distribution ($VaR_{\alpha}$), VaR at the right tail of the distribution ($VaR_{1-\alpha}$), CVaR at the left tail of the distribution ($CVaR_{\alpha}$) and CVaR at the right tail of the distribution ($CVaR_{1-\alpha}$) respectively.

Note

The EMP keyword var is a synonym to varup and cvar is a synonym to cvarup.

The specifications that follow all four keywords have a long and a short version. In the long version, the random variable $rv$ and the variable that is assigned to be the respective risk measure (VaR or CVaR) are named explicitly. The scalar is a number in the interval $(0, 1)$, it defines the percentile in VaR and confidence level in CVaR. In the short version, only the scalar is specified. In this case the risk measure will applied to the objective variable implicitly.

Note

These five keywords are only supported by the solver DE.

4.51.11.3 Chance Constraints with EMP

In stochastic programs with chance constraints the goal is to make an optimal decision prior to the realization of random data while allowing the constraints (or some of them) to be violated with a certain probability. Note that chance constraints are also called probabilistic constraints.

This section is organized as follows. After introducing a mathematical formulation of chance constraints, we show how such problems can be modeled with GAMS EMP using a simple example with only one chance constraint. Then we extend the model to include multiple chance constraints. We discuss the two ways to model problems with multiple chance constraints: using joint chance constraints and using individual chance constraints. Joint chance constraints require that all constraints are satisfied simultaneously with a given probability. Individual chance constraints require each constraint to be satisfied with a given probability independently of other constraints. Further, the EMP framework offers the option to penalize the violation of chance constraints. This is the topic of subsection Penalizing Violations of Chance Constraints. We conclude this section with an overview of the EMP annotations that are specific to chance constraints.
4.51.11.3.1 Chance Constraints: Mathematical Formulation  

Mathematically, a stochastic linear program with chance constraints can be expressed as follows:

\[
\begin{align*}
\text{Min} & \quad c^T x \\
\text{s.t.} & \quad P(Ax \leq b) \geq p \\
& \quad x \geq 0,
\end{align*}
\]

where \( x \in \mathbb{R}^n \) is the decision variable and \( c^T \) denotes the coefficients of the objective function. \( A \in \mathbb{R}^{m \times n} \) is a random matrix and represents the coefficients and \( b \in \mathbb{R}^m \) is a random vector and denotes the right-hand side of the constraints. The distinctive feature of stochastic programs with chance constraints is that the constraints (or some of them) may be violated with probability \( \epsilon = 1 - p \), where \( 0 < p \leq 1 \). Note that \( \epsilon \) is sometimes called the risk tolerance.

One way to solve a stochastic problem with chance constraints is to convert it to a mixed-integer problem (MIP) first and then solve the MIP equivalent. The idea is to introduce a set of scenarios \( S \) and a vector with binary variables, say \( y_k \in \mathbb{R}^m \), for each scenario \( k \in S \). The binary variables take value 1 if the corresponding constraint is satisfied in a scenario and 0 otherwise. A scenario-based formulation of the chance-constrained stochastic linear program above can be written as:

\[
\begin{align*}
\text{Min} & \quad c^T x \\
\text{s.t.} & \quad A^k x \leq b^k + M^k (1 - y_k) \\
& \quad \sum_{k \in S} y_k \geq p \times |S| \\
& \quad x \geq 0, \quad y \in (0, 1)^{|S|},
\end{align*}
\]

where \( M^k \in \mathbb{R}^m \) is a chosen big-M vector. The entries of the vector \( M^k \) should be chosen such that it does not cut off any feasible solution if \( y_k = 0 \).

4.51.11.3.2 Example with a Single Chance Constraint  

We start with the simplest case, where the random matrix \( A \) consists of just one random vector \( a \), resulting in a problem with a single chance constraint. The following example is adapted from model [SIMPLECHANCE].

\[
\begin{align*}
\text{Min} & \quad x_1 + x_2 \\
\text{s.t.} & \quad P(\omega x_1 + x_2 \geq 7) \geq 0.75, \quad \omega \in \Omega = \{1, 2, 3, 4\}
\end{align*}
\]

Here the random parameter \( \omega \) has four possible realizations. Thus we have four scenarios and we assume that each scenario is equally likely to be realized, i.e. \( \pi^k = \frac{1}{4} \), where \( \pi^k \) denotes the probability that scenario \( k \) is realized. Note that in this example \( b \) is fixed at 7. As \( p = 0.75 \) and each scenario is equally likely to be realized, we need to choose \( x_1 \) and \( x_2 \) such that the inequality is satisfied in at least 3 scenarios. For clarity, we spell out the inequalities for the scenarios:

\[
\begin{align*}
& k = 1: \quad \omega_1 = 1 \quad \omega_1 x_1 + x_2 \geq 7 \\
& k = 2: \quad \omega_2 = 2 \quad \omega_2 x_1 + x_2 \geq 7 \\
& k = 3: \quad \omega_3 = 3 \quad \omega_3 x_1 + x_2 \geq 7 \\
& k = 4: \quad \omega_4 = 4 \quad \omega_4 x_1 + x_2 \geq 7.
\end{align*}
\]
The MIP equivalent of problem (49) is given below:

\[
\begin{align*}
\text{Min} & \quad x_1 + x_2 \\
\text{s.t.} & \quad 1x_1 + x_2 \geq 7 - M(1 - y_1) \\
& \quad 2x_1 + x_2 \geq 7 - M(1 - y_2) \\
& \quad 3x_1 + x_2 \geq 7 - M(1 - y_3) \\
& \quad 4x_1 + x_2 \geq 7 - M(1 - y_4) \\
cc_1 &= 1 - \sum_k \pi^k y_k, \quad k = 1, \ldots, 4, \quad \pi^k = \frac{1}{4} \\
x_1, x_2 &\geq 0 \\
0 \leq cc_1 \leq (1 - 0.75) \\
y_k &\in (0, 1).
\end{align*}
\] (51)

Observe that the first four constraints cover the four possible scenarios with \( \omega \) taking the values 1, 2, 3 and 4 respectively. On the right-hand side we introduce a big-M factor and \( y_k \), a binary indicator variable. \( y_k \) takes the value 1 if the constraint is satisfied and zero otherwise. The new variable \( cc_1 \) represents the probability that the constraint is violated. If \( cc_1 = 0 \), the sum will equal 1, indicating that the constraint is satisfied in all four scenarios. If \( cc_1 = 0.25 \), the constraint will be unsatisfied in one scenario out of four (for this scenario \( y_k = 0 \)).

The problem can be modeled in GAMS EMP as follows:

* Core Model
Positive Variables x1, x2;
Variables z;
Scalar om / 1 /;
Equations obj, e1;
obj.. z =e= x1 + x2;
e1.. om*x1 + x2 =g= 7;
Model sc / all /;

* EMP Annotations
File emp / '%emp.info%' /;
put emp;
$onput
randvar om discrete 0.25 1 0.25 2 0.25 3 0.25 4
chance e1 0.75
$offput
putclose emp;

* Dictionary
Set scen "scenarios" / s1*s4 /;
Parameter _s_om(scen)
x1_l (scen)
x2_l (scen)
e1_l (scen);
Set dict / scen .scenario.

om .randvar ._s_om
x1 .level .x1_l
x2 .level .x2_l
Extended Mathematical Programming (EMP)

\[ e_1 \ .level .e_1_l /; \]

solve sc min z use EMP scenario dict;
display s_om, x_1_l, x_2_l, e_1_l;

Like other EMP stochastic programming models, the model consists of three parts: the core model, the EMP annotations and the dictionary with output-handling information. As usual, the core model is defined as a deterministic model and the specifications relating to the stochastic structure of the problem are written to the file `emp.info`. In the EMP annotations, the EMP keyword `randvar` is used to declare a parameter from the core model as a random variable. The keyword is followed by `om`, the random variable, and the distribution. The EMP keyword `discrete` indicates that we have a discrete distribution. The discrete distribution is specified via probability-numerical value pairs. Note that continuous distributions are also possible. See section Random Variables with Continuous Distributions for more information.

The second line in the EMP annotations starts with the EMP keyword `chance` followed by the equation `e_1` and a probability. The specification means that the constraints `e_1` must hold for at least 75% of all scenarios. We can verify that this requirement has been enforced by checking in the listing file the level value of the constraint `e_1_l`. We will see that in the first scenario the constraint was violated, but it was satisfied in all other scenarios.

Observe that the EMP keyword `chance` allows for an optional specification that is related to a penalization factor for constraints that are violated. This topic is discussed in section Penalizing Violations of Chance Constraints below.

Note

Currently, there are no stages in stochastic problems with chance constraints, unlike in stochastic problems with recourse.

As the problem is solved as a MIP, it is important that the options OptCA and OptCR are assigned appropriate values.

Note that the default value of \( M \) is 1e7 for the solver Lindo. To customize this and set it to, e.g., 1000 instead, one could insert the following five lines before the solve statement:

```plaintext
option emp = lindo;
$onecho > lindo.opt
STOC_BIGM 1e3
$offecho
sc.optfile = 1;
```

For DE the default value of \( M \) is 10000 and it could be changed to 1000 in a similar way as seen above for Lindo:

```plaintext
option emp = de;
$onecho > de.opt
ccreform bigM 1e3
$offecho
sc.optfile = 1;
```

Note that `ccreform` is a DE option. This option allows to specify two alternative solution strategies: a reformulation using a convex hull and a reformulation using indicator variables and indicator constraints. The following line indicates that a convex hull with \( M = 1000 \) and \( \epsilon = 0.00001 \) is to be used:

```plaintext
ccreform cHull 1e3 1e-6
```

For indicator variables and constraints, the following line is used:

```plaintext
ccreform indic
```

Note that currently only the solver CPLEX supports indicator variables, so the resulting reformulated problem has to be solved with CPLEX.
4.51.11.3.3 Examples with Multiple Chance Constraints  Stochastic problems with multiple chance constraints have two different forms: problems with joint chance constraints and problems with multiple individual chance constraints. In problems with joint chance constraints the constraints all have to be satisfied simultaneously with probability \( p \). In problems with multiple individual chance constraints each constraint carries its own risk tolerance. We illustrate with two examples.

4.51.11.3.3.1 Joint Chance Constraints  We illustrate joint chance constraints by extending the example above by one constraint resulting in a problem with two chance constraints:

\[
\begin{align*}
\text{Min} & \quad x_1 + x_2 \\
s.t. & \quad P(\omega_1 x_1 + x_2 \geq 7; \omega_2 x_1 + 3x_2 \geq 12) \geq 0.6, \quad (\omega_1, \omega_2) \in \Omega \\
& \quad x_1, x_2 \geq 0,
\end{align*}
\]

where

\[
\Omega = \{(1,1), (1,2), (1,3), (2,1), (2,2), (2,3), (3,1), (3,2), (3,3), (4,1), (4,2), (4,3)\}
\]

and

\[
\pi^k = \pi(\omega_1, \omega_2) = \frac{1}{12} \quad \text{for all} \quad (\omega_1, \omega_2) \in \Omega.
\]

Note that both random variables follow discrete uniform distributions, \( \omega_1 \) has four realizations and \( \omega_2 \) has three realizations. Thus we have 12 scenarios that are all equally likely. The MIP equivalent takes the following form:

\[
\begin{align*}
\text{Min} & \quad x_1 + x_2 \\
s.t. & \quad 1x_1 + x_2 \geq 7 - M(1 - y_1) \\
& \quad 1x_1 + 3x_2 \geq 12 - M(1 - y_1) \\
& \quad 2x_1 + x_2 \geq 7 - M(1 - y_2) \\
& \quad 1x_1 + 3x_2 \geq 12 - M(1 - y_2) \\
& \quad \vdots \\
& \quad 4x_1 + x_2 \geq 7 - M(1 - y_{12}) \\
& \quad 3x_1 + 3x_2 \geq 12 - M(1 - y_{12}) \\
& \quad cc_1 = 1 - \sum_k \pi^k y_k, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12} \\
& \quad x_1, x_2 \geq 0 \\
& \quad 0 \leq cc_1 \leq (1 - 0.6) \\
& \quad y_k \in (0, 1).
\end{align*}
\]

Note that the first set of constraints covers the 12 scenarios, where each scenario has two constraints. The other constraints are similar to those introduced in the previous model.

The problem can be modeled with GAMS EMP as follows:

* Core Model
Positive Variables x1, x2;
Variables z;
Scalars om1, om2;
om1 = 1;
om2 = 1;
Equations obj, e1, e2;

obj.. z =e= x1 + x2;
e1.. om1*x1 + x2 =g= 7;
e2.. om2*x1 + 3*x2 =g= 12;

Model sc / all /;

* EMP Annotations
File emp / '%emp.info%' /;
put emp '* problem %gams.i%'/;
$onput
randvar om1 discrete 0.25 1 0.25 2 0.25 3 0.25 4
randvar om2 discrete 0.3333 1 0.3334 2 0.3333 3
chance e1 e2 0.6
$offput
putclose emp;

* Dictionary
Set scen "scenarios" / s1*s12 /;
Parameters s_om1(scen)
s_om2(scen)
x1_l (scen)
x2_l (scen)
e1_l (scen)
e2_l (scen);
Set dict / scen .scenario.''
om1 .randvar .s_om1
om2 .randvar .s_om2
x1 .level .x1_l
x2 .level .x2_l
e1 .level .e1_l
e2 .level .e2_l/;
solve sc min z use emp scenario dict;
display s_om1, s_om2, x1_l, x2_l, e1_l, e2_l;

In the EMP annotations, the line chance e1 e2 0.6 specifies that in at least 60% of all scenarios both constraints e1 and e2 must be satisfied at the same time. There are a total of 12 scenarios, hence both constraints must be satisfied in at least 8 scenarios (i.e. $12 \times 0.6 = 7.2 \leq 8$). We can verify that this requirement has been enforced by checking in the listing file the level values of the constraints, e1_l and e2_l. Indeed, in the optimal solution both constraints hold in scenarios 4 to 12, meaning that there are 9 scenarios that satisfy both inequalities.

4.51.11.3.3.2 Individual Chance Constraints In stochastic problems with individual chance constraints there is no correlation between the probabilities of the rows of the matrix $A$. Hence problem (47) takes the following form:

$$
\begin{align*}
\text{Min}_x & \quad c^T x \\
\text{s.t.} & \quad P(A_i x \leq b_i) \geq p_i, \quad i = 1, \ldots, m \\
x & \geq 0.
\end{align*}
$$

(54)
To illustrate, we use an extended version of the example from the previous section and replace the joint chance constraints by individual chance constraints:

\[
\begin{align*}
\text{Min} & \quad x_1 + x_2 \\
\text{s.t.} & \quad P(\omega_1 x_1 + x_2 \geq 7) \geq 0.75, \quad \omega_1 \in \Omega_1 = \{1, 2, 3, 4\} \\
& \quad P(\omega_2 x_1 + 3x_2 \geq 12) \geq 0.6, \quad \omega_2 \in \Omega_2 = \{1, 2, 3\} \\
& \quad P(\omega_1 x_1 + \omega_2 x_2 \geq 10) \geq 0.5, \quad (\omega_1, \omega_2) \in \Omega_1 \times \Omega_2 = \Omega \\
& \quad x_1, x_2 \geq 0.
\end{align*}
\]

Note that \(\Omega\) is defined as in (52) above, we have again 12 scenarios, each with probability \(\pi^k = \frac{1}{12}\). However, in this example, the first inequality must hold in 9 out of 12 scenarios (0.75 \times 12 = 9), the second inequality must hold in 8 out of 12 inequalities (0.6 \times 12 = 7.2 \leq 8) and the third inequality must hold in 6 out of 12 scenarios. Note further, that we may have four types of scenarios: scenarios where all constraints are violated, scenarios where two constraints are violated, scenarios where one constraint is violated and scenarios where all three constraints are satisfied. The only condition is that for each constraint there is the respective number of scenarios where the constraint is satisfied. Observe that the random data in the third inequality is a combination of the random data of the first two inequalities. The inequalities for the scenarios are given below:

\[
\begin{align*}
k = 1: & \quad \omega_1^1 = 1, \ \omega_2^1 = 1 \quad \omega_1^1 x_1 + x_2 \geq 7 \\
& \quad \omega_2^1 x_1 + 3x_2 \geq 12 \\
& \quad \omega_1^1 x_1 + \omega_2^1 x_2 \geq 10 \\
k = 2: & \quad \omega_1^2 = 1, \ \omega_2^2 = 2 \quad \omega_1^2 x_1 + x_2 \geq 7 \\
& \quad \omega_2^2 x_1 + 3x_2 \geq 12 \\
& \quad \omega_1^2 x_1 + \omega_2^2 x_2 \geq 10 \\
& \quad \vdots \\
k = 12: & \quad \omega_1^{12} = 4, \ \omega_2^{12} = 3 \quad \omega_1^{12} x_1 + x_2 \geq 7 \\
& \quad \omega_2^{12} x_1 + 3x_2 \geq 12 \\
& \quad \omega_1^{12} x_1 + \omega_2^{12} x_2 \geq 10
\end{align*}
\]

The MIP equivalent follows:

\[
\begin{align*}
\text{Min} & \quad x_1 + x_2 \\
\text{s.t.} & \quad 1x_1 + x_2 \geq 7 - M(1 - y_1^1) \\
& \quad 1x_1 + 3x_2 \geq 12 - M(1 - y_1^2) \\
& \quad 1x_1 + 1x_2 \geq 10 - M(1 - y_1^3) \\
& \quad 2x_1 + x_2 \geq 7 - M(1 - y_1^4) \\
& \quad 1x_1 + 3x_2 \geq 12 - M(1 - y_1^5) \\
& \quad 2x_1 + 1x_2 \geq 10 - M(1 - y_1^6) \\
& \quad \vdots \\
& \quad 4x_1 + x_2 \geq 7 - M(1 - y_{12}^1) \\
& \quad 3x_1 + 3x_2 \geq 12 - M(1 - y_{12}^2) \\
& \quad 4x_1 + 3x_2 \geq 10 - M(1 - y_{12}^3) \\
& \quad cc_1 = 1 - \sum_{k=1}^{12} \pi^k y_k^1, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12} \\
& \quad cc_2 = 1 - \sum_{k=1}^{12} \pi^k y_k^2, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12} \\
& \quad cc_3 = 1 - \sum_{k=1}^{12} \pi^k y_k^3, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12} \\
& \quad x_1, x_2 \geq 0 \\
& \quad 0 \leq cc_1 \leq (1 - 0.75) \\
& \quad 0 \leq cc_2 \leq (1 - 0.6) \\
& \quad 0 \leq cc_3 \leq (1 - 0.5) \\
& \quad y_k^i \in (0, 1).
\end{align*}
\]
As expected, there are three constraints for every scenario. Note that we introduced three new variables, \( cc_1 \), \( cc_2 \) and \( cc_3 \) and three corresponding constraints. Each of the variables has a different range reflecting the different probabilities with which a constraint may be violated.

The core model of the GAMS code is very similar to the core model with joint chance constraints. We just add the third inequality:

Equations obj, e1, e2, e3;

\[
\begin{align*}
\text{obj..} & \quad z =e= x_1 + x_2; \\
\text{e1..} & \quad \text{om}_1 x_1 + x_2 \geq 7; \\
\text{e2..} & \quad \text{om}_2 x_1 + 3x_2 \geq 12; \\
\text{e3..} & \quad \text{om}_1 x_1 + \text{om}_2 x_2 \geq 10;
\end{align*}
\]

There is a slight modification in the annotations:

File emp / '%emp.info%' /;
put emp '* problem %gams.i%'/;
$onput
randvar om1 discrete 0.25 1 0.25 2 0.25 3 0.25 4
randvar om2 discrete 0.3333 1 0.3334 2 0.3333 3
chance e1 0.75
chance e2 0.6
chance e3 0.5
$offput
putclose emp;

Observe that we have three lines that start with the EMP keyword chance: every constraint is listed separately with its respective probability.

Note
In case one constraint has to be satisfied in all scenarios (so it is strictly speaking not a chance constraint), then it has to be listed with probability 1.0.

An overview of which constraints are satisfied in which scenarios in the optimal solution is given in the following table:

<table>
<thead>
<tr>
<th>Scenarios Where</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
<th>11</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>
<td>e1 is satisfied</td>
<td></td>
<td></td>
<td></td>
<td></td>

<td>x</td>
<td>x</td>
<td>x</td>
<td>x</td>
<td>x</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 7: Overview of constraint satisfaction per scenario

Observe that all constraints are satisfied in as many scenarios as required and there are scenarios where all three constraints are satisfied (\( k = 6, 8, 9, 11, 12 \)), scenarios where only two constraints are satisfied (\( k = 5, 7, 10 \), scenarios where only one constraint is satisfied (\( k = 2, 3, 4 \)) and one scenario where all constraints are violated (\( k = 1 \)).

The choice whether joint or individual chance constraints should be used depends on the system being modeled. Both approaches have their own advantages. Individual chance constraints are weaker since not
all constraints have to be satisfied at the same time. This can be clearly observed in the optimal solution for example (55). The objective value is 5.20 in the model with joint chance constraints and 4.75 in the model with individual chance constraints (assuming that each constraint is satisfied in 60% of all scenarios). As it is a minimizing problem, the model with individual chance constraints yields the better result. However, in this solution we have only 6 scenarios where both constraints are simultaneously satisfied while each constraint is satisfied in eight scenarios in total for the joint chance constraint formulation, as required.

4.5.11.3.4 Penalizing Violations of Chance Constraints The EMP framework provides the syntax for a penalty factor for each scenario that violates one or more constraints. In the example with joint constraints above, the EMP annotations could be modified in the following way:

```
$onput
randvar om1 discrete 0.25 1 0.25 2 0.25 3 0.25 4
randvar om2 discrete 0.3333 1 0.3334 2 0.3333 3
chance e1 e2 0.6 3
$offput
```

Note that we added the number 3 at the end of the last line. This new entry represents a penalty factor. Recall that the MIP equivalent (53) takes the following form:

\[
\begin{align*}
\text{Min} & \quad z = x_1 + x_2 \\
\text{s.t.} & \quad 1x_1 + x_2 \geq 7 - M(1 - y_1) \\
& \quad 1x_1 + 3x_2 \geq 12 - M(1 - y_1) \\
& \quad \vdots \\
& \quad 4x_1 + x_2 \geq 7 - M(1 - y_{12}) \\
& \quad 3x_1 + 3x_2 \geq 12 - M(1 - y_{12}) \\
& \quad cc_1 = 1 - \sum_k \pi^k y_k, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12} \\
& \quad x_1, x_2 \geq 0 \\
& \quad 0 \leq cc_1 \leq (1 - 0.6) \\
& \quad y_k \in (0, 1).
\end{align*}
\]  

(58)

Observe that the probability with which the constraints are allowed to be violated is stored in the variable \(cc_1\). Introducing a penalty factor or weight \(w\) has the effect that the term \((w \times cc_1)\) is added to the objective function:

\[
z = x_1 + x_2 + w \times cc_1 = x_1 + x_2 + 3 cc_1
\]

(4.29)

Similarly, we could add weights in the example with individual chance constraints:

```
chance E1 0.75 5
chance E2 0.6 6
chance E3 0.5 7
```

Given these annotations, we obtain the following objective function in the MIP equivalent:

\[
z = x_1 + x_2 + 5 cc_1 + 6 cc_2 + 7 cc_3.
\]

(4.30)

Penalty terms can be useful to explore sensitivities to slight changes.
Note

Like in the context of soft constraints, the penalty term is added in minimization problems and subtracted in maximization problems.

Moreover, the probability expression $cc_1$ in the MIP equivalent may be used as a variable in the original model. For example, in the joint chance constraints problem above, we could introduce a new variable, $viol$, in the objective function:

$$\text{Min } z = x_1 + x_2 + 3 * viol$$  \hspace{1cm} (4.31)

Then we write the chance constraint specification in the EMP annotations as follows:

```
chance E1 E2 0.6 viol
```

The addition of the variable $viol$ as penalty factor causes $cc_1$ to be replaced by $viol$ in the MIP equivalent. Thus we have:

$$viol = 1 - \sum_k \pi^k y_k, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12}, \quad viol \in [0, 0.4].$$  \hspace{1cm} (4.32)

Note that the corresponding model is equivalent to the joint chance constraints model with penalty factor 3 with which we started this subsection.

### 4.51.11.3.5 EMP Syntax for Chance Constraints

The general syntax of the EMP annotations used to specify stochastic problems with chance constraints is as follows:

```plaintext
[randvar rv discrete prob val {prob val}]
[randvar rv distr par {par}]
[jrandvar rv rv {rv} prob val {val} {prob val val {val}}]
chance equ {equ} [holds] minRatio [weight|var]
{chance equ {equ} [holds] minRatio [weight|var]}
```

The first three lines present three ways to specify random variables. The syntax and logic is the same as in stochastic problems with recourse, see above for details. Note that at least one random variable has to be specified. The EMP keyword `chance` is used to define the constraint(s) that only have to hold for a certain ratio of the possible outcomes. This ratio is given with the number `minRatio` ($0 \leq \text{minRatio} \leq 1$). The keyword `holds` is optional and does not affect the solver. The remaining specifications are optional and relate to the penalization of chance constraints that are violated. If `weight` is defined, the violation of a chance constraint will be penalized in the objective function ($\text{weight} \times \text{violationRatio}$). Alternatively, if the name of a variable of the model (`var`) is specified, the violation will be multiplied by the value of this variable instead of the fixed multiplier `weight`.

In this section we have introduced various versions of problems with chance constraints with simple examples. For a more complex example, see the farming model `[KILOSAFARM]` in the GAMS EMP Model Library.

### 4.51.12 EMP Keywords

Some words act as keywords in the context of the EMP annotations in the file `emp.info`, but they are not GAMS reserved words, i.e. they are not keywords in the GAMS code apart from the EMP annotations. In this section we present an overview of all GAMS EMP keywords, ordered according to the type of programming where they are used.

#### 4.51.12.1 GAMS EMP Keywords for Soft Constraints
### 4.51.12.2 GAMS EMP Keywords for Variational Inequalities

<table>
<thead>
<tr>
<th>EMP Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VI</td>
<td>Indicates that the specifications that follow are a variational inequality. See the discussion of EMP specifications for VI and the example above.</td>
</tr>
<tr>
<td>QVI</td>
<td>Indicates that the specifications that follow are a quasi-variational inequality. See the discussion of EMP specifications for QVI and the example above.</td>
</tr>
</tbody>
</table>

### 4.51.12.3 GAMS EMP Keywords for Equilibrium Problems

<table>
<thead>
<tr>
<th>EMP Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dualvar</td>
<td>See below.</td>
</tr>
<tr>
<td>Equilibrium</td>
<td>Indicates that the specifications that follow define the structure of an equilibrium problem. For examples, see sections Equilibrium Problems with EMP: A Simple Example and Equilibrium Problems with EMP: Example with Dual Variables. The general syntax of EMP annotations for equilibrium problems is introduced in section EMP Syntax for Equilibrium Problems.</td>
</tr>
<tr>
<td>implicit</td>
<td>Specifies a shared variable and its defining constraint. For details, see section Equilibrium Problems with Shared Variables.</td>
</tr>
<tr>
<td>max</td>
<td>This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the maximization problem of one agent.</td>
</tr>
<tr>
<td>min</td>
<td>This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the minimization problem of one agent.</td>
</tr>
<tr>
<td>VI</td>
<td>Indicates that the specifications that follow define a VI, as in this example.</td>
</tr>
<tr>
<td>VIsol</td>
<td>Specifies that the equation that follows is a shared constraint and prompts the EMP framework to use the MCP reformulation where a variational inequality is associated with the shared constraint. For more information and an example, see section Equilibrium Problems with Shared Constraints.</td>
</tr>
</tbody>
</table>

### 4.51.12.4 GAMS EMP Keywords for Embedded Complementarity Systems

<table>
<thead>
<tr>
<th>EMP Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DualEqu</td>
<td>This keyword is followed by an equation-variable pair. It establishes a complementarity relationship between an external equation and the named variable of the model. An example is given above. See also the spatial price equilibrium model [HARK-MONOP].</td>
</tr>
<tr>
<td>DualVar</td>
<td>This keyword is followed by a variable-equation pair. It specifies that the variable is the dual of the equation. Examples are discussed in sections Equilibrium Problems with EMP: Example with Dual Variables and Embedded Complementarity Systems.</td>
</tr>
</tbody>
</table>
Note that problems with embedded complementarity systems can be recast as equilibrium problems. Details are given in section Embedded Complementarity Systems.

### 4.51.12.5 GAMS EMP Keywords for Bilevel Programming

<table>
<thead>
<tr>
<th>EMP Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bilevel</td>
<td>Indicates that the specifications that follow relate to a bilevel programming problem. The keyword is followed by the decision variable(s) of the upper-level problem and the definition(s) of the lower-level problem(s). For examples and more details, see section Bilevel Programs.</td>
</tr>
<tr>
<td>dualvar</td>
<td>See above.</td>
</tr>
<tr>
<td>max</td>
<td>This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the maximization problem of one agent.</td>
</tr>
<tr>
<td>min</td>
<td>This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the minimization problem of one agent, as in this example.</td>
</tr>
<tr>
<td>VI</td>
<td>Indicates that the specifications that follow define a VI, as in this example.</td>
</tr>
</tbody>
</table>

### 4.51.12.6 GAMS EMP Keywords for Disjunctive Programming

<table>
<thead>
<tr>
<th>EMP Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bigM</td>
<td>Indicates that the big M reformulation method shall be used.</td>
</tr>
<tr>
<td>chull</td>
<td>Indicates that a convex hull shall be used for the reformulation. Note that this is the default method.</td>
</tr>
<tr>
<td>default</td>
<td>Indicates that the specification that follows is the reformulation method.</td>
</tr>
<tr>
<td>disjunction</td>
<td>Indicates that the specification that follows is a disjunction. For a discussion of the general syntax following this keyword, see above.</td>
</tr>
<tr>
<td>indic</td>
<td>Indicates that indicator constraints shall be used as reformulation method.</td>
</tr>
<tr>
<td>star (*)</td>
<td>The symbol * will be replaced by internal default binary variables, thus explicit binary variables that model the Boolean variables are not needed. Note that default binary variables may only be used if there are no logic equations in the model. For an example and more details, see above.</td>
</tr>
</tbody>
</table>

### 4.51.12.7 GAMS EMP Keywords for Stochastic Programming

<table>
<thead>
<tr>
<th>EMP Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chance</td>
<td>Defines individual or joint chance constraints.</td>
</tr>
<tr>
<td>cvar</td>
<td>Synonym to cvarup.</td>
</tr>
<tr>
<td>cvarlo</td>
<td>This keyword assigns a variable to have the value $\text{CVaR}_\alpha$, where $\alpha$ is a scalar that represents the confidence level for the Conditional Value at Risk. Note that cvarlo refers to the left tail of the distribution. For more details and examples, see section Conditional Value at Risk (CVaR).</td>
</tr>
<tr>
<td>cvarup</td>
<td>This keyword assigns a variable to have the value $\text{CVaR}_\alpha$. $\alpha$ is a scalar that represents the confidence level for the Conditional Value at Risk. Note that cvarup refers to the right tail of the distribution.</td>
</tr>
<tr>
<td>discrete</td>
<td>Indicates that the specification that follows is the discrete distribution of one or more random variables.</td>
</tr>
<tr>
<td>ExpectedValue</td>
<td>This keyword is used to state that a variable is the expected value of a random variable.</td>
</tr>
<tr>
<td>EMP Keyword</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>jrandvar</td>
<td>This keyword is used to define discrete random variables that are jointly distributed. At least two random variables must be named. For an example, see the news vendor model ([\text{NBDISCJOINT}]).</td>
</tr>
<tr>
<td>randvar</td>
<td>This keyword declares that a parameter of the model is in fact a stochastic random variable. The keyword is followed by the name of the parameter and details about the probability distribution (discrete or parametric). A list of all supported parametric distributions is given in Table 4.</td>
</tr>
<tr>
<td>sample</td>
<td>This keyword allows users to customize the size of the sample of one or more random variables from a continuous distribution and - optionally - to determine the variance reduction method to be used. An example and further details are given above. Note that without a valid LINDO license this is limited to the Normal and Binomial distributions with a maximum sample size of 10.</td>
</tr>
<tr>
<td>setSeed</td>
<td>This keyword sets the seed for the random number generator of the sampling routines that are called via the keyword sample. If setSeed is used in EMP annotations, the seed will be set once before all samples will be generated. Note that a valid LINDO license is required to use this keyword.</td>
</tr>
<tr>
<td>stage</td>
<td>This keyword is followed by a number and the names of the random variables, variables and equations that are assigned to the respective stage. Stage 1 is the default stage for all random variables, variables and equations that are not assigned a stage explicitly except for objective equation and variable. Their default stage is the highest stage in the model.</td>
</tr>
<tr>
<td>stageDefault</td>
<td>This keyword is followed by a number. This specifies the default stage for all random variables, variables and equations that are not assigned a stage explicitly (except for objective equation and variable). If this keyword is not used explicitly, the default is 1.</td>
</tr>
<tr>
<td>var</td>
<td>Synonym to varup.</td>
</tr>
<tr>
<td>varlo</td>
<td>This keyword assigns a variable to have the value (\text{VaR}_\alpha), where (\alpha) is a scalar that represents the percentile of the Value at Risk. Note that varlo refers to the left tail of the distribution. For more details and examples, see section Value at Risk (VaR).</td>
</tr>
<tr>
<td>varup</td>
<td>This keyword assigns a variable to have the value (\text{VaR}_\alpha), where (\alpha) is a scalar that represents the percentile of the Value at Risk. Note that varup refers to the right tail of the distribution and (\alpha) typically equals 0.95 or 0.9. For further information, see section Value at Risk (VaR).</td>
</tr>
</tbody>
</table>

Currently, three GAMS solvers can be used to solve stochastic programming models with EMP: DE, DECIS, and LINDO. Not all keywords mentioned above are supported by all those solvers. The following table specifies which keywords can be used with which solvers. The keywords not mentioned in the table are supported by all solvers mentioned.

<table>

4.52 Accessing Model Libraries

Table 8: Solver capabilities

Note

In general, JAMS is the default solver for models of type EMP. However, since JAMS cannot handle stochastic EMP models, GAMS switches the solver to DE automatically when a stochastic EMP model is tried to be solved with JAMS.

Further information about these solvers can be found in the corresponding solver manuals. The stochastic programming options for the solver LINDO might be of particular interest.

4.52 Accessing Model Libraries

Professor Paul Samuelson is fond of saying that he hopes each generation of economists will be able to "stand on the shoulders" of the previous generation. The library of models included with the GAMS system is a reflection of this desire. We believe that the quality of modeling will be greatly improved and the productivity of modelers enhanced if each generation can stand on the shoulders of the previous generation by beginning with the previous models and enhancing and improving them. The Model Libraries includes a large number of models, collectively organized as:

- **GAMS Model Library** - includes GAMS models representing interesting and sometimes classic problems, ranged from production and shipment by firms, investment planning, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and many more.

- **GAMS Test Library** - includes GAMS models developed for testing and quality control, both for the GAMS base module and the many solvers distributed with the GAMS system.

- **GAMS Data Utilities Library** - includes GAMS models demonstrating various utilities to interface GAMS with other tools and applications such as spreadsheets and database interface.

- **GAMS EMP Library** - includes GAMS Extended Mathematical Programming (EMP) models that illustrate and test the capabilities of GAMS/EMP.

- **GAMS API Library** - includes GAMS Models used as scripts to compile and execute application programs in various programming languages interfacing to GAMS.

- **NOA Library** - includes GAMS nonlinear optimization applications models based on the book *Nonlinear Optimization Applications Using the GAMS Technology* by Neculai Andrei.

- **PSOPT Library** - includes GAMS optimization models based on the book *Power System Optimization Modelling in GAMS* by Alireza Soroudi.

The models included have been selected not only because they collectively provide strong shoulders for new users to stand on, but also because they represent interesting and sometimes classic problems. For example the trade-off between consumption and investment is richly illustrated in the Ramsey problem, which can be solved using nonlinear programming methods. Examples of other problems included in the library are production and shipment by firms, investment planning in time and space, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and relational databases.
Another criterion for including models in the library is that they illustrate the modeling capabilities GAMS offers. For example, the mathematical specification of cropping patterns can be represented handily in GAMS. Another example of the system's capability is the style for specifying initial solutions as staring points in the search for the optimal solution of dynamic nonlinear optimization problems.

Finally, some models have been selected for inclusion because they have been used in other modeling systems. Examples are network problems and production planning models. These models permit the user to compare how problems are set up and solved in different modeling systems.

Most of the models have been contributed by GAMS users. The submission of new models is encouraged. If you would like to see your model in a future release of the library, please send the model and associated documents and reports to GAMS Development Corporation.

4.52.1 Usage

4.52.1.1 Command Line Approach

One way to access the library is through command line. The following commands copy a model from the library directory into the current directory.

<table>
<thead>
<tr>
<th>Command</th>
<th>Library to access</th>
</tr>
</thead>
<tbody>
<tr>
<td>gamslib</td>
<td>GAMS Model Library</td>
</tr>
<tr>
<td>testlib</td>
<td>GAMS Test Library</td>
</tr>
<tr>
<td>datalib</td>
<td>GAMS Data Library</td>
</tr>
<tr>
<td>emplib</td>
<td>GAMS EMP Library</td>
</tr>
<tr>
<td>apilib</td>
<td>GAMS API Library</td>
</tr>
<tr>
<td>finlib</td>
<td>FIN Library</td>
</tr>
<tr>
<td>noalib</td>
<td>NOA Library</td>
</tr>
<tr>
<td>psoptlib</td>
<td>PSOPT Library</td>
</tr>
</tbody>
</table>

Take the command gamslib for an example, if you enter gamslib without any parameters, the command syntax will be displayed as shown below:

> gamslib modelname [target]

or

> gamslib modelnum [target]

where

- modelname is the modelname
- modelnum is the model sequence number, and
- target is the target file name.

If the target file name is not provided, the default is modelname.gms. The file will be automatically copied into the current working directory. For example, the [TRNSPORT] model from the GAMS Model library has sequence number 1 and could be copied in any of the following ways.

To copy [TRNSPORT] model file to target file trnsport.gms under the current directory:
4.53 Mathematical Programming System for General Equilibrium analysis (MPSGE)

> gamslib trnsport

> gamslib 1

To copy [TRNSPORT] model file to target file myname.gms under the current directory:

> gamslib trnsport myname

> gamslib 1 myname

The other commands have similar usage to gamslib command.

4.52.1.2 IDE Approach

A convenient way to access the model library on the major platforms is the "Model Library Explorer" from GAMS Studio. It is described in detail in the GAMS Studio documentation.

Users may define their own library by using a GLB file. These libraries can also be accessed through Studio.

4.53 Mathematical Programming System for General Equilibrium analysis (MPSGE)

- Introduction to MPSGE
- MPSGE Models in GAMS
- Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE
- Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae
- A Library of Small Examples for Self-Study
- Linking Implan Social Accounts to MPSGE
- The MPSGE guide is also available as PDF.
4.53.1 Introduction to MPSGE

MPSGE is a language used for formulating and solving Arrow–Debreu economic equilibrium models and exists as a subsystem within GAMS. The name stands for ‘mathematical programming system for general equilibrium’. MPSGE provides a short-hand non-algebraic representation for the systems of nonlinear inequalities which underly general equilibrium models. The MPSGE framework is based on nested constant elasticity of substitution utility and production functions. The data requirements for a model include share and elasticity parameters, endowments, and tax rates for all the consumers and production sectors in the model. These may or may not be calibrated from a consistent benchmark equilibrium dataset.

The main benefit of using MPSGE is that modelers are released from having to write the equations of the model and the calibrated demand and supply functions. Experience shows that even computing the parameters of the functions is error-prone. The tabular input format of MPSGE facilitates a compact, non-algebraic representation of the equations of a model. Thus algebraic tedium and the scope for programming errors are reduced, and more attention can be paid to economic interpretation and testing of alternative formulations.

This chapter offers an introduction to MPSGE for users who are familiar with GAMS. For more information on MPSGE and details on more advanced features, see [156] and [130]. In addition, a library of small examples for self-study is available here.

This chapter is organized as follows. We start with an overview of some basic economic ideas and general remarks on specifying an MPSGE model. Next, we introduce a first simple example. Then we demonstrate how intermediate demand and joint production are modeled with MPSGE. We follow with a third model that features a small open economy and also includes taxes on inputs and outputs, labor-leisure choice, classical unemployment, and nested demand functions. We conclude the chapter with an overview of MPSGE keywords and the syntax for specifying functions, some other features like domain restrictions on variable declarations, and a few brief comments on MPSGE-specific output in the GAMS listing file. Note that a full version of all MPSGE models that are discussed, including standard GAMS versions, are given in the Appendix.

4.53.1.1 Some Basic Economic Ideas

MPSGE models are based on the following economic ideas. In each model there are multiple interacting agents, where each agent solves an optimization problem. For example, consumers maximize utility subject to their budget constraint, and producers minimize their cost given available technology. Agent interactions are mediated by markets and prices and the optimal solution is an equilibrium where prices and activity levels have adjusted so that markets for produced goods and input factors clear. In equilibrium, each agent cannot do better by altering their behavior (given the constraints they face). In this section we give more details on these basic economic ideas. In particular, we offer brief introductions to consumer demand theory, producer supply theory and general economic equilibrium.

4.53.1.1.1 Consumer Demand Theory

Consumer choice is modeled using an optimization paradigm: consumers form a consumption bundle which maximizes welfare subject to a budget constraint. As an abstract notion, this seems plausible, but certain details must be dealt with to provide an operational application of the idea.

Consider the following example. Thomas lives in Ann Arbor where he spends 30% on housing and the rest of his income on other goods. This information is essentially an observation of a benchmark equilibrium, consisting of the prevailing prices and quantities of goods demanded. Now, Thomas has an employment offer in Berlin which pays 50% more than he currently earns, but he is hesitant to take the job since rental rates in Berlin are three times higher than in Ann Arbor. The question is: On purely economic grounds, should he move?
Thomas’ choices are illustrated below. Point $a$ represents the benchmark point, where he spends the amount $H_a$ on housing in Ann Arbor. Point $b$ represents a potential trade-off between housing and other goods in Berlin, where he spends a lower percentage of his income on housing and more on other goods.

![Figure 4.4 Thomas’ Choices](image)

Whether Thomas derives the same welfare from the choices represented by point $b$ like those represented by point $a$ depends on the elasticity of substitution. The elasticity of substitution is the willingness to exchange some amount of one good for more of the other good. The three curves in the figure above represent three elasticities of substitution. Note that the less convex (flatter) the curve is, the higher is the elasticity, i.e. the more willing is Thomas to substitute housing for other goods.

If the elasticity of substitution equals $\sigma^*$, Thomas is indifferent between choices $a$ and $b$, since both points lie on the respective indifference curve. However, if the elasticity of substitution is lower, say equals $\sigma_L$, or higher, say it equals $\sigma_H$, then $b$ will be worse than $a$ and Thomas will not choose it. Hence, the elasticity of substitution is crucial in determining whether Thomas should move on economic grounds.

The utility function can be deduced if prices and the associated choices are observed and the elasticity of substitution is given. Thus, in MPSGE, a utility function is represented by benchmark (or observed) quantities, benchmark prices and the associated elasticity of substitution. Benchmark quantities determine an anchor point for the set of indifference curves. Benchmark prices fix the slope of the indifference curve at that point. The elasticity of substitution is a measure of the curvature of the indifference curve and specifies the utility function unambiguously.

### 4.53.1.1.2 Producer Supply Theory

While consumers aim to maximize their utility subject to a budget, producers aim to reduce their cost of production given available technology. The activity of a firm is modeled as a production function that maps inputs into outputs. Inputs are primary factors like labor, capital, land, raw materials etc. and outputs are goods and services. Similarly to utility functions, in MPSGE, a production function is represented by reference quantities of reference prices of inputs and outputs, elasticities of substitution and elasticities of transformation.

Summarizing, the main principle for both, consumers and producers, is choice. Consumers choose quantities of goods given their preferences, prices and budgets. Producers choose quantities of primary factors and output levels given available technology. Available technology is modeled via elasticities of substitution between inputs and elasticities of transformation between outputs.
4.53.1.1.3 General Economic Equilibrium  As mentioned above, MPSGE is a system for modeling general economic equilibria. General economic equilibrium analysis studies the working of an economic system as a whole. The basic assumption is that there are two types of agents in the economy: producers and consumers. Producers are assumed to operate with constant return to scale and to be perfectly competitive price-taking firms. Further, they are assumed to select factor inputs and output levels in order to maximize their profits given available technology. Consumers are assumed to maximize their welfare subject to budget constraints (incomes and endowments). An economy is in economic equilibrium if all consumers spend their given incomes such that they gain maximum satisfaction, all firms in each sector minimize their costs given available technology, and prices (for primary factors and commodities) and activity levels have adjusted such that all agents cannot do better by altering their behavior given the constraints they face. In equilibrium, all markets have cleared: in both, goods and factors markets, total demand equals total supply.

Mathematically, such an economy is modeled as a system of weak inequalities, where each inequality is associated with a non-negative variable denoting a price or a quantity. If a particular weak inequality holds as an equation, then the associated variable is strictly positive. If it holds as a strict inequality, then the associated variable equals zero. This is a mixed complementarity problem that can be formulated and solved with standard GAMS syntax. For details see section Mixed Complementarity Problems (MCPs). As we will demonstrate, MPSGE models can be translated to standard GAMS MCP models. However, the framework that MPSGE offers is much more user-friendly, since modelers do not have to input the complex equations manually.

4.53.1.2 Specifying an MPSGE Model

In this section we give an overview of the MPSGE model specification, a simple introductory example follows in the next section. Like any standard GAMS program, a program with an embedded MPSGE model begins with set and parameter definitions that will later be used in the model. The MPSGE model is specified within an $ontext / $offtext block.

First, the name of the model must be defined:

\$MODEL:mymodel

Here $MODEL is an MPSGE keyword and the model name mymodel is a GAMS identifier.

In a GAMS program lines within $on/offtext are are treated as a block comment. However, if the preprocessor encounters the MPSGE model definition statement, it will recognize that an MPSGE model specification follows and will process the code accordingly.

Note

Like GAMS, MPSGE is not case sensitive.

Secondly, the variables for an MPSGE model are declared. In every model, there are three classes central variables:

- $SECTORS: variables for activity levels associated with constant returns to scale production sectors in the economy, which are non-negative,
- $COMMODITIES: variables for commodity prices including all final goods, intermediate goods and primary factors of production, which are also non-negative, and
- $CONSUMERS: variables for income levels, one for each “household” in the model, including any government entities.

In addition, models may include auxiliary variables ($AUXILIARY) that are used to introduce endogenous tax instruments or endogenous endowment quantities to a model.
Note

Unlike GAMS models, variables in an MPSGE model must be declared over an explicit domain. Only variables that have been declared as one of the four MPSGE variable types may be used in the MPSGE model. Error messages are generated for variables which are declared but not referenced.

Thirdly, the parameters for functions are specified in a structured manner. The general syntax for all possible entries is given in section Syntax for Production and Demand Functions below. The MPSGE framework uses these specifications to automatically generate the respective market-clearing and income-balance equations. There are two types of functions:

- **$PROD**: This block defines a production function, specifying inputs, outputs and elasticities of substitution and transformation. A production function must be given for each sector in the model. Note that most of the power and subtleties of the MPSGE framework center on the $PROD tables.

- **$DEMAND**: This block defines a demand function. This function represents preferences (using reference demands), initial factor endowments and elasticities of substitution. A demand function must be specified for each consumer in the model.

Finally, any auxiliary variable has an associated equilibrium condition that is defined by the user with conventional GAMS algebraic syntax and placed in a block called $CONSTR.

These four parts - model definition, variable declarations, function specifications and possibly side constraints for auxiliary variables - are the core of the MPSGE model specification. The model specification is followed by the dollar control option $offtext and the following compiler directive:

```
$sysinclude mpsgeset mymodel
```

This compiler directive instructs MPSGE to compile the functions and generates an external file called MYMODEL.GEN. This external file is then loaded to the GAMS file with the following directive:

```
$include MYMODEL.GEN
```

Finally, a standard GAMS solve statement follows and the model will be handed for solution to one of the MCP solvers:

```
solve mymodel using mcp;
```

Observe that the appropriate GAMS model type is MCP.

Most often the model is first evaluated at the benchmark point to test whether it is properly calibrated and everything works as expected. This is achieved by setting the option iterlim to zero. Then one or more counterfactuals are solved: first some parameter is modified using standard GAMS syntax, then the $include statement is repeated and the model is solved again.
4.53.1.3 An Introductory Example: Two Goods and Two Factors in a Closed Economy

In the canonical 2x2 model, two final goods, X and Y, are produced with two primary factors, labor L and capital K, and there is a single representative agent (consumer) RA. The model is defined by technology, preferences and endowments. We can describe preferences by a utility function which provides an ordinal ranking of consumption levels for X and Y. We assume that both factors are in fixed supply, thus in equilibrium, factor endowments equal factor demands, and the supply of the two goods equal their demand.

The problem can be cast as consisting of three production activities, X, Y and U, and five markets X, Y, U, K and L. The initial data for the model are given by the following matrix.

<table>
<thead>
<tr>
<th>Production Sectors</th>
<th>Consumers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Markets</td>
<td>X</td>
</tr>
<tr>
<td>---------------------</td>
<td>----</td>
</tr>
<tr>
<td>PX</td>
<td>100</td>
</tr>
<tr>
<td>PY</td>
<td>50</td>
</tr>
<tr>
<td>PU</td>
<td>150</td>
</tr>
<tr>
<td>PK</td>
<td>-50</td>
</tr>
<tr>
<td>PL</td>
<td>-50</td>
</tr>
<tr>
<td>Column Sums</td>
<td>0</td>
</tr>
</tbody>
</table>

The data describes a representative equilibrium. Rows correspond to markets, where PX, PY, PU, PK and PL are the prices for the commodity X, the commodity Y, the utility U, and capital and labor respectively. Positive entries denote the value of commodity flows into the economy (sales or factor supplies) and negative entries represent the value of commodity flows out of the economy (factor demands and good demands). Observe that the sum of a row will equal zero if the market clears, i.e. the total amount of commodity that flows into the economy equals the total amount of this commodity that flows out of the economy. The matrix is called balanced if all rows and columns sum to zero.

Note that the layout of the matrix ensures that a complete list of the transactions associated with an activity is given in each production column. The sum of a production sector column is zero if the value of the outputs equals the costs of the inputs. A consumer column is balanced if the sum of primary factor sales equals the value of final demands. Hence columns that sum to zero indicate zero profits. This type of matrix is related to the concept of a social accounting matrix (or short: SAM).

The problem can be modeled with GAMS MPSGE as follows:

```plaintext
Parameter endow index of labour endowment / 1.0 /;

$ontext
$MODEL:twobytwo

$SECTORS:
  X  ! Activity level for sector X -- benchmark=1
  Y  ! Activity level for sector Y -- benchmark=1
  U  ! Activity level for sector U -- benchmark=1

$COMMODITIES:
  PX  ! Relative price index for commodity X -- benchmark=1
  PY  ! Relative price index for commodity Y -- benchmark=1
  PU  ! Relative price index for commodity U -- benchmark=1
```
PL ! Relative price index for labor -- benchmark=1
PK ! Relative price index for capital -- benchmark=1

$CONSUMERS:
   RA ! Income level for representative agent -- benchmark=150;

$PROD:X s:1
   0:PX Q:100
   I:PL Q:50 ! Variable LX in the algebraic model
   I:PK Q:50 ! Variable KX in the algebraic model

$PROD:Y s:1
   0:PY Q:50
   I:PL Q:20 ! Variable LY in the algebraic model
   I:PK Q:30 ! Variable KY in the algebraic model

$PROD:U s:1
   0:PU Q:150
   I:PX Q:100 ! Variable DX in the algebraic model
   I:PY Q:50 ! Variable DY in the algebraic model

$DEMAND:RA
   D:PU
   E:PL Q: (70*endow)
   E:PK Q: 80

* Compiler directive instructing MPSGE to compile the functions
$sysinclude mpsgeset twobytwo

* Benchmark replication
twobytwo.iterlim = 0;
include TWOBYTWO.GEN
solve twobytwo using mcp;
abort$(abs(twobytwo.objval) gt 1e-7) "*** twobytwo does not calibrate ! ***";
twobytwo.iterlim = 1000;

* Counterfactual : 10% increase in labor endowment
endow = 1.1;

* Solve the model with the default normalization of prices which
* fixes the income level of the representative agent. The RA
* income level at the initial prices equals 80 + 1.1*70 = 157.
include TWOBYTWO.GEN
solve twobytwo using mcp;

Note that an algebraic version of this model using standard GAMS syntax is given in the Appendix.

After the model statement where the model is named, variables are declared in each of the three central
variable classes. Unlike conventional GAMS syntax, in MPSGE, trailing comments in variable declarations
(starting with the symbol !) are interpreted as variable descriptors that will appear in the listing file.

Then three production blocks $PROD - one for each sector - follow. Output parameters are specified in
the line starting with the label O and input parameters are given in the line starting with the label I,
the respective quantities are listed in the field $Q$. Note that the first input in the production block for sector $X$ represents labor demand in sector $X$ and the second input represents capital demand in sector $X$. Similarly, the inputs in the production block for sector $Y$ represent labor and capital demand for sector $Y$. In the production block for sector $U$, the inputs represent demand for $X$ and $Y$ in sector $U$. In the field $s$: next to the name of the sector the elasticity of substitution between the inputs is specified.

A demand block $\$DEMAND$ for the consumer $RA$ completes the model specification. Demand parameters are specified in the line starting with the label $D$ and endowment parameters are given in the line starting with the label $E$. Note that all possible entries for production and demand blocks are discussed in section Syntax for Production and Demand Functions. Observe that there is no algebraic formulation of equations, only parameter specifications. Given this input, the MPSGE framework generates the respective equations automatically.

Note that it is not necessary to fix a numeraire. If a numeraire is not specified, the normalization of prices is arbitrary. For example, in the model above, $RA$ is used as a numeraire and the following remark appears in the listing file:

Default price normalization using income for $RA$

Note that the version of this model in the Appendix includes two additional counterfactual scenarios, where first sector $X$ is used as numeraire commodity and then the wage rate $PL$ is fixed as numeraire. In the Appendix, there are also two alternative versions of the model above: a model in standard GAMS syntax where the equations that are automatically generated by the MPSGE framework are given explicitly, and an MPSGE model that uses vector notation instead of scalars.

4.53.1.4 Modeling Intermediate Demand and Joint Production

In this section we extend the two by two model above in the following three ways:

1. We distinguish between production sectors and produced goods.
2. Each sector produces both goods, so we have joint production.
3. In addition to primary factors like labor and capital, goods enter the production process as inputs. Thus we have intermediate demand.

The full MPSGE model and MCP and NLP versions of the model are given in the Appendix. Here we reproduce and discuss only selected code snippets. The main difference to the simple model above is the specification of the production block:

$\$PROD:X(j) s:1 t:1
0:P(i) Q:make0(i,j) ! S(i,j) in the MCP and NLP models
I:P(i) Q:use0(i,j) ! D(i,j) in the MCP and NLP models
I:PF(f) Q:fd0(f,j) ! FD(f,j) in the MCP and NLP models

Note that the supply is specified in the output line, the intermediate demand is given in the first input line and the factor demand is listed in the second input line. Thus each sector $j$ produces the goods $i$ using the intermediate goods $i$ and the primary factors $f$. Consider the fully spelled-out production block for sector $s1$:

$\$PROD:X("s1") s:1 t:1
0:P("g1") Q:6.0
0:P("g2") Q:2.0
I:P("g1") Q:4.0
I:P("g2") Q:2.0
I:PF("labor") Q:1.0
I:PF("capital") Q:1.0

At benchmark, sector $s1$ produces 6 units of good $g1$ and 2 units of good $g2$. The input for this output is 4 units of the good $g1$, 2 units of the good $g2$ and labor (one unit) and capital (one unit).
Note

*Double* quotes have to be used if a singleton set element is referenced in an MPSGE model. Single quotes are not recognized.

Observe that the technology used to combine these four production factors is based on a Cobb-Douglas production function, i.e. the elasticity of substitution equals 1, as indicated by the value in field $s$. In addition, the curvature of the production possibility frontier (the constant elasticity of transformation function) is given in field $t$.

### 4.53.1.5 Modeling a Small Open Economy

An open economy is one in which goods are traded on international markets, typically at fixed international prices, i.e. there are imports and exports. One class of models for small open economies are known as "123 models" [42]. In the original 123 model, there was one small country, two producing sectors and three goods (one domestic good, one import good and one export good). The 123 model we present and discuss in this section has exogenously given world prices for imports and exports, taxes, labor-leisure choice, classical unemployment and joint production. The programming language keeps track of tax revenue flows, equations which are otherwise tedious to program. The model is a tiny version of the open economy GTAP model [115]. It follows the canonical microeconomic optimization framework: (i) consumers maximize welfare subject to a budget constraint with fixed levels of investment and public expenditure, and (ii) producers combine intermediate inputs and primary factors at least cost for given technology.

Note that the full MPSGE model mge123 and an algebraic version are given in the Appendix. In addition, we introduce and discuss a version of the model that includes nesting. Note further, that the data for the model and its variants are included in a separate GAMS file. Observe that the input-output matrix in the data file provides data on value flows for primary production factors, intermediate goods and final consumption products. In the following, we comment on selected code snippets and thereby discuss the most important features of the model.

Consider the production block for the entire production of the small economy:

```
$PROD: Y  t: etadx s: esubkl
  0: PD Q: d0 P: 1 ! YD
  0: PX Q: x0 P: px0 A: GOVT T: tx ! YX
  I: RK Q: kd0 P: rr0 A: GOVT T: tk ! KD
  I: PL Q: ly0 P: pl0 A: GOVT T: tl N: TAU_TL ! LY
```

Note that the first output line represents production for the domestic market, which is denoted by the variable $YD$ in the algebraic version of the model. The reference price at benchmark is given in the new field $P$.

Note

The default value for both P and Q fields is 1.0

The second output line represents production for the export market (variable $YX$ in the algebraic version). Observe that taxes are specified in the two new fields $A$ and $T$: the tax recipient is specified in field $A$ and the tax rate is listed in field $T$. Note that the tax recipient must reference a $\$CONSUMER$ variable and the tax rate $tx$ (tax rate on exports) is given exogenously.
Attention

In MPSGE, the way exogenous taxes are computed depends on whether they are imposed on outputs or inputs. Taxes on outputs are specified on a gross basis. Hence, if a tax on outputs has proportional rate \( t \), the producer price will be \( p(1 - t) \), where \( p \) is the market price. However, taxes on inputs are specified on a net basis. Hence, if a tax on inputs has ad valorem rate \( t \), the user cost will be \( p(1 + t) \), where \( p \) is the market price.

The first input line represents capital demand (variable \( KD \) in the algebraic version). The model includes investment by the private (domestic) households, thus the variable \( RK \) denotes a rental price index. Observe that capital is taxed exogenously at the capital tax rate \( tk \).

The second input line represents labor demand (variable \( LY \) in the algebraic version). In addition to an exogenous labor tax \( tl \), an endogenous tax is imposed on this input. The endogenous tax rate is determined by the auxiliary variable \( TAU_{TL} \), which is the entry in the field \( N \) at the end of the line. Note that an equation associated with the auxiliary variable is specified in the following block:

\[
\text{CONSTRAINT: TAU_{TL} }
\]
\[
\text{GOVT } = e = PA * g0;
\]

Note

When an auxiliary variable is fixed no constraint is required. When the lower bound of the auxiliary variable is less than the upper bound, a constraint is required.

Note further, that the variable \( TAU_{TL} \) is a wage replacement tax and at benchmark, it is fixed at zero. It is positive in two of the four counterfactual scenarios.

Domestic demand is modeled using the Armington assumption: consumers demand one single good which is an aggregation of composite goods consisting of the goods produced domestically and the imported versions, where imports and domestic goods in the same sector are imperfect substitutes. The aggregated composite good is given by a constant elasticity of substitution aggregation function of the domestic goods and the imported goods with elasticity of substitution \( \text{sigmadm} \). In our model, \( \text{sigmadm} \) equals 4 (domestic versus imported goods). The production of the Armington good is specified in the following block:

\[
\text{PROD: A s: \text{sigmadm}}
\]
\[
\text{Q:a0 A:GOVT t:ta}
\]
\[
\text{Q:d0 I:PD ! DA}
\]
\[
\text{Q:m0 p:pm0 A:GOVT t:tm ! MA}
\]

Note that both inputs are intermediate goods. The first input line represents domestic absorption (variable \( DA \) in the algebraic version of the model) and the second input line represents imports (variable \( MA \) in the algebraic version). Imports are taxed with the import tariff rate \( tm \) and the composite good is taxed with the excise and sales tax rate \( ta \). Both taxes are exogenous.

In addition, the model contains production blocks for imports and exports. Foreign exchange (denoted by the MPSGE variable \( PFX \)) is used in these two production blocks. It is the input in the production block for imports and the output in the production block for exports.

The two consumers in the model are the government (MPSGE variable \( GOVT \)) and aggregated private households (MPSGE variable \( HH \)). The demand block for the government agent is as follows:
Note that the first endowment line represents the balance of payment in the current account (denoted by the $COMMODITIES variable PFX). In our model, exports exceed imports resulting in the deficit bopdef. If imports are larger than exports there will be a surplus. The other two endowment lines represent taxes that are paid by the households: a direct tax dtax and a lumpsum labor replacement tax that is specified as an auxiliary variable and determined by the respective complementarity equation. In this model the labor replacement tax is either a lumpsum tax (TAU_LS) or it is levied on labor at a tax rate of TAU_TL (see above). Note that the direct tax and the lumpsum tax feature in the demand block for HH as negative endowments. Negative endowments represent payments to be made. The demand block for HH follows:

\$DEMAND:HH
s:sigma
E:PA Q:(-g0) R:TAU_LS
E:PA Q:(-dtax)
E:RK Q:kd0
E:PA Q:(-i0)
E:PL Q:(ly0+l0) ! Labor endowment = ly0+10 - UR * (ly0+10)
E:PL Q:(-(ly0+l0)) R:UR
D:PA Q:c0
D:PL Q:l0

Households demand two goods: the Armington composite good PA (first demand line) and leisure (second demand line). Note that the first two endowment lines represent taxes as discussed above. The third and fourth endowment line relate to capital: the third line represents the income generated by capital investment and the fourth line represents capital investments. The last two endowment lines refer to labor. Labor endowment for the aggregated households equals the sum of labor and leisure minus the percentage of unemployment. Note that at benchmark, the unemployment rate UG is fixed at zero, other scenarios are explored in the counterfactuals.

In model mge123, the rate of substitution for domestic and imported goods that constitute the Armington good PA is fixed at sigmadm = 4. Suppose that we want more control over substitution possibilities. For example, we may wish to model a substitution rate in final demand that is different than for other uses of the Armington good. MPSGE facilitates modeling this additional degree of freedom through nesting. Consider the following demand block for HH from model mgenested, a variant of model mge123:

\$DEMAND:HH
s:sigma c:sigmac
E:PA Q:(-g0) R:TAU_LS
E:PA Q:(-dtax)
E:RK Q:kd0
E:PA Q:(-i0)
E:PL Q:(ly0+l0) ! Labor endowment = ly0+10 - UR * (ly0+10)
E:PL Q:(-(ly0+l0)) R:UR
D:PD Q:cd0 c:
D:PM Q:cm0 c:
D:PL Q:l0

Note that in this formulation the endowment lines are unchanged and we have three demand lines. The first two demand lines have an additional field (c:). This tag indicates that these two goods are part of a nest: they are combined to an intermediate good called C. The rate of substitution for the goods in the nest is given in the first line of the demand block: c:sigmac. Observe that except for the substitution
rate, $C$ equals $PA$. The structure of the final demand can be presented graphically using the following nesting diagram:

\[
\begin{array}{c}
\text{U} \\
\Rightarrow \\
\ell \\
\Rightarrow \\
\sigma = \text{SIGMA} = 0.4 \\
\Rightarrow \\
C \\
\Rightarrow \\
\sigma_C = \text{SIGMAC} = 0.5 \\
\Rightarrow \\
\text{D} \\
\rightarrow \\
\text{M} \\
\rightarrow
\end{array}
\]

Figure 4.5 Structure of nested demand for HH

The nested utility function, expressed as a unit function is:

\[
U = \left[ \theta \left( \frac{\ell}{\bar{\ell}} \right)^{1-1/\sigma} + (1-\theta) \left( \alpha \left( \frac{D}{\bar{D}} \right)^{1-1/\sigma_C} + (1-\alpha) \left( \frac{M}{\bar{M}} \right)^{1-1/\sigma_C} \right)^{1-1/\sigma} \right]^{1/(1-1/\sigma)}
\]

in which $\theta$ is the budget share of leisure ($\ell$) in aggregate expenditure, and $\alpha$ is the budget share of domestic goods ($D$) in commodity expenditure, both evaluated at the benchmark point:

\[
\theta = \frac{\bar{\ell}}{\bar{\ell} + \bar{D} + \bar{M}}
\]

and

\[
\alpha = \frac{\bar{D}}{\bar{D} + \bar{M}}
\]

The demand for leisure is a function of extended income ($HH$):

\[
\ell = \bar{\ell} \left( \frac{p_U}{p_{\ell}} \right)^{\sigma} \frac{HH}{p_U(\ell + D + M)}
\]

The demand for domestic and imported goods is a function of both the top-level elasticity of substitution, $\sigma$, as well as the elasticity of substitution between consumption goods, $\sigma_C$:

\[
D = \bar{D} \left( \frac{p_U}{p_D} \right)^{\sigma} \left( \frac{p_C}{p_D} \right)^{\sigma_C} \frac{HH}{p_U(\ell + D + M)}
\]

and

\[
M = \bar{M} \left( \frac{p_U}{p_M} \right)^{\sigma} \left( \frac{p_C}{p_M} \right)^{\sigma_C} \frac{HH}{p_H(\ell + D + M)}
\]

The graph illustrates the two-level nesting structure. Domestic goods and imports are combined in the second-level nest with an elasticity of substitution of $\text{SIGMAC}$. Here we use the identifier $C$. 
Note

The name space of nesting assignments is segmented from that of sets, parameters and variables in the GAMS code. Two set identifiers are predefined: s: and t:. All other identifiers are accepted provided they have four or fewer characters.

The full model mgenested is given in the Appendix. Observe that as the substitution rate of the Armington good in final demand has changed, some parameters are modified at the beginning of the program in order to recalibrate the model.

A tariff reform is similar to a tax reform, it has a major influence on the structure of the budget of a government. Suppose we wish to keep government expenditure constant and experiment with different scenarios that represent different combinations of tax instruments. For example, at benchmark, in our model the unemployment rate UR and the endogenous wage tax TAU_TL are fixed at zero. Four alternative closures are explored in the counterfactuals. They depend on revenue replacement (lumpsum versus wage tax) and labor market (flexible versus fixed wages). An overview of the outcomes are given in the following table:

</tbody>
</table>

Note that the classical unemployment part in this model provides a good way to motivate the usefulness of the modeling framework. We easily produce a model which illustrates the importance of the labor market formulation. When the real wage is downward rigid, replacement of tariffs with wage taxes reduces welfare (denoted by W) by 7.9%, output by 6.6% and employment by 10%. If the wage is flexible, replacement of tariffs by wage taxes leads to a 0.1% decrease in welfare.

4.53.1.6 MPSGE Keywords and Syntax

In the presentation of the general syntax in this section, we use the usual GAMS syntax symbols: [ ] (the enclosed construct is optional), { } (the enclosed construct may be repeated zero or more times) and | (exclusive OR). EOL means "end-of-line" and num_expr denotes a number or GAMS numerical expression that may include a dollar condition for exception handling.
4.53.1.6.1 MPSGE Keywords  MPSGE provides nine keywords that are used to specify an MPSGE model. They are given in Table 1. Note that these keywords are not GAMS reserved words, i.e. they are not keywords in the GAMS code apart from the MPSGE model specification.

<table>
<thead>
<tr>
<th>MPSGE Keyword and Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$MODEL:model_name</td>
<td>This keyword is used to assign the identifier model_name to the model. Model_name must be a valid file name, since it is used to form model_name.GEN. This must be the first statement within the $ontext - $offtext block containing the MPSGE code; all lines in an $ontext - $offtext block before this keyword are treated as comments.</td>
</tr>
<tr>
<td>$SECTORS: sect1 ! Description1 sect2 ! Description2 ...</td>
<td>This keyword is used to declare one or more variables for sectors that are used in the model.</td>
</tr>
<tr>
<td>$COMMODITIES: com1 ! Description1 com2 ! Description2 ...</td>
<td>This keyword is used to declare one or more variables for commodities that are used in the model.</td>
</tr>
<tr>
<td>$CONSUMERS: cons1 ! Description1 cons2 ! Description2 ...</td>
<td>This keyword is used to declare one or more variables for consumers that are used in the model.</td>
</tr>
<tr>
<td>$AUXILIARY: aux1 ! Description1 aux2 ! Description2 ...</td>
<td>This keyword is used to declare one or more auxiliary variables. It is only used in models with side constraints and endogenous taxes or rationed endowments.</td>
</tr>
<tr>
<td>$PROD:sector</td>
<td>This keyword is used to specify a production function. A production function must be specified for each sector in the model. Note that sector must have been previously declared with a $SECTORS statement.</td>
</tr>
<tr>
<td>$DEMAND:consumer</td>
<td>This keyword is used to define a demand function. A demand function must be specified for each consumer in the model. Note that consumer must have been previously declared with a $CONSUMERS statement.</td>
</tr>
<tr>
<td>$CONSTRAINT:auxiliary</td>
<td>This keyword is used to specify a side constraint to be associated with the auxiliary variable auxiliary. Note that auxiliary must have been previously declared with an $AUXILIARY statement.</td>
</tr>
<tr>
<td>$REPORT:</td>
<td>This keyword identifies the set of additional variables to be calculated. These variables are used for reports and include outputs and inputs by sector, and demands and welfare by individual consumers. The variables declared in $REPORT blocks may not be used in model equations. Note that we did not discuss report blocks in this chapter. For details see [130] .</td>
</tr>
</tbody>
</table>

Table 1: MPSGE Keywords

4.53.1.6.2 Syntax for Production and Demand Functions  In addition to the keywords above, MPSGE provides a fixed structure for specifying production and demand functions. This structure has a tabular format with pre-specified fields (or labels). The names of most fields are single letters that are reserved words in MPSGE. The exception are nest identifiers: they are arbitrary names with up to four characters.

The syntax for the definition of a production function is as follows.
4.53 Mathematical Programming System for General Equilibrium analysis (MPSGE) 1271

Each production function block starts with the MPSGE keyword $PROD$ and the respective sector. Note that the variable sector must have been previously defined in the $SECTORS$ block. The labels that follow are optional. They include the following:

- **s**: Top level elasticity of substitution between inputs. The default value is zero.
- **t**: Elasticity of transformation between outputs in production. Can be zero, but not infinity.
- **a:, b:, ...**: Elasticities of substitution in individual input nests. Here a and b are nest identifiers.

Each production block has at least one output line O and one input line I. The value in the fields O and I is a commodity that has been previously declared in the $COMMODITIES$ block. Note that only this first field is mandatory, all other entries are optional and depend on the model. The valid labels for both lines include the following:

- **Q**: Reference quantity. Default value is 1. When specified, it must be the second entry.
- **P**: Reference price. Default value is 1.
- **A**: Tax revenue agent, the entry must be a consumer that has been previously defined in the $CONSUMERS$ block. This field must appear before the corresponding T or N field.
- **T**: Tax rate of the exogenous tax rate. Note that more than one tax rate may be listed in one line.
- **N**: Endogenous tax, the entry is an auxiliary variable that has been previously defined in the $AUXILIARY$ block.
- **M**: Endogenous tax multiplier. The ad valorem tax rate is the product of the value of the endogenous tax and this multiplier. Note that if the M field is omitted in a line with an N field, M:1 will be assumed. Observe that the M field cannot be included in the absence of an N field.
- **a:, b:, ...**: Nesting assignments. Only one such label may appear per line.

The syntax for the specification of a demand function is as follows.

Each demand function block starts with the MPSGE keyword $DEMAND$ and the respective consumer. Note that the variable consumer must have been previously declared in the $CONSUMERS$ block. The labels that follow are optional. They include the following:

- **s**: Top level elasticity of substitution between demands.
- **a:, b:, ...**: Elasticities of substitution in individual demand nests.

Each demand block has at least one demand line D and it may have one or more endowment lines E. The value in the fields D and E is a commodity that has been previously declared in the $COMMODITIES$ block. Note that only this first field is mandatory, all other entries are optional and depend on the model. The valid labels in a D line include the following:
• **Q**: Reference quantity. Default value is 1. When specified, it must be the second entry.

• **P**: Reference price. Default value is 1.

• **a:,b:,..**: Nesting assignments. Only one such label may appear per line.

The valid labels in an **E** line include the following:

• **Q**: Reference quantity. Default value is 1. When specified, it must be the second entry.

• **R**: Rationing instrument, the entry is an auxiliary variable that has been previously defined in the **$\text{AUXILIARY}$$** block.

Auxiliary constraints in MPSGE models conform to standard GAMS equation syntax. They may refer to any of the four classes of variables, **$\text{SECTORS}$$**, **$\text{COMMODITIES}$$**, **$\text{CONSUMERS}$$** and **$\text{AUXILIARY}$$**, but they may not reference variables names declared within a **$\text{REPORT}$$** block. Complementarity conditions apply to upper and lower bounds on auxiliary variables and the associated constraints. For this reason, the orientation of the equation is important. When an auxiliary variable is designated **POSITIVE** (the default), the auxiliary constraint should be expressed as an equation of the type \( \leq \). If an auxiliary variable is designated **FREE**, the associated constraint must be expressed as an equality \( = \).

### 4.53.1.6.3 Domain Restrictions on Variable Declarations

Domain restrictions on variable declarations are a crucial difference between models formulated in GAMS and those formulated in MPSGE. In GAMS, variables are defined over a domain, but the explicit domain used in the model is determined by CMEX at the point when the model is generated. In an MPSGE model, users are required to declare the explicit domain for every variable. If they include variables which are not referenced in the model, they will get a "No source" or "No sink" error message. If a variable is referenced which is not declared, an error message will be generated by the MPSGE function evaluator.

Consider the following example of a sector declaration in MPSGE:

```gams
$\text{SECTORS}:
  Y(i)$y0(i)
  M(i)$m0(i)
...
```

The corresponding production blocks need to have the corresponding exception operators:

```gams
$\text{PROD}:Y(i)$y0(i)
...

$\text{PROD}:M(i)$m0(i)
...
```

For more information on exception handling in GAMS, see chapter Conditional Expressions, Assignments and Equations.
4.53.1.6.4 The Nest Labor Operator and the Spanning Operator

The nest labor operator (.tl) is used to create a set of nests. The following example serves as illustration and is self-explanatory:

```plaintext
$PROD:Y s:0.5 m:0 i.tl(m):esubdm(i) va:1
  O:PY Q:y0
  I:PD(i) Q:d0(i) i.tl:
  I:PM(i) Q:m0(i) i.tl:
  I:PK Q:k0 va:
  I:PL Q:l0 va:
```

The spanning operator (#) is a way to provide multiple inputs of one commodity. For example, a commodity with price PM is a wholesale/retail trade margin. The benchmark value of margins on commodity $i$ is md0($i$), and the net of margin (wholesale) value of commodity $i$ sales is d0($i$). If goods trade off in a Cobb-Douglas nest at the gross of margin price, we can represent this in an MPSGE model as:

```plaintext
$PROD:A s:1 i.tl:0
  O:PA Q:a0
  I:P(i) Q:d0(i) i.tl:
  I:PM#(i) Q:md0(i) i.tl:
```

4.53.1.7 MPSGE-Specific Output

The output in the listing file of an MPSGE model has some distinctive features. Note that the MPSGE model specification is reproduced in the echo print. After the directive $offtext, the echo print is interrupted and a symbol reference map is inserted. In this map, both, the identifiers defined using standard GAMS syntax and MPSGE variables are listed. In addition to the standard GAMS data types, the following MPSGE shorthand symbols may appear in this listing:

<table>
<thead>
<tr>
<th>Shorthand Symbol</th>
<th>MPSGE Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTIV</td>
<td>sector variable</td>
</tr>
<tr>
<td>AUXIL</td>
<td>auxiliary variable</td>
</tr>
<tr>
<td>CONSU</td>
<td>consumer variable</td>
</tr>
<tr>
<td>PRICE</td>
<td>commodity variable</td>
</tr>
</tbody>
</table>

Table 2: Shorthand Symbols for MPSGE Data Types

For example, the symbol reference map for the first simple model in vector notation reads as follows:

Symbol Listing

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Type</th>
<th>References</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONS</td>
<td>PARAM</td>
<td>19 23</td>
</tr>
<tr>
<td>DEMAND</td>
<td>PARAM</td>
<td>20</td>
</tr>
<tr>
<td>ENDOW</td>
<td>PARAM</td>
<td>24</td>
</tr>
<tr>
<td>F</td>
<td>SET</td>
<td>9 16 16 24 24</td>
</tr>
<tr>
<td>FACTOR</td>
<td>PARAM</td>
<td>16</td>
</tr>
<tr>
<td>I</td>
<td>SET</td>
<td>3 14 15 15 16 20 20</td>
</tr>
<tr>
<td>PC</td>
<td>PRICE</td>
<td>8 15 20</td>
</tr>
<tr>
<td>PF</td>
<td>PRICE</td>
<td>9 16 24</td>
</tr>
<tr>
<td>PU</td>
<td>PRICE</td>
<td>7 19 23</td>
</tr>
</tbody>
</table>
Note that if the normalization was done automatically, a comment will appear after the solve summary detailing which variable was used as a numeraire. For example,

Default price normalization using income for RA

Observe that the lower, level, upper and marginal values of the MPSGE variables are given in the solution listing like for any other GAMS variable. For more information on standard GAMS output, see chapter GAMS Output.

\text{display equilibrium;} \\
\end{align*}
\]

4.53.1.8.1.2 Model TWOBYTWO: Algebraic Version in GAMS MCP
$title A two by two general equilibrium model -- scalar GAMS/MCP

parameter endow index of labour endowment / 1.0 /;

* =====================================================
* Variables which appear explicitly in the MPSGE model:
* Nonnegative Variables
  X Activity level for sector X -- benchmark=1
  Y Activity level for sector Y -- benchmark=1
  U Activity level for sector U -- benchmark=1
  PU Relative price index for commodity U -- benchmark=1,
  PX Relative price index for commodity X -- benchmark=1,
  PY Relative price index for commodity Y -- benchmark=1
  PL Relative price index for labor -- benchmark=1
  PK Relative price index for capital -- benchmark=1;

Free Variable
  RA Income level for representative agent -- benchmark=150;

* Assign default prices and activity levels:
X.L = 1; Y.L = 1; U.L = 1; PX.L = 1; PY.L = 1; PK.L = 1; PU.L = 1; RA.L = 150;

* Insert lower bounds to avoid bad function calls:
PX.LO = 0.001; PY.LO = 0.001; PU.LO = 0.001; PL.LO = 0.001; PK.LO = 0.001;

* =====================================================
* Variables that enter the MPSGE model implicitly:
variables
  LX 'compensated labor demand in sector x'
  LY 'compensated labor demand in sector y'
  KX 'compensated capital demand in sector x'
  KY 'compensated capital demand in sector y'
  DX 'compensated demand for x in sector u'
  DY 'compensated demand for y in sector u';

* Equations for the implicit variables:
Equations
  lxdef 'compensated labor demand in sector x'
  lydef 'compensated labor demand in sector y'
  kxdef 'compensated capital demand in sector x'
  kydef 'compensated capital demand in sector y'
  dxdef 'compensated demand for x in sector u'
  dydef 'compensated demand for y in sector u';

lxdef..  LX =e=  50 * (PL**0.5 * PK**0.5)/PL;
lydef..  LY =e=  20 * (PL**0.4 * PK**0.6)/PL;
kxdef..  KX =e=  50 * (PL**0.5 * PK**0.5)/PK;
kydef..  KY =e=  30 * (PL**0.4 * PK**0.6)/PK;
dxdef..  DX =e= 100 * (PX**(2/3) * PY**(1/3))/PX;
dydef..    DY =e= 50 * (PX**(2/3) * PY**(1/3))/PY;

* Initial values:
LX.L = 50; LY.L = 20; KX.L = 50; KY.L = 30; DX.L = 100; DY.L = 50;

* =====================================================

Equations
prf_x  'zero profit for sector x'
prf_y  'zero profit for sector y'
prf_u  'zero profit for sector u (Hicksian welfare index)'
mkt_x  'supply-demand balance for commodity x'
mkt_y  'supply-demand balance for commodity y'
mkt_l  'supply-demand balance for primary factor l'
mkt_k  'supply-demand balance for primary factor k'
mkt_u  'supply-demand balance for aggregate demand'
i_ra   'income definition for consumer (ra)';

* Zero profit:
prf_x..    PL*LX + PK*KX =e= 100 * PX;
prf_y..    PL*LY + PK*KY =E= 50 * PY;
prf_u..    PX*DX + PY*DY =E= 150*PU;

* Market clearance:
mkt_x..    100 * X =e= DX*U;
mkt_y..    50 * Y =e= DY*U;
mkt_u..    150 * U =E= RA / PU;
mkt_l..    70 * endow =e= LX*X + LY*Y;
mkt_k..    80 =e= KX*X + KY*Y;

* Income balance:
i_ra..     RA =e= (70*endow)*PL + 80*PK;

* We declare the model using the mixed complementarity syntax
* in which equation identifiers are associated with variables.

model algebraic / prf_x.X, prf_y.Y, prf_u.U, mkt_x.PX, mkt_y.PY, mkt_l.PL,
                   mkt_k.PK, mkt_u.PU, I_ra.RA,
                   lxdef.LX, lydef.LY, kxdef.KX, kydef.KY, dxdef.DX, dydef.DY /;

* Use sector x as the numeraire commodity
PX.FX = PX.L;

algebraic.iterlim = 0;
solve algebraic using MCP;
algebraic.iterlim = 1000;

* Solve the same counterfactual:
endow = 1.1;
* Fix the income level at the default level, i.e. the income level corresponding to the counterfactual endowment at benchmark price:

\[ RA.FX = 80 + 1.1 \times 70; \]

solve algebraic using MCP;

parameter equilibrium Equilibrium values;

* Save counterfactual values:

\[ \text{equilibrium("X.L","RA=157") = X.L;} \]
\[ \text{equilibrium("Y.L","RA=157") = Y.L;} \]
\[ \text{equilibrium("U.L","RA=157") = U.L;} \]
\[ \text{equilibrium("PX.L","RA=157") = PX.L;} \]
\[ \text{equilibrium("PY.L","RA=157") = PY.L;} \]
\[ \text{equilibrium("PU.L","RA=157") = PU.L;} \]
\[ \text{equilibrium("PL.L","RA=157") = PL.L;} \]
\[ \text{equilibrium("PK.L","RA=157") = PK.L;} \]
\[ \text{equilibrium("RA.L","RA=157") = RA.L;} \]
\[ \text{equilibrium("PX.L/PX.L","RA=157") = PX.L/PX.L;} \]
\[ \text{equilibrium("PY.L/PX.L","RA=157") = PY.L/PX.L;} \]
\[ \text{equilibrium("PU.L/PX.L","RA=157") = PU.L/PX.L;} \]
\[ \text{equilibrium("PL.L/PX.L","RA=157") = PL.L/PX.L;} \]
\[ \text{equilibrium("PK.L/PX.L","RA=157") = PK.L/PX.L;} \]
\[ \text{equilibrium("RA.L/PX.L","RA=157") = RA.L/PX.L;} \]

* Fix a numeraire price index and recalculate:

\[ RA.LO = -\infty; \]
\[ RA.UP = \infty; \]
\[ PX.FX = 1; \]

solve algebraic using mcp;

\[ \text{equilibrium("X.L","PX=1") = X.L;} \]
\[ \text{equilibrium("Y.L","PX=1") = Y.L;} \]
\[ \text{equilibrium("U.L","PX=1") = U.L;} \]

4.53.1.8.3.3 Model MCP123: Algebraic Version in GAMS MCP

This GAMS model is the model mge123 translated verbatim into GAMS/MCP (algebraic) format. This is the way the model will look in the MPSGEv2 framework.

\text{\$title Static 123 Model Ala Devarjan -- GAMS/MCP Format}
$include 123data

* Variables which appear explicitly in the MPSGE model:

Nonnegative Variables

*$SECTORS:
  Y Production
  A Armington composite
  M Imports
  X Exports

*$COMMODITIES:
  PD Domestic price index
  PX Export price index
  PM Import price index
  PA Armington price index
  PL Wage rate index
  RK Rental price index
  PFX Foreign exchange

*$CONSUMERS:
  HH Private households
  GOVT Government

*$AUXILIARY:
  TAU_TL Wage replacement tax,
  TAU_LS Lump sum replacement tax
  UR Unemployment rate;

* Assign default prices and activity levels:

  Y.L = 1; A.L = 1; M.L = 1; X.L = 1;
  PD.L = 1; PX.L = 1; PM.L = 1; PA.L = 1; PL.L = 1; RK.L = 1; PFX.L = 1;
  HH.L = c0+l0; GOVT.L=g0;
  TAU_TL.L = 0; TAU_LS.L = 0; UR.L = 0;

* Insert lower bounds to avoid bad function calls:

  PD.LO = 1e-4; PX.LO = 1e-4; PM.LO = 1e-4; PA.LO = 1e-4; PL.LO = 1e-4; RK.LO = 1e-4; PFX.LO = 1e-4;

* Variables enter the MPSGE model implicitly:

Variable
  YD Production for the domestic market,
  YX Production for the export market,
  KD Capital demand,
  LY Labor demand,
  DA Domestic absorption,
  MA Imports,
  C Consumption of goods (uncompensated),
  LD Leisure demand (uncompensated);

* Equations for the implicit variables:
Equations YDdef, YXdef, KDdef, LYdef, DAdef, MAdef, Cdef, LDdef;

* Macros defining composite prices (unit cost and unit revenue):

Parameter thetal Labor share in cost function, 
thetac Consumption share in expenditure function, 
thetam Share parameter in Armington function 
thetaz Share parameter in transformation function ; 

thetal = ly0*pl0 /(kd0*rr0+ly0*pl0); 
thetaz = x0 *px0 /((d0+x0*px0); 
thetam = m0 *pm0 /((d0+m0*pm0); 
thetac = c0/(c0+10);

$macro CY ((PL*(1+tl+TAU_TL)/pl0)**thetal * (RK*(1+tk)/rr0)**(1-thetal))$macro RY ((thetaz * (PX*(1-tx)/px0)**(1+etadx) + (1-thetaz) * PD**(1+etadx))**(1/(1+etadx)))$macro CA ((thetam *(PM*(1+tm)/pm0)**(1-sigmadm) + (1-thetam)*PD**(1-sigmadm))**(1/(1-sigmadm)))$macro CU ((thetac*PA**(1-sigma) + (1-thetac)*PL**(1-sigma))**(1/(1-sigma)))$macro W (HH.L/((c0+l0)*CU))

* Definitions of demand and supply functions:

YDdef.. YD =e= d0 * (PD/RY)**etadx; 
YXdef.. YX =e= x0 * (PX*(1-tx)/px0*RY)**etadx; 
KDdef.. KD =e= kd0 * (CY*rr0/(RK*(1+tk)))**esubkl; 
LYdef.. LY =e= ly0 * (CY*pl0/(PL*(1+tl+TAU_TL)))**esubkl; 

DAdef.. DA =e= d0 * (CA/PD)**sigmadm; 
MAdef.. MA =e= m0 * (CA*pm0/(PM*(1+tm)))**sigmadm; 

Cdef.. C =e= c0 * W * (CU/PA)**sigma; 
LDdef.. LD =e= 10 * W * (CU/PL)**sigma; 

* Initialize: 

YD.L = d0; YX.L = x0; KD.L = kd0; LY.L = ly0; DA.L = d0; MA.L = m0; 
C.L = c0; LD.L = 10; 

* ============================================================== 

Equations 

* Zero profit condition 

profitd domestic production, 
profita Armington supply, 
profitm imported goods production 
profitx exported goods production 

* Market clearing condition 

marktd domestic goods market, 
marketa Armington goods market 
marktm imported goods market 
marktx exported goods market 
marktfx balance of payment 
marketk capital market 
marketl labor market
* Income balance
  incomeg budget
  incomeh household budget

* Additional constraints
  tauTLdef Equal yield constraint (TL),

$title Static 123 Model Ala Devarjan

$include 123data.gms

parameter
cd0 Final demand for domestic goods
   cm0 Final demand for imports
   sigmac Armington elasticity in final demand /0.5/;

* In this version of the model, we apply the tariff on imports
* in the M block, so we then can measure imports as value gross
* of tariff:
m0 = pm0*m0;

* Store the benchmark tax revenue in the tax rate parameter:
ta = a0 * ta;

* Impute final demand for domestic and imported goods:
cd0 = c0 * d0/(d0+m0);
cm0 = c0 * m0/(d0+m0);

* Armington supply net final demand:
a0 = d0+m0-cd0-cm0+ta;

* Recalibrate taxes on A so that tax revenue remains unchanged:
ta = ta/a0;

4.53.2 MPSGE Models in GAMS

MPSGE is a mathematical programming system for general equilibrium analysis which operates as a subsystem within GAMS. MPSGE is essentially a library of function and Jacobian evaluation routines which facilitates the formulation and analysis of AGE models. MPSGE simplifies the modeling process and makes AGE modeling accessible to any economist who is interested in the application of these models. In addition to solving specific modeling problems, the system serves a didactic role as a structured framework in which to think about general equilibrium systems.

MPSGE requires the GAMS/BASE Module including the MILES MCP solver. Optionally it can use the PATH MCP solver.

4.53.2.1 Introduction

This paper introduces a programming language for economic equilibrium modeling. The paper presents the motivation for the system, the programming syntax, and three small scale examples. A library of larger models are provided with the program. The purpose of the paper is to provide a concise introduction to the modeling environment.

MPSGE is a modeling language specially designed for solving Arrow-Debreu economic equilibrium models. (See Rutherford (1987, 1989).) The name stands for "mathematical programming system for general equilibrium". The idea of the MPSGE program is to provide a transparent and relatively painless way to write down and analyze complicated systems of nonlinear inequalities. The language is based on nested constant elasticity of substitution utility functions and production functions. The data requirements for a model include share and elasticity parameters for all the consumers and production sectors included in the model. These may or may not be calibrated from a consistent benchmark equilibrium dataset.

GAMS, the "Generalized Algebraic Modeling System", is a modeling language which was originally developed for linear, nonlinear and integer programming. This language was developed over 15 years ago by Alex Meeraus when he was working at the World Bank. (See Brooke, Kendrick and Meeraus (1988).) Since that time, GAMS has been widely applied for large-scale economic and operations research modeling projects.

MPSGE and GAMS embody different philosophies in their designs. MPSGE is appropriate for a specific class of nonlinear equations, while GAMS is capable of representing any system of algebraic equations. While GAMS is applicable in several disciplines, MPSGE is only applicable in the analysis of economic models within a particular domain. The expert knowledge embodied in MPSGE is of particular use to
economists who are interested in the insights provided by formal models but who are unable to devote many hours to programming. *MPSGE* provides a structured framework for novice modellers. When used by experts, *MPSGE* reduces the setup cost of producing an operational model and the cost of testing alternative specifications.

Prior to the connection with *GAMS*, the "achilles heel" of *MPSGE* had been the process by which input data was translated into the tabular format of the *MPSGE* input file. For small models, this translation was not difficult. Given a calibrated "benchmark equilibrium dataset", a couple of hours with a word processor is usually enough time to generate and investigate a moderately large model. If, however, a model involves several classes of sectors and agents, a wide range of tax instruments and large tables of input data, the word-processor approach is impossible. When there are many numbers, there are many opportunities for oversights and typographical errors.

In contrast, the *GAMS* modeling language is designed for managing large datasets. The use of sets and detached-coefficient matrix notation makes the *GAMS* environment very nice for both developing balanced benchmark datasets and for writing solution reports. For large complicated models, a shortcoming of the *GAMS* modeling environment lies in the specification of the nonlinear equations. Economic equilibrium models, particularly those based on complicated functions such as nested CES, are easier to understand at an abstract level than they are to specify in detail, and the translation of a model from input data into algebraic relations can be a tedious and error-prone undertaking.

The interface between *GAMS* and *MPSGE* combines the strengths of both programs. The system uses *GAMS* as the "front end" and "back end" to *MPSGE* facilitating data handling and report writing. The language employs an extended *MPSGE* syntax based on *GAMS* sets, so that model specification is very concise. In addition, the system includes two large-scale solvers, MILES (Rutherford (1993)) and PATH (Ferris and Dirkse (1993)), which may be used interchangeably. The availability of two algorithms greatly enhances robustness and reliability.

The remainder of this paper is organized as follows. Section 2 introduces *MPSGE* input syntax and the *GAMS* interface using a small two-sector model of taxation. Section 3 extends the 2x2 model to illustrate how the software is used to perform equal-yield (differential) tax policy analysis and to analyze tax reform in a model with endogenous taxation. Section 4 provides a brief summary and conclusion. The paper introduces language features largely through example. Details on language syntax and program structure are provided in two appendices. Appendix A provides a complete statement of *MPSGE* syntax and a summary of differences with the original (1989) language. Appendix B provides an overview of the modeling environment and the structure of *GAMS* input files which employ *MPSGE*.

Before proceeding, both to placate impatient readers and to provide some hands-on experience for novices, I recommend that readers install the *GAMS* system, then retrieve and process the library file THREEMGE which contains three *MPSGE* models (*HARBERGER*, *SHOVEN* and *SAMUELSON*). Two commands to retrieve and run these models:

```
gamslib threemge
```
```
gams threemge
```

After having processed this file, print the listing files (*THREEMGE.LST*) for reference.

### 4.53.2.2 A Mathematical Introduction

Mathiesen (1985) demonstrated that an Arrow-Debreu general economic equilibrium model could be formulated and efficiently solved as a complementarity problem. Mathiesen's formulation may be posed in terms of three sets of "central variables":

---
\( p = \) a non-negative \( n \)-vector of commodity prices including all final goods, intermediate goods and primary factors of production;

\( y = \) a non-negative \( m \)-vector of activity levels for constant returns to scale production sectors in the economy; and

\( M = \) an \( h \)-vector of income levels, one for each "household" in the model, including any government entities.

An equilibrium in these variables satisfies a system of three classes of nonlinear inequalities.

**Zero Profit**

The first class of constraint requires that in equilibrium no producer earns an "excess" profit, i.e. the value of inputs per unit activity must be equal to or greater than the value of outputs. This can be written in compact form as:

\[
- \prod_j(p) = C_j(p) - R_j(p) \geq 0 \quad \forall j
\]

where \( \prod_j(p) \) is the unit profit function, the difference between unit revenue and unit cost, defined as:

\[
C_j(p) = \min \{ \sum_i p_i x_i | f_j(x) = 1 \}
\]

and

\[
R_j(p) = \max \{ \sum_i p_i y_i | g_j(y) = 1 \}
\]

where \( f \) and \( g \) are the associated production functions characterizing feasible input and output. For example, if we have:

\[
f(x) = \phi \prod_i x_i^{\alpha_i} \quad \sum_i \alpha_i = 1, \quad \alpha_i \geq 0
\]

and

\[
g(y) = \psi \max_i \frac{y_i}{\beta_i} \quad \beta_i \geq 0
\]

then the dual functions will be:

\[
C(p) = \frac{1}{\phi} \prod_i \left( \frac{p_i}{\alpha_i} \right)^{\alpha_i}
\]

and

\[
R(p) = \sum_i \beta_i p_i
\]

**Market Clearance**

The second class of equilibrium conditions is that at equilibrium prices and activity levels, the supply of any commodity must balance or exceed excess demand by consumers. We can express these conditions as:

\[
\sum_j y_i \frac{\delta \prod_j(p)}{\delta p_i} + \sum_k \omega_{ik} \geq \sum_k d_{ik}(p, M_k)
\]
in which the first sum, by Shepard’s lemma, represents the net supply of good \( i \) by the constant-returns to scale production sectors, the second sum represents the aggregate initial endowment of good \( i \) by households, and the sum on the right-hand-side represents aggregate final demand for good \( i \) by households, given market prices \( p \) and household income levels \( M \). Final demand are derived from budget-constrained utility maximization:

\[
d_{ih}(p, M_h) = \arg\max \{ U_h(x) \mid \sum_i p_i x_i = M_h \}
\]

in which \( U_h \) is the utility function for household \( h \).

**Income Balance**

The third condition is that at an equilibrium, the value of each agent’s income must equal the value of factor endowments:

\[
M_h = \sum_i p_i \omega_{ih}
\]

We always work with utility functions which exhibit non-satiation, so Walras’ law will always hold:

\[
\sum_i p_i d_{ih} = M_h = \sum_i p_i \omega_{ih}
\]

Aggregating market clearance conditions using equilibrium prices and the zero profit conditions using equilibrium activity levels, it then follows that:

\[
\sum_j y_{ij} \Pi_j(p) = 0
\]

or

\[
y_{ij} \Pi_j(p) = 0 \quad \forall_j
\]

Furthermore, it follows that:

\[
p_i \left( \sum_j y_{ij} \frac{\delta \Pi_j(p)}{\delta p_i} + \sum_h \omega_{ih} - \sum_h d_{ih}(p, M_h) \right) = 0 \quad \forall_i
\]

In other words, complementary slackness is a feature of the equilibrium allocation even though it is not imposed as an equilibrium condition, per-se. This means that in equilibrium, an production activity which is operated makes zero profit and any production activity which earns a negative net return is idle. Likewise, any commodity which commands a positive price has a balance between aggregate supply and demand, and any commodity in excess supply has an equilibrium price of zero.

### 4.53.2.3 A small example: Harberger

This section of the paper introduces MPSGE model building using a two-good, two-factor (2x2) example. This is addressed to readers who may be unfamiliar with GAMS and/or the original (scalar) MPSGE syntax. The discussion provides some details on the formulation and specification of one small model from the MPSGE library. Subsequently, two extensions are presented, one which illustrates equal yield constraints and another which introduces a pure public good. These examples are by no means exhaustive of the classes of equilibrium structures which can be investigated using the software, but they do provide a starting point for new users.

The structure of MPSGE model HARBERGER is “generic” Arrow-Debreu with taxes. Households obtain income by supplying factors of production to industry or collecting tax revenue. This income is then allocated between alternative goods in order to maximize welfare subject to the budget constraint.
Firms operate subject to constant returns to scale, selecting factor inputs in order to minimize cost subject to technological constraints. For an algebraic description of a model closely related to this one, see Shoven and Whalley (1984). The present model differs in two respects from the Shoven-Whalley example. First, in this model there are intermediate inputs to production while in the Shoven-Whalley model goods are produced using only value-added. Second, this model incorporates a labor-leisure choice so that the excess burden of factor taxes here incorporates the disincentive to work associated with a lower net wage.

**Benchmark Data**

Table 1 presents most of the input data for a two good, two factor, closed economy model. This is an economy in which, initially, taxes are levied only on capital inputs to production. We treat tax revenue as though it were returned lump-sum to the households.

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

The input data is presented in the form of a balanced matrix, the entries in which represent the value of economic transactions in a given period (typically one year). Social accounting matrices (SAMs) can be quite detailed in their representation of an economy, and they are also quite flexible. All sorts of inter-account taxes, subsidies and transfers can be represented through an appropriate definition of the accounts.

Traditionally, a SAM is square with an exact correspondence between rows and columns. (For an introduction, see Pyatt and Round, "Social Accounting Matrices: A Basis for Planning", The World Bank, 1985.) The numbers which appear in a conventional SAM are typically positive, apart from very special circumstances, whereas the rectangular SAM displayed in Table 1 follows a sign convention wherein supplies or receipts are represented by positive numbers and demands or payments are represented by negative numbers. Internal consistency of a rectangular SAM implies that row sums and column sums are zero. This means that supply equals demand for all goods and factors, tax payments equal tax receipts, there are no excess profits in production, the value of each household expenditure equals the value of factor income plus transfers, and the value of government tax revenue equals the value of transfers to households.

With simple MPSGE models, it is convenient to use a rectangular SAM format. This format emphasizes how the MPSGE program structure is connected to the benchmark data. In the rectangular SAM, we have one row for every market (traded commodity). In the present model, there are four markets, for goods X and Y and factors L and K.

There are two types of columns in the rectangular SAM, corresponding to production sectors and consumers. In the present model, there are two production sectors (X and Y) and three consumers (OWNERS, WORKERS and GOVT).

**Data Entry in GAMS**

Consider a generalized version of the model in which the set of production sectors be denoted \( S \) (here, \( S = \{X, Y\} \)). Let the set of goods be \( G \). Production sectors are mapped one-to-one with the goods, so we see that sets \( S \) and \( G \) are in fact the same set. Let \( F \) denote the set of primary factors (here, \( F = L, K \)), and let \( H \) denote the set of households (here \( H = \{\text{OWNER, WORKER}\} \)). Now that we have identified the underlying sets, we may interpret the input matrix as a set of parameters with which we can easily specify the benchmark equilibrium. (See Table 2.) It is quite common to begin a general equilibrium modeling project with a large input-output table or social accounting matrix which may then be mapped onto a number of submatrices, each of which is dimensioned according to the underlying sets used in the model.
The GAMS specification of benchmark data is presented in Table 3 which begins with a statement of the underlying sets \((G,F,H)\). The statement "ALIAS \((S,G)\)"; simply says that \(S\) and \(G\) both reference \(X,Y\). Thereafter follows the social accounting data table and declarations for the various submatrices. The parameters \(ELAS()\) and \(ESUB()\) are elasticities ("free parameters") which can be chosen independently from the benchmark accounts. The parameters \(TF\) and \(PF\) are calibrated tax and reference price arrays which are computed given benchmark factor and tax payments. (In this model, average and marginal tax rates are not distinguished, so the benchmark marginal tax rate is simply the tax payment divided by the net factor income.)

A general equilibrium model determines only relative prices. For purposes of reporting or constructing value-indices, we use Laspeyres quantity index, \(\theta(G)\), the elements of which correspond to shares of aggregate consumer expenditure in the benchmark period.

\end{align*}
\]

Model Specification

The MPSGE description of this model is shown in Table 4. Declarations following the $MODEL statement indicate that the model involves one class of production activities (AL(S)), three classes of commodities (P(G), W(F) and PT), and two types of consumers, private consumers (RA(H)), and a government "consumer" (GOVT).

One $PROD: block describes the single class of production activities, and two $DEMAND: blocks characterize endowments and preferences for the two classes of consumers.

Consider the records associated with production sector AL(S). The entries on the first line of a $PROD: block are elasticity values. The "s:0" field indicates that the top-level elasticity of substitution between inputs is zero (Leontief). The entry "a:ELAS(S)" indicates that inputs identified as belonging to the "a:" aggregate trade off with an elasticity of substitution ELAS(S) (at the second level of the production function). In these production functions, the primary factors (W(F)) are identified as entering in the a: aggregate.

The records within a $PROD: block begin with "O:" or "I:". An "O:" indicates an output and an "I:" represents an input. In both types of records, "Q:" is a "quantity field" indicating a reference input or output level of the named commodity. A "P:" signifies a reference price field. This price is measured as a user cost, gross of applicable taxes. The default values for reference price and reference quantity are both unity (i.e., a value of 1 is installed if a P: or Q: field is missing).

The A: and T: fields in a $PROD: block indicate tax agent and ad-valorem tax rate, respectively. The tax agent is specified before the tax rate. A single input or output coefficient may have two or more taxes applied. Consumers are treated symmetrically, and there is thus no restriction on the consumer to whom the tax is paid. Typically, however, one consumer is associated with the government.

To better understand the relationship between reference prices and tax rate specification, consider inputs of W.K to sector AL.X in this model. The benchmark payment to capital in the X sector is 20 and the tax payment is 20. Hence the ad-valorem tax rate in the benchmark equilibrium is 100% (T: 1), and the reference price of capital, market price of unity times (1 + 100%), is 2 (P: 2). If in a counterfactual experiment the tax rate on capital inputs to sector X is altered, this will change the T: field but it will
not change the $P: field. $Q: and $P: characterize a reference equilibrium point, and these are therefore unaffected by subsequent changes in the exogenous parameters.

It is important to remember that the $PROD:AL(S)$ block represents as many individual production functions as there are elements in set $S$ (two in this case). Within the $PROD:AL(S)$ block, inputs refer to sets $G$ and $F$, while the output coefficient, $O : P(S)$, refers only to set $S$. Sets referenced within a commodity name in an $I :$ or $O :$ field may be sets which are ”controlled” by the sets referenced in the function itself, in which case only a scalar entry is produced. In $PROD:AL(S)$ there are only outputs of commodity $S$ in sector $S$.

The first line of a $DEMAND$ block also contains fields (e.g., $a:,$ $b:,$ etc.) which represent elasticities of substitution. The subsequent records may begin with either an $E :$ field or a $D :$ field. These, respectively, represent commodity endowments and demands. In the demand fields, the $P :$ and $Q :$ entries are interpreted as reference price and reference quantity, analogous to the input fields in a $PROD$ block. Ad-valorem taxes may not be applied on final demands, so that if consumption taxes are to be applied in a model they must be levied on production activities upstream of the final demand.

The benchmark values for all activity levels and prices are equal to the default value of unity, and therefore we are able to specify values in the $Q :$ fields directly from the benchmark data. An equivalent model could be specified in which the benchmark activity levels for $AL(S)$ equal, for example, $A(S,S)$. This would then require rescaling the input and output coefficients for those sectors, and it would not necessarily be helpful, because in a scaled model it is more difficult to verify consistency of the benchmark accounts and MPSGE input file. Furthermore, for numerical reasons it is advisable to scale equilibrium values for the central variables to be close to unity.

Government transfers to households are accomplished through the use of an ”artificial commodity” (PT). The government is identified as the agent who receives all tax revenue (see the $A:GOVT$ entry in both of the $PROD :$ blocks). Commodity PT is the only commodity on which GOVT spends this income, hence government tax revenue is divided between the two households in proportion to their endowments of the artificial good. In order to scale units so that the benchmark price of PT is unity, the $30 of government tax revenue chases 10 units of PT assigned to OWNER and 20 units assigned to WORKER. (See values for $TRN(H)$ in Table 3.)

The $REPORT$ section of the input file requests the solution system to return values for inputs, outputs, final demands or welfare indices at the equilibrium. Only those items which are requested will be written to the solution file. Each record in the report block begins with a $V :$ (variable name) field. These names must be distinct from all other names in the model. The second field of the report record must have one of the labels $I :,$ $O :$ or $D :$ followed by a commodity name, or the label $W :$ followed by a consumer name. The third field’s label must be $"PROD:"$ in an $I :$ or $O :$ record, and it must be $"DEMAND:"$ if it is a $D :$ record.

An Algebraic Formulation of Harberger Model

The unit cost of production in sector $A_h$ is given by a nested Leontief-CES function defined over the cost of intermediate inputs and primary factors with ad-valorem taxes on factor demands. In equilibrium, the unit cost must be no less than the market price of output:

**Zero Net Profit**

\[- \Pi_s = \sum_g p_g B_{bs} + \phi_s \left( \sum_f \alpha \omega_f (1 + t_f) \right)^{1 - \sigma_s} - p_s \geq 0 \quad \forall s | \sigma_s \neq 1\]

and

\[- \Pi_s = \sum_g p_g B_{bs} + \phi_s \left( \Pi_f (1 + t_f) \right)^{\alpha_f} - p_s \geq 0 \quad \forall s | \sigma_s = 1\]
Income Balance for Government

Government tax income (PT) is determined by the value of tax revenue, calculated using activity levels, compensated demands, market prices and ad-valorem tax rates:

\[ PT = \sum_s \frac{\partial \Pi_s}{\partial (\omega_f (1+ t_f s))} AL_s \omega_f t_f s \]

Income Balance for Households

Household income is determined by the net of tax return to primary factors plus the household share of government revenue:

\[ M_h = \sum_f \omega_f E_{fh} + s_h PT \]

Market Clearance for Goods

Producer output is equal to the sum of intermediate plus final demand:

\[ AL_g \geq \sum_s AL_s B_{gs} + \sum_h \frac{\gamma_h M_h}{e_h(p)} \left( \frac{\epsilon_h(p)}{p_g} \right)^{\frac{1}{1-\sigma_h}} \]

where \( \gamma_h \) is the household budget share devoted to the consumption of goods, and \( e_h \) is the “unit expenditure function” which may be written:

\[ e_h(p) \equiv \left( \sum_i \beta_{ih} p_i^{1-\sigma_h} \right)^{\frac{1}{1-\sigma_h}} \]

Market Clearance for Factors

The aggregate supply of factors equals the sum of producer and consumer demand. Producers pay taxes on factor inputs, consumers do not because we consider these demands to be “leisure” or “household production”. Consumer demands for factors are specified as Cobb-Douglas (constant budget shares):

\[ \sum_h E_{fh} = \sum_s AL_s \frac{\partial \Pi_s}{\partial (\omega_f (1+ t_f s))} + \sum_h \frac{\mu_h M_h}{\omega_f} \]

MPSGE Formulation: Key Ideas

There are two points regarding the MPSGE function format which are important yet easily misunderstood by new users:

1. The elasticities together with the reference quantities and reference prices of inputs and outputs completely characterize the underlying nested CES functions. No other data fields in the $PROD$ block alters the technology. If, for example, a tax rate changes as part of a counter-factual experiment, this has no effect on the reference price. The value in the $P$ : field depends on the benchmark value of the $T$ : field if the model has been calibrated, but subsequent changes in $T$ : do not change the underlying technology.

2. Tax rates are interpreted differently for inputs and outputs. The tax rate on inputs is specified on a net basis, while the tax rate on outputs is specified on a gross basis. That is, the user cost of an input with market price \( p \) subject to an ad-valorem tax at rate \( t \) is \( p(1 + t) \), while the user cost of an output subject to an ad-valorem tax at rate \( t \) is \( p(1 - t) \). (A tax increases the producer cost of inputs and decreases the producer value of outputs.)
MPSGE provides a limited number of economic components with which complex models can be constructed. There are some models which lie outside the MPSGE domain, but in many cases it is possible to recast the equilibrium structure in order to produce an MPSGE model which is logically equivalent to the original model - usually after having introduced some sort of artificial commodity or consumer. In the present model, the use of commodity PT to allocate government revenue between households provides a fairly typical example of how this can be done. In the process of making such a transformation, one often gains a meaningful economic insight.

The Solution Listing

The detailed solution listing for model HARBERGER is shown in Table 5. The standard GAMS report facilities display solution values. Central variables are always either fixed (upper = lower), or they are non-negative (lower bound = 0, upper bound = +INF). The MARGINAL column in the solution report returns the value of the associated slack variable. Complementarity implies that in equilibrium, either the level value of a variable will be positive or the marginal value will be positive, but not both.

The output file (not shown) also provides details on the computational process. For an explanation of these statistics, see Rutherford (1993).

Computing Counter-factual Scenarios

Table 6 presents the GAMS code for specification and solution of three counterfactual equilibria. In these experiments, the nonuniform system of capital taxes from the benchmark is replaced by three alternative uniform factor tax structures: a tax on labor, a tax on capital, and a tax on both labor and capital. In each case, the tax rate is chosen to replace the benchmark tax revenue at benchmark prices and demand (ignoring induced substitution effects). Following each solution, the equilibrium values for tax revenue, welfare (Hicksian equivalent variation), employment, prices and output are stored in parameter REPORT.

4.53.2.4 Alternative models: Shoven and Samuelson

The "standard" MPSGE model is based on fixed endowments and tax rates, but many empirical models
do not fit into this structure. For example, in the model HARBERGER, the level of each replacement tax
was specified to be consistent with "equal yield", but as a result of the endogenous response of prices
and quantities, the resulting tax revenues differed significantly from the benchmark levels. For example,
when the capital tax is replaced by a uniform labor tax at a rate which, in the absence of labor supply
response, produces "equal yield", we find that tax revenue in fact declines by 39%. In order to perform
differential (equal yield) tax policy analysis, it is therefore necessary to accommodate the endogenous
determination of tax rates as part of the equilibrium computation. This is one of many possible uses of
"auxiliary variables" in MPSGE.

Tax Analysis with Equal Yield

Table 7 presents the MPSGE model definition for test problem SHOVEN. This model is equivalent to
the HARBERGER, apart from the addition of an auxiliary variable TAU. Within MPSGE, auxiliary variables
can either represent price-adjustment instruments (endogenous taxes) or they can represent a quantity-
adjustment instruments (endowment rations). In model SHOVEN, TAU is used to proportionally scale factor
taxes in order to achieve a target level of government revenue. The auxiliary variable first appears in
the $PROD:AL(S) block, following the declaration of a tax agent. There are two fields associated with an
endogenous tax. The first field (N:) gives the name of the auxiliary variable which will scale the tax rate.
The second field (M:) specifies the multiplier. If the $M: field is omitted, the multiplier assumes a default
value of unity. If the value in the $M: field is zero, the tax does not apply.

The auxiliary variable TAU also appears at the bottom of the file where it labels an associated inequality
constraint. This constraint exhibits complementary slackness with the associated non-negative auxiliary
variable (i.e., if TAU is positive, the constraint must hold with an equality, whereas if the constraint is
non-binding TAU must be zero). An auxiliary variable may or may not appear in its associated constraint.
The constraint associated with $\text{TAU}$ is based on a price index defined by $\text{THETA(G)}$. The constraint assures a level of tax revenue such that the value of transfers to households is held constant. (Endowments of the commodity $\text{PT}$ are fixed, so when the value of $\text{PT}$ is fixed, then so too are the value of transfers from $\text{GOVT}$ to each of the households.)

\textit{SHOVEN} illustrates how an auxiliary variable can be interpreted as a tax instrument. In the \textit{MPSGE} syntax, auxiliary variables may also be employed to endogenously determine commodity endowments. There is no restrictions on how a particular auxiliary variable is to be interpreted. A single variable could conceivably serve simultaneously as an endogenous tax as well as a endowment ratio, although this would be rather unusual.

\textbf{TABLE 7: Differential Tax Policy Analysis}

An Algebraic Formulation of Shoven Model

Zero Net Profit
The unit cost of production in sector $A_s$ is given by a nested Leontief-CES function defined over the cost of intermediate inputs and primary factors with ad-valorem taxes on factor demands. Unlike the Harberger models, tax rates in this model are determined endogenously. In equilibrium, the unit cost must be no less than the market price of output:

$$-\Pi_s = \sum_g p_g B_{gs} + \phi_s \left( \sum_f \alpha_{fs} (\omega_f (1 + \tau t_{fs}))^{1 - \sigma_s} \right)^{1/1 - \sigma_s} - p_s \geq 0 \quad \forall s | \sigma_s \neq 1$$

and

$$-\Pi_s = \sum_g p_g B_{gs} + \phi_s \left( \prod_f (\omega_f (1 + \tau t_{fs}))^{\alpha_{fs}} \right) - p_s \geq 0 \quad \forall s | \sigma_s = 1$$

**Income Balance for Government**

Government tax income (PT) is determined by the value of tax revenue, calculated using activity levels, compensated demands, market prices and ad-valorem tax rates:

$$PT = \sum_s \frac{\partial \Pi_s}{\partial (\omega_f (1 + \tau t_{fs}))} AL_s \omega_f \tau t_{fs}$$

**Equal Yield**

In equilibrium, tax rates are multiplicatively adjusted to achieve a target level of government revenue:

$$PT = \sum_g \theta_g p_g$$

**Income Balance for Households**

Household income is determined by the net of tax return to primary factors plus the household share of government revenue:

$$M_h = \sum_f \omega_f E_{fh} + \delta_h PT$$

**Market Clearance for Goods**

Producer output is equal to the sum of intermediate plus final demand:

$$AL_g \geq \sum_s AL_s B_{gs} + \sum_h \gamma_h M_h \left( \frac{\epsilon_h(p)}{p_h} \right)^{\sigma_h}$$

where $\gamma_h$ is the household budget share devoted to the consumption of goods, and $\epsilon_h$ is the "unit expenditure function" which may be written:

$$\epsilon_h(p) \equiv \left( \sum_i \beta_{ih} p_i^{1 - \sigma_h} \right)^{1/1 - \sigma_h}$$

**Market Clearance for Factors**
The aggregate supply of factors equals the sum of producer and consumer demand. Producers pay taxes on factor inputs, consumers do not because we consider these demands to be “leisure” or “household production”. Consumer demands for factors are specified as Cobb-Douglas (constant budget shares):

\[
\sum_h E_{fh} = \sum_s AL_s \frac{\partial \Pi_s}{\partial (\omega_f (1 + \tau_t s))} + \sum_h \frac{\mu_h M_h}{\omega_f}
\]

Public Goods and Endogenous Taxation

Consider a final extension of the 2x2 model in which tax revenue funds a pure public good. Model SAMUELSON presented in Table 8. This model illustrates one of several ways that public goods can be modelled in MPSGE. Here the level of public provision is determined by a Samuelson-condition equaling the sum of individual marginal rates of substitution (marginal benefit) with the marginal rate of transformation (marginal cost). Unlike the equal yield formulation, the tax revenues collected by GOVTare not returned lump-sum but are instead used to finance provision of a pure public good. This representation of government has not been widely adopted in the CGE literature, perhaps because of the difficulties involved in specifying preferences for public goods.

The relevant characteristic of a pure public good entering final demand is that each consumer “owns” the same quantity. Agents’ attitudes toward public goods differ, and because there is no market, agents’ valuations of the public good will also differ. In an MPSGE model, the separate valuations are accommodated through the introduction of “personalized” markets for public good - one market for each consumer. In the model, consumer expenditure encompasses both private and public “purchases”, and consumer income encompasses both private and public ”endowments”. An individual is endowed with a quantity of her own version of the public good determined by the level of public expenditures. An increase in taxes, to the extent that it increases tax revenue, will increase the level of public provision.

In this model, the structure of relative factor taxes is exogenous but the aggregate level of taxes is not. Tax rates are scaled up or down so that the sum of individual valuations of the public good (the marginal benefit) equals the cost of supply of the public good (the direct marginal cost).

Consider features of model SAMUELSON which do not appear in SHOVEN:

1. There are new commodities PG and VG(H). The first of these represents the direct marginal cost of public output from sector GP, a Leontief technology which converts private goods inputs into the public good. For the SAMUELSON structure, all government revenues apply to purchases of the public good (observe that the only good demanded by consumer GOVTis PG ). The prices VG(H) represent the individual consumer valuations of the public good. Commodity VG(H) appears only in the endowments and demands of consumer RA(H). The endowment record for VG(H) includes a quantity V(H) which is the benchmark valuation of the public good by agent H.

2. There are two auxiliary variables. TAU has the same interpretation as in the SHOVEN, determining the aggregate tax level. Auxiliary variable LGP is a rationing instrument representing an index of the “level of public goods provision”, scale to equal 1 in the benchmark. Consumer RA(H) thus is endowed with a quantity of VG(H) given by V(H) * LGP.

3. The constraint for TAU in SAMUELSON differs from the TAU constraint in SHOVEN. Here the constraint represents the Samuelson condition, equating the marginal cost (PG*GREV) and the sum of individuals' marginal benefit (SUM(H, VG(H) + V(H))). The constraint for LGP simply assigns LGP equal to the sector GP activity level. (The LGP variable and constraint are only needed because the R: field only accepts auxiliary variables.)

| TABLE 8: Endogenous Determination of Tax Revenue |
An Algebraic Formulation of Samuelson Model

Zero Net Profit for Private Production

The unit cost of production in sector $A_h$ is given by a nested Leontief - Cobb-Douglas function defined over the cost of intermediate inputs and primary factors with ad-valorem taxes on factor demands. Unlike the Harberger models, tax rates in this model are determined endogenously. In equilibrium, the unit cost must be no less than the market price of output:
\[-\Pi_s = \sum_g p_g B_{gs} + \phi_s \left( \prod_f (\omega_f(1 + \tau f_s))^\alpha f_s \right) - p_s \geq 0 \quad \forall s\]

**Zero Net Profit for Public Sector Contractors**

The unit cost of public provision is determined by the market price of commodity inputs to the Leontief activity. Input requirements are defined by a vector of public sector input coefficients, \(A_h g\). In equilibrium, the price paid by the government equals the cost of market inputs:

\[\sum_g p_g a_g = p_G \geq 0\]

**Income Balance for Government**

Government tax income (PT) is determined by the value of tax revenue, calculated using activity levels, compensated demands, market prices and ad-valorem tax rates. In equilibrium, the value of tax revenue equals the market cost of public sector output:

\[PT = \sum_s \frac{\partial \Pi_s}{\partial (\omega_f(1 + \tau f_s))} AL_s \omega_f \tau f_s = p_G G\]

**Income Balance for Households**

Household income is determined by the net of tax return to primary factors plus the imputed value of public provision:

\[M_h = \sum_f \omega_f E_{fh} + v_h G\]

**Market Clearance for Private Goods**

Producer output is equal to the sum of intermediate plus final demand:

\[AL_g \geq \sum_s AL_s B_{gs} + \sum_h \gamma_h M_h \left( \frac{e_h(p)}{p_g} \right)^{\sigma_h}\]

where \(\gamma_h\) is the household budget share devoted to the consumption of goods, and \(e_h(p)\) is the “unit expenditure function” which may be written:

\[e_h(p) \equiv \left( \sum_i \beta_i h P_i^{1-\sigma_h} \right)^{-\frac{1}{\sigma_h}}\]

**Personalized Markets for Public Goods**

We assume a “pure” public good in this model, hence each household may attach a different marginal valuation to public provision in an equilibrium. In order to compute these marginal values, we include a separate public good “market” for each household which balances the level of provision with the household “demand”:

\[G = \frac{\mu_G M_h}{v_h}\]
in which \( \mu_{G,h} \) is the budget share of public goods in the top-level Cobb-Douglas preferences of household \( h \).

**Market Clearance for Factors**

The aggregate supply of factors equals the sum of producer and consumer demand. Producers pay taxes on factor inputs, consumers do not because we consider these demands to be “leisure” or “household production”. Consumer demands for factors are specified as Cobb-Douglas (constant budget shares):

\[
\sum_h E_{fh} = \sum_s AL_s \frac{\prod_{t} \omega_{f(t+1)}}{\omega_f} + \sum_h \mu_{f,h} M_h \omega_f
\]

**Samuelson Rule for “Optimal” Provision of Public Goods**

The tax rate multiplier is adjusted to balance the marginal cost of public provision with the summation across households of marginal willingness to pay. Due to the existence of household factor demand, factor taxes are necessarily distortionary and there will be an excess social cost of public funds. For this reason, the Samuelson rule is neither necessary nor sufficient for optimal provision. We apply the rule here merely to illustrate the programming methodology, even though the resulting equilibrium may be “suboptimal”:

\[
PG = \sum_h v_h
\]

**Comparing Model Results**

Although the foregoing discussion has focused on the nuances of MPSGE model syntax, but there are many interesting economic questions which can be addressed using even small-scale models such as those described here. Consider the output listing from parameter REPORT is displayed in Table 9. It is perhaps surprising to note that none of the uniform tax structures represents a Pareto-superior choice compared to the benchmark tax structure. Furthermore, from the standpoint of aggregate welfare ("WELFARE.TOTAL" = income-weighted sum of individual EV's), only the uniform capital tax represents an improvement.

#### 4.53.2.5 Summary

This paper has provided an introduction to a new GAMS subsystem for applied general modeling. This extension of GAMS accommodates a tabular representation of highly nonlinear cost and expenditure functions through which model specification is concise and transparent. The paper has presented three small examples which illustrate the programming environment and its application to traditional economic issues in public finance for which applied general equilibrium analysis is a standard tool. Further work is underway in the development and evaluation of solution algorithms for applied general equilibrium models implemented within GAMS/MPSGE. In addition to providing a convenient framework for model-builders, the new GAMS/MPSGE system also simplifies the implementation and testing of algorithms for complementarity problems. Information on the relative effectiveness of different solution strategies should prove quite helpful to users who are using the system to solve very large systems of nonlinear equations.

#### 4.53.2.6 References

4.53.2.7 Appendix A: Language Syntax

General syntax rules

- All input is free format (spaces and tabs are ignored) except keywords for which "$" must appear in column 1.
- End-of-line is significant. Continuation lines are indicated by a "+" in column 1.
- In general, input is not case sensitive, except in the specification of sub-nests for production and demand functions.
- Numeric expression involving GAMS parameters or constants must be enclosed in parentheses.

Keywords

Keywords typically appear in the following order:

<table>
<thead>
<tr>
<th>Keywords</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$ONTENT</td>
<td>Indicate the beginning of a GAMS comment block containing an MPSGE model.</td>
</tr>
<tr>
<td>$MODEL: model_name</td>
<td>model_name must be a legitimate file name. This name is subsequently used</td>
</tr>
<tr>
<td></td>
<td>to form MODEL_NAME.GEN (this file name must be upper case when running</td>
</tr>
<tr>
<td></td>
<td>under UNIX).</td>
</tr>
<tr>
<td>$SECTORS:, $COMMODITIES:, $AUXILIARY:, $CONSUMERS:</td>
<td>Four keywords define variables which are used in the model. Entries in these blocks share the same syntax. The $AUXILIARY block is only used in models with side constraints and endogenous taxes or rationed endowments.</td>
</tr>
<tr>
<td>$PROD: sector</td>
<td>Production functions must be specified for each production sector in the model.</td>
</tr>
<tr>
<td>$DEMAND: consumer</td>
<td>Demand functions must be specified for every consumer in the model. General structure is the same as for production functions above.</td>
</tr>
<tr>
<td>$CONSTRAINT: auxiliary</td>
<td>Specifies a side constraint to be associated with a specified auxiliary variable.</td>
</tr>
<tr>
<td>$REPORT:</td>
<td>Identifies the set of additional variables to be calculated. These include outputs and inputs by sector and demands by individual consumers.</td>
</tr>
<tr>
<td>$OFFTEXT</td>
<td>Indicates the end of model specification.</td>
</tr>
</tbody>
</table>

Variable Declarations

There are four classes of variables within an MPSGE model: activity levels for production sectors, prices for commodities, income levels for consumers and level values for auxiliary variables. These classes of variables are distinguished in order to permit additional semantic checking by the MPSGE preprocessor. For example, if P has been declared as a price (within the $COMMODITIES: block), then the preprocessor would report an error if it encountered "$PROD:P".

The $SECTORS:, $COMMODITIES:, $CONSUMERS: and $AUXILIARY blocks contain implicit GAMS variable declarations in which the index sets must be specified in the GAMS program above and the variable names must be distinct from all other symbols in the GAMS program. One or more variables may be declared per line separated by one or more spaces.
4.53 Mathematical Programming System for General Equilibrium analysis (MPSGE) 1325

$SECTORS:

Y(R,T) ! Output in region R in period T
K(T) ! "Aggregate capital stock, period T"

In these declarations, the trailing comments (signified by "!") are interpreted as variable name descriptors which subsequently appear in the solution listing.

The equivalent GAMS declaration for these variables would be:

VARIABLES Y(R,T) Output in region R in period T
K(T) "Aggregate capital stock, period T";

As with the usual GAMS syntax, when a variable descriptor contains a punctuation symbol such as ",", it is required to enclosed in quotes.

$SECTORS:

X(R,T)$X0(R) GT 0)

Here, the GAMS conditional operator "$" is used to restrict the domain of the variable X. The expression following the dollar sign is passed through to the GAMS compiler and must conform to GAMS syntax rules.

$SECTORS:

X Y(R)$Y0(R) Z ! Descriptor for Z
W(G,R,T) ! Descriptor for W

More than one symbol may appear on a single line. The descriptor only applies to the last one.

All MPSGE variables must be declared. When multidimensional variables are specified, they must be declared explicitly - declarations like X(∗) are not permitted. Two further restrictions are that the sets used in the declaration must be static rather than dynamic, and any variable which is declared must be used in the model. There is a simple way to work around these restrictions. Let me illustrate with an example. Suppose that in a model the set of production sectors AL is employed for all elements of a static set S which satisfy a particular condition, for example BMX(S) not equal to 0. This would require that AL be declared as follows:

$SECTORS:

AL(S)$BMX(S)

In this context, the symbol "$" is used as an "exception operator" which should be read as "such that". In this case, we have generated one AL sector for each element of the set S for which BMX(S) is nonzero.

Function Declarations

Functional declarations characterize nested CES functions which characterize both preferences and technology. The former are written within a $DEMAND: block and the latter within a $PROD: block. Tax entries may appear within a $PROD: block but not within a $DEMAND: block, otherwise the syntax is nearly identical. The syntax for these blocks will be described through a sequence of examples:

$PROD:Y(R) s:1
0:P(R) Q:Y0(R)
I:W(F,R) Q:FDO(F,R)
This block characterizes a Cobb-Douglas production function in which the elasticity of substitution between inputs is one - "s:1" in the first line which sets a top level substitution elasticity equal to unity.

Variable Y(R) is an activity level declared within the $SECTORS: block. Variables P(R) and W(F,R) are prices declared within the $COMMODITIES: block. The O: label indicates an output, and the I: prefix indicates an input. The Q: fields in both records represent "reference quantities". Y0(R) and F00(F,R) must be GAMS parameters defined previously in the program.

$$PROD:X(R) \quad s:ESUB(R) \quad a:0 \quad b: (ESUB(R)*0.2)$$

The keyword line specifies three separate elasticities related to this function. ESUB(R) is the top level elasticity of substitution. There are two sub-nests in the function. Nest a: is a Leontief nest (in which the compensated elasticity is zero). The elasticity of substitution in nest b: is one-fifth of the top level elasticity.

In the function specification, commodities PY(G) (one input for each element of set G) enter in fixed proportions. Commodities PL and PK enter in nest b.

If this function has been specified using a balance benchmark dataset with reference prices equal to unity, then the following identity should be satisfied:

$$X0(R) = \text{SUM}(G, YX0(G,R)) + LX0(R) + KX0(R)$$

$$PROD:AL(S) \quad s:0 \quad a:ELAS(S)$$

In this function, we have two new ideas. The first is the use of a reference price denoted by "P:". This entry indicates that the function should be calibrated to a reference point where individual input prices (gross of tax) equal PF(F,S). If P: does not appear, prices of one are assumed.

The second new idea here is that taxes may be levied on production inputs. The A: label identifies the name of the tax agent (a $CONSUMER:). The T: label identifies the ad-valorem tax rate.

$$DEMAND:RA(R)\quad RA0(R) \quad s:1$$

This function specification demonstrates the use of conditionals. This function is only generated when RA0(R) is nonzero. The demands D: for a particular element of set G are suppressed entirely when DG(G) equals 0. The Q: field also has an exception operator, so that the default value for Q: (unity) is applied when DD(G,R) equals zero.

This example is somewhat artificial, but it illustrates the distinction between how exception operators affect lead entries (I:, O:, D: and E:) and subsequent entries. When an exception is encountered on the lead entry, the entire record may be suppressed. Exceptions on subsequent entries only applied to a single field.

The valid labels in a function declaration ($PROD: or $DEMAND: ) line include:
Mathematical Programming System for General Equilibrium analysis (MPSGE)

\( s \): Top level elasticity of substitution between inputs or demands.

\( t \): Elasticity of transformation between outputs in production. (valid only in $PROD$ blocks)

\( a;,b;,… \) Elasticities of substitution in individual input nests.

The recognized labels in an \( I; \) or \( O; \) line include:

- \( Q \): Reference quantity. Default value is 1. When specified, it must be the second entry.
- \( P \): Reference price. Default value is 1.
- \( A \): Tax revenue agent. Must be followed by a consumer name.
- \( T \): Tax rate field identifier. (More than one tax may apply to a single entry.)
- \( N \): Endogenous tax. This label must be followed by the name of an auxiliary variable.
- \( M \): Endogenous tax multiplier. The advalorem tax rate is the product of the value of the endogenous tax and this multiplier.

\( a;,b;,… \) Nesting assignments. Only one such label may appear per line.

The valid labels in an \( E; \) line include:

- \( Q \): Reference quantity
- \( R \): Rationing instrument indicating an auxiliary variable.

The valid labels in a \( D; \) line include:

- \( Q \): Reference quantity
- \( P \): Reference price

\( a;,b;,… \) Nesting assignment

**Constraints**

Auxiliary constraints in MPSGE models conform to standard \( GAMS \) equation syntax. The may refer to any of the four classes of variables, \( \$SECTORS, \$COMMODITIES, \$CONSUMERS \) and \( \$AUXILIARY \), but they may not reference variables names declared within a \( \$REPORT \) block. Complementarity conditions apply to upper and lower bounds on auxiliary variables and the associated constraints. For this reason, the orientation of the equation is important. When an auxiliary variable is designated POSITIVE (the default), the auxiliary constraint should be expressed as a "greater or equal" inequality (\( =G= \)). If an auxiliary variable is designated FREE, the associated constraint must be expressed as an equality (\( =E= \)).

\[
\$CONSTRAINT:TAU
\begin{align*}
G & =G= X \ast Y; \\
\$CONSTRAINT:MU(I)$MU0(I)
\end{align*}
\]

\[
MU(I) \ast P(I) \ast Q(I) =G= \text{SUM}(J, \text{THETA}(I,J) \ast PX(J));
\]
The exception applied in this example restricts the equation only to those elements of set $I$ for which $MU_0(I)$ is not zero.

**Report Declaration**

The GAMS interface to MPSGE normally returns level values only for the central variables - those declared within $\$SECTORS$, $\$COMMODITIES$, $\$CONSUMERS$: and $\$ AUXILIARY$: sections. An equilibrium determines not only these values, but also levels of demand and supply by individual sectors and consumers. Given benchmark information, elasticities and the equilibrium values, all such demands can be computed, but this can be tedious to do by hand. In order to have these values returned by MPSGE, it is necessary to indicate the name of the variable into which the value is to be returned. The general form is as follows:

\[
\begin{align*}
\$REPORT: & \\
V: & \text{variable name} & I: & \text{commodity} & \text{PROD:} & \text{sector} \\
V: & \text{variable name} & O: & \text{commodity} & \text{PROD:} & \text{sector} \\
V: & \text{variable name} & D: & \text{commodity} & \text{DEMAND:} & \text{consumer} \\
V: & \text{variable name} & W: & \text{consumer} & \text{} & \text{} \\
\end{align*}
\]

The first row returns an input quantity, the second row returns an output quantity, the third returns a demand quantity, and the fourth row returns a consumer welfare index. (Note: the level value returned for a "consumer variable" is an income level, not a welfare index.)

\[
\begin{align*}
\$REPORT: & \\
V: & DL(S) & I: & \text{PF("L")} & \text{PROD:} & Y(S) \\
V: & DK(S) & I: & \text{PF("K")} & \text{PROD:} & Y(S) \\
V: & SX(G,S) & D: & PX(G) & \text{PROD:} & X(S) \\
V: & D(G,H) & D: & P(G) & \text{DEMAND:} & RA(H) \\
V: & W(H) & W: & RA(H) & \text{} & \text{} \\
\end{align*}
\]

Note that the "$" exception is only meaningful on the first entry. Also notice that the domain of the report variable must conform to the domain of the subsequent two entries.

**Differences between Scalar and Vector MPSGE Syntax**

1. $\$MODEL$: statement The $\$MODEL$ statement is required in the vector format and it must precede all other statements. A name which is an acceptable file name prefix must be used. The preprocessor does not begin translation of an MPSGE model until it encounters a $\$MODEL$ statement following an $\$ONTEXT$ record. The preprocessor continues to translate until it reaches an $\$OFFTEXT$ statement, skipping blank lines and comment lines identified by a "∗" in column 1.

2. Case folding: In the vector syntax, upper and lower case letters are not distinguished. The entire file is processed as though it were written in upper case. This is not compatible with the earlier version of MPSGE in which "P" and "p" were distinct.

3. Distinct names: Names used for variables in the MPSGE model must be distinct from each other as well as from all other symbols in the GAMS program. If there is a GAMS set or parameter or model named $X$, then $X$ may not be used to identify an MPSGE sector or commodity.

4. Tabs: MPSGE fields are free format and tabs are translated to spaces by the preprocessor. Tabs are permitted in GAMS provided that the compiler is properly configured (under DOS, "TABIN 8" must be inserted in file GAMSPARM.TXT in the GAMS system directory).

**Exception Handling**

The GAMS exception operator can be used on virtually any entry in the MPSGE input file. For example, if you want to have sector $X(S)$ have one production structure for elements $S$ in a subset $T(S)$, you can provide separate production function declarations as follows:
4.53 Mathematical Programming System for General Equilibrium analysis (MPSGE) 1329

\$
\text{PROD:} X(S) \text{T}(S) \\
\ldots \quad \text{! sector X described for S in T} \\
\$

\$
\text{PROD:} X(S) \text{(NOT T(S))} \\
\ldots \quad \text{! sector X described for S not in T.} \\
\$

The preprocessor does not require one and exactly one declaration for each sector. If multiple declarations appear, the later set of coefficients overwrites the earlier set.

Switches and Debug Output

Run-time tolerances and output switches may be specified within the vector-syntex model specification or using the PUT facility, they can be written directly to the MPS input file. Output switches control the level of debug output written by the MPSGE subsystem to the solver status file. Reports provided by \$ECHOP, \$FUNLOG and \$DATECH can be returned to the listing file by specifying "OPTION SYSOUT=ON;" within the GAMS program prior to the SOLVE statement. The recognized MPSGE parameters are:

\$
\text{ECHOP: logical Default=.FALSE.} \\
\$

is a switch for returning all or part of the scalar MPSGE file to the solver status file. In order to have this output printed in the listing file, enter the GAMS statement "OPTION SYSOUT=ON;" prior to solving the model.

\$
\text{PEPS: real Default=1.0E-6} \\
\$

is the smallest price for which price-responsive demand and supply functions are evaluated. If a price is below PEPS, it is perturbed (set equal to PEPS) prior to the evaluation.

\$
\text{EULCHK: logical Default=.TRUE.} \\
\$

is a switch for evaluating Euler's identity for homogeneous equations. The output is useful for monitoring the numerical precision of a Jacobian evaluation. When a price or income level is perturbed in a function, the Euler check may fail.

\$
\text{WALCHK: logical Default=.TRUE.} \\
\$

is a switch for checking Walras's law. Like EULCHK, this switch is provided primarily to monitor numerical precision. When an income level is perturbed, the Walras check may fail.

\$
\text{FUNLOG: logical Default=.FALSE.} \\
\$

is a switch to generate a detailed listing of function evaluations for all production sectors and consumers.

FUNLOG triggers a function evaluation report which provides detailed output describing the evaluation of supply and demand coefficients. The information provide is sufficient that an industrious graduate student should be able to reproduce the results (given a pencil, paper and slide rule).

The evaluation report has the following headings:
When `$FUNLOG:.TRUE.` is specified, a complete report of demand and supply coefficients for every production and demand function in every iteration. Be warned that with large models this can produce an enormous amount of output!

The following two function evaluation reports are generated in the first iteration in solving case "L" for model `HARBERGER`:

Function Evaluation for: `AL.X`

`$DATECH`: logical Default=.FALSE.

is a switch to generate a annotated listing of the function and Jacobian evaluation including a complete listing of all the nonzero coefficients.
MPSGE generates an analytic full first-order Taylor series expansion of the nonlinear equations in every iteration. Nonzero elements of the Jacobian matrix are passed to the system solver (MILES or PATH) which uses this information in the direction-finding step of the Newton algorithm. Coefficients are produced with codes which help interpret where they came from. The following codes are used:

- **W0** indicates an element from the orthogonal part of \( F() \).
- **W1** indicates an element from the non-orthogonal part of \( F() \).
- **B** indicates a linear term from \( F \).
- **E0** indicates a homogeneous Jacobian entry.
- **E1** indicates a non-homogeneous Jacobian entry.

The Euler checksum examines elements from the linearization which are type "E0". The Walras checksum examines elements from the function evaluation which are type "W0".

Needless to say, the \$DATECH: .TRUE. switch produces a very big status file for large models. It is not something which is very useful for the casual user.

Here is a partial listing of nonzeros generated during the first linearization for scenario "L" in model HARBERGER:

```
---------------------------------------- Coefficients for sector:AL.X
  P.X  AL.X       1.0000E+02  B
  AL.X  P.X       -1.0000E+02  B

  P.X  RA.OWNER    -4.2857E-01  E0 -3.0000E+01
  P.Y  RA.OWNER    -5.7143E-01  E0 -4.0000E+01
```
4.53.2.8 Appendix B: File Structure

This appendix provides an overview of the structure of GAMS input files which include MPSGE models. The text of the paper presents many of these ideas by way of example, but it may also be helpful for some users to have a "template" for constructing MPSGE models. The discussion in this section focuses on a "generic" input file, the schematic form of which is presented in Table 10. This section first presents a "top down" view of program organization, and then it discusses aspects of the new syntax for model specification.

Flow of Control

When a model is developed using GAMS as a front-end to MPSGE, the input file generally has five sections as identified in Table 10. Section (i), the benchmarking section, contains standard GAMS statements. This includes GAMS SET declarations, input data (SCALARS, PARAMETERS and TABLES), and PARAMETER declarations for intermediate arrays used in benchmarking or model specification. In complex models, this section of the file will typically contain some algebraic derivations, the result of which is a calibrated benchmark equilibrium dataset.

Users who are unfamiliar with GAMS can consult the manual. Beginning GAMS programmers should remember that the MPSGE interface to GAMS is unlike other solution subsystems. "Level values" are passed between the GAMS program and MPSGE in the usual fashion, but MPSGE models do not require the explicit use of the VARIABLE or EQUATION statements.)

The second section of the file consists of a GAMS comment range, beginning with an $ONTEXT record and ending with an $OFFTEXT record, followed by an invocation of the preprocessor. The preprocessor writes operates on statements in the MPSGE model declaration which are "invisible" to the GAMS compiler. This program reads the MPSGE model statements and generates GAMS-readable code, including a model_name.gen file. Additional GAMS code produced by the preprocessor includes declarations for each of the central variables and report variables in the MPSGE model.

The third section of the generic input file performs a "benchmark replication" and may not be present in all applications. There are four statements required for benchmark validation. The first statement sets the iteration limit to be zero; the second statement causes the MPSGE model to be "generated", and the third statement causes the MPSGE solver to read the model and return the deviations. In this call, the level values passed to the solver are unaltered because the iteration limit is zero. Market excess supplies and zero profit checks are returned in the "marginals" of the associated commodity prices and activity levels, respectively. The final statement in this section resets the iteration limit to 1000 (the default value) for subsequent counter-factual computations.

Section (iv) defines and then computes a counter-factual equilibrium. A counter-factual equilibrium is defined by parameter values such as tax rates or endowments which take on values different from those in the benchmark equilibrium. Within the GAMS interface to MPSGE, it is also possible to fix one or more central variables. When any variable is fixed, the associated equation is omitted from the equilibrium system during the solution process but the resulting imbalance is then reported in the solution returned through the marginal.

The final section of the file represents the GAMS algebra required for comparing counter-factual equilibria. It would be possible, for example, to construct welfare measures or to report percentage changes in certain values. All of these calculations are quite easy because the equilibrium values are returned as level values in the associated variables.

The final section of the file represents the GAMS algebra required for comparing counter-factual equilibria. It would be possible, for example, to construct welfare measures or to report percentage changes in certain values. All of these calculations are quite easy because the equilibrium values are returned as level values in the associated variables.

For large models, the advantage of the vector format is that by using appropriately defined GAMS sets, the number of individual functions which need to be defined is reduced only to the number of "classes" of functions. This makes it possible to represent large dimensional models using only a few lines of code.

To summarize, here are the basic features of a program which uses GAMS as a front-end to MPSGE:
1. An MPSGE model is defined within a GAMS comment range followed by
   
   $\text{sysinclude mpsgeset model_name}$

2. Every SOLVE statement for a particular model is preceded by $\text{INCLUDE MODEL.GEN}$. The GEN file is written by the preprocessor based on the model structure.

3. Solution values for the central variables in the MPSGE model and any declared "report variables" are returned in GAMS variable level values. Level values for slacks are returned as "marginals" for the associated variables.

4. The model description follows a format which is a direct extension of the scalar data format. Certain aspects of the new language, such as case folding, are incompatible with the original MPSGE syntax.

GAMS Code Generated by the Preprocessor: the GEN File

Most novice users will find it easiest to treat the preprocessor output files as "black boxes". These files contain GAMS source code required for declaring and generating the MPSGE input file. Table 11 contains portions of the GEN file for the same model. Table 12 shows the preprocessor-generated listing and symbol table which are always appended to the bottom of the GEN file. If a preprocessor error occurs, it can be helpful to consult the symbol table to track down the bug. Finally, Table 13 shows the first page of scalar format MPSGE input file produced by HARBERGER.GEN. Normally, this file is written and then erased in the course of a GAMS run, although all or part of the file may be retained using the $\text{ECHOP}$: switch.

4.53.3 Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE

This research supported by the GAMS Applied General Equilibrium Research Fund. The software described here operates only with GAMS 2.25.085 or later on the PC, shipped in July, 1995. The author remains responsible for any bugs which exist in this software.

4.53.3.1 An Overview

This document describes a mathematical programming system for general equilibrium analysis named MPSGE which operates as a subsystem to the mathematical programming language GAMS. MPSGE is library of function and Jacobian evaluation routines which facilitates the formulation and analysis of AGE models. MPSGE simplifies the modeling process and makes AGE modeling accessible to any economist who is interested in the application of these models. In addition to solving specific modeling problems, the system serves a didactic role as a structured framework in which to think about general equilibrium systems.

MPSGE separates the tasks of model formulation and model solution, thereby freeing model builders from the tedious task of writing model-specific function evaluation subroutines. All features of a particular
model are communicated to GAMS/MPSGE through a tabular input format. To use MPSGE, a user must learn the syntax and conventions of this model definition language.

The present paper is intended for students who have completed two semesters of study in microeconomics. The purpose of this presentation is to give students a practical perspective on microeconomic theory. The diligent student who works through all of the examples provided here should be capable of building small models "from scratch" to illustrate basic theory. This is a first step to acquiring a set of useable tools for applied work.

The remainder of this paper is organized as follows. Section The Theory of Consumer Demand review the theory of consumer demand; section Getting Started provides guidance on the mechanics of numerical modeling, including instructions on how to install and test the GAMS/MPSGE software; section Modeling Consumer Demand introduces the modeling framework with three models illustrating the representation of consumer demand within the MPSGE language. Section The Pure Exchange Model reviews the pure exchange model, and section Modeling Pure Exchange with MPSGE presents two MPSGE models of exchange. Each of the model-oriented sections present exercises based on the models which give students a chance to work through the material on their own. Additional introductory examples for self-study can be found in the Markusen library as well as in the GAMS model library (look for models with names ending in "MGE").

The ultimate objective of this piece is to remind students of some theory which they have already seen and illustrate how these ideas can be used to build numerical models using GAMS with MPSGE. It is not my intention to provide a graduate level presentation of this material. So far as possible, I have avoided calculus and even algebra. The objective here is to demonstrate that what matters are economic ideas. With the proper tools, it is possible to do concrete economic modeling without a lot of mathematical formalism.

### 4.53.3.2 The Theory of Consumer Demand

A central idea underlying most microeconomic theory is that agents optimize subject to constraints. The optimizing principle applied to consumer choice begins from the notion that agents have preferences over consumption bundles and will always choose the most preferred bundle subject to applicable constraints. To operationalize this theory, three issues which must be addressed:

1. How can we represent preferences?
2. What is the nature of constraints on consumer choice? and
3. How can the choice be modelled?

Preferences are relationships between alternative consumption "bundles". These can be represented graphically using "indifference curves", as illustrated in Figure 1. Focusing now on the preferences of a single consumer, the indifference curve is a line which connects all combinations of two goods x and y between which our consumer is indifferent. As this curve is drawn, we have represented an agent with "well-behaved preferences": at any allocation, more is better (monotonicity), and averages are preferred to extremes (convexity). Exactly one such indifference curve goes through each positive combination of x and y. Higher indifference curves lie to the "north-east".

Figure 1: An Indifference Curve
If we wish to characterize an agent's preferences, the "marginal rate of substitution" (MRS) is a useful point of reference. At a given combination of $x$ and $y$, the marginal rate of substitution is the slope of the associated indifference curve. As drawn, the MRS increases in magnitude as we move to the northwest and the MRS decreases as we move to the southeast. The intuitive understanding is that the MRS measures the willingness of the consumer to trade off one good for the other. As the consumer has greater amounts of $x$, she will be willing to trade more units of $x$ for each additional unit of $y$ – this results from convexity.

An "ordinal" utility function $U(x, y)$ provides a helpful tool for representing preferences. This is a function which associates a number with each indifference curve. These numbers increase as we move to the northeast, with each successive indifference curve representing bundles which are preferred over the last. The particular number assigned to an indifference curve has no intrinsic meaning. All we know is that if $U(x_1, y_1) > U(x_2, y_2)$, then the consumer prefers bundle 1 to bundle 2.

Figure 2 illustrates how it is possible to use a utility function to generate a diagram with the associated indifference curves. This figure illustrates Cobb-Douglas well-behaved preferences which are commonly employed in applied work.

Figure 2: Indifference Curves and Utility Levels

Up to this point, we have we have focused exclusively on the characterization of preferences. Let us now consider the other side of the consumer model – the budget constraint. The simplest approach to
characterizing consumer income is to assume that the consumer has a fixed money income which she may spend on any goods. The only constraint on this choice is that the value of the expenditure may not exceed the money income. This is the standard budget constraint:

\[ Px \, x + Py \, y = M. \]

Graphically, this equation defines the line depicted in Figure 3. All points inside the budget line are affordable. The consumer faces a choice of which affordable bundle to select.

**Figure 3: The Budget Set**

Within the framework of our theory, the answer is straightforward – the consumer will choose the one combination of x and y from the set of affordable bundles which maximizes her utility. This combination of x and y will be at the point where the indifference curve is tangent the budget line. This point is called the optimal choice. We see this illustrated in Figure 4.
Figure 4: Utility Maximization on the Budget Set

The standard model of consumer behavior provides a starting point for learning MPSGE. This introduction is "hands on" – I will discuss issues as they arise, assuming that you have access to a computer and can invoke the program and read the output file. You may wish to learn the rudiments of GAMS syntax before starting out, although you may be able to pick up these ideas as they come, depending on your aptitude for computer languages.

4.53.3 Getting Started

1. You need to know how to generate a standard text file. There are several methods for doing this. One approach is to use EDIT, the standard DOS text editor. Another approach favored by many people who have used text processors like WordPerfect or Microsoft Word is to use the word processor as a text editor. A disadvantage of this approach is that you will need to remember to always save the edited file in a text format. A final approach, one which I suggest to graduate students who are interested in numerical modeling, is that you develop facility with a "real" programmer's editor like Emacs, Epsilon or Brief. These editors are far more powerful than the DOS Edit, and they are far better suited to computational work than a word processor.

2. You need to have a copy of GAMS with MPSGE to run on your computer. There are versions of this program for 386/486/586 PCs as well as for most widely-used workstations (SUN, DEC, HP, IBM, etc.). Copies of the program can be obtained directly from GAMS (gams@gams.com), or you may take a copy from someone who already has the program. (Copyright restrictions apply only to GAMS license files.) You may copy the GAMS programs without the license files and the program will only operate in student/demonstration mode. The student version is perfectly adequate for learning about modeling – in fact, it may be better because it's dimensionality restrictions prevent the novice model builder from adding unnecessary details.

3. You need to install GAMS with MPSGE on your computer. To do this, follow the standard installation procedure:

   (a) Make a GAMS system directory, e.g.
   c:\>mkdir gams

   (b) Copy all the files from the GAMS distribution diskette(s) into the GAMS system directory; e.g.
   c:\>copy a:\.*.* c:\gams

   (c) Connect to the GAMS system directory and run the GAMS installation program e.g.
   c:\>cd gams
c:\>gams\gamsinst

   The installation program gives you choices regarding which solver you wish to use for various problem classes. For MPSGE models, the key choice is the MCP solver. I recommend that you select MPSGE if you have this solver on your computer. It is the most efficient and robust solver currently available for this class of models. (MPSGE by Michael Ferris and Steve Dirkse of the University of Wisconsin at Madison.)

   You complete the installation by adding the GAMS system directory to your DOS environment variable, MPSGE. Normally, MPSGE is initialized at startup in the file C:\AUTOEXEC.BAT. Look for a line which looks like "PATH C:\DOS" and modify this to read something like: "PATH C:\DOS;C:\GAMS" using a text editor.

4. You should verify that the system is operational. Connect to a working directory (never run models from the GAMS system directory!). Then, extract and run one of the library models, e.g.
If the GAMS system is properly installed, these commands will cause GAMS to solve a sequence of models from the SCARFMGE sample problem. The output from this process is written to file SCARFMGE.LST. If you search for the word "STATUS", you can verify that all the cases are processed.

There are a number of MPSGE models included in the GAMS library. If you are using a student version of GAMS, you will be able to process some but not all of the library models. The student version of the program limits the number of variables in the model to 100. (I believe that GAMS imposes other limits on use of the student version, but the variable limitation is the most severe constraint.)

Assuming that you have successfully installed the software, let us now proceed to some examples which illustrate both the computing syntax and the underlying economics.

4.53.3.4 Modeling Consumer Demand

4.53.3.4.1 Example 1: Evaluating a Demand Function

Consider a standard consumer choice problem, one which might appear on a midterm examination in intermediate microeconomics:

\[
\begin{align*}
\text{max} & \quad U(x, y) = \ln(x) + 2 \ln(y) \\
\text{subject to:} & \quad lx + 2y = 120
\end{align*}
\]

where 1 is the exogenous price of x and 2 is the price of y.

This type of problem is solved easily using GAMS/MINOS (as a nonlinear program). Strictly speaking, it is not the sort of model for which you would need to use MPSGE. At the same time, this can be an instructive example.

The key issue in this example is learning how to represent utility functions. MPSGE is "non-algebraic"—so function specification depends on an intuitive understanding of the underlying economic structure.

Consider Figure 5 and focus on a single point, \(x = 1, y = 1\). There is an indifference curve through this point, and the marginal rate of substitution (MRS) at this point is simply the slope of this curve. The benchmark MRS does not uniquely determine the underlying preferences.

**Figure 5: A Calibrated Benchmark**

A utility function is represented in MPSGE by the specification of: (i) benchmark demand quantities, (ii) benchmark demand prices (iii) an elasticity of substitution at the benchmark point. Benchmark quantities determine an anchor point for the set of indifference curves. Benchmark prices fix the slope of the indifference curve at that point, and the elasticity describes the curvature of the indifference curve. Speaking formally, elasticities provide a "second order approximation" of the utility function. To understand the importance of the benchmark elasticity of substitution, consider Figure 6. This figure shows three indifference curves all of which share the same benchmark quantities and benchmark prices. They differ only in the elasticities of substitution. The least convex (flattest) curve has the highest elasticity, the most convex curve has the lowest elasticity. (When the elasticity of substitution is 0, the indifference curve is L-shaped with the corner at the benchmark point.)
Let us now consider how the consumer optimization problem can be cast as a general equilibrium model. We do this by adding a single factor of production and two "production" sectors. For concreteness, let the factor of production be called labor with a price PL. One production function converts one unit of labor into one unit of $x$, the other sector converts 2 units of labor into one unit of $y$. Setting the labor endowment equal 120, the market clearance condition for labor reads:

\[ x + 2y = 120 \]

which is precisely the budget constraint for the consumer's problem.

We will now present the program code, a few lines at a time. As part of working through the example, the student should type these lines into a file.

A MPSGE model specification is always listed between $\text{ONTEXT}$ and $\text{OFFTEXT}$ statements. The first statement within an MPSGE model-description assigns a name to the model. The model name must begin with a letter and must have 10 or fewer characters.

$\text{ONTEXT}$

$\text{MODEL:DEMAND}$
The model specification begins by declaring variables for the model. In a standard model, there are three types of variables: commodity prices, sectoral activity levels, and consumer incomes. The end of each line may include "! variable description ".

_N.B. The variables associated with commodities are prices, not quantities. (In this and subsequent models, I use P as the first letter for each of the commodity variables to remind us that these variables are prices.)_

_N.B. The variable associated with a consumer is an income level, not a welfare index._

```plaintext
$SECTORS:
  X ! ACTIVITY LEVEL FOR X = DEMAND FOR GOOD X
  Y ! ACTIVITY LEVEL FOR Y = DEMAND FOR GOOD Y

$COMMODITIES:
  PX ! PRICE OF X WHICH WILL EQUAL PL
  PY ! PRICE OF Y WHICH WILL EQUAL 2 PL
  PL ! PRICE OF THE ARTIFICIAL FACTOR L

$CONSUMERS:
  RA ! REPRESENTATIVE AGENT INCOME
```

Function specifications follow the variable declarations. In this model, our first declarations correspond to the two production sectors. In this model, the production structures are particularly simple. Each of the sectors has one input and one output. In the MPSGE syntax, _I_: denotes an input and _O_: denotes an output. The output quantity coefficients for both sectors are unity (_Q:1_). This means that the level values for x and y correspond to the actual quantities produced. The final function specified in the model represents the utility function and endowments for our single consumer. In this function, the _E_: entries correspond to endowments and the _D_: entries are demands. Reference demands, reference prices and the substitution elasticity (_s:1_) characterize preferences.

The demand entries shown here are consistent with a Cobb-Douglas utility function in which the budget share for y is twice the budget share for x (i.e. the MRS at (1,1) equals 1/2):

```plaintext
$PROD:X
  O:PX Q:1
  I:PL Q:1

$PROD:Y
  O:PY Q:1
  I:PL Q:2

$DEMAND:RA s:1
  E:PL Q:120
  D:PX Q:1 P:(1/2)
  D:PY Q:1 P:1
```

The final three statements in this file invoke the MPSGE preprocessor, ”generate” and solve the model:

```plaintext
$SYSINCLUDE mpsgeset DEMAND

$INCLUDE DEMAND.GEN

SOLVE DEMAND USING MCP;
```
The preprocessor invocation ($SYSINCLUDE mpsget$) should be placed immediately following the $OFFTEXT block containing the model description. The model generator code, DEMAND.GEN, is produced by the previous statement and must be referenced immediately before each subsequent SOLVE statement.

At this point, the reader should take the time to type the example into a file and execute the program with GAMS/MPSGE.

This is possibly the first GAMS model which some readers have solved, so it is worth looking through the listing file in some detail. After running the solver, we examine the listing file. I typically begin my assessment of a model's solution by searching for "STATUS". For this model, we have the following:

```
SOLVE SUMMARY

MODEL DEMAND
TYPE MCP
SOLVER PATH FROM LINE 263

**** SOLVER STATUS 1 NORMAL COMPLETION
**** MODEL STATUS 1 OPTIMAL

RESOURCE USAGE, LIMIT 1.432 1000.000
ITERATION COUNT, LIMIT 5 1000
EVALUATION ERRORS 0 0

Work space allocated -- 4.86 Mb
```

Default price normalization using income for RA

This information is largely self-explanatory. The most important items are the SOLVER STATUS and MODEL STATUS indicators. When the solver status is 1 and the model status is 1, the system has returned an equilibrium.

For small models such as this, the limits on resource usage (time) and solver iterations have no effect. (You can modify these values with the statements:

```
model.RESLIM = number of cpu seconds ;
model.ITERLIM = number of iterations ;
```

entered into the program before the SOLVE statement.)

The work space allocation for MPSGE models is determined by the number of variables in the model. It is possible to exogenously specify the work space allocation by assigning

```
model.WORKSPACE = xx ;
```

where xx is the desired number of megabytes.

The final message, "Default price normalization...", is significant. It reminds the user that an Arrow-Debreu general equilibrium model determines only relative prices. In such an equilibrium, the absolute scaling of prices is indeterminant. (I.e., if $(p^*, M^*)$ are a set of equilibrium prices and income levels, then $(2 p^*, 2 M^*)$ is also a solution, etc.)

It is common practice in economics to address the normalization issue through the specification of a numeraire commodity. You can do this for an MPSGE model by "fixing" a price, with a statement like:
entered following the model declaration ($SYSINCLUDE mpsgeset) but prior to the solver invocation. When any price or income level is fixed, MPSGE recognizes that a numeraire has been specified and does no automatic normalization.

Following some output from the solver (PATH in this case), the listing file provides a complete report of equilibrium values. With MPSGE models, the equation listings are superfluous. The variable listings provide all the relevant information.

For this model, the solution listing appears as follows:

<table>
<thead>
<tr>
<th>LOWER</th>
<th>LEVEL</th>
<th>UPPER</th>
<th>MARGINAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
<td>VAR X</td>
<td>40.000</td>
<td>+INF</td>
</tr>
<tr>
<td>----</td>
<td>VAR Y</td>
<td>40.000</td>
<td>+INF</td>
</tr>
<tr>
<td>----</td>
<td>VAR PX</td>
<td>1.000</td>
<td>+INF</td>
</tr>
<tr>
<td>----</td>
<td>VAR PY</td>
<td>2.000</td>
<td>+INF</td>
</tr>
<tr>
<td>----</td>
<td>VAR PL</td>
<td>1.000</td>
<td>+INF</td>
</tr>
<tr>
<td>----</td>
<td>VAR RA</td>
<td>120.000</td>
<td>+INF</td>
</tr>
</tbody>
</table>

X SUPPLY AND DEMAND OF GOOD X
Y SUPPLY AND DEMAND OF GOOD Y
PX PRICE OF X WHICH WILL EQUAL CX * PL
PY PRICE OF Y WHICH WILL EQUAL CY * PL
PL PRICE OF THE ARTIFICIAL FACTOR L
RA REPRESENTATIVE AGENT INCOME

The LOWER and UPPER columns report variable bounds applied in the model. In these columns, zero is represented by "." and infinity is represented by "+INF". The LEVEL column reports the solution value returned by the algorithm. Here we see that the equilibrium price of $x$ is 1 and the price of $y$ is 2, as determined by the specification of labor inputs.

4.53.3.4.2 Exercises 1 (a) The utility function calibration point is arbitrary. Here, we have selected $x = y = 1$ as the reference quantity. Revise the program to use a different calibration point where $x = 2$ and $y = 1$, where $MRS(2, 1) = 1/4$. (Remember to modify both the $Q:$ and $P:$ fields.) Rerun the model to demonstrate that this does not change the result.

(b) Increase the price of $x$ from 1 to 2 by changing the $Q:$ coefficient for PL in sector X from 1 to 2. What happens to the demand for $x$? Explain why a change in the price of $x$ is represented by a change in the $Q:$ field for sector X.

(c) Compute an equilibrium in which commodity $y$ is defined as the numeraire.

4.53.3.4.3 Example 2: Evaluating the MRS This example further explores the representation of demand functions with MPSGE. It sets up a trivial equilibrium model with two goods and one consumer which returns the marginal rate of substitution of good $x$ for good $y$ at a given level of demand. The underlying utility function is:

$$U(x, y) = \ln(x) + 4\ln(y)$$

When $x = y = 1$, the marginal rate of substitution of $x$ for $y$ is $1/4$. We use this information to calibrate the demand function, specifying the ratio of the reference prices of $x$ to $y$ equal to $1/4$. 
In an equilibrium, final demand always equals endowments for both goods, because these are the only sources of demand and supply. The model as parameterized demonstrates that if we set endowments for this model equal to the demand function calibration point, the model equilibrium price ratio equals the benchmark MRS.

This program begins with some GAMS statements in which three scalar parameters are declared. These parameters will be used in the place of numbers within the MPSGE model. The syntax for these GAMS statements is introduced in Chapter 2 of the GAMS manual. In short, we declare $x$, $y$ and MRS as scalar parameters and initialize the first two of these to unity. The MRS parameter is assigned a value following the solution of the model.

SCALAR
  X  QUANTITY OF X FOR WHICH THE MRS IS TO BE EVALUATED /1/
  Y  QUANTITY OF Y FOR WHICH THE MRS IS TO BE EVALUATED /1/
  MRS COMPUTED MARGINAL RATE OF SUBSTITUTION;

The remainder of the MPSGE program is, in fact, simpler than Example 1.

$ONTEXT
$MODEL:MRSCAL

$COMMODITIES:
  PX   ! PRICE INDEX FOR GOOD X
  PY   ! PRICE INDEX FOR GOOD Y

$CONSUMERS:
  RA   ! REPRESENTATIVE AGENT

$DEMAND:RA  s:1
  D:PX  Q:1  P:(1/4)

  E:PX  Q:X
  E:PY  Q:Y

$OFFTEXT
$SYSINCLUDE mpsgeset MRSCAL

$INCLUDE MRSCAL.GEN
SOLVE MRSCAL USING MCP;

Following the solution, we compute a function of the solution values, the ratio of the price of $x$ to the price of $y$. We do this using the GAMS syntax which references the equilibrium level values of the PX and PY and storing this result in the scalar MRS. This scalar value is then displayed in the listing file with 8 digits:

\[ \text{MRS} = \frac{\text{PX.L}}{\text{PY.L}}; \]

OPTION MRS:8;
DISPLAY MRS;

4.53.3.4.4 Exercises 2 (a) Show that the demand function is homothetic by uniform scaling of the $x$ and $y$ endowments. The resulting MRS should remain unchanged.

(b) Modify the demand function calibration point so that the reference prices of both $x$ and $y$ equal unity (hint: the marginal rate of substitution is:

\[ \text{MRS} = \frac{x}{4y}. \]
4.53.3.4.5 Example 3: Leisure Demand and Labor Supply  This model investigates the labor-leisure decision. A single consumer is endowed with labor which is either supplied to the market or "repurchased" as leisure. The consumer utility function over market goods (x and y) and leisure is Cobb-Douglas:

\[ U(x, y, L) = \ln(x) + \ln(y) + \ln(L) \]

Goods x and y may only be purchased using funds obtained from labor sales. This constraint is written:

\[ x + y = \text{LPROD} \times \text{LS} \]

where goods x and y both have a price of unity at base year productivity and LPROD is an index of labor productivity. An increase in productivity is equivalent to a proportional decrease in the prices of x and y.

The model declaration is as follows:

```plaintext
SCALAR LPROD AGGREGATE LABOR PRODUCTIVITY /1/
       CX COST OF X AT BASE YEAR PRODUCTIVITY /1/
       CY COST OF Y AT BASE YEAR PRODUCTIVITY /1/;
$ONTEXT
$MODEL:LSUPPLY
$SECTORS:

   PY ! MARKET PRICE OF GOOD Y
   PL ! MARKET WAGE
   PLS ! CONSUMER VALUE OF LEISURE
$CONSUMERS:
   RA ! REPRESENTATIVE AGENT
$PROD:LS
   O:PL Q:LPROD
   I:PLS Q:1
$PROD:X
   O:PX Q:1
   I:PL Q:CX
$PROD:Y
   O:PY Q:1
   I:PL Q:CY
$DEMAND:RA s:1
   E:PLS Q:120
   D:PLS Q:1   P:1
   D:PX Q:1   P:1
   D:PY Q:1   P:1
$OFFTEXT
```
We can use this model to evaluate the wage elasticity of labor supply. In the initial equilibrium (computed in the last statement) the demands for $x$, $y$ and $L$ all equal 40. A subsequent assignment to $LPROD$ (below) increases labor productivity. After computing a new equilibrium, we can use the change in labor supply to determine the wage elasticity of labor supply, an important parameter in labor market studies. It should be emphasized that the elasticity of labor supply should be an input rather than an output of a general equilibrium model – this is a parameter for which econometric estimates can be obtained.

Here is how the programming works. First, we declare some scalar parameters which we will use for reporting, then save the "benchmark" labor supply in $LS0$:

```
SCALAR
  LS0   REFERENCE LEVEL OF LABOR SUPPLY
  ELS   ELASTICITY OF LABOR SUPPLY WRT REAL WAGE;

LS0 = LS.L;
```

Next, we modify the value of scalar $LPROD$, increasing labor productivity by 1%. Because this is a neoclassical model, this change is equivalent to increasing the real wage by 1%. We need to recompute equilibrium prices after having changed the $LPROD$ value:

```
LPROD = 1.01;
$INCLUDE LSUPPLY.GEN
SOLVE LSUPPLY USING MCP;
```

We use this solution to compute and report the elasticity of labor supply as the percentage change in the $LS$ activity:

```
ELS = 100 * (LS.L - LS0) / LS0;
DISPLAY ELS;
```

As the model is currently constructed, the wage elasticity of labor supply equals zero. This is because the utility function is Cobb-Douglas over goods and leisure, and the consumer's only source of income is labor. As the real wage rises, this increases both the demand for goods (labor supply) and the demand for leisure. These effect exactly balance out and the supply of labor is unchanged.

### 4.53.3.4.6 Exercises 3

(a) One way in which the labor supply elasticity might differ from zero in a model with Cobb-Douglas final demand is if there were income from some other source. Let the consumer be endowed with good $x$ in addition to labor. What $x$ endowment is consistent with a labor supply elasticity equal to 0.15?

(b) A second way to "calibrate" the labor supply elasticity is to change the utility function. We can do this by changing the $s:1$ to $s:SIGMA$, where $SIGMA$ is a scalar value representing the benchmark elasticity of substitution between $x$, $y$ and $L$ in final demand. Modify the program to include $SIGMA$ as a scalar, and find the value for $SIGMA$ consistent with a labor supply elasticity equal to 0.15.
4.53.3.5 The Pure Exchange Model

Partial equilibrium analysis forms the basis of most economics courses at the undergraduate level. In these models we focus on price, supply and demand for a single commodity. The partial equilibrium approach neglects indirect effects, through which changes in the market for one good may influence the market for another good.

In the previous section, we focused on the choices of a single consumer. In the present section, we will explore the implications of interactions between many consumers with heterogeneous preferences. Furthermore, the analysis will explore the potentially important interaction between market prices and income which are determined jointly in a general equilibrium.

The most widely-used graphical framework for multi-agent exchange equilibrium analysis is the Edgeworth-Bowley box as illustrated in Figure 7. In this diagram we model the following economy:

**Figure 7: The Edgeworth-Bowley Box**

- Two types of consumers, denoted $A$ and $B$. We consider $A$ and $B$ to each represent multiple consumers, each with the same endowments and preferences. This assumption is helpful for justifying our assumption of perfectly competitive, price-taking behavior.
- Two commodities, denoted $x$ and $y$.
- Fixed endowments of both goods. The horizontal axis measures the total world endowment of good $X$. The vertical axis measure the total world endowment of good $Y$. Any point in the box then represents an allocation of goods between the two agents. The agent $H$ allocation is measured with respect to the lower left origin. The agent $F$ allocation is measured with respect to the upper right origin.

Each agent has a given initial endowment, here denoted point $E$. Furthermore, we assume that there is no possibility for trade. The indifference curves through point $E$ therefore represent autarchy welfare levels.

The key idea in this model is that trade can improve both agents' welfare. One agent gives some amount good $x$ to the other in return for an amount of good $y$. The "terms of trade", the rate of exchange between $x$ and $y$, is determined by the model. The model illustrates a number of important properties of market economies:
• Trade is mutually beneficial. So long as the transactions are voluntary, neither H nor F will be hurt by engaging in trade.

• Market prices can be used to guide the economy to a Pareto-efficient allocation, a state of affairs in which further mutually-beneficial trades are not possible.

• There is no guarantee that the gains from trade will be "fairly distributed" across consumers. A competitive equilibrium may produce a significant welfare increase for one consumer while have negligible impact on the other.

• There are multiple Pareto-efficient allocations, typically only one of which is a competitive equilibrium. We can use this model to demonstrate that the issues of efficiency and equity can be separated when there is the possibility of lump-sum income transfers between agents.

4.53.3.6 Modeling Pure Exchange with MPSGE

4.53.3.6.1 Example 4: A 2x2 Exchange Model In this program, we examine the simple two good, two agent model of exchange equilibrium. The world endowments for goods $x$ and $y$ are both equal to 1. Six parameters are used to parameterize the model. These are declared as scalars at the top of the program:

```
SCALAR XA AGENT A ENDOWMENT OF X ( 0 < XA < 1) /0.2/ 
YA AGENT A ENDOWMENT OF Y ( 0 < YA < 1) /0.8/ 
THETA_A AGENT A DEMAND SHARE PARAMETER FOR X /0.5/ 
THETA_B AGENT B DEMAND SHARE PARAMETER FOR X /0.8/ 
SIGMA_A AGENT A ELASTICITY PARAMETER /2.0/ 
SIGMA_B AGENT B ELASTICITY PARAMETER /0.5/ 
```

This model is actually simpler than the models presented above because we have no need for production. There are simply two commodities and two consumers. The consumers differ in terms of commodity endowments and preferences. The competitive equilibrium prices are such that supply equals demand for both goods and both agents spend an amount equal to their endowment income.

This model illustrates how to use computed function coefficients. See, for example, $Q:(1-\text{THETA\_A})$ in the $\text{DEMAND:\_A}$ block. Any numeric input field in an MPSGE model may be "computed", provided that the algebraic expression is enclosed within parentheses and legitimate GAMS code.

This model specification uses the default values for reference prices in the demand function blocks. When P:value is not specified in a D:\_I: or O:\_record, P:1 is assumed.

This model uses the more general constant-elasticity-of-substitution utility function.

```gams
$ONTEXT
$MODEL:EXCHANGE
$COMMODITIES:
PX ! EXCHANGE PRICE OF GOOD X
PY ! EXCHANGE PRICE OF GOOD Y
$CONSUMERS:
A ! CONSUMER A
B ! CONSUMER B
$DEMAND:A s:SIGMA\_A
E:PX Q:XA
```
The foregoing sets up the model and computes the competitive equilibrium. After GAMS returns from the solver, we declare and compute some report values.

Absolute levels of income and price returned from a general equilibrium model are not meaningful because a model determines only relative prices. For this reason, we report equilibrium income and price levels in relative terms.

In the final step, we compute an alternative efficient equilibrium, one in which the income levels for A and B are equal. The purpose of this exercise is to demonstrate the second welfare theorem. When incomes are both fixed, the equilibrium remains efficient, but the connection between market prices and endowment income is eliminated.

In GAMS/MPSGE, a variable may be fixed using the GAMS syntax

```
variable.fx = value;
```

as illustrated in this model:

```
A.FX = 1;
B.FX = 1;
$INCLUDE EXCHANGE.GEN
SOLVE EXCHANGE USING MCP;

SCALAR TRANSFER IMPLIED TRANSFER FROM A TO B AS A PERCENTAGE OF INCOME;

TRANSFER = 100 * ( A.L - PX.L * XA - PY.L * YA ); PRATIO = PX.L / PY.L;
IRATIO = A.L / B.L;

DISPLAY TRANSFER, PRATIO, IRATIO;
```
4.53.3.6.2 Exercises 4  (a) Set up a separate models which computes the autarchy price ratios for consumers A and B. (You can use one of the earlier models as a starting point.)

(b) Determine parameter values for which the endowment point is the equilibrium point.

(c) Set up a series of computations from which you can sketch the efficiency locus. Draw the Edgeworth box diagram which is consistent with these values.

4.53.3.6.3 Example 5: Import Tariffs and Market Power  The exchange model provides a remarkably useful tool for analyzing issues related to international trade. Formal trade theory is more complicated with the inclusion of separate production technologies. We will present some of those models below. Before going forward, however, we will consider a slight generalization of the 2x2 model exchange model. In this extension, we introduce independent markets for consumers A and B and trade activities which deliver goods from one market to the other.

The set of input parameters largely the same as in the previous example. Two new parameters are ad-valorem tariffs which apply on imports to each of the regions.

```
SCALAR XA  AGENT A ENDOWMENT OF X ( 0 le XA le 1) /0.2/ 
YA  AGENT A ENDOWMENT OF Y ( 0 le YA le 1) /0.8/ 
THETA_A  AGENT A DEMAND SHARE PARAMETER FOR X /0.4/ 
THETA_B  AGENT B DEMAND SHARE PARAMETER FOR X /0.6/ 
SIGMA_A  AGENT A ELASTICITY PARAMETER /1.0/ 
SIGMA_B  AGENT B ELASTICITY PARAMETER /1.0/ 
T_A  AD-VALOREM TARIFF ON IMPORTS TO AGENT A /0.10/ 
T_B  AD-VALOREM TARIFF ON IMPORTS TO AGENT B /0.10/ 
```

The program differs from the previous example in several respects. First, we introduce a separate commodity price for each agent. In the absence of tariffs, these prices are identical.

A second difference is that in this model trade activities deliver goods from one agent to the other. These are denoted \( M\{\text{good}\}\{\text{agent}\} \) for imports of \{good\} to \{agent\}. There are four flows which may be operated in only one direction (the activity levels are non-negative). In terms of initial endowments and preferences, this model has exactly the same economic structure as the previous model.

$END
The trade activities each have one input and one output. They simply deliver a good (X or Y) from one agent to the other. The new syntax presented here is specification of an ad-valorem tax. Adding a tax requires two new fields. The first is "A:" which specifies the tax agent, a consumer who collects the tax revenue as part of income. The second is "T:" which specifies the ad-valorem tax rate.

MPSGE permits taxes to be applied on production inputs and outputs but it does not permit taxes on final demand.

The tax applies on a net basis on inputs. For example, if we consider the MXA sector, the price of one unit of input is given by:

\[ P_{x,B} \times (1 + T_a) \]

where \( P_{x,B} \) is the net of tax price of a unit of \( x \) in the agent \( B \) market and \( T_a \) is the ad-valorem tariff rate.

The final portions of the file introduce one use of "MPSGE report variables". In this case, report variables are used to recover a Hicksian money-metric welfare index for each of the agents. We compute the initial, tariff-ridden equilibrium in order to compute the benchmark welfare levels. We then set all tariffs to zero and compute the free-trade equilibrium. Using the final welfare indices and the saved values of the benchmark welfare levels, we are able to report the change in welfare from removing tariff distortions.

4.53.4 Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae

Notes prepared for GAMS General Equilibrium Workshop held December, 1995 in Boulder Colorado

Author

Thomas F. Rutherford, Department of Economics, University of Colorado

Date
December, 1995
4.53 Mathematical Programming System for General Equilibrium analysis (MPSGE) 1355

4.53.4.1 The Basics

In many economic textbooks the constant elasticity of substitution (CES) utility function is defined as:

\[ U(x, y) = (\alpha x^\rho + (1 - \alpha) y^\rho)^{\frac{1}{\rho}}, \]

It is a fairly routine but tedious calculus exercise to demonstrate that the associated demand functions are:

\[ x(p_x, p_y, M) = \frac{\alpha}{p_x} \left( \frac{M}{\alpha \sigma p_x^{1-\sigma} + (1 - \alpha) \sigma p_y^{1-\sigma}} \right)^{\frac{1}{\sigma}}, \]

and

\[ y(p_x, p_y, M) = \frac{1 - \alpha}{p_y} \left( \frac{M}{\alpha \sigma p_x^{1-\sigma} + (1 - \alpha) \sigma p_y^{1-\sigma}} \right)^{\frac{1}{\sigma}}, \]

The corresponding indirect utility function has is:

\[ V(p_x, p_y, M) = \left( \frac{\alpha \sigma p_x^{1-\sigma} + (1 - \alpha) \sigma p_y^{1-\sigma}}{1} \right)^{\frac{1}{1 - \sigma}}, \]

Note that \( U(x, y) \) is linearly homogeneous:

\[ U(\lambda x, \lambda y) = \lambda U(x, y) \]

This is a convenient cardinalization of utility, because percentage changes in \( U \) are equivalent to percentage Hicksian equivalent variations in income.

Because \( U \) is linearly homogeneous, \( V \) is homogeneous of degree one in \( M \) and degree \(-1\) in \( p \).

In the representation of technology, we have an analogous set of relationships, based on the cost and compensated demand functions. If we have a CES production function of the form:

\[ y(K, L) = \gamma (\alpha K^\rho + (1 - \alpha) L^\rho)^{\frac{1}{\rho}}, \]

the unit cost function then has the form:

\[ c(p_K, p_L) = \left( \frac{1}{\gamma} \right) \left( \alpha \sigma p_K^{1-\sigma} + (1 - \alpha) \sigma p_L^{1-\sigma} \right)^{\frac{1}{1 - \sigma}}, \]

and associated demand functions are:

\[ K(p_K, p_L) = \left( \frac{y}{\gamma} \right) \left( \frac{\alpha \gamma c(p_K, p_L)}{p_K} \right)^{\sigma}, \]

and

\[ L(p_K, p_L) = \left( \frac{y}{\gamma} \right) \left( \frac{(1 - \alpha) \gamma c(p_K, p_L)}{p_L} \right)^{\sigma}. \]

In most large-scale applied general equilibrium models, we have many function parameters to specify with relatively few observations. The conventional approach is to *calibrate* functional parameters to a single benchmark equilibrium. For example, if we have benchmark estimates for output, labor, capital inputs and factor prices, we calibrate function coefficients by inverting the factor demand functions:

\[ \theta = \frac{p_K}{p_K + p_L}, \quad \rho = \frac{\sigma - 1}{\sigma}, \quad \alpha = \theta \bar{K}^\frac{\sigma - 1}{\rho}, \]

and

\[ \gamma = \bar{y} \left[ \alpha \bar{K}^\rho + (1 - \alpha) \bar{L}^\rho \right]^\frac{1}{\rho}. \]
### 4.53.4.2 The Calibrated Share Form

Calibration formulae for CES functions are messy and difficult to remember. Consequently, the specification of function coefficients is complicated and error-prone. For applied work using calibrated functions, it is much easier to use the “calibrated share form” of the CES function. In the calibrated form, the cost and demand functions explicitly incorporate:

- benchmark factor demands
- benchmark factor prices
- the elasticity of substitution
- benchmark cost
- benchmark output
- benchmark value shares

In this form, the production function is written:

\[ y = \bar{y} \left[ \theta \left( \frac{K}{\bar{K}} \right)^{\rho} + (1 - \theta) \left( \frac{L}{\bar{L}} \right)^{\rho} \right]^{\frac{1}{\rho}} \]

The only calibrated parameter, \( \theta \), represents the value share of capital at the benchmark point. The corresponding cost functions in the calibrated form is written:

\[ c(p_K, p_L) = \tilde{c} \left[ \theta \left( \frac{p_K}{\tilde{p}_K} \right)^{1-\sigma} + (1 - \theta) \left( \frac{p_L}{\tilde{p}_L} \right)^{1-\sigma} \right]^{\frac{1}{1-\sigma}} \]

where \( \tilde{c} = \tilde{p}_L \tilde{L} + \tilde{p}_K \tilde{K} \) and the compensated demand functions are:

\[ K(p_K, p_L, y) = \bar{K} \frac{y}{\tilde{c}} \left( \frac{p_K}{\tilde{p}_K} \right)^{\frac{\sigma}{\rho}} \]

and

\[ L(p_K, p_L, y) = \bar{L} \frac{y}{\tilde{c}} \left( \frac{p_L}{\tilde{p}_L} \right)^{\frac{\sigma}{\rho}}. \]

Normalizing the benchmark utility index to unity, the utility function in calibrated share form is written:

\[ U(x, y) = \left[ \theta \left( \frac{x}{\bar{x}} \right)^{\rho} + (1 - \theta) \left( \frac{y}{\bar{y}} \right)^{\rho} \right]^{\frac{1}{\rho}} \]

Defining the unit expenditure function as:

\[ e(p_x, p_y) = \left[ \theta \left( \frac{p_x}{\bar{p}_x} \right)^{1-\sigma} + (1 - \theta) \left( \frac{p_y}{\bar{p}_y} \right)^{1-\sigma} \right]^{\frac{1}{1-\sigma}} \]

the indirect utility function is:

\[ V(p_x, p_y, M) = \frac{M}{Me(p_x, p_y)} \]
and the demand functions are:

\[ x(p_x, p_y, M) = \bar{x} V(p_x, p_y, M) \left( \frac{e(p_x, p_y)p_x}{p_x} \right)^{\sigma} \]

and

\[ y(p_x, p_y, M) = \bar{y} V(p_x, p_y, M) \left( \frac{e(p_x, p_y)p_y}{p_y} \right)^{\sigma} \]

The calibrated form extends directly to the n-factor case. An n-factor production function is written:

\[ y = f(x) = \bar{y} \left[ \sum_i \theta_i \left( \frac{x_i}{\bar{x}_i} \right)^{\rho} \right]^{\frac{1}{\rho}} \]

and has unit cost function:

\[ C(p) = \bar{C} \left[ \sum_i \theta_i \left( \frac{p_i}{\bar{p}_i} \right)^{1-\sigma} \right] \frac{1}{1-\sigma} \]

and compensated factor demands:

\[ x_i = \bar{x}_i \frac{y}{\bar{y}} \left( \frac{C \bar{p}_i}{C p_i} \right)^{\sigma} \]

4.53.4.3 Excercises

(i) Show that given a generic CES utility function:

\[ U(x, y) = (\alpha \rho + (1 - \alpha) y^\rho)^{\frac{1}{\rho}} \]

can be represented in share form using:

\[ \bar{x} = 1, \quad \bar{y} = 1, \quad \bar{p}_x = t\alpha, \quad \bar{p}_y = t(1 - \alpha), \quad \bar{M} = t. \]

for any value of \( t > 0 \).

(ii) Consider the utility function defined:

\[ U(x, y) = (x - a)^\alpha (y - b)^{1-\alpha} \]

A benchmark demand point with both prices equal and demand for \( y \) equal to twice the demand for \( x \). Find values for which are consistent with optimal choice at the benchmark. Select these parameters so that the income elasticity of demand for \( x \) at the benchmark point equals 1.1.

(iii) Consider the utility function:

\[ U(x, L) = (\alpha L^\rho + (1 - \alpha) x^\rho)^{\frac{1}{\rho}} \]
which is maximized subject to the budget constraint:

\[ p_k x = M + \omega (L - L) \]

in which \( M \) is interpreted as non-wage income, \( \omega \) is the market wage rate. Assume a benchmark equilibrium in which prices for \( x \) and \( L \) are equal, demands for \( x \) and \( L \) are equal, and non-wage income equals one-half of expenditure on \( x \). Find values of \( \alpha \) and \( \rho \) consistent with these choices and for which the price elasticity of labor supply equals 0.2.

(iv) Consider a consumer with CES preferences over two goods. A price change makes the benchmark consumption bundle unaffordable, yet the consumer is indifferent. Graph the choice. Find an equation which determines the elasticity of substitution as a function of the benchmark value shares. (You can write down the equation, but it cannot be solved in closed form.)

(v) Consider a model with three commodities, \( x \), \( y \), and \( z \). Preferences are CES. Benchmark demands and prices are equal for all goods. Find demands for \( x \), \( y \) and \( z \) for a doubling in the price of \( x \) as a function of the elasticity of substitution.

(iv) Consider the same model in the immediately preceding question, except assume that preferences are instead given by:

\[ U(x, y, z) = \left( \beta \min(x, y)^\rho + (1 - \beta)z^\rho \right)^{\frac{1}{\rho}} \]

Determine \( \beta \) from the benchmark, and find demands for \( x \), \( y \) and \( z \) if the price of \( x \) doubles.

4.53.4.4 Flexibility and Non-Separable CES functions

We let \( \pi_i \) denote the user price of the \( i \)th input, and let \( x_i(\pi) \) be the cost-minimizing demand for the \( i \)th input. The reference price and quantities are \( \bar{\pi} \) and \( \bar{x}_i \). One can think of set \( i \) as \( \{K, L, E, M\} \) but the methods we employ may be applied to any number of inputs. Define the reference cost, and reference value share for \( i \)th input by \( \bar{C} \) and \( \theta_i \), where

\[ \bar{C} \equiv \sum_i \bar{\pi}_i \bar{x}_i \]

and

\[ \theta_i \equiv \frac{\pi_i \bar{x}_i}{\bar{C}}. \]

The single-level constant elasticity of substitution cost function in "calibrated share form" is written:

\[ C(\pi) = \bar{C} \left( \sum_i \theta_i \left( \frac{\pi_i}{\bar{\pi}_i} \right)^{1-\sigma} \right)^{\frac{1}{1-\sigma}} \]

Compensated demands may be obtained from Shephard’s lemma:

\[ x_i(\pi) = \frac{\delta C}{\delta \pi_i} \equiv C_i = \bar{x}_i \left( \frac{C(\pi) \bar{\pi}_i}{\bar{C} \pi_i} \right)^\sigma \]
Cross-price Allen-Uzawa elasticities of substitution (AUES) are defined as:

$$\sigma_{ij} \equiv \frac{C_{ij}C}{C_i C_j}$$

where

$$C_{ij} = \frac{\delta^2 C(\pi)}{\delta \pi_i \delta \pi_j} = \frac{\delta x_i}{\delta \pi_j} = \frac{\delta x_j}{\delta \pi_i}$$

For single-level CES functions:

$$\sigma_{ij} = \sigma \quad \forall i \neq j$$

The CES cost function exhibits homogeneity of degree one, hence Euler's condition applies to the second derivatives of the cost function (the Slutsky matrix):

$$\sum_j C_{ij}(\pi)(\pi_j) = 0$$

or, equivalently:

$$\sum_j \sigma_{ij}(\theta_j) = 0$$

The Euler condition provides a simple formula for the diagonal AUES values:

$$\sigma_{ii} = -\sum_{j \neq i} \sigma_{ij} \theta_j \theta_i$$

As an aside, note that convexity of the cost function implies that all minors of order 1 are negative, i.e. $$\sigma_{ii} < 0 \quad \forall i$$. Hence, there must be at least one positive off-diagonal element in each row of the AUES or Slutsky matrices. When there are only two factors, then the off-diagonals must be negative. When there are three factors, then only one pair of negative goods may be complements.

Let:

- $k$ be the reference the index of second-level nest
- $s_{ik}$ denote the fraction of good $i$ inputs assigned to the $k$th nest
- $\omega_k$ denote the benchmark value share of total cost which enters through the $k$th nest
- $\gamma$ denote the top-level elasticity of substitution
- $\sigma^k$ denote the elasticity of substitution in the $k$th aggregate
- $p_k(\pi)$ denote the price index associated with aggregate $k$, normalized to equal unity in the benchmark, i.e.:

$$p_k(\pi) = \left[ \frac{\sum_i s_{ik} \theta_i}{\omega_k \left( \frac{\pi_i}{\pi_i^*} \right)^{1-\sigma^k}} \right]^{1-\sigma^k}$$
The two-level nested, nonseparable constant-elasticity-of-substitution (NNCES) cost function is then defined as:

\[ C(\pi) = \bar{C} \left( \sum_k \omega_k p_k(\pi)^{1-\gamma} \right)^{\gamma} \]

Demand indices for second-level aggregates are needed to express demand functions in a compact form. Let \( z_k(\pi) \) denote the demand index for aggregate \( k \), normalized to unity in the benchmark; i.e.

\[ z_k(\pi) = \left( \frac{C(\pi)}{\bar{C}} \frac{1}{p_k(\pi)} \right)^{\gamma} \]

Compensated demand functions are obtained by differentiating \( C(\pi) \). In this derivative, one term arise for each nest in which the commodity enters, so:

\[ x_i(\pi) = \bar{x}_i \sum_k z_k(\pi) \left( \frac{p_k(\pi)\bar{\pi}_i}{\pi_i} \right)^{\sigma^k} = \bar{x}_i \sum_k \left( \frac{C(\pi)}{\bar{C}} \frac{1}{p_k(\pi)} \right)^{\gamma} \left( \frac{p_k(\pi)\bar{\pi}_i}{\pi_i} \right)^{\sigma^k} \]

Simple differentiation shows that benchmark cross-elasticities of substitution have the form:

\[ \sigma_{ij} = \gamma + \sum_k \left( \sigma^k - \gamma \right) s_{ik} s_{jk} \omega_k \]

Given the benchmark value shares \( \theta_i \) and the benchmark cross-price elasticities of substitution, \( \sigma_{ij} \), we can solve for values of \( s_{ik} \), \( \omega_k \), \( \sigma^k \) and \( \gamma \). We compute these parameters using a constrained nonlinear programming algorithm, CONOPT, which is available through GAMS, the same programming environment in which the equilibrium model is specified. Perroni and Rutherford (EER, 1994) prove that calibration of the NNCES form is possible for arbitrary dimensions whenever the given Slutsky matrix is negative semi-definite. The two-level (NxN) function is flexible for three inputs; and although we have not proven that it is flexible for 4 inputs, the only difficulties we have encountered have resulted from indefinite calibration data points.

Two GAMS programs are listed below. The first illustrates two analytic calibrations of the three-factor cost function. The second illustrates the use of numerical methods to calibrate a four-factor cost function.

**4.53.4.5 Two NNCES calibrations for a 3-input cost functions**

ABORT$SUM((I,J), ABS(AUES(I,J)-AUES(J,I))) " AUES values non-symmetric?";

*  Check that all value shares are positive:

ABORT$(SMIN(I, THETA(I)) LE 0) " Zero value shares are not valid:" ,THETA;

*  Fill in the elasticity matrices:

AUES(I,I) = 0; AUES(I,I) = -SUM(J, AUES(I,J)*THETA(J))/THETA(I); DISPLAY AUES;

*  Define variables and equations for NNCES calibration:

SET N Nests within the two-level NNCES function /N1*N4/,
      K(N) Nests which are in use;

VARIABLES
   S(I,N) Fraction of good I which enters through nest N,
   SHARE(N) Value share of nest N,
   SIGMA(N) Elasticity of substitution within nest N,
   GAMMA Elasticity of substitution at the top level,
   OBJ Objective function;

POSITIVE VARIABLES S, SHARE, SIGMA, GAMMA;

EQUATIONS
   SDEF(I) Nest shares must sum to one,
   TDEF(N) Nest share in total cost,
   ELAST(I,J) Consistency with given AUES values,
   OBJDEF Maximize concentration;

ELAST(I,J)$(ORD(I) GT ORD(J))..

   AUES(I,J) =E=  GAMMA +
   SUM(K, (SIGMA(K)-GAMMA) * S(I,K) * S(J,K)/SHARE(K));

TDEF(K)..
   SHARE(K) =E= SUM(I, THETA(I) * S(I,K));

SDEF(I)..
   SUM(N, S(I,N)) =E= 1;

*  Maximize concentration at the same time keeping the elasticities
*  to be reasonable:

OBJDEF..
   OBJ =E= SUM((I,K),S(I,K)*S(I,K))
   - SQR(GAMMA) - SUM(K, SQR(SIGMA(K)));

MODEL CESCALIB /ELAST, TDEF, SDEF, OBJDEF/;
* Apply some bounds to avoid divide by zero:

\[
SHARE.LO(N) = EPSILON;
\]

** SCALAR SOLVED Flag for having solved the calibration problem /0/
** MINSHR Minimum share in candidate calibration;

** SET TRIES Counter on the number of attempted calibrations /T1*T10/;
** We use the random number generator to select starting points,
** so it is helpful to initialize the seed so that the results
** will be reproducible:

** OPTION SEED=0;

** LOOP(TRIES$(NOT SOLVED),
** Initialize the set of active nests and the bounds:

\[
K(N) = YES;
S.LO(I,N) = 0; \quad S.UP(I,N) = 1;
SHARE.LO(N) = EPSILON; \quad SHARE.UP(N) = 1;
SIGMA.LO(N) = 0; \quad SIGMA.UP(N) = +INF;
\]

** Install a starting point:

\[
SHARE.L(K) = \max(\text{UNIFORM}(0,1), EPSILON);
S.L(I,K) = \text{UNIFORM}(0,1);
\]
\[
\text{GAMMA.L} = \text{UNIFORM}(0,1);
\]
\[
\text{SIGMA.L}(K) = \text{UNIFORM}(0,1);
\]

** Drop any basis information so that we start from scratch:

\[
SDEF.M(I) = 0; \quad TDEF.M(K) = 0; \quad ELAST.M(I,J) = 0;
\]

** SOLVE CESCALIB USING NLP MAXIMIZING OBJ;
** SOLVED = 1$(CESCALIB.MODELSTAT LE 2);
** We have a solution -- now see if it is not on a bound:

** IF (SOLVED,
** \[
\text{MINSHR} = \text{SMIN}(K, SHARE.L(K)) - EPSILON;
\]
** IF (MINSHR EQ 0,
** Drop nests which have shares equal to EPSILON in the current
** solution:

\[
K(N)$(SHARE.L(N) EQ EPSILON) = NO;
S.FX(I,N)$(NOT K(N)) = 0;
SHARE.FX(N)$(NOT K(N)) = 0;
SIGMA.FX(N)$(NOT K(N)) = 0;
\]
DISPLAY "Recalibrating with the following nests:", K;

SOLVE CESCALIB USING NLP MAXIMIZING OBJ;

IF (CESCALIB.MODELSTAT GT 2, SOLVED = 0);
    MINSHR = SMIN(K, SHARE.L(K)) - EPSILON;
    IF (MINSHR EQ 0, SOLVED = 0);
);

IF (SOLVED,
    DISPLAY "Function calibrated:", GAMMA.L, SIGMA.L, SHARE.L, S.L;
ELSE
    DISPLAY "Function calibration fails!";
);

*==========================================================================

Solution from MINOS5 obtained on the second try, following an
ITERATION INTERRUPT on the first:

----  151 Function calibrated:

----  151 VARIABLE GAMMA.L = 0.300 Elasticity of
         substitution at the
         top level

----  151 VARIABLE SIGMA.L Elasticity of substitution within nest N
         N3 7.804

----  151 VARIABLE SHARE.L Value share of nest N
         N1 0.604,  N2 0.266,  N3 0.030,  N4 0.100

----  151 VARIABLE S.L Fraction of good I which enters through
         nest N
         N1 0.797  0.069  0.133
         N2 0.960  0.040
         N3  E 1.000
         N4  0.630  0.304  0.067

*==========================================================================

The following solution is obtained by CONOPT on the second try, following a LOCALLY INFEASIBLE
termination on the first problem. Notice that it is identical to the MINOS5 solution except that the
nesting assignments have been permuted:
---- 149 Function calibrated:

---- 149 VARIABLE GAMMA.L = 0.300 Elasticity of substitution at the top level

---- 149 VARIABLE SIGMA.L Elasticity of substitution within nest N

N4 7.804

---- 149 VARIABLE SHARE.L Value share of nest N

N1 0.100, N2 0.604, N3 0.266, N4 0.030

---- 149 VARIABLE S.L Fraction of good I which enters through nest N

4.53.4.8 Calibrating Labor Supply and Savings Demand

This material was published in the MUG newsletter, 8/95.

Following Ballard, Fullerton, Shoven and Whalley (BFSW), we consider a representative agent whose utility is based upon current consumption, future consumption and current leisure. Changes in “future consumption” in this static framework are associated with changes in the level of savings. There are three prices which jointly determine the price index for future consumption. These are:

\[ P_I \] the composite price index for investment goods

\[ P_K \] the composite rental price for capital services

\[ P_C \] the composite price of current consumption.

All of these prices equal unity in the benchmark equilibrium.

Capital income in each future year finances future consumption, which is expected to cost the same as in the current period, \( P_C \) (static expectations). The consumer demand for savings therefore depends not only on \( P_I \), but also on \( P_K \) and \( P_C \), namely:

\[ P_S = \frac{P_I P_C}{P_K} \]

The price index for savings is unity in the benchmark period. In a counter-factual equilibrium, however, we would expect generally that \( P_S \neq P_I \). When these price indices are not equal, there is a “virtual tax payment” associated with savings demand.
Following BFSW, we adopt a nested constant-elasticity-of-substitution function to represent preferences. In this function, at the top level demand for savings (future consumption) trades off with a second CES aggregate of leisure and current consumption. These preferences can be summarized with the following expenditure function:

\[
P_U = \left[ \alpha P_H^{1-\sigma_S} + (1 - \alpha)P_H^{1-\sigma_S} \right]^{\frac{1}{1-\sigma_S}}
\]

Preferences are homothetic, so we have defined \( P_U \) as a linearly homogeneous cost index for a unit of utility. We conveniently scale this price index to equal unity in the benchmark. In this definition, \( \alpha \) is the benchmark value share for current consumption (goods and leisure). \( P_H \) is a compositive price for current consumption defined as:

\[
P_H = \left[ \beta P_I^{1-\sigma_L} + (1 - \beta)P_C^{1-\sigma_L} \right]^{\frac{1}{1-\sigma_L}}
\]

in which \( \beta \) is the benchmark value share for leisure within current consumption. Demand functions can be written as follows:

\[
S = S_0 \left( \frac{P_U}{P_F} \right)^{\frac{\sigma_S}{1-\sigma_S}} \frac{I}{I_0 P_U},
\]

\[
C = C_0 \left( \frac{P_H}{P_C} \right)^{\frac{\sigma_L}{1-\sigma_L}} \left( \frac{P_U}{P_H} \right)^{\frac{\sigma_S}{1-\sigma_S}} \frac{I}{I_0 P_U},
\]

and

\[
\ell = \ell_0 \left( \frac{P_H}{P_L} \right)^{\frac{\sigma_L}{1-\sigma_L}} \left( \frac{P_U}{P_H} \right)^{\frac{\sigma_S}{1-\sigma_S}} \frac{I}{I_0 P_U},
\]

Demands are written here in terms of their benchmark values (\( S_0, C_0 \) and \( \ell_0 \)) and current and benchmark income (\( I \) and \( I_0 \)).

There are four components in income. The first is the value of labor endowment (\( E \)), defined inclusive of leisure. The second is the value of capital endowment (\( K \)). The third is all other income (\( M \)). The fourth is the value of "virtual tax revenue" associated with differences between the shadow price of savings and the cost of investment.

\[
I = P_L E + P_K K + M + (P_S - P_I)S
\]

The following parameter values are specified exogenously:

1. \( \zeta = 1.75 \) is the ratio of labor endowment:

\[
\zeta \equiv \frac{E}{L_0}
\]

where \( L_0 \) is the benchmark labor supply. Given \( \zeta \) and \( L_0 \) we have:

\[
\ell_0 = L_0 (\zeta - 1)
\]

2. \( \xi = 0.15 \) is the uncompensated elasticity of labor supply with respect to the net of tax wage, i.e.

\[
\xi = \frac{\delta L}{\delta P_L} \frac{P_L}{L} = \frac{\delta(E - \ell)}{\delta P_L} \frac{P_L}{L} = -\frac{\delta \ell}{\delta P_L} \frac{P_L}{L}
\]
3. $\eta = 0.4$ is the elasticity of savings with respect to the return to capital:

\[
\eta \equiv \frac{\delta S}{\delta P_K} \frac{S}{P_K}
\]

Shephard's lemma applied at benchmark prices provides the following identities which are helpful in deriving expressions for $\eta$ and $\xi$:

\[
\frac{\delta P_U}{\delta P_H} = \alpha, \quad \frac{\delta P_U}{\delta P_S} = 1 - \alpha, \quad \frac{\delta P_H}{\delta P_L} = \beta, \quad \frac{\delta P_H}{\delta P_C} = 1 - \beta,
\]

It is then a relatively routine application of the chain rule to show that:

\[
\xi = (\zeta - 1) \left[ \sigma_L + \beta(\sigma_S - \sigma_L) - \alpha \beta(\sigma_S - 1) - \frac{E}{I_0} \right]
\]

and

\[
\eta = \sigma_S \alpha + \frac{K}{I_0}
\]

The expression for $\eta$ does not involve $\sigma_L$, so we may first solve for $\sigma_S$ and use this value in determining $\sigma_L$:

\[
\sigma_S = \frac{\eta - \frac{K}{I_0}}{\alpha}
\]

and

\[
\alpha_L = \frac{\xi - \sigma_S \beta(1 - \alpha) - \alpha \beta + \frac{E}{I_0}}{1 - \beta}
\]

### 4.53.4.9 A Maquette Illustrating Labor Supply and Savings Demand Calibration

* Exogenous elasticity:

SCALAR XI UNCOMPENSATED ELASTICITY OF LABOR SUPPLY /0.15/,
ETA ELASTICITY OF SAVINGS WRT RATE OF RETURN /0.40/,
ZETA RATIO OF LABOR ENDOWMENT TO LABOR SUPPLY /1.75/;

* Benchmark data:

SCALAR C0 CONSUMPTION /2.998845E+2/,
S0 SAVINGS /70.02698974/,
LS0 LABOR SUPPLY / 2.317271E+2/,
K0 CAPITAL INCOME /93.46960577/,
PLO MARGINAL WAGE /0.60000000/;

* Calibrated parameters:

SCALAR EL0 LABOR ENDOWMENT
L0 LEISURE DEMAND
M0 NON-WAGE INCOME
I EXTENDED GROSS INCOME
ETAMIN SMALLEST PERMISSIBLE VALUE FOR ETA,
XIMIN SMALLEST PERMISSIBLE VALUE FOR XI,
ALPHA CURRENT CONSUMPTION VALUE SHARE
BETA LEISURE VALUE SHARE IN CURRENT CONSUMPTION
SIGMA_L ELASTICITY OF SUBSTITUTION WITHIN CURRENT CONSUMPTION
SIGMA_S ELASTICITY OF SUBSTITUTION - SAVINGS VS CURRENT CONSUMPTION
TS SAVINGS PRICE ADJUSTMENT;

* Convert labor supply into net of tax units:
LS0 = LS0 * PL0;
* Labor endowment (exogenous):
ELO = ZETA * LS0;
* Leisure demand:
L0 = ELO - LS0;
* Non-labor, non-capital income:
M0 = C0 + S0 - LS0 - K0;
* Extended gross income:
I = L0 + C0 + S0;
* Leisure share of current consumption:
BETA = L0 / (C0 + L0);
* Current consumption value share:
ALPHA = (L0 + C0) / I;
* Calibrated elasticity:
SIGMA_S = (ETA - K0 / I) / ALPHA;
ETAMIN = K0 / I;
ABORT$(SIGMA_S LT 0) " Error: cannot calibrate SIGMA_S", ETAMIN;
* Calibrated elasticity of substitution between leisure and consumption:
SIGMA_L = (XI*(LS0/L0)-SIGMA_S*BETA*(1-ALPHA)-ALPHA*BETA+EL0/I)/(1-BETA);
XIMIN = -(L0/LS0) * (- SIGMA_S * BETA * (1-ALPHA) - ALPHA*BETA + EL0/I);
ABORT$(SIGMA_L LT 0) " Error: cannot calibrate SIGMA_L", XIMIN;
DISPLAY "Calibrated elasticities:", SIGMA_S, SIGMA_L;

* VERIFY THE BENCHMARK:

CHKCAL.ITERLIM = 0;
$INCLUDE CHKCAL.GEN
SOLVE CHKCAL USING MCP;

* CHECK THE LABOR SUPPLY ELASTICITY:

PL.L = 1.001;

CHKCAL.ITERLIM = 0;
$INCLUDE CHKCAL.GEN
SOLVE CHKCAL USING MCP;

* Compute induced changes in labor supply using the labor market
* "marginal", PL.M. This marginal returns the net excess supply of
* labor at the given prices. We started from a balanced benchmark,
* with no change in labor demand (the iteration limit was zero).
* Hence, PL.M returns the magnitude of the change in labor supply.
* We multiply by the benchmark wage (1) and divide by the benchmark
* labor supply (LS0) to produce a finite difference approximation
* of the elasticity:

DISPLAY "CALIBRATION CHECK -- THE FOLLOWING VALUES SHOULD BE IDENTICAL:", XI;
XI = (PL.M / 0.001) * (1 / LS0);
DISPLAY XI;

PL.L = 1.0;

* CHECK THE ELASTICITY OF SAVINGS WRT RENTAL RATE OF CAPITAL:

PK.L = 1.001;
PS.L = 1 / 1.001;
TS = 1 / 1.001 - 1;

CHKCAL.ITERLIM = 0;
Compute elasticity of savings with respect to the rental rate of capital. This requires some recursion in order to account for the effect of changes in savings on effective income. When PK increases, PS declines -- there is an effective "subsidy" for saving, paid from consumer income. In order to obtain a difference approximation for the elasticity of savings response, we need to make sure the virtual tax payments are properly handled. In the MPSGE model, this means that the level value for S must be adjusted so that it exactly equals the savings. We do this recursively:

SET ITER /IT1*IT5/;

PS.M = 1;
LOOP(ITER$(ABS(PS.M) GT 1.0E-8),
$INCLUDE CHKCAL.GEN
    SOLVE CHKCAL USING MCP;
    S.L = S.L - PS.M;
);
DISPLAY "CALIBRATION CHECK -- THE FOLLOWING VALUES SHOULD BE IDENTICAL. ", ETA;
ETA = ((S.L - S0) / 0.001) * (1 / S0);
DISPLAY ETA;

4.54 Glossary

<table>
<thead>
<tr>
<th>acronym</th>
<th>A GAMS data type used for storing non-numeric (aka logical or categorical) data. For more details, see section Acronyms.</th>
</tr>
</thead>
<tbody>
<tr>
<td>alias</td>
<td>An alternative name for a set, used to have multiple indices running over a common set. For more information, see section The Alias Statement: Multiple Names for a Set.</td>
</tr>
<tr>
<td>algorithm</td>
<td>A sequence of actions to perform in order to solve a problem. GAMS solvers contain algorithm implementations, so the two terms are sometimes used interchangeably.</td>
</tr>
<tr>
<td>assignment</td>
<td>The statement used to assign values to an identifier. For a detailed introduction, see section The Assignment Statement.</td>
</tr>
<tr>
<td>basic</td>
<td>A column is basic if it is in the basis maintained by the solution method for the problem in question (e.g. by the simplex method for LP). A row is basic if the elementary column associated with its slack variable is basic. For more details, see Mathematical Programming Glossary.</td>
</tr>
<tr>
<td>binding</td>
<td>An inequality constraint or variable bound is binding when the value of the associated slack is zero, i.e. when it is satisfied as an equality. See also Mathematical Programming Glossary.</td>
</tr>
<tr>
<td>bounds</td>
<td>Upper and lower limits on the possible values that a column may assume in a feasible solution. May be infinite, i.e. no limit is imposed.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>column</td>
<td>An individual decision variable in the model passed to a solver. Also called a single variable in the GAMS listing file. An indexed GAMS variable typically contains many columns.</td>
</tr>
<tr>
<td>compilation</td>
<td>The initial phase of GAMS processing, when the program is being checked for syntax and consistency.</td>
</tr>
<tr>
<td>compile-time constant</td>
<td>A compile-time constant is a string that will be replaced at compile-time with a fixed value. These constants are usually related to a function, model attribute or option and are used for their mnemonic and descriptive value. See section Compile-Time Constants.</td>
</tr>
<tr>
<td>compile-time variable</td>
<td>Special variables that are substituted with their values at compile-time. For further information, see section Compile-Time Variables.</td>
</tr>
<tr>
<td>constraint</td>
<td>A relationship between variables that must hold in a feasible solution. A constraint can refer to a single relationship (i.e. a row) or to a collection of rows, such as an equation. For further details, see Mathematical Programming Glossary.</td>
</tr>
<tr>
<td>continuous</td>
<td>Used to describe functions (in the usual mathematical way) and variables. Roughly speaking, a function is continuous if its graph has no breaks or jumps in it. A continuous variable may assume any value within its bounds, in contrast to binary or integer variables.</td>
</tr>
<tr>
<td>controlling sets</td>
<td>See driving sets.</td>
</tr>
<tr>
<td>data types</td>
<td>Each symbol or identifier must be declared as one of the available data types, e.g set, parameter, equation, or model. Note that scalars and tables are not separate data types, but convenient input formats for certain parameters. See also section Data Types and Definitions.</td>
</tr>
<tr>
<td>decision variable</td>
<td>A decision variable (aka endogenous variable) represents a decision to be made, e.g. the amount to produce or consume or the unit price to charge. Decision variables are the unknowns of a mathematical programming model. In contrast, exogenous variables or parameters are outside of the decision maker's control. See also the Mathematical Programming Glossary.</td>
</tr>
<tr>
<td>declaration</td>
<td>The introduction of an identifier along with the specification of its data type. A declaration may also include the specification of data or initial values, in which case it also acts as a definition. See also section Classification of GAMS Statements.</td>
</tr>
<tr>
<td>default</td>
<td>The value used, or the action taken, if the user provides no information.</td>
</tr>
<tr>
<td>definition</td>
<td>A statement specifying the content or data associated with a GAMS identifier, e.g. the equations in a model, the algebra of an equation, the elements of a set, or the initial values of a parameter. Definitions are processed during compilation. See also section Classification of GAMS Statements.</td>
</tr>
<tr>
<td>direction</td>
<td>The direction of optimization, i.e. maximization or minimization.</td>
</tr>
<tr>
<td>discontinuous</td>
<td>A function is discontinuous if it is not continuous. Sometimes, we call a function discontinuous if its derivatives are not continuous, i.e. it is nonsmooth.</td>
</tr>
<tr>
<td><strong>discrete</strong></td>
<td>A discrete variable is any variable that is not continuous. For example, binary and integer variables are discrete. For more details, see section &quot;Types of Discrete Variables.&quot;</td>
</tr>
<tr>
<td><strong>dollar control option</strong></td>
<td>Directives or options used to control input or output details associated with the GAMS compiler. They are introduced in chapter &quot;Dollar Control Options.&quot;</td>
</tr>
<tr>
<td><strong>dollar operator</strong></td>
<td>An operator used to indicate and define conditional expressions in assignment statements and equation definitions. For more information, see section &quot;The Dollar Condition.&quot;</td>
</tr>
<tr>
<td><strong>domain checking</strong></td>
<td>A system of checks that ensures that operations and relationships involving sets and domains are logically consistent. For example, referencing ( \text{pop}(t,\text{city}) ) when we have a declaration of ( \text{pop}(\text{city},t) ) is a logical error that domain checking will catch. For more information, see section &quot;Domain Checking.&quot;</td>
</tr>
<tr>
<td><strong>domain of definition</strong></td>
<td>The set of tuples (i.e. label combinations) for which an indexed equation is defined. When a solve statement is executed, a row of the equation is generated for each member of the domain of definition.</td>
</tr>
<tr>
<td><strong>domain restriction condition</strong></td>
<td>The narrowing of the domain of definition with a dollar operator. When used in this way, the dollar operator occurs on the left of the symbol &quot;.&quot; in an equation definition. For more details, see section &quot;Dollar Control over the Domain of Definition.&quot;</td>
</tr>
<tr>
<td><strong>driving set</strong></td>
<td>The set or list of sets that an indexed operation or domain runs or is defined over. Loops, indexed operations like ( \text{sum} ), and domains of definition all make use of driving sets.</td>
</tr>
<tr>
<td><strong>dynamic set</strong></td>
<td>A set is dynamic if it has been changed with an assignment statement. Dynamic sets cannot be used with lag operations or in domain declarations. For more information, see chapter &quot;Dynamic Sets.&quot;</td>
</tr>
<tr>
<td><strong>echo print</strong></td>
<td>In the output file, the echo print is a listing of the input with added line numbers. Details are given in section &quot;The Echo Print of the Input File.&quot;</td>
</tr>
<tr>
<td><strong>endogenous</strong></td>
<td>Endogenous variables are used in economics, statistics, and other disciplines. In the GAMS context, they are synonymous with variables, i.e. values that change when a solve statement is processed. See also the discussion in section &quot;Functions in Equation Definitions.&quot;</td>
</tr>
<tr>
<td><strong>equation</strong></td>
<td>The GAMS data type used to specify required relationships between activity levels of variables. They are introduced and discussed in detail in chapter &quot;Equations.&quot;</td>
</tr>
<tr>
<td><strong>execution</strong></td>
<td>The second phase of GAMS processing, when GAMS is actually carrying out data transformations or generating a model.</td>
</tr>
<tr>
<td><strong>execution statements</strong></td>
<td>Instructions to carry out actions such as data transformations, model solves and report generation. Examples include the assignment statement, the loop statement and the solve statement. For a full list, see section &quot;Classification of GAMS Statements.&quot;</td>
</tr>
<tr>
<td><strong>Exogenous</strong></td>
<td>Exogenous variables are used in economics, statistics, and other disciplines. In the GAMS context, they are synonymous with constants, i.e. values that do not change when a solve statement is processed. These are most often parameters but any variable or equation field will be treated exogenously when it appears in an equation. See also the discussion in section Functions in Equation Definitions.</td>
</tr>
<tr>
<td><strong>Explanatory text</strong></td>
<td>See text.</td>
</tr>
<tr>
<td><strong>Extended arithmetic</strong></td>
<td>In GAMS, the usual computer arithmetic is extended to include special values (e.g. inf) and the results of operations and functions that use them. For example, 6 + inf is inf and min(6, inf) is 6. See section Extended Range Arithmetic and Error Handling for details.</td>
</tr>
<tr>
<td><strong>External equation</strong></td>
<td>An equation defined in an external module. For example, on Windows systems, external equations are defined by a DLL. See section External Equations for details.</td>
</tr>
<tr>
<td><strong>Extrinsic function</strong></td>
<td>A function that is imported into a GAMS program from an external function library. Once imported, extrinsic functions can be used in the same way as intrinsic functions like cos and exp. See section Extrinsic Functions for details.</td>
</tr>
<tr>
<td><strong>E-format</strong></td>
<td>A convenient text-based (i.e. unsuperscripted) way to represent numbers in scientific notation in which the exponent of the 10 is prefixed by the letter e. For example, one US mile = 1.609344e+03 meters.</td>
</tr>
<tr>
<td><strong>Feasible</strong></td>
<td>Often used to describe a model (or a subset of constraints within a model) that has at least one feasible solution, but also used to describe a point that satisfies a set of constraints. For more information, see Mathematical Programming Glossary. See also infeasible.</td>
</tr>
<tr>
<td><strong>Feasible solution</strong></td>
<td>A solution to a model in which all column activity levels are within the bounds and all the constraints are satisfied. For more information, see Mathematical Programming Glossary.</td>
</tr>
<tr>
<td><strong>Identifier</strong></td>
<td>The name given to a data entity in a GAMS program. Also called a symbol. See section Identifiers for further details.</td>
</tr>
<tr>
<td><strong>Indexed operation</strong></td>
<td>An operation (e.g. sum or max) that is performed over one or more indices. See also section Indexed Operations.</td>
</tr>
<tr>
<td><strong>Inequality constraint</strong></td>
<td>A constraint in which the imposed relationship between the columns is not specified with an equality but instead with an inequality (e.g. “greater than or equal to”, “less than or equal to”). The GAMS syntax =G= and =L= is used in equation definitions to specify these relationships.</td>
</tr>
<tr>
<td><strong>Infeasible</strong></td>
<td>Not feasible. Used to describe either a model that has no feasible solution or an intermediate solution or point that is not feasible (although feasible solutions may exist).</td>
</tr>
<tr>
<td><strong>initialization</strong></td>
<td>Associating or assigning <em>initial values</em> to an identifier as part of the declaration or definition of the identifier. We typically talk about the initialization of only those identifiers (e.g. sets and parameters) that can be <em>assigned</em> different values later. For identifiers like models and equations, we say they are <em>defined</em>, not <em>initialized</em>.</td>
</tr>
<tr>
<td><strong>intrinsic function</strong></td>
<td>Functions that are provided by and part of GAMS, including mathematical, string, logical, time/calendar, and utility functions. Contrast to extrinsic functions.</td>
</tr>
<tr>
<td><strong>label</strong></td>
<td>Sets are built up from labels (aka <em>elements</em>). One-dimensional sets are collections of labels, while multi-dimensional sets contain tuples of labels. See section Labels for details.</td>
</tr>
<tr>
<td><strong>list</strong></td>
<td>See list format.</td>
</tr>
<tr>
<td><strong>list format</strong></td>
<td>GAMS data may be initialized by data in list format, i.e. a list where each tuple of labels in the data is specified in full. Data may also be displayed in list format, in which case each nondefault value is displayed via a fully-specified tuple of labels.</td>
</tr>
<tr>
<td><strong>macro</strong></td>
<td>A macro is a fragment of code that has been given a name: whenever the name is used, that name is replaced by the contents of the macro (i.e. the fragment of code). This is useful for defining and automating structured text replacement, e.g. to replace the text $MYOBJ(x)$ with $[sqr(x) + exp(x-2)/7]$. See section Macros in GAMS for details.</td>
</tr>
<tr>
<td><strong>marginal</strong></td>
<td>Marginal values (aka &quot;dual values&quot;, &quot;reduced costs&quot;, &quot;shadow prices&quot;, or &quot;multipliers&quot;) are stored in the &quot;<em>m</em>&quot; variable attribute or equation attribute. The GAMS sign convention is this: the marginal value represents the amount and direction of change in the objective value given a <em>unit increase</em> in the binding constant (e.g. an active variable bound or right-hand side). For further information, see Mathematical Programming Glossary.</td>
</tr>
<tr>
<td><strong>matrix element</strong></td>
<td>See nonzero element.</td>
</tr>
<tr>
<td><strong>model generation</strong></td>
<td>An initial step in processing a solve statement, where a model instance is generated (based on the equation definitions and the data referenced by those definitions) for the solver.</td>
</tr>
<tr>
<td><strong>model list</strong></td>
<td>The list of <em>equations</em> that are part of the model, as specified in the model statement. For further details, see section The Model Statement.</td>
</tr>
<tr>
<td><strong>model status</strong></td>
<td>An integer returned by the solver that gives information about the model (e.g. INFEASIBLE), about the point returned by the solver (e.g. LOCALLY INFEASIBLE), or both (UNBOUNDED NO SOLUTION RETURNED). For an overview of all values, see section Model Status.</td>
</tr>
<tr>
<td><strong>nonbasic</strong></td>
<td>A column that is not basic and (in nonlinear problems) not superbasic. Typically, nonbasic columns behave or are treated as if they are fixed at a bound. If the solution is feasible, the value of a nonbasic column will equal a finite bound (or zero if there are no finite bounds).</td>
</tr>
<tr>
<td><strong>nonlinear nonzero</strong></td>
<td>In a linear programming problem, the nonzero elements of the constraint matrix are constant. In a nonlinear problem, elements of the Jacobian matrix vary where variables appear nonlinearly. These non-constant Jacobian elements are called nonlinear nonzeros.</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>nonoptimal</strong></td>
<td>Not optimal. A solution is nonoptimal if other solutions exist with better objective values. A variable is nonoptimal if its marginal (aka reduced cost) has the wrong sign. For example, in a minimization, a variable at lower bound having a negative marginal is nonoptimal. In the simplex method, a variable is nonoptimal if it is nonbasic and would improve the objective if it entered the basis.</td>
</tr>
<tr>
<td><strong>nonsmooth</strong></td>
<td>A function is nonsmooth if it is not smooth, i.e. if the function itself or its derivatives are not continuous. For example, the absolute value function is nonsmooth because of the kink at the origin: its derivative is not continuous there.</td>
</tr>
<tr>
<td><strong>nonzero element</strong></td>
<td>An element or coefficient of a matrix (e.g. the constraint matrix of an LP or the Jacobian matrix of an NLP) that is not zero. Most mathematical programming problems are sparse, i.e. only a small proportion of the elements in the constraint or Jacobian matrix are nonzero.</td>
</tr>
<tr>
<td><strong>objective row (or function)</strong></td>
<td>Solver systems often require the specification of a row or (for nonlinear systems) a function whose value will be optimized. A GAMS model, in contrast, is solved by specifying a scalar objective variable to be optimized.</td>
</tr>
<tr>
<td><strong>objective value</strong></td>
<td>The current value of the objective row or of the objective variable.</td>
</tr>
<tr>
<td><strong>objective variable</strong></td>
<td>The variable to be optimized, as specified in the solve statement.</td>
</tr>
<tr>
<td><strong>optimal</strong></td>
<td>A feasible solution in which the objective value is the best possible. For more details, see Mathematical Programming Glossary.</td>
</tr>
<tr>
<td><strong>optimality gap</strong></td>
<td>The optimality gap is a metric for the distance (or an upper bound on the distance) between the objective value of the current feasible solution and the optimal objective value. For more information, see Mathematical Programming Glossary. In GAMS, MIP and global solvers terminate when the optimality gap is sufficiently reduced: see the options optCA and optCR for details.</td>
</tr>
<tr>
<td><strong>option</strong></td>
<td>A control that allows users to change or influence the behavior or parameters in many different parts of the system. Options in GAMS may be set in three different ways: with model attributes, command line parameters, and option statements. A full list of all options with detailed descriptions is given in section Detailed Descriptions of All Options.</td>
</tr>
<tr>
<td><strong>ordered set</strong></td>
<td>A one-dimensional set is ordered if the definition or initialization of the elements in the set corresponds to the order of the labels in the universe. Only sets that are ordered (and static) can be treated as sequences, i.e. used in lags and leads and with Ord-type operations. For more information, see chapter Sets as Sequences: Ordered Sets.</td>
</tr>
<tr>
<td><strong>output file</strong></td>
<td>A file, also called the listing file, produced (by default) by the run of a GAMS program. It contains output that describes or logs the run in question. For details see chapter GAMS Output.</td>
</tr>
<tr>
<td><strong>parameter</strong></td>
<td>A data type in GAMS used to store (indexed) constant data. For details on parameters, see chapter Data Entry: Parameters, Scalars and Tables.</td>
</tr>
<tr>
<td><strong>problem type</strong></td>
<td>A class of models that is characterized or defined by the type of algebra accepted (e.g. linear or nonlinear), the GLOSSARY_variable_type &quot;variable types&quot; allowed (e.g. continuous vs. discrete), and the definition of what it means to solve the model or problem (e.g. optimization vs. MCP). A list of all problem types in GAMS is given in section Classification of Models.</td>
</tr>
<tr>
<td><strong>program</strong></td>
<td>A GAMS input file. Typically a program defines a model and solves it, but programs can also work only with data or act as scripts that call other programs.</td>
</tr>
<tr>
<td><strong>relational operator</strong></td>
<td>This term may be used in two ways. First, in an equation definition, it describes the type of relationship that the equation specifies. An example is equality, as specified with the symbol $=$. For more information, see Table Equation Types. Second, in a logical expression, a relational operator compares two numerical expressions and returns a logical value. For details see section Logical Conditions: Numerical Relational Operators.</td>
</tr>
<tr>
<td><strong>right-hand side</strong></td>
<td>The value of the constant term in a constraint.</td>
</tr>
<tr>
<td><strong>row</strong></td>
<td>An individual constraint in the model passed to a solver. Also called a single equation in the GAMS listing file. An indexed GAMS equation typically contains many rows.</td>
</tr>
<tr>
<td><strong>scalar</strong></td>
<td>An un-indexed parameter, or the statement used to declare or define this parameter. See also section Scalars.</td>
</tr>
<tr>
<td><strong>set</strong></td>
<td>A collection of elements (aka labels) or element tuples. The set statement is used to declare and define a set. Sets are introduced and discussed in detail in chapter Set Definition.</td>
</tr>
<tr>
<td><strong>simplex method</strong></td>
<td>An algorithm often used to solve linear programming problems. For more details, see Mathematical Programming Glossary.</td>
</tr>
<tr>
<td><strong>singleton set</strong></td>
<td>A special set that has at most one element (zero elements are allowed as well). For more information, see section Singleton Sets.</td>
</tr>
<tr>
<td><strong>slack</strong></td>
<td>The amount by which an inequality constraint or variable bound is not binding.</td>
</tr>
<tr>
<td><strong>slack variable</strong></td>
<td>A non-negative variable introduced to represent the slack in an inequality constraint and to convert the inequality into an equality. For further information, see Mathematical Programming Glossary.</td>
</tr>
<tr>
<td><strong>smooth</strong></td>
<td>A function that is continuous and whose derivatives are all continuous is smooth. Sometimes we consider a function smooth if enough of its derivatives are continuous.</td>
</tr>
<tr>
<td><strong>solver</strong></td>
<td>An implementation of an algorithm or algorithms for solving models of a given problem type or types. An example is MINOS and QUADMINOS, which is used to solve both linear and nonlinear programming problems.</td>
</tr>
<tr>
<td><strong>solver status</strong></td>
<td>An integer returned by the solver that indicates the solver termination condition, i.e. why the solver stopped. For details, see section Solver Status.</td>
</tr>
<tr>
<td><strong>statements</strong></td>
<td>Statements (aka units or sentences) are the fundamental building blocks of GAMS programs: each program is a sequence of statements. Statements are used to declare identifiers, define equations, create loops, and solve models. A full list of GAMS statements is given in section Classification of GAMS Statements.</td>
</tr>
<tr>
<td><strong>static set</strong></td>
<td>Used in two slightly different ways: a set is static if it has not changed (i.e. it is not dynamic) or if it cannot change, i.e. it is immutable. Usually, sets are either used in ways that make them immutable (e.g. as domains or with lags and leads) or in ways that make them dynamic (i.e. by assigning to them): in such cases, static is synonymous with immutable.</td>
</tr>
<tr>
<td><strong>superbasic</strong></td>
<td>Some algorithms for nonlinear programming make use of superbasic variables that are neither basic (i.e. in the basis) nor nonbasic (i.e. temporarily fixed at a bound). These algorithms often search in the space defined by these superbasic variables. For further information, see Mathematical Programming Glossary.</td>
</tr>
<tr>
<td><strong>symbol</strong></td>
<td>An identifier.</td>
</tr>
<tr>
<td><strong>table</strong></td>
<td>A table statement is often a convenient way to define a parameter having two or more dimensions. For details see section Tables.</td>
</tr>
<tr>
<td><strong>text</strong></td>
<td>An optional description associated with an identifier or with an element of a set. For details see section Text.</td>
</tr>
<tr>
<td><strong>unique element</strong></td>
<td>A label used to define set membership.</td>
</tr>
<tr>
<td><strong>universe</strong></td>
<td>Also called the universal set, it is denoted by the symbol ‘*’ and contains all the labels that have been declared in the program plus any labels used as if they were declared (e.g. link(‘sink’,j) = NO;). If an identifier is declared using the universe, that effectively turns off or limits domain checking for that identifier. For more details, see section The Universal Set: * as Set Identifier.</td>
</tr>
<tr>
<td><strong>variable type</strong></td>
<td>Variables are classified or typed based on their default bounds and the values they are allowed to take. This latter classification partitions variables into continuous or discrete. For example, free variables have no default bounds and can take any value between their bounds: they are continuous. In contrast, binary variables can take only the values zero and one. See section Variable Types for details.</td>
</tr>
<tr>
<td><strong>zero default</strong></td>
<td>Some GAMS data (e.g. parameters, lower bounds for positive variables) have a default value of zero. These default zero values are not stored. However, unless other values are provided via initialization or assignment, zero will be used when the data value is taken.</td>
</tr>
</tbody>
</table>
Chapter 5

Solver Manuals

A large number of solvers for mathematical programming models have been hooked up to GAMS. The tables below provide a brief description of each solver, the model types each solver is capable of solving, and the platforms supported by each solver. For general information on using GAMS solvers, see Solver Usage.

### 5.1 Model Types

GAMS is able to formulate models in many different types of problem classes or model types. Typically, a solver will be capable of solving (i.e. will accept as input) more than one model type. The solver/model type matrix shows which solver is capable of which model type:

* Deterministic global solver

When choosing a solver, some judgement should be applied when considering the listed model type capabilities for the solver - the same capability "check boxes" does not imply equality in capacity or suitability. For example, take a hypothetical solver WeOpt designed to solve MINLP models. Since the problem class MINLP includes NLP, MIP, and LP as subclasses, solver WeOpt could include these capabilities also. If WeOpt is also a good performer on NLP models, it would include that capability. But if it does not shine at all as a MIP or LP solver, we would choose not to include MIP and LP in the capability list for WeOpt. In such a case one can always solve using a more general model type (e.g. solve an LP model as NLP so WeOpt can be used), but WeOpt will not advertise itself as an LP solver. Since the WeOpt solver does not even recognize MCP or MPEC models, we don't include those capabilities.

There are two types of non-linear solvers: local and global. A local solver can find a local optimum but generally cannot comment on global optimality of the solution. A local optimum is a point where the objective value is better than its neighboring points but could be worse than a distant point. On the other
hand, a global solver can find and prove that the obtained solution is a global optimum i.e., there is no feasible solution that would result in a better objective value. It is worth noting that a local solver can solve a model to global optimality in some special cases. In the table shown, the entries with * in the column Global indicate solvers that can solve a model to global optimality.

There are other differences in solvers that are difficult to quantify or cannot be captured by a capability table like the one shown. For example, for nonconvex NLP or QCP models, one solver could look only for first-order stationary points, another for local solutions, a third for local solutions using a scatter search or similar search heuristic, and a fourth could do a true global search for the global optimum. The relative merits (measured typically by speed alone) of solvers is the subject of considerable benchmarking activity and discussion.

The GAMS sales team can help answer questions you may have about solver capability. We also offer free evaluation licenses to help you decide what solvers are most suitable for your models.

### 5.2 Supported Platforms

The solver/platform matrix shows which platforms each solver is supported on. In addition, where a vendor has discontinued solver support for a particular platform and we continue to ship the last available supported version, this version number is indicated as well.

5.3 AlphaECP

5.3.1 Introduction

AlphaECP is a Mixed-Integer Non-Linear Programming (MINLP) solver based on the extended cutting plane (ECP) method. The solver can be applied to general MINLP problems and it can ensure global optimal solutions for pseudo-convex MINLP problems. The documentation is written as if the considered problem is a minimization problem, if not otherwise denoted.

The ECP method is an extension of Kelley’s cutting plane method, which was originally given for convex NLP problems [105]. The method only requires the solution of a MIP sub-problem in each iteration. The MIP sub-problems can be solved to optimality, to feasibility, or only to an integer relaxed solution in intermediate iterations. This makes the ECP algorithm efficient and easy to implement. Further information about the underlying algorithm can be found in [200] and [145] [174] [199] [201].

Further developments of the GAMS/AlphaECP algorithm have introduced additional functionality. A NLP solver can now be called at MIP solutions. This improves AlphaECP’s ability to find feasible and accurate solutions, especially for MINLP problems which mainly contain continuous variables. Furthermore, a heuristic that reselects cutting planes during the iteration procedure can be used to improve the capability of solving non-convex problems. In addition to the termination based on constraint tolerance the algorithm can terminate also if relative objective gap termination criterion is satisfied. This is only supported for convex problems.

5.3.1.1 Licensing and software requirements

Users need to have a GAMS/AlphaECP license in order to use GAMS/AlphaECP. In addition, a licensed MIP solver is required for solving the mixed integer sub-problem, and a licensed NLP solver is required if the NLP option is used.

5.3.1.2 Running AlphaECP

AlphaECP solves MINLP models. If AlphaECP is not specified as the default solver for these models it can be invoked by issuing the following command before the solve statement:

```
option minlp=alphaecp, miqcp=alphaecp;
```
In principle AlphaECP can also handle NLP models, but it is more suitable for MINLP problems. However, when combined with an NLP solver it can find solutions the NLP solver cannot find by itself. In this case it acts as a good starting point generator. If you want to solve NLPs with AlphaECP you need to \textit{trick} the GAMS system by solving your NLP as an MINLP:

\begin{verbatim}
solve mynlpmodel minimizing obj using minlp;
\end{verbatim}

Constraint violations are reported throughout the progress of AlphaECP and at the end of the algorithm. The violation is reported for the non-linear constraints only. The violation of the linear constraints is subject to the feasibility tolerance of the MIP/NLP solver.

### 5.3.2 GAMS/AlphaECP Output

The log output below is obtained for the MINLP model fuel.gms from the GAMS model library:

---

Welcome to AlphaECP v2.11.01
MINLP Problem Solver using the Extended Cutting Plane Approach.
Method development - T.Westerlund, Abo Akademi University, FIN
Algorithm development - T.Lastusilta, Abo Akademi University, FIN
Algorithm development - V.-P. Eronen, Turku University, FIN

Minimization problem: "fuel.gms"
The GAMS-model has in total 39 elements of which 15\% are non-linear(NL)
included in 16 constraints of which 25\% are NL
The NL constraint signs: =E=(3), =Q=(1), =L=(0)
The number of variables in NL elements are 6 from a total of 16
variables: Continuous(13), Binary(3), Integer(0)
---

Using following settings
AlphaECP option file optfile=0
Time limit for AlphaECP (in seconds) reslim=10000000000
SolveLink for NLP and MIP sub-solver solvelink=5
Solver trace file solvetrace=(Inactive)
Cutting plane strategy (0-3) CUTdelcrit=3
Cut generation pace CUTnrcuts=0
Updating multiplier if MIP is infeasible ECPbeta=1.3

AlphaECP: Iteration procedure terminated normally

---

Problem : fuel.gms
Solver Status : Normal Completion
Model Status : Locally Optimal
Exit comment : No Issues
Final solution : NLP
Objective value : 8566.1189616876672517
Max constraint (4) : 1.1368683772161602974e-13
Alternative solution : MIP
Alt. objective value : 8566.1189616876672517
Max constraint (4) : 1.1368683772161602974e-13
Time used (seconds) : 0.81
Time limit (seconds) : 10000000000
Iterations used : 102
Iteration limit : -1
Function evaluations : 496
Gradient evaluations : 186
Domain violations : 0
Gradients unusable : 0
Alphamax bound violations : 0
ECP time usage : 3.9 %
NLP time usage : 3.8 %
MIP time usage : 92.3 %
Optimal/total MIPs : 19/102
NLP solver calls    : 8
--------------------------------------------------------------------------

In every iteration, information about the MIP problem and modifications to it is given in 10 columns. Here is a description of the different columns:

**Iteration:** Iteration identifier.

**Stepcode, Problems:** Letter for what actions were taken in this iteration, i.e. MIP problem modifications before the next iteration.

- **A:** MIP solver feasible.
- **B:** MIP solver feasible after moving cutting planes, i.e. alpha update.
- **C:** MIP solver feasible after moving cutting planes close to their generation point. The movement is done to make it easier to satisfy nonlinear equality constraints.
- **D:** Line search was successful (in ECPstrategy 3).
- **E:** Line search failed (in ECPstrategy 3).
- **F:** A NLP solver was called.
- **G:** Found a MINLP solution.
- **H:** Added linearization(s) to the next MIP problem.
- **I:** Updated alpha values and possibly added linearizations.
- **J:** All cutting planes are valid underestimators for the pseudo-convex constraints, except for the nonlinear objective function constraint.
- **K:** The nonlinear objective function constraint value and MIP solution value differ more than $\epsilon_f$. A linearization was done to reduce the difference (in ECPstrategy 3).
- **L:** Removed all temporal linearizations.
- **M:** Domain violation(s), some of the constraint could not be evaluated.
- **N:** Some cutting plane(s) could not be generated because of gradient problems.
- **O:** No cutting planes could be generated.
- **P:** Reselecting cuts because cutting planes are repeatedly moved close to their generation point.
- **Q:** Added temporal linearization(s).
- **R:** Failed to add temporal linearization(s).
- **S:** MIP solver strategy to find encountered solutions selected.
- **T:** MIP solver strategy to require MIPnrsols solutions selected.
- **U:** MIP solver strategy to require MIPnrsols solutions with a MIPoptcr $\leq 0.2$ selected.
**Number of Cuts:** The number of cutting planes the solved MIP problem had.

**Point usage:** Number of points used to generate the cuts in the solved MIP problem.

**Alpha Upd.:** The number of times the alpha values has been increased.

**OPTCR:** Relative MIP gap. Note that this is different from TOLoptcr.

**Movement Norm:** The Euclidean norm of the current and previous MIP solution.

**Viol Cons:** Number of unsatisfied (violating) nonlinear constraints.

**Maximum Violation:** The most violating nonlinear constraint value.

**MIPobjval/NLobjval:** MIP or nonlinear objective variable value depending on ECPstrategy setting.

The cut reselection heuristic is called in the following cases:

1. If the MIP solver would otherwise return infeasible.
2. When the violation is not reducing, but the cutting planes are repeatedly moved close to their generation point.
3. When the violation is not reducing and domain violations are repeatedly encountered.

The heuristic reselects cutting planes in different ways, but always ensures that the same point cannot be found twice.

\[
\text{Pointusage} \quad 6/90 \quad \text{Cutusage} \quad 15/341 \quad (0,135)
\]

**Pointusage** informs how many points of all usable points have been used to generate the cutting planes. **Cutusage** tells how many cuts of all usable cuts have been used. The first number in \((0,135)\) tells how many cuts is required by the user, see CUTnrcuts and the second number gives the sum of added and removed cuts, i.e. a measure of how much the MIP problem has been modified. AlphaECP may fix some cuts and remove points and cuts during the cut reselection procedure in order to save memory.

At the end of each solve AlphaECP gives a summary which includes Problem, Solver Status, Model Status, etc. Note the following lines:

- **Exit comment** may give further information than solverstatus on why the solution procedure stopped.
- **Domain violations** (function evaluation failed) or **Gradients unusable** (all gradients < TOLgrad) might be caused by poor variable bounds.
- **Alphamax bound violations** inform the user how many times an alphamax value was calculated to be \(>10^{154}\) and was reset to \(10^{154}\).
5.3.3 Notes about Options

To instruct AlphaECP to read an option file you may use `ModelName.OptFile = 1`. The name of the option file is in this case `alphaecp.opt`. For further information, see The Solver Options File. AlphaECP supports the GAMS parameters `reslim` and `optCR`, however, other GAMS parameters are passed on to the sub-solvers. Note that `optCR` is transferred to option `TOoptcr`. Furthermore, you may also pass additional sub-solver specific options to the sub-solvers. For example, if you want to use all available threads and sub-solver CPLEX in opportunistic parallel search mode, then you may specify this in a GAMS model, in a similar way, as follows:

```gams
Model m / all /;
Option threads=0;
m.optfile=1;
$echo MIPsolver cplex.1 > alphaecp.opt
$echo parallelmode -1 > cplex.opt
Solve m using MINLP minimizing objvar;
```

The following information is worth noting when you are interested in AlphaECP options. A linearization of a nonlinear constraint is called a cutting plane or cut. Here a point refers to the variable levels. Global optimality can be guaranteed for pseudo-convex problems. However, if the objective variable is in a nonlinear constraint and pseudo-convex, then `ECPstrategy >= 3` needs to be used to guarantee global optimality (because one non-linear equality constraint makes a problem non-pseudo-convex, and hence also non-convex). The basic options might significantly impact the solution procedure, and the best values are likely to be problem specific. The user is therefore encouraged to try different values for the basic options.

5.3.4 Summary of AlphaECP Options

5.3.4.1 Basic options

<table>

5.3.5 Detailed Descriptions of AlphaECP Options

**CUTdelcrit (integer):** Cutting plane strategy

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not remove any valid cuts.</td>
</tr>
<tr>
<td>1</td>
<td>As 0 and allow temporary cuts at semirandom points if normal cuts can not be made.</td>
</tr>
<tr>
<td>2</td>
<td>Allow temporary cuts and cut reselection, and use memory to save points and cuts.</td>
</tr>
<tr>
<td>3</td>
<td>As 2 and call the reselection heuristic before termination to improve the solution.</td>
</tr>
</tbody>
</table>

**CUTnrcuts (real):** Cut generation pace

The number of linearizations that are generated during an iteration can be chosen by AlphaECP, proportional to the number of violating constraints, or can be determined by a fixed amount. Furthermore, the cut reselection \( \text{CUTdelcrit} \geq 2 \) adds cuts to the problem so that the requested cut generation pace is taken into consideration.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Let AlphaECP decide.</td>
</tr>
<tr>
<td>( 0 &lt; n &lt; 1 )</td>
<td>Number of linearizations = ( n \times ) the number of linearizations that is possible to generate.</td>
</tr>
<tr>
<td>&gt;1</td>
<td>Specifies the number of linearizations to generate.</td>
</tr>
</tbody>
</table>

**ECPbeta (real):** Updating multiplier if MIP is infeasible

In case of an infeasible MIP solution, the invalid cuts are updated with the \( \text{ECPbeta} \) multiplier.

Range: \([1.001, \infty]\)

Default: 1.3

**ECPdumpsol (integer):** Write encountered solutions to gdx files

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No.</td>
</tr>
<tr>
<td>1</td>
<td>Solutions that the NLP solver found.</td>
</tr>
<tr>
<td>2</td>
<td>Solutions that the NLP or MIP solver found.</td>
</tr>
</tbody>
</table>

**ECPgamma (real):** Updating multiplier when verifying solution

...
If a MINLP solution is obtained but some cuts are not valid underestimators they are updated with the ECPgamma multiplier in order to make them into valid underestimators.

Range: \([1.001, \infty]\)

Default: 2.0

**ECPiterlim (integer):** Maximum number of AlphaECP iterations

This is the maximum number of iterations given to AlphaECP to perform the optimization. Value -1 deactivates the AlphaECP iteration limit.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>No limit.</td>
</tr>
<tr>
<td>&gt;=0</td>
<td>Specifies an iteration limit.</td>
</tr>
</tbody>
</table>

**ECPloglevel (integer):** Level of AlphaECP output to statusfile

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No additional output to statusfile.</td>
</tr>
<tr>
<td>1</td>
<td>Report solutions. Report all encountered solutions with their corresponding variable levels.</td>
</tr>
<tr>
<td>2</td>
<td>Report main actions at iteration level (available for minimization problems).</td>
</tr>
<tr>
<td>3</td>
<td>Report main actions at linearization level (available for minimization problems).</td>
</tr>
<tr>
<td>4</td>
<td>Full reporting. Report the main actions taken, the linearizations, function values, and solution points for every iteration and line search details (available for minimization problems).</td>
</tr>
</tbody>
</table>

**ECPmaster (integer):** Master strategy (0=User 1=Convex)

The master strategy sets some options in order to solve a model with specific characteristics more efficiently. The affected options are noted in the log output. The set options take precedence over the value set by the user for the affected options.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use only user defined options.</td>
</tr>
<tr>
<td>1</td>
<td>The model is convex. Set option ECPstrategy, CUTdelcrit and ECPtoltype.</td>
</tr>
</tbody>
</table>

**ECPpcostrategy (integer):** Pseudo-convex objective function strategy

Default: 3
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Remove support. Remove old support planes when a new pseudo-convex problem is formed.</td>
</tr>
<tr>
<td>2</td>
<td>Replace support. Replace old support planes with linearizations of the reduction constraint when a new pseudo-convex problem is formed.</td>
</tr>
<tr>
<td>3</td>
<td>Remove support and line search. Remove old support planes when a new pseudo-convex problem is formed and perform a line search when it is possible.</td>
</tr>
<tr>
<td>4</td>
<td>Replace support and line search. Replace old support planes with linearizations of the reduction constraint when a new pseudo-convex problem is formed and perform a line search when it is possible.</td>
</tr>
</tbody>
</table>

**ECPretsol (integer):** Return solution (1.MIP/2.NLP/3.QUALITY/4.PERFORMANCE) ←

The reported solution can be extracted from either the MIP or NLP solver result. If the MIP solution is returned only the primal values are available.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Choose MIP solution if it is available.</td>
</tr>
<tr>
<td>2</td>
<td>Choose NLP solution if it is available.</td>
</tr>
<tr>
<td>3</td>
<td>Choose the solution with the best tolerance.</td>
</tr>
<tr>
<td>4</td>
<td>Choose the solution with the best objective value.</td>
</tr>
</tbody>
</table>

**ECPstart (integer):** User specified start-point ←

Define which variable levels are used when the optimization is started.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use a start-point; start the algorithm by solving the linear part (MIP) of the problem.</td>
</tr>
<tr>
<td>1</td>
<td>Use the user specified startpoint, but adjust the variable levels with a small value.</td>
</tr>
<tr>
<td>2</td>
<td>Use the exact start-point set by the user.</td>
</tr>
<tr>
<td>3</td>
<td>Use the exact start-point if linearly feasible; else adjust variable levels with a small value.</td>
</tr>
</tbody>
</table>

**ECPstrategy (integer):** AlphaECP strategy ←

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Convex strategy. Ensures global optimality for problems with convex objective function and convex constraints.</td>
</tr>
<tr>
<td>2</td>
<td>Pseudo-convex constraints. Ensures global optimality for problems with convex objective function and pseudo-convex constraints.</td>
</tr>
</tbody>
</table>
Pseudo-convex objective. Ensures global optimality for problems with pseudo-convex objective function and pseudo-convex constraints. The reformulation of a non-linear objective function into a constraint must be done in a specific way. The requirement is that the objective variable must be in a linear part of the non-linear function. Assuming that the minimized or maximized variable is called objvar, the reformulation can be done as follows: (objective function expression) - objvar =E= 0. Furthermore, this strategy can effectively use a feasible start-point.

4 Pseudo-convex objective, but first complete with ECPstrategy 2. (Only the necessary linearizations are removed when the ECPstrategy is changed.)

5 Pseudo-convex objective, but find the first solution with ECPstrategy 2. (Only the necessary linearizations are removed when the ECPstrategy is changed.)

ECPtoltpe (integer): AlphaECP termination criterion

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Use termination based on tolerances TOLeps and TOLepsf.</td>
</tr>
<tr>
<td>2</td>
<td>Terminate also if relative objective gap is satisfied according to TOLopter. The relative objective gap termination criterion also called relative termination criterion is only supported for convex problems when using ECPstrategy=1. The relative termination criterion can be used for non-convex problems, as well as, with ECPstrategy=2, however, in this case it may not work properly because the lower bound may be invalid.</td>
</tr>
</tbody>
</table>

MIPloglevel (boolean): Level of MIP solver output

By default the detailed log of the MIP solver is suppressed in the AlphaECP log stream. If this option is turned on and the GAMS LogOption is set to 1 or 3, the MIP log will be merged into the AlphaECP log.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No output.</td>
</tr>
<tr>
<td>1</td>
<td>MIP solver log goes to GAMS log.</td>
</tr>
</tbody>
</table>

MIPnrscs (integer): Upper limit of considered MIP solutions per MIP call

When the MIP solver returns several solutions the most suitable solution is chosen. Many times the solutions from the MIP solver are similar and a larger number might help to find a feasible MINLP solution if the constraints are almost satisfied. See MIPsolstrat to change the solution collection strategy.

Range: {1, ..., ∞}

Default: 50

MIPoptcr (real): Relative MIP gap in intermediate sub-problems
The relative stopping tolerance sent to the MIP solver for intermediate MIP problems. Note that the `MIPoptcr` value is decreased automatically to zero during the optimization.

**Range:** $[0, 1]$

**Default:** 1.0

**MIPoptcrlim (integer):** Initial iteration limit when MIPoptcr is reduced

The `MIPoptcr` parameter is reduced in steps: From 1 to 0.5 to 0.3 to 0.2 to 0.1 to 0.0. The first reduction is at iteration `MIPoptcrlim`. The following reductions occur also at iteration `MIPoptcrlim` but it is updated with a strategy defined by parameter `MIPoptcrlimtype`. Note that a step reduction may happen for other reasons.

**Range:** $\{1, \ldots, \infty\}$

**Default:** 200

**MIPoptcrlimtype (integer):** Strategy to increase MIPoptcrlim

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exponential increase of MIPoptcrlim. The parameter MIPoptcrlim is increased by multiplying it by 2. The increase occurs at iteration &quot;MIPoptcrlim&quot;. If MIPoptcrlim=200 it will have values 200,400,800 etc.</td>
</tr>
<tr>
<td>1</td>
<td>Linear increase of MIPoptcrlim. The parameter MIPoptcrlim is increased by adding the original value of MIPoptcrlim to it. If MIPoptcrlim=200 it will have values 200,400,600 etc.</td>
</tr>
</tbody>
</table>

**MIPoptimaliter (integer):** MIP is solved to optimality with this frequency

Defines the frequency to solve the MIP problem to optimum before the algorithm sets `MIPoptcr=0` and, hence, solves MIP problems to optimum. For example if `MIPoptimaliter=n`, then at least every nth iteration the MIP problem is solved to the optimum. Solving MIP problem to optimum yields a lower bound for a convex MINLP problem which can help to terminate the algorithm faster if `ECPtoltype=2` is used. Non-default value is not recommended for non-convex problems nor if `ECPstrategy >1`.

**Default:** 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Never.</td>
</tr>
<tr>
<td>n&gt;0</td>
<td>Every nth iteration, where n is the given value.</td>
</tr>
</tbody>
</table>

**MIPsolstrat (integer):** MIP solution collection strategy

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Instruct MIP solver to return only one solution.</td>
</tr>
<tr>
<td>1</td>
<td>Instruct MIP solver to return any solutions encountered during MIP procedure.</td>
</tr>
</tbody>
</table>
### MIPsolver (string): MIP solver for sub-problems and . option file number

MIPsolver specifies the GAMS MIP solver for sub-problems and the option file number. The solver is the name of the GAMS MIP solver and `n` is the integer corresponding to `optfile`. The option file is appended to the option file that is written by AlphaECP. Hence, the specified options take precedence over the options set by AlphaECP. If the `.n` is missing, the `optfile` is treated as zero; i.e., the MIP solver will not look for an options file specified by the user. This option can be used to overwrite the default that uses the MIP solver specified with an `Option NLP = solver;` statement or the default GAMS solver for NLP.

Default: GAMS MIP solver

### NLPcall (integer): NLP strategy

NLPcall determines when the NLP solver is called.

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No output.</td>
</tr>
<tr>
<td>1</td>
<td>Call the NLP solver at end of AlphaECP algorithm.</td>
</tr>
<tr>
<td>2</td>
<td>As 1 and when a better solution is found.</td>
</tr>
<tr>
<td>3</td>
<td>As 2 and when the same integer solution is encountered NLPlimsameint times.</td>
</tr>
<tr>
<td>4</td>
<td>Let AlphaECP decide.</td>
</tr>
<tr>
<td>5</td>
<td>Let AlphaECP decide and add noise to the variable levels before call.</td>
</tr>
</tbody>
</table>

### NLPcalliter (integer): NLP solver call at next (incremental) iteration

NLPcalliter specifies an iteration interval for the NLP solver calls.

Default: 0

### NLPlimsameint (integer): NLP call after a number of recurring integer solutions

NLPlimsameint specifies the number of recurring integer solutions before the NLP solver is called. If the same integer solution is encountered `NLPlimsameint` times in a row then the NLP solver is called. The counter is reset after the NLP solver is called.

Range: `{1, ..., ∞}`

Default: 5

### NLPloglevel (boolean): Level of NLP solver output

NLPloglevel specifies the level of NLP solver output. By default, the detailed log of the NLP solver is suppressed in the AlphaECP log stream. If this option is turned on and the GAMS `LogOption` is set to 1 or 3, the NLP log will be merged into the AlphaECP log.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No output.</td>
</tr>
<tr>
<td>1</td>
<td>NLP solver log goes to GAMS log.</td>
</tr>
</tbody>
</table>

**NLPreslim** *(real)*: NLP time limit per call

The time limit (in seconds) given to the chosen NLP solver at each NLP solver call. Setting this option to 0 calculates a time limit which is relative to the problem size.

Default: 0

**NLPsolver** *(string)*: NLP solver for sub-problems and . option file number

*solver[n]* Solver is the name of the GAMS NLP solver that should be used in the root node, and *n* is the integer corresponding to optfile. If .n is missing, the optfile is treated as zero, i.e., the NLP solver will not look for an options file. This option can be used to overwrite the default that uses the NLP solver specified with an `Option NLP = solver;` statement or the default GAMS solver for NLP.

Default: GAMS NLP solver

**reslim** *(real)*: Time limit for AlphaECP (in seconds)

Default: GAMS reslim

**solvelink** *(integer)*: Solvelink for NLP and MIP sub-solver

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Call NLP and MIP solver via script.</td>
</tr>
<tr>
<td>2</td>
<td>Call NLP and MIP solver via module.</td>
</tr>
<tr>
<td>5</td>
<td>Call NLP and MIP solver in memory.</td>
</tr>
</tbody>
</table>

**solvetrace** *(string)*: Filename of solvetrace file

**solvetracetime** *(real)*: Time interval when a trace record is written

Default: 1

**TOLepsf** *(real)*: Pseudo-convex objective function termination tolerance

Maximum allowed absolute difference between the nonlinear and the MIP objective function value (used only in ECPstrategy 3).

Range: [1e-20, 1]

Default: 1e-3

**TOLepsg** *(real)*: Constraint tolerance
The nonlinear constraint tolerance defines the maximum value that a nonlinear constraint may violate. For example, a constraint required to be zero may hold a value $\pm TOL_{e epsg}$ at a solution.

Range: $[1e-20, 1]$  
Default: $1e-3$

**TOL_{epsz}** (*real*): Distance tolerance for a new linearization

The maximum perpendicular distance between a valid cutting plane and its generation point (MIP solution).

Range: $[1e-20, 1]$  
Default: $1e-1$

**TOL_{grad}** (*real*): Gradient tolerance

The absolute value of a gradient's partial derivative must be above $TOL_{grad}$ value in order for it to be considered nonzero.

Range: $[1e-20, 1]$  
Default: $1e-6$

**TOL_{infbnd}** (*real*): Infinity bound (MIP variable bound)

All variables must have a positive and a negative finite bound in order to ensure a bounded MIP problem. The finite bound value $TOL_{infbnd}$ will be applied to single or double unbounded variables.

Default: $1e10$

**TOL_{optcr}** (*real*): Relative termination tolerance for MINLP

The relative objective gap termination criterion is satisfied if $|UB-LB|/ (10^{E-12}+\max(|LB|,|UB|)) < TOL_{optcr}$, where UB is the current best upper bound and LB is the current best lower bound. Upper bounds are obtained from solving NLP problems and lower bounds are obtained from lower bounds of MIP problems. If the inequality holds true and ECPtoltype=2, the algorithm terminates.

Range: $[1e-20, \infty]$  
Default: GAMS optCR

### 5.3.6 FAQ

- **What are good settings to solve a convex problem?**
  
  Use ECPmaster 1.

- **What are good settings if the solution speed is essential?**
  
  Try ECPstrategy 1 and CUTdeltcrit 1 to see if using multiple threads for the MIP solver improves the solution speed. However, there is considerable chance that a feasible solution for a non-convex problem with nonlinear equality constraints cannot be found.

- **What are good settings when the solution quality is essential?**
  
  Use NLPcalliter 1 and MIPsolstrat 4 or 3, and also try different values, for CUTnrcuts option, for example 0.1.

- **The objective function is non-linear, should the default ECPstrategy be used?**
  
  If the objective function constraint can be written in the required form of ECPstrategy 3 then this strategy may find a better solution. If the constraints and the objective function are pseudo-convex the global optimal solution will be found.

ANTIGONE 1.0

5.4.1 Introduction

ANTIGONE, Algorithms for coNTinuous / Integer Global Optimization of Nonlinear Equations, is a
deterministic general mixed-integer nonlinear global optimization framework [134] [135] [137] [136] [138].

MINLP is defined:

$$\begin{align*}
\text{min} & \quad f_0(x, y, z) \\
\text{s.t.} & \quad b_m^{\text{LO}} \leq f_m(x, y, z) \leq b_m^{\text{UP}} \quad \forall \ m \in \{1, \ldots, M\} \\
& \quad x \in \mathbb{R}^C; \ y \in \{0, 1\}^B; \ z \in \mathbb{Z}^I
\end{align*}$$

where $C$, $B$, $I$, and $M$ represent the number of continuous variables, binary variables, integer variables, and constraints, respectively. Parameters vectors $b_m^{\text{LO}}$ and $b_m^{\text{UP}}$ bound the constraints. We assume that it is possible to infer finite bounds $[x^L_i, x^U_i]$ on the variables participating in nonlinear terms $f_m$ and that the image of $f_m$ is finite on $x$. Typical expressions for $f_0(x, y, z)$ and $f_m(x, y, z)$ are:

$$f_m(x, y, z) = c_m + a_m^T [x; y; z] + [x; y; z]^T Q_m [x; y; z]$$

$$+ \sum_{s=1}^{S_m} c_{s,m} \cdot \prod_{c=1}^C x^{p_{s,m,c}}_c + \sum_{e=1}^{E_m} c_{e,m} \cdot e^x + \sum_{l=1}^{L_m} c_{l,m} \cdot \log x$$

where the powers $p_{s,m,c}$ are constant reals; $c_m$, $a_m$, $Q_m$, $c_{s,m}$, $c_{e,m}$, $c_{l,m}$ are constant coefficients; $S_m$, $E_m$, $L_m$ are the number of signomial, exponential, and logarithmic terms, respectively.

As illustrated in Figure 5.1, ANTIGONE responds dynamically to exploit special structure within (MINLP). ANTIGONE falls broadly into the category of branch-and-bound global optimization because it: generates and solves convex relaxations of the nonconvex MINLP that rigorously bound the global solution; finds feasible solutions via local optimization; divides and conquers the feasible set to generate a sequence of convex relaxations converging to the global optimum [68] [67].
5.4 ANTIGONE

Figure 5.1 Given an MINLP optimization problem, ANTIGONE reformulates the model, detects special structure in the reformulated MINLP, solves the optimization problem, and returns the model with respect to the original problem variables.

5.4.1.1 Licensing and software requirements

Using GAMS/ANTIGONE requires

1. an ANTIGONE license,
2. a CPLEX license, and
3. a CONOPT or SNOPT license.

5.4.1.2 Running GAMS/ANTIGONE

GAMS/ANTIGONE solves: NLP; MINLP; RMINLP; QCP; MIQCP; RMIQCP; CNS. If GAMS/ANTIGONE is not the default solver for these models, it can be called using the following command before the solve statement:

```plaintext
option nlp=antigone, minlp=antigone, rminlp=antigone;
```

5.4.2 GAMS/ANTIGONE Output

The log output shown below is generated using the MINLP model cecil_13 from the MINLPLib.

#### 5.4.4 Detailed Descriptions of ANTIGONE Options

**abs_opt_tol** (*real*): absolute stopping tolerance

Default: GAMS `optca`

**adaptive_add_rlt** (*boolean*): use the dynamic approach to adaptively determine deep RLT cuts?

In the first few levels of the branch-and-bound tree, query the RLT equations after solving an initial relaxation. Add violated equations to the relaxation and resolve. Track the most commonly-violated equations and include those cuts in later nodes.

Default: 1

**adaptive_add_rlt_tree_depth** (*integer*): tree depth for heuristic that adaptively determines deep RLT cuts

To the specified tree depth, solve the relaxation of a node twice if RLT equations are violated. After this depth, automatically add the most commonly violated cuts to the solution of each node.

Range: \(\{1, ..., 100\}\)

Default: 3

**add_bilinear_terms** (*boolean*): allow addition of nonconvex bilinear terms to generate deep RLT cuts

Default: 1

**branching_bounds_push-away** (*real*): branch a minimum fraction away from the variable bounds

Range: \([0, 0.5]\)

Default: 0.1
**branching_weight** *(real)*: branch on a convex combination of midpoint and solution

The branching weight specifies the emphasis on the midpoint of a variable, so larger branching weights imply branching closer to the center of a variable range.

Range: \([0, 1]\)

Default: 0.25

**conopt_optfile** *(string)*: read a secondary GAMS/CONOPT options file that will be applied to every NLP subsolve

Gain direct access to the GAMS/CONOPT options. The value of the string should match the name of the GAMS/CONOPT options file.

**convexity_cuts** *(boolean)*: derive convexity-based separating cuts for multivariable terms?

Default: 1

**cplex_optfile** *(string)*: read a secondary GAMS/CPLEX options file that will be applied to every LP and MILP subsolve

Gain direct access to the GAMS/CPLEX options. Specifying an options file allows, for example, the possibility of running the CPLEX subsolver with multiple threads. The value of the string should match the name of the GAMS/CPLEX options file.

**cut_generation_epsilon** *(real)*: absolute violation threshold for separating hyperplanes

Absolute violation threshold to generate separating hyperplanes for convex multivariable terms

Range: \([1e^{-7}, 10]\)

Default: 1e-4

**dominant_ec_only** *(boolean)*: add only the low-dimension edge-concave aggregations introducing dominant cuts into relaxations?

Default: 1

**dumpsolutions** *(string)*: name of solutions index gdx file for writing alternate solutions

The GDX file specified by this option will contain a set call `index` that contains the names of GDX files with the individual solutions. For details see example model `dumpsol` in the GAMS Test Library.

**eigenvector_projections** *(boolean)*: use eigenvector projections as additional cuts?

Default: 1

**eigenvector_projection_partitioning** *(boolean)*: allow partitioning on eigenvector projections?

Default: 1

**fbbt_improvement_bound** *(real)*: bounds reduction improvement threshold needed to exit FBBT loop

Range: \([0, 1]\)

Default: 0.999
feas_soln_time_limit (real): time limit (s) for an NLP solve

    Range: [1, ∞]
    Default: 30

feas_tolerance (real): absolute feasibility tolerance

    Default: 1e-6

logging_freq (real): how often should we log progress to the console?

    Wait at least the specified time in seconds before next output to the console
    Range: [1, ∞]
    Default: 5

logging_level (integer): logging information level

    Log to the console at the specified level (-1: default; 0: minimal logging; 3: extensive logging)
    Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

<td>includes Cplex updates</td>
</tr>
</tbody>
</table>

low_dim_edge_concave_agg (boolean): use low-dimension edge-concave aggregations?

    Default: 1

max_fbbt_iterations (integer): maximum number of FBBT iterations

    Range: {1, ..., 100}
    Default: 50

max_number_nodes (integer): node limit

    Default: GAMS nodlim

max_obbt_iterations (integer): maximum number of OBBT iterations

    Range: {1, ..., 100}
    Default: 30

max_partitioned_quantities (integer): number of partitioned quantities

    Range: {0, ..., 50}
    Default: 0
**max_rlt_cuts (integer):** maximum number of violated RLT cuts to add before resolving the relaxation?

Range: \(\{1, \ldots, 1000\}\)

Default: 100

**max_time (real):** resource limit

Default: GAMS reslim

**max_time_each_obbt (real):** time limit (s) for each OBBT LP

Range: \([1, 100]\)

Default: 10

**naive_add_ec (boolean):** naively integrate all low-dimension edge-concave aggregations into relaxations?

Default: 0

**naive_add_rlt (boolean):** naively add all RLT cuts to the relaxations?

Default: 0

**nlp_solver (string):** use CONOPT or SNOPT to find feasible solutions

Note, that independent of the setting for this option, for the initial NLP solve from the user provided starting point, always CONOPT is used, if available. Further, for the final NLP solve (see trydual), always CONOPT is used, if available, otherwise SNOPT is used.

Default: conopt

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>conopt</td>
<td>Conopt</td>
</tr>
<tr>
<td>snopt</td>
<td>Snopt</td>
</tr>
</tbody>
</table>

**nominal_time_limit (real):** nominal time limit for solving MILP subproblems

Nominal time limit for solving MILP subproblems. Terminate long-running MILP subproblems over this time limit once they reach an integer feasible point

Range: \([0.1, 1000]\)

Default: 100

**number_of_partitions (integer):** how many partitions per variable?

Range: \(\{0, \ldots, 16\}\)

Default: 1

**num_reliability_tests (integer):** number of strong branching initialization tests
5.4 ANTIGONE

Range: \{1, ..., 100\}

Default: 8

**obbt_improvement_bound** *(real)*: bounds reduction improvement threshold

Bounds reduction improvement threshold needed to exit OBBT loop. This parameter also determines whether to continue obbt in child; if the parent bound improvement is less than this threshold, then child node won’t try OBBT.

Range: \([0, 1]\)

Default: 0.95

**partitioning_scheme** *(string)*: Partitioning scheme can be linear or logarithmic

Linear partitioning uses a number of binary variables linear in the number of partitions while logarithmic partitioning uses a number of binary variables logarithmic in the number of breakpoints. Linear partitioning tends to be numerically favorable for a few breakpoints while logarithmic partitioning is better for a larger number of breakpoints.

Default: linear

<table>

**piecewise_linear_partitions** *(boolean)*: use piecewise-linear partitioning?

Default: 0

**populate_solution_pool** *(integer)*: emphasis on generating starting points

Emphasis on generating many starting points for NLP solves using the CPLEX solution pool feature. Larger number implies more starting points.

Range: \{0, ..., 4\}

Default: 3

**print_options** *(boolean)*: print the option parameter choices used in a single run?

Default: 1

**readparams** *(string)*: read secondary option file in ANTIGONE syntax

**reliability_branching** *(string)*: heuristic choice for building reliable pseudocosts

Default: error

<table>

Default: 1

use_obbt (boolean): use optimality-based bounds tightening?←

Default: 1

use_reliability_branching (boolean): use reliability branching?←

Default: 1

5.4.5 ANTIGONE Algorithmic Features

As illustrated in Figure 5.1, the primary algorithmic features in ANTIGONE are reformulating model input, elucidating special structure, and branch-and-bound global optimization [134] [135] [137] [136] [138] .

5.4.5.1 Reformulating Model Input

As illustrated in Figure 5.2, ANTIGONE transforms a factorable programming tree into a flattened expression tree to capitalize on the development of tight convex underestimators for specific classes of nonlinear terms. ANTIGONE extends the efficacy of hybrid strategies by meaningfully integrating mutually reinforcing operator- and term-based strategies [27] [76] [136] . This approach reformulates towards multivariable terms with specialized underestimators while maintaining a tree-like representation of powers that cannot be distributed and convex operators that can be exploited by dynamic cut generation.
5.4 ANTIGONE

5.4.5.2 Elucidating Special Structure

After reformulating the user-defined MINLP, ANTIGONE detects special mathematical structure that it will exploit in the branch-and-cut phase (Section Branch-and-Bound Global Optimization). The types of special structure that ANTIGONE considers are: reformulation-linearization technique (RLT) equations; convexity/concavity; edge-convexity/edge-concavity; \( \alpha \)BB relaxations; term-specific underestimators [134] [135] [136] [137] [138] .

- RLT multiplies every pairwise combination of: variables; nonlinear terms; equations [11] [119] [135] [136] [138] [169] [170] [171] [172] [173] . ANTIGONE saves the combinations that do not introduce new terms into the model formulation and updates these equations at every node of the branch-and-cut tree. Special RLT equations are added directly to the model formulation; other RLT equations are used as cutting planes and integrated into the feasibility-based bounds tightening routines.

- Convexity/Concavity permits the easy generation of a cutting plane at a point \( \hat{x} \):

\[
\begin{align*}
  f(x) &\geq f(\hat{x}) + f'(\hat{x}) \cdot (x - \hat{x}) \quad \text{(convex)} \\
  f(x) &\leq f(\hat{x}) + f'(\hat{x}) \cdot (x - \hat{x}) \quad \text{(concave)}
\end{align*}
\]

Based on interval arithmetic, terms and multi-term expressions are labeled as always/sometimes/never convex/ concave; this information is used in the branch-and-cut phase.

- Edge-Convexity/Edge-Concavity implies a vertex polyhedral envelope; ANTIGONE labels terms and multi-term expressions as always/sometimes/never edge-convex/edge-concave with a simple interval arithmetic test [133] [175] [176] [177] .

- \( \alpha \)BB underestimators convexify an expression with univariate quadratics [5] [6] [10] [66] [128]; ANTIGONE uses \( \alpha \)BB to relax aggregates of bilinear terms.

- Term-Specific Underestimators are diagrammed in Figure 5.3; their implementation is based on work available in the open literature [53] [52] [65] [77] [118] [125] [123] [124] [129] [133] [134] [146] [175] [176] [178] .
5.4.5.3 Branch-and-Bound Global Optimization

After the reformulation and special structure detection phases, ANTIGONE initiates a branch-and-cut global optimization algorithm that generates tight convex underestimators, dynamically generates separating hyperplanes, bounds the variables \([6] [10] [5] [11] [18] [49] [50] [116] [157] [158] [172] [173] [191]\); branches on the search space \([3] [18]\), and finds feasible solutions.

5.5.1 Introduction

The Branch-And-Reduce Optimization Navigator (BARON) is a GAMS solver for the global solution of nonlinear (NLP) and mixed-integer nonlinear programs (MINLP).

While traditional NLP and MINLP algorithms are guaranteed to converge only under certain convexity assumptions, BARON implements deterministic global optimization algorithms of the branch-and-bound type that are guaranteed to provide global optima under fairly general assumptions. These include the existence of finite lower and upper bounds on nonlinear expressions in the NLP or MINLP to be solved.

BARON implements algorithms of the branch-and-bound type enhanced with a variety of constraint propagation, interval analysis, and duality techniques for reducing ranges of variables in the course of the algorithm. Rigorous relaxations are constructed by enlarging the feasible region and/or underestimating the objective function.

Parts of the BARON software were created at the University of Illinois at Urbana-Champaign. The algorithms implemented in the software, the theory behind them, and some related applications are (partly) described in \([157] [51] [158] [161] [93] [120] [78] [187] [168] [188] [163] [79] [159] [178] [179] [180] [183] [184] [165] [160] [162] [7] [181] [164] [182] [36] [12] [149] [13] [106] [107] [208] [209] [108] [210] [14] \).
5.5 BARON

5.5.1 Licensing and software requirements

In order to use GAMS/BARON, users will need to have a GAMS/BARON license. BARON comes with several embedded LP/MIP and NLP solvers (CBC; IPOPT, FilterSD, FilterSQP). Additionally, GAMS/BARON users can expedite convergence by accessing CPLEX and XPRESS to solve BARON's LP/MIP subproblems and MINOS, SNOPT, and any GAMS NLP solver, such as CONOPT, to solve BARON's NLP subproblems. These solvers need to be licensed with GAMS separately.

By default, GAMS/BARON will attempt to use CPLEX as the LP solver and select an NLP solver automatically. The user can use the options LPSol and NLPSol to specify the LP or NLP solver. If the user does not have a license for the user-specified LP and NLP solver, BARON will automatically select a licensed LP and NLP solver and may default to CLP and IPOPT if no other LP and NLP solver is available, respectively. BARON can be used without a local NLP solver by setting DoLocal and NumLoc to 0.

5.5.1.2 Running GAMS/BARON

BARON is capable of solving models of the following types: LP, MIP, RMIP, NLP, DNLP, RMINLP, and MINLP. If BARON is not specified as the default solver for these models, it can be invoked by issuing the following command before the solve statement:

```plaintext
option <modeltype>=baron;
```

where `<modeltype>` stands for LP, MIP, RMIP, QCP, MIQCP, RMIQCP, CNS, NLP, DNLP, MINLP, or RMINLP.

5.5.2 Model requirements

In order to achieve convergence to global optimality, additional model constraints may be required. The additional constraints may speed up solver time and increase the probability of success.

5.5.2.1 Variable and expression bounds

All nonlinear expressions in the mathematical program to be solved must be bounded below and/or above. It is important that finite lower and upper bounds be provided by the user on all problem variables. Note that providing finite bounds on variables alone may not suffice to guarantee finite bounds on nonlinear expressions arising in the model.

For example, consider the term 1/x for x ∈ [0,1], which has finite variable bounds, but is unbounded. It is important to provide bounds for problem variables that guarantee that the problem functions are finitely-valued. If the user model does not include variable bounds that guarantee that all nonlinear expressions are finitely-valued, BARON will attempt to infer appropriate bounds from problem constraints. If this step fails, global optimality of the solutions provided is not guaranteed. Occasionally, because of the lack of bounds no numerically stable lower bounding problems can be constructed, in which case BARON may terminate.

See section Some BARON features on how to specify variable bounds.

5.5.2.2 Allowable nonlinear functions

In addition to multiplication and division, GAMS/BARON can handle nonlinear functions that involve \( \exp(x) \), \( \ln(x) \), \( x^\alpha \) for real \( \alpha \), \( x^\beta \) for real \( \beta \), \( x^2 \), and \( |x| \). Currently, there is no support for other functions, including the trigonometric functions \( \sin(x) \), \( \cos(x) \), etc.
5.5.3 BARON output

5.5.3.1 BARON log output

The log output below is obtained for the MINLP model gear.gms from the GAMS model library using absolute and relative optimality tolerances of 1e-6.

===========================================================================
BARON version 15.6.5. Built: LNX-64 Fri Jun 5 08:34:09 EDT 2015

If you use this software, please cite:

BARON is a product of The Optimization Firm, LLC. http://www.minlp.com/
Parts of the BARON software were created at the University of Illinois at Urbana-Champaign.

===========================================================================
This BARON run may utilize the following subsolver(s)
For LP/MIP: ILOG CPLEX
For NLP: MINOS, SNOPT, GAMS external NLP, COIN IPOPT with MUMPS and METIS, FILTERSD

===========================================================================
Starting solution is feasible with a value of 36.1767610000
Doing local search
Solving bounding LP
Starting multi-start local search
Preprocessing found feasible solution with value 4.23791612465
Done with local search

Cleaning up

*** Normal completion ***

Wall clock time: 0.05
Total CPU time used: 0.05

Total no. of BaR iterations: 30
Best solution found at node: 30
Max. no. of nodes in memory: 11

All done

===========================================================================
The solver first tests feasibility of the user-supplied starting point. This point is found to be feasible with an objective function value of 36.1767610000. BARON subsequently performs a randomized local search procedure and, eventually, finds a feasible solution with an objective of 4.23791612465. Then, the iteration log provides information every 1,000,000 branch-and-bound iterations and every 30 seconds. Additionally, information is printed at the end of the root node, whenever the value of the incumbent is improved by at least $10^{-5}$, and at the end of the search. A star (*) in the first position of a line indicates that a better feasible solution was found that improves the value of previous best known solution by at least $10^{-5}$. The log fields include the iteration number, number of open branch-and-bound nodes, the CPU time taken thus far, the lower bound, and the upper bound for the problem. The log output fields are summarized below:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Itn. no.</td>
<td>The number of the current iteration. A plus (+) following the iteration number denotes reporting while solving a probing (as opposed to a relaxation) subproblem of the corresponding node.</td>
</tr>
<tr>
<td>Open Nodes</td>
<td>Number of open nodes in branch-and-reduce tree.</td>
</tr>
<tr>
<td>Time</td>
<td>Current computational time in seconds. CPU time is reported for single-threaded jobs and wall clock time is reported for multi-threaded jobs.</td>
</tr>
<tr>
<td>Lower Bound</td>
<td>Current lower bound on the model.</td>
</tr>
<tr>
<td>Upper Bound</td>
<td>Current upper bound on the model.</td>
</tr>
</tbody>
</table>

Once the branch-and-reduce tree is searched, the best solution is isolated and a corresponding dual solution is calculated. Finally, the total number of branch-and-reduce iterations (number of search tree nodes) is reported, followed by the node where the best solution was identified (a -1 indicates preprocessing as explained in the next section on termination messages).

### 5.5.3.2 Termination messages, model and solver statuses

Upon normal termination, BARON will report the node where the optimal solution was found. We refer to this node as `nodeopt`. Associated with this node is a return code indicating the status of the solution found at `nodeopt`. The return code is given in the log line:

**Best solution found at node: (return code)**

The return codes have the following interpretation:

- `-3` : no feasible solution found
- `-2` : the best solution found was the user-supplied
- `-1` : the best solution was found during preprocessing
- `i` : the best solution was found in the i-th node of the tree

In addition to reporting `nodeopt`, upon termination, BARON will issue one of the following statements:

*** Normal completion ***

This is the most desirable termination status. The problem has been solved within tolerances in this case. If BARON returns a code of -3, then no feasible solution exists.

*** Heuristic termination ***
While global optimality is not guaranteed in this case, BARON will terminate with this message when (a) a feasible solution has been found and (b) the progress of lower/upper bounds satisfies the heuristic termination criterion set by the user through BARON's *DeltaTerm* option.

*** User did not provide appropriate variable bounds ***

The user will need to read the BARON output (in file *sum.dat* in the scratch directory, use GAMS parameter *keep=1* to prevent the automatic removal of this directory) for pointers to variables and expressions with missing bounds. The model should be modified in order to provide bounds for variables and intermediate expressions that make it possible for BARON to construct reliable relaxations. Even though relaxation bounds are printed on the screen to give the user a feeling for convergence, these bounds may not be valid for the problem at hand. This message is followed by one of the following two messages:

*** Infeasibility is therefore not guaranteed ***

This indicates that, because of missing bounds, no feasible solution was found, but model infeasibility was not proven.

*** Globality is therefore not guaranteed ***

This indicates that, because of missing bounds, a feasible solution was found, but global optimality was not proven.

*** Max. allowable nodes in memory reached ***

The user will need to increase the physical memory of the computer or change algorihmic options, such as branching and node selection rules, to reduce the size of the search tree and memory required for storage.

*** Max. allowable BarR iterations reached ***

The user will need to increase the maximum number of allowable iterations. The BARON option is *MaxIter*. To specify this in GAMS, one can use the *NodLim* option. We remark that the BARON option *MaxIter* overrides *NodLim*.

*** Max. allowable CPU time exceeded ***

The user will need to increase the maximum of allowable CPU time. The BARON option is *MaxTime*. To specify this in GAMS, one can use the *ResLim* option. We remark that the BARON option *MaxTime* overrides *ResLim*.

*** Problem is numerically sensitive ***

BARON is designed to automatically handle problems with numerical difficulties. However, for certain problems, the global optimum is numerically sensitive. This occurs, for instance, when the objective function value varies significantly over small neighborhoods of points that are strictly outside the feasible region but nonetheless feasible within numerical tolerances. When BARON returns this message, the "Best possible" reported on the objective is likely correct.

*** Search interrupted by user ***

The run was interrupted by the user (Ctrl-C).

*** Insufficient memory for data structures ***

More memory is needed to set up the problem data structures. The user will need to increase the physical memory available on the computer in order to accommodate problems of this size.

*** A potentially catastrophic access violation just took place ***

In the unlikely event of a memory access violation, BARON will terminate the search and return the best known solution. Please report problems that lead to this condition to Nick Sahinidis ([niksah@minlp.com](mailto:niksah@minlp.com)).
5.5.4 Some BARON features

The features described in this section rely on options that are further detailed in the next section. For details of the algorithmic implementations, the user may wish to consult publications cited at the end of this document.

5.5.4.1 No starting point is required

In contrast to many NLP algorithms that require a feasible starting point, a starting point is not required for BARON. A user may optionally provide a starting point for all or even some of the problem variables. BARON will judiciously initialize any variables that are not initialized by the user. Even when the problem functions cannot be evaluated at a user-provided starting point, BARON is still capable of carrying out its global search.

For problems for which GAMS compilation is aborted because the nonlinear functions cannot be evaluated at the starting point, the user can use the following commands before the SOLVE statement:

\[
\begin{align*}
\text{MaxExecError} & = 100000; \\
\text{option sys12 = 1; }
\end{align*}
\]

The first command asks GAMS to continue compilation for as many as MaxExecError execution errors. The sys12 option will pass the model to the BARON despite the execution errors. Even though the starting point is bad in this case, BARON is capable of carrying out its global search.

5.5.4.2 Finding a few of the best or all feasible solutions

BARON offers a facility, through its NumSol option, to find the best few, or even all feasible, solutions to a model. The development of this facility was motivated by combinatorial optimization problems but the facility is applicable to continuous problems as well. Even for combinatorial problems, BARON does not rely on integer cuts to find multiple solutions. Instead, it utilizes a single search tree, thus providing a computationally efficient method for finding multiple solutions. Furthermore, because BARON's approach applies to integer as well as continuous programs, it can be used to find all feasible solutions to a system of nonlinear equality and inequality constraints.

Once a model is solved by BARON with the NumSol option, the solutions found can be recovered using the GAMS GDX facility. An example is provided below.

```
$eolcom !
$Ontext

Purpose: demonstrate use of BARON option 'numsol' to obtain the best numsol solutions of an optimization problem in a single branch-and-bound search tree.

The model solved here is a linear general integer problem with 18 feasible solutions. BARON is run with a request to find up to 20 solutions. The model solved is the same as the one solved in gamslib/icut.gms.

$Offtext

set i index of integer variables / 1 * 4 /

variables x(i) variables

z objective variable
```
integer variable x;

x.lo(i) = 2; x.up(i) = 4; x.fx('2') = 3;  ! fix one variable
x.up('4') = 3;  ! only two values

equation obj obj definition;
* pick an objective function which will order the solutions
obj .. z =e= sum(i, power(10,card(i)-ord(i))*x(i));

model enum / all /;
* instruct BARON to return numsol solutions
$onecho > baron.opt
numsol 20
gdxout multsol
$offecho
enum.optfile=1; option mip=baron, limrow=0, limcol=0, optca=1e-5,
optcr=1e-5; solve enum minimizing z using mip;

* recover BARON solutions through GDX
set sol /multsol1*multsol100/; variables xsol(sol,i), zsol(sol);
execute 'gdxmerge multsol*.gdx > %gams.scrdir%merge.%gams.scrext%';
execute_load 'merged.gdx', xsol=x, zsol=z;

option decimals=8;
display xsol.l, zsol.l;

5.5.4.3 Using BARON as a multi-start heuristic solver

To gain insight into the difficulty of a nonlinear program, especially with regard to existence of multiple
local solutions, modelers often make use of multiple local searches from randomly generated starting points.
This can be easily done with BARON's NumLoc option, which determines the number of local searches to
be done by BARON's preprocessor. BARON can be forced to terminate after preprocessing by setting
the number of iterations to 0 through the MaxIter option. In addition to local search, BARON's preprocessor
performs extensive reduction of variable ranges. To sample the search space for local minima without range
reduction, one would have to set to 0 the range reduction options TDo, MDo, LBTTD0, and OBTTDo.
On the other hand, leaving these options to their default values increases the likelihood of finding high
quality local optima during preprocessing. If NumLoc is set to -1, local searches in preprocessing will be
done from randomly generated starting points until global optimality is proved or MaxTime seconds have elapsed.

5.5.4.4 Systematic treatment of unbounded problems

If BARON declares a problem as unbounded, it will search for and may report a vertex and direction of
an unbounded ray. In addition, BARON will report the best solution found. This will be a feasible point
that is as far as possible along an unbounded ray while avoiding numerical errors due to floating point
arithmetic.
5.5.4.5 Systematic treatment of infeasible problems

If BARON declares a problem as infeasible, it has the capability to identify a subset of the constraints that are infeasible and become feasible once any one of them is eliminated. This, so-called, irreducibly inconsistent system (IIS) can be obtained by BARON for all types of problems handled by BARON, including linear and nonlinear, continuous and integer, convex and nonconvex, and problems with complementarity constraints. BARON's CompIIS option can be used to identify an IIS.

As an example, consider the problem of minimizing the nonconvex function \( x_1 x_3 \) over the following nonconvex constrained set:

\[
\begin{align*}
  e_1 : & \quad 85 + 0.006x_2 x_5 + 0.0006x_1 x_4 - 0.002x_3 x_5 \leq 92 \\
  e_2 : & \quad 0.8x_2 x_5 + 0.003x_1 x_2 + 0.002x_3^2 = 110 \\
  e_3 : & \quad 9 + 0.005x_3 x_5 + 0.001x_1 x_3 + 0.002x_4 x_1 \leq 25 \\
  & \quad 78 \leq x_1 \leq 102 \\
  & \quad 33 \leq x_2 \leq 45 \\
  & \quad 27 \leq x_i \leq 45, \quad i = 3, \ldots, 5
\end{align*}
\]

When this problem is solved with CompIIS equal to 1, BARON provides the following result in the listing file:

Number of equations in the IIS: 1.
Upper: \( e_2 \leq 110 \)

Number of variables in the IIS: 3.
Lower: \( x_1 \geq 78 \)
Lower: \( x_2 \geq 33 \)
Lower: \( x_5 \geq 27 \)

The IIS consists of the lower bounds of variables \( x_1, x_2, \) and \( x_5 \), along with the \( \leq \) part of the equality constraint \( e_2 \). This suggests that constraint \( e_2 \) and the entire model can be made feasible by lowering the lower bound of any of the three variables that are part of the IIS, whereas modifying the bounds of \( x_3 \) would not make the model feasible.

If a problem is known to be infeasible and the user desires to identify an IIS, it may be beneficial to set BARON’s NumLoc option to zero. Doing so will deactivate BARON's initial upper bounding search, which involves multiple local searches. On the other hand, DoLocal should be nonzero in order to permit local search during the solution of certain subproblems that BARON solves while searching for an IIS.

5.5.4.6 Handling of complementarity constraints

Complementarity relationships of the type \( f(x) g(x) = 0 \) are automatically recognized and exploited algorithmically by BARON. The functions \( f \) and \( g \) may be univariate or multivariate, linear or nonlinear, convex or nonconvex, in terms of continuous and/or integer variables, and may be subject to additional constraints in the model. These complementarity relationships can be inferred by BARON even when implied by problem constraints and variable bounds. As a result, BARON can solve general mathematical programs with equilibrium constraints (MPECs). This class of problems includes the classical linear complementarity problem

\[(LCP): \text{Find } z \geq 0 \text{ and } q \text{ such that }\]
\[ Mz + q \geq 0, \]
\[ z^t(Mz + q) = 0 \]

as well as the more general mixed complementarity problem

(MCP): Given a function \( f : \mathbb{R}^n \rightarrow \mathbb{R}^n \) and bounds \( l, u \in \mathbb{R}^n \) with \( \mathbb{R} = \mathbb{R} \cup \{-\infty, +\infty\} \), find \( z \in \mathbb{R}^n \) and \( w, v \in \mathbb{R}_+^n \) such that

\[ f(z) = w - v, \]
\[ l \leq z \leq u, \]
\[ (z - l)^t w = 0, \]
\[ (u - z)^t v = 0. \]

Both problems are automatically recognized and exploited by BARON without the user having to mark complementarities in any special way. In GAMS, all these problems can be solved by BARON when declared as NLP or MINLP models.

5.5.4.7 Parallel capabilities

For difficult problems with integer variables, most of BARON's time is spent on solving MIP relaxations. Hence, considerable speedups may be obtained via parallel solution of the MIP subproblems. For this purpose, the option threads may be used to specify the number of cores that BARON's MIP subsolver is allowed to use. By default, this option has the value of 1, meaning that a single core will be utilized.

5.5.5 The BARON options

The BARON options allow the user to control termination tolerances, branching and relaxation strategies, heuristic local search options, and output options as detailed in this section.

Many options can also be set in the GAMS model. The most relevant GAMS options are ResLim, NodLim, OptCA, OptCR, OptFile, and CutOff. The IterLim option is not implemented. Specify BARON iterations, the user can set the MaxIter option, which is equivalent to the GAMS option NodLim.

Additionally, a BARON Options file can be provided. See section The Solver Options File for general use of solver option files.

For branching, users can specify separate branching priorities for any discrete and continuous variables using Dot Options. To specify variable branching priorities, one specifies

\[(variable).prior(value)\]

in the BARON options file, where \((value)\) can be any non-negative real value. The lower the value, the higher the priority for branching, see also Setting Priorities for Branching. Specifying maxdouble for \((value)\) translates to passing 0 as branching priority for \((variable)\).

5.5.5.1 Termination options
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>AbsConFeasTol</td>
<td>Absolute constraint feasibility tolerance. This tolerance is used for general constraints and variable bounds. ( \text{AbsConFeasTol} ) must be ( \geq 1e^{-12} ). A point is considered feasible for a constraint/bound if the absolute or relative constraint feasibility tolerance is satisfied. Range: ([1e^{-12}, \infty])</td>
<td>1e-5</td>
</tr>
<tr>
<td>AbsIntFeasTol</td>
<td>Absolute integer feasibility tolerance. All integer variable values must satisfy this tolerance. ( \text{AbsIntFeasTol} ) must be ( \geq 1e^{-12} ). A point is considered integer feasible for a variable if integrality is satisfied using the absolute or relative integer feasibility tolerance. Range: ([1e^{-12}, \infty])</td>
<td>1e-5</td>
</tr>
<tr>
<td>BoxTol</td>
<td>Box elimination tolerance. Boxes will be eliminated if smaller than this tolerance. ( \text{BoxTol} ) must be ( \geq 1e^{-12} ).</td>
<td>1e-8</td>
</tr>
<tr>
<td>CutOff</td>
<td>Eliminate solutions that are no better than this value. Can also be used with the GAMS model attribute option ( \text{CutOff} ).</td>
<td>GAMS CutOff</td>
</tr>
<tr>
<td>DeltaA</td>
<td>Absolute improvement for insufficient progress termination. ( \text{DeltaA} (\delta_a) ) must be ( \geq 1e^{-12} ). Range: ([1e^{-12}, \infty])</td>
<td>(\infty)</td>
</tr>
<tr>
<td>DeltaR</td>
<td>Relative improvement for insufficient progress termination. ( \text{DeltaR} (\delta_r) ) must be ( \geq 1e^{-12} ). Range: ([1e^{-12}, \infty])</td>
<td>1</td>
</tr>
<tr>
<td>DeltaT</td>
<td>Time interval for insufficient progress termination. If ( \text{DeltaTerm} ) is set to 1, BARON will terminate if insufficient progress is made over ( \text{DeltaT} (\delta_t) ) consecutive seconds. If ( \delta_t ) is set to a non-positive quantity, BARON will automatically set ( \delta_t ) equal to (-\delta_t ) times the CPU time taken till the end of root node processing. ( \text{DeltaT} ) can take any real value. Range: ([-\infty, \infty])</td>
<td>-100</td>
</tr>
<tr>
<td>DeltaTerm</td>
<td>Indicates whether insufficient progress termination is on or off. Users have the option to request BARON to terminate if insufficient progress is made over ( \text{DeltaT} (\delta_t) ) consecutive seconds. Progress is measured using the absolute and relative improvement thresholds ( \text{DeltaA} (\delta_a) ) and ( \text{DeltaR} (\delta_r) ). Termination will occur if, over a period of ( \delta_t ) consecutive seconds, the value of the best solution found by BARON is not improved by at least an absolute amount ( \delta_a ) or an amount equal to ( \delta_r ) times the value of the incumbent at time ( t-\delta_t ). This termination condition is enforced after processing the root node and only after a feasible solution has been obtained. Because it relies on CPU time measurements, which may depend on machine load, this option may result in nondeterministic behavior. 0: do not enforce this termination condition 1: terminate if progress is insufficient.</td>
<td>0</td>
</tr>
<tr>
<td>EpsA</td>
<td>Absolute termination tolerance. BARON terminates if (</td>
<td>U-L</td>
</tr>
<tr>
<td>EpsR</td>
<td>Relative termination tolerance. BARON terminates if (</td>
<td>U-L</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>FirstFeas</td>
<td>Changes the search for first <code>numsol</code> solutions. If set to 1, BARON will terminate once it finds <code>numSol</code> feasible solutions, irrespective of solution quality. 0: search for the best <code>numSol</code> feasible solutions 1: find <code>numSol</code> solutions irrespective of solution quality.</td>
<td>0</td>
</tr>
<tr>
<td>FirstLoc</td>
<td>Terminate the search as soon as a local optimum is found</td>
<td>0</td>
</tr>
<tr>
<td>ISolTol</td>
<td>Solution Distance. Separation distance between solutions. This option is used in conjunction with <code>numSol</code>. For combinatorial optimization problems, feasible solutions are isolated. For continuous problems, feasible solution points within an $l_\infty$ distance that does not exceed <code>IsolTol</code> will be treated as identical by BARON. <code>IsolTol</code> must be $\geq 1e-12$.</td>
<td>$1e-4$</td>
</tr>
<tr>
<td>MaxIter</td>
<td>Maximum number of branch-and-reduce iterations allowed. Setting <code>MaxIter</code> to 0 will force BARON to terminate after root node preprocessing. Setting <code>MaxIter</code> to 1 will result in termination after the solution of the root node. <code>MaxIter</code> must be $\geq -1$, where -1 implies unlimited. Range: ${-1, \ldots, \infty}$</td>
<td>GAMS NodeLim</td>
</tr>
<tr>
<td>MaxTime</td>
<td>Maximum time allowed (sec). <code>MaxTime</code> must be $\geq 0$, where 0 implies unlimited. For single-threaded jobs, i.e., when <code>threads</code> equals 1, this limit is enforced on CPU time consumed by the job. For multi-threaded jobs, the limit is enforced on wall clock time.</td>
<td>GAMS ResLim</td>
</tr>
<tr>
<td>NumSol</td>
<td>Number of feasible solutions to be found. Solutions found will be listed in the <code>results</code> file. As long as <code>NumSol</code> $\neq -1$, these solutions will be sorted from best to worse. If <code>NumSol</code> is set to -1, BARON will search for all feasible solutions to the given model and print them, in the order in which they are found, in the <code>results</code> file. <code>NumSol</code> must be $\geq -1$. Range: ${-1, \ldots, \infty}$</td>
<td>1</td>
</tr>
<tr>
<td>RelConFeasTol</td>
<td>Relative constraint feasibility tolerance. This tolerance is used for general constraints and variable bounds. <code>RelConFeasTol</code> must be $\geq 0$. A point is considered feasible for a constraint/bound if the absolute or relative constraint feasibility tolerance is satisfied. Range: $[0, 0.1]$</td>
<td>0</td>
</tr>
<tr>
<td>RelIntFeasTol</td>
<td>Relative integer feasibility tolerance. All integer variable values must satisfy this tolerance. <code>RelIntFeasTol</code> must be $\geq 0$. A point is considered integer feasible for a variable if integrality is satisfied using the absolute or relative integer feasibility tolerance. Range: $[0, 0.1]$</td>

</tr>
</tbody>
</table>
5.6 CBC

CBC (COIN-OR Branch and Cut) is an open-source mixed integer programming solver working with the COIN-OR LP solver CLP and the COIN-OR Cut generator library Cgl. The code has been written primarily by John J. Forrest. Most of the CBC documentation in the section was copied from the help in the CBC standalone version.

The CBC link in GAMS supports continuous, binary, integer, semicontinuous, semiinteger variables, special ordered sets of type 1 and 2, and branching priorities.

5.6.1 Usage

The following statement can be used inside your GAMS program to specify using CBC

```
Option LP = CBC;  { or MIP or RMIP }
```

The above statement should appear before the Solve statement. If CBC was specified as the default solver during GAMS installation, the above statement is not necessary.

For usage and syntax of solver options file, see Section The Solver Option File. Following is an example options file cbc.opt.
cuts root
perturbation off

It will cause CBC to use cut generators only in the root node and turns off the perturbation of the LP relaxation.

GAMS/CBC currently does not support the GAMS Branch-and-Cut-and-Heuristic (BCH) Facility. If you need to use GAMS/CBC with BCH, please consider to use a GAMS system of version \leq 23.3.

The following GAMS parameters are currently supported by GAMS/CBC: reslim, iterlim, nodlim, optca, optcr, cheat, cutoff, and threads.

### 5.6.2 List of Options

There are many parameters which can affect the performance the CBCs Branch and Cut Algorithm. First just try with default settings and look carefully at the log file. Did cuts help? Did they take too long? Look at the output to see which cuts were effective and then do some tuning (see the option cuts). If the preprocessing reduced the size of the problem or strengthened many coefficients then it is probably wise to leave it on. Switch off heuristics which did not provide solutions. The other major area to look at is the search. Hopefully good solutions were obtained fairly early in the search so the important point is to select the best variable to branch on. See whether strong branching did a good job – or did it just take a lot of iterations? Adjust the options strongBranching and trustpseudocosts.

In the following, we summarize all available CBC options.

#### 5.6.2.1 General Options

<table>
<thead>
<tr>
<th>Option</th>

### 5.6.3 Detailed Options Description

In the following, we give a detailed description of all available CBC options.

**autoScale**: Whether to scale objective, rhs and bounds of problem if they look odd (experimental) ←

Range: boolean

Default: 0

**biasLU**: Whether factorization biased towards U ←

Range: UU, UX, LX, LL

Default: LX
bscale: Whether to scale in barrier (and ordering speed) ←

Range: off, on, off1, on1, off2, on2

Default: off

cliqueCuts: Whether to use Clique cuts ←

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglClique

Range: off, on, root, ifmove, forceOn, onglobal

Default: ifmove

clocktype: type of clock for time measurement ←

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpu</td>
<td>CPU clock</td>
</tr>
<tr>
<td>wall</td>
<td>Wall clock</td>
</tr>
</tbody>
</table>

Default: wall

combine2Solutions: Whether to use crossover solution heuristic ←

This heuristic does branch and cut on the problem given by fixing variables which have the same value in two or more solutions. It obviously only tries after two or more solutions. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before

Default: off

combineSolutions: Whether to use combine solution heuristic ←

This heuristic does branch and cut on given problem by just using variables which have appeared in one or more solutions. It is obviously only tried after two or more solutions have been found. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

</tr>
</tbody>
</table>
conflictcuts: Conflict Cuts

Equivalent to setting cutoffconstraint=conflict

Range: boolean

Default: 0

costStrategy: How to use costs for branching priorities

Value 'priorities' assigns highest priority to variables with largest absolute cost. This primitive strategy can be surprisingly effective. Value 'columnorder' assigns the priorities 1, 2, 3, ... with respect to the column ordering. Value '01first' ('01last') assigns two sets of priorities such that binary variables get high (low) priority. Value 'length' assigns high priority to variables that occur in many equations.

<td></td>
</tr>
<tr>
<td>nonzero</td>
<td></td>
</tr>
<tr>
<td>generalForce</td>
<td></td>
</tr>
</tbody>
</table>

Default: off

crash: Whether to create basis for problem

If crash is set to 'on' and there is an all slack basis then Clp will flip or put structural variables into the basis with the aim of getting dual feasible. On average, dual simplex seems to perform better without it and there are alternative types of 'crash' for primal simplex, e.g. 'idiot' or 'sprint'. A variant due to Solow and Halim which is as 'on' but just flips is also available.

Range: off, on, solow_halim, lots, idiot1, idiot2, idiot3, idiot4, idiot5, idiot6, idiot7

Default: off

crossover: Whether to get a basic solution with the simplex algorithm after the barrier algorithm finished

Interior point algorithms do not obtain a basic solution. This option will crossover to a basic solution suitable for ranging or branch and cut.

<table>

<tr>
<td>0</td>
<td>Same as off. This is a deprecated setting.</td>
</tr>
<tr>
<td>1</td>
<td>Same as on. This is a deprecated setting.</td>
</tr>
</tbody>
</table>
cut\_passes\_root: Number of rounds that cut generators are applied in the root node

The default is to do 100 passes if the problem has less than 500 columns, 100 passes (but stop if the drop in the objective function value is small) if the problem has less than 5000 columns, and 20 passes otherwise. A negative value -n means that n passes are also applied if the objective does not drop.

Range: \{-\infty, ..., \infty\}

Default: 20 or 100

Synonym: passCuts

cut\_passes\_slow: Maximum number of rounds for slower cut generators

Some cut generators are fairly slow - this limits the number of times they are tried. The cut generators identified as 'may be slow' at present are Lift and project cuts and both versions of Reduce and Split cuts.

Range: \{-1, ..., \infty\}

Default: 10

Synonym: slowcutpasses

cut\_passes\_tree: Number of rounds that cut generators are applied in the tree

The default is to do one pass. A negative value -n means that n passes are also applied if the objective does not drop.

Range: \{-\infty, ..., \infty\}

Default: 10

Synonym: passTreeCuts

cutDepth: Depth in tree at which to do cuts

Cut generators may be off, on, on only at the root node, or on if they look useful. Setting this option to a positive value K let CBC call a cutgenerator on a node whenever the depth in the tree is a multiple of K. The default of -1 lets CBC decide.

Range: \{-1, ..., \infty\}

Default: -1

cutLength: Length of a cut

At present this only applies to Gomory cuts. -1 (default) leaves as is. Any value \geq 0 says that all cuts \leq this length can be generated both at root node and in tree. 0 says to use some dynamic lengths. If value \geq 10,000,000 then the length in tree is value\%10000000 - so 10000100 means unlimited length at root and 100 in tree.

Range: \{-1, ..., \infty\}

Default: -1

cutoff: Bound on the objective value for all solutions

All solutions must have a better objective value than the value of this option. CBC also updates this value whenever it obtains a solution to the value of the objective function of the solution minus the cutoff increment.

Range: real

Default: GAMS cutoff

cutoffConstraint: Whether to use cutoff as constraint

For some problems, cut generators and general branching work better if the problem would be infeasible if the cost is too high. If this option is enabled, the objective function is added as a constraint which right hand side is set to the current cutoff value (objective value of best known solution)
<table>

<tr>
<td>1</td>
<td>Same as on. This is a deprecated setting.</td>
</tr>
</tbody>
</table>

Default: off

**cuts:** Switches all cut generators on or off ←

This can be used to switch on or off all cut generators (apart from Reduce and Split). Then one can turn individual ones on or off. Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node.

Range: off, on, root, ifmove, forceOn

Default: on

**denseThreshold:** Threshold for using dense factorization ←

If processed problem ≤ this use dense factorization

Range: \{-1, ..., 10000\}

Default: -1

**Dins:** Whether to try Distance Induced Neighborhood Search ←

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

<table>

</tr>
</tbody>
</table>

Default: off

**diveSolves:** Diving solve option ←
If >0 then do up to this many solves. However, the last digit is ignored and used for extra options: 1-3 enables fixing of satisfied integer variables (but not at bound), where 1 switches this off for that dive if the dive goes infeasible, and 2 switches it off permanently if the dive goes infeasible.

Range: {-1, ..., 200000}

Default: 100

**DivingCoefficient**: Whether to try Coefficient diving heuristic

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

<tr>
<td>1</td>
<td>Same as on. This is a deprecated setting.</td>
</tr>
</tbody>
</table>

Default: off

**DivingRandom**: Whether to try Diving heuristics

This switches on a random diving heuristic at various times. One may prefer to individually turn diving heuristics on or off. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

Synonym: DivingSome
DivingVectorLength: Whether to try Vectorlength diving heuristic

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

dualPivot: Dual pivot choice algorithm

The Dantzig method is simple but its use is deprecated. Steepest is the method of choice and there are two variants which keep all weights updated but only scan a subset each iteration. Partial switches this on while automatic decides at each iteration based on information about the factorization. The PE variants add the Positive Edge criterion. This selects incoming variables to try to avoid degenerate moves. See also option psi.

Default: automatic

dumpsolutions: name of solutions index gdx file for writing alternate solutions

The name of a solutions index gdx file for writing alternate solutions found by CBC. The GDX file specified by this option will contain a set called index that contains the names of GDX files with the individual solutions.

Range: string

Default: empty

dumpsolutionsmerged: name of gdx file for writing all alternate solutions

Range: string

Default: empty

dwHeuristic: Whether to try Dantzig Wolfe heuristic
This heuristic is very very compute intensive. It tries to find a Dantzig Wolfe structure and use that. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before
Default: off

**expensiveStrong:** Whether to do even more strong branching

Strategy for extra strong branching. 0 is normal strong branching. 1, 2, 4, and 6 does strong branching on all fractional variables if at the root node (1), at depth less than modifier (2), objective equals best possible (4), or at depth less than modifier and objective equals best possible (6). 11, 12, 14, and 16 are like 1, 2, 4, and 6, respectively, but do strong branching on all integer (incl. non-fractional) variables. Values ≥ 100 are used to specify a depth limit (value/100), otherwise 5 is used. If the values ≥ 100, then above rules are applied to value%100.

Range: \{0, ..., \infty\}
Default: 0

**extraVariables:** Allow creation of extra integer variables

Switches on a trivial re-formulation that introduces extra integer variables to group together variables with same cost.

Range: \{-\infty, ..., \infty\}
Default: 0

**factorization:** Which factorization to use

The default is to use the normal CoinFactorization, but other choices are a dense one, OSL's, or one designed for small problems.

Range: normal, dense, simple, osl
Default: normal

**feaspump:** Whether to try the Feasibility Pump heuristic

This heuristic is due to Fischetti, Glover, and Lodi and uses a sequence of LPs to try and get an integer feasible solution. Some fine tuning is available by options passFeasibilityPump and pumpTune. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

<table>

<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>
Default: on

Synonym: feasibilityPump

**feaspump_artcost:** Costs $\geq$ this treated as artificials in feasibility pump

A value of 0.0 means off. Otherwise, variables with costs $\geq$ this are treated as artificial variables and fixed to lower bound in feasibility pump.

Range: $[0, \infty]$  
Default: 0  

Synonym: artificialCost

**feaspump_cutoff:** Fake cutoff for use in feasibility pump

A value of 0.0 means off. Otherwise, add a constraint forcing objective below this value in feasibility pump

Range: real  
Default: 0  

Synonym: pumpCutoff

**feaspump_fracbab:** Fraction in feasibility pump

After a pass in the feasibility pump, variables which have not moved about are fixed and if the preprocessed model is smaller than this fraction of the original problem, a few nodes of branch and bound are done on the reduced problem.

Range: $[1e-05, 1.1]$  
Default: 0.5  

Synonym: fractionforBAB

**feaspump_increment:** Fake increment for use in feasibility pump

A value of 0.0 means off. Otherwise use as absolute increment to cutoff when solution found in feasibility pump

Range: real  
Default: 0  

Synonym: pumpIncrement

**feaspump_passes:** How many passes to do in the Feasibility Pump heuristic

Range: $\{0, ..., 10000\}$  
Default: 20  

Synonym: passFeasibilityPump

**fixOnDj:** Try heuristic based on fixing variables with reduced costs greater than this

If this is set integer variables with reduced costs greater than this will be fixed before branch
and bound - use with extreme caution!

Range: real

Default: -1

**flowCoverCuts**: Whether to use Flow Cover cuts

- Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see
  cutDepth on how to fine tune the behavior).
- Value 'root' lets CBC run the cut generator generate only at the root node.
- Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good
  and moves the objective value.
- Value 'forceon' turns on the cut generator and forces CBC to use it at every node.

Reference: [https://github.com/coin-or/Cgl/wiki/CglFlowCover](https://github.com/coin-or/Cgl/wiki/CglFlowCover)

Range: off, on, root, ifmove, forceOn, onglobal

Default: ifmove

**gamma**: Whether to regularize barrier

Range: off, on, gamma, delta, onstrong, gammastrong, deltastrong

Default: off

**gomoryCuts**: Whether to use Gomory cuts

The original cuts - beware of imitations! Having gone out of favor, they are now more
fashionable as LP solvers are more robust and they interact well with other cuts. They
will almost always give cuts (although in this executable they are limited as to number of
variables in cut). However the cuts may be dense so it is worth experimenting (Long allows
any length).

- Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see
  cutDepth on how to fine tune the behavior).
- Value 'root' lets CBC run the cut generator generate only at the root node.
- Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good
  and moves the objective value.
- Value 'forceon' turns on the cut generator and forces CBC to use it at every node.

Reference: [https://github.com/coin-or/Cgl/wiki/CglGomory](https://github.com/coin-or/Cgl/wiki/CglGomory)

Range: off, on, root, ifmove, forceOn, onglobal, forceandglobal, forceLongOn, long

Default: ifmove

**gomorycuts2**: Whether to use alternative Gomory cuts

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see
cutDepth on how to fine tune the behavior).

Value 'root' lets CBC run the cut generator generate only at the root node.

Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good
and moves the objective value.

Value 'forceon' turns on the cut generator and forces CBC to use it at every node.

This version is by Giacomo Nannicini and may be more robust than gomoryCuts.

Range: off, on, root, ifmove, forceOn, endonly, long, longroot, longifmove, forceLongOn, longendonly

Default: off

**Synonym**: GMICuts
**greedyHeuristic**: Whether to use a greedy heuristic

This heuristic tries to obtain a feasible solution by just fixing a percentage of variables and then try a small branch and cut run. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before

Default: on

**heuristics**: Switches most primal heuristics on or off

This option can be used to switch on or off all heuristics that search for feasible solutions, except for the local tree search, as it dramatically alters the search. Then individual heuristics can be turned off or on.

Range: boolean

Default: 1

Synonym: heuristicsOnOff

**hOptions**: Heuristic options

Value 1 stops heuristics immediately if the allowable gap has been reached. Other values are for the feasibility pump - 2 says do exact number of passes given, 4 only applies if an initial cutoff has been given and says relax after 50 passes, while 8 will adapt the cutoff rhs after the first solution if it looks as if the code is stalling.

Range: {-∞, ..., ∞}

Default: 0

**idiotCrash**: Whether to try idiot crash

This is a type of 'crash' which works well on some homogeneous problems. It works best on problems with unit elements and rhs but will do something to any model. It should only be used before the primal simplex algorithm. It can be set to -1 when the code decides for itself whether to use it, 0 to switch off, or n > 0 to do n passes.

Range: {-1, ..., ∞}

Default: -1

**increment**: A valid solution must be at least this much better than last integer solution

Whenever a solution is found the bound on the objective value for new solutions is set to the objective function of the found solution (in a minimization sense) plus this. If it is not set then CBC will try and work one out, e.g. if all objective coefficients are multiples of 0.01 and only integer variables have entries in the objective function, then the increment can be set to 0.01. Be careful if setting this to a negative value!

Range: real

Default: GAMS cheat

**infeasibilityWeight**: Each integer infeasibility is expected to cost this much
A primitive way of deciding which node to explore next. Satisfying each integer infeasibility is expected to cost this much.

Range: $[0, \infty]$

Default: 0

**iterlim**: Maximum number of iterations before stopping

For an LP, this is the maximum number of iterations to solve the LP. For a MIP, this option is ignored.

Range: $\{0, \ldots, \infty\}$

Default: GAMS iterlim

Synonym: maxIterations

**KKT**: Whether to use KKT factorization in barrier

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: [https://github.com/coin-or/Cgl/wiki/CglKnapsackCover](https://github.com/coin-or/Cgl/wiki/CglKnapsackCover)

Range: off, on, root, ifmove, forceOn, onglobal, forceandglobal

Default: ifmove

**knapsackCuts**: Whether to use Knapsack cuts

This is a gross simplification of 'A Relax-and-Cut Framework for Gomory's Mixed-Integer Cuts' by Matteo Fischetti & Domenico Salvagnin. This simplification just uses original constraints while modifying objective using other cuts. So you don't use messy constraints generated by Gomory etc. A variant is to allow non messy cuts e.g. clique cuts. So 'only' does this while 'clean' also allows integral valued cuts. 'End' is recommended and waits until other cuts have finished before it does a few passes. The length options for gomory cuts are used.

Range: off, endonlyroot, endcleanroot, root, endonly, endclean, endboth, onlyaswell, cleanaswell, bothaswell, onlyinstead, cleaninstead, bothinstead, onlyaswellroot, cleanaswellroot, bothaswellroot

Default: off

**lagomoryCuts**: Whether to use Lagrangean Gomory cuts

This is a gross simplification of 'A Relax-and-Cut Framework for Gomory's Mixed-Integer Cuts' by Matteo Fischetti & Domenico Salvagnin. This simplification just uses original constraints while modifying objective using other cuts. So you don't use messy constraints generated by Gomory etc. A variant is to allow non messy cuts e.g. clique cuts. So 'only' does this while 'clean' also allows integral valued cuts. 'End' is recommended and waits until other cuts have finished before it does a few passes. The length options for gomory cuts are used.

Range: off, endonlyroot, endcleanroot, root, endonly, endclean, endboth, onlyaswell, cleanaswell, bothaswell, onlyinstead, cleaninstead, bothinstead, onlyaswellroot, cleanaswellroot, bothaswellroot

Default: off

**latwomirCuts**: Whether to use Lagrangean TwoMir cuts

This is a Lagrangean relaxation for TwoMir cuts. See lagomoryCuts for description of options.

Range: off, endonlyroot, endcleanroot, endbothroot, endonly, endclean, endboth, onlyaswell, cleanaswell, bothaswell, onlyinstead, cleaninstead, bothinstead

Default: off
**liftAndProjectCuts**: Whether to use Lift and Project cuts

These cuts may be expensive to compute. Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: [https://github.com/coin-or/Cgl/wiki/CglLandP](https://github.com/coin-or/Cgl/wiki/CglLandP)

- Range: off, on, root, ifmove, forceOn
- Default: off

**localTreeSearch**: Whether to use local tree search when a solution is found

The heuristic is from Fischetti and Lodi and is not really a heuristic although it can be used as one (with limited functionality). It is not switched on when heuristics are switched on.

- Range: boolean
- Default: 0

**loglevel**: amount of output printed by CBC

- Range: \(\{0, \ldots, \infty\}\)
- Default: 1

**maxFactor**: Maximum number of iterations between refactorizations

If this is left at its default value of 200 then CLP will guess a value to use. CLP may decide to re-factorize earlier for accuracy.

- Range: \(\{1, \ldots, \infty\}\)
- Default: 200

**maxsol**: Maximum number of solutions to save

Maximal number of solutions to store during search and to dump into gdx files if dumpSolutions options is set.

- Range: \(\{0, \ldots, \infty\}\)
- Default: 100
- Synonym: maxSavedSolutions

**mipstart**: whether it should be tried to use the initial variable levels as initial MIP solution

This option controls the use of advanced starting values for mixed integer programs. A setting of 1 indicates that the variable level values should be checked to see if they provide an integer feasible solution before starting optimization.

- Range: boolean
- Default: 0

**mirCuts**: Whether to use Mixed Integer Rounding cuts
Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglMixedIntegerRounding2

Range: off, on, root, ifmove, forceOn, onglobal

Default: ifmove

Synonym: mixedIntegerRoundingCuts

**multipleRootPasses:** Do multiple root passes to collect cuts and solutions

Solve (in parallel, if enabled) the root phase this number of times, each with its own different seed, and collect all solutions and cuts generated. The actual format is aabbcc where aa is the number of extra passes; if bb is non zero, then it is number of threads to use (otherwise uses threads setting); and cc is the number of times to do root phase. The solvers do not interact with each other. However if extra passes are specified then cuts are collected and used in later passes - so there is interaction there. Some parts of this implementation have their origin in idea of Andrea Lodi, Matteo Fischetti, Michele Monaci, Domenico Salvagnin, and Andrea Tramontani.

Range: \( \{0, \ldots, \infty\} \)

Default: 0

**naiveHeuristics:** Whether to try some stupid heuristic

This is naive heuristics which, e.g., fix all integers with costs to zero! Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

<tr>
<td>both</td>
<td>Same as on. This is a deprecated setting.</td>
</tr>
</tbody>
</table>

Default: off

**nodeStrategy:** What strategy to use to select the next node from the branch and cut tree

Normally before a feasible solution is found, CBC will choose a node with fewest infeasibilities. Alternatively, one may choose tree-depth as the criterion. This requires the minimal amount of memory, but may take a long time to find the best solution. Additionally, one may specify whether up or down branches must be selected first (the up-down choice will carry on after a first solution has been bound). The default choice 'hybrid' does breadth first on small depth nodes and then switches to 'fewest'.

Range: hybrid, fewest, depth, upfewest, downfewest, updepth, downdepth

Default: fewest
nodlim: node limit

Maximum number of nodes that are enumerated in the Branch and Bound tree search.

Range: \{-1, ..., \infty\}

Default: GAMS nodlim

Synonyms: maxNodes nodelim

optca: Stop when gap between best possible and best less than this

If the gap between best known solution and the best possible solution is less than this value, then the search will be terminated. Also see ratioGap.

Range: \([0, \infty]\)

Default: GAMS optca

Synonym: allowableGap

optcr: Stop when gap between best possible and best known is less than this fraction of larger of two

If the gap between the best known solution and the best possible solution is less than this fraction of the objective value at the root node then the search will terminate. See 'allowableGap' for a way of using absolute value rather than fraction.

Range: \([0, \infty]\)

Default: GAMS optcr

Synonym: ratioGap

OrbitalBranching: Whether to try orbital branching

This switches on Orbital branching. Value 'on' just adds orbital, 'strong' tries extra fixing in strong branching.

Range: off, on, strong, force, simple

Default: off

parallelmode: whether to run opportunistic or deterministic

Determines whether a parallel MIP search (threads > 1) should be done in a deterministic (i.e., reproducible) way or in a possibly faster but not necessarily reproducible way

Range: opportunistic, deterministic

Default: deterministic

passPresolve: How many passes in presolve

Normally Presolve does 10 passes but you may want to do less to make it more lightweight or do more if improvements are still being made. As Presolve will return if nothing is being taken out, you should not normally need to use this fine tuning.

Range: \{-200, ..., 100\}

Default: 5
perturbation: Whether to perturb the problem

Perturbation helps to stop cycling, but CLP uses other measures for this. However, large problems and especially ones with unit elements and unit right hand sides or costs benefit from perturbation. Normally CLP tries to be intelligent, but one can switch this off.

Range: boolean

Default: 1

pivotAndComplement: Whether to try Pivot and Complement heuristic

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before

Default: off

pivotAndFix: Whether to try Pivot and Fix heuristic

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

<table>

</tr>
<tr>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

Default: off

preprocess: Whether to use integer preprocessing

This tries to reduce size of model in a similar way to presolve and it also tries to strengthen the model - this can be very useful and is worth trying. Value 'save' saves the presolved problem to a file presolved.mps. Value 'equal' will turn inequality-cliques into equalities. Value 'sos' lets CBC search for rows with upper bound 1 and where all nonzero coefficients are 1 and creates special ordered sets if the sets are not overlapping and all integer variables (except for at most one) are in the sets. Value 'trysos' is same as 'sos', but allows any number of integer variables outside of sets. Value 'equalall' lets CBC turn all valid inequalities into equalities by adding integer slack variables.

Range: off, on, save, equal, sos, trysos, equalall, strategy, aggregate, force esos, stopaftersaving

Default: sos

presolve: Whether to presolve problem

Presolve analyzes the model to find such things as redundant equations, equations which fix some variables, equations which can be transformed into bounds, etc. For the initial solve of any problem this is worth doing unless one knows that it will have no effect. Option 'on' will normally do 5 passes, while using 'more' will do 10.
5.6 CBC

**primalPivot**: Primal pivot choice algorithm

The Dantzig method is simple but its use is deprecated. Exact devex is the method of choice and there are two variants which keep all weights updated but only scan a subset each iteration. Partial switches this on while 'change' initially does 'dantzig' until the factorization becomes denser. This is still a work in progress. The PE variants add the Positive Edge criterion. This selects incoming variables to try to avoid degenerate moves. See also Towhid, M., Desrosiers, J., Soumis, F., The positive edge criterion within COIN-OR’s CLP; Omer, J., Towhid, M., Soumis, F., The positive edge pricing rule for the dual simplex.

Default: automatic

**primalWeight**: Initially algorithm acts as if it costs this much to be infeasible

The primal algorithm in Clp is a single phase algorithm as opposed to a two phase algorithm where you first get feasible then optimal. So Clp is minimizing this weight times the sum of primal infeasibilities plus the true objective function (in minimization sense). Too high a value may mean more iterations, while too low a value means the algorithm may iterate into the wrong directory for long and then has to increase the weight in order to get feasible.

Range: [1e-20, ∞]

Default: 1e+10

**printfrequency**: frequency of status prints

Controls the number of nodes that are evaluated between status prints.

Range: {0, ..., ∞}

Default: 0
**probingCuts**: Whether to use Probing cuts

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Value 'forceOnBut' turns on probing and forces CBC to do probing at every node, but does only probing, not strengthening etc. Value 'strong' forces CBC to strongly do probing at every node, that is, also when CBC would usually turn it off because it hasn't found something. Value 'forceOnButStrong' is like 'forceOnStrong', but does only probing (column fixing) and turns off row strengthening, so the matrix will not change inside the branch and bound. Reference: [https://github.com/coin-or/Cgl/wiki/CglProbing](https://github.com/coin-or/Cgl/wiki/CglProbing)

Range: off, on, root, ifmove, forceOn, onglobal, forceonglobal, forceOnBut, forceOnStrong, forceOnButStrong, strongRoot

Default: ifmove

**proximitySearch**: Whether to do proximity search heuristic

This heuristic looks for a solution close to the incumbent solution (Fischetti and Monaci, 2012). The idea is to define a sub-MIP without additional constraints but with a modified objective function intended to attract the search in the proximity of the incumbent. The approach works well for 0-1 MIPs whose solution landscape is not too irregular (meaning the there is reasonable probability of finding an improved solution by flipping a small number of binary variables), in particular when it is applied to the first heuristic solutions found at the root node. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Default: off

**psi**: Two-dimension pricing factor for Positive Edge criterion

The Positive Edge criterion has been added to select incoming variables to try and avoid degenerate moves. Variables not in the promising set have their infeasibility weight multiplied by psi, so 0.01 would mean that if there were any promising variables, then they would always be chosen, while 1.0 effectively switches the algorithm off. There are two ways of switching this feature on. One way is to set psi to a positive value and then the Positive Edge criterion will be used for both primal and dual simplex. The other way is to select PEsteepest in dualpivot choice (for example), then the absolute value of psi is used. Code donated by Jeremy Omer. See Towhidi, M., Desrosiers, J., Soumis, F., The positive edge criterion within COIN-OR’s CLP; Omer, J., Towhidi, M., Soumis, F., The positive edge pricing rule for the dual simplex.

Range: [-1.1, 1.1]

Default: -0.5
randomizedRounding: Whether to try randomized rounding heuristic ←

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

randomSeedCbc: Random seed for Cbc ←

Allows initialization of the random seed for pseudo-random numbers used in heuristics such as the Feasibility Pump to decide whether to round up or down. The special value of 0 lets Cbc use the time of the day for the initial seed.

Range: \{-1, ..., \infty\}

Default: -1

Synonym: randomCbcSeed

randomSeedClp: Random seed for Clp ←

Initialization of the random seed for pseudo-random numbers used to break ties in degenerate problems. This may yield a different continuous optimum and, in the context of Cbc, different cuts and heuristic solutions. The special value of 0 lets CLP use the time of the day for the initial seed.

Range: \{0, ..., \infty\}

Default: 1234567

Synonym: randomSeed

reduceAndSplitCuts: Whether to use Reduce-and-Split cuts ←

These cuts may be expensive to generate. Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node.

Reference: https://github.com/coin-or/Cgl/wiki/CglRedSplit

Range: off, on, root, ifmove, forceOn

Default: off

reduceAndSplitCuts2: Whether to use Reduce-and-Split cuts - style 2 ←
This switches on reduce and split cuts (either at root or in entire tree). This version is by Giacomo Nannicini based on Francois Margot’s version. Standard setting only uses rows in tableau $\leq 256$, long uses all. These cuts may be expensive to generate. See option cuts for more information on the possible values.

Range: off, on, root, longOn, longRoot

Default: off

Synonym: reduce2AndSplitCuts

**Rens**: Whether to try Relaxation Enforced Neighborhood Search $\leftrightarrow$

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve. Value 'on' just does 50 nodes. 200, 1000, and 10000 does that many nodes.

**residualCapacityCuts**: Whether to use Residual Capacity cuts $\leftrightarrow$

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglResidualCapacity

Range: off, on, root, ifmove, forceOn

Default: off

**reslim**: maximum seconds $\leftrightarrow$

Range: $[-1, \infty]$  
Default: GAMS reslim  
Synonym: seconds

**Rins**: Whether to try Relaxed Induced Neighborhood Search $\leftrightarrow$

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

**scaling**: Whether to scale problem

Scaling can help in solving problems which might otherwise fail because of lack of accuracy. It can also reduce the number of iterations. It is not applied if the range of elements is small. When the solution is evaluated in the unscaled problem, it is possible that small primal and/or dual infeasibilities occur. Option 'equilibrium' uses the largest element for scaling. Option 'geometric' uses the squareroot of the product of largest and smallest element. Option 'auto' let CLP choose a method that gives the best ratio of the largest element to the smallest one.

<table>

</tbody>
</table>

Default: automatic

**smallFactorization**: Threshold for using small factorization

If processed problem ≤ this use small factorization
Range: \{-1, ..., 10000\}
Default: -1

**sollim:** Maximum number of feasible solutions to get \(\rightarrow\)

Range: \(\{1, ..., \infty\}\)
Default: \(\infty\)
Synonym: maxSolutions

**solvefinal:** final solve of MIP with fixed discrete variables \(\leftrightarrow\)

Whether the MIP with discrete variables fixed to solution values should be solved after CBC finished.
Range: boolean
Default: 1

**solvetrace:** name of trace file for solving information \(\leftrightarrow\)

Name of file for writing solving progress information during solve.
Range: string
Default: *empty*

**solvetracenodefreq:** frequency in number of nodes for writing to solve trace file \(\leftrightarrow\)

Range: \(\{0, ..., \infty\}\)
Default: 100

**solvetracetimefreq:** frequency in seconds for writing to solve trace file \(\leftrightarrow\)

Range: \([0, \infty]\]
Default: 5

**sosPrioritize:** How to deal with SOS priorities \(\leftrightarrow\)

This sets priorities for SOS. Values 'high' and 'low' just set a priority relative to the for integer variables. Value 'orderhigh' gives first highest priority to the first SOS and integer variables a low priority. Value 'orderlow' gives integer variables a high priority then SOS in order.

Range: off, high, low, orderhigh, orderlow
Default: off

**sparseFactor:** Whether factorization treated as sparse \(\leftrightarrow\)

Range: boolean
Default: 1

**special:** options passed unseen to CBC \(\leftrightarrow\)
This parameter lets you specify CBC options which are not supported by the GAMS/CBC interface. The string value given to this parameter is split up into parts at each space and added to the array of parameters given to CBC (in front of the -solve command). Hence, you can use it like the command line parameters for the CBC standalone version.

Range: string

Default: empty

**sprintCrash**: Whether to try sprint crash

For long and thin problems this method may solve a series of small problems created by taking a subset of the columns. The idea as 'Sprint' was introduced by J. Forrest after an LP code of that name of the 60's which tried the same tactic (not totally successfully). CPLEX calls it 'sifting'. -1 lets CLP automatically choose the number of passes, 0 is off, n is number of passes

Range: {-1, ..., ∞}

Default: -1

Synonym: sifting

**startalg**: LP solver for root node

Determines the algorithm to use for an LP or the initial LP relaxation if the problem is a MIP.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>primal</td>
<td>Primal Simplex algorithm</td>
</tr>
<tr>
<td>dual</td>
<td>Dual Simplex algorithm</td>
</tr>
<tr>
<td>barrier</td>
<td>Primal-dual predictor-corrector algorithm</td>
</tr>
</tbody>
</table>

Default: dual

**strategy**: Switches on groups of features

This turns on newer features. Use 0 for easy problems, 1 is default, 2 is aggressive. 1 uses Gomory cuts with a tolerance of 0.01 at the root node, does a possible restart after 100 nodes if many variables could be fixed, activates a diving and RINS heuristic, and makes the feasibility pump more aggressive.

Range: {0, ..., 2}

Default: 1

**strongBranching**: Number of variables to look at in strong branching

In order to decide which variable to branch on, the code will choose up to this number of unsatisfied variables to try minimal up and down branches on. Then the most effective one is chosen. If a variable is branched on many times then the previous average up and down costs may be used - see also option trustPseudoCosts.

Range: {0, ..., ∞}

Default: 5

**substitution**: How long a column to substitute for in presolve
Normally Presolve gets rid of 'free' variables when there are no more than 3 coefficients in a row. If you increase this, the number of rows may decrease but the number of coefficients may increase.

Range: \([0, ..., 10000]\)

Default: 3

**threads**: Number of threads to try and use

Range: \([1, ..., 99]\)

Default: GAMS threads

**tol_dual**: For an optimal solution no dual infeasibility may exceed this value

Normally the default tolerance is fine, but one may want to increase it a bit if the dual simplex algorithm seems to be having a hard time. One method which can be faster is to use a large tolerance e.g. 1.0e-4 and the dual simplex algorithm and then to clean up the problem using the primal simplex algorithm with the correct tolerance (remembering to switch off presolve for this final short clean up phase).

Range: \([1e-20, \infty]\)

Default: 1e-07

Synonym: dualTolerance

**tol_integer**: For a feasible solution no integer variable may be more than this away from an integer value

Beware of setting this smaller than the primal feasibility tolerance.

Range: \([1e-20, 0.5]\)

Default: 1e-07

Synonym: integerTolerance

**tol_presolve**: Tolerance to use in presolve

One may want to increase this tolerance if presolve says the problem is infeasible and one has awkward numbers and is sure that the problem is really feasible.

Range: \([1e-20, \infty]\)

Default: 1e-08

Synonym: preTolerance

**tol_primal**: For a feasible solution no primal infeasibility, i.e., constraint violation, may exceed this value

Normally the default tolerance is fine, but one may want to increase it a bit if the primal simplex algorithm seems to be having a hard time.

Range: \([1e-20, \infty]\)

Default: 1e-07

Synonym: primalTolerance
**trustPseudoCosts**: Number of branches before we trust pseudocosts 🔄

Using strong branching computes pseudo-costs. This parameter determines after how many branches for a variable we just trust the pseudo costs and do not do any more strong branching.

Range: \(-3, \ldots, \infty\)

Default: 10

**twoMirCuts**: Whether to use Two phase Mixed Integer Rounding cuts 🔄

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: [https://github.com/coin-or/Cgl/wiki/CglTwomir](https://github.com/coin-or/Cgl/wiki/CglTwomir)

Range: off, on, root, ifmove, forceOn, onglobal, forceandglobal, forceLongOn

Default: root

**VndVariableNeighborhoodSearch**: Whether to try Variable Neighborhood Search 🔄

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before, intree

Default: off

**vubheuristic**: Type of VUB heuristic 🔄

This heuristic tries and fix some integer variables.

Range: \{-2, \ldots, 20\}

Default: -1

**writemps**: create MPS file for problem 🔄

Write the problem formulation in MPS format. The parameter value is the name of the MPS file.

Range: string

Default: empty

**zeroHalfCuts**: Whether to use zero half cuts 🔄

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. This implementation was written by Alberto Caprara.

Range: off, on, root, ifmove, forceOn, onglobal

Default: ifmove
5.7 CONOPT

Author
Arne Drud, ARKI Consulting and Development A/S, Bagsvaerd, Denmark

5.7.1 Introduction

Nonlinear models created with GAMS must be solved with a nonlinear programming (NLP) algorithm. Currently, there is a large number of different solvers available and the number is growing.

The most important distinction between the solvers is whether they attempt to find a local or a global solution. Solvers that attempt to find a global solution (so called Global Solvers) can usually not solve very large models. As a contrast most Local Solvers can work with much larger models, and models with over 10,000 variables and constraints are not unusual. If the model has the right mathematical properties, e.g. is convex, then Local Solvers will find a global optimum. Unfortunately, the mathematical machinery for testing whether a general NLP model is convex or not has not yet been developed (and is expected to be in the class or hard problems).

It is almost impossible to predict how difficult it is to solve a particular model with a particular algorithm, especially for NLP models, so GAMS cannot select the best algorithm for you automatically. When GAMS is installed you must select one of the nonlinear programming algorithms as the default solver for NLP models. If you want to switch between algorithms for a particular model you may add the statement

Option NLP = <solvername>, in your GAMS source file before the Solve statement, you may add NLP = <solvername> on the GAMS command line or by rerunning the gamsinst program.

The only reliable way to find which solver to use for a particular class of models is so far to experiment. However, there are a few rules of thumb:

GAMS/CONOPT is well suited for models with very nonlinear constraints. If you experience that a solver has problems maintaining feasibility during the optimization you should try CONOPT. On the other hand, if you have a model with few nonlinearities outside the objective function then other solvers could be the best solver.

GAMS/CONOPT has a fast method for finding a first feasible solution that is particularly well suited for models with few degrees of freedom. If you have a model with roughly the same number of constraints as variable you should try CONOPT. CONOPT can also be used to solve square systems of equations without an objective function corresponding to the GAMS model class CNS - Constrained Nonlinear System.

GAMS/CONOPT can use second derivatives. If the number of variables is much larger than the number of constraints CONOPT will use second derivatives and overall progress can be considerably faster than for MINOS or SNOPT. IPOPT and KNITRO will also use second derivatives, but the method is very different and it is not possible to predict which solver will be better.

GAMS/CONOPT has a preprocessing step in which recursive equations and variables are solved and removed from the model. If you have a model where many equations can be solved one by one then CONOPT will take advantage of this property. Similarly, intermediate variables only used to define objective terms are eliminated from the model and the constraints are moved into the objective function.

GAMS/CONOPT has many built-in tests and messages, and many models that can and should be improved by the modeler are rejected with a constructive message. CONOPT is therefore also a helpful debugging tool during model development. The best solver for the final, debugged model may or may not be CONOPT.
GAMS/CONOPT has been designed for large and sparse models. This means that both the number of variables and equations can be large. Indeed, NLP models with over 100,000 equations and variables have been solved successfully, and CNS models with over 1,000,000 equations and variables have also been solved. The components used to build CONOPT have been selected under the assumptions that the model is sparse, i.e. that most functions only depend on a small number of variables. CONOPT can also be used for denser models, but the performance will suffer significantly.

GAMS/CONOPT is designed for models with smooth functions, but it can also be applied to models that do not have differentiable functions, in GAMS called DNLP models. However, CONOPT will use the same algorithm used for a real NLP model and it will search for a point that satisfies standard first-order optimality conditions without taking into account that parts of the model could be non-smooth or non-differentiable. The lack of smoothness may confuse the algorithm in CONOPT causing slow convergence, and a point that satisfies standard first-order optimality conditions may not even exist. There are therefore no guarantees whatsoever for this class of models. If CONOPT terminates with a locally optimal solution then the solution will indeed be locally optimal. However, you will sometimes get termination messages like "Convergence too slow" or "No change in objective although the reduced gradient is greater than the tolerance" that indicate unsuccessful termination. The final point may or may not be locally optimal. If possible, you should try to reformulate a DNLP model to an equivalent or approximately equivalent form as described in section NLP and DNLP Models.

Most modelers should not be concerned with algorithmic details such as choice of algorithmic sub-components or tolerances. CONOPT has considerable build-in logic that selects a solution approach that seems to be best suited for the type of model at hand, and the approach is adjusted dynamically as information about the behavior of the model is collected and updated. The description of the CONOPT algorithm has therefore been moved to an appendix (Appendix A) and most modelers can skip it. However, if you are solving very large or complex models or if you are experiencing solution difficulties you may benefit from using non-standard tolerances or options, in which case you will need some understanding of what CONOPT is doing to your model. Some guidelines for selecting options can be found at the end of Appendix A and a list of all options and tolerances is shown in Appendix B.

The main text of this User's Guide will give a short overview over the iteration output you will see on the screen (section Iteration Output), and explain the termination messages (section GAMS/CONOPT Termination Messages). We will then discuss function evaluation errors (section Function Evaluation Errors), the use of options (section The CONOPT Options File), and give a CONOPT perspective on good model formulation including topics such as initial values and bounds, simplification of expressions, and scaling (section Hints on Good Model Formulation). Finally, we will discuss the difference between NLP and DNLP models (section NLP and DNLP Models).

5.7.2 Iteration Output

On most machines you will by default get a logline on your screen or terminal at regular intervals. The iteration log may look something like this:

```

** Optimal solution. Reduced gradient less than tolerance.

The first few lines identify the version of CONOPT you use.

The first iterations have a special interpretation: iteration 0 represents the initial point exactly as received from GAMS, iteration 1 represents the point that is the result of CONOPT’s pre-processing, and iteration 2 represents the same point after scaling (even if scaling is turned off).

The remaining iterations are characterized by the value of "Phase" in column 2. The model is infeasible during Phase 0, 1, and 2 and the Sum of Infeasibilities in column 4 (labeled "Infeasibility") is being minimized; the model is feasible during Phase 3 and 4 and the actual objective function, also shown in column 4 (now labeled "Objective"), is minimized or maximized. Phase 0 iterations are Newton-like iterations. They are very cheap so you should not be concerned if there are many of these Phase 0 iterations. During Phase 1 and 3 the model behaves almost linearly and CONOPT applies special linear iterations that take advantage of the linearity. These iterations are sometimes augmented with some inner "Sequential Linear Programming" (SLP) iterations, indicated by a number of inner SLP iterations in the "InItr" column. During Phase 2 and 4 the model behaves more nonlinear and most aspects of the
iterations are therefore changed: the line search is more elaborate, and CONOPT needs second order information to improve the convergence. For small and simple models CONOPT will approximate second order information as a byproduct of the line searches. For larger and more complex models CONOPT will use some inner "Sequential Quadratic Programming" (SQP) iterations based on exact second derivatives. These SQP iterations are identified by the number of inner SQP iterations in the "InItr" column.

The column "NSB" for Number of SuperBasics defines the degree of freedom or the dimension of the current search space, and "rgmax" measures the largest reduced gradient among the non-optimal variables. Rgmax should eventually converge towards zero, but convergence is not expected to be monotone. The last two columns labeled "MX" and "OK" gives information about the line search: OK = T means that the line search was well-behaved, and OK = F means that the line search was terminated before an optimal step length was found because it was not possible to find a feasible solution for large step lengths. MX = T means that the line search was terminated by a variable reaching a bound (always combined with OK = T), and MX = F means that the step length was determined by nonlinearities. If OK = T then the step length was optimal; if OK = F then the constraints were too nonlinear to allow CONOPT to make a full optimal step.

5.7.3 GAMS/CONOPT Termination Messages

GAMS/CONOPT may terminate in a number of ways. This section will show most of the termination messages and explain their meaning. It will also show the Model Status returned to GAMS in `<model>.ModelStat`, where `<model>` represents the name of the GAMS model. The Solver Status returned in `<model>.SolveStat` will be given if it is different from 1 (Normal Completion). We will in all cases first show the message from CONOPT followed by a short explanation. The first 4 messages are used for optimal solutions and CONOPT will return ModelStat = 2 (Locally Optimal), except as noted below:

** Optimal solution. There are no superbasic variables.

The solution is a locally optimal corner solution. The solution is determined by constraints only, and it is usually very accurate. In some cases CONOPT can determine that the solution is globally optimal and it will return ModelStat = 1 (Optimal).

** Optimal solution. Reduced gradient less than tolerance.

The solution is a locally optimal interior solution. The largest component of the reduced gradient is less than the tolerance `rtredg` with default value 1.e-7. The value of the objective function is very accurate while the values of the variables are less accurate due to a flat objective function in the interior of the feasible area.

** Optimal solution. The error on the optimal objective function value estimated from the reduced gradient and the estimated Hessian is less than the minimal tolerance on the objective.

The solution is a locally optimal interior solution. The largest component of the reduced gradient is larger than the tolerance `rtredg`. However, when the reduced gradient is scaled with information from the estimated Hessian of the reduced objective function the solution seems optimal. For this to happen the objective must be large or the reduced objective must have large second derivatives so it is advisable to scale the model. See the sections on "Scaling" and "Using the Scale Option in GAMS" for details on how to scale a model.
** Optimal solution. Convergence too slow. The change in objective has been less than xx.xx for xx consecutive iterations.

CONOPT stops with a solution that seems optimal. The solution process is stopped because of slow progress. The largest component of the reduced gradient is greater than the optimality tolerance \texttt{rtredg}, but less than \texttt{rtredg} multiplied by the largest Jacobian element divided by 100. The model must have large derivatives so it is advisable to scale it.

The four messages above all exist in versions where "Optimal" is replaced by "Infeasible" and ModelStat will be 5 (Locally Infeasible) or 4 (Infeasible). The infeasible messages indicate that a Sum of Infeasibility objective function is locally minimal, but positive. If the model is convex it does not have a feasible solution; if the model is non-convex it may have a feasible solution in a different region. See the section on "Initial Values" for hints on what to do.

** Feasible solution. Convergence too slow. The change in objective has been less than xx.xx for xx consecutive iterations.

** Feasible solution. The tolerances are minimal and there is no change in objective although the reduced gradient is greater than the tolerance.

The two messages above tell that CONOPT stops with a feasible solution. In the first case the solution process is very slow and in the second there is no progress at all. However, the optimality criteria have not been satisfied. These messages are accompanied by ModelStat = 7 (Feasible Solution) and SolveStat = 4 (Terminated by Solver). The problem can be caused by discontinuities if the model is of type DNLP; in this case you should consider alternative, smooth formulations as discussed in section NLP and DNLP Models. The problem can also be caused by a poorly scaled model. See section Scaling for hints on model scaling. Finally, it can be caused by stalling as described in section Stalling in Appendix A. The two messages also exist in a version where "Feasible" is replaced by "Infeasible". ModelStat is in this case 6 (Intermediate Infeasible) and SolveStat is still 4 (Terminated by Solver); these versions tell that CONOPT cannot make progress towards feasibility, but the Sum of Infeasibility objective function does not have a well defined local minimum.

** Unbounded solution. A variable has reached 'infinity'.
Largest legal value (Rtmaxv) is xx.xx

CONOPT considers a solution to be unbounded if a variable exceeds the indicated value of \texttt{rtmaxv} (default \texttt{1.e10}) and it returns with ModelStat = 3 (Unbounded). The check for unboundedness is done at every iteration which means that CONOPT will stop if an intermediate solution has a variable that is very large, even if none of the variables in the optimal solution have large values. Check whether the solution appears unbounded or the problem is caused by the scaling of the unbounded variable "<var>" mentioned in the first line of the message. If the model seems correct you are advised to scale it. There is also a lazy solution: you can increase the largest legal value, \texttt{rtmaxv}, as mentioned in the section on options. However, you will pay through reduced reliability or increased solution times. Unlike LP models, where an unbounded model is recognized by an unbounded ray and the iterations are stopped far from "infinity", CONOPT will actually have to make a line search and move to a region with large values of the variables. This may lead to bad scaling and to many different kinds of tolerance and roundoff problems, including problems of determining whether a solution is feasible or not.

The message above exists in a version where "Unbounded" is replaced by "Infeasible" and ModelStat is 5 (Locally Infeasible). You may also see a message like
5.7 CONOPT

**<var>: Free variable becomes too large**

- Free variable becomes too large

**Infeasible solution. A free variable exceeds the allowable range. Current value is 1.02E+10 and current upper bound (Rtmaxv) is 1.00E+10**

These two messages indicate that some variables become very large before a feasible solution has been found. You should again check whether the problem is caused by the scaling of the unbounded variable "<var>" mentioned in the first line of the message. If the model seems correct you should scale it.

**The time limit has been reached.**

The time or resource limit defined in GAMS, either by default (usually 1000 seconds) or by Option ResLim = xx; or <model>.ResLim = xx; statements, has been reached. CONOPT will return with SolveStat = 3 (Resource Interrupt) and ModelStat either 6 (Locally Infeasible) or 7 (Feasible Solution).

**The iteration limit has been reached.**

The iteration limit defined in GAMS, either by default (usually 2000000000 iterations) or by Option IterLim = xx; or <model>.IterLim = xx; statements, has been reached. CONOPT will return with SolveStat = 2 (Iteration Interrupt) and ModelStat either 6 (Locally Infeasible) or 7 (Feasible Solution).

**Domain errors in nonlinear functions.**

- Check bounds on variables.

- The number of function evaluation errors has reached the limit defined in GAMS by Option DomLim = xx; or <model>.DomLim = xx; statements or the default limit of 0 function evaluation errors. CONOPT will return with SolveStat = 5 (Evaluation Error Limit) and ModelStat either 6 (Locally Infeasible) or 7 (Feasible Solution). See more details in section Function Evaluation Errors.

**An initial derivative is too large (larger than Rtmaxj= xx.xx)**

- Scale the variables and/or equations or add bounds.

- **<var> appearing in**

- **<equ>: Initial Jacobian element too large = xx.xx**

and

**A derivative is too large (larger than Rtmaxj= xx.xx).**

- Scale the variables and/or equations or add bounds.

- **<var> appearing in**

- **<equ>: Jacobian element too large = xx.xx**

These two messages appear if a derivative or Jacobian element is very large, either in the initial point or in a later intermediate point. The relevant variable and equation pair(s) will show you where to look. A large derivative means that the function changes very rapidly even after a very small change in the variable and it will most likely create numerical problems for many parts of the optimization algorithm. Instead of attempting to solve a model that most likely will fail, CONOPT will stop and you are advised to adjust the model if at all possible.

If the offending derivative is associated with a Log(x) or 1/x term you may try to increase the lower bound on x. If the offending derivative is associated with an Exp(x) term you must decrease the upper bound on x. You may also try to scale the model, either manually or using the variable.Scale and/or equation.Scale option in GAMS as described in section Scaling. There is also in this case a lazy solution: increase the limit on Jacobian elements, rtmaxj; however, you will pay through reduced reliability or longer solution times.

In addition to the messages shown above you may see messages like
** An equation in the pre-triangular part of the model cannot be solved because the critical variable is at a bound.

** An equation in the pre-triangular part of the model cannot be solved because of too small pivot.

or

** An equation is inconsistent with other equations in the pre-triangular part of the model.

These messages containing the word "Pre-triangular" are all related to infeasibilities identified by CONOPT's pre-processing stage and they are explained in detail in section Iteration 1: Preprocessing in Appendix A.

Usually, CONOPT will be able to estimate the amount of memory needed for the model based on statistics provided by GAMS. However, in some cases with unusual models, e.g. very dense models or very large models, the estimate will be too small and you must request more memory yourself using a statement like `<model>.WorkFactor = x.x;` or `<model>.WorkSpace = xx;` in GAMS or by adding `WorkFactor=xx` to the command line call of GAMS. The message you will see is similar to the following:

** FATAL ERROR ** Insufficient memory to continue the optimization.

You must request more memory.
Current CONOPT space = 0.29 Mbytes
Estimated CONOPT space = 0.64 Mbytes
Minimum CONOPT space = 0.33 Mbytes

CONOPT time Total 0.109 seconds
of which: Function evaluations 0.000 = 0.0%
1st derivative evaluations 0.000 = 0.0%

The text after "Insufficient memory to" may be different; it says something about where CONOPT ran out of memory. If the memory problem appears during model setup the message will be accompanied by SolveStat = 13 (System Failure) and ModelStat = 13 (Error No Solution) and CONOPT will not return any values. If the memory problem appears later during the optimization SolveStat will be 11 (Internal Solver Failure) and ModelStat will be either 6 (Intermediate Infeasible) or 7 (Feasible Solution) and CONOPT will return primal solution values. The marginals of both equations and variables will be zero or EPS.

It is recommended that you use the WorkFactor option if you must change the amount of memory. The same number will usually work for a whole family of models. If you prefer to use WorkSpace, the GAMS WorkSpace option corresponds to the amount of memory, measured in Mbytes.

A new termination message has been added from version 3.16C:

** Feasible solution. The solution process has been terminated because intermediate results have become NaN (Not A Number).

and similar with Infeasible. To prevent non-sensible results and/or infinite loops in special degenerate cases CONOPT has added checks for internal intermediate results being NaN (Not A Number) or very large. If this happens CONOPT will try to change some tolerances and try to continue the optimization. If this attempt fails CONOPT will stop and return the message above. The solver status will return 4 "Terminated by Solver" and model status 6 or 7, "Intermediate Infeasible" or "Intermediate Feasible." Section Overflow and NaN (Not A Number) in Appendix A has more details on the sources of NaN and the actions that can be taken by the user and by CONOPT.
5.7.4 Function Evaluation Errors

Many of the nonlinear functions available with GAMS are not defined for all values of their arguments. Log is not defined for negative arguments, Exp overflows for large arguments, and division by zero is illegal. To avoid evaluating functions outside their domain of definition you should add reasonable variable bounds. CONOPT will in return guarantee that the nonlinear functions never are evaluated with variables outside their bounds.

In some cases bounds are not sufficient, e.g. in the expression Log( Sum(i, x(i) ) ): in some models each individual x should be allowed to become zero, but the Sum should not. In this case you should introduce an intermediate variable and an extra equation, e.g. xSumDef .. xSum =E= sum(i,x(i)); add a lower bound on xSum; and use xSum as the argument to the Log function. See section Simple Expressions for additional comments on this topic.

Whenever a nonlinear function is called outside its domain of definition, GAMS’ function evaluator will intercept the function evaluation error and prevent the system to crash. GAMS will replace the undefined result by some appropriate real number, and it will make sure the error is reported to the modeler as part of the standard solution output in the GAMS listing file. GAMS will also report the error to CONOPT, so CONOPT can try to correct the problem by backtracking to a safe point. Finally, CONOPT will be instructed to stop after DomLim errors.

During Phase 0, 1, and 3 CONOPT will often use large steps as the initial step in a line search and functions will very likely be called with some of the variables at their lower or upper bound. You are therefore likely to get a division-by-zero error if your model contains a division by x and x has a lower bound of zero. And you are likely to get an exponentiation overflow error if your model contains Exp(x) and x has no upper bound. However, CONOPT will usually not get trapped in a point outside the domain of definition for the model. When GAMS’ function evaluator reports that a point is ”bad”, CONOPT will decrease the step length, and it will for most models be able to recover and continue to an optimal solution. It is therefore safe to use a large value for DomLim instead of GAMS default value of 0.

CONOPT may get stuck in some cases, for example because there is no previous point to backtrack to, because ”bad” points are very close to ”reasonable” feasible points, or because the derivatives are not defined in a feasible point. The more common messages are:

** Fatal Error ** Function error in initial point in Phase 0 procedure.

** Fatal Error ** Function error after small step in Phase 0 procedure.

** Fatal Error ** Function error very close to a feasible point.

** Fatal Error ** Function error while reducing tolerances.

** Fatal Error ** Function error in Pre-triangular equations.

** Fatal Error ** Function error after Preprocessing.

** Fatal Error ** Function error in Post-triangular equation.

In the first four cases you must either add better bounds or define better initial values. If the problem is related to a pre- or post-triangular equation as shown by the last three messages then you can turn part of the pre-processing off as described in section Iteration 1: Preprocessing . in Appendix A. However, this may make the model harder to solve, so it is usually better to add bounds and/or initial values.
5.7.5 The CONOPT Options File

CONOPT has been designed to be self-tuning. Most tolerances are dynamic. As an example: The feasibility of a constraint is always judged relative to the dual variable on the constraint and relative to the expected change in objective in the coming iteration. If the dual variable is large then the constraint must be satisfied with a small tolerance, and if the dual variable is small then the tolerance is larger. When the expected change in objective in the first iterations is large then the feasibility tolerances are also large. And when we approach the optimum and the expected change in objective becomes smaller then the feasibility tolerances become smaller.

Because of the self-tuning nature of CONOPT you should in most cases be well off with default tolerances. If you do need to change some tolerances, possibly following the advice in Appendix A, it can be done in the CONOPT Options file. The name of the CONOPT Options file is on most systems "conopt.opt". You must tell the solver that you want to use an options file with the statement <model>.OptFile = 1 in your GAMS source file before the Solve statement or with OptFile = 1 on the command line.

The format of the CONOPT Options file consists in its simplest form of a number of lines like these:

```
rtmaxv = 1.e12
lfnsup = 500
```

The value must be written using legal GAMS format, i.e. a real number may contain an optional E exponent, but a number may not contain blanks. The value must have the same type as the option, i.e. real options must be assigned real values, integer options must be assigned integer values, and logical options must be assigned logical values. The logical value representing true are true, t, yes, or 1, and the logical values representing false are false, f, no, or 0.

In previous versions of CONOPT you could add "SET" in front of the option assignment. This is no longer supported. You can still replace the equal sign with := and you can add end of line comments after a # or ! character. Lines starting with * in column 1 are treated as comment lines.

5.7.6 Hints on Good Model Formulation

This section will contain some comments on how to formulate a nonlinear model so it becomes easier to solve with CONOPT. Most of the recommendations will be useful for any nonlinear solver, but not all. We will try to mention when a recommendation is CONOPT specific.

5.7.6.1 Initial Values

Good initial values are important for many reasons. Initial values that satisfy or closely satisfy many of the constraints reduces the work involved in finding a first feasible solution. Initial values that in addition are close to the optimal ones also reduce the distance to the final point and therefore indirectly the computational effort. The progress of the optimization algorithm is based on good directional information and therefore on good derivatives. The derivatives in a nonlinear model depend on the current point, and the initial point in which the initial derivatives are computed is therefore again important. Finally, non-convex models may have multiple solutions, but the modeler is looking for one in a particular part of the search space; an initial point in the right neighborhood is more likely to return the desired solution.

The initial values used by CONOPT are all coming from GAMS. The initial values used by GAMS are by default the value zero projected on the bounds. I.e. if a variable is free or has a lower bound of zero, then its default initial value is zero. Unfortunately, zero is in many cases a bad initial value for a nonlinear variable. An initial value of zero is especially bad if the variable appears in a product term since the initial derivative becomes zero, and it appears as if the function does not depend on the variable. CONOPT will
warn you and ask you to supply better initial values if the number of derivatives equal to zero is larger than 20 percent.

If a variable has a small positive lower bound, for example because it appears as an argument to the Log function or as a denominator, then the default initial value is this small lower bound and it is also bad since this point will have very large first and second derivatives.

You should therefore supply as many sensible initial values as possible by making assignment to the level value, var.L, in GAMS. An easy possibility is to initialize all variables to 1, or to the scale factor if you use GAMS’ scaling option. A better possibility is to select reasonable values for some variables that from the context are known to be important, and then use some of the equations of the model to derive values for other variables. A model may contain the following equation:

\[
\text{pmDef(it)} \quad \text{pm(it) =e= pwm(it)*er*(1 + tm(it))};
\]

where pm, pwm, and er are variables and tm is a parameter. The following assignment statements use the equation to derive consistent initial values for PM from sensible initial values for pwm and er:

\[
er.l = 1;\quad \text{pwm.l(it)} = 1;
\]

\[
\text{pm.l(it)} = \text{pwm.l(it)}*\text{er.l}*(1 + \text{tm(it)});
\]

With these assignments equation pmDef will be feasible in the initial point, and since CONOPT uses a feasible path method it will remain feasible throughout the optimization (unless the pre-processor destroys it, see section Iteration 1: Preprocessing in Appendix A).

If CONOPT has difficulties finding a feasible solution for your model you should try to use this technique to create an initial point in which as many equations as possible are satisfied. You may also try the optional Crash procedure described in section Preprocessing: The Optional Crash Procedure in Appendix A by adding the line `lstcrs=t` to the CONOPT options file. The crash procedure tries to identify equations with a mixture of uninitialized variables and variables with initial values, and it solves the equations with respect to the uninitialized variables; the effect is similar to the manual procedure shown above.

### 5.7.6.2 Bounds

Bounds have two purposes in nonlinear models. Some bounds represent constraints on the reality that is being modeled, e.g. a variable must be positive. These bounds are called model bounds. Other bounds help the algorithm by preventing it from moving far away from any optimal solution and into regions with singularities in the nonlinear functions or unreasonably large function or derivative values. These bounds are called algorithmic bounds.

Model bounds have natural roots and do not cause any problems. Algorithmic bounds require a closer look at the functional form of the model. The content of a Log should be greater than say 1.e-3, the content of an Exp should be less than 5 to 8, and a denominator should be greater than say 1.e-2. These recommended lower bounds of 1.e-3 and 1.e-2 may appear to be unreasonably large. However, both Log(x) and 1/x are extremely nonlinear for small arguments. The first and second derivatives of Log(x) at x=1.e-3 are 1.e+3 and -1.e6, respectively, and the first and second derivatives of 1/x at x=1.e-2 are -1.e+4 and 2.e+6, respectively.

If the content of a Log or Exp function or a denominator is an expression then it may be advantageous to introduce a bounded intermediate variable as discussed in the next section.

Note that bounds in some cases can slow the solution process down. Too many bounds may for example introduce degeneracy. If you have constraints of the following type
vub(i) .. x(i) =l= y;

or

ysum .. y =e= sum( i, x(i) );

and x is a Positive Variable then you should in general not declare y a Positive Variable or add a lower bound of zero on y. If y appears in a nonlinear function you may need a strictly positive bound. Otherwise, you should declare y a free variable; CONOPT will then make y basic in the initial point and y will remain basic throughout the optimization. New logic in CONOPT tries to remove this problem by detecting when a harmful bound is redundant so it can be removed, but it is not yet a fool proof procedure.

Section Iteration 1: Preprocessing in Appendix A gives another example of bounds that can be counter productive.

5.7.6.3 Simple Expressions

The following model component

Parameter mu(i);
Variable x(i), s(i), obj;
Equation objDef;
objDef .. obj =e= Exp( Sum( i, Sqr( x(i) - mu(i) ) / s(i) ) );

can be re-written in the slightly longer but simpler form

Parameter mu(i);
Variable x(i), s(i), obj, inTerm;
Equation intDef, objDef;
intDef .. inTerm =e= Sum( i, Sqr( x(i) - mu(i) ) / s(i) );
objDef .. obj =e= Exp( inTerm );

The first formulation has very complex derivatives because Exp is taken of a long expression. The second formulation has much simpler derivatives; Exp is taken of a single variable, and the variables in intDef appear in a sum of simple independent terms.

In general, try to avoid nonlinear functions of expressions, divisions by expressions, and products of expressions, especially if the expressions depend on many variables. Define intermediate variables that are equal to the expressions and apply the nonlinear function, division, or product to the intermediate variable. The model will become larger, but the increased size is taken care of by CONOPT's sparse matrix routines, and it is compensated by the reduced complexity. If the model is solved with CONOPT using explicit second derivatives then simple expressions will result in sparser second derivatives that are both faster to compute and to use.

The reduction in complexity can be significant if an intermediate expression is linear. The following model fragment:

Variable x(i), y;
Equation yDef;
yDef .. y =e= 1 / Sum( i, x(i) );
should be written as

```
Variable x(i), xSum, y;
Equation xSumDef, yDef;
xSumDef .. xSum =e= Sum(i, x(i) );
yDef .. y =e= 1 / xSum;
xSum.lo = 1.e-2;
```

for three reasons. First, because the number of nonlinear derivatives is reduced in number and complexity. Second, because the lower bound on the intermediate result will bound the search away from the singularity at xSum = 0. And third, because the matrix of second derivatives for the last model only depend on xSum while it depends on all x in the first model.

The last example shows an added potential saving by expanding functions of linear expressions. A constraint depends in a nonlinear fashion on the accumulated investments, inv, like

```
con(i) .. f( Sum( j$(ord(j) le ord(i)), inv(j) ) ) <= b(i);
```

A new intermediate variable, cap(i), that is equal to the content of the Sum can be defined recursively with the constraints

```
cDef(i) .. cap(i) =e= inv(i) + cap(i-1);
```

and the original constraints become

```
con(i) .. f( cap(i) ) =l= b(i);
```

The reformulated model has n additional variables and n additional linear constraints. In return, the original n complex nonlinear constraints have been changed into n simpler nonlinear constraints. And the number of Jacobian elements, that has a direct influence on much of the computational work both in GAMS and in CONOPT, has been reduced from n*(n+1)/2 nonlinear elements to 3*n-1 linear elements and only n nonlinear element. If f is an invertible increasing function you may even rewrite the last constraint as a simple bound:

```
cap.10(i) = finv(b(i));
```

Some NLP solvers encourage you to move as many nonlinearities as possible into the objective which may make the objective very complex. This is neither recommended nor necessary with CONOPT. A special pre-processing step (discussed in section Iteration 1: Preprocessing in Appendix A) will aggregate parts of the model if it is useful for CONOPT without increasing the complexity in GAMS.
5.7.6.4 Scaling

Nonlinear as well as Linear Programming Algorithms use the derivatives of the objective function and the constraints to determine good search directions, and they use function values to determine if constraints are satisfied or not. The scaling of the variables and constraints, i.e. the units of measurement used for the variables and constraints, determine the relative size of the derivatives and of the function values and thereby also the search path taken by the algorithm.

Assume for example that two goods of equal importance both cost $1 per kg. The first is measured in gram, the second in tons. The coefficients in the cost function will be $1000/g and $0.001/ton, respectively. If cost is measured in $1000 units then the coefficients will be 1 and 1.e-6, and the smaller may be ignored by the algorithm since it is comparable to some of the zero tolerances.

CONOPT assumes implicitly that the model to be solved is well scaled. In this context well scaled means:

- Basic and superbasic solution values are expected to be around 1, e.g. from 0.01 to 100. Nonbasic variables will be at a bound, and the bound values should not be larger than say 100.
- Dual variables (or marginals) on active constraints are expected to be around 1, e.g. from 0.01 to 100. Dual variables on non-binding constraints will of course be zero.
- Derivatives (or Jacobian elements) are expected to be around 1, e.g. from 0.01 to 100.

Variables become well scaled if they are measured in appropriate units. In most cases you should select the unit of measurement for the variables so their expected value is around unity. Of course there will always be some variation. Assume x(i) is the production at location i. In most cases you should select the same unit of measurement for all components of x, for example a value around the average capacity.

Equations become well scaled if the individual terms are measured in appropriate units. After you have selected units for the variables you should select the unit of measurement for the equations so the expected values of the individual terms are around one. If you follow these rules, material balance equations will usually have coefficients of plus and minus one.

Derivatives will usually be well scaled whenever the variables and equations are well scaled. To see if the derivatives are well scaled, run your model with a positive Option LimRow and look for very large or very small coefficients in the equation listing in the GAMS output file.

CONOPT computes a measure of the scaling of the Jacobian, both in the initial and in the final point, and if it seems large it will be printed. The message looks like:

** WARNING ** The variance of the derivatives in the initial point is large (= 4.1 ). A better initial point, a better scaling, or better bounds on the variables will probably help the optimization.

The variance is computed as Sqrt(Sum(Log(Abs(jac(i)))**2)/nz) where jac(i) represents the nz nonzero derivatives (Jacobian elements) in the model. A variance of 4.1 corresponds to an average value of Log(jac)**2 of 4.1**2, which means that Jacobian values outside the range Exp(-4.1)=0.017 to Exp(+4.1)=60.4 are about as common at values inside. This range is for most models acceptable, while a variance of 5, corresponding to about half the derivatives outside the range Exp(-5)=0.0067 to Exp(+5)=148, can be dangerous.
5.7.6.4.1 Scaling of Intermediate Variables Many models have a set of variables with a real economic or physical interpretation plus a set of intermediate or helping variables that are used to simplify the model. We have seen some of these in section Simple Expressions on Simple Expressions. It is usually rather easy to select good scaling units for the real variables since we know their order of magnitude from economic or physical considerations. However, the intermediate variables and their defining equations should preferably also be well scaled, even if they do not have an immediate interpretation. Consider the following model fragment where \( x, y, \) and \( z \) are variables and \( y \) is the intermediate variable:

```
Set p / p0*p4 /
Parameter a(p) / p0 211, p1 103, p2 42, p3 31, p4 6 /
yDef .. y =e= Sum(p, a(p)*Power(x,Ord(p)-1));
zDef .. z =e= Log(y);
```

\( x \) lies in the interval 1 to 10 which means that \( y \) will be between 211 and 96441 and \( Z \) will be between 5.35 and 11.47. Both \( x \) and \( z \) are reasonably scaled while \( y \) and the terms and derivatives in \( yDef \) are about a factor 1.e4 too large. Scaling \( y \) by 1.e4 and renaming it \( ys \) gives the following scaled version of the model fragment:

```
yDefs1 .. ys =e= Sum(p, a(p)*Power(x,Ord(p)-1))*1.e-4;
zDefs1 .. z =e= Log(ys*1.e4);
```

The \( z \) equation can also be written as

```
zDefs2 .. z =e= Log(ys) + Log(1.e4);
```

Note that the scale factor 1.e-4 in the \( yDefs1 \) equation has been placed on the right hand side. The mathematically equivalent equation

```
yDefs2 .. ys*1.e4 =e= Sum(p, a(p)*Power(x,Ord(p)-1));
```

will give a well scaled \( ys \), but the right hand side terms of the equation and their derivatives have not changed from the original equation \( yDef \) and they are still far too large.

5.7.6.4.2 Using the Scale Option in GAMS The rules for good scaling mentioned above are exclusively based on algorithmic needs. GAMS has been developed to improve the effectiveness of modelers, and one of the best ways seems to be to encourage modelers to write their models using a notation that is as "natural" as possible. The units of measurement is one part of this natural notation, and there is unfortunately often a conflict between what the modeler thinks is a good unit and what constitutes a well scaled model.

To facilitate the translation between a natural model and a well scaled model GAMS has introduced the concept of a scale factor, both for variables and equations. The notation and the definitions are quite simple. First of all, scaling is by default turned off. To turn it on, enter the statement `<model>.ScaleOpt = 1;` in your GAMS program somewhere after the `Model` statement and before the `Solve` statement. `<model>` is the name of the model to be solved. If you want to turn scaling off again, enter the statement `<model>.ScaleOpt = 0;` somewhere before the next `Solve`.

The scale factor of a variable or an equation is referenced with the suffix ".Scale", i.e. the scale factor of variable \( x(i) \) is referenced as \( x.Scale(i) \). Note that there is one scale value for each individual component of a multidimensional variable or equation. Scale factors can be defined in assignment statements with \( x.Scale(i) \) on the left hand side, and scale factors, both from variables and equations, can be used on the right hand side, for example to define other scale factors. The default scale factor is always 1, and a scale factor must be positive; GAMS will generate an execution time error if the scale factor is less than 1.e-20.

The mathematical definition of scale factors is as follows: The scale factor on a variable, \( V^x \) is used to related the variable as seen by the modeler, \( V^m \), to the variable as seen by the algorithm, \( V^a \), as follows:
\[ V^m = V^a \times V^s \]

This means, that if the variable scale, \( V^s \), is chosen to represent the order of magnitude of the modeler's variable, \( V^m \), then the variable seen by the algorithm, \( V^a \), will be around 1. The scale factor on an equation, \( G^s \), is used to related the equation as seen by the modeler, \( G^m \), to the equation as seen by the algorithm, \( G^a \), as follows:

\[ G^m = G^a \times G^s \]

This means, that if the equation scale, \( G^s \), is chosen to represent the order of magnitude of the individual terms in the modeler's version of the equation, \( G^m \), then the terms seen by the algorithm, \( G^a \), will be around 1.

The derivatives in the scaled model seen by the algorithm, i.e. \( dG^a/dV^a \), are related to the derivatives in the modeler's model, \( dG^m/dV^m \), through the formula:

\[ dG^a/dV^a = dG^m/dV^m \times V^s/G^s \]

i.e. the modelers derivative is multiplied by the scale factor of the variable and divided by the scale factor of the equation. Note, that the derivative is unchanged if \( V^s = G^s \). Therefore, if you have a GAMS equation like

\[ G .. V =e= \text{expression}; \]

and you select \( G^s = V^s \) then the derivative of \( V \) will remain 1. If we apply these rules to the example above with an intermediate variable we can get the following automatic scale calculation, based on an "average" reference value for \( x \):

```gams
Scalar xRef; xRef = 6;
y.Scale = Sum(p, a(p)*Power(xRef,Ord(p)-1));
yDef.Scale = y.Scale;
```

or we could scale \( y \) using values at the end of the \( x \) interval and add safeguards as follows:

```gams
y.Scale = Max( Abs(Sum(p, a(p)*Power(x.Lo,Ord(p)-1))),
                 Abs(Sum(p, a(p)*Power(x.Up,Ord(p)-1)));
```

Lower and upper bounds on variables are automatically scaled in the same way as the variable itself. Integer and binary variables cannot be scaled.

GAMS' scaling is in most respects hidden for the modeler. The solution values reported back from a solution algorithm, both primal and dual, are always reported in the user's notation. The algorithm's versions of the equations and variables are only reflected in the derivatives in the equation and column listings in the GAMS output if Option LimRow and/or LimCol are positive, and in debugging output from the solution algorithm, generated with Option SysOut = On. In addition, the numbers in the algorithms iteration log will represent the scaled model: the infeasibilities and reduced gradients will correspond to the scaled model, and if the objective variable is scaled, the value of the objective function will be the scaled value.

A final warning about scaling of multidimensional variables is appropriate. Assume variable \( x(i,j,k) \) only appears in the model when the parameter \( ijk(i,j,k) \) is nonzero, and assume that \( \text{Card}(i) = \text{Card}(j) = \text{Card}(k) = 100 \) while \( \text{Card}(ijk) \) is much smaller than \( 100^3 = 1.e6 \). Then you should only scale the variables that appear in the model, i.e.

```gams
x.Scale(i,j,k)$ijk(i,j,k) = expression;
```

The statement

```gams
x.Scale(i,j,k) = expression;
```

will generate records for \( x \) in the GAMS database for all combinations of \( i, j, \) and \( k \) for which the expression is different from 1, i.e. up to \( 1.e6 \) records, and apart from spending a lot of time you will very likely run out of memory. Note that this warning also applies to non-default lower and upper bounds.
5.7.7 NLP and DNLP Models

GAMS has two classes of nonlinear model, NLP and DNLP. NLP models are defined as models in which all functions that appear with endogenous arguments, i.e. arguments that depend on model variables, are smooth with smooth derivatives. DNLP models can in addition use functions that are smooth but have discontinuous derivatives. The usual arithmetic operators (+, -, ∗, /, and ∗∗) can appear on both model classes.

The functions that can be used with endogenous arguments in a DNLP model and not in an NLP model are Abs, Min, and Max and as a consequence the indexed operators SMin and SMax.

Note that the offending functions can be applied to expressions that only involve constants such as parameters, var.l, and equ.m. Fixed variables are in principle constants, but GAMS makes its tests based on the functional form of a model, ignoring numerical parameter values and numerical bound values, and terms involving fixed variables can therefore not be used with Abs, Min, or Max in an NLP model.

The NLP solvers used by GAMS can also be applied to DNLP models. However, it is important to know that the NLP solvers attempt to solve the DNLP model as if it was an NLP model. The solver uses the derivatives of the constraints with respect to the variables to guide the search, and it ignores the fact that some of the derivatives may change discontinuously. There are at the moment no GAMS solvers designed specifically for DNLP models and no solvers that take into account the discontinuous nature of the derivatives in a DNLP model.

5.7.7.1 DNLP Models: What Can Go Wrong?

Solvers for NLP Models are all based on making marginal improvements to some initial solution until some optimality conditions ensure no direction with marginal improvements exist. A point with no marginally improving direction is called a Local Optimum.

The theory about marginal improvements is based on the assumption that the derivatives of the constraints with respect to the variables are a good approximations to the marginal changes in some neighborhood around the current point.

Consider the simple NLP model, Min Sqr(x), where x is a free variable. The marginal change in the objective is the derivative of Sqr(x) with respect to x, which is 2x. At x = 0, the marginal change in all directions is zero and x = 0 is therefore a Local Optimum.

Next consider the simple DNLP model, Min Abs(x), where x again is a free variable. The marginal change in the objective is still the derivative, which is +1 if x > 0 and -1 if x < 0. When x = 0, the derivative depends on whether we are going to increase or decrease x. Internally in the DNLP solver, we cannot be sure whether the derivative at 0 will be -1 or +1; it can depend on rounding tolerances. An NLP solver will start in some initial point, say x = 1, and look at the derivative, here +1. Since the derivative is positive, x is reduced to reduce the objective. After some iterations, x will be zero or very close to zero. The derivative will be +1 or -1, so the solver will try to change x. however, even small changes will not lead to a better objective function. The point x = 0 does not look like a Local Optimum, even though it is a Local Optimum. The result is that the NLP solver will muddle around for some time and then stop with a message saying something like: "The solution cannot be improved, but it does not appear to be optimal."

In this first case we got the optimal solution so we can just ignore the message. However, consider the following simple two-dimensional DNLP model: Min Abs(x1+x2) + 5∗Abs(x1-x2) with x1 and x2 free variables. Start the optimization from x1 = x2 = 1. Small increases in x1 will increase both terms and small decreases in x1 (by dx) will decrease the first term by dx but it will increase the second term by 5∗dx. Any change in x1 only is therefore bad, and it is easy to see that any change in x2 only also is bad. An NLP solver may therefore be stuck in the point x1 = x2 = 1, even though it is not a local solution: the direction (dx1, dx2) = (-1,-1) will lead to the optimum in x1 = x2 = 0. However, the NLP solver cannot distinguish what happens with this model from what happened in the previous model; the message will be of the same type: "The solution cannot be improved, but it does not appear to be optimal."
5.7.7.2 Reformulation from DNLP to NLP

The only reliable way to solve a DNLP model is to reformulate it as an equivalent smooth NLP model. Unfortunately, it may not always be possible. In this section we will give some examples of reformulations.

The standard reformulation approach for the ABS function is to introduce positive and negative deviations as extra variables: The term \( z = \text{Abs}(f(x)) \) is replaced by \( z = f_{\text{Plus}} + f_{\text{Minus}} \), \( f_{\text{Plus}} \) and \( f_{\text{Minus}} \) are declared as positive variables and they are defined with the identity: \( f(x) = f_{\text{Plus}} - f_{\text{Minus}} \). The discontinuous derivative from the Abs function has disappeared and the part of the model shown here is smooth. The discontinuity has been converted into lower bounds on the new variables, but bounds are handled routinely by any NLP solver. The feasible space is larger than before; \( f(x) = 5 \) can be obtained both with \( f_{\text{Plus}} = 5, f_{\text{Minus}} = 0 \), and \( z = 5 \), and with \( f_{\text{Plus}} = 1000, f_{\text{Minus}} = 995 \), and \( z = 1995 \). Provided the objective function has some term that tries to minimize \( z \), either \( f_{\text{Plus}} \) or \( f_{\text{Minus}} \) will become zero and \( z \) will end with its proper value.

You may think that adding the smooth constraint \( f_{\text{Plus}} \cdot f_{\text{Minus}} = 0 \) would ensure that either \( f_{\text{Plus}} \) or \( f_{\text{Minus}} \) is zero. However, this type of so-called complementarity constraint is "bad" in any NLP model. The feasible space consists of the two half lines: \( (f_{\text{Plus}} = 0 \) and \( f_{\text{Minus}} \geq 0 \) ) and \( (f_{\text{Plus}} \geq 0 \) and \( f_{\text{Minus}} = 0 \). Unfortunately, the marginal change methods used by most NLP solvers cannot move from one half line to the other, and the solution is stuck at the half line it happens to reach first.

There is also a standard reformulation approach for the Max function. The equation \( z = \max(f(x),g(y)) \) is replace by the two inequalities, \( z = g \cdot f(x) \) and \( z = g \cdot g(y) \). Provided the objective function has some term that tries to minimize \( z \), one of the constraints will become binding as equality and \( z \) will indeed be the maximum of the two terms.

The reformulation for the Min function is similar. The equation \( z = \min(f(x),g(y)) \) is replaced by the two inequalities, \( z = l \cdot f(x) \) and \( z = l \cdot g(y) \). Provided the objective function has some term that tries to maximize \( z \), one of the constraints will become binding as equality and \( z \) is indeed the minimum of the two terms.

Max and Min can have more than two arguments and the extension should be obvious.

The non-smooth indexed operators, SMax and SMin can be handled using a similar technique: for example, \( z = \text{SMax}(i, f(x,i)) \) is replaced by the indexed inequality: \( \text{inEq}(i) \cdot z = l \cdot f(x,i) \);

The reformulations that are suggested here all enlarge the feasible space. They require the objective function to move the final solution to the intersection of this larger space with the original feasible space. Unfortunately, the objective function is not always so helpful. If it is not, you may try using one of the smooth approximations described next. However, you should realize, that if the objective function cannot help the "good" approximations described here, then your overall model is definitely non-convex and it is likely to have multiple local optima.

5.7.7.3 Smooth Approximations

Smooth approximations to the non-smooth functions ABS, MAX, and MIN are approximations that have function values close to the original functions, but have smooth derivatives.

A smooth GAMS approximation for Abs(f(x)) is

\[
\text{Sqrt}( \text{Sqr}(f(x)) + \text{Sqr}(\delta) )
\]
where delta is a small scalar. The value of delta can be used to control the accuracy of the approximation and the curvature around \( f(x) = 0 \). The approximation error is largest when \( f(x) \) is zero, in which case the error is delta. The error is reduced to approximately \( \sqrt{\delta^2 + \delta^2} / 2 \) for \( f(x) = 1 \). The second derivative is \( 1/\delta \) at \( f(x) = 0 \) (excluding terms related to the second derivative of \( f(x) \)). A delta value between 1.e-3 and 1.e-4 should in most cases be appropriate. It is possible to use a larger value in an initial optimization, reduce it and solve the model again. You should note, that if you reduce delta below 1.e-4 then large second order terms might lead to slow convergence or even prevent convergence.

The approximation shown above has its largest error when \( f(x) = 0 \) and smaller errors when \( f(x) \) is far from zero. If it is important to get accurate values of Abs exactly when \( f(x) = 0 \), then you may use the alternative approximation

\[
\sqrt{\Delta (f(x)^2 + \delta^2)} - \delta
\]

instead. The only difference is the constant term. The error is zero when \( f(x) \) is zero and the error grows to \( -\delta \) when \( f(x) \) is far from zero.

Some theoretical work uses the Huber, \( H(\cdot) \), function as an approximation for Abs. The Huber function is defined as

\[
H(x) = \begin{cases} 
  x & \text{for } x > \delta, \\
  -x & \text{for } x < -\delta \text{ and} \\
  \frac{\sqrt{x^2}}{2\delta} + \frac{\delta}{2} & \text{for } -\delta < x < \delta.
\end{cases}
\]

Although the Huber function has some nice properties, it is for example accurate when \( \text{Abs}(x) > \delta \), it is not so useful for GAMS work because it is defined with different formula for the three pieces.

A smooth GAMS approximation for \( \text{Max}(f(x),g(y)) \) is

\[
( f(x) + g(y) + \sqrt{\Delta (f(x)-g(y)^2 + \delta^2)} )/2
\]

where delta again is a small scalar. The approximation error is delta/2 when \( f(x) = g(y) \) and decreases with the difference between the two terms. As before, you may subtract a constant term to shift the approximation error from the area \( f(x) = g(y) \) to areas where the difference is large. The resulting approximation becomes

\[
( f(x) + g(y) + \sqrt{\Delta (f(x)-g(y)^2 + \delta^2)} - \delta )/2
\]

Similar smooth GAMS approximations for \( \text{Min}(f(x),g(y)) \) are

\[
( f(x) + g(y) - \sqrt{\Delta (f(x)-g(y)^2 + \delta^2)} )/2
\]

and

\[
( f(x) + g(y) - \sqrt{\Delta (f(x)-g(y)^2 + \delta^2)} + \delta )/2
\]

Appropriate delta values are the same as for the Abs approximation: in the range from 1.e-2 to 1.e-4.

It appears that there are no simple symmetric extensions for Max and Min of three or more arguments or for indexed SMax and SMin.
5.7.7.4 Are DNLP Models Always Non-smooth?

A DNLP model is defined as a model that has an equation with an Abs, Max, or Min function with endogenous arguments. The non-smooth properties of DNLP models are derived from the non-smooth properties of these functions through the use of the chain rule. However, composite expressions involving Abs, Max, or Min can in some cases have smooth derivatives and the model can therefore in some cases be smooth.

One example of a smooth expression involving an Abs function is common in water systems modeling. The pressure loss over a pipe, \( dH \), is proportional to the flow, \( Q \), to some power, \( P \). \( P \) is usually around +2. The sign of the loss depend on the direction of the flow so \( dH \) is positive if \( Q \) is positive and negative if \( Q \) is negative. Although GAMS has a Sign function, it cannot be used in a model because of its discontinuous nature. Instead, the pressure loss can be modeled with the equation

\[
dH = \text{const} \ast Q \ast \text{Abs}(Q)^{(P-1)}
\]

where the sign of the Q-term takes care of the sign of \( dH \), and the Abs function guaranties that the real power \( ^{(P-1)} \) is applied to a non-negative number. Although the expression involves the Abs function, the derivatives are smooth as long as \( P \) is greater than 1. The derivative with respect to \( Q \) is \( \text{const} \ast (P-1) \ast \text{Abs}(Q)^{(P-1)} \) for \( Q > 0 \) and \( -\text{const} \ast (P-1) \ast \text{Abs}(Q)^{(P-1)} \) for \( Q < 0 \). The limit for \( Q \) going to zero from both right and left is 0, so the derivative is smooth in the critical point \( Q = 0 \) and the overall model is therefore smooth.

Another example of a smooth expression is the following terribly looking Sigmoid expression:

\[
\text{Sigmoid}(x) = \frac{\text{Exp}(\text{Min}(x,0))}{1+\text{Exp}(-\text{Abs}(x))}
\]

The standard definition of the sigmoid function is

\[
\text{Sigmoid}(x) = \frac{\text{Exp}(x)}{1+\text{Exp}(x)}
\]

This definition is well behaved for negative and small positive \( x \), but it not well behaved for large positive \( x \) since \( \text{Exp} \) overflows. The alternative definition:

\[
\text{Sigmoid}(x) = \frac{1}{1+\text{Exp}(-x)}
\]

is well behaved for positive and slightly negative \( x \), but it overflows for very negative \( x \). Ideally, we would like to select the first expression when \( x \) is negative and the second when \( x \) is positive, i.e.

\[
\text{Sigmoid}(x) = \frac{\text{Exp}(x)/(1+\text{Exp}(x))}{(x < 0)} + \frac{(1/(1+\text{Exp}(-x)))}{(x > 0)}
\]

but a \$\$ -control that depends on an endogenous variable is illegal. The first expression above solves this problem. When \( x \) is negative, the nominator becomes \( \text{Exp}(x) \) and the denominator becomes \( 1+\text{Exp}(x) \). And when \( x \) is positive, the nominator becomes \( \text{Exp}(0) = 1 \) and the denominator becomes \( 1+\text{Exp}(-x) \). Since the two expressions are mathematically identical, the combined expression is of course smooth, and the \( \text{Exp} \) function is never evaluated for a positive argument.

Unfortunately, GAMS cannot recognize this and similar special cases so you must always solve models with endogenous Abs, Max, or Min as DNLP models, even in the cases where the model is smooth.
5.7 CONOPT

5.7.7.5 Are NLP Models Always Smooth?

NLP models are defined as models in which all operators and functions are smooth. The derivatives of composite functions, that can be derived using the chain rule, will therefore in general be smooth. However, it is not always the case. The following simple composite function is not smooth: \( y = \text{Sqrt}(\text{Sqr}(x)) \). The composite function is equivalent to \( y = \text{Abs}(x) \), one of the non-smooth DNLP functions.

What went wrong? The chain rule for computing derivatives of a composite function assumes that all intermediate expressions are well defined. However, the derivative of Sqrt grows without bound when the argument approaches zero, violating the assumption.

There are not many cases that can lead to non-smooth composite functions, and they are all related to the case above: The real power, \( x^{**y} \), for \( 0 < y < 1 \) and \( x \) approaching zero. The Sqrt function is a special case since it is equivalent to \( x^{**y} \) for \( y = 0.5 \).

If you have expressions involving a real power with an exponent between 0 and 1 or a Sqrt, you should in most cases add bounds to your variables to ensure that the derivative or any intermediate terms used in their calculation become undefined. In the example above, Sqrt( Sqr(x) ), a bound on \( x \) is not possible since \( x \) should be allowed to be both positive and negative. Instead, changing the expression to Sqrt( Sqr(x) + Sqr(delta) ) may lead to an appropriate smooth formulation.

Again, GAMS cannot recognize the potential danger in an expression involving a real power, and the presence of a real power operator is not considered enough to flag a model as a DNLP model. During the solution process, the NLP solver will compute constraint values and derivatives in various points within the bounds defined by the modeler. If these calculations result in undefined intermediate or final values, a function evaluation error is reported, an error counter is incremented, and the point is flagged as a bad point. The following action will then depend on the solver. The solver may try to continue, but only if the modeler has allowed it with an `Option DomLim = xxx;`. The problem of detecting discontinuities is changed from a structural test at the GAMS model generation stage to a dynamic test during the solution process.

You may have a perfectly nice model in which intermediate terms become undefined. The composite function Sqrt( Power(x,3) ) is mathematically well defined around \( x = 0 \), but the computation will involve the derivative of Sqrt at zero, that is undefined. It is the modeler's responsibility to write expressions in a way that avoids undefined intermediate terms in the function and derivatives computations. In this case, you may either add a small strictly positive lower bound on \( x \) or rewrite the function as \( x^{**1.5} \).

5.7.8 APPENDIX A: Algorithmic Information

The objective of this Appendix is to give technically oriented users some understanding of what CONOPT is doing so they can get more information out of the iteration log. This information can be used to prevent or circumvent algorithmic difficulties or to make informed guesses about which options to experiment with to improve CONOPT's performance on particular model classes.

5.7.8.1 Overview of GAMS/CONOPT

GAMS/CONOPT is a GRG-based algorithm specifically designed for large nonlinear programming problems expressed in the following form

\[
\begin{align*}
\text{min or max} & \quad f(x) \\
\text{subject to} & \quad g(x) = b \\
\text{lo} & \quad < x < \text{up}
\end{align*}
\]
where \( x \) is the vector of optimization variables, \( \text{lo} \) and \( \text{up} \) are vectors of lower and upper bounds, some of which may be minus or plus infinity, \( b \) is a vector of right hand sides, and \( f \) and \( g \) are differentiable nonlinear functions that define the model. \( n \) will in the following denote the number of variables and \( m \) the number of equations. (2) will be referred to as the (general) constraints and (3) as the bounds.

The relationship between the mathematical model in (1)-(3) above and the GAMS model is simple: The inequalities defined in GAMS with \( =l= \) or \( =g= \) are converted into equalities by addition of properly bounded slacks. Slacks with lower and upper bound of zero are added to all GAMS equalities to ensure that the Jacobian matrix, i.e. the matrix of derivatives of the functions \( g \) with respect to the variables \( x \), has full row rank. All these slacks are together with the normal GAMS variables included in \( x \). \( \text{lo} \) represent the lower bounds defined in GAMS, either implicitly with the Positive Variable declaration, or explicitly with the Var.Lo notation, as well as any bounds on the slacks. Similarly, \( \text{up} \) represent upper bounds defined in GAMS, e.g. with the Var.Up notation, as well as any bounds on the slacks. \( g \) represent the non-constant terms of the GAMS equations themselves; non-constant terms appearing on the right hand side are moved to the left hand side and constant terms on the left hand side are moved to the right. The objective function \( f \) is simply the GAMS variable to be minimized or maximized.

Additional comments on assumptions and design criteria can be found in the Introduction to the main text.

5.7.8.2 The CONOPT Algorithm

The algorithm used in GAMS/CONOPT is based on the GRG algorithm first suggested by Abadie and Carpentier (1969). The actual implementation has many modifications to make it efficient for large models and for models written in the GAMS language. Details on the algorithm can be found in Drud (1985 and 1992). Here we will just give a short verbal description of the major steps in a generic GRG algorithm. The later sections in this Appendix will discuss some of the enhancements in CONOPT that make it possible to solve large models.

The key steps in any GRG algorithm are:

1. Initialize and Find a feasible solution.
2. Compute the Jacobian of the constraints, \( J \).
3. Select a set of \( n \) basic variables, \( x_b \), such that \( B \), the sub-matrix of basic column from \( J \), is nonsingular. Factorize \( B \). The remaining variables, \( x_n \), are called nonbasic.
4. Solve \( B^T u = df/dx_b \) for the multipliers \( u \).
5. Compute the reduced gradient, \( r = df/dx - J^T u \). \( r \) will by definition be zero for the basic variables.
6. If \( r \) projected on the bounds is small, then stop. The current point is close to optimal.
7. Select the set of superbasic variables, \( x_s \), as a subset of the nonbasic variables that profitably can be changed, and find a search direction, \( d_s \), for the superbasic variables based on \( r_s \) and possibly on some second order information.
8. Perform a line search along the direction \( d \). For each step, \( x_s \) is changed in the direction \( d_s \) and \( x_b \) is subsequently adjusted to satisfy \( g(x_b, x_s) = b \) in a pseudo-Newton process using the factored \( B \) from step 3.
9. Go to 2.
The individual steps are of course much more detailed in a practical implementation like CONOPT. Step 1 consists of several pre-processing steps as well as a special Phase 0 and a scaling procedure as described in the following sections. The optimizing steps are specialized in several versions according to the whether the model appears to be almost linear or not. For "almost" linear models some of the linear algebra work involving the matrices $J$ and $B$ can be avoided or done using cheap LP-type updating techniques, second order information is not relevant in step 7, and the line search in step 8 can be improved by observing that the optimal step as in LP almost always will be determined by the first variable that reaches a bound. Similarly, when the model appears to be fairly nonlinear other aspects can be optimized: the set of basic variables will often remain constant over several iterations, and other parts of the sparse matrix algebra will take advantage of this (section Finding a Feasible Solution: Phase 1 and 2 and Linear and Nonlinear Mode: Phase 1 to 4). If the model is "very" linear an improved search direction (step 7) can be computed using specialized inner LP-like iterations (section Linear Mode: The SLP Procedure) and a steepest edge procedure can be useful for certain models that needs very many iterations (section Linear Mode: The Steepest Edge Procedure). If the model is "very" nonlinear and has many degrees of freedom an improved search direction (step 7) can be computed using specialized inner SQP-like iterations based on exact second derivatives for the model (section Nonlinear Mode: The SQP Procedure).

The remaining two sections give some short guidelines for selecting non-default options (section How to Select Non-default Options), and discuss miscellaneous topics (section Miscellaneous Topics) such as CONOPT's facilities for strictly triangular models (section Triangular Models) and for square systems of equations, in GAMS represented by the model class called CNS or Constrained Nonlinear System (section Constrained Nonlinear System or Square Systems of Equations), as well as numerical difficulties due to loss of feasibility (section Loss of Feasibility) and slow or no progress due to stalling (section Stalling).

5.7.8.3 Iteration 0: The Initial Point

The first few "iterations" in the iteration log (See section Iteration Output), in the main text for an example) are special initialization iterations, but they have been counted as real iterations to allow the user to interrupt at various stages during initialization. Iteration 0 corresponds to the input point exactly as it was received from GAMS. The sum of infeasibilities in the column labeled "Infeasibility" includes all residuals, also from the objective constraint where "z =e= expression" will give rise to the term $\text{Abs}(z - \text{expression})$ that may be nonzero if $z$ has not been initialized. You may stop CONOPT after iteration 0 with Option IterLim = 0; in GAMS. The solution returned to GAMS will contain the input point and the values of the constraints in this point. The marginals of both variables and equations have not yet been computed and they will be returned as EPS.

This possibility can be used for debugging when you have a reference point that should be feasible, but is infeasible for unknown reasons. Initialize all variables to their reference values, also all intermediate variables, and call CONOPT with IterLim = 0. Then compute and display the following measures of infeasibility for each block of constraints, represented by the generic name eq:

\[
\begin{align*}
\text{=} & \text{ constraints: Round}(\text{Abs}(\text{eq.L} - \text{eq.Lo}),3) \\
\text{\leq} & \text{ constraints: Round}(\text{Min}(0,\text{eq.L} - \text{eq.Up}),3) \\
\text{\geq} & \text{ constraints: Round}(\text{Min}(0,\text{eq.Lo} - \text{eq.L}),3)
\end{align*}
\]

The Round function rounds to 3 decimal places so GAMS will only display the infeasibilities that are larger than 5.e-4.

Similar information can be derived from inspection of the equation listing generated by GAMS with Option LimRow = nn; but although the method of going via CONOPT requires a little more work during implementation it can be convenient in many cases, for example for large models and for automated model checking.
5.7.8.4 Iteration 1: Preprocessing

Iteration 1 corresponds to a pre-processing step. Constraint-variable pairs that can be solved a priori (so-called pre-triangular equations and variables) are solved and the corresponding variables are assigned their final values. Constraints that always can be made feasible because they contain a free variable with a constant coefficient (so-called post-triangular equation-variable pairs) are excluded from the search for a feasible solution and from the Infeasibility measure in the iteration log. Implicitly, equations and variables are ordered as shown in Figure 1.

5.7.8.4.1 Preprocessing: Pre-triangular Variables and Constraints

The pre-triangular equations are those labeled A in Figure 1. They are solved one by one along the "diagonal" with respect to the pre-triangular variables labeled I. In practice, GAMS/CONOPT looks for equations with only one non-fixed variable. If such an equation exists, GAMS/CONOPT tries to solve it with respect to this non-fixed variable. If this is not possible the overall model is infeasible, and the exact reason for the infeasibility is easy to identify as shown in the examples below. Otherwise, the final value of the variable has been determined, the variable can for the rest of the optimization be considered fixed, and the equation can be removed from further consideration. The result is that the model has one equation and one non-fixed variable less. As variables are fixed new equations with only one non-fixed variable may emerge, and CONOPT repeats the process until no more equations with one non-fixed variable can be found.

This pre-processing step will often reduce the effective size of the model to be solved. Although the pre-triangular variables and equations are removed from the model during the optimization, CONOPT keeps them around until the final solution is found. The dual variables for the pre-triangular equations are then computed so they become available in GAMS.

CONOPT has a special option for analyzing and solving completely triangular models. This option is described in section Triangular Models.

The following small GAMS model shows an example of a model with pre-triangular variables and equations:

```gams
Variable x1, x2, x3, obj;
Equation e1, e2, e3;
e1 .. Log(x1) + x2 =e= 1.6;
e2 .. 5 * x2 =e= 3;
e3 .. obj =e= Sqr(x1) + 2 * Sqr(x2) + 3 * Sqr(x3);
x1.Lo = 0.1;
Model demo / All /; Solve demo using NLP Minimizing obj;
```
Equation \( e2 \) is first solved with respect to \( x2 \) (result \( 3/5 = 0.6 \)). It is easy to solve the equation since \( x2 \) appears linearly, and the result will be unique. \( x2 \) is then fixed and the equation is removed. Equation \( e1 \) is now a candidate since \( x1 \) is the only remaining non-fixed variable in the equation. Here \( x1 \) appears nonlinear and the value of \( x1 \) is found using an iterative scheme based on Newton's method. The iterations are started from the value provided by the modeler or from the default initial value. In this case \( x1 \) is started from the default initial value, i.e. the lower bound of 0.1, and the result after some iterations is \( x1 = 2.718 = \text{Exp}(1) \).

During the recursive solution process it may not be possible to solve one of the equations. If the lower bound on \( x1 \) in the model above is changed to 3.0 you will get the following output:

** An equation in the pre-triangular part of the model cannot be solved because the critical variable is at a bound.

- Residual= 9.86122887E-02
- Tolerance (RTNWTR)= 6.34931126E-07

\( e1: \) Infeasibility in pre-triangular part of model.
\( x1: \) Infeasibility in pre-triangular part of model.

The solution order of the critical equations and variables is:

\( e2 \) is solved with respect to \( x2 \). Solution value = 6.0000000000E-01

\( e1 \) could not be solved with respect to \( x1 \). Final solution value = 3.0000000000E+00
\( e1 \) remains infeasible with residual = 9.8612288668E-02

The problem is as indicated that the variable to be solved for is at a bound, and the value suggested by Newton's method is on the infeasible side of the bound. The critical variable is \( x1 \) and the critical equation is \( e1 \), i.e. \( x1 \) tries to exceed its bound when CONOPT solves equation \( e1 \) with respect to \( x1 \). To help you analyze the problem, especially for larger models, CONOPT reports the solution sequence that led to the infeasibility: In this case equation \( e2 \) was first solved with respect to variable \( x2 \), then equation \( e1 \) was attempted to be solved with respect to \( x1 \) at which stage the problem appeared. To make the analysis easier CONOPT will always report the minimal set of equations and variables that caused the infeasibility.

Another type of infeasibility is shown by the following model:

Variable \( x1, x2, x3, \) obj;
Equation \( e1, e2, e3; \)
\( e1 .. \text{Sqr}(x1) + x2 =e= 1.6; \)
\( e2 .. 5 * x2 =e= 3; \)
\( e3 .. \text{obj} =e= \text{Sqr}(x1) + 2 * \text{Sqr}(x2) + 3 * \text{Sqr}(x3); \)
Model demo / All /; Solve demo using NLP Minimizing obj;

where \( \log(x1) \) has been replaced by \( \text{Sqr}(x1) \) and the lower bound on \( x1 \) has been removed. This model gives the message:

** An equation in the pre-triangular part of the model cannot be solved because of too small pivot. Adding a bound or initial value may help.

- Residual= 4.0000000
Tolerance (RTNWTR)= 6.34931126E-07

e1: Infeasibility in pre-triangular part of model.
x1: Infeasibility in pre-triangular part of model.

The solution order of the critical equations and variables is:

e2 is solved with respect to
x2. Solution value = 6.0000000000E-01

e1 could not be solved with respect to
x1. Final solution value = 0.0000000000E+00

After equation e2 has been solved with respect to x2, equation e1 that contains the term Sqr(x) should be solved with respect to x1. The initial value of x1 is the default value zero. The derivative of e1 with respect to x1 is therefore zero, and it is not possible for CONOPT to determine whether to increase or decrease x1. If x1 is given a nonzero initial value the model will solve. If x1 is given a positive initial value the equation will give x1 = 1, and if x1 is given a negative initial value the equation will give x1 = -1. The last type of infeasibility that can be detected during the solution of the pre-triangular or recursive equations is shown by the following example

Variable x1, x2, x3, obj;
Equation e1, e2, e3;
e1 .. Log(x1) + x2 =e= 1.6;
e2 .. 5 * x2 =e= 3;
e3 .. obj =e= Sqr(x1) + 2 * Sqr(x2) + 3 * Sqr(x3);
e4 .. x1 + x2 =e= 3.318;
x1.Lo = 0.1;
Model demo / All /; Solve demo using NLP Minimizing obj;

that is derived from the first model by the addition of equation e4. This model produces the following output

** An equation is inconsistent with other equations in the pre-triangular part of the model.
Residual= 2.81828458E-04
Tolerance (RTNWTR)= 6.34931126E-07

The pre-triangular feasibility tolerance may be relaxed with a line:

    SET RTNWTR X.XX

in the CONOPT control program.

e4: Inconsistency in pre-triangular part of model.

The solution order of the critical equations and variables is:

e2 is solved with respect to
x2. Solution value = 6.0000000000E-01

e1 is solved with respect to
x1. Solution value = 2.7182818285E+00

All variables in equation e4 are now fixed
and the equation is infeasible. Residual = 2.8182845830E-04

First e2 is solved with respect to x2, then e1 is solved with respect to x1 as indicated by the last part of
the output. At this point all variables that appear in equation e4, namely x1 and x2, are fixed, but the
equation is not feasible. e4 is therefore inconsistent with e1 and e2 as indicated by the first part of the
output. In this case the inconsistency is fairly small, 2.8E-04, so it could be a tolerance problem. CONOPT
will always report the tolerance that was used, rtnewtr - the triangular Newton tolerance, and if the
infeasibility is small it will also tell how the tolerance can be relaxed. Section The CONOPT Options File
gives further details on how to change tolerances, and a complete list of options is given in Appendix B.

You can turn the identification and solution of pre-triangular variables and equations off by adding the
line lspret = f in the CONOPT control program. This can be useful in some special cases where the
point defined by the pre-triangular equations gives a function evaluation error in the remaining equations.
The following example shows this:

Variable x1, x2, x3, x4, obj;
Equation e1, e2, e3, e4;
e1 .. Log(1+x1) + x2 =e= 0;
e2 .. 5 * x2 =e= -3;
e3 .. obj =e= 1*Sqr(x1) + 2*Sqrt(0.01 + x2 - x4) + 3*Sqr(x3);
e4 .. x4 =l= x2;
Model fer / All /; Solve fer Minimizing obj using NLP;

All the nonlinear functions are defined in the initial point in which all variables have their default value
of zero. The pre-processor will compute x2 = -0.6 from e2 and x1 = 0.822 from e1. When CONOPT
continues and attempts to evaluate e3, the argument to the Sqrt function is negative when these new
triangular values are used together with the initial x4 = 0, and CONOPT cannot backtrack to some safe
point since the function evaluation error appears the first time e3 is evaluated. When the pre-triangular
preprocessor is turned off, x2 and x4 are changed at the same time and the argument to the Sqrt function
remains positive throughout the computations. Note, that although the purpose of the e4 inequality is to
guarantee that the argument of the Sqrt function is positive in all points, and although e4 is satisfied
in the initial point, it is not satisfied after the pre-triangular constraints have been solved. Only simple
bounds are strictly enforced at all times. Also note that if the option lspret = f is used then feasible
linear constraints will in fact remain feasible.

An alternative (and preferable) way of avoiding the function evaluation error is to define an intermediate
variable equal to 0.01+x2-x4 and add a lower bound of 0.01 on this variable. The inequality e4 could then
be removed and the overall model would have the same number of constraints.

5.7.8.4.2 Preprocessing: Post-triangular Variables and Constraints  Consider the following
fragment of a larger GAMS model:

Variable util(t) Utility in period t
totutil Total Utility;
Equation utilDef(T) Definition of Utility
tutilDef Definition of Total Utility;
utilDef(T).. util(t) =e= nonlinear function of other variables;
tutilDef .. totutil =e= Sum( t, util(t) / (1+r)**Ord(t) );
Model demo / All /; Solve demo Maximizing totutil using NLP;
The part of the model shown here is easy to read and from a modeling point of view it should be considered well written. However, it could be more difficult to solve than a model in which variable \( \text{util}(t) \) was substituted out because all the \( \text{utilDef} \) equations are nonlinear constraints that the algorithms must ensure are satisfied.

To make well written models like this easy to solve CONOPT will move as many nonlinearities as possible from the constraints to the objective function. This automatically changes the model from the form that is preferable for the modeler to the form that is preferable for the algorithm. In this process CONOPT looks for free variables that only appear in one equation outside the objective function. If such a variable exists and it appears linearly in the equation, like \( \text{util}(t) \) appears with coefficient 1 in equation \( \text{utilDef}(t) \), then the equation can always be solved with respect to the variable. This means that the variable logically can be substituted out of the model and the equation can be removed. The result is a model that has one variable and one equation less, and a more complex objective function. As variables and equations are substituted out, new candidates for elimination may emerge, so CONOPT repeats the process until no more candidates exist.

This so-called post-triangular preprocessing step will often move several nonlinear constraints into the objective function where they are much easier to handle, and the effective size of the model will decrease. In some cases the result can even be a model without any general constraints. The name post-triangular is derived from the way the equations and variables appear in the permuted Jacobian in Figure 1. The post-triangular equations and variables are the ones on the lower right hand corner labeled B and II, respectively.

In the example above, the \( \text{util} \) variables will be substituted out of the model together with the nonlinear \( \text{utilDef} \) equations provided the \( \text{util} \) variables are free and do not appear elsewhere in the model. The resulting model will have fewer nonlinear constraints, but more nonlinear terms in the objective function.

Although you may know that the nonlinear functions on the right hand side of \( \text{utilDef} \) always will produce positive \( \text{util} \) values, you should in general not declare \( \text{util} \) to be a Positive Variable. If you do, GAMS/CONOPT may not be able to eliminate \( \text{util}(t) \), and the model will be harder to solve. It is of course unfortunate that a redundant bound changes the solution behavior, and to reduce this problem CONOPT will try to estimate the range of nonlinear expressions using interval arithmetic. If the computed range of the right hand side of the \( \text{utilDef} \) constraint is within the bounds of \( \text{util} \), then these bounds cannot be binding and \( \text{util} \) is a so-called implied free variable that can be eliminated.

The following model fragment from a least squares model shows another case where the preprocessing step in GAMS/CONOPT is useful:

```gams
Variable residual(case) Residuals
ssq Sum of Squared Residuals;
Equation eqEst(case) Equation to be estimated
ssqDef Definition of objective;
  eqEst(case).. residual(case) =e= expression in other variables;
SSQDEF .. ssq =e= Sum( case, Sqr( residual(case) ) );
Model lsqLarge / All /; Solve lsqLarge using NLP Minimizing ssq;
```

GAMS/CONOPT will substitute the residual variables out of the model using the \( \text{eqEst} \) equations. The model solved by GAMS/CONOPT is therefore mathematically equivalent to the following GAMS model

```gams
Variable ssq Sum of Squared Residuals;
Equation ssqd Definition of objective;
  ssqd .. ssq =e= Sum( case, Sqr(expression in other variables));
Model lsqSmall / All /;
Solve lsqSmall using NLP Minimizing ssq;
```
However, if the "expression in other variables" is a little complicated, e.g. if it depends on several variables, then the first model, lsqLarge, will be much faster to generate with GAMS because its derivatives in equation qEst and ssqDef are much simpler than the derivatives in the combined ssqd equation in the second model, lsqSmall. The larger model will therefore be faster to generate, and it will also be faster to solve because the computation of both first and second derivatives will be faster.

Note that the comments about what are good model formulations are dependent on the preprocessing capabilities in GAMS/CONOPT. Other algorithms may prefer models like lsqSmall over lsqLarge. Also note that the variables and equations that are substituted out are still indirectly part of the model. GAMS/CONOPT evaluates the equations and computes values for the variables each time the value of the objective function is needed, and their values are available in the GAMS solution.

It is not necessary to have a coefficient of 1 for the variable to be substituted out in the post-triangular phase. However, a non-zero coefficient cannot be smaller than the absolute pivot tolerance used by CONOPT, rtpiva.

The number of pre- and post-triangular equations and variables is printed in the log file between iteration 0 and 1 as shown in the iteration log in section Iteration Output of the main text. The sum of infeasibilities will usually decrease from iteration 0 to 1 because fewer constraints usually will be infeasible. However, it may increase as shown by the following example:

```
Positive Variable x, y, z;
Equation e1, e2;
e1.. x =e= 1;
e2.. 10*x - y + z =e= 0;
```

started from the default values x.L = 0, y.L = 0, and z.L = 0. The initial sum of infeasibilities is 1 (from e1 only). During pre-processing x is selected as a pre-triangular variable in equation e1 and it is assigned its final value 1 so e1 becomes feasible. After this change the sum of infeasibilities increases to 10 (from e2 only).

You may stop CONOPT after iteration 1 with Option IterLim = 1; in GAMS. The solution returned to GAMS will contain the pre-processed values for the variables that can be assigned values from the pre-triangular equations, the computed values for the variables used to solve the post-triangular equations, and the input values for all other variables. The pre- and post-triangular constraints will be feasible, and the remaining constraints will have values that correspond to this point. The marginals of both variables and equations have not been computed yet and will be returned as EPS.

The crash procedure described in the following sub-section is an optional part of iteration 1.

### 5.7.8.4.3 Preprocessing: The Optional Crash Procedure

In the initial point given to CONOPT the variables are usually split into a group with initial value provided by the modeler (in the following called the assigned variables) and a group of variables for which no initial value has been provided (in the following called the default variables). The objective of the optional crash procedure is to find a point in which as many of the constraints as possible are feasible, primarily by assigning values to the default variables and by keeping the assigned variables at their initial values. The implicit assumption in this procedure is that if the modeler has assigned an initial value to a variable then this value is "better" than a default initial value.

The crash procedure is an extension of the triangular pre-processing procedure described above and is based on a simple heuristic: As long as there is an equation with only one non-fixed variable (a singleton row) then we should assign a value to the variable so the equation is satisfied or satisfied as closely as possible, and we should then temporarily fix the variable. When variables are fixed additional singleton rows may emerge and we repeat the process. When there are no singleton rows we fix one or more variables at their initial value until a singleton row appears, or until all variables have been fixed. The variables to be fixed at their initial value are selected using a heuristic that both tries to create many row singletons
and tries to select variables with "good values". Since the values of many variables will come to depend in the fixed variables, the procedure favors assigned variables and among these it favors variables that appear in many feasible constraints.

Figure 2 shows a reordered version of Figure 1. The variables labeled IV are the variables that are kept at their initial values, primarily selected from the assigned variables. The equations labeled C are then solved with respect to the variables labeled III, called the crash-triangular variables. The crash-triangular variables will often be variables without initial values, e.g. intermediate variables. The number of crash-triangular variables is shown on the iteration output between iteration 0 and 1, but only if the crash procedure is turned on.

The result of the crash procedure is an updated initial point in which usually a large number of equations will be feasible, namely all equations labeled A, B, and C in Figure 2. There is, as already shown with the small example in Section Preprocessing: Post-triangular Variables and Constraints above, no guarantee that the sum of infeasibilities will be reduced, but it is often the case, and the point will often provide a good starting point for the following procedures that finds an initial feasible solution.

The crash procedure is activated by adding the line \texttt{lstcrs=t} in the options file. The default value of \texttt{lstcrs} (\texttt{lstcrs} = Logical Switch for Triangular Crash) is \texttt{f} or \texttt{false}, i.e. the crash procedure is not normally used. Before turning the crash procedure on you must turn the definitional equations (see next sub-section) off.

5.7.8.4.4 Preprocessing: Definitional Equations From version 3.16 CONOPT has introduced the concept of Definitional Equations. In section Simple Expressions it was recommended to introduce intermediate variables to simplify complex expressions. If the intermediate variables are free or if the bounds defined by the modeler cannot be binding then we call the constraints that define the intermediate variables "Definitional Equations" and the intermediate variables "Defined Variables". Some models have a large number of definitional equations, and CONOPT tries to recognize them and take advantage of the special structure. Defined variables that only appear in or feed into the objective are recognized as post-triangular variables as discussed in section Preprocessing: Post-triangular Variables and Constraints but defined variables can also be used in the simultaneous constraints. The picture is similar to fig 2. with the C-rows representing the definitional constraints and the III-variables the defined variables. The main differences between crash-triangular variables and defined variable are that (1) defined variables are free or have non-binding bounds and the definitional equations can therefore always be made feasible, (2) defined variables are cheaper to recognize, (3) since they have a natural interpretation, using them is probably more numerical stable, and (4) there are most likely fewer defined variables than crash-triangular variables.

The number of definitional equations is printed in the log file between iteration 0 and 1 if CONOPT finds any. The definitional equations are used to give the defined variables new values, so it is no longer so important the give intermediate variables initial values. In the process the sum of infeasibilities may grow but CONOPT consider it more important to keep these constraints feasible. The defined variables are also made basic and they will most likely stay basic throughout the solution process.

There are three new options introduced to controls the detection of definitional equations: \texttt{lsusdf}, \texttt{lsuqdf}, and \texttt{lfusdf}. They are described in Appendix B. By default CONOPT will only look for unique definitional constraints, but the options allow the user to experiment with a more aggressive strategy.

From version 3.16F there is an additional option, \texttt{lmusdf}, used to control how the definitional equations are used during the optimization. The option is summarized in Appendix B. By default, definitional equations are only used to define initial values and an initial basis and their special properties are ignored during the optimization. If there are many definitional equations and they are fairly nonlinear then it can sometimes be beneficial to force the definitional variables to remain basic and to use the definitional equations to compute values for the defined variables in all intermediate trial points. This behavior is turned on with \texttt{lmusdf = 1}. The point where \texttt{lmusdf = 1} start to pay off depends on the model and the degree of nonlinearity, but a guess is that the number of definitional equations should exceed half the number of equations remaining after the pre- and post-triangular equations have been removed before it is worth while.
5.7.8.4.5 Preprocessing and Function evaluation errors  Function evaluation errors may occur during pre-processing is an equation that is a candidate for becoming pre-triangular. Since GAMS requires all functions to be defined in the starting point this can only happen if a previously solved pre-triangular variable has received a new value that makes the function undefined. An example is:

```plaintext
positive variable x1, x2
equation e1, e2;
e1 .. x1 =E= 10;
e2 .. x2 =E= log( 5-x1 );
```

The pre-triangular variable x1 is changed to 10, a value that is inconsistent with equation e2. You can see the changes that CONOPT has made during pre-processing with the option `prprec = true` and this should help identify why the model does not solve.

After identifying and solving the pre-triangular part of the model CONOPT looks for implied bounds, and if an initial variable violates such an implied bound, CONOPT will move it inside the bound. This change can give rise to a function evaluation error in one of the remaining constraints. An example is:

```plaintext
positive variable x1, x2, x3, x4;
equation e1, e2;
e1.. x1 + x2 =L= 10;
e2.. x4 =E= log(x1+x3-20);
x1.l = 100; x3.up = 100;
```

From constraint e1 we can derive that both x1 and x2 must have (implied) upper bounds of 10. Since the initial value of x1 is above this implied bound it is changed by the pre-processor. After the pre-processor finishes, e2 will give a function evaluation error. Again, option `prprec = true` will give output that describes the changes in the variables which should help identify the problem.

5.7.8.5 Iteration 2: Scaling

Iteration 2 is the last dummy iteration during which the model is scaled, if scaling is turned on. The default is to turn scaling on. The Infeasibility column shows the scaled sum of infeasibilities. You may again stop CONOPT after iteration 2 with `Option IterLim = 2` in GAMS, but the solution that is reported in GAMS will have been scaled back again so there will be no change from iteration 1 to iteration 2.

The following description of the automatic scaling procedure is included for completeness. Experiments have so far given mixed results with some advantage for scaling, and scaling is therefore by default turned on, corresponding to the CONOPT option `lsscal = t`. Users are recommended to be cautious with the automatic scaling procedure. If scaling is a problem, try to use manual scaling or scaling in GAMS (see section Scaling in the main text) based on an understanding of the model.

The scaling procedure multiplies all variables in group III and all constraints in group C (see Figure 1) by scale factors computed as follows:

1. CONOPT computes the largest term for each constraint, i. This is defined as the maximum of the constant right hand side, the slack (if any), and `Abs(jac(i,j)*x(j))` where `jac(i,j)` is the derivative and `x(j)` is the variable.
2. The constraint scale factor is defined as the largest term in the constraint, projected on the interval \([\text{rtmins}, \text{rtmaxs}]\). The constraint is then divided by the constraint scale factor. Ignoring the projection, the result is a model in which the largest term in each constraint is exactly 1. The purpose of the projection is to prevent extreme scaling. The default value of \(\text{rtmins}\) is 1 which implies that we do not scale the constraints up. Constraints with only small terms remain unchanged. The default value of \(\text{rtmaxs}\) is \(2^{*30}\) or around \(1.07e9\) so terms much larger than \(1.e9\) are only partially scaled down and will still remain large.

3. The terms \(\text{Abs}(\text{jac}(i,j)\times x(j))\) after constraint scaling measure the importance of each variable in the particular constraint. The variable scale is selected so the largest importance of the variable over all constraints is 1. This gives a very simple variable scale factor, namely the absolute value of the variable. The variable is then divided by the variable scale factor. To avoid extreme scaling we again project on the interval \([\text{rtmins}, \text{rtmaxs}]\). Variables less than \(\text{rtmins}\) (default 1) are therefore not scaled up and variables over \(\text{rtmaxs}\) (default \(2^{*30} = 1.07e9\)) are only partially scaled down.

You should note that CONOPT by default scales large numbers down, but it does not scale small numbers up. You should therefore try to avoid having variables or terms in expressions that are small but significant. If this is not possible, allow CONOPT to scale up by giving the option \(\text{rtmins}\) a value less than 1.

All scale factors are rounded down to a power of 2 to preserve precision in the internal computations. To avoid difficulties with rapidly varying variables and derivatives CONOPT recomputes the scale factors at regular intervals (see \(\text{lfscal}\)).

The options that control scaling, \(\text{lsscal}, \text{lfscal}, \text{rtmins},\) and \(\text{rtmaxs}\), are all described in Appendix B.

5.7.8.6 Finding a Feasible Solution: Phase 0

The GRG algorithm used by CONOPT is a feasible path algorithm. This means that once it has found a feasible point it tries to remain feasible and follow a path of improving feasible points until it reaches a local optimum. CONOPT starts with the point provided by GAMS. This point will always satisfy the bounds (3): GAMS will simply move a variable that is outside its bounds to the nearer bound before it is presented to the solver. If the general constraints (2) also are feasible then CONOPT will work with feasible solutions throughout the optimization. However, the initial point may not satisfy the general constraints (2). If this is not the case, GAMS/CONOPT must first find an initial feasible point. This first step can be just as hard as finding an optimum for some models. For some models feasibility is the only problem.

GAMS/CONOPT has two methods for finding an initial feasible point. The first method is not very reliable but it is fast when it works; the second method is reliable but slower. The fast method is called Phase 0 and it is described in this section. It is used first. The reliable method, called Phase 1 and 2, will be used if Phase 0 terminates without a feasible solution.

Phase 0 is based on the observation that Newton's method for solving a set of equations usually is very fast, but it may not always converge. Newton's method in its pure form is defined for a model with the same number of variables as equations, and no bounds on the variables. With our type of model there are usually too many variables, i.e. too many degrees of freedom, and there are bounds. To get around the problem of too many variables, GAMS/CONOPT selects a subset with exactly \(m\) "basic" variables to be changed. The rest of the variables will remain fixed at their current values, that are not necessarily at bounds. To accommodate the bounds, GAMS/CONOPT will try to select variables that are away from their bounds as basic, subject to the requirement that the Basis matrix, consisting of the corresponding columns in the Jacobian, must have full rank and be well conditioned.

The Newton equations are solved to yield a vector of proposed changes for the basic variables. If the full proposed step can be applied we can hope for the fast convergence of Newton's method. However, several things may go wrong:
1. The infeasibilities, measured by the 1-norm of g (i.e. the sum of the absolute infeasibilities, excluding the pre- and post-triangular equations), may not decrease as expected due to nonlinearities.

2. The maximum step length may have to be reduced if a basic variable otherwise would exceed one of its bounds.

In case 1. GAMS/CONOPT tries various heuristics to find a more appropriate set of basic variables. If this does not work, some "difficult" equations, i.e. equations with large infeasibilities and significant nonlinearities, are temporarily removed from the model, and Newton's method is applied to the remaining set of "easy" equations.

In case 2. GAMS/CONOPT will remove the basic variable that first reaches one of its bounds from the basis and replace it by one of the nonbasic variables. Newton's method is then applied to the new set of basic variables. The logic is very close to that of the dual simplex method. In cases where some of the basic variables are exactly at a bound GAMS/CONOPT uses an anti degeneracy procedure based on Ryan and Osborne (1988) to prevent cycling.

Phase 0 will end when all equations except possibly some "difficult" equations are feasible within some small tolerance. If there are no difficult equations, GAMS/CONOPT has found a feasible solution and it will proceed with Phase 3 and 4. Otherwise, Phase 1 and 2 is used to make the difficult equations feasible.

The iteration output will during Phase 0 have the following columns in the iteration log: Iter, Phase, Ninf, Infeasibility, Step, MX, and OK. The number in the Ninf column counts the number of "difficult" infeasible equations, and the number in the Infeasibility column shows the sum of the absolute infeasibilities in all the general constraints, both in the easy and in the difficult ones. There are three possible combinations of values in the MX and OK columns: combination (1) has F in the MX column and T in the OK column and it will always be combined with 1.0 in the Step column: this is an ideal Newton step. The infeasibilities in the easy equations should be reduced quickly, but the difficult equations may dominate the number in the Infeasibility column so you may not observe it. However, a few of these iterations is usually enough to terminate Phase 0. Combination (2) has T in the MX column indicating that a basic variable has reached its bound and is removed from the basis as in case 2. above. This will always be combined with T in the OK column. The Step column will show a step length less than the ideal Newton step of 1.0. Combination (3) has F in both the MX and OK column. It is the bad case and will always be combined with a step of 0.0: this is an iteration where nonlinearities are dominating and one of the heuristics from case 1. must be used.

The success of the Phase 0 procedure is based on being able to choose a good basis that will allow a full Newton step. It is therefore important that as many variables as possible have been assigned reasonable initial values so GAMS/CONOPT has some variables away from their bounds to select from. This topic was discussed in more detail in section Initial Values.

The start and the iterations of Phase 0 can, in addition to the crash option described in section Finding a Feasible Solution: Phase 0 be controlled with the three options lslack, lsmxbs, and lmmxsf described in Appendix B.

5.7.8.7 Finding a Feasible Solution: Phase 1 and 2

Most of the equations will be feasible when phase 0 stops. To remove the remaining infeasibilities CONOPT uses a procedure similar to the phase 1 procedure used in Linear Programming: artificial variables are added to the infeasible equations (the equations with Large Residuals), and the sum of these artificial variables is minimized subject to the feasible constraints remaining feasible. The artificial variable are already part of the model as slack variables; their bounds are simply relaxed temporarily.

This infeasibility minimization problem is similar to the overall optimization problem: minimize an objective function subject to equality constraints and bounds on the variables. The feasibility problem is therefore solved with the ordinary GRG optimization procedure. As the artificial variables gradually become zero, i.e. as the infeasible equations become feasible, they are taken out of the auxiliary objective function. The number of infeasibilities (shown in the Ninf column of the log file) and the sum of infeasibilities (in the Infeasibility column) will therefore both decrease monotonically.

The iteration output will label these iterations as phase 1 and/or phase 2. The distinction between phases 1 (linear mode) and 2 (nonlinear mode) is similar to the distinction between phases 3 and 4, which are described in the next sections.
5.7.8.8 Linear and Nonlinear Mode: Phase 1 to 4

The optimization itself follows step 2 to 9 of the GRG algorithm shown in The CONOPT Algorithm above. The factorization in step 3 is performed using an efficient sparse LU factorization similar to the one described by Suhl and Suhl (1990). The matrix operations in step 4 and 5 are also performed sparse.

Step 7, selection of the search direction, has several variants, depending on how nonlinear the model is locally. When the model appears to be fairly linear in the area in which the optimization is performed, i.e., when the function and constraint values are close to their linear approximation for the steps that are taken, then CONOPT takes advantage of the linearity. The derivatives (the Jacobian) are not computed in every iteration, the basis factorization is updated using cheap LP techniques as described by Reid (1982), the search direction is determined without use of second order information, i.e. similar to a steepest descent algorithm, and the initial step length is estimated as the step length where the first variable reaches a bound; very often, this is the only step length that has to be evaluated. These cheap almost linear iterations are referred to as Linear Mode and they are labeled Phase 1 when the model is infeasible and objective is the sum of infeasibilities and Phase 3 when the model is feasible and the real objective function is optimized.

When the constraints and/or the objective appear to be more nonlinear CONOPT will still follow step 2 to 9 of the GRG algorithm. However, the detailed content of each step is different. In step 2, the Jacobian must be recomputed in each iteration since the nonlinearities imply that the derivatives change. On the other hand, the set of basic variables will often be the same and CONOPT will take advantage of this during the factorization of the basis. In step 7 CONOPT uses the BFGS algorithm to estimate second order information and determine search directions. And in step 8 it will often be necessary to perform more than one step in the line search. These nonlinear iterations are labeled Phase 2 in the output if the solution is still infeasible, and Phase 4 if it is feasible. The iterations in phase 2 and 4 are in general more expensive than the iteration in phase 1 and 3.

Some models will remain in phase 1 (linear mode) until a feasible solution is found and then continue in phase 3 until the optimum is found, even if the model is truly nonlinear. However, most nonlinear models will have some iterations in phase 2 and/or 4 (nonlinear mode). Phase 2 and 4 indicates that the model has significant nonlinear terms around the current point: the objective or the constraints deviate significantly from a linear model for the steps that are taken. To improve the rate of convergence CONOPT tries to estimate second order information in the form of an estimated reduced Hessian using the BFGS formula.

Each iteration is, in addition to the step length shown in column "Step", characterized by two logicals: MX and OK. MX = T means that the step was maximal, i.e. it was determined by a variable reaching a bound. This is the expected value in Phase 1 and 3. MX = F means that no variable reached a bound and the optimal step length will in general be determined by nonlinearities. OK = T means that the line search was well-behaved and an optimal step length was found; OK = F means that the line search was ill-behaved, which means that CONOPT would like to take a larger step, but the feasibility restoring Newton process used during the line search did not converge for large step lengths. Iterations marked with OK = F (and therefore also with MX = F) will usually be expensive, while iterations marked with MX = T and OK = T will be cheap.

5.7.8.9 Linear Mode: The SLP Procedure

When the model continues to appear linear CONOPT will often take many small steps, each determined by a new variable reaching a bound. Although the line searches are fast in linear mode, each require one or more evaluations of the nonlinear constraints, and the overall cost may become high relative to the progress. In order to avoid the many nonlinear constraint evaluations CONOPT may replace the steepest descend direction in step 7 of the GRG algorithm with a sequential linear programming (SLP) technique to find a search direction that anticipates the bounds on all variables and therefore gives a larger expected change in objective in each line search. The search direction and the last basis from the SLP procedure are used in an ordinary GRG-type line search in which the solution is made feasible at each step. The
SLP procedure is only used to generate good directions; the usual feasibility preserving steps in CONOPT are maintained, so CONOPT is still a feasible path method with all its advantages, especially related to reliability.

Iterations in this so-called SLP-mode are identified by numbers in the column labeled InItr in the iteration log. The number in the InItr column is the number of non-degenerate SLP iterations. This number is adjusted dynamically according to the success of the previous iterations and the perceived linearity of the model.

The SLP procedure generates a scaled search direction and the expected step length in the following line search is therefore 1.0. The step length may be less than 1.0 for several reasons:

- The line search is ill-behaved. This is indicated with OK = F and MX = F.
- A basic variable reaches a bound before predicted by the linear model. This is indicated with MX = T and OK = T.
- The objective is nonlinear along the search direction and the optimal step is less than one. This is indicated with OK = T and MX = F.

CONOPT will by default determine if it should use the SLP procedure or not, based on progress information. You may turn it off completely with the line lseslp = f in the CONOPT options file (usually conopt.opt). The default value of lseslp (l seslp = Logical Switch Enabling SLP mode) is t or true, i.e. the SLP procedure is enabled and CONOPT may use it when considered appropriate. It is seldom necessary to define lseslp, but it can be useful if CONOPT repeatedly turns SLP on and off, i.e. if you see a mixture of lines in the iteration log with and without numbers in the InItr column.

5.7.8.10 Linear Mode: The Steepest Edge Procedure

When optimizing in linear mode (Phase 1 or 3) CONOPT will by default use a steepest descend algorithm to determine the search direction. CONOPT allows you to use a Steepest Edge Algorithm as an alternative. The idea, borrowed from Linear Programming, is to scale the nonbasic variables according to the Euclidean norm of the “updated column” in a standard LP tableau, the so-called edge length. A unit step for a nonbasic variable will give rise to changes in the basic variables proportional to the edge length. A unit step for a nonbasic variable with a large edge length will therefore give large changes in the basic variables which has two adverse effects relative to a unit step for a nonbasic variable with a small edge length: a basic variable is more likely to reach a bound after a very short step length, and the large change in basic variables is more likely to give rise to larger nonlinear terms.

The steepest edge algorithm has been very successful for linear programs, and our initial experience has also shown that it will give fewer iterations for most nonlinear models. However, the cost of maintaining the edge lengths can be more expensive in the nonlinear case and it depends on the model whether steepest edge results in faster overall solution times or not. CONOPT uses the updating methods for the edge lengths from LP, but it must re-initialize the edge lengths more frequently, e.g. when an inversion fails, which happens more frequently in nonlinear models than in linear models, especially in models with many product terms, e.g. blending models, where the rank of the Jacobian can change from point to point.

Steepest edge is turned on with the line l sanrm = t, in the CONOPT options file (usually conopt.opt). The default value of l sanrm (l san rm = Logical Switch for A- Norm) is f or false, i.e. the steepest edge procedure is turned off.

The steepest edge procedure is mainly useful during linear mode iterations. However, it has some influence in phase 2 and 4 also: The estimated reduced Hessian in the BFGS method is initialized to a diagonal matrix with elements on the diagonal computed from the edge lengths, instead of the usual scaled unit matrix.
5.7.8.11 Nonlinear Mode: The SQP Procedure

When progress is determined by nonlinearities CONOPT needs second order information. Some second order information can be derived from the line search and is used in the first iterations in Phase 2 or 4. Depending on progress, CONOPT may switch to a Sequential Quadratic Programming (SQP) procedure that works on a sub-model with linear constraints and a quadratic objective function. The constraints are a linearization of the nonlinear constraints, and the objective function is derived from the Hessian of the Lagrangian function. CONOPT will inside the SQP procedure use exact second order information computed by GAMS. The result of the SQP procedure is a search direction and a basis and CONOPT will afterwards use the same line search procedure and feasibility preserving steps as after the SLP procedure.

CONOPT remains a feasible path method with all its advantages, especially related to reliability.

Iterations in this so-called SQP-mode are identified by numbers in the column labeled "InItr" in the iteration log. The number in the InItr column is the number of non-degenerate SQP iterations. The effort spend inside the SQP procedure is adjusted dynamically according to the success of the previous iterations and the reduction in reduced gradient in the quadratic model.

The SQP procedure generates a scaled search direction and the expected step length in the following line search is therefore 1.0. The step length may be less than 1.0 for several reasons:

- The line search is ill-behaved. This is indicated with OK = F and MX = F.
- A basic variable reaches a bound before predicted by the linear model of the constraints. This is indicated with MX = T and OK = T.
- The objective is much more nonlinear along the search direction than expected and the optimal step is not one. This is indicated with OK = T and MX = F.

CONOPT will by default determine if it should use the SQP procedure or not, based on progress information. You may turn it off completely with the line \texttt{lsesqp = f} in the CONOPT options file (usually \texttt{conopt.opt}). The default value of \texttt{lsesqp} (\texttt{lsesqp = Logical Switch Enabling SQP mode}) is \texttt{t} or \texttt{true}, i.e. the SQP procedure is enabled and CONOPT may use it when considered appropriate. It is seldom necessary to define \texttt{lsesqp}, but it can be used for experimentation.

In connection with 1st and 2nd derivatives the listing file (*.lst) will have a few extra lines. The first looks as follows:

```
The model has 537 variables and 457 constraints
with 1597 Jacobian elements, 380 of which are nonlinear.
The Hessian of the Lagrangian has 152 elements on the diagonal,
228 elements below the diagonal, and 304 nonlinear variables.
```

The first two lines repeat information given in the GAMS model statistics and the last two lines describe second order information. CONOPT uses the matrix of second derivatives (the Hessian) of a linear combination of the objective and the constraints (the Lagrangian). The Hessian is symmetric and the statistics show that it has 152 elements on the diagonal and 228 below for a total of 380 elements in this case. This compares favorably to the number of elements in the matrix of first derivatives (the Jacobian).

For some models you may see the following message instead (before the usual CONOPT banner):

```
** Warning ** Memory Limit for Hessians exceeded.
You can use the Conopt option "rvhess"
```
The creation of the matrix of second derivatives has been interrupted because the matrix became too dense. A dense matrix of second derivatives will be slow to compute and it will need a lot of memory. In addition, it is likely that a dense Hessian will make some of the computations inside the SQP iterations so slow that the potential saving in number of iterations is used up computing and manipulating the Hessian.

GAMS/CONOPT can use second derivatives even if the Hessian is not available. A special version of the function evaluation routine can compute the Hessian multiplied by a vector (the so-called directional second derivative) without computing the Hessian itself. This routine is used when the Hessian is not available. The directional second derivative approach will require one directional second derivative evaluation call per inner SQP iteration instead of one Hessian evaluation per SQP sub-model.

If you get the "Memory Limit for Hessians exceeded" message you may consider rewriting some equation. Look for nonlinear functions applied to long linear or separable expressions such as \( \log(\text{sum}(i,x(i))) \); as discussed in Section Simple Expressions . An expression like this will create a dense Hessian with \( \text{card}(i) \) rows and columns. You should consider introducing an intermediate variable that is equal to the long linear or separable expression and then apply the nonlinear function to this single variable. You may also experiment with allocating more memory for the dense Hessian and use it despite the higher cost; it may reduce the number of iterations. This can be done by adding the option \( \text{rvhess} = \text{XX} \) to the CONOPT options file. rvhess is a memory factor with default value 10 so you need a larger value. The value 0.0 is special; it means do not impose a memory limit on the Hessian.

The time spend on the many types of function and derivative evaluations are reported in the listing file in a section like this:

```
CONOPT time Total 0.734 seconds
  of which: Function evaluations 0.031 = 4.3%
            1st Derivative evaluations 0.020 = 2.7%
            2nd Derivative evaluations 0.113 = 15.4%
            Directional 2nd Derivative 0.016 = 2.1%
```

The function evaluations are computations of the nonlinear terms in the model, and 1st Derivatives evaluations are computations of the Jacobian of the model. 2nd Derivative evaluations are computations of the Hessian of the Lagrangian, and Directional 2nd derivative evaluations are computations of the Hessian multiplied by a vector, computed without computing the Hessian itself. The lines for 2nd derivatives will only be present if CONOPT has used this type of 2nd derivative.

If your model is not likely to benefit from 2nd derivative information or if you know you will run out of memory anyway you can save a small setup cost by telling GAMS/CONOPT not to generate it using option \( \text{dobess} = \text{f} \).

5.7.8.12 How to Select Non-default Options

The non-default options have an influence on different phases of the optimization and you must therefore first observe whether most of the time is spend in Phase 0, Phase 1 and 3, or in Phase 2 and 4.

**Phase 0:** The quality of Phase 0 depends on the number of iterations and on the number and sum of infeasibilities after Phase 0. The iterations in Phase 0 are much faster than the other iterations, but the overall time spend in Phase 0 may still be rather large. If this is the case, or if the infeasibilities after Phase 0 are large you may try to use the triangular crash options:

```
lstcrs = t
```

Observe if the initial sum of infeasibility after iteration 1 has been reduced, and if the number of phase 0 iterations and the number of infeasibilities at the start of phase 1 have been reduced. If lstcrs reduces the initial sum of infeasibilities but the number of iterations still is large you may try:
lslack = t

CONOPT will after the preprocessor immediately add artificial variables to all infeasible constraints so Phase 0 will be eliminated, but the sum and number of infeasibilities at the start of Phase 1 will be larger. You are in reality trading Phase 0 iterations for Phase 1 iterations.

You may also try the experimental bending line search with

lmmxsf = 1

The line search in Phase 0 will with this option be different and the infeasibilities may be reduced faster than with the default lmmxsf = 0. It is likely to be better if the number of iterations with both MX = F and OK~=-~F is large. This option may be combined with lstcrs = t. Usually, linear constraints that are feasible will remain feasible. However, you should note that with the bending linesearch linear feasible constraints could become infeasible.

**Phase 1 and 3:** The number of iterations in Phase 1 and Phase 3 will probably be reduced if you use steepest edge, lsanrm = t, but the overall time may increase. Steepest edge seems to be best for models with less than 5000 constraints, but work in progress tries to push this limit upwards. Try it when the number of iterations is very large, or when many iterations are poorly behaved identified with OK = F in the iteration log. The default SLP mode is usually an advantage, but it is too expensive for a few models. If you observe frequent changes between SLP mode and non-SLP mode, or if many line searches in the SLP iterations are ill-behaved with OK = F, then it may be better to turn SLP off with lssslp = f.

**Phase 2 and 4:** There are currently not many options available if most of the time is spend in Phase 2 and Phase 4. If the change in objective during the last iterations is very small, you may reduce computer time in return for a slightly worse objective by reducing the optimality tolerance, rtredg.

5.7.8.13 Miscellaneous Topics

5.7.8.13.1 Triangular Models A triangular model is one in which the non-fixed variables and the equations can be sorted such that the first equation only depends on the first variable, the second equation only depends on the first two variables, and the p-th equation only depends on the first p variables. Provided there are no difficulties with bounds or small pivots, triangular models can be solved one equation at a time using the method describe in section Preprocessing: Pre-triangular Variables and Constraints and the solution process will be very fast and reliable.

Triangular models can in many cases be useful for finding a good initial feasible solution: Fix a subset of the variables so the remaining model is known to be triangular and solve this triangular simulation model. Then reset the bounds on the fixed variables to their original values and solve the original model. The first solve will be very fast and if the fixed variables have been fixed at good values then the solution will also be good. The second solve will start from the good feasible solution generated by the first solve and it will usually optimize much more quickly than from a poor start.

The modeler can instruct CONOPT that a model is supposed to be triangular with the option lstria = t. CONOPT will then use a special version of the preprocessing routine (see section Preprocessing: Pre-triangular Variables and Constraints) that solves the model very efficiently. If the model is solved successfully then CONOPT terminates with the message:

** Feasible solution to a recursive model.**
and the Model Status will be 2, Locally Optimal, or 1, Optimal, depending on whether there were any nonlinear pivots or not. All marginals on both variables and equations are returned as 0 (zero) or EPS.

Two SOLVEs with different option files can be arranged by writing the option files as they are needed from within the GAMS program with PUT statements followed by a PutClose. You can also have two different option files, e.g., conopt.opt and conopt.op2, and select the second with the GAMS statement <model>.OptFile = 2;

The triangular facility handles a number of error situations:

1. Non-triangular models: CONOPT will ensure that the model is indeed triangular. If it is not, CONOPT will return model status 5, Locally Infeasible, plus some information that allows the modeler to identify the mistake. The necessary information is related to the order of the variables and equations and number of occurrences of variables and equations, and since GAMS does no have a natural place for this type of information CONOPT returns it in the marginals of the equations and variables. The solution order for the triangular equations and variables that have been solved successfully are defined with positive numbers in the marginals of the equations and variables. For the remaining non-triangular variables and equations CONOPT shows the number of places they appear as negative numbers, i.e. a negative marginal for an equation shows how many of the non-triangular variables that appear in this equation. You must fix one or more variables until at least one of the non-triangular equation only has one non-fixed variable left.

2. Infeasibilities due to bounds: If some of the triangular equations cannot be solved with respect to their variable because the variable will exceed the bounds, then CONOPT will flag the equation as infeasible, keep the variable at the bound, and continue the triangular solve. The solution to the triangular model will therefore satisfy all bounds and almost all equations. The termination message will be

** Infeasible solution. xx artificial(s) have been introduced into the recursive equations.

and the model status will be 5, Locally Infeasible.

The modeler may in this case add explicit artificial variables with high costs to the infeasible constraints and the resulting point will be an initial feasible point to the overall optimization model. You will often from the mathematics of the model know that only some of the constraints can be infeasible, so you will only need to check whether to add artificials in these equations. Assume that a block of equations matbal(m,t) could become infeasible. Then the artificials that may be needed in this equation can be modeled and identified automatically with the following GAMS constructs:

```
Set aposart(m,t) Add a positive artificial in Matbal
anegart(m,t) Add a negative artificial in Matbal;
aposart(m,t) = No; anegart(m,t) = No;

Positive Variable
vposart(m,t) Positive artificial variable in Matbal
vnegart(m,t) Negative artificial variable in Matbal;

matbal(m,t).. Left hand side =e= right hand side
  + vposart(m,t)$aposart(m,t) - vnegart(m,t)$anegart(m,t);

objDef.. obj =e= other_terms +
  weight * Sum((m,t), vposart(m,t)$aposart(m,t)
  +vnegart(m,t)$anegart(m,t) );

Solve triangular model ...
aposart(m,t)$$(matbal.l(m,t) > matbal.Up(m,t)) = Yes;
anegart(m,t)$$(matbal.l(m,t) < matbal.Lo(m,t)) = Yes;

Solve final model ...
```
3. Small pivots: The triangular facility requires the solution of each equation to be locally unique which also means that the pivots used to solve each equation must be nonzero. The model segment

\[
\begin{align*}
e_1 & \quad x_1 = e = 0; \\
e_2 & \quad x_1 \times x_2 = e = 0;
\end{align*}
\]

will give the message

```
x2 appearing in
  e2: Pivot too small for triangular model. Value=0.000E+00
```

** Infeasible solution. The equations were assumed to be recursive but they are not. A pivot element is too small.

However, the uniqueness of \(x_2\) may not be relevant if the solution just is going to be used as an initial point for a second model. The option `lsismp = t` (for Logical Switch: Ignore Small Pivots) will allow zero pivots as long as the corresponding equation is feasible for the given initial values.

### 5.7.8.13.2 Constrained Nonlinear System or Square Systems of Equations

There is a special model class in GAMS called CNS - Constrained Nonlinear System. A constrained nonlinear system is a square system of equations, i.e. a model in which the number of non-fixed variables is equal to the number of constraints. Currently, CONOPT and PATH are the only solvers for this model class. A CNS model can be solved with a solve statement like

```
Solve <model> using CNS;
```

without an objective term. In some cases it may be convenient to solve a CNS model with a standard solve statement combined with an options file that has the statement `lssqrs = t`. In the latter case, CONOPT will check that the number of non-fixed variables is equal to the number of constraints. In either case, CONOPT will attempt to solve the constraints with respect to the non-fixed variables using Newton's method. The solution process does not include a lot of the safeguards used for ordinary NLP models and when it work it is often very fast and it uses less memory than for the corresponding NLP model. The lack of safeguards means that the solution process just will stop with an error message in some difficult situations and return the current intermediate infeasible solution. Examples of difficulties are that the Jacobian to be inverted is singular, or if one of the non-fixed variables tries to move outside their bounds as described with examples below.

Slacks in inequalities are counted as non-fixed variables which effectively means that inequalities should not be binding. Bounds on the variables are allowed, especially to prevent function evaluation errors for functions that only are defined for some arguments, but the bounds should not be binding in the final solution.

The solution returned to GAMS will in all cases have marginal values equal to 0 or EPS, both for the variables and the constraints.

The termination messages for CNS models are different from the termination messages for optimization models. The message you hope for is

```
** Feasible solution to a square system.
```

that usually will be combined with model status 16-Solved. If CONOPT in special cases can guarantee that the solution is unique, for example if the model is linear, then the model status will be 15-Solved Unique.

There are two potential error termination messages related to CNS models. A model with the following two constraints
5.7 CONOPT

\begin{verbatim}
e1 .. x1 + x2 =e= 1;
e2 .. 2*x1 + 2*x2 =e= 2;
\end{verbatim}

will result in the message

** Error in Square System: Pivot too small.
   e2: Pivot too small.
   x1: Pivot too small.

"Pivot too small" means that the set of constraints is linearly dependent in the current point and there is no unique search direction for Newton's method so CONOPT terminates. The message points to one variable and one constraint. However, this just indicates that the linearly dependent set of constraints and variables include the constraint and variable mentioned. The offending constraint and variable will also be labeled 'DEPND' for linearly dependent in the equation listing. The error will usually be combined with model status 5 - Locally Infeasible. In the cases where CONOPT can guarantee that the infeasibility is not caused by nonlinearities the model status will be 4 - Infeasible. If the constraints are linearly dependent but the current point satisfy the constraints then the solution status will be 17 - Solved Singular, indicating that the point is feasible, but there is probably a whole ray of feasible solution through the current point.

It should be mentioned that the linear dependency and small pivot could be caused by the initial point and that the model could have a solution. An example is

\begin{verbatim}
e1 .. x1*x2 =E= 1;
e2 .. x1+x2 =E= 3;
x1.l = 1; x2.l = 1;
\end{verbatim}

A model with these two constraints and the bound

\begin{verbatim}
e1 .. x1 + x2 =e= 2;
e2 .. x1 - x2 =e= 0;
x1.lo = 1.5;
\end{verbatim}

will result in the message

** Error in Square System: A variable tries to exceed its bound.
   x1: The variable tries to exceed its bound.

because the solution, \((x1,x2) = (1,1)\) violates the bound on \(x1\). This error case will also be combined with model status 5-Locally Infeasible. In the cases where CONOPT can guarantee that the infeasibility is not caused by nonlinearities the model status will be 4 - Infeasible. If you encounter problems with active bounds but you think it is caused by nonlinearities and that there is a solution, then you may try to use the bending linesearch with option \textit{lmmxsfs} = t.

The CNS facility can be used to generate an initial feasible solution in almost the same way as the triangular model facility: Fix a subset of the variables so the remaining model is uniquely solvable, solve this model with the CNS solver or with \textit{1ssqrs} = t, reset the bounds on the fixed variables, and solve the original model. The CNS facility can be used on a larger class of models that include simultaneous sets of equations. However, the square system must be non-singular and feasible; CONOPT cannot, like in the triangular case, add artificial variables to some of the constraints and solve the remaining system when a variable reaches one of its bounds.

Additional information on CNS can be found in the GAMS User's Guide.
5.7.8.13.3 Loss of Feasibility  During the optimization you may sometimes see a phase 0 iteration and in rare cases you will see the message ”Loss of Feasibility - Return to Phase 0”. The background for this is as follows:

To work efficiently, CONOPT uses dynamic tolerances for feasibility and during the initial part of the optimization where the objective changes rapidly fairly large infeasibilities may be acceptable. As the change in objective in each iteration becomes smaller it will be necessary to solve the constraints more accurately so the ”noise” in objective value from the inaccurate constraints will remain smaller than the real change. The noise is measured as the scalar product of the constraint residuals with the constraint marginals.

Sometimes it is necessary to revise the accuracy of the solution, for example because the algorithmic progress has slowed down or because the marginal of an inaccurate constraint has grown significantly after a basis change, e.g. when an inequality becomes binding. In these cases CONOPT will tighten the feasibility tolerance and perform one or more Newton iterations on the basic variables. This will usually be very quick and it happens silently. However, Newton's method may fail, for example in cases where the model is degenerate and Newton tries to move a basic variable outside a bound. In this case CONOPT uses some special iteration similar to those discussed in section Finding a Feasible Solution: Phase 0 and they are labeled Phase 0.

These Phase 0 iterations may not converge, for example if the degeneracy is significant, if the model is very nonlinear locally, if the model has many product terms involving variables at zero, or if the model is poorly scaled and some constraints contain very large terms. If the iterations do not converge, CONOPT will issue the ”Loss of feasibility ...” message, return to the real Phase 0 procedure, find a feasible solution with the smaller tolerance, and resume the optimization.

In rare cases you will see that CONOPT cannot find a feasible solution after the tolerances have been reduced, even though it has declared the model feasible at an earlier stage. We are working on reducing this problem. Until a final solution has been implemented you are encouraged to (1) consider if bounds on some degenerate variables can be removed, (2) look at scaling of constraints with large terms, and (3) experiment with the two feasibility tolerances, rtwma and rtwmi (see Appendix B), if this happens with your model.

5.7.8.13.4 Stalling  CONOPT will usually make steady progress towards the final solution. A degeneracy breaking strategy and the monotonicity of the objective function in other iterations should ensure that CONOPT cannot cycle. Unfortunately, there are a few places in the code where the objective function may move in the wrong direction and CONOPT may in fact cycle or move very slowly.

The objective value used to compare two points, in the following called the adjusted objective value, is computed as the true objective plus a noise adjustment term equal to the scalar product of the residuals with the marginals (see section Loss of Feasibility where this noise term also is used). The noise adjustment term is very useful in allowing CONOPT to work smoothly with fairly inaccurate intermediate solutions. However, there is a disadvantage: the noise adjustment term can change even though the point itself does not change, namely when the marginals change in connection with a basis change. The adjusted objective is therefore not always monotone. When CONOPT loses feasibility and returns to Phase 0 there is an even larger chance of non-monotone behavior.

To avoid infinite loops and to allow the modeler to stop in cases with very slow progress CONOPT has an anti-stalling option. An iteration is counted as a stalled iteration if it is not degenerate and (1) the adjusted objective is worse than the best adjusted objective seen so far, or (2) the step length was zero without being degenerate (see OK = F in section Linear and Nonlinear Mode: Phase 1 to 4). CONOPT will stop if the number of consecutive stalled iterations (again not counting degenerate iterations) exceeds lfstal and lfstal is positive. The default value of lfstal is 100. The message will be:

** Feasible solution. The tolerances are minimal and there is no change in objective although the reduced gradient is greater than the tolerance.

Large models with very flat optima can sometimes be stopped prematurely due to stalling. If it is important to find a local optimum fairly accurately then you may have to increase the value of lfstal.
5.7.8.13.5 Overflow and NaN (Not A Number)  Very large values or overflow can appear in a number of places. CONOPT cannot use these values in the optimization since the results would be unreliable or useless. CONOPT is therefore trying to detect these values and take appropriate action.

Even though most modern computers can work with numbers from 1.e-300 to 1.e+300 CONOPT considers all numbers that are larger than 1.e40 or NaN to be 'bad' and useless. NaN means Not A Number and includes Infinity and Real Overflow.

Bad numbers can have two sources. They can come from the modeler expressions or they can be generated internally in CONOPT. The nonlinear constraints or the derivatives of these constraints may return very large values. If a constraint returns a bad number you will see a message like

** A function value is very large or NaN (Not a Number).
Add bound to ensure that the function values are defined and bounded.

and if a derivatives returns a bad number the message will be something like

** A derivative is very large or NaN (Not a Number).
Add bound to ensure that the derivatives are defined and bounded.

The modeler must in both cases adjust the model to prevent that CONOPT receives these bad numbers so CONOPT stops immediately.

Bad numbers can also in rare cases appear as a result of computations inside CONOPT. Since all primal variables and all derivatives are bounded the bad numbers can only appear as a result of operations involving the factorization of the basis matrix, including the dual variables. You will in this case see a message like

** Overflow or Nan (Not A Number) has been encountered indicating numerical difficulties. Trying to repair by increasing the absolute and relative pivot tolerances (Rtpiva and Rvpivr) and allowing small values to be scaled up by decreasing the minimum scale factor, Rtmins.

Since the source of the problem is the factorization of the basis CONOPT will adjust the tolerances that are used while computing this factorization. Essentially, we must avoid very small pivots and the pivoting tolerances are therefore increased. The source of very small pivots can also be constraints were all terms are very small so CONOPT will also change the minimum scaling factor to try to avoid this source. CONOPT will continue the optimization after changing the tolerances and if the problem appears again if will change the tolerances even more, but since there is a limit to how much they can be adjusted CONOPT may have to give up and it will happen with this message

** Overflow or Nan (Not A Number) continues to be encountered after multiple attempt to repair by changed tolerances. CONOPT will give up.

The termination message will in this case be

** Feasible solution. The solution process has been terminated because intermediate results have become NaN (Not A Number).

or
** Feasible solution. The solution process has been terminated because intermediate results have become NaN (Not A Number).

If you encounter messages with NaN it is always a problem with scaling or structure. The most likely source is constraints with only small terms. Try to avoid them by scaling the variables and constraints appropriately, or try to use option `rtmins`. Or make CONOPT ignore these constraints by using a larger absolute pivot tolerance, `rtpiva`.

Another source are structured models with long chains of relationships. These models will usually have lags or leads and neighboring variables are related with a factor different from one, i.e.

```plaintext
dyn(i) .. x(i) =e= x(i-1)*1.5 + u(i);
```

or

```plaintext
dif(i) .. 2*x(i) =e= x(i-1) + x(i+1) + u(i);
```

CONOPT will try to solve the constraints in the proper order to avoid exploding variables, but a larger relative pivot tolerance, `rtpivr`, may also help. If you have a dynamic model and the variables are supposed to grow rapidly over time then you may consider having a scale factor that also grows with time.

### 5.7.8.13.6 External Equations and Extrinsic Functions

CONOPT can be used with external equations and extrinsic functions written in a programming language such as Fortran or C. Additional information is available in the GAMS User's Guide "External Equations and Extrinsic Functions."

Extrinsic functions can be debugged using the function suffixes `gradn` and `hessn` which use finite differences to approximate the gradient and Hessian using multiple function calls. For details check model `drivtst` in the GAMS Model Library. If external equations are present CONOPT will automatically turn the Function and Derivative Debugger on in the initial point to discover potential errors in the gradient calculation inside the external library. The debugger will not only check the gradients of the external library but even check the gradients calculated by GAMS. In rare cases the debugger may report problems in the regular algebra part of the model for which GAMS has calculated the gradients. These violates should be small and can be ignored. After verifying that the external part of the model has been programmed correctly you may turn debugging off again by setting `lkdebg` to 0 in an options file.

The debugger has two types of check. The first type ensures that the external equations do not depend on other variables than the ones you have specified in the GAMS representation. Structural errors found by these check are usually caused by programming mistakes and must be corrected. The second type of check verifies that the derivatives returned by the external equations and extrinsic functions are consistent with the rate of change in function values. A derivative is considered to be wrong if the value returned by the modeler deviates from the value computed using numerical differences by more than `rtmxj2` times the step used for the numerical difference (usually around 1.e-7). This check is correct if second derivatives are less than `rtmxj2`. `rtmxj2` has a default value of 1.e4. If your model has larger second derivatives you may increase it in order not to get wrong error messages.

The number of error messages from the Function and Derivative Debugger is limited by `lfderr` with a default value of 10.

See Debugging options for a list of options that control the debugger.

### 5.7.9 Appendix B - Options

The options that ordinary GAMS users can access are listed below. Options starting on R assume real values, options starting on LS assume logical values (TRUE, T, 1, or FALSE, F, or 0), and all other CR-Cells starting on L assume integer values. The logical option `dohess` is only used by the interface between GAMS and CONOPT.

#### 5.7.9.1 Algorithmic options
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>LF2DRV</td>
<td>Limit on errors in Directional Second Derivative evaluation.</td>
<td>10</td>
</tr>
<tr>
<td>LFDEGI</td>
<td>Limit on number of degenerate iterations before starting degeneracy breaking strategy.</td>
<td>10</td>
</tr>
<tr>
<td>LFEERR</td>
<td>Limit on number of function evaluation errors. Overwrites GAMS Domlim option</td>
<td>GAMS DomLim</td>
</tr>
<tr>
<td>LFHSOK</td>
<td>Limit on errors in Hessian evaluation.</td>
<td>10</td>
</tr>
<tr>
<td>LFITER</td>
<td>Maximum number of iterations. Overwrites GAMS Iterlim option.</td>
<td>GAMS IterLim</td>
</tr>
<tr>
<td>LFMXNS</td>
<td>Maximum number of new superbasic variables added in one iteration.</td>
<td>auto</td>
</tr>
<tr>
<td>LFNICR</td>
<td>Limit on number of iterations with slow progress (relative less than Rtobjl).</td>
<td>20</td>
</tr>
<tr>
<td>LFNSUP</td>
<td>Maximum number of superbasic variables in the approximation to the Reduced Hessian.</td>
<td>auto</td>
</tr>
<tr>
<td>LFSCAL</td>
<td>Rescaling frequency.</td>
<td>5</td>
</tr>
<tr>
<td>LFSTAL</td>
<td>Limit on the number of stalled iterations.</td>
<td>100</td>
</tr>
<tr>
<td>LFUSDF</td>
<td>Limit on the number of candidates for defined variable in one constraint</td>
<td>2</td>
</tr>
<tr>
<td>LMDEBG</td>
<td>Method used by the function and derivative debugger.</td>
<td>0</td>
</tr>
<tr>
<td>LMMXSF</td>
<td>Method used to determine the step in Phase 0.</td>
<td>0</td>
</tr>
<tr>
<td>LMMXST</td>
<td>Method used to determine the maximum step while tightening tolerances.</td>
<td>0</td>

<tr>
<td>RVHESS</td>
<td>Memory factor for Hessian generation: Skip if #Hessian elements &gt; #Jacobian elements∗Rvhess, 0 means unlimited.</td>
<td>10</td>
</tr>
</tbody>
</table>

cooptfile (string): ←

DO2DIR (boolean): Flag for computing and using directional 2nd derivatives. ←

If turned on, make directional second derivatives (Hessian matrix times directional vector) available to CONOPT. The default is on, but it will be turned off of the model has external equations (defined with =X=) and the user has not provided directional second derivatives. If both the Hessian of the Lagrangian (see DOHESS) and directional second derivatives are available then CONOPT will use both: directional second derivatives are used when the expected number of iterations in the SQP sub-solver is low and the Hessian is used when the expected number of iterations is large.

Default: auto

DOHESS (boolean): Flag for computing and using 2nd derivatives as Hessian of Lagrangian. ←
If turned on, compute the structure of the Hessian of the Lagrangian and make it available to CONOPT. The default is usually on, but it will be turned off if the model has external equations (defined with =X=) or if the Hessian becomes too dense. See also DO2DIR and RVHESS.

Default: auto

heaplimit (real): Maximum Heap size in MB allowed

Default: Infinite

LF2DRV (integer): Limit on errors in Directional Second Derivative evaluation.

If the evaluation of Directional Second Derivatives (Hessian information in a particular direction) has failed more than Lf2drv times CONOPT will not attempt to evaluate them any more and will switch to methods that do not use Directional Second Derivatives. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: 10

LFDEGI (integer): Limit on number of degenerate iterations before starting degeneracy breaking strategy.

The default CONOPT pivoting strategy has focus on numerical stability, but it can potentially cycle. When the number of consecutive degenerate iterations exceeds LFDEGI CONOPT will switch to a pivoting strategy that is guaranteed to break degeneracy but with slightly weaker numerical properties.

Default: 10

LFDERR (integer): Limit on number of error messages from function and derivative debugger.

The function and derivative debugger (see LKDEBG) may find a very large number of errors, all derived from the same source. To avoid very large amounts of output CONOPT will stop the debugger after LFDERR error have been found.

Range: \{1, ..., \infty\}

Default: 10

LFEERR (integer): Limit on number of function evaluation errors. Overwrites GAMS Domlim option

Synonym: domlim

Function values and their derivatives are assumed to be defined in all points that satisfy the bounds of the model. If the function value or a derivative is not defined in a point CONOPT will try to recover by going back to a previous safe point (if one exists), but it will not do it more than at most Lfeerr times. If CONOPT is stopped by functions or derivatives not being defined it will return with a intermediate infeasible or intermediate non-optimal model status.

Default: GAMS DomLim

LFEMSG (integer): Limit on number of error messages related to large function value and Jacobian elements.
Very large function value or derivatives (Jacobian elements) in a model will lead to numerical difficulties and most likely to inaccurate primal and/or dual solutions. CONOPT is therefore imposing an upper bound on the value of all function value and derivatives. This bound is $1\times10^30$ for scaled models and RTMAXJ for unscaled models. If the bound is violated CONOPT will return with an intermediate infeasible or intermediate non-optimal solution and it will issue error messages for all the violating function value and Jacobian elements, up to a limit of Lfemsg error messages.

Range: $\{1, \ldots, \infty\}$

Default: 10

**LFHSOK** *(integer)*: Limit on errors in Hessian evaluation.

If the evaluation of Hessian information has failed more than Lfhsok times CONOPT will not attempt to evaluate it any more and will switch to methods that do not use the Hessian. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: 10

**LFILOG** *(integer)*: Frequency for log-lines for non-SLP/SQP iterations.

Lfilog and Lfilos can be used to control the amount of iteration send to the log file. The non-SLP/SQP iterations, i.e. iterations in phase 0, 1, and 3, are usually fast and writing a log line for each iteration may be too much, especially for smaller models. The default value for the log frequency for these iterations is therefore set to 10 for small models, 5 for models with more than 500 constraints or 1000 variables and 1 for models with more than 2000 constraints or 3000 variables.

Range: $\{1, \ldots, \infty\}$

Default: auto

**LFILOS** *(integer)*: Frequency for log-lines for SLP or SQP iterations.

Lfilog and Lfilos can be used to control the amount of iteration send to the log file. Iterations using the SLP and/or SQP sub-solver, i.e. iterations in phase 2 and 4, may involve several inner iterations and the work per iteration is therefore larger than for the non-SLP/SQP iterations and it may be relevant to write log lines more frequently. The default value for the log frequency is therefore 5 for small models and 1 for models with more than 500 constraints or 1000 variables.

Range: $\{1, \ldots, \infty\}$

Default: auto

**LFITER** *(integer)*: Maximum number of iterations. Overwrites GAMS Iterlim option.

Synonym: iterlim

The iteration limit can be used to prevent models from spending too many resources. You should note that the cost of the different types of CONOPT iterations (phase 0 to 4) can be very different so the time limit (GAMS Reslim or option RVTIME) is often a better stopping criterion. However, the iteration limit is better for reproducing solution behavior across machines.

Default: GAMS IterLim
**LFXMNS** *(integer)*: Maximum number of new superbasic variables added in one iteration. 

When there has been a sufficient reduction in the reduced gradient in one subspace new non-basics can be selected to enter the superbasis. The ones with largest reduced gradient of proper sign are selected, up to a limit. If Lfxmns is positive then the limit is min(500,Lfxmns). If Lfxmns is zero (the default) then the limit is selected dynamically by CONOPT depending on model characteristics.

Default: **auto**

**LFNICR** *(integer)*: Limit on number of iterations with slow progress (relative less than **RTOBJL**).

The optimization is stopped if the relative change in objective is less than **RTOBJL** for Lfnicr consecutive well-behaved iterations.

Range: \{2, ..., ∞\}

Default: 20

**LFNSUP** *(integer)*: Maximum number of superbasic variables in the approximation to the Reduced Hessian.

CONOPT uses and stores a dense lower-triangular matrix as an approximation to the Reduced Hessian. The rows and columns correspond to the superbasic variable. This matrix can use a large amount of memory and computations involving the matrix can be time consuming so CONOPT imposes a limit on on the size. The limit is LFNSUP if LFNSUP is defined by the modeler and otherwise a value determined from the overall size of the model. If the number of superbasics exceeds the limit, CONOPT will switch to a method based on a combination of SQP and Conjugate Gradient iterations assuming some kind of second order information is available. If no second order information is available CONOPT will use a quasi-Newton method on a subset of the superbasic variables and rotate the subset as the reduced gradient becomes small.

Range: \{5, ..., ∞\}

Default: **auto**

**LFSCAL** *(integer)*: Rescaling frequency.

The row and column scales are recalculated at least every Lfscal new point (degenerate iterations do not count), or more frequently if conditions require it.

Range: \{1, ..., ∞\}

Default: 5

**LFSTAL** *(integer)*: Limit on the number of stalled iterations.

An iteration is considered a stalled iteration if there is no change in objective because the linesearch is limited by nonlinearities or numerical difficulties. Stalled iterations will have Step = 0 and F in the OK column of the log file. After a stalled iteration CONOPT will usually try various heuristics to get a better basis and a better search direction. However, the heuristics may not work as intended or they may even return to the original bad basis, so to prevent cycling CONOPT stops after Lfstal stalled iterations and returns an Intermediate Infeasible or Intermediate Nonoptimal solution.

Range: \{2, ..., ∞\}

Default: 100
**LFTMSG (integer):** Limit on number of error messages related to infeasible pre-triangle.

If the pre-processor determines that the model is infeasible it tries to define a minimal set of variables and constraints that define the infeasibility. If this set is larger than LFTMSG elements the report is considered difficult to use and it is skipped.

Default: 25

**LFUSDF (integer):** Limit on the number of candidates for defined variable in one constraint

When there are more than one candidate to be selected as a defined variable in a constraint CONOPT tries to select the most appropriate in order to select as many defined variables as possible. However, to avoid too much arbitrariness this is only attempted if there are not more than Lfusdf candidates.

Default: 2

**LKDEBG (integer):** Flag for debugging of first derivatives

Lkdebg controls how often the derivatives are tested. Debugging of derivatives is only relevant for user-written functions in external equations defined with =X=. The amount of debugging is controlled by LMDEBG. See RTMXJ2 for a definition of when derivatives are considered wrong.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The derivatives are tested in the initial point only.</td>
</tr>
<tr>
<td>0</td>
<td>No debugging</td>
</tr>
<tr>
<td>+n</td>
<td>The derivatives are tested in all iterations that can be divided by Lkdebg, provided the derivatives are computed in this iteration. (During phase 0, 1, and 3 derivatives are only computed when it appears to be necessary.)</td>
</tr>
</tbody>
</table>

**LMDEBG (integer):** Method used by the function and derivative debugger.

The function and derivative debugger (turned on with LKDEBG) can perform a fairly cheap test or a more extensive test, controlled by LMDEBG. See RTMXJ2 for a definition of when derivatives are considered wrong. All tests are performed in the current point found by the optimization algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform tests for sparsity pattern and tests that the numerical values of the derivatives appear to be correct. This is the default.</td>
</tr>
<tr>
<td>1</td>
<td>As 0 plus make extensive test to determine if the functions and their derivatives are continuous around the current point. These tests are much more expensive and should only be used of the cheap test does not find an error but one is expected to exist.</td>
</tr>
</tbody>
</table>

**LMMXSF (integer):** Method used to determine the step in Phase 0.

The steplength used by the Newton process in phase 0 is computed by one of two alternative methods controlled by LMMXSF:
Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this default method.</td>
</tr>
<tr>
<td>1</td>
<td>A method based on bending (projecting the target values of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum. Linear constraints that initially are feasible may become infeasible due to bending. The method does not use anti-degeneracy. This will to be taken care off by removing difficult constraints from the Newton Process at regular intervals. The bending method can sometimes be useful for CNS models that stop when a variable exceeds its bound in an intermediate point even though the final solution is known to be inside the bounds.</td>
</tr>
</tbody>
</table>

**LMMXST (integer):** Method used to determine the maximum step while tightening tolerances.

The steplength used by the Newton process when tightening tolerances is computed by one of two alternative methods controlled by LMMXST:

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this default method.</td>
</tr>
<tr>
<td>1</td>
<td>A method based on bending (projecting the target value of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum.</td>
</tr>
</tbody>
</table>

**LMNDIA (integer):** Method for initializing the diagonal of the approximate Reduced Hessian

Each time a nonbasic variable is made superbasic a new row and column is added to the approximate Reduced Hessian. The off-diagonal elements are set to zero and the diagonal to a value controlled by LMNDIA:

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The new diagonal element is set to the geometric mean of the existing diagonal elements. This gives the new diagonal element an intermediate value and new superbasic variables are therefore not given any special treatment. The initial steps should be of good size, but build-up of second order information in the new sub-space may be slower. The larger diagonal element may also in bad cases cause premature convergence.</td>
</tr>
<tr>
<td>1</td>
<td>The new diagonal elements is set to the minimum of the existing diagonal elements. This makes the new diagonal element small and the importance of the new superbasic variable will therefore be high. The initial steps can be rather small, but better second order information in the new sub-space should be build up faster.</td>
</tr>
</tbody>
</table>

**LMSCAL (integer):** Method used for scaling.

CONOPT will by default use scaling of the equations and variables of the model to improve the numerical behavior of the solution algorithm and the accuracy of the final solution, see
LSSCAL and LMSCAL. The objective of the scaling process is to reduce the values of all large primal and dual variables as well as the values of all large first derivatives so they become closer to 1. Small values are usually not scaled up, see RTMAXS and RTMINS. Scaling method 3 is recommended. The others are only kept for backward compatibility.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Scaling is based on repeatedly dividing the rows and columns by the geometric means of the largest and smallest elements in each row and column. Very small elements less than RTMINJ are considered equal to RTMINJ.</td>
</tr>
<tr>
<td>1</td>
<td>Similar to 3 below, but the projection on the interval [Rtmins,Rtmaxs] is applied at a different stage. With method 1, abs(X)∗abs(Jac) with small X and very large Jac is scaled very aggressively with a factor abs(Jac). With method 3, the scale factor is abs(X)∗abs(Jac). The difference is seen in models with terms like Sqrt(X) close to X = 0.</td>
</tr>
<tr>
<td>2</td>
<td>As 1 but the terms are computed based on a moving average of the squares X and Jac. The purpose of the moving average is to keep the scale factor more stable. This is often an advantage, but for models with very large terms (large variables and in particular large derivatives) in the initial point the averaging process may not have enough time to bring the scale factors into the right region.</td>
</tr>
<tr>
<td>3</td>
<td>Rows are first scaled by dividing by the largest term in the row, then columns are scaled by dividing by the maximum of the largest term and the value of the variable. A term is here defined as abs(X)∗abs(Jac) where X is the value of the variable and Jac is the value of the derivative (Jacobian element). The scale factors are then projected on the interval between Rtmins and Rtmaxs.</td>
</tr>
</tbody>
</table>

LMUSDF (integer): Method used with defined variables

When defined variables are identified (see LSUSDF) they can be used in two ways, controlled by LMUSDF:

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Defined variables are only used in the initial point and for the initial basis (default).</td>
</tr>
<tr>
<td>1</td>
<td>Defined variables are kept basic and the defining constraints are used to recursively assign values to the defined variables in all trial points.</td>
</tr>
</tbody>
</table>

LS2NDI (boolean): Flag for approximating Hessian information for incoming superbasics.

If LS2NDI is turned on (1) CONOPT will try to estimate second order Hessian information for incoming superbasic variables based on directional second derivatives. This is more costly than the standard method described under LMNDIA.

Default: 0

LS2PTJ (boolean): Flag for use of perturbations to compute 2nd derivatives in SQP method.

If on (1) CONOPT may use perturbations of the Jacobian to compute directional 2nd derivatives if they are not provided with other cheaper and more accurate methods. With GAMS it is only relevant for models with functions defined in external function libraries or models with external equations defined with the =X= equation type.

Default: 1
5.7 CONOPT

LSANRM (boolean): Flag for turning Steepest Edge on. ↔

Flag used to turn steepest edge pricing on (1) or off (0). Steepest edge pricing makes the individual iterations more expensive but it may decrease their number. Only experimentation can show if it is worth while.

Default: 0

LSCRSH (boolean): Flag for crashing an initial basis without fixed slacks ↔

When turned on (1) CONOPT will try to crash a basis without fixed slacks in the basis. Fixed slacks are only included in a last round to fill linearly dependent rows. When turned off, large infeasible slacks will be included in the initial basis with preference for variables and slacks far from bound.

Default: 1

LSESQP (boolean): Flag for enabling SQP mode. ↔

If Lsesqp is on (the default) then the SQP (sequential quadratic programming) sub-solver can be used, otherwise it is turned off.

Default: 1

LSISMP (boolean): Flag for Ignoring Small Pivots in Triangular models ↔

Ignore Small Pivots. When turned on CONOPT will ignore the non-uniqueness from small pivots during a triangular solve (see LSTRIA). Note, that the non-uniqueness may propagate to later equations, but we cannot check for it in nonlinear equations.

Default: 0

LSLACK (boolean): Flag for selecting initial basis as Crash-triangular variables plus slacks. ↔

When turned on together with LSTCRS CONOPT will use the triangular crash procedure and select the initial basis as the crash-triangular variables plus slacks in all remaining rows.

Default: 0

LSPOST (boolean): Pre-processor flag for identifying and using post-triangular equations. ↔

When turned on (the default) CONOPT will try to identify post-triangular equations. Otherwise this phase is ignored.

Default: 1

LSPRET (boolean): Pre-processor flag for identifying and using pre-triangular equations. ↔

When turned on (the default) CONOPT will try to identify pre-triangular equations. Otherwise this phase is ignored.

Default: 1
**LSSCAL (boolean):** Flag for dynamic scaling.

When Lsscal is on (the default) CONOPT will use dynamic scaling of equations and variables. See also **LMSCAL**.

Default: 1

**LSSQRS (boolean):** Flag for Square System. Alternative to defining modeltype=CNS in GAMS

When turned on the modeler declares that this is a square system, i.e. the number of non-fixed variables must be equal to the number of constraints, no bounds must be active in the final solution, and the basis selected from the non-fixed variables must always be nonsingular.

Default: 0

**LSTCRS (boolean):** Flag for using the triangular crash method.

When turned on CONOPT will try to crash a triangular basis using ideas by Gould and Reid. The procedure relies on identifying and using good initial values provided by the modeler and only assigning values to variables that are not initialized. Should only be used when several important variables have been given reasonable initial values. The sum of infeasibilities may for some models grow during the crash procedure, so modelers are advised that the option should be used with caution. The option will be ignored if defined variables are forced into the bases **Lsusdf**.

Default: 0

**LSTRIA (boolean):** Flag for triangular or recursive system of equations.

If turned on the equations must form a recursive system. Equations that depend on known variables are allowed as long as they are consistent, e.g. $x = 1$ and $2x = 2$. If the equations are not recursive the model is considered infeasible, and the equations with minimum row count are flagged together with the columns they intersect. See also **LSISMP**.

Default: 0

**LSTRID (boolean):** Flag for turning diagnostics on for the post-triangular equations.

If turned on certain diagnostic messages related to the post-triangular equations will be printed. The messages are mainly related to unusual modeling constructs where linear variables for example only appear in the objective or where certain constraints are guaranteed redundant.

Default: 0

**LSUQDF (boolean):** Flag for requiring defined variables to be unique

When turned on (1) CONOPT will not allow defined variables unless they are unique. We exclude a variable if it can be defined from more than one equation, and we exclude equations if they can be used to define more than one variable.

Default: 1

**LSUSDF (boolean):** Flag for forcing defined variables into the basis

When turned on (1) CONOPT will identify defined variables from constraints of the type $x(i) = f(x)$ where $x(i)$ is free or implied free. The largest number of defined variables possible will be made basic and will be assigned initial values that are consistent with their defining constraint. When turned off (0) defined variables and their defining constraints are treated like all other variables and constraints. When turned on the triangular crash (**LSTCRS**) will not be used.

Default: 1
**PRDEF** *(boolean)*: Flag for printing the defined variables and their defining constraints. →

When turned on (1) CONOPT will print a list of the defined variables and their defining constraints in the order in which they can be evaluated.

Default: 0

**pretri2log** *(boolean)*: Send messages about the pre-triangular analyser to the log →

Default: 0

**PRPOST** *(boolean)*: Flag for printing the post-triangular part of the model →

When turned on (1) CONOPT will print a list of the post-triangular constraints and the variables they are solved for in the order in which they can be evaluated.

Default: 0

**PRPREC** *(boolean)*: Flag for printing the variables changed by the pre-processor →

When turned on (1) CONOPT will print a list of the variables that are changed by the pre-processor. The list includes pre-triangular variables, variables changed by implied bounds, and definitional variables. The three lists can for some models be very long and you can limit the list to variables that are changed by more than (RTPREC)

Default: 0

**PRPRET** *(boolean)*: Flag for printing the pre-triangular part of the model →

When turned on (1) CONOPT will print a list of the pre-triangular constraints and the variables they are solved for, including the solution values, in the order in which they are solved.

Default: 0

**RTBND1** *(real)*: Bound filter tolerance for solution values close to a bound. →

A variable is considered to be at a bound if its distance from the bound is less than Rtbnd1 \( \text{Max}(1,\text{ABS}(\text{Bound})) \). If you need a very small value then your model is probably poorly scaled.

Range: \([3.e-13, 1.e-5]\)

Default: 1.e-7

**RTBNDT** *(real)*: Bound tolerance for defining variables as fixed. →

A variable is considered fixed if the distance between the bounds is less than Rtbndt \( * \text{Max}(1,\text{Abs}(\text{Bound})) \). The tolerance is also used on implied bounds (from converted inequalities) and these implied bounds may be infeasible up to Rtbndt.

Range: \([3.e-13, 1.e-5]\)

Default: 1.e-7

**RTIPVA** *(real)*: Absolute Pivot Tolerance for building initial basis. →
Absolute pivot tolerance used during the search for a first logically non-singular basis. The default is fairly large to encourage a better conditioned initial basis.

Range: \([3.\text{e}-13, 1.\text{e}-3]\)

Default: \(1.\text{e}-7\)

**RTIPVR (real):** Relative Pivot Tolerance for building initial basis

Relative pivot tolerance used during the search for a first logically non-singular basis.

Range: \([1.\text{e}-4, 0.9]\)

Default: \(1.\text{e}-3\)

**RTMAXJ (real):** Upper bound on the value of a function value or Jacobian element.

Very large values of variables, function value, and derivatives and in particular large variations in the absolute value of the variables, functions, and derivatives makes the model harder to solve and poses problems for both feasibility and optimality tests. CONOPT will usually try to scale the model (see LSSCAL) to remove these problems. However, scaling can also make important aspects of a model appear un-important and there is therefore a limit to how aggressively we can scale a model (see RTMAXS and RTMINS). To avoid serious scaling problems CONOPT poses upper bounds on all variables (see RTMAXV) and all function value and derivatives, RTMAXJ.

Range: \([1.\text{e}4, 1.\text{e}30]\)

Default: \(1.\text{e}10\)

**RTMAXS (real):** Upper bound on scale factors.

Scale factors are projected on the interval from Rtmins to Rtmaxs. Is used to prevent very large or very small scale factors due to pathological types of constraints. RTMAXS is silently increased to \(\text{max}(\text{RTMAXV,RTMAXS})/100\) if RTMAXV or RTMAXJ have large non-default values.

Range: \([1, 1.\text{e}20]\)

Default: \(1.\text{e}9\)

**RTMAXV (real):** Upper bound on solution values and equation activity levels

See RTMAXJ for a discussion of why CONOPT poses upper bounds on variables and derivatives. If the value of a variable, including the objective function value, exceeds RTMAXV then the model is considered to be unbounded and the optimization process returns the solution with the large variable flagged as unbounded.

Range: \([1.\text{e}5, 1.\text{e}30]\)

Default: \(1.\text{e}10\)

**RTMINA (real):** Zero filter for Jacobian elements and inversion results.

Contains the smallest absolute value that an intermediate result can have. If it is smaller, it is set to zero. It must be smaller than RTPIVA/10.

Range: \([1.\text{e}-30, \infty]\)

Default: \(1.\text{e}-20\)
RTMINJ (real): Filter for small Jacobian elements to be ignored during scaling.

A Jacobian element is considered insignificant if it is less than $\text{Rtminj}$. The value is used to select which small values are scaled up during scaling of the Jacobian.

Range: $[1.e-7, 1.e-3]$  
Default: $1.e-5$

RTMINS (real): Lower bound for scale factors computed from values and 1st derivatives.

Scale factors used to scale variables and equations are projected on the range $\text{Rtmins}$ to $\text{Rtmaxs}$. The limits are used to prevent very large or very small scale factors due to pathological types of constraints. The default value for $\text{Rtmins}$ is 1 which means that small values are not scaled up. If you need to scale small value up towards 1 then you must define a value of $\text{Rtmins} < 1$.

Range: $[1.e-10, 1]$  
Default: 1

RTMNS2 (real): Lower bound for scale factors based on large 2nd derivatives.

Scaling of the model is in most cases based on the values of the variables and the first derivatives. However, if the scaled variables and derivatives are reasonable but there are large values in the Hessian of the Lagrangian (the matrix of 2nd derivatives) then the lower bound on the scale factor can be made smaller than $\text{Rtmins}$. CONOPT will try to scale variables with large 2nd derivatives by one over the square root of the diagonal elements of the Hessian. However, the revised scale factors cannot be less than $\text{Rtmins2}$.

Range: $[1.e-9, 1]$  
Default: $1.e-6$

RTMXJ2 (real): Upper bound on second order terms.

The function and derivative debugger (see LKDEBG) tests if derivatives computed using the modelers routine are sufficiently close to the values computed using finite differences. The term for the acceptable difference includes a second order term and uses $\text{RTMXJ2}$ as an upper bound on second order derivatives in the model. Larger $\text{RTMXJ2}$ values will allow larger deviations between the user-defined derivatives and the numerically computed derivatives.

Range: $[1, \infty]$  
Default: $1.e4$

RTNWMA (real): Maximum feasibility tolerance (after scaling).

The feasibility tolerance used by CONOPT is dynamic. As long as we are far from the optimal solution and make large steps it is not necessary to compute intermediate solutions very accurately. When we approach the optimum and make smaller steps we need more accuracy. $\text{RTNWMA}$ is the upper bound on the dynamic feasibility tolerance and $\text{RTNWMI}$ is the lower bound.

Range: $[1.e-10, 1.e-3]$  
Default: $1.e-7$

RTNWMI (real): Minimum feasibility tolerance (after scaling).
See RTNWMA for a discussion of the dynamic feasibility tolerances used by CONOPT.

Range: [4.e-11, 1.e-5]

Default: 4.e-10

RTNWTR (real): Feasibility tolerance for triangular equations.

Triangular equations are usually solved to an accuracy of RTNWMI. However, if a variable reaches a bound or a constraint only has pre-determined variables then the feasibility tolerance can be relaxed to Rtnwtr.

Range: [3.e-13, 1.e-4]

Default: 2.0e-8

RTOBJL (real): Limit for relative change in objective for well-behaved iterations.

The change in objective in a well-behaved iteration is considered small and the iteration counts as slow progress if the change is less than Rtobjl * Max(1,Abs(Objective)). See also LFNICR.

Range: [3.0e-13, 1.0e-5]

Default: 3.0e-12

RTOBJR (real): Relative accuracy of the objective function.

It is assumed that the objective function can be computed to an accuracy of Rtobjr * max( 1, abs(Objective) ). Smaller changes in objective are considered to be caused by round-off errors.

Range: [3.0e-14, 10.e-6]

Default: 3.0e-13

RTONED (real): Accuracy of One-dimensional search.

The onedimensional search is stopped if the expected decrease in then objective estimated from a quadratic approximation is less than Rtoned times the decrease so far in this onedimensional search.

Range: [0.05, 0.8]

Default: 0.2

RTPIVA (real): Absolute pivot tolerance.

During LU-factorization of the basis matrix a pivot element is considered large enough if its absolute value is larger than Rtpiva. There is also a relative test, see RTPIVR.

Range: [2.2e-16, 1.e-7]

Default: 1.e-10

RTPIVR (real): Relative pivot tolerance during basis factorizations.
During LU-factorization of the basis matrix a pivot element is considered large enough relative to other elements in the column if its absolute value is at least \( R_{tpivr} \) * the largest absolute value in the column. Small values or \( R_{tpivr} \) will often give a sparser basis factorization at the expense of the numerical accuracy. The value used internally is therefore adjusted dynamically between the users value and 0.9, based on various statistics collected during the solution process. Certain models derived from finite element approximations of partial differential equations can give rise to poor numerical accuracy and a larger user-value of \( R_{tpivr} \) may help.

Range: \([1.0e-3, 0.9]\]

Default: 0.05

\textbf{RTPIVT (real)}: Absolute pivot tolerance for nonlinear elements in pre-triangular equations. \( \leftarrow \)

The smallest pivot that can be used for nonlinear or variable Jacobian elements during the pre-triangular solve. The pivot tolerance for linear or constant Jacobian elements is \( R_{tpiva} \). The value cannot be less that \( R_{tpiva} \).

Range: \([2.2e-16, 1.0e-3]\]

Default: \( 1.0e-5 \)

\textbf{RTPIVU (real)}: Relative pivot tolerance during basis updates. \( \leftarrow \)

During basis changes CONOPT attempts to use cheap updates of the LU-factors of the basis. A pivot is considered large enough relative to the alternatives in the column if its absolute value is at least \( R_{tpivu} \) * the other element. Smaller values of \( R_{tpivu} \) will allow sparser basis updates but may cause accumulation of larger numerical errors.

Range: \([1.0e-3, 0.9]\]

Default: 0.05

\textbf{RTPREC (real)}: Tolerance for printing variables changed by the pre-processor \( \leftarrow \)

The list of variables changed by the pre-processor (see (PRPREC)) can be limited to the variables that are changed by more than \( RTPREC \), defined as \( \text{deltaX} > RTPREC \times \max(1, \text{abs}(X)) \).

Range: \([0.0, \infty]\)

Default: 0.0

\textbf{RTPREL (real)}: Tolerance for defining large changes in variables in pre-processor \( \leftarrow \)

The statistics for the number of variables that are changed in the pro-processor are classified as small and large changes. The change, \( \text{DeltaX} \), is defined as large if \( \text{deltaX} > RTPREL \times \max(1, \text{abs}(X)) \).

Range: \([0.0, \infty]\)

Default: 0.01

\textbf{RTREDG (real)}: Optimality tolerance for reduced gradient. \( \leftarrow \)
The reduced gradient is considered zero and the solution optimal if the largest superbasic component of the reduced gradient is less than $R_{\text{tredg}}$.

Range: $[3.\text{e-13}, 1]$

Default: $1.\text{e-7}$

**RTZERN** *(real): Zero-Noise in external equations ←*

By default CONOPT will debug the derivatives returned from External functions in GAMS in the initial point (see **LKDEBG**). If external functions have constant derivatives then the constant terms are still part of the external function and this can give rise to small inaccuracies in the contribution of the constant derivatives to the function value. This noise can cause the debugger to incorrectly state that a the external equation depend on the variable with the constant derivative. A larger value of Rtzern should remove the error.

Range: $[0.0, 1]$

Default: 0.0

**RVFILL** *(real): Fill in factor for basis factorization. ←*

Rvfill is used in the initial allocation of memory for the factorization of the basis. The fill-in (number of new nonzeros) is assumed to be Rvfill-1 times the initial number of nonzeros in the basis. The default is 5 but you may experiment with a smaller value (down to 1.0) for models that use too much memory to get started. If Rvfill is small you may get slower execution due to increased memory movement. And you may still run out of memory later in the optimization.

Range: $[1.00, 20]$

Default: 5

**RVHESS** *(real): Memory factor for Hessian generation: Skip if $\#\text{Hessian elements} > \#\text{Jacobian elements} \times \text{Rvhess}$, 0 means unlimited. ←

The Hessian of the Lagrangian is considered too dense and is not passed on to CONOPT if the number of nonzero elements in the Hessian of the Lagrangian is greater than the number of nonlinear Jacobian elements multiplied by Rvhess. The assumption is that a very dense Hessian is expensive both to compute and use. If Rvhess = 0.0 then there is no limit on the number of Hessian elements.

Default: 10

**RVTIME** *(real): Time Limit. Overwrites the GAMS Reslim option. ←*

Synonym: reslim

The upper bound on the total number of seconds that can be used in the execution phase. There are only tests for time limit once per iteration. The default value is 10000. Rvtime is overwritten by Reslim when called from GAMS. Rvtime is defined in ProbSize and/or UpdtSize when used as a subroutine library.

Default: GAMS ResLim
5.7.10 APPENDIX C: References

5.8 CONOPT4

Author
Arne Drud, ARKI Consulting and Development A/S, Bagsvaerd, Denmark

5.8.1 Introduction

CONOPT4 is an NLP solver derived from CONOPT3 but with many changes. This initial note will describe some of the more important changes from CONOPT3 to CONOPT4 and some of the new options that control these changes. Selected parts of the log-file are also shown and explained. The note is fairly technical and the casual user does not have to understand the details.

More self-contained documentation for CONOPT4 without numerous references to CONOPT3 will appear later.

5.8.2 When should you use CONOPT4?

CONOPT3 is a mature solver with a lot of build-in heuristics developed over years of experimentation and CONOPT3 works well for a large class of models. Initially, CONOPT4 is being developed and tuned for models where CONOPT3 has problems or where small adjustments have given a better solver. Our initial recommendations are:

- CONOPT4 should be tried on models that take more than a few minutes to solve. CONOPT3 is probably your best guess for small and medium sized models, i.e. models with less than 1,000 to 10,000 variables and constraints.
- CONOPT4 should be tried for large CNS models, i.e. models with more than 100,000 variables and constraints.
- CONOPT4 should be tried for models where CONOPT3 runs out of memory. However, note that models of this size under all circumstances are very large and good behavior cannot be guaranteed.
- CONOPT4 should be tried on models where CONOPT3 ends in a locally infeasible solution. CONOPT4 has several new components that avoid obviously infeasible areas and let CONOPT4 move away from saddle points.
- CONOPT4 should be tried on models where CONOPT3 finds a large number of definitional constraints.
5.8.3 Memory Management

CONOPT3 has a limit on the amount of memory that can be used of 8 GBytes. The way memory is allocated and used has been completely rewritten and there is no longer a logical limit in CONOPT4.

5.8.4 Revised Preprocessor

The preprocessor in CONOPT3 identifies pre- and post-triangular variables and constraints, and it handles these variables and constraints in a special way so some internal routines can run more efficiently. The triangular variables are for example always basic. CONOPT3 does not include these variables in tests for entering and leaving the basis. And triangular variables are processed before other variables in the inversion routine. Despite the special status of some variables and constraints, they are all part of the model to be solved.

CONOPT4 distinguished between a 'user model' as defined by the user via the GAMS language, and an 'internal model'. Pre-triangular variables and constraints are simply removed from the user model. Post-triangular variables and constraints are collapsed into a single condensed objective function. And definitional constraints are eliminated. After the internal model has been solved CONOPT4 translates the internal solution back into the solution for the user model and reports this solution to the user. Because CONOPT4 uses these two different models it is no longer possible to turn the preprocessor off.

In addition to the simple pre- and post-triangular variables and constraints from CONOPT3, the preprocessor in CONOPT4 looks at more possibilities for simplifying the model. Some of the new features are:

- Fixed variables are removed completely.
- Constraints that represent simple inequalities are identified and changed into simple bounds on the variables and the constraints are removed.
- Simple monotone constraints such as \( \exp(x) \leq c1 \) or \( \log(y) \leq c2 \) are converted into simple bounds on the variables and then removed.
- Forcing constraints such as \( x_1 + x_2 \leq 0 \) with \( x_1.lo = 0 \) and \( x_2.lo = 0 \) are identified, the variables are fixed, and the constraints are removed. If a forcing constraint is identified then other constraints may become pre-triangular so they also can be removed.
- Linear and monotone constraints are used to compute 'implied bounds' on many variables and these bounds can help CONOPT4 get a better starting point for finding an initial feasible solution.
- Some non-monotone constraints such as \( \text{sqr}(x_1) + \text{sqr}(x_2) \leq 1 \) can also be used to derive implied bounds (here \(-1 < x_1 < +1 \text{ and } -1 < x_2 < +1\)) that both can improve the starting point and can be used to determine that other terms are monotone.
- Constraints with exactly two variables, e.g. simple linear identities such as \( x_1 = a \times x_2 + b \) or simple monotone identities such as \( x_3 = \exp(x_4) \), are used to move bounds between the two variables and this may result in more variables being included in the post-triangle.
- Linear constraints that are identical or proportional to others are identified and removed.
- Pairs of constraints that define a lower and an upper bound on the same linear expression or proportional linear expressions, e.g. \( 1 \leq x_1 + x_2 \) and \( 2x_1 + 2x_2 \leq 4 \), are turned into a single ranged constraint implemented with a double-bounded slack variable.
- Nonlinear constraints that become linear when the pre-triangular variables are fixed are recognized as being linear with the resulting simplifications.
Some of the new preprocessing steps are useful when solving sub-models in a Branch and Bound environment. A constraint like \( x \leq M y \) where \( y \) is a binary variable fixed at either 0 or 1 is turned into a simple bound on \( x \). And a constraint like \( \sum(i, x(i)) \leq \text{Cap} \times y \) (with \( x\.lo(i) = 0 \)) combined with \( y \) fixed at zero will force all \( x(i) \) to zero.

The preprocessor also identifies constructs that are easy to make feasible. There are currently two types:

- **Penalty terms:** We define a penalty constraint as a constraint of the form \( f(x_1, x_2, \ldots) + p - n = 0 \), where \( p \) and \( n \) are positive variables, and where \( p \) and \( n \) only appear in post-triangular constraints or in previously identified penalty constraint. For any feasible values of the \( x \)-variables it is easy to find values of \( p \) and \( n \) that makes the penalty constraint feasible: \( p = \max(0, -f(x)) \) and \( n = \max(0, f(x)) \). The definition is easily generalized to constraints where \( p \) and \( n \) have coefficients different from one and nonzero bounds; the essence is the presence of two linear unbounded terms of opposite sign.

- **Minimax terms:** We define a minimax group as a group of constraints of the form \( e_{q(i)}..fi(x_1, x_2, \ldots) \leq z \) where \( z \) is common to the group and otherwise only appear in post-triangular constraints, and \( z \) is unbounded from above. For any feasible value of the \( x \)-variables it is easy to find a value of \( z \) that makes the minimax group feasible: \( z = \text{smin}(i: fi(x)) \). The definition is easily generalized to groups of constraints where \( z \) has coefficients different from one and where the direction of the inequality is reversed.

The preprocessor will also recognize definitional equations: constraints of the form \( x = f(y) \), where \( x \) is a free variable or the bounds on \( x \) cannot be binding, are called definitional equations and \( x \) is called a defined variable. If there are many potential defined variable the preprocessor will select a recursive set and logically eliminate them from the internal model: The values of the defined variables are easily derived from the values of all other variables by evaluating the definitional equations in their recursive order, and these values are substituted into the remaining constraints before their residuals are computed. The matrix of derivatives of the remaining constraints is computed from the overall matrix of derivatives via an elimination of the triangular definitional equations.

The procedure used to recognize definitional equation is similar to the one used in CONOPT3. However, the actual use of the definitional equations is quite different in CONOPT4. The definitional equations are eliminated from the internal model and they are not present in the internal operations used to solve this model. For some models this can make a big difference.

We will show a few examples of log files where the output from the preprocessor is shown. The first is from the `otpop.gms` model in the GAMS Library:

The user model has 104 variables and 77 constraints
with 285 Jacobian elements, 100 of which are nonlinear.
The Hessian of the Lagrangian has 17 elements on the diagonal,
33 elements below the diagonal, and 66 nonlinear variables.

Iter  Phase  Ninf  Infeasibility  RGmax  NSB  Step  InItr  MX  OK
0     0     4.0939901439E+03 (Input point)

The pre-triangular part of the model has 32 constraints and 43 variables.
The post-triangular part of the model has 9 constraints and variables.
There are 13 definitional constraints and defined variables.
```
Preprocessed model has 39 variables and 23 constraints with 88 Jacobian elements, 22 of which are nonlinear.

</tr>
</tbody>
</table>

The first few lines define the size of the user model. Usually there will also be information on the Hessian of the Lagrangian; these two lines are missing from models where the Hessian is not generated, usually because it is very large and dense (or because the generation has been turned off with the option Flg.Hessian = false).

After the description of the initial sum of infeasibilities there are three lines with statistics from the preprocessor. Note that the pre-triangular part of the model has more variables than constraints, in this case because there are fixed variables. The post-triangular part will always have the same number of constraints as variables, and the same is true for definitional constraints and defined variables.

After the statistics from the preprocessor the size of the resulting internal model is shown. There is no Hessian information; it is costly to derive the Hessian for the internal model and it will in most cases be very dense so all use of 2nd order information in the internal model is computed by mapping data to the user model and using the real Hessian.

The next lines show the change in the sum of infeasibilities during the initial stages. The first line is after the preprocessor has changed some variables and removed many constraints. The second line is after the internal model has been scaled. And last line is after some variables have been adjusted as described in the next section.

The second example is from the prolog.gms model in the GAMS Library:

</tr>
</tbody>
</table>

There are no pre-triangular variables and constraints and the pre-triangular line is therefore missing, just like the line describing definitional constraints. On the other hand, there is a line telling that the model has 17 penalty and minimax constraints involving a total of 3 variables.

The internal model that is generated is here without the penalty and minimax constraints. This particular sub-model and other internal sub-models are described in more detail later in this note.
5.8 CONOPT4

5.8.5 Phase 0 - Finding an Initial Feasible Solution

Phase 0 is started with a new 'Adjust Initial Point' procedure that tries to minimize the sum of infeasibilities by changing individual variables one at a time. The procedure is very cheap since each change of a single variable only involve a small part of the overall model, and it will as a by-product produce a large part of a good initial basis and many constraints will become feasible. As the log file examples above shows, the procedure can in some cases reduce the sum of infeasibilities significantly.

Phase 0 in CONOPT3 is based on Newton's method with a heuristic for taking some constraints out if they do not behave well for Newton. The method can be very fast if a good initial basis is found, but for larger models it can also use a large number of basis changes without any real improvement and can therefore be very slow. CONOPT4 has replaced the heuristic with a rigorous LP framework that iteratively finds a better basis for Newton's method. CONOPT4 can therefore be slower for very easy models but the variability in solution time is smaller and it should never be very slow.

The new Phase 0 procedure replaces the Triangular Crash procedure from CONOPT3.

The following example shows the relevant part of the log file for GAMS Library model otpop.gms:

```
<table>

</tr>
</tbody>
</table>
```

For some of the iterations Step is less than 1 indicating that the direction found by the inner linear model could not be used in full due to nonlinearities. Also note the lines with 'S0' in the Phase column. The S tells that the model was scaled before the iteration and the sum of infeasibilities was increased during this scaling procedure. The sum of infeasibilities is therefore not monotone decreasing even if each outer iteration does decrease them.
5.8.6 Transition between SLP and SQP

The transition from SLP to SQP and back again is in CONOPT3 based on monitoring failure. The logic has been changed in CONOPT4 so transition is based on continuous measurements of curvature, both in the general constraints and in the objective function, combined with estimates of computational costs and progress for SLP and SQP.

The continuation of the log file for GAMS Library model otpop.gms shows some of this:

<table>

** Optimal solution. Reduced gradient less than tolerance.

Iterations 6 to 9 are SLP iterations (Phase 3) and iterations 10 to 14 are SQP iterations (Phase 4). The SLP iterations have Step less than 1 due to nonlinear objective terms and CONOPT4 jumps directly from SLP to SQP. CONOPT3 needed some steepest descend and some Quasi-Newton iterations as a transition, and although these iterations are fast, the transition could sometimes be slow.

5.8.7 Bad Iterations

Bad iterations (for both solvers flagged with “F” in the “OK” column of the log file) are an important problem for both CONOPT3 and CONOPT4. They appear if the output from the SLP or SQP procedure is a search direction where CONOPT cannot move very far because it is difficult to make the nonlinear constraints feasible again. The efforts spend in solving the SLP or SQP procedure is therefore partially wasted. The problem is usually associated with a basis that is ill-conditioned or changes very fast.

CONOPT3 has some heuristics for changing the basis in these cases. For models with many basic and superbasic variables this can be a slow and not very reliable procedure.

CONOPT4 uses a more rigorous procedure based on monitoring the size of some intermediate terms. It can be the size of elements of the tangent for basic variables relative to similar elements for superbasic variables. Or it can be intermediate results from the computation of the reduced costs. The monitoring procedure is cheap and it is used to maintain a well-conditioned basis throughout the optimization instead of waiting until something does not work well.

5.8.8 Saddle Points and Directions of Negative Curvature

CONOPT is based on moving in a direction derived from the gradient (or the reduced gradient for models with constraints). If the reduced gradient (projected on the bounds) is zero then the solution satisfies the first-order optimality conditions and it is standard procedure to stop. Unfortunately, this means that we can stop in a saddle-point.

It is not very common to move towards a saddle-point and get stuck in it. However, it is not uncommon that the initial point, provided by a user or by default, is a saddle point. A simple example is the
constraint $x \cdot y = 1$ started with $x.l = y.l = 0$ that easily can end with a locally infeasible solution. Or minimize $z$, $z = x \cdot y$ with the same starting point that could end locally optimal without moving even though better points exist in the neighborhood.

CONOPT4 has an added procedure that tries to find a direction of negative curvature that can move the solution point away from a saddle-point. The procedure is only called in points that satisfy the first order optimality conditions and it is therefore a cheap safeguard. The theory behind the method is developed for models without degeneracy and it works very well in practice for these models. Models with some kind of degeneracy (basic variables at bound or nonbasic variables with zero reduced cost) use the same procedure, but it is in this case only a heuristic that cannot be guaranteed to find a direction of negative curvature, even if one exists.

If you know that there are no directions of negative curvature you can turn the procedure of by setting the logical option Flg_NegCurve to false. If the model is known to be convex you can set the logical option Flg_Convex to true and it will also turn this procedure off. The saving is usually very small, except for models that solve in very few iterations and for model with a large number of superbasics.

There is no output in the log file for negative curvature. If a useful direction is found CONOPT4 will follow it and the optimization continues. Otherwise, the solution is declared locally optimal.

5.8.9 Use of Alternative Sub-Models

During the course of an optimization CONOPT4 can work with up to three different internal sub-models. These models are:

- Full Model: This model consists of the constraints in the user's model excluding all pre- and post-triangular constraints and with the definitional variables eliminated by their defining constraints.
- No-Penalty Model: This model consists of the Full Model excluding all penalty and mini-max constraints. This model does not have an objective function.
- Linear Feasibility Model: This model consists of the linear constraints of the Full Model. The Linear Feasibility model is either solved without an objective function or minimizing a quadratic distance measure; this is discussed below.

The pre-triangular variables are considered fixed and they do not appear in any of the sub-models. Their influence comes through their contribution to coefficients and constant terms. The post-triangular variables are considered intermediate variables in the definition of the objective function. They do not appear in the last two models that only are concerned with feasibility, and they only appear indirectly via the objective in the Full Model. The defined variables are considered intermediate variables in the definition of the remaining constraints in the same way as post-triangular variables are intermediate in the objective. The variables in the Full Model are all variables excluding pre- and post-triangular variables and excluding defined variables; this set can include variables that do not appear in any constraints. The constraints of the full models are all constraints excluding pre- and post-triangular constraints and with the definitional equations logically eliminated. The variables in the Linear Feasibility Model and in the No-Penalty Model are the variables that appear in the constraints of these models (excluding pre-triangular variables).

CONOPT always starts by searching for a feasible solution and the sub-models only play a role in this part of the optimization so if the initial point provided by the modeler is feasible then these sub-models are irrelevant. If there are many penalty and/or minimax constraints then the No-Penalty Model will be much smaller than the Full Model and it is more efficient to use the smaller model while searching for feasibility. So the No-Penalty model is only introduced for efficiency reasons. It is by default solved before the Full Model if all of the following conditions are satisfied:

- The Flg_NoPen options is true (the default value)
- The model is not a CNS model
- The user did not provide an initial basis
- Some of the constraints in the No-Penalty Model are infeasible.
- The number of penalty and minimax constraints is more than the number of constraints in the Full Model multiplied by the value of option Rat.NoPen. The default value of Rat.NoPen is 0.1, i.e. the No-Penalty Model is only defined and solved if it is at least 10% smaller than the Full Model.

The GAMS Library model prolog.gms used earlier has many penalty and minimax constraints. The relevant part of the log file is:

```
Iter Phase Ninf Infeasibility RGmax NSB Step InItr MX OK
0 0 1.2977431398E+03 (Input point)
The post-triangular part of the model has 1 constraints and variables.
There are 17 penalty and minimax constraints with 3 variables.
Reduced model without penalty components has 17 variables and 5 constraints with 46 Jacobian elements, 0 of which are nonlinear.

Iter Phase Ninf Infeasibility RGmax NSB Step InItr MX OK
1.2960000000E+03 (Model without penalty constraints)
5.0625000000E+00 (After scaling)
0.0000000000E+00 (After adjusting individual variables)
```

Previous model terminated and penalty components are added back in.
Full preprocessed model has 20 variables and 22 constraints with 120 Jacobian elements, 8 of which are nonlinear.

```
Iter Phase Ninf Infeasibility RGmax NSB Step InItr MX OK
0.0000000000E+00 (After adjusting penalty variables)
```

** Feasible solution. Value of objective = -1147.54681404

The No-Penalty model is small with only 5 constraints and 17 variables and it solves already in the 'Adjust Individual Point' procedure. The Full Model is significantly larger with 22 constraints and 20 variables, and it is feasible when started from the solution to the No-Penalty model.

The Linear Feasibility Model is introduced to help avoid locally infeasible solutions. It produces a starting point to the nonlinear models (No-Penalty Model or Full Model) that satisfies all linear constraints. If the Linear Feasibility Model is infeasible then the overall model is proved to be infeasible (independent of nonlinearities) and there is no reason to proceed with the nonlinear part of the model.

The Linear Feasibility Model is only useful if the model has some linear constraints and if the initial point provided by the modeler does not satisfy these constraints. If a feasible solution to the linear constraints is found there are several possible ways to continue before the No-Penalty Model and/or the Full Model are started:

A. Use the solution point as is.

B. Perform an approximate minimization of the weighted distance from the user's initial point. Include only the variables that have non-default initial values, i.e. variables with an initial value (xini) that is different from zero projected on the bounds, i.e. xini ne min(max(0,x.lo),x.up). The distance measure is \(\text{sqr}\left(\frac{x-xini}{\max(1,\text{abs}(xini))}\right)\).

C. As in B, but include all variables in the distance measure.

D. As in C, but define xini to 1 projected on the bounds for all variables with default initial value.
Possibility A is fast but may give a starting point for the nonlinear model far from the initial point provided by the user, B is slower but gives a starting point for the nonlinear model that is close to the point provided by the user, and C and D are also slower but may provide reasonably good and different starting points for the nonlinear model.

The order in which the sub-models are solved depends on a Linear Feasibility Model strategy option, \texttt{Lin\_Method}:

1. If \texttt{Lin\_Method} has the default value 1 then the initial point and basis is assumed to be fairly good and CONOPT4 will start with the No-Penalty Model (only if the conditions mentioned above are satisfied) followed by the Full Model. If the model terminates locally optimal, unbounded, or on some resource limit (time, iterations, function evaluations) then we are done and CONOPT terminates. But if the model is locally infeasible then we build and solve the Linear Feasibility Model. If this model is infeasible, the overall model is infeasible and we are again done. If it is feasible we minimize objective B and use the solution point as a second starting point for the nonlinear model. If this attempt also terminates locally infeasible we try to generate an alternative initial point with objective C and then with objective D. If all fails, the model is labeled locally infeasible.

2. With \texttt{Lin\_Method} = 2 CONOPT will start with the Linear Feasibility Model with objective A before looking at the No-Penalty and Full models. If they are locally infeasible from this starting point we followed the procedure from above with objective B, C, and then D.

3. \texttt{Lin\_Method} = 3 is similar to \texttt{Lin\_Method} = 2 except that the first objective A is skipped.

An example where all Linear Feasibility objectives are used is taken from \texttt{ex5.3.2.gms} in the GlobalLib collection of test models. It shows the repeated starts of the Linear Feasibility Model followed by the Full Preprocessed model:

Preprocessed model has 22 variables and 16 constraints with 59 Jacobian elements, 24 of which are nonlinear.

** Optimal solution. There are no superbasic variables.
The Full Model is infeasible when started directly from the values provided by the user. The Linear Feasibility model is then solved to get a different starting point for the Full model where the linear part is feasible. The Full Model is also infeasible from this point and it is necessary to solve the Linear Feasibility model three times with different objective functions before the full model becomes feasible.

The number of submodels that are solved is limited by the option, Num_Rounds. The default value is 4, i.e. we will try very hard to find a feasible point as shown in the example above. The value 1 will make CONOPT terminate immediately when a locally infeasible point is found. You can use Num_Rounds if you are not interested in spending a lot of time on a model that is likely to be infeasible. It can be particularly relevant if CONOPT4 is used as the sub-solver inside SBB where infeasible sub-problems are fairly likely.

If the model is defined to be convex with the option Flg_Convex = true then a locally infeasible solution is labeled (globally) infeasible and the Linear Feasibility Model will not be used. (A locally optimal solution is also labeled (globally) optimal.)

5.8.10 Multiple Threads

CONOPT4 can use multiple threads for some internal computations and in collaboration with GAMS for function and derivative evaluations. Multiple threads are currently only used for certain fairly large and dense computations and there are not so many of these in the types of model usually build with GAMS. In addition, multiple threads have quite high overhead and they are therefore only useful for fairly large models. Currently the best improvements have been for very large models with more than 100,000 variables or constraints, in particular for CNS models if this size.

It is the intention to implement multiple threads into more parts of CONOPT4 in the future.

Threads can be turned on with the GAMS command-line option Threads=n or with the CONOPT4 option threads.

5.8.11 Solving CNS Models

CONOPT4 is a general NLP (Nonlinear Programming) solver, but it also has some specialized routines for solving CNS (Constrained Nonlinear System) models. Due to the specialized routines, it is in general possible to solve much larger CNS models than NLP models, and there are users that solve models with more than 1 million variables and equations, mainly in the area of Economic General Equilibrium models.

5.8.11.1 Basic CNS Theory

CONOPT4’s CNS procedure is based on Newton’s method: The constraints are linearized around the starting point and the suggested change in variables is computed by solving a square set of linear equations where the right-hand-side is the vector of residuals:

\[ g(x_0 + dx) = 0 \]  

is approximated by

\[ g(x_0) + J \cdot dx = 0 \iff dx = J^{-1} g(x_0) \]  

The matrix \( J \) is the Jacobian or the matrix of first derivatives of the constraint functions \( g \). For a CNS model \( J \) will be a square matrix. In the optimization part of CONOPT4 we work with a sub-matrix selected from a subset of columns of the Jacobian and this matrix is called a Basis and we will therefore sometimes use the term basis and inverse basis when referring to \( J \) and \( J^{-1} \). If the starting point is close to the solution, Newton’s method is known to converge very quickly. We may even use the same \( J^{-1} \) for several iterations. The rate of convergence, defined as the norm of \( g \) after the iteration relative to the
norm of $g$ before the iteration, using a fixed $J^{-1}$ is approximately equal to the largest eigenvalue in the matrix

$$I - J_I^{-1} J_F$$  \hspace{1cm} (5.3)

where $J_I$ is the initial Jacobian matrix, that is used in the inversion, and $J_F$ is the final Jacobian matrix, computed the final solution point. Approximating $J_F = J_I + dJ$ we get an approximation of the rate of convergence, $\rho$, as

$$\rho = \max_{\text{eigenvalue}} \left( I - J_I^{-1} (J_I + dJ) \right) = \max_{\text{eigenvalue}} \left( J_I^{-1} dJ \right)$$  \hspace{1cm} (5.4)

When the change in Jacobian, $dJ$, is small, the largest eigenvalue will also be small and we will get fast convergence. If the starting point is far from the final point, then the linearization may not be very good with a large $dJ$ and the suggested change in variables may give rise to growing residuals. The procedure used inside CONOPT4’s CNS solver is to find a step in the suggested direction, $dx$, where the residuals are approximately minimized and use this step. The solution will gradually come closer, the linearization will become better, $dJ$ will become smaller, the optimal step will come closer to one, and the procedure will (usually) terminate with fast convergence.

5.8.11.2 Evaluating External Chocks using CNS

Economic General Equilibrium / CNS models are often used to evaluate the effect of policies changes or external chocks. The setup in GAMS is often of this type:

* Define model and initialize data
  Solve M using CNS;

* Store the base solution

* Define the chock by changing some exogenous variables
  Solve M using CNS;

* Compare the new solution with base solution.

The second `Solve` will start from the base solution and this point will in many cases be a very good starting point and the second `Solve` will therefore run quickly. However, for large chocks and very complex models, the second `Solve` may converge very slowly and it may not solve at all, because the new solution is too far from the base solution. For these cases it is not unusual to break the large chock down into a sequence of smaller chocks and solve the model several times. With smaller chocks each `Solve` will start from a point that is not too far away from the final solution for this chock. The GAMS model with smaller chocks will look like this:

* Define model and initialize data
  Solve M using CNS;

* Store the base solution

        Parameter ExoDiff(indx) The change in exogenous variables;
        ExoDiff(indx) = ExoTarget(indx) - ExoBase(Indx);

        Set Iter / Iter1*Iter5 /
        Parameter Step(Iter); Step(Iter) = ord(Iter)/card(Iter);
        Loop(Iter,
          Exo(indx) = ExoBase(indx) + Step(Iter)*ExoDiff(indx);
          Solve M using CNS;
        );

* Compare new solution with base solution.

The number of iterations and the way the `Step`-parameter is defined may vary and there is often no good a-priori rule for deciding. The smaller chocks will give $dJ$-matrices with smaller value and therefore smaller (equal to better) rates of convergence. Easy experiments can be solved with few steps while difficult experiments require more steps to converge. More iterations will give smaller steps and the individual `Solve` will be faster, but the overhead in model generation and extra solves can be large. For some chocks there is no solution to the model: some of the model variables may go outside their bounds, some may move towards infinity, or the model may no longer be well-defined because the basis matrix becomes singular. In practice, one of the `Solve` in the `Loop` will violate a bound or it will converge extremely slowly, but it is often not possible to pinpoint exactly how large the chock should be before the model breaks down.
5.8.11.3 Evaluating External Chocks using NLP

The theoretical solution to avoiding the choice of iteration steps is to change the model to an NLP and maximize the chock:

\* Define model and initialize data
Solve M using CNS;
\* Store the base solution
Parameter ExoDiff(indx) The change in exogenous variables
ExoDiff(indx) = ExoTarget(indx) - ExoBase(Indx);
\* Define the chock using variables and equations
Variable Exov(indx) Exogenous variables as a function of step;
Variable Step Share of the chock;
Equation Exod(indx) Define Exov;
Exod(indx).. Exov(indx) =E= ExoBase(indx)+Step*ExoDiff(indx);
Model m1 / M + Exod /
Step.lo = 0; Step.up = 1; Step.l = 0;
Exov.l(indx) = ExoBase(indx) + Step.l*ExoDiff(indx);
Solve M1 using NLP maximizing Step;
\* Compare new solution with base solution.

The NLP approach follows the solution from the feasible solution at Step = 0 through solutions for larger and larger steps and the change in Step is determined by how easy it is to maintain feasibility of the constraints. This NLP works well for small or simple models. However, for very large models such as the 1 million plus models mention above, the overhead associated with NLP can be very large because the specialized CNS routines no longer are used. Some statistics using CONOPT 4.26 on a 6 million model shows the problems:

- Pre-processor: The special CNS version locates pre- and post-triangular variables in 5 seconds; the NLP version used another 25 second to derive bounds and find defined variables. Analysing the 2 mill defined variables took 4000 seconds; it is now reduced to 8 seconds in CONOPT 4.27.
- Initial Basis: The special CNS version assigns all non-fixed variables to the basis and this is very fast; the NLP version makes sure that the basis is non-singular and it takes 1000 seconds, and the basis is not complete and many hours are needed to repair it.

5.8.11.4 Option TraceCNS

The NLP model defined above is not a general NLP. It has exactly one degree of freedom, namely the Step variable (the objective variable in the model), and the rest of the model, including the extra Exod-equations and Exov variables, is a CNS model. To take advantage of the specialized CNS routines CONOPT 4.27 introduced a new logical option, Flg_TraceCNS or just TraceCNS. If Flg_TraceCNS is defined as true (default is false), then CONOPT will use the special CNS pre-processor, it will define the initial CNS basis, it will fix the objective variable (here Step) to its initial value and find an initial feasible solution using the old CNS procedure. When a feasible solution has been found, the bounds on the objective variable are reset and the standard optimization routine is started from a feasible solution and a good basis. There are a few adjustments in the optimization routine; some are related to the iteration output, and some take advantage of the special properties of the TraceCNS model.

An example of the log-file for a large model can explain some of the key aspects. The chock is a tax-rate that is changed from a base value of 500 to the target of 1250:
Will use up to 12 threads.

15674 constant coefficients less than 1.0E-20 (=Tol_Zero) have been removed. 20865735 coefficients left.

The user model has 6444864 constraints and 6444865 variables with 20865735 Jacobian elements, 8039142 of which are nonlinear.

** TraceCNS terminates with objective at optimal bound.

The original CNS model had 6285822 equations. We have added 159042 equations to define the 159042 exogenous variables, that have been made endogenous (representing the Exod equations and Exov variables above). Since these extra equations have a very simple structure, they will not add much complexity to the solution process.

In this case we do not start from a feasible solution. The first iterations down to the line Feasible solution to a square system are CNS iterations. Each line represents an inversion of the basis and the numbers in the InItr column are the number of Newton iterations that use the same basis.

Starting TraceCNS .. identifies the start of the NLP procedure and the Objective defines the starting step. The numbers in the Objective column represent the progress of the step or here the tax rate. There are two types of iteration lines. The lines without a number in the Iter column represents a re-computation of the Jacobian and inversion of the basis inside the linesearch and the numbers in the InItr column are the number of Newton iterations using this basis. The lines with a number in the Iter column are the standard output from CONOPT4's NLP procedure and the number in the InItr column
are the number of LP or QP iterations used to define the search direction, usually just 1. The last line without a value in the Iter column will have the same Objective value as the line with a value in the Iter column. The new iteration lines with a number in the Iter column have been added to show that the solution process is alive and the InItr numbers show how much work is done. In very large CNS models each inversion may take more than one minute, and one linesearch or NLP iteration with several inversion may take much longer. Because progress may be slow, CONOPT4 will check for time or resource limit and for user interrupt (Cntrl-C) after each of these lines.

Inside the linesearch CONOPT4 will use Newton iterations to restore feasibility as discussed in Basic CNS Theory. The change in Jacobian, $dJ$, will approximately grow with the size of the step, $dJ = M \cdot Step$, where $M$ is a matrix of 2nd derivatives in the direction we are moving. The rate of convergence can therefore be approximated by

$$\rho(Step) = \max_{\text{eigenvalue}} (J^{-1}M \cdot Step) = \max_{\text{eigenvalue}} (J^{-1}M) \cdot Step = \rho(1) \cdot Step$$  \hspace{1cm} (5.5)

CONOPT4 will approximate $\rho(1)$ and use it to decide on the largest Step that will lead to convergence. Once we have moved this step the Jacobian has changed so much that further progress is impossible with the current Jacobian and its inverse, and it is necessary to recompute the Jacobian and its inverse. Since this process is the most expensive part of the optimization procedure, often accounting for more than 75% of the overall time for large models, we use the steps where the Jacobian is recomputed and reinverted to identify the overall progress.

The final line **TraceCNS terminates with objective at the optimal bound** tells us that the tax rate has been changed to the target value and that the model is solved with this value. Since the model is considered a special case of a CNS model the solution returned to GAMS will not have any dual variables, just as for regular CNS models.

The particular case was originally solved using four CNS Solve statements. The total time was 12.43 minutes with 5.23 minutes in the four CONOPT4 runs and 7.20 minutes in GAMS where most of the time was used for the four model generations.

With the NLP model and the Flg_TraceCNS option the total time was 6.47 minutes; CONOPT4 used 5.20 minutes and since there is only one model generation, GAMS only used 1.27 minutes. Notice that the time spend in CONOPT4 is about the same, but there is a big saving in the time spend in GAMS. It should be mentioned that the same NLP model without the Flg_TraceCNS option ran for 36 hours without reaching a solution.

5.8.11.5 Option Trace_MinStep

A more difficult case was also originally solved using four CNS Solve statements. The two first CNS models solved in 2 min 23 seconds and 1 min 31 seconds, respectively. The third CNS had problems; it used 1 hour 5 minutes and the last part of the iteration log was:

<table>

** Domain error(s) in nonlinear functions.**
Check bounds on variables.

The long time is caused by the many small steps, and the solution process finally terminates because a variable, $x$, that appears in an $x^{**p}$ expression with $p < 1$ becomes negative. The same model solved as an NLP model with Flg_TraceCNS solved in 28 min 10 sec. The first part of the iteration log is similar to the one shown above. The last part of the iteration log is:
** TraceCNS. Convergence too slow. Change in objective between reinversion has been less than 0.75 for three consecutive reinversions. 

The objective or the step changes more and more slowly between the reinversions. This indicates that the Jacobian changes faster and faster so the change, $dJ$, is about the same size as the initial Jacobian after smaller and smaller steps.

Unfortunately, it is not easy to identify where and why the Jacobian changes too much. It requires knowledge of the actual model, and an expert user must combine this knowledge with the final solution reported in GAMS. The problem is often some variables that become very large or very small.

By default, CONOPT4 will stop when the change in objective between reinversions is less than 0.1% of the target step for three consecutive reinversions. This tolerance can be changed with option Trace_MinStep to get a more or less accurate solution. A smaller value will seldom change much but it can be costly in time.

$\text{Trace}_{\text{MinStep}} = 0$ forces CONOPT4 to move as far as possible. For this model the final step changes from 653.2 to 657.9 compared to the start at 500 and the target at 1250, and the solution time changes from 28 minutes to 3 hours 20 minutes.

### 5.8.11.6 Termination Messages from TraceCNS

The first example showed the ideal termination message

** TraceCNS terminates with objective at optimal bound. 

Sometimes the objective cannot be moved all the way to the target value. There are several different cases:
• We saw the slow convergence message in the previous section.

** CONOPT may terminate with messages like:**

- **TraceCNS: An endogenous variable has reached its bound.**

The solution process is stopped because a variable has reached a bound. The offending bound will be shown in the listing file with a message like:

**** ERRORS/WARNINGS IN VARIABLE x(i2)

1 error(s): The variable has reached its bound

In this case the solution will include dual variables.

• Another termination message is:

** TraceCNS: The basis has become singular.**

The basis has become singular at the final step and it is not possible to move further. Unfortunately, it is not possible to give a detailed description of a variable or equation that causes the problem; detailed knowledge of the actual model must be combined with the solution. The solution returned to GAMS will include dual variables that may help in the analysis. Most models that could terminate with a singular basis will in practice terminate with a slow convergence message because the path to the final singular basis often will require a large number of small steps.

• CONOPT4 may also terminate due to functions evaluation error with a message like this:

** Domain error(s) in nonlinear functions.**

Check bounds on variables.

The equation(s) with function evaluation errors will be shown in the listing file with a message like:

**** ERRORS/WARNINGS IN EQUATION e(i1)

2 error(s): sqrt: FUNC DOMAIN: x < 0 (RETURNED 0)

• Finally, CONOPT4 may terminate due to an unbounded variable with a message like this:

** Unbounded solution. A variable has reached 'Infinity'.**

Largest legal value (Lim_Variable) is 1.00E+15

The variable that has become too large will be shown in the listing file with a message like:

**** ERRORS/WARNINGS IN VARIABLE x(i3)

1 error(s): The variable has reached 'infinity'
5.8.11.7 Error Messages from TraceCNS

**Flag TraceCNS** can only be used on a very special type of model and if the requirements are not satisfied you may see some of the following messages.

First of all, the model must be an optimization model with an objective variable. This is tested by GAMS during compile time and an error message will come from GAMS.

**Flag TraceCNS** requires that the objective variable is bounded in the optimization direction. If this is not satisfied you will get this message:

** Error in TraceCNS: The objective must be bounded.

after the pre-processor.

There must only be one degree of freedom represented by the objective variable. If there are extra free variables you will get this message:

** Error in TraceCNS: The number of non-fixed variables excluding the objective (nn) is not equal to the number of equations (mm).

also right after the pre-processor.

5.8.12 APPENDIX A - Options

The options that ordinary GAMS users can access are listed below.

5.8.12.1 Algorithmic options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flg_Conv</td>
<td>Flag for defining a model to be convex</td>

</tbody>
</table>

**cooptfile** *(string):* ↔

**Flg_2DDir** *(boolean):* Flag for computing and using directional 2nd derivatives. ↔

If turned on, make directional second derivatives (Hessian matrix times directional vector) available to CONOPT. The default is on, but it will be turned off of the model has external equations (defined with =X=) and the user has not provided directional second derivatives. If both the Hessian of the Lagrangian (see **Flg_Hessian**) and directional second derivatives are available then CONOPT will use both: directional second derivatives are used when the expected number of iterations in the SQP sub-solver is low and the Hessian is used when the expected number of iterations is large.

Default: auto

**Flg_Convex** *(boolean):* Flag for defining a model to be convex ↔

When turned on (the default is off) CONOPT knows that a local solution is also a global solution, whether it is optimal or infeasible, and it will be labeled appropriately. At the moment, Flg_NegCurve will be turned off. Other parts of the code will gradually learn to take advantage of this flag.

Default: 0

**Flg_Crash_Slack** *(boolean):* Flag for pre-selecting slacks for the initial basis. ↔

When turned on (1) CONOPT will select all infeasible slacks as the first part of the initial basis.

Default: 0

**Flg_DBG_Inv** *(boolean):* Flag for debugging interval evaluations. ↔
Flg_Dbg_Intv controls whether interval evaluations are debugged. Currently we check that
the lower bound does not exceed the upper bound for all intervals returned, both for function
values and for derivatives.

Default: 0

**Flg_Hessian (boolean):** Flag for computing and using 2nd derivatives as Hessian of Lagrangian.

If turned on, compute the structure of the Hessian of the Lagrangian and make it available
to CONOPT. The default is usually on, but it will be turned off if the model has external
equations (defined with =X=) or cone constraints (defined with =C=) or if the Hessian
becomes too dense. See also Flg_2DDir and HessianMemFac.

Default: auto

**Flg_Interv (boolean):** Flag for using intervals in the Preprocessor

If turned on (default), CONOPT will attempt to use interval evaluations in the preprocessor
to determine if functions are monotone or if intervals for some of the variables can be excluded
as infeasible.

Default: 1

**Flg_NegCurve (boolean):** Flag for testing for negative curvature when apparently optimal

When turned on (the default) CONOPT will try to identify directions with negative curvature
when the model appears to be optimal. The objective is to move away from saddlepoints. Can
be turned off when the model is known to be convex and cannot have negative curvature.

Default: 1

**Flg_NoPen (boolean):** Flag for allowing the Model without penalty constraints

When turned on (the default) CONOPT will create and solve a smaller model without the
penalty constraints and variables and the minimax constraints and variables if the remaining
constraints are infeasible in the initial point. This is often a faster way to start the solution
process.

Default: 1

**Flg_Prep (boolean):** Flag for using the Preprocessor

If turned on (default), CONOPT will use its preprocessor to try to determine pre- and
post-triangluar components of the model and find definitional constraints.

Default: 1

**Flg_Range (boolean):** Flag for identifying sets of ranged constraints

If turned on (default), CONOPT will as part of its preprocessor look for sets of parallel linear
constraints and turn each set into a single ranged constraints. There is currently a potential
problem with the duals on these constraints and if duals are important ranges can be turned
off with this flag.

Default: 1

**Flg_SLPMode (boolean):** Flag for enabling SLP mode.
If Flg.SLPMode is on (the default) then the SLP (sequential linear programming) sub-solver can be used, otherwise it is turned off.

Default: 1

**Flg.SQPMode (boolean):** Flag for enabling of SQP mode.

If Flg.SQPMode is on (the default) then the SQP (sequential quadratic programming) sub-solver can be used, otherwise it is turned off.

Default: 1

**Flg_Square (boolean):** Flag for Square System. Alternative to defining modeltype=CNS in GAMS

When turned on the modeler declares that this is a square system, i.e. the number of non-fixed variables must be equal to the number of constraints, no bounds must be active in the final solution, and the basis selected from the non-fixed variables must always be nonsingular.

Default: 0

**Flg.TraceCNS (boolean):** Flag for tracing a CNS solution.

When turned on the model must, for fixed value of the objective variable, be a CNS model and must satisfy the conditions of a CNS. The model is first solved as a CNS with the initial value of the objective fixed and the objective is then minimized or maximized subject to the CNS constraints.

Default: 0

**Frq_Log_Simple (integer):** Frequency for log-lines for non-SLP/SQP iterations.

Frq_Log_Simple and Frq_Log_SlpSqp can be used to control the amount of iteration send to the log file. The non-SLP/SQP iterations, i.e. iterations in phase 0, 1, and 3, are usually fast and writing a log line for each iteration may be too much, especially for smaller models. The default value for the log frequency for these iterations is therefore set to 10 for small models, 5 for models with more than 500 constraints or 1000 variables and 1 for models with more than 2000 constraints or 3000 variables.

Default: auto

**Frq_Log_SlpSqp (integer):** Frequency for log-lines for SLP or SQP iterations.

Frq_Log_Simple and Frq_Log_SlpSqp can be used to control the amount of iteration send to the log file. Iterations using the SLP and/or SQP sub-solver, i.e. iterations in phase 2 and 4, may involve several inner iterations and the work per iteration is therefore larger than for the non-SLP/SQP iterations and it may be relevant to write log lines more frequently. The default value for the log frequency is therefore 5 for small models and 1 for models with more than 50 constraints or 1000 variables.

Default: auto

**Frq_Rescale (integer):** Rescaling frequency.

The row and column scales are recalculated at least every Frq_Rescale new point (degenerate iterations do not count), or more frequently if conditions require it.

Default: 5

**HEAPLIMIT (real):** Maximum Heap size in MB allowed
Range: \([0, \infty)\]

Default: \(1e20\)

**HessianMemFac** (real): Memory factor for Hessian generation: Skip if Hessian elements > Nonlinear Jacobian elements*HessianMemFac, 0 means unlimited.

The Hessian of the Lagrangian is considered too dense therefore too expensive to evaluate and use, and it is not passed on to CONOPT if the number of nonzero elements in the Hessian of the Lagrangian is greater than the number of nonlinear Jacobian elements multiplied by HessianMemFac. See also Flg_Hessian. If HessianMemFac = 0.0 (the default value) then there is no limit on the number of Hessian elements.

The following cells are used to count calls of various routines and the time spend in them. The timing is usually only turned on if some debugging level is on and the statistics is only printed in these cases.

Default: 0

**Lim_Dbg_1Drv** (integer): Flag for debugging of first derivatives

Lim_Dbg_1Drv controls how often the derivatives are tested. Debugging of derivatives is only relevant for user-written functions in external equations defined with \(=X=\). The amount of debugging is controlled by **Mtd_Dbg_1Drv**. See **Lim_Hess_Est** for a definition of when derivatives are considered wrong.

Default: 0

<table>
<thead>
<tr>

<td>The derivatives are tested in all iterations that can be divided by Lim_Dbg_1Drv, provided the derivatives are computed in this iteration. (During phase 0, 1, and 3 derivatives are only computed when it appears to be necessary.)</td>
</tr>
</tbody>
</table>

**Lim_Err_2DDir** (integer): Limit on errors in Directional Second Derivative evaluation.

If the evaluation of Directional Second Derivatives (Hessian information in a particular direction) has failed more than Lim_Err_2DDir times CONOPT will not attempt to evaluate them any more and will switch to methods that do not use Directional Second Derivatives. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: 10

**Lim_Err_Fnc_Drv** (integer): Limit on number of function evaluation errors. Overwrites GAMS Domlim option

Function values and their derivatives are assumed to be defined in all points that satisfy the bounds of the model. If the function value or a derivative is not defined in a point CONOPT will try to recover by going back to a previous safe point (if one exists), but it will not do it more than at most Lim_Err_Fnc_Drv times. If CONOPT is stopped by functions or derivatives not being defined it will return with a intermediate infeasible or intermediate non-optimal model status.

Default: GAMS DomLim

**Lim_Err_Hessian** (integer): Limit on errors in Hessian evaluation.
If the evaluation of Hessian information has failed more than Lim_Err_Hessian times CONOPT will not attempt to evaluate it any more and will switch to methods that do not use the Hessian. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: 10

**Lim_Hess_Est (real):** Upper bound on second order terms. →

The function and derivative debugger (see Lim_Dbgs_1Drv) tests if derivatives computed using the modelers routine are sufficiently close to the values computed using finite differences. The term for the acceptable difference includes a second order term and uses Lim_Hess_Est as an estimate of the upper bound on second order derivatives in the model. Larger Lim_Hess_Est values will allow larger deviations between the user-defined derivatives and the numerically computed derivatives.

Default: 1.e4

**Lim_Iteration (integer):** Maximum number of iterations. Overwrites GAMS Iterlim option. ←

The iteration limit can be used to prevent models from spending too many resources. You should note that the cost of the different types of CONOPT iterations (phase 0 to 4) can be very different so the time limit (GAMS Reslim or option Lim_Time) is often a better stopping criterion. However, the iteration limit is better for reproducing solution behavior across machines.

Default: GAMS IterLim

**Lim_Msg_Dbg_1Drv (integer):** Limit on number of error messages from function and derivative debugger. ←

The function and derivative debugger (see Lim_Dbgs_1Drv) may find a very large number of errors, all derived from the same source. To avoid very large amounts of output CONOPT will stop the debugger after Lim_Msg_Dbg_1Drv error(s) have been found.

Default: 10

**Lim_Msg_Large (integer):** Limit on number of error messages related to large function value and Jacobian elements. ←

Very large function value or derivatives (Jacobian elements) in a model will lead to numerical difficulties and most likely to inaccurate primal and/or dual solutions. CONOPT is therefore imposing an upper bound on the value of all function values and derivatives. This bound is 1.e30. If the bound is violated CONOPT will return with an intermediate infeasible or intermediate non-optimal solution and it will issue error messages for all the violating Jacobian elements, up to a limit of Lim_Msg_Large error messages.

Default: 10

**Lim_NewSuper (integer):** Maximum number of new superbasic variables added in one iteration. ←

When there has been a sufficient reduction in the reduced gradient in one subspace new non-basics can be selected to enter the superbasis. The ones with largest reduced gradient of proper sign are selected, up to a limit. If Lim_NewSuper is positive then the limit is min(500,Lim_NewSuper). If Lim_NewSuper is zero (the default) then the limit is selected dynamically by CONOPT depending on model characteristics.

Default: auto
**Lim_Pre_Msg** (*integer*): Limit on number of error messages related to infeasible pre-triangle.

If the pre-processor determines that the model is infeasible it tries to define a minimal set of variables and constraints that define the infeasibility. If this set is larger than Lim_Pre_Msg elements the report is considered difficult to use and it is skipped.

Default: 25

**Lim_RedHess** (*integer*): Maximum number of superbasic variables in the approximation to the Reduced Hessian.

CONOPT uses and stores a dense lower-triangular matrix as an approximation to the Reduced Hessian. The rows and columns correspond to the superbasic variable. This matrix can use a large amount of memory and computations involving the matrix can be time consuming so CONOPT imposes a limit on on the size. The limit is Lim_RedHess if Lim_RedHess is defined by the modeler and otherwise a value determined from the overall size of the model. If the number of superbasics exceeds the limit, CONOPT will switch to a method based on a combination of SQP and Conjugate Gradient iterations assuming some kind of second order information is available. If no second order information is available CONOPT will use a quasi-Newton method on a subset of the superbasic variables and rotate the subset as the reduced gradient becomes small.

Default: auto

**Lim_SlowPrg** (*integer*): Limit on number of iterations with slow progress (relative less than Tol_Obj_Change).

The optimization is stopped if the relative change in objective is less than Tol_Obj_Change for Lim_SlowPrg consecutive well-behaved iterations.

Default: 20

**Lim_StallIter** (*integer*): Limit on the number of stalled iterations.

An iteration is considered a stalled iteration if there is no change in objective because the linesearch is limited by nonlinearities or numerical difficulties. Stalled iterations will have Step = 0 and F in the OK column of the log file. After a stalled iteration CONOPT will try various heuristics to get a better basis and a better search direction. However, the heuristics may not work as intended or they may even return to the original bad basis, especially if the model does not satisfy standard constraints qualifications and does not have a KKT point. To prevent cycling CONOPT will therefore stop after Lim_StallIter stalled iterations and returns an Intermediate Infeasible or Intermediate Nonoptimal solution.

Default: 100

**Lim_Start_Degen** (*integer*): Limit on number of degenerate iterations before starting degeneracy breaking strategy.

The default CONOPT pivoting strategy has focus on numerical stability, but it can potentially cycle. When the number of consecutive degenerate iterations exceeds Lim_Start_Degen CONOPT will switch to a pivoting strategy that is guaranteed to break degeneracy but with slightly weaker numerical properties.

Default: 100

**Lim_Time** (*real*): Time Limit. Overwrites the GAMS Reslim option.

The upper bound on the total number of seconds that can be used in the execution phase. There are only tests for time limit once per iteration. The default value is 10000. Lim_Time is overwritten by Reslim when called from GAMS.

Range: \([0, \infty]\)

Default: GAMS ResLim

**Lim_Variable (real):** Upper bound on solution values and equation activity levels

If the value of a variable, including the objective function value and the value of slack variables, exceeds Lim_Variable then the model is considered to be unbounded and the optimization process returns the solution with the large variable flagged as unbounded. A bound cannot exceed this value.

Range: \([1.e5, 1.e30]\)

Default: 1.e15

**Lim_Method (integer):** Method used to determine if and/or which Linear Feasibility Models to use

The Linear Feasibility Model can use different objectives: Objective 1 is no objective, i.e. the first point that satisfies the Linear Feasibility Model is used as a starting point for the Full Model. Objective 2 minimizes a scaled distance from the initial point for all variables defined by the modeler. Objective 3 minimizes a scaled distance from the initial point for all variables including those not defined by the modeler. Objective 4 minimizes a scaled distance from random a point selected away from bounds.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Ignore Linear Feasibility Model in the first round and use objective 2, 3, and 4 (see above) in the following rounds as long as model is locally infeasible. This is the default method.</td>
</tr>
<tr>
<td>2</td>
<td>Use Linear Feasibility Model with objective 1 in the first round and continue with objective 2, 3, and 4 in the following rounds as long as model is locally infeasible.</td>
</tr>
<tr>
<td>3</td>
<td>Use Linear Feasibility Model with objective 2 in the first round and continue with objective 3 and 4 in the following rounds as long as model is locally infeasible.</td>
</tr>
</tbody>
</table>

**Mtd_Dbg_1Drv (integer):** Method used by the function and derivative debugger.

The function and derivative debugger (turned on with Lim_Dbg_1Drv) can perform a fairly cheap test or a more extensive test, controlled by Mtd_Dbg_1Drv. See Lim_Hess_Est for a definition of when derivatives are considered wrong. All tests are performed in the current point found by the optimization algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform tests for sparsity pattern and tests that the numerical values of the derivatives appear to be correct. This is the default.</td>
</tr>
<tr>
<td>1</td>
<td>As 0 plus make extensive test to determine if the functions and their derivatives are continuous around the current point. These tests are much more expensive and should only be used of the cheap test does not find an error but one is expected to exist.</td>
</tr>
</tbody>
</table>

**Mtd\_RedHess (integer):** Method for initializing the diagonal of the approximate Reduced Hessian

Each time a nonbasic variable is made superbasic a new row and column is added to the approximate Reduced Hessian. The off-diagonal elements are set to zero and the diagonal to a value controlled by Mtd\_RedHess:

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The new diagonal element is set to the geometric mean of the existing diagonal elements. This gives the new diagonal element an intermediate value and new superbasic variables are therefore not given any special treatment. The initial steps should be of good size, but build-up of second order information in the new sub-space may be slower. The larger diagonal element may also in bad cases cause premature convergence.</td>
</tr>
<tr>
<td>1</td>
<td>The new diagonal elements is set to the minimum of the existing diagonal elements. This makes the new diagonal element small and the importance of the new superbasic variable will therefore be high. The initial steps can be rather small, but better second order information in the new sub-space should be build up faster.</td>
</tr>
</tbody>
</table>

**Mtd\_Scale (integer):** Method used for scaling.

CONOPT will by default use scaling of the equations and variables of the model to improve the numerical behavior of the solution algorithm and the accuracy of the final solution (see also Frq\_Rescale.) The objective of the scaling process is to reduce the values of all large primal and dual variables as well as the values of all large first derivatives so they become closer to 1. Small values are usually not scaled up, see Tol\_Scale\_Max and Tol\_Scale\_Min. Scaling method 3 is recommended. The others are only kept for backward compatibility.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Scaling is based on repeatedly dividing the rows and columns by the geometric means of the largest and smallest elements in each row and column. Very small elements less than Tol_Jac_Min are considered equal to Tol_Jac_Min.</td>
</tr>
<tr>
<td>1</td>
<td>Similar to 3 below, but the projection on the interval [Tol_Scale_Min,Tol_Scale_Max] is applied at a different stage. With method 1, abs(X)*abs(Jac) with small X and very large Jac is scaled very aggressively with a factor abs(Jac). With method 3, the scale factor is abs(X)*abs(Jac). The difference is seen in models with terms like Sqrt(X) close to X = 0.</td>
</tr>
<tr>
<td>2</td>
<td>As 1 but the terms are computed based on a moving average of the squares X and Jac. The purpose of the moving average is to keep the scale factor more stable. This is often an advantage, but for models with very large terms (large variables and in particular large derivatives) in the initial point the averaging process may not have enough time to bring the scale factors into the right region.</td>
</tr>
<tr>
<td>3</td>
<td>Rows are first scaled by dividing by the largest term in the row, then columns are scaled by dividing by the maximum of the largest term and the value of the variable. A term is here defined as abs(X)*abs(Jac) where X is the value of the variable and Jac is the value of the derivative (Jacobian element). The scale factor are then projected on the interval between Tol_Scale_Min and Tol_Scale_Max.</td>
</tr>
</tbody>
</table>

**Mtd\_Step\_Phase0 (integer):** Method used to determine the step in Phase 0.

The steplength used by the Newton process in phase 0 is computed by one of two alternative methods controlled by Mtd\_Step\_Phase0:
Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this method. It is the default method for optimization models.</td>
</tr>
<tr>
<td>1</td>
<td>A method based on bending (projecting the target values of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum. Linear constraints that initially are feasible may become infeasible due to bending.</td>
</tr>
</tbody>
</table>

\textbf{Mtd\_Step\_Tight (integer):} Method used to determine the maximum step while tightening tolerances.

The steplength used by the Newton process when tightening tolerances is computed by one of two alternative methods controlled by \texttt{Mtd\_Step\_Tight}:

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this method.</td>
</tr>
<tr>
<td>1</td>
<td>A method based on bending (projecting the target value of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum.</td>
</tr>
</tbody>
</table>

\textbf{Num\_Rounds (integer):} Number of rounds with Linear Feasibility Model

Lin\_Method defined which Linear Feasibility Model are going to be solved if the previous models end Locally Infeasible. The number of rounds is limited by \texttt{Num\_Rounds}.

Range: \{1, \ldots, 4\}

Default: 4

\textbf{Rat\_NoPen (real):} Limit on ratio of penalty constraints for the No\_Penalty model to be solved

The No-Penalty model can only be generated and solved if the number of penalty and minimax constraints exceed \texttt{Rat\_NoPen} times the constraints in the Full Model.

Default: 0.1

\textbf{THREAD2D (integer):} Number of threads used for second derivatives

Range: \{0, \ldots, \infty\}

Default: 1

\textbf{THREADC (integer):} Number of compatibility threads used for comparing different values of THREADS

Range: \{0, \ldots, \infty\}

Default: 1
**ThreadF (integer):** Number of threads used for function evaluation

Range: \{0, ..., \infty\}

Default: 1

**Threads (integer):** Number of threads used by Conopt internally

Range: \{0, ..., \infty\}

Default: GAMS Threads

**Tol_Bound (real):** Bound filter tolerance for solution values close to a bound.

A variable is considered to be at a bound if its distance from the bound is less than \(\text{Tol\_Bound} \times \text{Max}(1, \text{ABS}(\text{Bound}))\). The tolerance is used to build the initial bases and is used to flag variables during output.

Range: \([3.e-13, 1.e-5]\]

Default: 1.e-7

**Tol_BoxSize (real):** Initial box size for trust region models for overall model

The new Phase 0 methods solves an LP model based on a scaled and linearized version of the model with an added trust region box constraint around the initial point. \(\text{Tol\_BoxSize}\) defines the size of the initial trust region box. During the optimization the trust region box is adjusted based on how well the linear approximation fits the real model.

Range: \([0.01, 1.e6]\]

Default: 10

**Tol_BoxSize_Lin (real):** Initial box size for trust region models for linear feasibility model

Similar to \(\text{Tol\_BoxSize}\) but applied to the linear feasibility model. Since this model has linear constraints the default initial box size is larger.

Range: \([0.01, 1.e8]\]

Default: 1000

**Tol_BoxLinFac (real):** Box size factor for linear variables applied to trust region box size

The trust region box used in the new Phase 0 method limits the change of variables so 2nd order terms will not become too large. Variables that appear linearly do not have 2nd order terms and the initial box size is therefore larger by a factor \(\text{Tol\_BoxLinFac}\).

Parameters related to growth factors and initial values in the definitional constraints

Range: \([1, 1.e4]\]

Default: 10

**Tol_Def_Mult (real):** Largest growth factor allowed in the block of definitional constraints
The block of definitional constraints form a triangular matrix. This triangular matrix can hide large accumulating growth factors that can lead to increases in the initial sum of infeasibilities and to numerical instability. Tol_Def_Mult is an upper bound on these growth factors. If it is exceeded some critical chains of definitional constraints will be broken leading to a larger internal model, that should be numerically better behaved.

Parameters related to scaling

Range: \([1.01, \infty]\)

Default: 1.e4

**Tol_Feas_Max** *(real)*: Maximum feasibility tolerance (after scaling). \(\leftarrow\)

The feasibility tolerance used by CONOPT is dynamic. As long as we are far from the optimal solution and make large steps it is not necessary to compute intermediate solutions very accurately. When we approach the optimum and make smaller steps we need more accuracy. Tol_Feas_Max is the upper bound on the dynamic feasibility tolerance and **Tol_Feas_Min** is the lower bound. It is NOT recommended to use loose feasibility tolerances since the objective, including the sum of infeasibility objective, will be less accurate and it may prevent convergence.

Range: \([1.e-10, 1.e-3]\)

Default: 1.e-7

**Tol_Feas_Min** *(real)*: Minimum feasibility tolerance (after scaling). \(\leftarrow\)

See **Tol_Feas_Max** for a discussion of the dynamic feasibility tolerances used by CONOPT.

Range: \([3.e-13, 1.e-5]\)

Default: 4.e-10

**Tol_Feas_Tria** *(real)*: Feasibility tolerance for triangular equations. \(\leftarrow\)

Triangular equations are usually solved to an accuracy of **Tol_Feas_Min**. However, if a variable reaches a bound or if a constraint only has pre-determined variables then the feasibility tolerance can be relaxed to Tol_Feas_Tria.

Range: \([3.e-13, 1.e-4]\)

Default: 1.0e-8

**Tol_Fixed** *(real)*: Tolerance for defining variables as fixed based on initial or derived bounds. \(\leftarrow\)

A variable is considered fixed if the distance between the bounds is less than Tol_Fixed \(*\ Max(1, Abs(Bound))\). The tolerance is used both on the users original bounds and on the derived bounds that the preprocessor implies from the constraints of the model.

Accuracies for linesearch and updates

Range: \([3.e-13, 1.e-8]\)

Default: 4.e-10

**Tol_Jac_Min** *(real)*: Filter for small Jacobian elements to be ignored during scaling. \(\leftarrow\)
A Jacobian element is considered insignificant if it is less than Tol_Jac_Min. The value is used to select which small values are scaled up during scaling of the Jacobian. It is only used with scaling method Mtd_Scale = 0.

Range: $[1.e^{-7}, 1.e^{-3}]$

Default: $1.e^{-5}$

**Tol_Linesearch** *(real)*: Accuracy of One-dimensional search.

The onedimensional search is stopped if the expected decrease in the objective estimated from a quadratic approximation is less than Tol_Linesearch times the decrease so far in this onedimensional search.

Range: $[0.05, 0.8]$  

Default: 0.2

**Tol_Obj_Acc** *(real)*: Relative accuracy of the objective function.

It is assumed that the objective function can be computed to an accuracy of Tol_Obj_Acc * max( 1, abs(Objective) ). Smaller changes in objective are considered to be caused by round-off errors.

Range: $[3.0e^{-14}, 10.e^{-6}]$

Default: $3.0e^{-13}$

**Tol_Obj_Change** *(real)*: Limit for relative change in objective for well-behaved iterations.

The change in objective in a well-behaved iteration is considered small and the iteration counts as slow progress if the change is less than Tol_Obj_Change * Max(1,Abs(Objective)). See also Lim_SlowPrg.

Range: $[3.0e^{-13}, 1.0e^{-5}]$

Default: $3.0e^{-12}$

**Tol_Optimality** *(real)*: Optimality tolerance for reduced gradient when feasible.

The reduced gradient is considered zero and the solution optimal if the largest superbasic component of the reduced gradient is less than Tol_Optimality.

Range: $[3.e^{-13}, 1]$

Default: $1.e^{-7}$

**Tol_Opt_Infeas** *(real)*: Optimality tolerance for reduced gradient when infeasible.

The reduced gradient is considered zero and the solution infeasible if the largest superbasic component of the reduced gradient is less than Tol_Opt_Infeas.

Range: $[3.e^{-13}, 1]$

Default: $1.e^{-7}$

**Tol_Opt_LinF** *(real)*: Optimality tolerance when infeasible in Linear Feasibility Model
This is a special optimality tolerance used when the Linear Feasibility Model is infeasible. Since the model is linear the default value is smaller than for nonlinear submodels.

Pivot tolerances

Range: \([3.e-13, 1.e-4]\)

Default: \(1.e-10\)

**Tol_Piv_Abs** *(real)*: Absolute pivot tolerance. \(\leftarrow\)

During LU-factorization of the basis matrix a pivot element is considered large enough if its absolute value is larger than Tol_Piv_Abs. There is also a relative test, see **Tol_Piv_Rel**.

Range: \([2.2e-16, 1.e-7]\)

Default: \(1.e-10\)

**Tol_Piv_Abs_Ini** *(real)*: Absolute Pivot Tolerance for building initial basis. \(\leftarrow\)

Absolute pivot tolerance used during the search for a first logically non-singular basis. The default is fairly large to encourage a better conditioned initial basis.

Range: \([3.e-13, 1.e-3]\)

Default: \(1.e-7\)

**Tol_Piv_Abs_NLTr** *(real)*: Absolute pivot tolerance for nonlinear elements in pre-triangular equations. \(\leftarrow\)

The smallest pivot that can be used for nonlinear or variable Jacobian elements during the pre-triangular solve. The pivot tolerance for linear or constant Jacobian elements is Tol_Piv_Abs. The value cannot be less than Tol_Piv_Abs.

Range: \([2.2e-16, 1.e-3]\)

Default: \(1.e-5\)

**Tol_Piv_Ratio** *(real)*: Relative pivot tolerance during ratio-test \(\leftarrow\)

During ratio-tests, the lower bound on the slope of a basic variable to potentially leave the basis is Tol_Piv_Ratio * the largest term in the computation of the tangent.

Range: \([1.e-10, 1.e-6]\)

Default: \(1.e-8\)

**Tol_Piv_Rel** *(real)*: Relative pivot tolerance during basis factorizations. \(\leftarrow\)

During LU-factorization of the basis matrix a pivot element is considered large enough relative to other elements in the column if its absolute value is at least Tol_Piv_Rel * the largest absolute value in the column. Small values or Tol_Piv_Rel will often give a sparser basis factorization at the expense of the numerical accuracy. The value used internally is therefore adjusted dynamically between the users value and 0.9, based on various statistics collected during the solution process. Certain models derived from finite element approximations of partial differential equations can give rise to poor numerical accuracy and a larger user-value of Tol_Piv_Rel may help.

Range: \([1.e-3, 0.9]\)

Default: \(0.05\)
**Tol_Piv_Rel_Init** *(real)*: Relative Pivot Tolerance for building initial basis

Relative pivot tolerance used during the search for a first logically non-singular basis.

Range: \([1.e^{-4}, 0.9]\]

Default: \(1.e^{-3}\)

**Tol_Piv_Rel_Updt** *(real)*: Relative pivot tolerance during basis updates.

During basis changes CONOPT attempts to use cheap updates of the LU-factors of the basis. A pivot is considered large enough relative to the alternatives in the column if its absolute value is at least \(\text{Tol}_{\text{Piv Rel Updt}} \times \text{the other element}\). Smaller values of \(\text{Tol}_{\text{Piv Rel Updt}}\) will allow sparser basis updates but may cause accumulation of larger numerical errors.

Range: \([1.e^{-3}, 0.9]\]

Default: 0.05

**Tol_Scale2D_Min** *(real)*: Lower bound for scale factors based on large 2nd derivatives.

Scaling of the model is in most cases based on the values of the variables and the first derivatives. However, if the scaled variables and derivatives are reasonable but there are large values in the Hessian of the Lagrangian (the matrix of 2nd derivatives) then the lower bound on the scale factor can be made smaller than \(\text{Tol}_{\text{Scale Min}}\). CONOPT will try to scale variables with large 2nd derivatives by one over the square root of the diagonal elements of the Hessian. However, the revised scale factors cannot be less than \(\text{Tol}_{\text{Scale2D Min}}\).

Range: \([1.e^{-9}, 1]\]

Default: 1.e-6

**Tol_Scale_Max** *(real)*: Upper bound on scale factors.

Scale factors are projected on the interval from \(\text{Tol}_{\text{Scale Min}}\) to \(\text{Tol}_{\text{Scale Max}}\). Is used to prevent very large or very small scale factors due to pathological types of constraints. The upper limit is selected such that \(\text{Square(X)}\) can be handled for \(X\) close to \(\text{Lim Variable}\). More nonlinear functions may not be scalable for very large variables.

Range: \([1, 1.e30]\]

Default: 1.e25

**Tol_Scale_Min** *(real)*: Lower bound for scale factors computed from values and 1st derivatives.

Scale factors used to scale variables and equations are projected on the range \(\text{Tol}_{\text{Scale Min}}\) to \(\text{Tol}_{\text{Scale Max}}\). The limits are used to prevent very large or very small scale factors due to pathological types of constraints. The default value for \(\text{Tol}_{\text{Scale Min}}\) is 1 which means that small values are not scaled up. If you need to scale small value up towards 1 then you must define a value of \(\text{Tol}_{\text{Scale Min}} < 1\).

Range: \([1.e^{-10}, 1]\]

Default: 1

**Tol_Scale_Var** *(real)*: Lower bound on \(x\) in \(x\times Jac\) used when scaling.
Rows are scaled so the largest term $x \cdot \text{Jac}$ is around 1. To avoid difficulties with models where \text{Jac} is very large and $x$ very small a lower bound of $\text{Tol\_Scale\_Var}$ is applied to the $x$-term.

Largest Jacobian element and tolerance in 2nd derivative tests:

Range: $[1.e^{-8}, 1]$  
Default: $1.e^{-5}$

**Tol\_Zero** *(real)*: Zero filter for Jacobian elements and inversion results.  
Contains the smallest absolute value that an intermediate result can have. If it is smaller, it is set to zero. It must be smaller than $\text{Tol\_Piv\_Abs}/10$.

Default: $1.e^{-20}$

**Trace\_MinStep** *(real)*: Minimum step between Reinversions when using TraceCNS.  
The optimization is stopped with a slow convergence message if the change in trace variable or objective is less than this tolerance between reinversions for more than two consecutive reinversions. The step is scaled by the distance from the initial value to the critical bound.

Range: $[0, 1]$  
Default: 0.001

### 5.9 CONVERT

#### 5.9.1 Introduction

CONVERT is a utility which transforms a GAMS model instance into a scalar model where all confidential information has been removed or into formats used by other modeling and solution systems. CONVERT is designed to achieve the following goals:

- Permit users to convert a confidential model into GAMS scalar format so that any identifiable structure is removed. It can then be passed on to others for investigation without confidentiality being lost.
- A way of sharing GAMS test problems for use with other modeling systems or solvers.

CONVERT comes free of charge with any licensed GAMS system and can convert GAMS models into a number of formats, see Section Target languages and formats for a list.

#### 5.9.2 How to use CONVERT

CONVERT is run like any other GAMS solver. From the command line this is:

```
>> gams modelname modeltype=convert
```

where *modelname* is the GAMS model name and *modeltype* the solver indicator for a particular model type (e.g. LP, MIP, RMIP, QCP, MIQCP, RMIQCP, NLP, DNLP, CNS, MINLP, or MCP). CONVERT can also be specified via the option statement within the model itself before the solve statement:

```
option modeltype=convert;
```
5.9.3 The GAMS Scalar Format

By default, CONVERT generates a scalar GAMS model \((\text{gams.gms})\) from the input model. The scalar model exhibits the following characteristics:

- A model without sets or indexed parameters. It does not exhibit any of the advanced characteristics of modeling systems and is easily transformable.
- A model with a new set of individual variables, depicting each variable in the GAMS model as one of 3 types: positive, integer or binary. Each variable is numbered sequentially, i.e. all positive GAMS variables are mapped into single variables \(x_1, x_2, \ldots, x_n\).
- A model with individual equations depicting each variable in the GAMS model. All equations are also numbered sequentially, that is equations \(e_1, e_2, \ldots, e_m\).

Equation and variable bounds, as well as variable starting values are preserved from the original GAMS formulation.

As an example, suppose the user wishes to translate the GAMS Model Library model \texttt{trnsport}\) into scalar format. One would run

\begin{verbatim}
gams trnsport.gms lp=convert
\end{verbatim}

which would generate the following scalar model \texttt{gams.gams}:

\begin{verbatim}
* LP written by GAMS Convert at 11/19/20 15:28:05
*
* Equation counts
* Total    E    G    L    N    X    C    B
*       6    1    3    2    0    0    0    0
*
* Variable counts
*                        x   b  i  s1s  s2s   sc   si  sint
*      Total   cont binary integer sos1 sos2 scont sint
*            7    7    0    0    0    0    0    0
*   FX        0
*
* Nonzero counts
*   Total const   NL
*        19    19    0
*
* Solve m using LP minimizing x7;

Variables
\quad x1, x2, x3, x4, x5, x6, x7;

Positive Variables
\quad x1, x2, x3, x4, x5, x6;

Equations
\quad e1, e2, e3, e4, e5, e6;

\begin{verbatim}
e1..  -0.225 * x1 - 0.153 * x2 - 0.162 * x3 - 0.225 * x4 - 0.162 * x5 - 0.126 * x6 + x7 =E= 0;
e2..  x1 + x2 + x3 =L= 350;
\end{verbatim}
\end{verbatim}
5.9 CONVERT

\[ e_3.. \ x_4 + x_5 + x_6 =L= 600; \]
\[ e_4.. \ x_1 + x_4 =G= 325; \]
\[ e_5.. \ x_2 + x_5 =G= 300; \]
\[ e_6.. \ x_3 + x_6 =G= 275; \]

Model m / all /;

m.limrow = 0;

m.limcol = 0;

Solve m using LP minimizing x_7;

Note that the resulting scalar model does not contain any of the descriptive information about the data or the context of the constraints.

Additionally, a dictionary file (dict.txt) is created by default which specifies a mapping between the variable and equation names in the scalar model and their corresponding names in the original model.

For the above example, the dictionary file is

LP written by GAMS Convert at 11/19/20 15:28:05

Equation counts

<table>
<thead>
<tr>
<th>Total</th>

</tr>
</tbody>
</table>

Nonzero counts

<table>
<thead>
<tr>
<th>Total</th>
<th>const</th>
<th>NL</th>
</tr>
</thead>
<tbody>
<tr>
<td>19</td>
<td>19</td>
<td>0</td>
</tr>
</tbody>
</table>

Equations 1 to 6
\[ e_1 \ \text{cost} \]
\[ e_2 \ \text{supply(seattle)} \]
\[ e_3 \ \text{supply(san-diego)} \]
\[ e_4 \ \text{demand(new-york)} \]
\[ e_5 \ \text{demand(chicago)} \]
\[ e_6 \ \text{demand(topeka)} \]

Variables 1 to 7
\[ x_1 \ \text{x(seattle,new-york)} \]
\[ x_2 \ \text{x(seattle,chicago)} \]
\[ x_3 \ \text{x(seattle,topeka)} \]
\[ x_4 \ \text{x(san-diego,new-york)} \]
\[ x_5 \ \text{x(san-diego,chicago)} \]
\[ x_6 \ \text{x(san-diego,topeka)} \]
\[ x_7 \ z \]

Conversion of a GAMS model to a scalar one may be handy for model debugging. However, in this case, it may be good to retain the original variable and equation names. The following simple sed command attempts to achieve this:
For the above example, this outputs:

**Variables**

\( x(\text{seattle,new-york}), x(\text{seattle,Chicago}), x(\text{seattle,topeka}), x(\text{san-diego,new-york}), x(\text{san-diego,Chicago}) \)

**Positive Variables**

\( x(\text{seattle,new-york}), x(\text{seattle,Chicago}), x(\text{seattle,topeka}), x(\text{san-diego,new-york}), x(\text{san-diego,Chicago}) \)

**Equations**

\[
\begin{align*}
\text{cost} & : -0.225 \times x(\text{seattle,new-york}) - 0.153 \times x(\text{seattle,Chicago}) - 0.162 \times x(\text{seattle,topeka}) - 0.225 \times x(\text{san-diego,new-york}) - 0.162 \times x(\text{san-diego,Chicago}) - 0.126 \times x(\text{san-diego,topeka}) + z = 0; \\
\text{supply(\text{seattle})} & : x(\text{seattle,new-york}) + x(\text{seattle,Chicago}) + x(\text{seattle,topeka}) = 350; \\
\text{supply(\text{san-diego})} & : x(\text{san-diego,new-york}) + x(\text{san-diego,Chicago}) + x(\text{san-diego,topeka}) = 600; \\
\text{demand(\text{new-york})} & : x(\text{seattle,new-york}) + x(\text{san-diego,new-york}) = 325; \\
\text{demand(\text{Chicago})} & : x(\text{seattle,Chicago}) + x(\text{san-diego,Chicago}) = 300; \\
\text{demand(\text{topeka})} & : x(\text{seattle,topeka}) + x(\text{san-diego,topeka}) = 275;
\end{align*}
\]

Of course, this is not a valid GAMS code and cannot be compiled, but it may be sufficient to view the model algebra as generated by the GAMS compiler.

By using

\[
\begin{align*}
\text{sed } -n -e "s:~ *((exbi)[0-9][0-9]*\}) \((.*):s/1/2/g:gp" \text{dict.txt } | \text{sed } -n '1!G;h;$p' > \text{mod.txt} \\
\text{sed -f mod.txt gams.gms}
\end{align*}
\]

one gets for this example

**Variables**

\( x_{\text{seattle,new-york}}, x_{\text{seattle,Chicago}}, x_{\text{seattle,topeka}}, x_{\text{san-diego,new-york}}, x_{\text{san-diego,Chicago}} \)

**Positive Variables**

\( x_{\text{seattle,new-york}}, x_{\text{seattle,Chicago}}, x_{\text{seattle,topeka}}, x_{\text{san-diego,new-york}}, x_{\text{san-diego,Chicago}} \)

**Equations**

\[
\begin{align*}
\text{cost} & : -0.225 \times x_{\text{seattle,new-york}} - 0.153 \times x_{\text{seattle,Chicago}} - 0.162 \times x_{\text{seattle,topeka}} - 0.225 \times x_{\text{san-diego,new-york}} - 0.162 \times x_{\text{san-diego,Chicago}} - 0.126 \times x_{\text{san-diego,topeka}} + z = 0; \\
\text{supply(\text{seattle})} & : x_{\text{seattle,new-york}} + x_{\text{seattle,Chicago}} + x_{\text{seattle,topeka}} = 350; \\
\text{supply(\text{san-diego})} & : x_{\text{san-diego,new-york}} + x_{\text{san-diego,Chicago}} + x_{\text{san-diego,topeka}} = 600; \\
\text{demand(\text{new-york})} & : x_{\text{seattle,new-york}} + x_{\text{san-diego,new-york}} = 325; \\
\text{demand(\text{Chicago})} & : x_{\text{seattle,Chicago}} + x_{\text{san-diego,Chicago}} = 300; \\
\text{demand(\text{topeka})} & : x_{\text{seattle,topeka}} + x_{\text{san-diego,topeka}} = 275;
\end{align*}
\]

This can even be compiled by GAMS and gives the correct solution.

The proposed commands come with several limitations and may not produce in all cases the desired output. For example, wrong results would be printed if the original model contains variable or equation names that start with \{b,i,e,x\} [digit]. Also semicontinuous or semiinteger variables or special ordered sets are not supported by the above. We leave it to the experienced user to extend the command appropriately.
5.9.4 The OSiL Format

The Optimization Services Instance Language (OSiL) [70] specifies an XML-based format to represent optimization problem instances. GAMS/CONVERT can write MINLP model instances in OSiL format. Expression trees are written in OSnL format.

Next to the indexed operations for sum, product, minimum, and maximum, and the operations for subtraction and division, the following intrinsic functions are mapped to their OSnL counterparts: \texttt{sqr}, \texttt{sqrt}, \texttt{exp}, \texttt{log}, \texttt{log2}, \texttt{abs}, \texttt{cos}, \texttt{sin}, \texttt{tan}, \texttt{arccos}, \texttt{arctan}, \texttt{sinh}, \texttt{cosh}, \texttt{tanh}, \texttt{pi}, \texttt{div}, \texttt{gamma}, \texttt{loggamma}, \texttt{floor}, \texttt{ceil}, \texttt{round}, \texttt{trunc}, \texttt{sign fact}, \texttt{binomial}. The functions \texttt{cvPower}, \texttt{power}, \texttt{rpower}, \texttt{vcpower} are all mapped to OSnL's power operator, thus conditions on arguments are not preserved. Functions \texttt{arctan2}, \texttt{centropy}, \texttt{edist}, \texttt{erf}, and \texttt{poly} are represented by an expression according to their algebraic definition. The intrinsic functions \texttt{signpower}, \texttt{entropy}, \texttt{sigmoid}, \texttt{gammareg}, \texttt{beta}, \texttt{logbeta}, and \texttt{betareg} are also written to OSiL files, but do not follow the OSnL standard (as it currently does not offer these functions). Thus, OSiL readers may reject XML files that use these functions. Finally, also the logical functions are written to OSiL by using their OSnL counterpart.

5.9.5 User-Specified Options

CONVERT options are passed on through option files. If you specify \texttt{<modelname>.optfile = 1;} before the SOLVE statement in your GAMS model, CONVERT will look for and read an option file with the name \texttt{convert.opt} (see The Solver Options File for general use of solver option files). The syntax for the CONVERT option file is

\begin{verbatim}
 optedname value
\end{verbatim}

with one option on each line. For example,

\begin{verbatim}
ampl
\end{verbatim}

This option file would tell CONVERT to produce an AMPL input file. For file format options, the user can specify the filename for the file to be generated. For example, the option file entry

\begin{verbatim}
lingo myfile.lng
\end{verbatim}

would generate a LINGO input file format called \texttt{myfile.lng}. Using the option \texttt{lingo} by itself, would produce the default output file for that option (\texttt{lingo.lng}).

All available options are listed in the following tables.
### 5.9.5.1 Target languages and formats

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

### 5.10 COPT

**Cardinal Optimizer** by Cardinal Operations is a solver for linear programming problems (LPs) and mixed-integer linear programming problems (MIPs).

#### 5.10.1 Usage

A GAMS/COPT or GAMS/COPT-Link license is required to use the GAMS/COPT interface that is distributed with GAMS. If only a GAMS/COPT-Link license is available, also a separate COPT license needs to be installed on the system, see the "Cardinal Operations User Guide" for details.

The following statement can be used inside your GAMS program to specify using COPT
Option MIP = COPT; { or LP, RMIP }

The above statement should appear before the Solve statement. If COPT was specified as the default solver during GAMS installation, the above statement is not necessary.

COPT supports special ordered sets (SOS), but no semicontinuous or semiinteger variables.

5.10.1.1 Specification of COPT Options

The following GAMS parameters are currently supported by GAMS/COPT: reslim, iterlim, nodlim, optcr, optca, tryint, and threads.

Further options can be set via a solver options file, see Section The Solver Option File for further information. Following is an example options file **copt.opt**:

```
TreeCutLevel 0
SimplexThreads 4
```

It will cause COPT to use cut generators only in the root node (for a MIP solve) and specifies to use 4 threads in the simplex algorithm.

5.10.1.2 Specification of Indicators

Indicators are a modeling tool to specify that certain equations in a model must only be satisfied if certain binary variables take a specified value. Indicators are not supported by the GAMS language, but can be passed to COPT via a GAMS/COPT solver options file, see Indicator Constraints for more details on its syntax.

5.10.1.3 MIP Starting Point

When solving a MIP, by default all values that are specified as variable levels in the GAMS model are passed as starting point to COPT (unless MipStartMode = 0). However, if GAMS option tryint is set to a nonzero value or MipStartMode = 2, then only values of binary and integer variables which fractionality is at most the value tryint are passed as starting point to COPT (possible fractional values are rounded to integers). COPT will then try to complete this partial solution to a feasible solution.

5.10.1.4 Solution Pool

When COPT solves a problem, it may find several solutions, whereof only the best one is available to the GAMS user via the variable level values in the GAMS model. If the option solnpooldump is specified, then all alternative solutions found by COPT are written into GDX files and an index file with the name given by the this option is written. If the option solnpooolmerge is specified, then all alternative solutions found by COPT are written into a single GDX file, which name is given by the this option.

The GAMS testlib model **dumpsol** shows an example use for this option.
5.10.1.5 Infeasible and unbounded LPs

If an LP is found infeasible by COPT, a primal infeasibility certificate in form of a Farkas proof (see also Mosek manual) is computed. The GAMS/COPT link returns the values of this certificate in the equations marginal values and sets the INFES markers (see solution listing) for those equations that are included in the Farkas proof.

If an LP is found unbounded by COPT, a dual infeasibility certificate in form of a primal ray is computed. If the problem is feasible, then the primal ray gives a direction in which the objective function can be infinitely improved. The GAMS/COPT link returns the values of the primal ray in the variable level values and sets UNBND markers (see solution listing) for those variables that are included in the ray.

COPT option ReqFarkasRay can be used to disable the calculation of these infeasibility certificates.

5.10.1.6 Finding an Irreducible Inconsistent Subsystem (IIS) of Constraints

If COPT declares an LP or MIP as infeasible, it has the capability to identify a subset of the constraints that are infeasible and become feasible once any one of them is eliminated. Option iis can be used to enable finding an IIS.

As an example, consider a GAMS model containing

Positive Variables x, y;
Equation e1;
e1.. x + y =l= -1;

The corresponding COPT output when iis has been enabled will look like

Starting the simplex solver using 1 thread

Method Iteration Objective Primal.NInf Dual.NInf Time
Dual 0 0.0000000000e+00 1 0 0.00s
Solving finished
Status: Infeasible Objective: - Iterations: 0 Time: 0.00s
Start the IIS computation for an LP

IIS summary: 1 rows, 2 bounds of columns
IIS computation finished (0.000s)
IIS is minimal
Number of equations in IIS: 1
  Upper: e1 <= -1
Number of variables in IIS: 2
  Lower: x >= 0
  Lower: y >= 0

That is, COPT finds the problem infeasible. Then the IIS computation is started and an IIS is found. The IIS is then printed to the log and listing file. It consists of the lower bounds of variables x and y and equation e1. This suggests that the entire model can be made feasible by lowering the lower bound of x or y or by increasing the right-hand side of e1.
5.10.1.7 Using the Feasibility Relaxation

The feasibility relaxation is enabled by the FeasRelax parameter in a COPT solver option file.

With the FeasRelax option COPT selectively relaxes the variable bounds and constraint sides of an infeasible model instance in a way that a weighted penalty function is minimized. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

Attention

At the moment, COPT can only relax sides of linear constraints. Indicator and quadratic constraints are not considered for relaxation.

By default all equation sides are candidates for relaxation and weighted equally but none of the variable bounds can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the dot option feaspref. A zero preference means that the associated bound or constraint side is not to be modified. The weighted penalty function is constructed from these preferences. The larger the preference, the more likely it will be that a given variable bound or constraint side will be relaxed. However, it is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a COPT solver option file. The syntax is:

(variable or equation).feaspref(value)

For example, suppose we have a GAMS declaration:

```
Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);
```

Then, the relaxation preference in the copt.opt file can be specified by:

```
fearsrelax 1
v.feaspref 1
v.feaspref('i1','*') 2
v.feaspref('i1','j2') 0
e.feaspref('i5','j4') 2
```

First we turn the feasible relaxation on. Furthermore, we specify that all variables v(i,j) have preference of 1, except variables over set element i1, which have a preference of 2. The variable over set element i1 and j2 has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords variables or equations instead of the individual variable and equations names (e.g. variables.feaspref 1).

The parameter FeasRelaxMode allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter FeasRelaxMode indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a sum of required relaxations; as the number of constraints and bounds required to be relaxed; as a sum of the squares of required relaxations). Also check model feasopt1 in the GAMS model library.

## 5.11 CPLEX

### 5.11.1 Introduction

GAMS/Cplex is a GAMS solver that allows users to combine the high level modeling capabilities of GAMS with the power of Cplex optimizers. Cplex optimizers are designed to solve large, difficult problems quickly and with minimal user intervention. Access is provided (subject to proper licensing) to Cplex solution algorithms for linear, quadratically constrained and mixed integer programming problems. While numerous solving options are available, GAMS/Cplex automatically calculates and sets most options at the best values for specific problems.

All Cplex options available through GAMS/Cplex are summarized at the end of this document.

### 5.11.2 How to Run a Model with Cplex

The following statement can be used inside your GAMS program to specify using Cplex

```plaintext
Option LP = Cplex;  { or QCP, MIP, MIQCP, RMIP or RMIQCP }
```

The above statement should appear before the Solve statement. If Cplex was specified as the default solver during GAMS installation, the above statement is not necessary.

Finally, a free of charge bare-bone interface to the LP and MIP solver of Cplex is available under the name **OSICPLEX**.

| writemst    | name of file to which to write MIP starting point                          |         |
5.11.3 Overview of Cplex

5.11.3.1 Linear Programming

Cplex solves LP problems using several alternative algorithms. The majority of LP problems solve best using Cplex’s state of the art dual simplex algorithm. Certain types of problems benefit from using the primal simplex algorithm, the network optimizer, the barrier algorithm, or the sifting algorithm. The concurrent option will allow solving with different algorithms in parallel. The solution is returned by the first to finish.

Solving linear programming problems is memory intensive. Even though Cplex manages memory very efficiently, insufficient physical memory is one of the most common problems when running large LPs. When memory is limited, Cplex will automatically make adjustments which may negatively impact performance. If you are working with large models, study the section entitled Physical Memory Limitations carefully.

Cplex is designed to solve the majority of LP problems using default option settings. These settings usually provide the best overall problem optimization speed and reliability. However, there are occasionally reasons for changing option settings to improve performance, avoid numerical difficulties, control optimization run duration, or control output options.

Some problems solve faster with the primal simplex algorithm rather than the default dual simplex algorithm. Very few problems exhibit poor numerical performance in both the primal and the dual. Therefore, consider trying primal simplex if numerical problems occur while using dual simplex.

Cplex has a very efficient algorithm for network models. Network constraints have the following property:

- each non-zero coefficient is either a +1 or a -1
- each column appearing in these constraints has > exactly 2 nonzero entries, one with a +1 > coefficient and one with a -1 coefficient

Cplex can also automatically extract networks that do not adhere to the above conventions as long as they can be transformed to have those properties.

The barrier algorithm is an alternative to the simplex method for solving linear programs. It employs a primal-dual logarithmic barrier algorithm which generates a sequence of strictly positive primal and dual solutions. Specifying the barrier algorithm may be advantageous for large, sparse problems.

Cplex provides a sifting algorithm which can be effective on problems with many more variables than equations. Sifting solves a sequence of LP subproblems where the results from one subproblem are used to select columns from the original model for inclusion in the next subproblem.

GAMS/Cplex also provides access to the Cplex Conflict Refiner previously known as IIS (Irreducibly Inconsistent Set). The conflict refinder takes an infeasible program and produces a set of conflicting constraints. Such a set consists of constraints and variable bounds which is infeasible but becomes feasible if any one member of the set is dropped. GAMS/Cplex reports the conflict in terms of GAMS equation and variable names and includes the conflict report as part of the normal solution listing.

5.11.3.2 Quadratically Constrained Programming

Cplex can solve models with quadratic constraints. These are formulated in GAMS as models of type QCP. QCP models are solved with the Cplex Barrier method.

QP models are a special case that can be reformulated to have a quadratic objective function and only linear constraints. These are automatically reformulated from GAMS QCP models. When such problems are convex, Cplex normally solves them efficiently in polynomial time. Nonconvex QPs, however, are known to be quite hard. Cplex applies various approaches to those problems, such approaches as barrier algorithms or branch and bound algorithms. Notably, in the branch and bound approach, there is no theoretical guarantee about the complexity of such a problem. Consequently, solution of such a problem (that is, a nonconvex QP) can take many orders of magnitude longer than the solution of a convex QP of comparable dimensions. Therefore, the default is to reject such model. The parameter OptimalityTarget allows to change this behavior.

For QCP models Cplex returns a primal and in most cases also dual values.
5.11.3.3 Mixed-Integer Programming

The methods used to solve pure integer and mixed integer programming problems require dramatically more mathematical computation than those for similarly sized pure linear programs. Many relatively small integer programming models take enormous amounts of time to solve.

For problems with integer variables, Cplex uses a branch and cut algorithm which solves a series of LP subproblems. Because a single mixed integer problem generates many subproblems, even small mixed integer problems can be very compute intensive and require significant amounts of physical memory.

GAMS and GAMS/Cplex support Special Order Sets of type 1 and type 2 as well as semi-continuous and semi-integer variables.

Cplex can also solve problems of GAMS model type MIQCP. As in the continuous case, if the base model is a QP the Simplex methods can be used and duals will be available at the solution. If the base model is a QCP, only the Barrier method can be used for the nodes and only primal values will be available at the solution.

5.11.3.4 Feasible Relaxation

The Conflict Refiner identifies the causes of infeasibility by means of inconsistent set of constraints. However, you may want to go beyond diagnosis to perform automatic correction of your model and then proceed with delivering a solution. One approach for doing so is to build your model with explicit slack variables and other modeling constructs, so that an infeasible outcome is never a possibility. An automated approach offered in GAMS/Cplex is known as FeasOpt (for Feasible Optimization) and turned on by parameter FeasOpt in a CPLEX option file. More details can be found in the section entitled Using the Feasibility Relaxation.

5.11.3.5 Solution Pool: Generating and Keeping Multiple Solutions

This section introduces the solution pool for storing multiple solutions to a mixed integer programming problem (MIP and MIQCP). The chapter also explains techniques for generating and managing those solutions.

The solution pool stores multiple solutions to a mixed integer programming (MIP and MIQCP) model. With this feature, you can direct the algorithm to generate multiple solutions in addition to the optimal solution. For example, some constraints may be difficult to formulate efficiently as linear expressions, or the objective may be difficult to quantify exactly. In such cases, obtaining multiple solutions will help you choose one which best fits all your criteria, including the criteria that could not be expressed easily in a conventional MIP or MIQCP model. For example,

- You can collect solutions within a given percentage of the optimal solution. To do so, apply the solution pool gap parameters SolnPoolAGap and SolnPoolGap.
- You can collect a set of diverse solutions. To do so, use the solution pool replacement parameter SolnPoolReplace to set the solution pool replacement strategy to 2. In order to control the diversity of solutions even more finely, apply a diversity filter.
- In an advanced application of this feature, you can collect solutions with specific properties. To do so, see the use of the incumbent filter.
- You can collect all solutions or all optimal solutions to model. To do so, set the solution pool intensity parameter SolnPoolIntensity to its highest value.

Please note, that the value for best possible can exceed the optimal solution value if CPLEX has already solved the model to optimality but continues to search for additional solutions.
5.11.3.5.1 Filling the Solution Pool  There are two ways to fill the solution pool associated with a model: You can accumulate successive incumbents or generate alternative solutions by populating the solution pool. The method is selected with the parameter \texttt{SolnPoolPop}:

- The regular optimization procedure automatically adds incumbents to the solution pool as they are discovered (\texttt{SolnPoolPop = 1}).
- Cplex also provides a procedure specifically to generate multiple solutions. You can invoke this procedure by setting option \texttt{SolnPoolPop = 2}. You can also invoke this procedure many times in a row in order to explore the solution space differently. In particular, you may invoke this procedure multiple times to find additional solutions, especially if the first solutions found are not satisfactory. This is done by specifying a GAMS program (option \texttt{SolnPoolPopRepeat}) that inspects the solutions. In case this GAMS program terminates normally, i.e. no execution or compilation error, the exploration for alternative solutions proceeds.

The option \texttt{SolnPoolReplace} designates the strategy for replacing a solution in the solution pool when the solution pool has reached its capacity. The value 0 replaces solutions according to a first-in, first-out policy. The value 1 keeps the solutions with the best objective values. The value 2 replaces solutions in order to build a set of diverse solutions.

If the solutions you obtain are too similar to each other, try setting \texttt{SolnPoolReplace} to 2.

The replacement strategy applies only to the subset of solutions created in the current call of populate. Solutions already in the pool are not affected by the replacement strategy. They will not be replaced, even if they satisfy the criterion of the replacement strategy. So with every repeated call of the populate procedure the solution pool will be extended by the newly found solution. After the GAMS program specified in \texttt{SolnPoolPopRepeat} determined to continue the search for alternative solutions, the file specified by option \texttt{SolnPoolPopDel} option is read in. The solution numbers present in this file will be delete from the solution pool before the populate routine is called again. The file is automatically deleted by the GAMS/Cplex link after processing.

5.11.3.5.2 Enumerating All Solutions  With the solution pool, you can collect all solutions to a model. To do so, set the solution pool intensity parameter \texttt{SolnPoolIntensity} to its highest value, 4 and set \texttt{SolnPoolPop = 2}.

You can also enumerate all solutions that are valid for a specific criterion. For example, if you want to enumerate all alternative optimal solutions, do the following:

- Set the pool absolute gap parameter \texttt{SolnPoolAGap} = 0.0 (for models with potential numerical issues, better use a small non-zero like 1e-6).
- Set the pool intensity parameter \texttt{SolnPoolIntensity} = 4.
- Set the populate limit parameter \texttt{PopulateLim} to a value sufficiently large for your model; for example, 2100000000.
- Set the pool population parameter \texttt{SolnPoolPop} = 2.

Beware, however, that, even for small models, the number of possible solutions is likely to be huge. Consequently, enumerating all of them will take time and consume a large quantity of memory.

There may be an infinite number of possible values for a continuous variable, and it is not practical to enumerate all of them on a finite-precision computer. Therefore, populate gives only one solution for each set of binary and integer variables, even though there may exist several solutions that have the same values for all binary and integer variables but different values for continuous variables.

Likewise, for the same reason, the populate procedure does not generate all possible solutions for unbounded models. As soon as the proof of unboundedness is obtained, the populate procedure stops.

Cplex uses numerical methods of finite-precision arithmetic. Consequently, the feasibility of a solution depends on the value given to tolerances. Two parameters define the tolerances that assess the feasibility of a solution:
5.11 CPLEX

• the integrality tolerance EpInt
• the feasibility tolerance EpRHS

A solution may be considered feasible for one pair of values for these two parameters, and infeasible for a different pair. This phenomenon is especially noticeable in models with numeric difficulties, for example, in models with BigM coefficients.

Since the definition of a feasible solution is subject to tolerances, the total number of solutions to a model may vary, depending on the approach used to enumerate solutions, and on precisely which tolerances are used. In most models, this tolerance issue is not problematic. But, in the presence of numeric difficulties, Cplex may create solutions that are slightly infeasible or integer infeasible, and therefore create more solutions than expected.

5.11.3.5.3 Filtering the Solution Pool Filtering allows you to control properties of the solutions generated and stored in the solution pool. Cplex provides two predefined ways to filter solutions.

If you want to filter solutions based on their difference as compared to a reference solution, use a diversity filter. This filter is practical for most purposes. However, if you require finer control of which solutions to keep and which to eliminate, use the incumbent filter.

5.11.3.5.4 Diversity Filter A diversity filter allows you to generate solutions that are similar to (or different from) a set of reference values that you specify for a set of binary variables using dot option DivFlt and lower and upper bounds DivFltLo and DivFltUp. In particular, you can use a diversity filter to generate more solutions that are similar to an existing solution or to an existing partial solution. If you need more than one diversity filter, for example, to generate solutions that share the characteristics of several different solutions, additional filters can be specified through a Cplex Filter File using parameter ReadFLT. Details can be found in the example model solnpool in the GAMS model library.

5.11.3.5.5 Incumbent Filter If you need to enforce more complex constraints on solutions (e.g. if you need to enforce nonlinear constraints), you can use the incumbent filtering. The incumbent checking routine is part of the GAMS BCH Facility. It will accept or reject incumbents independent of a solution pool. During the populate or regular optimize procedure, the incumbent checking routine specified by the parameter UserIncbCall is called each time a new solution is found, even if the new solution does not improve the objective value of the incumbent. The incumbent filter allows your application to accept or reject the new solution based on your own criteria. If the GAMS program specified by UserIncbCall terminates normally, the solution is rejected. If this program returns with a compilation or execution error, the incumbent is accepted.

5.11.3.5.6 Accessing the Solution Pool The solutions are stored in GAMS Data eXchange (GDX) file and can be loaded by your GAMS program. Details can be found in the model solnpool in the GAMS model library and in . If you instruct Cplex to generate thousands of solution this becomes inefficient. The option SolnPoolMerge triggers the creation of a single GDX file containing all solutions.

The GAMS/Cplex link produces, if properly instructed, a GAMS Data eXchange(GDX) file with name specified in SolnPool that contains a set Index with elements file1, file2, ... The associated text of these elements contain the file names of the individual GDX solution file. The name is constructed using the prefix soln (which can be specified differently by option SolnPoolPrefix), the name of the model and a sequence number. For example soln_loc_pl.gdx. GAMS/Cplex will overwrite existing GDX files without warning. The set Index allows us to conveniently walk through the different solutions in the solution pool. A complete model can be found in the model solnpool in the GAMS model library.
... solve mymodel min z using mip;
set soln possible solutions in the solution pool /file1*file1000/
   solnpool(soln) actual solutions;
file fsol;
execute_load 'solnpool.gdx', solnpool=Index;
loop(solnpool(soln),
   put_utility fsol 'gdxin' / solnpool.te(soln):0:0;
   execute_loadpoint;
   display z.l;
);

If you instruct Cplex to generate thousands of solution this method becomes inefficient. The option
SolnPooMerge triggers the creation of a single GDX file containing all solutions. Details on usage of this
option can be found in the model solmpool in the GAMS model library.

5.11.3.6 Benders Algorithm

CPLEX implements Benders algorithm.

Given a formulation of a problem, CPLEX can decompose the model into a single master and (possibly
multiple) subproblems. To do so, CPLEX makes use of annotations that you supply for your model. This
approach can be applied to mixed-integer linear programs (MILP). For certain types of problems, this
approach can offer significant performance improvements.

The parameter, BendersStrategy, specifies to CPLEX how you want to apply Benders algorithm as a
strategy to solve your model. By default, if you did not annotate your model to specify a decomposition,
CPLEX executes conventional branch and bound. If you annotated your model, CPLEX attempts to
refine your decomposition and applies Benders algorithm. With this parameter, you can direct CPLEX to
decompose your model and to apply its implementation of Benders algorithm in one of these alternative
ways:

• 1: CPLEX attempts to decompose your model strictly according to your annotations.
• 2: CPLEX decomposes your model by using your annotations as hints and refining the decomposition
  where it can. CPLEX initially decomposes your model according to your annotation and then
  attempts to refine that decomposition by further decomposing the specified subproblems. This
  approach can be useful if you annotate certain variables to go into master, and all others to go into
  a single subproblem, which CPLEX can then decompose further for you.
• 3: CPLEX automatically decomposes your model, ignoring any annotations you may have supplied.
  CPLEX puts all integer variables into the master, puts all continuous variables into a subproblem
  and decomposes that subproblem, if possible.

If you want to specify a decomposition to CPLEX, you need to annotate your model and specify a Benders
partition of your variable space. These Benders partition can be conveniently specified with the dot option
BendersPartition or through the .stage variable suffix.

These Benders partition values specify to CPLEX whether certain variables belong to the master or to
one of the subproblems assigned to workers (where the subproblems are numbered from 1 (one) to N, the
number of subproblems). If you annotate a given variable with the value 0 (zero), CPLEX assigns that
variable to the master. If you annotate a given variable with the value i, where i is greater than or equal to
1 (one), CPLEX assigns that variable to subproblem i. If a variable is not specified, the default will be to
go into the master problem. Note that with variable.BendersPartition 1 you can assign all variables to the subproblem and then selectively assign the master variables with varname.BendersPartition 0.

If you want to communicate the Benders partition values via the .stage variable suffix, the partition numbers are off by one compared to the partition number via the dot option. So the master variables have stage 1, and the subproblems start with stage 2. If you want to leave a variable unassigned you can either make the stage 0 or fractional (e.g. 1.5). Discrete variables are automatically put into the master problem and don’t need to be set. In addition to specifying the Benders partition values via the .stage variable suffix the link option BendersPartitionInStage needs to be set to 1.

CPLEX produces an error if the annotated decomposition does not yield disjoint subproblems. For example, if your annotations specify that two (or more) variables belong in different subproblems, yet your model specifies that these variables participate in the same constraint, then these variables are linked. Consequently, the subproblems where these variables appear according to your annotations are not disjoint with respect to the partition.

5.11.3.7 Multiple Objectives

While typical optimization models have a single objective function, real-world optimization problems often have multiple, competing objectives. For example, in a production planning model, you may want to both maximize profits and minimize late orders, or in a workforce scheduling application, you may want to both minimize the number of shifts that are short-staffed while also respecting worker’s shift preferences.

The main challenge you face when working with multiple, competing objectives is deciding how to manage the tradeoffs between them. Cplex provides tools that simplify the task: Cplex allows you to blend multiple objectives, to treat them hierarchically, or to combine the two approaches. In a blended approach, you optimize a weighted combination of the individual objectives. In a hierarchical or lexicographic approach, you set a priority for each objective, and optimize in priority order. When optimizing for one objective, you only consider solutions that would not degrade the objective values of higher-priority objectives. Cplex allows you to enter and manage your objectives, to provide weights for a blended approach, or to set priorities for a hierarchical approach. Cplex will only solve multi-objective models with strictly linear objectives. Moreover, for continous models, Cplex will report a primal only solution (not dual information).

Following the workforce application the specifications of the objectives would be done as follows:

```plaintext
equations defObj, defNumShifts, defSumPreferences;
variables obj, numShifts, sumPreferences;

defObj.. obj =e= numShifts - 1/100*sumPreferences;
defNumShifts.. numShifts =e= ....;
defSumPreferences.. sumPreferences =e= ....;

model workforce /all/;
solve workforce minimizing obj using mip;
```

With the default setting Cplex will solve the blended objective. Using the parameter MultObj Cplex will use a hierarchical approach. A hierarchical or lexicographic approach assigns a priority to each objective, and optimizes for the objectives in decreasing priority order. At each step, it finds the best solution for the current objective, but only from among those that would not degrade the solution quality for higher-priority objectives. The priority is specified by the absolute value of the objective coefficient in the blended objective function (defObj). In the example, the numShifts objective with coefficient 1 has higher priority than the sumPreferences objective with absolute objective coefficient 1/100. The sign of the objective coefficient determines the direction of the particular objective function. So here numShifts will be minimized (same direction as on the solve statement) while sumPreferences will be maximized.
GAMS needs to identify the various objective functions, therefore the objective variables can only appear in the blended objective functions and in the particular objective defining equation.

By default, the hierarchical approach won't allow later objectives to degrade earlier objectives. This behavior can be relaxed through a pair of attributes: \texttt{ObjNRelTol} and \texttt{ObjNAbsTol}. Their meaning differs for continuous and discrete models:

- **Discrete models**: By setting one of the two tolerances for a particular objective, you can indicate that later objectives are allowed to degrade this objective by the specified relative or absolute amount, respectively. In our earlier example, if the optimal value for \texttt{numShifts} is 100, and if we set \texttt{ObjNAbsTol} for this objective to 20, then the second optimization step maximizing \texttt{sumPreferences} would find the best solution for the second objective from among all solutions with objective 120 or better for \texttt{numShifts}. Note that if you modify both tolerances, later optimizations would use the looser of the two values (i.e., the one that allows the larger degradation).

- **Continuous Models**: \texttt{ObjNAbsTol} does not include a hard constraint for previous objective functions in subsequent solves. Instead, \texttt{ObjNAbsTol} defines a threshold for the reduced costs above which nonbasic variables in the associated LP solve will be fixed at the bound at which they reside. The option \texttt{ObjNRelTol} has no effect here. In order to apply the above discrete strategy for continuous models, set \texttt{MultiObjTolMip} to 1.

### 5.11.4 GAMS Options

The following GAMS options are used by GAMS/Cplex:

- **Option BRatio = x;**
  
  Determines whether or not to use an advanced basis. A value of 1.0 causes GAMS to instruct Cplex not to use an advanced basis. A value of 0.0 causes GAMS to construct a basis from whatever information is available. The default value of 0.25 will nearly always cause GAMS to pass along an advanced basis if a solve statement has previously been executed.

- **Option IterLim = n;**
  
  Sets the simplex iteration limit. Simplex algorithms will terminate and pass on the current solution to GAMS.

  Cplex handles the iteration limit for MIP problems differently than some other GAMS solvers. The iteration limit is applied per node instead of as a total over all nodes. For MIP problems, controlling the length of the solution run by limiting the execution time (\texttt{ResLim}) is preferable.

  Similarly, when using the sifting algorithm, the iteration limit is applied per sifting iteration (i.e. per LP). The number of sifting iterations (LPs) can be limited by setting Cplex parameter \texttt{SiftItLim}. It is the number of sifting iterations that is reported back to GAMS as iterations used.

- **Option ResLim = x;**
  
  Sets the time limit in seconds. In case \texttt{ResLim} assumes its default value (1e+10) Cplex will use its own default (1e+75). The algorithm will terminate and pass on the current solution to GAMS.

- **Option SysOut = On;**
  
  Will echo Cplex messages to the GAMS listing file. This option may be useful in case of a solver failure.

- **\texttt{ModelName}.Cheat = x;**
Cheat value: each new integer solution must be at least x better than the previous one. Can speed up the search, but you may miss the optimal solution. The cheat parameter is specified in absolute terms (like the OptCA option). The Cplex option ObjDif overrides the GAMS cheat parameter.

- **ModelName.Cutoff = x;**
  Cutoff value. When the branch and bound search starts, the parts of the tree with an objective worse than x are deleted. This can sometimes speed up the initial phase of the branch and bound algorithm.

- **ModelName.NodLim = x;**
  Maximum number of nodes to process for a MIP problem.

- **Option OptCA = x;**
  Absolute optimality criterion for a MIP problem. The OptCA option asks Cplex to stop when
  \[ |BP - BF| < OptCA \]
  where \( BF \) is the objective function value of the current best integer solution while \( BP \) is the best possible integer solution.
  Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

- **ModelName.OptCR = x;**
  Relative optimality criterion for a MIP problem. Notice that Cplex uses a different definition than GAMS normally uses. The OptCR option asks Cplex to stop when
  \[ \frac{|BP - BF|}{(1.0e - 10 + |BF|)} < OptCR \]
  where \( BF \) is the objective function value of the current best integer solution while \( BP \) is the best possible integer solution. The GAMS definition is:
  \[ \frac{|BP - BF|}{|BP|} < OptCR \]
  Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

- **ModelName.OptFile= 1;**
  Instructs Cplex to read the option file. The name of the option file is `cplex.opt`.

- **ModelName.PriorOpt= 1;**
  Instructs Cplex to use priority branching information passed by GAMS through the `variable.prior` parameters.

- **ModelName.TryInt= x;**
  Causes GAMS/Cplex to make use of current variable values when solving a MIP problem. If a variable value is within x of a bound, it will be moved to the bound and the preferred branching direction for that variable will be set toward the bound. The preferred branching direction will only be effective when priorities are used. Priorities and tryint are sometimes not very effective and often outperformed by GAMS/CPLEX default settings. Supporting GAMS/CPLEX with knowledge about a known solution can be passed on by different means, please read more about this in section entitled Starting from a MIP Solution.

GAMS/Cplex also sets many model attributes that can by used in your GAMS program by accessing **ModelName.suffix**. A list of model attributes available after the solve can be found here Model Attributes Mainly Used After Solve.

Cplex has the concept of deterministic time i.e. a measure of time that respects the same solution path to arrive at the same values in the solution while it yields the same level of performance for repeated solving
of the same model with the same parameter settings, on the same computing platform. The length of
deterministic time tick may vary by platform. Nevertheless, ticks are normally consistent measures
for a given platform (combination of hardware and software) carrying the same load. In other words,
the correspondence of ticks to clock time depends on the hardware, software, and the current load of
the machine. For the same platform and same load, the ratio of ticks per second stays roughly constant,
independent of the model solved. However, for very short optimization runs, the variation of this ratio
is typically high. GAMS/Cplex reports the deterministic time ticks spend inside Cplex in the model
attribute $\text{ETA1g}$. Normally $\text{ETA1g}$ is reporting the seconds.

5.11.5 Summary of CPLEX Options

The various Cplex options are listed here by category, with a few words about each to indicate its function.
The options are listed again, in alphabetical order and with detailed descriptions, in the last section of
this document.

5.11.5.1 Preprocessing and General Options

<table>

<td>postfixes if, o on call adds –userjobid to the call. Postfixes gdxname, gdxnameinc and gdxin</td>
<td></td>
</tr>
</tbody>
</table>
### 5.11.5.13 The GAMS/Cplex Options File

The GAMS/Cplex options file consists of one option or comment per line. An asterisk (∗) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by any amount of white space (blanks or tabs).

Following is an example options file `cplex.opt`.

```plaintext
scaind 1
simdisplay 2
```

It will cause Cplex to use a more aggressive scaling method than the default. The iteration log will have an entry for each iteration instead of an entry for each refactorization.

### 5.11.6 Special Notes

#### 5.11.6.1 Physical Memory Limitations

For the sake of computational speed, Cplex should use only available physical memory rather than virtual or paged memory. When Cplex recognizes that a limited amount of memory is available it automatically makes algorithmic adjustments to compensate. These adjustments almost always reduce optimization speed. Learning to recognize when these automatic adjustments occur can help to determine when additional memory should be added to the computer.

On virtual memory systems, if memory paging to disk is observed, a considerable performance penalty is incurred. Increasing available memory will speed the solution process dramatically. Also consider option `MemoryEmphasis` to conserve memory where possible.

When solving LPs, the Simplex algorithm (lpmethod 1 or 2) usually consumes less memory than the Barrier algorithm (lpmethod 2). During the Simplex algorithm, Cplex performs an operation called refactorization at a frequency determined by the `ReInv` option setting. The longer Cplex works between refactorizations, the greater the amount of memory required to complete each iteration. Therefore, one means for conserving memory is to increase the refactorization frequency. Since refactorization is an expensive operation, increasing the refactorization frequency by reducing the `ReInv` option setting generally will slow performance. Cplex will automatically increase the refactorization frequency if it encounters low memory availability. This can be seen by watching the iteration log. The default log reports problem status at every refactorization. If the number of iterations between iteration log entries is decreasing, Cplex is increasing the refactorization frequency. Since Cplex might increase the frequency to once per iteration, the impact on performance can be dramatic. Providing additional memory should be beneficial.

GAMS/Cplex also provides the option `FreeGAMSModel` to free some memory allocated by the GAMS link and making it available to Cplex. This only works when the GAMS parameter `SolveLink` is set 0 which should be always done when memory is tight because GAMS completely vacates memory.

The `Threads` options also has a significant impact on memory consumption. The concurrent solvers keep multiple copies of the problem in memory which double or even triples the amount of memory consumed. If memory tight, set the `Threads` parameter to 1.

Not loading GAMS names into CPLEX can also help in saving some memory. This can be done by setting the model attribute `dictFile` or by using CPLEX option `names`.

---

<table>

<tr>
<td>userlazyconcall</td>
<td>the GAMS command line to call the lazy constraint generator</td>
<td></td>
</tr>
</tbody>
</table>
5.11.6.2 Using Special Ordered Sets

For some models a special structure can be exploited. GAMS allows you to declare SOS1 and SOS2 variables (Special Ordered Sets of type 1 and 2).

In Cplex the definition for SOS1 variables is:

- A set of variables for which at most one variable may be non-zero.

The definition for SOS2 variables is:

- A set of variables for which at most two variables may be non-zero. If two variables are non-zero, they must be adjacent in the set.

5.11.6.3 Using Semi-Continuous and Semi-Integer Variables

GAMS allows the declaration of semi-continuous and semi-integer variables. These variable types are directly supported by GAMS/Cplex. For example:

```plaintext
SemiCont Variable x;
x.lo = 3.2;
x.up = 8.7;

SemiInt Variable y;
y.lo = 5;
y.up = 10;
```

Variable x will be allowed to take on a value of 0.0 or any value between 3.2 and 8.7. Variable y will be allowed to take on a value of 0 or any integral value between 5 and 10.

5.11.6.4 Running Out of Memory for MIP Problems

The most common difficulty when solving MIP problems is running out of memory. This problem arises when the branch and bound tree becomes so large that insufficient memory is available to solve an LP subproblem. As memory gets tight, you may observe frequent warning messages while Cplex attempts to navigate through various operations within limited memory. If a solution is not found shortly the solution process will be terminated with an unrecoverable integer failure message.

The tree information saved in memory can be substantial. Cplex saves a basis for every unexplored node. When utilizing the best bound method of node selection, the list of such nodes can become very long for large or difficult problems. How large the unexplored node list can become is entirely dependent on the actual amount of physical memory available and the actual size of the problem. Certainly increasing the amount of memory available extends the problem solving capability. Unfortunately, once a problem has failed because of insufficient memory, you can neither project how much further the process needed to go nor how much memory would be required to ultimately solve it.

Memory requirements can be limited by using the WorkMem, option with the NodeFileInd option. Setting NodeFileInd to 2 or 3 will cause Cplex to store portions of the branch and bound tree on disk whenever it grows to larger than the size specified by option WorkMem. That size should be set to something less than the amount of physical memory available.

Another approach is to modify the solution process to utilize less memory.
Set option NodeSel to use a best estimate strategy or, more drastically a depth-first-search. Depth first search rarely generates a large unexplored node list since Cplex will be diving deep into the branch and bound tree rather than jumping around within it.

Set option VarSel to use strong branching. Strong branching spends extra computation time at each node to choose a better branching variable. As a result it generates a smaller tree. It is often faster overall, as well.

On some problems, a large number of cuts will be generated without a correspondingly large benefit in solution speed. Cut generation can be turned off using option Cuts.

Use the Simplex algorithm instead of the Barrier algorithm using options StartAlg and SubAlg.

Use option solvefinal to avoid solving the final LP.

See also Physical Memory Limitations.

### 5.11.6.5 Failing to Prove Integer Optimality

One frustrating aspect of the branch and bound technique for solving MIP problems is that the solution process can continue long after the best solution has been found. Remember that the branch and bound tree may be as large as $2^n$ nodes, where $n$ equals the number of binary variables. A problem containing only 30 binary variables could produce a tree having over one billion nodes! If no other stopping criteria have been set, the process might continue ad infinitum until the search is complete or your computer's memory is exhausted.

In general you should set at least one limit on the optimization process before beginning an optimization. Setting limits ensures that an exhaustive tree search will terminate in reasonable time. Once terminated, you can rerun the problem using some different option settings.

### 5.11.6.6 Starting from a MIP Solution

You can provide a known solution (for example, from a MIP problem previously solved or from your knowledge of the problem) to serve as the first integer solution. When you provide such a starting solution, you may invoke relaxation induced neighborhood search (RINS heuristic) or solution polishing to improve the given solution. This first integer solution may include continuous and discrete variables of various types, such as semi-continuous variables or special ordered sets.

If you specify values for all discrete variables, GAMS/CPLEX will check the validity of the values as an integer-feasible solution; if you specify values for only a portion of the discrete variables, GAMS/CPLEX will attempt to fill in the missing values in a way that leads to an integer-feasible solution. If the specified values do not lead directly to an integer-feasible solution, GAMS/CPLEX will apply a quick heuristic to try to repair the MIP Start. The number of times that GAMS/CPLEX applies the heuristic is controlled by the repair tries parameter (RepairTries). If this process succeeds, the solution will be treated as an integer solution of the current problem.

A MIP start will only be used by GAMS/CPLEX if the MipStart parameter is set to 1. The starting values must be set via the .L variable attribute in the GAMS model before the solve statement.
5.11.6.7 Using the Feasibility Relaxation

The feasibility relaxation is enabled by the FeasOpt parameter in a CPLEX solver option file.

With the FeasOpt option CPLEX accepts an infeasible model and selectively relaxes the bounds and constraints in a way that minimizes a weighted penalty function. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

By default all equations are candidates for relaxation and weighted equally but none of the variables can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the dot option FeasPref. A negative or zero preference means that the associated bound or constraint is not to be modified. The weighted penalty function is constructed from these preferences. The larger the preference, the more likely it will be that a given bound or constraint will be relaxed. However, it is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a CPLEX solver option file. The syntax is:

(variable or equation) .feaspref (value)

For example, suppose we have a GAMS declaration:

Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);

Then, the relaxation preference in the cplex.opt file can be specified by:

```
feasopt 1
v.feaspref 1
v.feaspref('i1','*) 2
v.feaspref('i1','j2') 0
e.feaspref('','j1') 0
e.feaspref('i5','j4') 2
```

First we turn the feasible relaxation on. Furthermore, we specify that all variables v(i,j) have preference of 1, except variables over set element i1, which have a preference of 2. The variable over set element i1 and j2 has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords variables or equations instead of the individual variable and equations names (e.g. variables.feaspref 1).

The parameter FeasOptMode allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter FeasOptMode indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a sum of required relaxations; as the number of constraints and bounds required to be relaxed; as a sum of the squares of required relaxations). Please check description of parameters FeasOpt and FeasOptMode for details. Also check example models feasopt* in the GAMS Model library.
5.11.6.8 Sensitivity Analysis

Sensitivity analysis (post-optimality analysis) in linear programming allows one to find out more about an optimal solution for a problem. In particular, objective ranging and right-hand-side ranging give information about how much an objective coefficient or a right-hand-side value can change without changing the optimal basis. In other words, they give information about how sensitive the optimal basis is to a change in the objective function or a right-hand-side.

Although not so much used for practical large scale problems and not available for mixed-integer or nonlinear models, ranging information can still be of use in some circumstances. This section describes how to produce ranging information with GAMS/CPLEX.

To obtain objective ranging information for a particular variable, the name of the GAMS variable should be specified with the ObjRng option. For example, to obtain ranging information for a variable prod, add the line

```
objrng prod
```
to a CPLEX options file. The ObjRng option can be repeated to specify ranging for more than one variable. To specify ranging for all variables, use the keyword all, i.e.,

```
objrng all
```

Similarly, to obtain right-hand-side ranging information for a particular equation, the name of the equation should be specified with the RhsRng option. Also this option can be repeated to obtain right-hand-side ranging information for several equations. To specify ranging for all equations use the keyword all.

As an example, consider solving the model [TRNSPORT] from the GAMS model library with CPLEX and options file

```
objrng all
rhrng all
```

This gives the following table in the listing file:

```
<table>
<thead>
<tr>
<th>EQUATION NAME</th>
<th>LOWER</th>
<th>CURRENT</th>
<th>UPPER</th>
</tr>
</thead>
<tbody>
<tr>
<td>cost</td>
<td>-INF</td>
<td>0</td>
<td>+INF</td>
</tr>
<tr>
<td>supply(seattle)</td>
<td>300</td>
<td>350</td>
<td>625</td>
</tr>
<tr>
<td>supply(san-diego)</td>
<td>550</td>
<td>600</td>
<td>+INF</td>
</tr>
<tr>
<td>demand(new-york)</td>
<td>50</td>
<td>325</td>
<td>375</td>
</tr>
<tr>
<td>demand(chicago)</td>
<td>25</td>
<td>300</td>
<td>350</td>
</tr>
<tr>
<td>demand(topeka)</td>
<td>0</td>
<td>275</td>
<td>325</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>VARIABLE NAME</th>
<th>LOWER</th>
<th>CURRENT</th>
<th>UPPER</th>
</tr>
</thead>
<tbody>
<tr>
<td>x(seattle, new-york)</td>
<td>0.216</td>
<td>0.225</td>
<td>0.225</td>
</tr>
<tr>
<td>x(seattle, chicago)</td>
<td>0</td>
<td>0.153</td>
<td>0.162</td>
</tr>
<tr>
<td>x(seattle, topeka)</td>
<td>0.126</td>
<td>0.162</td>
<td>+INF</td>
</tr>
<tr>
<td>x(san-diego, new-york)</td>
<td>0.225</td>
<td>0.225</td>
<td>0.234</td>
</tr>
<tr>
<td>x(san-diego, chicago)</td>
<td>0.153</td>
<td>0.162</td>
<td>+INF</td>
</tr>
<tr>
<td>x(san-diego, topeka)</td>
<td>0</td>
<td>0.126</td>
<td>0.162</td>
</tr>
<tr>
<td>z</td>
<td>-INF</td>
<td>1</td>
<td>+INF</td>
</tr>
</tbody>
</table>
```
If obtaining ranging information in a listing file is not sufficient, option \texttt{RngRestart} can be used to specify a file to which to write ranging information in GAMS syntax. For example, using an options file containing

\begin{verbatim}
  rhsrng supply
  rhsrng demand
  rngrestart ranges.inc
\end{verbatim}

will result in a file named \texttt{ranges.inc} being written with the following content:

\begin{verbatim}
* Include file with ranging information
* The set RNGLIM /LO,UP/ is assumed to be declared.
PARAMETER supplyRNG(i,RNGLIM) /
  seattle.LO  300
  seattle.UP  625
  san-diego.LO 550
  san-diego.UP +INF
/;
PARAMETER demandRNG(j,RNGLIM) /
  new-york.LO   50
  new-york.UP  375
  chicago.LO   25
  chicago.UP   350
  topeka.LO    0
  topeka.UP   325
/;
\end{verbatim}

For each equation specified, the ranging information is stored in a newly declared corresponding GAMS parameter. The name of the parameter is based on the name of the equation, but with \texttt{RNG} appended. The user is responsible for ensuring that the new name does not exceed the maximum symbol name length of GAMS identifiers. Further, the domain list of the new parameter is the same as the domain list for the corresponding equation with an additional dimension added to the end. The user is responsible for ensuring that the new parameter does not exceed the maximum number of index positions.

5.11.7 GAMS/Cplex Log File

Cplex reports its progress by writing to the GAMS log file as the problem solves. Normally the GAMS log file is directed to the computer screen.

The log file shows statistics about the presolve and continues with an iteration log.

For the primal simplex algorithm, the iteration log starts with the iteration number followed by the scaled infeasibility value. Once feasibility has been attained, the objective function value is listed instead. At the default value for option \texttt{simdisplay} there is a log line for each refactorization. The screen log has the following appearance:

\begin{verbatim}
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time = 0.01 sec.
Using conservative initial basis.
\end{verbatim}
Iteration log . . .
Iteration:  1  Scaled infeas  =  193998.067174
Iteration:  29  Objective  =  -3484.286415
Switched to devex.
Iteration:  98  Objective  =  -1852.931117
Iteration:  166  Objective  =  -349.706562

Optimal solution found.

Objective :  901.161538

The iteration log for the dual simplex algorithm is similar, but the dual infeasibility and dual objective are reported instead of the corresponding primal values:

Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time =  0.01 sec.

Iteration log . . .
Iteration:  1  Scaled dual infeas  =  3.890823
Iteration:  53  Dual objective  =  4844.392441
Iteration:  114  Dual objective  =  1794.360714
Iteration:  176  Dual objective  =  1120.183325
Iteration:  238  Dual objective  =  915.143030
Removing shift (1).

Optimal solution found.

Objective :  901.161538

The log for the network algorithm adds statistics about the extracted network and a log of the network iterations. The optimization is finished by one of the simplex algorithms and an iteration log for that is produced as well.

Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time =  0.01 sec.

Iteration log . . .
Iteration:  0  Infeasibility  =  1232.378800 (-1.32326e+12)

Network - Optimal:  Objective  =  1.5716820779e+03
Network time =  0.01 sec.  Iterations = 26 (24)

Iteration log . . .
Iteration:  1  Scaled infeas  =  212696.154729
Iteration:  62  Scaled infeas  =  10020.401232
Iteration:  142  Scaled infeas  =  4985.200129
Switched to devex.
Iteration:  217  Objective  =  -3883.782587
Iteration: 291  Objective  =  -1423.126582

Optimal solution found.

Objective : 901.161538

The log for the barrier algorithm adds various algorithm specific statistics about the problem before starting the iteration log. The iteration log includes columns for primal and dual objective values and infeasibility values. A special log follows for the crossover to a basic solution.

Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time = 0.02 sec.
Number of nonzeros in lower triangle of A'A' = 6545
Using Approximate Minimum Degree ordering
Total time for automatic ordering = 0.01 sec.

For MIP problems, during the branch and bound search, Cplex reports the node number, the number of nodes left, the value of the Objective function, the number of integer variables that have fractional values, the current best integer solution, the best relaxed solution at a node and an iteration count. The last column show the current optimality gap as a percentage. CPLEX logs an asterisk (*) in the left-most column for any node where it finds an integer-feasible solution or new incumbent. The + denotes an incumbent generated by the heuristic.

Relative gap: 1.5

5.11.8 Detailed Descriptions of CPLEX Options

These options should be entered in the options file after setting the GAMS ModelName.OptFile parameter to 1. The name of the options file is cplex.opt. The options file is case insensitive and the keywords should be given in full.

**advind** (integer): advanced basis use

Use an Advanced Basis. GAMS/Cplex will automatically use an advanced basis from a previous solve statement. The GAMS BRatio option can be used to specify when not to use an advanced basis. The Cplex option AdvInd can be used to ignore a basis passed on by GAMS (it overrides BRatio).

Default: determined by GAMS Bratio

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tr>
<tr>
<td>1</td>
<td>Use advanced basis if available</td>
</tr>
<tr>
<td>2</td>
<td>Crash an advanced basis if available (use basis with presolve)</td>
</tr>
</tbody>
</table>

**aggcutlim** (integer): aggregation limit for cut generation

Limits the number of constraints that can be aggregated for generating flow cover and mixed integer rounding cuts. For most purposes, the default will be satisfactory.

Default: 3

**aggfill** (integer): aggregator fill parameter

Aggregator fill limit. If the net result of a single substitution is more non-zeros than the setting of the AggFill parameter, the substitution will not be made.

Default: 10

**aggind** (integer): aggregator on/off

This option, when set to a nonzero value, will cause the Cplex aggregator to use substitution where possible to reduce the number of rows and columns in the problem. If set to a positive value, the aggregator will be applied the specified number of times, or until no more reductions are possible. At the default value of -1, the aggregator is applied once for linear programs and an unlimited number of times for mixed integer problems.

Default: -1

<table>
<thead>
<tr>

<td>Do not use</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Aggregator will be applied the specified number of times</td>
</tr>
</tbody>
</table>
auxrootthreads (integer): number of threads for auxiliary tasks at the root node

Partitions the number of threads for CPLEX to use for auxiliary tasks while it solves the root node of a problem. On a system that offers $N$ processors or $N$ global threads, if you set this parameter to $n$, where $N>n>0$ then CPLEX uses at most $n$ threads for auxiliary tasks and at most $N-n$ threads to solve the root node. See also the parameter Threads.

You cannot set $n$, the value of this parameter, to a value greater than or equal to $N$, the number of processors or global threads offered on your system. In other words, when you set this parameter to a value other than its default, that value must be strictly less than the number of processors or global threads on your system. Independent of the auxiliary root threads parameter, CPLEX will never use more threads than those defined by the global default thread count parameter. CPLEX also makes sure that there is at least one thread available for the main root tasks. For example, if you set the global threads parameter to 3 and the auxiliary root threads parameter to 4, CPLEX still uses only two threads for auxiliary root tasks in order to keep one thread available for the main root tasks. At its default value, 0 (zero), CPLEX automatically chooses the number of threads to use for the primary root tasks and for auxiliary tasks. The number of threads that CPLEX uses to solve the root node depends on several factors: 1) the number of processors available on your system; 2) the number of threads available to your application on your system (for example, as a result of limited resources or competition with other applications); 3) the value of the global default thread count parameter Threads.

Default: 0

<table>

<tr>
<td>$N&gt;n&gt;0$</td>
<td>Use $n$ threads for auxiliary root tasks</td>
</tr>
</tbody>
</table>

baralg (integer): algorithm selection

Selects which barrier algorithm to use. The default setting of 0 uses the infeasibility-estimate start algorithm for LPs and MIP subproblems and the standard barrier algorithm, option 3, for other cases. The standard barrier algorithm is almost always fastest. The alternative algorithms, options 1 and 2, may eliminate numerical difficulties related to infeasibility, but will generally be slower.

Default: 0

<table>

</tr>
<tr>
<td>3</td>
<td>standard barrier algorithm</td>
</tr>
</tbody>
</table>

barcolnz (integer): dense column handling

Determines whether or not columns are considered dense for special barrier algorithm handling. At the default setting of 0, this parameter is determined dynamically. Values above 0 specify the number of entries in columns to be considered as dense.

Default: 0

barcrossalg (integer): barrier crossover method
Selects which crossover method is used at the end of a barrier optimization. To turn off crossover set `SolutionType` to 2.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>Primal crossover</td>

`barrdisplay` (integer): progress display level

Determines the level of progress information to be displayed while the barrier method is running.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No progress information</td>
</tr>
<tr>
<td>1</td>
<td>Display normal information</td>
</tr>
<tr>
<td>2</td>
<td>Display diagnostic information</td>
</tr>
</tbody>
</table>

`barepcomp` (real): convergence tolerance

Determines the tolerance on complementarity for convergence of the barrier algorithm. The algorithm will terminate with an optimal solution if the relative complementarity is smaller than this value.

Default: 1.0e-08

`bargrowth` (real): unbounded face detection

Used by the barrier algorithm to detect unbounded optimal faces. At higher values, the barrier algorithm will be less likely to conclude that the problem has an unbounded optimal face, but more likely to have numerical difficulties if the problem does have an unbounded face.

Default: 1.0e+12

`baritlim` (integer): iteration limit

Determines the maximum number of iterations for the barrier algorithm. When set to 0, no Barrier iterations occur, but problem setup occurs and information about the setup is displayed (such as Cholesky factorization information). When left at the default value, there is no explicit limit on the number of iterations.

Default: `large`

`barmaxcor` (integer): maximum correction limit

Specifies the maximum number of centering corrections that should be done on each iteration. Larger values may improve the numerical performance of the barrier algorithm at the expense of computation time. The default of -1 means the number is automatically determined.

Default: -1
**barobjrng** *(real): maximum objective function* →

Determines the maximum absolute value of the objective function. The barrier algorithm looks at this limit to detect unbounded problems.

Default: 1.0e+20

**barorder** *(integer): row ordering algorithm selection* →

Determines the ordering algorithm to be used by the barrier method. By default, Cplex attempts to choose the most effective of the available alternatives. Higher numbers tend to favor better orderings at the expense of longer ordering run times. The automatic option includes additional processing and may yield results that differ from the explicit choice.

Default: 0

<table>

</tbody>
</table>

**barqcpepcomp** *(real): convergence tolerance for the barrier optimizer for QCPs* →

Range: [1.0e-12, 1.0e+75]

Default: 1.0e-07

**barstartalg** *(integer): barrier starting point algorithm* →

This option sets the algorithm to be used to compute the initial starting point for the barrier solver. The default starting point is satisfactory for most problems. Since the default starting point is tuned for primal problems, using the other starting points may be worthwhile in conjunction with the **PreDual** parameter.

Default: 1

<table>
<thead>
<tr>

<tr>
<td>3</td>
<td>primal average, dual is 0</td>
</tr>
<tr>
<td>4</td>
<td>primal average, estimate dual</td>
</tr>
</tbody>
</table>

**bbinterval** *(integer): best bound interval* →

Set interval for selecting a best bound node when doing a best estimate search. Active only when **NodeSel** is 2 (best estimate). Decreasing this interval may be useful when best estimate is finding good solutions but making little progress in moving the bound. Increasing this interval may help when the best estimate node selection is not finding any good integer solutions. Setting the interval to 1 is equivalent to setting **NodeSel** to 1.

Default: 7
**bendersfeascuttol** (real): Tolerance for whether a feasibility cut has been violated in Benders decomposition

Default: $1.0 \times 10^{-6}$

**bendersoptcuttol** (real): Tolerance for optimality cuts in Benders decomposition

Default: $1.0 \times 10^{-6}$

**.benderspartition** (integer): Benders partition

Default: 0

**benderspartitioninstage** (boolean): Benders partition through stage variable suffix

Default: 0

**bendersstrategy** (integer): Benders decomposition algorithm as a strategy

Given a formulation of a problem, CPLEX can decompose the model into a single master and (possibly multiple) subproblems. To do so, CPLEX can make use of annotations that you supply for your model. The strategy can be applied to mixed-integer linear programs (MILP). For certain types of problems, this approach offers significant performance improvements as subproblems can be solved in parallel.

For mixed integer programs (MIP), under certain conditions, CPLEX can apply Benders algorithm to improve the search to find more feasible solutions more quickly.

Default: 0

<table>
<thead>
<tr>

<td>Apply user annotations</td>
</tr>
<tr>
<td>2</td>
<td>Apply user annotations with automatic support for subproblems</td>
</tr>
</tbody>
</table>
value | meaning
---|---
3 | Apply automatic decomposition. CPLEX ignores any annotation supplied with the model; CPLEX applies presolve; CPLEX then automatically generates a Benders partition, putting integer variables in master and continuous linear variables into disjoint subproblems. CPLEX then solves the Benders decomposition of the model. If the problem is a strictly linear program (LP), that is, there are no integer-constrained variables to put into master, then CPLEX reports an error. If the problem is a mixed integer linear program (MILP) where all variables are integer-constrained, (that is, there are no continuous linear variables to decompose into disjoint subproblems) then CPLEX reports an error.

bndrng (string): do lower / upper bound ranging

Calculate sensitivity ranges for the specified GAMS lower and upper bounds. Unlike most options, BNDRng can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS lower and upper bound named. Specifying all will cause range information to be produced for all lower and upper bounds. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option RngRestart is specified.

bndstrenind (integer): bound strengthening

Use bound strengthening when solving mixed integer problems. Bound strengthening tightens the bounds on variables, perhaps to the point where the variable can be fixed and thus removed from consideration during the branch and bound algorithm. This reduction is usually beneficial, but occasionally, due to its iterative nature, takes a long time.

Default: -1

<table>

</tr>
<tr>
<td>3</td>
<td>Generate BQP cuts very aggressively</td>
</tr>
</tbody>
</table>

brdir (integer): set branching direction

Used to decide which branch (up or down) should be taken first at each node.

Default: 0
### bttol (real): backtracking limit

This option controls how often backtracking is done during the branching process. At each node, Cplex compares the objective function value or estimated integer objective value to these values at parent nodes; the value of the `bttol` parameter dictates how much relative degradation is tolerated before backtracking. Lower values tend to increase the amount of backtracking, making the search more of a pure best-bound search. Higher values tend to decrease the amount of backtracking, making the search more of a depth-first search. This parameter is used only once a first integer solution is found or when a cutoff has been specified.

Range: $[0.0, 1.0]$

Default: 1.0

### calcqcpduals (integer): calculate the dual values of a quadratically constrained problem

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not calculate dual values</td>
</tr>
<tr>
<td>1</td>
<td>Calculate dual values as long as it does not interfere with presolve reductions</td>
</tr>
<tr>
<td>2</td>
<td>Calculate dual values and disable any presolve reductions that would interfere</td>
</tr>
</tbody>
</table>

### cliques (integer): clique cut generation

Determines whether or not clique cuts should be generated during optimization.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Do not generate clique cuts</td>
</tr>
<tr>
<td>0</td>

<tr>
<td>2</td>
<td>Generate clique cuts aggressively</td>
</tr>
<tr>
<td>3</td>
<td>Generate clique cuts very aggressively</td>
</tr>
</tbody>
</table>

### clocktype (integer): clock type for computation time

Decides how computation times are measured for both reporting performance and terminating optimization when a time limit has been set. Small variations in measured time on identical runs may be expected on any computer system with any setting of this parameter.

Default: 2

<table>
<thead>
<tr>
<th>value</th>

</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>CPU time</td>
</tr>
<tr>
<td>2</td>
<td>Wall clock time</td>
</tr>
</tbody>
</table>
**clonelog (integer):** enable clone logs

The clone logs contain information normally recorded in the ordinary log file but inconvenient to send through the normal log channel in case of parallel execution. The information likely to be of most interest to you are special messages, such as error messages, that result from calls to the LP optimizers called for the subproblems. The clone log files are named cloneK.log, where $K$ is the index of the clone, ranging from 0 (zero) to the number of threads minus one. Since the clones are created at each call to a parallel optimizer and discarded when it exits, the clone logs are opened at each call and closed at each exit. The clone log files are not removed when the clones themselves are discarded.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Clone log files off</td>
</tr>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>Clone log files on</td>
</tr>
</tbody>
</table>

**coeredind (integer):** coefficient reduction on/off

Coefficient reduction is a technique used when presolving mixed integer programs. The benefit is to improve the objective value of the initial (and subsequent) linear programming relaxations by reducing the number of non-integral vertexes. However, the linear programs generated at each node may become more difficult to solve.

Default: -1

<table>
<thead>
<tr>
<th>value</th>

<td>No output</td>
</tr>
<tr>
<td>1</td>
<td>Summary display</td>
</tr>
<tr>
<td>2</td>
<td>Detailed display</td>
</tr>
</tbody>
</table>

**covers (integer):** cover cut generation

Determines whether or not cover cuts should be generated during optimization.
Default: 0
The value of this parameter serves as a switch to turn on (or to turn off) CPLEX binding of multiple threads to multiple processors on platforms where this feature is available. Hexadecimal values of this parameter serve as a mask to specify to CPLEX which processors (or cores) to use in binding multiple threads to multiple processors. CPU binding is also sometimes known as processor affinity. CPU binding reduces the variability of CPLEX runs. On some occasions, running the same CPLEX on the same (non trivial) models would produce a big variation in runtime, e.g. 1000 seconds versus 900 seconds on a 12 core machine. These differences happen while CPLEX still gets exactly the same results and executes the exact same path, thanks to its completely deterministic algorithms. Running the same tests with CPU binding enabled reduced this variability in running time significantly.

If not set to off or auto CPLEX treats the value of this parameter as a string that resembles a hexadecimal number without the usual 0x prefix. A valid string consists of these elements: a) any digit from 0 (zero) through 9 (inclusive), b) any lower case character in the range a through f (inclusive), and c) any upper case character in the range A through F (inclusive). CPLEX rejects a string containing any other digits or characters than those.

When the value of this parameter is a valid string, each bit of this string corresponds to a central processing unit (CPU), that is, to a processor or core. The lowest order bit of the string corresponds to the first logical CPU, and the highest order corresponds to the last logical CPU. For example, 00000001 designates processor #0, 00000003 designates processors #0 and #1, FFFFFFFF designates all processors #0 through #31. CPLEX uses the ith CPU if and only if the ith bit of this string is set to 1 (one). Tip: For GNU/Linux users, this parameter behaves like the taskset command (except that this parameter lacks the prefix 0x).

If this CPU mask parameter is set to a valid string that designates a hexadecimal number, but global Threads count is set to 0 (zero), then CPLEX still starts as many threads as the number of cores on the machine, but only the cores enabled in the mask will be used.

For example, if a user sets this CPU mask parameter to the hexadecimal value "f" on a 16-core machine, and the user sets the global Threads count to 0 (zero), the result is 16 threads. These 16 threads will be bound to the first four cores in a round-robin way: threads 1,5,9,13 to core 1, threads 2,6,10,14 to core 2 and so on. This situation is probably not what the user intended. Therefore, if you set this CPU mask parameter, then you should also set global threads count; indeed, you should set the threads parameter to the number of active cores designated by the mask.

For example, on a 16 core machine, consider the difference between the value "off" and the value ffff. If the value of this parameter is "off" CPLEX does no binding. If the value of this parameter is ffff, CPLEX binds threads to cores.

Default: auto
**craind (integer):** crash strategy (used to obtain starting basis) ➞

The crash option biases the way Cplex orders variables relative to the objective function when selecting an initial basis.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Primal: alternate ways of using objective coefficients. Dual: aggressive starting basis</td>
</tr>
<tr>
<td>0</td>
<td>Primal: ignore objective coefficients during crash. Dual: aggressive starting basis</td>
</tr>
<tr>
<td>1</td>
<td>Primal: alternate ways of using objective coefficients. Dual: default starting basis</td>
</tr>
</tbody>
</table>

**cutlo (real):** lower cutoff for tree search ➞

Sets the lower cutoff tolerance. When the problem is a maximization problem, CPLEX cuts off or discards solutions that are less than the specified cutoff value. If the model has no solution with an objective value greater than or equal to the cutoff value, then CPLEX declares the model infeasible. In other words, setting the lower cutoff value \( c \) for a maximization problem is similar to adding this constraint to the objective function of the model: \( \text{obj} \geq c \).

This option overrides the GAMS Cutoff setting.

This parameter is not effective with FeasOpt. FeasOpt cannot analyze an infeasibility introduced by this parameter. If you want to analyze such a condition, add an explicit objective constraint to your model instead.

Default: \(-1.0e+75\)

**cutpass (integer):** maximum number of cutting plane passes ➞

Sets the upper limit on the number of passes that will be performed when generating cutting planes on a mixed integer model.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>None</td>
</tr>
<tr>
<td>0</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Maximum passes to perform</td>
</tr>
</tbody>
</table>

**cuts (string):** default cut generation ➞

Allows generation setting of all optional cuts at once. This is done by changing the meaning of the default value (0: automatic) for the various Cplex cut generation options. The options affected are Cliques, Covers, DisjCuts, FlowCovers, FlowPaths, FracCuts, GUBCovers, ImplBd, LiftProjCuts, MCFCuts, MIDCuts, and Symmetry.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Do not generate cuts</td>
</tr>
<tr>
<td>0</td>
<td>Determined automatically</td>
</tr>
</tbody>
</table>
### cutsfactor (real): cut limit

This option limits the number of cuts that can be added. For values between zero and one inclusive (that is, in the range \([0.0, 1.0]\), CPLEX generates no cuts.

For values strictly greater than 1.0 (one), CPLEX limits the number of rows in the model with cuts added.

The limit on this total is the product of \textit{CutsFactor} times the original number of rows. If CPLEX has presolved the model, the \textit{original number of rows} is the number of rows in the presolved model. (This behavior with respect to a presolved model is unchanged.)

CPLEX regards negative values of this parameter as equivalent to the default value -1.0. That is, a negative value specifies no particular limit on the number of cuts. CPLEX computes and dynamically adjusts such a limit automatically.

Default: \(-1.0\)

### cutup (real): upper cutoff for tree search

Sets the upper cutoff tolerance. When the problem is a minimization problem, CPLEX cuts off or discards any solutions that are greater than the specified upper cutoff value. If the model has no solution with an objective value less than or equal to the cutoff value, CPLEX declares the model infeasible. In other words, setting an upper cutoff value \(c\) for a minimization problem is similar to adding this constraint to the objective function of the model: \(\text{obj} \leq c\).

This option overrides the GAMS Cutoff setting.

This parameter is not effective with FeasOpt. FeasOpt cannot analyze an infeasibility introduced by this parameter. If you want to analyze such a condition, add an explicit objective constraint to your model instead.

Default: \(1.0e+75\)

### datacheck (integer): controls data consistency checking and modeling assistance

When the value of this parameter is set to level 2, CPLEX turns on both data consistency checking and modeling assistance. At this level, CPLEX issues warnings at the start of the optimization about disproportionate values (too large, too small) in coefficients, bounds, and right-hand sides (RHS).

Default: 0
**depind** (*integer*): dependency checker on/off

This option determines if and when the dependency checker will be used.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic</td>
</tr>
<tr>
<td>0</td>
<td>Turn off dependency checking</td>
</tr>
<tr>
<td>1</td>
<td>Turn on only at the beginning of preprocessing</td>
</tr>
<tr>
<td>2</td>
<td>Turn on only at the end of preprocessing</td>
</tr>
<tr>
<td>3</td>
<td>Turn on at the beginning and at the end of preprocessing</td>
</tr>
</tbody>
</table>

**dettilim** (*real*): deterministic time limit

Sets a time limit expressed in ticks, a unit to measure work done deterministically.

The length of a deterministic tick may vary by platform. Nevertheless, ticks are normally consistent measures for a given platform (combination of hardware and software) carrying the same load. In other words, the correspondence of ticks to clock time depends on the hardware, software, and the current load of the machine. For the same platform and same load, the ratio of ticks per second stays roughly constant, independent of the model solved. However, for very short optimization runs, the variation of this ratio is typically high.

Default: 1.0e+75

**disjcuts** (*integer*): disjunctive cuts generation

Determines whether or not to generate disjunctive cuts during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Do not generate disjunctive cuts</td>
</tr>
<tr>
<td>0</td>
<td>Determined automatically</td>
</tr>
<tr>
<td>1</td>
<td>Generate disjunctive cuts moderately</td>
</tr>
<tr>
<td>2</td>
<td>Generate disjunctive cuts aggressively</td>
</tr>
<tr>
<td>3</td>
<td>Generate disjunctive cuts very aggressively</td>
</tr>
</tbody>
</table>

**divetype** (*integer*): MIP dive strategy

The MIP traversal strategy occasionally performs probing dives, where it looks ahead at both children nodes before deciding which node to choose. The default (automatic) setting chooses when to perform a probing dive, and the other two settings direct Cplex when to perform probing dives: never or always.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>Traditional dive</td>
</tr>
<tr>
<td>2</td>
<td>Probing dive</td>
</tr>
<tr>
<td>3</td>
<td>Guided dive</td>
</tr>
</tbody>
</table>
.divflt (real): solution pool range filter coefficients

A diversity filter for a solution pool (see option SolnPoo1) allows you generate solutions that
are similar to (or different from) a set of reference values that you specify for a set of binary
variables. In particular, you can use a diversity filter to generate more solutions that are
similar to an existing solution or to an existing partial solution.

A diversity filter drives the search for multiple solutions toward new solutions that satisfy
a measure of diversity specified in the filter. This diversity measure applies only to binary
variables. Potential new solutions are compared to a reference set. This reference set is
specified with this dot option. If no reference set is specified, the difference measure will be
computed relative to the other solutions in the pool. The diversity measure is computed by
summing the pair-wise absolute differences from solution and the reference values.

Default: 0

divfltlo (real): lower bound on diversity

Please check option DivFlt for general information on a diversity filter.

If you specify a lower bound on the diversity using DivFltLo, Cplex will look for solutions
that are different from the reference values. In other words, you can say, Give me solutions
that differ by at least this amount in this set of variables.

Default: mindouble

divfltup (real): upper bound on diversity

Please check option DivFlt for general information on a diversity filter.

If you specify an upper bound on diversity DivFltUp, Cplex will look for solutions similar to
the reference values. In other words, you can say, Give me solutions that are close to this one,
within this set of variables.

Default: maxdouble

dpriind (integer): dual simplex pricing

Pricing strategy for dual simplex method. Consider using dual steepest-edge pricing. Dual
steepest-edge is particularly efficient and does not carry as much computational burden as the
primal steepest-edge pricing.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tbody>
</table>

dynamicrows (integer): switch for dynamic management of rows

This parameter specifies how CPLEX should manage rows in the current model during dual
simplex optimization. More specifically, this parameter controls the use of the kernel simplex
method (KSM) for the dual simplex algorithm. That is, CPLEX dynamically adjusts the
dimensions of the basis matrix during execution of the dual simplex algorithm, according to
the settings of this parameter.

When the value of this parameter is -1, its default value, this parameter specifies that the
user wants CPLEX to manage rows dynamically, adjusting the dimensions of the basis matrix
during dual simplex optimization. When it is set to 0, this parameter specifies that CPLEX
must keep all rows. When it is set to 1, this parameter specifies that CPLEX can keep or
discard rows according to its internal calculations.

Default: -1

</tbody>
</table>

eachcutlim (integer): sets a limit for each type of cut

This parameter allows you to set a uniform limit on the number of cuts of each type that
Cplex generates. By default, the limit is a large integer; that is, there is no effective limit by
default.

Tighter limits on the number of cuts of each type may benefit certain models. For example, a
limit on each type of cut will prevent any one type of cut from being created in such large
number that the limit on the total number of all types of cuts is reached before other types of
cuts have an opportunity to be created. A setting of 0 means no cuts.

This parameter does not influence the number of Gomory cuts. For means to control the
number of Gomory cuts, see also the fractional cut parameters: FracCand, FracCuts, and
FracPass.

Default: 2100000000

epagap (real): absolute stopping tolerance

Synonym: optca

Absolute tolerance on the gap between the best integer objective and the objective of the best
node remaining. When the value falls below the value of the epagap setting, the optimization
is stopped. This option overrides GAMS OptCA which provides its initial value.

Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can
thus influence the solution path.

Default: GAMS OptCA

epgap (real): relative stopping tolerance

Synonym: optcr

Relative tolerance on the gap between the best integer objective and the objective of the best
node remaining. When the value falls below the value of the epgap setting, the mixed integer
optimization is stopped. Note the difference in the Cplex definition of the relative tolerance
with the GAMS definition. This option overrides GAMS OptCR which provides its initial
value.

Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can
thus influence the solution path.

Range: [0.0, 1.0]

Default: GAMS OptCR
epint (real): integrality tolerance

Integality Tolerance. This specifies the amount by which an integer variable can be different than an integer and still be considered feasible.
Range: [0.0, 0.5]
Default: 1.0e-05

eplin (real): degree of tolerance used in linearization

Default: 0.001

epmrk (real): Markowitz pivot tolerance

The Markowitz tolerance influences pivot selection during basis factorization. Increasing the Markowitz threshold may improve the numerical properties of the solution.
Range: [1.0e-04, 1.0]
Default: 0.01

epopt (real): optimality tolerance

The optimality tolerance influences the reduced-cost tolerance for optimality. This option setting governs how closely Cplex must approach the theoretically optimal solution.
Range: [1.0e-09, 0.1]
Default: 1.0e-06

epper (real): perturbation constant

Perturbation setting. Highly degenerate problems tend to stall optimization progress. Cplex automatically perturbs the variable bounds when this occurs. Perturbation expands the bounds on every variable by a small amount thereby creating a different but closely related problem. Generally, the solution to the less constrained problem is easier to solve. Once the solution to the perturbed problem has advanced as far as it can go, Cplex removes the perturbation by resetting the bounds to their original values.

If the problem is perturbed more than once, the perturbation constant is probably too large. Reduce the epper option to a level where only one perturbation is required. Any value greater than or equal to 1.0e-8 is valid.
Default: 1.0e-06

eprhs (real): feasibility tolerance

Feasibility tolerance. This specifies the degree to which a problem’s basic variables may violate their bounds. This tolerance influences the selection of an optimal basis and can be reset to a higher value when a problem is having difficulty maintaining feasibility during optimization. You may also wish to lower this tolerance after finding an optimal solution if there is any doubt that the solution is truly optimal. If the feasibility tolerance is set too low, Cplex may falsely conclude that a problem is infeasible.
Range: [1.0e-09, 0.1]
Default: 1.0e-06

exactkappa (boolean): report exact condition number in quality report

Default: 0

feasopt (boolean): computes a minimum-cost relaxation to make an infeasible model feasible

With Feasopt turned on, a minimum-cost relaxation of the right hand side values of constraints or bounds on variables is computed in order to make an infeasible model feasible. It marks the relaxed right hand side values and bounds in the solution listing.
Several options are available for the metric used to determine what constitutes a minimum-cost relaxation which can be set by option FeasOptMode.
Feasible relaxations are available for all problem types with the exception of quadratically constrained problems.
Default: 0
feasoptmode (integer): mode of FeasOpt

The parameter FeasOptMode allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter FeasOptMode indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the minimality of the relaxation (as a sum of required relaxations; as the number of constraints and bounds required to be relaxed; as a sum of the squares of required relaxations).

Default: 0

</tbody>
</table>

.feaspref (real): feasibility preference

You can express the costs associated with relaxing a bound or right hand side value during a FeasOpt run through the .feaspref option. The input value denotes the users willingness to relax a constraint or bound. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed.

Default: 1

fixoptfile (string): name of option file which is read just before solving the fixed problem

flowcovers (integer): flow cover cut generation

Determines whether or not flow cover cuts should be generated during optimization.

Default: 0
**flowpaths (integer):** flow path cut generation

Determines whether or not flow path cuts should be generated during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

freegamsmodel (boolean): preserves memory by dumping the GAMS model instance representation temporarily to disk ←

In order to provide the maximum amount of memory to the solver this option dumps the internal representation of the model instance temporarily to disk and frees memory. This option only works with SolveLink=0 and only for models without quadratic constraints.

Default: 0

gubcovers (integer): GUB cover cut generation ←

Determines whether or not GUB (Generalized Upper Bound) cover cuts should be generated during optimization. The default of 0 indicates that the attempt to generate GUB cuts should continue only if it seems to be helping.

Default: 0

<table>
<thead>
<tr>

<td>Call heuristic at the requested node interval</td>
</tr>
</tbody>
</table>

**heuristicEffort** *(real)*: the effort that CPLEX spends on heuristics during a MIP solve ↔

The value is used to increase (if >1) or decrease (if <1) the effort that CPLEX spends on heuristics during a MIP solve. If set to 0, no heuristic will run.

Default: 1.0

**iafile** *(string)*: secondary option file to be read in interactive mode triggered by iatiggerfile ↔

If in interactive mode and this option is set, options will be read from the file specified by this option instead of direct user input (as described in interactive). This option file read can be triggered by interrupting Cplex with a Control-C or using the option iatiggerfile. If defined, GAMS/CPLEX looks for this file (content irrelevant) all iatriggertime seconds and if found, reads the option file iafile. The iatiggerfile is removed afterwards so it does not trigger twice.

**iatiggerfile** *(string)*: file that triggers the reading of a secondary option file in interactive mode ↔

See iafile.

**iatriggertime** *(real)*: time interval in seconds the link looks for the trigger file in interactive mode ↔

See iafile.

Default: 60

**iis** *(boolean)*: run the conflict refiner also known as IIS finder if the problem is infeasible ↔

Find an set of conflicting constraints or IIS (Irreducably Inconsistent Set) and write an conflict report to the GAMS solution listing if the model is found to be infeasible.

Default: 0

**implbd** *(integer)*: implied bound cut generation ↔

Determines whether or not implied bound cuts should be generated during optimization.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Do not generate implied bound cuts</td>
</tr>
<tr>
<td>0</td>
<td>Determined automatically</td>
</tr>
<tr>
<td>1</td>
<td>Generate implied bound cuts moderately</td>
</tr>
<tr>
<td>2</td>
<td>Generate implied bound cuts aggressively</td>
</tr>
</tbody>
</table>

**indicoptstrict** *(boolean)*: abort in case of an error in indicator constraint in solver option file ↔

If enabled and a variable or equation specified in an indicator constraint is not present in the model, model generation will abort with an error message. Otherwise, if this option is disabled, erroneous indicator constraints are ignored and a warning is printed.
Default: 1

**interactive (boolean):** allow interactive option setting after a Control-C

When set to yes, options can be set interactively after interrupting Cplex with a Control-C. Options are entered just as if they were being entered in the `cplex.opt` file. Control is returned to Cplex by entering `continue`. The optimization can be aborted by entering `abort`. This option can only be used when running from the command line. Moreover, the GAMS option `InteractiveSolver` needs to be set to 1.

Default: 0

**intsollim (integer):** maximum number of integer solutions

This option limits the MIP optimization to finding only this number of mixed integer solutions before stopping.

Default: `large`

**itlim (integer):** iteration limit

Synonym: `iterlim`

The iteration limit option sets the maximum number of iterations before the algorithm terminates, without reaching optimality. This Cplex option overrides the GAMS `IterLim` option. Any non-negative integer value is valid.

Default: `GAMS IterLim`

**.lazy (boolean):** Lazy constraints activation

Determines whether a linear constraint is treated as a lazy constraint. At the beginning of the MIP solution process, any constraint whose Lazy attribute is set to 1 (the default value is 0) is removed from the model and placed in the lazy constraint pool. Lazy constraints remain inactive until a feasible solution is found, at which point the solution is checked against the lazy constraint pool. If the solution violates any lazy constraint, the solution is discarded and one or more of the violated lazy constraints are pulled into the active model.

Lazy constraints are only active if option `LazyConstraints` is enabled and are specified through the option `.lazy`. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: 0

**lazysolver (boolean):** Indicator to use lazy constraints

Default: 0

**lbheur (boolean):** local branching heuristic

This parameter lets you control whether Cplex applies a local branching heuristic to try to improve new incumbents found during a MIP search. By default, this parameter is off. If you turn it on, Cplex will invoke a local branching heuristic only when it finds a new incumbent. If Cplex finds multiple incumbents at a single node, the local branching heuristic will be applied only to the last one found.

Default: 0
liftprojcuts \((\text{integer})\): lift-and-project cuts

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>

</tr>
</tbody>
</table>

lowerobjstop \((\text{real})\): in a minimization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value lower than or equal to the specified value

Default: \(-1e75\)

lpmethod \((\text{integer})\): algorithm to be used for LP problems

Specifies which LP algorithm to use. If left at the default value (0 for automatic), and a primal-feasible basis is available, primal simplex will be used. If no primal-feasible basis is available, and Threads is equal to 1, dual simplex will be used. If Threads is greater than 1 and no primal-feasible basis is available, the concurrent option will be used.

Sifting may be useful for problems with many more variables than equations.

The concurrent option runs multiple methods in parallel. The first thread uses dual simplex. The second thread uses barrier. The next thread uses primal simplex. Remaining threads are used by the barrier run. If the aspect ratio (number of columns versus number of rows) is large, and if more than 10 threads are available, then concurrent optimization also invokes sifting on the LP. The solution is returned by first method to finish.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>Primal Simplex</td>
</tr>
</tbody>
</table>
**ltol (real)**: basis identification primal tolerance

Default: 0

**mcfcuts (integer)**: multi-commodity flow cut generation

Specifies whether Cplex should generate multi-commodity flow (MCF) cuts in a problem where Cplex detects the characteristics of a multi-commodity flow network with arc capacities. By default, Cplex decides whether or not to generate such cuts. To turn off generation of such cuts, set this parameter to -1. Cplex is able to recognize the structure of a network as represented in many real-world models. When it recognizes such a network structure, Cplex is able to generate cutting planes that usually help solve such problems. In this case, the cuts that Cplex generates state that the capacities installed on arcs pointing into a component of the network must be at least as large as the total flow demand of the component that cannot be satisfied by flow sources within the component.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>2</td>
<td>Generate MCF cuts aggressively</td>
</tr>
</tbody>
</table>

**memoryemphasis (boolean)**: reduces use of memory

This parameter lets you indicate to Cplex that it should conserve memory where possible. When you set this parameter to its non default value, Cplex will choose tactics, such as data compression or disk storage, for some of the data computed by the barrier and MIP optimizers. Of course, conserving memory may impact performance in some models. Also, while solution information will be available after optimization, certain computations that require a basis that has been factored (for example, for the computation of the condition number Kappa) may be unavailable.

Default: 0

<table>
<thead>

</tr>
</tbody>
</table>

**mipinterval** *(integer):* progress display interval

Controls the frequency of node logging when the parameter MIPDisplay is set higher than 1 (one). Frequency must be an integer; it may be 0 (zero), positive, or negative. By default, CPLEX displays new information in the node log during a MIP solve at relatively high frequency during the early stages of solving a MIP model, and adds lines to the log at progressively longer intervals as solving continues. In other words, CPLEX logs information frequently in the beginning and progressively less often as it works. When the value is a positive integer n, CPLEX displays new incumbents, plus it displays a new line in the log every n nodes. When the value is a negative integer n, CPLEX displays new incumbents, and the negative value determines how much processing CPLEX does before it displays a new line in the node log. A negative value close to zero means that CPLEX displays new lines in the log frequently. A negative value far from zero means that CPLEX displays new lines in the log less frequently. In other words, a negative value of this parameter contracts or dilates the interval at which CPLEX displays information in the node log.

Default: 0

**mipkappastats** *(integer):* MIP kappa computation

MIP kappa summarizes the distribution of the condition number of the optimal bases CPLEX encountered during the solution of a MIP model. That summary may let you know more about the numerical difficulties of your MIP model. Because MIP kappa (as a statistical distribution) requires CPLEX to compute the condition number of the optimal bases of the subproblems during branch-and-cut search, you can compute the MIP kappa only when CPLEX solves the subproblem with its simplex optimizer. In other words, in order to obtain results with this parameter, you can not use the sifting optimizer nor the barrier without crossover to solve the subproblems. See the parameters StartAlg and SubAlg.

Computing the kappa of a subproblem has a cost. In fact, computing MIP kappa for the basis matrices can be computationally expensive and thus generally slows down the solution of a
problem. Therefore, the setting 0 (automatic) tells CPLEX generally not to compute MIP kappa, but in cases where the parameter NumericalEmphasis is turned on, CPLEX computes MIP kappa for a sample of subproblems. The value 1 (sample) leads to a negligible performance degradation on average, but can slow down the branch-and-cut exploration by as much as 10% on certain models. The value 2 (full) leads to a 2% performance degradation on average, but can significantly slow the branch-and-cut exploration on certain models. In practice, the value 1 (sample) is a good trade-off between performance and accuracy of statistics. If you need very accurate statistics, then use value 2 (full).

In case CPLEX is instructed to compute a MIP kappa distribution, the parameter Quality is automatically turned on.

</tr>
</tbody>
</table>

mipordind (boolean): priority list on/off

Synonym: prioropt

Use priorities. Priorities should be assigned based on your knowledge of the problem. Variables with higher priorities will be branched upon before variables of lower priorities. This direction of the tree search can often dramatically reduce the number of nodes searched. For example, consider a problem with a binary variable representing a yes/no decision to build a factory, and other binary variables representing equipment selections within that factory. You would naturally want to explore whether or not the factory should be built before considering what specific equipment to purchased within the factory. By assigning a higher priority to the build/no build decision variable, you can force this logic into the tree search and eliminate wasted computation time exploring uninteresting portions of the tree. When set at 0 (default), the MIPOrdInd option instructs Cplex not to use priorities for branching. When set to 1, priority orders are utilized.

Note: Priorities are assigned to discrete variables using the .prior suffix in the GAMS model. Lower .prior values mean higher priority. The .prioropt model suffix has to be used to signal GAMS to export the priorities to the solver.

Default: GAMS PriorOpt

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use priorities for branching</td>
</tr>
<tr>
<td>1</td>
<td>Priority orders are utilized</td>
</tr>

<tr>
<td>3</td>
<td>increasing cost per coefficient count</td>
</tr>
</tbody>
</table>

mipstart (integer): use mip starting values

This option controls the use of advanced starting values for mixed integer programs. A setting of 2 indicates that the values should be checked to see if they provide an integer feasible solution before starting optimization. For mipstart equals 1, 2, 3 or 4 fractional values are rounded to the nearest integer value if the integrality violation is larger than CPLEX's integer tolerance and smaller or equal to tryint. A partial MIP start is applied for mipstart equals 1, 3 or 4. Here, for discrete variables only integer values (after possible rounding) are added to the advanced starting values.

Default: 0

<table>

| 2     | LP relaxation  
Cplex will solve a LP relaxation of the model at each node. |

mircuts (integer): mixed integer rounding cut generation

Determines whether or not to generate mixed integer rounding (MIR) cuts during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Do not generate MIR cuts</td>
</tr>
<tr>
<td>0</td>
<td>Determined automatically</td>
</tr>
<tr>
<td>1</td>

</tr>
<tr>
<td>2</td>
<td>Generate MIR cuts aggressively</td>
</tr>
</tbody>
</table>

mpslongnum (boolean): MPS file format precision of numeric output

Determines the precision of numeric output in the MPS file formats. When this parameter is set to its default value 1 (one), numbers are written to MPS files in full-precision; that is, up to 15 significant digits may be written. The setting 0 (zero) writes files that correspond to the standard MPS format, where at most 12 characters can be used to represent a value. This limit may result in loss of precision.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use limited MPS precision</td>
</tr>
<tr>
<td>1</td>
<td>Use full-precision</td>
</tr>
</tbody>
</table>

mtol (real): basis identification dual tolerance

Default: 0

multimipstart (string): use multiple mipstarts provided via gdx files

Specifies (multiple) GDX files with values for the variables. Each file is treated as one initial guess for the MIP start. These MIP starts are added in addition to the initial guess provided by the level attribute. A MIP start GDX file can be created, for example, by using the command line option savepoint.

multobj (boolean): controls the hierarchical optimization of multiple objectives
Default: 0

**multobjdisplay (integer):** level of display during multiobjective optimization ↔

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No display</td>
</tr>
<tr>
<td>1</td>
<td>Summary display after each subproblem</td>
</tr>
<tr>
<td>2</td>
<td>Summary display after each subproblem, as well as subproblem logs</td>
</tr>
</tbody>
</table>

**multobjmethod (integer):** method used for multi-objective solves ↔

When solving a continuous multi-objective model using a hierarchical approach, the model is solved once for each objective. The algorithm used to solve for the highest priority objective is controlled by the *LPMethod* parameter. This parameter determines the algorithm used to solve for subsequent objectives.

Default: 0

**multobjoptfiles (string):** List of option files used for individual solves within multi-objective optimization ↔

The options given by the option files in *multobjoptfiles* are applied on top of the default GAMS/CPLEX options. This includes options set by the user via the standard option file.

If the list of option files in *multobjoptfiles* is less than the number of objective functions, the default GAMS/CPLEX options (incl. user options as before) are used to solve the remaining instances. Additional option files (i.e. more than objective functions) are ignored.

Applied options can be verified by setting *multobjdisplay* to 2.

**multobjtolmip (boolean):** enables hard constraints for hierarchical optimization objectives based on degradation tolerances ↔

CPLEX supports two different strategies to handle the degradation tolerances *objnabstol* and *objnreltol* depending on the problem type (continuous or discrete), see *objnabstol*. This setting enables the discrete strategy for continuous models. Note that *objnreltol* has no effect for discrete models. Enabling this option can lead to higher solution times.

Default: 1

**names (boolean):** load GAMS names into Cplex ↔

This option causes GAMS names for the variables and equations to be loaded into Cplex. These names will then be used for error messages, log entries, and so forth. Setting names to no may help if memory is very tight.

Default: 1

**netdisplay (integer):** network display level ↔

This option controls the log for network iterations.

Default: 2
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No network log.</td>
</tr>
<tr>
<td>1</td>
<td>Displays true objective values</td>

<tr>
<td>2</td>
<td>Displays penalized objective values</td>
</tr>
</tbody>
</table>

**netepopt** *(real)*: optimality tolerance for the network simplex method

This optimality tolerance influences the reduced-cost tolerance for optimality when using the network simplex method. This option setting governs how closely Cplex must approach the theoretically optimal solution.

Range: \([1.0\text{e}-11, 0.1]\)

Default: 1.0e-06

**neteprhs** *(real)*: feasibility tolerance for the network simplex method

This feasibility tolerance determines the degree to which the network simplex algorithm will allow a flow value to violate its bounds.

Range: \([1.0\text{e}-11, 0.1]\)

Default: 1.0e-06

**netfind** *(integer)*: attempt network extraction

Specifies the level of network extraction to be done.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Extract pure network only</td>
</tr>
<tr>
<td>2</td>
<td>Try reflection scaling</td>
</tr>
<tr>
<td>3</td>
<td>Try general scaling</td>
</tr>
</tbody>
</table>

**netitlim** *(integer)*: iteration limit for network simplex

Iteration limit for the network simplex method.

Default: large

**netppriind** *(integer)*: network simplex pricing

Network simplex pricing algorithm. The default of 0 (currently equivalent to 3) shows best performance for most problems.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>

<td>Multiple partial pricing with sorting</td>
</tr>
</tbody>
</table>
nodecuts (integer): decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree

Default: 0

nodefileind (integer): node storage file indicator

Specifies how node files are handled during MIP processing. Used when parameter WorkMem has been exceeded by the size of the branch and cut tree. If set to 0 when the tree memory limit is reached, optimization is terminated. Otherwise a group of nodes is removed from the in-memory set as needed. By default, Cplex transfers nodes to node files when the in-memory set is larger than 128 MBytes, and it keeps the resulting node files in compressed form in memory. At settings 2 and 3, the node files are transferred to disk. They are stored under a directory specified by parameter WorkDir and Cplex actively manages which nodes remain in memory for processing.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No node files</td>
</tr>
<tr>
<td>1</td>
<td>Node files in memory and compressed</td>
</tr>
<tr>
<td>2</td>
<td>Node files on disk</td>
</tr>
<tr>
<td>3</td>
<td>Node files on disk and compressed</td>
</tr>
</tbody>
</table>

nodelim (integer): maximum number of nodes to solve

Synonym: nodlim

The maximum number of nodes solved before the algorithm terminates, without reaching optimality. This option overrides the GAMS NodLim model suffix. When this parameter is set to 0 (this is only possible through an option file), Cplex completes processing at the root; that is, it creates cuts and applies heuristics at the root. When this parameter is set to 1 (one), it allows branching from the root; that is, nodes are created but not solved.

Default: GAMS NodLim

nodesel (integer): node selection strategy

This option is used to set the rule for selecting the next node to process when backtracking.

Default: 1

<table>
<thead>
<tr>

</tbody>
</table>

numericaemphasis (boolean): emphasizes precision in numerically unstable or difficult problems
This parameter lets you indicate to Cplex that it should emphasize precision in numerically
difficult or unstable problems, with consequent performance trade-offs in time and memory.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Exercise extreme caution in computation</td>
</tr>
</tbody>
</table>

**objdif** *(real):* overrides GAMS Cheat parameter

Synonym: cheat

A means for automatically updating the cutoff to more restrictive values. Normally the most
recently found integer feasible solution objective value is used as the cutoff for subsequent
nodes. When this option is set to a positive value, the value will be subtracted from (added
to) the newly found integer objective value when minimizing (maximizing). This forces the
MIP optimization to ignore integer solutions that are not at least this amount better than
the one found so far. The option can be adjusted to improve problem solving efficiency by
limiting the number of nodes; however, setting this option at a value other than zero (the
default) can cause some integer solutions, including the true integer optimum, to be missed.
Negative values for this option will result in some integer solutions that are worse than or
the same as those previously generated, but will not necessarily result in the generation of all
possible integer solutions. This option overrides the GAMS Cheat parameter.

Default: 0.0

**objllim** *(real):* objective function lower limit

Setting a lower objective function limit will cause Cplex to halt the optimization process once
the minimum objective function value limit has been exceeded.

Default: -1.0e+75

**objnabstol** *(string):* allowable absolute degradation for objective

This parameter is used to set the allowable degradation for an objective when doing hierar-
chical multi-objective optimization *(MultObj).* The syntax for this parameter is `ObjNAbsTol
ObjVarName value`.

Hierarchical multi-objective optimization will optimize for the different objectives in the model
one at a time, in priority order. For MIPs *(or if MultObjTolMip is enabled)*, if it achieves
objective value `z` when it optimizes for this objective, then subsequent steps are allowed to
degrade this value by at most `ObjNAbsTol`. For LPs, `ObjNAbsTol` defines a threshold for
reduced costs above which nonbasic variables in the associated LP solve will be fixed at the
bound at which they reside.

**objnrealtol** *(string):* allowable relative degradation for objective

This parameter is used to set the allowable degradation for an objective when doing hierar-
chical multi-objective optimization *(MultObj).* The syntax for this parameter is `ObjNRelTol
ObjVarName value`.

Hierarchical multi-objective optimization will optimize for the different objectives in the model
one at a time, in priority order. For MIPs *(or if MultObjTolMip is enabled)*, if it achieves
objective value `z` when it optimizes for this objective, then subsequent steps are allowed to
degrade this value by at most `ObjNRelTol*|z|`. This option has no effect for continuous models.
objrng (string): do objective ranging

Calculate sensitivity ranges for the specified GAMS variables. Unlike most options, ObjRng can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS variable named. Specifying all will cause range information to be produced for all variables. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option RngRestart is specified.

Default: no objective ranging is done

objulim (real): objective function upper limit

Setting an upper objective function limit will cause Cplex to halt the optimization process once the maximum objective function value limit has been exceeded.

Default: 1.0e+75

optimalitytarget (integer): type of optimality that Cplex targets

This parameter specifies the type of solution that CPLEX attempts to compute with respect to the optimality of that solution when CPLEX solves a continuous (QP) or mixed integer (MIQP) quadratic model. In other words, the variables of the model can be continuous or mixed integer and continuous; the objective function includes a quadratic term, and perhaps the objective function is not positive semi-definite (non PSD). This parameter does not apply to quadratically constrained mixed integer problems (MIQCP); that is, this parameter does not apply to mixed integer problems that include a quadratic term among the constraints.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic CPLEX first attempts to compute a provably optimal solution. If CPLEX cannot compute a provably optimal solution because the objective function is not convex, CPLEX will return with an error (Q is not PSD).</td>
</tr>
<tr>
<td>1</td>
<td>Search for a globally optimal solution to a convex model CPLEX searches for a globally optimal solution to a convex model. In problems of type QP or MIQP, this setting interacts with linearization switch QToLin for QP, MIQP</td>
</tr>
<tr>
<td>2</td>
<td>Search for a solution that satisfies first-order optimality conditions no optimality guarantee CPLEX first attempt to compute a provably optimal solution. If CPLEX cannot compute a provably optimal solution because the objective function is not convex, CPLEX searches for a solution that satisfies first-order optimality conditions but is not necessarily globally optimal.</td>
</tr>
<tr>
<td>3</td>
<td>Search for a globally optimal solution regardless of convexity If the problem type is QP, CPLEX first changes the problem type to MIQP. CPLEX then solves the problem (whether originally QP or MIQP) to global optimality. In problems of type QP or MIQP, this setting interacts with with linearization switch QToLin for QP, MIQP. With this setting information about dual values is not available for the solution.</td>
</tr>
</tbody>
</table>

parallelmode (integer): parallel optimization mode

Sets the parallel optimization mode. Possible modes are automatic, deterministic, and opportunistic.
In this context, deterministic means that multiple runs with the same model at the same parameter settings on the same platform will reproduce the same solution path and results. In contrast, opportunistic implies that even slight differences in timing among threads or in the order in which tasks are executed in different threads may produce a different solution path and consequently different timings or different solution vectors during optimization executed in parallel threads. When running with multiple threads, the opportunistic setting entails less synchronization between threads and consequently may provide better performance.

In deterministic mode, Cplex applies as much parallelism as possible while still achieving deterministic results. That is, when you run the same model twice on the same platform with the same parameter settings, you will see the same solution and optimization run.

More opportunities to exploit parallelism are available if you do not require determinism. In other words, Cplex can find more opportunities for parallelism if you do not require an invariant, repeatable solution path and precisely the same solution vector. To use all available parallelism, you need to select the opportunistic parallel mode. In this mode, Cplex will utilize all opportunities for parallelism in order to achieve best performance.

However, in opportunistic mode, the actual optimization may differ from run to run, including the solution time itself. A truly parallel deterministic algorithm is available only for MIP optimization. Only opportunistic parallel algorithms (barrier and concurrent optimizers) are available for continuous models. (Each of the simplex algorithms runs sequentially on a continuous model.) Consequently, when parallel mode is set to deterministic, both barrier and concurrent optimizers are restricted to run only sequentially, not in parallel.

A GAMS/Cplex run will use deterministic mode unless explicitly specified.

If `ParallelMode` is explicitly set to 0 (automatic) the settings of this parallel mode parameter interact with settings of the `Threads` parameter. Let the result number of threads available to Cplex be $n$ (note that negative values for the threads parameter are possible to exclude work on some cores).

Here is is list of possible value:

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Enable opportunistic parallel search mode</td>
</tr>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>Enable deterministic parallel search mode</td>
</tr>
</tbody>
</table>

`perind (boolean): force initial perturbation ←`

Perturbation Indicator. If a problem automatically perturbs early in the solution process, consider starting the solution process with a perturbation by setting `PerInd` to 1. Manually perturbing the problem will save the time of first allowing the optimization to stall before activating the perturbation mechanism, but is useful only rarely, for extremely degenerate problems.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>not automatically perturbed</td>
</tr>
<tr>
<td>1</td>
<td>automatically perturbed</td>
</tr>
</tbody>
</table>
**perlim (integer):** number of stalled iterations before perturbation

Perturbation limit. The number of stalled iterations before perturbation is invoked. The default value of 0 means the number is determined automatically.

Default: 0

**polishafterdett ime (real):** deterministic time before starting to polish a feasible solution

Default: $1.0 \times 10^{75}$

**polishafterepgap (real):** absolute MIP gap before starting to polish a feasible solution

Solution polishing can yield better solutions in situations where good solutions are otherwise hard to find. More time-intensive than other heuristics, solution polishing is actually a variety of branch-and-cut that works after an initial solution is available. In fact, it requires a solution to be available for polishing, either a solution produced by branch-and-cut, or a MIP start supplied by a user. Because of the high cost entailed by solution polishing, it is not called throughout branch-and-cut like other heuristics. Instead, solution polishing works in a second phase after a first phase of conventional branch-and-cut. As an additional step after branch-and-cut, solution polishing can improve the best known solution. As a kind of branch-and-cut algorithm itself, solution polishing focuses solely on finding better solutions. Consequently, it may not prove optimality, even if the optimal solution has indeed been found. Like the RINS heuristic, solution polishing explores neighborhoods of previously found solutions by solving subMIPs.

Sets an absolute MIP gap (that is, the difference between the best integer objective and the objective of the best node remaining) after which CPLEX stops branch-and-cut and begins polishing a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: 0.0

**polishafterepgap (real):** relative MIP gap before starting to polish a solution

Sets a relative MIP gap after which CPLEX will stop branch-and-cut and begin polishing a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: 0.0

**polishafterintsol (integer):** MIP integer solutions to find before starting to polish a feasible solution

Sets the number of integer solutions to find before CPLEX stops branch-and-cut and begins to polish a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: 2147483647

**polishafternode (integer):** nodes to process before starting to polish a feasible solution

Sets the number of nodes processed in branch-and-cut before CPLEX starts solution polishing, if a feasible solution is available.

Default: 2147483647

**polishaftertime (real):** time before starting to polish a feasible solution
Tells CPLEX how much time in seconds to spend during mixed integer optimization before CPLEX starts polishing a feasible solution. The default value is such that CPLEX does not start solution polishing by default.

Default: 1.0e+75

**populatelim (integer):** limit of solutions generated for the solution pool by populate method

Limits the number of solutions generated for the solution pool during each call to the populate procedure. Populate stops when it has generated `PopulateLim` solutions. A solution is counted if it is valid for all filters (see `DivFlt` and consistent with the relative and absolute pool gap parameters (see `SlnPoolGap` and `SlnPoolAGap`), and has not been rejected by the incumbent checking routine (see `UserIncbCall`), whether or not it improves the objective of the model. This parameter does not apply to MIP optimization generally; it applies only to the populate procedure.

If you are looking for a parameter to control the number of solutions stored in the solution pool, consider the parameter `SlnPoolCapacity` instead.

Populate will stop before it reaches the limit set by this parameter if it reaches another limit, such as a time or node limit set by the user.

Default: 20

**pPriInd (integer):** primal simplex pricing

Pricing algorithm. Likely to show the biggest impact on performance. Look at overall solution time and the number of Phase I and total iterations as a guide in selecting alternate pricing algorithms. If you are using the dual Simplex method use `DPriInd` to select a pricing algorithm. If the number of iterations required to solve your problem is approximately the same as the number of rows in your problem, then you are doing well. Iteration counts more than three times greater than the number of rows suggest that improvements might be possible.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| -1    | Reduced-cost pricing  
This is less compute intensive and may be preferred if the problem is small or easy. This option may also be advantageous for dense problems (say 20 to 30 nonzeros per column). |
| 0     | Hybrid reduced-cost and Devex pricing |
| 1     | Devex pricing  
This may be useful for more difficult problems which take many iterations to complete Phase I. Each iteration may consume more time, but the reduced number of total iterations may lead to an overall reduction in time. Tenfold iteration count reductions leading to threefold speed improvements have been observed. Do not use devex pricing if the problem has many columns and relatively few rows. The number of calculations required per iteration will usually be disadvantageous. |
| 2     | Steepest edge pricing  
If devex pricing helps, this option may be beneficial. Steepest-edge pricing is computationally expensive, but may produce the best results on exceptionally difficult problems. |
| 3     | Steepest edge pricing with slack initial norms  
This reduces the computationally intensive nature of steepest edge pricing. |
| 4     | Full pricing |
**predual (integer):** give dual problem to the optimizer

Solve the dual. Some linear programs with many more rows than columns may be solved faster by explicitly solving the dual. The `PreDual` option will cause Cplex to solve the dual while returning the solution in the context of the original problem. This option is ignored if presolve is turned off.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>do not give dual to optimizer</td>
</tr>
<tr>
<td>0</td>
<td>automatic</td>
</tr>
<tr>
<td>1</td>
<td>give dual to optimizer</td>
</tr>
</tbody>
</table>

**preind (boolean):** turn presolver on/off

Perform Presolve. This helps most problems by simplifying, reducing and eliminating redundancies. However, if there are no redundancies or opportunities for simplification in the model, it may be faster to turn presolve off to avoid this step. On rare occasions, the presolved model, although smaller, may be more difficult than the original problem. In this case turning the presolve off leads to better performance. Specifying 0 turns the aggregator off as well.

Default: 1

**prepass (integer):** number of presolve applications to perform

Number of MIP presolve applications to perform. By default, Cplex determines this automatically. Specifying 0 turns off the presolve but not the aggregator. Set `PreInd` to 0 to turn both off.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Determined automatically</td>
</tr>
<tr>
<td>0</td>
<td>No presolve</td>
</tr>
<tr>
<td>&gt;0</td>

<td>Perform aggressive node probing</td>
</tr>
</tbody>
</table>
**pricelim** *(integer)*: pricing candidate list

Size for the pricing candidate list. Cplex dynamically determines a good value based on problem dimensions. Only very rarely will setting this option manually improve performance. Any non-negative integer values are valid.

Default: 0, in which case it is determined automatically

**printoptions** *(boolean)*: list values of all options to GAMS listing file

Write the values of all options to the GAMS listing file. Valid values are no or yes.

Default: 0

**probe** *(integer)*: perform probing before solving a MIP

Determines the amount of probing performed on a MIP. Probing can be both very powerful and very time consuming. Setting the value to 1 can result in dramatic reductions or dramatic increases in solution time depending on the particular model.

Default: 0

<table>
<thead>
<tr>
<th>value</th>

<td>DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.</td>
</tr>
</tbody>
</table>

**qpmakepsdind** *(boolean)*: adjust MIQP formulation to make the quadratic matrix positive-semi-definite

Determines whether Cplex will attempt to adjust a MIQP formulation, in which all the variables appearing in the quadratic term are binary. When this feature is active, adjustments will be made to the elements of a quadratic matrix that is not nominally positive semi-definite (PSD, as required by Cplex for all QP formulations), to make it PSD, and will also attempt to tighten an already PSD matrix for better numerical behavior. The default setting of 1 means yes but you can turn it of if necessary; most models should benefit from the default setting.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>

</tbody>
</table>

**qtolin (integer):** linearization of the quadratic terms in the objective function of a QP or MIQP model

This parameter switches on or off linearization of the quadratic terms in the objective function of a quadratic program or of a mixed integer quadratic program.

In a convex mixed integer quadratic program, this parameter controls whether Cplex linearizes the product of binary variables in the objective function during presolve. In a nonconvex quadratic program or mixed integer quadratic program solved to global optimality according to OptimalityTarget, this parameter controls how Cplex linearizes the product of bounded variables in the objective function during presolve.

This parameter interacts with the existing parameter OptimalityTarget: When the solution target type is set to 1 (that is, Cplex searches for a globally optimal solution to a convex model), then in a convex MIQP, this parameter tells Cplex to replace the product of a binary variable and a bounded linear variable by a linearly constrained variable. When the solution target type is set to 3, then in a nonconvex QP or nonconvex MIQP, this parameter controls the initial relaxation.

Default: −1

<table>

</tbody>
</table>

Condition number of the scaled basis matrix = 9.000e+00

Default: 0

**randomseed** (integer): sets the random seed differently for diversity of solutions

Default: changes with each Cplex release

**readflt** (string): reads Cplex solution pool filter file

The GAMS/Cplex solution pool options cover the basic use of diversity and range filters for producing multiple solutions. If you need multiple filters, weights on diversity filters or other advanced uses of solution pool filters, you could produce a Cplex filter file with your favorite editor or the GAMS Put Facility and read this into GAMS/Cplex using this option.

**readparams** (string): read Cplex parameter file

**reduce** (integer): primal and dual reduction type

Determines whether primal reductions, dual reductions, or both, are performed during preprocessing. It is occasionally advisable to do only one or the other when diagnosing infeasible or unbounded models.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No primal or dual reductions</td>
</tr>
<tr>
<td>1</td>
<td>Only primal reductions</td>
</tr>
<tr>
<td>2</td>
<td>Only dual reductions</td>
</tr>
<tr>
<td>3</td>
<td>Both primal and dual reductions</td>
</tr>
</tbody>
</table>

**reinv** (integer): refactorization frequency

Refactorization Frequency. This option determines the number of iterations between refactorizations of the basis matrix. The default should be optimal for most problems. Cplex's
performance is relatively insensitive to changes in refactorization frequency. Only for extremely large, difficult problems should reducing the number of iterations between refactorizations be considered. Any non-negative integer value is valid.

Default: 0, in which case it is determined automatically

relaxfixedinfeas (boolean): accept small infeasibilities in the solve of the fixed problem

Sometimes the solution of the fixed problem of a MIP does not solve to optimality due to small (dual) infeasibilities. The default behavior of the GAMS/Cplex link is to return the primal solution values only. If the option is set to 1, the small infeasibilities are ignored and a full solution including the dual values are reported back to GAMS.

Default: 0

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

relobjdif (real): relative cheat parameter

The relative version of the ObjDif option. Ignored if ObjDif is non-zero.

Default: 0.0

repairtries (integer): try to repair infeasible MIP start

This parameter lets you indicate to Cplex whether and how many times it should try to repair an infeasible MIP start that you supplied. The parameter has no effect if the MIP start you supplied is feasible. It has no effect if no MIP start was supplied.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>None: do not try to repair</td>
</tr>
<tr>
<td>0</td>

</tr>
<tr>
<td>3</td>
<td>Represolve with cuts and allow new root cuts</td>
</tr>
</tbody>
</table>

rerun (string): rerun problem if presolve infeasible or unbounded

The Cplex presolve can sometimes diagnose a problem as being infeasible or unbounded. When this happens, GAMS/Cplex can, in order to get better diagnostic information, rerun the problem with presolve turned off. The GAMS solution listing will then mark variables and equations as infeasible or unbounded according to the final solution returned by the simplex algorithm. The IIS option can be used to get even more diagnostic information. The rerun option controls this behavior. Valid values are auto, yes, no and nono. The value of auto is equivalent to no if names are successfully loaded into Cplex and option IIS is set to no. In that case the Cplex messages from presolve help identify the cause of infeasibility or unboundedness in terms of GAMS variable and equation names. If names are not successfully loaded, rerun defaults to yes. Loading of GAMS names into Cplex is controlled by option Names. The value of nono only affects MIP models for which Cplex finds a feasible solution in the branch-and-bound tree but the fixed problem turns out to be infeasible. In this case the value nono also disables the rerun without presolve, while the value of no still tries this run. Feasible integer solution but an infeasible fixed problem happens in few cases and mostly with badly scaled models. If you experience this try more aggressive scaling (ScaInd) or tightening the integer feasibility tolerance EPInt. If the fixed model is infeasible only the primal solution is returned to GAMS. You can recognize this inside GAMS by checking the marginal of the objective defining constraint which is always nonzero.

Default: yes

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>Automatic</td>

</tr>
<tr>
<td>nono</td>
<td>Do not rerun infeasible fixed MIP models</td>
</tr>
</tbody>
</table>

rhsrng (string): do right-hand-side ranging

Calculate sensitivity ranges for the specified GAMS equations. Unlike most options, RHSRng can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS equation named. Specifying all will cause range information to be produced for all equations. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option RngRestart is specified.

Default: no right-hand-side ranging is done

rinsheur (integer): relaxation induced neighborhood search frequency
Cplex implements a heuristic known a Relaxation Induced Neighborhood Search (RINS) for MIP and MIQCP problems. RINS explores a neighborhood of the current incumbent to try to find a new, improved incumbent. It formulates the neighborhood exploration as a MIP, a subproblem known as the subMIP, and truncates the subMIP solution by limiting the number of nodes explored in the search tree.

Parameter `RINSHeur` controls how often RINS is invoked. A value of 100, for example, means that RINS is invoked every hundredth node in the tree.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Disable RINS</td>
</tr>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>

<td>Call RINS at the requested node interval</td>
</tr>
</tbody>
</table>

`rltcuts (integer)`: Reformulation Linearization Technique (RLT) cuts

This parameter controls the addition of cuts based on the Reformulation Linearization Technique (RLT) for nonconvex quadratic programs (QP) or mixed integer quadratic programs (MIQP) solved to global optimality. That is, the `OptimalityTarget` parameter must be set to 3. The `RLTCuts` option is not controlled by the option `Cuts`.

Default: 0

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

`rngrestart (string)`: write GAMS readable ranging information file

Write ranging information, in GAMS readable format, to the file named. If the file extension is GDX, the ranging information is exported as GDX file. Options `ObjRng` and `RHSRng` are used to specify which GAMS variables or equations are included.

Default: ranging information is printed to the listing file

`scaind (integer)`: matrix scaling on/off

This option influences the scaling of the problem matrix.

Default: 0

<table>
<thead>
<tr>
<th>value</th>

</tbody>
</table>

sifting *(boolean)*: switch for sifting from simplex optimization

Default: 1

siftitlim *(integer)*: limit on sifting iterations

Sets the maximum number of sifting iterations that may be performed if convergence to optimality has not been reached.

Default: large

simdisplay *(integer)*: simplex display level

This option controls what Cplex reports (normally to the screen) during optimization. The amount of information displayed increases as the setting value increases.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No iteration messages are issued until the optimal solution is reported</td>
</tr>
<tr>
<td>1</td>

</tr>
<tr>
<td></td>
<td>The variables, slacks and artificials entering and leaving the basis</td>
</tr>
<tr>
<td></td>
<td>will also be reported.</td>
</tr>
</tbody>
</table>

singlim *(integer)*: limit on singularity repairs
The singularity limit setting restricts the number of times Cplex will attempt to repair the basis when singularities are encountered. Once the limit is exceeded, Cplex replaces the current basis with the best factorizable basis that has been found. Any non-negative integer value is valid.

Default: 10

**solnpool** *(string)*: solution pool file name

The solution pool enables you to generate and store multiple solutions to a MIP problem. The option expects a GDX filename. This GDX file name contains the information about the different solutions generated by Cplex. Inside your GAMS program you can process the GDX file and read the different solution point files. Please check the GAMS/Cplex solver guide document and the example model solnpool.gms from the GAMS model library.

**solnpoolagap** *(real)*: absolute tolerance for the solutions in the solution pool

Sets an absolute tolerance on the objective bound for the solutions in the solution pool. Solutions that are worse (either greater in the case of a minimization, or less in the case of a maximization) than the objective of the incumbent solution according to this measure are not kept in the solution pool.

Values of the solution pool absolute gap and the solution pool relative gap $\text{SolnPoolGap}$ may differ: For example, you may specify that solutions must be within 15 units by means of the solution pool absolute gap and also within 1% of the incumbent by means of the solution pool relative gap. A solution is accepted in the pool only if it is valid for both the relative and the absolute gaps.

The solution pool absolute gap parameter can also be used as a stopping criterion for the populate procedure: if populate cannot enumerate any more solutions that satisfy this objective quality, then it will stop. In the presence of both an absolute and a relative solution pool gap parameter, populate will stop when the smaller of the two is reached.

Default: $1.0e+75$

**solnpoolcapacity** *(integer)*: limits of solutions kept in the solution pool

Limits the number of solutions kept in the solution pool. At most, $\text{SolnPoolCapacity}$ solutions will be stored in the pool. Superfluous solutions are managed according to the replacement strategy set by the solution pool replacement parameter $\text{SolnPoolReplace}$.

The optimization (whether by MIP optimization or the populate procedure) will not stop if more than $\text{SolnPoolCapacity}$ are generated. Instead, stopping criteria are regular node and time limits and $\text{PopulateLim}$, $\text{SolnPoolGap}$ and $\text{SolnPoolAGap}$.

Default: 2100000000

**solnpoolgap** *(real)*: relative tolerance for the solutions in the solution pool

Sets a relative tolerance on the objective bound for the solutions in the solution pool. Solutions that are worse (either greater in the case of a minimization, or less in the case of a maximization) than the incumbent solution by this measure are not kept in the solution pool.

Values of the solution pool absolute gap and the solution pool relative gap may differ: For example, you may specify that solutions must be within 15 units by means of the solution pool absolute gap and within 1% of the incumbent by means of the solution pool relative gap. A solution is accepted in the pool only if it is valid for both the relative and the absolute gaps.

The solution pool relative gap parameter can also be used as a stopping criterion for the populate procedure: if populate cannot enumerate any more solutions that satisfy this objective quality, then it will stop. In the presence of both an absolute and a relative solution pool gap parameter, populate will stop when the smaller of the two is reached.

Default: $1.0e+75$
**solnpoolintensity (integer):** solution pool intensity for ability to produce multiple solutions

Controls the trade-off between the number of solutions generated for the solution pool and the amount of time or memory consumed. This parameter applies both to MIP optimization and to the populate procedure.

Values from 1 to 4 invoke increasing effort to find larger numbers of solutions. Higher values are more expensive in terms of time and memory but are likely to yield more solutions.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic&lt;br&gt;Its default value, 0, lets Cplex choose which intensity to apply.</td>
</tr>
<tr>
<td>1</td>
<td>Mild: generate few solutions quickly&lt;br&gt;For value 1, the performance of MIP optimization is not affected. There is no slowdown and no additional consumption of memory due to this setting. However, populate will quickly generate only a small number of solutions. Generating more than a few solutions with this setting will be slow. When you are looking for a larger number of solutions, use a higher value of this parameter.</td>
</tr>
<tr>
<td>2</td>
<td>Moderate: generate a larger number of solutions&lt;br&gt;For value 2, some information is stored in the branch and cut tree so that it is easier to generate a larger number of solutions. This storage has an impact on memory used but does not lead to a slowdown in the performance of MIP optimization. With this value, calling populate is likely to yield a number of solutions large enough for most purposes. This value is a good choice for most models.</td>
</tr>
<tr>
<td>3</td>
<td>Aggressive: generate many solutions and expect performance penalty&lt;br&gt;For value 3, the algorithm is more aggressive in computing and storing information in order to generate a large number of solutions. Compared to values 1 and 2, this value will generate a larger number of solutions, but it will slow MIP optimization and increase memory consumption. Use this value only if setting this parameter to 2 does not generate enough solutions.</td>
</tr>
<tr>
<td>4</td>
<td>Very aggressive: enumerate all practical solutions&lt;br&gt;For value 4, the algorithm generates all solutions to your model. Even for small models, the number of possible solutions is likely to be huge; thus enumerating all of them will take time and consume a large quantity of memory.</td>
</tr>
</tbody>
</table>

**solnpoolmerge (string):** solution pool file name for merged solutions

Similar to solnpool this option enables you to generate and store multiple solutions to a MIP problem. The option expects a GDX filename. This GDX file contains all variables with an additional first index (determined through SolnPoolPrefix) as parameters (Cplex only reports the primal solution). Inside your GAMS program you can process the GDX file and read all solutions in one read operation. Please check the GAMS/Cplex solver guide document for further solution pool options and the example model solmpool.gms from the GAMS model library.

**solnpoolnumsym (integer):** maximum number of variable symbols when writing merged solutions

Default: 10

**solnpoolpop (integer):** methods to populate the solution pool
Regular MIP optimization automatically adds incumbents to the solution pool as they are discovered. Cplex also provides a procedure known as populate specifically to generate multiple solutions. You can invoke this procedure either as an alternative to the usual MIP optimizer or as a successor to the MIP optimizer. You can also invoke this procedure many times in a row in order to explore the solution space differently (see option SolnPoolPopRepeat). In particular, you may invoke this procedure multiple times to find additional solutions, especially if the first solutions found are not satisfactory.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Just collect the incumbents found during regular optimization</td>
</tr>
<tr>
<td>2</td>
<td>Calls the populate procedure</td>
</tr>
</tbody>
</table>

solnpoolpopdel (string): file with solution numbers to delete from the solution pool

After the GAMS program specified in SolnPoolPopRepeat determined to continue the search for alternative solutions, the file specified by this option is read in. The solution numbers present in this file will be delete from the solution pool before the populate routine is called again. The file is automatically deleted by the GAMS/Cplex link after processing.

solnpoolpoprepeat (string): method to decide if populating the solution should be repeated

After the termination of the populate procedure (see option SolnPoolPop). The GAMS program specified in this option will be called which can examine the solutions in the solution pool and can decide to run the populate procedure again. If the GAMS program terminates normally (not compilation or execution time error) the search for new alternative solutions will be repeated.

solnpoolprefix (string): file name prefix for GDX solution files

Default: soln

solnpoolexplicit (integer): strategy for replacing a solution in the solution pool

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Replace the first solution (oldest) by the most recent solution; first in, first out</td>
</tr>
<tr>
<td>1</td>
<td>Replace the solution which has the worst objective</td>
</tr>
<tr>
<td>2</td>
<td>Replace solutions in order to build a set of diverse solutions</td>
</tr>
</tbody>
</table>

solutiontype (integer): type of solution (basic or non basic) for an LP or QP

Specifies the type of solution (basic or non basic) that CPLEX attempts to compute for a linear program (LP) or for a quadratic program (QP). In this context, basic means having to do with the basis, and non basic applies to the variables and constraints not participating in the basis.

By default (that is, when the value of this parameter is 0 (zero) automatic), CPLEX seeks a basic solution (that is, a solution with a basis) for all linear programs (LP) and for all quadratic programs (QP).

When the value of this parameter is 1 (one), CPLEX seeks a basic solution, that is, a solution that includes a basis with a basic status for variables and constraints. In other words, CPLEX behaves the same way for the values 0 (zero) and 1 (one) of this parameter.
When the value of this parameter is 2, CPLEX seeks a pair of primal-dual solution vectors. This setting does not prevent CPLEX from producing status information, but in seeking a pair of primal-dual solution vectors, CPLEX possibly may not produce basic status information; that is, it is possible that CPLEX does not produce status information about which variables and constraints participate in the basis at this setting.

Do not use the deprecated value -1 (minus one) of the parameter barrier crossover algorithm to turn off crossover of the barrier algorithm but use this parameter to indicate that a primal-dual pair is sufficient.

Default: 0

<table>

**solvefinal (boolean):** switch to solve the problem with fixed discrete variables

Sometimes the solution process after the branch-and-cut that solves the problem with fixed discrete variables takes a long time and the user is interested in the primal values of the solution only. In these cases, solvefinal can be used to turn this final solve off. Without the final solve no proper marginal values are available and only NAs are returned to GAMS.

Default: 1

<table>
<thead>
<tr>

<tr>
<td>5</td>
<td>Extremely aggressive level of symmetry breaking</td>
</tr>
</tbody>
</table>

**threads** (integer): global default thread count

Synonym: gthreads

Default number of parallel threads allowed for any solution method. Negative values are interpreted as the number of cores to leave free so setting threads to -1 leaves one core free for other tasks. Cplex does not understand negative values for the threads parameter. GAMS/Cplex will translate this into a positive number by applying the following formula: max(1, number of cores−|threads|). Setting threads to 0 lets Cplex use at most 32 threads or the number of cores of the machine, whichever is smaller.

Default: GAMS Threads

**tilim** (real): overrides the GAMS ResLim option

Synonym: reslim

The time limit setting determines the amount of time in seconds that Cplex will continue to solve a problem. This Cplex option overrides the GAMS ResLim option. Any non-negative value is valid.

Default: GAMS ResLim
**trelim (real):** maximum space in memory for tree

Sets an absolute upper limit on the size (in megabytes) of the branch and cut tree. If this limit is exceeded, Cplex terminates optimization.

Default: $1.0e+75$

**tuning (string):** invokes parameter tuning tool

Invokes the Cplex parameter tuning tool. The mandatory value following the keyword specifies a GAMS/Cplex option file. All options found in this option file will be used but not modified during the tuning. A sequence of file names specifying existing problem files may follow the option file name. The files can be in LP, MPS or SAV format. Cplex will tune the parameters either for the problem provided by GAMS (no additional problem files specified) or for the suite of problems listed after the GAMS/Cplex option file name without considering the problem provided by GAMS. Due to technical reasons a single option input line is limited by 256 characters. If the list of model files exceeds this length you can provide a second, third, ... line starting again with keyword tuning and a list of model instance files.

The result of such a tuning run is the updated GAMS/Cplex option file with a tuned set of parameters. The solver and model status returned to GAMS will be **NORMAL COMPLETION** and **NO SOLUTION**. More details on Cplex tuning can be found on IBM’s web page. Tuning is incompatible with the BCH facility and other advanced features of GAMS/Cplex.

**tuningdettlim (real):** tuning deterministic time limit per model or suite

Default: $1.0e+75$

**tuningdisplay (integer):** level of information reported by the tuning tool

Specifies the level of information reported by the tuning tool as it works.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Turn off display</td>
</tr>
<tr>
<td>1</td>
<td>Display standard minimal reporting</td>
</tr>
<tr>
<td>2</td>
<td>Display standard report plus parameter settings being tried</td>
</tr>
<tr>
<td>3</td>
<td>Display exhaustive report and log</td>
</tr>
</tbody>
</table>

**tuningmeasure (integer):** measure for evaluating progress for a suite of models

Controls the measure for evaluating progress when a suite of models is being tuned. Choices are mean average and minmax of time to compare different parameter sets over a suite of models.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>mean average</td>
</tr>
<tr>
<td>2</td>
<td>minmax</td>
</tr>
</tbody>
</table>

**tuningrepeat (integer):** number of times tuning is to be repeated on perturbed versions
Specifies the number of times tuning is to be repeated on perturbed versions of a given problem. The problem is perturbed automatically by Cplex permuting its rows and columns. This repetition is helpful when only one problem is being tuned, as repeated perturbation and re-tuning may lead to more robust tuning results. This parameter applies to only one problem in a tuning session.

Default: 1

**tuningtilim** *(real)*: tuning time limit per model or suite

Sets a time limit per model and per test set (that is, suite of models).

As an example, suppose that you want to spend an overall amount of time tuning the parameter settings for a given model, say, 2000 seconds. Also suppose that you want Cplex to make multiple attempts within that overall time limit to tune the parameter settings for your model. Suppose further that you want to set a time limit on each of those attempts, say, 200 seconds per attempt. In this case you need to specify an overall time limit of 2000 using GAMS option `reslim` or Cplex option `TiLim` and `tuningtilim` to 200.

Default: 0.2×GAMS `ResLim`

**upperobjstop** *(real)*: in a maximization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value greater than or equal to the specified value

Default: 1e75

**usercallparmfile** *(string)*: Command-line parameter include file used in GAMS command-line calls triggered by BCH

**.usercut** *(boolean)*: User cut activation

Determines whether a linear constraint is treated as a user cut. At the beginning of the MIP solution process, any constraint whose usercut attribute is set to 1 (the default value is 0) is removed from the model and placed in the user cut pool. User cuts may be used by CPLEX at any time to improve the solution process. There is no guarantee that they are actually used.

The user cut pool is only active if option `usercutpool` is enabled and are specified through the option `.usercut`. The syntax for `dotoptions` is explained in the Introduction chapter of the Solver Manual.

Default: 0

**usercutcall** *(string)*: the GAMS command line to call the cut generator

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**usercutfirst** *(integer)*: calls the cut generator for the first n nodes

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

**usercutfreq** *(integer)*: determines the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10
usercutinterval (integer): determines the interval when to apply the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 100

usercutmult (integer): determines the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 2

usercutnewint (boolean): calls the cut generator if the solver found a new integer feasible solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 1

usercutpool (boolean): Indicator to use user cuts

Default: 0

usergdxin (string): the name of the GDX file read back into Cplex

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchin.gdx

usergdxname (string): the name of the GDX file exported from the solver with the solution at the node

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchout.gdx

usergdxnameinc (string): the name of the GDX file exported from the solver with the incumbent solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchout_i.gdx

usergdxprefix (string): prefixes usergdxin, usergdxname, and usergdxnameinc

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

usergdxsol (string): the name of the GDX file exported by Cplex to store the solution of extra columns

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchsol.gdx

userheurcall (string): the GAMS command line to call the heuristic

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userheurfirst (integer): calls the heuristic for the first n nodes
More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

**userheurfreq (integer):** determines the frequency of the heuristic model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

**userheurinterval (integer):** determines the interval when to apply the multiplier for the frequency of the heuristic model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 100

**userheurmult (integer):** determines the multiplier for the frequency of the heuristic model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 2

**userheurnewint (boolean):** calls the heuristic if the solver found a new integer feasible solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 1

**userheurobjfirst (integer):** Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 0

**userincbcall (string):** the GAMS command line to call the incumbent checking program

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**userincbicall (string):** the GAMS command line to call the incumbent reporting program

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**userjobid (string):** postfixes If, o on call adds –userjobid to the call. Postfixes gdxname, gdxnameinc and gdxin

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**userkeep (boolean):** calls gamskeep instead of gams

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 0

**userlazyconcall (string):** the GAMS command line to call the lazy constraint generator

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Note: There is no guarantee that CPLEX will use all of the added violated lazy constraints provided due to technical and/or efficiency reasons. It may thus happen that a later candidate solution violates previously provided lazy constraints. In this case consider passing the constraint again.

**varsel (integer):** variable selection strategy at each node

This option is used to set the rule for selecting the branching variable at the node which has been selected for branching. The default value of 0 allows Cplex to select the best rule based on the problem and its progress.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Branch on variable with minimum infeasibility. This rule may lead more quickly to a first integer feasible solution, but will usually be slower overall to reach the optimal integer solution.</td>
</tr>
<tr>
<td>0</td>
<td>Branch variable automatically selected</td>
</tr>
<tr>
<td>1</td>
<td>Branch on variable with maximum infeasibility. This rule forces larger changes earlier in the tree, which tends to produce faster overall times to reach the optimal integer solution.</td>
</tr>
<tr>
<td>2</td>
<td>Branch based on pseudo costs. Generally, the pseudo-cost setting is more effective when the problem contains complex trade-offs and the dual values have an economic interpretation.</td>
</tr>
<tr>
<td>3</td>
<td>Strong Branching. This setting causes variable selection based on partially solving a number of subproblems with tentative branches to see which branch is most promising. This is often effective on large, difficult problems.</td>
</tr>
<tr>
<td>4</td>
<td>Branch based on pseudo reduced costs</td>
</tr>
</tbody>
</table>

**warninglimit** *(integer)*: determines how many times warnings of a specific type *(datacheck=2)* will be displayed \(\leftarrow\)

By default, when modeling assistance is turned on via the *data consistency checking* parameter, CPLEX will display 10 warnings for a given modeling issue and then omit the rest. This parameter controls this limit and allows the user to display all of the warnings if desired. In order to see all warnings change the value to its negative.

Default: 10

**workdir** *(string)*: directory for working files \(\leftarrow\)

The name of an existing directory into which Cplex may store temporary working files. Used for MIP node files and by out-of-core Barrier.

Default: current or project directory

**workeralgorithm** *(integer)*: set method for optimizing benders subproblems \(\leftarrow\)

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>Primal Simplex</td>
</tr>
<tr>
<td>2</td>
<td>Dual Simplex</td>
</tr>
<tr>
<td>3</td>
<td>Network Simplex</td>
</tr>
<tr>
<td>4</td>
<td>Barrier</td>
</tr>
<tr>
<td>5</td>
<td>Sifting</td>
</tr>
</tbody>
</table>

**workmem** *(real)*: memory available for working storage \(\leftarrow\)

Upper limit on the amount of memory, in megabytes, that Cplex is permitted to use for working files. See parameter *WorkDir*.

Default: 2048.0
writeannotation (string): produce a Cplex annotation file

writebas (string): produce a Cplex basis file

Write a basis file.

writeflt (string): produce a Cplex solution pool filter file

Write the diversity filter to a Cplex FLT file.

writelp (string): produce a Cplex LP file

Write a file in Cplex LP format.

writemps (string): produce a Cplex MPS file

Write an MPS problem file.

writemst (string): produce a Cplex mst file

Write a Cplex MST (containing the MIP start) file.

writeord (string): produce a Cplex ord file

Write a Cplex ORD (containing priority and branch direction information) file.

writeparam (string): produce a Cplex parameter file with all active options

Write a Cplex parameter (containing all modified Cplex options) file.

writepre (string): produce a Cplex LP/MPS/SAV file of the presolved problem

Synonym: writepremps

Write a Cplex LP, MPS, or SAV file of the presolved problem. The file extension determines the problem format. For example, `WritePre presolved.lp` creates a file `presolved.lp` in Cplex LP format.

writeprob (string): produce a Cplex problem file and infers the type from the extension

Write a problem file in a format inferred from the extension. Possible formats are

- **SAV**: Binary matrix and basis file
- **MPS**: MPS format
- **LP**: CPLEX LP format with names modified to conform to LP format
- **REW**: MPS format, with all names changed to generic names
- **RLP**: LP format, with all names changed to generic names
- **ALP**: LP format, with generic name of each variable, type of each variable, bound of each variable If the file name ends with `.bz2` or `.gz`, a compressed file is written.

writesav (string): produce a Cplex binary problem file

Write a binary problem file.

zerohalfcuts (integer): zero-half cuts

Decides whether or not to generate zero-half cuts for the problem. The value 0, the default, specifies that the attempt to generate zero-half cuts should continue only if it seems to be helping. If the dual bound of your model does not make sufficient progress, consider setting this parameter to 2 to generate zero-half cuts more aggressively.

Default: 0
5.11.9 Setting up a GAMS/Cplex-Link license

The GAMS/Cplex-Link license requires that you have a valid license agreement with IBM for use of the current version of the Cplex library.

To add the Cplex-Link to your GAMS license, please write to sales@gams.com to confirm that you have such a license agreement and that your use of the GAMS solver will comply with the terms of that license agreement. Please reference your GAMS License ID, DCxxxx.

5.12 Deterministic Equivalent (DE)

Author
Martha Loewe

5.12.1 Introduction

DE is a solver for stochastic programs modeled with GAMS Extended Mathematical Programming for Stochastic Programming (EMP SP). DE can solve multi-stage LP, MIP, QCP, NLP and MINLP stochastic programming models. For details about EMP SP and the syntax to modify an existing GAMS model to be an stochastic programming model in GAMS EMP SP see Stochastic Programming. A list of DE solver options is given at the end of this document.

Stochastic programs are mathematical programs that include data that is not known with certainty, but is approximated by probability distributions. The simplest form of a stochastic program is the two-stage stochastic linear program with recourse. In mathematical terms it is defined as follows.

Let $x \in \mathbb{R}^n$ and $y \in \mathbb{R}^m$ be two variables and let the set of all realizations of the unknown data be given by $\Omega$, $\Omega = \{\omega_1, \ldots, \omega_S\} \subseteq \mathbb{R}^r$, where $r$ is the number of the random variables representing the uncertain parameters. Then the stochastic program is given by

$$
\begin{align}
\text{Min}_x \quad & z = c^T x + \mathbb{E}[Q(x, \omega)] \\
\text{s.t.} \quad & A x = b, \quad x \geq 0,
\end{align}
$$

where $Q(x, \omega) = \begin{align}
\text{Min}_y \\
\text{s.t.} \\
T_\omega x + W_\omega y(\omega) = h_\omega, \quad y(\omega) \geq 0, \quad \forall \omega \in \Omega.
\end{align}$

The first two lines define the first-stage problem and the last two lines define the second-stage problem. In the first stage, $x$ is the decision variable, $c^T$ represents the cost coefficients of the objective function and $\mathbb{E}[Q(x, \omega)]$ denotes the expected value of the optimal solution of the second stage problem. In addition, $A$ denotes the coefficients and $b$ the right-hand side of the first stage constraints. In the second stage, $y$ is the decision variable, $T$ represents the transition matrix, $W$ the recourse matrix (cost of recourse) and $h$
the right-hand side of the second stage constraints. Note that all parameters and the decision variable of the second stage are dependent on $\omega$. The objective variable $z$ is also a random variable, since it is a function of $\omega$. As a random variable cannot be optimized, DE automatically optimizes the expected value of the objective variable $z$. DE is also able to optimize other risk measures, as will be discussed later.

In the first stage, a decision has to be made before the realization of the uncertain data is clear. The optimal solution of the first stage is fixed and only then the values that the uncertain parameters take will become known. Given the fixed solution of the first stage and the new data, in the second stage recourse action can be taken and the optimal solution determined. Each possible realization of the uncertain data is represented by an $\omega_s \in \Omega$ and is called a scenario. The objective is to find a feasible solution $x$ that minimizes the total cost, namely the sum of the first-stage costs and the expected second-stage costs.

One of the most common methods to solve a two-stage stochastic LP is to build and solve the deterministic equivalent. Assume that the uncertain parameters follow a (finite) discrete distribution and that each scenario $\omega_s$ occurs with probability $P(\omega_s) = p_s$ for all $s = 1, \ldots, S$ and $\sum_s p_s = 1$. So $E[Q(x, \omega)] = \sum_s p_s q^T y_s$, where $y_s$ denotes the optimal second-stage decision for the scenario $\omega_s$. Then the deterministic equivalent can be expressed as follows:

$$
\begin{align*}
& c^T x + p_1 q^T y_1 + p_2 q^T y_2 + \ldots + p_S q^T y_S \\
& \text{s.t.} \\
& Ax + W_1 y_1 = b \\
& T_2 x + W_2 y_2 = h_2 \\
& \vdots \\
& T_S x + W_S y_S = h_S \\
& x \in \mathbb{R}^n, \quad y_1 \in \mathbb{R}^m, \quad y_2 \in \mathbb{R}^m, \ldots, \quad y_S \in \mathbb{R}^m
\end{align*}
$$

(5.7)

Note that for stochastic linear programs the deterministic equivalent is just a very large linear program.

The solver DE automatically generates the deterministic equivalent of a stochastic program and then hands it over for solution to a solver, termed the subsolver. The subsolver is the default solver for the type of model to be solved. The user may choose another subsolver with the option subsolver.

If modelers want to use DE, they may either add the option

```
option emp = de;
```

before the solve statement in the model or they may choose the solver DE on the command line, e.g.

```
gams mymodel.gms emp=de
```

### 5.12.2 Random Variables

Random variables and their distributions and stages determine the number of scenarios in the model and thus the number of equations that are generated for the deterministic equivalent. If there are two or more random variables in one stage they may be jointly distributed or not.

Assume that there is a two-stage stochastic model $\mathcal{M}_2$ that has two random variables $a$ and $b$ in the second stage. The random variables both follow a discrete distribution, the uncertain data for $a$ is given by $\Omega_a$ and the uncertain data for $b$ is given by $\Omega_b$. If the random variables are not jointly distributed, then $|\Omega_a| \times |\Omega_b|$ scenarios are generated. If the random variables are jointly distributed, then we need to have $|\Omega_a| = |\Omega_b|$ and the number of scenarios is $|\Omega_a|$. 
In addition to two-stage stochastic models, DE can also solve multi-stage stochastic models. Let $M_4$ be a stochastic model with four stages. In each of the stages after the first stage new data is revealed that was unknown in the previous stages. Assume that in each stage there is just one random variable. Let $\Omega_I$ denote the uncertain data in the second stage and $\Omega_{II}$ and $\Omega_{III}$ represent the uncertain data of the third and fourth stage respectively. Let $|\Omega_I| = n_1$, $|\Omega_{II}| = n_2$ and $|\Omega_{III}| = n_3$. DE builds the deterministic equivalent of this model by recursively generating a scenario tree. In the second stage the number of scenarios is $n_1$, in the third stage there are $n_1 \times n_2$ scenarios and in the fourth stage there are $n_1 \times n_2 \times n_3$ scenarios. Note that the number of scenarios in the model equals the number of scenarios in the last stage. However, the number of equations generated for the deterministic equivalent is the sum of the scenarios in each stage, so in this example it is $n_1 + n_1 \times n_2 + n_1 \times n_2 \times n_3 = n_1 \times (1 + n_2 \times (1 + n_3))$.

The following figure illustrates the scenario tree of a stochastic model with four stages.

![Scenario Tree Illustration](image)

Note that the structure of the scenario tree is limited: each node in a stage has exactly the same number of arcs.

If there is more than one random variable per stage, then the number of scenarios increases accordingly. Note that there is no absolute limit to the number of stages and random variables, but the model can become very large very quickly as the number of stages and random variables increases. Note further that the random variables are stagewise independent. The realization of the random variables in one stage does not influence the realization of the random variables in a later stage.

### 5.12.3 Sampling Procedures

DE can solve only stochastic programs with random variables that follow discrete probability distributions. If the random data follows a continuous probability distribution the set $\Omega$ has an infinite number of elements. Sampling is a process that generates a finite approximation $\Omega_N$ to $\Omega$. The size of $\Omega_N$ is $N$ and each element of $\Omega_N$ has the same probability $p = \frac{1}{N}$. Thus continuous probability distributions are approximated by discrete distributions. EMP SP provides the keyword `sample` to facilitate sampling. An example follows.

```
randvar d normal 45 10
sample d 100
```
These two lines are a portion of the `emp.info` file. In the first line `d` is defined as a random variable that follows a Normal distribution with mean 45 and standard deviation 10. In the second line it is specified that the continuous distribution is approximated by a sample of size 100. Note that the user determines the sample size \( N \). Note further that the use of the keyword `sample` is mandatory for random variables with continuous distributions. Otherwise the following error message will appear:

*** Only random variables with sampled continuous distributions supported.

Observe that behind the scenes the sampling is performed by the LINDO system. So the modeler needs a LINDO licence for sample sizes larger than 10 (smaller sample sizes are included in the demo version). The LINDO system offers three variance reduction algorithms: the Antithetic algorithm, the Latin Square algorithm and the Monte Carlo algorithm. They may be enabled using either the option `svr_ls_antithetic` or `svr_ls_latinsquare` or `svr_ls_montecarlo` respectively.

Alternatively, the modeler may chose to generate a sample of the distribution first and then enter the sample as a discrete distribution in the `emp.info` file. There are two stochastic libraries that can be used for this procedure: the GAMS Stochastic Library and the LINDO Sampling Library. An example and details about the procedure using the LINDO library are given in section Sampling in the EMP manual.

### 5.12.4 The Expected Value Problem

Consider the special case where the sample size is 1 and the "sampled" value equals the expected value of the random variable. This entails that the random variable is replaced by its expected value. The resulting model is deterministic and is called the Expected Value Program. DE facilitates solving the Expected Value Problem through the option `solveEVProb`. If this option is specified in the option file (see example below) the Expected Value Problem is solved after the original stochastic model and the solution is reported. In addition, DE offers the option to choose a separate subsolver for the Expected Value Problem, the option `evsubsolver`.

In the following example the stochastic model is solved with the subsolver Conopt and the Expected Value Problem is solved with the subsolver Minos.

```plaintext
$onecho > de.opt
subsolver conopt
solveEVProb
evsubsolver minos
$offecho
mymodel.optfile=1;
solve mymodel min obj using emp scenario dict;
```

Note that the option `solveEVProb` is not defined for models with chance constraints and models featuring VaR and CVaR. These model types are discussed in the next section.

### 5.12.5 What types of models can DE handle?

As mentioned earlier, DE can solve two-stage and multi-stage stochastic linear, quadratic and nonlinear models and the mixed-integer versions of all these models. There are two further classes of stochastic models that DE is equipped to solve: stochastic programs with chance constraints and stochastic programs with other risk measures such as Variance at Risk (VaR) and Conditional Variance at Risk (CVaR). CVaR is also called Expected Shortfall.
In stochastic programs with chance constraints the goal is to make an optimal decision prior to the realization of random data while allowing the constraints to be violated with a certain probability. Mathematically, a stochastic linear program with chance constraints can be expressed as follows:

\[
\begin{align*}
\text{Min} & \quad c^T x \\
\text{s.t.} & \quad P(Ax \leq b) \geq p \\
& \quad x \geq 0,
\end{align*}
\]  \hspace{1cm} (5.8)

where \( x \in \mathbb{R}^n \) is the decision variable and \( c^T \) denotes the coefficients of the objective function, \( A \in \mathbb{R}^{m \times n} \) is a random matrix and represents the coefficients and \( b \in \mathbb{R}^m \) is a random vector and denotes the right-hand side of the constraints. The distinctive feature of stochastic programs with chance constraints is that the constraints (or some of them) may be violated with probability \( \epsilon = 1 - p \), where \( 0 < p \leq 1 \).

DE offers three reformulation options to solve stochastic programs with chance constraints: a reformulation using a mixed-integer program with big \( M \) notation, a convex hull reformulation and the use of indicator variables and indicator constraints. Note that the default is the MIP reformulation (the default value of \( M \) is set to 10000 and can be customized). With the option ccreform the reformulation method can be determined by the user.

For details on single and joint chance constraints and examples how to use the option ccreform, see the section Chance Constraints with EMP in the EMP manual. Note that random variables in programs with chance constraints may follow discrete or continuous probability distributions. Note further that there are no stages in stochastic programs with chance constraints.

As mentioned earlier, DE automatically optimizes the expected value of the objective function variable. DE also supports other risk measures, such as VaR and CVaR. In mathematical terms, DE is able to solve the following:

\[
\text{Min}_x \quad \mathcal{R}(z),
\]  \hspace{1cm} (5.9)

where \( z \) represents the objective function variable and \( \mathcal{R} \) denotes a risk measure such as the Expected Value, VaR and CVaR or a combination of risk measures (e.g. the weighted sum of Expected Value and CVaR). In addition, the modeler can also choose to trade off risk measures. For more details about risk measures see section Risk Measures with EMP in the EMP manual.

### 5.12.6 Reformulation Techniques

In this section some details are given about the reformulations that DE is performing behind the scenes.

#### 5.12.6.1 Simple two-stage stochastic model

As mentioned previously, DE converts a stochastic model into its deterministic equivalent. Using the model nbsimple.gms from the GAMS EMP model library as an example, we show how exactly the deterministic equivalent is built. Note that this model is also discussed in detail in the section A Simple Example: The News Vendor Problem of the EMP manual.

The model is given by the following equations:

\[
\begin{align*}
\text{Max}_x \quad z(x) = -cx + \mathbb{E}[Q(x, \omega)], & \quad x \geq 0,
\end{align*}
\]  \hspace{1cm} (5.10)
where
\[ Q(x, \omega) = \max_{s, i, l} vs(\omega) - hi(\omega) - pl(\omega) \]
subject to
\[ x - s(\omega) - i(\omega) = 0 \]
\[ s(\omega) + l(\omega) = d(\omega) \]
\[ s(\omega), i(\omega), l(\omega) \geq 0 \quad \forall \omega \in \Omega. \]

Here \( c, v, h \) and \( p \) are some given parameters, the first-stage decision variable is \( x \), the second-stage decision variables are \( s, i \) and \( l \) and the uncertain data is represented by the random variable \( d(\omega) \). We assume that the annotations specify that \( d \) follows a Normal distribution and the sample size to approximate this continuous distribution is 4 (where all scenarios are equally likely, so \( p(s) = 0.25 \)).

First, DE draws 4 values from the Normal distribution specified in the annotations. These 4 values are the basis for the 4 scenarios that are generated. For each scenario, a separate equation for the two second-stage constraints is built (that are 8 equations). In the process, for each of the three decision variables of the second stage 4 variables are generated since the second-stage decision variables may take different values for each scenario. Next, an equation for the profit for each scenario is generated (4 equations) and finally, the equation to compute the average profit is built. So there are a total of 13 equations. They are given here:

\[
\begin{align*}
& x - s_1 - i_1 = 0 \\
& x - s_2 - i_2 = 0 \\
& x - s_3 - i_3 = 0 \\
& x - s_4 - i_4 = 0 \\
& s_1 + l_1 = d_1 \\
& s_2 + l_2 = d_2 \\
& s_3 + l_3 = d_3 \\
& s_4 + l_4 = d_4 \\
& z_1 = -cx + vs_1 - hi_1 - pl_1 \\
& z_2 = -cx + vs_2 - hi_2 - pl_2 \\
& z_3 = -cx + vs_3 - hi_3 - pl_3 \\
& z_4 = -cx + vs_4 - hi_4 - pl_4 \\
& z = 0.25z_1 + 0.25z_2 + 0.25z_3 + 0.25z_4
\end{align*}
\]

Note that there is only one realization of the first-stage decision variable \( x \) while for the second-stage decision variables there as many realizations as there are scenarios.

### 5.12.6.2 A multi-stage stochastic model

DE recursively builds a scenario tree to generate the deterministic equivalent of multi-stage models. We take the model inventory from the EMP manual to demonstrate how this is done. The 4-stage model is given by the following equations:

\[
\begin{align*}
\max_{y_1, i_1} & \quad z = -\alpha y_1 - \gamma i_1 + \mathbb{E}[Q((y_1, i_1), \omega_1)] + \mathbb{E}[Q((y_1, i_1), \omega_{II})] + \mathbb{E}[Q((y_1, i_1), \omega_{III})] \\
\text{s.t.} & \quad i_1 = y_1 \\
& \quad y_1, i_1 \geq 0,
\end{align*}
\]

where
\[
Q((y_1, i_1), \omega_1^t) = \max_{s_t, y_t, i_t} \beta s_t(\omega_1^t) - \alpha y_t(\omega_1^t) - \delta i_t(\omega_1^t) \\
\text{s.t.} & \quad i_{t-1} + y_t = s_t + i_t \\
& \quad s_t \leq i_{t-1} \\
& \quad s_t \leq d_t(\omega_1^t) \\
& \quad i_t \leq \kappa \\
& \quad s_t, y_t, i_t \geq 0 \quad \text{for} \quad t = 2, 3, 4.
\]
Here \( y_t \) and \( i_t \) are the first-stage decision variables and \( y_t, i_t \) and \( s_t \) are the decision variables of the later stages; \( \alpha, \beta, \gamma, \delta \) and \( \kappa \) denote fixed parameters. The uncertain data is represented by the random variable \( d_t(\omega_\zeta) \), where \( \omega_\zeta \in \Omega_\zeta \) and \( \zeta = I, II, III \). Note that \( s_t, y_t \) and \( i_t \) depend on the realization of \( d_t \). Now assume that \( d_t \) follows a continuous distribution and the sample size to approximate this distribution is just 3 for stages 2 to 4. Note that in multi-stage models the sample size may vary for each stage. Note further that for all practical purposes this sample size is too small, it was chosen here for reasons of clarity of exposition. As usual, the distribution(s) and sample size(s) are specified in the annotations. Observe that the last constraint \( i_t \leq \kappa \) is implemented as a bound on the variable \( i_t \), not as an equation. So, in addition to the objective equations, there is one equation in the first stage and three equations in each of the later stages.

This model is reformulated in the following way. First, an equation for the first stage constraint is generated. Secondly, three realizations of \( d_2 \) are chosen through a sampling procedure, so there are three scenarios at stage 2. For each of these three realizations of the random variable the equations for the second stage are generated (9 equations). Thirdly, three realizations of \( d_3 \) are sampled for stage 3. Each of these three realizations may follow one of the three scenarios of the second stage, so there are nine scenarios in stage 3 and hence \( 9 \times 3 = 27 \) equations are generated for stage 3. The procedure is repeated in stage 4 where there are 27 scenarios and \( 27 \times 3 = 81 \) equations. Next, the value of the objective variable for each scenario is computed by generating 27 equations for \( z_s \) and finally, an equation to compute \( z \) is built, where \( z = \sum_s p(s)z_s \).

5.12.6.3 Chance Constraints

Models with chance constraints are reformulated as mixed integer problems by default. This reformulation is discussed in detail in the section Chance Constraints with EMP in the EMP manual. Reformulations using a convex hull or indicator variables and indicator constraints are also possible. The reformulation method may be determined by the user with the option ccreform.

5.12.6.4 Computing VaR

Models involving VaR are reformulated using mixed integer programs with big \( M \) notation. By the example model portfolio.gms we demonstrate how this is done. This model is discussed in the section Value at Risk (VaR) in the EMP manual. The model is given by the following equations:

\[
\begin{align*}
\text{Max} & \quad \text{VaR}_\theta[R] \\
\text{s.t} & \quad R = \sum_j w_j v_j(\omega) \quad \forall \omega \in \Omega \\
& \quad \sum_j w_j = 1 \\
& \quad w_j \geq 0,
\end{align*}
\]

where \( \text{VaR}_\theta \) is the VaR at the lower \( \theta \)th percentile, the variable \( R \) is the return (and is a function of the random variable \( v_j(\omega) \)), \( w_j \) the weight associated with each asset \( j \) and \( v_j(\omega) \) is the (random variable) return of each asset \( j \). The weights can also be interpreted as proportions of the amount to be invested, their sum must be 1. Note that \( w_j \) is the decision variable in this problem.

Let \( y(s) \) be a binary variable that acts as an indicator variable. For each scenario, it equals 1 if the return \( R \geq \text{VaR}_\theta[R] \) and it is 0 otherwise. Then the model is reformulated to the following MIP:

\[
\begin{align*}
\text{Max} & \quad \text{VaR}_\theta[R] \\
\text{s.t} & \quad r(s) = \sum_j w_j v_j(s) \\
& \quad r(s) \geq \text{VaR}_\theta[R] - M(1 - y(s)) \quad \forall s = 1, \ldots, S \\
& \quad cc = 1 - \sum_s p(s)y(s) \\
& \quad \sum_j w_j = 1 \\
& \quad 0 \leq cc \leq \theta \\
& \quad w_j \geq 0.
\end{align*}
\]
Here \( r(s) \) denotes the return per scenario and \( cc \) is a variable that represents the probability of violations (a violation occurs if in a scenario the return is smaller than \( VaR_\theta[R] \)). As usual, \( p(s) \) is the probability that a scenario occurs and \( M \) is the big \( M \). The first three constraints together with the bounds on \( cc \) ensure that the probability of violations is smaller than or equal to \( \theta \).

Note that the default value for big \( M \) for models with VaR is 1000 (and it is different from the default value for big \( M \) for chance constraints). It may be customized with the option varbigm.

5.12.6.5 Computing CVaR

Models with CVaR are reformulated by converting the annotations into new variables and equations. Using the model portfolio.gms as an example we demonstrate how this is done. This model features in the GAMS EMP library and is also discussed in the section Conditional Value at Risk (CVaR) in the EMP manual. The model is given by:

\[
\begin{align*}
\text{Max} & \quad CVaR_\theta[R] \\
\text{s.t} & \quad R = \sum_j w_j v_j(\omega) \quad \forall \omega \in \Omega \\
& \quad \sum_j w_j = 1 \\
& \quad w_j \geq 0,
\end{align*}
\]  

(5.14)

where \( CVaR_\theta \) is the CVaR at the left tail of the distribution at the confidence level \( \theta \) and all other variables are as defined above. Note that again, \( w_j \) is the decision variable in this problem.

DE reformulates this model by introducing three new variables and three associated equations. Let \( r(s) \) denote the return per scenario, \( t \) the target return to be achieved with probability approximately \( 1 - \theta \) and \( d(s) \), \( d(s) \geq 0 \), the lower deviation from \( t \) per scenario. The equations follow.

\[
\begin{align*}
\text{Max} & \quad CVaR_\theta[R] \\
\text{s.t} & \quad R = \sum_j w_j v_j(s) \\
& \quad d(s) \geq t - r(s) \\
& \quad CVaR_\theta[R] = t - \frac{1}{\theta} \sum p(s) d(s)
\end{align*}
\]  

(5.15)

Thus the model is reformulated to an LP and may be solved by an appropriate solver. It is easy to see that \( t \) equals \( VaR_\theta[R] \).

5.12.7 Logfile

The logfile gives much information about the solver progress. The following is the DE log output from running the nbdiscjoint model from the GAMS EMP Model Library:

--- Starting compilation
--- nbdisjoint.gms(74) 3 Mb
--- Starting execution: elapsed 0:00:00.024
--- nbdisjoint.gms(72) 4 Mb
---
--- collecting and writing gdx file
---
--- Generating EMP model nb
--- nbdisjoint.gms(72) 6 Mb
--- 5 rows 9 columns 19 non-zeroes
--- 6 nl-code 2 nl-non-zeroes
First, the model in scalar form is generated. It has 5 equations, so the model statistics report 5 rows. Further, it has 6 positive variables, one free variable and 2 random variables, so there are 9 columns. A matrix form representation of the model with the variables as columns and the equations as rows has 19 non-zero entries. Next, DE generates the deterministic equivalent. The statistics for the deterministic equivalent indicate that there are 26 rows, 50 columns and 116 non-zeroes. The stochastic model has 6 scenarios, so for each second-stage equation there are 6 equations in the deterministic equivalent (i.e. a total of 24 equations). In addition, there is one first-stage equation and one equation to compute the expected value of the objective variable, which brings the sum total to 26 equations or rows. Similarly, for each second-stage variable in the stochastic model there are 6 variables in the deterministic equivalent (i.e. a total of 48 variables). In addition, there is the first-stage decision variable and a variable for the expected value of the objective adding up to a total of 50 variables or columns.

Note that the model type is identified as an LP and thus the default LP solver is invoked. In this case the subsolver is Cplex and most of the remainder of the logfile is output from the subsolver. At the end the mapping specified in the dictionary is performed.
The logfile of solving stochastic models with VaR or CVaR is similar. It reports that the model type is being determined, the deterministic equivalent built and then handed over to the appropriate subsolver to be solved. However, when solving stochastic programs with chance constraints there is much more happening behind the scenes. DE automatically hands over the model to the subsolver JAMS. By default, JAMS reformulates the model and generates a scalar version of it. The scalar version of the reformulated model is then handed back to the GAMS system to be solved by an appropriate subsolver. The logfile reports the progress of the subsolver until the model is solved. Then the solution from the GAMS subsolver is handed to JAMS and a list of disjunctions and their activity level is reported. (The equations in the scalar version of the reformulated model that may be left unsatisfied are called disjunctions. Active disjunctions refer to equations that are satisfied and not active disjunctions refer to equations that are not satisfied.)

Parts of the DE logfile from running the simplechance model from the GAMS EMP Model Library are given below. These parts of the logfile demonstrate the solution process for stochastic models with chance constraints that was just described.

### 5.12.9 Detailed Descriptions of DE Options

**ccreform (string):** Reformulation option passed to JAMS

This option determines how to formulate the indicator constraints of the chance constraints in the deterministic equivalent. The model is passed to JAMS for the actual reformulation and solution with a subsolver. The possible reformulation options are `bigM [big eps threshold]`, `chull [big eps]`, and `indic`. The `indic` setting only works with solver that under stand the indicator syntax in a GAMS option file.

Default: `bigM`

**correlationtype (integer):** Sample correlation type

Default: 0

5.13.1 DECIS

5.13.1.1 Introduction

DECIS is a system for solving large-scale stochastic programs, i.e. programs that include parameters (coefficients and right-hand sides) that are not known with certainty, but are assumed to be known by their probability distribution. It employs Benders decomposition and advanced Monte Carlo sampling techniques. DECIS includes a variety of solution strategies, such as solving the universe problem, the expected value problem, Monte Carlo sampling within the Benders decomposition algorithm, and Monte Carlo pre-sampling. When using Monte Carlo sampling the user has the option of employing crude Monte Carlo without variance reduction techniques, or using as variance reduction techniques importance sampling or control variates, based on either an additive or a multiplicative approximation function. Pre-sampling is limited to using crude Monte Carlo only.

For solving linear and nonlinear programs (master and subproblems arising from the decomposition) DECIS interfaces with MINOS or CPLEX. MINOS, see Murtagh and Saunders (1983) [142], is a state-of-the-art solver for large-scale linear and nonlinear programs, and CPLEX is one of the fastest linear programming solvers available.

For details about the DECIS system consult the DECIS User’s Guide see Infanger (1997) [100]. It includes a comprehensive mathematical description of the methods used by DECIS. In this Guide we concentrate on how to use DECIS directly from GAMS, and especially on how to model stochastic programs using the GAMS/DECIS interface. First, however, in section What DECIS Can Do we give a brief description of what DECIS can do and what solution strategies it uses. This description has been adapted from the DECIS User’s Guide. In section GAMS/DECIS we discuss in detail how to set up a stochastic problem using GAMS/DECIS and give a description of the parameter setting and outputs obtained. In Appendix A - GAMS/DECIS Illustrative Examples we show the GAMS/DECIS formulation of two illustrative examples (APL1P and APL1PC) discussed in the DECIS User’s Guide. A list of DECIS error messages are represented in Appendix B - Error Messages.

In addition to using the syntax explained in this document, it is also possible to use the Extended Mathematical Programming (EMP) framework to define a stochastic program for GAMS/DECIS. This possibility was introduced with GAMS 23.8 and allows one to solve a stochastic program not only with GAMS/DECIS but also with GAMS/DE and GAMS/Lindo. Further information about this can be found in the chapter Stochastic Programming (SP) with EMP.

5.13.1.2 What DECIS Can Do

DECIS solves two-stage stochastic linear programs with recourse:

\[
\min \quad z = cx + Ef^\omega y^\omega \\
\text{s.t.} \quad Ax = b \\
\quad -B^\omega x + D^\omega y^\omega = d^\omega \\
\quad x, y^\omega \geq 0, \quad \omega \in \Omega.
\]

where \( x \) denotes the first-stage, \( y^\omega \) the second-stage decision variables, \( c \) represents the first-stage and \( f^\omega \) the second-stage objective coefficients, \( A, b \) represent the coefficients and right hand sides of the first-stage constraints, and \( B^\omega, D^\omega, d^\omega \) represent the parameters of the second-stage constraints, where the transition matrix \( B^\omega \) couples the two stages. In the literature \( D^\omega \) is often referred to as the technology matrix or recourse matrix. The first stage parameters are known with certainty. The second stage parameters are
random parameters that assume outcomes labeled $\omega$ with probability $p(\omega)$, where $\Omega$ denotes the set of all possible outcome labels.

At the time the first-stage decision $x$ has to be made, the second-stage parameters are only known by their probability distribution of possible outcomes. Later, after $x$ has already been determined, an actual outcome of the second-stage parameters will become known, and the second-stage decision $y^\omega$ is made based on knowledge of the actual outcome $\omega$. The objective is to find a feasible decision $x$ that minimizes the total expected costs, the sum of first-stage costs and expected second-stage costs.

For discrete distributions of the random parameters, the stochastic linear program can be represented by the corresponding equivalent deterministic linear program:

$$
\min z = cx + p_1fy_1 + p_2fy_2 + \cdots + p_Wfy_W \\
\text{s/t } Ax - B_1x + Dy_1 - B_2x + Dy_2 - \cdots - B_Wx + Dy_W = b \\
\quad x, y_1, y_2, \ldots, y_W \geq 0,
$$

which contains all possible outcomes $\omega \in \Omega$. Note that for practical problems $W$ is very large, e.g., a typical number could be $10^{20}$, and the resulting equivalent deterministic linear problem is too large to be solved directly.

In order to see the two-stage nature of the underlying decision making process the following representation is also often used:

$$
\min cx + E z^\omega(x) \\
\text{s/t } Ax = b \\
x \geq 0,
$$

where

$$
z^\omega(x) = \min f^\omega y^\omega \\
D^\omega y^\omega = d^\omega + B^\omega x \\
y^\omega \geq 0, \omega \in \Omega = \{1, 2, \ldots, W\}.
$$

DECIS employs different strategies to solve two-stage stochastic linear programs. It computes an exact optimal solution to the problem or approximates the true optimal solution very closely and gives a confidence interval within which the true optimal objective lies with, say, 95% confidence.

5.13.1.3 Representing Uncertainty

It is favorable to represent the uncertain second-stage parameters in a structure. Using $V = (V_1, \ldots, V_h)$ an $h$-dimensional independent random vector parameter that assumes outcomes $v^\omega = (v_1, \ldots, v_h)^\omega$ with probability $p^\omega = p(v^\omega)$, we represent the uncertain second-stage parameters of the problem as functions of the independent random parameter $V$: 
Each component $V_i$ has outcomes $v_{i\omega}^i$, $\omega_i \in \Omega_i$, where $\omega_i$ labels a possible outcome of component $i$, and $\Omega_i$ represents the set of all possible outcomes of component $i$. An outcome of the random vector

$$v^\omega = (v_{1\omega}^1, \ldots, v_{h\omega}^h)$$

consists of $h$ independent component outcomes. The set

$$\Omega = \Omega_1 \times \Omega_2 \times \ldots \times \Omega_h$$

represents the crossing of sets $\Omega_i$. Assuming each set $\Omega_i$ contains $W_i$ possible outcomes, $|\Omega_i| = W_i$, the set $\Omega$ contains $W = \prod W_i$ elements, where $|\Omega| = W$ represents the number of all possible outcomes of the random vector $V$. Based on independence, the joint probability is the product

$$p^\omega = p_{1\omega}^1 p_{2\omega}^2 \cdots p_{h\omega}^h.$$
5.13.1.6 Using Monte Carlo Sampling

As noted above, for many practical problems it is impossible to obtain the universe solution, because the number of possible realizations $|\Omega|$ is way too large. The power of DECIS lies in its ability to compute excellent approximate solutions by employing Monte Carlo sampling techniques. Instead of computing the expected cost and the coefficients and the right-hand sides of the Benders cuts exactly (as it is done when solving the universe problem), DECIS, when using Monte Carlo sampling, estimates the quantities in each iteration using an independent sample drawn from the distribution of the random parameters. In addition to using crude Monte Carlo, DECIS uses importance sampling or control variates as variance reduction techniques.

The details of the algorithm and the different techniques used are described in the DECIS User's Manual. You can choose crude Monte Carlo, referred to as strategy 6, Monte Carlo importance sampling, referred to as strategy 2, or control variates, referred to as strategy 10. Both Monte Carlo importance sampling and control variates have been shown for many problems to give a better approximation compared to employing crude Monte Carlo sampling.

When using Monte Carlo sampling DECIS computes a close approximation to the true solution of the problem, and estimates a close approximation of the true optimal objective value. It also computes a confidence interval within which the true optimal objective of the problem lies, say with 95% confidence. The confidence interval is based on rigorous statistical theory. An outline of how the confidence interval is computed is given in the DECIS User's Manual. The size of the confidence interval depends on the variance of the second-stage cost of the stochastic problem and on the sample size used for the estimation. You can expect the confidence interval to be very small, especially when you employ importance sampling or control variates as a variance reduction technique.

When employing Monte Carlo sampling techniques you have to choose a sample size (set in the parameter file). Clearly, the larger the sample size the better will be the approximate solution DECIS computes, and the smaller will be the confidence interval for the true optimal objective value. The default value for the sample size is 100. Setting the sample size too small may lead to bias in the estimation of the confidence interval, therefore the sample size should be at least 30.

5.13.1.7 Monte Carlo Pre-sampling

We refer to pre-sampling when we first take a random sample from the distribution of the random parameters and then generate the approximate stochastic problem defined by the sample. The obtained approximate problem is then solved exactly using decomposition. This is in contrast to the way we used Monte Carlo sampling in the previous section, where we used Monte Carlo sampling in each iteration of the decomposition.

The details of the techniques used for pre-sampling are discussed in the DECIS User's Manual. DECIS computes the exact solution of the sampled problem using decomposition. This solution is an approximate solution of the original stochastic problem. Besides this approximate solution, DECIS computes an estimate of the expected cost corresponding to this approximate solution and a confidence interval within which the true optimal objective of the original stochastic problem lies with, say, 95% confidence. The confidence interval is based on statistical theory, while its size depends on the variance of the second-stage cost of the stochastic problem and on the sample size used for generating the approximate problem. In conjunction with pre-sampling no variance reduction techniques are currently implemented.

Using Monte Carlo pre-sampling you have to choose a sample size. Clearly, the larger the sample size you choose, the better will be the solution DECIS computes, and the smaller will be the confidence interval for the true optimal objective value. The default value for the sample size is 100. Again, setting the sample size too small may lead to a bias in the estimation of the confidence interval, therefore the sample size should be at least 30.

To use Monte Carlo pre-sampling choose strategy 8.
5.13.1.8 Regularized Decomposition

When solving practical problems, the number of Benders iterations can be quite large. In order to control the decomposition, with the hope to reduce the iteration count and the solution time, DECIS makes use of regularization. When employing regularization, an additional quadratic term is added to the objective of the master problem, representing the square of the distance between the best solution found so far (the incumbent solution) and the variable $x$. Using this term, DECIS controls the distance between solutions in successive decomposition iterations.

To enable regularization you have to set the corresponding parameter. You also have to choose the value of the constant rho in the regularization term. The default is regularization disabled. Details of how DECIS carries out regularization are represented in the DECIS User's Manual.

Regularization is only implemented when using MINOS as the optimizer for solving subproblems. Regularization has proven to be helpful for problems that need a large number of Benders iteration when solved without regularization. Problems that need only a small number of Benders iterations without regularization are not expected to improve much with regularization, and may need even more iterations with regularization than without.

5.13.2 GAMS/DECIS

GAMS stands for General Algebraic Modeling Language, and is one of the most widely used modeling languages. Using DECIS directly from GAMS spares you from worrying about all the details of the input formats. It makes the problem formulation much easier but still gives you almost all the flexibility of using DECIS directly.

The link from GAMS to DECIS has been designed in such a way that almost no extensions to the GAMS modeling language were necessary for carrying out the formulation and solution of stochastic programs. In a future release of GAMS, however, additions to the language are planned that will allow you to model stochastic programs in an even more elegant way.

5.13.2.1 Setting up a Stochastic Program Using GAMS/DECIS

The interface from GAMS to DECIS supports the formulation and solution of stochastic linear programs. DECIS solves them using two-stage decomposition. The GAMS/DECIS interface resembles closely the structure of the SMPS (stochastic mathematical programming interface) discussed in the DECIS User's Manual. The specification of a stochastic problem using GAMS/DECIS uses the following components:

- the deterministic (core) model,
- the specification of the decision stages,
- the specification of the random parameters, and
- setting DECIS as the optimizer to be used.
5.13.2.2 Starting with the Deterministic Model

The core model is a deterministic linear program where all random parameters are replaced by their mean or by a particular realization. One could also see it as a GAMS model without any randomness. It could be a deterministic model that you have, that you intend to expand to a stochastic one. Using DECIS with GAMS allows you to easily extend a deterministic linear programming model to a stochastic one. For example, the following GAMS model represents a deterministic version of the electric power expansion planning illustrative example discussed in Infanger (1994).

* APL1P test model
* Dr. Gerd Infanger, November 1997
* Deterministic Program

set g generators / g1, g2/;
set dl demand levels /h, m, l/;

parameter alpha(g) availability / g1 0.68, g2 0.64 /;
parameter ccmin(g) min capacity / g1 1000, g2 1000 /;
parameter ccmax(g) max capacity / g1 10000, g2 10000 /;
parameter c(g) investment / g1 4.0, g2 2.5 /;

table f(g,dl) operating cost
   h   m   l
  g1 4.3 2.0 0.5
  g2 8.7 4.0 1.0;

parameter d(dl) demand / h 1040, m 1040, l 1040 /;
parameter us(dl) cost of unserved demand / h 10, m 10, l 10 /;

free variable tcost total cost;
positive variable x(g) capacity of generators;
positive variable y(g, dl) operating level;
positive variable s(dl) unserved demand;

equations
   cost total cost
   cmin(g) minimum capacity
   cmax(g) maximum capacity
   omax(g) maximum operating level
   demand(dl) satisfy demand;

   cost .. tcost =e= sum(g, c(g)*x(g))
            + sum(g, sum(dl, f(g,dl)*y(g,dl)))
            + sum(dl,us(dl)*s(dl));

   cmin(g) .. x(g) =g= ccmin(g);
   cmax(g) .. x(g) =l= ccmax(g);
   omax(g) .. sum(dl, y(g,dl)) =l= alpha(g)*x(g);
   demand(dl) .. sum(g, y(g,dl)) + s(dl) =g= d(dl);

model apl1p /all/;

option lp=minos5;
solve apl1p using lp minimizing tcost;

scalar ccost capital cost;
scalar ocost operating cost;
ccost = sum(g, c(g) * x.l(g));
ocost = tcost.l - ccost;
display x.l, tcost.l, ccost, ocost, y.l, s.l;

5.13.2.3 Setting the Decision Stages

Next in order to extend a deterministic model to a stochastic one you must specify the decision stages. DECIS solves stochastic programs by two-stage decomposition. Accordingly, you must specify which variables belong to the first stage and which to the second stage, as well as which constraints are first-stage constraints and which are second-stage constraints. First stage constraints involve only first-stage variables, while second-stage constraints involve both first- and second-stage variables. You must specify the stage of a variable or a constraint by setting the stage suffix ".STAGE" to either one or two depending on if it is a first or second stage variable or constraint. For example, expanding the illustrative model above by

* setting decision stages
x.stage(g) = 1;
y.stage(g, dl) = 2;
s.stage(dl) = 2;
cmin.stage(g) = 1;
cmax.stage(g) = 1;
omax.stage(g) = 2;
demand.stage(dl) = 2;

would make x(g) first-stage variables, y(g, dl) and s(dl) second-stage variables, cmin(g) and cmax(g) first-stage constraints, and omax(g) and demand(g) second-stage constraints. The objective is treated separately, you don’t need to set the stage suffix for the objective variable and objective equation.

Note that the use of the .stage variable and equation suffix causes the GAMS scaling facility (i.e. the .scale suffix) to be unavailable. Stochastic models have to be scaled manually.

5.13.2.4 Specifying the Stochastic Model

DECIS supports any linear dependency model, i.e., the outcomes of an uncertain parameter in the linear program are a linear function of a number of independent random parameter outcomes. DECIS considers only discrete distributions: you must approximate any continuous distributions by discrete ones. The number of possible realizations of the discrete random parameters determines the accuracy of the approximation. A special case of a linear dependency model arises when you have only independent random parameters in your model. In this case the independent random parameters are mapped one to one into the random parameters of the stochastic program. We will present the independent case first and then expand to the case with linear dependency. According to setting up a linear dependency model we present the formulation in GAMS by first defining independent random parameters and then defining the distributions of the uncertain parameters in your model.

5.13.2.4.1 Specifying Independent Random Parameters

There are of course many different ways you can set up independent random parameters in GAMS. In the following we show one possible way that is generic and thus can be adapted for different models. The set-up uses the set stoch for labeling outcome named "out" and probability named "pro" of each independent random parameter. In the following we show how to define an independent random parameter, say, v1. The formulation uses the set omegal as driving set, where the set contains one element for each possible realization the random parameter can assume. For example, the set omegal has four elements according to a discrete distribution of four possible outcomes. The distribution of the random parameter is defined as the parameter v1, a two-dimensional array of outcomes "out" and corresponding probability "pro" for each of the possible
realizations of the set omega1, "o11", "o12", "o13", and "o14". For example, the random parameter v1 has outcomes of −1.0, −0.9, −0.5, −0.1 with probabilities 0.2, 0.3, 0.4, 0.1, respectively. Instead of using assignment statements for inputting the different realizations and corresponding probabilities you could also use the table statement. Always make sure that the sum of the probabilities of each independent random parameter adds to one.

* defining independent stochastic parameters

```gams
set stoch /out, pro /;
set omega1 / o11, o12, o13, o14 /;
table v1(stoch, omega1)
      o11 o12 o13 o14
out   -1.0 -0.9 -0.5 -0.1
pro    0.2  0.3  0.4  0.1
;
```

Random parameter v1 is the first out of five independent random parameters of the illustrative model APL1P, where the first two represent the independent availabilities of the generators g1 and g2 and the latter three represent the independent demands of the demand levels h, m, and l. We also represent the definitions of the remaining four independent random parameters. Note that random parameters v3, v4, and v5 are identically distributed.

```gams
set omega2 / o21, o22, o23, o24, o25 /;
table v2(stoch, omega2)
      o21 o22 o23 o24 o25
out   -1.0 -0.9 -0.7 -0.1 -0.0
pro    0.1  0.2  0.5  0.1  0.1
;
```

```gams
set omega3 / o31, o32, o33, o34 /;
table v3(stoch, omega1)
      o11 o12 o13 o14
out   900  1000 1100 1200
pro    0.15 0.45 0.25 0.15
;
```

```gams
set omega4 / o41, o42, o43, o44 /;
table v4(stoch, omega1)
      o11 o12 o13 o14
out   900  1000 1100 1200
pro    0.15 0.45 0.25 0.15
;
```

```gams
set omega5 / o51, o52, o53, o54 /;
table v5(stoch, omega1)
      o11 o12 o13 o14
out   900  1000 1100 1200
pro    0.15 0.45 0.25 0.15
;
```

5.13.2.4.2 Defining the Distributions of the Uncertain Parameters in the Model Having defined the independent stochastic parameters (you may copy the setup above and adapt it for your model), we next define the stochastic parameters in the GAMS model. The stochastic parameters of the
model are defined by writing a file, the GAMS stochastic file, using the put facility of GAMS. The GAMS stochastic file resembles closely the stochastic file of the SMPS input format. The main difference is that we use the row, column, bounds, and right hand side names of the GAMS model and that we can write it in free format.

Independent Stochastic Parameters

First we describe the case where all stochastic parameters in the model are independent, see below the representation of the stochastic parameters for the illustrative example APL1P, which has five independent stochastic parameters.

First define the GAMS stochastic file "MODEL.STG" (only the exact name in uppercase letters is supported) and set up GAMS to write to it. This is done by the first two statements. You may want to consult the GAMS manual for how to use put for writing files. The next statement "INDEP DISCRETE" indicates that a section of independent stochastic parameters follows. We then write all possible outcomes and corresponding probabilities for each stochastic parameter by using loop statements. Of course one could also write each line separately, but the loops work nicely. Writing a "*" between the definitions of the independent stochastic parameters is merely for optical reasons and can be omitted.

* defining distributions (writing file MODEL.STG)
file stg /MODEL.STG/;
put stg;

put "INDEP DISCRETE" /;
loop(omega1,
  put "x g1 omax g1 ", v1("out", omega1), " period2 ", v1("pro", omega1) /;
  put "*" /;
  loop(omega2,
    put "x g2 omax g2 ", v2("out", omega2), " period2 ", v2("pro", omega2) /;
    put "*" /;
    loop(omega3,
      put "RHS demand h ", v3("out", omega3), " period2 ", v3("pro", omega3) /;
      put "*" /;
      loop(omega4,
        put "RHS demand m ", v4("out", omega4), " period2 ", v4("pro", omega4) /;
      )
      put "*" /;
      loop(omega5,
        put "RHS demand l ", v5("out", omega5), " period2 ", v5("pro", omega5) /;
      )
    )
  )
)
putclose stg;

In the example APL1P the first stochastic parameter is the availability of generator g1. In the model the parameter appears as the coefficient of variable x(g1) in equation omax(g1). The definition using the put statement first gives the stochastic parameter as the intersection of variable x(g1) with equation omax(g1), but without having to type the braces, thus \( x g1 omax g1 \), then the outcome \( v1("out", omega1) \) and the probability \( v1("pro", omega1) \) separated by "period2". The different elements of the statement must be separated by blanks. Since the outcomes and probabilities of the first stochastic parameters are driven by the set omega1 we loop over all elements of the set omega1. We continue and define all possible outcomes for each of the five independent stochastic parameters.

In the example of independent stochastic parameters, the specification of the distribution of the stochastic parameters using the put facility creates the following file "MODEL.STG", which then is processed by the GAMS/DECIS interface:
INDEP DISCRETE
x g1 omax g1 -1.00 period2 0.20
x g1 omax g1 -0.90 period2 0.30
x g1 omax g1 -0.50 period2 0.40
x g1 omax g1 -0.10 period2 0.10
*
x g2 omax g2 -1.00 period2 0.10
x g2 omax g2 -0.90 period2 0.20
x g2 omax g2 -0.70 period2 0.50
x g2 omax g2 -0.10 period2 0.10
x g2 omax g2 0.00 period2 0.10
*
RHS demand h 900.00 period2 0.15
RHS demand h 1000.00 period2 0.45
RHS demand h 1100.00 period2 0.25
RHS demand h 1200.00 period2 0.15
*
RHS demand m 900.00 period2 0.15
RHS demand m 1000.00 period2 0.45
RHS demand m 1100.00 period2 0.25
RHS demand m 1200.00 period2 0.15
*
RHS demand l 900.00 period2 0.15
RHS demand l 1000.00 period2 0.45
RHS demand l 1100.00 period2 0.25
RHS demand l 1200.00 period2 0.15

For defining stochastic parameters in the right-hand side of the model use the keyword RHS as the column name, and the equation name of the equation which right-hand side is uncertain, see for example the specification of the uncertain demands RHS demand h, RHS demand m, and RHS demand l. For defining uncertain bound parameters you would use the keywords UP, LO, or FX, the string bnd, and the variable name of the variable whose upper, lower, or fixed bound is uncertain.

Note all the keywords for the definitions are in capital letters, i.e., "INDEP DISCRETE", "RHS", and not represented in the example "UP", "LO", and "FX".

Note that in GAMS equations, variables may appear in the right-hand side, e.g. "EQ. X+1 =L= 2*Y". When the coefficient 2 is a random variable, we need to be aware that GAMS will generate the following LP row X - 2*Y =L= -1. Suppose the probability distribution of this random variable is given by:

```gams
set s scenario /pessimistic, average, optimistic/;
parameter outcome(s) / pessimistic 1.5
  average 2.0
  optimistic 2.3 /;
parameter prob(s) / pessimistic 0.2
  average 0.6
  optimistic 0.2 /;
```

then the correct way of generating the entries in the stochastic file would be:

```gams
loop(s,
  put "Y EQ ",(-outcome(s))," PERIOD2 ",prob(s)/;
);
```

Note the negation of the outcome parameter. Also note that expressions in a PUT statement have to be surrounded by parentheses. GAMS reports in the row listing section of the listing file how equations are generated. You are encouraged to inspect the row listing to discover or confirm how coefficients appear in a generated LP row.
5.13.2.4.3 Dependent Stochastic Parameters  Next we describe the case of general linear dependency of the stochastic parameters in the model, see below the representation of the stochastic parameters for the illustrative example APL1PCA, which has three dependent stochastic demands driven by two independent stochastic random parameters. First we give the definition of the two independent stochastic parameters, which in the example happen to have two outcomes each.

* defining independent stochastic parameters
set stoch /out, pro/;
set omega1 / o11, o12 /;
table v1(stoch,omega1)
  o11  o12
  out  2.1  1.0
  pro  0.5  0.5 ;
set omega2 / o21, o22 /;
table v2(stoch, omega2)
  o21  o22
  out  2.0  1.0
  pro  0.2  0.8 ;

We next define the parameters of the transition matrix from the independent stochastic parameters to the dependent stochastic parameters of the model. We do this by defining two parameter vectors, where the vector \( hm1 \) gives the coefficients of the independent random parameter \( v1 \) in each of the three demand levels and the vector \( hm2 \) gives the coefficients of the independent random parameter \( v2 \) in each of the three demand levels.

parameter hm1(dl) / h 300., m 400., l 200. /;
parameter hm2(dl) / h 100., m 150., l 300. /;

Again first define the GAMS stochastic file "MODEL.STG" and set GAMS to write to it. The statement BLOCKS DISCRETE indicates that a section of linear dependent stochastic parameters follows.

* defining distributions (writing file MODEL.STG)
file stg / MODEL.STG /;
put stg;

put "BLOCKS DISCRETE" /;
scalar h1;
loop(omega1,
  put "BL v1 period2 ", v1("pro", omega1)/;
  loop(dl,
    h1 = hm1(dl) * v1("out", omega1);
    put "RHS demand ", dl.tl:1, " ", h1/;
  );
);
loop(omega2,
  put " BL v2 period2 ", v2("pro", omega2) /;
  loop(dl,
    h1 = hm2(dl) * v2("out", omega2);
    put "RHS demand ", dl.tl:1, " ", h1/;
  );
);
putclose stg;
Dependent stochastic parameters are defined as functions of independent random parameters. The keyword BL labels a possible realization of an independent random parameter. The name besides the BL keyword is used to distinguish between different outcomes of the same independent random parameter or a different one. While you could use any unique names for the independent random parameters, it appears natural to use the names you have already defined above, e.g., v1 and v2. For each realization of each independent random parameter define the outcome of every dependent random parameter (as a function of the independent one). If a dependent random parameter in the GAMS model depends on two or more different independent random parameters the contributions of each of the independent parameters are added. We are therefore in the position to model any linear dependency model. (Note that the class of models that can be accommodated here is more general than linear. The functions, with which an independent random variable contributes to the dependent random variables can be any ones in one argument. As a general rule, any stochastic model that can be estimated by linear regression is supported by GAMS/DECIS.)

Define each independent random parameter outcome and the probability associated with it. For example, the statement starting with BL v1 period2 indicates that an outcome of (independent random parameter) v1 is being defined. The name period2 indicates that it is a second-stage random parameter, and v1("pro", omega1) gives the probability associated with this outcome. Next list all random parameters dependent on the independent random parameter outcome just defined. Define the dependent stochastic parameter coefficients by the GAMS variable name and equation name, or "RHS" and variable name, together with the value of the parameter associated with this realization. In the example, we have three dependent demands. Using the scalar h1 for internally storing the results of the calculation, looping over the different demand levels dl we calculate h1 = h1(dl) * v1("out", omega1) and define the dependent random parameters as the right-hand sides of equation demand(dl).

When defining an independent random parameter outcome, if the block name is the same as the previous one (e.g., when BL v1 appears the second time), a different outcome of the same independent random parameter is being defined, while a different block name (e.g., when BL v2 appears the first time) indicates that the first outcome of a different independent random parameter is being defined. You must ensure that the probabilities of the different outcomes of each of the independent random parameters add up to one. The loop over all elements of omega1 defines all realizations of the independent random parameter v1 and the loop over all elements of omega2 defines all realizations of the independent random parameter v2.

Note that for the first realization of an independent random parameter, you must define all dependent parameters and their realizations. The values entered serve as a base case. For any other realization of an independent random parameter you only need to define the dependent parameters that have different coefficients than have been defined in the base case. For those not defined in a particular realization, their values of the base case are automatically added.

In the example of dependent stochastic parameters above, the specification of the distribution of the stochastic parameters using the put facility creates the following file "MODEL.STG", which then is processed by the GAMS/DECIS interface:

```
BLOCKS DISCRETE
BL v1 period2 0.50
RHS demand h 630.00
RHS demand m 840.00
RHS demand l 420.00
BL v1 period2 0.50
RHS demand h 300.00
RHS demand m 400.00
RHS demand l 200.00
BL v1 period2 0.50
RHS demand h 200.00
RHS demand m 300.00
RHS demand l 600.00
BL v2 period2 0.20
RHS demand h 300.00
RHS demand m 400.00
RHS demand l 200.00
BL v2 period2 0.20
RHS demand h 200.00
RHS demand m 300.00
RHS demand l 600.00
BL v2 period2 0.80
RHS demand h 100.00
RHS demand m 150.00
RHS demand l 300.00
```
Again all the keywords for the definitions are in capital letters, i.e., "BLOCKS DISCRETE", "BL", "RHS", and not represented in the example "UP", "LO", and "FX".

Note that you can only define random parameter coefficients that are nonzero in your GAMS model. When setting up the deterministic core model put a nonzero entry as a placeholder for any coefficient that you wish to specify as a stochastic parameter. Specifying a random parameter at the location of a zero coefficient in the GAMS model causes DECIS to terminate with an error message.

5.13.2.5 Setting DECIS as the Optimizer

After having finished the stochastic definitions you must set DECIS as the optimizer. This is done by issuing the following statements:

* setting DECIS as optimizer
* DECISM uses MINOS, DECISC uses CPLEX

```
option lp=decism;
aplp.optfile = 1;
```

The statement `option lp = decism` sets DECIS with the MINOS LP engine as the optimizer to be used for solving the stochastic problem. Note that if you do not use DECIS, but instead use any other linear programming optimizer, your GAMS model will still run and optimize the deterministic core model that you have specified. The statement `aplp.optfile = 1` directs GAMS to process the file `DECIS.OPT`, in which you may define any DECIS parameters.

5.13.2.5.1 Setting Parameter Options in the GAMS Model  The options iteration limit and resource limit can be set directly in your GAMS model file. For example, the following statements

```
option iterlim = 1000;
option reslim = 6000;
```

limit the number of decomposition iterations to be less than or equal to 1000, and the elapsed time for running DECIS to be less than or equal to 6000 seconds or 100 minutes.

5.13.2.5.2 Setting Parameters in the DECIS Options File  In the DECIS options file you can specify parameters regarding the solution algorithm used and control the output of the DECIS program. There is a record for each parameter you want to specify. Each record consists of the value of the parameter you want to specify and the keyword identifying the parameter, separated by a blank character or a comma. You may specify parameters with the following keywords: istrat, nsamples, nzrows, iwrite, ibug, iscratch, ireg, rho, tolben, and tolw in any order. Each keyword can be specified in lower case or upper case text in the format (A10). Since DECIS reads the records in free format you don't have to worry about the format, but some computers require that the text is inputted in quotes. Parameters that are not specified in the parameter file automatically assume their default values. See details of these parameters from Section Description of GAMS/DECIS Options.

5.13.2.5.3 Example  In the following example the parameters istrat = 7, nsamples = 200, and nzrows = 200 are specified. All other parameters are set at their default values. DECIS first solves the expected value problem and then the stochastic problem using crude Monte Carlo sampling with a sample size of nsamples = 200. DECIS reserves space for a maximum of nzrows = 50 cuts.

```
7 "ISTRAT"
200 "NSAMPLES"
50 "NZROWS"
```
5.13.2.5.4 Setting MINOS Parameters in the MINOS Specification File  When you use MINOS as the optimizer for solving the master and the subproblems, you must specify optimization parameters in the MINOS specification file "MINOS.SPC". Each record of the file corresponds to the specification of one parameter and consists of a keyword and the value of the parameter in free format. Records having a "∗" as their first character are considered as comment lines and are not further processed. For a detailed description of these parameters, see the MINOS Users' Guide (Murtagh and Saunders (1983) [142]). The following parameters should be specified with some consideration:

- **AIJ TOLERANCE** — Specifies the nonzero tolerance for constraint matrix elements of the problem. Matrix elements $a_{ij}$ that have a value for which $|a_{ij}|$ is less than "AIJ TOLERANCE" are considered by MINOS as zero and are automatically eliminated from the problem. It is wise to specify "AIJ TOLERANCE 0.0"

- **SCALE** — Specifies MINOS to scale the problem ("SCALE YES") or not ("SCALE NO"). It is wise to specify "SCALE NO".

- **ROWS** — Specifies the number of rows in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "ROWS" should be specified as the number of constraints in the core problem or greater.

- **COLUMNS** — Specifies the number of columns in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "COLUMNS" should be specified as the number of variables in the core problem or greater.

- **ELEMENTS** — Specifies the number of nonzero matrix coefficients in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "ELEMENTS" should be specified as the number of nonzero matrix coefficients in the core problem or greater.

5.13.2.5.5 Example  The following example represents typical specifications for running DECIS with MINOS as the optimizer.

```
BEGIN SPECS
PRINT LEVEL 1
LOG FREQUENCY 10
SUMMARY FREQUENCY 10
MPS FILE 12
ROWS 20000
COLUMNS 50000
ELEMENTS 100000
ITERATIONS LIMIT 30000
*
FACTORIZATION FREQUENCY 100
AIJ TOLERANCE 0.0
*
SCALE NO
END OF SPECS
```

5.13.2.5.6 Setting CPLEX Parameters Using System Environment Variables  When you use CPLEX as the optimizer for solving the master and the subproblems, optimization parameters must be specified through system environment variables. You can specify the parameters "CPLEXLICDIR", "SCALELP", "NOPRESOLVE", "ITERLOG", "OPTIMALITYTOL", "FEASIBILITYTOL", and "DUALSIMPLEX".

- **CPLEXLICDIR** — Contains the path to the CPLEX license directory. For example, on a Unix system with the CPLEX license directory in /usr/users/cplex/cplexlicdir you issue the command `setenv CPLEXLICDIR /usr/users/cplex/cplexlicdir`. 

• SCALELP — Specifies CPLEX to scale the master and subproblems before solving them. If the environment variable is not set no scaling is used. Setting the environment variable, e.g., by issuing the command `setenv SCALELP yes`, scaling is switched on.

• NOPRESOLVE — Allows to switch off CPLEX's presolver. If the environment variable is not set, presolve will be used. Setting the environment variable, e.g., by setting `setenv NOPRESOLVE yes`, no presolve will be used.

• ITERLOG — Specifies the iteration log of the CPLEX iterations to be printed to the file "MODEL.CPX". If you do not set the environment variable no iteration log will be printed. Setting the environment variable, e.g., by setting `setenv ITERLOG yes`, the CPLEX iteration log is printed.

• OPTIMALITYTOL — Specifies the optimality tolerance for the CPLEX optimizer. If you do not set the environment variable the CPLEX default values are used. For example, setting `setenv OPTIMALITYTOL 1.0E-7` sets the CPLEX optimality tolerance to 0.0000001.

• FEASIBILITYTOL — Specifies the feasibility tolerance for the CPLEX optimizer. If you do not set the environment variable the CPLEX default values are used. For example, setting `setenv FEASIBILITYTOL 1.0E-7` sets the CPLEX optimality tolerance to 0.0000001.

• DUALSIMPLEX — Specifies the dual simplex algorithm of CPLEX to be used. If the environment variable is not set the primal simplex algorithm will be used. This is the default and works beautifully for most problems. If the environment variable is set, e.g., by setting `setenv DUALSIMPLEX yes`, CPLEX uses the dual simplex algorithm for solving both master and subproblems.

5.13.2.6 GAMS/DECIS Output

After successfully having solved a problem, DECIS returns the objective, the optimal primal and optimal dual solution, the status of variables (if basic or not), and the status of equations (if binding or not) to GAMS. In the case of first-stage variables and equations you have all information available in GAMS, as you would with any other solver, but instead of obtaining the optimal values for a deterministic core problem you actually have the optimal values for the stochastic problem. However, for second-stage variables and constraints the expected values of the optimal primal and optimal dual solution are reported. This saves space and is useful for the calculation of risk measures. However, the information as to what the optimal primal and dual solutions were in the different scenarios of the stochastic programs is not reported back to GAMS. In a future release of the GAMS/DECIS interface the GAMS language is planned to be extended to handle the scenario second-stage optimal primal and dual values at least for selected variables and equations.

While running, DECIS outputs important information about the progress of the execution to your computer screen. After successfully solving a problem, DECIS also outputs its optimal solution to the solution output file "MODEL.SOL". The debug output file "MODEL.SCR" contains important information about the optimization run, and the optimzer output files "MODEL.MO" (when using DECIS with MINOS) or "MODEL.CPX" (when using DECIS with CPLEX) contain solution output from the optimizer used. In the DECIS User's Guide you find a detailed discussion of how to interpret the screen output, the solution report and the information in the output files.

5.13.2.6.1 The Screen Output The output to the screen allows you to observe the progress of a DECIS run. After the program logo and the copyright statement, you see four columns of output being written to the screen as long as the program proceeds. The first column (from left to right) represents the iteration count, the second column the lower bound (the optimal objective of the master problem), the third column the best upper bound (exact value or estimate of the total expected cost of the best solution found so far), and the fourth column the current upper bound (exact value or estimate of the total expected cost of current solution). After successful completion, DECIS quits with "Normal Exit", otherwise, if an error has been encountered, the programs stops with the message "Error Exit".
5.13.2.6.2 Example  When solving the illustrative example APL1P using strategy 5, we obtain the following report on the screen:

```

Normal Exit

5.13.2.6.3 The Solution Output File  The solution output file contains the solution report from the DECIS run. Its name is "MODEL.SOL". The file contains the best objective function value found, the corresponding values of the first-stage variables, the corresponding optimal second-stage cost, and a lower and an upper bound on the optimal objective of the problem. In addition, the number of universe scenarios and the settings for the stopping tolerance are reported. In the case of using a deterministic strategy for solving the problem, exact values are reported. When using Monte Carlo sampling, estimated values, their variances, and the sample size used for the estimation are reported. Instead of exact upper and lower bounds, probabilistic upper and lower bounds, and a 95% confidence interval, within which the true optimal solution lies with 95% confidence, are reported. A detailed description of the solution output file can be found in the DECIS User's Guide.

5.13.2.6.4 The Debug Output File  The debug output file contains the standard output of a run of DECIS containing important information about the problem, its parameters, and its solution. It also contains any error messages that may occur during a run of DECIS. In the case that DECIS does not complete a run successfully, the cause of the trouble can usually be located using the information in the debug output file. If the standard output does not give enough information you can set the debug parameter ibug in the parameter input file to a higher value and obtain additional debug output. A detailed description of the debug output file can be found in the DECIS User's Guide.

5.13.2.6.5 The Optimizer Output Files  The optimizer output file "MODEL.MO" contains all the output from MINOS when called as a subroutine by DECIS. You can specify what degree of detail should be outputted by setting the appropriate "PRINT LEVEL" in the MINOS specification file. The optimizer output file "MODEL.CPX" reports messages and the iteration log (if switchwd on using the environment variable) from CPLEX when solving master and sub problems.
5.13.3 Description of GAMS/DECIS Options
