2 Release Notes ............................................. 3
  2.1 Release Types ......................................... 3
  2.2 Release History ...................................... 3
  2.3 27 Distribution ....................................... 6
    2.3.1 27.1.0 Major release (April 24, 2019) ............... 6
    2.3.2 27.2.0 Minor release (May 23, 2019) ............... 11
    2.3.3 27.3.0 Minor release (July 04, 2019) ............... 13
  2.4 26 Distribution ....................................... 15
    2.4.1 26.1.0 Major release (February 02, 2019) .......... 15
  2.5 25.1 Distribution .................................... 27
    2.5.1 25.1.1 Major release (May 19, 2018) ............... 27
    2.5.2 25.1.2 Minor release (August 01, 2018) ............ 35
    2.5.3 25.1.3 Minor release (October 30, 2018) .......... 37
  2.6 25.0 Distribution .................................... 39
    2.6.1 25.0.1 Major release (January 17, 2018) .......... 39
    2.6.2 25.0.2 Maintenance release (January 31, 2018) ...... 49
    2.6.3 25.0.3 Minor release (March 21, 2018) ............ 50
  2.7 24.9 Distribution .................................... 52
    2.7.1 24.9.1 Major release (August 30, 2017) .......... 52
    2.7.2 24.9.2 Minor release (November 14, 2017) .......... 62
2.8 24.8 Distribution ............................................................. 65
  2.8.1 24.8.1 Major release (December 21, 2016) ......................... 65
  2.8.2 24.8.2 Maintenance release (January 03, 2017) .................... 75
  2.8.3 24.8.3 Minor release (January 28, 2017) .......................... 75
  2.8.4 24.8.4 Minor release (April 10, 2017) ............................ 77
  2.8.5 24.8.5 Maintenance release (May 10, 2017) ....................... 79

2.9 24.7 Distribution ............................................................. 80
  2.9.1 24.7.1 Major release (March 14, 2016) ............................ 80
  2.9.2 24.7.2 Minor release (July 07, 2016) ................................ 83
  2.9.3 24.7.3 Maintenance release (July 11, 2016) ....................... 86
  2.9.4 24.7.4 Minor release (September 19, 2016) ...................... 86

2.10 24.6 Distribution ........................................................... 88
  2.10.1 24.6.1 Major release (January 18, 2016) ......................... 88

2.11 24.5 Distribution ........................................................... 93
  2.11.1 24.5.1 Major release (September 23, 2015) ..................... 93
  2.11.2 24.5.2 Maintenance release (September 29, 2015) .............. 102
  2.11.3 24.5.3 Maintenance release (October 01, 2015) ............... 103
  2.11.4 24.5.4 Maintenance release (October 15, 2015) ............... 103
  2.11.5 24.5.5 Maintenance release (November 25, 2015) ............ 104
  2.11.6 24.5.6 Maintenance release (November 27, 2015) ............. 105

2.12 24.4 Distribution ........................................................... 106
  2.12.1 24.4.1 Major release (December 20, 2014) ..................... 106
  2.12.2 24.4.2 Minor release (March 15, 2015) .......................... 115
  2.12.3 24.4.3 Maintenance release (April 02, 2015) .................. 118
  2.12.4 24.4.4 Maintenance release (May 12, 2015) ................... 118
  2.12.5 24.4.5 Maintenance release (May 26, 2015) ................... 120
  2.12.6 24.4.6 Minor release (June 26, 2015) ........................... 120

2.13 24.3 Distribution ........................................................... 121
  2.13.1 24.3.1 Major release (July 31, 2014) ........................... 121
  2.13.2 24.3.2 Minor release (August 29, 2014) ......................... 131
2.13.3  24.3.3 Minor release (September 19, 2014) ........................................... 134
2.14  24.2 Distribution .......................................................... 135
  2.14.1  24.2.1 Major release (December 09, 2013) ...................... 135
  2.14.2  24.2.2 Maintenance release (March 04, 2014) ............. 135
  2.14.3  24.2.3 Maintenance release (May 22, 2014) ............. 135
2.15  24.1 Distribution ...................................................... 135
  2.15.1  24.1.1 Major release (May 30, 2013) ....................... 135
  2.15.2  24.1.2 Maintenance release (June 16, 2013) ............. 135
  2.15.3  24.1.3 Maintenance release (July 26, 2013) .......... 135
2.16  24.0 Distribution ...................................................... 135
  2.16.1  24.0.1 Major release (December 24, 2012) ............. 135
  2.16.2  24.0.2 Maintenance release (February 14, 2013) ........ 135
2.17  23.9 Distribution ...................................................... 135
  2.17.1  23.9.1 Major release (July 04, 2012) ....................... 135
  2.17.2  23.9.2 Maintenance release (August 29, 2012) .......... 135
  2.17.3  23.9.3 Maintenance release (September 26, 2012) .... 135
  2.17.4  23.9.4 Maintenance release (October 20, 2012) ...... 135
  2.17.5  23.9.5 Maintenance release (November 09, 2012) .... 135
2.18  23.8 Distribution ...................................................... 135
  2.18.1  23.8.1 Major release (March 17, 2012) .................... 135
  2.18.2  23.8.2 Maintenance release (April 05, 2012) .......... 135
2.19  23.7 Distribution ...................................................... 136
  2.19.1  23.7.1 Major release (July 14, 2011) ...................... 136
  2.19.2  23.7.2 Maintenance release (July 22, 2011) .......... 136
  2.19.3  23.7.3 Maintenance release (August 23, 2011) .... 136
2.20  23.6 Distribution ...................................................... 137
  2.20.1  23.6.2 Major release (December 13, 2010) ............ 137
  2.20.2  23.6.3 Maintenance release (February 15, 2011) .... 137
  2.20.3  23.6.4 Maintenance release (April 01, 2011) .......... 137
  2.20.4  23.6.5 Maintenance release (April 08, 2011) ....... 138
2.21 23.5 Distribution ................................................................. 138
  2.21.1 23.5.1 Major release (July 05, 2010) ............................ 138
  2.21.2 23.5.2 Maintenance release (August 18, 2010) .............. 138
2.22 23.4 Distribution ............................................................... 138
  2.22.1 23.4.1 Major release (May 21, 2010) ......................... 138
  2.22.2 23.4.3 Maintenance release (May 24, 2010) ............... 138
2.23 23.3 Distribution ............................................................... 138
  2.23.1 23.3.1 Major release (November 01, 2009) ............... 138
  2.23.2 23.3.2 Maintenance release (November 18, 2009) .......... 138
  2.23.3 23.3.3 Maintenance release (December 17, 2009) ....... 139
2.24 23.2 Distribution ............................................................... 139
  2.24.1 23.2.1 Minor release (August 14, 2009) .................. 139
2.25 23.1 Distribution ............................................................... 139
  2.25.1 23.1.1 Major release (July 13, 2009) ....................... 139
  2.25.2 23.1.2 Maintenance release (July 23, 2009) ........... 139
2.26 23.0 Distribution ............................................................... 139
  2.26.1 23.0.2 Major release (February 14, 2009) .............. 139
2.27 22.9 Distribution ............................................................... 139
  2.27.1 22.9.2 Major release (December 01, 2008) ........... 139
2.28 22.8 Distribution ............................................................... 139
  2.28.1 22.8.1 Major release (August 01, 2008) .................. 139
2.29 22.7 Distribution ............................................................... 139
  2.29.1 22.7.1 Major release (May 01, 2008) .................... 139
  2.29.2 22.7.2 Maintenance release (May 13, 2008) .......... 139
2.30 22.6 Major release (December 24, 2007) ....................... 140
2.31 22.5 Major release (June 01, 2007) ................................. 140
2.32 22.4 Major release (February 12, 2007) ....................... 140
2.33 22.3 Major release (November 27, 2006) ..................... 140
2.34 22.2 Minor release (April 21, 2006) ................................. 140
2.35 22.1 Major release (March 15, 2006) ................................. 140
3 User's Guide

3.1 Preface ........................................ 141
3.2 Installation and Licensing .................. 141
3.3 Tutorials and Examples ..................... 141
3.4 GAMS Language and Environment .......... 142
3.5 Glossary .................................. 143
3.6 McCarl GAMS User Guide ................... 144
3.7 Preface .................................. 144
   3.7.1 Timeline for documentation released with GAMS software .... 145
3.8 Supported Platforms ....................... 146
3.9 Installation Notes for Mac OS X .......... 147
   3.9.1 Installation using the DMG installer (GAMS27.3.0.dmg) .... 147
   3.9.2 Installation using the self-extracting archive (osx_x64_64_sfx.exe) . 148
   3.9.3 Installation of the Windows version using Wine ........ 152

GAMS Documentation Center

The GAMS Documentation Center provides you with the technical information on getting started, using and maintaining our GAMS (General Algebraic Modeling System) products.

- Release Notes - 27.3.0 Minor release (July 04, 2019)
- User's Guide
  - Installation and Licensing - Guides on installing GAMS for various platforms and using a GAMS license
  - Tutorials and Examples - Step-by-step guides including a number of examples
  - GAMS Language and Environment - Guide through components of GAMS Language and the environment for executing a GAMS model
- Solver Manuals - Manuals of solvers available in the distribution
- Tools Manuals - Manuals of tools available in the distribution
- Application Programming Interfaces - Manuals of Application Programming Interfaces
- Glossary - An alphabetical list of GAMS terms.
- Bibliography

1.1 Model Libraries

From the early stages of the development of GAMS we have collected models to be used in libraries of examples. Many of these are standard textbook examples and can be used in classes on problem formulation or to illustrate points about GAMS. Others are models that have been used in policy or sector analysis and are interesting for both the methods and the data they use. These model libraries are included with all GAMS systems and are also available online.

The following model libraries are available:

- **GAMS Model Library** - includes GAMS models representing interesting and sometimes classic problems, ranged from production and shipment by firms, investment planning, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and many more.
• **GAMS Test Library** - includes GAMS models developed for testing and quality control, both for the GAMS base module and the many solvers distributed with the GAMS system.

• **GAMS Data Library** - includes GAMS models demonstrating various utilities to interface GAMS with other tools and applications such as spreadsheets and database interface.

• **GAMS EMP Library** - includes GAMS Extended Mathematical Programming (EMP) models that illustrate and test the capabilities of GAMS/EMP.

• **GAMS API Library** - includes GAMS Models used as scripts to compile and execute application programs in various programming languages interfacing to GAMS.

• **FIN Library** - includes GAMS practical financial optimization models described in the book *Practical Financial Optimization: Decision Making for Financial Engineers* by Consiglio, Nielsen and Zenios,

• **NOA Library** - includes GAMS nonlinear optimization applications models based on the book *Nonlinear Optimization Applications Using the GAMS Technology* by Neculai Andrei.

• **PSOPT Library** - includes GAMS optimization models based on the book *Power System Optimization Modelling in GAMS* by by Alireza Soroudi.

See [Accessing Model Libraries](#) on how to access a GAMS model from the model libraries.

For large parts of the documentation, references to models from the model libraries are enclosed in square parenthesis (for example, [TRNSPORT]).

### 1.2 Further Help

If you have a further question which is not answered by the documentation above, you can get further help from our [Support Wiki page](#) which contains some materials collected from various support activities including [Frequently Asked Questions (FAQ)](#) or post your question to [GAMS World](#), a GAMS Google discussion group. You can also subscribe to our [Mailing List](#) and browse our [Newsletters](#) to get the latest information from GAMS. There is also [GAMS Lessons](#), a YouTube Video Channel providing you with some tutorials on how to use our system.

There are a number of contributed documentations that have been contributed by GAMS users as well as [presentations, books, posters, and advertisements](#) contributed by people working with GAMS. The McCarl GAMS User Guide (CHM and PDF) can also be found in the mccarl/ subdirectory in the GAMS distribution. You can also visit our upcoming [courses and workshops](#) or contact one of [solution specialists](#) who have wide experience in GAMS modeling.

If you experience a problem using GAMS please contact our [Technical Support](#). Please consult this [check list](#) and read information on conversion of models before submitting your models to our technical support.
Chapter 2

Release Notes

2.1 Release Types

**Major releases** contain substantial changes to the GAMS system. The License Check date is set to the release date of the major release.

**Minor releases** are mainly issued to provide bug fixes, performance improvements, and maintenance releases of solver libraries. Additionally, they can provide a few new features that do not change existing behavior. The License Check Date remains the same as for the prior major release. This means that any license file that worked with the prior major release will also work with this minor release.

**Maintenance releases** do not provide any new features. They are issued to provide bug fixes, performance improvements, and maintenance releases of solver libraries. The License Check Date remains the same as for the prior major release. This means that any license file that worked with the prior major release will also work with this maintenance release.

2.2 Release History

- **27 Distribution** *(Download)*
  - 27.1.0 Major release (April 24, 2019)
  - 27.2.0 Minor release (May 23, 2019)
  - 27.3.0 Minor release (July 04, 2019)
- **26 Distribution** *(Download)*
  - 26.1.0 Major release (February 02, 2019)
- **25.1 Distribution** *(Download)*
  - 25.1.1 Major release (May 19, 2018)
  - 25.1.2 Minor release (August 01, 2018)
  - 25.1.3 Minor release (October 30, 2018)
- **25.0 Distribution** *(Download)*
  - 25.0.1 Major release (January 17, 2018)
  - 25.0.2 Maintenance release (January 31, 2018)
  - 25.0.3 Minor release (March 21, 2018)
• 24.9 Distribution (Download)
  – 24.9.1 Major release (August 30, 2017)
  – 24.9.2 Minor release (November 14, 2017)

• 24.8 Distribution (Download)
  – 24.8.1 Major release (December 21, 2016)
  – 24.8.2 Maintenance release (January 03, 2017)
  – 24.8.3 Minor release (January 28, 2017)
  – 24.8.4 Minor release (April 10, 2017)
  – 24.8.5 Maintenance release (May 10, 2017)

• 24.7 Distribution (Download)
  – 24.7.1 Major release (March 14, 2016)
  – 24.7.2 Minor release (July 07, 2016)
  – 24.7.3 Maintenance release (July 11, 2016)
  – 24.7.4 Minor release (September 19, 2016)

• 24.6 Distribution (Download)
  – 24.6.1 Major release (January 18, 2016)

• 24.5 Distribution (Download)
  – 24.5.1 Major release (September 23, 2015)
  – 24.5.2 Maintenance release (September 29, 2015)
  – 24.5.3 Maintenance release (October 01, 2015)
  – 24.5.4 Maintenance release (October 15, 2015)
  – 24.5.5 Maintenance release (November 25, 2015)
  – 24.5.6 Maintenance release (November 27, 2015)

• 24.4 Distribution (Download)
  – 24.4.1 Major release (December 20, 2014)
  – 24.4.2 Minor release (March 15, 2015)
  – 24.4.3 Maintenance release (April 02, 2015)
  – 24.4.4 Maintenance release (May 12, 2015)
  – 24.4.5 Maintenance release (May 26, 2015)
  – 24.4.6 Minor release (June 26, 2015)

• 24.3 Distribution (Download)
  – 24.3.1 Major release (July 31, 2014)
  – 24.3.2 Minor release (August 29, 2014)
  – 24.3.3 Minor release (September 19, 2014)

• 24.2 Distribution (Download)
  – 24.2.1 Major release (December 09, 2013)
  – 24.2.2 Maintenance release (March 04, 2014)
  – 24.2.3 Maintenance release (May 22, 2014)

• 24.1 Distribution (Download)
  – 24.1.1 Major release (May 30, 2013)
2.2 Release History

- 24.1.2 Maintenance release (June 16, 2013)
- 24.1.3 Maintenance release (July 26, 2013)

- 24.0 Distribution (Download)
  - 24.0.1 Major release (December 24, 2012)
  - 24.0.2 Maintenance release (February 14, 2013)

- 23.9 Distribution (Download)
  - 23.9.1 Major release (July 04, 2012)
  - 23.9.2 Maintenance release (August 29, 2012)
  - 23.9.3 Maintenance release (September 26, 2012)
  - 23.9.4 Maintenance release (October 20, 2012)
  - 23.9.5 Maintenance release (November 09, 2012)

- 23.8 Distribution (Download)
  - 23.8.1 Major release (March 17, 2012)
  - 23.8.2 Maintenance release (April 05, 2012)

- 23.7 Distribution (Download)
  - 23.7.1 Major release (July 14, 2011)
  - 23.7.2 Maintenance release (July 22, 2011)
  - 23.7.3 Maintenance release (August 23, 2011)

- 23.6 Distribution (Download)
  - 23.6.2 Major release (December 13, 2010)
  - 23.6.3 Maintenance release (February 15, 2011)
  - 23.6.4 Maintenance release (April 01, 2011)
  - 23.6.5 Maintenance release (April 08, 2011)

- 23.5 Distribution (Download)
  - 23.5.1 Major release (July 05, 2010)
  - 23.5.2 Maintenance release (August 18, 2010)

- 23.4 Distribution (Download)
  - 23.4.1 Major release (May 21, 2010)
  - 23.4.3 Maintenance release (May 24, 2010)

- 23.3 Distribution (Download)
  - 23.3.1 Major release (November 01, 2009)
  - 23.3.2 Maintenance release (November 18, 2009)
  - 23.3.3 Maintenance release (December 17, 2009)

- 23.2 Distribution (Download)
  - 23.2.1 Minor release (August 14, 2009)

• 20.7 Maintenance release (June 14, 2002) (Download)

• 20.6 Major release (May 25, 2002) (Download)

• 20.5 Maintenance release (January 28, 2002) (Download)

• 20.4 Maintenance release (January 21, 2002) (Download)

• 20.3 Major release (December 24, 2001) (Download)

• 20.2 Maintenance release (November 22, 2001) (Download)

• 20.1 Major release (October 31, 2001) (Download)

2.3 27 Distribution

2.3.1 27.1.0 Major release (April 24, 2019)

2.3.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Arne Drud, Jan-Erik Justkowiak, Renger van Nieuwkoop, and Manuel Wetzel.
2.3.1.2 Platforms

- As announced, support for Mac OS X 10.11 (El Capitan) has been dropped.
- As announced, support for Windows Vista has been dropped.

2.3.1.3 GAMS System

2.3.1.3.1 GAMS

- Embedded Python Code:
  - Allow Implicit Set Definition (or: Domain Defining Symbol Declarations) now for symbols loaded from embedded code as well.
  - Changed the default behavior of $offEmbeddedCode and endEmbeddedCode: Previously, internal resources got freed and with the next start of an embedded Python code section, the Python environment had to be reinitialized. This is not the case anymore. Also, the interpreter stays "alive" now, which allows to access Python symbols defined in one embedded code block in a following block. The old behavior could still be activated by setting the new command line parameter freeEmbeddedPython to 1.
  - Changed the optional boolean argument merge to an enumerated option mergeType in the gams.set method in embedded code. This might break existing code. Even if the merge argument was not used, the default behavior at compile time changes. In previous versions the content of an already defined symbol was quietly replaced while GAMS now triggers a compilation error 194 Symbol redefined.
  - Fixed a bug in embedded code when setting pySetup to 0. Additional steps are required on Linux and Mac OS X to use an alternative Python installation. Details can be found in section Porting to a Different Version of Python.
  - A GAMSDatabase created in embedded code via gams.ws.add_database(source_database = gams.db) had all the symbols but no data. This has been fixed.
  - gams.db.export(file_name) in embedded code resulted in an error for scalar symbols without data. This has been fixed.
  - Fixed a problem with embeddedCode/continueEmbeddedCode after an assignment that was not finished with a ; like in this example:

    ```gams
    Set i /1*3/;
    Parameter xl(i);
    xl(i) = uniform(0.5,1)
    embeddedCode Python:
    print(list(gams.get('xl')))
    endEmbeddedCode
    Display xl;
    ```

    This leads to an error now. In the past, the assignment in line 3 was executed after the embeddedCode block leading to unexpected results.

- Extended the GAMS log to print out the non-default Command Line Parameters.

- Improved performance of execute.Unload when option gdxUELs is set to full.

- Improve performance of model generation when multi-dimensional variables are used, where the controlling set for dimension n>1 is big, e.g.:

  ```gams
  Set tiny /1*2/, huge /1*100000/ ;
  Variable x(i,j); Equation e;
  ...
  e.. sum((tiny,huge), x(tiny,huge)) =e= 42;
  ```
• Fixed a potential crash when more than 250 million labels are used in one model.

• Fixed a bug with Implicit Set Definition: When used with $onMulti to merge data into a non-empty set, it could have happened that an element was added twice in some cases.

• Fixed a bug causing a broken dump file if $onVerbatim and $ifThen was used with DumpOpt.

2.3.1.3.2 Documentation

• Added documentation for the put utility keyword assignText (which has been in the system since 24.6).

2.3.1.3.3 GDX library

• Improve the behavior of GDX when handling large data sets (e.g. writing a set with 210 million elements, each having its own lengthy set text). Performance is better - less memory and less time are required. The limits on the amount of data that can be handled have been extended somewhat, and when these limits are reached this is handled more gracefully than previously - with a helpful message instead of a segmentation fault or erroneous results.

• Introduce consistent handling of the empty string vis-a-vis set text for UELs. This is only relevant for user applications that use the low-level GDX API in an unsupported way.
  
  – Previously the proper usage was to avoid adding the empty string to the list of set text strings. Applications that broke this rule would produce a GDX file with an abnormal internal structure. This structure may lead to jumbled set text.
  
  – With the updated GDX, it is not necessary to avoid adding an empty string to the set text list.
  
  – Applications holding to previous proper usage (i.e. those that avoid adding the empty string to the list of set text strings) will produce good GDX files regardless of GAMS version, and these files will behave as expected regardless of the GAMS version in which they are used.

2.3.1.4 Solvers

2.3.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

• Updated Intel MKL libraries to version 2019.3 on Linux and Mac OS X and to 2018.4 on Windows 64-bit.

2.3.1.4.2 BARON

• New libraries 19.3.24.
  
  – Improved automatic differentiator that is up to two orders of magnitude faster for large-scale problems.
  
  – Improved data structures and cut pool manager to reduce memory footprint and time requirements for large-scale problems.
  
  – Improvements in various components, including parallel threads and BARON's IPOPT interface for Mac OS X.
  
  – New tree management algorithms.
  
  – Improved range reduction and probing algorithms.
  
  – Using Intel MKL for faster BLAS and LAPACK routines.
  
  – Ipopt now uses METIS for linear system partitioning.
  
  – New option FirstLoc to terminate BARON as soon as a local optimum is found.

• New option ClockType to determine whether wall-clock or CPU time should be reported back to GAMS.
2.3.1.4.3  BDMLP and SBB

- The definition of SOS1 and SOS2 variables has changed. BDMLP and SBB used to count the number of elements in a set that are off the lower bound. BDMLP and SBB were the only two solvers in the GAMS solver portfolio with this definition. All other solvers counted elements that are off zero. The definition of SOS1 and SOS2 variables in BDMLP and SBB has been changed to the off zero definition to make their behavior more consistent with other GAMS solvers.

2.3.1.4.4  CBC

- New libraries 2.10.
  - Improved handling of SOS, starting point, and symmetries.
  - Improved performance of primal heuristics regarding the handling of implicit integer variables.
  - Mini-B&B is now disabled when solving with multiple threads.
  - Changed default value for zero half cuts parameter from off to ifmove.

2.3.1.4.5  CONOPT 4

- New library 4.11 with improvements in reliability and efficiency for large and difficult models.
- New option Tol_Opt_LinF: Optimality tolerance when infeasible in Linear Feasibility Model.

2.3.1.4.6  CPLEX/CPLEXD

- New libraries 12.9.0.
  - New options: CPLEXfolding, CPLEXwriteprob (CplexD only), CPLEXwarninglimit.
  - New hierarchical multi-objective optimization (CplexD only): CPLEXmultobj, CPLEXmultobjmethod, CPLEXobjnabstol, CPLEXobjnreltol.
  - The symmetry breaking parameter CPLEXsymmetry now applies only to MIP models. Use the new CPLEXfolding parameter for LP models.

2.3.1.4.7  GUROBI

- New libraries 8.1.1.

2.3.1.4.8  JAMS

- Experimental indexed EMP syntax has been updated: It can now take all the equilibrium related keywords (max, min, vi, qvi, dualvar, visol, and implicit) and shared constraints and variables.

2.3.1.4.9  LocalSolver

- New libraries 8.5 (20190130).
  - Strong lower bounds based on nonlinear relaxation techniques coupled with innovative branch-and-bound heuristics.
2.3.1.10 Mosek

- New libraries 8.1.0.80.

2.3.1.11 ODHCPLEX

- New libraries 4.23.

2.3.1.12 OQNLP

- As announced, OQNLP has been dropped.

2.3.1.5 Tools

2.3.1.5.1 CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.
- New library 6.2.0 on Mac OS X.

2.3.1.5.2 GAMS Studio

- New version 0.11.1.
  - Stability and performance improvements.
  - Introduced a toolbar to replace the "Execution and Option Parameter Editor".
  - Editor
    * Improved the syntax highlighting.
    * Allow to open huge read-only (lst) files without significant memory requirement.
    * Added bookmark support.
    * Added Ctrl+Up/Ctrl+Down as shortcut for line wise scrolling without moving the text cursor.
    * Added Ctrl+Home/Ctrl+End as shortcut for page wise scrolling without moving the text cursor.
    * Added warning pop-up when trying to open a >50 Mb file in edit mode.
  - Various
    * Added Ctrl+Alt+L to extend/collapse the extended option editor
  - Forced light application theme on Mac OS X to circumvent problems using the Dark Mode of Mac OS X Mojave.

2.3.1.5.3 GDXDUMP

- New command line option setText to show the list of set text stored in a GDX file.
- Option symbols now lists the cardinality of a symbol in the column Records.
2.3 Distribution

2.3.1.5.4 GDXXRW

- Fixed exit behavior if there were some duplicate records found when reading a symbol but less than specified by `maxDupeErrors`: If there are no other errors the exit code is 0 now (it was 16 in the past)

2.3.1.5.5 GMSZIP/GMSUNZIP

- Replaced the 32bit binaries `gmszip` and `gmsunzip` by more recent 64bit versions on Mac OS X.

2.3.1.5.6 MPS2GMS

- Turn some errors that can be safely ignored when reading an MPS file into warnings.

2.3.1.6 Object Oriented APIs

2.3.1.6.1 Python

- Fixed a bug with default variable levels being 1.0 instead of 0.0.

2.3.1.7 Model Libraries

2.3.1.7.1 GAMS Data Library

- `GDX2ACCESSExample1.gms` : Dumping the Contents of `trnsport.gdx` (125)
- `GDX2ACCESSExample2.gms` : Writing Explanatory Text to Database (126)
- `GDX2ACCESSExample3.gms` : Dumping a large Table to Database (127)
- `GDX2ACCESSExample4.gms` : Special Value Mapping (128)
- `GDX2ACCESSExample5.gms` : Renaming Fields (129)

2.3.1.7.2 GAMS Test Library

- `sosmiqcp01.gms` : SOS1 and SOS2 behavior - MIQCP (794)
- `sosmip01.gms` : SOS1 and SOS2 behavior - MIP (795)
- `sosminlp01.gms` : SOS1 and SOS2 behavior - MINLP (796)

2.3.2 27.2.0 Minor release (May 23, 2019)

2.3.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Michael Burkhardt, and Karlo Šepetanc.
2.3.2.2  GAMS System

2.3.2.2.1  GAMS

- Fix problem with missing entries for scalar variables and equations in the index file for the GAMS Output in certain cases.

2.3.2.3  Solvers

2.3.2.3.1  CONOPT

- New library 3.17J.
- New library 4.12.

2.3.2.3.2  Lindo/LindoGlobal

- New libraries 12.0.157.

2.3.2.3.3  LOCALSOLVER

- New libraries 8.5 (20190430).

2.3.2.3.4  NLPEC

- Added new option parmFile to allow to point to additional options for the GAMS run of the scalar model produced by NLPEC.

2.3.2.3.5  ODHCPLEX

2.3.2.3.6  OSIXPRESS

- Fixed use of standalone Xpress license.

2.3.2.4  Tools

2.3.2.4.1  GAMS Studio

- New version 0.11.2.
  - Stability and performance improvements.
  - GDX Viewer
    - Added Drag and Drop feature in GDX Table View
2.3.2.5 Object Oriented APIs

2.3.2.5.1 Python

- Fixed a memory leak in the Python 3 version of the API.
- We plan to drop support for Python 2.6 with the next major release.

2.3.2.6 Expert Level APIs

- Fixed a memory leak in the Python 3 version of the APIs.
- We plan to drop support for Python 2.6 with the next major release.

2.3.3 27.3.0 Minor release (July 04, 2019)

2.3.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Erwin Kalvelagen, Wolfgang Kuehn, Bruce McCarl, and Michael Winkler.

2.3.3.2 GAMS System

- Fixed a bug that resulted in undercounting the number of physical and logical processors on Windows systems with more than 64 logical processors. GAMS/Base and many solvers use this count, e.g. when setting threads to 0 or -1.

2.3.3.2.1 GAMS

- Allow domain projection with $\text{load}$ also if the source symbol is a variable or equation.
- Fixed the cause for an unwanted compilation error with $\text{embeddedCode}$ in certain situations.
- Unified behavior of the profile option: In the past, the Profile Summary was always written, when the profiling was activated from the command line, but was sometimes omitted when set as an option. Now, the summary gets always written. It does not matter anymore, where profiling was activated.

2.3.3.2.2 Documentation

- Added a Preface that reflects the history of the GAMS documentation. In particular it points out the importance of external contributors, in particular Bruce McCarl.

2.3.3.3 Solvers

2.3.3.3.1 BARON

- Fixed load of Xpress library on Linux.
2.3.3.3.2 CBC

- New libraries.

2.3.3.3.3 CONOPT

- New library 3.17K.
- Bug fix in library 4.12.

2.3.3.3.4 GAMSCHK

- Fixed error in postopt report. Previously, the report for the column occurring last in the listing file would be omitted, and all its entries would appear in the report for the preceding column.
- Fixed crash that occurred in some cases.
- The above problems occurred in GAMS 26 and previous. A fix was introduced with GAMS 27, but this fix went too far and introduced new problems. With this version, the fix to 27.1 is reverted and a more moderate fix is used instead.

2.3.3.3.5 LocalSolver

- Fixed missing solver log.

2.3.3.3.6 Mosek

- New libraries 8.1.0.81.
- Fixed ignoring option `solvefinal`.

2.3.3.3.7 SCIP

- New libraries 6.0.2.

2.3.3.3.8 SoPlex

- New libraries 4.0.2.
2.3.3.4 Tools

2.3.3.4.1 GAMS Studio

- New version 0.11.5
  - Stability and performance improvements.
  - Added buttons to toolbar to show/hide Project Explorer, Output-, and Help widget.
  - Added shortcut $\text{Ctrl+H}$ to focus Main widget.
  - Added shortcut $\text{Ctrl+Shift+G}$ to focus Output widget.
  - Added shortcut $\text{Esc}$ to close several widgets.
  - GDX Viewer:
    * Columns in the data view are now resized to the minimum width necessary to see all the data automatically.
    * Added shortcut to auto-resize all columns in the data view after the width was changed by hand ($\text{Ctrl+R}$).
  - Search:
    * Added shortcut $\text{Ctrl+Enter}$ for "Search All".
    * Added ability to replace in more than one file at a time.
    * Find Next/Previous now respects all search options and will jump to the next file if there are also matches.

2.3.3.5 Object Oriented APIs

2.3.3.5.1 Python

- Fixed a bug in GamsJob.interrupt() that caused an $\text{OverflowError}$ on 64 bit platforms.

2.4 26 Distribution

2.4.1 26.1.0 Major release (February 02, 2019)

2.4.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Stefano Alva, Adam Christensen, Hanna Donau, Stephen Frank, Anastasis Giannousakis, Jan-Erik Justkowiak, David Laudy, Andreas Lundell, Thomas Maindl, Nils Mattus, Scott McDonald, Noah Rhodes, Tom Rutherford, and Anna Straubinger.
2.4.1.2 Versioning

From this release on, we use a new interpretation on the GAMS version number scheme XX.Y.Z. XX alone now indicates the GAMS distribution number (was XX.Y before). Y is used to distinguish between beta, major, and minor releases of the XX distribution. Z is used to distinguish different maintenance releases. That is, we now use

- XX.0.Z for beta versions,
- XX.1.0 for the major release of distribution XX,
- XX.Y.0, Y > 1, for minor releases,
- XX.Y.Z, Y ≥ 1, Z > 0, for maintenance releases.

See Release Types regarding the meaning or what constitutes a major, minor, or maintenance release. As before, we increase the required license date for major releases only.

Further, we changed the default installation directory of the GAMS system from using only the distribution number to also include the minor version number. Thus, as before, GAMS is now installed into directory names which contain the XX.Y part of the GAMS version number.

2.4.1.3 Platforms

- We plan to drop support for Mac OS X 10.11 (El Capitan) with the next major release.
- We plan to drop support for Windows Vista with the next major release.
- Fixed problem using solvers with Fortran dependencies on a Mac OS X 10.11 system.

2.4.1.4 GAMS System

2.4.1.4.1 GAMS

- Changed behavior of $compress, $decompress, and $encrypt: source and target cannot be identical anymore; this could have lead to unreliable behavior in the past.
- Extended the influence of $onMulti: This affects the model statement as well now.
- Added new dollar control option $onMultiR, which is similar to $onMulti but replaces existing data instead of merging into it.
- Added put_utility keyword solver to select a solver for a given or all possible model types by name at execution time.
- Extended the syntax to allow Implicit Set Definition (or: Domain Defining Symbol Declarations). Here is a small example showing how this can be used:

```plaintext
Set
   i 'canning plants'
   j 'markets';
Table d(i<,j<) 'distance in thousands of miles'
  new-york  chicago  topeka
seattle    2.5    1.7    1.8
san-diego  2.5    1.8    1.4;
Display i,j;
```
And this is the result of the `Display` statement:

```plaintext
---- 10 SET i canning plants
    seattle , san-diego

---- 10 SET j markets
    new-york, chicago , topeka
```

- Updated the base module and components as necessary to allow for spaces in names of any files and directory used by GAMS, including the system directory, the working directory, the scratch directory, the process directory, and remove any checks warning about and preventing this. While the Windows system had already allowed spaces in previous versions, this change updates the other platforms to behave similarly.

- Changed the reading of command-line arguments on non-Windows platforms! This should only affect how arguments with spaces in them are passed on to GAMS. Previously, such arguments needed extra quoting or protection on non-Windows platforms. With this update, the extra protection is no longer needed: the same quoting of space-containing arguments can be used on all platforms. For example, with GAMS 25.1 and previous, two pairs of quotes were required on non-Windows platforms to protect spaces in an argument:

```plaintext
gams xx.gms --MY_GDX "outer space"
```

while now only one pair of quotes is needed on all platforms:

```plaintext
gams xx.gms --MY_GDX "outer space"
```

- Increased the number of labels, which can be handled by GAMS from 200 million to \( \sim 2.1 \) billion and let GAMS terminate with the meaningful error message, if that limit is reached.

- Windows only: Fixed a bug which treated a path (e.g. to an input file or used as input-Dir) as relative path, if it starts with `/`. Example: When running `cd C:\tmp & gams.exe /data/myModel.gms`, GAMS tried to load the file `C:\tmp\data\myModel.gms` in the past. Now, it loads `C:\data\myModel.gms`.

- Fixed some problems with option `asyncSolLst`.

- Fixed a bug which could have caused GAMS to accept duplicate entries in a data statement, when they came in unsorted order.

- Fixed the dollar control option `$onUpper` (it did not do anything before).

### 2.4.1.4.2 GMSPython

- Updated `pip` to work with recent Mac OS X versions.

### 2.4.1.5 Solvers

#### 2.4.1.5.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Fixed an MKL error when running any of these solvers after CPLEX with solvelink=5 in the same GAMS run on Linux.

- Updated Intel MKL libraries to version 2019.0 on Linux and to version 2018.3 on Windows 64-bit.
2.4.1.5.2 BARON

• New libraries 18.11.12 for 64-bit platforms.
  – New cutting planes for convex-transformable functions.
  – New cutting planes for polynomial optimization problems.
  – More robust treatment of cutting planes.
  – Improved optimality-based range reduction mechanisms.
  – CBC can now use multiple threads on Windows, too.

• We plan to drop BARON for Windows 32-bit with some future release.

• The solver time reported back to GAMS (resource usage) is now the wall clock time instead of the CPU time.

2.4.1.5.3 Bonmin, CBC, Couenne, Ipopt

• New libraries.

2.4.1.5.4 CONOPT 4

• New library 4.09 with many reliability improvements and a fix for wrong non-opt markers.

2.4.1.5.5 CPLEX

• Ctrl-C (or Interrupt) was broken for GAMS/CplexD. This has been fixed.

• Improved performance of retrieving the solution for a QCP with many quadratic rows.

2.4.1.5.6 Gurobi

• The solver time reported back to GAMS (resource usage) is now the wall clock time instead of the CPU time on Unix.

• Allow quadratic rows with $=$ and let Gurobi deal with potential errors. Gurobi can sometimes substitute quadratic terms defined by $=$ rows. The check of quadratic row to be either $<=$ or $=>$ in the GAMS/Gurobi link prevented this.

2.4.1.5.7 KESTREL

• Added support for MPSGE models.

2.4.1.5.8 Knitro

• New libraries 11.1.1 (11.0.1 for 32-bit Windows) containing several bug fixes and performance improvements, including:
  – improved performance on convex quadratic models,
  – improved generation of knapsack cuts, resulting in faster performance on some MINLP models,
  – improved performance when using the SQP algorithm,
  – new values for option lin solver to choose parallel factorization routines MA97 and MA86.

• Artelys has announced that Knitro 11.0 was the last Knitro release to support 32-bit Windows. We will be dropping GAMS/Knitro for 32-bit Windows in the near future.
2.4.1.5.9 Lindo/LindoGlobal

- New libraries 12.0.90.
  - LP Solver Improvements:
    * With new enhancements made to the simplex solvers, the average performance on large instances has increased by 18% for the primal simplex and 15% for the dual simplex compared to the previous version.
    * Improved performance on LP’s when using multiple cores with concurrent execution of Primal, Dual, and Barrier.
  - Quadratic and Nonlinear Solver Improvements:
    * Much faster handling of large quadratic matrices, e.g. 1000 x 1000.
  - Global Solver Improvements:
    * Improved handling of discontinuous functions, e.g., MOD(x,k), ROUND(x).

2.4.1.5.10 LocalSolver

- New libraries 8.0 (20181106).
  - Performance improvements on routing & scheduling problems, especially Pickup & Delivery problems.
  - Learning algorithms inside LocalSolver, which allow to automatically and dynamically tune up the search process for each solved instance, were improved. This leads to improved performances, especially for short resolution times (minutes).

2.4.1.5.11 Mosek

- New libraries 8.1.0.72.

2.4.1.5.12 ODHCPLEX

- New libraries 4.09 for Linux with many reliability improvements.
- New libraries 4.13 for Windows 64-bit with many reliability improvements and addressing dynamic loading in concurrent threads and processes.
- Updated options: DynamicSearch, FirstFeas, and Strategy
- New options: DecompDensity, Divisor, ODHFeasOpt, MaxBacktrack, NewCallback, Recurse, RecurseDecomp, RecurseIterLim, RecurseLog, RecurseMinIterLim, RecurseSolIterLim, RelaxSOS2, and ThreadLog.

2.4.1.5.13 OQNLP

- We plan to drop OQNLP with the next major release.
2.4.1.5.14 PATH

- New libraries 5.0.00.
  - Fixed crash in Lemke’s method that could happen for models with extremely poor scaling.
  - New capability to use alternate basis-handling packages via dynamic loading of shared libraries.
    Two alternate packages are currently supported:
    - BLU-LUSOL: Block LU updating using the LUSOL routines. The shared library required for this is included in the distribution.
    - UMFPACK: Tim Davis’ multifrontal LU factorization package. The shared library required for this is \textbf{not} included in the GAMS distribution, but can be downloaded from the \texttt{SuiteSparse} site. N.B.: We have verified UMFPACK on Linux, Mac OS X, and Windows using UMFPACK v5.7.7 from SuiteSparse 5.3.0.

2.4.1.5.15 SCIP

- New libraries 6.0.1.
  - Primal Heuristics
    * new diving heuristic \texttt{farkasdiving} that dives into the direction of the pseudosolution and tries to construct Farkas-proofs
    * new diving heuristic \texttt{conflictdiving} that considers locks from conflict constraints
    * performance improvements for Adaptive Large Neighborhood Search
      - changed default of parameter \texttt{heuristics/als/adjustminimprove} from 1 to 0
      - changed default of parameter \texttt{heuristics/als/alpha} from 0.2 to 0.0016
      - new parameter \texttt{heuristics/als/adjusttargetnodes}
      - changed default of parameter \texttt{heuristics/als/eps} from 0.5 to 0.468584
      - changed default of parameter \texttt{heuristics/als/gamma} from 0.2 to 0.0704146
      - changed default of parameter \texttt{heuristics/als/minimprovehigh} from 0.1 to 0.01
      - changed default of parameter \texttt{heuristics/als/minimprovelow} from 0.0001 to 0.01
      - removed parameter \texttt{heuristics/als/stallnodefactor}
      - changed default of parameter \texttt{heuristics/als/startminimprove} from 0.05 to 0.01
      - changed default of parameter \texttt{heuristics/als/targetnodefactor} from 1.5 to 1.05
      - new parameter \texttt{heuristics/als/unfixtol}
      - changed default of parameter \texttt{heuristics/als/crossover/minfixingrate} from 0.4 to 0.3
      - changed default of parameter \texttt{heuristics/als/dins/maxfixingrate} from 0.5 to 0.9
      - changed default of parameter \texttt{heuristics/als/dins/minfixingrate} from 0.1 to 0.3
      - changed default of parameter \texttt{heuristics/als/localbranching/minfixingrate} from 0 to 0.3
      - changed default of parameter \texttt{heuristics/als/mutation/minfixingrate} from 0.4 to 0.3
      - changed default of parameter \texttt{heuristics/als/proximity/minfixingrate} from 0 to 0.3
      - changed default of parameter \texttt{heuristics/als/rens/maxfixingrate} from 0.7 to 0.9
      - changed default of parameter \texttt{heuristics/als/rins/maxfixingrate} from 0.6 to 0.9
      - changed default of parameter \texttt{heuristics/als/rins/minfixingrate} from 0.2 to 0.3
      - changed default of parameter \texttt{heuristics/als/zeroobjective/minfixingrate} from 0 to 0.3
    - New branching rule \texttt{lookahead} that evaluates potential child and grandchild nodes to determine a branching decision
  - LP Solver Interface
    * \texttt{lp/checkstability} is now properly implemented for use with SoPlex
    * new parameter \texttt{lp/alwaysgetduals}
    * new parameter \texttt{lp/checkfarkas}
2.4.26 Distribution

- Separation (cutting planes)
  - Cuts generated from certain quadratic constraints with convex feasible region are now global
  - New parameter `separating/cutdistfac`
  - New parameter `separating/efficacyfac`
  - Removed parameter `separating/maxincrounds`
  - New parameter `separating/zerohalf/cutdistweight`
  - New parameter `separating/zerohalf/efficacyweight`
  - Changed default of parameter `separating/zerohalf/goodscore` from 0.9 to 1
  - New parameter `separating/zerohalf/maxparall`
  - New parameter `separating/zerohalf/objparalweight`

- Symmetry Handling
  - Restructured timing of symmetry computation to allow to add symmetry handling components within presolving
  - Changed default of parameter `constraints/symresack/psymresack` from 0 to 1
  - New parameter `presolving/symbreak/addeconsstming`
  - Changed default of parameter `presolving/symbreak/detectorbitopes` from 1 to 0
  - Removed parameter "presolving/symmetry/computepresolved"
  - New parameter `propagating/orbitalfixing/enableafterrestarts`
  - New parameter `propagating/orbitalfixing/performpresolving`
  - Changed default of parameter `propagating/orbitalfixing/presolpriority` from 0 to -100000
  - Changed default of parameter `propagating/orbitalfixing/presoltime` from 28 to 16
  - New parameter `propagating/orbitalfixing/symcomptiming`
  - Improved bound tightening for some quadratic equations
  - New parameter `display/relevantstats`
  - New parameter `misc/scaleobj`
  - Removed `implfree` presolver
  - See also the full release notes and the release paper.

2.4.1.5.16 SELKIE

The SELKIE solver - new to GAMS with this release - is an EMP solver that implements decomposition methods for multi-agent equilibrium and related models.

2.4.1.5.17 SoPlex

- New libraries 4.0.1.
  - New simplifier step to perform variable aggregation for equations with two variables
  - New parameter `bool:ensureray` to re-solve the original problem in case of infeasibility/unboundedness to get a valid proof/ray
  - See also the full release notes and the release paper.

2.4.1.5.18 Xpress

- New libraries 33.01.10.
  - Local symmetry re-detection in MIP tree search
  - Improved branching for highly symmetric MIPs
  - New or improved cuts, degeneracy handling, crossover, preprocessing
  - FICO does not release patches for all platforms with each patch release, so some platforms lag behind the most-used ones.

- See also the full release notes and the release paper.
2.4.1.6 Tools

2.4.1.6.1 CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.

2.4.1.6.2 CSV2GDX

- Extended recognition of special values:
  - N/A is recognized as NA,
  - TRUE is recognized as 1,
  - FALSE, NONE and NULL are recognized as 0.
- Added new option text to specify the column to get explanatory text from when reading a set.
- Changed handling of bad UELs: Reading a bad UEL (e.g. a UEL exceeding the maximum length) causes an error now. The old behavior can be enabled again using the new option acceptBadUels.

2.4.1.6.3 GAMS Studio

- New version 0.10.3
  - Stability and performance improvements.
  - Added a new section Comparing GAMS Studio and GAMSIDE to the documentation.
  - Added a Reference File Viewer to navigate the source code of GAMS models via a reference file, especially when multiple files are involved. A reference file contains all symbol references of GAMS models and is created using the reference parameter when running the model.
  - Added a Tab Browser to list and search through all open files. It is accessible with a button next to the main tab bar or via the shortcut Ctrl+K.
  - GDX Viewer:
    * Added a first, basic version of a Table View: The new button "Table View" switches the view to a table based representation. The button is only enabled for multidimensional symbols and puts the last dimension into the header of the table. Drag and drop of items is not yet supported but will be in the future.
    * Added option to hide specific value columns for variables and equations.
    * Added support for the use of different encodings using the "Edit->Encoding" menu. The default encoding for a GDX file generated in Studio by running a GMS file with automatic GDX creation (F10) is the one used by the GMS file.
  - Editor
    * Added smart typing: Automatic insertion of closing character for brackets and quotes.
    * Added ability to select text and press either a opening bracket or quote to surround text with these symbols.
    * Improved backspace behavior, if auto indentation is active.
  - Output Widget
    * Added info, warning, and error messages to GAMS Studio system log.
    * GAMS log files are now written to disk (can be disabled in settings).
    * Added "clear log" context menu entry.
  - Project Explorer
* Studio automatically adds all files specified through GAMS parameters (.gdx, .ref, .lst) to the Project Explorer.
* Allow to rename Project Explorer groups.
* Groups are closed if they are empty.
* If a group is closed the associated GAMS process will be stopped.
* Added drag and drop of files between groups.
* Added shortcut to focus Project Explorer (Ctrl+J) and allow to navigate using arrow keys to select a file.
* Added "Select all", "Expand all" and "Collapse all" to the context menu.
* Added shortcut to select all files (Ctrl+A).

– Various

* Added context menu for tabs (offering different close actions).
* Added animation for groups with running GAMS processes.
* Studio comes to foreground when double clicking a Studio-associated file.
* The "About GAMS" dialog contains many important information like used GAMS version, system directory, or license information. It features a "Copy System Information" button which copies all of these information to easily attach them to a support request. The dialog has a second tab which gives an overview about solvers, their license status, and what kinds of capabilities they have.
* "File -> New..." dialog starts with a default for a new file name.
* "File -> Open..." (or drag'n'drop) of one file now focuses that file if it is already present in the Project Explorer.
* New entry "File -> Open... in new group" to force creation of new group (even if the is already present in the Project Explorer).
* "File -> Open..." (or drag'n'drop) of multiple files puts all files opened at once into a single group instead of individuals.
* Added shortcut to focus command line parameter edit field (Ctrl+L).
* Added Ctrl+F as close shortcut for search dialog.
* Changed shortcut to open Settings dialog to F7.

Note

This version of GAMS Studio does not support the Dark Mode of MacOS Mojave. Please disable this mode to use GAMS Studio.

2.4.1.6.4 GDXDUMP

* New options for writing out special values: NAOut, UndfOut, PInfOut, MInfOut, and ZeroOut.
* Fixed broken generated GAMS code, if UelTable option was used, but there were no UELs.
* Lower and upper bounds of equations are dumped always now (even if their values are the default). This fixes a potential problem, that the equation type is unknown for the generated GAMS code.
* When writing CSV files the element text of set elements could not be written. Now with enabled option CSVSetText the element text of a set element is written as the last column in the CSV file.

2.4.1.6.5 GDXXRW

* Fixed a bug which could have caused a crash when reading merged cells from Excel using the GDXXRW options useRC and cMmerge=1.
2.4.1.6.6 MODEL2TEX

- The new script `model2tex.sh` sets the required dependencies for the model2tex tool on Linux and Mac OS X. Using this script is the recommended way for using model2tex. Calling the Python script directly is not recommended anymore since the used Python interpreter would need to be configured manually. `model2tex.sh` uses the Python interpreter that comes with the GAMS distribution.

2.4.1.7 Object Oriented APIs

2.4.1.7.1 Python

- The `setup.py` script now installs the idx expert-level API.

2.4.1.8 Model Libraries

2.4.1.8.1 GAMS Data Library  New models added:

- `csv2gdx2.gms` : CSV2GDX Example 2 - Reading CSV Files with CSV2GDX (111)
- `csv2gdx3.gms` : CSV2GDX Example 3 - Reading Semicolon separated Data (112)
- `csv2gdx4.gms` : CSV2GDX Example 4 - Dealing with missing Labels and Duplicates (113)
- `csv2gdx5.gms` : CSV2GDX Example 5 - Reading more than one Parameter from a single Input File (114)
- `csv2gdx6.gms` : CSV2GDX Example 6 - Reading economic Data from the World Bank Data Catalog (115)
- `csv2gdx7.gms` : CSV2GDX Example 7 - Reading special Values with CSV2GDX (116)
- `csv2gdx8.gms` : CSV2GDX Example 8 - Reading an compressed encrypted Input File (117)
- `csv2gdx9.gms` : CSV2GDX Example 9 - Reading Options from an external File (118)
- `GDXXRWExample17.gms` : Reading several Scalars from Spreadsheet (119)
- `GDXXRWExample18.gms` : Reading Sets from Spreadsheet (120)
- `GDXXRWExample19.gms` : Writing Parameter to Spreadsheet including Zero Values (121)
- `GDXXRWExample20.gms` : Reading empty Cells with colMerge and reading merged Excel Ranges with cMerge (122)
- `GDXXRWExample21.gms` : Skipping empty Rows or Columns and Ignoring Rows or Columns (123)
- `GDXDUMPExample1.gms` : GDXDUMP - Adding double Quotes to an user defined Header when writing to CSV (124)

2.4.1.8.2 GAMS EMP Library  New model added:

- `emppython1.gms` : Three Simple EMP Models with Indexed EMP Syntax and Python Parser (104)
2.4.1.8.3  GAMS Test Library  New models added:

- csv2gdx7.gms : CSV2GDX - Checking the Error Messages for incorrect Parameter
  Input (752)
- csv2gdx8.gms : CSV2GDX - Testing the valueDim Option (753)
- csv2gdx9.gms : CSV2GDX - Testing the Field Separator Tab (754)
- csv2gdx10.gms : CSV2GDX - Testing the Field Separator Semicolon (755)
- csv2gdx11.gms : CSV2GDX - Testing the Field Separator Comma (756)
- selkie01.gms : SELKIE test suite (757)
- selkie02.gms : SELKIE test suite (758)
- selkie03.gms : SELKIE test suite (759)
- selkie04.gms : SELKIE test suite (760)
- selkie05.gms : SELKIE test suite (761)
- selkie06.gms : SELKIE test suite (762)
- selkie07.gms : SELKIE test suite (763)
- selkie08.gms : SELKIE test suite (764)
- selkie09.gms : SELKIE test suite (765)
- selkie10.gms : SELKIE test suite (766)
- selkie11.gms : SELKIE test suite (767)
- selkie12.gms : SELKIE test suite: sub-diagonalization (768)
- selkie13.gms : SELKIE test suite: dualvar (769)
- selkie14.gms : SELKIE test suite: isolated implicit variable (770)
- selkie15.gms : SELKIE test suite: proximal perturbation (771)
- selkie16.gms : SELKIE test suite: obj variable setting (772)
- selkie17.gms : SELKIE test suite: obj variable setting (773)
- selkie18.gms : SELKIE test suite: obj variable not free (774)
- selkie19.gms : SELKIE test suite: equation marginal values (775)
- put12.gms : Testing put_utility solver (776)
- gdxrwx8.gms : GDXXRW - Testing the Option intAsText (777)
- gdxrwx9.gms : GDXXRW - Testing the Option checkDate (778)
- gdxrwx10.gms : GDXXRW - Testing cMerge when reading Sets with the values
  Option (779)
- gdxrwx11.gms : GDXXRW - Reading and writing special Values (780)
- gdxrwx12.gms : GDXXRW - Testing the skipEmpty and cMerge Option (781)
- gdxrwx13.gms : GDXXRW - Testing the values Option when reading or writing Set
  Elements (782)
- gdxrwx14.gms : GDXXRW - Testing different Excel Range Specifications (783)
- `gdxdump2.gms`: GDXDUMP - Testing the dumping Functionality on several GDX Files (784)
- `gdxdump3.gms`: GDXDUMP - Dumping special Values of a Parameter from GDX (785)
- `gdxdump4.gms`: GDXDUMP - Dumping special Values of Variable-Subfields from GDX (786)
- `onmulti8.gms`: Test for $\$onMultiR$ (787)
- `implset1.gms`: Test for Implicit Set Definition (788)
- `emppy1.gms`: Test an equilibrium model using emp python (789)
- `emppy2.gms`: Formulate the simplevi.gms example using emp python (790)
- `emppy3.gms`: Test a combination of optimization and vi agents using emp python (791)
- `miqcp04.gms`: Test behavior for integer infeasible model (792)
- `duplic01.gms`: Detecting duplicate entries in unsorted data (793)

</table>

- On Windows, some solvers in the GAMS distribution as well as GAMS Studio have dependencies on certain MS Visual C++ runtime libraries. Most of them are included in the GAMS distribution or are present on most Windows systems. However, we are aware that in in rare cases, some libraries are missing. In such situations, we advise to run the appropriate installer for these libraries:
  - On a 32-bit GAMS version, execute \[GAMS\ system]\apifiles\C++\lib\vs2013\vcredist_x86.exe, followed by \[GAMS\ system]\apifiles\C++\lib\vs2015\vcredist_x86.exe.
  - On a 64-bit GAMS version, execute \[GAMS\ system]\apifiles\C++\lib\vs2017\vcredist_x64.exe.
2.5.1.3 GAMS System

2.5.1.3.1 GAMS

- New conditional expressions to be used in conditional compilation, namely gdxDimension, gdxEquType, gdxParType, gdxSetType, gdxSymExist, gdxVarType, and uelExist. Details about these can be found here.

- New command line option LstTitleLeftAligned: Write title of LST file left aligned.

- New command line option ShowOSMemory: Show the memory usage reported by the operating system (either resident set size or virtual set size) instead of the internal counting.

- GAMS throws now a compilation error if an unexpected suffix at a symbol is encountered in an option statement involving identifiers. In the past such suffixes were ignored, which could have given the impression that they were actually doing something. So, all the .dim1 suffixes in the following example will create an error now:

  Set i(*)
  j(*)
  ij(*,*) / i1.j1, i1.j2, i2.j1, i2.j2 /

  Option i < ij.dim1;
  Option i <= ij.dim1;

  Set k / k1*k6 /
  Parameter ii(*) / i1 4, i2 5, i3 6 /
     iii(k,*)

  Option iii > ii.dim1;
  Option shuffle = ii.dim1;

- The details of the expansion of multi-line macros were changed with this release. In the past, trailing white space in the macro definition was always removed. Now, in multi-line macros, the white space before the continuation character \ is preserved. This example demonstrates the difference:

  \$macro xAndY(x,y) x and \y
  scalar x /1/;
  if(xAndY(1,x), display 'true');

  In the past, this caused a compilation error, since the macro was expanded to if(1 andy, display 'true'); ("and" and "y" were concatenated to "andy"). Now that the white space after "and" is preserved, this does not cause a problem anymore.

- The statement Alias (k,k); for an unknown symbol k causes a compilation error now.

- In rare cases, embedded code recognized indented Python code incorrectly. This has been fixed.

- New property gams.debug for controlling debug information of the Object-oriented API in embedded code sections.

- Fixed a problem related to SSL support in GMSPython that prevented certain tools (e.g. pip) from working on Linux and Mac OS X.

- Models of type MCP can now be solved with modifiable parameters in the GUSS framework and as OO-API GAMSModelInstance.
2.5.1.4 Solvers

2.5.1.4.1 BARON

- New libraries 18.5.8.
  - Updated to Ipopt 3.12.8 and CBC 2.9.9.
  - Replaced Ipopt’s linear solver MUMPS by MA57 from HSL, a collection of Fortran codes for large-scale scientific computation. Thus, when using IPOPT as NLP solver, BARON may now be more robust and a little faster, especially for problems without integer variables.
  - New bounds reduction strategies based on optimality conditions can reduce the size of the branch-and-bound tree.
  - Rewrote core memory management routines for speed increase and memory reduction.
  - On some problems, BARON currently provides incorrect marginal values. This problem will be fixed in the near future.
- The use of Ipopt in BARON on MacOS X is no longer disabled by default.
- There will be no future updates of BARON for Windows 32-bit.

2.5.1.4.2 Bonmin(H), CBC, Couenne

- Wall-clock time is now always used to apply a timelimit to Branch-and-Bound. The nww option clocktype can be used to switch back to CPU time.

2.5.1.4.3 CONOPT

- New libraries 4.05 for CONOPT 4.
  - Improvements for multi-threading.
- New libraries for CONOPT 3.
- Fixed problems with redundancy in preprocessor and an issue related to system error 2024.

2.5.1.4.4 ConvertD

- Added options PermuteVars and PermuteEqus to permute the declaration of variables and equations, respectively, in scalar GAMS output.
- Tweaked printing of variable bounds and activity levels in scalar GAMS output.
- Fixed handling of infinite upper bounds for integer variables in scalar GAMS output: A line that sets GAMS option intvarup to 0 is now added to the output.

2.5.1.4.5 Couenne

- New libraries.
2.5.1.4.6 DICOPT

- Improvements to Feasibility Pump:
  - Fixed handling of nonlinear objective function when maximizing.
  - Fixed update of cutoff decrement after a solution with objective value very close to zero has been found.
  - Fixed translation of NLP projection problem optimal value to norm of associated projection. Changed default for option fp_projzerotol from 1e-6 to 1e-4.
  - Added creation of cuts derived from solution of NLP projection problem. Use option fp_projcuts to disable.
  - Added option fp_integercuts to disable integer cuts or enable them for mixed-binary problems only. The latter is the new default.
  - Added option fp_mipgap to specify an optimality tolerance (relative gap limit) for the MIP projection problem.
  - The stall limit is now only applied after a first solution has been found. Changed default for option fp_iterlimit to 20.

2.5.1.4.7 GUROBI

- New libraries 8.0.
  - As announced for GAMS 24.9, Gurobi 8 is no longer supported for Windows 32-bit. We continue to ship Gurobi 7.5 for this platform.
- New partition heuristic based on user annotation via the new dot option .partition and enabled with new option PartitionPlace.
- Completely new interface to Gurobi's Remote Services (i.e. compute server, distributed algorithm, and instant cloud). For details see Compute Server and the following sections.

2.5.1.4.8 JAMS

- Added capability to handle QVI models.
- The options controlling the reformulation strategy for shared variables in multi-agent EMP models have changed: see ImplVarModel for details.

2.5.1.4.9 LocalSolver

- New libraries 7.5 (20180405).
- To use LocalSolver 7.5, a machine-specific LocalSolver license is now required on Linux, too. See here on how to obtain such a license. Alternatively, it is still possible to use LocalSolver 7.0 by choosing LOCALSOLVER70 instead of LOCALSOLVER as solver.

2.5.1.4.10 Mosek

- New libraries 8.1.0.53.
2.5.1.4.11 ODHCPLEX

- A new solver GAMS/ODHCPLEX from Optimization Direct Inc. has been added to the GAMS solver portfolio.
- The solver implements a set of heuristic methods (named ODHeuristics) for finding feasible solutions to Mixed Integer Programming (MIP and MIQCP) models and uses IBM CPLEX as its underlying solver engine.
- The heuristics decomposition method works in an automatic fashion or can be guided by user specified selections.
- Users will need a GAMS/CPLEX or GAMS/Cplex link license for this solver to work. Commercial users will also need a GAMS/ODHCPLEX license.
- Currently, the solver is available for Windows 64-bit only.

2.5.1.4.12 SCIP

- New libraries 5.0 (09c736f).
  - changed default for parameter constraints/quadratic/gaucuts from 1 to 0
  - changed default for parameter heuristics/completesol/freq from 1 to 0
  - changed default for parameter separating/cmir/freq from -1 to 10
  - changed default for parameter separating/cmir/freq from 1 to 0
  - changed default for parameter separating/flowcover/freq from -1 to 10
  - changed default for parameter separating/flowcover/freq from 1 to 0

2.5.1.4.13 Xpress

- New libraries 32.01.10 containing several minor bug fixes and performance improvements.

2.5.1.5 Tools

2.5.1.5.1 GAMS Studio

- This release contains the first preview version of GAMS Studio - a completely new integrated development environment for GAMS. GAMS Studio is still in a very early stage of development, but we believe it is already mature enough to be a productive tool. GAMS Studio is available for Linux, Mac OS X, and Windows only.
- GAMS Studio combines many (but not all) features of the classic GAMS IDE with some new elements:
  - a code editor to write GAMS models (including basic syntax coloring, block edit mode, etc.),
  - execution of GAMS models,
  - an output panel that presents the progressing GAMS log,
  - a listing viewer (including a tree view to navigate through the file) to inspect the listing file,
  - an interactive option editor to set GAMS parameters,
  - a GDX viewer that shows the table of content and data of GDX files and offers useful details like sorting and filtering of data,
a project explorer helps to manage different projects in one session, and

an integrated help system to make it easier to find additional information, e.g., by pressing F1 while the cursor is on a GAMS keyword in the code editor.

• We encourage our users to weigh in, help prioritize GAMS Studio's future development directions, or provide any other feedback. If you find problems, miss features, or have comments, please send a note to studio@gams.com.

• It is also possible to contribute directly or build on top of GAMS Studio, since the source code is available on GitHub (https://github.com/GAMS-dev/studio) under the GNU GPL license (see https://github.com/GAMS-dev/studio).

• We plan to provide updates for GAMS Studio frequently in the near future, also separate from new releases of the GAMS distribution. To facilitate the update process, Studio includes an interactive check (requiring an Internet connection) for the availability of newer versions. This "Check for Update" button can be found below the menu "Help".

• A short overview about GAMS Studio can be found in the YouTube channel GAMS Lessons.

Note

- New options to define the association for GAMS files (.gms) have been added to the installer for GAMS on Windows. For now, the GAMS IDE is still the default choice, but this may change for future releases.
- On Linux, Studio is installed in the form of an AppImage as part of the GAMS system directory.
- On Mac OS X, Studio is part of the DMG installer only. It is installed as an additional application in the Applications directory next to the GAMS Terminal application and is available through the Launchpad. GAMS files (.gms) are associated with GAMS Studio.

Attention

- In rare cases, GAMS Studio crashes when the Open or Save dialog gets opened. This is mostly related to third party software, e.g., older versions of "Dell Backup and Recovery". It is recommend to update, switch off or uninstall the software.
- We are aware of some performance issues at this stage of development. So while things work well, for example, with the models from our model libraries, you might experience some delay when working with huge files, e.g., while searching or when the log is processed for very long output.

2.5.1.5.2 XLSDump

• Sometimes, Excel Spreadsheets contain links to pictures, which cannot be found. This situation caused an error in XLSDump in previous versions. Now, such an error is ignored.

2.5.1.6 Object Oriented APIs

• New implementation of GAMSJob.Interrupt() on Linux and Mac OS X that removes dependency to the command line tool pstree.

2.5.1.6.1 C++

• Added support for Microsoft Visual Studio 2015 on Windows 32-bit.
2.5.1.6.2 Java

- Changed the naming scheme of a temporary working directory to be created from \texttt{yyyyMMddHHmmss} to the prefixed \texttt{gams} (defined by \texttt{GAMSGlobals.workingDirectoryPrefix}), in case no working directory has been specified.

- Fixed the behavior when a GAMSDatabase is added with a name that already exists. A \texttt{GAMSException} will be raised now (see \texttt{GAMSWorkspace.addDatabase(String databaseName)} and \texttt{GAMSWorkspace.addDatabaseFromGDX(String gdxFileName, String databaseName)}).

- Calls on \texttt{GAMSWorkspace.finalize} and \texttt{GAMSSymbolIterator.finalize} are no longer available, because calling a finalizer method can arbitrarily delay the reclamation of object instances and potentially create unpredictable outcome. Whenever the object is no longer needed it is recommended to explicitly dispose the object rather than to rely on the Java garbage collector to do the job. See \texttt{GAMSDatabase.dispose}, \texttt{GAMSModelInstance.dispose}, and \texttt{GAMSOptions.dispose}.

2.5.1.7 Expert Level APIs

- All Java native interfaces to expert-level APIs are now included in ‘[Path/To/GAMS]/apifiles/Java/api/GAMSJavaAPI.jar’.

2.5.1.7.1 GMO

- The constant \texttt{MAXEVALTHREADS} (i.e. the number of parallel threads supported for function and derivative evaluations in the solver interface library GMO) has been increased from 16 to 64. This effectively increases the same limit in the CONOPT4 solver.

2.5.1.8 Model Libraries

2.5.1.8.1 PSOPTLIB - Power System Optimization Modelling in GAMS

- This new library by Alireza Soroudi has been added to the GAMS system. This is a collection of the models based on the book \textit{Power System Optimization Modelling in GAMS} by Alireza Soroudi. The library contains a selection of 32 models from various areas of power system optimization expressed in GAMS. Book and library describe how the General Algebraic Modeling System (GAMS) can be used to solve various power system operation and planning optimization problems. The book is the first of its kind to provide readers with a comprehensive reference that includes the solution codes for basic/advanced power system optimization problems in GAMS, a computationally efficient tool for analyzing optimization problems in power and energy systems. The book covers theoretical background as well as the application examples and test case studies. It is a suitable reference for dedicated and general audiences including power system professionals as well as researchers and developers from the energy sector and electrical power engineering community and will be helpful to undergraduate and graduate students.

- You can retrieve the individual models through the IDE and Studio model library browser, via the command line utility \texttt{psoptlib} or through calls in the Object Oriented APIs.

2.5.1.8.2 GAMS EMP Library

- \texttt{simpleqviol.gms} : Simple Quasi-Variational Inequality (101)
- \texttt{simpleqviol2.gms} : Simple Quasi-Variational Inequality (102)
- \texttt{simpequil3.gms} : Simple Generalized Nash Equilibrium Problem (103)
2.5.1.8.3 GAMS Model Library

- `guss2dim.gms`: Two dimensional scenario GUSS Example (423)
- `obstacle.gms`: An Obstacle Problem (424)
- `csched`: Added two more formulations for a related problem. Contributed by Tapio Westerlund.

2.5.2 25.1.2 Minor release (August 01, 2018)

2.5.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Shaoyan Guo, Eden Huang, David Laudy, Evangelos Panos, Wilfredo Sifuentes and Larissa de Vries.

2.5.2.2 Platforms

- Fixed problem using solvers with Fortran dependencies on a Mac OS X 10.11 system.

2.5.2.3 GAMS System

2.5.2.3.1 GAMS

- Fixed a bug which caused an unexpected error when using the + operator in a model statement with the following symbol being a model itself, like this:

```plaintext
variable x;
equation e1, e2;
e1.. x =L= 5;
e2.. x =G= 3;
model m2 /e2/;
model m /e1+m2/;
solve m min x use lp;
```

2.5.2.4 Solvers

2.5.2.4.1 BARON

- Fixed translation of branching priority values when specified in BARON options file and GAMS option PriorOpt not enabled.
- Specifying maxdouble as branching priority in a BARON options file now behaves as if specifying inf as branching priority in a GAMS model.
2.5.2.4.2 BONMIN

- The default for option `number_cpx_threads` is now initialized according to the value of the GAMS option `threads`.

2.5.2.4.3 CONOPT

- New libraries 3.17I for CONOPT 3.
- New libraries 4.06 for CONOPT 4.

2.5.2.4.4 GUSS

- Models with variable parameters and model attribute `holdFixed=1` could not be solved with 25.1.1. In this release the `holdFixed` option is automatically turned off.

2.5.2.4.5 Ipopt

- New libraries.
  - Fixed problems in handling of time limit (reslim).

2.5.2.4.6 LocalSolver

- New libraries 7.5 (20180601).

2.5.2.4.7 ODHCPLEX

- New libraries 3.4.3.
- ODHCPLEX is now available for Linux, too.

2.5.2.4.8 SoPlex

- New libraries 3.1 (b0e0048).

2.5.2.4.9 SCIP

- New libraries 5.0 (1d9c207).

2.5.2.5 Tools

2.5.2.5.1 MODEL2TEX

- Backslashes in the explanatory text of symbols are replaced automatically with `\textbackslash`.
2.5.2.5.2 GAMS Studio

- New version 0.9.2
  - Stability improvements
  - Allow only one instance of Studio to run at the same time (when file association for Studio is active, a double click on a gms file will open that file in a running Studio instance and does not open a new Studio)
  - Added startup parameter \texttt{--gams-dir} to specify a non-default GAMS system folder to be used
  - Added shortcuts for \texttt{Interrupt} and \texttt{Stop} (F12 and Shift+F12)
  - Restructured the \texttt{File -> Encoding} menu
  - About dialog: added button to copy product information to clipboard
  - GDX Viewer: added facility to search for symbols
  - Option Editor: allow to use F1 to open help
  - Project Explorer:
    - "Add Existing Files" allows to add multiple files at once
    - Added context menu entry to open the log for a group-node
  Note
  - When migrating from an older version of GAMS Studio, one might have an empty project explorer and no recent files listed. This is expected behavior because of a bug fix within the GAMS Studio settings file.

2.5.2.6 Object Oriented APIs

2.5.2.6.1 Python

- Fixed a bug that prevented the setup.py file to be called with parameter \texttt{--noCheck} for turning off the version check.
- The setup.py script can be used from an arbitrary location. It is not required anymore to switch to the files location before installing.

2.5.3 25.1.3 Minor release (October 30, 2018)

2.5.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

2.5.3.2 GAMS System

2.5.3.2.1 GAMS

- Fixed a bug which caused the \texttt{sysIdent} property not being set correctly after a solve statement.
- Fixed a bug which could have caused a problem with \texttt{execute_load} being called after \texttt{endEmbeddedCode} in a loop.
2.5.3.3 Solvers

2.5.3.3.1 ANTIGONE

- If interrupting ANTIGONE (using Ctrl+C, for example), the final trydual NLP solve does no longer stop immediately in the first iteration.

2.5.3.3.2 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2018.4 on Mac OS X.

2.5.3.3.3 CONVERTD

- When using options Jacobian or Hessian, new symbols iobj, objConst, and objJacVal are written to the GDX file. If the model can be reformulated with a true objection function, the symbol iobj contains the label of the objective defining equation, while the symbols objConst and objJacVal contain the objective constant and the coefficient of the objective variable. If the model cannot be reformulated with a true objective, iobj will be empty and objConst and objJacVal will be 0.

2.5.3.3.4 GUROBI

- New libraries 8.1.0.
- Option GUROBIpreqlinearize allows the value of 2 (Force Linearization and get compact relaxation).

2.5.3.3.5 JAMS

- Added some experimental indexed EMP syntax. See example model emppython1.gms: Three Simple EMP Models with Indexed EMP Syntax and Python Parser.

2.5.3.3.6 Lindo/LindoGlobal

- New libraries 11.0.338.

2.5.3.3.7 MOSEK

- New libraries 8.1.0.64.

2.5.3.4 Tools

2.5.3.4.1 CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.
2.5.3.5 Object Oriented APIs

2.5.3.5.1 Python

- The UpdateAction Primal and Dual in a GamsModifier were not recognized and triggered an exception. This has been fixed.

2.5.3.6 Model Libraries

2.5.3.6.1 GAMS EMP Library

- emppython1.gms: Three Simple EMP Models with Indexed EMP Syntax and Python Parser (104)

2.6 25.0 Distribution

2.6.1 25.0.1 Major release (January 17, 2018)

2.6.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Jeff Dischler, Michael Ferris, Dhruv Gupta, Erwin Kalvelagen, Florian Landis, Andre Lemelin, Erfan Mohagheghi, Anthony Paul, and Nathan Sudermann-Merx.

2.6.1.2 Platforms

- Due to the discontinuation of Cplex on Windows 32bit (with Cplex 12.7 in 2016) we are faced with potentially phasing out/dropping solvers depending on Cplex on Windows 32bit with the next major release. The most likely candidate for this is ANTIGONE. These solvers will still be available for 64-bit Windows and other supported platforms. Other solver vendors (e.g. Gurobi and FICO-Xpress) have also announced the discontinuation of their product on the Windows 32bit platform. If you rely heavily on the availability and support of the Windows 32bit platform please contact support@gams.com to discuss your options.

- As announced, dropped support for x86-64 Solaris.

- As announced, increased the minimal required MacOS X version to 10.11.

- As announced, increased the minimal required GLIBC version on Linux to 2.12.
2.6.1.3 GAMS System

2.6.1.3.1 GAMS

- Extended the `$offEmbeddedCode` facility to allow the use of a "projection operator":
  ```gams
  $offEmbeddedCode {symbol[<>=embSymbol.[dim]]}
  ```
  More information can be found here.

- Added support for the Object-oriented GAMS Python API in the Embedded Code Facility for Python. The method `gams.set()` accepts instances of type `GamsParameter`, `GamsSet`, etc. as data. Instances of `GamsWorkspace` and `GamsDatabase` can be retrieved using the properties `gams.ws` and `gams.db`. The property `gams.wsWorkingDir` can be used to specify the working directory of the created GamsWorkspace.

- Added `$libinclude pyEmbMI` to conveniently work with Python OO-API `GamsModelInstance` from embedded code. See `embmiex1.gms : Simple Embedded Code ModelInstance example`.

- Fixed a problem in embedded code when reading an empty scalar symbol.

- Fixed a problem when solving a model with `solveLink 5, 6, or 7` with communicating scales without `scaleOpt` active.

- The EPS value in the Embedded Code Facility for Python has been changed to `4.94066E-324`. This is the same value that is used for EPS in the Object-oriented Python API.

- New Put Utility `save`: Writes a save file of the current state of execution.

- Improvement for the Put Utility Statement: It is no longer required to define a file and activate it, just to use a put utility.

- New command line option `fileStemApFromEnv`: Append a string read from an environment variable to the `fileStem`.

- Change to command line option `fileStem`: Create an immediate error when the value contains a "\" or "/" character to avoid problems later on.

- Fixed a bug with `execute unload`, which could have caused a `set` to be exported mistakenly as `alias` to a different `set`, if symbol renaming was used.

- Fixed a bug which prevented to open more than 65,000 put files.

- Solves with `scaleOpt=1` using GUSS or instantiations of OO-API `GAMSMModelInstances` resulted in some circumstances in the report of scaled solutions or other erroneous behavior. Hence GAMS will now reset the `modelName.scaleOpt` attribute to NA before such a solve or `GAMSMModelInstance` generation. As a consequence, models solved via GUSS or as a `GAMSMModelInstance` in the OO-APIs will not be scaled by GAMS.

- Solving MCP models with `scaleOpt=1` using the solvers AMPL or PYOMO creates an execution error now. In the past this lead to wrong results potentially.

2.6.1.4 Solvers

2.6.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2018.0 for Linux and Mac OS X and to version 2018.1 on Windows 64-bit.

2.6.1.4.2 CBC

- New libraries.
2.6.1.4.3 CONOPT

- New libraries 3.17G (Conopt3).
- New libraries 4.04 (Conopt4).
  - Fixed a system error 65666.

2.6.1.4.4 Couenne

- New libraries.
  - Bugfixes and tuning for fixed point bound tightening.
- If Couenne does not find a feasible solution, but the initial point is feasible, then the initial point is now reported back to GAMS.

2.6.1.4.5 CONVERT

- If the filename provided for the jacobian or hessian option contains the string novenames ConvertD will not export the original equation and variable names as set text to elements of sets i and j. Having the original equation and variable names can make the GDX file significantly larger and slow to write and read.
- Fixed a problem when trying to write scaled MCP models.

2.6.1.4.6 CPLEX

- New libraries 12.8.0.
- New parameters
  - SubMIPScale: Parameter to scale the problem matrix when CPLEX solves a subMIP during MIP optimization
  - SubMIPStartAlg: Starting algorithm for subMIP of a MIP
  - SubMIPSubAlg: Algorithm for subproblems of a subMIP of a MIP
  - DynamicRows: Switch for dynamic management of rows
  - Sifting: Switch for sifting from simplex optimization
- In CplexD allow the BendersPartition to be set via the .stage variable suffix together with option BendersPartitionInStage.

2.6.1.4.7 Gurobi

- Fixed a problem for model with SOS variables but no constraints.

2.6.1.4.8 KESTREL

- New options neos_username and neos_user_password can be used in the option file in order to submit authenticated jobs using a NEOS user account.
2.6.1.4.9 LocalSolver

- New libraries 7.5 (20171117) for Mac OS X and Windows.
  - Preprocessing entirely rewritten: size reduction by a factor up to 10 on some huge instances.
  - Combinatorial models based on booleans and integers: performance improvement and increased ability to prove optimality.
  - Continuous linear and nonlinear models: performance improvement through the integration of state-of-the-art algorithms.
- Note, that to use LocalSolver 7.5, a machine-specific LocalSolver license is now required. See here on how to obtain such a license. Alternatively, it is still possible to use LocalSolver 7.0 by choosing LOCALSOLVER70 instead of LOCALSOLVER as solver.

2.6.1.4.10 Mosek

- New libraries 8.1.0.34.

2.6.1.4.11 SBB

- Fixed a bug introduced in 24.8 that prevents the infeasSeq option to work.

2.6.1.4.12 SCIP

- New libraries 5.0 (2b35b18).
  - SCIP can now automatically detect and exploit symmetries in MIPs (Linux and MacOS X only)
    * added parameter misc/usesymmetry to determine which symmetry handling should be used
    * added parameter groups presolving/symmetry, presolving/symbreak, constraints/symresack, constraints/orbisack, constraints/orbitope
  - Presolving
    * new presolver sparsify that tries to cancel nonzero coefficients in linear constraints by adding multiples of linear equalities
    * disabled reformulation of products of a binary variable with a linear term that does not solely involve binary variables
      * added parameter constraints/quadratic/binreformbinaryonly to disable reformulation of products of binary and non-binary variables
    * revised disaggregation of quadratic constraints: the number of created constraints can now be controlled and the disaggregated constraints are scaled in order to increase numerical accuracy
      * replaced constraints/quadratic/disaggregate by constraints/quadratic/maxdisaggrsize to bound the total number of created constraints when disaggregating a quadratic constraint
      * added parameter constraints/quadratic/disaggrmergemethod to change the strategy of how to merge independent blocks of quadratic constraints
  - Primal Heuristics
    * new primal heuristic ALNS that orchestrates eight different LNS heuristics adaptively using algorithms for the multi-armed bandit problem
• new primal heuristic MPEC that solves a MPEC reformulation of a mixed-binary nonlinear problem by regularized NLP reformulations
• improved the clique and variable bound pre-root heuristics, which are now often able to fix many more variables
  • removed parameters heuristics/clique/\{multiplier,initseed\}
  • replaced parameter heuristics/\{clique,vbounds\}/minfixingrate by heuristics/clique/minintfixingrate, heuristics/vbounds/minintfixingrate, heuristics/clique/minmipfixingrate, and heuristics/vbounds/minmipfixingrate, which check the fixing rate before LP solving and after sub-MIP presolve
  • added parameters heuristics/clique/maxbacktracks and heuristics/vbounds/maxbacktracks to limit the number of backtracks in the fix-and-propagate phase
  • added parameters heuristics/clique/uselockfixings and heuristics/vbounds/uselockfixings to enable fixing of additional variables based on variable locks
  • added parameters heuristics/vbounds/feasvariant and heuristics/vbounds/tightenvariant to specify the fixing variants used by the vbounds heuristic
  • changed default for parameters heuristics/clique/freq and heuristics/vbounds/freq from -1 to 0
  • changed default for parameter heuristics/clique/priority from -1000500 to 5000
  • changed default for parameter heuristics/vbounds/priority from -1100600 to 2501
• added parameters heuristics/completesol/beforepresol, heuristics/completesol/maxlpiter, and heuristics/completesol/maxcontvars
• changed default for parameter heuristics/indicator/oneopt from 1 to 0
• changed default for parameter heuristics/locks/minfixingrate from 0.25 to 0.65
• changed default for parameter heuristics/locks/priority from 2000 to 3000

– Separation (cutting planes)
• utilizing linear inequalities (computed in the OBBT propagator) to compute stronger linearizations for bilinear terms
  • added parameters constraints/quadratic/usebilineneqbranch, constraints/quadratic/mincrevbiqnels, and constraints/quadratic/bilinoneqmaxseparounds
  • added parameter constraints/quadratic/mincrevcollectbiqterms to change the minimal curvature of constraints to be considered when returning bilinear terms to other plugins
  • added parameters propagating/obbt/itlimitfactorbilin, propagating/obbt/minnonconvexity, and propagating/obbt/createbilinineqs
• improved cut post-processing (apply coefficient tightening, enforce maximal dynamism), selection, and management
  • added parameters separating/maxlocalbounddist, separating/maxcoefficientratio, and separating/intsupportfac
  • removed parameter separating/orthofac
  • changed default for parameter separating/cutagelimit from 100 to 80
  • changed default for parameter separating/minefficacy from 0.05 to 0.0001
  • changed default for parameter separating/minefficacyroot from 0.001 to 0.0001
  • changed defaults for parameters separating/minortho and separating/minorthoroot from 0.5 to 0.9
  • changed default for parameter separating/objparalfac from 0.0001 to 0.1
  • changed default for parameter separating/poolfreq from 0 to 10
• MIP cutting planes are now separated within the tree search, too
  • parameter separating/maxstallrounds only applies to nodes in the tree (not the root node, anymore); use the new parameter separating/maxstallroundsroot for the root node
  • added parameters separating/*/expsbackoff to all separators, which increases the frequency exponentially over the depth in the tree
  • added parameter separating/maxincrounds
  • changed default for parameter separating/maxstallrounds from 5 to 1
· changed default for parameter separating/maxrounds from 5 to -1
· changed default for parameter separating/maxroundsrootsubrun from 1 to -1
· changed default for parameter separating/gomory/delayedcuts from 1 to 0
· changed default for parameter separating/gomory/freq from 0 to 10
· changed default for parameter separating/gomory/maxrounds from 0 to 1
· changed default for parameter separating/impliedbounds/freq from 0 to 10
· changed default for parameter separating/impliedbounds/maxbounddist from 0 to 1
· changed default for parameter separating/strongcg/freq from 0 to 10
· changed default for parameter separating/strongcg/maxbounddist from 0 to 1
· changed default for parameter separating/strongcg/maxsepacuts from 50 to 20
· changed default for parameter separating/zerohalf/freq from -1 to 4
· changed default for parameter separating/zerohalf/maxbounddist from 0 to 1

* new implementation of zerohalf separator
· added parameters separating/zerohalf/badscore, separating/zerohalf/densityoffset, separating/zerohalf/goodscore, separating/zerohalf/maxcutcands, separating/zerohalf/maxrowdensity, separating/zerohalf/maxslack, separating/zerohalf/maxslackroot, and separating/zerohalf/minviol
· removed parameters separating/zerohalf/delayedcuts, separating/zerohalf/ignoreprevzhcuts, separating/zerohalf/maxcutfound, separating/zerohalf/maxcutfoundroot separating/zerohalf/maxdepth, separating/zerohalf/maxncalls, separating/zerohalf/maxtestdelta, separating/zerohalf/onlyorigrows, separating/zerohalf/relaxcontvars, separating/zerohalf/scalefraccoeffs, separating/zerohalf/trynegscaling, separating/zerohalf/usezhcutpool, separating/zerohalf/preprocessing/*, and separating/zerohalf/separating/*
· changed default for parameter separating/zerohalf/maxroundsroot from 10 to 20
· changed default for parameter separating/zerohalf/maxsepacuts from 50 to 20
· changed default for parameter separating/zerohalf/maxsepacutsroot from 500 to 100

* faster implementation of CMIR cut generation heuristic
· moved many parameters for flowcover and cmir separators to new parameter group separating/aggregation
· changed default for parameters separating/cmir/freq and separating/flowcover/freq from 0 to -1
· changed default for parameters separating/cmir/maxbounddist and separating/flowcover/maxbounddist from 0 to 1
· changed default for parameter separating/cmir/priority from -3000 to -100000
· changed default for parameter separating/flowcover/priority from -4000 to -100000

* additional parameter changes
· removed parameter separating/feastolfac
· removed parameter separating/cgmip/allowlocal
· removed parameters separating/{gomory,strongcg}/maxweightrange
· changed default for parameter separating/gomory/makeintegral from 1 to 0
· changed default for parameter separating/gomory/maxrank from 3 to -1
· changed default for parameter separating/gomory/sidetypebasis from 0 to 1
· added parameter constraints/indicator/maxsepanonviolated to stop separation after separation of non violated cuts
· removed parameters constraints/{abspower,bivariate,quadratic,nonlinear}/mincutefficacysepa, constraints/{abspower,bivariate,quadratic,nonlinear}/mincutefficacyenfoc, and constraints/soc/minefficacy

Propagation
* use disjoint set to reduce peak memory usage and time to compute clique table connectedness information
* added analysis of the clique table which identifies possible aggregations via the search for strongly connected components and may detect infeasible assignments on the way
2.6.1.4.13 SolveEngine

- The GAMS time limit (reslim) is now passed to SolveEngine. Added solver option hardtimelimit to specify a time limit that is enforced on the GAMS side.

2.6.1.4.14 SoPlex

- New libraries 3.1.0 (876e6e8).
  - New scaling method that combines geometric and equilibrium scaling. Use new value 6 for option int:scaler to activate this.
  - See also the release paper.

2.6.1.4.15 Xpress

- New libraries 32.01.05.

2.6.1.5 Tools

2.6.1.5.1 CDSP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.
2.6.1.5.2 GDXXRW

- Sometimes, Excel is not ready (e.g. because some data needs to be refreshed, when a worksheet is opened), when a read request is sent by GDXXRW. This could cause an exception. With this release we changed the behavior of GDXXRW to wait a second and resend the request in this case. This basically mimics the behavior of setting RWait to 1000 in case of the mentioned exception.

2.6.1.6 Object Oriented APIs

2.6.1.6.1 C++

- Changed the compiler from GCC to Clang on Mac OS X.
- API binaries have been moved to apifiles/C++/lib. On Windows, there are further subdirectories for different compiler versions.
- Update of Visual Studio solutions for the examples on Windows. Three different solutions reflecting the supported versions of Microsoft Visual Studio are available (e.g. examples-vs2013.sln, examples-vs2015.sln, examples-vs2017.sln).
- The GAMS C++ API tutorial has been reworked. Information about building the C++ API examples via cmake, qmake, and Microsoft Visual Studio has been added.
- New example TransportGDX that shows how to import and export GDX files. A description has been added to the tutorial.

2.6.1.6.2 .NET

- Changes for GAMSSymbol and GAMSSymbolRecord: Both classes got the IComparable<T> Interface. As a result the behavior of the Equals function as well as the == and != operators were modified. For both classes Equals and == returns now true, if the internal data reference is the same. Here is an example:

```csharp
GAMSVariable x1 = db.GetVariable("x");
GAMSVariable x2 = db.GetVariable("x");

if(x1 == x2)
    Console.WriteLine("x1 == x2");
else
    Console.WriteLine("x1 != x2");
if (x1.Equals(x2))
    Console.WriteLine("x1 equals x2");
else
    Console.WriteLine("x1 does not equal x2");
```

In previous versions we got this output:

```
x1 != x2
x1 does not equal x2
```

Now we get:

```
x1 == x2
x1 equals x2
```

- New example TransportGDX that shows how to import and export GDX files.
2.6.1.6.3 Java

- The minimum version requirement of the Java Runtime Environment for using the GAMS Java API is now Java SE 7.
- New TransportGDX example to demonstrate how to import and export GDX files.
- Removed method GAMSSymbol.compact, deprecated since 24.8.1 (December 2016).
- Changed equivalence behavior of GAMSSymbol and GAMSSymbolRecord objects. As a result, two symbol objects with the same internal reference are now equivalent, similar to symbol record objects:
  - Two symbols are equivalent if and only if they have the same internal reference.
  - Two symbol records are equivalent if and only if they have the same internal reference.

The behavior of operator \(==\) remains unchanged. The following example illustrates the new equivalence behavior:

```java
GAMSVariable x1 = db.getVariable("x");
GAMSVariable x2 = db.getVariable("x");
GAMSVariable x3 = x1;
assertTrue(x1.equals(x2)); // true, previously false
assertFalse(x1 == x2); // false, previously false
assertTrue(x1.equals(x3)); // true, previously true
assertTrue(x1 == x3); // true, previously true
```

2.6.1.6.4 Python

- Added implementation of \_eq\_() and \_ne\_() to classes _GamsSymbol and _GamsSymbolRecord and its derived classes. As a result the behavior of the operators \(==\) and \(!=\) has changed. \(==\) now returns True, if the internal data reference is the same. The behavior of \(is\) remains unchanged. The following example illustrates the change:

```python
x1 = db["x"]
x2 = db["x"]
print(x1 == x2) # now: True, before: False
print(x1 is x2) # now: False, before: False
```

- New example `transport_gdx.py` that shows how to import and export GDX files. A description has been added to the tutorial.

2.6.1.7 Expert Level APIs

- As announced, the expert-level C++ API files were removed from the distribution. Users should switch to the expert-level C API files. The object-oriented C++ API introduced in the last major release could also be a good alternative for replacement if the user C++ code exchanges data and runs a GAMS model.
- The expert-level Java API files now ensure the load of jni libraries in the similar order as those employed by the Object Oriented Java API: first load from `java.library.path`, if neither specified nor found then from the directory where the API classes are located.

2.6.1.7.1 GDX

- Do not allow empty filename as argument for `gdxOpenAppend`, `gdxOpenRead`, `gdxOpenWrite`, and `gdxOpenWriteEx`. This will create an error right away now.
2.6.1.8 Model Libraries

2.6.1.8.1 GAMS Model Library

- embmiex1.gms: Simple Embedded Code ModelInstance example (417)
- spbenders1.gms: Stochastic Benders - Sequential GAMS Loop (418)
- spbenders2.gms: Stochastic Benders - Async Subsolve GAMS Loop (419)
- spbenders3.gms: Stochastic Benders - Sequential GamsModelInstance (420)
- spbenders4.gms: Stochastic Benders - Parallel MPI (421)
- spbenders5.gms: Stochastic Benders - Parallel MPI with GAMSModelInstance (422)

Most models in the GAMS Model library have been refurbished to reflect a common syntax style and features introduced since the model was added.

- prime: Make use of the break statement for a little nicer and faster formulation.

2.6.1.8.2 GAMS Test Library

- scensol7.gms: Test GUSS Option ReportLastScen (737)
- emp27.gms: Test LOGMIP/EMP on x.fx=0 handling (738)
- emppy03.gms: Test projection operator when loading data from embedded code (739)
- qcp11.gms: Test dual solution of SOCP (740)
- put11.gms: Put Utility without file handle (741)

### 2.6.2 25.0 Distribution

#### 2.6.2.2 Maintenance release (January 31, 2018)

#### 2.6.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Tom Rutherford.

#### 2.6.2.2.1 GAMS System

**GAMS**

- Bugfix: `$offEmbeddedCode` does not ignore `$onUNDF` anymore.
- Bugfix: Special values (NA, EPS, INF, ...) are correctly communicated from embedded code back to GAMS.
- Bugfix: Took care about a problem, which caused an unexpected execution error for certain uses of `Put_Utility`.
- Fixed a bug in GMSPython on Mac OS X which prevented the Python interpreter from working. This problem occurred with the DMG installer only.
2.6.2.3 Solvers

2.6.2.3.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- On Linux, removed the MKL libraries that were optimized to certain x86 instruction sets (AVX, etc.) as this resulted in errors when running ANTIGONE or SCIP, probably due to library conflicts.

2.6.2.3.2 CPLEX

- Option Tuning can be repeated in a GAMS/Cplex option file to provide a larger number of model instances for tuning. Before this change the number was restricted by the maximum line length of an option line (256 characters).

2.6.2.3.3 LocalSolver

- New libraries 7.5 (20180119) for Mac OS X and Windows.

2.6.2.4 Tools

2.6.2.4.1 CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.

2.6.2.4.2 CSV2GDX

- Bugfix: Reading sets (no Value or Values option) with the option AutoRow works again.

2.6.3 25.0.3 Minor release (March 21, 2018)

2.6.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Dominik Bongartz, Wolfgang Britz, Erwin Kalvelagen, Maria Kannavou, Hans Mittelmann, Christoph Pahmeyer, Gilles Scouvart, and Hermann Westerholt.

2.6.3.2 GAMS System

2.6.3.2.1 GAMS

- Bugfix for Put_Utility: If a put_utility statement was used as the first statement to mark a file as active (so no statement like put fx; was used before) and following put or put_utility statements did not mention this file explicitly, then the file association got lost.

- Bugfix: Avoid a crash when one of the following attributes was used on an empty Singleton Set: .len, .uel, .val (an execution error is generated instead now)

- Bugfix for command line option fileStemApFromEnv: In the past, if the input file was defined including a file extension, the value of this option was extended to the extension and not to the file stem as intended. This is fixed now.

- Bugfix for $if exist File on Windows: In the past, if a file was specified as <Drive>:/<File>, e.g., C:/t.txt (note the forward slash '/' after the colon ':'), this always returned false, even if the file exists. That has been fixed now.
2.6.3.3 Solvers

2.6.3.3.1 BARON

- Fixed use of .EquClass option.

2.6.3.3.2 BONMIN(H), CBC, Couenne

- Branch-and-bound now checks wallclock-time, if running with multiple threads.

2.6.3.3.3 CONOPT4

- New libraries 4.05.
  - Improved the selection of post-triangular variables when there are multiple candidates.

2.6.3.3.4 CPLEX

- Bugfix: If the Cplex conflict refiner (triggered by option iis) could not identify a conflict the behavior was erratic. This has been fixed.
- Bugfix: Value 6 for option MIPStart was documented but got rejected. This has been fixed.

2.6.3.3.5 DICOPT

- Fixed setup of NLP projection problem in feasibility pump.
- Fixed stopping criterion when using stop on crossover: DICOPT was stopping as soon as the relative gap between the objective value of the best known solution and the bound provided by the MIP relaxation was below 0.001, thus might have declared suboptimal solutions as optimal. With this release, DICOPT will use the value of GAMS option optcr as optimality tolerance. Note, that the default for this option is 0.1 (!).

2.6.3.3.6 Ipopt(H)

- New libraries.

2.6.3.3.7 MOSEK

- No update, but be aware that Mosek announced to drop the convex nonlinear optimizer in their next major release (Mosek 9). Thus, in a future GAMS release, GAMS/Mosek will not accept models with model types NLP or DNLP anymore. Note, that linear or quadratic problems (LP, MIP, (MI)QCP) are not affected.
2.6.3.3.8 SCIP

- New libraries 5.0.1 (227c4c7).
  - New option presolving/symmetry/displaynorbitvars.

2.6.3.3.9 SoPlex

- New libraries 3.1.1 (ab921a5).

2.6.3.4 Tools

2.6.3.4.1 MODEL2TEX

- Added support for singleton sets.
- Fixed a dependency bug on Mac OS X which prevented model2tex from working.
- Fixed a bug regarding SOS variables.
- Fixed a bug regarding domain jumps.
- Added support for Python 3 on Linux and Mac OS X.

2.7 24.9 Distribution

2.7.1 24.9.1 Major release (August 30, 2017)

2.7.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jan Abrell, Etienne Ayotte-Sauvé, Wolfgang Britz, Florian Habermacher, Florian Häberlein, Maximilian Held, Ignacio Herrero, Hanspeter Höschle, Erwin Kalvelagen, Toni Lastusilta, John Ross, Tom Rutherford, and Linus Schrage.

2.7.1.2 Platforms

- The set of supported platforms has not changed, but we've divided it into the core platforms (Windows 32-bit, Windows 64-bit, Linux, and Mac OS X) and the peripheral platforms (AIX, x86-64 Solaris, and Sparc64 Solaris). See Supported Platforms for more details. Please note, however, that we are not changing the content or behavior of GAMS based on this division: GAMS models will continue to work in the same cross-platform way for both core and peripheral platforms.
- We will drop support for x86-64 Solaris with GAMS 25.0.
- We may increase the minimal required GLIBC version on Linux to 2.12 with GAMS 25.0.
- We may increase the minimal required MacOS X version to 10.11 with GAMS 25.0.
2.7.1.3 GAMS System

2.7.1.3.1 GAMS

- New feature, the **Embedded Code Facility**: This extends the connectivity of GAMS to other programming languages. It allows the use of Python code during compile and execution time. GAMS symbols are shared with the external code, so no communication via disk is necessary. The embedded code feature is available on Linux, MacOS X, and Windows. For these platforms, a Python 3.6 installation is included with the GAMS distribution. If the user wants to work with a different Python 3.6, installed separately, for models with embedded code the new command line option `pySetup` needs to be set to 0.

  **Note**
  
  This feature is currently in beta status. Any feedback to support@gams.com is appreciated.

- New command line option `procDirPath`: Specifies the directory where the process directory should be created.

- New compile time constants to set the model attribute `solPrint`:
  - `0 = %solPrint.Off%`
  - `1 = %solPrint.On%`
  - `2 = %solPrint.Silent%`

- New compile time constants to set the model attribute `solveOpt`:
  - `0 = %solveOpt.Replace%`
  - `1 = %solveOpt.Merge%`
  - `2 = %solveOpt.Clear%`

- Allow new string synonyms to set the integer values of the following command line options:
  - `solPrint`: Off ( =0); On ( =1); Silent ( =2)
  - `sysOut`: Off ( =0); On ( =1);

- Fixed a bug where the following dollar control options did not get written to the dump file when the command line parameter `dumpOpt` was used. Sometimes this caused an error in the generated file.
  - `$[on|off]DotScale`
  - `$[on|off]Embedded`
  - `$[on|off]Expand`
  - `$[on|off]Local`
  - `$[on|off]Macro`
  - `$[on|off]Margin`
  - `$[on|off]Order`
  - `$[on|off]StrictSingleton`
  - `$[on|off]UNDF`

- Fixed an error which caused the loss of equation information when using the **Grid facility** in certain cases. This could have caused problems when a hot start should be performed.

- A parameter error is now created if the key of a 'double dash' GAMS parameter exceeds 63 characters (in the past, the key was truncated silently in this case).

- Fixed a crash which happened if the `.tl` suffix was used on an empty Singleton Set in a put statement.

- Fixed a bug which could have caused a crash if nested loops where used in a particular combination.

- Fixed a bug with `$onPut ... $offPut` in a `for` and `repeat` structure: When `$onPut` was the first statement inside one of these programming flow control features, it was executed just once and not repeatedly.
2.7.1.3.2 Special Functions

- Several of the more exotic GAMS intrinsic functions (aka "special functions") were re-implemented to address some bug reports and to pass a more rigorous set of tests. The updated functions include the loggamma, gamma, logbeta, beta, and binomial functions. In general, the updated functions offer improved precision and a more consistent behavior in exceptional cases (e.g. overflows, singularities, and domain violations) compared to the previous versions. In addition, the gamma and beta functions are now classified as smooth (NLP) instead of nonsmooth (DNLP) and the domains of the beta and binomial functions have been changed.

2.7.1.3.3 Documentation

- The contents of GAMS User's Guide and the McCarl (Expanded) User's Guide have been merged, revised, and reorganized as User's Guide as well as A GAMS Tutorial by Richard E. Rosenthal. Also other parts of the documentation has been reorganized and are now more closely integrated.
- The McCarl GAMS User Guide (CHM and PDF) can now be found in the mccarl/ subdirectory in the distribution.
- The PDFs containing the solver manuals and the GAMS User's Guide have been replaced by a single PDF containing large parts of the current documentation. However, the main format for the documentation is HTML.

2.7.1.4 Solvers

2.7.1.4.1 BARON

- New libraries 17.8.7.
  - New range reduction techniques and relaxations for quadratic constraints.
  - New heuristics for finding feasible solutions of integer programs.
  - Improvements in interfaces to local NLP solvers, including the use of second-order derivatives.
  - FilterSQP added to the list of local solvers. New option AllowFilterSQP and added new possible value 14 for option NLPSol.
  - Bugfixes.

2.7.1.4.2 CBC

- New libraries.
  - Fixed some problems with the handling of SOS type 2 in presolve.
- Added option dump solutions merged to write all found alternate solutions into a single GDX file.

2.7.1.4.3 Conopt

- New libraries 3.17E and 4.03.
  - Fixed a serious error in Conopt4 for exactly threads=8. Moreover, improved multi-threading performance.
  - Major revisions to Conopt4 for reliability and performance.
- The option Rtzern is now user settable for Conopt3.
2.7.1.4.4 CONVERT

- The GAMS equation and variable scale values (suffix .scale) will be communicated to CONVERT independent of the ScaleOpt model attribute.

2.7.1.4.5 CPLEX

- Added option workerAlgorithm to select the method for optimizing Benders subproblems.
- Added option writeAnnotation to create Cplex annotation file.
- The header of MIP/solve trace files contains now the option number and the name of the model.

2.7.1.4.6 DECIS

- DecisC, DecisM, and the EMP-SP solver Decis are now available for MacOS X.

2.7.1.4.7 GAMSCHK

- The procedures that generate output in the listing file are summarized at the end of the GAMSCHK execution. If you use the IDE, these summary lines are clickable and locate the cursor to the corresponding subsection in the IDE. Moreover, the procedures are also entered in the listing file index after the Solution Report.
- The lower bound for options LevelFilt and MargFilt has been reset from 1 to -5.

2.7.1.4.8 GUROBI

- New libraries 7.5.1.
  - Fewer constraint violations in MIQP solutions: Gurobi has tightened the internal tolerances for MIQP models to reduce the number of cases where the solution exhibits small constraint violations.
- New parameter startNodeLimit provides additional control over how much is performed to complete a partial MIP start.
- Gurobi 7.5 will be the last Gurobi release that supports 32-bit Windows. You should plan to migrate your applications to 64-bit Windows in the future.
- The header of MIP/solve trace files contain now the active option number and the name of the model.

2.7.1.4.9 GUSS/Scenario Solver

- Fixed a problem when initializing variables bounds to 0 (updateType=0) that have scenario update parameters for lower and upper bounds.
2.7.1.4.10 Lindo/LindoGlobal

- New libraries 11.0
  - LP Solver Improvements:
    * With new enhancements made to the simplex solvers, the average performance on large instances has increased by 20% for the primal simplex and 15% for the dual simplex compared to the previous version.
  - MIP Solver Improvements:
    * New symmetry detection capabilities to reduce overall branch-bound effort. This may dramatically reduce the time needed to prove optimality on some models with integer variables.
    * Perspective and soft-clique cuts effective on difficult MIQP and models with assignment constraints.
  - Global Solver Improvements:
    * Improved stability and robustness through several enhancements to quadratic recognition and range reduction.
  - Nonlinear Solver Improvements:
    * New major release of the nonlinear solver.
    * Improved preprocessor.
    * Use of interval function and derivative computations.
    * Advanced scaling leading to improved solution quality.

2.7.1.4.11 LocalSolver

- New libraries 7.0 (20170728).
  - Reinforcement of mixed-integer linear programming (LP & MIP) techniques for combinatorial optimization.
  - Reinforcement of nonlinear programming techniques (NLP) for numerical optimization.

2.7.1.4.12 MINOS

- New libraries 5.6 (dated July 2016).
  - Improved handling of singularites and empty cols in pivoting code.
  - Further bug fixes and improvements.
- Fix improper handling of scaled CNS models.
- Fix handling of logging frequency.
- QUADMINOS, the quadruple-precision version of MINOS, has been available in previous releases (since 24.4). This release includes the library model [DQQ], an example of how to use MINOS and QUADMINOS together to compute greatly improved solutions at moderate cost.

2.7.1.4.13 MOSEK

- New libraries 8.1.0.23.
  - Performance of the presolve has been improved slightly.
  - Multi-thread performance of the conic optimizer has been improved for certain large models.
  - Changed scaling for quadratic and quadratically constraint optimization problems.
  - Bugfixes.
2.7.1.4.14 MPSGE

- The MPSGE $sysInclude mpsgeset allows now for an optional argument -mt=0 or 1 after the model name. The default value for the argument mt can be controlled via the double dash option --MPSGEMT=0 or 1. If the mt option is set to 1 the MODEL.GEN file is created in the GAMS scratch directory. Hence the $include before the solve needs to read $include "%gams.scrdir%MODEL.GEN". This allows to run multiple MPSGE jobs with the same model in the same working directory. The default of this option is 0. The model hansmge demonstrates the use.

2.7.1.4.15 SBB

- The header of MIP/solve trace files contains now the option number and the name of the model.

2.7.1.4.16 SCIP

- New libraries 4.0 (9d3c1b1).
  - Improved conflict analysis through central conflict pool and dual ray analysis for primal infeasible LPs.
  - New solution polishing to improve integrality of LP solutions when using SoPlex as LP solver.
  - Added adaptive solving behavior of SCIP based on solving phases and heuristic transitions.
  - Revised pseudo random number generation and introduced central random seed for all plugins.
  - Randomized tie-breaking in different parts of the code to reduce performance variability.
  - New primal heuristics GINS, LP face, Complete Sol, Locks, Repair, and Multistart.
  - The 1-opt heuristic is now iterated as long as new incumbents are found.
  - Improved tuning of heuristic timings.
  - Reduced memory usage of primal heuristics that use problem copies.
  - New presolving steps that disaggregate SOC constraints, reformulate QP's by adding KKT conditions, and treat variables appearing only in a single quadratic constraint with proper square coefficients.
  - New separators for gauge cuts, convex projection cuts, and perspective cuts for indicator constraints.
  - Improved knapsack approximation algorithms, greedy knapsack solution for the flow cover separation, clique partitioning, and clique separation.
  - New propagator for OBBT on convex NLP relaxation.
  - Tuned propagation methods of several constraint handlers and propagation timings.
  - Improved and extended stuffing for linear constraints.
  - Changed handling of coupling constraints for indicator constraints.
  - See also the full release notes, the changelog, and the release paper.
  - Changed parameters:
    - presolving/components/* moved to constraints/components/*
    - conflict/deptscorefac renamed to conflict/graph/deptscorefac
    - misc/permutationseed renamed to randomization/permutationseed
    - misc/permutecons renamed to randomization/permutecons
    - misc/permuteseps renamed to randomization/permuteseps
    - branching/random/seed: default changed from 0 to 41
    - constraints/indicator/sepcouplingcuts: default changed from 0 to 1
    - constraints/SOS1/perfimplanalysis: default changed from 1 to 0
• heuristics/ofins/freq: default changed from -1 to 0
• heuristics/reoptsols/freq: default changed from -1 to 0
• heuristics/trivialnegation/freq: default changed from -1 to 0
• heuristics/clique/initseed: default changed from 0 to 61
• lp/solver: default changed from soplex to soplex2, if CPLEX is not licensed
• presolving/abortfac: default changed from 0.001 to 0.0008
• separating/clique/cliquedensity: default changed from 0.05 to 0
• conflict/usesb: default changed from 0 to 1

• Added option gams/dumpsolutionsmerged to write all found alternate solutions into a single GDX file.

• Changed default for timing/clocktype to wallclock time.

• Initial variable levels can now be passed as partial solution to SCIP. To control the various possibilities, the type of option gams/mipstart has changed from bool to integer. See also subsection Starting point in the GAMS/SCIP solver manual.

2.7.1.4.17 SolveEngine

• New solver SolveEngine to solve LP and MIP problems remotely via the Satalia SolveEngine. The SolveEngine aggregates different solution algorithms for optimization problems and automatically selects an algorithm that seems to suite best for a given model instance.

• GAMS/SolveEngine comes free of charge with any licensed GAMS system. Users must have an API key for the Satalia SolveEngine to submit jobs.

2.7.1.4.18 SoPlex

• New libraries 3.0 (c32e55a).
  – Added a new scaling implementation Least squares (Curtis-Reid scaling).
  – Added persistent scaling to keep scaled LP for multiple reoptimizations.
  – Added an experimental version of a decomposition based approach to avoid degeneracy in the dual simplex method. This feature is activated by setting the parameter bool:decompositiondualsimplex to true, which sets the basis representation to 'row' and the algorithm to 'dual'.
  – New parameter bool:computedegen to enable computation of the degeneracy of the basis in each iteration.
  – New parameter int:printcondition to enable printing the condition number of the basis during solve.
  – Automatically use the row representation for problems with more than 20% more constraints than variables.
  – Changed default for parameter int:factor_update_max from 200 to new value 0.
  – See also the full release notes and the release paper.

• Changed default type of timer to wallclock time.
2.7.1.4.19  XPRESS

- New libraries: Optimizer 31.01.09 (aka XPRESS 8.3). There are many improvements and additions:
  - The parallel MIP code has been completely rewritten to improve performance and scalability.
    - Reduced overhead for small, easy MIPs.
    - Reduced the memory usage for very large MIPs, especially those that are significantly reduced during the initial preprocessing.
    - Heuristics can now be run in parallel with cutting in deterministic mode. Previously, heuristics would only be run in parallel after cutting.
    - Improved implementation of zero-half cutting.
    - Aggregated Mixed Integer Rounding cuts have been improved for network-type problems.
  - New presolve reductions, strengthenings and reformulations for convex quadratic problems.
  - Improved performance and numerical stability of crossover.
  - Code support for AVX2 in the barrier solver: use option cpuPlatform to select the target instruction set.
  - Crossover after a barrier solve is now multi-threaded: see option crossoverThreads for details.
- The header of MIP/solve trace files contains now the option number and the name of the model.

2.7.1.5  Tools

2.7.1.5.1  CSV2GDX

- New option ValueDim: Indicate if an extra dimension for values is added even if there is just one value column. This is ignored, if there is no value column.

2.7.1.5.2  GDXDUMP

- Fixed a problem with writing a scalar variable or equation in CSV format with all fields.

2.7.1.5.3  GDXMERGE

- Improved feedback about problems when processing input files.

2.7.1.6  Object Oriented APIs

- Fixed a bug regarding SymbolUpdateType.Zero that prevented records from being updated in GAMSModelInstance.Solve().

2.7.1.6.1  C++

- This release contains a beta version of the object-oriented C++ API that can be used to control GAMS from within C++11 and later. It allows the seamless integration of GAMS into C++ applications by providing appropriate classes for the interaction with GAMS. The GAMSDatabase class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the GAMSJob class and by using the GAMSModelInstance class a sequence of closely related model instances can be solved in an efficient way.
- The API is available in the distributions for Linux, MacOS X, and Windows.
- Furthermore, the C++ API is published under MIT license and is hosted at the GAMS GitHub organization.
- To use this API please check the GAMS API documentation.
2.7.1.6.2 .NET

- New functions `GAMSWorkspace.AddJobFromApiLib`, `GAMSWorkspace.AddJobFromNoaLib` to create `GAMSJob` from models from the GAMS API Library and the Nonlinear Optimization Applications Library.

2.7.1.6.3 Python

- New functions `GamsWorkspace.add_job_from_apilib`, `GamsWorkspace.add_job_from_noalib` to create `GamsJob` from models from the GAMS API Library and the Nonlinear Optimization Applications Library.
- Added a version check for the setup.py scripts to avoid unintentional installation of wrong versions.

2.7.1.7 Expert Level APIs

- With GAMS 25.0, the expert-level C++ API files will be removed from the distribution. Users should switch to the expert-level C API files. The object-oriented C++ API introduced in this release could also be a good alternative for replacement if the user C++ code exchanges data and runs a GAMS model.

2.7.1.7.1 GAMS Modeling Object

- Changed the function `gmoGetModelTypeTxt`: Added argument for model type number instead of using the model type of the stored model.

2.7.1.8 Model Libraries

2.7.1.8.1 GAMS Data Library

- `embeddedSort.gms`: Sorting of numerical data using the embedded code facility (108)
- `embeddedSplit.gms`: Splitting of labels using the embedded code facility (109)
- `embeddedMultiInstance.gms`: Handling multiple instances of the embedded code facility at once (110)

2.7.1.8.2 GAMS Model Library

- `dqq.gms`: Warm-starting quad-precision MINOS (414)
- `cbenders.gms`: Cplex Benders for a Simple Facility Location Problem (415)
- `robustlp.gms`: Robust linear programming as an SOCP (416)
2.7.1.8.3 GAMS Test Library

- mpsge14.gms: MPSGE sync test: .GEN/integer1/nsolves (713)
- fnsincosintrl.gms: Test sin/cos func/grad interval evals (714)
- procdir1.gms: Test correct behavior of procDir, scrDir and procDirPath (715)
- empbp06.gms: Bilevel model with phantom vars owned by leader (716)
- fns lexp.gms: Test correctness of slexp intrinsic (717)
- fns lexp2.gms: Test correctness of slexp intrinsic (718)
- fnsqexp.gms: Test correctness of sqexp intrinsic (719)
- fnsqexp2.gms: Test correctness of sqexp intrinsic (720)
- fnslog10.gms: Test correctness of slog10 intrinsic (721)
- fnslog102.gms: Test correctness of slog10 intrinsic (722)
- fnsqlog10.gms: Test correctness of sqlog10 intrinsic (723)
- fnsqlog102.gms: Test correctness of sqlog10 intrinsic (724)
- fn srec.gms: Test correctness of srec intrinsic (725)
- fn srec2.gms: Test correctness of srec intrinsic (726)
- fn sqrec.gms: Test correctness of sqrec intrinsic (727)
- fn sqrec2.gms: Test correctness of sqrec intrinsic (728)
- fn loggamma.gms: Test correctness of loggamma intrinsic (729)
- fnbinomial.gms: Test correctness of binomial intrinsic (730)
- breakcont2.gms: Advanced test for break and continue statements (731)
- fnlogbeta.gms: Test correctness of logbeta intrinsic (732)
- fnbeta.gms: Test correctness of beta intrinsic (733)
- ssuffix.gms: List of all System Suffixes (734)
- embpy01.gms: Test for embedded code facility (735)
- embpy02.gms: Test for embedded code facility (736)

2.7.2  24.9.2 Minor release (November 14, 2017)

2.7.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Paul Buckland, William N. Caballero, Xin Fang, Christophe Gouel, Fabricio Porras-Ortiz, Shigeru Tsubakitani, and Haoshui Yu.
2.7.2.2 GAMS System

2.7.2.2.1 GAMS

- Added prefixing of PYTHONPATH with the site-packages directory of the GAMS Python 3.6 installation in GMSPython.
- Added support for Python sets in the Embedded Python Code method gams.set().
- Speed up detection/extraction of quadratic terms for QCP models.
- Do not allow the use of Embedded Code if execMode is set to 2 or higher.

2.7.2.2.2 Installer

- Removed the execution of a Python script during the Windows installation process that patches the path of certain Python programs in GMSPython\Scripts.

2.7.2.3 Solvers

2.7.2.3.1 BARON

- New libraries 17.10.16.
- Due to a problem with the Ipopt interface in BARON on Mac OS X, the use of Ipopt in BARON is currently disabled on Mac OS X.
- GAMS can now pass a term like (negativeConstant)**negativeIntegerVariable to BARON.

Note
By default, GAMS correctly rejects such a formulation, though. To work around this, MaxExecError needs to be set to a positive number and the option sys12 needs to be set to 1. Here is an example, how this could be used:

```plaintext
class a /-2/;
integer variable x;
x.lo = -3;
x.up = 3;

variable z;
equation e;
e.. z =e=a**x;
model m /e/;
x.l=1;
MaxExecError = 10;
option sys12 = 1;
solve m min z use minlp;
```

2.7.2.3.2 CPLEX

- Removed any limits on the number of Threads in a GAMS/CPLEX option file. Previously, the maximum for option Threads was 128.
2.7.2.3.3 CONOPT

- New libraries 3.17F.
  - Fixed an infinite loop when using option LMMXSF.

2.7.2.3.4 CONVERT

- Fix for variables with negative lower and infinite upper bound in LINGO output. The LINGO output has been changed to always use the @Bnd keyword to write variable bounds.

2.7.2.3.5 GUROBI

- New libraries 7.5.2.

2.7.2.3.6 GUSS/Scenario Solver

- Added the GUSS option ReportLastScen. If this is set to 1 the solution of the last scenario will be reported back to GAMS rather than solution of the base case. This is particularly useful when GUSS is used to implement a homotopy approach where the shock to a parameter is sliced in several small shocks and hence the last scenario represents the solution to the shocked system.

2.7.2.3.7 Lindo/LindoGlobal

- New libraries 11.0.300.

2.7.2.3.8 LogMIP

- Fixed improper handling of variables fixed at zero that occurred if they were used in nonlinear equations in a disjunction reformulated via the convex hull.

2.7.2.3.9 Mosek

- New libraries 8.1.0.31.
  - Fixed dual solution for conic quadratic problems.

2.7.2.3.10 SCIP

- New libraries 4.0 (#22b4564).

2.7.2.3.11 SoPlex

- New libraries 3.0 (#3bfa247).
2.7.2.4 Object Oriented APIs

2.7.2.4.1 C++

- Added a try/catch block around the code that uses the classes from the GAMS C++ OO-API in all examples. Without this, the exceptions thrown by the methods of the GAMS classes will not be reported and *harmless* exceptions, like a compilation or execution error in the GAMSJob.run method result in application crashes.

2.7.2.4.2 Python

- Fixed a bug in the setup script that prevented files from being installed in the correct location in certain cases.

2.8 24.8 Distribution

2.8.1 24.8.1 Major release (December 21, 2016)

2.8.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Etienne Ayotte-Sauvé, Wolfgang Britz, Göran Bylund, Wietse Dol, Gregory Dourbois, Katja Jensen, Josef Kallrath, Toni Lastusilta, Renger van Nieuwkoop, and Tom Rutherford.

2.8.1.2 Platforms

- On Linux, the minimal required GLIBC version is now 2.7.
- On MacOS X, for some solvers (ANTIGONE, BARON, CPLEX, COIN-OR, SOPLEX, SCIP) the minimal required Mac OS X version is now 10.10. We will drop support for older Mac OS X versions for the complete GAMS system with the next major release.
- A generic license (with platform code GEN) is now limited to the platforms Windows, Linux, and Mac OS X. If you have a generic license and need a license for one of the other platforms (e.g. AIX), please contact sales or support to receive an additional license file for that platform free of charge.

2.8.1.3 GAMS System

2.8.1.3.1 GAMS

- The statements *Break* and *Continue* were added to allow more control over the execution of control structures (loop/while/repeat/for):
  - *Break [n]*: Terminate the n inner most control structures (n is optional, if it is omitted, it is set to 1).
  - *Continue*: Jump to the end of the inner most control structure.
• Extend the report summary of the solution report to print the number of variables and equations where the level was projected to one of the bounds (compare model attribute tolProj), if that number is greater than 0.

• The model attribute tolProj to project levels to bounds is no longer ignored when the GAMS Grid Facility (SolveLink = 3 or 4) is used.

• New command line option fileStem: Sets the file stem for output files which use the input file name as stem by default, see fileStem for more details.

• New option MCPRHoldfx (can be set using the option statement, a command line parameter, or model attribute):
  – Prints list of rows that are perpendicular to variables removed due to the holdfixed setting if set to 1.

• New option AsyncSolLst (can be set using the option statement, or a command line parameter):
  – If set to 1, GAMS prints a solution listing to the lst file also when an asynchronous solve (see The Grid and Multi-Threaded Solve Facility) is used.
  – The default value is 0.

• New variant for the SolveLink option and model attribute: 7 (compile time constant %solveLink.Threads Simulate%) - The problem is passed to the solver in core without use of temporary files, GAMS waits for the solver to come back but uses same submission process as 6 (see Multi-threading Submission Testing)

• New function numCores (available at both compile and execution time): Returns the number of logical cores in the system.

• Allow macro expansion in the domain list of a symbol declaration.

• New dollar control splitOption that splits a string representing a option/value pair into option name and option value.

• Fixed a problem with the optional maxWait parameter of the function readyCollect.

• Fixed potential error in file created by dumpOpt, if there were symbols loaded from GDX.

• Fixed an error which could lead to wrong results when assigning to a symbol while the symbol’s alias was used on the right hand side of the assignment.

• Fixed an error which could lead to a crash if a phantom set element was used to control an assignment inside a loop.

• Fixed a problem with unscaling solutions for MCP models that resulted in incorrect dual values for scaled MCPs. For an example, compare the new test library model mcp11 when run with 24.8 and with something previous.

2.8.1.3.2 Documentation

• The offline documentation now provides search and keyword indexing functionalities in addition to navigating the documentation.

• The Microsoft Compiled HTML help file gams.chm is no longer available.

• The table of contents for browsing the GAMS model libraries is now available offline in HTML format.
2.8.1.4 Solvers

2.8.1.4.1 BARON

2.8.1.4.2 CPLEX

- New libraries 12.7.0.0.
- Support for the platforms MS Windows 32 bit, Solaris i86pc, and Solaris SPARC 64bit has been dropped by IBM for Cplex 12.7. The GAMS system for these platforms contains Cplex 12.6.3.
- Cplex 12.7 implements Benders Algorithm. This is available in CplexD only.
- The IIS option triggers now the conflict refiner. The IIS function in Cplex 12.7 has been replaced by the conflict refiner. The IIS option now also works on infeasible models with model status Infeasible No Solution as well as on problems with discrete variables.
- New parameters
  - BendersFeasCutTol: Tolerance for whether a feasibility cut has been violated in Benders decomposition
  - BendersOptCutTol: Tolerance for optimality cuts in Benders decomposition
  - BendersStrategy: Benders decomposition algorithm as a strategy
  - DataCheck: Data consistency checking and modeling assistance
  - RLTcuts: Reformulation Linearization Technique (RLT) cuts
- Modified parameters:
  - MipStart: A value of 6 accepts the (partial) MipStart without any checks

2.8.1.4.3 CONOPT

- This distribution includes the first official release of the CONOPT4 solver. The chapter in the solver manual has an interesting subsection on when you should use CONOPT4 for all existing CONOPT users.
- The current solver alias CONOPT still points to the CONOPT3 solver. This might change in the next, or next but one major release. We invite you to share your experience with this new version of CONOPT via support (support@gams.com) with us.

2.8.1.4.4 ConvertD

- Write proper scale and prior information for equations and variables with option Jacobian.

2.8.1.4.5 DICOPT

- An implementation of a Feasibility Pump primal heuristic (for convex MINLP) has been added to DICOPT. This heuristic can be run before the actual DICOPT algorithm. Outer approximation cuts from the MIP subproblem of the Feasibility Pump are transferred to initialize the MIP outer approximation of the main DICOPT algorithm. Option feaspump can be used to enable the Feasibility Pump and various other options are available to tune the feasibility pump.
- Option convex has been added to indicate the presence of convex MINLP. If this option is set, the defaults for various other options are modified.
2.8.1.4.6 GUROBI

- New libraries 7.0.1.
- Explore alternative solutions via the Solution Pool.
- New parameters
  - BestObjStop: Objective value to stop optimization
  - BestBdStop: Objective bound to stop optimization
  - InfProofCuts: Infeasibility proof cut generation
  - StrongCGCuts: Strong-CG cut generation
  - DegenMoves: Degenerate simplex moves
  - TuneCriterion: Tuning criterion
  - SolNPoos: Activate export of alternative solution
  - PoolSolutions, PoolSearchMode, and PoolGap to control generation of alternative solutions
- Gurobi 7 supports general constraints. With the help of the dot-option .GenConstrType the user can classify a constraint to be of type \texttt{Max}, \texttt{Min}, \texttt{Abs}, \texttt{And}, and \texttt{Or}.
- Gurobi 7 supports indicator constraints.
- Gurobi 7 supports multi objective hierarchical optimization. Details can be found in the GAMS/Gurobi manual, in subsection Multiple Objectives.

2.8.1.4.7 JAMS

- New option ZipDebug=xxx.zip to specify that, in the event of abnormal termination or behavior, a zip file of debugging info be created.
- New reformulation options to handle shared or duplicated equations and variables in equilibrium models.

2.8.1.4.8 Knitro

- New libraries 10.2.0.
  - Significant speed and robustness improvements when using BFGS (hessopt=2) or L-BFGS (hessopt=6) Hessian approximations with the default Knitro interior-point method.
  - General performance improvement on mixed-integer models.
  - Minor bug fixes.
  - New mixed-integer SQP (MISQP) algorithm for nonlinear mixed-integer models (mip.method=3). This new algorithm is intended for small, potentially non-convex models with possibly expensive function evaluations. It can be used even when integer variables are not relaxable (i.e. functions can only be evaluated with integer variables at integer points) by setting \texttt{mip.relaxable=0}, and can be used with parallel multistart.
  - New option \texttt{mip.nodealg} to control algorithm used at B&B nodes: overrides the generic algorithm option.
- The Knitro Tuner is now available from the GAMS/Knitro link.
2.8.1.4.9 Lindo/LindoGlobal

- New libraries 10.0.131.
  - LP Solver Improvements:
    * With new enhancements made to the simplex solvers, the average performance on large instances has increased by 35% for the primal simplex and by 20% for the dual simplex compared to the previous version.
  - MIP Solver Improvements:
    * New heuristic algorithms help to find significantly better solutions for many models with knapsack constraints and block structures.
    * New MIP preprocessing level devoted to tightening variable bounds for some nonlinear models.
  - Stochastic Solver Improvements:
    * Improved cut management for Nested Benders Decomposition Method leading to speed improvements over 60% for large linear multistage SP instances.
    * Better handling of multistage SP models which do not have full-recourse.
  - Global Solver Improvements:
    * Incorporates bound tightening process to the linearization procedure and improve solvability of linearized model.

2.8.1.4.10 LocalSolver

- New libraries 6.5 (20160729).
  - For near-linear (discrete or continuous) problems, new moves have been introduced based on linear programming and mixed-integer linear programming techniques. These moves allow to intensify the search on near-linear models by exploring optimally larger neighborhoods.
- Added possibility for Hierarchical Optimization of Multiple Objective Functions.
- Removed option `origlog`. GAMS/LocalSolver will now always print the original LocalSolver log.
- Fixed level values of aggregated variables in solution.

2.8.1.4.11 Mosek

- New libraries 8.0.0.48 (Mosek release notes)
  - Presolve performance has been improved.
  - The eliminator in the presolve has been reimplemented, is usually faster, and requires much less memory.
  - Presolve has been improved on conic quadratic problems.
  - The numerical stability of conic optimizer has been improved significantly, particularly for semidefinite optimization problems.
  - The scaling routine for the conic optimizer is more aggressive.
  - Quadratic and quadratically constrained problems are now internally converted to conic form and are solved using the conic optimizer. Nevertheless full primal and dual information to the original problems is available.
  - A dualizer for conic quadratic problems is now available. By default it dualize the problems before optimizing if deemed worthwhile. The dualization is transparent to the user and can be turned off.
– The conic optimizer linear algebra is now parallelized using Cilk Plus and scales better when the number of threads is increased for large problems. Moreover, for smallish problems using too many threads does not hurt performance.

– The computational efficiency graph partitioning based ordering method in the interior-point optimizer has been improved.

– It is now possible to force the interior-point optimizer to run in the calling thread.

– Only one mixed integer optimizer is available now, which corresponds to the mixed integer conic optimizer that was introduced with version 7.

– The primal network simplex optimizer has been removed. It is suggested to use the dual simplex optimizer instead.

– The primal-dual simplex optimizer has been removed. It is suggested to use the dual simplex optimizer instead.

– The concurrent optimizer has been removed. It is suggested to use the interior-point optimizer instead.

– The following GAMS/Mosek options have been removed:

* MSK_IPAR_ANA_SOL_BASIS
* MSK_IPAR_ANA_SOL_PRINT_VIOLATED
* MSK_IPAR_CONCURRENT_NUM_OPTIMIZERS
* MSK_IPAR_CONCURRENT_PRIORITY_DUAL_SIMPLEX
* MSK_IPAR_CONCURRENT_PRIORITY_FREE_SIMPLEX
* MSK_IPAR_CONCURRENT_PRIORITY_INTPNT
* MSK_IPAR_CONCURRENT_PRIORITY_PRIMAL_SIMPLEX
* MSK_DPAR_FEASREPAIR_TOL
* MSK_IPAR_FEASREPAIR_OPTIMIZE
* MSK_IPAR_INTPNT_FACTOR_DEBUG_LVL
* MSK_IPAR_INTPNT_FACTOR_METHOD
* MSK_IPAR_LOG_CONCURRENT
* MSK_IPAR_LOG_NONCONVEX
* MSK_IPAR_LOG_PARAM
* MSK_IPAR_LOG_SENSITIVITY
* MSK_IPAR_LOG_SENSITIVITY_OPT
* MSK_IPAR_MAX_NUM_WARNINGS
* MSK_IPAR_MIO_CONT_SOL
* MSK_IPAR_MIO_CUT_CG
* MSK_IPAR_MIO_CUT_LEVEL_ROOT
* MSK_IPAR_MIO_CUT_LEVEL_TREE
* MSK_IPAR_MIO_FEASPUMP_LEVEL
* MSK_DPAR_MIO_HEURISTIC_TIME
* MSK_IPAR_MIO_HOTSTART
* MSK_IPAR_MIO_KEEP_BASIS
* MSK_IPAR_MIO_LOCAL_BRANCH_NUMBER
* MSK_DPAR_MIO_MAX_TIME_APRX_OPT
* MSK_IPAR_MIO_PRESOLVE_AGGREGATE
* MSK_IPAR_MIO_PRESOLVE_PROBING
* MSK_IPAR_MIO_PRESOLVE_USE
* MSK_DPAR_MIO_REL_ADD_CUT_LIMITED
* MSK_IPAR_MIO_STRONG_BRANCH
* MSK_DPAR_MIO_TOL_MAX_CUT_FRAC_RHS
* MSK_DPAR_MIO_TOL_MIN_CUT_FRAC_RHS
* MSK_DPAR_MIO_TOL_REL_RELAX_INT
- The following GAMS/Mosek options have been added:
  - MSK_DPAR_DATA_SYM_MAT_TOL: Absolute zero tolerance for elements in symmetric matrices.
  - MSK_DPAR_DATA_SYM_MAT_TOL_HUGE: An element in a symmetric matrix which is larger than this value in absolute size causes an error.
  - MSK_DPAR_DATA_SYM_MAT_TOL_LARGE: An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed.
  - MSK_DPAR_INTPNT_QO_TOL_DFEAS: Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
  - MSK_DPAR_INTPNT_QO_TOL_INFEAS: Controls when the conic interior-point optimizer declares the model primal or dual infeasible.
  - MSK_DPAR_INTPNT_QO_TOL_MU_RED: Relative complementarity gap feasibility tolerance used when interior-point optimizer is applied to a quadratic optimization problem.
  - MSK_DPAR_INTPNT_QO_TOL_NEAR_REL: Termination tolerance multiplier that is used if no accurate solution can be found.
  - MSK_DPAR_INTPNT_QO_TOL_PFEAS: Primal feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
  - MSK_DPAR_INTPNT_QO_TOL_REL_GAP: Relative gap termination tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
  - MSK_IPAR_INTPNT_MULTI_THREAD: Controls whether the interior-point optimizers can employ multiple threads if available.
  - MSK_IPAR_MIO_CUT_CLIQUE: Controls whether clique cuts should be generated.
  - MSK_IPAR_MIO_CUT_GMI: Controls whether GMI cuts should be generated.
  - MSK_IPAR_MIO_CUT_IMPLIED_BOUND: Controls whether implied bound cuts should be generated.
  - MSK_IPAR_MIO_CUT_KNAPSACKCOVER: Controls whether knapsack cover cuts should be generated.
  - MSK_IPAR_MIO_CUT_SELECTION_LEVEL: Controls how aggressively generated cuts are selected to be included in the relaxation.
  - MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE: Enables or disables perspective reformulation in presolve.
  - MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL: Controls whether presolve can be repeated at root node.
  - MSK_IPAR_MIO_VB_DETECTION_LEVEL: Controls how much effort is put into detecting variable bounds.
  - MSK_IPAR_OPF_WRITE_HEADER: Write a text header with date and MOSEK version in an OPF file.
**MSK_IPAR_OPF_WRITE_HINTS**: Write a hint subsection with problem dimensions in the beginning of an OPF file.

**MSK_IPAR_OPF_WRITE_PROBLEM**: Write objective, constraints, bounds etc.

**MSK_IPAR_OPF_WRITE_SOL_BAS**: Whether to include basic solution in OPF files.

**MSK_IPAR_OPF_WRITE_SOL_ITG**: Whether to include integer solution in OPF files.

**MSK_IPAR_OPF_WRITE_SOL_ITR**: Whether to include interior solution in OPF files.

**MSK_IPAR_OPF_WRITE_SOLUTIONS**: Enable inclusion of solutions in the OPF files.

**MSK_IPAR_WRITE_DATA_PARAM**: If this option is turned on the parameter settings are written to the data file as parameters.

**MSK_IPAR_WRITE_LP_FULL_OBJ**: Write all variables, including the ones with 0-coefficients, in the objective.

**MSK_IPAR_WRITE_MPS_FORMAT**: Controls in which format the MPS is written.

**MSK_IPAR_WRITE_TASK_INC_SOL**: Controls whether the solutions are stored in the task file too.

**MSK_SPAR_WRITE_LP_GEN_VAR_NAME**: Sometimes when an LP file is written additional variables must be inserted.

- For the following options, the default value has changed:
  
  **MSK_DPAR_MIO_TOL_FEAS** from 1e-7 to 1e-6
  
  **MSK_IPAR_LOG_MIO_FREQ** from 1000 to 10
  
  **MSK_IPAR_WRITE_PRECISION** from 8 to 15

- Fixed selection of optimizer for “fixed solve” of a mixed-integer conic problem.

### 2.8.1.4.12 Pyomo

- Fixed compatibility issues with different versions of Pyomo.

### 2.8.1.4.13 SCIP

- New libraries 3.2 (#0d4fc08).

- Changed the default LP solver to SoPlex also for the case where a CPLEX license is available, due to problems when using CPLEX 12.7.0.0 as LP solver in SCIP.

### 2.8.1.4.14 SoPlex

- The GAMS/SoPlex interface has been rewritten and does not use the OsiSpx layer anymore. The solver OSISOLEX is now an alias for the solver SoPlex.

- SoPlex parameter files can now be used.

- SoPlex can now be warmstarted when only the model instance data changes (e.g., via GUSS).

- New libraries 2.2 (df190de).
2.8.1.5 Tools

2.8.1.5.1 CSV2GDX

- Improved error reporting.

2.8.1.5.2 GDXDUMP

- New command line option CSVAllFields to get all fields (level, marginal, lower, upper, and scale) when writing a variable or equation symbol in CSV format.

2.8.1.5.3 MODEL2TEX

- Increased the page width of the txt file generated by the GAMS command line option docfile to 32767 (max. value).
- Changed the default encoding to latin and added a new command line parameter that allows to change the encoding (-e=ENCODING)
- Changed the default format of the symbol tables.
- The JSON style file contains a new property called columnSetting that allows to adjust the columns.
- Avoid some unnecessary parentheses in sum and product operators.
- Minor change in the equations subsection that removes several warnings.
- Several minor bug fixes.

2.8.1.5.4 GDXXRW

- Fixed a problem when writing a symbol with option merge or clear to a range with CDim=0 or RDim=0.

2.8.1.5.5 GMSZIP/GMSUNZIP

- New versions of Info-ZIP’s tools zip (version 3.1c02) and unzip (version 6.00). The executable names have been prefixed with “gms” for clear identification.

2.8.1.6 Object Oriented APIs

- New option GAMSOptions.ErrorLog: Maximal number of error message lines written to the log for each error.

2.8.1.6.1 .NET

- New examples that demonstrate the use of the API in a graphical environment: TransportGUI, CutstockGUI, FarmGUI.
- Distribute compiled GUI examples in directory <GAMSDir>\apifiles\GUIexamples on Windows.
- GAMSWorkspace.AddJobFromFile: Throw an exception if a given file does not exist.
2.8.1.6.2 Python

- The option `GamsOptions.errorlog` has been renamed to `GamsOptions.errorlog` in order to indicate it as public.

2.8.1.7 Model Libraries

2.8.1.7.1 GAMS API Library

- `PInterrupt.gms`: Test GamsJob interrupt mechanism in object oriented Python API (54)
- `CSInterrupt.gms`: Test GamsJob interrupt mechanism in object oriented .Net API (55)

2.8.1.7.2 GAMS Model Library

- `asyncloop.gms`: Transportation Problem with async loop body execution (411)
- `trnsindic.gms`: Fixed Charge Transportation Problem with Indicator Constraints (412)
- `timesteps.gms`: Accessing previous (or next) time steps in an equation fast (413)
- Modified models:
  - Make use of the new `break` statement to formulate the following models a little nicer: `tsp1`, `tsp4`, `cutstock`, `awktsp`, `sddp`, `sipres`, `allbases`, `qfilter`
  - `tgridmix`: The logic of submission and collection has been reworked so that the scenario sets do not have to be one dimensional and ordered (contributed by Tom Rutherford).
  - `asyncjobs`: The logic for putting out the log line in time intervals was flawed and has been corrected.

2.8.1.7.3 GAMS Test Library

- `emp17.gms`: Simple test of one optimizing agent (693)
- `breakcont1.gms`: Test break and continue statements (694)
- `lindgl04.gms`: Test non-convex quadratic program with Lindo(Global) (695)
- `mcp11.gms`: Test marginals for a scaled MCP problem (696)
- `csv2gdx1.gms`: Test csv2gdx on input containing spaces (697)
- `gdxxrw7.gms`: Test merge and clear option for special data layout (698)
- `scale02.gms`: Test that an MCP with scales is rejected when appropriate (699)
- `emp18.gms`: Test JAMS/EMP on implicit variable handling (700)
- `emp19.gms`: Test JAMS/EMP on implicit variable handling (701)
- `emp20.gms`: Test JAMS/EMP on implicit variable handling (702)
- `emp21.gms`: Test JAMS/EMP on implicit variable handling (703)
• emp22.gms : Test JAMS/EMP on implicit variable handling (704)
• emp23.gms : Test JAMS/EMP on implicit variable handling (705)
• emp24.gms : Test JAMS/EMP on implicit variable handling (706)
• emp25.gms : Test JAMS/EMP on implicit variable handling (707)
• emp26.gms : Test JAMS/EMP on implicit variable handling (708)
• gurobi02.gms : GUROBI test suite - general constraints max,min,abs (709)
• gurobi03.gms : GUROBI test suite - general constraints and,or (710)
• slx01.gms : run tests for different solvelink values (711)
• gurobi04.gms : GUROBI test suite - multi objective (712)

2.8.2 24.8.2 Maintenance release (January 03, 2017)

2.8.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Evangelos Panos.

2.8.2.2 GAMS System

2.8.2.2.1 GAMS

• Change for command line parameter MultiPass: If it is set to 2, all errors from $gdxIn are ignored now
• Fixed a bug which caused wrong results in some assignments which use symbols that were used out-of-order in previous assignments.

2.8.2.3 Solvers

2.8.2.3.1 SCIP

• Added a workaround that allows for using CPLEX 12.7.0.0 as LP solver in SCIP again. For the moment, the default is still to use SoPlex.

2.8.3 24.8.3 Minor release (January 28, 2017)

2.8.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Mohammad R. Hesamzadeh, and Katja Jensen.
2.8.3.2 GAMS System

2.8.3.2.1 GAMS

- Fixed potentially wrong values for model attribute `etSolver` for cases where the command line option `solveLink` was set to 1, 2 or 5.

2.8.3.3 Solvers

2.8.3.3.1 BARON

- New libraries 17.1.2.
  - More robust links with COIN-OR solvers and a better link with FICO Xpress.
  - Some new RLT cuts are included in relaxations.

2.8.3.3.2 DE

- Create a capability error if DE is called to solve a model of type EMP without stochastic information.

2.8.3.3.3 DECIS

- Create a capability error if DECIS is called to solve a model of type EMP without stochastic information.

2.8.3.3.4 Examiner2

- Fix behavior when the subsolver returns a model status like 19 Infeasible - No Solution. The model status can be passed unchanged back to GAMS in such a case.

2.8.3.3.5 Kestrel

- Adjusted the default URL to https using port 3333.
- Fixed a bug that prevented to specify the protocol in the `neos_server` parameter in an option file. The complete format of the parameter is now `protocol://host:port`.

2.8.3.3.6 LINDO

- Create a capability error if LINDO is called to solve a model of type EMP without stochastic information.

2.8.3.3.7 MOSEK

- New libraries 8.0.0.53.
2.8.3.3.8 SCIP

- Changed the default LP solver back to CPLEX, if available (see also 24.8.1 and 24.8.2 release notes).

2.8.3.4 Tools

2.8.3.4.1 GDXDUMP

- Fixed wrong output in case of nested quotes in symbol text.

2.8.3.5 Model Libraries

2.8.3.5.1 GAMS Model Library

- linearne: Minor fix to model formulation (contributed by Mohammad R. Hesamzadeh).

2.8.4 24.8.4 Minor release (April 10, 2017)

2.8.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Ivan Leung, Tara Rengarajan, and Sajjad Shafiei.

2.8.4.2 GAMS System

2.8.4.2.1 GAMS

- Fixed an issue which caused unnecessary memory consumption if many indexed symbols with explicit labels were used.

2.8.4.3 Solvers

2.8.4.3.1 BARON

- New libraries 17.4.1.
  - Bug fixes and an enhanced convexity detector.

2.8.4.3.2 CPLEX

- New libraries 12.7.1.0.
  - Note that with this update the log generated by Cplex changed in a way that the Cplex options set (either by the user or by GAMS defaults) are displayed. This is intentional and no sign of a problem. So one could see something like this in the log when running GAMS/Cplex:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPXPARAM_Simplex_Limits_Iterations</td>
<td>2000000000</td>
</tr>
<tr>
<td>CPXPARAM_TimeLimit</td>
<td>1000</td>
</tr>
<tr>
<td>CPXPARAM_Threads</td>
<td>1</td>
</tr>
</tbody>
</table>
2.8.4.3.3 DICOPT

- Fixed serious bug in feasibility pump implementation.

2.8.4.3.4 Examiner, Examiner2

- The list of checks to perform for solved models was set incorrectly when the trace option was used.

2.8.4.3.5 GUROBI

- New libraries Gurobi 7.0.2.
- Added options MultiObjMethod and MultiObjPre.
- Fixed a problem that lead to wrong error messages when setting the ObjNAbsTol and ObjNRelTol parameters.
- Fixed a problem that reported back the wrong alternative solution.

2.8.4.3.6 JAMS

- Fix problem with bilevel models having variables owned by the leader but not appearing in the leader objective or constraints.

2.8.4.3.7 Lindo/LindoGlobal

- New libraries 10.0.179.

2.8.4.3.8 MOSEK

- New libraries 8.0.0.60.

2.8.4.3.9 NLPEC

- Fix problem handling empty constraints (e.g. $f \cdot e x = G = 0$) that appear in MPEC models. Note that such models can easily be produced by JAMS/EMP.

2.8.4.4 Object Oriented APIs

2.8.4.4.1 Python

- Added support for Python 3.6.
- Fixed a bug in GamsJob.run() that prevented the underlying GAMS model from terminating, if executables spawned by GAMS generate log output that is not captured.
2.8.5 24.8.5 Maintenance release (May 10, 2017)

2.8.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Ana Carolina, Gary Goldstein, Erwin Kalvelagen, Amit Kanudia, Toni Lastusilta, Antti Lehtila, Bruce McCarl, and Hans Kristian Ringkjob.

2.8.5.2 Platforms

- The AIX system is now build on AIX 7.1.

2.8.5.3 GAMS System

2.8.5.3.1 GAMS

- Fixed a bug which could cause a crash in particular assignments involving singleton sets or explicit labels. This was introduced with GAMS 24.8.4.
- Fixed problems with the break statement:
  - There was a potential crash if break was used in a "sparse loop", e.g., `loop(j\$x(j), ...)`.  
  - If break was used in a loop with more than one index, e.g., `loop((i,j), ...)`, that loop was treated as multiple loops for the break statement, one for each index. Now it is treated as just one loop as intended.  
  - Fixed a problem where a loop was not correctly recognized as a loop if it runs over just one fixed element, e.g., `loop(i('12'), ...)`.  

2.8.5.4 Solvers

2.8.5.4.1 BARON

- Initialize BARON option Threads with value of GAMS option Threads, if the latter is at least 1.

2.8.5.4.2 CBC

- New libraries.
  - Fixed a bug in presolve that caused problems with fixed discrete variables.

2.8.5.4.3 GUROBI

- Suboptimal solutions were not reported back to GAMS. This has been fixed.

2.8.5.4.4 Lindo/LindoGlobal

- New libraries 10.0.182.
2.8.5.4.5 MOSEK

- New libraries 8.0.0.69.

2.9 24.7 Distribution

2.9.1 24.7.1 Major release (March 14, 2016)

2.9.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Alex Dowling, Johannes Hedtrich, Austin Milt, and Salvador Pineda.

2.9.1.2 GAMS System

2.9.1.2.1 GAMS

- Be more strict when the syntax $LOAD par=var.L is used: This creates an error now, if par is not a parameter (if par was a variable before, the complete variable var was loaded as if the suffix was omitted)

- GAMS Grid Facility (SolveLink = 3 or 4)
  - Fixed a bug for the model attribute objval: This could have been wrong when the objective variable was scaled.
  - Fixed a bug for the marginals: These could have been wrong when the objective variable was scaled.

- Solving in parallel threads (SolveLink = 6)
  - Allow to solve scaled models (model attribute scaleOpt is set to 1) as well (this generated an execution error before).

2.9.1.3 Solvers

2.9.1.3.1 BARON

- New libraries 16.3.4.
  - Faster LP interfaces.
  - Additional checks on solution reliability of LP and NLP subsolvers.
  - New automatic differentiation routines.
  - Improved handling of memory-intensive problems.
  - Enhanced presolving for continuous and integer programs.
  - New primal heuristic for integer programs.
  - New facilities for solving constraint (non)linear systems (CNS).
2.9.1.3.2 CBC

- New libraries.

2.9.1.3.3 ConvertD

- The GDX file created with option Jacobian contains now a set ANl that indicates the non-linear Jacobian elements.

2.9.1.3.4 CPLEX

- For an unbounded model Cplex did not mark the unbounded variables correctly. This has been fixed.

2.9.1.3.5 GUROBI

- Gurobi Optimization, Inc. has decided to end the current arrangement that allows us to offer GAMS/Gurobi integrated licenses. GAMS will continue to offer the latest version of Gurobi but users will need to get a Gurobi license from Gurobi Optimization, Inc. plus a GAMS/Gurobi link license from GAMS or use the free OsiGurobi link. This includes evaluation and demo licenses. For existing GAMS/Gurobi customers the following transition arrangements have been negotiated. The GAMS/Gurobi integrated license will continue to work as long as the license stays under maintenance. Academic GAMS/Gurobi customers will not be able to renew maintenance on their GAMS/Gurobi integrated license, their license will be changed into a GAMS/Gurobi link license. Academic users can get free Gurobi licenses from www.gurobi.com. In the past, academic GAMS/Gurobi link or GAMS/OsiGurobi licenses did not require a Gurobi license installed. This has changed with this release
  - New libraries 6.5.1
  - The option PreSOS1BigM and PreSOS2BigM were incorrectly classified as integer options. They have been reclassified as real option.

2.9.1.3.6 IPOPT

- Fixed a memory access issue in the linear solver HSL MA86 in case of very large models.

2.9.1.3.7 LocalSolver

- New libraries 6.0 (20160308).

2.9.1.3.8 MOSEK

- New libraries 7.1.0.49.
2.9.1.3.9 SBB

- Fixed a problem with option UserHeurCall. This option required that all discrete variables were declared first in the model. This is not necessary anymore.

2.9.1.3.10 SCIP

- New libraries 3.2 (#f69c505).
  - The timing mask for parameters constraints/.../presoltiming, presolving/.../timing, and propagating/.../presoltiming changed from 2/4/8 for fast/medium/exhaustive to 4/8/16.
  - Parameter constraints/SOS1/updateconflpresol has been renamed to constraints/SOS1/perfimplanalysis.
  - Detailed Changelog.

2.9.1.3.11 SOPLEX

- New libraries 2.2 (#12d3858).

2.9.1.4 Tools

2.9.1.4.1 GAMS IDE

- Fixed a bug which caused an error when opening the FINLIB (Practical Financial Optimization Models).

2.9.1.4.2 MODEL2TEX

- Fixed a bug regarding negative variables.
- Fixed a bug regarding subscripts of symbol names with underscores.
- Fixed a bug that prevented alternative names from being replaced in Ord constructs.
- New parameter -o (-OUTPUT) that allows to specify an alternative output file.
- Use UTF8 encoding.
- The columns of the symbol table have a fixed (equal) width.
- The original name of a symbol that is changed using the JSON style file is displayed in the symbol table.
- The JSON style file is alphabetically sorted by keys.

2.9.1.5 Object Oriented APIs

- Fixed a bug with the property GAMSOpt.ions Defines (.NET), GAMSOptions defines (Java), and GamsOptions. defines (Python): When too many entries were added, all of them were ignored.
2.9.1.5.1 Python

- Fixed a memory leak in GamsDatabase.

2.9.1.6 Model Libraries

2.9.1.6.1 GAMS Test Library

- scale01.gms : Test results of scaled model (692)

2.9.2 24.7.2 Minor release (July 07, 2016)

2.9.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Peter Alexander, Daniel Balistrieri, Paul Buckland, Denis Hess, Eden Huang, Josef Kallrath, Sherman Robinson, Tom Rutherford, Jhih-Shyang Shih, and Loic Ventre.

2.9.2.2 Platforms

- With the next major release, the minimal glibc version requirement for the GAMS distribution on Linux will be increased to 2.7.

2.9.2.3 GAMS System

2.9.2.3.1 GAMS

- Improved the performance for assignments from one large symbol to itself inside a loop, when only one element gets changed, e.g.:

  \[
  \text{loop}((j, cty, yrs, sim), \ldots; \text{par}(j, cty, 'Total', yrs, sim) = \text{sum}(lnd, \text{par}(j, cty, lnd, yrs, sim));)
  \]

- Fixed a performance issue which caused very long model generation time for large scalar models.

2.9.2.4 Solvers

2.9.2.4.1 BARON

- New libraries 16.5.16.
  - Added option \texttt{WantDual} to indicate whether BARON should make a final call to an NLP solver to try to compute duals if an inexpensive method of calculating them failed.

- \texttt{CompIIS} option did not print IIS into listing file. This has been fixed.

2.9.2.4.2 CBC

- New libraries.
2.9.2.4.3 CPLEX

- New libraries 12.6.3.0.2.
- A memory leak in Cplex has been fixed that showed up in combination with the OO-API GAMSModelInstance class.
- Fixed a problem with CplexD option FreeGamsModel.
- Fixed a problem with MipStart in combination with SemiInt or SemiCont variables with lower bound 0.

2.9.2.4.4 GUROBI

- New libraries 6.5.2.

2.9.2.4.5 JAMS

- Fix handling of objectives in optimizing agents of equilibrium systems in cases where the objective coefficient was not 1 or -1, and in the equation level returned for the objective row(s).

2.9.2.4.6 LocalSolver

- New libraries 6.0 (20160625).

2.9.2.4.7 Mosek

- New libraries 7.1.0.52.

2.9.2.4.8 OsiMosek

- Fixed handling of gap tolerances and node limit of MIP solves.

2.9.2.4.9 SBB

- Fixed a problem with models that have domain violations in the root NLP.
- Clearly identify text written to the listing file as output from the root solver.

2.9.2.4.10 SCIP

- New libraries 3.2 (#e99d344).

2.9.2.4.11 SoPlex

- New libraries 2.2 (#3c5e86f).
2.9.2.4.12 PATH

- Fixed a problem with bogus report of empty rows/cols when benchmarking a model, i.e. solving with iterlim=0.

2.9.2.4.13 XPRESS

- Several minor bug fixes that affect correctness and performance in some uncommon cases.

2.9.2.5 Tools

- Increase maximum available memory for GDXVIEWER, MDB2GMS, SQL2GMS, XLS2GMS, GDX2HAR, and HAR2GDX to 3GB.

2.9.2.5.1 CSV2GDX

- Fixed a problem with labels with trailing blanks. Labels with trailing blanks potentially resulted in a broken GDX file.
- Introduced the symbolic constant `LastCol` for the `Values` parameter.
- Report duplicate keys.

2.9.2.5.2 GDXXRW

- Fixed a problem with unnecessary memory consumption when writing with option clear or merge.
- Symbols and text were not written in sequence as instructed. This has been fixed.
- Added command line parameter `ReCalc` that by default prevents frequent recalculations in Excel while writing to the spreadsheet.

2.9.2.6 Object Oriented APIs

- Fixed a bug which did not clear a pending Ctrl-C event, so that it might have been applied to a following GAMSModelinstance.Solve by accident.
- Fixed a problem, that caused a crash instead of a GAMSException in some rare cases.

2.9.2.6.1 Python

- Fixed a minor bug regarding the names of GamsJob listing files.

2.9.2.7 Model Libraries

- Some URLs in various models have been updated.
2.9.3 24.7.3 Maintenance release (July 11, 2016)

2.9.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Josef Kallrath, and Toni Lastusilta.

2.9.3.2 Tools

2.9.3.2.1 CSV2GDX

- Fixed a bug which caused an error when reading sets from a csv file.

2.9.3.2.2 MODEL2TEX

- Fixed a bug regarding wrongly generated equations in the generated LaTeX file.

2.9.4 24.7.4 Minor release (September 19, 2016)

2.9.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Manuel Alvarez, Felix Färber, Ricardo Manuel Pinto de Lima, and Tara Rengarajan.

2.9.4.2 GAMS System

2.9.4.2.1 GAMS

- Fixed a problem when using extrinsic function libraries using API version 1.
- Extend possible range of \( n \) in \texttt{fact}(n) at compile time. It was limited to 20 in the past. Now it can be up to 166 (as in assignments at execution time).

2.9.4.2.2 Installer

- New default group name (\texttt{GAMS xx.x (xx bit)}) for the start menu on Windows 10.

2.9.4.3 Solvers

2.9.4.3.1 BARON

  - Small performance improvements and robustification of LP solver interfaces and bugfixes.
  - The starting point is now utilized before invoking projection and other initialization strategies.
  - The option \texttt{DeltaTerm} is now recognized again.
2.9.4.3.2 Couenne

- New libraries.

2.9.4.3.3 CPLEXD

- The option MipStart accepts now values other than 0 and 1. The value describes the effort level Cplex uses to determine a MipStart from the starting variable levels. The value 2 is interesting because it just checks for feasibility of the MipStart. In this case the level of all variables, not only the discrete ones, are passed on to Cplex.

2.9.4.3.4 DE

- DE crashed if multiple joint variables were present in one stage. This has been fixed.

2.9.4.3.5 Lindo/LindoGlobal

- New libraries 9.0.293.

2.9.4.3.6 Mosek

- New libraries 7.1.0.55.

2.9.4.3.7 SCIP

- New libraries 3.1 (#6b9196f).

2.9.4.3.8 SoPlex

- New libraries 2.2 (#074950a).

2.9.4.4 Tools

2.9.4.4.1 CSV2GDX

- Fixed a bug which lead to a rejection of unquoted labels with spaces. This bug was introduced in 24.7.2.

2.9.4.4.2 GDXXRW

- Fixed a bug which caused an error message when reading a sheet with a non-empty range that contained no data.
2.9.4.5 Object Oriented APIs

- `GAMSModelInstance.Instantiate`: Skip creation of GDX file, which was unreachable from within the APIs anyway.

2.9.4.5.1 Python

- Added support for Python 3.4 on Mac OS X.
- Fixed a problems with Exceptions in `GamsWorkspace`.

2.10 24.6 Distribution

2.10.1 24.6.1 Major release (January 18, 2016)

2.10.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Etienne Ayotte-Sauvé, Michael Ferris, Per Ivar Helgesen, Erwin Kalvelagen, Martha Loewe, Geoff Moore, and Renger van Nieuwkoop.

2.10.1.2 Platforms

- The minimal supported Mac OS X version has been increased to 10.9 (Mavericks). COIN-OR solvers, Gurobi, SCIP, and SoPlex now require a system with at least Mac OS X 10.9. The GAMS base system, tools, and other solvers are still working on Mac OS X 10.7 and 10.8, but may stop working in a future release without extra announcement.
- The installer for Wine on Linux has been dropped. To continue using Windows GAMS under Wine, see Installation of the Windows system under Linux using Wine for (expert) instructions.

2.10.1.3 GAMS System

2.10.1.3.1 GAMS

- Increased controlled set nesting limit from 120 to 300.
- New option `SHUFFLE`.
- New option for command line parameter `MultiPass`:
  - 0: standard compilation
  - 1: check-out compilation
  - 2: as 1 and in addition skip `$call` and ignore errors because of missing files with `$include` (NEW)
- Allow to load variable and equation attributes into a parameter at compile time, e.g. `$LOAD par=var.L` (par being a parameter and var a variable)
• Solving in parallel threads (beta feature)

A new variant for the SolveLink option and model attribute has been added. If SolveLink is set to 6 (compile time constant %solveLink.Async Threads%), GAMS does not wait for the solver to return and does not collect the result when a solve statement is executed. Instead, the model is generated and then passed to the solver in a separate thread while GAMS continues the execution. This way, multiple models can be solved in parallel and the results can be collected later.

This is similar to the Grid Facility (SolveLink = %solveLink.Async Grid%=3) with the difference, that the solver does not operate in its own process space but in a separate thread, which allows efficient in-memory communication between GAMS and the solver (like it is done with SolveLink = %solveLink.Load Library%=5). After the solve statement, one can store a handle of the model instance (using the model attribute mymodel.handle) and use the same functions that are used for the Grid Facility to collect the solution and deal with the model instance: HandleCollect(handle), HandleStatus(handle), and HandleDelete(handle).

The new function ReadyCollect(handleParameter [, maxWait]) can be used to wait until a model is ready to be collected. It can be used for both SolveLink = %solveLink.Async Threads% and SolveLink = %solveLink.Async Grid%. The arguments and return codes are:

- Arguments
  * handleParameter: parameter holding handles of model instances to wait for
  * maxWait: maximum time to wait (+INF if omitted)
- Return Codes
  * 0: (one of) the requested job(s) is ready
  * 1: no active job to wait for
  * 2: no handle provided
  * 3: invalid handle
  * 4: user specified time-out when using a SolveLink = %solveLink.Async Threads% handle
  * 5: user specified time-out when using a SolveLink = %solveLink.Async Grid% handle
  * 8: unknown error (should not happen)

The new option threadsAsync (available on the command line and with the option statement) sets the maximum number of threads that should be used for the asynchronous solves. If a negative number is set, this specifies how many of the available processors on the host machine should not be used. The default setting is -1.

Currently, the following solvers can be used with SolveLink = %solveLink.Async Threads%:

- CONOPT
- CPLEXD
- GUROBI
- MOSEK
- OSICPLEX
- OSIGUROBI
- SCIP

If another solver is selected, SolveLink = %solveLink.Async Grid% will be used instead (which is noted in the log).

An example of how this new feature can be used, can be seen in the GAMS Model Library model tgridmix.

2.10.1.3.2 Stochastic Programming with EMP

• Fixed a bug which caused wrong expected values for parametric distribution using the RandVar keyword.
2.10.1.4 Solvers

2.10.1.4.1 ANTIGONE

- New libraries.

2.10.1.4.2 BARON

- The handling of branching priorities in a GAMS/BARON options file has changed. Priorities should now always be given in the GAMS convention.

2.10.1.4.3 Convert

- GAMS branching priorities are now converted to BARON branching priorities when writing a BARON input file.

2.10.1.4.4 CPLEX

- New libraries 12.6.3.
- Cplex and CplexD now report the deterministic time spend (in ticks not in seconds) in the model attribute ETAlg.
- IBM’s Cplex cloud offering "DOcloud" can be accessed via the Kestrel solver.

2.10.1.4.5 DICOPT

- New option usexinit instructs DICOPT to start the NLP sub-solves from the user supplied input point.

2.10.1.4.6 GUROBI

- New libraries 6.5.
- New option PreMIQCPForm that determines the format of the presolved version of an MIQCP model.
- New option WorkerPort specifies a non-default port number for the distributed worker machines.
- New option VarHint. The variable hints communicated through level and tryint will affect the heuristics that Gurobi uses to find feasible solutions, and the branching decisions that Gurobi makes to explore the MIP search tree.
- GAMS/Gurobi supports solving models in the Gurobi Instant Cloud.
- Fixed a problem with option IIS for models with SOS variables.

2.10.1.4.7 IPOPT

- MKL Pardiso is now available as linear solver on Mac OS X, too.
2.10.1.4.8 KESTREL

- The Kestrel client provides experimental access to IBM’s DOcloud offering.

2.10.1.4.9 PATH

- Minor fix for zero tolerance in the basis reset routine of the Lemke method.

2.10.1.4.10 Sulum

- Sulum will be dropped from the distribution with GAMS 24.8.

2.10.1.4.11 XPRESS

- Updated Optimizer libraries for Windows and Linux: 28.01.05 → 28.01.10.
- Several minor bug fixes that affect correctness and performance in some corner cases.

2.10.1.5 Tools

2.10.1.5.1 ASK

- New feature SelectDirectory.

2.10.1.5.2 GAMS IDE

- Sorting by symbol name is no longer case sensitive.
- GDX viewer can now show numbers with full precision.
- The option editor no longer shows the dot options.
- Fixed a bug where the cursor was not shown after double-clicking on a red line.

2.10.1.5.3 GDX2SQLITE

- New version 0.7.
  - Added option varchar to export character columns as VARCHAR(255) instead of TEXT.
  - Better names of columns when option small is used.
  - Adding timing info.

2.10.1.5.4 GDXMERGE

- Protect against very large symbols causing memory errors.
- Added option EXCLUDE to exclude symbols from being merged.
2.10.1.5.5 GDXXRW

- An empty range is no longer an error.

2.10.1.5.6 SQL2GMS

- In the old version double quotes were removed when reading a command file. In this version we keep double quotes to be able to escape SQL names (table names, column names). E.g. we now can handle non-standard names by double quoting them in a query. Depending on the database you can do:

  \[
  q=\text{select "Some COLUMN" from "This Table"}
  \]

  Note that some databases (such as SQL Server) use [ ] for this goal.

  In the special case where you write:

  \[
  q=\text{"select c from t"}
  \]

  the surrounding double quotes are removed before passing the query on to the database.

2.10.1.5.7 MODEL2TEX

- If an identifier is changed using the specifications in the JSON style file, underscores are no longer changed from \"_\" to \"\\_\". This makes it possible to use subscripts when replacing an identifier.

2.10.1.6 Object Oriented APIs

2.10.1.6.1 Java

- Fixed a bug in \texttt{GAMSModelInstance.copyModelInstance} method when duplicating scratch directory.

2.10.1.6.2 Python

- New example \texttt{transport8a.py}.

2.10.1.7 Model Libraries

2.10.1.7.1 GAMS EMP Library

- \texttt{nbcontindep}: use sampling for continuous distributions if another solver than Lindo is selected
- \texttt{nbcontjoint}: use sampling for continuous distributions if another solver than Lindo is selected
- \texttt{nbsimple}: use discrete distribution
2.10.1.7.2 GAMS Test Library

- shuffle1.gms: Test for option shuffle (690)
- sl601.gms: Check correct behavior when using solveLink=6 (691)

2.11 24.5 Distribution

2.11.1 24.5.1 Major release (September 23, 2015)

2.11.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Guillaume Erbs, Michael Ferris, Mahbube Habibian, Josef Kallrath, Jean Mercenier, Stan Peter, Ingmar Schlecht, and Mark Thissen.

2.11.1.2 Platforms

- Support for Windows XP has been dropped completely with this release (as announced).

2.11.1.3 GAMS System

2.11.1.3.1 GAMS

- New model attributes
  - maxInfes: Maximum of infeasibilities
  - meanInfes: Arithmetic mean of infeasibilities
- New option solver. This simplifies the selection of the (default) solver for multiple model types.
  - The command line option solver=abc initializes the default solver for the model types solver abc is capable of to abc. This initialization is done before the default solvers of individual model types are set via command line options. So a command line with lp=conopt solver=bdmlp will first set BDMLP as the default solver for model types LP, RMIP, and MIP (these are the model types BDMLP can handle) and then reset Conopt as the default solver for LP. The order of these parameters on the command line has no impact (i.e. lp=conopt solver=bdmlp behaves identically to solver=bdmlp lp=conopt). If multiple occurrences of option solver appear, the last one sets the option as it is with other options, including LP, MIP, ...
  - The solver for multiple model types can be set via the Option solver=abc; in the GAMS model source code. This sets the solver for model types abc can handle to abc. With the option solver=abc; the order among other solver setting options is significant. For example, option lp=conopt, solver=bdmlp; will first set the solver for LP to Conopt and in the next step to BDMLP because BDMLP is capable of handling model type LP. Setting solver twice can also make sense: option solver=conopt, solver=cbc; will result into setting the solver for model types CNS, DNLP, NLP, QCP, RMIQCP, and RMINLP to Conopt and the solver for model types LP, RMIP, and MIP to CBC.
- When using $LOADDC the reporting of domain errors has been improved.
- This release features several improvements of the execution system. The following lists some (extreme) examples:
- Improved performance when indices of accessed symbol are in "wrong" order, e.g.:

```gams
$if not set size $set size 10000
set v / v1*v%size% /
e / e1*e%size% /;
alias(v,w);
set evw(e,v,w) /#e:#v:#w/
vw(v,w);
vw(v,w) = sum(e, evw(e,v,w));
```

The final assignment can be done in less than 1% of the time required by GAMS 24.4.

- Improved performance when assigning to non-empty symbols when the assignment is driven by their domain, e.g.:

```gams
$if not set size $set size 5000
set i / i1*i%size% /; alias (i,j);
parameter a(i,j), b(i,j);
a(i,j)$uniform(0,1)<0.95 = 1;
b(i,j) = not a(i,j);
a(i,j) = b(i,j);
```

The final assignment can be done in just \(\sim\)5% of the time required by GAMS 24.4.

- Improved performance when executing certain combinations of mappings, e.g.:

```gams
$if not set size1 $set size1 8000
$if not set size2 $set size2 24
set hi / 1*%size1% /;
ti / 1*%size2% /;
h / hi*h%size1% /;
t / ti*t%size2% /;
hmapx(h,hi) / #h:#hi /
tmapx(t,ti) / #t:#ti /;
parameter xi(hi,ti), x1(h,t);
xi(hi,ti) = uniform(0,1);
x1(h,t) = sum((hmapx(h,hi),tmapx(t,ti)), xi(hi,ti));
```

The final assignment can be done in just \(\sim\)2% of the time required by GAMS 24.4.

- Improved performance when "searching" a lot in a large symbol, e.g.:

```gams
$if not set size1 $set size1 50
$if not set size2 $set size2 20000
$if not set size3 $set size3 150000
set f /f1*f%size1%/;
j /j1*j%size2%/;
l /l1*l%size3%/;
flmap(f,l) =uniform(0,1)<0.25;
parameter jlpar(j,l) /#j:#l 10/
jlpar(f,j) = sum(l$flmap(f,l), jlpar(j,l));
```

The final assignment can be done in just \(\sim\)1% of the time required by GAMS 24.4.

---

### 2.11.1.3.2 Documentation

- The complete GAMS technical documentation (release and installation notes, user's guides, solver and tools manuals, API reference manuals) is now available in HTML format with a unified table of contents. The documentation is available in the following forms:

  - The online GAMS documentation provides search and keyword indexing functionalities in addition to navigating the GAMS documentation.
– The offline documentation allows access without a network connection:
  * The main navigation page can be found at [GAMS system directory]/docs/index.html (not linked from the GAMS IDE).
  * For Windows, additionally a Microsoft Compiled HTML Help file is available at [GAMS system directory]/docs/gams.chm and linked from the GAMS IDE Menu: Help -> GAMS Documentation.

– The following documents are still available in PDF format: GAMS User's guide, McCarl Expanded GAMS User's guide, all solver manuals, and GAMS GDX API.

2.11.1.3.3 Installer

– New way to install GAMS on Mac OS X using a DMG file, see the installation notes.

2.11.1.4 Solvers

2.11.1.4.1 ANTIGONE

– Added option conopt.optfile to set name of options file to be used for CONOPT calls in ANTIGONE.

2.11.1.4.2 BARON

– Now also available for Mac OS X.
– New libraries 15.9.22.
– New NLP solver for local search: FilterSD.
– Options:
  – New option Threads: Number of cores used for solution of MIP subproblems.
  – New option IISOrder: Order in which constraints are considered in the search for an IIS.
  – Options ConTol and IntTol removed. Tolerances are now set by AbsConFeasTol, RelConFeasTol, AbsIntFeasTol, and RelIntFeasTol.
  – Options MultMSize, MultiRel, NLPDoLin, MipGap, MipNodes, MipRel, NoutIterMip, BilRel, Cvxbt, CvxInitOA, CvxRel, MipCuts, and RLTRel: Algorithmic features that have been parameterized are now handle in an automatic way.
– The time limit is enforced based on CPU time for single-threaded jobs and based on wall-clock time for multi-threaded jobs.
– Simplified the screen output (eliminated some details and simplified time to a real number in seconds).
– Updated CBC to 2.9.5.
– Updated Ipopt to 3.12.3.

2.11.1.4.3 CBC

– New libraries 2.9.
  – Introduced specialized branching methods for dealing with "big Ms".
  – Introduction of conflict cuts (off by default, enable with option conflictcuts).
  – Introduced new methods for dealing with symmetry.
2.11.1.4.4 Conopt

- New libraries 3.17A.
  - Corrected problem with options Ls2ndi and Lmusdf.
  - Systems errors related to very tight memory (984) and the inversion routine (2027) have been removed.
  - Three new options have been added to allow the modeler to see the order of the pre-triangular and post-triangular part of the model and the definitional equations:
    * PRPRET: Flag for printing the pre-triangular part of the model.
    * PRDEF: Flag for printing the defined variables and their defining constraints.
    * PRPOST: Flag for printing the post-triangular part of the model.

2.11.1.4.5 Couenne

- New libraries 0.5 (major update).
- Better handling of function $\text{signpower}(x,k)$ for positive integer $k \leq 10$.
- The default values for the following options have changed:
  - $\text{cont}_\text{var}_\text{priority}$ from 2000 to 99.
  - $\text{int}_\text{var}_\text{priority}$ from 1000 to 98.
  - $\text{feas}_\text{pump}_\text{milpmethod}$ from -1 to 0.
  - $\text{feas}_\text{pump}_\text{poolcomp}$ from 0 to 4.
  - $\text{output}_\text{level}$ from 0 to 4.

2.11.1.4.6 CPLEX

- New option FreeGamsModel. This option preserves memory by dumping the GAMS model instance representation temporarily to disk. This option is available in CplexD only.

2.11.1.4.7 GUROBI

- New libraries 6.0.5 (technical release).
- New option FreeGamsModel. This option preserves memory by dumping the GAMS model instance representation temporarily to disk.

2.11.1.4.8 GUSS/ScenarioSolver

- The set of GUSS model attributes ($\text{Set ma "GUSS Model Attributes" / System.GUSSModelAttributes /;}$) has changed:
  - The attribute $\text{NumNOpt}$ has been removed.
  - The attributes $\text{MaxInfes}$ and $\text{MeanInfes}$ have been added.

2.11.1.4.9 IPOPT

- New libraries 3.12 (minor changes).
2.11.1.4.10 JAMS

- SubSolver option fixed: it was sometimes ignored.

2.11.1.4.11 Kestrel

- The option file can be omitted. In this case, the Kestrel call is done with default settings.

2.11.1.4.12 Lindo/LindoGlobal

- Dropped Lindo/LindoGlobal libraries for Intel Solaris as announced previously.
- New libraries 9.0.225.

2.11.1.4.13 LocalSolver

- New libraries 5.5.
  - Improved accuracy and performance on numerical or mixed-variable optimization problems.

2.11.1.4.14 MINOS

- Adjusted default upper bound on the superbasics limit from 500 to 5000 and consider the number of nonlinear constraint variables, not just the nonlinear objective variables, when computing the superbasics limit: memory is plentiful and cheap.
- Fixed case of memory corruption that resulted when using an initial point containing very many superbasic variables. If the initial point contains more than 5000 superbasics, limit the Hessian dimension to 5000 even though the superbasic limit is larger.

2.11.1.4.15 MOSEK

- New libraries 7.1.0.33.
- The GAMS option iterlim now sets the iteration limit for both simplex and interior point algorithms.
- More MOSEK options are now available in GAMS/Mosek:
  - `MSK_IPAR_MIO_CUT.CG`: Controls whether CG (Chvatal-Gomory) cuts should be generated.
  - `MSK_IPAR_MIO_CUT.CMIR`: Controls whether mixed integer rounding cuts should be generated.
  - `MSK_IPAR_MIO_PROBING_LEVEL`: Controls the amount of probing employed by the mixed-integer optimizer in presolve.
  - `MSK_IPAR_MIO_RINS_MAX_NODES`: Controls the maximum number of nodes allowed in each call to the RINS heuristic.
  - `MSK_DPAR_MIO_TOL_MAX_CUT_FRAC_RHS`: Maximum value of fractional part of right hand side to generate CMIR and CG cuts for.
  - `MSK_DPAR_MIO_TOL_MIN_CUT_FRAC_RHS`: Minimum value of fractional part of right hand side to generate CMIR and CG cuts for.
  - `MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT`: If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation.
2.11.1.4.16 OS

- Now a hidden solver. Will be dropped from the distribution at some time (without further notice).

2.11.1.4.17 PATH

- New libraries 4.07.03.
- Adjusted to use wall-clock time on all platforms.
- Time limit checked more frequently, e.g. at each pivot.
- The presolve has been extended to find more reductions.
- Minor bug fixes.

2.11.1.4.18 SCIP

- New libraries 3.2 #c9c4375 (major update):
  - Presolving levels FAST, MEDIUM, and EXHAUSTIVE are now used to better coordinate the various presolvers.
  - Generalized upgrade from (SOC-representable) quadratic constraints to SOC constraints.
  - New primal heuristics "distribution diving", "indicator", and "bound", improved clique and variable bound heuristics, and adjusted diving heuristics to solve fewer LPs.
  - New branching rules "distribution", "multaggr", and a new rule for SOS1 constraints.
  - New reliability notions and improved treatment of nonlinearities in hybrid reliability pseudo cost branching.
  - New separator "eccuts" for generating edge-concave cuts for quadratic constraints and improved separation for convex quadratic constraints.
  - Decreased total memory usage by using more buffer data structures.
  - Improved propagation and separation for SOS of type 1 by using information from a conflict graph.
  - See also the full release notes, the change log, and the technical report.

- The following options were removed or replaced:
  - constraints/.../delaypresol and constraints/.../timingmask replaced by constraints/.../presoltiming and constraints/.../proptiming.
  - presolving/domcol/singcolstuffing replaced by presolving/stuffing/....
  - presolving/.../delay replaced by presolving/.../timing.
  - propagating/.../presoldelay replaced by propagating/.../presoltiming.
  - propagating/obbt/maxlookahead removed.

- For the following options, the default value changed:
  - constraints/SOS1/sepfreq from 0 to 10.
  - "heuristics/clique/minfixingrate" from 0.5 to 0.25.
  - "heuristics/vbounds/minfixingrate" from 0.5 to 0.25.
  - heuristics/actconsdiving/maxdiveavgquotnosol from 0 to 1.
- heuristics/actconsdiving/maxdiveubquotnosol from 0.1 to 1.
- heuristics/dins/nwaitingnodes from 0 to 200.
- lp/rowrepswitch from -1 to 1.2.
- presolving/abortfac from 0.0001 to 0.001.
- presolving/restartfac from 0.05 to 0.025.
- presolving/immrestartfac from 0.2 to 0.1.
- presolving/dualinfer/priority from 20010000 to -200.
- propagating/obbt/itlimitfactor from 5 to 10.

2.11.1.4.19 SoPlex

- New libraries 2.2.0 (major update).

2.11.1.4.20 SULUM

- New libraries 4.3.892.
  - Several bug fixes in both the MIP solver and the LP solver.
  - Improved numeric stability, degeneracy handling, and perturbation scheme in LP optimizer.
  - Added a new combined pricing scheme to the dual simplex optimizer.
  - Improved presolve and restart in MIP optimizer.

2.11.1.4.21 XPRESS

- New libraries for XPRESS v7.9: Optimizer 28.01.05.
  - Significantly improved linear algebra routines for the simplex solvers improving efficiency of a wide range of problems.
  - Improvement heuristics called more often.
  - The MIP log now provides information which heuristic finds a solution.
  - Improved linear dependency checker for large problems.
  - Improved scaling, including scaling of big-M type rows and of the Curtis-Reid scaling option.
  - Improved inference-learning from infeasible subproblem during the MIP search.
  - Improved presolver for quadratic instances.
  - Improved handling of Special Ordered Sets.
  - Improved propagation of conflict cuts.

2.11.1.5 Tools

2.11.1.5.1 GAMS IDE

- In the model library browser the IDE may provide hints about the content of the column when hovering over the headers.
- Option to specify file extensions for files that will be reloaded without a confirmation dialog.
2.11.1.5.2 GDXDIFF

- When renaming the temporary file to `gdxdiff.gdx` fails, issue a ViewClose command in case the file is open in the GAMSIDE and try to rename again.
- If no difference was found, issue a message in the log indicating this.
- Add a set with two elements with explanatory text of the two files compared.

2.11.1.5.3 GDXMERGE

- When a filename cannot be used as a UEL, use a generated name instead.

2.11.1.5.4 GDXXRW

- New options `IgnoreRows` and `IgnoreColumns` to ignore a set of rows or columns for a symbol. Rows can be specified as `IgnoreRows=1,4:5` and columns `IgnoreColumns=A,D:F` or `IgnoreColumns=1,4:6`.

2.11.1.5.5 MODEL2TEX

- The beta version of this tool allows the automatic generation of LaTeX code that documents a given GAMS model.

2.11.1.5.6 MPSGE

- The documentation of MPSGE has moved again. It can now be found in the User's Guide.

2.11.1.6 Object Oriented APIs

- New examples `SpecialValues` and `Clad` (Java: `specialvalues/SpecialValues.java`, `clad/Clad.java`; Python: `special_values.py`, `clad.py`).
- New functions to retrieve models from the GAMS API Library and the Nonlinear Optimization Applications Library:
  - Java: `GAMSWorkspace.addJobFromApiLib` and `GAMSWorkspace.addJobFromNoaLib`.
  - Python: `GamsWorkspace.apilib` and `GamsWorkspace.noalib`.

2.11.1.6.1 Python

- Added support for Python 3.4 (Windows and Linux only). The examples have been changed to be compatible with all supported Python versions.
2.11.1.7 Model Libraries

2.11.1.7.1 NOALIB - Nonlinear Optimization Applications Using the GAMS Technology

- This new library by Neculai Andrei has been added to the GAMS system. This is a collection of the models based on the book *Nonlinear Optimization Applications Using the GAMS Technology* by Neculai Andrei. The library contains a wide spectrum of nonlinear optimization applications expressed in GAMS. The book and library emphasize the local solutions of the large-scale, complex, continuous nonlinear optimization applications, and the abundant examples in GAMS are highlighted by those involving ODEs, PDEs, and optimal control. The collection of these examples will be useful for software developers and testers.

- You can retrieve the individual models through the IDE model library browser or via the command line utility `noalib`.

2.11.1.7.2 GAMS API Library

- CSSpecialValues.gms : Test handling of Special Values in object oriented C# API (47)
- PSpecialValues.gms : Test handling of Special Values in object oriented Python API (48)
- JSpecialValues.gms : Test handling of Special Values in object oriented Java API (49)
- CSNUnit.gms : Compiles and runs NUnit tests for object oriented C# API (50)
- CSClad.gms : Test changing solver options while running using the interrupt method (51)
- PClad.gms : Test changing solver options while running using the interrupt method (52)
- JClad.gms : Test changing solver options while running using the interrupt method (53)

2.11.1.7.3 GAMS Data Library

- invert1: Pass `gams.sysdir%` to R script to make linkage between GAMS and R explicit.
- gdxmrw_tr3: Canonical form LP created in Matlab and solved via `gams()` Mex-function.
- gdxmrw_tr4: Better example of `gams()` usage.
- gdxmrw_tr5: Better example of `gams()` usage.

2.11.1.7.4 GAMS EMP Library

- transecs: Fix formulation as embedded complementarity system and provide equivalent alternative as single-agent equilibrium system.
- farmnbd.gms : The Farmer's Problem - Stochastic with NBD (100)
2.11.1.7.5 GAMS Model Library

- In the IDE the GAMS Model Library browser has now a Lic column indicating the license requirement of a model. The letters D and G indicate that the model does not require a license. Models with G can even be solved by a global solver without a license (the demo limit for global solvers is 10 variables and 10 equations). A letter L indicates that a license is required.
  - tgridmix: Fix the logic for sleeping. Only do that if no more jobs to be scheduled or all cores are busy.

2.11.1.7.6 GAMS Test Library

- asynntrp: Make this model work under Unix that have the pstree utility available.
- call6.gms: Call GAMS in a folder containing a % (674)
- cmexrc01.gms: Trigger unexpected cmexRC error (675)
- rs02.gms: Solving Three-dimensional Noughts and Crosses using Cplex and Gurobi distributed MIP (676)
- single04.gms: Check handling of singleton sets assigned and referenced in a loop (677)
- model2tex1.gms: Test that model2tex produces a tex file (678)
- exmcp6.gms: External Equation - Example MCP 6 (679)
- scenso16.gms: Test execute_loadhandle for GUSS/GRID (680)
- idxperm1.gms: Check correct behavior when permuting indices in model generation (684)
- idxperm2.gms: Check correct behavior when permuting indices in loop etc (685)

2.11.2 24.5.2 Maintenance release (September 29, 2015)

2.11.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Kevin Doran and Renger van Nieuwkoop.

2.11.2.2 GAMS System

2.11.2.2.1 GAMS

- Fixed a bug which caused a crash for certain assignments, in particular it had to be an assignment to a symbol that was also referenced on the RHS, with permuted indices and we actually set some of the records to zero which were non-zero before.

2.11.2.3 Object Oriented APIs

2.11.2.3.1 .NET

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. (This is for Mono only.)
2.11.2.3.2 Python

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. The property GamsWorkspace.system_directory now always returns the canonical path with all symbolic links resolved.

2.11.2.4 Model Libraries

2.11.2.4.1 GAMS Test Library

- idxperm3.gms: Check correct behavior when permuting indices of symbol used on LHS and RHS (686)

2.11.3 24.5.3 Maintenance release (October 01, 2015)

2.11.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz.

2.11.3.2 GAMS System

2.11.3.2.1 GAMS

- Fixed a bug which caused wrong results in some cases of out-of-order assignments

2.11.4 24.5.4 Maintenance release (October 15, 2015)

2.11.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Per Ivar Helgesen and Jan Imhof.

2.11.4.2 GAMS System

2.11.4.2.1 GAMS

- Fixed a bug which caused wrong results in some cases of out-of-order assignments, in particular it had to be an assignment using the same controlling set more than once in one symbol, e.g. p(i,j,i).
- Fixed a bug when handling suffixes (e.g. .val) of Singleton Sets in Equations.

2.11.4.3 Object Oriented APIs

2.11.4.3.1 .NET

- Fixed a bug with the property GAMSOptions.IDir.
2.11.4.4 Model Libraries

2.11.4.4.1 GAMS Test Library

- single05.gms: Check correctness of set attributes for singleton sets (687)
- idxperm4.gms: Check correct behavior when permuting indices of symbol using same controlling set multiple times (688)

2.11.5 24.5.5 Maintenance release (November 25, 2015)

2.11.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Albrecht, Stefan Kemnitz, Martha Loewe, Thomas Maindl, Bruce McCarl, and Andres Ramos.

2.11.5.2 GAMS System

2.11.5.2.1 GAMS

- GAMS now always reports the upper bound that is sent to the solver in the column listing and solution report. Hence, with `IntVarUp=1` GAMS prints the value of 100 for integer and semiint variables that are at default bound value +INF.
- Fixed a bug which could cause a crash when referencing attributes of equations (e.g. marginals) after a model was solved with a non-default solveLink setting and there was no solution returned.

2.11.5.2.2 Stochastic Programming with EMP

- Fixed a bug which caused wrong sample sizes if the sample keyword was used more than once and with different sample sizes.

2.11.5.3 Solvers

2.11.5.3.1 Cbc

- New libraries.

2.11.5.3.2 CplexD

- Fixed a problem with the computeserver option. The value for the computeserver option is limited to 255 characters. In order to specify a longer list of workers, one can now use multiple lines with the computeserver option.
2.11.5.3.3 Ipopt

- New libraries.

2.11.5.3.4 LocalSolver

- New libraries 5.5 (20151028).

2.11.5.3.5 Mosek

- New libraries 7.1.0.41.

2.11.5.3.6 SCIP

- New libraries 3.2 (#e9a5ca7).
  - Removed options `constraints/SOS1/bipbranch`, `constraints/SOS1/neighbranch`, and `constraints/SOS1/sos1branch`.

2.11.5.3.7 SoPlex

- New libraries 2.2 (#f17b9e7).

2.11.5.4 Tools

2.11.5.4.1 put_toexcel, put_tohtml

- Fixed a problem with `put_toexcel` and `put_tohtml`.

2.11.6 24.5.6 Maintenance release (November 27, 2015)

2.11.6.1 Solvers

2.11.6.1.1 COUENNE

- New libraries.

2.11.6.1.2 IPOPT, BONMIN, SCIP

- Fixed issue that Ipopt and Bonmin always read `ipopt.opt`, despite of the `optfile` setting in GAMS.
2.12 24.4 Distribution

2.12.1 24.4.1 Major release (December 20, 2014)

2.12.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Erwin Kalvelagen, Jeff Linderoth, and Erika Rinne.

2.12.1.2 GAMS System

2.12.1.2.1 GAMS

- Fixed a bug causing a potential crash when solving an EMP model having an open file handle without an external file name at the same time.
- The execMode setting is not ignored by put utility anymore.
- Added gbin/md5sum.exe to Windows distribution. This utility allows users to verify the file integrity of newly downloaded GAMS installation files.
- The gbin_new directory will be removed with the next distribution.

2.12.1.2.2 Installer

- Windows installer removes the GAMS entry in the current user hive of the registry, if GAMS is installed for all users. Previously, the hive for the current user remained unchanged in this situation.

2.12.1.2.3 Extrinsic Function libraries

- The new extrinsic function library parcclib was added to the system. This library demonstrates how to access the GAMS parameter file and use it's information through the GAMS Option Object. Further information can be found in the GAMS User's Guide, Appendix J.
- Allow up to 20 arguments (used to be 10).
- Support for extrinsic function libraries that do not provide gradient and/or Hessian values. GAMS uses finite differences (same method as for .gradn and .hessn) to approximate the derivatives, even inside a solver. The example function library trilib now implements function Sine without any derivatives and leaves their calculation to GAMS.
- New GAMS options have been introduced to parameterize the numerical derivative calculations. While these are most important for extrinsic functions, they also apply to the .gradn/.hessn calculations of intrinsic functions.
  - FDDelta: step size in the numeric gradient and Hessian calculation. For single argument functions, GAMS evaluates the function at f(x-d) and f(x+d) for the numerical gradient. If function values are used for the numerical Hessian, GAMS evaluates at f(x-2d), f(x), and f(x+2d). For multi argument functions, the same is done for the components of the input argument vector. The default for FDDelta is 1e-5. This option can be set from the command line, in an option statement, and as a model attribute.
  - Note: In previous releases it was possible to set the step size for .gradn/.hessn using the option Real1. This does not work anymore.
2.12.4 Distribution

- **FDOpt**: The option value packs two option in the different digits: $ij$. The $i$ digit indicates if scaling of the step size ($FDDelta$) by the value of the input argument should be turned off. If $i=0$ (scaling on) the following step size is used: $\max(1,|x|) \times FDDelta$. The $j$ digit is mostly for testing, but has one setting that might be relevant when the extrinsic function provides gradient but no Hessian values. The numerical derivatives routine in this case uses the gradient calculation from the extrinsic function to approximate the Hessian. If the gradient is expensive to calculate compared to a function evaluation, it could be beneficial to use multiple function values to approximate the Hessian. In this case set the $j$ digit to 1. Here are all possible values for this option:
  * 0: All derivatives analytically if available, for numerical Hessian use gradient values, scale delta
  * 1: All derivatives analytically if available, for numerical Hessian use function values, scale delta
  * 2: Gradient analytically, force Hessian numerically using gradient values, scale delta (testing only)
  * 3: Gradient analytically, force Hessian numerically using function values, scale delta (testing only)
  * 4: Force gradient and Hessian numerically, scale delta (testing only)
  * 10: Same as 0, but no scale of delta
  * 11: Same as 1, but no scale of delta
  * 12: Same as 2, but no scale of delta (testing only)
  * 13: Same as 3, but no scale of delta (testing only)
  * 14: Same as 4, but no scale of delta (testing only)

- **Note**: In previous releases it was possible to deactivate the scaling for .gradn/.hessn using the option Integer1. This does not work anymore.

- Renamed and better documented the `EXTRFUNC_ERROR` enum to `EXTRFUNC_EVALERROR` in the C header `extrfunc.h`. The old values are deprecated and will be removed in a future release.

2.12.1.2.4 Documentation

- The manuals of all solver and several tools are now available in HTML format. A PDF that contains all solver manuals is still available (`docs/solvers/allsolvers.pdf`).

2.12.1.3 Solvers

2.12.1.3.1 AlphaECP

- Alpha-ECP v2.10.06.
  - Added support for solver trace file, i.e. new option `solvtrace`.

2.12.1.3.2 ANTIGONE, GloMIQO

- Now also available for Mac OS X.

2.12.1.3.3 BARON

- New libraries 14.4.0.
  - Added reliability branching for integer variables.
  - Bug fixes in CBC interface and IIS module.
  - Improved performance of problem reading and reformulation.
  - Updated Ipopt to version 3.11.9.
2.12.1.3.4 BENCH

- Removed option `cumulative`. This option makes no sense anymore since all solvers are spawned asynchronously and all get the same limits.

2.12.1.3.5 CBC

- Fixed a race-condition in log output when using multiple threads.
- New libraries.

2.12.1.3.6 Couenne

- New libraries.

2.12.1.3.7 CONOPT

- New libraries 3.16D.
  - Tolerance adjustments that make sense if NaN appears in intermediate calculations.

2.12.1.3.8 CPLEX

- Don't rerun primal simplex in cases where there is already an infeasibility status.
- New libraries 12.6.1.
- New parameters:
  - `qtolin` controls the linearization of the quadratic terms in the objective function of a QP or MIQP model
  - `localimplied` controls the generation of locally valid implied bound cuts

2.12.1.3.9 DICOPT

- Added support for `=`N= rows.

2.12.1.3.10 GUROBI

- New libraries 6.0.0.
- Fixed problem in tuning. Previous version did not write out link options in the tuned option file.
- Gurobi 6.0 supports a distributed MIP algorithm (option `DistributedMIPJobs`). This requires the Gurobi Compute Server to be licensed.
- Explicit lazy constraint: Users can use the "dot" option `.lazy` to mark constraints as lazy. Possible values are 0, 1, 2, and 3. See option `.lazy` for details.
- Option `ConcurrentMIPJobs` has been renamed to `ConcurrentJobs`. The distributed concurrent optimizer now also handles LP models.
- Option `ScaleFlag` allows now value 2 which enables aggressive scaling.
- New parameters:
  - `DistributedMIPJobs` controls the number of workers of the distributed MIP algorithm
  - `.lazy` marks constraints as lazy constraints
  - `LazyConstraints` controls the use of lazy constraints
2.12.1.3.11 Knitro

- New libraries 9.1.0.
  - Overall speed and robustness improvements on NLP and MINLP models.
  - New algorithm choice introduced: active-set SQP.
  - Optional barrier solution refinement procedure: option \texttt{bar.refinement = NO/yes}.
  - Deterministic parallel multi-start: option \texttt{ms.deterministic = no/YES}.
- Dropped Knitro for Solaris on Intel CPUs (as announced).

2.12.1.3.12 LocalSolver

- Added the hybrid mathematical programming solver \texttt{LocalSolver 5.0 (Beta)} from Innovation 24 to the GAMS solvers portfolio.
- LocalSolver can be applied to large-scale, mixed-variable, non-convex optimization problems (GAMS model types MIP, (MI)QCP, (MI/D)NLP). It combines local search techniques, constraint propagation and inference techniques, linear and mixed-integer programming techniques, and nonlinear programming techniques in a unique hybrid neighborhood search approach to find high-quality feasible solutions. Hence, LocalSolver offers an alternative for problems where conventional branch-and-bound and/or outer-approximation based solution methods do not provide satisfactory results.
- It is suggested to set the GAMS options for iteration or timelimit (iterlim, reslim) appropriately to limit the effort that LocalSolver spends on the problem.

2.12.1.3.13 Lindo/LindoGlobal

- We will drop Lindo/LindoGlobal libraries for Intel Solaris with the next major release (24.5).
- New libraries 9.0.142 for Linux, Mac OS X, and Windows:
  - Support for semi-continuous variables.
  - Simplex LP algorithm implementation has been improved for speed and robustness. The performance improvements compared to previous version are 90% for primal simplex and 45% for the dual simplex.
  - Knapsack related cuts improvements. Significantly faster solve times on models with certain knapsack-like constraints.
  - Improved default node selection rules improves performance on most MIPs.
  - New branching variable rule options: maximum coefficients and neighborhood branching. Can reduce number of branches on certain MIPs.
  - Perspective reformulation capability gives improved performance on quadratic portfolio models with semi-continuous variables, e.g. min-buy quantities.
  - Improved default settings for NLPs gives 5% average speed improvement.
  - New preprocessing for LP/MIP significantly reduces coefficient density of certain dense matrices.

2.12.1.3.14 Mosek

- New libraries 7.1.0.12.
  - Improved performance of the mixed-integer conic optimizer.
2.12.1.3.15 MSNLPOQNLPLP

- These solvers now use Conopt as their default solver if Conopt is licensed. Otherwise they will use lsqr as before.

2.12.1.3.16 OS

- We plan to drop the OS solver with GAMS 24.5. The capability of convert to write OSIL files will be kept.

2.12.1.3.17 SCIP

- New libraries 3.1 #020d055.

2.12.1.3.18 SoPlex

- New libraries 2.0 #d67b17b.

2.12.1.3.19 Sulum

- New libraries 4.0.665.
  - Improvements in presolve, leading to more reductions.
  - General improvements in obtaining a feasible solution faster, especially with focus on the root node to obtain a good bound. Rewrite and improvements of feasibility pump, objective diving.
  - The simplex algorithm is now exchanging more information with the branch and cut method. Improvement of SINS heuristic (finding a better basis after the node solve).
  - Added a MIP root restart feature based on reductions.
  - Cutting planes generation was both improved and extended.
  - Changed default for option mipmaxrestarts from 5 to 1.

2.12.1.3.20 XPRESS

- New libraries for XPRESS v7.8: Optimizer 27.01.02.
  - Automatic solution refinement for LP and MIP models.
  - Improved deterministic concurrent LP.

2.12.1.4 Tools

2.12.1.4.1 GAMSIDE

- Added option to suppress trailing zeroes in GDX viewer.
- Improved ability to open files from the Windows Shell.
- Cutoff for number of lines to be syntax colored or not.
- When saving a file, the Undo buffer is no longer cleared.
2.12.1.4.2  GDXDUMP

- Text quoted with a single quote did not have a separator when writing SymbolAsSet.
- Added option SymbolAsSetDI.
- Avoid string overflow when quoting text.
- Added more types for sets and equations.

2.12.1.4.3  GDXRW

- Added option values=All which is the new default when CDim=0 or RDim=0.

2.12.1.4.4  GDXVIEWER

- Added ACCDB format as an output option for MSAccess.

2.12.1.4.5  GDX2SQLite, Scenred, Scenred2

- These tools are now also available for AIX.
- Moved documentation of Scenred and Scenred2 from docs/solvers to docs/tools.

2.12.1.4.6  IDECMDS

- Allow a pattern to be specified to close files.

2.12.1.4.7  MPS2GMS

- The mps2gms tool now produces proper generic GAMS source for models with quadratic terms.
- Bug fix for MPS files written by Cplex that contain SOS constraints.

2.12.1.4.8  MPSGE

- Moved manual to "docs/tools".

2.12.1.5  Expert Level APIs

- There are new API files for the "Indexed GDX" (IDX) library in `<GAMS Dir>\apifiles\<Language>\api`:
  - The indexed GDX library can be used to read and write indexed GDX files.
  - Each symbol in such a GDX file must be a parameter.
  - Each parameter must have a domain consisting of a UELs which forms an integer sequence starting at 1.
  - This way the data is provided in a format convenient to store in arrays in the target language.
  - In GAMS such a file can be read using `$LoadIDX` during compilation.
  - In GAMS such a file can be written using `execute_unloadIDX` during execution.
  - The new example `<GAMS Dir>\apifiles\CSharp\xp_CalcInverseIDX` makes use of this API, this example is also used in the APILib model `CSCalcInverse`.
2.12.1.5.1 Python

- Fixed a bug regarding lists of strings in Python 3 (e.g. `gdxDataWriteStr()`).

2.12.1.6 Object Oriented APIs

- We changed the handling of GAMS Aliases in the object oriented APIs:
  - If we ask for the number of GAMSSymbols in a GAMSDatabase, the Aliases will be excluded.
  - If we iterate over all GAMSSymbols in a GAMSDatabase, Aliases will be skipped.
  - If we ask explicitly for an Alias in a GAMSDatabase (`GAMSDatabase.GetSet("a")` with `a` being an Alias) we will get a reference to the GAMSSet referenced by the Alias, not the Alias itself.
  - Note: Aliases can appear in a GAMSDatabase only, if it was initialized by a GDX file containing an Alias.
  - The new examples `Alias` demonstrate this new behavior for the different OO API languages.

2.12.1.6.1 Python

- Fixed a bug in `GamsDatabase.merge_record` that prevented the function from creating a record if none was found.

2.12.1.7 Model Libraries

2.12.1.7.1 GAMS API Library  This is a new collection of GAMS models. It can be accessed in the GAMS IDE at Model Libraries -> GAMS API Library or through the command line tool `apilib`. The models in this collection can be used as scripts to compile and execute the example applications using the GAMS object oriented APIs as well as the expert level APIs, which can be found in `<GAMS Dir>/apifiles`.

- `apiutil.gms` : Generates the API Model Library files (01)
- `testapi.gms` : API Quality Assurance Test (02)
- `Cex1.gms` : Test expert level C API to read and write GDX (03)
- `CSex1.gms` : Test expert level C# API to read and write GDX (04)
- `CPPex1.gms` : Test expert level C API to read and write GDX in C++ (05)
- `DCex1.gms` : Test expert level Delphi (function) API to read and write GDX (06)
- `DOex1.gms` : Test expert level Delphi (object) API to read and write GDX (07)
- `DPex1.gms` : Test expert level Delphi (pure) API to read and write GDX (08)
- `Fex1.gms` : Test expert level Fortran API to read and write GDX (09)
- `Jex1.gms` : Test expert level Java API to read and write GDX (10)
- `Pex1.gms` : Test expert level Python API to read and write GDX (11)
- `VBex1.gms` : Test expert level VB.Net API to read and write GDX (12)
- `Cex2.gms` : Test expert level C API to read and write GDX, set options and execute GAMS (13)
• CSex2.gms : Test expert level C# API to read and write GDX, set options and execute GAMS (14)
• CPPex2.gms : Test expert level C API to read and write GDX, set options, and execute GAMS in C++ (15)
• DOex2.gms : Test expert level Delphi (object) API to read and write GDX, set options and execute GAMS (16)
• Fex2.gms : Test expert level Fortran API to read and write GDX, set options and execute GAMS (17)
• Jex2.gms : Test expert level Java API to read and write GDX, set options and execute GAMS (18)
• Pex2.gms : Test expert level Python API to read and write GDX, set options and execute GAMS (19)
• VBex2.gms : Test expert level VB.Net API to read and write GDX, set options and execute GAMS (20)
• CStrseq.gms : Test object oriented C# API running a sequence of examples based on a transport model (21)
• CPPtrseq.gms : Test object oriented C++ API running a sequence of examples based on a transport model (22)
• Jtrseq.gms : Test object oriented Java API running a sequence of examples based on a transport model (23)
• PStrseq.gms : Test object oriented Python API running a sequence of examples based on a transport model (24)
• VBtrseq.gms : Test object oriented VB.Net API running a sequence of examples based on a transport model (25)
• CSBenders.gms : Test object oriented C# API using a (multi-threaded) Benders Decomposition Algorithm (26)
• JBenders.gms : Test object oriented Java API using a (multi-threaded) Benders Decomposition Algorithm (27)
• PBenders.gms : Test object oriented Python API using a (multi-threaded) Benders Decomposition Algorithm (28)

2.12.1.7.3 GAMS Model Library

- Modified models
  - tsp1 and tsp4 now use Singleton Sets
  - flowchan had incorrect boundary conditions
  - licememo: give a full solver/model type matrix independent of the actual license

- partssupply.gms: Parts Supply Problem (404) (contains ps2.f.s .. ps5.s.imn, which are still available, as submodels)

- qfilter.gms: Audio filter design using quad-precision MINOS (405)

- derivtst.gms: How to test derivatives of functions (406)

- carseq.gms: Car Sequencing (407)

- pmedian.gms: P-Median problem (408)

- sgolfer.gms: Social Golfer Problem (409)

2.12.1.7.4 GAMS Test Library

- Modified Models
  - trilib01, trilib02, and trilib03: Compare numeric gradient and Hessian values in the models. Function Sine in the library does not provide derivatives anymore. Lower the tolerances for acceptance due to numerical derivatives of function Sine

- indic04.gms: Test of indicator constraints with explicit labels (663)

- parlib01.gms: Test extrinsic functions in parcclib (667)

- convert10.gms: CONVERT test suite - check interval evaluator in ConvertD (668)

- convert11.gms: CONVERT test suite - check interval evaluator in ConvertD (669)

- convert12.gms: CONVERT test suite - check interval evaluator in ConvertD (670)

- lazy01.gms: Test lazy constraints (671)

- mps2gms1.gms: Test mps2gms (672)

- execmode01.gms: Test execmode behavior (673)

2.12.2 24.4.2 Minor release (March 15, 2015)

2.12.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Sergey Kuznetsov, Ricardo M. De Lima, and Corey Noone.

2.12.2.2 GAMS System

2.12.2.2.1 GAMS

- Fixed potential problem when running on Windows in a workDir containing a %.

- Fixed problem with EMP solves with solvelink=Solvelink.AsyncGrid%.

- Fixed problem with GUSS/Grid when using execute_loadhandle instead of handlecollect.
2.12.2.3 Solvers

2.12.2.3.1 ANTIGONE

- New libraries.

2.12.2.3.2 CONOPT

- Introduced new boolean option PreTri2Log that send message from Conopt's pre-triangular analyzer that go to the listing file also to the GAMS log. The option requires the generation of the model dictionary, so mymodel.DictFile=1; has to be added before the Solve statement.

2.12.2.3.3 CONVERT

- Convert and ConvertD: Fix for writing scalar MCP models that contained fixed variables removed by holdfixed=1.
- ConvertD: Add support for external equations in scalar GAMS models.
- ConvertD: Propagate EPS to scalar GAMS models.

2.12.2.3.4 Couenne

- New libraries.

2.12.2.3.5 Examiner2

- Support added for custom trace files.

2.12.2.3.6 GUROBI

- New libraries 6.0.2.

2.12.2.3.7 Lindo/LindoGlobal

- New libraries 9.0.157 for Linux, Mac OS X, and Windows.

2.12.2.3.8 LocalSolver

- New libraries 5.0 (20150119).

2.12.2.3.9 Mosek

- New libraries 7.1.0.24.
2.12.2.3.10 SCIP

- New libraries 3.1 #67d713c.
- Fixed overwriting of solvetrace file by final NLP resolving.

2.12.2.3.11 SoPlex

- New libraries 2.0 #8381aa4.

2.12.2.4 Tools

2.12.2.4.1 GDXMRW

- gdxInfo: fix output of domains in symbol declaration
- gdxInfo: handle aliases properly

2.12.2.5 Object Oriented APIs

- Fixed overwriting of the default value for the `integer1` option when running with `GAMSModelInstance`, which lead to unexpected solver behavior.
- Fixed potential problem with `GAMSModelInstance` used with BARON.

2.12.2.5.1 .NET

- New property `GAMSSymbol.DomainsAsStrings`: Domains of Symbol, each element is a string, if the domain is an alias in GAMS, this call will return the name of the Alias, not the name of the aliased Set.

2.12.2.5.2 Java

- Changed naming scheme of GDX output scratch file to sequence number.

2.12.2.5.3 Python

- Fixed a bug in the constructor of all subclasses of `GamsSymbol` that occurred when the explanatory text was omitted.
- New property `_GamsSymbol.domains_as_strings`: Domains of Symbol, each element is a string. If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set.
2.12.2.6 Expert Level APIs

2.12.2.6.1 GMO

- Fixes to \texttt{gmoGetRowJacInfoOne} and \texttt{gmoGetColJacInfoOne}: In case of an empty row/column, now return -1 in colidx/rowidx if index base is 0.

2.12.2.7 Model Libraries

2.12.2.7.1 GAMS Model Library

- \texttt{dyncge.gms}: A Recursive-Dynamic Standard CGE Model (410)

2.12.3 24.4.3 Maintenance release (April 02, 2015)

2.12.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Guillaume Erbs and Emiliano Traversi.

2.12.3.2 Solvers

2.12.3.2.1 Examiner2

- Fixed incapability to continue on a trace file that already has trace records in it.

2.12.3.2.2 LocalSolver

- Corrected computation of values for free variables that appeared (linearly) in one equation only.

2.12.3.3 Tools

2.12.3.3.1 GDXXRW

- In 24.4.2 we quietly introduced a new way to determine the content of a sheet. This resulted in a bug for empty sheets and sheets that have been saved with an active filter. This has been fixed.

2.12.4 24.4.4 Maintenance release (May 12, 2015)

2.12.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Thomas Counsell, Michael Ferris, Jean Mercenier, and Loïc Ventre.
2.12.4.2 Solvers

2.12.4.2.1 Gurobi

- New libraries 6.0.4.
- The new libraries do not work on Windows XP anymore. As the library for COIN-OR solvers, SCIP, and SoPlex link to the Gurobi library, these solvers also do not work on Windows XP anymore.

2.12.4.2.2 Ipopt

- New libraries for Linux and Mac OS X.
  - Fixed an issue in the MA97 interface that lead to convergence problems.

2.12.4.2.3 Minos

- Consider the number of nonlinear constraint variables, not just the nonlinear objective variables, when computing the superbasics limit: memory is plentiful and cheap.
- Fixed case of memory corruption that resulted when using an initial point containing very many superbasic variables. If the initial point contains more than 500 superbasics, limit the Hessian dimension to 500 even though the superbasic limit is larger.

2.12.4.2.4 Mosek

- New libraries 7.1.0.30.

2.12.4.2.5 Xpress

- New libraries Optimizer 27.01.08 (was 27.01.02 before).

2.12.4.3 Tools

2.12.4.3.1 GDXDUMP

- Fixed a problem when writing a scalar or scalar variable/equation in format CSV.

2.12.4.4 Object Oriented APIs

- Fixed a potential problem with GAMSModelinstance and certain OS culture settings.

2.12.4.5 Model Libraries

2.12.4.5.1 GAMS EMP Library

- transecs: Fixed formulation as embedded complementarity system and provide equivalent alternative as single-agent equilibrium system.
2.12.5 24.4.5 Maintenance release (May 26, 2015)

2.12.5.1 Solvers

2.12.5.1.1 COIN-OR solvers, SCIP, SoPlex

- On Windows 32bit, OsiGurobi was split off into a separate library, so that other COIN-OR solvers (e.g., Bonmin, Cbc, Couenne, Ipopt) and SCIP and SoPlex do not require the Gurobi 6.0.4 library anymore. Thus, for this release, only Gurobi and OsiGurobi do not run on Windows XP anymore (see 24.4.4 notes on Gurobi).

2.12.6 24.4.6 Minor release (June 26, 2015)

2.12.6.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Erwin Kalvelagen, Rich Roberts, and Jens Schulz.

2.12.6.2 Solvers

2.12.6.2.1 CONOPT

- New libraries 3.16F.
- New option LMUSDF for handling definitional equations.
- New option RVFILL for memory allocation when memory is tight.
- Changed a sorting procedure in the preprocessor. Models with some very dense rows and many pre-triangular variables can experience a significant speedup for the preprocessor.

2.12.6.2.2 CPLEX

- New libraries 12.6.2.0.
- Option changes:
  - The popular option value -1 for BarCrossAlg to turn off the crossover after a run with barrier has been deprecated. The new way to turn off crossover is to set the new option SolutionType to 2.
  - The option SolutionTarget has been renamed to OptimalityTarget.
  - The option CutsFactor has a new default (-1).
- New options:
  - BQPCuts: Boolean Quadric Polytope cuts for solving nonconvex QP or MIQP to global optimality.
  - CPUMask: Switch and mask to bind threads to processors. Binding threads to processors/cores helps to reduce variability in running time when using multiple threads.
  - SolutionType: Type of solution (basic or non basic) for an LP or QP. Set this option to 2 to prevent crossover after barrier.
2.12.6.2.3 MOSEK

- New libraries 7.1.0.31.

2.12.6.3 Tools

2.12.6.3.1 GAMSIDE

- Added .ref for reference file to the files open dialog.
- Left arrow in the first character position now moves to the end of the previous line.

2.12.6.3.2 GDXXRW

- Restore the old behavior when reading a set with Values=Strings; all elements will be included, not only the ones with a string.
  - Option Values=String and All are now deprecated and results in a warning; replaced with Dense.
  - New options Values=Dense or Sparse.

2.12.6.3.3 XLSTalk

- Allow for up to 9 parameters for macro call.

2.13 24.3 Distribution

2.13.1 24.3.1 Major release (July 31, 2014)

2.13.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Michael Bond, Sebastian Bothor, Jared Erickson, Michael Ferris, Josef Kallrath, Bastian Niebel, Matt Preston, and Tom Rutherford.

2.13.1.2 Platforms

- The Linux 32bit and Solaris 32bit distributions have been dropped (as announced).
- Support for Windows XP may be dropped with some future GAMS version. As several of our solver vendors have already dropped support for Windows XP, some components of a GAMS system may cease to work under Windows XP in the future. If you notice that a 64bit GAMS system is not working on your Windows XP 64bit machine, please let us know.
2.13.1.3 GAMS System

2.13.1.3.1 GAMS

- Introduced new keyword Singleton Set: A Singleton Set in GAMS is a special Set that has at most one element (zero elements are allowed as well). Singleton Sets can be especially useful in assignment statements since they don't need to be controlled by a controlling index nor an indexed operator, e.g.:

```gams
Set s / s1*s3 /;
Singleton Set single(s) / s2 /;
Parameter p(s);
Scalar x;

p(s) = ord(s);
x = p(single);
```

NOTE: Assigning membership to Singleton Sets is different than to usual sets. Since Singleton Sets can never have more than one element, any assignment to a Singleton Set first clears or empties the set, so no explicit clear is necessary. This is illustrated in the following example:

```gams
Set i Static Set / a, b, c /;
ii(i) Dynamic Set / b /;
Singleton Set si(i) Dynamic Singleton Set / b /;

ii('c') = yes;
si('c') = yes;
Display ii, si;
```

Here is the output from the display statement in the listing file:

```
----- 8 SET ii Dynamic Set
b, c
----- 8 SET si Dynamic Singleton Set
c
```

More information can be found in the GAMS Users Guide.

- The behavior of assignments to Singleton Sets can be influenced by the new option strictSingleton [0/1]: This option affects the behavior of a membership assignment to a Singleton Set. With strictSingleton = 0 GAMS does not complain about an assignment with more than one element on the right hand side but takes the first one. With strictSingleton = 1 (default), such an assignment raises an error. This option be set via an option statement and via a command line option.

- Similarly, data statements for Singleton Sets can be influenced by the new dollar control options $onStrictSingleton/$offStrictSingleton: With $offStrictSingleton GAMS does not complain about a data statement for a Singleton Set that has more than one element but takes the first one. With $onStrictSingleton (default), such an assignment raises an error.

- Introduced so-called obfuscated save files, which are save files where symbol and UEL names have been obfuscated. The new options saveobfuscate (so) and xsaveobfuscate (xso) can be used to generate uncompressed and compressed, respectively, obfuscated save files. Additionally, a new option restartNamed (rn) has been added which can be used to bring back the original names when restarting from an obfuscated save file. The intended use is the following.
2.13 24.3 Distribution

- Compile (only) a GAMS model into a named and an obfuscated save file:

   \$call gams transport a=c s=0named saveobfuscate=0anon

- Move the obfuscated save file to a non-secure machine and execute it there:

   \$echo * Empty > empty.gms
   \$call gams empty r=0anon s=1anon

- Bring the new (still obfuscated) save file with the results back to the safe machine and do a continued compilation with reporting and export. The continued save file restarts from the obfuscated save file with all the results, etc., but gets a second save file with proper names through option restartNamed:

   \$echo execute_unload 'supply', supply.m; > unload.gms
   \$call gams unload r=1anon restartNamed=0named

In this execution, everything is taken from the obfuscated restart file, except for the symbol and UEL names and the listing file title and subtitle, which are taken from the file specified via restartNamed.

- Allow to load the universe of labels from a GDX file into a set at run-time:

   execute_load 'someFile', someSet=*

   Note, that only labels known to the GAMS program will be loaded.

- Fixed a bug that caused wrong results when evaluating \texttt{prod} (or \texttt{smin/smax}) over an empty set inside \texttt{sum} like in the following example:

   \begin{verbatim}
   sets r / 1 /
   s / 1, 2 /
   rs(r,s) / 1.1 /
   subrs(r,s) / 1.2 /
   scalar z1;
   z1 = sum(rs, prod(subrs(rs), 2));
   display z1;
   \end{verbatim}

- Fixed a bug in calling error logging routine for extrinsic functions from within solvers.

2.13.1.3.2 Function libraries

- The extrinsic function library \texttt{cppcclib} has been expanded to include functions for the PDF and CDF of the trivariate normal distribution. Additionally, documentation for \texttt{cppcclib} has been added to Appendix J of the GAMS User’s Guide and the relevant testlib models cpplib00 thru cpplib05 have been added or updated.

2.13.1.4 Solvers

2.13.1.4.1 ANTIGONE, Bonmin, Cbc, Couenne, SCIP, Sulum

- Solvtrace files now include the GAMS input name (usually GAMS model name with \texttt{.gms} extension stripped) in the header line.
2.13.1.4.2 BARON

- New libraries 14.0.2
  - Significant advances in the handling of integer programs. In addition to several classes of integer cutting planes, calls to MIP solvers and hybrid LP/MIP/NLP relaxations for MINLPs have been added.
  - Complete rewrite of the interfaces to LP solvers.
  - Improvements in probing routines.
  - More robust checks for the validity of the solution of LP/NLP subsolvers.
  - Introduced interfaces to COIN-OR/OSI and CBC 2.8.9.
  - Increased numerical robustness for numerically challenging problems.
  - Systematic treatment of infeasible problems. With the CompIIS option, which by default is 0, the computation of an Irreducible Inconsistent Set (IIS) can be requested. Five different algorithms are available, with corresponding values of CompIIS equal to 1, ..., 5. Algorithm 1 is a fast heuristic, while algorithms 2 through 5 are more time consuming exact algorithms. If an IIS is found, it is reported in the GAMS listing file. BARON does not consider bounds on binary variables to be part of the IIS. For general integers, the option IISint can be be be used to signal that general integers should be considered as potential members of the IIS, i.e, integrality constraints are questioned.
- Fixed handling of BARON termination status when activating DeltaTerm option.

2.13.1.4.3 BONMIN

- Dropped MIP capability (use CBC instead).

2.13.1.4.4 CONOPT

- New libraries 3.16B.
  - The new option Lsusdf was added. If turned on (the default) CONOPT's preprocessor will look for definitional constraints which are constraints of the form \( x = f(y) \) where the bounds on \( x \) are wider than the range of the function \( f \), given the bounds on \( y \). CONOPT will search for and select a maximal set of independent definitional constraints. The dependent variable in a definitional constraints will be selected for the initial basis and CONOPT will try to use the definition to initialize \( x \). There are two other options associated with this procedure: If Lsusdf is enabled (default), then only unique definitional constraints are selected. If it is disabled, then option Lsusdf specifies a limit (default 2) on the number of candidates a definitional constraint can have.
  - The option Lsflush – flush the buffer, has now been implemented and is automatically turned on if there is a systems error.
  - The lower bound on option Rtipvr changed from 1.e-3 to 1.e-10.

2.13.1.4.5 Convert

- The AMPL writer supports special ordered sets, semicontinuous variables, and semiinteger variables now.
- Row names in .lp and .mps files now start with 'e' instead of 'c', so they match the names written by the dict option.
2.13.1.4.6 CPLEX

- New libraries 12.6.0.1.

2.13.1.4.7 CPLEX, SCIP, XPRESS

- Fixed handling of indicator constraints when specified with explicit labels.

2.13.1.4.8 DE

- New option VaRBigM to control the Big M for a Value at Risk reformulation.

2.13.1.4.9 EMPSP

- New keywords VaRUp (=VaR) and VaRLo: These keywords can be used to optimize the Value at Risk for a certain confidence level. The syntax is similar to the one from cVaRUp (=cVaR) and cVaRLo:

  \[
  \text{VaR [rv var] scalar}
  \]

  More information can be found here.

- Changed the order of the parameters for the triangular distribution from

  \[
  \text{randvar <name> triangular <low> <high> <mid>}
  \]

to

  \[
  \text{randvar <name> triangular <low> <mid> <high>}
  \]

2.13.1.4.10 Examiner2

- Fixed a bug in processing special ordered sets.

2.13.1.4.11 GUSS/Scenario Solver

- GUSS/Scenario solver can now be combined with the GAMS Grid Facility (see example GUSSGRID in the GAMS Model Library).

- New option RestartType to determines restart point for the scenarios:
  - 0: Restart from last solution (default)
  - 1: Restart from solution of base case
  - 2: Restart from input point

- New option SolveEmpty (default 0) to limit the number of empty scenarios (no scenario data) that are being solved. When the limit is reached, further empty scenarios will be skipped. Skipped scenarios will be reported to the log and listing file.
2.13.1.4.12 Ipopt

- New libraries.

2.13.1.4.13 Knitro

- As Ziena Optimization has dropped support for Knitro on Solaris (x86) a while ago, we plan to drop GAMS/Knitro on Solaris with the next release.

2.13.1.4.14 Lindo/LindoGlobal

- New libraries 8.0.550.
- LindoGlobal is no longer available for Sparc Solaris (as announced).

2.13.1.4.15 Mosek

- New libraries 7.0.0.121 (Linux, Mac OS X) and 7.0.0.123 (Windows).

2.13.1.4.16 OQNLP

- OQNLP is no longer available for Linux (as announced).

2.13.1.4.17 OS

- GAMS to OSiL conversion now creates more compact instances, especially for quadratic equations and long sums or products in general nonlinear expressions.

2.13.1.4.18 SCIP

- New libraries 3.1 #695c979.
  - Added new primal heuristics "random rounding", "proximity", and "dual value", new branching rule "cloud branching", and new node selectors "breadthfirst" and "uct".
  - Added support for strong branching with domain propagation in full strong and reliability pseudo cost branching.
  - Improved numerical stability (now taking the rank of cuts into account; more checks on LP solution; disabled scaling in feasibility check of nonlinear constraints).
  - Many improvements in presolving.
  - Strong branching LP solutions are now checked for feasibility.
  - Changed or removed parameters:
    * branching/relpscost/maxlookahead: default changed from 9 to 8.
    * branching/relpscost/maxreliable: default changed from 8 to 5.
    * constraints/bivariate/scaling: default changed from TRUE to 'o' (type changed to character).
* constraints/quadratic/scaling: default changed from TRUE to 'o' (type changed to character).
* constraints/soc/scaling: default changed from TRUE to 'o' (type changed to character).
* constraints/varbound/maxlpcoef: default changed from 1E6 to 1E9.
* heuristics/crossover/minnodes: default changed from 500 to 50.
* heuristics/dins/minnodes: default changed from 500 to 50.
* heuristics/feaspump/objfactor: default changed from 1 to 0.1.
* heuristics/rens/minnodes: default changed from 500 to 50.
* heuristics/rins/freq: default changed from -1 to 25.
* heuristics/rins/freqofs: default changed from 5 to 0.
* heuristics/rins/minfixingrate: default changed from 0 to 0.3.
* heuristics/rins/minnodes: default changed from 500 to 50.
* heuristics/shiftandpropagate/sortkey: default changed from 'u' to 'v'.
* lp/checkfeas: replaced by new parameters lp/checkdualfeas and lp/checkprimfeas.
* numerics/dualfeastol: default changed from 1E-6 to 1E-7.
* propagating/dualfix/+: replaced by propagating/dualfix/*
* propagating/pseudoojbj/presoldelay: default changed from TRUE to FALSE.
* propagating/pseudoojbj/timingmask: default changed from 5 to 7.
* propagating/redcost/timingmask: default changed from 2 to 6.
* separating/cgmip/objweighsize: renamed to separating/cgmip/objweightsize and default changed from FALSE to TRUE.
* separating/minefficacyroot: default changed from 0.01 to 0.001.
* separating/closecuts/relintnormtype: removed

2.13.1.4.19 SoPlex

- New libraries 2.0.0.

2.13.1.4.20 XPRESS

- New libraries 26.01.08.

2.13.1.5 Tools

2.13.1.5.1 GDX2SQLITE

- GDX2SQLITE is a new tool to dump the complete contents of a GAMS GDX file into a SQLite database file.

2.13.1.5.2 GDXDUMP

- New option SymbolsAsSet to write the symbol table for a set as data.

2.13.1.5.3 GDXMRW

- New utilities irgdx and iwgdx for exchanging indexed GDX data with Matlab.
2.13.1.5.4 GDXRENAME

- New utility to rename the same unique elements in a GDX file using a mapping given by a second GDX file.

2.13.1.5.5 GDXXRW

- New option to allow the use of R1C1 notation to specify a cell or a range.
- Reading a set using the option \texttt{Values=string} now skips empty cells.

2.13.1.6 Expert Level APIs

2.13.1.6.1 GMO

- Removed previously deprecated function \texttt{gmoDirtyExtractDefVar}.
- Added a number of functions to access information from an EMP info file, to compute the optimality gap, to access extrinsic function libraries, and to get the name of the GAMS input file.

2.13.1.7 Object Oriented APIs

- New example \texttt{transport14}.
- New method \texttt{GAMSSymbolRecord.Key(int index)} (Java: \texttt{GAMSSymbolRecord.getKey}, Python: \texttt{GamsSymbolRecord.key(int index)}) to retrieve the key of \texttt{GAMSSymbolRecord} (Python: \texttt{GamsSymbolRecord}) for a given positional index.
- \texttt{GAMSSymbol.CopySymbol} now works for the universe of a \texttt{GAMSDatabase} (\texttt{GAMSDatabase.GetSet("*")}). When copying into the Universe, a merge will be performed.
- Real domains are now registered when exporting a \texttt{GAMSDatabase} to GDX (so far, only relaxed domains were registered).
- \texttt{GAMSJob.Run} (Python: \texttt{GamsJob.run}) now creates \texttt{OutDB} (Python: \texttt{out_db}) also if it raises a \texttt{GAMSExceptionExecution}.
- \texttt{GamsModelInstance.Solve} (Java/Python: \texttt{GamsModelInstance.solve}) now also works for solvers which require a subsolver, e.g., DICOPT.

2.13.1.7.1 .NET

- Fixed default value for \texttt{systemDirectory} argument in \texttt{GAMSWorkspace} constructor when using MONO: If no value is given, first the \texttt{PATH} and then the \texttt{(DY)LD_LIBRARY_PATH} is checked for a valid GAMS system directory.
2.13.1.7.2 Java

- It is no longer necessary to specify `-Djava.library.path` when running a program. If `java.library.path` is specified, the shared libraries will be loaded from `java.library.path`. Otherwise, the shared libraries will be loaded from the class path that contains `GAMSJavaAPI.jar`.

- It is no longer necessary to set up environment variables (`PATH`, `(DY)LD_LIBRARY_PATH`) before running a program to find the GAMS system directory, as it can now be specified during run time.

- In the `GAMSWorkspace` default constructor, the default setting for finding the GAMS system directory from environment variables in the following order (depends on the target platform) are applied:
  - Windows: first from `PATH` environment variable. If not found, then from the Windows registry `$gams.location`.
  - Mac OS X: first from `PATH` environment variable. If not found, then from `DYLD_LIBRARY_PATH`.
  - other Unix: from `PATH` environment variable. If not found, then from `LD_LIBRARY_PATH`.

- In the non-default `GAMSWorkspace` constructor, the following rules are applied:
  - In case a user specifies a system directory, the API will verify the directory and will not search for GAMS system directory from an environment variable, even when the directory is invalid.
  - In case the specified system directory is `null` or a user does not specify a system directory, the API will apply the default setting from above.

- A memory leak in `GAMSDatabaseIterator` has been closed.

- Issues when using a non-standard locale (`LANG` environment variable) have been fixed.

- All deprecated classes and methods since 24.1 have been removed.

2.13.1.7.3 Python

- New behavior on determining a system directory automatically when a workspace is created.
  - Linux: If no system directory is specified in the `GamsWorkspace` constructor, check `PATH` first. If no system directory was found, check `LD_LIBRARY_PATH`.
  - Mac OS X: If no system directory is specified in the `GamsWorkspace` constructor, check `PATH` first. If no system directory was found, check `DYLD_LIBRARY_PATH`.
  - Windows: If no system directory is specified in the `GamsWorkspace` constructor, check the Windows registry.

2.13.1.8 Model Libraries

2.13.1.8.1 GAMS Data Library

- `MakeQL`: Moved querylibrary generator into `trisource.zip`, which comes with Test Library models `trilib01`, `trilib02`, `trilib03`, and `trilib04`. Removed `MakeQL` model.

- `invert1.gms`: Matrix inversion via R (89)

- `invert2.gms`: Matrix inversion via Matlab (90)
2.13.1.8.2 GAMS Model Library

- **clad.gms**: Computation of Fairs extramarital affairs model estimates (397)
- **gussex1.gms**: Simple GUSS example (398)
- **gussrisk.gms**: Simple investment example with varying weight for risk using GUSS (399)
- **gussgrid.gms**: Simple GUSS Grid example (400)
- **circpack.gms**: Pack circles in the smallest possible rectangle (401)
- **tablelayout.gms**: Configuring text layout in table cells to minimize table height (402)
- **asyncjobs.gms**: Execute asynchronously several GAMS jobs and collect the fastest (403)

2.13.1.8.3 GAMS Test Library

- **trilib01**: Reworked triclib.c source code. Rewrote querylibrary generator.
- **single01.gms**: Check handling of singleton sets (639)
- **execerr1.gms**: Test for execerr option (640)
- **single02.gms**: Check assignment to singleton sets (641)
- **scensol4.gms**: Basic GUSS Test (642)
- **gdxmrw06.gms**: run a battery of GDXMRW tests (643)
- **single03.gms**: Check singleton sets in put statement (644)
- **unload11.gms**: Check that GAMS does not crash when writing to non-existing folder (645)
- **refact00.gms**: Check that GAMS produces expected workfile with option sys14=1 (646)
- **refact01.gms**: Refactor suite test 1 (647)
- **scenempty.gms**: Empty scenario GUSS Test (648)
- **obfusc01.gms**: Test use if obfuscated workfile (649)
- **load11.gms**: Load UEL Table (650)
- **gussskip.gms**: Simple GUSS example with skipped scenario (651)
- **refact02.gms**: Refactor suite test 2 (653)
- **cpplib03.gms**: Test extrinsic functions in cppcclib (654)
- **cpplib04.gms**: Test extrinsic functions in cppcclib (655)
- **cpplib05.gms**: Test extrinsic functions in cppcclib (656)
- **cpplib00.gms**: Test build of CPP library (657)
- **syschk2.gms**: Test impact of sys10 setting (658)
- **scenol5.gms**: Test handling of scenario dictionary sets with more than 50 entries (659)
- **call5.gms**: Check that gams works with COMSPEC unset (660)
- **idxoper1.gms**: Test indexed operations (661)
- **gdxsqlite1.gms**: Test basic functionality of GDX2SQLITE tool (662)
2.13.2 24.3.2 Minor release (August 29, 2014)

2.13.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Alvaro Lorca Galvez, Scott McDonald, Tom Rutherford, Nick Sahinidis, and Uwe Schneider.

2.13.2.2 GAMS System

2.13.2.2.1 GAMS

- Allow empty scalar data statements:

  ```
  $onempty
  scalar xyz / /;
  ```

2.13.2.2.2 Extrinsic Function libraries

- Pass on parameter file name via LibInit call.

2.13.2.3 Solvers

2.13.2.3.1 BARON

- New libraries 14.0.3.

2.13.2.3.2 CBC

- New libraries.

2.13.2.3.3 CONOPT

- New libraries 3.16C.
  - Added checks for internal intermediate results being NaN (Not A Number). If this happens, CONOPT will stop and return a message about it. The solver status will return 4 "Terminated by Solver" and model status 6 or 7, "Intermediate Infeasible" or "Intermediate Feasible."

2.13.2.3.4 CONVERT

- Fixed bug in interval evaluations for functions and gradients.
- The interval evaluations are now triggered by their own option (e.g. `intervalEval=yes`) instead of being part of every Jacobian or Hessian dump.
2.13.2.3.5  Cplex

- Some Cplex tuning parameters had no or the wrong effect. This has been fixed.
- The BCH usercutcall was not called in case of new constrains only for true cuts (see e.g. GAMS Model library model bchtsp). This has been fixed.

2.13.2.3.6  Examiner2

- Fixed error in processing options file.
- Fixed error in trace file generation.

2.13.2.3.7  Ipopt

- New libraries.

2.13.2.3.8  Mosel

- New libraries 7.0.0.126.
  - Fixed an issue with using the Mosel extended license for MIP solving on Mac OS X.

2.13.2.3.9  Osi links

- Fixed writing MPS files with row and column names.

2.13.2.3.10  SCIP

- New libraries 3.1 #322574a
  - Changed default of option heuristics/proximity/minimprove from 0.25 to 0.02.
  - Changed default of option heuristics/proximity/usefinallp from TRUE to FALSE.

2.13.2.3.11  XPRESS

- New libraries 26.01.14 for Linux and Windows.

2.13.2.4  Tools

2.13.2.4.1  GDXDUMP

- When generating $GDXIN filename, the filename now includes the full path of the GDX input file.
2.13.2.4.2 GDXXRW

- In the previous release, we changed the behavior that when reading with \texttt{Values=String}, the empty cells no longer created an entry. Because reading with this option was the default for the cases with \texttt{RDim=0} or \texttt{CDim=0}, we changed this default to \texttt{Values=NoData} in order not to break existing code.

2.13.2.4.3 Shellexecute

- Fixed error causing problems during parameter processing.

2.13.2.5 Expert Level APIs

- Delphi: Distinguish between 32 bit and 64 bit compiler.

2.13.2.6 Object Oriented APIs

- Make more GAMS options available through the GAMSOptions class:
  - GAMSOptions.AppendExpand: Expand file append option
  - GAMSOptions.AppendOut: Output file append option
  - GAMSOptions.DumpOpt: Writes preprocessed input to the file input.dmp
  - GAMSOptions.DumpParms: GAMS parameter logging
  - GAMSOptions.ErrMsg: Placing of compilation error messages
  - GAMSOptions.Expand: Expanded (include) input file name
  - GAMSOptions.FErr: Alternative error message file
  - GAMSOptions.JobTrace: Job trace string to be written to the trace file at the end of a Gams job
  - GAMSOptions.LimCol: Maximum number of columns listed in one variable block
  - GAMSOptions.LimRow: Maximum number of rows listed in one equation block
  - GAMSOptions.LogLine: Amount of line tracing to the log file
  - GAMSOptions.On115: Generate errors for unknown unique element in an equation
  - GAMSOptions.Output: Output file
  - GAMSOptions.PageContr: Output file page control option
  - GAMSOptions.PageSize: Output file page size (=0 no paging)
  - GAMSOptions.PageWidth: Output file page width
  - GAMSOptions.Reference: Symbol reference file
  - GAMSOptions.ScriptExit: Program or script to be executed at the end of a GAMS run
  - GAMSOptions.Suppress: Compiler listing option
  - GAMSOptions.Symbol: Symbol table file
  - GAMSOptions.TraceLevel: Solvestate threshold used in conjunction with a=GT

2.13.2.7 Model Libraries

2.13.2.7.1 GAMS Data Library

- Fixed some errors in some Matlab examples.
2.13.3 24.3.3 Minor release (September 19, 2014)

2.13.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Henrik Dahl.

2.13.3.2 Solvers

2.13.3.2.1 ANTIGONE, Bonmin, CBC, Couenne, Ipopt, SCIP

- Fixed issue loading MKL libraries on Linux machines with AVX2 instruction set.

2.13.3.3 Tools

2.13.3.3.1 ASK, GDXVIEWER, SQL2GMS, XLS2GMS

- Fixed problem with character set used for error messages.

2.13.3.3.2 GDXXRW

- Fixed error when reading special values from Excel.

2.13.3.3.3 MDB2GMS, SQL2GMS

- Fixed problem when using comma as decimal separator.

2.13.3.4 Object Oriented APIs

2.13.3.4.1 Java

- Fixed a location of listing file when creating a job from (full-path) file without giving a job name.
2.14 24.2 Distribution

2.14.1 24.2.1 Major release (December 09, 2013)

2.14.2 24.2.2 Maintenance release (March 04, 2014)

2.14.3 24.2.3 Maintenance release (May 22, 2014)

2.15 24.1 Distribution

2.15.1 24.1.1 Major release (May 30, 2013)

2.15.2 24.1.2 Maintenance release (June 16, 2013)

2.15.3 24.1.3 Maintenance release (July 26, 2013)

2.16 24.0 Distribution

2.16.1 24.0.1 Major release (December 24, 2012)

2.16.2 24.0.2 Maintenance release (February 14, 2013)

2.17 23.9 Distribution

2.17.1 23.9.1 Major release (July 04, 2012)

2.17.2 23.9.2 Maintenance release (August 29, 2012)

2.17.3 23.9.3 Maintenance release (September 26, 2012)

2.17.4 23.9.4 Maintenance release (October 20, 2012)

2.17.5 23.9.5 Maintenance release (November 09, 2012)

2.18 23.8 Distribution

2.18.1 23.8.1 Major release (March 17, 2012)

2.18.2 23.8.2 Maintenance release (April 05, 2012)

- Bugfix for models with =X= rows and MCP (i.e. MPSGE)
- GloMIQO resets OptCR=0 properly to 1e-9 and accepts now Ctrl-C on Windows
- Knitro handles MINLP failures better
- XPRESS handles =E= quadratic constraints better now
- Changed position of Library Form in GAMSIDE (avoid hang in corner to corner screen setup)
- Model Trnsxc11 added to GAMS Data Library
- Model ps5.a.mn added to GAMS Model Library
2.19 23.7 Distribution

2.19.1 23.7.1 Major release (July 14, 2011)

2.19.2 23.7.2 Maintenance release (July 22, 2011)

- Alphaecp: Alphaecp v2.04.02
- Conopt3: Fixed a system error 2003
- Dicopt: Fixed a bug for accidentally determined crossovers
- Inclib: put_reorderit.gms update from Bruce McCarl
- Cbc: Disabled preprocessing in case of semicon/semiint variables, it seems buggy
- Cplex: Does no longer require finite bounds on semicon variables
- Gamsinst: Fix problem with blanks in sysdir and IDE error when not having a license

2.19.3 23.7.3 Maintenance release (August 23, 2011)

- alphaecp: fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
- apifiles:
  - get rid of warnings in cc interface,
  - fix problem with compilation of fat binaries on Darwin in cc interface
  - fix error in gdxSymbolGetDomain in Python interface
  - fix errors with constant definitions in C# interface
  - add constant definitions and additional constructor (which gets a handle) in Java interfaces
- conopt3: Version 3.15A maintenance release
- cplex:
  - fix for interrupt (Ctrl-C) when running with solvelink=5
  - fix memory leak
- dicopt:
  - fix reporting of objest in case of a crossover
  - fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
- gamscmex: fix bug related to the internal organization of non-linear code, affects two-argument functions in rare cases
- gamside:
  - close chart files too when changing system directory
  - GAMS project file name independent of casing
- gdxdump: suppress on/off empty when writing single symbol
- gdxmrw: was missing on 64bit Linux
- grid: fix potential problem with scaling
• kestrel: added Xpress support
• minos fix: for interrupt (Ctrl-C)
• sbb: fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
• snopt fix: for interrupt (Ctrl-C)
• xpress: update global search to use callbacks called during root node processing and improve scheme to stop XPRESS when gap is achieved or on user interrupt

2.20 23.6 Distribution

2.20.1 23.6.2 Major release (December 13, 2010)

2.20.2 23.6.3 Maintenance release (February 15, 2011)

• Cmex: Fix for variable level projection
• Bonmin: Several fixes for outer-approximation based algorithms
• Cplex: New version 12.2.0.2
• Gurobi: New version 4.0.1
• Knitro: Documentation update
• Scip: New version 2.0.1
• Xpress: Fix for crash on 64 bit Solaris
• McCarl Guide: Updates for 23.6
• Gdxxrw: Includes system error message when we cannot start Excel
• Gdxmrw: Minor bugfixes

2.20.3 23.6.4 Maintenance release (April 01, 2011)

• CMEX: Maximal nested includes were raised to 40
• Mosek: New Version6 Rev 105
• Lindoglobal: New Version 6.1.1.553
• Conopt: New Version 3.14W
• Xpress: Memory leak fix
• Coin: Solver fixes
• JAMS: Updates for disjunctions
• GDXXRW: Fixes
• GDXMRW: Updates
• McCarl and GDXUtils: Documentation updates
• Model Libraries: Updates
2.20.4  23.6.5 Maintenance release (April 08, 2011)

- CMEX: Bug fix related to situations with very large number of labels in connection with a restart with continued compilation

2.21  23.5 Distribution

2.21.1  23.5.1 Major release (July 05, 2010)

2.21.2  23.5.2 Maintenance release (August 18, 2010)

- AlphaECP: Fix for crash running under IDE
- API: Updated Python and Java APIs and examples
- Baron: Fixed issue with output formatting under Linux
- Baron: Memory leak when using BARON with external NLP solver
- Gdxmerge: Do not use path when checking for merged.gdx
- Gurobi: Fixed typo for option displayinterval
- McCarl Guide: Updates for 23.5
- Mosek 6 rev 85 libraries
- MPS2GMS: Removed mps2gms debug message
- Snopt: Fix for wrong return code (local,global)
- Xlsdump utility added

2.22  23.4 Distribution

2.22.1  23.4.1 Major release (May 21, 2010)

2.22.2  23.4.3 Maintenance release (May 24, 2010)

2.23  23.3 Distribution

2.23.1  23.3.1 Major release (November 01, 2009)

2.23.2  23.3.2 Maintenance release (November 18, 2009)

- Gurobi 2.0.1 library with bug fixes
- MOSEK 6 rev 53 library with bug fixes
- Updated CoinOS library with bug fixes
- Solver optfile bug fix in GAMSCHK
- Synchronized tolproj (1e-8) option for solvemethod=3
2.23.3 23.3.3 Maintenance release (December 17, 2009)

- MOSEK 6 rev 55 library with bug fixes
- 32bit HAR utilities available in 64bit Windows System
- Slow solution reporting in GAMS/Gurobi and other solvers fixed

2.24 23.2 Distribution

2.24.1 23.2.1 Minor release (August 14, 2009)

2.25 23.1 Distribution

2.25.1 23.1.1 Major release (July 13, 2009)

2.25.2 23.1.2 Maintenance release (July 23, 2009)

- MPSGE: MPSGE ignored the m.workspace and m.workfactor settings
- GAMSCHK: Fixed a problem with the layout of the reports in some models

2.26 23.0 Distribution

2.26.1 23.0.2 Major release (February 14, 2009)

2.27 22.9 Distribution

2.27.1 22.9.2 Major release (December 01, 2008)

2.28 22.8 Distribution

2.28.1 22.8.1 Major release (August 01, 2008)

2.29 22.7 Distribution

2.29.1 22.7.1 Major release (May 01, 2008)

2.29.2 22.7.2 Maintenance release (May 13, 2008)

- DICOPT/ALPHAECP/LOGMIPLBOA: Fixed Cplex scaling bug
- GAMS/CPLEX: Small cosmetic Cplex bug fix. We got "CPLEX Error 3003: Not a mixed-integer problem." In case we cannot solve the fixed problem. This was due to some query calls about nodes and iteration.
- GAMSIDE: Fixed a bug that could cause an out of memory error when moving a row or column to the plane index in the gdx data viewer
- GAMS/DEA: Avoid writing zeros to GDX files
- GAMS/LGOLIB: Fixed a memory leak
- Minor documentation updates
- Note: AIX and Mac OS X PPC were not updated.
2.30 22.6 Major release (December 24, 2007)
2.31 22.5 Major release (June 01, 2007)
2.32 22.4 Major release (February 12, 2007)
2.33 22.3 Major release (November 27, 2006)
2.34 22.2 Minor release (April 21, 2006)
2.35 22.1 Major release (March 15, 2006)
2.36 22.0 Major release (August 01, 2005)
2.37 21.7 Major release (April 01, 2005)
2.38 21.6 Minor release (January 26, 2005)
2.39 21.5 Minor release (November 11, 2004)
2.40 21.4 Major release (September 06, 2004)
2.41 21.3 Major release (January 19, 2004)
2.42 21.2 Maintenance release (September 03, 2003)
2.43 21.1 Maintenance release (June 02, 2003)
2.44 21.0 Major release (May 15, 2003)
2.45 20.7 Maintenance release (June 14, 2002)
2.46 20.6 Major release (May 25, 2002)
2.47 20.5 Maintenance release (January 28, 2002)
2.48 20.4 Maintenance release (January 21, 2002)
2.49 20.3 Major release (December 24, 2001)
2.50 20.2 Maintenance release (November 22, 2001)
2.51 20.1 Major release (October 31, 2001)
Chapter 3

User's Guide

This documentation guides GAMS users through several topics in the GAMS system.

3.1 Preface

- Preface

3.2 Installation and Licensing

This part leads step by step through the installation process on three main platforms and describes the GAMS licensing system:

- Supported Platforms
- Installation Notes for Mac OS X
- Installation Notes for Unix
- Installation Notes for Windows
- Licensing

3.3 Tutorials and Examples

This part describes step by step through several selected tutorials and a small number of examples.

- A GAMS Tutorial by Richard E. Rosenthal
- Quick Start Tutorial
- Good Coding Practices
- Fixing Compilation Errors
- Finding and Fixing Execution Errors and Performance Problems
• Comparative Analyses with GAMS
• Good NLP Formulations
• Data Exchange with Other Applications
  – Data Exchange with Text Files
  – Data Exchange with Microsoft Excel
  – Data Exchange with Databases
• Executing GAMS from other Environments

There are also tutorials and examples of the Application Programming Interfaces

• .NET Tutorial and Examples
• C++ Tutorial and Examples
• Java Tutorial and Examples
• Python Tutorial and Examples

3.4 GAMS Language and Environment

This part introduces the components of the GAMS language in an ordered way, interspersed with detailed examples that are often drawn from the model library.

• Introduction - an introductory to GAMS User’s Guide.
• GAMS Programs - The structure of the GAMS language and its components
• Set Definition - The declaration and initialization of sets, subsets, and domain checking.
• Dynamic Sets - The membership assignment, the usage of dollar controls, and set operations.
• Sets as Sequences: Ordered Sets - Special features used to deal with a set as if it were a sequence.
• Data Manipulations with Parameters - The declaration and assignment of GAMS parameters.
• Data Entry: Parameters, Scalars and Tables - Three basic forms of GAMS data types: Parameters, Scalars and Tables.
• Variables - The declaration and attributes of GAMS variables.
• Equations - The definition and declaration of GAMS equations.
• Model and Solve Statements Model - The specificiation of a GAMS model and how to solve it.
• Conditional Expressions, Assignments and Equations - The conditional assignments, expressions and equations in GAMS.
• The Display Statement - The syntax, control, and label order in display.
• Programming Flow Control Features - The GAMS programing flow control features: loop, if-elseif, while, and for statements.
• The Option Statement - The list and detailed description of options.
• System Attributes - The system attributes
• The Grid and Multi-Threading Solve Facility - The basic concepts and Grid Features.
Special Features for Mathematical Programs - Special features in GAMS that do not translate across solvers, or are specific to certain model types.

The following discusses the execution of GAMS, the use of special features, and other miscellaneous topics.

- **GAMS Output** - The control of GAMS compilation output, execution output, output produced by a solve statement, and error reporting.
- **The GAMS Call and Command Line Parameters** - The list and detailed description of GAMS command line parameters.
- **Dollar Control Options** - The list and detailed description of dollar control options.
- **The Put Writing Facility** - The put writing facility of the GAMS language.
- **Solver Usage** - Controlling solvers.
- **The Save and Restart Feature** - The GAMS save and restart feature and the work file.
- **Embedded Code Facility** - The Embedded Code Facility (e.g. how to embed Python code into GAMS).
- **Extrinsic Functions** - The extrinsic function library and comparison with external equations.
- **External Equations** - A facility for connecting code written in different programming languages to equations and variables in a GAMS model.
- **GAMS Return Codes** - The structure of error codes, the return codes of the GAMS compiler and execution system, and the driver return codes.
- **GAMS Data eXchange (GDX)** - GAMS Data eXchange (GDX) facilities and utilities for Binary Data Exchange.
- **Extended Mathematical Programming (EMP)** - Extended Mathematical Programming (EMP).
- **Accessing Model Libraries** - Introduction of GAMS Model Library.
- **Mathematical Programming System for General Equilibrium analysis (MPSGE)** - A mathematical programming system for general equilibrium analysis which operates as a subsystem within GAMS.
  - Introduction to MPSGE
  - MPSGE Models in GAMS
  - Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE
  - Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae
  - A Library of Small Examples for Self-Study
  - Comparing the Performance of Flexible Functional Forms
  - General Equilibrium with Public Goods
  - Kevin O’Rourke: CGE and Economic History
  - Linking Implan Social Accounts to MPSGE
  - A partial list of publications based on MPSGE
  - The MPSGE guide is also available as PDF

### 3.5 Glossary

An alphabetically list of GAMS terms is available in the Glossary.
3.6 McCarl GAMS User Guide

The McCarl GAMS User Guide (CHM and PDF) can be found in the mccarl/ subdirectory in the distribution as well as contributed documentations under Bruce McCarl's Collection section.

3.7 Preface

The GAMS documentation has changed considerably since it was first released in 1988: in format, in scope and content, and in how it is distributed and accessed. At the same time, it maintains many elements of the original style: part tutorial, part user's guide, and part reference manual. We describe here the evolution of the GAMS documentation and related topics.

The first published GAMS documentation is the book GAMS: A User's Guide (aka the "red book") by Brooke, Kendrick, and Meeraus, published in 1988 by The Scientific Press. Copies were sold at bookstores, and like all the others, it included a chapter on the model library (100 models at that time), a much-appreciated and well-used index, appendices describing the solvers available (MINOS and ZOOM), and a 5.25 inch floppy disk containing a student version of "PC-GAMS version 2.05". This was followed up in 1992 with GAMS: A User's Guide, Release 2.25 (aka the "blue book") by a different publisher (Boyd & Fraser), a soft cover, and no floppy disk: by this time the software was available directly from GAMS. The final section of installation notes in the red book was replaced in the blue book by notes on the new features in GAMS 2.25, but the content was otherwise unchanged.

As the pace of development increased, it became clear that we needed a new documentation scheme, one that would allow us to update the document continuously as language features, models and model libraries, solvers, and tools/utilities were added to or updated in the system. Consequently, we converted the existing documentation to MS Word, expanded, updated, and edited it as appropriate, and sent it to the copy shop to be printed. This was a group effort spearheaded by Ramesh Raman, whose name was included as an author in the User's Guide first included (along with a CD) in shipments of our 18.0 release in Feb 1999. The solver manuals in this release were collected from various sources (with varying styles, content, and organization) and put into a separate binder. A further push was required to unify this solver documentation (using LaTeX) to use a common style and organization: this unified Solver Manual was included with the 21.0 release of May 2003. In addition to hard-copy, all of these documents were included as PDF in the GAMS system and freely available via the Web. Thus, the shift away from published documentation to manuals produced in-house went hand-in-hand with a shift from printed documents to viewing and searching PDF documents.

During this time Bruce McCarl had been regularly teaching GAMS courses: basic and advanced, targeting a general audience but with a distinct flavor of agricultural economics. As part of this he developed course material to use in his classes, and he was in a good position to notice that the GAMS User Guide was not...
keeping up with all the updates to the software. With some encouragement from GAMS, Bruce started
the ambitious project of creating a new GAMS User's Guide, one that would be more complete, more to
his taste with an increase in tutorial flavor, and designed to take full advantage of being a Web document:
linked, cross-referenced, searchable, and indexed. The end result was the McCarl Guide that emerged as a
PDF based on a Word document in 2002. This was redone in the more convenient CHM format with the
22.1 release of Mar 2006 and renamed as the Expanded GAMS Guide (McCarl) in release 22.3 of Nov
2006. We also kept the original GAMS User's Guide, by this time as PDF generated from LaTeX source.
With its improved content, organization, and navigability, Bruce's new guide was a boon to all GAMS
users, not just those taking his courses. We owe a debt of gratitude to Bruce for this and many other
contributions.

The Expanded GAMS Guide (McCarl) was never intended to be printed and was not shipped as hard-copy
with GAMS. In 2013, GAMS stopped making physical shipments altogether and moved to an online
order-fulfillment system. For those who still wanted printed documentation, the documents were also
made available via Amazon's CreateSpace, but most users browsed the documents online or as part of
an installed GAMS system, often via the GAMS IDE, so the need for printable documents was small and
growing smaller.

Having two user's guides was counter-intuitive or confusing for some users, especially when the content for
some topics was different, missing, or even contradictory. The additional effort required to maintain two
documents became more noticeable, especially since the Expanded User Guide (McCarl) was implemented
using a Windows-only product that did not lend itself to version control via SVN or git. When we
documented our object-oriented APIs in Feb 2013, we used the opportunity to experiment with a doxygen-
based authoring process that uses text files as source, is platform-independent, and produces output in
multiple formats. The results were good, and in 2015 we hired a consultant, Martha Loewe, to research
what it would take to convert all of the GAMS documentation to use the doxygen-based process and to
set up a framework for this. We eventually committed fully to this process and produced a unified set
of documentation as of release 24.9 in Aug 2017. This involved reorganizing things somewhat to better
fit a linked document, merging the two user guides into one (while trying to maintain the best qualities
of each), adding links throughout, and submitting everything to review and editing by internal subject
matter experts so the content is accurate, updated, and complete. The end result is something we believe
is an improvement over its predecessors, but it is also something we are committed to maintaining and
improving. The current system allows and encourages immediate updates by the whole GAMS team and
has helped foster a culture and attitude where this takes place.

### 3.7.1 Timeline for documentation released with GAMS software

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Month/Year</th>
<th>Change</th>

</table>

### 3.8 Supported Platforms

GAMS divides the set of supported platforms into so-called *core* platforms and *peripheral* platforms to recognize and better describe how the two sets of platforms have evolved. The user communities for core platforms are large, active, and well-identified, but not so for the peripheral platforms. For the core platforms, GAMS will continue to make each new release of GAMS directly available for download, while the peripheral platforms will be available by request only. Finally, changes in the availability of core platforms will be announced well in advance of the event, while changes to support for peripheral platforms may occur with little or no notice.

The core platforms are the following:

<table>
<thead>
<tr>
<th>Core Platform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x86 64 bit Linux</td>
<td>AMD- or Intel-based 64-bit (x86,64) Linux systems with glibc 2.12 or higher.</td>
</tr>
<tr>
<td>x86 64 bit Mac OS X</td>
<td>Intel-based 64-bit (x86,64) Macintosh system with OS X 10.12 (Sierra) or higher.</td>
</tr>
<tr>
<td>x86 32 bit MS Windows</td>
<td>Windows 7 or newer on AMD- or Intel-based (x86,32) architectures.</td>
</tr>
<tr>
<td>x86 64 bit MS Windows</td>
<td>Windows 7 or newer on AMD- or Intel-based (x86,64) architectures.</td>
</tr>
</tbody>
</table>

**Note**

Compared to most of the GAMS system, **GAMS Studio** has some additional system requirements which are detailed [here](#).

The peripheral platforms are the following:

<table>
<thead>
<tr>
<th>Peripheral Platform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerPC 64 bit AIX</td>
<td>PowerPC based 64-bit (ppc,64) AIX system. Built on AIX 7.1.</td>
</tr>
<tr>
<td>Sparc 64 bit Solaris</td>
<td>Sparc-based 64-bit (sparc,64) Solaris system. Built on Solaris 10.</td>
</tr>
</tbody>
</table>

While the GAMS execution system itself is available on all supported platforms, for certain solvers, tools, and APIs, different availabilities can apply. For details, see

- [Supported Platforms for Solvers](#)
- [Supported Platforms for Tools](#)
• Supported Platforms for High-level APIs
• Supported Platforms for Low-level APIs

3.9 Installation Notes for Mac OS X

To install GAMS, please follow the steps below as closely as possible. We advise you to read this entire document before beginning the installation procedure. Furthermore, we recommend to use the DMG installer for Mac OS X because it includes the GAMS Studio and it integrates GAMS into Mac OS X, e.g. it is possible to open the GAMS Studio and GAMS Terminal via Launchpad.

Two installation procedures are available for GAMS on Mac OS X:

• Installation using the DMG installer (GAMS27.3.0.dmg)
• Installation using the self-extracting archive (osx_x64_64.sfx.exe)

Additionally, there are instructions on how to install the GAMS Windows version using Wine.

3.9.1 Installation using the DMG installer (GAMS27.3.0.dmg)

1. Obtain the GAMS DMG file, which is available from http://www.gams.com/download.
2. Mount the downloaded file by double clicking.
3. If the mounted device does not open automatically, open it manually by double clicking on the device.
4. Drag the GAMS icon onto the Applications folder in order to copy the files to your Applications.
5. Optionally, create the license file gamslice.txt in the GAMS system directory. The license file is nowadays sent via email, with instructions. If no license file is present, GAMS will still function in the demonstration mode but can only solve small problems. Student and demonstration systems do not include a license file. A license file can easily be added later, so if you cannot find a license file, you can safely proceed without one.
6. In order to test the GAMS installation with GAMS Studio open the Launchpad and click the GAMS Studio icon to open the application. Alternatively, go to Applications and open the GAMS Studio application found in the GAMS installation directory. Open the Model Library Explorer and open the TRANSPORT model (sequence number 001). Execute the model and review the content of the process log, which shall be similar to the output of the GAMS Terminal application listed below in bullet point 7.
7. In order to test the GAMS installation without using GAMS Studio open the Launchpad and click the GAMS Terminal icon to open the application. Alternatively, go to Applications and open the GAMS Terminal application found in the GAMS installation directory. This small application opens a new terminal, adds the GAMS system directory to the PATH environment variable, and changes the current directory to the home directory. Execute the following commands to see if everything works as expected:

    gamslib trnsport
    gams trnsport

    The output should be similar to this:
--- Job trnsport Start 06/26/14 11:24:56 24.3.1 r46409 DEX-DEG Mac x86_64/Darwin

3.9.2 Installation using the self-extracting archive (osx_x64_64_sfx.exe)

For this procedure, an additional video is available at https://www.youtube.com/watch?v=OLtvjc0ZkTM.

1. Obtain the GAMS distribution file, which is available from http://www.gams.com/download, in one large self-extracting zip archive with a .sfx.exe file extension, e.g., osx_x64_64_sfx.exe. Check that it has the execute permission set. If you are not sure how to do this, just type in the command chmod 755 osx_x64_64_sfx.exe.

2. Choose a location where you want to create the GAMS system directory (the GAMS system directory is the directory where the GAMS system files should reside). At this location the GAMS installer will create a subdirectory with a name that indicates the distribution of GAMS you are installing. For example, if you are installing the 24.3 distribution in /Applications/GAMS, the installer will create the GAMS system directory /Applications/GAMS/gams24.3_osx_x64_64_sfx. If the directory where you want to install GAMS is not below your home directory, you may need to have root privileges on the machine.
3. Create the directory that should contain the GAMS system directory, for instance
/Applications/GAMS. Change to this directory (cd /Applications/GAMS). Make sure pwd
returns the name of this directory correctly.

4. Run the distribution file, either from its current location or after transfering it to the directory
that should contain the GAMS system directory. By executing the distribution file, the GAMS
distribution should be extracted. For example, if you downloaded the distribution file into your
home directory, you might execute the following commands:

  mkdir /Applications/GAMS
cd /Applications/GAMS
~/osx_x64_64_sfx.exe

5. Optionally, create the license file gamslice.txt in the GAMS system directory. The license file is
nowadays sent via email, with instructions. If no license file is present, GAMS will still function in
the demonstration mode but can only solve small problems. Student and demonstration systems do
not include a license file. A license file can easily be added later, so if you cannot find a license file,
you can safely proceed without one.

6. Change to the GAMS system directory and run the program ./gamsinst. It will prompt you for
default solvers to be used for each class of models. If possible, choose solvers you have licensed since
unlicensed solvers will only run in demonstration mode. These solver defaults can be changed or
overridden by:
   a. rerunning ./gamsinst and resetting the default values
   b. setting a command line default, e.g., gams trnsport lp=bdmlp
   c. an option statement in the GAMS model, e.g: option lp=bdmlp;

7. Add the GAMS system directory to your path (see below).

8. To test the installation, log in as a normal user and run a few models from your home directory, but
not the GAMS system directory:

   LP:  trnsport (objective value: 153.675)
   NLP: chenery (objective value: 1058.9)
   MIP:  bid (optimal solution: 15210109.512)
   MINLP: procsel (optimal solution: 1.9231)
   MCP:  scarfmcp (no objective function)
   MPSGE: scarfge (no objective function)

9. If you move the GAMS system to another directory, remember to rerun ./gamsinst. It is also good
practice to rerun ./gamsinst when you add or change your license file if this has changed the set of
licensed solvers.

3.9.2.1 Access to GAMS

To run GAMS you must be able to execute the GAMS programs located in the GAMS system directory.
There are several ways to do this. Remember that the GAMS system directory in the examples below
may not correspond to the directory where you have installed your GAMS system.

1. If you are using the C shell (csh) and its variants you can modify your .cshrc file by adding the
second of the two lines given below:

        set path = (/your/previous/path/setting )
set path = ( $path /Applications/GAMS/gams24.3_osx_x64_64_sfx ) # new

2. Those of you using the Bourne (sh) or Korn (ksh) shells and their variants can modify their .profile
file by adding the second of the three lines below:

PATH=$PATH:/Applications/GAMS/gams24.3_osx_x64_64_sfx # new export PATH

If the .profile file does not exist yet, it needs to be created. You should log out and log in again after you have made any changes to your path.

3. You may prefer to use an alias for the names of the programs instead of modifying the path as described above. C shell users can use the following commands on the command line or in their .cshrc file:

```bash
alias gams /Applications/GAMS/gams24.3_osx_x64_64_sfx/gams
alias gamslib /Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib
```

The correct Bourne or Korn shell syntax (either command line or .profile) is:

```bash
alias gams=/Applications/GAMS/gams24.3_osx_x64_64_sfx/gams
alias gamslib=/Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib
```

Again, you should log out and log in in order to put the alias settings in .cshrc or .profile into effect.

4. Casual users can always type the absolute path names of the GAMS programs, e.g.:

```
/Applications/GAMS/gams24.3_osx_x64_64_sfx/gams trnsport
```

### 3.9.2.2 Example

The following shows the log of a session, where a user downloads a GAMS 24.3.1 system and installs it under Applications/GAMS/gams24.3_osx_x64_64_sfx. It is assumed that a GAMS license file has been stored as /Users/doe/gamsinst.txt.

```
doe@mac:/Users/doe$ curl -L -k -O http://d37drm4t2jghv5.cloudfront.net/distributions/24.3.1/macosx/osx_x64_64_sfx.exe
% Total    % Received % Xferd Average Speed Time Time Time Current
          0      0  148M     0          0            0           0            0          0:00:34 0:00:34 --:--:--  5906k

doe@mac:/Users/doe$ chmod 755 osx_x64_64_sfx.exe

doe@mac:/Users/doe$ cd /Applications/GAMS

```
inflating: gams24.3_osx_x64_64_sfx/apifiles/CSHarp/xp_example2.cs
inflating: gams24.3_osx_x64_64_sfx/optdicopt.html

doe@mac:/Applications/GAMS$cd gams24.3_osx_x64_64_sfx
doe@mac:/Applications/GAMS/gams24.3_osx_x64_64_sfx$cp ~/gamslice.txt .
doe@mac:/Applications/GAMS/gams24.3_osx_x64_64_sfx$./gamsinst

-----------------------------------------------------
GAMS sysdir is "/Applications/GAMS/gams24.3_osx_x64_64_sfx"

LP (Linear Programming) models can be solved by:
1. BDMLP (demo or student license)
2. CBC (demo or student license)
3. CONOPT (demo or student license)
4. CPLEX (demo or student license)
5. GUROBI (demo or student license)
6. IPOPT (demo or student license)
7. IPOPTH (demo or student license)

... 

Installed defaults:

 LP: CPLEX
MIP: CPLEX
RMIP: CPLEX
NLP: CONOPT
MCP: PATH
MPEC: NLPEC
RMPEC: NLPEC
CNS: CONOPT
DNLP: CONOPT
RMINLP: CONOPT
MINLP: DICOPT
QCP: CONOPT
MIQCP: SBB
RMIQCP: CONOPT
EMP: JAMS

We are now prepared to set read and execute permissions on the
GAMS system files. If you are not sure which option to choose,
we recommend option 3.
You can set read (and execute) permission for:
1. user only.
2. user and group.
3. user, group, and world.
Enter your choice now

3

The files "gams", "gamslib", etc., are now executable.
You can run these commands in a number of ways:
1. Call them using an absolute path (i.e. /Applications/GAMS/gams24.3_osx_x64_64_sfx/gams).
2. Create your own aliases for them.
3. Add the GAMS system directory "/Applications/GAMS/gams24.3_osx_x64_64_sfx" to your path.
Method 3. is recommended.
3.9.3 Installation of the Windows version using Wine

The 32-bit Windows version of the GAMS system can be installed and used under 32-bit Wine. However, note that using GAMS for Windows under Wine is neither tested nor officially supported by GAMS.

For this procedure, an additional video is available at https://www.youtube.com/watch?v=NZ0uS1p-UU.
3.10 Installation Notes for Unix

3.10.1 Installation

To install GAMS, please follow the steps below as closely as possible. We advise you to read this entire document before beginning the installation procedure. Additionally, a video on how to install GAMS on Linux is available at https://www.youtube.com/watch?v=Mx_tYI3wP4.

1. Obtain the GAMS distribution file, which is available from http://www.gams.com/latest, in one large self-extracting zip archive with a _sfx.exe file extension, e.g., linux_x64_64_sfx.exe on a Linux 64bit system. Check that it has the execute permission set. If you are not sure how to do this, just type in the command, e.g., chmod 755 linux_x64_64_sfx.exe.

2. Choose a location where you want to create the GAMS system directory (the GAMS system directory is the directory where the GAMS system files should reside). At this location the GAMS installer will create a subdirectory with a name that indicates the distribution of GAMS you are installing. For example, if you are installing the 24.3 distribution in /opt/gams, the installer will create the GAMS system directory /opt/gams/gams24.3_linux_x64_64_sfx. If the directory where you want to install GAMS is not below your home directory, you may need to have root privileges on the machine.

3. Create the directory that should contain the GAMS system directory, for instance /opt/gams. Change to this directory (cd /opt/gams). Make sure pwd returns the name of this directory correctly.

4. Run the distribution file, either from its current location or after transferring it to the directory that should contain the GAMS system directory. By executing the distribution file, the GAMS distribution should be extracted. For example, if you downloaded the distribution file into your home directory, you might execute the following commands:

```
mkdir /opt/gams
cd /opt/gams
~/linux_x64_64_sfx.exe
```
5. Optionally, create the license file `gamslice.txt` in the GAMS system directory. The license file is nowadays sent via email, with instructions. If no license file is present, GAMS will still function in the demonstration mode but can only solve small problems. Student and demonstration systems do not include a license file. A license file can easily be added later, so if you cannot find a license file, you can safely proceed without one.

6. Change to the GAMS system directory and run the program `.gamsinst`. It will prompt you for default solvers to be used for each class of models. If possible, choose solvers you have licensed since unlicensed solvers will only run in demonstration mode. These solver defaults can be changed or overridden by:
   a. rerunning `.gamsinst` and resetting the default values
   b. setting a command line default, e.g., `gams trnsport lp=bdmlp`
   c. an option statement in the GAMS model, e.g: `option lp=bdmlp;`

7. Add the GAMS system directory to your path (see below).

8. To test the installation, log in as a normal user and run a few models from your home directory, but not the GAMS system directory:

   LP:     trnsport (objective value:  153.675)
   NLP:    chenery (objective value:  1058.9)
   MIP:    bid     (optimal solution: 15210109.512)
   MINLP:  procsel (optimal solution: 1.9231)
   MCP:    scarfmcp (no objective function)
   MPSGE:  scarfmge (no objective function)

9. If you move the GAMS system to another directory, remember to rerun `.gamsinst`. It is also good practice to rerun `.gamsinst` when you add or change your license file if this has changed the set of licensed solvers.

3.10.2 Access to GAMS

To run GAMS you must be able to execute the GAMS programs located in the GAMS system directory. There are several ways to do this. Remember that the GAMS system directory in the examples below may not correspond to the directory where you have installed your GAMS system.

1. If you are using the C shell (`csh`) and its variants you can modify your `.cshrc` file by adding the line

   ```
   set path = ( $path /opt/gams/gams24.3_linux_x64_64_sfx )
   ```

2. Those of you using the Bourne (`sh`) or Korn (`ksh`) shells and their variants can modify their `.profile` or `.bashrc` file by adding the line

   ```
   PATH=$PATH:/opt/gams/gams24.3_linux_x64_64_sfx
   ```

   If neither `.profile` nor `.bashrc` exist yet, `.profile` needs to be created. You should log out and log in again after you have made any changes to your path.

3. You may prefer to use an alias for the names of the programs instead of modifying the path as described above. C shell users can use the following commands on the command line or in their `.cshrc` file:

   ```
   alias gams  /opt/gams/gams24.3_linux_x64_64_sfx/gams
   alias gamslib /opt/gams/gams24.3_linux_x64_64_sfx/gamslib
   ```

   The correct Bourne or Korn shell syntax (either command line or `.profile`) is:
3.10 Installation Notes for Unix

alias gams=/opt/gams/gams24.3_linux_x64_64_sfx/gams
alias gamslib=/opt/gams/gams24.3_linux_x64_64_sfx/gamslib

Again, you should log out and log in order to put the alias settings in .cshrc or .profile into effect.

4. Casual users can always type the absolute path names of the GAMS programs, e.g.:

/opt/gams/gams24.3_linux_x64_64_sfx/gams transport

3.10.3 Installation of the Windows system under Linux using Wine

The 32-bit Windows version of the GAMS system can be installed and used under 32-bit Wine. However, note that using GAMS for Windows under Wine is neither tested nor officially supported by GAMS. Nevertheless, for experienced Linux users, we here provide some instructions on how to install a Windows GAMS system under Wine.

Many components of the GAMS system, including the IDE and solvers, should work under Wine. When running under Wine on Linux, the GAMS distribution accepts GAMS licenses for Windows, Linux, or generic platforms. See here for a list of known compatibility issues.

We encourage here the use of the 32-bit GAMS system instead of the 64-bit system, as also the 64-bit GAMS distribution includes certain components, including the IDE, as 32-bit version only. Using these 32-bit components with a 64-bit Wine system may not work.

1. Install a 32-bit Wine system and the winetricks tool using the package manager your distribution. If winetricks is not available via the package manager, follow the instructions on http://wiki.winehq.org/winetricks

2. Install additional fonts by executing

    winetricks allfonts

3. If you had a pure 64-bit Linux system, then some 32-bit support libraries might be needed to run the 32-bit GAMS system. On a CentOS 7 system, these libraries were installed via

    yum install freetype.i686
    yum install libgcc.i686
    yum install libSM.i686
    yum install libXext.i686

5. Start the GAMS Windows installer by executing the following command from the command line:

    wine windows_x86_32.exe

    Follow the instructions from the GAMS installer, possibly also installing a GAMS license file (see also Installation Notes for Windows).

6. You should now be able to run the GAMS IDE by executing gamside.exe via wine. On a system where the WINEPREFIX has not been changed (default: ~/.wine) and with GAMS installed in the default location, the command to start the IDE is

    wine ~/.wine/drive_c/GAMS/win32/27.3/gamside.exe
3.11 Installation Notes for Windows

3.11.1 Installation

1. Run `windows_x86_32.exe` (Windows 32bit) or `windows_x64_64.exe` (Windows 64bit): Both files are available from [http://www.gams.com/latest](http://www.gams.com/latest). The 32 bit version works both on a 32bit and on a 64bit operating system. Please note that the installation may require administrative privileges on your machine.

You have two options to run the installer: In default or advanced mode. In the default mode, the installer will prompt you for the name of the directory in which to install GAMS. We call this directory the **GAMS directory**. You may accept the default choice or pick another directory. Please remember: if you want to install two different versions of GAMS, they must be in separate directories.

If you choose to use the advanced mode, the installer will also ask you for a name of a start menu folder, if GAMS should be installed for all users, if the **GAMS directory** should be added to the **PATH** environment variable and if a desktop icon should be created.

For automating the installation of GAMS, it is possible to provide the command line parameters `/SP- /SILENT`. This will install GAMS in a non-interactive manner using default settings. Note that depending on the security settings, the User Account Control asking for permission might still be active.

Attention

Under Windows 10 the Windows Installer package may not update system environment variables (see Microsoft Support). To work around this issue, log off of Windows after the installation, and then log on again.

2. Copy the GAMS license file: You will be asked for the GAMS license file (`gamslicetext.txt`) during the installation. If you are not sure or you have no a license file, choose **No license, demo only** when asked for the GAMS license options. You can always do this later. If no valid license file is found, GAMS will still function in the demonstration mode, but will only solve small problems. All demonstration and student systems do not include a license file.

If you have a license file you wish to copy to the GAMS directory at this time, answer **Copy license file**. You will now be given the opportunity to browse the file system and find the license file `gamslicetext.txt`. When you have found the correct file, choose **open** to perform the copy. Instead of copying a license file you could also copy the content of that file to the clipboard. If you have done this, select **Copy license text from clipboard**.

3. Create a project file: If this is the first installation of GAMS on your system, the installation program will create a default GAMS project in a subdirectory of your documents folder. Otherwise, your existing GAMS projects will be preserved.

4. Choose the default solvers: Run the GAMS IDE by double clicking `gamside.exe` from the GAMS directory. To view or edit the default solvers, choose **File → Options → Solvers** from the IDE. You can accept the existing defaults if you wish, but most users want to select new default solvers for each model type.

5. Run a few models to test the GAMS system: The on-line help for the IDE (Help → GAMS IDE Help Topics → Guided Tour) describes how to copy a model from the GAMS model library, run it, and view the solution. To test your installation, run the following models from the GAMS model library:

   **LP**: `trnsport` (objective value: 153.675)
   **NLP**: `chenery` (objective value: 1058.9)
   **MIP**: `bid` (optimal solution: 15210109.512)
   **MINLP**: `procsel` (optimal solution: 1.9231)
   **MCP**: `scarfmcp` (no objective function)
   **MPSGE**: `scarfmge` (no objective function)
3.11.2 Visual C++ Redistributable Dependency

- Some solvers in the system as well as GAMS Studio have dependencies on certain Visual C++ libraries. These are present on most Windows systems but are missing on some. If you get a complaint about missing libraries on startup of GAMS Studio or when solving a model, please run the appropriate installer for these libraries, which can be found in the GAMS installation folder:
  - 32-bit GAMS version: run vcredist_x86.exe, found in [GAMS system]\apifiles\C++\lib\vs2013, followed by vcredist_x86.exe, found in [GAMS system]\apifiles\C++\lib\vs2015
  - 64-bit GAMS version: run vcredist_x64.exe, found in [GAMS system]\apifiles\C++\lib\vs2017

3.11.3 Command Line Use of GAMS

Users wishing to use GAMS from the command line (aka the console mode) may want to perform the following steps. These steps are not necessary to run GAMS via the IDE.

1. We recommend to add the GAMS directory to your environment path in order to avoid having to type in an absolute path name each time you run GAMS. Run the installer in advanced mode and mark the check-box Add GAMS directory to PATH environment variable.

2. Run the program gamsinst: gamsinst is a command line program used to configure GAMS. It prompts the user for default solvers to be used for each model type. If possible, choose solvers you have licensed, since unlicensed solvers will only run in demonstration mode. The solver defaults can be changed by:
   a. rerunning gamsinst and resetting the default values
   b. setting a command line default, e.g. gams trnsport lp=bdmlp
   c. by an option statement in the GAMS model, e.g: option lp=bdmlp;
   The system wide solver defaults are shared by the command line and the GAMS IDE, so you can also choose to set these defaults using the GAMS IDE.

3.12 Licensing

3.12.1 General Information

The GAMS system and all connected solvers can be downloaded from the GAMS website at https://www.gams.com/download. The use of the software is governed by the GAMS End User License Agreement, which is available on our website and can also be found in the GAMS System directory (eula.pdf). Without a valid GAMS license the system will operate as a free demo system and these size-limitations will apply:

- Model limits:
  - Number of constraints and variables: 300
  - Number of nonzero elements: 2000 (of which 1000 nonlinear)
  - Number of discrete variables: 50 (including semi continuous, semi integer and member of SOS-Sets)

- Additional Global solver limits: Number of constraints and variables: 10

The GAMS log will indicate that your GAMS system is running in demo mode:

GAMS 24.8.5 Copyright (C) 1987-2017 GAMS Development. All rights reserved Licensee: GAMS Development Corporation, Washington, DC G871201/0000CA-ANY Free Demo, 202-342-0180, sales@gams.com, www.gams.com DC0000

GAMS will terminate with an error message, if it hits one of the limits above:

*** Status: Terminated due to a licensing error
*** Inspect listing file for more information
3.12.2 GAMS Licenses

The use of GAMS beyond the limits of the free demo system requires the presence of a valid GAMS license file (gamslice.txt). An appropriate license is required for the GAMS Base Module and for most of the GAMS/Solvers and the GAMS/Solver-Links:

- The **GAMS Base Module** includes the GAMS Language Compiler, GAMS-APIs, many utilities, some solvers without size restrictions, and most solvers in "demo" mode with a model size limitation. See details below.
- A **GAMS/Solver** connects the GAMS Base module to a particular solver and includes a license for this solver to be used through GAMS. It is not necessary to install additional software. A **GAMS/Solver-Link** connects the GAMS Base Module to a particular solver, but does not include a license for the solver. It may be necessary to install additional software before the solver can be used.

We distinguish between academic and commercial licenses. Academic licenses can only be used for teaching and research at degree granting institutions. Other than evaluation and course licenses, GAMS licenses are perpetual. The first year of maintenance, support and updates is included in the initial purchase of the software. Maintained licenses qualify for free updates, adding components, platform-switching without additional charge, and multi-copy discounts on the same platform. After the first year maintenance can be extended by paying a fee. Licenses are typically limited to a single computer platform type (e.g. Windows or Linux), but there are also licenses available, which will work on any platform supported by GAMS. Free academic licenses are available for certain solvers, for details please follow this link. Please visit the GAMS website for further information about the pricing of an appropriate license.

3.12.3 Installing or updating a license file

A GAMS license file is an ASCII file of six lines, which was sent to you via e-mail. Please copy all six lines into a file gamslice.txt. To use the license please follow these steps:

- **MS Windows:**
  - During the setup of the GAMS system you will be asked for the license file. Follow these instructions or watch this video.
  - If you have already installed the GAMS system without a license file or want to replace an existing license file with a new one, copy the file as gamslice.txt into your GAMS System Directory. Alternatively follow these steps: Copy the contents of the license file to your clipboard. Then open the GAMSIDE and navigate to: Help → About. The GAMSIDE will recognize the presence of the license in your clipboard and ask, whether you want to create a license. Note: An existing license file will be overwritten.

- **Linux / Mac OS X:** Please copy the file as gamslice.txt into your GAMS System Directory (e.g. /usr/bin/gams).

Below are the references to the detailed installation notes:

- GAMS Installation Notes for Windows
- GAMS Installation Notes for Mac OS X
- GAMS Installation Notes for Unix
3.12 Licensing

Before installing a new GAMS version, please check whether it will work with your current GAMS license. The utility CHK4UPD can be used to see if a newer GAMS version is available and what the newest version is that can be used with a given license. This is done by running CHK4UPD without arguments or by giving the name of a local license file. CHK4UPD is also available through the GAMS IDE and can be accessed through: Help -> Check for GAMS Updates. Below is a sample output for a license, which is still under maintenance:

D:\>chk4upd
*** Processing GAMS system directory C:\gams\win64\24.8
*** Reading license file C:\gams\win64\24.8\gamslice.txt
*** Your system is up to date
D:\>

If your license is no longer under maintenance, you will receive a message like the one below:

*** Processing GAMS system directory C:\GAMS\win64\23.9
*** Reading license file C:\GAMS\win64\23.9\gamslice.txt
*** Your license is 1276 days too old to run with the most recent system
*** The version of your GAMS system is 23.9.5
*** The last GAMS version you can use is 24.1.3
*** Please visit http://www.gams.com/download/download_old.htm
*** For ordering an update to use the most recent version (24.8.5)
*** please contact your distributor

3.12.4 License Problems

Errors or warnings triggered by a problem with the GAMS license file (license.txt) are reported both in the log file and in the lst file. Below are some typical error and warning messages and instructions how to overcome them.

3.12.4.1 No License File present

Without a license file GAMS will work as a free demonstration mode with the size limitations stated above. If you have received a license file (gamslice.txt), follow the instruction from the previous section. Do not try to rename it or to modify the contents of the license file.

3.12.4.2 License File Invalid or Corrupted

Running GAMS with an invalid license will give you an error message like the one below:

*** License File validation failed
*** System downgraded to demonstration mode

Do not try to modify your license file, any change will break it. If the original license file is no longer available, please contact sales@gams.com and ask for a copy of your license file. Please attach the license file you are currently using. This error also pops up, if you are using a license file, which was issued for a different platform.
3.12.4.3 License File expired

If you are trying to run an old license file with a newer GAMS distribution, you may get an error message stating:

*** License file too old for this version of GAMS.
*** Maintenance expired 2840 days ago.
*** More than 60 days since expiration, sorry...
*** System downgraded to demonstration mode
*** Run an older GAMS system or renew the license

Replace that GAMS system with the one you got together with your license file (use the CHK4UPD utility mentioned above to find out the latest version you can use with the current license; old systems are available at the GAMS website) or update your license to the current version.

3.12.4.4 No License (for a particular Solver) found

If one of the solvers you are trying to use is not included in your license file and the size of the model exceed the limits of the free demo version, you will get an error stating:

*** No license found
*** To update your license, please contact your distributor.
*** Too many equations for demo mode

Check whether the default solvers for a particular problem class are included in the license. Please note that some of the solvers call other solvers as a sub-solver, e.g.:

- GAMS/DICOPT requires an NLP and a MIP solver
- GAMS/SBB requires an NLP solver
- MPSGE: If GAMS/PATH is not included in your license, please select GAMS/MILES, which is included in the base system as the default solver for MCP problems.

3.12.5 Warnings

3.12.5.1 License file too old for this version of GAMS

The complete message is:

*** License file too old for this version of GAMS.
*** Maintenance expired xx days ago.

If GAMS continues working, you can ignore this warning. However, any forthcoming GAMS distribution will most likely not work, but downgrade to the limits of the free demo system.

3.12.5.2 License File has expired xx days ago

This warning (without further error messages) indicates that the time limited license (e.g. an evaluation license) will stop working soon and the system will continue with the limits of the free demo version.
3.12 Licensing

3.12.6 The GAMS/BASE Module

The GAMS/BASE module includes:

- **Language Compiler and Execution System**
- **GAMS IDE (Integrated Development Environment) (Windows only)**
  - Project Management
  - Editor, Syntax coloring, Spell checking
  - Launching and monitoring of (multiple) GAMS processes
  - Listing file / Tree view / Syntax-error navigation
  - Solver selection / option selection
  - GDX Viewer: Data cube and export (e.g. to MS Excel), charting facilities
- **GAMS Studio (platform independent, Beta version)**
  - Editor, Syntax coloring
  - Launching and monitoring of (multiple) GAMS processes
  - Listing file / Tree view / Syntax-error navigation
  - GDX Viewer
- **GAMS Free Solvers and Links**
  - Open Source (COIN-OR): Bonmin, CBC, Couenne, Ipopt
  - CONVERT, JAMS and LOGMIP, NLPEC
  - BDMLP, MILES, LS
  - BENCH, EXAMINER, GAMSCHK
  - Academic licenses only: ODHeuristic, SCIP, Soplex
  - OSI Solver Links
  - GAMS/KESTREL for using the NEOS Server with a local GAMS system
- **Most other solvers in limited versions**: 300 constraints, 300 variables, 50 discrete variables, 2000 linear non-zeroes, 1000 non-linear non-zeroes, Global solvers: 10 constraints, 10 variables
- **EMP (Extended Mathematical Programming Framework)**
- **Posix Utilities**
- **GDX (GAMSData eXchange) and related GDX Utilities**
  - Binary data exchange between application, GAMS, and the solver (fast, saves disk space, tailored for large sparse matrices, platform independent, direct GDX interfaces, API support for high-level programming languages)
  - GDX Utilities: GDX Viewer, GDXRANK, GDX2HAR, HAR2GDX, GDXMERGE, GDXDUMP, GDXCOPY, GDXDIFF, MDB2GMS, GDXMRW, GDXRRW, GDXWRW, GDX2XLS, XLSdump, XLSTalk, INVERT, CHOLESKY, EIGENVALUE, EIGENVECTOR
- **Various other tools**
- **GAMS APIs**
  - Expert-Level GAMS APIs
    - GAMS
    - GDX
    - Option
      - Supported Languages: C, C++, C#, Delphi, Fortran, Java, Python, VBA, VB.Net
  - Object-Oriented GAMS APIs
    - Supported Languages: C++, C#, Java, Python, VB.Net
- **Documentation**
- **Model Libraries**
3.13 A GAMS Tutorial by Richard E. Rosenthal

3.13.1 Introduction

Richard E. Rosenthal of the Naval Postgraduate School in Monterey, California wrote a detailed example of the use of GAMS for formulating, solving, and analyzing a small and simple optimization problem. The example is a quick overview of GAMS and its main features. Many references are made to other parts of the documentation, but they are only to tell you where to look for more details; the material here can be read profitably without reference to the rest of the documentation.

The example is an instance of the transportation problem of linear programming, which has historically served as a 'laboratory animal' in the development of optimization technology. [See, for example, Dantzig (1963) 1. ] It is a good choice for illustrating the power of algebraic modeling languages like GAMS because the transportation problem, no matter how large the instance at hand, possesses a simple, exploitable algebraic structure. You will see that almost all of the statements in the GAMS input file we are about to present would remain unchanged if a much larger transportation problem were considered.

In the familiar transportation problem, we are given the supplies at several plants and the demands at several markets for a single commodity, and we are given the unit costs of shipping the commodity from plants to markets. The economic question is: how much shipment should there be between each plant and each market so as to minimize total transport cost?

The algebraic representation of this problem is usually presented in a format similar to the following.

Indices:

\[ i = \text{plants} \]
\[ j = \text{markets} \]

Given Data:

\[ a_i = \text{supply of commodity of plant } i \text{ (in cases)} \]
\[ b_j = \text{demand for commodity at market } j \]
\[ c_{ij} = \text{cost per unit shipment between plant } i \text{ and market } j \]

Decision Variables:

\[ x_{ij} = \text{amount of commodity to ship from plant } i \text{ to market } j \]
where \( x_{ij} \geq 0 \), for all \( i, j \)

Constraints:

\[ \sum_j x_{ij} \leq a_i \text{ for all } i \text{ (cases)} \]
\[ \sum_i x_{ij} \geq b_j \text{ for all } j \text{ (cases)} \]

Objective Function: Minimize \( \sum_i \sum_j c_{ij} x_{ij} \) \( \text{($K$)} \)

---

Note that this simple example reveals some modeling practices that we regard as good habits in general and that are consistent with the design of GAMS. First, all the entities of the model are identified (and grouped) by type. Second, the ordering of entities is chosen so that no symbol is referred to before it is defined. Third, the units of all entities are specified, and, fourth, the units are chosen to a scale such that the numerical values to be encountered by the optimizer have relatively small absolute orders of magnitude. (The symbol $\$K$ here means thousands of dollars.)

The names of the types of entities may differ among modelers. For example, economists use the terms *exogenous variable* and *endogenous variable* for given data and decision variable, respectively. In GAMS, the terminology adopted is as follows: indices are called *sets*, given data are called *parameters*, decision variables are called *variables*, and constraints and the objective function are called *equations*.

The GAMS representation of the transportation problem closely resembles the algebraic representation above. The most important difference, however, is that the GAMS version can be read and processed by a computer.

<table>
<thead>
<tr>
<th>Plants ↓</th>
<th>New York</th>
<th>Chicago</th>
<th>Topeka</th>
<th>← Markets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
<td>350</td>
</tr>
<tr>
<td>San Diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
<td>600</td>
</tr>
<tr>
<td>Demands →</td>
<td>325</td>
<td>300</td>
<td>275</td>
<td>Supplies ↑</td>
</tr>
</tbody>
</table>

As an instance of the transportation problem, suppose there are two canning plants and three markets, with the data given in table Table 1. Shipping distances are in thousands of miles, and shipping costs are assumed to be $90.00 per case per thousand miles. The GAMS representation of this problem is as follows:

Sets

i  canning plants / seattle, san-diego /
j  markets    / new-york, chicago, topeka / ;

Parameters

a(i) capacity of plant i in cases
   /  seattle  350
   san-diego  600  / 

b(j) demand at market j in cases
   /  new-york 325
   chicago  300
   topeka  275  / ;

Table d(i,j) distance in thousands of miles

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

Scalar f  freight in dollars per case per thousand miles  /90/ ;

Parameter c(i,j) transport cost in thousands of dollars per case ;

\[ c(i,j) = f \times d(i,j) / 1000 ; \]

Variables
x(i,j)  shipment quantities in cases
z  total transportation costs in thousands of dollars ;

Positive Variable x ;

Equations
  cost  define objective function
  supply(i)  observe supply limit at plant i
  demand(j)  satisfy demand at market j ;

  cost ..  z =e=  sum((i,j), c(i,j)*x(i,j)) ;
  supply(i) ..  sum(j, x(i,j)) =l=  a(i) ;
  demand(j) ..  sum(i, x(i,j)) =g=  b(j) ;

Model transport /all/ ;
Solve transport using lp minimizing z ;

Display x.l, x.m ;

If you submit a file containing the statements above as input to GAMS, the transportation model will be formulated and solved. Details vary on how to invoke GAMS on different of computers, but the simplest ('no frills') way to call GAMS is to enter the word GAMS followed by the input file’s name. You will see a number of terse lines describing the progress GAMS is making, including the name of the file onto which the output is being written. When GAMS has finished, examine this file, and if all has gone well the optimal shipments will be displayed at the bottom as follows.

<table>
<thead>
<tr>
<th>City</th>
<th>New York</th>
<th>Chicago</th>
<th>Topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>50.000</td>
<td>300.000</td>
<td></td>
</tr>
<tr>
<td>San Diego</td>
<td>275.000</td>
<td>275.000</td>
<td></td>
</tr>
</tbody>
</table>

You will also receive the marginal costs (simplex multipliers) below.

<table>
<thead>
<tr>
<th>City</th>
<th>Chicago</th>
<th>Topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>0.036</td>
<td></td>
</tr>
<tr>
<td>San Diego</td>
<td>0.009</td>
<td></td>
</tr>
</tbody>
</table>

These results indicate, for example, that it is optimal to send nothing from Seattle to Topeka, but if you insist on sending one case it will add $.036$ (or $36.00$) to the optimal cost.

### 3.13.2 Structure of a GAMS Model

For the remainder of the tutorial, we will discuss the basic components of a GAMS model, with reference to the example above. The basic components are listed in table Table 2.

| Table 2: The basic components of a GAMS model |
There are optional input components, such as edit checks for bad data and requests for customized reports of results. Other optional advanced features include saving and restoring old models, and creating multiple models in a single run, but this tutorial will discuss only the basic components.

Before treating the individual components, we give a few general remarks.

1. A GAMS model is a collection of statements in the GAMS Language. The only rule governing the ordering of statements is that an entity of the model cannot be referenced before it is declared to exist.

2. GAMS statements may be laid out typographically in almost any style that is appealing to the user. Multiple lines per statement, embedded blank lines, and multiple statements per line are allowed. You will get a good idea of what is allowed from the examples in this tutorial, but precise rules of the road are given in the next Chapter.

3. When you are a beginning GAMS user, you should terminate every statement with a semicolon, as in our examples. The GAMS compiler does not distinguish between upper-and lowercase letters, so you are free to use either.

4. Documentation is crucial to the usefulness of mathematical models. It is more useful (and most likely to be accurate) if it is embedded within the model itself rather than written up separately. There are at least two ways to insert documentation within a GAMS model. First, any line that starts with an asterisk in column 1 is disregarded as a comment line by the GAMS compiler. Second, perhaps more important, documentary text can be inserted within specific GAMS statements.

5. As you can see from the list of input components above, the creation of GAMS entities involves two steps: a declaration and an assignment or definition. Declaration means declaring the existence of something and giving it a name. Assignment or definition means giving something a specific value or form. In the case of equations, you must make the declaration and definition in separate GAMS statements. For all other GAMS entities, however, you have the option of making declarations and assignments in the same statement or separately.

6. The names given to the entities of the model must start with a letter and can be followed by up to 62 more letters or digits.
3.13.3 Sets

Sets are the basic building blocks of a GAMS model, corresponding exactly to the indices in the algebraic representations of models. The Transportation example above contains just one Set statement:

Sets
i canning plants / seattle, san-diego /
j markets / new-york, chicago, topeka /
;

The effect of this statement is probably self-evident. We declared two sets and gave them the names i and j. We also assigned members to the sets as follows:

\[
\begin{align*}
i &= \{\text{Seattle, San Diego}\} \\
j &= \{\text{New York, Chicago, Topeka}\}.
\end{align*}
\]

You should note the typographical differences between the GAMS format and the usual mathematical format for listing the elements of a set. GAMS uses slashes ‘/’ rather than curly braces ‘{}’ to delineate the set simply because not all computer keyboards have keys for curly braces. Note also that multiword names like 'New York' have to be quoted ((e.g. 'New York' or "New York") or you must use hyphens instead of blanks (e.g. New-York').

The words after the set names in the sets statement above are called text. Text is optional. It is there only for internal documentation, serving no formal purpose in the model. The GAMS compiler makes no attempt to interpret the text, but it saves the text and 'parrots' it back to you at various times for your convenience.

It was not necessary to combine the creation of sets i and j in one statement. We could have put them into separate statements as follows:

Set i canning plants / seattle, san-diego /
Set j markets / new-york, chicago, topeka /
;

The placement of blank spaces and lines (as well as the choice of upper- or lowercase) is up to you. Each GAMS user tends to develop individual stylistic conventions. (The use of the singular set is also up to you. Using set in a statement that makes a single declaration and sets in one that makes several is good English, but GAMS treats the singular and plural synonymously.)

A convenient feature to use when you are assigning members to a set is the asterisk. It applies to cases when the elements follow a sequence. For example, the following are valid set statements in GAMS.

Set t time periods /1991*2000/;
Set m machines /mach1*mach24/;

Here the effect is to assign

\[
\begin{align*}
m &= \{\text{mach } 1, \text{ mach } 2, \ldots, \text{ mach } 24\}.
\end{align*}
\]

Note that set elements are stored as character strings, so the elements of t are not numbers.

Another convenient feature is the alias statement, which is used to give another name to a previously declared set. In the following example:

Alias (t,tp);

the name tp is like a t' in mathematical notation. It is useful in models that are concerned with the interactions of elements within the same set.

The sets i, j, t, and m in the statements above are examples of static sets, i.e., they are assigned their members directly by the user and do not change. GAMS has several capabilities for creating dynamic sets, which acquire their members through the execution of set-theoretic and logical operations. Dynamic sets are discussed in chapter Dynamic Sets. Another valuable advanced feature is multidimensional sets, which are discussed in section Multi-Dimensional Sets.
3.13.4 Data

The GAMS model of the transportation problem demonstrates three of the different formats that are allowable for entering data. The three formats are:

- Lists
- Tables
- Direct assignments

The next three subsections will discuss each of these formats in turn.

3.13.4.1 Data Entry by Lists

The first format is illustrated by the first Parameters statement of the example, which is repeated below.

Parameters

\[
\begin{align*}
\text{a(i)} & \quad \text{capacity of plant i in cases} \\
& \quad / \\
& \quad \text{seattle} \quad 350 \\
& \quad \text{san-diego} \quad 600 \\
\end{align*}
\]

\[
\begin{align*}
\text{b(j)} & \quad \text{demand at market j in cases} \\
& \quad / \\
& \quad \text{new-york} \quad 325 \\
& \quad \text{chicago} \quad 300 \\
& \quad \text{topeka} \quad 275 \\
\end{align*}
\]

This statement has several effects. Again, they may be self-evident, but it is worthwhile to analyze them in detail. The statement declares the existence of two parameters, gives them the names \(a\) and \(b\), and declares their domains to be \(i\) and \(j\), respectively. (A domain is the set, or tuple of sets, over which a parameter, variable, or equation is defined.) The statement also gives documentary text for each parameter and assigns values of \(a(i)\) and \(b(j)\) for each element of \(i\) and \(j\). It is perfectly acceptable to break this one statement into two, if you prefer, as follows.

Parameters \(a(i)\)

\[
\begin{align*}
\text{capacity of plant i in cases} \\
& \quad / \\
& \quad \text{seattle} \quad 350 \\
& \quad \text{san-diego} \quad 600 \\
\end{align*}
\]

Parameters \(b(j)\)

\[
\begin{align*}
\text{demand at market j in cases} \\
& \quad / \\
& \quad \text{new-york} \quad 325 \\
& \quad \text{chicago} \quad 300 \\
& \quad \text{topeka} \quad 275 \\
\end{align*}
\]

Here are some points to remember when using the list format.

1. The list of domain elements and their respective parameter values can be laid out in almost any way you like. The only rules are that the entire list must be enclosed in slashes and that the element-value pairs must be separated by commas or entered on separate lines.
2. There is no semicolon separating the element-value list from the name, domain, and text that precede it. This is because the same statement is being used for declaration and assignment when you use the list format. (An element-value list by itself is not interpretable by GAMS and will result in an error message.)

3. The GAMS compiler has an unusual feature called domain checking, which verifies that each domain element in the list is in fact a member of the appropriate set. For example, if you were to spell 'Seattle' correctly in the statement declaring Set i but misspell it as 'Seatle' in a subsequent element-value list, the GAMS compiler would give you an error message that the element 'Seatle' does not belong to the set i.

4. Zero is the default value for all parameters. Therefore, you only need to include the nonzero entries in the element-value list, and these can be entered in any order.

5. A scalar is regarded as a parameter that has no domain. It can be declared and assigned with a Scalar statement containing a degenerate list of only one value, as in the following statement from the transportation model.

   Scalar f freight in dollars per case per thousand miles /90/;

If the domain of a parameter has two or more dimensions, it can still have its values entered by the list format. This is very useful for entering arrays that are sparse (having few non-zeros) and super-sparse (having few distinct non-zeros).

### 3.13.4.2 Data Entry by Tables

Optimization practitioners have noticed for some time that many of the input data for a large model are derived from relatively small tables of numbers. Thus, it is very useful to have the table format for data entry. An example of a two-dimensional table (or matrix) is provided in the transportation model:

<table>
<thead>
<tr>
<th>Table d(i,j) distance in thousands of miles</th>
</tr>
</thead>
<tbody>
<tr>
<td>new-york</td>
</tr>
<tr>
<td>seattle</td>
</tr>
<tr>
<td>san-diego</td>
</tr>
</tbody>
</table>

The effect of this statement is to declare the parameter d and to specify its domain as the set of ordered pairs in the Cartesian product of i and j. The values of d are also given in this statement under the appropriate heading. If there are blank entries in the table, they are interpreted as zeroes.

As in the list format, GAMS will perform domain checking to make sure that the row and column names of the table are members of the appropriate sets. Formats for entering tables with more columns than you can fit on one line and for entering tables with more than two dimensions are given in Chapter Data Entry: Parameters, Scalars and Tables.

### 3.13.4.3 Data Entry by Direct Assignment

The direct assignment method of data entry differs from the list and table methods in that it divides the tasks of parameter declaration and parameter assignment between separate statements. The transportation model contains the following example of this method.

Parameter c(i,j) transport cost in thousands of dollars per case;

\[
c(i,j) = f \cdot d(i,j) / 1000 ;
\]
It is important to emphasize the presence of the semicolon at the end of the first line. Without it, the GAMS compiler would attempt to interpret both lines as parts of the same statement. (GAMS would fail to discern a valid interpretation, so it would send you an error message.)

The effects of the first statement above are to declare the parameter \( c \), to specify the domain \( (i,j) \), and to provide some documentary text. The second statement assigns to \( c(i,j) \) the product of the values of the parameters \( f \) and \( d(i,j) \). Naturally, this is legal in GAMS only if you have already assigned values to \( f \) and \( d(i,j) \) in previous statements.

The direct assignment above applies to all \( (i,j) \) pairs in the domain of \( c \). If you wish to make assignments for specific elements in the domain, you enclose the element names in quotes. For example,

\[
c('Seattle', 'New-York') = 0.40;
\]

is a valid GAMS assignment statement.

The same parameter can be assigned a value more than once. Each assignment statement takes effect immediately and overrides any previous values. (In contrast, the same parameter may not be declared more than once. This is a GAMS error check to keep you from accidentally using the same name for two different things.)

The right-hand side of an assignment statement can contain a great variety of mathematical expressions and built-in functions. If you are familiar with a scientific programming language such as C, you will have no trouble in becoming comfortable writing assignment statements in GAMS. (Notice, however, that GAMS has some efficiencies not shared by C. For example, we were able to assign \( c(i,j) \) values for all \( (i,j) \) pairs without constructing 'loops'.)

The GAMS standard operations and supplied functions are given later. Here are some examples of valid assignments. In all cases, assume the left-hand-side parameter has already been declared and the right-hand-side parameters have already been assigned values in previous statements.

\[
csquared = sqr(c);
e = m*csquared;
w = 1/lambda;
eoq(i) = sqrt(2*demand(i)*ordcost(i)/holdcost(i));
t(i) = min(p(i), q(i)/r(i), log(s(i))); 
euclidean(i,j) = sqrt(sqr(xi(i) - xi(j) + sqr(x2(i) - x2(j)));
present(j) = future(j)*exp(-interest*time(j));
\]

The summation and product operators to be introduced later can also be used in direct assignments.

### 3.13.5 Variables

The decision variables (or endogenous variables) of a GAMS-expressed model must be declared with a `Variables` statement. Each variable is given a name, a domain if appropriate, and (optionally) text. The transportation model contains the following example of a `Variables` statement.

```plaintext
Variables
  x(i,j)  shipment quantities in cases
  z       total transportation costs in thousands of dollars
;
```

This statement results in the declaration of a shipment variable for each \( (i,j) \) pair. (You will see in chapter `Equations`, how GAMS can handle the typical real-world situation in which only a subset of the \( (i,j) \) pairs is allowable for shipment.)

The \( z \) variable is declared without a domain because it is a scalar quantity. Every GAMS optimization model must contain one such variable to serve as the quantity to be minimized or maximized.

Once declared, every variable must be assigned a type. A selection of permissible types are given in table `Table 3`. For a full list, see section `Variable Types`.

**Table 3**: Permissible variable types
<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Allowed Range of Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>free (default)</td>
<td>$-\infty$ to $+\infty$</td>
</tr>
<tr>
<td>positive</td>
<td>0 to $+\infty$</td>
</tr>
<tr>
<td>negative</td>
<td>$-\infty$ to 0</td>
</tr>
<tr>
<td>binary</td>
<td>0 or 1</td>
</tr>
<tr>
<td>integer</td>
<td>0, 1,..., 100 (default)</td>
</tr>
</tbody>
</table>

The variable that serves as the quantity to be optimized must be a scalar and must be of the \textit{free} type. In our transportation example, $z$ is kept free by default, but $x(i,j)$ is constrained to non-negativity by the following statement.

Positive variable $x$ ;

Note that the domain of $x$ should not be repeated in the type assignment. All entries in the domain automatically have the same variable type.

Section \textit{The .lo, .l, .up, .m Database} describes how to assign lower bounds, upper bounds, and initial values to variables.

### 3.13.6 Equations

The power of algebraic modeling languages like GAMS is most apparent in the creation of the equations and inequalities that comprise the model under construction. This is because whenever a group of equations or inequalities has the same algebraic structure, all the members of the group are created simultaneously, not individually.

#### 3.13.6.1 Equation Declaration

Equations must be declared and defined in separate statements. The format of the declaration is the same as for other GAMS entities. First comes the keyword, \textit{Equations} in this case, followed by the name, domain and text of one or more groups of equations or inequalities being declared. Our transportation model contains the following equation declaration:

\begin{verbatim}
Equations
cost       define objective function
supply(i)   observe supply limit at plant i
demand(j)    satisfy demand at market j ;
\end{verbatim}

Keep in mind that the word \textit{Equation} has a broad meaning in GAMS. It encompasses both equality and inequality relationships, and a GAMS equation with a single name can refer to one or several of these relationships. For example, \textit{cost} has no domain so it is a single equation, but \textit{supply} refers to a set of inequalities defined over the domain \textit{i}.
3.13.6.2 GAMS Summation (and Product) Notation

Before going into equation definition we describe the summation notation in GAMS. Remember that GAMS is designed for standard keyboards and line-by-line input readers, so it is not possible (nor would it be convenient for the user) to employ the standard mathematical notation for summations.

The summation notation in GAMS can be used for simple and complex expressions. The format is based on the idea of always thinking of a summation as an operator with two arguments: \texttt{Sum(index of summation, summand)} A comma separates the two arguments, and if the first argument requires a comma then it should be in parentheses. The second argument can be any mathematical expression including another summation.

As a simple example, the transportation problem contains the expression

\[ \texttt{Sum(j, x(i,j))} \]

that is equivalent to \( \sum_j x_{ij} \).

A slightly more complex summation is used in the following example:

\[ \texttt{Sum((i,j), c(i,j)*x(i,j))} \]

that is equivalent to \( \sum_i \sum_j c_{ij}x_{ij} \).

The last expression could also have been written as a nested summation as follows:

\[ \texttt{Sum(i, Sum(j, c(i,j)*x(i,j)))} \]

In section Conditional Indexed Operations, we describe how to use the dollar operator to impose restrictions on the summation operator so that only the elements of \( i \) and \( j \) that satisfy specified conditions are included in the summation.

Products are defined in GAMS using exactly the same format as summations, replacing \texttt{Sum} by \texttt{Prod}. For example,

\[ \texttt{prod(j, x(i, j))} \]

is equivalent to: \( \prod_j x_{ij} \).

Summation and product operators may be used in direct assignment statements for parameters. For example,

\begin{verbatim}
scalar totsupply   total supply over all plants;
totsupply = sum(i, a(i));
\end{verbatim}
3.13.6.3 Equation Definition

Equation definitions are the most complex statements in GAMS in terms of their variety. The components of an equation definition are, in order:

1. The name of the equation being defined
2. The domain
3. Domain restriction condition (optional)
4. The symbol ' .= '
5. Left-hand side expression
6. Relational operator: =l=, =e=, =g= or others. For a complete list, see Table Equation Types.
7. Right-hand side expression

The transportation example contains three of these statements.

\[
\begin{align*}
\text{cost} & \,. & z &= \text{sum}((i,j), c(i,j)*x(i,j)) ; \\
\text{supply}(i) & \,. & \text{sum}(j, x(i,j)) &= a(i) ; \\
\text{demand}(j) & \,. & \text{sum}(i, x(i,j)) &= b(j) ;
\end{align*}
\]

Here are some points to remember.

- The power to create multiple equations with a single GAMS statement is controlled by the domain. For example, the definition for the demand constraint will result in the creation of one constraint for each element of the domain \( j \), as shown in the following excerpt from the GAMS output.

\[
\begin{align*}
\text{demand(new-york)} & \,. & x(\text{seattle,new-york}) + x(\text{san-diego,new-york}) &= 325 ; \\
\text{demand(chicago)} & \,. & x(\text{seattle,chicago}) + x(\text{san-diego,chicago}) &= 300 ; \\
\text{demand(topeka)} & \,. & x(\text{seattle,topeka}) + x(\text{san-diego,topeka}) &= 275 ;
\end{align*}
\]

- The key idea here is that the definition of the demand constraints is exactly the same whether we are solving the toy-sized example above or a 20,000-node real-world problem. In either case, the user enters just one generic equation algebraically, and GAMS creates the specific equations that are appropriate for the model instance at hand. (Using some other optimization packages, something like the extract above would be part of the input, not the output.)

- In many real-world problems, some of the members of an equation domain need to be omitted or differentiated from the pattern of the others because of an exception of some kind. GAMS can readily accommodate this loss of structure using a powerful feature known as the dollar or ' such-that ' operator, which is not illustrated here. The domain restriction feature can be absolutely essential for keeping the size of a real-world model within the range of solvability.

- The relational operators have the following meanings:
  - =l= less than or equal to
  - =g= greater than or equal to
  - =e= equal to

- It is important to understand the difference between the symbols '=' and ' =e= '. The '=' symbol is used only in direct assignments, and the ' =e= ' symbol is used only in equation definitions. These two contexts are very different. A direct assignment gives a desired value to a parameter before the solver is called. An equation definition also describes a desired relationship, but it cannot be satisfied until after the solver is called. It follows that equation definitions must contain variables and direct assignments must not.
• Variables can appear on the left or right-hand side of an equation or both. The same variable can appear in an equation more than once. The GAMS processor will automatically convert the equation to its equivalent standard form (variables on the left, no duplicate appearances) before calling the solver.

• An equation definition may appear anywhere in the GAMS input, provided the equation and all variables and parameters to which it refers were previously declared. (Note that it is permissible for a parameter appearing in the equation to be assigned or reassigned a value after the definition. This is useful when doing multiple model runs with one GAMS input.) The equations need not be defined in the same order in which they were declared.

3.13.7 Objective Function

This is just a reminder that GAMS has no explicit entity called the objective function. To specify the function to be optimized, you must create a variable, which is free (unconstrained in sign) and scalar-valued (has no domain) and which appears in an equation definition that equates it to the objective function.

3.13.8 Model and Solve Statements

The word model has a very precise meaning in GAMS. It is simply a collection of equations. Like other GAMS entities, it must be given a name in a declaration. The format of the declaration is the keyword model followed by the name of the model, followed by a list of equation names enclosed in slashes. If all previously defined equations are to be included, you can enter /all/ in place of the explicit list. In our example, there is one model statement:

model transport /all/ ;

This statement may seem superfluous, but it is useful to advanced users who may create several models in one GAMS run. If we were to use the explicit list rather than the shortcut /all/, the statement would be written as

model transport / cost, supply, demand / ;

The domains are omitted from the list since they are not part of the equation name. The list option is used when only a subset of the existing equations comprises a specific model (or sub-model) being generated.

Once a model has been declared and assigned equations, we are ready to call the solver. This is done with a solve statement, which in our example is written as

solve transport using lp minimizing z ;

The format of the solve statement is as follows:

1. The key word solve
2. The name of the model to be solved
3. The key word using
4. An available solution procedure. A complete list is given below. For further details, see section Classification of Models.
<table>
<thead>
<tr>
<th>Solution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lp</td>
<td>for linear programming</td>
</tr>
<tr>
<td>qcp</td>
<td>for quadratic constraint programming</td>
</tr>

<tr>
<td>emp</td>
<td>for extended mathematical programming</td>
</tr>
</tbody>
</table>

5. The keyword 'minimizing' or 'maximizing'

5. The name of the variable to be optimized

### 3.13.9 Display Statements

The `solve` statement will cause several things to happen when executed. The specific instance of interest of the model will be generated, the appropriate data structures for inputting this problem to the solver will be created, the solver will be invoked, and the output from the solver will be printed to a file. To get the optimal values of the primal and/or dual variables, we can look at the solver output, or, if we wish, we can request a display of these results from GAMS. Our example contains the following statement:

```gams
display x.l, x.m ;
```

that calls for a printout of the final levels, `x.l`, and marginal (or reduced costs), `x.m`, of the shipment variables, `x(i,j)`. GAMS will automatically format this printout in to dimensional tables with appropriate headings.

### 3.13.10 The .lo, .l, .up, .m Database

GAMS was designed with a small database system in which records are maintained for the variables and equations. The most important fields in each record are:

- `.lo` lower bound
- `.l` level or primal value
- `.up` upper bound
- `.m` marginal or dual value

The format for referencing these quantities is the variable or equation's name followed by the field's name, followed (if necessary) by the domain (or an element of the domain).

GAMS allows the user complete read-and write-access to the database. This may not seem remarkable to you now, but it can become a greatly appreciated feature in advanced use. Some examples of use of the database follow.
3.13.10.1 Assignment of Variable Bounds and/or Initial Values

The lower and upper bounds of a variable are set automatically according to the variable's type (free, positive, negative, binary, or integer), but these bounds can be overwritten by the GAMS user. Some examples follow.

\[
x_{\text{up}}(i,j) = \text{capacity}(i,j) ;
\]
\[
x_{\text{lo}}(i,j) = 10.0 ;
\]
\[
x_{\text{up}}('seattle','new-york') = 1.2*\text{capacity('seattle','new-york')} ;
\]

It is assumed in the first and third examples that \text{capacity}(i,j) is a parameter that was previously declared and assigned values. These statements must appear after the variable declaration and before the \text{Solve} statement. All the mathematical expressions available for direct assignments are usable on the right-hand side.

In nonlinear programming it is very important for the modeler to help the solver by specifying as narrow a range as possible between lower and upper bound. It is also very helpful to specify an initial solution from which the solver can start searching for the optimum. For example, in a constrained inventory model, the variables are \text{quantity}(i), and it is known that the optimal solution to the unconstrained version of the problem is a parameter called \text{eoq}(i). As a guess for the optimum of the constrained problem we enter

\[
\text{quantity.l}(i) = 0.5*\text{eoq}(i) ;
\]

(The default initial level is zero unless zero is not within the bounded range, in which case it is the bound closest to zero.)

It is important to understand that the .lo and .up fields are entirely under the control of the GAMS user. The .l and .l.m fields, in contrast, can be initialized by the user but are then controlled by the solver.

3.13.10.2 Transformation and Display of Optimal Values

(This section may be skipped on first reading if desired.)

After the optimizer is called via the \text{solve} statement, the values it computes for the primal and dual variables are placed in the database in the .l and .l.m fields. We can then read these results and transform and display them with GAMS statements.

For example, in the transportation problem, suppose we wish to know the percentage of each market's demand that is filled by each plant. After the solve statement, we would enter

\[
\text{parameter pctx}(i,j) \text{ perc of market j's demand filled by plant i;}
\]
\[
\text{pctx}(i,j) = 100.0*\text{x.l}(i,j)/b(j) ;
\]
\[
\text{display pctx ;}
\]

Appending these commands to the original transportation problem input results in the following output:

\[
\begin{array}{ccc}
\text{pctx} & \text{percent of market j's demand filled by plant I} \\
\text{new-york} & \text{15.385} & \text{100.000} \\
\text{seattle} & \text{84.615} & \text{100.000} \\
\text{san-diego} & \text{15.385} & \text{100.000}
\end{array}
\]
For an example involving marginal, we briefly consider the *ratio constraints* that commonly appear in blending and refining problems. These linear programming models are concerned with determining the optimal amount of each of several available raw materials to put into each of several desired finished products. Let \( y(i,j) \) be the variable for the number of tons of raw material \( i \) put into finished product \( j \). Suppose the *ratio constraint* is that no product can consist of more than 25 percent of one ingredient, that is,

\[
y(i,j)/q(j) = l= 0.25 ;
\]

for all \( i, j \). To keep the model linear, the constraint is written as

\[
\text{ratio}(i,j) .. y(i,j) - 0.25 * q(j) = l= 0.0 ;
\]

rather than explicitly as a ratio.

The problem here is that \( \text{ratio}.m(i,j) \), the marginal value associated with the linear form of the constraint, has no intrinsic meaning. At optimality, it tells us by at most how much we can benefit from relaxing the linear constraint to

\[
y(i,j) - 0.25 * q(j) = l= 1.0 ;
\]

Unfortunately, this relaxed constraint has no realistic significance. The constraint we are interested in relaxing (or tightening) is the nonlinear form of the ratio constraint. For example, we would like to know the marginal benefit arising from changing the ratio constraint to

\[
y(i,j)/q(j) = l= 0.26 ;
\]

We can in fact obtain the desired marginals by entering the following transformation on the undesired marginals:

\[
\text{parameter } \text{amr}(i,j) \text{ appropriate marginal for ratio constraint ;} \\
\text{amr}(i,j) = \text{ratio}.m(i,j)*0.01* \text{q}.l(j) ; \\
\text{display amr ;}
\]

Notice that the assignment statement for \( \text{amr} \) accesses both \( .m \) and \( .l \) records from the database. The idea behind the transformation is to notice that

\[
y(i,j)/q(j) = l= 0.26 ;
\]

is equivalent to

\[
y(i,j) - 0.25 * q(j) = l= 0.01 * q(j) ;
\]
3.13 A GAMS Tutorial by Richard E. Rosenthal

3.13.11 GAMS Output

The default output of a GAMS run is extensive and informative. For a complete discussion, see chapter GAMS Output. This tutorial discusses output partially as follows:

- Echo Print
- Reference Maps
- Status Reports
- Error Messages
- Model Statistics
- Solution Reports

A great deal of unnecessary anxiety has been caused by textbooks and users' manuals that give the reader the false impression that flawless use of advanced software should be easy for anyone with a positive pulse rate. GAMS is designed with the understanding that even the most experienced users will make errors. GAMS attempts to catch the errors as soon as possible and to minimize their consequences.

3.13.11.1 Echo Prints

Whether or not errors prevent your optimization problem from being solved, the first section of output from a GAMS run is an echo, or copy, of your input file. For the sake of future reference, GAMS puts line numbers on the left-hand side of the echo. For our transportation example, which luckily contained no errors, the echo print is as follows:

```plaintext
2 Sets
3 i canning plants / seattle, san-diego /
4 j markets / new-york, chicago, topeka /
5
6 Parameters
7
8 a(i) capacity of plant i in cases
9 / seattle 350
10 san-diego 600 /
11
12 b(j) demand at market j in cases
13 / new-york 325
14 chicago 300
15 topeka 275 /
16
17 Table d(i,j) distance in thousands of miles
18 new-york chicago topeka
19 seattle 2.5 1.7 1.8

Model transport /all/;
Solve transport using lp minimizing z;
Display x.l, x.m;

The reason this echo print starts with line number 2 rather than line number 1 is because the input file contains a dollar-print-control statement. This type of instruction controls the output printing, but since it has nothing to do with defining the optimization model, it is omitted from the echo. The dollar print controls must start in column 1.

$title a transportation model

The $title statement causes the subsequent text to be printed at the top of each page of output. Other available instructions are given in chapter Dollar Control Options.

3.13.11.2 Error Messages

When the GAMS compiler encounters an error in the input file, it inserts a coded error message inside the echo print on the line immediately following the scene of the offense. These messages always start with **** and contain a '$' directly below the point at which the compiler thinks the error occurred. The $ is followed by a numerical error code, which is explained after the echo print. Several examples follow.

Example 1: Entering the statement

set q quarterly time periods / spring, sos1, fall, wtr /;

results in the echo

1 set q quarterly time periods / spring, sos1, fall, wtr /;
**** $160

In this case, the GAMS compiler indicates that something is wrong with the set element sum. At the bottom of the echo print, we see the interpretation of error code 160:

Error Message
160 Unique element expected....
The problem is that `sos1` is a reserved word, which cannot be used as identifiers in general. The complete list of reserved words is shown in this chapter. Thus our set element must have a unique name like 'summer'. This is a common beginner's error.

**Example 2:** Another common error is the omission of a semicolon preceding a direct assignment or equation definition. In our transportation example, suppose we omit the semicolon prior to the assignment of `c(i,j)`, as follows.

```plaintext
Parameter c(i,j) transport cost in 1000s of dollars per case
\[ c(i,j) = f \times d(i,j) / 1000 \]
```

Here is the resulting output.

```plaintext
16 Parameter c(i,j) transport cost in 1000s of dollars per case
17 c(i,j) = f * d(i,j)/1000
**** $97 $195,96,409
Error Message
96 Blank needed between identifier and text
(-or- illegal character in identifier)
(-or- check for missing ';' on previous line)
97 Explanatory text can not start with '$', '=' or '..'
(-or- check for missing ';' on previous line)
195 Symbol redefined with a different type
409 Unrecognizable item - skip to find a new statement
looking for a ';' or a key word to get started again
```

It is not uncommon for one little offense like our missing semicolon to generate five intimidating error messages. The lesson here is: concentrate on fixing the first error and ignore the other! The first error detected (in line 17), code 97, indicate that GAMS thinks the symbols in line 17 are a continuation of the documentary text at the end of line 16 rather than a direct assignment as we intended. The error message also appropriately advises us to check the preceding line for a missing semicolon.

Unfortunately, you cannot always expect error messages to be so accurate in their advice. The compiler cannot read your mind. It will at times fail to comprehend your intentions, so learn to detect the causes of errors by picking up the clues that abound in the GAMS output. For example, the missing semicolon could have been detected by looking up the `c` entry in the cross-reference list (to be explained in the next section) and noticing that it was never assigned.

```plaintext
SYMBOL TYPE REFERENCES
  c PARAM declared 15 ref 17
```

**Example 3:** Many errors are caused merely by spelling mistakes and are caught before they can be damaging. For example, with 'Seattle' spelled in the table differently from the way it was introduced in the set declaration, we get the following error message.

```plaintext
4 sets
5 i canning plants /seattle, san-diego /
6 j markets /new-york, chicago, topeka /
7 table d(i,j) distance in thousand of miles
8 new-york chicago topeka
9  seatle 2.5 1.7 1.8
**** $170
11 san-diego 2.5 1.8 1.4
Error Message
170 Domain violation for element
```
Example 4: Similarly, if we mistakenly enter dem(j) instead of b(j) as the right-hand side of the demand constraint, the result is

\[ 45 \quad \text{demand}(j) \quad . \quad \text{sum}(i, x(i,j)) \quad \text{=} \quad \text{dem}(j) ; \]

****
Error Message
140 Unknown symbol

Example 5: The next example is a mathematical error, which is sometimes committed by novice modelers and which GAMS is adept at catching. The following is mathematically inconsistent and, hence, is not an interpretable statement.

For all \( i \), \( \sum_{i} x_{ij} = 100 \)

There are two errors in this equation, both having to do with the control of indices. Index \( i \) is over-controlled and index \( j \) is under-controlled.

You should see that index \( i \) is getting conflicting orders. By appearing in the quantifier 'for all \( i \)', it is supposed to remain fixed for each instance of the equation. Yet, by appearing as an index of summation, it is supposed to vary. It can't do both. On the other hand, index \( j \) is not controlled in any way, so we have no way of knowing which of its possible values to use.

If we enter this meaningless equation into GAMS, both errors are correctly diagnosed.

\[ \text{meaninglss}(i) \quad . \quad \text{sum}(i, x(i,j)) \quad \text{=} \quad 100 ; \]

****
Error Messages
125 Set is under control already [This refers to set \( i \).]
149 Uncontrolled set entered as constant [This refers to set \( j \).]

More information about error reporting is given in section Error Reporting. Comprehensive error detection and well-designed error messages are a big help in getting models implemented quickly and correctly.

3.13.11.3 Reference Maps

The next section of output, which is the last if errors have been detected, is a pair of reference maps that contain summaries and analyses of the input file for the purposes of debugging and documentation.

The first reference map is a cross-reference map such as one finds in most modern compilers. It is an alphabetical, cross-referenced list of all the entities (sets, parameters, variables, and equations) of the model. The list shows the type of each entity and a coded reference for each appearance of the entity in the input. The cross-reference map for our transportation example is as follows (we do not display all tables). To turn the cross-reference map on, please add the line

\$onSymXRef

to your model.
For example, the cross-reference list tells us that the symbol \( a \) is a parameter that was declared in line 9, defined (assigned value) in line 10, and referenced in line 42. The symbol \( i \) has a more complicated entry in the cross-reference list. It is shown to be a set that was declared and defined in line 5. It is referenced once in lines 10, 19, 26, 28, 31, 38, 45 and referenced twice in lines 41 and 43. Set \( i \) is also used as a controlling index in a summation, equation definition or direct parameter assignment in lines 28, 41, 43 and 45.

For the GAMS novice, the detailed analysis of the cross-reference list may not be important. Perhaps the most likely benefit he or she will get from the reference maps will be the discovery of an unwanted entity that mistakenly entered the model owing to a punctuation or syntax error.

The second part of the reference map is a list of model entities grouped by type and listed with their associated documentary text. For example, this list is as follows.

**SETS**

\[
\begin{align*}
\text{i} & \quad \text{canning plants} \\
\text{j} & \quad \text{markets}
\end{align*}
\]

**PARAMETERS**

\[
\begin{align*}
\text{a} & \quad \text{capacity of plant } i \text{ in cases} \\
\text{b} & \quad \text{demand at market } j \text{ in cases} \\
\text{c} & \quad \text{transport cost in thousands of dollars per case} \\
\text{d} & \quad \text{distance in thousands of miles} \\
\text{f} & \quad \text{freight in dollars per case per thousand miles}
\end{align*}
\]

**VARIABLES**

\[
\begin{align*}
\text{x} & \quad \text{shipment quantities in cases}
\end{align*}
\]
z total transportation costs in thousands of dollars

EQUATIONS

cost define objective function
demand satisfy demand at market j
supply observe supply limit at plant i

MODELS

transport

3.13.11.4 Equation Listings

Once you succeed in building an input file devoid of compilation errors, GAMS is able to generate a model. The question remains, and only you can answer it, does GAMS generate the model you intended?

The equation listing is probably the best device for studying this extremely important question. A product of the solve command, the equation listing shows the specific instance of the model that is created when the current values of the sets and parameters are plugged into the general algebraic form of the model. For example, the generic demand constraint given in the input file for the transportation model is

\[
\text{demand}(j) \quad . \quad \text{sum}(i, x(i,j)) = \text{g= b(j)} ;
\]

while the equation listing of specific constraints is

\[
--------\text{demand = g= satisfy demand at market j}
demand(new-york).. x(seattle, new-york) +x(san-diego, new-york) = \text{g= 325} ;
demand(chicago).. x(seattle, chicago) +x(san-diego, chicago ) = \text{g= 300} ;
demand(topeka).. x(seattle, topeka) +x(san-diego, topeka) = \text{g= 275} ;
\]

The default output is a maximum of three specific equations for each generic equation. To change the default, insert an input statement prior to the solve statement:

\[
\text{option limrow = r ;}
\]

where \( r \) is the desired number.

The default output also contains a section called the column listing, analogous to the equation listing, which shows the coefficients of three specific variables for each generic variable. This listing would be particularly useful for verifying a GAMS model that was previously implemented in MPS format. To change the default number of specific column printouts per generic variable, the above command can be extended:

\[
\text{option limrow = r, limcol = c ;}
\]

where \( c \) is the desired number of columns. (Setting \text{limrow} and \text{limcol} to 0 is a good way to reduce the size of your lst file after your model has been debugged.) In nonlinear models, the GAMS equation listing shows first-order Taylor approximations of the nonlinear equations. The approximations are taken at the starting values of the variables.
3.13.11.5 Model Statistics

The last section of output that GAMS produces before invoking the solver is a group of statistics about the model's size, as shown below for the transportation example.

MODEL STATISTICS

<table>
<thead>
<tr>
<th>BLOCKS OF EQUATIONS</th>
<th>SINGLE EQUATIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>6</td>
</tr>
<tr>
<td>BLOCKS OF VARIABLES</td>
<td>SINGLE VARIABLES</td>
</tr>
<tr>
<td>2</td>
<td>7</td>
</tr>
<tr>
<td>NON ZERO ELEMENTS</td>
<td></td>
</tr>
<tr>
<td>19</td>
<td></td>
</tr>
</tbody>
</table>

The BLOCK counts refer to the number of generic equations and variables. The SINGLE counts refer to individual rows and columns in the specific model instance being generated. For nonlinear models, some other statistics are given to describe the degree of non-linearity in the problem.

3.13.11.6 Status Reports

After the solver executes, GAMS prints out a brief Solve Summary whose two most important entries are SOLVER STATUS and the MODEL STATUS. For our transportation problem the solve summary is as follows:

```
SOLVE SUMMARY
MODEL TRANSPORT OBJECTIVE z
TYPE LP DIRECTION MINIMIZE
SOLVER CPLEX FROM LINE 49
**** SOLVER STATUS 1 Normal Completion
**** MODEL STATUS 1 Optimal
**** OBJECTIVE VALUE 153.6750
RESOURCE USAGE, LIMIT 0.031 1000.000
ITERATION COUNT, LIMIT 4 2000000000
```

The status reports are preceded by the same **** string as an error message, so you should probably develop the habit of searching for all occurrences of this string whenever you look at an output file for the first time. The desired solver status is 1 NORMAL COMPLETION, but there are other possibilities, documented in section The Solve Summary, which relate to various types of errors and mishaps.

There are eleven possible model statuses, including the usual linear programming termination states (1 Optimal, 3 Unbounded, 4 Infeasible), and others relating to nonlinear and integer programming. In nonlinear programming, the status to look for is 2 Locally Optimal. The most the software can guarantee for nonlinear programming is a local optimum. The user is responsible for analyzing the convexity of the problem to determine whether local optimality is sufficient for global optimality. In integer programming, the status to look for is 8 Integer Solution. This means that a feasible integer solution has been found. More detail follows as to whether the solution meets the relative and absolute optimality tolerances that the user specifies.
3.13.11.7 Solution Reports

If the solver status and model status are acceptable, then you will be interested in examining the results of the optimization. The results are first presented in as standard mathematical programming output format, with the added feature that rows and columns are grouped and labeled according to names that are appropriate for the specific model just solved. In this format, there is a line of printout for each row and column giving the lower limit, level, upper limit, and marginal. Generic equation block and the column output group the row output by generic variable block. Set element names are embedded in the output for easy reading. In the transportation example, the solver outputs for supply(i), demand(j), and x(i,j) are as follows:

```
---- EQU supply observe supply limit at plant i
       LOWER     LEVEL     UPPER     MARGINAL
  seattle -INF     350.000   350.000    EPS
   san-diego -INF     550.000   600.000     .

---- EQU demand satisfy demand at market j
       LOWER    LEVEL     UPPER     MARGINAL
  new-york  325.000     325.000   +INF   0.225
    chicago  300.000     300.000   +INF   0.153
    topeka  275.000     275.000   +INF   0.126

---- VAR x shipment quantities in cases
       LOWER     LEVEL     UPPER     MARGINAL
  seattle  .new-york    .     50.000   +INF     .
  seattle  .chicago     .     300.000   +INF     .
  seattle  .topeka     .     .       +INF   0.036
  san-diego.new-york .     .     275.000   +INF     .
   san-diego.chicago .     .     .       +INF   0.009
  san-diego.topeka .     .     275.000   +INF     .
```

The single dots '.' in the output represent zeroes. The entry EPS, which stands for epsilon, mean very small but nonzero. In this case, EPS indicates degeneracy. (The slack variable for the Seattle supply constraint is in the basis at zero level. The marginal is marked with EPS rather than zero to facilitate restarting the optimizer from the old basis.)

If the solvers results contain either infeasibilities or marginal costs of the wrong sign, then the offending entries are marked with INFES or NOPT, respectively. If the problem terminates unbounded, then the rows and columns corresponding to extreme rays are marked UNBND.

At the end of the solvers solution report is a very important report summary, which gives a tally of the total number of non-optimal, infeasible, and unbounded rows and columns. For our example, the report summary shows all zero tallies as desired.

```
**** REPORT SUMMARY : 0 NONOPT
0 INFEASIBLE
0 UNBOUNDED
```
After the solver's report is written, control is returned from the solver back to GAMS. All the levels and marginals obtained by the solver are entered into the GAMS database in the .l and .m fields. These values can then be transformed and displayed in any desired report. As noted earlier, the user merely lists the quantities to be displayed, and GAMS automatically formats and labels an appropriate array. For example, the input statement.

\[\text{display x.l, x.m ;}\]

results in the following output.

\begin{verbatim}
---- 50 VARIABLE x.L shipment quantities in cases
     new-york  chicago  topeka
     seattle    50.000   300.000
     san-diego  275.000   275.000

---- 50 VARIABLE x.M shipment quantities in cases
     chicago  topeka
     seattle    0.036
     san-diego  0.009
\end{verbatim}

As seen in reference maps, equation listings, solution reports, and optional displays, GAMS saves the documentary text and "parrots" it back throughout the output to help keep the model well documented.

### 3.13.12 Summary

This tutorial has demonstrated several of the design features of GAMS that enable you to build practical optimization models quickly and effectively. The following discussion summarizes the advantages of using an algebraic modeling language such as GAMS versus a matrix generator or conversational solver.

- By using an algebra-based notation, you can describe an optimization model to a computer nearly as easily as you can describe it to another mathematically trained person.
- Because an algebraic description of a problem has generality, most of the statements in a GAMS model are reusable when new instances of the same or related problems arise. This is especially important in environments where models are constantly changing.
- You save time and reduce generation errors by creating whole sets of closely related constraints in one statement.
- You can save time and reduce input errors by providing formulae for calculating the data rather than entering them explicitly.
- The model is self-documenting. Since the tasks of model development and model documentation can be done simultaneously, the modeler is much more likely to be conscientious about keeping the documentation accurate and up to date.
- The output of GAMS is easy to read and use. The solution report from the solver is automatically reformatted so that related equations and variables are grouped together and appropriately labeled. Also, the \texttt{display} command allows you to modify and tabulate results very easily.
If you are teaching or learning modeling, you can benefit from the insistence of the GAMS compiler that every equation be mathematically consistent. Even if you are an experienced modeler, the hundreds of ways in which errors are detected should greatly reduce development time.

By using the dollar operator and other advanced features not covered in this tutorial, one can efficiently implement large-scale models. Specific applications of the dollar operator include:

1. It can enforce logical restrictions on the allowable combinations of indices for the variables and equations to be included in the model. You can thereby screen out unnecessary rows and columns and keep the size of the problem within the range of solvability.
2. It can be used to build complex summations and products, which can then be used in equations or customized reports.
3. It can be used for issuing warning messages or for terminating prematurely conditioned upon context-specific data edits.

### 3.14 Quick Start Tutorial

GAMS (the General Algebraic Modeling System) is a high-level modeling system for mathematical programming problems. This tutorial is aimed at modelers who are new to GAMS and are looking for a quick introduction to the core features of GAMS. Note that the text contains many links to the GAMS User's Guide for further exploration. Observe that this tutorial is adapted from the Quick Start Tutorial from Bruce McCarl. Another introductory text is the tutorial A GAMS Tutorial by Richard E. Rosenthal.

#### 3.14.1 Three Basic Models

Most modelers who are interested in GAMS have one (or more) of the following backgrounds:

- They wish to solve constrained optimization problems with objective functions.
- They are looking for a system to solve general equilibrium problems that arise in various areas of economics.
- They wish to solve nonlinear systems of equations that arise in engineering.

GAMS is well equipped to model and solve all three types of problems. We will start by introducing examples for all three areas and the discussions that will follow will refer to these three basic examples.

#### 3.14.1.1 First Example: Solving a Linear Programming Problem (LP)

The simplest constrained optimization problem is an LP. Assume we wish to solve the following LP that represents a simple farm model where profit is maximized:

\[
\begin{align*}
\text{max} & \quad 109X_{\text{corn}} + 90X_{\text{wheat}} + 115X_{\text{cotton}} \\
\text{s.t.} & \quad X_{\text{corn}} + X_{\text{wheat}} + X_{\text{cotton}} \leq 100 \quad \text{(land)} \\
& \quad 6X_{\text{corn}} + 4X_{\text{wheat}} + 8X_{\text{cotton}} \leq 500 \quad \text{(labor)} \\
& \quad X_{\text{corn}} \geq 0 \quad \text{(nonnegativity)} \\
& \quad X_{\text{wheat}} \geq 0 \quad \text{(nonnegativity)} \\
& \quad X_{\text{cotton}} \geq 0 \quad \text{(nonnegativity)}
\end{align*}
\]

Note that there are three decision variables: \(X_{\text{corn}}\) denotes the land assigned to growing corn, \(X_{\text{wheat}}\) is the land assigned to growing wheat and \(X_{\text{cotton}}\) represents the land where cotton is grown. In the first line the total profit is expressed as a function of the land allotted to the three crops, the multipliers represent the expected profit per acre depending of the type of crop. The first inequality imposes a limit on the available land, the second inequality imposes a limit on the available labor and the final three lines restrict the decision variables to nonnegative values.

This problem may be expressed in GAMS as follows:
Positive Variables Xcorn, Xwheat, Xcotton;
Variables Z;

Equations obj, land, labor;

obj.. Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
land.. Xcorn + Xwheat + Xcotton =l= 100;
labor.. 6 * Xcorn + 4 * Xwheat + 8 * Xcotton =l= 500;

Model farmproblem / obj, land, labor /;
solve farmproblem using LP maximizing Z;

We will analyze this formulation and discuss every part of it after introducing the other two basic examples.

3.14.1.2 Second Example: Solving for an Economic Equilibrium

The simplest general equilibrium model is the single good, single market problem. Assume we wish to solve the following equilibrium problem:

Demand Price: \( P \geq P_d = 6 - 0.3Q_d \)
Supply Price: \( P \leq P_s = 1 + 0.2Q_s \)
Quantity Equilibrium: \( Q_s \geq Q_d \)
Nonnegativity: \( P \geq 0 \)
\( Q_s \geq 0 \)
\( Q_d \geq 0 \)

Here \( P \) is the market clearing price, \( P_d \) is the demand curve, \( Q_d \) denotes the quantity demanded, \( P_s \) the supply curve and \( Q_s \) the quantity supplied. Note that this is a problem in 3 equations and 3 variables. The variables are \( P, Q_d, \) and \( Q_s \). Note that \( P_d \) and \( P_s \) are not variables, since they can be computed from the equality relations.

Usually all equality constraints are used for such a set up. However, we will use a more general setup, because it relaxes some assumptions and more accurately depicts a model ready to be implemented in GAMS. In particular, we permit the case where the supply curve price intercept may be above the demand curve price intercept and thus the market may clear with a nonzero price but a zero quantity. In addition, we allow the market price to be above the demand curve price and below the supply curve price. We also impose some additional conditions based on Walras’ Law to ensure a proper solution in such cases.

\[
Q_d(P - P_d) = 0 \quad \text{or} \quad Q_d(P_d - (6 - 0.3Q_d)) = 0
\]
\[
Q_s(P - P_s) = 0 \quad \text{or} \quad Q_s(P_s - (1 + 0.2Q_s)) = 0
\]
\[
P(Q_s - Q_d) = 0
\]

Here the quantity demanded is nonzero only if the market clearing price equals the demand curve price, the quantity supplied is nonzero only if the market clearing price equals the supply curve price and the market clearing price is only nonzero if \( Q_s = Q_d \).

The simplest GAMS formulation is given below. Note that we needed to rearrange the equation Psupply in order to achieve a greater than inequality, thus we accomodated the requirements of the solver PATH.

Positive Variables P, Qd , Qs;

Equations Pdemand, Psupply, Equilibrium;
Pdemand.. P =g= 6 - 0.3*Qd;
Psupply.. ( 1 + 0.2*Qs) =g= P;
Equilibrium.. Qs =g= Qd;

Model problem / Pdemand.Qd, Psupply.Qs, Equilibrium.P /;
solve problem using MCP;

We will analyze this formulation and discuss every component of it after introducing the third example.
3.14.1.3 Third Example: Solving a Nonlinear Equation System

Engineers often wish to solve a nonlinear system of equations. Examples include chemical equilibria or problems in the context of oil refining. Many other such problems of this type exist. The problem that follows is adapted from the paper Wall, T W, Greening, D, and Woolsey, R F D, "Solving Complex Chemical Equilibria Using a Geometric-Programming Based Technique" Operations Research 34, 3 (1987).

\begin{align*}
ba \times so4 &= 1 \\
baoh / ba / oh &= 4.8 \\
hso4 / so4 / h &= 0.98 \\
h \times oh &= 1 \\
ba + 1e-7*baoh &= so4 + 1e-5*hso4 \\
2 \times ba + 1e-7*baoh + 1e-2*h &= 2 \times so4 + 1e-5*hso4 + 1e-2*oh 
\end{align*}

Note that this is a nonlinear system of equations with the variables $ba$, $so4$, $baoh$, $oh$, $hso4$ and $h$. The following formulation in GAMS is from the model [WALL] in the GAMS model library.

\begin{verbatim}
Variables ba, so4, baoh, oh, hso4, h ;
Equations r1, r2, r3, r4, b1, b2 ;
\begin{align*}
r1.. ba * so4 &= 1 ; \\
r2.. baoh / ba / oh &= 4.8 ; \\
r3.. hso4 / so4 / h &= 0.98 ; \\
r4.. h * oh &= 1 ; \\
b1.. ba + 1e-7*baoh &= so4 + 1e-5*hso4 ; \\
b2.. 2 * ba + 1e-7*baoh + 1e-2*h &= 2 * so4 + 1e-5*hso4 + 1e-2*oh ; \\
\end{align*}
Model wall / all / ;
ba.l=1; so4.l=1; baoh.l=1; oh.l=1; hso4.l=1; h.l=1;
solve wall using nlp minimizing ba;
\end{verbatim}

3.14.2 Components of the Example Models

Now that we have our three basic models in place, we will analyze them and identify and discuss their components, including variables, equations, model definitions, solve statements and starting points.

3.14.2.1 Variables in the Example Models

Variables in GAMS have to be declared as variables with a variable statement. The variable statements in the examples above are repeated below:

- First example:
Positive Variables Xcorn, Xwheat, Xcotton;
Variables Z;

• Second example:
Positive Variables P, Qd, Qs;

• Third example:
Variables ba, so4, baoh, oh, hso4, h;

Note that variable(s) is a keyword in GAMS. Positive is another keyword, it serves as a modifier to the keyword variable and has the effect that the variables that follow may take only nonnegative values. Variables that are declared with the keyword variable without a modifier are unrestricted in sign. For more details on variable declarations and variable types, see sections Variable Declarations and Variable Types respectively.

Observe that GAMS is not case sensitive and allows a line feed to be used instead of a comma. Thus, the following three variable declarations are all valid and have the same effect:

POSITIVE VARIABLES Xcorn, Xwheat, Xcotton;
Positive Variables xcorn, xwheat, xcotton;
positive variables Xcorn, Xwheat, Xcotton;

In the GAMS formulation of the first example, we have introduced the variable Z in addition to the three variables that featured in the mathematical formulation. Note that GAMS requires the optimization model

Maximize cx

to have the following form:

Maximize z
z = cx

Here z is a variable, also called objective variable. Observe that it is the objective variable that is maximized, not the function cx. The name of the objective variable may be chosen freely by the user, like any other variable name. The objective variable is a free variable, which means that it has no bounds. Hence, it each optimization problem there must always be at least one free variable.

Given the requirement of an objective variable in an optimization problem, we need to declare a new free variable and introduce an equation for it. In our first example we declared Z as a free variable, then we declared and specified the equation obj setting Z equal to the objective function expression and we instructed the solver to maximize Z. The relevant lines of code from the first example follow:

Variables Z;
Equation obj, land, labor;
obj.. Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
solve farmproblem using LP maximizing Z;

Note
In some optimization problems users do not need to introduce a new variable to serve as an objective variable, but a free variable that already features in the model may be used. For example, in the second example above, ba is a free variable that is used as objective variable, since the model type NLP requires an objective variable. We will discuss this further below.
3.14.2.2 Equations in the Example Models

Each equation in a model must first be declared with an equation declaration statement and then defined with an equation definition statement. We repeat the respective statement from the three examples below:

- First example:

  Equations         obj, land, labor;

  obj.. Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
  land.. Xcorn + Xwheat + Xcotton =l= 100;
  labor.. 6 * Xcorn + 4 * Xwheat + 8 * Xcotton =l= 500;

- Second example:

  Equations         Pdemand, Psupply, Equilibrium;

  Pdemand.. P =g= 6 - 0.3*Qd;
  Psupply.. ( 1 + 0.2*Qs) =g= P;
  Equilibrium.. Qs =g= Qd;

- Third example:

  Equations r1, r2, r3, r4, b1, b2;

  r1.. ba * so4 =e= 1 ;
  r2.. baoh / ba / oh =e= 4.8 ;
  r3.. hso4 / so4 / h =e= .98 ;
  r4.. h * oh =e= 1 ;
  b1.. ba + 1e-7*baoh =e= so4 + 1e-5*hso4 ;
  b2.. 2 * ba + 1e-7*baoh + 1e-2*h =e= 2 * so4 + 1e-5*hso4 + 1e-2*oh ;

Note that the equation declaration statement begins with the keyword Equation(s). Its main purpose is to name the equation(s). For further details on equation declarations, see section Declaring Equations.

The algebraic structure of the equation is specified in the equation definition statement, where the name of the equation is followed by two dots .. and the algebra. The relation between the left-hand side and right-hand side is specified by special symbols indicating the equation type. The most common symbols are =e= for equality, =l= for a less than or equal to relation and =g= for a greater than or equal to relation. An overview of all GAMS equation types is given in Table Equation Types. For more information on equation definitions, see sections Defining Equations and Conditional Equations.

3.14.2.3 Model Definitions in the Example Models

Once all structural elements of a model have been defined and specified, a model statement is used to define the model that will be solved. The model statement form the three examples follow:

- First example:

  Model farmproblem / obj, land, labor /;

- Second example:

  Model problem / Pdemand.Qd, Psupply.Qs, Equilibrium.P /;
• Third example:

    Model wall / all / ;

Note that a model statement always starts with the keyword model. It is followed by the name of the model which users may choose freely and a list of the equations that are part of the model. Observe that the list of equations in the first example contains all equations that were declared and defined. However, this need not be the case. It is possible to declare and define an equation and then not use it in a model. For example, users could define several models that contain different subsets of equations. If all equations that were previously declared and defined enter the model, the keyword all may be used as a shortcut, like in the third example.

Attention

Only equations that have been declared may be listed in a model statement. All equations in a model must have been defined before the model can be solved.

Note that equilibrium problems like the second example are solved as Mixed Complementarity Problems (MCPs). MCPs require a special variant of the model statement where not only the equations are listed, but also their complementarity relationships. The complementarity relationship between an equation and its associated variable is marked with a dot ".". Hence, in the second example, the equation $P_{demand}$ is perpendicular to the variable $Q_d$, the equation $P_{supply}$ is perpendicular to the variable $Q_s$ and the equation $Equilibrium$ is perpendicular to the variable $P$.

In the three model statements above the name of the model was immediately followed by the list of the equations included in the model. Observe that an optional explanatory text may be inserted after the name of the model.

3.14.2.4 Solve Statements in the Example Models

After the model has been defined it remains to be solved, i.e. to find a solution for the variables. The solve statement directs GAMS to use a solver to optimize the model or solve the system of equations. The solve statements of the three examples follow:

• First example:

    solve farmproblem using LP maximizing Z;

• Second example:

    solve problem using MCP;

• Third example:

    solve wall using nlp minimizing ba;

Note that a solve statement always begins with the keyword solve followed by the name of the model, as previously specified with a model statement, the keyword using and the type of the model. We have an LP (linear programming problem) in the first example, an MCP (mixed complementarity problem) in the second example and an NLP (nonlinear programming program) in the third example. A complete list of GAMS model types is given in section Classification of Models. After the model type the direction of the optimization is given: either maximizing as in the first example or minimizing as in the third example. In the final position is the name of the objective variable that is to be optimized.
MCPs and systems of equations of the model type Constrained Nonlinear System (CNS) do not have objective variables. Therefore their solve statements end with the model type.

Observe that the system of nonlinear equations in the second example was expressed as an NLP that requires an objective function and a related objective variable. Actually this is an older practice in GAMS as the GAMS model type CNS was added after this example was initially formulated. Hence, we could alternatively use the following solve statement:

```
solve wall using cns;
```

However, note that the model type CNS can only be solved by select solvers and cannot incorporate integer variables. A formulation as an optimization problem relaxes these restrictions, thus allowing the use of the model type MINLP and all NLP solvers. If the model type NLP or one of its variants is chosen, one of the variables must be selected as objective variable to be optimized. Observe that which variable is chosen may not really have any effect since a feasible solution requires all of the simultaneous equations to be solved. Thus, while in the third example the variable $ba$ is maximized, there is no inherent interest in attaining its maximum - it is just convenient.

### 3.14.2.5 Starting Points

In the third example we have the following line before the solve statement:

```
ba.l=1; so4.l=1; baoh.l=1; oh.l=1; hso4.l=1; h.l=1;
```

Note that this line provides starting points for the variables in the model. The suffix .l appended to a variable name denotes the level value of that variable. If a level value of a variable is specified before the solve statement, this value will act as a starting point for the search algorithms. The level value of a variable is one example of a variable attribute. Other examples include lower and upper bounds which may be set with the suffixes .lo and .up. For more information on variable attributes, see section Variable Attributes. For guidance on how to choose good starting points, see the tutorial Good NLP Formulations. Specifying starting points may be important for avoiding numerical problems in the model solution. For more on this topic, see the tutorial Finding and Fixing Execution Errors and Performance Problems.

Observe that the statements above are the first examples of assignment statements in this tutorial. Assignment statements play a crucial role in GAMS, they are introduced in section The Assignment Statement.

### 3.14.3 Running a GAMS Job

The model formulation of a GAMS model is saved in a text file with the extension .gms, say myfile.gms. Then the file is submitted to GAMS. GAMS will execute the instructions in the .gms file, with the result that calculations are done, solvers are used and an output file with the solution results is created. The output file is also called the listing file. By default, the name listing file of the input file myfile.gms will be myfile.lst.

There are two ways to submit a job to GAMS: via the command line and via the GAMS IDE.
3.14.3.1 Running GAMS on the Command Line

The model formulation of a GAMS model is saved in a text file with the extension .gms, say myfile.gms. This file may be run with GAMS using the following call:

```plaintext
> gams myfile
```

Note the extension .gms may be omitted. This basic GAMS call may be extended with arguments that are called command line parameters. The following example serves as illustration:

```plaintext
> gams transport pw=80 ps=9999 s=mysave
```

Note that there are three command line parameters: the first will set the page width to 80, the second will set the page length to 9999 and the third will have the effect that a work file named mysave is saved. GAMS offers many command line parameters, they are introduced and discussed in detail in chapter The GAMS Call and Command Line Parameters.

3.14.3.2 Running GAMS with the IDE

The GAMS Integrated Development Environment is a graphical user interface for Windows that facilitates editing, development, debugging GAMS models and running GAMS jobs.

3.14.4 Examining The Output

The output of a GAMS run is saved in the output or listing file. The listing file may contain many parts. Some parts may be suppressed by the modeler, other parts are suppressed by default and need to be activated. For an introduction and detailed discussion, see chapter GAMS Output.

In this section we will review the output that is generated by running the three example models.

3.14.4.1 The Echo Print

The listing file always begins with the echo print. The echo print is a copy of the input file with added line numbers. For example, the echo print of the first example is given below:

```plaintext
1 Positive Variables Xcorn, Xwheat, Xcotton;
2 Variables Z;
3 Equations obj, land, labor;
4
5 obj.. Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
6 land.. Xcorn + Xwheat + Xcotton =l= 100;
7 labor.. 6 * Xcorn + 4 * Xwheat + 8 * Xcotton =l= 500;
8
9 Model farmproblem / obj, land, labor /;
10
11 solve farmproblem using LP maximizing Z;
```

Note that the echo print of the other two examples follows the same principles. Note further, that the echo print serves as an important reference guide since GAMS reports the line numbers of any errors that were detected and of solve and display statements.

Observe that usually the code of even experienced GAMS modelers will contain compilation errors. They are marked in the echo print. For more information on compilation error and how to resolve them, see section Compilation Errors and the tutorial Fixing Compilation Errors.
3.14.4.2 Model Generation Output

Once GAMS has successfully compiled the input file and any numerical computations in assignments have been performed, the solve statements will be executed. The first step is generating a computer readable version of the equations in the problem that will be passed on to an appropriate solver system. During the model generation phase GAMS creates the following output:

- A listing of the equations of the model.
- A listing of the variables of the model.
- A summary of the model structure.
- If errors were detected during model generation they will be reported as well.

3.14.4.2.1 The Equation Listing

The equation listing is the first part of the output generated by a solve statement. By default, the first three equations in every block are listed. The equation listing of the first two equations of each of the three examples are given below:

- **First example:**
  
  Equation Listing SOLVE farmproblem Using LP From line 12

  
  ---- obj =E=
  obj.. -109*Xcorn - 90*Xwheat - 115*Xcotton + Z =E= 0 ; (LHS = 0)

  ---- land =L=
  land.. Xcorn + Xwheat + Xcotton =L= 100 ; (LHS = 0)

- **Second example:**
  
  Equation Listing SOLVE problem Using MCP From line 10

  
  ---- Pdemand =G=
  Pdemand.. P + 0.3*Qd =G= 6 ; (LHS = 0, INFES = 6 ****)

  ---- Psupply =G=
  Psupply.. -P + 0.2*Qs =G= -1 ; (LHS = 0)

- **Third example:**
  
  Equation Listing SOLVE wall Using NLP From line 16

  
  ---- r1 =E=
  r1.. (1)*ba + (1)*so4 =E= 1 ; (LHS = 1)

  ---- r2 =E=
  r2.. - (1)*ba + (1)*baoh - (1)*oh =E= 4.8 ; (LHS = 1, INFES = 3.8 ****)
Note that the equation listing is a representation of the algebraic structure of the linear terms in the equation and a local representation containing the first derivatives of the nonlinear terms. The nonlinear terms are automatically placed in parentheses to indicate a local approximation. For further details, see section The Equation Listing in chapter GAMS Output.

3.14.4.2.2 The Column Listing  The column or variable listing contains a list of the individual coefficients sorted by column rather than by row (like in the equation listing). By default, the first three entries for each variable are shown, along with their lower bound .lo, upper bound .up and current level values .l. The column listing of the first two variables for each of the three examples are given below.

• First example:

Column Listing  SOLVE farmproblem Using LP From line 12

---- Xcorn

Xcorn

 (.LO, .L, .UP, .M = 0, 0, +INF, 0)
-109   obj
1      land
6      labor

---- Xwheat

Xwheat

 (.LO, .L, .UP, .M = 0, 0, +INF, 0)
-90    obj
1      land
4      labor

• Second example:

Column Listing  SOLVE problem Using MCP From line 10

---- P

P

 (.LO, .L, .UP, .M = 0, 0, +INF, 0)
1      Pdemand
-1     Psupply

---- Qd

Qd

 (.LO, .L, .UP, .M = 0, 0, +INF, 0)
0.3    Pdemand
-1     Equilibrium

• Third example:

Column Listing  SOLVE wall Using NLP From line 16
---- ba

ba

(.LO, .L, .UP, .M = -INF, 1, +INF, 0)

(1) r1
(-1) r2
1 b1
2 b2

---- so4

so4

(.LO, .L, .UP, .M = -INF, 1, +INF, 0)

(1) r1
(-1) r3
-1 b1
-2 b2

3.14.4.2.3 Model Statistics  The final information generated while a model is being prepared for solution, is the statistics block. Its most obvious use is to provide details on the size and nonlinearity of the model. The model statistics of the third example follow.

MODEL STATISTICS

BLOCKS OF EQUATIONS 6
SINGLE EQUATIONS 6
BLOCKS OF VARIABLES 6
SINGLE VARIABLES 6
NON ZERO ELEMENTS 20
NON LINEAR N-Z 10
DERIVATIVE POOL 20
CONSTANT POOL 16
CODE LENGTH 22

For more information on model statistics, see section The Model Statistics in chapter GAMS Output.

3.14.4.3 The Solution Report

The final major component of the listing file is the solution output. It consists of a summary, some solver-specific output and a report of the solutions for equations and variables.

3.14.4.3.1 The Solve Summary  The solve summary is very important since it contains an overview of key information of the solution. The solve summary of the third example is given below.

SOLVE SUMMARY

MODEL wall
OBJECTIVE ba
TYPE NLP
DIRECTION MINIMIZE
SOLVER CONOPT
FROM LINE 16

**** SOLVER STATUS 1 Normal Completion
**** MODEL STATUS 2 Locally Optimal
**** OBJECTIVE VALUE 1.0000

RESOURCE USAGE, LIMIT 0.034 1000.000
ITERATION COUNT, LIMIT 7 2000000000
EVALUATION ERRORS 0 0

For details on the solve summary including possible values for SOLVER STATUS and MODEL STATUS, see section The Solve Summary in chapter GAMS Output.
3.14.4.3.2 The Solver Report  

The next part of the listing file is the solver report. It contains solver specific output. The respective output of the third example follows:

CONOPT 3 24.7.3 r58181 Released Jul 11, 2016 DEG x86 64bit/MacOS X

CONOPT 3 version 3.17A
Copyright (C) ARKI Consulting and Development A/S
Bagsvaerdvej 246 A
DK-2880 Bagsvaerd, Denmark

Pre-triangular equations: 0
Post-triangular equations: 0

** Optimal solution. There are no superbasic variables.

For more on solver reports, see section Solver Report in chapter GAMS Output.

3.14.4.3.3 The Solution Listing  

The solution listing is a row-by-row then column-by-column listing of the solutions returned to GAMS by the solver program. Each individual equation and variable is listed including their level and marginal values and their lower and upper bounds. The solution listing of the first example follows:

```
LOWER  LEVEL  UPPER  MARGINAL
---- EQU obj . . . 1.0000
---- EQU land -INF 100.0000 100.0000 52.0000
---- EQU labor -INF 500.0000 500.0000 9.5000

LOWER  LEVEL  UPPER  MARGINAL
---- VAR Xcorn . 50.0000 +INF .
---- VAR Xwheat . 50.0000 +INF .
---- VAR Xcotton . . +INF -13.0000
---- VAR Z -INF 9950.0000 +INF .
```

Note that single dots '.' represent zeros. The extended range arithmetic symbols -INF and +INF denote minus and plus infinity respectively. EPS is another extended range arithmetic symbol that often appears in solution listings. In this context, it is used to indicate basis status in the degenerate case. For example, a basic variable is indicated by a zero (single dot) marginal, while a non-basic variable whose marginal is (nearly) zero is indicated by a marginal of EPS. For further details, see section The Solution Listing in chapter GAMS Output.

3.14.5 Exploiting the Algebraic Structure

GAMS was deliberately designed to make it easy to express algebraic relationships. Thus it provides notation for indexed operations like sums. Assume that z is defined as the sum over \( x_i \) where \( i = \{1, 2, 3\} \):

\[
z = \sum_{i=1}^{3} x_i = x_1 + x_2 + x_3
\]

This can be expressed in GAMS in the following way:
\[ z = \text{sum}(i, x(i)) \]

Here \( i \) is a set with three elements, \( z \) is a scalar or variable and \( x(i) \) is a parameter or variable defined over the set \( i \). Note that the keyword \text{sum} automatically cycles through all elements of the set \( i \).

Indexed operations like \text{sum} may be used in the algebraic specification of equations or in the context of assignments where the value of identifiers are computed. In the following two sections we will introduce revised versions of the first two examples, where we illustrate how using \text{sum} simplifies the code and enables more general formulations.

### 3.14.5.1 Revised First Example

Recall that the first example is the following LP:

\[
\begin{align*}
\text{max} & \quad 109X_{\text{corn}} + 90X_{\text{wheat}} + 115X_{\text{corn}} \\
\text{s.t.} & \quad X_{\text{corn}} + X_{\text{wheat}} + X_{\text{cotton}} \leq 100 \quad \text{(land)} \\
& \quad 6X_{\text{corn}} + 4X_{\text{wheat}} + 8X_{\text{cotton}} \leq 500 \quad \text{(labor)} \\
& \quad X_{\text{corn}} \geq 0 \quad \text{(nonnegativity)} \\
& \quad X_{\text{wheat}} \geq 0 \quad \text{(nonnegativity)} \\
& \quad X_{\text{cotton}} \geq 0 \quad \text{(nonnegativity)}
\end{align*}
\]

Note that this is a special case of the general resource allocation problem that can be written as follows:

\[
\begin{align*}
\text{max} & \quad \sum_j c_j X_j \\
\text{s.t.} & \quad \sum_j a_{ij} X_j \leq b_i \quad \text{for all } i \\
& \quad X_j \geq 0 \quad \text{for all } j,
\end{align*}
\]

where

- \( j = \{\text{corn, wheat, cotton}\} \)
- \( i = \{\text{land, labor}\} \)
- \( X_j = \{X_{\text{corn}}, X_{\text{wheat}}, X_{\text{cotton}}\} \)
- \( c_j = \{109, 90, 115\} \)
- \( a_{ij} = \begin{pmatrix} 1 & 1 & 1 \\ 6 & 4 & 8 \end{pmatrix} \)
- \( b_i = \{100, 500\} \).

This model may be formulated in GAMS in the following way:

```plaintext
Set     j / corn, wheat, cotton /     i / land, labor /;
Parameter c(j) / corn 109, wheat 90, cotton 115 /     b(i) / land 100 , labor 500 /;
Table    a(i,j) corn wheat cotton
land 1 1 1
labor 6 4 8 ;
```
Positive Variables \( x(j) \);
Variables profit;

Equations

\[
\text{objective} \\
\text{constraint}(i) \\
\text{objective}.. \quad \text{profit} = \sum(j, (c(j))\cdot x(j)); \\
\text{constraint}(i) .. \quad \sum(j, a(i,j) \cdot x(j)) = b(i); \\
\]

Model resalloc /all/;
solve resalloc using LP maximizing profit;

We will discuss the components of this model in section Components of the Revised Example Models below.

3.14.5.2 Revised Second Example

Recall that the second example is an economic equilibrium model with a single commodity:

- **Demand Price:** \( P \geq P_d = 6 - 0.3Q_d \)
- **Supply Price:** \( P \leq P_s = 1 + 0.2Q_s \)
- **Quantity Equilibrium:** \( Q_s \geq Q_d \)
- **Nonnegativity:** \( P \geq 0 \), \( Q_s \geq 0 \), \( Q_d \geq 0 \)

A more general formulation of this model accommodates multiple commodities. Consider the following formulation where \( c \) denotes the commodities:

- **Demand Price for c:** \( P_c \geq P_{d,c} = \Id_c - \sum_{cc} S_{d,c,cc} Q_{d,cc} \) for all \( c \)
- **Supply Price for c:** \( P \leq P_{s,c} = \Is_c + \sum_{cc} S_{s,c,cc} Q_{s,cc} \) for all \( c \)
- **Quantity Equilibrium for c:** \( Q_{s,c} \geq Q_{d,c} \) for all \( c \)
- **Nonnegativity:** \( P_c \geq 0 \) for all \( c \), \( Q_{s,c} \geq 0 \) for all \( c \), \( Q_{d,c} \geq 0 \) for all \( c \),

where

- \( P_c \) is the price of commodity \( c \),
- \( Q_{d,c} \) is the quantity demanded of commodity \( c \),
- \( P_{d,c} \) is the price from the inverse demand curve for commodity \( c \),
- \( Q_{s,c} \) is the quantity supplied of commodity \( c \),
- \( P_{s,c} \) is the price from the inverse supply curve for commodity \( c \),
- \( cc \) is an alternative notation for the commodities and is equivalent to \( c \),
- \( \Id_c \) is the inverse demand curve intercept for \( c \),
- \( S_{d,c,cc} \) is the slope of the inverse demand curve. It is used to model the effect of buying one unit of commodity \( cc \) on the demand price of commodity \( c \). When \( c = cc \) it is an own commodity effect and when \( c \neq cc \) it is a cross commodity effect.
• $I_{sc}$ is the inverse supply curve intercept for $c$,

• $Ssc, cc$ is the slope of the inverse supply curve. It is used to model the effect of supplying one unit of commodity $cc$ on the supply price of commodity $c$. When $c = cc$ it is an own commodity effect and when $c \neq cc$ it is a cross commodity effect.

This model may be formulated in GAMS in the following way:

Set commodities / corn, wheat /;
Set curvetype / supply, demand/;
Table intercepts(curvetype,commodities)
     corn     wheat
  demand    4        8
  supply    1        2;
Table slopes(curvetype,commodities,commodities)
     corn     wheat
  demand.corn -.3      -.1
  demand.wheat -.07     -.4
  supply.corn  .5       .1
  supply.wheat  .1      .3 ;
Positive Variables P(commodities)
  Qd(commodities)
  Qs(commodities);
Equations PDemand(commodities)
  PSupply(commodities)
  Equilibrium(commodities);
Alias (cc,commodities);
Pdemand(commodities).
  P(commodities) =g= intercepts("demand",commodities)
                    + sum(cc,slopes("demand",commodities,cc)*Qd(cc));
Psupply(commodities).
  intercepts("supply",commodities)
    + sum(cc,slopes("supply",commodities,cc)* Qs(cc)) =g= P(commodities);
Equilibrium(commodities).
  Qs(commodities) =g=  Qd(commodities);
Model problem / Pdemand.Qd, Psupply.Qs,Equilibrium.P /;
solve problem using MCP;

3.14.6 Components of the Revised Example Models

The revised example models have several new features including sets, specific data entry, and variables and equations that are defined over sets. In addition, if the models are run, modelers will notice some differences in the output. In this section we will discuss these new language features and the differences in the output they entail.
3.14 Quick Start Tutorial

3.14.6.1 Sets in the Revised Examples

In the revised examples we used the subscripts \(i, j\), commodities and \(cc\). In GAMS, subscripts are sets. They have to be defined before they may be used as subscripts. Sets are defined with set statements. Consider the set statement from the first revised example:

```gams
Set    j   / corn, wheat, cotton /
     i   / land, labor /;
```

Note that the statement begins with the keyword set followed by the name of the set and a list of the elements of the set. Note further, that more than one set may be defined with one set statement. In addition, an optional explanatory text may be inserted after the name of the set and also after each set element. For more details on set definitions, see chapter Set Definition.

Observe that the following line appears in the revised second example:

```gams
Alias (cc, commodities);
```

This is an alias statement that introduces a new alternative name for a set that was defined earlier. In our example, the set commodities was defined in the first line of the code and cc is the alias, the alternative name for the set commodities. Note that more than one alias may be defined in an alias statement. For further information on aliases, see section The Alias Statement: Multiple Names for a Set.

Note that in our example the alias facilitates to consider both the effects of own and cross commodity quantity on the demand and supply price for an item.

3.14.6.2 Data Entry in the Revised Examples

GAMS provides three formats for data entry: scalars, parameters and tables. Usually scalars are defined with a scalar statement, data vectors are defined with a parameter statement and matrices are defined with a table statement.

Note that we used parameter and table statements in the revised examples. In this section we will discuss parameter and table statements. For details on scalar statements, see section Scalars.

Parameters

The parameter format is used to enter items defined over sets. Generally, the parameter format is used for data items that are one-dimensional (vectors), but multi-dimensional data may be entered with a parameter statement as well. Consider the parameter statement from the first revised example:

```gams
Parameter c(j)   / corn 109, wheat 90, cotton 115 /
     b(i)   / land 100, labor 500 /;
```

Note that the statement begins with the keyword parameter followed by the name of the parameter and the set over which the parameter is defined, the index or domain. Then a list follows where a numerical value is assigned to each member of the index set. Note that the referenced elements must have been defined to be members of the respective set. By default, elements of the domain that are not listed in the parameter statement are assigned the value of zero. Note that more than one parameter may be defined with one parameter statement. For further details on parameter statements, see section Parameters.

Tables

The table format is used to enter data that are dependent on two or more sets. Consider the following two table statements from the revised examples:
Table a(i,j) crop data
    corn   wheat  cotton
land    1       1      1
labor   6       4      8 ;

Table intercepts(curvetype,commodities)
    corn   wheat
demand  4       8
supply  1       2;

Note that the statement begins with the keyword table followed by the name of the table and the sets over which the table is defined. The next line serves as header for the columns of the table, the elements of the set in the second index position are listed here. The elements of the set in the first index position are the headers of the rows. Thus the elements of the two index positions span a grid where numerical values may be entered. Like in the parameter format, the referenced set elements must have been defined to be members of the respective set.

Note
Alignment is crucial in table statements. The numerical entries must be placed in one and only one column of the table.

By default, elements of the domain that are not listed in the table statement are assigned the value of zero. Note that only one table may be defined with a table statement. For further details on table statements, see section Tables. Observe that data may also be entered with assignment statements. For more information, see section Data Entry by Assignment.

3.14.6.3 Indexed Variables and Equations in the Revised Examples

When the algebraic structure of a problem is exploited in modeling, variables and equations are often defined over one or more sets, they are indexed. For example, in the first revised example we have the following lines:

Positive Variable x(j);
Equations    constraint(i);

Note that here the variable x is defined over the set j and the equation constraint is indexed over the set i. Similarly, in the second revised example we have the following variable and equation statements:

Positive Variables P(commodities)
    Qd(commodities)
    Qs(commodities);
Equations   PDemand(commodities)
    PSupply(commodities)
    Equilibrium(commodities);

Observe that here all positive variables and all equations are indexed over the set commodities. Such definitions indicate that the variables and equations are potentially defined for every element of the defining set. Thus, for example, a variable P could exist for each and every element of the set commodities. However, how many of these potential cases are activated is determined by the respective equation definition statement(s) where the variable P is used. For further details on indexed variables and equations, see chapter Variables and section Indexed Equations respectively.

Next, we will discuss the equation definition statements. The respective lines from the first revised example follow:
objective.. profit =e= sum(j, (c(j))*x(j));
constraint(i).. sum(j, a(i,j) *x(j)) =l= b(i);

Note that the equation constraint is indexed over the set i and there are no restrictions specified in the equation definition statement. Thus, GAMS will generate a separate equation for every element of the set i in the model generation phase.

The same logic applies to the indexed equations of the second revised example whose definition statements are repeated below:

Pdemand(commodities).. 
P(commodities) =g= intercepts("demand",commodities) + sum(cc,slopes("demand",commodities,cc)*Qd(cc));
Psupply(commodities).. 
intercepts("supply",commodities) + sum(cc,slopes("supply",commodities,cc)* Qs(cc)) =g= P(commodities);
Equilibrium(commodities).. 
Qs(commodities) =g= Qd(commodities);

Observe that equations may be defined over only a part of their domain. This restriction is usually achieved with dollar conditions. For details see section Conditional Equations.

3.14.6.4 Differences in the Output

If variables and equations are defined over sets, some parts of the listing file will look different. In particular, there are some changes in the equation listing, the variable listing and the solution listing.

Revised Models: The Equation Listing

Note that indexed variables are given with their indices in the equation listing. In addition, the specific equations generated for each element of the domain are listed under the name of an indexed equation. To illustrate, we present the equation listing of the first revised example below:

----- objective =E=
objective.. - 109*x(corn) - 90*x(wheat) - 115*x(cotton) + profit =E= 0 ; (LHS = 0)

----- constraint =L=
constraint(land).. x(corn) + x(wheat) + x(cotton) =L= 100 ; (LHS = 0)
constraint(labor).. 6*x(corn) + 4*x(wheat) + 8*x(cotton) =L= 500 ; (LHS = 0)

Revised Models: The Column Listing

Similar to indexed equations in the equation listing, each instance of a variable is listed under the name of an indexed variable in the variable listing. The respective output of the first revised model follows.
---- x

\text{x(corn)}

\text{\((.LO, .L, .UP, .M = 0, 0, +INF, 0)\)}

-109 \text{ objective}
1 \text{ constraint(land)}
6 \text{ constraint(labor)}

\text{x(wheat)}

\text{\((.LO, .L, .UP, .M = 0, 0, +INF, 0)\)}

-90 \text{ objective}
1 \text{ constraint(land)}
4 \text{ constraint(labor)}

\text{x(cotton)}

\text{\((.LO, .L, .UP, .M = 0, 0, +INF, 0)\)}

-115 \text{ objective}
1 \text{ constraint(land)}
8 \text{ constraint(labor)}

--- Revised Models: The Solution Listing

In the solution listing of the revised models there is a separate line for each element of the index set. The respective output of the first revised model is given below:

--- EQU constraint

<table>
<thead>
<tr>
<th>LOWER</th>
<th>LEVEL</th>
<th>UPPER</th>
<th>MARGINAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>land</td>
<td>-INF</td>
<td>100.0000</td>
<td>100.0000</td>
</tr>
<tr>
<td>labor</td>
<td>-INF</td>
<td>500.0000</td>
<td>500.0000</td>
</tr>
</tbody>
</table>

--- VAR x

<table>
<thead>
<tr>
<th>LOWER</th>
<th>LEVEL</th>
<th>UPPER</th>
<th>MARGINAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>corn</td>
<td>.</td>
<td>50.0000</td>
<td>+INF</td>
</tr>
<tr>
<td>wheat</td>
<td>.</td>
<td>50.0000</td>
<td>+INF</td>
</tr>
<tr>
<td>cotton</td>
<td>.</td>
<td>.</td>
<td>+INF</td>
</tr>
</tbody>
</table>

--- 3.14.7 Documenting the GAMS Code

We have now covered the essential GAMS features. However, any good code includes documentation, otherwise it might be useless if it is revisited after a longer time. GAMS offers three ways to document the code: comments, explanatory texts and naming.

Comments

There are several ways to add comments in GAMS. The most common are \textit{single line comments} and \textit{block comments}. Single line comments may be inserted on any line by placing an asterisk * in the first column position. The text that follows the asterisk will be completely ignored by the GAMS compiler and may contain any content including GAMS \textit{keywords}. Note that several successive lines may be single line comments. Block comments are marked with the dollar control option \$context at the beginning of the comment block and the dollar control option \$offtext at the end of the comment. Block comments usually
span several lines, but they may also contain just one line on the one hand and whole sections of the code on the other hand.

In addition, users may freely enter blank lines to set off certain sections of the code and generally enhance readability. For further details on comments, see section Comments.

Explanatory Text

Declarations of sets, parameters, variables and equations may include an optional descriptive text that follows the name of the identifier. In addition, the elements of sets may be accompanied by a text. This text is more than a comment: it is retained by GAMS and is displayed whenever results are written for the respective identifier in the output file. Note that the explanatory text may be quoted or unquoted and single or double quotes may be used, but they must match. An example is given below. For further details, see section Text.

Naming

Apart from avoiding reserved words, names for identifiers in GAMS may be freely chosen. Some modelers, particularly if they have a background in mathematics, prefer short names like \( x(i) \). Other modelers strongly prefer longer descriptive names that makes it easier for them to recall what quantities are denoted. In this case naming is regarded as part of the documentation. GAMS accommodates both styles and modelers may choose which style works best for them. If short names are used, we recommend to generously use descriptive texts and comments for documentation.

To illustrate the virtues of comments, blank lines, explanatory text and long names we will repeat the code of the revised LP from above and then offer an alternative, documented formulation.

```
Set    j   / corn, wheat, cotton /
       i   / land, labor /;

Parameter c(j)   / corn 109, wheat 90, cotton 115 /
                  b(i) / land 100, labor 500 /;

Table   a(i,j)
         corn  wheat  cotton
       land  1      1      1
         labor 6      4      8

Positive Variables x(j);
Variables   profit;

Equations  objective
            constraint(i) ;

objective..  profit =e= sum(j, (c(j))*x(j));
constraint(i).. sum(j, a(i,j) *x(j)) =l= b(i);

Model resalloc /all/;
solve resalloc using LP maximizing profit;
```

The documented version with longer names follows:

```
$ontext
   well formatted algebraic version of the first example model
$offtext
Set    products 'Items produced by farm'
```
Parameter netreturns(products) 'Net returns per unit produced'
/ corn 109, wheat 90, cotton 115 /
endowments(resources) 'Amount of each resource available'
/ land 100, labor 500 /;

Table resourceusage(resources,products) 'Resource usage per unit produced'
corn wheat cotton
land 1 1 1
labor 6 4 8 ;

Positive Variables production(products) 'Number of units produced';
Variables profit 'Total sum of net returns';

Equations profitAcct 'Profit accounting equation'
available(resources) 'Resource availability limit';

$ontext
Specify definition of profit
$offtext

profitAcct..
profit =e= sum(products, netreturns(products)*production(products));

$ontext
Limit available resources
Fix at exogenous levels
$offtext

available(resources)..
sum(products,
    resourceusage(resources,products) *production(products))
=l= endowments(resources);

Model resalloc /all/;
solve resalloc using LP maximizing profit;

3.14.8 Guidelines on Ordering GAMS Statements and Formatting GAMS Programs

A GAMS program is a collection of GAMS statements. In this section we will offer some general guidelines on ordering GAMS statements and formatting GAMS programs.

- GAMS is case insensitive. This applies to GAMS keywords as well as to user-defined names. For example, the keyword VARIABLE is identical to Variable and variable and the user-defined name mincost is identical to minCost and minCOST. However, note that the spelling in the output file is determined by the spelling in the first occurrence of an identifier or label.
• Individual GAMS statements may be formatted in almost any style. Multiple lines may be used for a statement, blank lines may be embedded and any number of spaces or tabs may be inserted. In addition, several statements may be placed on one line. Note that they have to be separated by semicolons ;.

• We recommend that every GAMS statement is terminated with a semicolon ;. However, note that semicolons are not mandatory if the next word is a GAMS keyword.

• Identifiers like sets, parameters, scalars, tables, acronyms, variables, equations, models and files must first be declared and defined before they may be used in the code. An identifier is named in a declaration statement and specific values are assigned to it when it is defined. Often identifiers are defined at the same time they are declared. Note that for equations the declaration and definition statements are always distinct.

• The names for identifiers and labels and the explanatory text must follow certain rules. See chapter GAMS Programs and the tutorial Good Coding Practices for more information.

• Statements must be ordered such that identifiers are declared before they are used. If identifiers are used on the right-hand side of an assignment statement, they must also have been defined. If they are used in an equation and the equation is included in a model, then they must be assigned data before a solve statement for the respective model. Note that compilation errors will be triggered if this order is not followed.

3.14.9 Adding Complexity

There are several GAMS features that are widely used and serve to add subtlety and complexity to models. They include exception handling through conditionals, displaying data in the output file and report writing where the information from the optimal solution is used to create reports that meet the needs of modelers and their clients.

3.14.9.1 Conditionals

Assignments are often valid only for certain cases and sometimes equations should reasonably be restricted to a subset of the domain over which they were defined. It is easy to model such assignments and equations in GAMS with conditionals. Conditional expressions in GAMS are introduced and discussed in detail in chapter Conditional Expressions, Assignments and Equations. In this section we will only give a quick overview to demonstrate the capabilities of conditionals in GAMS.

Note that the dollar condition is at the heart of conditionals in GAMS. The general form of a conditional expression is as follows:

```
term $ logical_condition
```

This translates to: "Do something with 'term' only if the logical condition is true." Observe that term may be a number, a set, a parameter, a variable or an equation. The dollar operator $ is a GAMS speciality and one of the most powerful features of GAMS. The logical condition may take many different forms, see section Logical Conditions for details.

The following examples illustrate how conditionals in GAMS may be used.

Conditional Assignments

Consider the following example:
\[ x \; \text{\$} \; (y > 0) = 10; \]

Note that \( x \) is assigned the value of ten only if the scalar \( y \) is greater than zero, otherwise no assignment is made and \( x \) keeps its previous value. For more information, see section Conditional Assignments.

**Conditional Indexed Operations**

Consider the following example:

\[ z = \text{sum}[i \; \text{\$} \; (y(i) <> 0), x(i)]; \]

Note that the term \( x(i) \) will only be included in the sum if \( y(i) \) is nonzero. For further information, see section Conditional Indexed Operations.

**Conditionals in the Domain of Definition of Equations**

Consider the following equation definition statements:

\[ \text{Eq1 \$ (qq > 0).. xvar =e= 3;} \]
\[ \text{Eq2$ (sum(i, q(i)) > 0).. yvar =l= 4;} \]
\[ \text{Eq3(i) \$ (a(i) > 0).. ivar(i) =g= -a(i);} \]

Note that in each equation the domain of definition is restricted to those cases where the logical condition evaluates to TRUE. For further details, see section Dollar Control over the Domain of Definition.

**Conditionals in the Algebraic Formulation of Equations**

Our last example illustrates how a dollar condition may be used in the body of an equation:

\[ \text{Eq4 . . xvar + yvar$ (qq > 0) =e= 3;} \]

Note that the term \( yvar \) is included in the equation only if \( qq \) is greater than zero, otherwise \( yvar \) is treated as if it were zero. For more information, see section Dollar Operators within the Algebra of Equations.

### 3.14.9.2 Displaying Data

In GAMS, the display statement is a quick way to write data into the output file. For example, assume we add the following statement after the solve statement in the revised and documented version of the farm linear programming model above:

\[ \text{display profit.l, production.l;} \]

Recall that \( \text{profit} \) and \( \text{production} \) are variables. The suffix .l indicates that we wish to display the variable attribute level. The following output will be generated in the listing file:

\[ \text{---- 47 VARIABLE profit.L = 9950.000 Total sum of net returns} \]
\[ \text{---- 47 VARIABLE production.L Number of units produced} \]
\[ \text{corn 50.000, wheat 50.000} \]

Observe that the name of the variable, the explanatory text and the respective numerical values are given. In addition to data like parameters, sets, variable attributes, equation attributes and model attributes, quoted text may be displayed. Note that numerical entries that equal zero will not be displayed. For a more detailed introduction, see chapter The Display Statement.
3.14.9.3 Report Writing

In many cases modelers wish to summarize the most important results of the solution in a table for a quick overview. GAMS allows post-solution computations where information from the solution may be used to assign values to new parameters that are then displayed. The information from the solution most often used for report writing includes the level values of variables and equations and the marginal values of equations (also called dual values or shadow prices). Note that variable and equation attributes are accessed as follows:

```
var_name.sfx
eqn_name.sfx
```

Here `var_name` and `eqn_name` is the name of the variable and equation in GAMS respectively. The `attribute` is denoted by `.sfx`, where `sfx` may be `1` for level and `m` for marginal. Note that the suffix `sfx` may take other values as well. For details see sections Variable Attributes and Equation Attributes.

Observe that the numerical values of the levels and marginals of variables and equations are generally undefined until a solve statement is executed. After GAMS has retrieved the solution from the solver, the respective values from the solution are assigned to the attributes. These values remain unchanged until the next solve, where they are replaced with the values from the most recent solution.

In the remainder of this section we will present two examples to illustrate report writing. Assume we add the following report writing sequence after the solve statement to the revised and documented version of the farm linear programming model above:

```
Set item / Total, "Use by", Marginal /;
Set qitem / Available, Corn, Wheat, Cotton, Value /;
Parameter Thisreport(resources,item,qitem) 'Report on resources';
Thisreport(resources,"Total","Available") = endowments(resources);
Thisreport(resources,"Use by",qitem) =
    sum(products$sameas(products,qitem),
        resourceusage(resources,products) * production.l(products));
Thisreport(resources,"Marginal","Value") =
    available.m(resources);

option thisreport:2:1:2;
display thisreport;
```

Note that both, equation marginals (`available.m(resources)`) and variable levels (`production.l(products)`) are included in the calculations. The function `sameas` in the logical condition above returns the value `TRUE` if the element of the set `products` is equivalent to the element of the set `qitem` and `FALSE` otherwise. Thus this condition ensures that the third index of the parameter `Thisreport` is identical to the element of the set `products` in the sum. Observe that with the option statement in the penultimate line the appearance of the display is customized. For details see section Local Display Control. The following report will be generated by the display statement:

```plaintext
---- 61 PARAMETER Thisreport Report on resources
          Total    Use by    Use by    Marginal
               Available corn  wheat  Value
land          100.00   50.00    50.00    52.00
labor         500.00   300.00   200.00    9.50
```
Similarly, we could add the following report writing sequence to the revised version of the equilibrium model above:

```gams
Set qitem / Demand, Supply, "Market Clearing" /;
Set item / Quantity, Price /;
Parameter myreport(qitem,item,commodities);
myreport("Demand","Quantity",commodities) = Qd.l(commodities);
myreport("Supply","Quantity",commodities) = Qs.l(commodities);
myreport("Market Clearing","Price",commodities) = P.l(commodities);

display myreport;
```

Note that in the new parameter the level values for supply and demand as well as the market clearing price are saved. The resulting report follows:

```
---- 39 PARAMETER myreport

<table>
<thead>
<tr>
<th></th>
<th>Corn</th>
<th>Wheat</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supply</td>
<td>.Quantity</td>
<td>1.711</td>
</tr>
<tr>
<td>Demand</td>
<td>.Quantity</td>
<td>1.711</td>
</tr>
<tr>
<td>Market Clearing</td>
<td>.Price</td>
<td>2.671</td>
</tr>
</tbody>
</table>
```

For more on report writing, see chapters The Display Statement and The Put Writing Facility.

### 3.14.10 Advantages of Algebraic Modeling in General

We will conclude this tutorial with a discussion of the advantages of using algebraic modeling in general.

Algebraic modeling languages like GAMS facilitate model formulations in general algebraic terms, that are very concise and readable. Language elements that are essential include sets that may serve as indices, algebraic expressions, indexed operations, powerful sparse index and data handling variables and constraints with user-defined names. Model formulations are largely independent of the data and exact application contexts. Such formulations may be easily transferred to different contexts, data may be added without the need to reformulate the model and the model may be extended to reflect additional complexity.

However, GAMS algebraic requirements and the summation notation are difficult for some users. Some modelers will always prefer the exact problem context, not an abstract general formulation. This may lead to a strategy most modelers use: Start with a small concrete formulations that capture the essence of the problem and support the development of more general GAMS models.

### 3.14.10.1 One Model - Different Contexts

In the linear programming problem above we modeled profit maximizing in a farm. This model may easily be transferred to another context as follows:
Set products 'Items produced'
   / Chairs, Tables, Dressers /
resources 'Resources limiting production'
   / RawWood, Labor, WarehouseSpace /;

Parameter Netreturns(products) 'Net returns per unit produced'
   / Chairs 19, Tables 50, Dressers 75 /
Endowments(resources) 'Amount of each resource available'
   / RawWood 700, Labor 1000, WarehouseSpace 240 /;

Table Resourceusage(resources,products) 'Resource usage per unit produced'

<table>
<thead>
<tr>
<th></th>
<th>Chairs</th>
<th>Tables</th>
<th>Dressers</th>
</tr>
</thead>
<tbody>
<tr>
<td>RawWood</td>
<td>8</td>
<td>20</td>
<td>32</td>
</tr>
<tr>
<td>Labor</td>
<td>12</td>
<td>32</td>
<td>45</td>
</tr>
<tr>
<td>WarehouseSpace</td>
<td>4</td>
<td>12</td>
<td>10</td>
</tr>
</tbody>
</table>

Positive Variables Production(products) 'Number of units produced';
Variables Profit 'Total sum of net returns';
Equations ProfitAcct 'Profit accounting equation',
Available(resources) 'Resource availability limit';

ProfitAcct..
Profit
  =e= sum(products, netreturns(products) * production(products)) ;
Available(resources).. 
  sum(products, 
    resourceusage(resources,products) * production(products)) 
  =l= endowments(resources);

Model resalloc /all/;
solve resalloc using LP maximizing Profit;

Note that in this model we have chairs, tables and dressers instead of corn, wheat and cotton and raw
wood, labor and warehouse space instead of land and labor, but the algebraic structure of the model is the
same. Thus we still have sets for products and resources, parameters for net returns per unit produced
and available resources, a table for resource usage per unit produced and exactly the same variables and
equations, the same model and solve statement. Hence, if the algebraic structure for a type of problem is
built, it may be used in another context of the same problem type with just minor modifications in the
data.

3.14.10.2 Adding More Data

It is easy to add more data to a model. For example, we could add two new products and two new
resources to the carpenter model above in the following way:

Set products 'Items produced'
   / Chairs, Tables, Dressers, HeadBoards, Cabinets /
resources 'Resources limiting production'
   / RawWood, Labor, WarehouseSpace, Hardware, ShopTime /;

Parameter Netreturns(products) 'Net returns per unit produced'
   / Chairs 19, Tables 50, Dressers 75, HeadBoards 28, Cabinets 25 /
Endowments(resources) 'Amount of each resource available'
Table ResourceUsage(resources, products) 'Resource usage per unit produced'

<table>
<thead>
<tr>
<th></th>
<th>Chairs</th>
<th>Tables</th>
<th>Dressers</th>
<th>HeadBoards</th>
<th>Cabinets</th>
</tr>
</thead>
<tbody>
<tr>
<td>RawWood</td>
<td>8</td>
<td>20</td>
<td>32</td>
<td>22</td>
<td>15</td>
</tr>
<tr>
<td>Labor</td>
<td>12</td>
<td>32</td>
<td>45</td>
<td>12</td>
<td>18</td>
</tr>
<tr>
<td>WarehouseSpace</td>
<td>4</td>
<td>12</td>
<td>10</td>
<td>3</td>
<td>7</td>
</tr>
<tr>
<td>Hardware</td>
<td>1</td>
<td>1</td>
<td>3</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>ShopTime</td>
<td>6</td>
<td>8</td>
<td>30</td>
<td>5</td>
<td>12</td>
</tr>
</tbody>
</table>

Positive Variables Production(products) 'Number of units produced';
Variables Profit 'Total sum of net returns';

Equations ProfitAcct 'Profit accounting equation'
Available(resources) 'Resource availability limit';

ProfitAcct..
Profit =e= sum(products, netreturns(products) * production(products));

Available(resources).. 
sum(products, 
    resourceusage(resources, products) * production(products)) 
=I= endowments(resources);

Model resalloc /all/;
solve resalloc using LP maximizing Profit;

Observe that the elements HeadBoards and Cabinets were added to the set Products and the elements Hardware and ShopTime were added to the set Resources. In addition, the data in the two parameters and the table was updated to reflect these new labels. However, the model structure remained unchanged. Thus, GAMS models may easily be extended from smaller to larger data sets. Note that this feature may be exploited for model development. Users may develop a model with a small data set and test and debug it. Afterwards, they may move to the full problem data set without having to alter the algebraic structure of the model. For more details on this strategy, see section Small to Large: Aid in Development and Debugging.

3.14.10.3 Extending the Model

Assume we wish to make a model more complex by adding new features. For example, we could extend the carpenter model above to reflect the possibility of renting or hiring additional resources subject to a maximum limit. Consider the following code:

Set products 'Items produced'
   / Chairs, Tables, Dressers /
resources 'Resources limiting production'
   / RawWood, Labor, WarehouseSpace/
hireterms 'Resource hiring terms'
   / Cost, Maxavailable /;

Parameter Netreturns(products) 'Net returns per unit produced'
   / Chairs 19, Tables 50, Dressers 75 /
Endowments(resources) 'Amount of each resource available'
   / RawWood 700, Labor 1000, WarehouseSpace 240 /;
Observe that we introduced the set hireterms, the table Hiredata, the positive variable HireResource and the equation Hirelimit. In addition, we included new terms in the equations Profit and Available to reflect that through hiring the resources are increased, but hiring comes with a cost diminishing the profit. Thus the algebraic structure of the earlier model could be used as the core for this model that has additional features.

Note that this method may also be exploited for model development. Users may adapt models from other studies customizing them for the problem at hand and thus speeding up the development process. In addition to adapting models from related earlier studies that were done by the modeler or his group, model development may be jumpstarted by adapting models from the extensive GAMS Model Library.

### 3.15 Good Coding Practices

The GAMS language is quite flexible regarding the syntax and format of the code it accepts, offering users considerable latitude in how they organize and format their GAMS code. Most modelers develop their own style as they gain experience with the GAMS system. This tutorial reflects the coding preferences of Bruce A. McCarl (currently professor of Agricultural Economics at Texas A&M University). Note that
Bruce has extensive experience with GAMS, both as a modeler and an educator, and many GAMS users know, use, and benefit from his work. The goal of this tutorial is not to present a rigid set of rules to follow arbitrarily, but rather to help users develop their own coding preferences and style. The larger goal is to build self-documenting models that are easy to read and understand, to edit, and to debug: both for the developer working in the present, and for a larger group of colleagues and consultants working with the model over a span of months or years.

We will cover the following topics:

- Using Longer Names and Descriptive Text
- Including Comments
- Choosing Raw Data Instead Of Computed Data
- Avoiding the Universal Set in the Context of Data Input
- Defining Sets and Subsets Wisely
- Structuring and Formatting Files to Improve Readability
- Other Suggestions

3.15.1 Using Longer Names and Descriptive Text

The readability of GAMS code may be significantly improved by using longer self-explanatory names for identifiers (e.g. names of sets, parameters, variables, etc). Consider the following lines of code from the production and inventory model [ROBERT]:

```gams
Sets p 'products' / low, medium, high /
    r 'raw materials' / scrap, new /
    tt 'long horizon' / 1*4 /
    t(tt) 'short horizon' / 1*3 /;

Table a(r,p) input 'coefficients'

    low medium high
  scrap  5    3    1
     new   1    2    3;

Table c(p,t) 'expected profits'

    1    2    3
  low  25   20   10
 medium 50   50   50
   high 75   80  100;

Variables x(p,tt) 'production and sales'
    s(r,tt) 'opening stocks'
    profit;

Positive variables x, s;

Equations cc(t) 'capacity constraint'
    sb(r,tt) 'stock balance'
    pd    'profit definition' ;
```
3.15 Good Coding Practices

cc(t).. \[ \sum(p, x(p,t)) = l= m; \]

sb(r,tt+1).. \[ s(r,tt+1) = e= s(r,tt) - \sum(p, a(r,p) \times x(p,tt)); \]

pd.. \[ \text{profit} = e= \sum(t, \sum(p, c(p,t) \times x(p,t)) - \sum(r, \text{misc("storage-c",} \ r) \times s(r,t))) + \sum(r, \text{misc("res-value",} \ r) \times s(r,"4")); \]

s.up(r,"1") = misc("max-stock",r);

These lines may be reformatted in the following way (see (good.gms)):

Sets
- process 'available production process'
  / low 'uses a low amount of new materials',
  medium 'uses a medium amount of new materials',
  high 'uses a high amount of new materials' /
- rawmaterial 'source of raw materials' / scrap, new /
- Quarters 'long horizon' / spring, summer, fall, winter /
- quarter(Quarters) 'short horizon' / spring, summer, fall /

Table usage(rawmaterial,process) 'input coefficients'
<table>
<thead>
<tr>
<th></th>
<th>low</th>
<th>medium</th>
<th>high</th>

</table>

Variables
- production(process,Quarters) 'production and sales'
- openstock(rawmaterial,Quarters) 'opening stocks'
- profit;

Positive variables production, openstock;

Equations
- capacity(quarter) 'capacity constraint'
- stockbalan(rawmaterial,Quarters) 'stock balance'
- profitacct 'profit definition';

capacity(quarter)
\[ \sum(process, \text{production(process,quarter)}) = l= \text{mxcapacity}; \]

stockbalan(rawmaterial,Quarters+1)
\[ \text{openstock(rawmaterial,Quarters+1)} = e= \text{openstock(rawmaterial,Quarters)} - \sum(process, \text{usage(rawmaterial,process)} \times \text{production(process,Quarters)}); \]

profitacct.. \[ \text{profit} = e= \sum(quarter, \sum(process, \text{expectprof(process,quarter)} \times \text{production(process,quarter)} - \sum(rawmaterial, \text{miscdata("store-cost",rawmaterial)} \times \text{openstock(rawmaterial,quarter)}) + \sum(rawmaterial, \text{miscdata("endinv-value",rawmaterial)}) \].
Note that the two formulations are equivalent in their effect, but in the second formulation longer, more descriptive names were used for the sets, tables, variables and equations. In addition, longer names were used for the set elements and in the definition of the set process the set elements have additional explanatory text. Observe that the second formulation is easier to understand. This will be particularly useful if and when the code is revisited in 5 years' time.

Note

- Recall that GAMS allows long names for identifiers and labels (set elements). Users may exploit this feature to introduce long descriptive names. However, note that names for labels that are longer than 10 characters do not work well in multi-column displays. See the paragraph on customizing display width for details.
- Use explanatory text for identifiers to indicate units, sources, descriptions, etc. It’s not that hard to do and it pays dividends later.
- Similarly, use explanatory text for set elements as appropriate.

For example, the descriptive text in the in the second line in the following code snippet is much more informative than the text in the first line:

```gams
Parameter vehsales(r) 'regional vehicle sales';
Parameter vehsales(r) 'regional vehicle sales ($ millions/yr)';
```

Note that the descriptive text will be displayed whenever the respective identifier is displayed. Hence, including units in the text will save time if results will have to be interpreted later.

### 3.15.2 Including Comments on Procedures and the Nature and Sources of Data

We recommend that the documentation of the code offers answers to the following questions:

- What are the units of the variables and parameters?
- Where did the data come from?
- What are the characteristics of the data such as units and year of applicability?
- Why was a constraint set up in the way it is implemented?

In addition, it is often helpful to add comments that describe assumptions, the intent of equation terms, data sources, including document name, page number, table number, year of applicability, units, URL etc.

Consider the following example where various forms of comments are illustrated:
3.15 Good Coding Practices

* this is a one line comment that could describe data
$ontext
My data could be described in this multi-line comment
This is the second line
$offtext

* The following dollar control option activates end-of-line comments
* and redefines the symbol for end-of-line comments
$eolCom #
x = sum(i, z(i)) ; # this is an end-of-line comment

* The following dollar control option activates in-line comments
* and redefines the symbols for in-line comments
$inLineCom (* *)
x = sum(i, z(i)) ; (* this is an in-line comment *) r = sum(i, z(i)) ;

For more information on comments in GAMS, see section Comments.

3.15.3 Choosing Raw Data Instead Of Computed Data

Modelers often have a choice how they enter data: they could either use raw data and transform it to the extent needed inside GAMS or process data externally and enter the final results into GAMS.

The second choice may be attractive if the raw data is available in a spreadsheet where it can be manipulated before it is introduced to GAMS. However, over time spreadsheets and other data manipulation programs change or get lost and often these programs are not documented well. Therefore, we recommend to enter data into GAMS in a form that is as close as possible to the actual collected data and then manipulate the data with GAMS to obtain the desired form. This will make it much easier to update models later or to work out implicit assumptions.

3.15.4 Avoiding the Universal Set in the Context of Data Input

While GAMS permits using the universal set * as an index in a parameter or table statement, in most cases it is not advisable to do so. Consider the following example from the production and inventory model [ROBERT]:

Sets r 'raw materials' / scrap, new /
Table misc(*,r) 'other data'
   scrap new
   max-stock 400 275
   storage-c .5 2
   res-value 15 25 ;
...

pd.. profit =e= sum(t, sum(p, c(p,t)*x(p,t))
   - sum(r, misc("storage-c",r)*s(r,t)))
   + sum(r, misc("res-value",r)*s(r,"4"));

Note that the definition of the table misc indicates that any entry in the first index position is allowed. There is no domain checking. Consequently, if the label res-value is misspelled as res-val in the equation pd, GAMS will compile and execute the program without signaling an error, but instead of the expected values (i.e. misc(r,"res-value")), the values of misc(r,"res-val") will be used in the equation. These zero values will lead to faulty results, and the modeler will not be alerted to this fact. To ensure that the results of a GAMS run are reliable and trustworthy, we strongly recommend to use domain checking by introducing a new set for the labels in the first index position of the table misc:
Sets  r  'raw materials'
     / scrap, new /
miscitem 'misc input items'
     / max-stock, storage-c, res-value /
Table  misc(miscitem,r)  'other data'
scrap  new
max-stock  400  275
storage-c .5  2
res-value  15  25

Observe that the new set miscitem contains exactly the labels that appear in the rows of the table misc. Hence the set miscitem may be used in the first index position of the definition of misc without loss of generality, but with the benefit of domain checking.

3.15.5  Defining Sets and Subsets Wisely

Generally, the elements of a set have a feature in common or they are similar in some way. In this section we will give some guidance on how to partition the labels in the data into sets. In addition, we will discuss in which contexts it is useful to introduce subsets. For an introduction to sets in GAMS, see chapter Set Definition.

For example, suppose we have three grades of oil and three processes to crack it. The question arises whether we should introduce one set with nine elements or two sets with three elements and a two-dimensional set. We recommend the second alternative.

In another example, we consider a budget for farm spending: we have annual (i.e. cumulative yearly) spending for fertilizer and for seed and also monthly spending for labor and for water. There are 26 decisions or items in the budget. We could introduce a set with 26 elements or we could use the following formulation:

Sets  resources / fertilizer, seed, labor, water /
     periods / jan, feb, mar, apr, may, jun, jul, aug, sep, oct, nov, dec, annual /
use(resources.periods)
     / (fertilizer,seed).annual
         (labor,water) .(jan,feb,mar,apr,may,jun,jul,aug,sep,oct,nov,dec) /

We recommend the formulation above and to err on the side of being more extensive or exact with set definitions.

Occasionally it is necessary to group some labels into one set for a certain purpose and then single out some of them for another purpose. Subsets facilitate modeling such a case. For example, a set of all cities in a model may be needed to enter distances and compute related transportation costs. In addition, a subset can be used to specify the cities that are hubs for some activity, since some equations should be restricted to these hubs.
3.15.6 Structuring and Formatting Files to Improve Readability

In this section we will offer some guidelines on structuring and formatting the GAMS code to make it easy to read.

There are several ways to structure the GAMS code. Two styles are outlined in section Organization of GAMS Programs. The following recommendation to enter the sections of the code in a fixed order is an extended version of the first style:

1. Set definitions for sets that are data related
2. Parameter, scalar and table definitions, possibly intermixed with calculations
3. Variable definitions
4. Equation declarations
5. Equation definitions (algebraic specification of equations)
6. Model and solve statement(s)
7. Definitions of sets and parameters for report writing
8. Calculations for report writing
9. Display statement(s) for reports

Note that the code will be easiest to navigate if each section of the code contains only one type of statements. For example, interspersing set definitions with parameter definitions will make the code unnecessarily difficult to read.

In addition to following a fixed structure, it is also essential to properly format the code. Of course, formatting is in many respects a matter of taste. The following list offers some ideas:

- Align the names of identifiers and descriptive text, as demonstrated in the examples in this tutorial and in the GAMS User's Guide in general.
- Use spacing and indents.
- Use blank lines to highlight something and to mark sections of the code.
- Ensure that variables and all their index positions are on one line in equation definitions.
- Indent in indexed operations like sums and programming flow control structures like loops and if statements to delineate terms. The structure of a long and complex statement may be revealed through careful indentation and thoughtful placement of closing parentheses.

We will demonstrate the effect of proper formatting with the following two examples. The first example contains valid GAMS code, but is deliberately poorly formatted:

Sets products 'available production process' / low 'uses low new materials'
      medium 'uses medium new materials', high 'uses high new materials'/
rawmaterial 'source of raw materials' / scrap, new /
Quarters 'long horizon' / spring, summer, fall ,winter /
quarter(Quarters) 'short horizon' / spring, summer, fall /
;
Variables production(products,Quarters) 'production and sales'
openstock(rawmaterial,Quarters) 'opening stocks', profit ;
Positive variables production, openstock;
Equations capacity(quarter) 'capacity constraint',
stockbalan(rawmaterial,Quarters) 'stock balance',
profitacct profit definition ;
profitacct.. profit =e= sum(quarter, sum(products, expectprof(
products,quarter) *production(products,quarter)))-sum(
rawmaterial,miscdata("store-cost",rawmaterial)*openstock(rawmaterial ,quarter)))+ sum(rawmaterial, miscdata("endinv-value",rawmaterial) *openstock(rawmaterial,"winter"));
The second example contains the same code as the first example, but is carefully formatted:

```
Sets products 'available production process'
   / low 'uses a low amount of new materials',
   medium 'uses a medium amount of new materials',
   high 'uses a high amount of new materials' /
rawmaterial 'source of raw materials' / scrap, new /
Quarters 'long horizon' / spring, summer, fall, winter /
quartern(Quarters) 'short horizon' / spring, summer, fall /;

Variables production(products,Quarters) 'production and sales'
   openstock(rawmaterial,Quarters) 'opening stocks'
   profit ;
Positive Variables production, openstock ;

Equations capacity(quarter) 'capacity constraint'
stockbalan(rawmaterial,Quarters) 'stock balance'
profitacct 'profit definition' ;

profitacct..
   profit =e=
      sum(quarter,
         sum(products, expectprof(products,quarter)
            *production(products,quarter)
         )
      - sum(rawmaterial, miscdata("store-cost",rawmaterial)*
         openstock(rawmaterial,quarter)
      )
   )
      + sum(rawmaterial, miscdata("endinv-value",rawmaterial)
         *openstock(rawmaterial,"winter")
      )
   ;
```

Observe that inserting blank lines, aligning the names of identifiers and descriptive text, and indenting and formatting closing parentheses in the sums makes the code much easier to read and understand (both now and in the future) and is well worth adopting as standard practice when writing GAMS code.

### 3.15.7 Other Suggestions

We will complete this tutorial by offering some other useful suggestions that may help modelers develop their own conventions.

Even though GAMS is case insensitive, it is advisable to establish some convention on the use of upper and lower case letters. For example, Paul N. Leiby (currently at Oak Ridge National Laboratory) uses lower case for texts and comments, and upper case for GAMS reserved words and variable and parameter names. The casing used when an identifier or label is first encountered in a GAMS program is the casing stored by GAMS and used in subsequent outputs like the listing file or a GDX file. Any casing can be used (so `nowhere` is equivalent to `nowHere`) but the casing stored is determined by first use.

A similar situation holds for label quoting: the type of quotes stored (if any) are determined by first use.

Note that the dollar control option `$onSymList` will cause a list of all identifier names to be displayed in the compilation output of the output file. This list may be used to review the spelling and casing of the identifiers as they will appear in output files. Similarly, the dollar control option `$onUELList` will cause
an ordered list of all labels to be displayed in the compilation output of the output file. This is useful for checking both the case and order of the labels used in the GAMS program. For more on issues related to label ordering, see section Ordered and Unordered Sets.

To keep track of the data types of identifier names, some modelers always start set names with s_, names of parameters with d_, variables names with v_ and equation names with e_.

Some experienced GAMS users always surround explanatory text with quotes: this makes the text stand out, prevents it from being interpreted as a label or identifier, and allows special characters like $, - and & to be used.

If a file is used by several modelers and is updated occasionally, a file modification log at the top of the file will be in order. It should contain the following information: the modification date, version number, modification(s) made and who made the modification. For example, a set called version may be used to keep track of the dates the input files were modified:

```gams
Set version(*,*/*,*/*);

version("my_file","May","19","2016") = yes;
version("my_include_file","Sep","30","2016") = yes;

display version;
```

Note that the display statement will generate a display of all elements of the set version, each indicating on which day a component of the model was modified.

3.16 Fixing Compilation Errors

As detailed in chapter GAMS Output, the execution of a GAMS program passes through several stages, where the compilation is the first stage. Often when a program is run for the first time, it cannot be solved successfully because of compilation errors. This can be very frustrating, especially for new users. In this tutorial we will explain the causes of the most common compilation errors and offer some advice on how to fix them. For an introduction to compilation errors, see section Compilation Errors. In addition, the tutorial A GAMS Tutorial by Richard E. Rosenthal offers some detailed material on this topic.

Note

Frequently, many compilation errors in the latter part of the code are actually consequential errors that will disappear as soon as the compilation errors in the beginning have been resolved. Therefore we recommend to start with fixing the first few errors and to run the program again. More often than not, many subsequent compilation errors will have vanished.

3.16.1 Preliminary Remarks

Before we will turn to an overview of the most common errors, examples that illustrate them and advice how to resolve them, we will provide some basic information on compilation errors and error messages.
3.16.1.1 Finding Compilation Errors

Compilation errors are marked with four asterisks (****) in the compilation output of the GAMS listing file (also called output file or lst file, since it has the extension .lst), hence it is easy to detect lines where compilation errors occurred by inspection.

Note

Compilation error messages also appear in the LOG file. And, if the GAMS IDE is used, a double-click at an error message in the LOG will navigate directly to the problematic code in the source file.

Consider the following simple example:

Set c "crops" / barley, wheat, soy, wheat, rice /;

If this set statement appears in a program, the resulting compilation output will contain the following lines:

1 Set c "crops" / barley, wheat, soy, wheat, rice /;

**** $172

... Error Messages

172 Element is redefined

Note that in the echo print of the input file a line starting with **** is inserted and the dollar sign $ followed by a number appears on this line. This indicates that a compilation error - in this case error 172 - was discovered in the line above. In addition, a list of all errors with explanatory error messages is given at the end of the echo print.

In our example, the error refers to wheat and the error message addresses the cause of the error: the respective element is redefined. Thus we check the other elements of the set and quickly realize that wheat appears a second time. If we delete the second instance of wheat and run the code again, this line will not cause any errors anymore. Note that many compilation errors are as easy to fix as demonstrated here.

3.16.1.2 Repositioning Compilation Error Messages

By default, the error messages are listed at the end of the echo print. GAMS allows to customize this position with the command line parameter ErrMsg: the value of 1 for ErrMsg will move the error messages directly beneath the line where the respective error is marked and the value of 2 will suppress the error messages in the lst file completely. Note that the default is 0.

Consider the following simple example.

Set a / a1 * a7 /;
Set b(a) / a7 * a9 /;
Parameter p(k) / i3 47 /;

The resulting compilation output will contain the following lines:
1 Set a / a1 * a7 /;
2 Set b(a) / a7 * a9 /;
**** $170
3 Parameter p(k) / i3 47 /;
**** $120
...

Error Messages

120 Unknown identifier entered as set
170 Domain violation for element

Next, we run the same code with the following call:

> gams test ErrMsg=1

The resulting compilation output follows.

1 Set a / a1 * a7 /;
2 Set b(a) / a7 * a9 /;
**** $170
**** 170 Domain violation for element
3 Parameter p(k) / i3 47 /;
**** $120
**** 120 Unknown identifier entered as set

Observe that the error messages are now placed on the line after the error is marked. This can be especially useful if the program contains many lines of code.

Note

Users may change the system level defaults by entering the line ErrMsg=1 in the file gmsprmnt.txt on Windows, or gmsprmun.txt on Unix machines as in the following example:

*********************
* GAMS 2.50 Default Parameterfile for Windows NT*
* Gams Development Corp.*
* Date : 20 Mar, 1998 *
*********************
* entries required by CMEX, put in by gams.exe:*
* SYSDIR*
* SCRDIR*
* SCRIPTNEXT*
* INPUT*
errmsg=1

3.16.2 Resolving Common Compilation Errors

There are hundreds of compilation errors in GAMS, but some of them are particularly frequent. In the table below we present these common errors, with a brief description of the possible cause and a link to a subsection below where examples and more details are given. We recommend that users also read the error messages, since they often contain additional hints.
<table>
<thead>
<tr>

3.16.2.1 Error A: Misplaced Semicolons

Maybe the most common error for new users is related to semicolons. Consider the following example adapted from the well-known transportation model [TRNSPORT]:

```gams
Sets i "canning plants" / Seattle, San-Diego / ;
   j "markets" / New-York, Chicago, Topeka / ;
```

The resulting compilation output will contain the following lines:

```
20 Sets i  canning plants / Seattle, San-Diego / ;
21   j      markets      / New-York, Chicago, Topeka / ;
**** $140 $36
...
```

Error Messages

36 '=' or '..' or ':=' or '$=' operator expected
   rest of statement ignored
140 Unknown symbol

What went wrong? GAMS statements like the set statement in our example have to terminate with a semicolon, unless the next line of code begins with a reserved word. Now, set statements may extend over several lines and define several sets. In our example, the set statement extends over two lines and two sets are declared. However, there is a semicolon at the end of the first line, therefore GAMS assumes that the set statement ends there. The symbol \( j \) at the beginning of the next line has not been declared yet and it is not a GAMS keyword, thus it is marked as Unknown symbol. Note that error 36 is a consequential error that will disappear as soon as the first error has been resolved.

How do we fix this? There are two ways: either we could drop the semicolon at the end of the first line and thus indicate that the set statement continues to the second line or we could insert the keyword Set at the start of the second line and thus introduce a new set statement. These two alternatives are illustrated below:

```gams
Sets i  "canning plants" / Seattle, San-Diego / ;
   j  "markets"     / New-York, Chicago, Topeka / ;
```

or

```gams
Sets i  "canning plants" / Seattle, San-Diego / ;
Set  j  "markets"     / New-York, Chicago, Topeka / ;
```

Note

- In general, GAMS statements have to be terminated with a semicolon. The semicolon may be omitted if the next line starts with a GAMS keyword.
- Even if it is not required, it is good practice to always end a statement with a semicolon.
3.16.2.2 Error B: Missing Semicolons

Consider the following example adapted from the well-known transportation model [TRNSPORT]:

Equations
  cost "define objective function"
  supply(i) "observe supply limit at plant i"
  demand(j) "satisfy demand at market j"
  cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;

The resulting compilation output will contain the following lines:

52 Equations
cost define objective function
54 supply(i) observe supply limit at plant i
55 demand(j) satisfy demand at market j
56
57 cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;
**** $97 $195,96,195,96 $195,96
...
Error Messages
96 Blank needed between identifier and text
   (-or- illegal character in identifier)
   (-or- check for missing ';' on previous line)
97 Explanatory text can not start with '$', '=' or '..'
   (-or- check for missing ';' on previous line)

What went wrong? GAMS statements like the equation declaration in our example have to terminate with a semicolon, unless the next line of code begins with a GAMS keyword. In our example, we omitted the semicolon at the end of the equation declaration statement and started a new statement after a blank line.

How do we fix this? We simply add a semicolon after the last explanatory text at the end of the equation declaration statement.

Note
A missing semicolon is often associated with error 96 or 97.

3.16.2.3 Error C: Spelling Mistakes

This error occurs if sets, set elements, parameters, etc. are referenced with a different name than the name they were declared with. Note that differences in capitalization are not considered spelling mistakes since GAMS is case insensitive.

Consider the following example adapted from the well-known transportation model [TRNSPORT]:

Sets i "canning plants" / Seattle, San-Diego /  
  j "markets" / New-York, Chicago, Topeka / ;

Parameters a(i) "capacity of plant i in cases"  
  / Seatle 350  
    san-diego 600 / ;

Equations  
  cost "define objective function"  
  supply(i) "observe supply limit at plant i"  
  demand(j) "satisfy demand at market j" ;

cst .. z =e= sum((i,j), c(i,j)*x(i,j)) ;

The resulting compilation output will contain the following lines:

20 Sets i canning plants / Seattle, San-Diego /  
21 j markets / New-York, Chicago, Topeka / ;  
22 23 Parameters a(i) capacity of plant i in cases  
24 / Seatle 350  
25  san-diego 600 / ;  
26 27 Equations  
28 cost define objective function  
29 supply(i) observe supply limit at plant i  
30 demand(j) satisfy demand at market j ;  
31 32 cst .. z =e= sum((i,j), c(i,j)*x(i,j)) ;  
33 34 **** $170  
35 36 Error Messages  
37 38 140 Unknown symbol  
39 40 170 Domain violation for element

What went wrong? Note that in line 24 the set element Seattle was referenced as Seatle. GAMS does not recognize this symbol as an element of the set i and thus marks this with error 170: Domain violation. GAMS catches this error since it automatically performs domain checking. The typo in line 54, where the equation cost is referenced as cst, is marked with error 140 (Unknown symbol), since cst was not declared before.

Note  
Set name misspellings are associated with error 120, set element misspellings with 170 and other misspellings with 140.

Fixing errors like these is as easy as fixing typos.
### 3.16.2.4 Error D: Missing Set Elements

Sometimes users forget to include an element in a set statement, but reference it later. Consider the following simple example:

```plaintext
Set   c  "crops" / barley, wheat, soy /;
Parameter d(c) "demand in metric tons" / rice 3, barley 1, wheat 4, soy 2 /;
```

The resulting compilation output will contain the following lines:

```plaintext
  1 Set      c  "crops" / barley, wheat, soy /;
  2 Parameter d(c) "demand in metric tons" / rice 3, barley 1, wheat 4, soy 2 /;
  ****
  ... 
Error Messages

170  Domain violation for element
```

What went wrong? Note that the symbol `rice` was not defined as an element of the set `c`, thus GAMS does not recognize it and marks it with error 170: *Domain violation*. GAMS catches this error since it automatically performs *domain checking*.

**Note**

If symbols are not defined as set elements, but are referenced as if they belong to the set later, error 170 will occur.

This is easy to fix: we just add the missing element(s) to the elements of the respective set.

### 3.16.2.5 Error E: Problems with Indices

Recall that variables, sets, parameters and equation may be defined over one or more indices. If the identifiers are referenced later in the program, the indices must appear exactly in the order that was specified in the respective definition statement. Consider the following example adapted from the well-known transportation model [TRNSPORT]:

```plaintext
Sets i  "canning plants" / seattle, san-diego /
      j  "markets" / new-york, chicago, topeka / ;
Table d(i,j) "distance in thousands of miles"
   new-york    chicago    topeka
  seattle    2.5         1.7          1.8
  san-diego  2.5         1.8          1.4
Scalar f  "freight in dollars per case per thousand miles" /90/ ;
Parameter c(i,j) "transport cost in thousands of dollars per case";
c(i,j,j) = f * d(j,i) / 1000 ;
```

The resulting compilation output will contain the following lines:
### 3.16 Fixing Compilation Errors

```latex
40 \quad \text{Parameter } c(i,j) \text{ transport cost in thousands of dollars per case ;}
41 \quad c(i,j) = f \ast d(j,i) / 1000 ;
**** \$148 \quad \$171,171
...
```

**Error Messages**

148 Dimension different - The symbol is referenced with more/less indices as declared
171 Domain violation for set

What went wrong? Note that the parameter $c$ was declared over two indices, but in the assignment statement in line 41 it is referenced with three indices. Such a mistake is marked with error 148. Note further, that the indices of $d$ are referenced in the wrong order, which is marked with error 171.

Note
If an identifier is referenced with more or less indices as declared, then the error 148 will be triggered.
If the indices are in the wrong order, the error 171 will be triggered.

This is easy to fix: we just check the declaration or definition statement(s) and adjust the reference.

Observe that the domain error 171 is also triggered if an identifier is referenced with index say $i$, but was defined over say $j$. However, there will be no domain error if $i$ is a subset of $j$ or $i$ and $j$ reference the same set since they are aliases.

### 3.16.2.6 Error F: Summing over Sets that are Already Indexed

Consider the following equation definition that is adapted from the well-known transportation model [TRANSPORT]:

```latex
\text{supply}(i) .. \quad \text{sum}((i,j), x(i,j)) \text{ =l= a}(i) ;
```

The resulting compilation output will contain the following lines:

```latex
59 \quad \text{supply}(i) .. \quad \text{sum}((i,j), x(i,j)) \text{ =l= a}(i) ;
**** \$125
...
```

**Error Messages**

125 Set is under control already

What went wrong? Note that the equation is indexed over the set $i$, therefore the indexed operation `sum` in the body of the equation may not be controlled by the index $i$ again.

Note
Summing over sets that are already indexed will trigger error 125.

How do we fix this? We need to carefully check the indexed operation and drop the surplus index. In other cases the controlling index may have to be dropped from the equation name. Note that an error like this is often indicative of a lack of clarity in thinking.
3.16.2.7 Error G: Uncontrolled Sets

Consider the following equation definition that is adapted from the well-known transportation model [TRNSPORT]:

\[
\text{demand .. } \sum(i, x(i,j)) \geq b(j) ;
\]

The resulting compilation output will contain the following lines:

\[
\begin{align*}
61 & \quad \text{demand .. } \sum(i, x(i,j)) \geq b(j) ; \\
& \quad \text{**** \$149 \$149} \\
& \quad \text{...}
\end{align*}
\]

Error Messages

149 Uncontrolled set entered as constant

What went wrong? Note that the variable \( x \) is indexed over the sets \( i \) and \( j \), but, while \( i \) is the index of the indexed operation \( \sum \), \( j \) is "free": it does neither appear as index of the equation nor as controlling index in \( \sum \). Therefore it was entered as if it were a constant. Note further, that \( j \) is also used as an index on the right-hand side of the equation without being controlled.

Note

Error 149 marks instances when an index is not controlled in the context of an equation or an indexed operation like \( \sum \) or \( \text{prod} \).

How do we fix this? We have to think what we actually want to model. In this case we need to enter \( j \) as a controlling index for the equation. But it would also be possible to add it as a controlling index for \( \sum \) (but not both!). In the latter case there would still be the error on the right-hand side which needed to be taken care of with another indexed operation, e.g., \( \sum \) again. Both approaches would remove the compilation error, but one has to think about what actually should be modeled to decide which is the right fix here.

3.16.2.8 Error H: Mismatched Parentheses

Consider the following two equations adapted from the model [CHENERY]:

\[
\begin{align*}
\text{mb}(i) .. x(i) = \geq y(i) + \sum(j, a_{i0}(i,j) \cdot x(j)) + (e(i) - m(i)) & \times t(i) \\
\text{dvv}(i)$(\text{sig}(i) \neq 0) .. v_v(i) = e = (p_i \cdot (1 - d_i) / d_i)^{-\rho(i)/(1+\rho(i))} & \\
\text{...}
\end{align*}
\]

The resulting compilation output will contain the following lines:

\[
\begin{align*}
137 & \quad \text{mb}(i) .. x(i) = \geq y(i) + \sum(j, a_{i0}(i,j) \cdot x(j)) + (e(i) - m(i)) \times t(i) \\
& \quad \text{**** \$408,409} \\
& \quad \text{...}
155 & \quad \text{dvv}(i)$(\text{sig}(i) \neq 0) .. v_v(i) = e = (p_i \cdot (1 - d_i) / d_i)^{-\rho(i)/(1+\rho(i))} \\
& \quad \text{**** \$8} \\
& \quad \text{...}
\end{align*}
\]

Error Messages

8 ‘)’ expected

... 408 Too many ),] or }

409 Unrecognizable item - skip to find a new statement

looking for a ‘;’ or a key word to get started again
What went wrong? Note that in the first equation we have one surplus closing parenthesis, this is marked with error 408. The error marked with 409 is a consequential error, it will disappear once the first error has been fixed. In the second equation, one closing parenthesis is missing resulting in error 8.

Attention

Opening and closing parentheses ( ), square brackets [ ] and braces (curly brackets) { } must match.

Note

Surplus closing parentheses, bracketes and braces are marked with error 408 and missing closing parenthesis, brackets and braces are marked with error 8. Missing opening parentheses, brackets and braces may result in GAMS marking surplus closing parentheses, brackets and braces; surplus opening parentheses, brackets and braces may result in GAMS marking missing closing parentheses, brackets and braces.

While fixing errors like these entails carefully counting opening and closing parentheses, there are strategies that help to prevent mismatching parentheses errors. Many text editors (like the GAMS IDE) offer a feature that identifies matching parentheses and will issue a warning if there is a mismatch. We recommend to use this feature. Further, we recommend to also use the alternatives to parentheses: square brackets and braces. They are especially useful if there are several opening parentheses since it is easier to determine by inspection if each has a matching closing symbol.

3.16.2.9 Error I: Mistakes Relating to Equations

Recall that each declared equation must be defined if it is to be used in a model statement. If the equation definition is missing, GAMS will mark an error beneath the solve statement that refers to a model which references the respective undefined equation. Consider the following example adapted from the well-known transportation model [TRNSPORT]:

Equations

\[
\begin{align*}
\text{cost} & \quad \text{"define objective function"} \\
\text{supply}(i) & \quad \text{"observe supply limit at plant } i\text{"} \\
\text{demand}(j) & \quad \text{"satisfy demand at market } j\text{"} \\
\end{align*}
\]

\[
\begin{align*}
\text{cost .. } z & \quad =e= \sum_{(i,j)} c(i,j) \times x(i,j) \\
\text{supply}(i) .. \sum_{j} x(i,j) & \quad =l= a(i) \\
\end{align*}
\]

Model transport /all/ \\
solve transport using lp minimizing z ;

The resulting compilation output will contain the following lines:

60 Model transport /all/ ;
61 solve transport using lp minimizing z ;
**** $71,256
**** The following LP errors were detected in model transport:
**** 71 demand is an undefined equation
...

Error Messages

71 The symbol shown has been declared as an equation, but no Symbolic equation (...) was found. hint - look for commas in the Documentation text for the equations. use quotes around the Text or eliminate the commas.

256 Error(s) in analyzing solve statement. More detail appears Below the solve statement above
What went wrong? Note that the equation demand was declared and included in the model transport, but it was not defined. GAMS detects that the equation definition is missing when it compiles the solve statement that relates to the model transport. Therefore the error 71 appears only there. The error 256 is a consequential error, it will disappear once the missing equation definition has been added (before the solve statement).

Note

Error 71 marks a missing equation definition. The message associated with this error is a nice example of an error message that is very descriptive and offers advice on how to fix the error.

Apart from forgetting to define a declared equation and forgetting to terminate the equation definition statement with a semicolon (see above), two other mistakes relating to equations are frequent: omitting the syntax element .. after the name of the equation and not properly defining the equation type in the equation definition statement. The following simple example adapted from the portfolio analysis model [ALAN] illustrates these mistakes:

fsum sum(i, x(i)) =e= 1.0;
dmean.. sum(i, mean(i)*x(i)) = target;

The resulting compilation output will contain the following lines:

45  fsum sum(i, x(i)) =e= 1.0;  
****  $36
46  dmean.. sum(i, mean(i)*x(i)) = target;  
****  $37
...
Error Messages

36 'e=' or '..' or ':=' or '$=' operator expected
rest of statement ignored
37 '=' or '=' or '=g=' operator expected

What went wrong? Note that in the first equation the two dots .. are missing, which is marked with error 36, and in the second equation the equation type is not properly specified, which leads to error 37.

3.16.2.10 Error J: Issues with Nonlinear Expressions

The compilation error messages 51 to 60 refer to issues with nonlinear expressions involving variables in equations. For example, nonlinear expressions in an LP model will cause errors of this sort. So will discontinuous functions with endogenous arguments in an NLP model. For information on endogenous arguments in functions, see section Functions in Equation Definitions. For an overview of GAMS model types, see section Classification of Models.

Consider the following simple artificial example:

Variables x, y, z ;
Equations eq1, eq2 ;
eq1.. x**2 - y =e= z ;
eq2.. min(x,y) =l= 20 ;
Model silly / all / ;
solve silly using lp maximizing z ;
The resulting compilation output will contain the following lines:

7 Model silly / all / ;
8 solve silly using lp maximizing z ;

**** $54,51,256
**** The following LP errors were detected in model silly:
**** 54 equation eq1.. VAR operands for **
**** 51 equation eq2.. the function MIN is called with non-constant arguments

Error Messages

51  Endogenous function argument(s) not allowed in linear models
54  Endogenous operands for ** not allowed in linear models
256 Error(s) in analyzing solve statement. More detail appears
    Below the solve statement above

Note that error 54 marks the nonlinear expression $x^2$ in a linear model and error 51 refers to the discontinuous function \( \text{min} \) that may be used with variables only in models of the type DNLP. The error 256 is a consequence of the two previous errors.

### 3.16.2.11 Error K: Using Undefined Data

Referencing data items that were not declared with a scalar, parameter or table statement will cause error 140: GAMS will indicate that the respective symbol is unknown. More often data items are declared, but not defined, i.e. they are not initialized with values.

Consider the following example adapted from the well-known transportation model [TRNSPORT]. Assume that the scalar \( f \) is declared, but has no numerical value. The resulting compilation output will contain the following lines:

40 Scalar f freight in dollars per case per thousand miles ;
41 42 Parameter c(i,j) transport cost in thousands of dollars per case ;
43 44 c(i,j) = f * d(i,j) / 1000 ;
**** $141
****
****
61 Model transport /all/ ;
62 solve transport using lp minimizing z ;
**** $257
63 64 display x.l, x.m ;
**** $141
****

Error Messages

141 Symbol declared but no values have been assigned. Check for missing
data definition, assignment, data loading or implicit assignment
via a solve statement.
A wild shot: You may have spurious commas in the explanatory
text of a declaration. Check symbol reference list.
257 Solve statement not checked because of previous errors
What went wrong? Note that the scalar \( f \) was declared, but there was no value assigned to it. Thus, when it is referenced in the calculation in line 44, the "empty" scalar causes error 141. Error 257 is a consequential error and leads to the second error 141. This error occurs in the context of variable attributes in the display statement. Recall that \textbf{variable attributes} are data associated with variables. As the solve statement could not be checked, the level and marginal values of the variable \( x \) are not defined and hence error 141 follows.

Note

Error 141 marks places where data items, that have not been defined, are referenced in computations in the context of assignment statements. It also marks places where undefined variable (or equation) attributes are referenced.

In addition, undefined data items may be referenced in the context of equation definitions. Suppose we declare the parameter \( c \) in model \texttt{[TRNSPORT]}, but forget the corresponding assignment statement. Then the compilation output will contain the following lines:

\begin{verbatim}
57      cost .. z =e= sum((i,j), c(i,j)* x(i,j)) ;
...   
62      solve transport using lp minimizing z ;
***** $66,256
***** The following LP errors were detected in model transport:
   66 equation cost.. symbol "c" has no values assigned
... Error Messages

66 The symbol shown has not been defined or assigned
   A wild shot: You may have spurious commas in the explanatory
   text of a declaration. Check symbol reference list.
256 Error(s) in analyzing solve statement. More detail appears
Below the solve statement above
\end{verbatim}

Note that the missing data in the body of the equation \texttt{cost} is marked with error 66 and the following error is a consequential error which will disappear once 66 has been fixed.

Note

Referencing undefined data items in the body of an equation causes error 66.

\textbf{3.16.2.12 Error L: Referencing Set Elements Without Quotes}

Recall that if set elements are referenced, they need to appear in single or double quotes. Omitting the quotes may cause different errors depending on the context. The following example is adapted from the well-known transportation model \texttt{[TRNSPORT]}. Suppose we start by defining the two sets and the two parameters and then add the following statements:

\begin{verbatim}
Scalar s;
s = a(seattle);
\end{verbatim}

The resulting compilation output will contain the following lines:
3.16 Fixing Compilation Errors

37 Scalar s;
38 s = a(seattle);
**** $120,340,149,171
...

Error Messages

120 Unknown identifier entered as set
149 Uncontrolled set entered as constant
171 Domain violation for set
340 A label/element with the same name exist. You may have forgotten to quote a label/element reference. For example, set i / a,b,c /; parameter x(i); x('a') = 10;

What went wrong? On the right-hand side of the assignment statement we have a reference with missing quotes. Note that this creates four (!) errors:

- 120 - GAMS expects a controlling set and Seattle is not recognized and therefore considered an unknown identifier.
- 340 - Then GAMS realizes that actually there is a label called Seattle in the program and helpfully offers a hint: You may have forgotten to quote a label/element reference.
- 149 - See section Error G: Uncontrolled Sets above.
- 171 - See section Error E: Problems with Indices above.

This is a nice example for one mistake triggering several errors that may look daunting. However, fixing them is as easy as adding single or double quotes.

3.16.2.13 Error M: Missing Declaration Statements

Recall that sets, parameters, variables and equations have to be declared before they may be used in definition or assignment statements. Suppose the equation demand in the well-known transportation model [TRNSPORT] was defined but not declared. Then the compilation output would contain the following lines:

59 demand(j) .. sum(i, x(i,j)) =g= b(j) ;
**** $140
...

Error Messages

140 Unknown symbol

Note that as demand was not declared, GAMS does not recognize it and therefore marks it with error 140: Unknown symbol.

Note

If error 140 is reported, the respective declaration statement is probably missing. However, the underlying cause may also be a simple typo.
3.16.2.14 Error N: Using the Same Name for Different Identifiers

Recall that each GAMS identifier must have a unique name. If the same name is used more than once, an error will be triggered. Consider the following modification of the transportation model [TRNSPORT]:

Parameters capacity(i) "capacity of plant i in cases"
    / Seattle 350, San-Diego 600 /

demand(j) "demand at market j in cases"
    / New-York 325, Chicago 300, Topeka 275 /;

Equations
cost "define objective function"
supply(i) "observe supply limit at plant i"
demand(j) "satisfy demand at market j";

The resulting compilation output will contain the following lines:

47   Equations
48       cost          define objective function
49       supply(i)  observe supply limit at plant i
50       demand(j)  satisfy demand at market j;
**** $195
...
Error Messages
195 Symbol redefined with a different type

What went wrong? Note that demand was first declared as a parameter and later as an equation. GAMS will mark this repeated use of the same name with error 195.

3.16.2.15 Error O: Using ORD with an Unordered Set

Recall that the operation ord is only defined for ordered sets. If ord is used with an unordered set, error 198 will be triggered.

Consider the following example:

Set   a "a couple of the elements"  / r2, r3 /;
Set   b "more elements"            / r1*r4 /;
Scalar c "counter"                / 0 /;

loop( b $ (ord(b) > 3),
    c = c + 1 );
display c;

The resulting compilation output will contain the following lines:
3.17 Finding and Fixing Execution Errors and Performance Problems

5 loop( b $(ord(b) > 3),
   **** $198
6   c = c + 1 );
...

Error Messages

198 Set used in 'ord' or lag is not ordered.
   Hint: Some of the elements of the set were used before this
   was initialized and the order was different from the order used
   in this set. Try to initialize the set earlier.
   $offOrder allows lag operations on dynamic sets, reset with
   $onOrder

What went wrong? Two elements of the set b featured already in set a that was defined before set b. Therefore the order of the elements in set b is as follows:

r2 r3 r1 r4

Obviously, this set is not ordered and hence GAMS marks error 198 when the operator ord is applied to it.

How do we fix this? In this case it is easy: we just define the set b before set a and b will be an ordered set.

Consider one last example:

Set a "all elements" / r1*r10 /;
Set b "elements in different order" / r3, r1, r4, r7 /;
Scalar c "counter" / 0 /;

loop( b $(ord(b) > 3),
   c = c +1 );
display c;

The resulting compilation output will contain the following lines:

5 loop( b $(ord(b) > 3),
   **** $198
6   c = c +1 );

What went wrong? Note that even though all elements in set b are also elements of set a, they are not specified in the same order. Therefore the set b is unordered. For more details, see section Ordered and Unordered Sets.

3.17 Finding and Fixing Execution Errors and Performance Problems

This tutorial is structured in four main parts: we will discuss how to find and resolve errors that are detected during execution of a GAMS model, we will give some guidance for model development and debugging and we will present techniques to increase efficiency by reducing GAMS execution time and memory use.
3.17.1 Resolving Execution Errors

Recall that GAMS passes through a program file several times in the process of generating and solving a model. Errors may occur in each phase. In this section we will give some guidance on how to resolve errors that occur during execution, so after compilation. For advice on resolving compilation errors, see the tutorial Fixing Compilation Errors. For more information on the process of generating and solving a model in GAMS, see the introduction to chapter GAMS Output.

At execution, several things could go wrong and cause an error. We will look at these potential error sources separately in this section. First we look at arithmetic errors and exceeded internal limits during data manipulation, we will continue with problems during model generation and model solution. At the end, we will briefly discuss how execution errors may be managed with the function execError.

3.17.1.1 Arithmetic Errors

GAMS execution errors may be caused by illegal arithmetic operations like a negative argument for log, division by zero and exponentiation where the base is a negative number. The following simple example serves as illustration:

```plaintext
Set s / s1*s5 /;
Parameter p(s) "data to be exponentiated"
   d(s) "divisors"
   r(s) "result";
p(s) = 1;
p("s2") = -1;
d(s) = 1;
d("s3") = 0;
r(s) = p(s)**2.1 / d(s)
display r;
```

The first sign that something in the execution went wrong is the following flag in the log output:

```plaintext
*** Status: Execution error(s)
```

The resulting execution output will contain the following lines:

```plaintext
EXECUTION
**** Exec Error at line 10: rPower: FUNC DOMAIN: x**y, x < 0
**** Exec Error at line 10: division by zero (0)
---- 11 PARAMETER r result
s1 1.000, s2 UNDF, s3 UNDF, s4 1.000, s5 1.000
```

Observe that the execution output begins with two error messages that can be easily found since they are marked with four asterisks ***. The error messages are very informative: they indicate the line where the errors occurred and provide details about the nature of the errors. Further, the output generated by the display statement shows that the errors occurred when the values for r("s2") and r("s3") were computed. Inspecting the assignment statement for these two values, we realize that in the first instance
the base for the exponentiation is -1, which obviously is a negative number and hence is not allowed in this operation. In the second instance, the problem is that we divide by \( d("s3") \) which equals zero.

In this example, the errors are easily resolved with data revisions. In general, we recommend to use conditional assignments to prevent errors like these.

Note that in the example above the error messages indicated exactly where the problem was and it was easy to find the cause of the error. However, this is not always the case. In particular, if the problem is within a multi-dimensional item the user will need more patience. Usually it helps to display the results of the problematic operation and look for faulty entries. In addition, displaying the input data to the respective operation will help to investigate the numerical properties of the data that was entered in the computation. Often more displays will be needed to trace faulty input data through the program. Eventually this will lead the user to understand why the data has taken on the specific numerical values it has.

### 3.17.1.2 Exceeding GAMS Limits

By default, GAMS stops the solve of a model after 1000 seconds (wall clock time) or 2e9 iterations. These limits may be adjusted with the options reslim and iterlim respectively. Note that both options are also available as command line parameters and model attributes. In addition, the workspace may be limited with the command line parameters WorkFactor and WorkSpace. Note that these options are also available as model attributes. If any of these limits are exceeded, the execution of the solve statement will be interrupted.

For example, we could add the following option statement somewhere before the solve statement in the production model [CHENERY]:

```gams
option iterlim = 20;
```

Note that this statement reduces the iteration limit to just 20. The log output will contain the following lines:

```
** Feasible solution. Value of objective = 1033.34069261
** The iteration limit has been reached.
--- Restarting execution
--- chenery.gms(228) 2 Mb
--- Reading solution for model chenrad
*** Status: Normal completion
--- Job chenery.gms Stop 11/21/16 16:52:43 elapsed 0:00:00.106
```

Also the solve summary in the listing file notes the interrupt:

```
SOLVE SUMMARY
MODEL chenrad OBJECTIVE td
TYPE NLP DIRECTION MAXIMIZE
SOLVER CONOPT FROM LINE 228

**** SOLVER STATUS 2 Iteration Interrupt
**** MODEL STATUS 7 Feasible Solution
**** OBJECTIVE VALUE 1058.9199

RESOURCE USAGE, LIMIT 0.078 1000.000
ITERATION COUNT, LIMIT 20 20
EVALUATION ERRORS 0 0
```
Observe that the solver status **Iteration Interrupt** indicates that the execution terminated because the iteration limit has been reached resulting in a feasible solution, but not the optimal solution. The line **ITERATION COUNT, LIMIT ...** reports that 20 iterations were performed and that 20 was also the limit for the number of iterations. Setting `iterlim` to a larger value will resolve this issue.

Similarly, allocating too little work space will cause the solver to terminate with no solution. For example, restricting the work space for the nonlinear test model [MHW4D] to just 0.1 MB and running it with the solver MINOS will produce the following lines in the log output:

```
Work space requested by solver -- 0.77 Mb
Work space requested by user -- 0.10 Mb
Work space allocated -- 0.10 Mb

Reading Rows...
Reading Columns...
Reading Instructions...

EXIT - Not enough storage to solve the model.
Request at least 0.19 Mbytes.
```

The **solve summary** in the listing file will contain the following information:

```
S O L V E   S U M M A R Y

MODEL wright             OBJECTIVE m
TYPE NLP                     DIRECTION MINIMIZE
SOLVER MINOS              FROM LINE 32

**** SOLVER STATUS 9 Setup Failure
**** MODEL STATUS 13 Error No Solution
```

Note that increasing the work space to at least the minimum amount requested by the solver will resolve this issue.

### 3.17.1.3 Resolving Model Generation Errors

Further execution errors may be detected when GAMS is generating the model before passing it to the solver. These errors may be arithmetic errors in the body of equations or errors in the structure of the model that cause the model to be inherently infeasible.

Consider the following simple example with arithmetic errors in the body of the equations. They are similar to the errors in the assignment in the example in section Arithmetic Errors above.

```
Set s / s1*s5 / ;
Parameter p(s) "data to be exponentiated"
              d(s) "divisors"
              m(s) "multipliers";

p(s) = 1;
p("s2") = -1;
d(s) = 1;
d("s3") = 0;
```
m(s) = 1;
m("s4") = 0;

Positive variable x(s);
Variable z;

Equations obj "objective function"
    xlim;
    obj.. z =e= sum(s,p(s)**2.2*x(s));
    xlim(s).. m(s) / d(s)*x(s) =e= 1;

Model mymodel / all /;
solve mymodel using lp maximizing z;

If we run this model, the log output will contain the following lines:

*** SOLVE aborted
--- Executing CPLEX: elapsed 0:00:00.006
--- test.gms(23) 4 Mb 3 Errors
*** Status: Execution error(s)
--- Job test.gms Stop 11/21/16 19:10:12 elapsed 0:00:00.006

Observe that the solve was aborted since there are 3 execution errors. The equation listing in the listing file will contain further details about these execution errors:

Equation Listing SOLVE mymodel Using LP From line 23

**** Exec Error at line 19: rPower: FUNC DOMAIN: x**y, x < 0
---- obj =E= objective function
obj.. - x(s1) + UNDF*x(s2) - x(s3) - x(s4) - x(s5) + z =E= UNDF ; (LHS = UNDF)

**** Exec Error at line 20: division by zero (0)
**** Exec Error at line 20: Equation infeasible due to rhs value

**** INFEASIBLE EQUATIONS ...
---- xlim =E=
xlim(s4).. 0 =E= 1 ; (LHS = 0, INFES = 1 ****)

REMAINING 4 ENTRIES SKIPPED

Note that there is an arithmetic error relating to exponentiation in the first equation and an arithmetic error and an infeasibility in the second equation.

In our example, it was easy to detect the execution errors and their cause. However, an error in a multi-dimensional equation block may be much more difficult to find. Note that by default, only the first three entries in each equation block are shown in the equation listing. We recommend to use the option limrow to get a full listing, as this is the easiest way to inspect execution errors in the body of equations.
3.17.1.4 Resolving Solve Errors

In the solution phase, an external solver program processes the model and creates output with details about the solution process. Solve errors may be either function evaluation errors or presolve errors.

3.17.1.4.1 Resolving Function Evaluation Errors

Some solve statements require the evaluation of nonlinear functions and the computation of derivatives. Since these calculations are not carried out by GAMS but by other subsystems not under the direct control of GAMS, errors associated with these calculations are reported in the solution report.

Function evaluation errors are numerical errors like those discussed in section Arithmetic Errors above. Other examples include square roots of negative variables and squaring a negative term, say x, using the syntax x**2.

Attention

Squaring a negative term, say x, using the syntax x**2 will cause an error. However, the alternatives sqr(x) and x*x will work (see here for an explanation).

Note that by default the solver subsystems will interrupt the solution process if arithmetic errors are encountered. Users may wish to permit a certain number of arithmetic errors and have reported error warnings instead. The option domlim facilitates this modification. Note that the default value for domlim is zero.

The best way to avoid evaluating functions outside their domain of definition is to specify reasonable variable bounds. However, there are cases when bounds are not enough. Consider the following simple example:

Set i / i1*i5 /;
Variables x(i), z;
Equations r1, r2(i);
r1.. z =e= log(sum(i, x(i)));
r2(i).. x(i) =l= 10;
x.lo(i) = 0;
x.l(i) = 5;
Model takeLog / all /;
solve takeLog using nlp minimizing z;

If we try to solve this little program with the solver MINOS, the log output will contain the following line:

EXIT - Function evaluation error limit exceeded.

The solution report in the listing file will have more detailed information:
3.17 Finding and Fixing Execution Errors and Performance Problems

2 error(s): log: FUNC DOMAIN: x < 0 (RETURNED 0)

...

**** REPORT SUMMARY : 1 NONOPT (NOPT)
0 INFEASIBLE
0 UNBOUNDED
1 ERRORS (****)

Note that the solver status has a value of 5 (Evaluation Interrupt), which means that the solver has been interrupted as more evaluation errors have been encountered than specified with the option domlim. In our case domlim equals its default value zero, thus one error is enough to cause the interruption. The equation in which the evaluation error occurred and the type of error is reported a few lines later. In our example, the equation r1 is problematic, since we take the logarithm of the expression \( \sum(i, x(i)) \), an expression which may become zero.

Note that in models such as this each individual variable \( x(i) \) should be allowed to become zero, but the sum should not. This may be achieved by introducing an intermediate variable, say \( xsum \), adding a lower bound greater than zero for it and using this variable as the argument for the function \( \log \):

```
Variable xsum;
  xsum.lo = 0.0001;
```

Equations defxsum, r1;

defxsum .. xsum =e= sum(i, x(i));
r1 .. z =e= log(xsum);

For more information on intermediate variables, see section Avoiding Expressions in Nonlinear Functions in the tutorial Good NLP Formulations.

Observe that solvers report the type of arithmetic problem encountered and the problematic equation, but do not identify the particular offending variable or the labels in the index of an equation that cause the error. If the cause is not obvious, users will have to investigate the numerical properties of the variables, labels and parameters in the body of the respective equation. This may involve the following:

- Displaying the input data items to the nonlinear terms in the respective equation.
• Searching the solution for equations that are infeasible (INFES) and variables that are nonoptimal (NOPT) in order to see where problems are present and which variables were being manipulated at the end of the run.

• Investigating variables and equations whose level values are zero, negative or very large at the end of the run.

• Deactivating part of the code to narrow down the problem as discussed in section Isolating Terms in Slow Statements below.

Resolving function evaluation errors will usually entail the following techniques:

• Adding lower bounds to variables to keep them above zero.

• Adding upper bounds to variables to prevent them from getting too large.

• Reformulating the model, for example, introducing intermediate variables.

• Providing better starting points that direct the solver search to a more relevant region. See section Specifying Initial Values in tutorial Good NLP Formulations for details.

• Fixing faulty input data.

3.17.1.4.2 Presolve Errors  Some solvers use a pre-processing step where the program is presolved to make the main solution process faster. During this step model errors could already be discovered, as in the following example:

```plaintext
Variables z;
Integer Variables y1, y2;
Equations r1, r2, r3, r4;
  r1.. z=e=y1+y2;
  r2.. y1=g=0.10;
  r3.. y2=g=0.10;
  r4.. y1+y2=l=1;
Model badpresol /all/;
solve badpresol using mip maximizing z;
```

For this problem, Cplex detects in the presolve already, that there is no feasible integer solution. This is reported in the log:

Row 'r4' infeasible, all entries at implied bounds.
Presolve time = 0.00 sec. (0.00 ticks)

...  
CPLLEX Error 1217: No solution exists.
Problem is integer infeasible.

Here, Cplex makes it clear, where we have a problem: Row r4 is infeasible, because all entries are at their "implied bounds". Lets look at r2 and r3 to see what this means: These equations set a lower bound of 0.1 for y1 and y2. Since both variables are defined as Integer Variables, they get an implicit lower bound of 1. Given that, equation r4 must be infeasible.
3.17 Finding and Fixing Execution Errors and Performance Problems

3.17.1.4.3 Solver Specific Limits  Many solvers have internal limits that may be exceeded and may cause the listing file to report an execution error. These errors may be resolved by using either GAMS options or solver specific options to increase the respective limits. Usually, the listing file will contain information about which options to use. Note that the solver manuals distributed with GAMS list the options that may be specified for each solver. For example, to relax the MINOS major iteration limit, the user may create a file named \texttt{minos.opt} with the following line:

\begin{verbatim}
Major iterations 1000
\end{verbatim}

More about solver option files can be found in section The Solver Options File.

3.17.1.5 Managing Execution Errors with the Function execError

The function \texttt{execError} facilitates implementing procedures that manage execution errors. Consider the following example, which is an extension of the example in section Arithmetic Errors above.

Set \( s \) / s1*s5 /;
Parameter \( p(s) \) "data to be exponentiated"
\( d(s) \) "divisors"
\( r(s) \) "result";
\( p(s) = 1; \)
\( p("s2") = -1; \)
\( d(s) = 1; \)
\( d("s3") = 0; \)
\( r(s) = p(s)**2.1 / d(s) \)
display r;

*cause \( z \) to be undefined
Scalar \( z \);
\( z = 1/0; \)

if(execError > 0,
   r(s)$(r(s) = z) = 0;);
display r;

Observe that we introduced a new scalar \( z \) that is deliberately undefined. In the if statement that follows, we use the function \texttt{execError} in the logical condition and the undefined scalar in the conditional assignment. The if statement has the effect that undefined entries are removed from the array of the parameter \( r \), as illustrated in the following lines of the execution output:

\begin{verbatim}
**** Exec Error at line 10: rPower: FUNC DOMAIN: x**y, x < 0
**** Exec Error at line 10: division by zero (0)
---- 11 PARAMETER r result
s1 1.000, s2 UNDF, s3 UNDF, s4 1.000, s5 1.000
**** Exec Error at line 16: division by zero (0)
---- 20 PARAMETER r result
s1 1.000, s4 1.000, s5 1.000
\end{verbatim}
In addition, the function execError may be used to reset the count of the number of execution errors. Typically, it is reset to zero so that GAMS will terminate with the status message Normal completion. For example, we could add the following line at the end of the code in the example above:

```plaintext
execError = 0;
```

Note

Setting `execError = 0;` will not only result in a normal completion in the example above. A solve statement will not be executed if there were execution errors before by default. Setting `execError = 0;` before the solve statement, will allow to execute it again.

Setting `execError = 0;` results also in a notification in the log:

```
********************
*** Errors have been cleared ***
********************
*** Status: Normal completion
```
Scalar f "freight in dollars per case per thousand miles" /90/;

Parameter c(i,j) "transport cost in thousands of dollars per case";

m(i,"total") = sum(j, x.l(i,j));
m("total","total")=sum(j, m("total",j));

option decimals = 0;
display m;

Observe that the two sets (i and j) were enlarged, the capacity (a) and demand (b) data were expanded to cover the new plant and market entries and the distance table (d) was adjusted accordingly. However, the data calculation, equations, model definition, model solution and report writing sections are identical in the two models.

3.17.2.2 Motivation and Step by Step Guide

As we have demonstrated in the example above, GAMS allows the model structure, calculations and report writing to be developed and implemented using a small data set, that may be easily expanded to larger data sets. Thus, we strongly recommend to start with a representative purposefully small data set and enlarge it to its full size once the work of model development, testing and debugging has been done. In short: work from small to large.

The larger the model the longer it takes to compile it, generate the model, execute and solve it. Generally, time expands exponentially. Working with a large model from the start will often lead to frustration even when the user is trying to find some relatively small data problems.

If a model that has already been completed needs some modification, it will be tempting to use the large data set instead of developing the modifications on a small data set. We strongly advise to use a small data set in this case, as experience shows that this way a considerable amount of time may be saved.

We recommend to follow these steps in model development:

1. Set up a small data set representing the full model with all structural features, set names, parameters etc.
2. Implement all data calculations, model features and report writing calculations.
3. Test the results of step 2 thoroughly.
4. Save the small model. Then implement a larger version with the full data set. Create separate files for data, calculation, model definition and report writing to maintain size independence. Use include files or the save and restart feature.
5. Test the larger model. Use the modeling techniques discussed below to facilitate your work.
6. Keep the small model current. As additional structural features are added to the large model, use it to test them. See section Introducing Strategical Subsets below for an easy way to maintain a small model.
3.17.2.3 Modeling Techniques

If users follow the steps for model development outlined in section Motivation and Step by Step Guide above, they will notice that it will not always be possible to model every needed feature with the small model. It is important to carefully choose the small data set so that it has all features of the larger data set. However, occasionally the peculiarities and interrelationships of the full data set cannot be reproduced in the small data set. In this section we will introduce some modeling techniques for finding problems that arise only when the full data set is used. They include saving and restarting to isolate the problem area, strategically introducing subsets and data reduction.

3.17.2.3.1 Isolating Problem Areas through Saving and Restarting

Suppose we have a model with a large data set that takes several hours to run and we wish to add some lines of code in a relatively small segment. The best way to do this is by isolating the relevant part. Isolating the part we wish to modify makes it possible to do tests and repairs without having to input data, do initial calculations and solve the whole model with each run. We recommend to use save and restart files.

For example, in chapter The Save and Restart Feature we demonstrate how to split the transportation model [TRNSPORT] in three parts: the file `tranmodel.gms` contains the data and the model, the file `transolve.gms` contains the solve statement and the file `tranreport.gms` contains a display statement. To run the whole model we use the following sequence, saving and restarting from the saved file:

```bash
> gams tranmodel s=s1
> gams transolve r=s1 s=s2
> gams tranreport r=s2
```

Assume we want a more elaborate report than just the display of some level values. As the file `tranreport.gms` contains the code relevant for reporting, we will modify only this file. Then we will test the result by running only this file, restarting from `s2`, without having to solve the whole model repeatedly.

3.17.2.3.2 Introducing Strategical Subsets

When full data sets are used in debugging or development, it is often helpful to narrow the focus on a few items in a set by introducing subsets. The following example is a modified version of the extended transportation model from section An Illustrative Example above.

```plaintext
* Data section
Sets    i   "canning plants" / Seattle, San-Diego, Baltimore, Dallas /
        j   "markets" / New-York, Chicago, Topeka, Boston, Miami / ;
Sets    plants(i) "a reduced set of canning plants"
          / Seattle, San-Diego /
        markets(j) "a reduced set of demand markets"
          / New-York, Chicago, Topeka / ;
*plants(i) = yes; markets(j) = yes;
Parameters a(i) "capacity of plant i in cases"
          / Seattle    350, San-Diego  600, Baltimore 450, Dallas  750 /
        b(j) "demand at market j in cases"
          / New-York 325, Chicago 300, Topeka 275, Boston 330, Miami 290 /;
Table    d(i,j) "distance in thousands of miles"
```
250 User’s Guide

<table>

Scalar f “freight in dollars per case per thousand miles” /90/ ;

Parameter c(i,j) "transport cost in thousands of dollars per case";
c(plants,markets) = f * d(plants,markets) / 1000 ;

* Model section
Positive Variable x(i,j) "shipment quantities in cases";
Variable z "total transportation costs in thousands of dollars";

Equations cost "define objective function"
supply(i) "observe supply limit at plant i"
demand(j) "satisfy demand at market j";

cost .. z =e= sum((plants,markets), c(plants,markets) * x(plants,markets)) ;
supply(plants) .. sum(markets, x(plants,markets)) =l= a(plants) ;
demand(markets) .. sum(plants, x(plants,markets)) =g= b(markets) ;

Model transport /all/ ;
solve transport using lp minimizing z ;

Observe that we introduced the subsets plants and markets that contain only some of the elements of their supersets i and j. Note that all tables, parameters and variables are defined with the supersets, the equations are declared over the supersets, but defined over the subsets and the calculation of the parameter c is also restricted to the subsets. Hence the model is restricted to the elements of the subsets. However, it is easy to change the restricted model back to the full model by removing the asterisks indicating a comment line:

plants(i) = yes; markets(j) = yes;

Observe that the sets plants and markets are now dynamic sets. Note that this assignment could be inserted anywhere in the code. Thus, introducing strategic subsets may be combined with isolating problem areas, as detailed in section Isolating Problem Areas through Saving and Restarting above.

Introducing strategic subsets has proven to be an effective way of maintaining a small data set with little effort. Users only have to choose elements that are representative for model development and debugging from the full sets.

3.17.2.3.3 Reducing Data Recall that GAMS skips cases where data items equal zero. Thus a large model may be reduced by temporarily removing data from data sets by simply setting items to zero. Consider the following example:

Sets o 'origin' /o1*o100 /
d 'destination' /d1*d100 /
Parameter dist(o,d) 'distance';
dist(o,d) = 120 + 50*ord(d) - 0.5*ord(o);
Sets so(o) 'small set of origins for testing' /o4, o47, o91 /
sd(d) 'small set of destinations' / d3, d44, d99 /;

dist(o,d) $ (not (so(o) and sd(d))) = 0;

Parameter cost(o,d) 'transportation cost';
cost(o,d) $ dist(o,d) = 3 + 2*dist(o,d);
display cost, dist;

Note that we introduced strategic subsets and used them in the logical condition of a conditional assignment to set almost all entries of the parameter dist to zero. Note further, that the assignment for the parameter cost is conditioned on nonzero entries for the distance. Now, if the model were conditioned on nonzero transportation costs, the size of the whole model would be greatly reduced.

3.17.3 Increasing Efficiency: Reducing GAMS Execution Time

GAMS can take a long time for computations and model generation. There are some signs which indicate that it may be possible to reduce the execution time, e.g., an execution time that is unexpectedly long in general or a long execution of a single line, which could be seen, if the log shows the same line number for a long time.

In this section we will discuss how to find the causes for slow program execution and how to eliminate the main causes for slow execution.

3.17.3.1 Finding the Causes for Slow Program Execution

The best strategy for discovering the causes for slow execution is a combination of the techniques discussed in section Small to Large: Aid in Development and Debugging above and the techniques that we will introduce in this section, including generating an execution profile and isolating terms in slow statements. We will also touch briefly on observing the log file and we will point out why this is not the first choice.

3.17.3.1.1 Generating an Execution Profile  The quickest way to find GAMS statements that take particularly long to execute, is generating an execution profile in the output file. The execution profile contains the individual and cumulative time required to execute the sections of the GAMS model as well as information on memory use. An execution profile is generated when the option profile is assigned a value larger than zero (zero is the default). This can be done either by setting a command line parameter or by using the option statement. We will show an example of an execution profile below. For more information on execution profiles, further examples and details on the values the option profile may take, see the detailed description here.

Consider the following example:

```
option profile = 1;
option limrow = 0; option limcol = 0;
option solprint = off;

Sets a / 1*12 /, b / 1*12 /, c / 1*10 /,
            d / 1*10 /, e / 1*12 /;

Parameters x(e,d,c,b,a), y, z(a,b,c,d,e);

x(e,d,c,b,a) = 10;

z(a,b,c,d,e) = x(e,d,c,b,a);
y = sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a));
```
Variable obj;
Positive Variable var(e,b,a);

Equations objeq, r(b,c,d), q(a,b,c);

objeq.. obj =e= sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a) * var(e,b,a));
r(b,c,d).. sum((a,e), var(e,b,a)) =l= sum((a,e), x(e,d,c,b,a)*z(a,b,c,d,e));
q(a,b,c).. sum((d,e), var(e,b,a)/x(e,d,c,b,a)*z(a,b,c,d,e)) =l= 20;

Model slow /all/;
solve slow maximizing obj using lp;

Parameter sumofvar;
sumofvar = sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a)*var.l(e,b,a));
display sumofvar;

The listing file will contain an execution profile like this (spread over the file):

-----   9 Assignment x       0.374 0.374 SECS  109 MB 4259200

-----   23 Solve Fini slow   0.780 18.080 SECS  470 MB 4482809
-----   23 GAMS Fini         0.359 0.359 SECS  470 MB        0
-----    1 InitE            0.032 0.032 SECS  213 MB        0
-----    1 ExecInit         0.000 0.032 SECS  213 MB        0
-----   23 Solve Alg slow    0.000 0.032 SECS  213 MB        0
-----   23 Solve Read slow   0.000 0.032 SECS  215 MB        0
-----   26 Assignment sumofvar 2.620 2.652 SECS  287 MB        0
-----    27 Display          0.032 2.684 SECS  287 MB        0
-----    27 GAMS Fini        0.000 0.000 SECS  287 MB        0

The first column shows the line number in the input file of the GAMS statement that is executed. The second column reports the type of statement. For an overview of all GAMS statements, see section Classification of GAMS Statements. The next two columns give the individual time needed to execute the respective statement and the cumulative time spent so far. The memory use follows and finally, the number of assignments generated in the respective line is shown.

In addition, there is a Profile Summary at the end of the lst file showing the most expensive statements:

---- Profile Summary (19 records processed)
      5.741  0.470GB  20 Equation q (9680)
      3.510  0.287GB  18 Equation objeq (1)
      3.088  0.464GB  19 Equation r (8800)
      2.620  0.287GB  26 Assignment sumofvar (0)
      2.324  0.286GB  11 Assignment y (0)
      2.231  0.286GB  10 Assignment z (4259200)
      0.780  0.470GB  23 Solve Fini slow (4482809)
      0.374  0.109GB  9 Assignment x (4259200)
      0.359  0.470GB   23 GAMS Fini
      0.032  0.213GB   1 InitE
This shows that the execution of the statements in line numbers 20, 18, 19, 26, 11 and 10 are the most expensive ones (in this order). One reason is an inconsistent order when sets are referenced; we will discuss this topic in section Ordering Indices Consistently below.

Note that the execution profile may contain many lines that are not informative since the execution times reported are negligible. These lines may be suppressed by using the the option \texttt{profileTol} to specify the minimum execution time (in seconds) that is to be included. Observe that the option \texttt{profileTol} is available as command line parameter and option statement.

Note further, that the command line parameter \texttt{profileFile} facilitates writing the profiling information to a separate file (instead of the listing file).

3.17.3.1.2 Isolating Terms in Slow Statements In some cases the execution profile shows that the cause for a long execution time is connected with a very long statement. For example, the objective function in some models and some report calculations may take hundreds of lines of code and can contain many terms that are added. If such a long statement is problematic in terms of execution time, it will be necessary to deactivate parts of the code and run the program repeatedly to find the precise lines that are at the root of the problem. This can be done by using comments.

3.17.3.1.3 Observing the Log File Some modelers choose to examine the log file or watch the screen during execution to find the causes for slow program execution. However, we advise against this approach for the following reasons:

- Statements that are executed slowly are easily missed and often statements are misidentified. In addition, screen watchers may be distracted and will have to repeat the process.

- GAMS line reporting can be misleading if flow control statements like if statements and loop statements are executed. For example, individual calculations in a loop are not reported to the screen. A user watching the screen would notice that the loop takes a lot of time, but there is no indication which statement within the loop is problematic. This applies to all GAMS control structures.

Therefore we recommend to use the option \texttt{profile} as the main tool for finding the causes for slow program execution. For details, see section Generating an Execution Profile above. In addition, see the techniques outlined in section Advice for Repairing Puzzling Nonworking Code below.

3.17.3.2 Eliminating the Main Causes for Slow Program Execution

The main reasons for a slow program execution include an inconsistent index order when sets are referenced and taking irrelevant cases into consideration. In this section we will give some guidance on how to eliminate these causes, and also point to problems due to the scaling of a model which could cause a unnecessarily long execution time for the solver.

3.17.3.2.1 Ordering Indices Consistently GAMS employs a sparse matrix data storage scheme. For example, consider the parameter $p(a, b, c)$. Assume that the set $a$ has $k$ elements, the set $b$ has $n$ elements and $c$ has $m$ elements. Then the entries for $p$ are stored in the following order:
Note that it is a systematic order where the last entry varies the fastest and the first the slowest. Observe that GAMS will withdraw entries from memory fastest if they are referenced in an order consistent with the storage order. Thus, in the following example, the first assignment statement will be processed faster than the second assignment statement.

\[
x(a,b,c) = p(a,b,c); \\
y(b,c,a) = p(a,b,c);
\]

Note

GAMS will execute a program fastest if the sets are always referenced in the same order in definitions, assignments and equations.

The example that follows illustrates this principle. First we will solve a program where the indices appear in an arbitrary order and we will record the output generated by setting the option profile to 1. Then we will reformulate the program so that the indices will always appear in an alphabetical order and solve it again, recording the profile output. In the final step, we will compare the execution times of the two runs. We will use the example introduced above.

Note that the indices in the parameters and equations appear in a random order. Here is the profile from the six most expensive statements again:

-----   10 Assignment z   2.231  2.605 SECS  286 MB  4259200  
-----   11 Assignment y   2.324  4.929 SECS  286 MB       0  
-----   18 Equation   objeq  3.510  8.471 SECS  287 MB       1  
-----   19 Equation   r    3.088 11.559 SECS  464 MB  8800  
-----   20 Equation   q    5.741 17.300 SECS  470 MB  9680  
-----   26 Assignment sumofvar  2.620  2.652 SECS  287 MB       0  

In the next step we reformulate the program such that the indices always appear in the same order. For example, we define the parameter \( x \) as \( x(a,b,c,d,e) \) instead of \( x(e,d,c,b,a) \). Here is the complete rewritten model:

```plaintext
option profile = 1;
option limrow = 0; option limcol = 0;
option solprint = off;

Sets   a / 1*22 /, b / 1*22 /, c / 1*20 /,
       d / 1*20 /, e / 1*22 /;
```
Parameters x(a,b,c,d,e), y, z(a,b,c,d,e);
x(a,b,c,d,e) = 10;
z(a,b,c,d,e) = x(a,b,c,d,e);
y = sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e));

Variable obj;
Positive Variable var(a,b,e);

Equations objeq, r(b,c,d), q(a,b,c);

objeq.. obj =e= sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e) * var(a,b,e));
r(b,c,d).. sum((a,e), var(a,b,e)) =l= sum((a,e), x(a,b,c,d,e)*z(a,b,c,d,e));
q(a,b,c).. sum((d,e), var(a,b,e)/x(a,b,c,d,e)*z(a,b,c,d,e)) =l= 20;

Model slow /all/;
solve slow maximizing obj using lp;

Parameter sumofvar;
sumofvar = sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e)*var.l(a,b,e));
display sumofvar;

After running the modified program, the profile for expensive statements looks like this:

|   |  10 Assignment z |   |  11 Assignment y |   |  18 Equation objeq |   |  19 Equation r |   |  20 Equation q |   |  26 Assignment sumofvar |
|---|------------------|---|------------------|---|-------------------|---|-----------------|---|-----------------|---|
|   | 0.593            |   | 0.671            |   | 1.778             |   | 2.215           |   | 1.763           |   | 0.952            |
|   | 0.983 SECS       |   | 1.654 SECS       |   | 3.432 SECS        |   | 5.647 SECS      |   | 7.410 SECS      |   | 0.983 SECS       |
|   | 215 MB 4259200   |   | 215 MB 0         |   | 215 MB 1          |   | 392 MB 8800     |   | 398 MB 9680     |   | 216 MB 0         |

Observe that executing for example the assignment to z took just 0.593 seconds compared to 2.231 seconds in the first run. Substantial percentage reductions were achieved in all time consuming cases by consistently referencing the sets in the same order.

### 3.17.3.2.2 Restricting Assignments and Equations to Relevant Cases

#### 3.17.3.2.2.1 Assignments

Assume that we have a set of cities with different production capacities and demands for various products. We want to know the maximum transportation cost (which depends on the distance, the amount shipped and a fixed factor) from each city to all others. This cost can be calculated in the following way:

Sets c "cities" / c1*c800 /
p "products" / p1*p10 /;
Alias (c,cc);

Parameter capacity(c,p) "Production capacity for product p in city c"
demand(c,p) "Demand for product p in city c"
distance(c,cc) "Distance between two cities";

*Generate some sparse, random data*
capacity(c,p)$(uniform(0,1)<0.05) = uniformInt(150,250);
demand(c,p)$(uniform(0,1)<0.025) = uniformInt(50,150);
distance(c,cc)$(not sameas(c,cc)) = uniformInt(10,800);

Parameter maxCost(c,cc) "Maximum transportation costs between two cities"
maxCost(c,cc) = sum(p, min(capacity(c,p), demand(cc,p))*distance(c,cc)*90);
The performance profile will tell us something like this:

```
---- 16 Assignment maxCost 0.265 0.436 SECS 19 MB 8756
```

Since we know, that the parameter `maxCost` will be zero for a pair of cities if there is no product with production capacity in the first city and demand in the second one, we could reduce the execution time for the last assignment:

```
Sets c "cities" / c1*c800 /
  p "products" / p1*p10 /;
Alias (c,cc);
Parameter capacity(c,p) "Production capacity for product p in city c"
  demand(c,p) "Demand for product p in city c"
  distance(c,cc) "Distance between two cities";

*Generate some sparse, random data
capacity(c,p)$((uniform(0,1)<0.05) = uniformInt(50,150);
demand(c,p)$((uniform(0,1)<0.025) = uniformInt(50,150);
distance(c,cc)$((not sameas(c,cc)) = uniformInt(10,800);

Parameter maxCost(c,cc) "Maximum transportation costs between two cities";

maxCost(c,cc)$sum(p, capacity(c,p)*demand(cc,p))
  = sum(p, min(capacity(c,p), demand(cc,p))*distance(c,cc)*90);
```

So we did not do the calculation of `maxCost` if we knew before, that it must be zero anyway. This results in a reduced runtime:

```
---- 17 Assignment maxCost 0.031 0.187 SECS 19 MB 8756
```

Note

To restrict computations in assignment to the relevant cases, we recommend using dollar conditions and filtering sets. These concepts are introduced and discussed in detail in chapter Conditional Expressions, Assignments and Equations.

For more examples, see sections Conditional Assignments and Conditional Indexed Operations.

### 3.17.3.2.2 Variables and Equations

Like assignments, variables and equations need to be restricted to relevant cases to avoid unnecessary inefficiencies. Dollar conditions and filtering sets may be used over the domain of definition as well as in the body of an equation.

Lets extend the assignment example from the previous paragraph and use the generated data in a transportation model:
Sets c "cities" / c1*c800 / 
p "products" / p1*p10 / ; 

Alias (c,cc);

Parameter capacity(c,p) "Production capacity for product p in city c"
  demand(c,p) "Demand for product p in city c"
  distance(c,cc) "Distance between two cities";

* Generate some sparse, random data 
  capacity(c,p)$(uniform(0,1)<0.05) = uniformInt(150,250);
  demand(c,p)$(uniform(0,1)<0.025) = uniformInt(50,150);
  distance(c,cc)$(not sameas(c,cc)) = uniformInt(10,800);

Parameter shipCost(c,cc) "Transportation costs between two cities per case"
  maxCost(c,cc) "Maximum transportation costs between two cities";

shipCost(c,cc) = distance(c,cc)*90;
maxCost(c,cc)$sum(p, capacity(c,p)*demand(cc,p))
  = sum(p, min(capacity(c,p), demand(cc,p))*shipCost(c,cc));

Variables
  x(c,cc,p) "shipment quantities in cases"
  z "total transportation costs in thousands of dollars";

Positive Variable x ;

Equations
  cost "define objective function"
  supply(c,p) "observe supply limit at plant i"
  dem(cc,p) "satisfy demand at market j";

  cost.. z =e= sum((c,cc,p), shipCost(c,cc)*x(c,cc,p)) ;
  supply(c,p).. sum(cc, x(c,cc,p)) =l= capacity(c,p) ;
  dem(cc,p).. sum(c, x(c,cc,p)) =g= demand(cc,p) ;

Model transport /all/ ;

Solve transport using lp minimizing z ;

The Profile Summary tells us, that the equations are rather expensive to generate and also the reading of the solution takes some time because of the size of the model:

----- Profile Summary (18 records processed)
  98.780 1.070GB 34 Equation  dem (8000)
  26.864 0.515GB 38 Solve Read transport
  25.303 0.454GB 32 Equation  cost (1)
  6.599 0.813GB 33 Equation  supply (8000)

However, as in the previous example, we know, that a product p won't be shipped from city c to city cc if there is either no production capacity in the first city or no demand in the second one. So we could reduce the size of our model by not generating variables and equations from which we know, that they are irrelevant for the solution. Here is a improved formulations of the equations:

cost.. z =e= sum((c,cc,p)$(capacity(c,p)*demand(cc,p)), shipCost(c,cc)*x(c,cc,p)) ;
supply(c,p)$capacity(c,p).. sum(cc$demand(cc,p), x(c,cc,p)) =l= capacity(c,p) ;
dem(cc,p)$demand(cc,p).. sum(c$capacity(c,p), x(c,cc,p)) =g= demand(cc,p) ;
This decreases the size of the model and thus the execution time to generate the model and load the solution significantly:

<table>
<thead>
<tr>
<th></th>
<th>GB</th>
<th>Equation</th>
<th>Cost</th>
<th>Solve</th>
<th>Transport</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.031</td>
<td>0.035GB</td>
<td>33</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0.031</td>
<td>0.034GB</td>
<td>39</td>
<td></td>
<td>Read</td>
<td>transport</td>
</tr>
<tr>
<td>0.016</td>
<td>0.035GB</td>
<td>34</td>
<td></td>
<td>supply</td>
<td>(380)</td>
</tr>
</tbody>
</table>

Note that the equation \texttt{dem} does not even show up in the summary anymore since its generation was done to quickly.

For more details on conditions in equations, see section Conditional Equations.

### 3.17.3.2.3 Keep the model well scaled
Model solutions within GAMS frequently require manipulation of large matrices and many computations. The heart of most solvers includes many numerical procedures such as a sparse matrix inverter and sets of convergence and infeasibility tolerances. Numerical problems often arise within such procedures. Poorly scaled models can cause excessive time to be taken in solving or can cause the solver to fail. GAMS can assist the user to formulate a well scaled model. Details about this can be found in the sections Model Scaling - The Scale Option and Scaling Variables and Equations.

### 3.17.3.3 Other Approaches
In addition to the techniques discussed in section Eliminating the Main Causes for Slow Program Execution above, the following approaches may help to reduce the time needed for program execution:

- Trying another appropriate solver.
- Reformulating the model. This may yield particularly good results, if the model is reformulated in such a way that another model type is used, that is easier to solve or for which more advanced solver technology is available.
- Using starting points for NLP models, as discussed in section Specifying Initial Values.
- Trading memory for time.

We conclude the discussion of this topic with an example that demonstrates how memory may be traded for time. If an extensive calculation is repeated many times in a model, it may be possible to restructure the code so that the calculation is performed only once, then the result is saved and accessed later. Consider the following equation:

\[
\text{obj.. } z = e = \sum((i,j,k,l), a(i,j,k,l) \times \sum(m, u(m,i)))
\]

The execution time may be substantially reduced by defining a new parameter, say \( p \), for the second sum and using this parameter in the equation:

\[
\text{Parameter } p(i);\\
\text{p(i) = sum(m, u(m,i));}
\]

\[
\text{obj.. } z = e = \sum((i,j,k,l), a(i,j,k,l) \times p(i));
\]

There is only one caveat: Users need to carefully consider whether the input data, here \( u(m,i) \), is modified between the assignment for the new parameter \( p \) and the equation where \( p \) is used. If \( u \) is updated, then the assignment statement needs to be repeated, otherwise the data that enters the equation will not be current.
3.17 Finding and Fixing Execution Errors and Performance Problems

3.17.4 Increasing Efficiency: Reducing Memory Use

Besides slow program execution, excessive memory use may be of concern for modelers. In this section we will present some approaches on how to find the causes for extraordinary memory use and give some advice on eliminating the main causes for it.

3.17.4.1 Finding the Causes for Excessive Memory Use

The main techniques for finding the causes for excessive memory use are the same as those for finding the causes for slow program execution. We discussed these techniques in section Finding the Causes for Slow Program Execution above.

In addition, the option `dmpSym` is useful in this context. GAMS will report the number of records stored for each symbol at the point in the program where the option `dmpSym` is inserted.

Consider the following example:

```plaintext
Sets i /1*5 /, j /1*5 /, k /1*5 /, l /1*5 /,
     m /1*5 /, n /1*5 /, o /1*5 /;
Parameters y(i,j,k,l,m,n,o)
    q(i,j,k);
Variables x(i,j,k,l,m,n,o)
    f(i,j,k)
    obj;
y(i,j,k,l,m,n,o) = 10;
q(i,j,k) = 10;
x.up(i,j,k,l,m,n,o) = 10;
x.scale(i,j,k,l,m,n,o) = 1000;
Equations z(i,j,k,l,m,n,o)
    res(i,j,k)
    ob;

ob..        obj =e= sum((i,j,k,l,m,n,o), x(i,j,k,l,m,n,o));

Model memory /all/;
option dmpsym;
solve memory maximizing obj using lp;
```

Note that an option statement with `dmpSym` was added before the solve statement. It generates the following memory dump that is included in the execution output of the listing file:

```
ENTRY ID TYPE DIM DIM-OK LENGTH DEFINED ASSIGNED DATAKNOWN ACCESS SPECVAL DOMAIN LAGLEAD
1 mapval FUNCT 0
2 ceil FUNCT 1
3 floor FUNCT 2
...
132 FILE FILE 0 FALSE 0 FALSE FALSE FALSE 0
133 i SET 1 TRUE 5 TRUE FALSE TRUE 0
134 j SET 1 TRUE 5 TRUE FALSE TRUE 0
135 k SET 1 TRUE 5 TRUE FALSE TRUE 0
136 l SET 1 TRUE 5 TRUE FALSE TRUE 0
```
Note

By default, the lines of the SYMBOL TABLE DUMP get wrapped when this option is used from the GAMSIDE. For a better overview it can be helpful to increase the pageWidth to e.g. 1024.

Observe that the SYMBOL TABLE DUMP has two parts: information on GAMS functions and a report with the number of records stored for each symbol in the program. The first part is not relevant for our context, thus we will restrict our discussion to the second part. The column ID contains the names of the symbols, the column TYPE gives the data type of the respective entry, the column DIM reports the number of indices and the column LENGTH gives the number of records that is related to memory use. Note that the other columns are not relevant for this discussion.

Observe that the rows with high counts in column LENGTH indicate symbols within the GAMS program which have large numbers of internal records that must be stored. This is associated with corresponding memory requirements. Note also that not all length counts are of equal significance. In particular, variables and equations use more memory per element than parameters, since they have bounds, levels, marginals and scales that are associated with them. Parameters use more memory per element than sets, since sets may need just one indicator for yes or no. However, the explanatory text for set elements might increase the memory requirements for set elements.

Nevertheless, users may use this report to identify items with many records and verify that all of them are actually needed. For more details, see section Eliminating the Main Causes for Excessive Memory Use below.

3.17.4.2 Eliminating the Main Causes for Excessive Memory Use

As detailed in section Eliminating the Main Causes for Slow Program Execution above, the main causes for a slow program execution include an inconsistent index order when sets are referenced and taking irrelevant cases into consideration. These programming habits also tend to cause excessive memory use. In this section we will give some advice on avoiding memory traps and show how the memory may be cleared of data that is no longer needed.

3.17.4.2.1 Avoiding Memory Traps

Users may inadvertently use a lot of memory if they import data from a database with long explanatory text for sets or set elements. In addition, setting variable attributes for scaling or bounds may be problematic. Consider the following example:

```
x.scale(i,j,k,l,m) = 100;
x.lo(i,j,k,l,m) = 10;
x.up(i,j,k,l,m) = 77;
```

These assignments will probably set many more values than are relevant for a particular problem. Therefore we recommend to carefully consider which label combinations are actually necessary and to restrict the assignments to these cases by the use of dollar conditions or filtering sets. For more information, see section Conditional Assignments.
3.17.4.2.2 Clearing Memory of Unneeded Data

Sometimes a lot of memory space is used for data that is needed at some point, but not later. Consider the following simple example:

```
set i /1*1000/
   j /1*1000/;
parameter distance(i,j)
   cost(i,j);
distance(i,j) = 100+ord(i)+ord(j);
cost(i,j) = 4+8*dist(i,j);
```

Assume that the parameter `distance` is used only here, but nowhere else in the program. Therefore users may wish to free the memory space occupied by the data connected with `distance`. The option `clear` may be used to achieve this:

```
option clear = distance;
```

This will reset all entries in the matrix associated with `distance` to zero.

Alternatively, an identifier that is no longer needed could be reset to its default value(s) with an assignment statement. In the example above, we could write:

```
distance(i,j) = 0;
```

This statement will have the same effect as the option statement. The advantage of the option statements is that they offer a more compact alternative that is particularly useful if equations or variables are to be cleared and multiple equation attributes or variable attributes are affected.

Note that the dollar control options `$clear` and `$kill` may also be used to free memory. These are compile time directives, which have a similar effect on the memory consumption but have different side effects: while `$clear` will reset the values to their defaults, `$kill` will completely remove the identifier from the program. Hence an identifier that was "killed" may be used later in another declaration and definition statement. For example, the following code snippet is legal:

```
Set i /1, 2, 3/;
$kill i
Set i /a, b, c/;
```

With `$clear` instead of `$kill` this would cause a compilation error.

3.17.4.3 Setting Memory Limits with HEAPLIMIT

In a server environment and in other cases (e.g. to avoid the use of virtual memory) the amount of memory a GAMS run is allowed to use may have to be limited. The command line parameter `heapLimit` serves this purpose: the amount of memory for GAMS compilation and execution is limited to a specified number (in MB). If the data storage exceeds this limit, the job will be terminated with return code 10, out of memory. In addition, the function `heapLimit` may be used to interrogate the current limit and to reset it.

Note that limiting memory use for solver execution is not possible from within the GAMS program. However, some solvers like the NLP solver CONOPT have their own heapLimit option which ensures that the solver will not use more dynamic memory than specified.
3.17.4.4 Advice for Repairing Puzzling Nonworking Code

Assume a GAMS run was terminated and we cannot get a profile output (e.g. because GAMS ran out of memory and crashes). A memory overrun error causes the operating system buffer handling procedures to generally lose the last few lines of profile information when the job malfunctioned. How do we find the problem in this case?

We recommend to use the techniques outlined in section Modeling Techniques above. In addition, successively deactivating code in search for the last GAMS statement that worked will help in most cases. This can be done by using comments. If at some point the run terminates properly, the user will slowly activate parts of the last statements that were deactivated until the code performance will get worse again. By iteratively activating and deactivating terms, the precise problematic terms may be found. The save and restart feature could also be used to save the results until a certain statement and then to execute only the statements that are suspected to be problematic.

3.18 Comparative Analyses with GAMS

Once a model is completed, it is almost always used to investigate alternative scenarios where the analyst compares the results of various scenario assumptions. In this tutorial we will show how such comparative analyses (also called sensitivity analyses) are done with GAMS. We will first demonstrate an easy approach, where we will manually change input parameters, use repeated solves and generate reports. In a second step, we will introduce another approach, where a loop structure will be used to automatically cycle through the scenarios. We recommend to read the sections on the manual approach first, since the sections on the automated approach build on code blocks developed in the early sections.

3.18.1 Manual Approach

Suppose we wish to do a comparative analysis by altering some input data in a model. We will use as an example the farm profit-maximizing model farmcomp.gms. The following vector of prices for primary commodities is a part of the input data:

Parameter price(primary) 'prices for products in USD'
   / corn 2.20, soybeans 5.00, beef 0.50 /;

We will use these data as a base case and compare it with two alternative scenarios: in the first scenario we will change the price of beef to $0.70 and in the second scenario we will change the price of corn to $2.70.

The GAMS file farmrep.gms is related to our example model. It contains only calculations for report writing and may be included with the dollar control option $include. It will generate a report based on the solution of the last solve that was executed in the GAMS program farmcomp.gms. The report consists of several tables. We will focus on the table Farm Summary that is associated with the parameter summary. The relevant code is given below:

Set alli 'allitems'
   / corn, soybeans, beef, cattle,
   water, cropland, pastureland,
   fertilizer, seed, othercost, veterinary, supplement,
   "April labor", "May labor", "summer labor", "Sept labor", "Oct labor",
   cattlefeed, total /;

Set measures 'output measures'
   / "Net Income", "Land Use", "Dry Cropping", "Irr Cropping",
   "Livestock", "Resource Value", "Product Value" /

Parameter summary(alli,measures) 'Farm Summary';
Note that the table for the parameter `summary` will contain rows for the commodities which are elements of the set `alli` and columns for all elements of the set `measures`.

We will use a third GAMS file, `mancomp.gms`, for our comparative analysis. The code of this third GAMS file follows:

```gams
$include farmcomp.gms
display price;
$include farmrep.gms
price("beef") = 0.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms
price("corn") = 2.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms
```

Note that this code first solves the original model that also contains the set definitions for the report, displays the initial prices and generates a report. In a second step the price for `beef` is changed to $0.70, the modified model is solved, the prices for the first alternative scenario are displayed and a report is generated. In a third step the price for `corn` is changed to $2.70, the model is solved again, the prices for the second alternative scenario are displayed and a third report is generated. Note that in the second alternative scenario (the third solve) the beef price is $0.70, since it was not reset to base levels after the second run.

There will be three tables associated with the parameter `summary` in the listing file, one for each solve. The first table reports the results associated with the base case:

```
---- 279 PARAMETER summary Farm Summary

<table>
<thead>
<tr>
<th></th>
<th>Net Income</th>
<th>Land use</th>
<th>Dry Cropp</th>
<th>Irr Cropp</th>
<th>Livestock</th>
<th>Resource</th>
<th>Product V</th>
</tr>
</thead>
<tbody>
<tr>
<td>Corn</td>
<td>20.00</td>
<td>200.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>2.20</td>
</tr>
<tr>
<td>Soybeans</td>
<td>480.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>5.00</td>
</tr>
<tr>
<td>Beef cattle</td>
<td>615.79</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Water</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>16.83</td>
<td></td>
</tr>
<tr>
<td>Cropland</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>128.49</td>
<td></td>
</tr>
<tr>
<td>Pastureland</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>84.26</td>
<td></td>
</tr>
<tr>
<td>April Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>32.34</td>
<td></td>
</tr>
<tr>
<td>May Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>27.01</td>
<td></td>
</tr>
<tr>
<td>Oct Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>11.50</td>
<td></td>
</tr>
<tr>
<td>Cattlefeed</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>4.71</td>
</tr>
<tr>
<td>Total</td>
<td>162685.05</td>
<td>500.00</td>
<td>200.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

The second table reports the results from the first alternative scenario where the price for beef was changed to $0.70:

```
---- 351 PARAMETER summary Farm Summary

<table>
<thead>
<tr>
<th></th>
<th>Net Income</th>
<th>Land use</th>
<th>Dry Cropp</th>
<th>Irr Cropp</th>
<th>Livestock</th>
<th>Resource</th>
<th>Product V</th>
</tr>
</thead>
<tbody>
<tr>
<td>Corn</td>
<td>20.00</td>
<td>200.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>2.20</td>
</tr>
<tr>
<td>Soybeans</td>
<td>480.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>5.00</td>
</tr>
<tr>
<td>Beef cattle</td>
<td>615.79</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Water</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>16.83</td>
<td></td>
</tr>
<tr>
<td>Cropland</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>128.49</td>
<td></td>
</tr>
<tr>
<td>Pastureland</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>84.26</td>
<td></td>
</tr>
<tr>
<td>April Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>32.34</td>
<td></td>
</tr>
<tr>
<td>May Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>27.01</td>
<td></td>
</tr>
<tr>
<td>Oct Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>11.50</td>
<td></td>
</tr>
<tr>
<td>Cattlefeed</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>4.71</td>
</tr>
<tr>
<td>Total</td>
<td>162685.05</td>
<td>500.00</td>
<td>200.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
And the third table reports the results from the second alternative scenario where the price for corn was changed to $2.70 and the price for beef stayed at $0.70:

<table>
<thead>
<tr>
<th></th>
<th>Net Income</th>
<th>Land use</th>
<th>Dry Crop</th>
<th>Irr Crop</th>
<th>Livestock</th>
<th>Resource</th>
<th>Product V</th>
</tr>
</thead>
<tbody>
<tr>
<td>Corn</td>
<td>31.98</td>
<td>31.98</td>
<td>200.00</td>
<td>2.70</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Soybeans</td>
<td>410.24</td>
<td>410.24</td>
<td>5.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Beef</td>
<td>0.70</td>
<td>0.70</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>cattle</td>
<td>866.67</td>
<td>866.67</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Cropland</td>
<td>642.22</td>
<td>642.22</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Pastureland</td>
<td>130.00</td>
<td>130.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>April Labor</td>
<td>61.39</td>
<td>61.39</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>May Labor</td>
<td>61.72</td>
<td>61.72</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sept Labor</td>
<td>84.92</td>
<td>84.92</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Oct Labor</td>
<td>87.21</td>
<td>87.21</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Cattlefeed</td>
<td>5.36</td>
<td>5.36</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>375839.30</td>
<td>442.22</td>
<td>200.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This quick way to do a comparative analysis has the following drawbacks:

- The relevant output is spread over more than 140 lines.
- There is no cross-scenario report.
- The price of beef in the second alternative scenario is problematic, since it was not automatically reset to the original base price.
- The handling of solves and report writing is repetitive.

The first two issues will be addressed in section Writing Cross-Scenario Reports, a solution for the third issue will be given in section Resetting Data to Base Levels and an alternative approach that will resolve the last issue is presented in section An Automated Approach - Avoiding Repeated Work.
3.18 Comparative Analyses with GAMS

3.18.1.1 Writing Cross-Scenario Reports

We will generate a cross-scenario report by introducing two new sets and a new parameter in a revised version of the third GAMS file, `mancompb.gms`:

Set scenarios / base, beefp, beefcorn /;
Set ordr / "Scenario Setup", "Scenario Results"/;
Parameter savsumm(ordr,*,alli,scenarios) 'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,alli,"base") = summary(alli,measures);

Note that the set `scenarios` contains the base case and the two alternative scenarios and the set `ordr` introduces places to save the assumptions and results of the different runs. The new parameter `savsumm` is similar to the parameter `summary` introduced above, but it has two additional dimensions. Observe that the first assignment copies the current setup of the price vector and the second assignment copies the results that are stored in the parameter `summary`.

The full code follows:

```gams
$include farmcomp.gms
$include farmrep.gms
Set ordr / "Scenario Setup", "Scenario Results" /;
Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*,alli,scenarios) 'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,alli,"base") = summary(alli,measures);

price("beef") = 0.70;
solve farm using LP maximizing netincome;
display price ;
$include farmrep.gms
savsumm("Scenario Setup","price",primary,"beefp") = price(primary);
savsumm("Scenario Results",measures,alli,"beefp") = summary(alli,measures);

price("corn") = 2.70;
display price ;
solve farm using LP maximizing netincome;
$include Farmrep.gms
savsumm("Scenario setup","price",primary,"beefcorn") = price(primary);
savsumm("Scenario Results",measures,alli,"beefcorn") = summary(alli,measures);

option savsumm:2:3:1;
display savsumm;
```

Observe that the last index in the assignments for `savsumm` is "base" after the first solve, "beefp" after the second solve and "beefcorn" after the third solve. Note that option statement in the penultimate line of the code customizes the output generated by the display statement that follows. For details see section Local Display Control. The listing file will contain the following output:

```
----  436 PARAMETER savsumm  Comparative Farm Summary

<table>
<thead>
<tr>
<th></th>
<th>base</th>
<th>beefp</th>
<th>beefcorn</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>price</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>price</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
In this cross-scenario report all output is in one table and it is easy to compare the base case with the two alternative scenarios.

We could also add percentage change calculations by introducing a further parameter, `savsummp`:

```
Parameter savsummp(ordr,*,alli,scenarios) 'Comparative Farm Summary (percent chg)';

savsummp(ordr,measures,alli,scenarios)$savsumm(ordr,measures,alli,"base") =
   round{ [savsumm(ordr,measures,alli,scenarios) - savsumm(ordr,measures,alli,"base")]*100
   / savsumm(ordr,measures,alli,"base"),1 };

savsummp(ordr,measures,alli,scenarios)
   $[(savsumm(ordr,measures,alli,"base") = 0) and (savsumm(ordr,measures,alli,scenarios) <> 0)]
   = na;

option savsummp:1:3:1;
display savsummp;
```

Note that both assignment statements are conditional assignments. The first assignment computes percentage changes rounded to one decimal place and the second assignment sets the percentage change to NA if the value in the base case is zero. The output generated by the display statement follows:
3.18 Comparative Analyses with GAMS

<table>
<thead>
<tr>
<th>Scenario Results</th>
<th>Resource Value</th>
<th>Pastureland</th>
<th>1629.0</th>
<th>1461.9</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scenario Results</td>
<td>Resource Value</td>
<td>April Labor</td>
<td>154.4</td>
<td>89.8</td>
</tr>
<tr>
<td>Scenario Results</td>
<td>Resource Value</td>
<td>May Labor</td>
<td>198.1</td>
<td>128.5</td>
</tr>
<tr>
<td>Scenario Results</td>
<td>Resource Value</td>
<td>Sept Labor</td>
<td>NA</td>
<td>NA</td>
</tr>
<tr>
<td>Scenario Results</td>
<td>Resource Value</td>
<td>Oct Labor</td>
<td>301.8</td>
<td>658.4</td>
</tr>
<tr>
<td>Scenario Results</td>
<td>Product Value</td>
<td>Corn</td>
<td>6.4</td>
<td>22.7</td>
</tr>
<tr>
<td>Scenario Results</td>
<td>Product Value</td>
<td>Beef</td>
<td>40.0</td>
<td>40.0</td>
</tr>
<tr>
<td>Scenario Results</td>
<td>Product Value</td>
<td>Cattlefeed</td>
<td>3.9</td>
<td>13.8</td>
</tr>
</tbody>
</table>

### 3.18.1.2 Resetting Data to Base Levels

In the example above the price for beef was changed to $0.70 for the first alternative scenario and it stayed at $0.70 in the second alternative scenario, since we did not reset it manually to the base level. However, in most cases users find it preferable to reset all data to base levels before a new scenario is run. This may be done by saving the base level data in a new parameter, say `saveprice`, and then resetting the data to base levels before each scenario. In the following final version of the third GAMS file, `mancompc.gms`, the levels of the commodity prices are reset before each new run:

```gams
$include farmcomp.gms
$include farmrep.gms

Parameter savepricealli saved prices;  
savepricealli = pricealli;

Set scenarios / base, beef, beefcorn /;
Parameter savsumm(ordr,*,alli,scenarios) 'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,alli,"base") = summary(alli,measures);

pricealli = savepricealli;
price("beef") = 0.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms
savsumm("Scenario setup","price",primary,"beef") = price(primary);
savsumm("Scenario Results",measures,alli,"beef") = summary(alli,measures);

pricealli = savepricealli;
price("corn") = 2.70;
display price;
solve farm using LP maximizing netincome;
$include farmrep.gms
savsumm("Scenario setup","price",primary,"beefcorn") = price(primary);
savsumm("Scenario Results",measures,alli,"beefcorn") = summary(alli,measures);

option savsumm:2:3:1;
display savsumm;
```

In this section we demonstrated how to do a comparative analysis manually, including a cross-scenario report and resetting the data before each new scenario is run. However, there is still a lot of repetition in how the solves and reports are handled. This issue will be addressed in the next section.
3.18.2 An Automated Approach - Avoiding Repeated Work

The basic structure of a comparative analysis that avoids repetitive instructions for solves and report writing is outlined in the Figure below. Note that the first three boxes represent preparatory steps that are the usual parts of a GAMS program: the initial data is set up, the model is defined and solved. The comparative model analysis begins with the box labeled "Step 1". In Step 1 names for the scenarios are introduced and the scenario data is defined. In Step 2 the base data that will be changed during the scenario runs are saved in a new parameter. We will use this parameter later to restore the data to their base levels before each new scenario run. Starting with Step 3 we enter a loop, where the looping set is the set of scenarios introduced in Step 1. As usual, the statements in the loop are executed for each scenario to be analyzed. The first statement restores the data to their base levels (Step 3). Thus we will always start with the same data. In Step 4 the data and the model is updated for the current scenario and in Step 5 the model solved. In Step 6 a report for the individual scenarios is generated. In Step 7 parameters for cross-scenario comparative reports are saved. In Step 8 we check if more scenarios are to be solved and if this is the case, we return to repeat Steps 3-8 until all scenarios are completed. Finally, we display a comparative report that presents the information saved across scenarios.
This flow chart is implemented in the file `compare.gms` that is given below. Note that it is based on the farm profit-maximizing example discussed in section Manual Approach above. All sets and parameters were introduced in the sections above, only the table `scenprice` in the implementation of Step 1 is new.

*Step 1 - Setup scenarios
Set ordr / "Scenario Setup", "Scenario Results" /;
Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*),alli,scenarios) 'Comparative Farm Summary';
Table scenprice(primary,scenarios) 'price changes by scenario'
<table>
<thead>
<tr>
<th></th>
<th>base</th>
<th>beefp</th>
<th>beefcorn</th>
</tr>
</thead>
<tbody>
<tr>
<td>corn</td>
<td>2.70</td>
<td></td>
<td></td>
</tr>
<tr>
<td>soybeans</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>beef</td>
<td>0.70</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Step 2 - Save data
Parameter savprice(primary) 'save primary commodity prices';
savprice(primary) = price(primary);

*Step 3 - Reset data to base level
loop(scenarios,
  price(primary) = savprice(primary);
)

*Step 4 - Change data to levels needed in scenario
  price(primary)$scenprice(primary,scenarios) = scenprice(primary,scenarios);
display price;

*Step 5 - Solve model
  solve farm using LP maximizing netincome;

*Step 6 - Single scenario report writing
  $include farmrep.gms

*Step 7 - Cross-scenario report writing
  savsumm("Scenario Setup","price",primary,scenarios) = price(primary);
  savsumm("Scenario Results",measures,alli,scenarios) = summary(alli,measures);

*Step 8 - End of loop
);

*Step 9 - Compute and display final results
  option savsumm:2:3:1;
display savsumm;

Note that the main feature that facilitates this automatic approach is a loop statement. Loop statements are introduced and discussed in section The Loop Statement. Note further, that in Step 4 we used a conditional assignment to restrict the change of data to those primary commodities that have nonzero entries for the respective scenario in parameter `scenprice`. For details on conditional assignments, see section Conditional Assignments.

### 3.18.2.1 Adding A Scenario

Given the implementation of an automated comparative analysis above, it is easy to add a new scenario. Only two small modifications are needed: a name for the new scenario has to be added to the set `scenarios` and the respective data has to be added to the table `scenprice`. Both changes are in Step 1. The lines of the respective code are given below:
Set scenarios / base, beefp, beefcorn, new /;
Table scenprice(primary,scenarios) 'price alterations by scenario'
   base    beefp   beefcorn   new
corn  2.70
soybeans  4.32
beef  0.70
;

Note that we added a third alternative scenario called new, where the price of soybeans is changed to $4.32. Note further, that the remainder of the code is not changed. Once the new scenario is added to the set scenarios and the respective data is specified in the table, it will enter the loop and thus all the statements in the loop will be executed for the new scenario.

Observe that the new scenario above was similar to the other scenarios: the price for a primary commodity was modified. However, in some cases new scenarios require that other data, like resources, are changed. For example, assume that in a new scenario the landtype "cropland" is increased by 30%. Note that the available resources were defined in the parameter available(alli), where available("cropland") equals 700. To accommodate this new scenario we will add the following lines of code to Steps 1 to 4:

*Step 1 - Setup scenarios
Set scenarios / base, beefp, beefcorn, new /;
Table scenavailable(alli,scenarios) 'resource alterations by scenario'
   base    beefp   beefcorn   new
cropland  1.3;

*Step 2 - Save data
Parameter saveavailable (alli) 'save available resources';
saveavailable (alli) = available (alli);

*Step 3 - Reset data to base level
loop(scenarios,
   available (alli) = saveavailable (alli);

*Step 4 - Change data to levels needed in scenario
   available(alli)$scenavailable(alli,scenarios) =
      available(alli)*scenavailable(alli,scenarios);
display price, available;

Note that in Step 1 we added a new table, scenavailable, to specify the resource alterations by scenario. Observe that the values of scenavailable will be used as multipliers in Step 4. In Step 2 we introduced the parameter saveavailable, that will play a similar role for the available resources like the parameter savprice does for the prices of the primary commodities: the base levels are saved in this parameter and we will use it to restore the values of available to their base levels before each new scenario run. This is implemented with the new assignment in Step 3. In Step 4 the data levels of the parameter available are modified as required for the current scenario using a conditional assignment. Note the similarities to the assignment for updating the values of price in Step 4 above. Steps 5 to 9 remain unchanged. Thus we achieved an automated comparative analysis with an additional scenario where another parameter is modified by adding just a few lines of code. The full code is given in the GAMS file compareother.gms.

3.18.2.2 Changing the Structure of a Model

Many studies require modifications of the structure of a model. In GAMS, context-sensitive model structures may be implemented with dollar conditions. Dollar conditions may be used to control equations as well as specific terms.

To illustrate, we will extend the profit-maximizing farm model from the previous sections to include a conditional constraint that limits the number of cattle. This constraint will be only active if a scalar that varies with the scenarios is nonzero. Consider the lines of code that follow. Note that the set animals is a subset of the set alli, the elements of the set livemanage denote various ways of managing crops and animals, and liveprod is a positive variable for livestock production.
3.18 Comparative Analyses with GAMS

$include farmcomp.gms
$include farmrep.gms

Scalar cowlim 'activates cowlimit constraint' /1/;
Equation cowlimit 'conditional equation on cow limits;
cowlimit$cowlim.. sum((animals,livemanage), liveprod(animals,livemanage)) =l= 100;
Model farmcowlim /all/;

Set ordr / "Scenario setup", "Scenario Results" /;
Set scenarios / base, cowlim /;
Parameter savprice(primary) 'save primary commodity prices';
savprice(primary) = price(primary);
Parameter cowlims(scenarios) 'cowlimit by scenario'
   / base 0, cowlim 1/;

loop(scenarios,
   cowlim = cowlims(scenarios);
   solve farmcowlim using LP maximizing netincome;
);

Note that in the loop the value of the scalar cowlim is updated before each scenario is run. Note further, that this value determines whether the new equation cowlimit will be active or not. The complete code is given in the GAMS file comparemod.gms.

3.18.2.3 Monitoring Comparative Analyses

Suppose we are running a comparative analysis that takes a long time since many solves need to be executed, and we wish to monitor the progress of the run. The following lines of GAMS code will send the relevant information to the screen. First, we will specify where the information is to sent depending on the operating system:

$set console con
$if %system.filesys% == UNIX $set console /dev/tty
file screen / '%console%' /;
file log /''/;

Then, we will use the following loop to send information about the current scenario to the screen and the log file:

loop(scenarios,
   put screen;
   put 'I am on scenario ' Scenarios.tl;
   putclose;
   put log;
   put 'I am on scenario ' Scenarios.tl;
   putclose;
);

3.18.3 Ranging analysis

Some users are interested in getting ranging output in the form of LP cost and right hand side ranging results. Unfortunately, the base version of GAMS does not yield such information. The user wishing such information has two alternatives. First, one may cause the model to be repeatedly solved under a set of values for the key parameter using the procedures discussed above, but this is cumbersome if a lot of parameters are involved. Second, one can use solver dependent features of GAMS that can be retrieved into a GAMS parameter. Please refer to the solver manuals (e.g. for GAMS/CPLEX: Sensitivity Analysis) for further information how to use them.
3.19 Good NLP Formulations

In this tutorial we offer some advice and guidance on how to set up or formulate an NLP model so that a solver will be able compute a good solution and do so quickly, reliably, and predictably. Much of this applies to other model classes allowing nonlinear functions, but for ease and simplicity of exposition we focus on the NLP case here.

A good formulation for an NLP model typically involves several things, including specifying sensible initial values, setting variable bounds, and scaling variables and equations. Other factors to consider are techniques for blocking degenerate cycling and the potential benefits of avoiding expressions in nonlinear functions. Finally we look at reformulations and approximations for discontinuous functions like abs, max and min in section Reformulating DNLP Models.

3.19.1 Specifying Initial Values

The variable levels and equation marginals in GAMS are typically passed to a solver to be used as the initial point. The initial values specified are especially important for NLP models for several reasons:

- Non-convex models may have multiple local solutions. Local NLP solvers search for a local solution and return it when it is found. An initial point in the neighborhood of a desired solution is more likely to return that solution.
- Initial values that (almost) satisfy many of the constraints reduce the work involved in finding a first feasible solution.
- Initial values that are close to a local optimum reduce the work required to find that local optimum, therefore reducing solution time.
- The progress of the optimization algorithm is based on good directional information, i.e. on good derivatives. The derivatives in a nonlinear model depend on the current point, so an improved initial point can improve solver performance.

Variable levels and equation marginals are specified by setting the variable attribute .L and the equation attribute .m before solution. This is often done with assignments that occur before the solve statement, e.g.:

```plaintext
domPrice.L(i,region,t) = domPrice0(i,region,t);
flowLim.m(arcs) = 1;
```

Note

The default value for the variable levels and equation marginals is 0.

The variable bounds also play a role in determining the initial point passed to the NLP solver. When a solve occurs, the levels for all variables in the model are first projected onto the set defined by the variable bounds. Thus, setting a variable's lower bound to a positive value ensures that the initial value of this variable will never be zero. This is very useful, since in many cases zero is an unsuitable initial value for nonlinear variables. For example, based on the product term \( x \cdot y \), an initial value of zero for \( x \) will lead to an initial derivative value of zero wrt \( y \), so it will appear as if the function does not depend on \( y \). Variables at zero can also cause numerical difficulties with logarithms, real powers, or divisions. These difficulties occur not just at zero but also for very small values (i.e. values very close to zero) as well.

We recommend to specify as many sensible initial values for the nonlinear variables as possible. It may be desirable to initialize all variables to 1 or to the scale factor if the GAMS scaling option is used. A better alternative is to first select reasonable values for some variables that are known from context or experience to be important and then to use some of the equations of the model to compute the values for other variables. For example, consider the following equation, where \( pm \), \( pwm \) and \( er \) are variables and \( tm \) is a parameter:
The following assignment statements use the equation to derive consistent initial values for the variable pm from sensible initial values for the variables pwm and er:

\[ \text{pwm}.L(i) = 1; \]
\[ \text{er}.L = 1; \]
\[ \text{pm}.L(i) = \text{pwm}.L(i) \times \text{er}.L \times (1 + \text{tm}(i)); \]

It would be a mistake to assign only to pwm and er and assume that the solver will choose to adjust the variable pm to make the equation feasible: it could choose to adjust pwm or er instead. With all the assignments above made, we can be assured that the equation pmDef will be satisfied at the initial point.

Setting the initial point by loading a prior solution that has been saved via the savepoint mechanism is also an effective strategy that is very easy to implement.

### 3.19.2 Setting Variable Bounds

Lower and upper bounds on variables are set by assigning values to the variable attributes .lo and .up in the following way:

\[ \text{price}.lo(i, \text{region}, t) = 1e-4; \]
\[ \text{flow}.up(\text{arcs}) = \text{arcCap}(\text{arcs}); \]

Lower and upper bounds on variables in nonlinear models serve multiple purposes. Some bounds represent constraints based on the reality that is being modeled. For example, a certain production level must be non-negative or an arc in a network has a flow capacity of at most ten. These bounds are called model bounds. Other bounds help the algorithm by preventing it from moving far away from any optimal solution and/or into regions with singularities in the nonlinear functions or unreasonably large function or derivative values. These bounds are called algorithmic bounds. Solver performance can be improved and execution errors (see domLim and domUsd) avoided when algorithmic bounds on variables are introduced.

Model bounds are determined by the reality being modeled and do not cause any problems. However, algorithmic bounds must be carefully chosen by the modeler. We recommend to pay particular attention if a variable is the argument in \( \log(x) \), \( \log10(x) \) or \( \exp(x) \) and if a variable occurs in the denominator of a division. If \( \log(x) \) or \( \log10(x) \) appears in a model, where \( x \) is a variable, we recommend a lower bound of \( 1.e-3 \) for \( x \) since \( \log(x) \) gets very small as \( x \) approaches zero and is undefined for negative values of \( x \). In addition, the first derivative gets very large as \( x \) approaches zero. If \( \exp(x) \) features in a model, where \( x \) is a variable, we recommend an upper bound between 20 and 25 for \( x \). If a variable \( x \) appears in the denominator, we recommend a lower bound of \( 1.e-2 \) for \( x \), since \( 1/x \) is extremely nonlinear for small arguments. Small values for variables used with negative exponents are also not desirable. Solver performance can be improved and execution errors avoided when one introduces algorithmic bounds on variables.

Note that lower and upper bounds facilitate finding a feasible solution as most solvers will honor bounds at all times, but inequalities are not necessarily satisfied at intermediate points. A further advantage of variable bounds compared to inequalities is improved presolve performance: NLP solver preprocessors will typically incur little or no computational overhead due to variable bounds.
3.19.3 Avoiding Expressions in Nonlinear Functions

It is often useful to avoid nonlinear functions of expressions (e.g. a division by the sum of many variables). Instead, an intermediate variable can be used for the expression. This applies in particular if the expressions depend on many variables. Consider the following example:

```plaintext
variable x(i), y;
equation ydef;
ydef.. y =e= 1 / sum(i, x(i));
```

This example could be reformulated via the intermediate variable `xsum` and its defining equation `xsumdef` in the following way:

```plaintext
variable x(i), y, xsum;
equation xsumdef, ydef;
xsumdef.. xsum =e= sum(i, x(i));
ydef .. y =e= 1/xsum;
xsum.lo = 1.e-2;
```

In the equation `ydef`, the intermediate variable `xsum` appears in the denominator instead of the original summation. This allows us to impose a lower bound on the variable `xsum` to avoid dividing by zero. Of course, the model will contain more rows and columns if intermediate variables are introduced, but this increase in size is offset by a decrease in complexity and, in many cases, by an increase in sparsity as well.

3.19.4 Scaling Variables and Equations

Recall that nonlinear programming algorithms use the derivatives of the objective function and the constraints to find good search directions and they use function values to determine if constraints are satisfied or not. The relative size of the derivatives and the function values is influenced by the units of measurement that are used for the variables and constraints, and will have an effect on the performance of the solver and the result computed. Therefore, a proper, consistent scaling of the model is important to the success of the solution algorithm and the quality of the answer returned.

For example, assume that two goods are equally costly: both cost $1 per kg. However, the first is specified in grams and the second in metric tons, so that their coefficients in the cost function will be vastly different: $1000 per gram and $0.001 per ton respectively. If cost is measured in $1000 units, then the coefficients will be 1 and 1.e-6 respectively. This discrepancy in size may cause the algorithm to ignore the variable with the smaller coefficient, since the coefficient is comparable to some of the zero tolerances. To avoid such problems, the units of measurements need to be carefully chosen, that is, variables and constraints need to be properly scaled.

We recommend scaling with the following goals in mind:

- Solution level values of variables should fall into a range around 1, e.g. from 0.01 to 100.
- The magnitude of the nonzero constraint marginals at solution should fall into a range around 1, e.g. from 0.01 to 100.
- The magnitude of the derivatives of the nonlinear terms (i.e. the Jacobian elements) should fall into a range around 1, e.g. from 0.01 to 100, both at the initial point and at the solution.
- The constants in the equations should have absolute values around 1, e.g. from 0.01 to 100.
Well-scaled variables are measured in appropriate units. In most cases users should select the unit of measurement for the variables such that their expected value is around unity. Of course, there will always be some variation. For example, if \( x(i) \) is the production at location \( i \), one could select the same unit of measurement for all components of \( x \), say, a value around the average capacity.

In well-scaled equations the individual terms are measured in appropriate units. After choosing units for the variables users should choose the unit of measurement for the equations such that the expected values of the individual terms are around 1. For example, if these rules are followed, material balance equations will usually have coefficients of 1 and -1.

Usually well-scaled variables and equations result in well-scaled derivatives. To check whether the derivatives are well-scaled, we recommend running the model with a positive value for the option limrow and inspecting the coefficients in the equation listing of the GAMS list file.

For more about scaling in GAMS, see section Model Scaling - The Scale Option. Note that while many solvers have internal scaling procedures, a better result can generally be achieved by a judicious choice of units by the model developer.

### 3.19.5 Blocking Degenerate Cycling

Most commercial linear programming solvers use a perturbation technique to avoid degenerate cycling during the solution process: they temporarily add small numbers to the right-hand sides of equations. In general, NLP solvers do not have such an internal feature. Sometimes the success and performance of an NLP solver can be enhanced by a manual perturbation formulation.

In particular, if users observe that the NLP solution process has a large number of iterations where the solver does not make significant progress in altering the objective function value, we recommend to modify the equations in the model by replacing the value of zero on the right-hand side with a small number. This may accelerate the solution process. Assume that we have the following equation:

\[
f(x) \leq 0
\]

This could be reformulated as:

\[
f(x) \leq \delta \times 0.001
\]

Here we set \( \delta \) to 1 if we wish to keep the addition and to zero otherwise. The value of 0.001 is just an example and needs to be adjusted based on the model context. The number should be chosen such that it does not introduce significant distortions into the problem solution. Such an addition quite frequently reduces solution time by helping the solver avoid degenerate cycling. If it is done correctly, the resulting model solution is not qualitatively different from the original model solution. Users may also first solve the model with \( \delta = 1 \) and subsequently with \( \delta = 0 \) to get rid of the effects of the small numbers.

We recommend that user avoid using the same number but instead use some systematically varying number or a random number. The technique of adding a small number on the right-hand side may also be used in problems where many equations have the same nonzero value on the right-hand side.
3.19.6 Reformulating DNLP Models

Nonlinear models in GAMS belong to one of the following two classes: smooth and discontinuous. Typically, all functions with endogenous arguments contained in the model are smooth functions (i.e. functions with continuous derivatives) like \( \sin, \exp \) and \( \log \). These models can be solved using NLP. If any of the endogenous functions in the model are not smooth (i.e. are discontinuous), the model cannot be solved as an NLP: the DNLP model type must be used instead. Examples of non-smooth functions include \( \text{ceil} \) and \( \text{sign} \), where the function itself is not continuous, and \( \max, \min \), and \( \text{abs} \), where the derivatives are not continuous. Typically, NLP solvers are designed to work with continuous derivatives, and much of the convergence theory behind them assumes this continuity. Discontinuous functions or derivatives may cause numerical problems, poor performance, spurious (i.e. wrong) solutions, and other issues, so they should be used with special care and only if necessary.

N.B.: to avoid a proliferation of model types, nonlinear programming is the only model type split into smooth (NLP) and nonsmooth (DNLP) variants. All other model types allowing nonlinear functions (e.g. MINLP, MCP, CNS) include both smooth and nonsmooth functions. This is not because nonsmooth functions are less problematic in these contexts. It simply became too unwieldy to maintain this distinction across all types of nonlinear models.

A powerful and effective way to model discontinuous functions is with binary variables, which results in a model of type MINLP. The model [ABSMIP] demonstrates this formulation technique for the functions \( \text{abs}, \min, \max \) and \( \text{sign} \). Alternatively, reformulations or approximations may be used to model discontinuous functions such that the resulting model is of type NLP. Here we offer some guidance on how to reformulate or approximate the discontinuous functions \( \text{abs}, \max \) and \( \min \) using only smooth functions and continuous variables and thus transform a DNLP model into an NLP. This transformation is generally more reliable than solving the original as a DNLP.

Note that some of the reformulations suggested below enlarge the feasible space. They rely on the objective function to choose a solution that is contained in the original feasible space, i.e. where the relationship defined by the nonsmooth function holds. If the objective cannot be relied on to do this, it is also possible to use one of the smooth approximations for the nonsmooth functions defined below.

3.19.6.1 Reformulating and Approximating the Function ABS

The function \( \text{abs}(x) \) returns the absolute value of the argument \( x \). If we are minimizing an absolute value, then we can split this value into its positive and negative parts (both represented by positive variables) and minimize the sum of these variables. This formulation enlarges the feasible region but the optimal solution will be the one where the sum of the positive and negative parts is equal to the absolute value.

```plaintext
variables x, y, z;
equations
   obj  '1-norm'
      f ;
   obj.. abs(x) + abs(y) =E= z;
   f .. sqr(x-3) + sqr(y+5) =L= 1;
model nonsmooth / obj, f /;
solve nonsmooth using dnlp min z;
positive variables xPlus, xMinus, yPlus, yMinus;
equations
   obj2 'smooth version of 1-norm'
      xDef
      yDef
      ;
   obj2.. xPlus + xMinus + yPlus + yMinus =E= z;
```

```plaintext
```
3.19 Good NLP Formulations

$$x_{\text{Def}}.. \ x = x_{\text{Plus}} - x_{\text{Minus}};$$
$$y_{\text{Def}}.. \ y = y_{\text{Plus}} - y_{\text{Minus}};$$

model smooth / obj2, xDef, yDef, f /;
solve smooth using nlp min z;

Note that the discontinuity in the derivative of the function $\text{abs}$ has been converted into lower bounds on the new variables $x_{\text{Plus}}, x_{\text{Minus}},$ etc: these bounds are handled routinely by any NLP solver. Note too that the feasible space is larger than before. For example, many pairs $x_{\text{Plus}}$ and $x_{\text{Minus}}$ satisfy our equation $x = x_{\text{Plus}} - x_{\text{Minus}}.$ However, our objective ensures that one of $x_{\text{Plus}}$ and $x_{\text{Minus}}$ will be zero at the solution so that the sum of $x_{\text{Plus}}$ and $x_{\text{Minus}}$ will be the absolute value of $x.$

In case the objective function does not contain a term that tries to minimize the absolute value, a smooth approximation can be used instead of the reformulation described above. This approximation should be close to the absolute value and also have smooth derivatives. Such an approximation for $\text{abs}(f(x))$ is:

$$\sqrt{(sqr(f(x)) + sqr(\delta))}$$

Here $\delta$ is a small scalar. The value of $\delta$ controls the accuracy of the approximation and the curvature around $f(x)=0.$ The approximation error is largest when $f(x)=0$ and decreases as $f(x)$ gets farther from zero. A value for $\delta$ ranging between $1.e-3$ and $1.e-4$ should be appropriate in most cases. Users could also use a larger value in an initial optimization, reduce it and solve the model again. If $\delta$ is reduced below $1.e-4,$ then large second order terms might lead to slow convergence or even prevent convergence. An example of this approximation used for the previous example is below:

$\$macro MYABS(t,d) [sqrt(sqr(t)+sqr(d))]$

$\$equation obj3;$
$\$obj3.. \ MYABS(x,1e-4) + MYABS(y,1e-4) =E= z;$

model approx / obj3, f /;
solve approx using nlp min z;

Note the use of the macro facility to encapsulate the smooth reformulation. As mentioned above, this approximation has its largest error where $f(x)=0.$ If it is important to get accurate values at this point, then we recommend the following alternative approximation:

$$\sqrt{(sqr(f(x)) + sqr(\delta))} - \delta$$

Note that the only difference is the subtraction of the constant term $\delta.$ In this case, the error will equal zero at $f(x)=0$ and it will increase to $-\delta$ as $f(x)$ moves away from zero.

3.19.6.2 Reformulating and Approximating the Function MAX

The function $\text{max}(x_1,x_2,x_3,\ldots)$ returns the maximum value of the arguments, where the number of the arguments may vary. Typically, the equation

$$t >= \text{max}(f(x),g(y))$$

is replaced by two inequalities:
t >= f(x)
t >= g(y)

Here x, y and t are variables and f(x) and g(y) are some functions depending x and y respectively. Provided the objective function has some term that tries to minimize t, one of the constraints will become binding at solution and t will equal the maximum of the two terms. The extension to more than two arguments in the function \textit{max} should be obvious. A simple example follows:

variables
  x / LO 0, L 0.2, UP [pi/2] /
  mx 'max[sin(x),cos(x)]'
  z 'objective var'
;
equation oDef;
oDef.. x / 100 + max[sin(x),cos(x)] =E= z;
model nonsmooth / oDef /;
solve nonsmooth using dnlp min z;
equations oDef2, sinBnd, cosBnd;
oDef2.. x / 100 + mx =E= z;
sinBnd.. mx =G= sin(x);
cosBnd.. mx =G= cos(x);
model smooth / oDef2, sinBnd, cosBnd /;
solve smooth using nlp min z;

In case the objective function does not force the max-term to be minimized, a smooth approximation for \textit{max}(f(x),g(y)) can be used, as in the following example code:

\[\frac{[f(x) + g(y) + \sqrt{\text{sqr}(f(x)-g(y)) + \text{sqr}(\text{delta})]}}{2}\]

$macro MYMAX(t1,t2,d) [0.5 * [t1 + t2 + \sqrt{\text{sqr}(t1-t2) + \text{sqr}(d)}] ]$
equation oDef3;
oDef3.. x / 100 + MYMAX(sin(x),cos(x),1e-4) =E= z;
model approx / oDef3 /;
solve approx using nlp min z;

Here \textit{delta} is a small scalar, preferably ranging from 1.e-2 to 1.e-4. The approximation error takes its maximum of \textit{delta}/2 when f(x)=g(y) and decreases as one moves away from this point. To shift the error away from the point of discontinuity, the following approximation can be used:

\[\frac{[f(x) + g(y) + \sqrt{\text{sqr}(f(x)-g(y)) + \text{sqr}(\text{delta})} - \text{delta}] }{2}\]

3.19.6.3 Reformulating and Approximating the Function MIN

The reformulation of and approximation to the \textit{min} function is similar to the \textit{max} case above and will not be repeated in full here. Briefly,

\[t =e= \text{min}(f(x),g(y))\]
is replaced by:
\[t =l= f(x)\]
\[t =l= g(y)\]
and is effective as long as the objective maximizes t. If not, this smooth approximation for \textit{min}(f(x),g(y)) can be used:

\[\frac{[f(x) + g(y) - \sqrt{\text{sqr}(f(x)-g(y)) + \text{sqr}(\text{delta})}]}{2}\]

3.20.1 Data Exchange with Text Files

This tutorial describes some ways on how to exchange data between GAMS and text files (usually in ASCII format).

3.20.1.1 Reading Text Files During Compilation

GAMS can read arbitrary text files during compile time by inserting them into the compiler input stream. The file content is then assumed to be GAMS code. Thus, including a text file within a data statement (see also Data Entry: Parameters, Scalars and Tables) allows for an easy way to include data from a text file, as long as the syntax in the text file can be understood by the GAMS compiler. This way, model specification and data input can be separated into different files.

The $include compile-time command is used to instruct the GAMS compiler to include the context of a different file at the current position of the input stream. As a result, the GAMS code behaves as if the $include statement has been replaced by the content of the file to be included. This can be very handy when including data from a separate text file. For instance, when data for a table is actually coming from another environment, one could replace the TABLE statement by an include statement. A GAMS table is in fact very well suited for a human being to be read or written, but it is rather awkward for programs to generate (e.g., the numbers have to be approximately below the corresponding headers). Therefore, often parameters are used and long series of assignment statements are generated. For instance, consider the following fragment from model [TRNSPORT]:

```
Table d(i,j) 'distance in thousands of miles'
    new-york  chicago  topeka
seattle   2.5     1.7     1.8
san-diego 2.5     1.8     1.4
```

When the data for this table is coming from a program it is more convenient to say in the main program:

```
Parameter d(i,j) 'distance in thousands of miles';
$include data.inc
display d;
```

and to have the include file `data.inc` contain the machine generated statements:
In fact, GAMS can deal quite comfortably with a large number of such assignment statements.

Note, that since the included file is considered as part of the GAMS input stream, it is also echoed in the listing file. When including large text files with data statements, echoing these files in the listing file can be undesired. To suppress echoing to the listing file, the $include statement can be surrounded by $offlisting and $onlisting instructions:

```gams
parameter d(i,j) 'distance in thousands of miles';
$offlisting
$include data.inc
$onlisting
display d;
```

In the listing file, line numbers are skipped where the $offlisting is in effect.

In some cases it may be more convenient to use the initialization syntax of parameters. That is, the main GAMS file could contain the fragment:

```gams
parameter d(i,j) 'distance in thousands of miles' / $include data2.inc /;
display d;
```

and the data file contains the following records:

```
seattle .new-york 2.5
san-diego.new-york 2.5
seattle .chicago 1.7
san-diego.chicago 1.8
seattle .topeka 1.8
san-diego.topeka 1.4
```

This approach is preferable for large data sets as it is more efficient for GAMS.

Note

* Tables and parameters are handled exactly the same way by GAMS internally. The only difference is in the specification of data.*

When using a table statement, data can also be specified in CSV (Comma-separated values) format if the $ondelim command has been issued. This format can, for instance, be generated by spreadsheet programs.

As example, consider again the following fragment from model [TRNSPORT]:

```
```
3.20 Data Exchange with Other Applications

Table d(i,j) 'distance in thousands of miles'

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

A file data.csv that specifies the data of this table in CSV format would have the content

```
,new-york,chicago,topeka
seattle,2.5,1.7,1.8
san-diego,2.5,1.8,1.4
```

Notice the empty first element in the first line, which corresponds to the top-left blank in the above table.

This file can now be included directly into GAMS by using the $ondelim and $offdelim commands:

```
Table d(i,j) 'distance in thousands of miles' ;
$ondelim
$include data.csv
$offdelim
```

Attention

The $ondelim command only enables the use of commas as a separation symbol. The use of a different separation character is not supported by GAMS. This can become an issue if, for example, a CSV file has been generated with a language setting where commas are used as decimal point and semicolons are used for separating entries in the CSV file. In such a situation, data.csv would have the content

```
,new-york;chicago;topeka
seattle;2,5;1,7;1,8
san-diego;2,5;1,8;1,4
```

Therefore, such text files need to be preprocessed before read into GAMS. The following code uses the POSIX tool tr to (simultaneously) replace commas by dots and semicolons by commas:

```
$call "tr ,; ., < data.csv > data2.csv"
```

```
Table d(i,j) 'distance in thousands of miles' ;
$ondelim
$include data2.csv
$offdelim
```

CSV files can also be used to input higher dimensional data into GAMS. For instance, consider the 3 dimensional table yieldtl from model [TURKEY]:

Table yieldtl(l,cl,ty) 'livestock yield time series (kg per head)'

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>sheep.meat</td>
<td>10.60</td>
<td>11.42</td>
<td>10.60</td>
<td>9.38</td>
<td>8.97</td>
<td>6.93</td>
</tr>
<tr>
<td>sheep.milk</td>
<td>23.7</td>
<td>24.1</td>
<td>24.2</td>
<td>24.2</td>
<td>24.0</td>
<td>23.9</td>
</tr>
<tr>
<td>sheep.wool</td>
<td>1.3</td>
<td>1.3</td>
<td>1.3</td>
<td>1.3</td>
<td>1.3</td>
<td>1.3</td>
</tr>
<tr>
<td>sheep.hide</td>
<td>0.5</td>
<td>0.6</td>
<td>0.6</td>
<td>0.5</td>
<td>0.6</td>
<td>0.4</td>
</tr>
<tr>
<td>goat.meat</td>
<td>6.39</td>
<td>7.31</td>
<td>8.68</td>
<td>7.31</td>
<td>6.39</td>
<td>6.85</td>
</tr>
<tr>
<td>goat.milk</td>
<td>37.7</td>
<td>38.1</td>
<td>38.2</td>
<td>38.2</td>
<td>38.3</td>
<td>37.8</td>
</tr>
<tr>
<td>goat.wool</td>
<td>0.6</td>
<td>0.6</td>
<td>0.6</td>
<td>0.6</td>
<td>0.6</td>
<td>0.6</td>
</tr>
</tbody>
</table>
When the data for this parameter is prepared by another application (such as a relational database), it may be more convenient to write it out in a comma-separated value form, e.g., a file `data.csv` could have the content

```
"sheep","meat","1974",10.60
"sheep","meat","1975",11.42
"sheep","meat","1976",10.60
"sheep","meat","1977",9.38
"sheep","meat","1978",8.97
"sheep","meat","1979",6.93
"sheep","milk","1974",23.70
"sheep","milk","1975",24.10
"sheep","milk","1976",24.20
"sheep","milk","1977",24.20
```

Including such formatted data into a GAMS model is possible by using `$ondelim` for Parameter Data for Higher Dimensions. Thus, the GAMS code would be

```
Parameter yieldtl(l,cl,ty) 'livestock yield time series (kg per head)'
/
$ondelim
$include data.csv
$offdelim
/;
```

### 3.20.1.2 Writing Text During Compilation

The commands `$echo`, `$onecho`, and `$offecho` send text to named files during compilation. `$echo` sends one line and is invoked using the syntax:

```
$echo 'text to be sent' > externalfile
```

or

```
$echo 'text to be sent' >> externalfile
```
The use of ">" generates a new file, while ">>" appends to an existing file.

For multi-line messages, the commands $onecho and $offecho can be used, e.g.,

```
$onecho > externalfile
line 1 of text to be sent
line 2 of text to be sent
...
last line of text to be sent
$offecho
```

A typical example for the usage of these commands is the generation of a solver options file.

Additionally, the $log command can be used to send messages to the log file during compilation.

### 3.20.1.3 Writing Text Files During Execution

The put writing facility allows customized text output. This is a fairly complex but powerful and flexible report writing facility.

Assume that the following GAMS code is added to the end of model [TRNSPORT]. It instructs GAMS to write the model and the solve status together with levels of the decision variables to a file results.txt:

```
File results / results.txt /;
prompt results;
prompt "Model status", transport.modelstat /;
prompt "Solver status", transport.solvestat /;
prompt "Objective", z.l /;
prompt "Shipments" /;
loop((i,j),
   prompt i.tl, j.tl, x.l(i,j) /;
)
promptclose;
```

First, a file object results is declared by using the File statement. The data of the file statement specifies the name of the file (results.txt). Next, line prompt results; instructs GAMS that for the following put statements, the file results should be used. In the following, the model status and the solve status are written, together with some descriptive text. These model attributes are set by a solve statement. The character '/' instructs GAMS to add a linebreak (newline character) to the results file. The next thing to write out are some variable values. Here, first the level value of variable z is written, followed by a loop that writes for each element of sets i and j the name of the elements (accessed via the .tl attribute) and the level value of x(i,j). Finally, the promptclose; statement instructs GAMS to close the current file. This will ensure that possibly cached data is flushed to the file.

The output will look like:

```
Model status   1.00
Solver status  1.00
Objective      153.67
Shipments
seattle   new-york   50.00
seattle   chicago     300.00
seattle   topeka      0.00
san-diego new-york   275.00
san-diego chicago     0.00
san-diego topeka     275.00
```
This form can be hard to read by other applications, e.g., because some space characters are to be considered as separators, while others are really part of a string (e.g., "Model status"). However, by using the print control option .pc of the put writing facility, comma-separated value files can be written. That is, by adding the line results.pc = 5; i.e.,

File results / results.txt /;
results.pc = 5;
put results;
put "Model status", transport.modelstat /;
put "Solver status", transport.solvestat /;
put "Objective", z.l /;
put "Shipments" /;
loop((i,j),
    put i.tl, j.tl, x.l(i,j) /);
putclose;

one obtains the following output:

"Model status",1.00
"Solver status",1.00
"Objective",153.67
"Shipments"
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00

If several parameters of the same dimension should be written to a file in a customized format, the put statements can become rather repetitive. For example, the level and marginal values of variable x and the parameters c and d from model [TRNSPORT] should be written. This can be coded easily as:

file results / results.txt /;
results.pc = 5;
put results;
loop((i,j), put "distance", i.tl, j.tl, d(i,j) /);
loop((i,j), put "cost", i.tl, j.tl, c(i,j) /);
loop((i,j), put "levels", i.tl, j.tl, x.l(i,j) /);
loop((i,j), put "marginals", i.tl, j.tl, x.m(i,j) /);
putclose;

A separation of the code that writes the data (loop and put statements) from the data that is written (descriptive text, set names, etc.) can be achieved by using $batinclude. This command works similar to the $include statement (see also Section Reading Text Files During Compilation above), but allows for additional arguments (separated by blanks). While including the file, markers %1, %2, etc., are replaced by the value of the 1st, 2nd, etc., argument.

By using $batinclude, the above example could be simplified to

file results / results.txt /;
results.pc = 5;
put results;
$batinclude put.inc distance i j d
$batinclude put.inc cost i j c
$batinclude put.inc level i j x.l
$batinclude put.inc marginal i j x.m
putclose;
where the file put.inc contain the actual loop and put statements:

```
loop((%2,%3), put "%1", %2.tl, %3.tl, %4(%2,%3) / );
```

Finally, the The Put_Utility Statement is referred, which is loosely connected to the put statement and allows the dynamic generation of file names, etc.

### 3.20.2 Data Exchange with Microsoft Excel

This tutorial gives an overview on how to exchange data between GAMS and Microsoft Excel.

GAMS can communicate with Microsoft Excel via GDX (GAMS Data Exchange) files. In order to write data from GAMS and to Excel, selected GAMS data can be written into a GDX file and then to an Excel file: GAMS \( \rightarrow \) GDX \( \rightarrow \) Excel. Similarly selected Excel data can be written to a GDX file and then read into GAMS: Excel \( \rightarrow \) GDX \( \rightarrow \) GAMS.

Some of GAMS/Excel data exchange tools that provide functionality to exchange data between GAMS and Excel are also discussed in the section Data Exchange Tools. The data exchange between GAMS and a CSV (Comma-separated values) file format and GAMS is covered in Data Exchange with Text Files.

#### 3.20.2.1 From GAMS to Excel

Consider the following modification of the [TRNSPORT] model from the gams model library.

Sets

```
i 'canning plants' / seattle, san-diego /
j 'markets' / new-york, chicago, topeka / ;
```

Parameters

```
a(i) 'capacity of plant i in cases'
   / seattle 350
   san-diego 600 /

b(j) 'demand at market j in cases'
   / new-york 325
   chicago 300
   topeka 275 / ;
```

Table d(i,j) 'distance in thousands of miles'

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

Scalar f 'freight in dollars per case per thousand miles' /90/ ;

```
c(i,j) 'transport cost in thousands of dollars per case'
c(i,j) = f * d(i,j) / 1000 ;
```

Variables

```
x(i,j) 'shipment quantities in cases'
z 'total transportation costs in thousands of dollars' ;
```
Positive Variable x;

Equations
cost 'define objective function'
supply(i) 'observe supply limit at plant i'
demand(j) 'satisfy demand at market j';
cost .. z =e= sum((i,j), c(i,j)*x(i,j));
supply(i) .. sum(j, x(i,j)) =l= a(i);
demand(j) .. sum(i, x(i,j)) =g= b(j);

Model transport /all/;
Solve transport using lp minimizing z;
Display x.l, x.m;

*=== Export to Excel using GDX utilities

*=== First unload to GDX file (occurs during execution phase)
execute_unload "results.gdx" x.L x.M

*=== Now write to variable levels to Excel file from GDX
*=== Since we do not specify a sheet, data is placed in first sheet
execute 'gdxxrw.exe results.gdx o=results.xls var=x.L'

*=== Write marginals to a different sheet with a specific range
execute 'gdxxrw.exe results.gdx o=results.xls var=x.M rng=NewSheet!f1:i4'

After the solve statement, the data (x.L and x.M) from variable x can be written into a GDX file during the execution time using the command execute_unload:

execute_unload "results.gdx" x.L x.M

The execute_unload command above is executed during the actual execution phase to create a GDX file called results.gdx. The solution x and the marginals of x in the GDX file can be written to the Excel file results.xls using GDXXRW tool:

execute 'gdxxrw.exe results.gdx var=x.L'
execute 'gdxxrw.exe results.gdx var=x.M rng=NewSheet!f1:i4'

For the first call for x.L, there is no range specified and the data is written in cell A1 and beyond in the first available sheet. For the second call for marginals x.M, data will be written to cells F1:I4 in the sheet named NewSheet.

Note that GAMS can also write data into a GDX file during compile time. It is also possible to convert data stored in a GDX file into an Excel file spreadsheets using GD2XLS tool and to write GAMS data to standard output formatted as a GAMS program with data statements using GDXDUMP tool.
Consider the following modification of the [TRNSPORT] model from the gams model library and the file results.xls file created from the previous example.

Sets

i 'canning plants' / seattle, san-diego /
    j 'markets' / new-york, chicago, topeka / ;

Parameters

a(i) 'capacity of plant i in cases'
    / seattle 350
    san-diego 600 /

b(j) 'demand at market j in cases'
    / new-york 325
    chicago 300
    topeka 275 / ;

Table d(i,j) 'distance in thousands of miles'

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

Scalar f 'freight in dollars per case per thousand miles' /90/ ;

Parameter c(i,j) 'transport cost in thousands of dollars per case' ;

\[
c(i,j) = f \times d(i,j) / 1000 ;
\]

Variables

x(i,j) 'shipment quantities in cases'

z 'total transportation costs in thousands of dollars' ;

Positive Variable x ;

Equations

cost 'define objective function'
supply(i) 'observe supply limit at plant i'
demand(j) 'satisfy demand at market j' ;

\[
\text{cost} \quad z = \sum_{(i,j)} c(i,j) \times x(i,j) ;
\]

\[
\text{supply}(i) \quad \sum_{j} x(i,j) = a(i) ;
\]

\[
\text{demand}(j) \quad \sum_{i} x(i,j) = b(j) ;
\]

Model transport /all/ ;

==== Import from Excel using GDX utilities

==== First unload to GDX file (occurs during compilation phase)
$call gdxxrw.exe results.xls par=Level rng=sheet1!A1:D3

==== Now import data from GDX
Parameter Level(i,j);
.gdxin results.gdx
$load Level
.gdxin

*=== Fix variables to values from Excel file
x.FX(i,j) = Level(i,j);
display Level, x.L;

Solve transport using lp minimizing z ;
Display x.l, x.m ;

The data in the Excel file can be loaded into a GDX file using the $call command and GDXXRW tool:

call gdxxrw.exe results.xls par=Level rng=A1:D3

The command $call above executes a program called GDXXRW during compile time. The GDXXRW reads data from the range A1:D3 in results.xls into a GAMS parameter called Level in the GDX file results.gdx. As an output GDX file is not specified when calling GDXXRW, the output file will be derived from the input file by changing the file extension of the input file and removing any path information.

To import data from a GDX file into a parameter, the parameter must be defined over appropriate sets before read. The data from a GDX file can be read during the compile time using the commands $gdxin and $load:

Parameter Level(i,j);
.gdxin results.gdx
$load Level
.gdxin

The first command $gdxin specifies the name of the GDX file results.gdx to be read. The command $load reads parameter Level from the GDX file. The second command $gdxin closed the GDX file.

GAMS can read from a GDX file either during compile time or during execution time. See Example 4 - Reading a GDX File when reading data with domain information and Example 5 - Reading a GDX File when reading from a GDX file during execution time.

Note that it is also possible to write all worksheets of an Excel workbook into a GDX file using XLSDUMP tool.

3.20.2.3 Data Exchange Tools

There are a number of tools that provide functionality to exchange data between GAMS and an Excel file. This section discusses some of the data exchange tools with some examples. The complete list of the tools can be found at GAMS/Excel Data Exchange tools.

3.20.2.3.1 GDXXRW  GDXXRW is a tool to read and write Excel spreadsheet data. GDXXRW can read multiple ranges in a spreadsheet and write the data to a ‘GDX’ file, or read from a ‘GDX’ file, and write the data to different ranges in a spreadsheet.

How to use GDXXRW to exchange data between GAMS and Excel is covered in the section From GAMS to Excel and the section From Excel to GAMS. More details on usage and examples of GDXXRW tool is covered in GDXXRW.
3.20.2.3.2 XLS2GMS  XLS2GMS is a simple utility that allows you to extract data from an Excel spreadsheet and convert it into a GAMS include file. XLS2GMS can be run interactively or in batch mode.

Consider the Excel data from the following spreadsheet:

The data can be imported from the Excel file into a GAMS include file by calling XLS2GMS tool and inserted an include file as parameter data elements using the command $include:

```gams
set ssi /
  'new york', 'washington dc', 'los angeles', 'san francisco'
/;
parameter ssdata(ssi) /
$call =d:\util\xls2gms I="c:\my documents\test2.xls" B O=d:\tmp\x.inc
$include d:\tmp\x.inc
/;
display ssdata;
```

Notice the B parameter, which is needed as there are embedded blanks in the labels.

Sometimes a translation between the labels used in the model and the ones used in the is needed. One way to do this is to use a mapping set in GAMS. Suppose the rest of the model is defined in terms of the set I which is defined as:

```gams
set i / ny, dc, la, sf/;
```

To map a parameter data defined over this set, the following simple GAMS fragment can be used:
set map(i,ssi) mapping set /
  ny.'new york'
  dc.'washington dc'
  la.'los angeles'
  sf.'san francisco'
/

display map;

parameter data(i);
data(i) = sum(map(i,ssi), ssdata(ssi));
display data;

3.20.2.3.3 SQL2GMS In some cases it is convenient to consider tabular data in an Excel spreadsheet as a database table and to import it via GDX file using the SQL2GMS tool.

Consider the following spreadsheet:

![Excel spreadsheet](image)

This table can be read using an SQL query:

```sql
SELECT year, loc, prod, 'sales', sales FROM [profitdata$] \
UNION SELECT year, loc, prod, 'profit', profit FROM [profitdata$]
```

The table name is equal to the sheet name(profitdata). We can pass the query to the Excel ODBC driver using the tool SQL2GMS tool as follows:
3.20 Data Exchange with Other Applications

```
set y 'years' /1997,1998/;
set c 'city' /la,nyc,sfo,was/;
set p 'product' /hardware,software/;
set k 'key' /sales,profit/;

$onecho > excelcmd.txt
c=DRIVER=Microsoft Excel Driver (*.xls);dbq=%system.fp%profit.xls;
q=SELECT year,loc,prod,'sales',sales FROM [profitdata$] \
  UNION SELECT year,loc,prod,'profit',profit FROM [profitdata$]
x=fromexcel.gdx
$offecho
$call =sql2gms @excelcmd.txt
parameter d(y,c,p,k) ;
$gdxin excel.gdx
$load d=p
display d;
```

and the DISPLAY results will be:

```
--- 21 PARAMETER d FROM SQL2GMS

INDEX 1 = 1997

<table>
<thead>
<tr>
<th></th>
<th>sales</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>la</td>
<td>80.000</td>
<td>5.000</td>
</tr>
<tr>
<td>la</td>
<td>60.000</td>
<td>10.000</td>
</tr>
<tr>
<td>nyc</td>
<td>100.000</td>
<td>15.000</td>
</tr>
<tr>
<td>nyc</td>
<td>130.000</td>
<td>25.000</td>
</tr>
<tr>
<td>sfo</td>
<td>50.000</td>
<td>9.000</td>
</tr>
<tr>
<td>sfo</td>
<td>60.000</td>
<td>6.000</td>
</tr>
<tr>
<td>was</td>
<td>80.000</td>
<td>7.000</td>
</tr>
<tr>
<td>was</td>
<td>90.000</td>
<td>8.000</td>
</tr>
</tbody>
</table>

INDEX 1 = 1998

<table>
<thead>
<tr>
<th></th>
<th>sales</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>la</td>
<td>88.000</td>
<td>5.250</td>
</tr>
<tr>
<td>la</td>
<td>66.000</td>
<td>10.500</td>
</tr>
<tr>
<td>nyc</td>
<td>110.000</td>
<td>15.750</td>
</tr>
<tr>
<td>nyc</td>
<td>143.000</td>
<td>26.250</td>
</tr>
<tr>
<td>sfo</td>
<td>55.000</td>
<td>9.450</td>
</tr>
<tr>
<td>sfo</td>
<td>66.000</td>
<td>6.300</td>
</tr>
<tr>
<td>was</td>
<td>88.000</td>
<td>7.350</td>
</tr>
<tr>
<td>was</td>
<td>99.000</td>
<td>8.400</td>
</tr>
</tbody>
</table>
```

3.20.2.3.4 GDXVIEWER  GDXVIEWER is a tool to view and convert data contained in GDX files. It can also export to csv, xls, xml-files and pivot tables. The usage and examples are covered in GDXVIEWER.

3.20.2.3.5 GDX2XLS  GDX2XLS tool o conver the contents of a GDX file into an Excel file or an xml-file. The usage and examples are covered in GDX2XLS.
3.20.3 Data Exchange with Databases

This tutorial provides a guidance on how to exchange data between GAMS and various Database Management System.

3.20.3.1 Data Exchange with DB2

DB2 is one of IBM's relational database management systems.

3.20.3.1.1 Import from DB2  DB2 has an EXPORT command that can be used to generate comma delimited files. An example of a DB2 session illustrating this is shown below:

------------------------------------- Command Entered -------------------------------------
describe table db2admin.dist
;
-----------------------------------------------------------------------------
<table>
<thead>
<tr>
<th>Column name</th>
<th>Type schema</th>
<th>Type name</th>
<th>Length</th>
<th>Scale</th>
<th>Nulls</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCA</td>
<td>SYSIBM</td>
<td>VARCHAR</td>
<td>10</td>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>LOCB</td>
<td>SYSIBM</td>
<td>VARCHAR</td>
<td>10</td>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>DISTANCE</td>
<td>SYSIBM</td>
<td>DOUBLE</td>
<td>8</td>
<td>0</td>
<td>Yes</td>
</tr>
</tbody>
</table>
-----------------------------------------------------------------------------
3 record(s) selected.

------------------------------------- Command Entered -------------------------------------
select * from dist ;
-----------------------------------------------------------------------------
<table>
<thead>
<tr>
<th>LOCA</th>
<th>LOCB</th>
<th>DISTANCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>new-york</td>
<td>+2.50000000000000E+000</td>
</tr>
<tr>
<td>seattle</td>
<td>chicago</td>
<td>+1.70000000000000E+000</td>
</tr>
<tr>
<td>seattle</td>
<td>topeka</td>
<td>+1.80000000000000E+000</td>
</tr>
<tr>
<td>san-diego</td>
<td>new-york</td>
<td>+2.50000000000000E+000</td>
</tr>
<tr>
<td>san-diego</td>
<td>chicago</td>
<td>+1.80000000000000E+000</td>
</tr>
<tr>
<td>san-diego</td>
<td>topeka</td>
<td>+1.40000000000000E+000</td>
</tr>
</tbody>
</table>
-----------------------------------------------------------------------------
6 record(s) selected.

------------------------------------- Command Entered -------------------------------------
export to c:\tmp\export.txt of del select * from dist ;
-----------------------------------------------------------------------------
SQL3104N The Export utility is beginning to export data to file "c:\tmp\export.txt".
SQL3105N The Export utility has finished exporting "6" rows.

Number of rows exported: 6
The resulting data file `export.txt` will look like:

"seattle","new-york",+2.50000000000000E+000
"seattle","chicago",+1.70000000000000E+000
"seattle","topeka",+1.80000000000000E+000
"san-diego","new-york",+2.50000000000000E+000
"san-diego","chicago",+1.80000000000000E+000
"san-diego","topeka",+1.40000000000000E+000

This file can be read into GAMS using `$include`:

```gams
parameter d(i,j) 'distance in thousands of miles' /
   $ondelim
   $include export.txt
   $offdelim
/;
display d;
```

### 3.20.3.1.2 Export to DB2

DB2 has an `IMPORT` command that can read delimited files. As an example consider the file generated by GAMS PUT statements:

"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00

A transcript of a DB2 session to read this file, is given below:

```
------------------------------------- Command Entered -------------------------------------
create table results(loca varchar(10) not null,
   locb varchar(10) not null,
   shipment double not null) ;
-------------------------------------------------------------------------------------------
DB20000I The SQL command completed successfully.

------------------------------------- Command Entered -------------------------------------
import from c:\tmp\import.txt of del insert into results ;
-------------------------------------------------------------------------------------------
SQL3109N The utility is beginning to load data from file "c:\tmp\import.txt".
SQL3110N The utility has completed processing. "6" rows were read from the input file.
SQL3221W ...Begin COMMIT WORK. Input Record Count = "6".
SQL3222W ...COMMIT of any database changes was successful.
SQL3149N "6" rows were processed from the input file. "6" rows were successfully inserted into the table. "0" rows were rejected.
```
Number of rows read               =  6
Number of rows skipped            =  0
Number of rows inserted           =  6
Number of rows updated            =  0
Number of rows rejected           =  0
Number of rows committed          =  6

For very large data sets it is advised to use the LOAD command:

---------------------------------------- Command Entered ----------------------------------------
load from c:\tmp\import.txt of del insert into results ;
-------------------------------------------------------------------------------------------

SQL3501W  The table space(s) in which the table resides will not be placed in
backup pending state since forward recovery is disabled for the database.

SQL3109N  The utility is beginning to load data from file "c:\tmp\import.txt".

SQL3500W  The utility is beginning the "LOAD" phase at time "03-20-2000
           18:11:50.213782".

SQL3519W  Begin Load Consistency Point. Input record count = "0".

SQL3520W  Load Consistency Point was successful.

SQL3110N  The utility has completed processing. "6" rows were read from the
           input file.

SQL3519W  Begin Load Consistency Point. Input record count = "6".

SQL3520W  Load Consistency Point was successful.

SQL3515W  The utility has finished the "LOAD" phase at time "03-20-2000
           18:11:50.337092".

Number of rows read               =  6
Number of rows skipped            =  0
Number of rows loaded             =  6
Number of rows rejected           =  0
Number of rows deleted            =  0
Number of rows committed          =  6

For smaller data sets one can also generate a series of INSERT statements using the PUT facility.

3.20.3.2  Data Exchange with MS Access

Microsoft Office Access, previously known as Microsoft Access, is a relational database management
system from Microsoft. It is a member of the Microsoft Office system.

3.20.3.2.1  Import from MS Access

3.20.3.2.1.1  MDB2GMS  MDB2GMS is a tool to convert data from an Microsoft Access database
into GAMS readable format. The source is an MS Access database file (*.MDB) and the target is
a GAMS Include File or a GAMS GDX File. MDB2GMS is part of the GAMS Data eXchange Tools, see
documentation for more information.
3.20.3.2.1.2 SQL2GMS  SQL2GMS is a tool to convert data from an SQL database into GAMS readable format. The source is any data source accessible through Microsoft's Data Access components including ADO, ODBC and OLEDB. The target is a GAMS Include File or a GAMS GDX File. SQL2GMS is part of the GAMS Data eXchange Tools, see documentation for more information.

3.20.3.2.1.3 CSV Files  Microsoft Access can export tables into comma delimited text files using its Save As/Export menu. Suppose we have the following table:

![Table Image]

After choosing Save As/Export and selecting Text Files we get the following window:
Just using the default settings, we get the following file:

"seattle","new-york",2.50
"seattle","chicago",1.70
"seattle","topeka",1.80
"san-diego","new-york",2.50
"san-diego","chicago",1.80
"san-diego","topeka",1.40

which can be handled in GAMS by $ondelim/$offdelim and $include:

```gams
parameter d(i,j) 'distance in thousands of miles' /
  $ondelim
  $include dist.txt
  $offdelim
/;
display d;
```

### 3.20.3.2.1.4 Import Dates from Access

GAMS dates are one day off when importing from MS Access. Suppose we have an MS Access table with one single date column:

```text
datefield
----------
3/12/2007
3/13/2007 10:00:00 AM
3/14/2007 8:30:00 PM
```
The date data above can be imported into GAMS using $call and MDB2GMS tool as follows:

$$\text{call = mdb2gms I="%system.fp%sample.mdb" Q="select datefield,Cdbl(datefield) from datetable" O=x.inc}$$

```gams
parameter p(*) /
   $include x.inc
/;
display p;
alias(*,i);
parameter q(*,*);
loop(i$p(i),
   q(i,'year') = gyear(p(i));
   q(i,'month') = gmonth(p(i));
   q(i,'day') = gday(p(i));
   q(i,'hour') = ghour(p(i));
   q(i,'minute') = gminute(p(i));
);
display q;
```

Note that the `Cdbl()` function converts the date to a floating point number (double precision). The generated include file looks like:

```
* -----------------------------------------------------
* MDB2GMS Version 2.8, January 2007
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* DAO version: 3.6
* Jet version: 4.0
* Database: D:\mdb2gms\examples\sample.mdb
* Query: select datefield,Cdbl(datefield) from datetable
* -----------------------------------------------------

'3/12/2007' 39153
'3/13/2007 10:00:00 AM' 39154.4166666667
'3/14/2007 8:30:00 PM' 39155.8541666667
* -----------------------------------------------------

which looks o.k. However, when we look at the GAMS results in the listing file we see:

```
---- 28 PARAMETER p

</tr>
</tbody>
</table>
```

Clearly the dates are off by one day: see the column `day`. We can fix this problem in different places, e.g. in the query or in the GAMS model by subtracting 1.0 from an imported date. This problem occurs not only in MS Access but also with other software packages.

### 3.20.3.2.2 Export to MS Access
3.20.3.2.2.1 GDX2ACCESS  GDX2ACCESS is a tool to dump the whole contents of a GDX file to a new MS Access file (.mdb file). GDX2ACCESS is part of the GAMS Data eXchange Tools, see documentation for more information.

3.20.3.2.2.2 GDXVIEWER  Access tables in MDB files can be directly generated by the GDXVIEWER tool. The GDXVIEWER tool uses OLE automation to export data to an MS Access database. This means that MS Access needs to be installed for the Access Export facility to work. GDXVIEWER is part of the GAMS Data eXchange Tools, see documentation for more information.

3.20.3.2.2.3 VBScript  VBScript is a scripting tool that can be used to talk to COM objects. In this case we use it to tell Access to import a CSV file.

```plaintext
$ontext
Import a table into MS Access using VBscript
$offtext
$if exist new.mdb $call del new.mdb
set i /i1*i10/;
alias (i,j);
parameter p(i,j);
p(i,j) = uniform(-100,100);
display p;
file f /data.csv/;
f.pc=5;
put f,'i','j','p'/;
loop((i,j),
   put i.tl, j.tl, p(i,j):12:8/)
);
putclose;
execute "=cscript access.vbs";

$onecho > access.vbs
'this is a VBscript script
WScript.Echo "Running script: access.vbs"
dbLangGeneral = ";LANGID=0x0409;CP=1252;COUNTRY=0"
strSQL = "SELECT * INTO mytable FROM [Text;HDR=Yes;Database=%system.fp%;FMT=Delimited].[data#csv]"
Wscript.Echo "Query : " & strSQL
Set oJet = CreateObject("DAO.DBEngine.36")
Wscript.Echo "Jet version : " & oJet.version
Set oDB = oJet.createDatabase("new.mdb",dbLangGeneral)
Wscript.Echo "Created : " & oDB.name
oDB.Execute strSQL
Set TableDef = oDB.TableDefs("mytable")
Wscript.Echo "Rows inserted in mytable : " & TableDef.RecordCount
oDB.Close
Wscript.Echo "Done"
$offecho

The CSV file contains a header row with the names of the fields:

"i","j","p"
"i1","i1",-65.65057360
"i1","i2",68.65334160
"i1","i3",10.07507120
"i1","i4",-39.77241920
"i1","i5",-41.55757660
....
```
3.20 Data Exchange with Other Applications

The text driver specification HDR=YES makes sure the first row in the CSV file is treated specially. The log will look like:

```
U:\temp>gams vbaccess.gms
--- Job vbaccess.gms Start 01/28/08 16:57:37
GAMS Rev 149 Copyright (C) 1987-2007 GAMS Development. All rights reserved
...
--- Starting compilation
--- vbaccess.gms(4) 2 Mb
--- call del new.mdb
--- vbaccess.gms(38) 3 Mb
--- Starting execution: elapsed 0:00:00.109
--- vbaccess.gms(18) 4 Mb
Microsoft (R) Windows Script Host Version 5.6
Copyright (C) Microsoft Corporation 1996-2001. All rights reserved.

Running script: access.vbs
Query : SELECT * INTO mytable FROM [Text;HDR=Yes;Database=U:\temp\;FMT=Delimited ].[data#csv]
Jet version : 3.6
Created : U:\temp\new.mdb
Rows inserted in mytable : 100
Done
--- Putfile f U:\temp\data.csv
*** Status: Normal completion
--- Job vbaccess.gms Stop 01/28/08 16:57:38 elapsed 0:00:00.609
U:\temp>
```

Please note that although the $onecho/$offecho is at the bottom of the GAMS file, the file access.vbs is created at compile time. I.e. before the executable statements like PUT, EXECUTE are executed.

3.20.3.2.2.4 JScript  The same script using JScript is similar to the one with VScript. We only price the script itself.

```
$ontext
  Import a table into MS Access using JScript
$offtext
$if exist new.mdb $call del new.mdb

set i /i1*i10/;
alias (i,j);
parameter p(i,j);

p(i,j) = uniform(-100,100);
display p;

file f /data.csv/;
f.pc=5;
put f,'i','j','p'/;
loop((i,j),
  put i.tl, j.tl, p(i,j):12:8/
);
putclose;

execute "=cscript access.js";
```
$onecho > access.js
// this is a JScript script
WScript.Echo("Running script: access.js");

dbLangGeneral = ";LANGID=0x0409;CP=1252;COUNTRY=0";
strSQL = "SELECT * INTO mytable FROM [Text;HDR=Yes;Database=.;FMT=Delimited].[data#csv]";
WScript.Echo("Query : ",strSQL);

oJet = new ActiveXObject("DAO.DBEngine.36");
WScript.Echo("Jet version : ",oJet.version);

oDB = oJet.createDatabase("new.mdb",dbLangGeneral);
WScript.Echo("Created : ",oDB.name);

oDB.Execute(strSQL);
TableDef = oDB.TableDefs("mytable");
WScript.Echo("Rows inserted in mytable : ",TableDef.RecordCount);

oDB.Close();
WScript.Echo("Done");
$offecho

3.20.3.2.2.5 Combining GDX2ACCESS and VBscript Data in a GDX file do not contain domain information. I.e. a parameter c(i,j) is really stored as c(*,*) As a result GDX2ACCESS will invent field names like dim1, dim2, Value. In some cases this may not be convenient, e.g. when more descriptive field names are required. We will show how a small script in VBscript can handle this task. The script will rename the fields dim1, dim2, Value in table c to i, j, and transportcost.

$call "gamslib 1"
$include trnsport.gms
* * export to gdx file.
* The domains i,j are lost: gdx only stores c(*,*)
execute_unload "c.gdx",c;
* * move to access database
* column names are dim1,dim2
* execute "+=gdx2access c.gdx";
* * rename columns
* execute "+=cscript access.vbs";

$onecho > access.vbs
'this is a VBscript script
WScript.Echo "Running script: access.vbs"
'
' Office 2000 DAO version
' Change to local situation.
Set oDAO = CreateObject("DAO.DBEngine.36")
script.Echo "DAO version : " & oDAO.version

Set oDB = oDAO.openDatabase("%system.fp%c.mdb")
Wscript.Echo "Opened : " & oDB.name
The above VBscript fragment needs to be adapted according to the DAO Data Access Objects version available on the client machine. This can be implemented in a more robust fashion by letting MS Access find the DAO engine:

```vbs
' this is a VBscript script
WScript.Echo "Running script: access.vbs"
set oa = CreateObject("Access.Application")
set oDAO = oa.DBEngine
Wscript.Echo "DAO Version: " & oDAO.version
Set oDB = oDAO.openDatabase("%system.fp%\c.mdb")
Wscript.Echo "Opened : " & oDB.name
Set oTable = oDB.TableDefs.Item("c")
Wscript.Echo "Table : " & oTable.name
'
rename fields
oTable.Fields.Item("dim1").name = "i"
oTable.Fields.Item("dim2").name = "j"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"
oDB.Close
Wscript.Echo "Done"
```

Please note that the macro `%system.fp%` is replaced by GAMS by the working directory (this is the project directory when running GAMS from the IDE).

### 3.20.3.3 Data Exchange with MySQL

MySQL is a multi-threaded, multi-user SQL database management system.

#### 3.20.3.3.1 Import from MySQL

MySQL can write the results of a `SELECT` statement to a file as follows:
mysql> select * from dist;
+-----------+----------+----------+
| loca      | locb     | distance |
+-----------+----------+----------+
| seattle   | new-york | 50       |
| seattle   | chicago  | 300      |
| seattle   | topeka   | 0        |
| san-diego | new-york | 275      |
| san-diego | chicago  | 0        |
| san-diego | topeka   | 275      |
+-----------+----------+----------+
6 rows in set (0.01 sec)

mysql> select * from dist into outfile '/tmp/data.csv'
    -> fields terminated by ','
    -> optionally enclosed by '"'
    -> lines terminated by '\n';
Query OK, 6 rows affected (0.00 sec)

The resulting CSV file looks like:

"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275

which can be read by GAMS directly. This approach can be automated as follows:

[erwin@localhost erwin]$ cat myscript
use test
select * from dist into outfile '/tmp/data.csv'
    fields terminated by ','
    optionally enclosed by '"'
    lines terminated by '\n';
[erwin@localhost erwin]$ cat x.gms
set i /seattle, san-diego/;
set j /new-york, chicago, topeka/;
$call 'mysql -u root < myscript'
parameter dist(i,j) /
$ondelim
$include /tmp/data.csv
$offdelim
/;
display dist;
[erwin@localhost erwin]$ gams x
GAMS Rev 132 Copyright (C) 1987-2002 GAMS Development. All rights reserved
Licensee: GAMS Development Corporation, Washington, DC G871201:0000XX-XXX
Free Demo, 202-342-0180, sales@gams.com, www.gams.com DC9999
--- Starting compilation
--- x.gms(5) 1 Mb
--- call mysql -u root < myscript
--- .data.csv(6) 1 Mb
--- x.gms(15) 1 Mb
--- Starting execution
--- x.gms(18) 1 Mb
*** Status: Normal completion
[erwin@localhost erwin]$ 

The listing file shows that the table is read correctly:

```gams
1 set i /seattle, san-diego/;
2 set j /new-york, chicago, topeka/;
3
4 parameter dist(i,j) / 
5 INCLUDE /tmp/data.csv 
6 "seattle","new-york",50 
7 "seattle","chicago",300 
8 "seattle","topeka",0 
9 "san-diego","new-york",275 
10 "san-diego","chicago",0 
11 "san-diego","topeka",275 
12 /; 
13 18 display dist;
14 20
15
16
17
18
19
20
21
```

SEQ GLOBAL TYPE PARENT LOCAL FILENAME
1 1 INPUT 0 0 /home/erwin/x.gms
2 5 CALL 1 5 mysql -u root < myscript
3 8 INCLUDE 1 8 ./tmp/data.csv

--- 18 PARAMETER dist

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>50.000</td>
<td>300.000</td>
<td></td>
</tr>
<tr>
<td>san-diego</td>
<td>275.000</td>
<td></td>
<td>275.000</td>
</tr>
</tbody>
</table>

Instead of maintaining the MySQL script in a separate file, it can also be written by GAMS using `$onecho/$offecho` and a statement like:

```gams
$onecho > myscript
use test
select * from dist into outfile '/tmp/data.csv'
   fields terminated by ','
   optionally enclosed by '"'
   lines terminated by '\n';
$offecho
```

This will write the script at compile time.
3.20.3.3.2 Export to MySQL  GAMS can export data to MySQL by creating a script containing a series of SQL INSERT statements, as shown in section Oracle CSV Import.

It is noted that MySQL does have a REPLACE statement which is a useful blend of an INSERT and UPDATE statement: update a row if it already exists, otherwise insert it. This is not standard SQL however, so it can cause problems when moving to another database.

For larger result sets it may be better to use the LOAD DATA INFILE command. This command can read directly ASCII text files such as comma delimited CSV files.

Consider again the data file created by the PUT statement:

"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00

The following transcript shows how to import this into MySQL:

```
mysql> create table dist(loca varchar(10), locb varchar(10), distance double precision);
Query OK, 0 rows affected (0.00 sec)

mysql> show tables;
+----------------+
| Tables_in_test |
+----------------+
| dist |
+----------------+
1 row in set (0.00 sec)

mysql> describe dist;
+----------+-------------+------+-----+---------+-------+
| Field    | Type        | Null | Key | Default | Extra |
|----------+-------------+------+-----+---------+-------+
| loca     | varchar(10) | YES  |     | NULL    |       |
| locb     | varchar(10) | YES  |     | NULL    |       |
| distance | double      | YES  |     | NULL    |       |
+----------+-------------+------+-----+---------+-------+
3 rows in set (0.00 sec)

mysql> load data infile '/tmp/data.txt' into table dist
   -> fields terminated by ','
   -> optionally enclosed by '"'
   -> lines terminated by '\n';
Query OK, 6 rows affected (0.00 sec)
Records: 6 Deleted: 0 Skipped: 0 Warnings: 0

mysql> select * from dist;
+-----------+----------+----------+
| loca      | locb     | distance |
|-----------+----------+----------+
| seattle   | new-york | 50       |
| seattle   | chicago  | 300      |
| seattle   | topeka   | 0        |
| san-diego | new-york | 275      |
```

Note that we used no keys in our table definition. In practice it is of course highly recommended to define proper keys.

### 3.20.3.4 Data Exchange with Oracle

The Oracle Database (commonly referred to as Oracle RDBMS or simply as Oracle) is a relational database management system (RDBMS) software product released by Oracle Corporation.

#### 3.20.3.4.1 Import from Oracle

**SQL*Plus**

To export an Oracle table a simple solution is to write an SQL*Plus script. E.g. if our table looks like:

```sql
SQL> describe dist;
Name Null? Type
----------------------------------- -------- ------------------------
LOCA NOT NULL VARCHAR2(10)
LOCB NOT NULL VARCHAR2(10)
DISTANCE NUMBER

SQL> select * from dist;
LOCA LOCB DISTANCE
---------- ---------- --------
seattle new-york 2.5
seattle chicago 1.7
seattle topeka 1.8
san-diego new-york 2.5
san-diego chicago 1.8
san-diego topeka 1.4
6 rows selected.

SQL>
```

then the following script will export this table:

```sql
set pagesize 0
set pause off
set heading off
spool data
select loca||','||locb||','||distance from dist;
spool off
```

The resulting data file "data.lst" will look like:

| san-diego | chicago | 0 |
| san-diego | topeka | 275 |
+-----------------+--------+-----+
6 rows in set (0.00 sec)
This almost looks like our data initialization syntax for parameters:

```
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
```

The only differences are in the delimiters that are being used. These differences are easily digested by GAMS once it is in ondelim mode. I.e. the following syntax can be used to read the data.lst file:

```
parameter d(i,j) 'distance in thousands of miles' /
$ondelim
$include data.lst
$offdelim
/;
```

3.20.3.4.1.2 **SQL2GMS** An alternative way to import data from Oracle is to use the tool SQL2GMS which can talk to any database with an ADO or ODBC interface.

3.20.3.4.1.3 **Import dates from Oracle databases and converting them to GAMS dates** For most softwares it is easy to generate dates that GAMS can import and understand. The most common issue is that GAMS is one day off compared to Excel, Delphi, Access, ODBC etc. Oracle is somewhat more involved. First it is useful to have the date/time exported as a Julian date. This can be done with the following stored procedure:

```sql
-- julian representation of a date/time
-- Erwin Kalvelagen, feb 2007
create or replace function to_julian(d IN TIMESTAMP)
return number
is
begin
return to_number(to_char(d,'J')) + to_number(to_char(d,'SSSSS'))/86400;
end;
```

This function can be used to export dates as simple floating point numbers. In GAMS we need just a simple adjustment by adding a constant `datediff` defined by:

```
scalar
   refdategams "march 16, 2006, 00:00"
   refdateoracle "march 16, 2006, 00:00" /2453811/
   datediff "difference between GAMS and Oracle date"
;
refdategams = jdate(2006,3,16);
datediff = refdategams-refdateoracle;
```

This trick has been applied in a complex scheduling application where dates are important data types that must be exchanged between the application logic and database tier and the optimization engine.
3.20 Data Exchange with Other Applications

3.20.3.4.2 Export to Oracle

3.20.3.4.2.1 Oracle CSV Import  
A familiar way of moving data into Oracle is to generate standard SQL INSERT statements. The PUT facility is flexible enough to handle this. For instance the following code:

```gams
file results /results.sql/;
results.lw=0;
results.nw=0;
put results;
loop((i,j),
    put "insert into result (loca, locb, shipment) ";
    put "values ('",i.tl,"','",j.tl,"',",x.l(i,j),")";"
);
putclose;
```

will generate these SQL statements:

```sql
insert into result (loca, locb, shipment) values ('seattle','new-york',50.00);
insert into result (loca, locb, shipment) values ('seattle','chicago',300.00);
insert into result (loca, locb, shipment) values ('seattle','topeka',0.00);
insert into result (loca, locb, shipment) values ('san-diego','new-york',275.00);
insert into result (loca, locb, shipment) values ('san-diego','chicago',0.00);
insert into result (loca, locb, shipment) values ('san-diego','topeka',275.00);
```

The .lw and .nw attributes for the put file indicate that no extra spaces around the labels and the numeric values are needed. These field width attributes have a default value of 12 which would cause the values to look like:

```
'seattle  ', 'new-york  ', 50.00
```

If the amount of data is large the utility SQL*Loader can be used to import comma delimited input. I.e. the GAMS code:

```gams
file results /results.txt/;
results.pc=5;
put results;
loop((i,j),
    put i.tl, j.tl, x.l(i,j)/
);
putchose;
```

produces a file results.txt:

```
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

The following SQL*Loader control file will read this file:

```sql
LOAD DATA
INFILE results.txt
INTO TABLE result
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
(loca,locb,shipment)
```
3.20.3.4.2.2 GDX to Oracle  Database tables in an SQL RDBMS can be directly generated by the GDXVIEWER tool. The GDXVIEWER can use three methods to export to Oracle and other RDBMSs:

1. The direct ADO/ODBC link can create a new table and populate it.
2. The SQL INSERT script generator can create a script with a number of INSERT statements.
3. The SQL UPDATE script generator can create a script with a number of UPDATE statements.

3.20.3.5 Data Exchange with SQL Server

3.20.3.5.1 Import from SQL Server  Microsoft SQL Server is Microsoft's flagship database. It comes in different flavors, including SQL Server, MSDE and SQL Server Express.

3.20.3.5.1.1 Using SQL2GMS  A good way to import SQL server data into GAMS is using the SQL2GMS tool. Below is an example of its use:

```gams
$set commandfile commands.txt
$onecho > %commandfile%
C=provider=sqloledb;data source=athlon\SQLExpress;Initial catalog=test;user id=sa;password=password
O=C:\WINNT\gamsdir\xx.inc
Q=SELECT * FROM x
$offecho
$call =sql2gms %commandfile%
parameter p(i,j) /
$include "C:\WINNT\gamsdir\xx.inc"
/;
display p;
```

3.20.3.5.1.2 Using the BCP utility and CSV files  To export SQL Server data to CSV files we can use the BCP utility.

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>bcp test..results out x.csv \\
-S athlon\sqlexpress -c -U sa -P password -t,
Starting copy...
6 rows copied.
Network packet size (bytes): 4096
Clock Time (ms.) Total : 10 Average : (600.00 rows per sec.)
C:\Program Files\Microsoft SQL Server\90\Tools\binn>type x.csv
seattle,new-york,50.0
seattle,chicago,300.0
seattle,topeka,0.0
san-diego,new-york,275.0
san-diego,chicago,0.0
san-diego,topeka,275.0
```

It is somewhat more difficult to create a proper CSV file. A format specification file can help here. For an example see the next section on Data Exchange with Sybase . Other tools to export files include DTS (Data Transformation Services) and linked ODBC data sources.
3.20.3.5.1.3 A direct interface between SQL server tables and GAMS GDX files

Finally we can program directly an interface between SQL server tables and GAMS GDX files. A small example in C# can look like:

```csharp
    gdxio = new csharpclient();
    // read a set
    gdxio.gdxdatawritestrstart(ap, "location", "from db", 1, csharpclient.dt_set, 0);
    String q = "select distinct(location) from exporttable";
    SqlCommand cmd = new SqlCommand(q, conn);
    SqlDataReader myReader = cmd.ExecuteReader();
    String[] astrelements = new String[10];
    for (int i = 0; i < 10; ++i)
        astrelements[i] = "";
    double[] avals = new double[5];
    while (myReader.Read())
    {
        astrelements[0] = myReader.GetString(0);
        avals[0] = 0.0;
        Boolean ok = gdxio.gdxdatawritestr(ap,astrelements,avals);
    }
    gdxio.gdxdatawritedone(ap);
    myReader.Close();

    // read a data table
    gdxio.gdxdatawritestrstart(ap, "data", "from db", 2, csharpclient.dt_par, 0);
    q = "select location, capacity, cost exporttable";
    cmd = new SqlCommand(q, conn);
    myReader = cmd.ExecuteReader();
    while (myReader.Read())
    {
        astrelements[0] = myReader.GetString(0);
        astrelements[1] = "capacity";
        avals[0] = myReader.GetInt32(1);
        Boolean ok = gdxio.gdxdatawritestr(ap,astrelements,avals);
        if (!myReader.IsDBNull(2))
        {
            astrelements[1] = "cost";
            avals[0] = myReader.GetDouble(2);
            ok = gdxio.gdxdatawritestr(ap,astrelements,avals);
        }
    }
    gdxio.gdxdatawritedone(ap);
    myReader.Close();
    gdxio.gdxclose(ref ap);
```

3.20.3.5.2 Export to SQL Server

SQL Server has two basic facilities to import CSV files: the BCP tool and the BULK INSERT statement. Advanced SQL Server users may also be able to use DTS (Data Transformation Services) or linked ODBC data sources. Of course for small data sets we can create standard SQL INSERT statements. In addition the tool GDXVIEWER can be used to get GAMS data into SQL Server.

3.20.3.5.2.1 Export using the BCP tool

A transcript showing the use of BCP is shown below:

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLEXPRESS
1> use test;
2> create table x(loca varchar(10), locb varchar(10), shipment float);
3> go
4> Changed database context to 'test'.
5> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
6> seattle,new-york,50.00
7> seattle,chicago,300.00
8> seattle,topeka,0.00
9> san-diego,new-york,275.00
```

san-diego,chicago,0.00
san-diego,topeka,275.00

C:\Program Files\Microsoft SQL Server\90\Tools\binn>bcp test..x in c:\winnt\gamsdir\results.csv \
-S athlon\sqlexpress -c -U sa -P password -t,

Starting copy...

6 rows copied.
Network packet size (bytes): 4096
Clock Time (ms.) Total : 10       Average : (600.00 rows per sec.)

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test
2> select * from x;
3> go
(6 rows affected)
1> quit

Unfortunately, dealing with quoted strings is not straightforward with this tool (an example using a format file is shown in the next section on Data Exchange with Sybase). The same thing holds for BULK INSERT, which can read:

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
seattle,new-york,50.00
seattle,chicago,300.00
seattle,topeka,0.00
san-diego,new-york,275.00
san-diego,chicago,0.00
san-diego,topeka,275.00

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test
2> create table x(loca varchar(10), locb varchar(10), shipment float)
3> go
(6 rows affected)
1> select * from x
2> go

loca   locb    shipment
---------- ---------- ------------------------
seattle new-york   50
seattle  chicago   300
seattle     topeka  0
san-diego new-york  275
san-diego  chicago  0
san-diego     topeka  275

(6 rows affected)
1> select * from x
2> go
loca   locb    shipment
---------- ---------- ------------------------
seattle new-york   50
seattle  chicago   300
seattle     topeka  0
3.20 Data Exchange with Other Applications

3.20.3.5.2.2 Export using the ODBC Text Driver

A slower but flexible way to load CSV files is to use a linked server through the ODBC Text Driver. First create an ODBC DSN using the Text Driver. This can be done through the ODBC Data Source Administrator Data Sources (ODBC) Then we can use the system procedure SP_AddLinkedServer.

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type transport.sql
--
-- test database
--
use test
--
-- create table in SQL server
--
create table results(loca varchar(10), locb varchar(10), ship float)
go
--
-- Create a linked server
--
EXEC sp_addlinkedserver txtsrv,'Jet 4.0','Microsoft.Jet.OLEDB.4.0','c:\winnt\gamsdir',NULL,'Text'
go
--
-- copy data from text file c:\winnt\gamsdir\results.csv
--
insert into results(loca,locb,ship)
select * from txtsrv...results#csv
go
--
-- check if all arrived
--
select * from results
go
--
-- release linked server
--
EXEC sp_dropserver txtsrv
GO
--
-- clean up
--
drop table results
go

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\sqlexpress
1> :r transport.sql
Changed database context to 'test'.

(6 rows affected)
loca     locb       ship
---------- ---------- ------------------------
seattle   new-york  50
seattle   chicago  300
seattle   topeka   0
san-diego new-york 275
san-diego chicago  0
san-diego topeka 275

(6 rows affected)
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>

A slightly different approach is the following:

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\sqlexpress
1> create table t(loca varchar(10), locb varchar(10), ship float)
go
1> insert into t
2> select * from
3> OpenRowSet('Microsoft.Jet.OLEDB.4.0',
4> 'Text;Database=c:\winnt\gamsdir\;HDR=NO',
5> 'select * from results.csv')
go

(6 rows affected)
1> select * from t
2> go
loca     locb       ship
---------- ---------- ------------------------
seattle   new-york  50
seattle   chicago  300
seattle   topeka   0
san-diego new-york 275
san-diego chicago  0
san-diego topeka 275

(6 rows affected)
1> drop table t
2> go
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>
This can be automated from GAMS as follows:

```gams
file results /results.csv/;
results.pc=5;
put results;
loop((i,j),
   put i.tl, j.tl, x.l(i,j)/
);
putclose;

file sqlinsert /insert.sql/;
put sqlinsert;
put "use test"/;
put "insert into t select * from OpenRowSet('Microsoft.Jet.OLEDB.4.0',"
    "'Text;Database=c:\winnt\gamsdir\;HDR=NO','select * from results.csv')"/;
putclose;

execute '="C:\Progra~1\Microsoft SQL Server\90\Tools\binn\sqlcmd" -S athlon\SQLExpress -i insert.sql';
```

### 3.20.3.5.2.3 Export using the GDXVIEWER

When using GDXVIEWER to export data to MS SQL server it is noted that MSSQL Server does not accept the default SQL type double for double precision numbers. You will need to set this setting to float or double precision.

When we export variable x from the transport model, we see:

```sql
C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test
2> go
Changed database context to 'test'.
1> select * from x
2> go

<table>
<thead>
<tr>
<th>dim1</th>
<th>dim2</th>
<th>level</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>new-york</td>
<td>50</td>
</tr>
<tr>
<td>seattle</td>
<td>chicago</td>
<td>300</td>
</tr>
<tr>
<td>seattle</td>
<td>topeka</td>
<td>0</td>
</tr>
<tr>
<td>san-diego</td>
<td>new-york</td>
<td>275</td>
</tr>
<tr>
<td>san-diego</td>
<td>chicago</td>
<td>0</td>
</tr>
<tr>
<td>san-diego</td>
<td>topeka</td>
<td>275</td>
</tr>
</tbody>
</table>

(6 rows affected)
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>
```

### 3.20.3.6 Data Exchange with SQLite

See GDX2SQLITE for more information.

### 3.20.3.7 Data Exchange with Sybase

#### 3.20.3.7.1 Import from Sybase
3.20.3.7.1.1 Import using the bcp utility  Sybase is largely the same as SQL Server. For exporting ASCII files from a Sybase table, the utility (Using the BCP utility and CSV files) can be used.

An example of use of this utility is shown below:

```
[erwin@fedora sybase]$ isql -U sa -S LOCALHOST -D testdb -P sybase -J iso_1
1> select * from results
2> go
loca   locb    shipment
---------- ---------- --------------------
seattle  new-york 50.000000
seattle  chicago 300.000000
seattle  topeka 0.000000
san-diego new-york 275.000000
san-diego chicago 0.000000
san-diego topeka 275.000000
(6 rows affected)
1> quit
[erwin@fedora sybase]$ cat bcp.fmt
10.0
4
1 SYBCHAR 0 0 "\\" 1 loca
2 SYBCHAR 0 10 "\\\\n" 1 loca
3 SYBCHAR 0 10 "\\n" 2 locb
4 SYBCHAR 0 17 "\\n" 3 shipment
[erwin@fedora sybase]$ bcp testdb..results out res.txt -S LOCALHOST -U sa -P sybase -J iso_1 -f bcp.fmt
Starting copy...
6 rows copied.
Clock Time (ms.): total = 1  Avg = 0 (6000.00 rows per sec.)
[erwin@fedora sybase]$ cat res.txt
"seattle","new-york",50.0
"seattle","chicago",300.0
"seattle","topeka",0.0
"san-diego","new-york",275.0
"san-diego","chicago",0.0
"san-diego","topeka",275.0

Note: the first column in the format file is a dummy (it has length 0). This is in order to write the leading quote, as bcp only allows for termination symbols.

This can be automated using the following GAMS code:

```
sets
i 'canning plants' / seattle, san-diego /
j 'markets' / new-york, chicago, topeka /;
$onecho > bcp.fmt
10.0
4
1 SYBCHAR 0 0 "\\" 1 loca
2 SYBCHAR 0 10 "\\\\n" 1 loca
```
3.20.3.7.1.2 Import using the SQL2GMS utility  The SQL2GMS tool uses ADO or ActiveX Data Objects to extract data from relational databases. It can connect to almost any database from any vendor as it supports standards like ODBC. See documentation for more information.

```

gdef1278Sybchar 0 positional "\", locb

gdef1278Sybchar 0 positional "\n" shipment

$offecho
$call "bcp testdb..results out res.txt -S LOCALHOST -U sa -P sybase -J iso_1 -f bcp.fmt"
parameter d(i,j) 'distance in thousands of miles'
/
$ondelim
$include res.txt
$offdelim
/;
display d;

3.20.3.7.1.3 Import using a 'SQL2GMS' VBS script  The following GAMS code will generate and execute a script written in VBScript. It mimics the behavior of SQL2GMS.EXE and can be used for debugging or the script can be passed on to the IT support people in case there are problems with accessing the database.

```

$ontext
This script mimics SQL2GMS.
Erwin Kalvelagen
November 2006

3.21 Executing GAMS from other Environments

3.21.1 Some General Comments

Nowadays the objected-oriented APIs are the most efficient and elegant way to interact with the GAMS system. They allow the effective communication of data, and do parameterized runs of GAMS. This whole chapter describes a much more basic interaction of GAMS through calling the GAMS executable from different environments. This still can be useful, e.g. if no object-oriented API is available for the particular target language (e.g. VBA).

While the principle of calling the GAMS executable holds for all operating systems, this chapter often focuses on the Windows platform.

One of the interesting problems one faces when spawning GAMS.EXE in a Windows environment is multi-threading. If one does not take precautions, a call to Shell (VB function) or CreateProcess (Win32 API function) causes GAMS to run asynchronously: the function will return while GAMS is still running. In order to read the results one would need to wait until the GAMS job has finished. The machinery for this requires some Windows trickery, and for Visual Basic version 6 and Delphi version 4 we have implemented some small examples that illustrate how this can be done.

Another issue that needs to be addressed is that GAMS needs a place to put its scratch files. By default this is the current directory, a concept that is not always clear in a windowing environment. A good way of dealing with this is to set both the current drive and the current directory before running the GAMS job. It should be noted that GAMS needs write permission there. In the examples we use the Windows TEMP directory for this, but in a real application you may want to use a designated directory. The Windows TEMP directory is found by calling the API function GetTempPath.

3.21.1.1 The GAMS architecture

GAMS itself is a 32 bit console mode application. In fact it is not a single program, but a driver program (GAMS.EXE) that executes in turn the GAMS language compiler (GAMSCMEX.EXE) or one of the solvers. For a model with a single solve statement, GAMS.EXE will first call GAMSCMEX to compile the GAMS model. Then GAMSCMEX will start executing the internal code that was generated by the compiler. As soon as it hits the instructions belonging to a SOLVE statement it will generate model instance, and GAMSCMEX will exit. Then GAMS.EXE will spawn a solver capable of solving the model. As soon as the solver is finished, GAMS.EXE will execute GAMSCMEX again so it can read the solution and can continue with executing instructions.
3.21 Executing GAMS from other Environments

3.21.2 Spawning GAMS from VBA

Visual Basic for Applications (VBA) is a programming language that is built into most Microsoft Office applications, e.g. Excel and Access. A VBA program may include modules, which can be imported from files, i.e. in the VBA editor you can choose menu “File”→“Import File”. The GAMS distribution includes some VBA modules, which can be found from:

<GAMS System Directory>\apifiles\VBA\api, e.g. "C:\GAMS\win64\24.5\apifiles\VBA\api"

Attention

- In order to avoid issues, it's recommended to use the latest version of the modules, i.e. the modules found in the latest GAMS release.

For example, the following modules can be found:

- gamsglobals.bas: Global constants that are used in other modules
- gamsxvba.bas: GAMS Execution Object
- gdxvba.bas: GAMS Data Exchange Object
- idxvba.bas: GAMS IDX Object
- optvba.bas: GAMS Option Object

For more information, see Expert-Level APIs. VBA programs that use the API can be found from:

<GAMS System Directory>\apifiles\VBA, e.g. "C:\GAMS\win64\24.5\apifiles\VBA"

The models can also be retrieved via GAMSIDE -> Model Libraries -> GAMS Data Utilities Models.

3.21.2.1 Spawning GAMS from Excel

Calling GAMS out of Excel requires some more work than just Data Exchange with Microsoft Excel. The application calling GAMS out of Excel has to:

1. Locate the GAMS system directory and adjust the system path accordingly.
2. Copy the GAMS model into a temporary directory (by default the temporary directory of Windows)
3. Extract the model data from the spreadsheet into a GAMS readable format (gdx)
4. Execute GAMS (solve the model, write the solution back to gdx file)
5. Import the model results back from the gdx files into the spreadsheet
6. Update the spreadsheet (graphics, tables)

Using Visual Basic for Applications (VBA) this can be implemented with a few lines of code:

```
Sub solve()
    Dim WorkDir As String
    WorkDir = TempDir()
    Call ClearSolution
    If (Not AddGAMSPath()) Then ' needed to find gdxio.dll and gams.exe
        Exit Sub
    End If
    Call ExportGDXFile(WorkDir)
    Call WriteGAMSModel(WorkDir & "portfolio.gms")
    Call RunGAMS(WorkDir & "portfolio.gms", WorkDir)
    Call ReadListing(WorkDir & "portfolio.lst")
    Call ImportGDXFile(WorkDir)
End Sub
```

For further details, please inspect the VBA part of the examples below.
3.21.2.2 A Simple Example

This very simple example shows how GAMS can be invoked from an Excel spreadsheet. The "example spreadsheet" has a button, which will cause GAMS to run the transport.gms model stored in c:/tmp. There is no data exchange.

A more complete application will write an include file for a GAMS model, and will import a comma delimited file with results when the run is finished. An example of such a complete application is described in http://www.gams.com/mccarl/excelgams.pdf.

3.21.2.3 Sudoku Example

This "spreadsheet" is a complete example that uses GDX files to exchange information solves a 25x25 Sudoku problem using CPLEX. You will need a GAMS/CPLEX license to be able to run the spreadsheet. The MIP model solves very easily: the solution is found in the presolve phase.

Note: This spreadsheet requires distribution 22.6 or younger to work properly. If you are using an older distribution, please download "this one".

3.21.2.3.1 Problem

3.21.2.3.2 Solution

3.21.2.4 Efficient frontier example

This "example" (screen shot below) solves a series of NLPs to create an efficient frontier of a portfolio optimization problem.

Note: This spreadsheet requires distribution 22.6 or younger to work properly. If you are using an older distribution, please download "this one".

3.21.3 Spawning GAMS from C

The example below shows an absolute minimal version of calling GAMS from a C program:

```
#include <stdio.h>

int main(int argc, char** argv)
{
    system("gams transport lo=2");
    return 0;
}
```

As can be seen the GAMS executable gams.exe is called via a simple invocation of system(). The extra command line parameter `lo=2` indicates that the log file is not written to the screen (this is the default) but to a file `model.log`.

If we want to generate some data from the application program (e.g. parameter `DEMAND`), we can use an include file which is written by the application. Of the way back results can be read from a PUT file. The GAMS file can now look like:
Sets
  i  canning plants  / seattle, san-diego /
  j  markets  / new-york, chicago, topeka /

Parameters
  a(i) capacity of plant i in cases
     / seattle 350
     san-diego 600 /
  b(j) demand at market j in cases
     / $include demand.inc /

Table d(i,j) distance in thousands of miles
new-york  chicago  topeka
seattle   2.5      1.7      1.8
san-diego 2.5      1.8      1.4

Scalar f freight in dollars per case per thousand miles /90/;

Parameter c(i,j) transport cost in thousands of dollars per case;
  c(i,j) = f * d(i,j) / 1000;

Variables
  x(i,j) shipment quantities in cases
  z    total transportation costs in thousands of dollars;

Positive Variable x;

Equations
  cost       define objective function
  supply(i) observe supply limit at plant i
  demand(j) satisfy demand at market j;

  cost..    z =e= sum((i,j), c(i,j)*x(i,j));
  supply(i).. sum(j, x(i,j)) =l= a(i);
  demand(j).. sum(i, x(i,j)) =g= b(j);

Model transport /all/;

Solve transport using lp minimizing z;

Display x.l, x.m;

file fout /results.txt/;
pout fout;
loop((i,j),
  pout x.l(i,j):17:5/);
poutclose;
The corresponding C program could look like:

//
// example of running a GAMS model

#include <stdio.h>

// number of supply and demand locations
#define M 2
#define N 3

char* dist[M] = {"seattle", "san-diego"};
char* city[N] = {"new-york", "chicago", "topeka"};
double demand[N] = {325.0, 300.0, 275.0};
double ship[M][N];

int main(int argc, char** argv)
{
  FILE *f;
  int i, j;

  // write include file
  FILE *f = fopen("demand.inc","wt");
  if (f == NULL)
  {
    perror("fopen");
    exit(1);
  }
  for (i=0; i<N; ++i)
    fprintf(f,"%s %g\n",city[i],demand[i]);
  fclose(f);

  // call GAMS
  system("gams trnsport lo=2");

  // read solution
  FILE *f = fopen("results.txt","rt");
  if (f == NULL)
  {
    perror("fopen");
    exit(1);
  }
  for (i=0; i<M; ++i)
    for (j=0; j<N; ++j)
      fscanf(f,"%lg", &ship[i][j]);
  fclose(f);

  // display results
  for (i=0; i<M; ++i)
    for (j=0; j<N; ++j)
      printf("%s->%s %g\n", dist[i], city[j], ship[i][j]);

  return 0;
}

3.21.4 Spawning GAMS from Visual Basic

This example shows how GAMS can be invoked from a VB program.

When executed a simple window appears where a GAMS model can be specified and possible other
command line options. The [GAMS] button will execute the model.

When the Normal display is used, a console window will be opened. This console window will be closed
automatically at the end of the run if the Close process window on completion check box is checked.
Minimized does not show a window, but in the taskbar an icon will appear. If the job takes a long time,
the user can click on this icon to make the console window visible. The Hidden option prevents any
GAMS associated window or icon to appear.

Note: it is required for this program to work, that the GAMS system directory is in the path. If this is
not the case, an error code of -1 is returned.

The main program is attached below, the full source for this example is "available for download".

3.21 Executing GAMS from other Environments

Attribute VB_Name = "vbGAMS"
Option Explicit

' Module Name: VBGams
' File: gams.bas
' Version: 1.1

' Functions:
' VB_Gams32 - sets up process directory, parameter file, and console, and manages
' looping of gams compiler and solver.

' --------
' Function VB_Gams32
' Sets up process directory, parameter file, and console, and manages
' looping of gams compiler and solver.

' Parameters
' sParams String Command line arguments
' nDisplayMode Integer GAMS_NORMAL, GAMS_MIN, or GAMS_HIDDEN
' bCloseWin Boolean Close the console on completion of gams job

3.21.5 Spawning GAMS from Delphi

This is a Delphi 4 application that has similar features as the Visual Basic application described in the previous paragraph.

Note: it is required for this program to work, that the GAMS system directory is in the path. If this is not the case, an error code of -1 is returned. The main code is attached below, the full source and the executable for this example are "available for download".

```pascal

3.21.6 Spawning GAMS from Visual C++

In "this example" we call GAMS from a simple Visual C++ application.

The additional concern is here that we want to intercept the GAMS screen output so it can be written to a multi-line edit control. For more information about the used technique see the Microsoft publication: HOWTO: Spawn Console Processes with Redirected Standard Handles (Q190351) in the Microsoft Knowledge Base.

3.21.7 Spawning GAMS from C#

Below is a simple example:

```csharp
using System.Diagnostics;

void RunGamsModel()
{
    Process p = new Process();
    p.StartInfo.FileName = gamsexe;
    ```
The command line formed here is `gams modelname LO=0 --runid=xxx`. The option `LO` (logoption) will disable writing a log, and the option `--runid` passes a parameter to the GAMS model (inside the model you can access this through `runid%`).

### 3.21.8 Spawning GAMS from Java

Java has a class `Runtime` that implements spawning of processes using the `Exec()` method. This is quite trivial to use in applications, but in applets the default security settings don’t allow this operation (in general). The problem can be solved by loading the applet from a local drive or by using a signed applet. Similarly if the Java classes are loaded from inside a database, this operation may require additional privileges. For an example see the previous section, where GAMS is called from Oracle using a Java Stored Procedure. The relevant code may look like:

```java
import java.io.File;

class RunGAMS {
    public static void main(String[] args) {
        System.out.println("Start");
        String[] cmdArray = new String[5];
        cmdArray[0] = "+<PATH/TO/GAMS>\" + File.separator + "gams\";
        cmdArray[1] = "<PATH>\" + File.separator + "trnsport.gms\";
        cmdArray[2] = "WDIR=<PATH>\" + File.separator + "TMP\";
        cmdArray[3] = "SCRDIR=<PATH>\" + File.separator + "TMP\";
        cmdArray[4] = "LO=2\";
        try {
            Process p = Runtime.getRuntime().exec(cmdArray);
            p.waitFor();
        } catch (java.io.IOException e) {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        } catch (InterruptedException e) {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        }
        System.out.println("Done");
    }
}
```

Below another example, which avoids problems, if the model has a long screen log (the buffer gets filled and locks the execution), which could happen if GAMS does not write the log to the file like above. This example is based on suggestion made by Edson Valle.

```java
import java.io.File;
import java.io.BufferedReader;
import java.io.InputStreamReader;

class RunGAMS {
    public static void main(String[] args) {
        System.out.println("Start");
        String[] cmdArray = new String[5];
        cmdArray[0] = "<PATH/TO/GAMS>\" + File.separator + "gams.exe\";
        cmdArray[1] = "<PATH>\" + File.separator + "trnsport.gms\";
        cmdArray[2] = "<PATH>\" + File.separator + "tmp\";
        cmdArray[3] = "LO=3\";
        try {
            Process p = Runtime.getRuntime().exec(cmdArray);
            BufferedReader stdInput = new BufferedReader(new InputStreamReader(p.getInputStream()));
            BufferedReader stdError = new BufferedReader(new InputStreamReader(p.getErrorStream()));
            String s;
            while ((s = stdInput.readLine()) != null) {
                System.out.println("<<<<" + s);
            }
            while ((s = stdError.readLine()) != null) {
                System.out.println("<<<<" + s);
            }
        } catch (java.io.IOException e) {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        } catch (InterruptedException e) {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        }
        System.out.println("Done");
    }
}
```
String s = null;
while((s=stdInput.readLine()) !=null){
    System.out.println(s);
}
p.waitFor();
} 

catch (java.io.IOException e )
{
    System.err.println(">>>>" + e.getMessage() );
e.printStackTrace();
}
catch (InterruptedException e )
{
    System.err.println(">>>>" + e.getMessage() );
e.printStackTrace();
} 
System.out.println("Done");

For an example of GAMS usage from a Java based server environment see Alexander Sokolov, Information environment and architecture of decision support system for nutrient reduction in the Baltic Sea, Department of Systems Ecology, Stockholm University.

3.21.9 Spawning GAMS from a Web Server

Running GAMS remotely using a Web based thin-client architecture requires that GAMS is executed directly or indirectly from the Web server or HTTP server. A simple way of doing this is via a CGI process. Common Gateway Interface (CGI) programs can be written in many languages such as C, Perl or Delphi. CGI is relatively slow, as for each interaction, even the most simple one, a process needs to be started. Alternatives exist in the form of CGI extensions such as FastCGI or using DLLs or shared libraries. A basic algorithm for a CGI script could be:

- Create a unique directory, and CD to that directory.
- Get information from user forms and save it as GAMS readable files.
- Run GAMS making sure it does not write the log to the screen (i.e. use the option LO=2 (log to a file) or LO=3 (log to stdout)).
- Let the model write solution info to text files using the PUT statement.
- Read solution, and create formatted HTML to send back to the user.
- Remove temp files and directory.

Complications arise when there is a need to show graphics (files need to be stored somewhere and discarded after a while), when jobs take a long time to finish (you will need to add a facility where the user can pick up results at a later moment) or when the server resources can be exhausted (e.g. because of a large number of simultaneous users or because of large models).

An important complicating issue in the above list are jobs that take more time to finish: web servers like to respond to the user within a short time, and time out errors will occur if a job takes a long time. The solution is to use a queue based approach. An actual implementation available is the NEOS Server - there is also a GAMS interface to NEOS: KESTREL - Remote Solver Execution on NEOS Servers.
3.21 Executing GAMS from other Environments

3.21.10 Spawning GAMS from PHP

A minimal example

index.html

```html
<html>
<body>
<form action="calling_gams.php" method="post">
  Solve transport with f = <select name="f">
    <option>70</option>
    <option>80</option>
    <option>90</option>
    <option>100</option>
  </select>
  <input type="submit" value="call GAMS"/>
</form>
</body>
</html>
```

calling_gams.php

```php
<?php
$f = $POST['f'];

//some model data
$modelfile = 'transport_php.gms';
$city = array('new-york','chicago', 'topeka');
$demand = array(325.0, 300.0, 275.0);

//write demand.inc
$fh = fopen('./demand.inc', 'w+');
for($i=0; $i<count($city); $i++){
  fwrite($fh, $city[$i]." "$demand[$i]."n");
}
fclose($fh);

//write f.inc
$fh = fopen('./f.inc', 'w+');
fwrite($fh, $f);
fclose($fh);

//call gams
system('gams '.$modelfile.' lo=2');

//read solutions
$fh = fopen('./results.txt', 'r');
echo '<p>result of '.basename($modelfile). ' (f='.$f.'):</p>';
while (!feof($fh)){
  $line = fgets($fh);
echo '<p>'.$line.'</p>';
}
fclose($fh);
?>
```

transport_php.gms

Sets

```plaintext
i  canning plants / seattle, san-diego /

3.22 Introduction

3.22.1 Summary

Today, algebraic modeling languages are widely accepted as the best way to represent and solve mathematical programming problems. Their main distinguishing features are the use of relational algebra and
the ability to provide partial derivatives on multidimensional, very large and sparse structures. In this chapter we will briefly describe some of the origins of GAMS and provide background information that shaped early design decisions.

3.22.2 The Origins of GAMS

The initial Research and Development of GAMS was funded by the International Bank for Reconstruction and Development, usually referred to as The World Bank. Since 1987, further Research and Development has been funded by GAMS Development Corporation. GAMS was developed in close cooperation of mathematical economists who were and still are an important group of GAMS users. The synergy between economics, computer science and operations research was the most important success factor in the development of the system. Mathematical Programming and economics theory are closely intertwined. The Nobel Prize in Economics awarded to Leonid Kantorovich and Tjalling Koopmans in 1975 for their “contribution to the theory of optimal allocation of resources” was really a prize in mathematical programming. Other Nobel laureates like Kenneth Arrow in 1972, Wassily Leontief in 1973, and Harry Markowitz in 1990 are well known names in math programming. Another early example of this synergy is the use of LP in refining operations, which was started by Alan Manne, an economist, with his book on Scheduling of Petroleum Refinery Operations in 1956.

The origins of linear programming algorithms all go back to George Dantzig’s early work in the 1940s and 1950s. Computing technology and algorithmic theory had developed at a rapid pace. Thirty years later, we could solve problems of practical size and complexity that allowed us to test of the economic theory on real life problems. The research agenda at the World Bank in the 1970s and 1980s created the perfect environment to bring different disciplines together to apply mathematical programming to research and operational questions in Economic Development.

3.22.3 Background and Motivation

From the very beginning, the driving force behind the development of the General Algebraic Modeling System (GAMS) has been the users of mathematical programming who believed in optimization as a the powerful and elegant framework for solving real life problems in the sciences and engineering. At the same time, these users were frustrated with the high cost, skill requirements, and overall low reliability of applying optimization tools. Most of our initiatives and support for new development came from the worlds of economics, finance, and chemical engineering. These disciplines find it natural to view and understand the world and its behavior as a mathematical program.

GAMS’s impetus for development arose out of the frustrating experiences of a large economic modeling group at the World Bank. In hindsight, one may call it a historical accident that in the 1970s mathematical economists and statisticians were assembled to address problems of development. They used the best techniques available at the time to solve multisectoral economy-wide models and large simulation and optimization models in agriculture, steel, fertilizer, power, water use, and other sectors. Although the group produced impressive research, initial successes were difficult to reproduce outside their well functioning research environment. The existing techniques to construct, manipulate, and solve such models required several manual, time-consuming, and error-prone translations into the different, problem-specific representations required by each solution method. During seminar presentations, modelers had to defend the existing versions of their models, sometimes quite irrationally, because the time and money needed to make proposed changes were prohibitive. Their models just could not be moved to other environments, because special programming knowledge was needed, and data formats and solution methods were not portable.

The idea of an algebraic approach to represent, manipulate, and solve largescale mathematical models fused old and new paradigms into a consistent and computationally tractable system. Using matrix generators (see appendix GAMS versus Fortran Matrix Generators) for linear programs taught us the importance of naming rows and columns in a consistent manner. The connection to the emerging relational data model became evident. Painful experience using traditional programming languages to manage
those name spaces naturally lead one to think in terms of sets and tuples, and this led to the relational data model. Combining multidimensional algebraic notation with the relational data model was the obvious answer. Compiler writing techniques were by now widespread, and languages like GAMS could be implemented relatively quickly. However, translating this rigorous mathematical representation into the algorithm specific format required the computation of partial derivatives on very large systems. In the 1970s, TRW developed a system called PROSE that took the ideas of chemical engineers to compute point derivatives that were exact derivatives at a given point, and to embed them in a consistent, fortran-style calculus modeling language. The resulting system allowed the user to use automatically generated exact first and second order derivatives. This was a pioneering system and an important demonstration of a concept. However, in our opinion PROSE had a number of shortcomings: it could not handle large systems, problem representation was tied to an array-type data structure that required address calculations, and the system did not provide access to state-of-the art solution methods. From linear programming, we learned that exploitation of sparsity was the key to solve large problems. Thus, the final piece of the puzzle was the use of sparse data structures.

With all pieces in place, all we had to do was adopt the techniques to fit into one consistent framework and make it work for large problems.

### 3.22.4 Design Goals and Changing Focus

The original and still valid goal is to improve the model builder’s productivity, reduce costs, and improve reliability and overall credibility of the modeling process. To achieve this, we established the following key principles to guide the GAMS development:

- The problem representation is independent of the solution method.
- The data representation follows the relational data model.
- The problem and data representations are independent of computing platforms.
- The problem and data representations are independent of user interfaces.
- Optimization methods will fail, and systems have to be designed to be fail-safe.

Another way to express these principles is to think in terms of layers of representations and capabilities that have clearly defined interfaces and functions. The oldest and most basic layer is the solver layer or implementation of a specific algorithm. Above the solver is the model layer, expressed in an algebraic modeling language. The modeling layer translates the mathematical representation into a computational structure required by a specific solution method and provides various services such as function and derivative evaluations and error recovery. Above the modeling layer is the application or domain layer, which is highly context sensitive and has knowledge about the problem to be solved and the kind of user interacting with the system.

The representation of the model in GAMS is in a form that can be easily read by humans and by machines. This means that the GAMS program itself is the documentation of the model, and that the separate description required in the past (which was a burden to maintain, and which was seldom up-to-date) is no longer needed. Moreover, the design of GAMS incorporates the following features that specifically address the user’s documentation needs:

- A GAMS model representation is concise, and makes full use of the elegance of the mathematical representation.
- All data transformations are specified concisely and algebraically. This means that all data can be entered in their most elemental form and that all transformations made in constructing the model and in reporting are available for inspection.
• Explanatory text can be made part of the definition of all symbols and is reproduced whenever associated values are displayed.

• All information needed to understand the model is in one document.

Of course some discipline is needed to take full advantage of these design features, but the aim is to make models more accessible, more understandable, more verifiable, and hence more credible.

It is instructive to put the development of modeling systems into some historic perspective and see how the focus and technical constraints have changed in the last 30 years. We can observe three major phases that shift the emphasis from computational issues to modeling issues and finally the application or the real problems. Each phase defined one of the main system layers discussed above. The dominant constraints in the first phase were the computational limits of our algorithms. Problem representation had to abide by algorithmic convenience, centralized expert groups managed large, expensive and long-lasting projects and end users were effectively left out. The second phase has the model in focus. Applications are limited by modeling skill, project groups are much smaller and decentralized, the computational cost are low and the users are involved in the design of the application. Applications are designed to be independent of computing platforms and frequently operate in a client-server environment.

We believe that we are entering a third phase which has the application as its focus and the optimization model is just one of many analytic tools that help making better decisions. The users are often completely unaware of any optimization model or use a mental model that is different from the actual model to solved by optimization techniques. User interfaces are build with off-the-shelf components and frequently change to adjust to evolving environments and new computing technologies. As with databases, modeling components have a much longer life than user interfaces. We have observed cases where the model has remained basically unchanged over many years, whereas the computing environments and user interfaces have changed several times. The solvers used to solve the models have changed, the computing platforms have changed, the user interfaces have changed and the overall performance of the model has changed without any change in the model representation.

3.23 GAMS Programs

3.23.1 Introduction

This chapter provides a look at the structure of the GAMS language and its components. It should be emphasized again that GAMS is a programming language, and that programs must be written in the language to use it. A GAMS program is contained in a disk file, which is usually constructed with a text editor of choice (e.g. the GAMS IDE). When GAMS is 'run', the file containing the program (the input file) is submitted to be processed. After this processing has finished, the results, which are in the output file(s), can be inspected. By default the GAMS log appears on the screen while GAMS runs, keeping the user informed about progress and error detection. It is the responsibility of the user to inspect the output file(s) carefully to see the results and to diagnose any errors.

3.23.2 The Structure of GAMS Programs

GAMS programs consist of one or more statements (sentences) that define data structures, initial values, data modifications, and symbolic relationships (equations). While there is no fixed order in which statements have to be arranged, the order in which data modifications are carried out is important. Symbols must be declared as to type before they are used, and must have values assigned before they can be referenced in assignment statements. Each statement is followed by a semicolon except the last statement, where a semicolon is optional.

Note

The semicolon at the end of a statement can be omitted if a new GAMS keyword follows. However, to improve readability of the code, it is recommended to use the semicolon at the end of a statement anyway.
3.23.2.1 Format of GAMS Input

GAMS input is free format. A statement may be placed anywhere on a line, multiple statements may appear on a line, or a statement may be continued over any number of lines as follows:

```
statement;
statement;
statement; statement; statement;
the words that you are now reading is an example of a very long statement which is stretched over two lines;
```

Blanks and end-of-lines may generally be used freely between individual symbols or words. GAMS is not case sensitive. This means that lower and upper case letters may be mixed freely but are treated identically. Up to 80,000 characters may be placed on a line and completely blank lines may be inserted for easier reading.

Not all lines are a part of the GAMS language. Two special symbols, the asterisk `*' and the dollar symbol `$` may be used in the first position on a line to indicate a non-language input line. An asterisk in column one means that the line will not be processed, but treated as a comment. For more on comments, see section Comments. A dollar symbol in the first position indicates that compiler options or directives are contained in the rest of the line (see chapter Dollar Control Options for more information).

For example, multiple files may be used as input through the use of the `$include` facility. In short, the statement

```
#include file1
```

inserts the contents of the specified file (`file1` in this case) at the location of the call. A more complex versions of this is the option `$batinclude`. Both options are introduced and discussed in details in chapter Dollar Control Options.

3.23.2.2 Classification of GAMS Statements

Each statement in GAMS is classified into one of two groups:

1. Declaration and definition statements.
2. Execution statements.

A declaration statement describes the class of a symbol. Often initial values are provided in a declaration, then it may be called a definition. The specification of symbolic relationships for an equation is a definition. The declaration and definition statements are:

- acronym
- alias
- equation declaration
- equation definition
- file
- function
Execution statements are instructions to carry out actions such as data transformation, model solution, and report generation. The execution statements are:

- abort
- assignment
- break
- continue
- display
- execute
- for
- if
- loop
- option
- put
- put_utility
- putclear
- putclose
- puthd
- putpage
- putl
- repeat
- solve
- while

Note

While an assignment is an execution statement, it also defines the symbol on the left hand side of the assignment.

Although there is great freedom about the order in which statements may be placed in a GAMS program, certain arrangements are commonly used. The two most common are discussed next.
3.23.2.3 Organization of GAMS Programs

One common style of organizing GAMS statements places the data first, followed by the model and the solution statements.

**Style 1:**

*Data:*

Set declarations and definitions
Parameter declarations and definitions
Assignments
Displays

*Model:*

Variable declarations
Equation declarations
Equation definitions
Model definition(s)

*Solutions:*

Solve(s)
Displays

In this style of organization, the sets are placed first. Then the data is specified with parameter, scalar, and table statements. Next, the model is defined with the variable declarations, equation declarations, equation definitions and one or more model statements. Finally, the model is solved and the results are displayed. One can refer to the model transport as an example for this style.

A second style emphasizes the model by placing it before the data. This is a particularly useful order when the model is to be solved repeatedly with different data sets.

**Style 2:**

*Model:*

Set declarations
Parameter declarations
Variable declarations
Equation declaration
Equation definition
Model definition

*Data:*

Here, there is a separation between declaration and definition. For example, sets and parameters may be declared first with the following statements:

Set c "crops" ;
Parameter yield(c) "crop yield" ;

Later they may be defined with the statements:

Set c / wheat, clover, beans / ;
Parameter yield(c) / wheat 1.5
                   clover 6.5
                   beans 1.0 / ;

The first statement declares that the identifier c is a set and the later statement defines the elements in this set. Similarly, in the second statement yield is declared to be a parameter and later the corresponding data is given.

Note

Sets and parameters that are used in equations must be declared before the equations are specified. However, they may be defined after the equation specifications but before the specific equation is used in a solve statement. This gives GAMS programs substantial organizational flexibility.

3.23.3 Data Types and Definitions

Each symbol or identifier has exactly one of the following basic GAMS data types:

- acronyms
- equations
- files
- functions
- models
- parameters
- sets
- variables
Note

- **Scalars** and **tables** are not separate data types but convenient input formats for the data type parameter. For details see the overview Parameters, Scalars and Tables.
- GAMS uses shorthand symbols for each data type in the output. For details see the overview GAMS Data Types and their Shorthand Symbols.

Declarations have common characteristics. The following example has a typical structure:

```
Parameter a(i,j) "input-output matrix" ;
```

The structure is:

**Keyword for data type** - **identifier (with index list)** - **explanatory text** ;

Note that the index list (or domain list) and the explanatory text are always optional characteristics. However, we recommend to specify the index list if the data type is defined over a domain; the advantages of this practice are outlined in section Domain Checking.

Note

Variables, sets, parameters and equations may be declared and defined over one or more indices or dimensions. Currently the maximum number of dimensions for all these data types is 20.

It is also recommend to add an explanatory text for reasons of clarity. For more on explanatory texts, see section Text below. Other examples for declarations follow:

```
Set time "time periods" ;
Model turkey "turkish fertilizer model" ;
Variables x,y,z ;
```

Observe that in the last example a number of identifiers (separated by commas) is declared in one statement.

### 3.23.4 Language Items

Before proceeding with more language details, a few basic symbols need to be defined and the rules for recognizing and writing them in GAMS established. These basic symbols are often called lexical elements and form the building blocks of the language. They are:

- **characters**
- **comments**
- **delimiters**
- **identifiers (idents)**
- **labels**
- **numbers**
- **reserved words and tokens**
- **text**

Each of these items is discussed in detail in the following subsections.

Attention

As noted previously, GAMS is not case sensitive, so we may use any mix of lower and upper case.
3.23.4.1 Characters

A few characters are not allowed in a GAMS program, because they are illegal or ambiguous on some machines. Generally, all unprintable and control characters are illegal. The only place where any character is legal, is in an $context-$softtext block as illustrated in section Block Comments below. For completeness, the full set of legal characters are listed in Table 1. Note that most of the uncommon punctuation characters are not part of the language, but they may be used freely in the context of explanatory texts, comments, and labels (if quoted). Similarly, special language specific characters (e.g. ä, ß, à, é, ç, ò, ñ) may also be used freely in explanatory texts, comments, and labels (if quoted).

Table 1: Legal Characters

<table>
<thead>
<tr>
<th>Legal Characters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A to Z</td>
<td>alphabet</td>
</tr>
<tr>
<td>a to z</td>
<td>alphabet</td>
</tr>
<tr>
<td>0 to 9</td>
<td>numerals</td>
</tr>
<tr>
<td>+</td>
<td>plus</td>
</tr>
<tr>
<td>-</td>
<td>minus</td>
</tr>
<tr>
<td>=</td>
<td>equals</td>
</tr>
<tr>
<td>&lt;</td>
<td>less than</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
</tr>
<tr>
<td>( )</td>
<td>parenthesis</td>
</tr>
<tr>
<td>[ ]</td>
<td>square brackets</td>
</tr>
<tr>
<td>{ }</td>
<td>braces</td>
</tr>
<tr>
<td>'</td>
<td>single quote</td>
</tr>
<tr>
<td>&quot;</td>
<td>double quote</td>
</tr>
<tr>
<td>\</td>
<td>back slash</td>
</tr>
<tr>
<td>/</td>
<td>slash</td>
</tr>
<tr>
<td>,</td>
<td>comma</td>
</tr>
<tr>
<td>:</td>
<td>colon</td>
</tr>
<tr>
<td>;</td>
<td>semicolon</td>
</tr>
<tr>
<td>.</td>
<td>dot</td>
</tr>
<tr>
<td>?</td>
<td>question mark</td>
</tr>
<tr>
<td>!</td>
<td>exclamation mark</td>
</tr>
<tr>
<td>space</td>
<td></td>
</tr>
<tr>
<td>_</td>
<td>underscore</td>
</tr>
<tr>
<td>&amp;</td>
<td>ampersand</td>
</tr>
<tr>
<td>^</td>
<td>circumflex</td>
</tr>
<tr>
<td>#</td>
<td>pound sign</td>
</tr>
<tr>
<td>*</td>
<td>asterisk</td>
</tr>
<tr>
<td>%</td>
<td>percent</td>
</tr>
<tr>
<td>@</td>
<td>at</td>
</tr>
<tr>
<td>$</td>
<td>dollar</td>
</tr>
</tbody>
</table>

Note

Not every character listed above is allowed to be used in every place (for example, identifiers have certain limitations).
3.23.4.2 Reserved Words

GAMS, like other programming languages such as C and Java, uses reserved words (often also called keywords) that have predefined meanings. Users are in general not permitted to use these for their own definitions, neither as identifiers nor labels. The complete list of reserved words is given below. In addition, a small number of symbols constructed from non-alphanumeric characters have a meaning in GAMS.

Note
While it is not allowed to use reserved words as identifiers and labels in general, it is still possible (put not recommended) in certain cases which are explained in more detail further below.

- abort
- acronym[s]
- alias
- all
- and
- binary
- break
- card
- continue
- diag
- display
- do*
- else
- elseif
- endif*
- endloop*
- endwhile*
- eps
- equation[s]
- execute
- execute_load
- execute_loadde
- execute_loadhandle
- execute_loadpoint
- execute_unload
- execute_unloaddi
- execute_unloadidx
• file[s]
• for
• free
• function[s]
• if
• inf
• integer
• logic
• loop
• model[s]
• na
• negative
• nonnegative
• no
• not
• option[s]
• or
• ord
• parameter[s]
• positive
• procedure[s] (deprecated)
• prod
• put
• put_utility/put_utilities
• putclear
• putclose
• putfmcl
• puthd
• putheader
• putpage
• puttitle
• puttl
• repeat
• sameas
• scalar[s]
• semicont
• semiint
• set[s]
• singleton
• smax
• smin
• solve
• sos1
• sos2
• sum
• system
• table[s]
• then*
• undf
• until
• variable[s]
• while
• xor
• yes

Attention

Some of the keywords above can actually be used as an identifier (e.g. sameas). But if they get used as identifier, their built-in meaning as part of the GAMS language can not be accessed anymore.

Note

The words marked with * in the list above are no reserved words by default. However, they get a special meaning if the dollar control option $onEnd is set.

The following list shows words which have a special meanings in GAMS (e.g. they are part of the solve statement), but can be used as identifiers anyway:

• eq
• eqv
• ge
• gt
• imp
• le
• lt
• maximizing
minimizing
ne
scenario
using

The reserved non-alphanumeric symbols are:

.. 
=1=
=2=
=3=
=4=
=5=
=6=
=7=
=8=
=9=
- -
++
**
->
<=>

3.23.4.3 Identifiers

Identifiers are the names given to sets, parameters, variables, models, etc. GAMS requires an identifier to start with a letter followed by more letters or digits. The length of an identifier is currently limited to 63 characters. Identifiers may only contain alphanumeric characters (letters or numbers) or underscores (_). Examples of legal identifiers are:

a a15 revenue x0051

Note that the following identifiers are incorrect:

15 $casg milk&meat

Attention
A name used for one data type cannot be reused for another.
3.23.4.4 Labels

Labels are set elements. They may be up to 63 characters long and may be used in quoted or unquoted form.

The unquoted form is simpler to use but places restrictions on characters allowed, in that any unquoted label must start with a letter or digit and can only be followed by letters, digits, underscores (\_\_) or the sign characters + and -. Examples of valid unquoted labels are:

Phos-Acid 1986 1952-53 A
September H2SO4 Line-1

Quotes can be used to delimit labels. Quoted labels may begin with and include any legal character. Either single or double quotes may be used but the closing quote has to match the opening quote. A label quoted with double quotes may contain a single quote (and vice versa). Most experienced users avoid quoted labels because they can be tedious to enter and confusing to read. There are a couple of special circumstances though. If we want to make a label stand out, we could put asterisks in it and indent it. A more subtle example is that GAMS keywords may be used as labels if they are quoted. So labels like parameter, put or while may be used if they are quoted. Some examples of quoted labels follow:

' *TOTAL*' "MATCH" '10%-INCR' '12" / FOOT' "line 1"

Note

- Labels do not have any numerical value. The label '1986' does not have the numerical value 1986 and the label '01' is different from the label '1'. One can access the numerical value of a label with the Set Attributes .val attribute.
- Leading blanks in a label are significant and preserved while trailing blanks are trimmed. So ' label1' is different from 'label1', but 'label1' is identical to 'label2'.

To summarize, set names are identifiers and set elements are labels. An overview of the rules for constructing identifiers and labels is given in the following table.

<table>
<thead>
<tr>
<th></th>
<th>Identifiers</th>
<th>Unquoted Labels</th>
<th>Quoted Labels</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of characters</td>
<td>63</td>
<td>63</td>
<td>63</td>
</tr>
<tr>
<td>Must begin with</td>
<td>A letter</td>
<td>A letter or a number</td>
<td>Any character</td>
</tr>
<tr>
<td>Permitted special characters</td>
<td>Underscore (_)</td>
<td>Underscore (_) and the characters + and -</td>
<td>Any but the starting quote</td>
</tr>
</tbody>
</table>

Table 2: Rules for constructing identifiers and labels

3.23.4.5 Text

Identifiers and set elements may also be associated with a line of descriptive text. This text is more than a comment: it is retained by GAMS and is displayed whenever results are written for the identifier.

Text may be quoted or unquoted. Quoted text may contain any character except the quote character used. Single or double quotes may be used but they must match. Text has to fit on one line and cannot exceed 255 characters in length. Text used in unquoted form must follow a number of mild restrictions.
Unquoted text cannot start with a reserved word, '.' or '=' and must not include semicolons ';', commas ',', or slashes '/'. End of lines terminate a text. These restrictions are a direct consequence of the GAMS syntax and are usually followed naturally by the user. Some examples are:

```
this is text
final product shipment (tpy)
"quoted text containing otherwise illegal characters ; /,"
'use single quotes to put a "double" quote in text'
```

### 3.23.4.6 Numbers

Numeric values are entered in a style similar to that used in other computer languages

**Attention**

- Blanks cannot be used in a number: GAMS treats a blank as a separator.
- The common distinction between real and integer data types does not exist in GAMS. If a number is used without a decimal point it is still stored as a real number.

In addition, GAMS uses an extended range arithmetic that contains special symbols for infinity (INF), negative infinity (-INF), undefined (UNDF), epsilon (EPS), and not available (NA). The user cannot enter UNDF; it is only produced by an operation that does not have a proper result, such as division by zero. All the other special symbols may be entered and used as if they were ordinary numbers. For more details, see section Extended Range Arithmetic.

The following example shows various legal ways of entering numbers:

```
0  156.70  -135  .095  1.
2e10  2e+10  15.e+10  .314e5  +1.7
0.0  .0  0.  INF  -INF
EPS  NA
```

The letter $e$ denotes the well-known scientific notation allowing convenient representation of very large or small numbers. For example,

```
1e-5 = 1 * 10^-5 = 0.00001;
3.56e6 = 3.56 * 10^6 = 3,560,000;
```

**Note**

- GAMS uses a smaller range of numbers than many computers are able to handle. This has been done to ensure that GAMS programs will behave in the same way on a wide variety of machines, including personal computers. GAMS will create an error if a number with an absolute value greater or equal to $1.0e+300$ is used.
- A number may be entered with up to 16 significant digits. The dollar control option $\$offDigit$ can be used to control the behavior if this number is exceeded.
3.23.4.7 Delimiters

As mentioned before, statements are separated by a semicolon ';'. However, if the next statement begins with a reserved word (often called keyword in succeeding chapters), then GAMS does not require that the semicolon is used.

The characters comma ',' and slash '/' are used as delimiters in data lists, to be introduced later. The comma terminates a data element (as does an end-of-line) and the slash terminates a data list.

3.23.4.8 Comments

A comment is an explanatory text that is not processed or retained by the computer. There are several ways to include comments in a GAMS program.

3.23.4.8.1 Blank Lines  The user may freely enter blank lines to set off certain sections and enhance readability. For example, in transport there are blank lines between the different parameters:

```
Sets
  i  "canning plants" / seattle, san-diego /
  j  "markets"      / new-york, chicago, topeka / ;

Parameters
  a(i)  "capacity of plant i in cases"
        / seattle  350
        san-diego 600  /
  b(j)  "demand at market j in cases"
        / new-york 325
        chicago  300
        topeka   275  / ;
```

3.23.4.8.2 Single Line Comments  Users may insert a single line comment on any line by placing an asterisk * in column 1. The text that follows the asterisk is the comment and may contain GAMS reserved words, messages or any other content. It is completely ignored by the GAMS compiler. Note that several successive lines may be single line comments as in the example below.

The default asterisk * may be replaced by other symbols. GAMS provides the dollar control option $comment to customize the comment character (for more on dollar control options, see chapter Dollar Control Options). The new comment character cannot be used in column 1 as before, since now it has a special meaning. The change of comment character should be used with great care. An example can be seen here:

```
*normal comment
*next line is a deactivated GAMS statement
  * x=sum(I,z(i));
$comment !
!comment with new character
$comment *
*now we are back to how it should be
```

In the fourth line, the new comment character ! replaces the GAMS default * as the comment delimiter. Note that single line comments appear in the echo print of the GAMS output as numbered lines. For details see section The Echo Print of the Input File.
### 3.23.4.8.3 Block Comments
For longer comments special 'block' delimiters may be used that cause GAMS to ignore an entire section of the program. The dollar control option $ontext marks the beginning of the comment block and the option $offtext marks the end. Note that the $ symbol must be in the first character position. The example below illustrates the use of the block comment and also contains some useful information. For more on dollar control options, see chapter Dollar Control Options.

$ontext
Following a $ontext directive in column 1 all lines are ignored by GAMS but printed on the output file until the matching $offtext is encountered, also in column 1. This facility is often used to logically remove parts of programs that are not used every time, such as statements producing voluminous reports. Every $ontext must have a matching $offtext in the same file $offtext

Note that block comments appear in the echo print without line numbers. For details see section The Echo Print of the Input File.

### 3.23.4.8.4 End-of-Line Comments
Comments may also be placed at the end of a line that contains GAMS code. The dollar control option $onEolCom activates end-of-line comments. The default symbol to indicate that the comment begins is a double exclamation mark !!. This symbol may be reset with the option $eolCom followed by the desired symbol which may be one character or a two-character sequence. The following example serves as illustration. For more on dollar control options, see chapter Dollar Control Options.

Scalar x /0/;
$onEolCom
x=x+1; !! eol comment
x = x !! eol comment in line of GAMS statement, where the GAMS statement continues to the next +1;
$eolCom &&
x=x+1; && eol comment with new symbol

Note that the option to add end-of-line comments may be deactivated with the dollar control option $offEolCom. End-of-line comments appear in the echo print on the appropriate lines. For details see section The Echo Print of the Input File.

### 3.23.4.8.5 In-Line Comments
Comments may also appear in a line of GAMS code. The dollar control option $onInline activates in-line comments. By default, the in-line comment symbols are set to the two character pairs '/∗' and '∗/', where '/∗' indicates that the in-line comment begins and '∗/' indicates that the in-line comment ends. The comment may span lines till the end-of-comment characters are encountered. The in-line comment symbols may be reset with the option $inLineCom followed by the desired pair of characters. The following example serves as illustration. For more on dollar control options, see chapter Dollar Control Options.

Scalar x /0/;
$onInLine
x=x /* in-line comment*/ +1;
x=x /* in-line comment in line
that continues to next line */
+1;
$inLineCom /& &/
x=x /* in-line comment with new character &/ +1;

Note that the option to add in-line comments may be deactivated with the dollar control option $offInLine. In-line comments appear in the echo print on the appropriate lines. For details see section The Echo Print of the Input File. Note that in-line comments may be allowed to be nested using the dollar control option $onNestCom.
3.23.4.8.6  Outside Margin Comments  GAMS provides the facility to define margins. The active code is within the margins, everything outside the set margins is ignored by the compiler and treated as comment. The dollar control option $onMargin activates margin marking and $offMargin deactivates it. The option $minCol is used to specify the first column, where GAMS code that is to be compiled may appear. Similarly, the option $maxCol is used to specify the last column for GAMS code. The following example shows how this works. For more on dollar control options, see chapter Dollar Control Options.

\$ontext

1 2 3 4 5 6
12345678901234567890123456789012345678901234567890
\$offtext

\$onMargin minCol 20 maxCol 45
Now I have
set i plant /US, UK/   This defines i
turned on the
scalar x / 3.145 /   A scalar example.
margin marking.
parameter a, b;
Define some
parameters.

\$offMargin

The text before column 20 and after column 45 is treated as a comment. Note that the full content of the lines is copied to the echo print, including everything outside the margins. For details see section The Echo Print of the Input File.

3.23.4.8.7  Hidden Comments  Finally, GAMS also allows hidden comments, that are not copied to the echo print of the GAMS output file. These comments contain information that is only relevant for the person manipulating the file. They are single line comments starting with the dollar control option $hidden. An example follows. For more on dollar control options, see chapter Dollar Control Options.

\$hidden a comment I do not want in LST file
set a /a1,a2/;
set b /a2,c2/;
set c /a3,d3/;

3.23.5  Summary

This completes the discussion of the components of the GAMS language. Many unfamiliar terms used in this chapter are further explained in the Glossary.

3.24  Set Definition

3.24.1  Introduction

Sets are fundamental building blocks in any GAMS model. They allow the model to be succinctly stated and easily read. In this chapter we will introduce how sets are declared and initialized. More advanced set concepts, such as assignments to sets, and lag and lead operations are covered in the chapters Dynamic Sets and Sets as Sequences. The topics discussed in this chapter will be enough to provide a good start on most models. We will introduce simple sets, subsets, multi-dimensional sets, singleton sets and the universal set. The chapter will be concluded by a topic on domain checking, a very important feature of GAMS, and a section about Domain Defining Symbol Declarations.
3.24.2 Simple Sets

Using common mathematical notation, a set $S$ that contains the elements $a$, $b$ and $c$ is written as:

$$S = \{a, b, c\}$$

Using GAMS notation, the same set is defined in the following way:

```gams
Set S / a, b, c /;
```

The set statement begins with the keyword `set`, $S$ is the name of the set, and its members are $a$, $b$, and $c$. They are labels, but are often referred to as elements or members.

3.24.2.1 Defining a Simple Set: The Syntax

In general, the syntax for simple sets in GAMS is as follows:

```gams
set[s] set_name ["text"] /element [text] {,element [text]} /
   {,set_name ["text"] /element [text] {,element [text]} /} ;
```

Set[s] is the keyword that indicates that this is a set statement. Set_name is the internal name of the set in GAMS, it is an identifier. The optional explanatory text may be used to describe the set or a specific set element for future reference and to ease readability. The list of set elements is delimited by forward slashes. Element is the name of the set element(s). Note that each element in a set must be separated from other elements by a comma or by an end-of-line, and each element is separated from any associated text by a blank.

Consider the following example from the Egyptian fertilizer model [FERTS], where the set of fertilizer nutrients could be written as

```gams
Set cq "nutrients" / N, P2O5 /;
```

or as

```gams
Set cq "nutrients" / N
   P2O5 /;
```

The order in which the set members are listed is usually not important. However, if the members represent, for example, time periods, then it may be useful to refer to the next or previous member. There are special operations to do this, and they are discussed in chapter Sets as Sequences: Ordered Sets. For now, it is enough to remember that the order in which set elements are specified is not relevant, unless and until some operation implying order is used. At that time, the rules change, and the set becomes what we will later call an ordered set.

Note
- The data statement, i.e. specification of set elements in forward slashes can be omitted. In such cases a set is declared without being defined.
- More than one set may be declared and defined in one set statement. Examples are given in subsection Declarating Multiple Sets below.
3.24.2.2 Illustrative Examples

Consider the following example based on the model [SHALE]:

Set cf "final products" / syncrude "refined crude (mil bbls)"
                      lpg "liquefied petroleum gas (million bbls)"
                      ammonia "ammonia (mil tons)"
                      coke "coke (mil tons)"
                      sulfur "sulfur (mil tons)" /;

The set statement is introduced with the keyword set, the name of the set is cf and the explanatory text "final products" describes the set. The set has five elements with explanatory texts that contain details of the units of measurement.

Usually sets are declared and defined once and then referenced in the model. There are two exceptions: the dollar control option onMulti allows adding more elements later, and dynamic sets. For details on dynamic sets, see chapter Dynamic Sets. The following code sightly varies the previous example to demonstrate the option $onMulti:

Set cf "final products" / syncrude "refined crude (mil bbls)"
                      lpg "liquefied petroleum gas (million bbls)"
                      ammonia "ammonia (mil tons)" /
                $onMulti
Set cf "more final products" / coke "coke (mil tons)"
                      sulfur "sulfur (mil tons)" /;

After $onMulti additional elements are added to the set cf. Note that without the dollar control option $onMulti that would generate an error as per default a symbol can have at most one data statement.

3.24.2.3 Sequences as Set Elements

The asterisk ‘∗’ plays a special role in set definitions. It is used to relieve the tedium of typing a sequence of elements for a set, and to make intent clearer. For example, in a simulation model there might be ten annual time periods from 1991 to 2000. Instead of typing ten years, the elements of this set can be written as:

Set t "time" / 1991 ∗ 2000 /;

This means that the set includes the ten elements 1991, 1992, ..., 2000. GAMS builds up these label lists by looking at the differences between the two labels. If the only characters that differ are digits, with the number L formed by these digits in the left and R in the right, then a label is constructed for every integer in the sequence L to R. Any non-numeric differences or other inconsistencies cause errors.

The following example illustrates the most general form of the 'asterisked' definition:

Set g1 / a1bc ∗ a20bc /;

Note that this is not the same as:

Set g2 / a01bc ∗ a20bc /;

Both sets have 20 members, but they have only 11 members in common.

Lists in decreasing order are also possible:

Set y "years in decreasing order" / 2000 ∗ 1991 /;

As a last example, the following set definitions are both illegal because they are not consistent with the rule given above for making lists:

Set illegal1 / a1x1 ∗ a9x9 /
    illegal2 / a1 ∗ b9 /;
3.24 Set Definition

3.24.2.4 Declarating Multiple Sets

The keyword set does not need to be used for each set, rather only at the beginning of a group of sets. It is often convenient to put a group of set declarations (and definitions) together at the beginning of the program. When this is done the set keyword needs only be used once. Those who prefer to intermingle set declarations with other statements, have to use a new set statement for each additional group of sets. Note that the keywords set and sets are equivalent. The following example below shows how two sets can be declared together. Note that the semicolon is used only after the last set is declared.

Sets s "Sectors" / manuf, agri, services, government / 
    r "Regions" / north, eastcoast, midwest, sunbelt / ;

3.24.2.5 Using Previously Defined Sets in Set Definitions

The following notation allows previously defined sets to be used in a new set definition:

Set i / i1 * i4 / 
    j / j6 * j9 / 
    k / #i, set.j / ;

The set k contains all elements of the sets i and j. Note that the hash sign '#' followed by a set name is a shorthand for referring to all the elements in a set. The notation set.set_name works identically and is just a different way to refer to all elements in a previously defined set.

3.24.3 The Alias Statement: Multiple Names for a Set

Sometimes it is necessary to have more than one name for the same set. In input-output models for example, each commodity may be used in the production of all other commodities and it is necessary to have two names for the set of commodities to specify the problem without ambiguity. In the general equilibrium model [ORANI], the set of commodities c is written as

Set c "Commodities" / food, clothing / ;

A second name for the set c is established with either of the following statements:

Alias (c, cp) ;
Alias (cp, c) ;

Here cp is the new set name that can be used instead of the original set name c.

Note

The newly introduced set name may be used as an alternative name for the original set; the associated set will always contain the same elements as the original set.

With the alias statement more than one new name may be introduced for the original set:

Alias (c,cp, cpp, cppp);

Here cp, cpp, cppp are all new names for the original set c.
Note

The order of the set names in the alias statement does not matter. The only restriction is that exactly one of the sets in the statement must be defined earlier. All the other sets are introduced by the alias statement.

Typical examples for the usage of aliases are problems where transportation costs between members of one set have to be modeled. The following code snippet is adapted from the Andean fertilizer model [ANDEAN]:

Set i "plant locations" / palmasola, pto-suarez, potosi, baranquill, cartagena /;
Alias(i,ip);

Table tran(i,i) "transport cost for interplant shipments (us$ per ton)"

<table>
<thead>
<tr>
<th></th>
<th>palmasola</th>
<th>pto-suarez</th>
<th>potosi</th>
<th>baranquill</th>
</tr>
</thead>
<tbody>
<tr>
<td>pto-suarez</td>
<td>87.22</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>potosi</td>
<td>31.25</td>
<td>55.97</td>
<td></td>
<td></td>
</tr>
<tr>
<td>baranquill</td>
<td>89.80</td>
<td>114.56</td>
<td>70.68</td>
<td></td>
</tr>
<tr>
<td>cartagena</td>
<td>89.80</td>
<td>114.56</td>
<td>70.68</td>
<td>5.00</td>
</tr>
</tbody>
</table>

Parameter mui(i,ip) "transport cost: interplant shipments (us$ per ton)";
mui(i,ip) = (tran(i,ip) + tran(ip,i));

The alias statement introduces ip as another name for the set i. The table tran is two-dimensional and both indices are the set i. The data for the transport cost between the plants is given in this table; note that the transport costs are given only for one direction here, i.e. the costs from pto-suarez to palmasola are explicitly specified in the table while the costs in the opposite direction are not given at all. The parameter mui is also two-dimensional and both indices refer to the set i, but this time the alias ip is used in the second position. The parameter mui is defined with the assignment statement in the next line: mui contains the transport costs from one plant location to the other, in both directions. Note that if mui were defined without the alias, then all its entries would have been zero. For other examples where aliases are used, see sections The Universal Set and Finding Sets from Data below.

3.24.4 Subsets

It is often necessary to define sets whose members must all be members of some larger set. The syntax is:

set set_ident1(set_ident2) ;

Here set is the keyword indicating that this is a set statement, and set_ident1 is a subset of the larger set set_ident2. The larger set is also called superset.

For instance, we may wish to define the sectors in an economic model following the style in [CHENERY].

Set i   "all sectors" / light-ind, food+agr, heavy-ind, services /;
t(i) "traded sectors" / light-ind, food+agr, heavy-ind /;
nt "non-traded sectors" / services /;

Some types of economic activity, for example exporting and importing, may be logically restricted to a subset of all sectors. In order to model the trade balance we need to know which sectors are traded, and one obvious way is to list them explicitly, as in the definition of the set t above. The specification t(i) means that each member of the set t must also be a member of the set i. GAMS will enforce this relationship, which is called domain checking. Obviously, the order of declaration and definition is important: the membership of i must be known before t is defined, otherwise checking cannot be done.
3.24 Set Definition

Note

All elements of the subset must also be elements of the superset.

It is legal but unwise to define a subset without reference to the larger set, as is done above for the set nt. In this case domain checking cannot be performed: if services were misspelled no error would be marked, but the model may give incorrect results. Hence, it is recommended to use domain checking whenever possible. It catches errors and allows to write models that are conceptually cleaner because logical relationships are made explicit.

An alternative way to define elements of a subset is with assignments:

\[ \text{Set } i \text{ "all sectors" / light-ind, food+agr, heavy-ind, services /} \]
\[ \quad \text{t(i) "traded sectors" / light-ind, heavy-ind /;} \]
\[ \quad \text{t('food+agr')} = \text{yes;} \]

In the last line the element \( \text{food+agr} \) of the set \( i \) is assigned to the subset \( t \). Assignments may also be used to remove an element from a subset:

\[ \text{t('light-ind')} = \text{no;} \]

Note that yes and no are reserved words in GAMS. Note further that if a subset is assigned to, it then becomes a dynamic set. For more on assignments in GAMS in general, see section The Assignment Statement.

Attention

A subset can be used as a domain in the declaration of other sets, variables, parameters and in equations as long as it is no dynamic set.

This completes the discussion of sets in which the elements are simple. This is sufficient for many GAMS applications. However, there are a variety of problems for which it is useful to have sets that are defined in terms of two or more other sets.

3.24.5 Multi-Dimensional Sets

It is often necessary to provide mappings between elements of different sets. For this purpose, GAMS allows the use of multi-dimensional sets. For the current maximum number of permitted dimensions, see Dimensions. The next two subsections explain how to express one-to-one and many-to-many mappings between sets.

3.24.5.1 One-to-one Mapping

Consider a set whose elements are pairs:
\[ \text{A} = \{(b,d), (a,c), (c,e)\} \]
In this set there are three elements and each element consists of a pair of letters. This kind of set is useful in many types of modeling. For example, in the world aluminum model [ALUM] a port has to be associated with a nearby mining region

\[ \text{Set } i \text{ "mining regions" / china, ghana, ee+ussr, s-leone /} \]
\[ \quad \text{n "ports" / accra, freetown, leningrad, shanghai /} \]
\[ \quad \text{in}(i,n) "mines to ports map" / china .shanghai \]
\[ \quad \quad \quad \text{ghana .accra} \]
\[ \quad \quad \quad \text{ee+ussr.leningrad} \]
\[ \quad \quad \quad \text{s-leone.freetown /}; \]

Here \( i \) is the set of mining regions, \( n \) is the set of ports and \( \text{in} \) is a two dimensional set that associates each port with a mining region. The dot between china and shanghai is used to create one such pair. Blanks may be used freely around the dot for readability. The set \( \text{in} \) has four elements, and each element consists of a region-port pair. The notation \((i,n)\) after the set name \( \text{in} \) indicates that the first member of each pair must be a member of the set \( i \) of mining regions, and that the second must be in the set \( n \) of ports. GAMS will domain check the set elements to ensure that all members belong to the appropriate sets.
3.24.5.2 Many-to-Many Mapping

A many-to-many mapping is needed in certain cases. Consider the following sets:

```
Set    i / a, b /          
       j / c, d, e /          
ij1(i,j) / a.c, a.d /          
ij2(i,j) / a.c, b.c /          
ij3(i,j) / a.c, b.c, a.d, b.d /;
```

Here the set `ij1` presents a one-to-many mapping where one element of the set `i` maps onto many elements of the set `j`. The set `ij2` represents a many-to-one mapping where many elements of the set `i` map onto one element of the set `j`. The set `ij3` is the most general case: a many-to-many mapping where many elements of the set `i` map to many elements of the set `j`.

These sets may be written compactly as:

```
Set    i / a, b /          
       j / c, d, e /          
ij1(i,j) / (a,c,d) /          
ij2(i,j) / (a,b,c) /          
ij3(i,j) / (a,b,c,d) /;
```

The parenthesis provides a list of elements that is expanded when creating pairs. Note that the dot `.` if used like above, acts as product operator and supports building the Cartesian product of sets.

Attention

When complex sets like this are created, it is important to check that the desired set has been obtained. The checking can for example be done by using a display statement.

GAMS provides more notation to define multi-dimensional sets in a succinct way. As introduced above the hash sign `#` followed by a set name is a shorthand for referring to all the elements in a set. The matching operator `:.` may be used to map ordered sets. This operator is similar to the product operator `.`. However, in this case elements are matched pairwise by mapping elements with the same order number. The examples below demonstrate these concepts.

```
Set          
i / a, b /          
j / c, d, e /          
ij4a(i,j) / a.#j /          
ij4b(i,j) / a.c, a.d, a.e /          
ij5a(i,j) / #i.#j /          
ij5b(i,j) / a.c, a.d, a.e, b.c, b.d, b.e /          
ij6a(i,j) / #i:#j /          
ij6b(i,j) / a.c, b.d /;
```

Note that set names that differ only by the last letter denote identical sets. For example, set `ij4a` is identical to set `ij4b`. Observe that set `i` has two elements and set `j` has three elements, where `e` is the element with the highest order. Set `ij6a` is an ordered mapping of all elements of set `i` to all elements of set `j`. However, since there is a mismatch in the number of elements, element `e` is not mapped to.

These concepts may be generalized to sets with higher dimensions. Mathematically, these are called 3-tuples, 4-tuples, or more generally, `n`-tuples. Some examples for the compact representation of sets of `n`-tuples using combinations of dots, parentheses, and commas are shown in Table 1.
### Compact Notation

<table>
<thead>
<tr>
<th>Compact Notation</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>((a,b).c.d)</td>
<td>(a.c.d, b.c.d)</td>
</tr>
<tr>
<td>((a,b).(c,d).e)</td>
<td>(a.c.e, b.c.e, a.d.e, b.d.e)</td>
</tr>
<tr>
<td>((a.1\ast3).c)</td>
<td>((a.1, a.2, a.3).c) or (a.1.c, a.2.c, a.3.c)</td>
</tr>
<tr>
<td>(1\ast3, 1\ast3, 1\ast3)</td>
<td>(1.1.1, 1.1.2, 1.1.3, ..., 3.3.3)</td>
</tr>
</tbody>
</table>

**Table 1:** Examples for compact representation of multi-dimensional sets

Note that the asterisk may also be used in conjunction with the dot. Recall that the elements of the list \(1\ast4\) are \(\{1,2,3,4\}\).

A powerful and very compact way to define multi-dimensional sets is with a special option that takes an identifier as value and carries out identifier operations like index matching using the matching operator `'` :`. The following example illustrates the method.

```plaintext
Set i / i1*i4 /  
  j / j1*j5 /  
  k / k1,k2 /  
  h / h1*h3 /; 

Set b(i,j,k), c(i,j,k,h); 

Option b(i:j,k), c(b:h); 

display b, c; 
```

The set \(b\) is a three-dimensional set, the option statement specifies which permutations of the elements of \(i, j,\) and \(k\) are elements of \(b\). The matching operator `'` :` is between \(i\) and \(j\), so we must first match the elements of the sets \(i\) and \(j\). That gives us the the first two positions. For the third position we cycle through all elements of the set \(k\). This results in the following elements for the set \(b\):

\[i1.j1.k1, i1.j1.k2, i2.j2.k1, ..., i4.j4.k2\]

The set \(c\) is a four-dimensional set. Note that the first three dimensions are identical to the domain of the set \(b\). The option statement specifies that in the first three positions we will have elements of the set \(b\) and these are matched with the elements of the fourth position of the set \(h\) which are in the fourth position. Now, the set \(h\) has only three elements, so only the first three elements of the set \(b\) are matched with the members of the set \(h\). This results in the following set:

\[i1.j1.k1.h1, i1.j1.k2.h2, i2.j2.k1.h3\]

As recommended above, it is important to always check whether the multi-dimensional sets generated with compact statement like these are indeed the sets that were intended.

For more sophisticated examples of how to use the matching operator within an option statement please see section **Index Matching**.
3.24.5.3 The Table Format for Multi-Dimensional Sets

An alternative way to declare multi-dimensional sets is with tables. We show by example how tables may be used in the context of set definitions:

Set origins / Berlin, Paris /
destinations / London, Chicago, Budapest /
linked_1(origins,destinations) "cities linked by railways"
/ Berlin.London, Berlin.Budapest,

Set Table linked_2(origins,destinations)
   London    Chicago     Budapest
   Berlin    yes         no          yes
   Paris     yes         yes         ;

The set linked_1 is a two-dimensional set that is defined with the dot notation introduced above. The set linked_2 is the same set defined using the table notation: the keyword set is followed by the keyword table and the name of the set with its domain. The table itself consists of the elements of the first index in the first column, the elements of the second index in the first row, and the data in the grid positions. Note that the keyword yes indicates that a label combination is part of the two-dimensional set and the keyword no or a blank indicates that the label combination is not contained in the new set. Please see section Tables for detailed requirements for inputting data in the table format.

Alternatively, the multi-dimensional set may be declared first without any elements, and the elements are added later in a separate table statement:

Set origins / Berlin, Paris /
destinations / London, Chicago, Budapest /
linked_2(origins,destinations) "cities linked by railways";
Table linked_2(origins,destinations)
   London    Chicago     Budapest
   Berlin    yes         no          yes
   Paris     yes         yes         ;

Instead of the keywords yes and no users may also use numbers to specify membership in the two-dimensional set: nonzero numeric entries mean that a label combination is part of the set and zero or a blank indicates that the label combination is not contained in the set.

3.24.5.4 Projection and Aggregation of Sets

In GAMS, projection and aggregation operations on sets can be performed in two different ways: with an option statement and with an assignment. For a detailed discussion, see section Projection and Aggregation of Sets and Parameters.
3.24 Set Definition

3.24.6 Singleton Sets

A *singleton set* in GAMS is a special set that has at most one element (zero elements are allowed as well). Like other sets, singleton sets may have a domain with several dimensions. For the current maximum number of permitted dimensions, see Dimensions. Singleton sets are declared and defined with the keyword `singleton` that acts as a modifier to the keyword `set`:

Set i / a, b, c /
Singleton Set j / d /
k(i) / b /
l(i,i) / b.c /

The sets j, k and l are declared as singleton sets, each of them has just one element. The set k is a subset of the set i and the set l is a two-dimensional set.

Note that a data statement for a singleton set with more than one element will create a compilation error:

```
1  Singleton Set s / s1*s3 /;
**** $844
2  display s;
```

Error Messages

844 Singleton with more than one entry (see $onStrictSingleton)

It also possible to assign an element to a singleton set. In this case the singleton set is automatically cleared of the previous element first. For example, adding the following line to the code above will result in set k containing only element `a` after execution:

```
k('a') = yes;
```

The dollar control option `offStrictSingleton` may be used to allow sets that are declared as singleton sets to have more than one element in compile time definitions. However, in this case only the first listed element is a valid element of the set. Note that the value of zero for the command line parameter `strictSingleton` has the same effect for execution time definitions of singleton sets via assignment statements.

For more on dollar control options, see chapter Dollar Control Options. For more on GAMS command line parameters, see chapter The GAMS Call and Command Line Parameters. For more on compilation errors, see section Compilation Errors.

Singleton sets can be especially useful in assignment statements since they do not need to be controlled by a controlling index or an indexed operator like other sets. Consider the following examples:

Set i / a, b, c /
Singleton Set k(i) / b /
h(i) / a /
Parameter n(i) / a 2, b 3, c 5 /
Scalar z1, z2;

z1 = n(k);
z2 = n(k) + 100*n(h);

The singleton sets k and h are both subsets of the set i. The parameter n is defined over the set i. The scalar z1 is assigned a value of the parameter n without naming the respective label explicitly in the assignment. It is already specified in the definition of the singleton set k. The assignment statement for the scalar z2 contains an expression where the singleton sets k and h are referenced without a controlling index or an indexed operation.

Note

Singleton sets cannot be used as domains.
3.24.7 The Universal Set: ∗ as Set Identifier

GAMS provides the universal set denoted by '∗' for cases where the user wishes not to specify an index but have only a placeholder for it. The following examples show two ways how the universal set is introduced in a model. We will discuss the advantages and disadvantages of using the universal set later. The first example is from the production and inventory model [ROBERT]:

Sets r "raw materials" / scrap, new /;
Table misc(*,r) "other data"
        scrap new
    max-stock  400  275
    storage-c  .5   2
    res-value  15   25;

A table is an input format for the data type parameter and has at least two dimensions. For details see section Tables. In our example, the first index is the universal set '∗' and the second index is the previously defined set r. Since the first index is the universal set any entry whatsoever is allowed in this position. In the second position elements of the set r must appear, they are domain checked, as usual.

The second example illustrates how the universal set is introduced in a model with an alias statement.

Alias (new_universe,∗);
Set k(new_universe) / Chicago / ;

The alias statement links the universal set with the set name new_universe. Set k is a subset of the universal set and Chicago is declared to be an element of k. Any item may be added freely to k.

The universal set is particularly useful for generating reports, since it allows the use of any labels without having to define special sets for them. For an example, see section Set Attributes below. For more on report writing, see chapter The Put Writing Facility.

Attention

It is recommended to not use the universal set for data input, since there is no domain checking and thus typos will not be detected and data that the user intends to be in the model might actually not be part of it.

Observe that in GAMS a simple set is always regarded as a subset of the universal set. Thus the set definition

Set i / i1*i10 /;

is the same as

Set i(*) / i1*i10 /;

GAMS follows the concept of a domain tree for domains in GAMS. It is assumed that a set and its subset are connected by an arc where the two sets are nodes. Now consider the following one dimensional subsets:

Set i, ii(i), j(i), jj(j), jjj(jj);

These subsets are connected with arcs to the set i and thus form a domain tree that is rooted in the universe node '∗'. This particular domain tree may be represented as follows:

* - i - ii
   |                
   - j - jj - jjj

Note that with the construct i(jjj) we may access ii iterating through the members of jjj. For an example, see domain tree in the loop statement.

Observe that the universal set is assumed to be ordered and operators for ordered sets such ord, lag and lead may be applied to any sets aliased with the universal set.
3.24.8 Set and Set Element Referencing

Sets or set elements are referenced in many contexts, including assignments, calculations, equation definitions and loops. Usually GAMS statements refer to the whole set or a single set element. In addition, GAMS provides several ways to refer to more than one, but not all elements of a set. In the following subsections we will show by example how this is done. GAMS also has set functions that specifically reference sets and introduced in the chapter about logical conditions.

3.24.8.1 Referencing the Whole Set

Most commonly whole sets are referenced as in the following examples:

```
Set i / i1*i100 /;
Parameter k(i);
k(i) = 4;
Scalar z;
z = sum(i, k(i));
```

The parameter $k$ is declared over the set $i$, in the assignment statement in the next line all elements of the set $i$ are assigned the value 4. The scalar $z$ is defined to be the sum of all values of the parameter $k(i)$.

3.24.8.2 Referencing a Single Element

Sometimes it is necessary to refer to specific set elements. This is done by using single or double quotes around the label(s). We may add the following line to the example above:

```
k('i77') = 15;
```

This statement changes the value of $k('i77')$ to 15, all the other values of $k$ remain 4.

3.24.8.3 Referencing a Part of a Set

There are multiple ways to restrict the domain to more than one element, e.g. subsets, conditionals and tuples. Suppose we want the parameter $k$ from the example above to be assigned the value 10 for the first 8 elements of the set $i$. The following two lines of code illustrate how easily this may be accomplished with a subset:

```
Set j(i) / i1*i8 /;
k(j) = 10;
```

First we define the set $j$ to be a subset of the set $i$ with exactly the elements we are interested in. Then we assign the new value to the elements of this subset. The other values of the parameter $k$ remain unchanged. For examples using conditionals and tuples, see sections Restricting the Domain: Conditionals and Restricting the Domain: Tuples respectively.

3.24.9 Set Attributes

A GAMS set element has several numbers attached to it. These values are called attributes; they may be recovered during execution. The attributes are listed in Table 3.
<table>
<thead>
<tr>
<th>Set Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Position</td>
<td>.pos</td>
<td>Element position in the current set (set does not have to be ordered), starting with 1.</td>
</tr>
<tr>
<td>Ord</td>
<td>.ord</td>
<td>Same as .pos but for ordered sets only.</td>
</tr>
<tr>
<td>Offset</td>
<td>.off</td>
<td>Element position in the current set minus 1. So .off = .pos - 1 (set does not have to be ordered).</td>
</tr>
<tr>
<td>Reverse</td>
<td>.rev</td>
<td>Reverse element position in the current set, so the value for the last element is 0, the value for the penultimate is 1, etc. (set does not have to be ordered).</td>
</tr>
<tr>
<td>Unique Element List</td>
<td>.uel</td>
<td>Element position in the unique element list. For details see section Ordered and Unordered Sets</td>
</tr>
<tr>
<td>Length</td>
<td>.len</td>
<td>Length of the set element name (a count of the number of characters).</td>
</tr>
<tr>
<td>Value</td>
<td>.val</td>
<td>If a set element is a number, this attribute gives the value of the number. For extended range arithmetic symbols, the symbols are reproduced. If a set element is a string that is not a number, then this attribute is not defined and trying to use it results in an error.</td>
</tr>
<tr>
<td>First set element</td>
<td>.first</td>
<td>Returns 1 for the first set element, otherwise 0.</td>
</tr>
<tr>
<td>Last set element</td>
<td>.last</td>
<td>Returns 1 for the last set element, otherwise 0.</td>
</tr>
</tbody>
</table>

Table 3: Set Attributes

The attributes may be accessed with an assignment statement:

data(set_name) = set_name.attribute ;

Here data is a parameter, set_name is the name of the set and .attribute is one of the attributes listed above. The following example serves as illustration:

Set id "example set" / Madison, tea-time, '-inf', '-7', '13.14'/;
Parameter report(id,*) "set attribute values";

report(id,'position') = id.pos ;
report(id,'reverse') = id.rev ;
report(id,'offset') = id.off ;
report(id,'length') = id.len ;
report(id,'first') = id.first ;
report(id,'last') = id.last ;

display report;

The parameter report is declared to have two dimensions with the set id in the first position and the universal set in the second position. In the following six statements the values of report are defined for six entries of the universal set. Note how the flexibility of the universal set is used here to make reporting easy. The display statement generates the output that follows.

```
---- 11 PARAMETER report set attribute values

<table>
<thead>
<tr>
<th></th>
<th>position</th>
<th>reverse</th>
<th>offset</th>
<th>length</th>
<th>first</th>
<th>last</th>
</tr>
</thead>
<tbody>
<tr>
<td>Madison</td>
<td>1.000</td>
<td>4.000</td>
<td>7.000</td>
<td>1.000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tea-time</td>
<td>2.000</td>
<td>3.000</td>
<td>1.000</td>
<td>8.000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-inf</td>
<td>3.000</td>
<td>2.000</td>
<td>2.000</td>
<td>4.000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-7</td>
<td>4.000</td>
<td>1.000</td>
<td>3.000</td>
<td>2.000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>13.14</td>
<td>5.000</td>
<td>4.000</td>
<td>5.000</td>
<td>1.000</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
Sometimes it is desirable to find a set from the available data in order to use it later in the model. We will show by example how this may be accomplished using the alias statement, the universal set and conditionals. Suppose we have only the data related to the transportation model \[\text{TRNSPORT}\] and we want to identify the sets. We can tell from the data that there are two sets that we are interested in. First, we define these two sets as aliases of the universal set, which means that no elements are specified:

\[
\text{Alias(sources, places, *)};
\]

Then we enter the data that contain an indicator of which set elements are valid entries in the sets to be computed. We use the table format.

<table>
<thead>
<tr>
<th>source</th>
<th>place</th>
<th>data from spreadsheet</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>2.5</td>
<td>1.7</td>
</tr>
<tr>
<td>Sandiego</td>
<td>2.5</td>
<td>1.8</td>
</tr>
<tr>
<td>totalneed</td>
<td>325</td>
<td>75</td>
</tr>
</tbody>
</table>

Next we define subsets that we will need in the calculations that follow:

\[
\text{Set source(sources) "sources in spreadsheet data" destination(places) "destination in spreadsheet data"};
\]

Now we have everything that we need to do the calculation using the data on hand. In our case, a label qualifies as an element of the set source if it has an entry for totalsupply in the table above, and a label is an element of the set destination if it has an entry for totalneed in the table trandata:

\[
\text{source(sources)$(trandata(sources,"totalsupply")) = yes;}
\text{destination(places)$(trandata("totalneed", places )) = yes;}
\]

These conditional assignments define the elements of the sets source and destination. From this point on these sets may be used in the model. However, note that the resulting sets are dynamic sets. Hence they cannot be used as domains in declaration statements of other sets, parameters, variables and equations. But they may be referenced and used in equation definitions.

Such computations may for example be useful if the user gets a data table from elsewhere and needs to specify the sets. Alternatively, if the data is available in gdx format, the dollar control option load provides functionality to project sets from data contained in a GDX file.

See also section Implicit Set Definition (or: Domain Defining Symbol Declarations).
3.24.11 Domain Checking

The GAMS compiler performs a check to ensure that each label quoted as a member of a set is indeed an element of the respective set, and each element defined in a subset is in fact a member of the superset. This screening for consistency is called domain checking. It is done whenever a domain is referenced, be it in set, variable, parameter or equation declarations and definitions, or in assignments. The following examples serve as illustration.

Set i "all cities" / Lima, Toronto, Wuhan, Shanghai /
   as(i) "Asian cities" / Wuhan, Shanhai, Calcutta /
   am "American cities" / Lima, Toront /;

The set as is declared to be a subset of the set i, therefore domain checking will test every label for inconsistencies. It will catch two errors: there is a typo in Shanhai and Calcutta is not a member of the set i, so it cannot legally be a member of a subset.

```
1 Set   i "all cities" / Lima, Toronto, Wuhan, Shanghai /
2       as(i) "Asian cities" / Wuhan, Shanhai, Calcutta /
**** $170 $170
**** 170 Domain violation for element
3       am "American cities" / Lima, Toront /;
```

The user can rectify the spelling error, and either delete Calcutta from the subset as or add it to the superset i. The following line will pass domain checking:

```
Set as(i) "Asian cities" / Wuhan, Shanghai /;
```

Note that am is not declared as a subset of the set i even though it apparently should contain cities contained in i. Hence, am cannot be domain checked and the typo in Toront will go undetected. This has consequences for the next line:

```
Parameter pam(am) "population in millions" / Lima 8.9, Toronto 5.6 /;
```

In this parameter definition the domain of the parameter pam is the set am. GAMS will report an error here, since domain checking does not recognize the label Toronto. Toront, as specified in the definition of the set am above would be accepted.

A further example for domain checking concerns multi-dimensional domains where the user accidentally switches the positions of the indices:

```
Parameter h(as,am) / Wuhan.Lima 10, Wuhan.Toronto 12, Shanghai.Lima 7/;
Parameter d(as,am);
d(as,am) = 5*h(am,as) + 78;
```

Observe that we assume that the typo in the label Toronto has been rectified. The parameter h is defined over the domain (as,am). However, in the assignment statement in the last line above, it is referenced with the domain (am,as). This mistake is caught by domain checking and an error is reported.

As we have seen in the definition of the set am above, domain checking is not compulsory. If the following statement is entered, GAMS makes no assumptions about rho until further information is provided.

---
The modeler may later choose to domain check \( \rho \) by continuing the definition with the following line:

\[
\text{Parameter} \quad \rho(t) \quad / 1988 \ 0.07, \ 1989*1994 \ 0.10, \ 1995 \ 0.09 /;
\]

Alternatively, the modeler may choose not to domain check the parameter \( \rho \), as is shown in the deliberately nonsensical (but legal) statement that follows:

\[
\text{Parameter} \quad \rho \quad / 1988.January \ 0.07, \ \text{strategy-1.cost} \ 44, \ \text{cat.capacity} \ 99 /;
\]

If a parameter is not domain-checked, the only restriction is that the dimensionality must be constant. Once the number of labels per data item has been established it is frozen; to refer to the parameter differently is an error.

Note

Domain checking is automatic; it is only suppressed in two cases:

1. The index is the universal set or a set aliased to the universal set, see the examples above.
2. The dollar control option \$onWarning is used. It has the effect that warnings rather than errors are reported for domain violations.

We urge modelers to use domain checking whenever possible. It catches errors and allows users to write models that are conceptually cleaner because logical relationships are made explicit.

Note that the dollar control option \$load is available in several variations to enable domain checking when loading data from a GDX file. For details, see \$loadDC, \$loadDCM and \$loadDCR and chapter GAMS Data eXchange (GDX).

### 3.24.12 Implicit Set Definition (or: Domain Defining Symbol Declarations)

As seen above, sets can be defined through data statements in the declaration. Alternatively, sets can be defined implicitly through data statements of other symbols which use these sets as domains. This is illustrated in the following example, which is derived from the \[\text{TRNSPORT}\] model:

\[
\text{Set} \\
\text{i} \quad \text{\textquotesingle canning plants\textquotesingle} \\
\text{j} \quad \text{\textquotesingle markets\textquotesingle};
\]

\[
\text{Table} \quad d(i, j) \quad \text{'distance in thousands of miles'} \\
\text{new-york} \quad \text{chicago} \quad \text{topeka} \\
\text{seattle} \quad 2.5 \quad 1.7 \quad 1.8 \\
\text{san-diego} \quad 2.5 \quad 1.8 \quad 1.4;
\]

\[
\text{Display} \quad i, j;
\]

Note the \(<\) signs in the domain list of the declaration of \( d(i, j) \). These signal, that the set \( i \) will contain all elements which define the first dimension of symbol \( d \) and that the set \( j \) will contain all elements which define the second dimension of symbol \( d \), respectively. So, this is the output of the \text{Display} statement at the end:
This syntax is not limited to the table statement, but can be used with any symbol declaration. Also, one domain set can be defined through multiple symbols using the same domain, when using the dollar control option onMulti:

```
Set
  food
  fruits(food<) / apple, orange /
$onMulti
  vegetable(food<) / carrot, cauliflower /
  meat(food<) / beef, pork /;
Display food;
```

This is the output of the Display statement:

```
---- 8 SET food
apple , orange , carrot , cauliflower, beef , pork
```

Note

If the < sign is used to mark a declaration as "domain defining", this attribute is not limited to the data statement following this declaration, but also influences other ways to define data at compile time like the dollar control option load, as shown in the following example:

```
Set
  i 'canning plants'
  j 'markets';
Parameter d(i<,j<) 'distance in thousands of miles';
$gdxIn data.gdx
$load d
```

Attention

Only non-zero elements in a symbol will add elements to an implicitly defined set. This is illustrated in the following two examples.

```
Set
  i 'canning plants'
  j 'markets';
Table d(i<,j<) 'distance in thousands of miles'
    new-york    chicago    topeka
seattle  2.5          1.8
san-diego  2.5         1.4;
Display i,j;
```
Note the empty column for chicago. Since there is no data, chicago will not end up in the set j, which can be seen in the output of the Display statement:

```
---- 10 SET j markets
new-york, topeka
```

Also, an explicit 0 in a data statement does not add elements to an an implicitly defined set (in contrast to an eps). This is shown in the following GAMS code and output:

```
Set
  j 'markets';

Parameter
  b(j<) 'demand at market j in cases'
    / new-york 325
    chicago 0
    topeka eps /;

Display j;
```

```
---- 10 SET j markets
new-york, topeka
```

See also section Finding Sets from Data.

### 3.24.13 Summary

In GAMS, a simple set consists of a set name and the elements of the set. Both the name and the elements may have associated text that explains the name or the elements in more detail. More complex sets have elements that are pairs or even n-tuples. These sets with pairs and n-tuples are ideal for establishing relationships between the elements in different sets. GAMS also uses a domain checking capability to help catch labeling inconsistencies and typographical errors made during the definition of related sets.

The discussion here has been limited to sets whose members are all specified as the set is being declared. For many models this is all the user needs to know about sets. Later we will discuss more complicated concepts, such as sets whose membership changes in different parts of the model (assignment to sets) and other set operations such as unions, complements and intersections.

### 3.25 Dynamic Sets

#### 3.25.1 Introduction

Sets in general are covered in chapter Set Definition. In this chapter we introduce a special type of sets: dynamic sets. The sets that we discuss in detail in chapter Set Definition have their elements stated at compile time (e.g. enclosed in slashes at the set declaration or when loading a set from gdx via $load) and during execution time the membership is never changed. Therefore they are called static sets. In contrast, the elements of dynamic sets are not fixed, but may be added and removed during execution of the program. Dynamic sets are most often used as controlling indices in assignments or equation definitions and as the conditional set in a dollar-controlled indexed operation. We will first show how assignments are used to change set membership in dynamic sets. Then we will introduce set operations and the last part of this chapter covers dynamic sets in the context of dollar conditions.
3.25.2 Assigning Membership to Dynamic Sets

Dynamic Sets may be assigned to in a similar way as other data types. There are only two possible values: yes and no. Note that arithmetic operations cannot be performed on sets in the same way as on value typed identifiers (parameters, variables and equations subtypes). However, there are special set operations.

3.25.2.1 The Syntax

Like any other set, a dynamic set has to be declared before it may be used in the model. Often, a dynamic set is declared as subset of a static set. Dynamic sets in GAMS may also be multi-dimensional like static sets. The maximum number of permitted dimensions follows the rules of the basic Data Types and Definitions. For multi-dimensional dynamic sets the index sets can also be specified explicitly at declaration. That way dynamic sets are domain checked. Of course it is also possible to use dynamic sets that are not domain checked. This provides additional power and flexibility but also a lack of intelligibility and danger. Any label is legal as long as such a set’s dimension, once established, is preserved.

In general, the syntax for assigning membership to dynamic sets in GAMS is:

```
set_name(index_list | label) = yes | no ;
```

Set name is the internal name of the set in GAMS, index_list refers to the domain of the dynamic set and label is one specific element of the domain. An assignment statement may assign membership to the dynamic set either to the whole domain or to a subset of the domain or to one specific element. Note that, as usual, a label must appear in double or single quotes. Yes and no are keywords in GAMS. They are used to add members to or remove them from the dynamic set. Examples are given in the following subsections.

3.25.2.2 Illustrative Example

Throughout this chapter we will use examples adapted from the database model [ZLOOF] to illustrate the introduced concepts. Here we start with assignments of membership to dynamic sets.

```
Set item "all items" / dish, ink, lipstick, pen, pencil, perfume /
subitem1(item) "first subset of item" / pen, pencil /
subitem2(item) "second subset of item";
subitem1('ink') = yes ;
subitem1('lipstick') = yes ;
subitem2(item) = yes ;
subitem2('perfume') = no ;
display subitem1, subitem2;
```

Note that the sets subitem1 and subitem2 are declared like any other set. The two sets become dynamic as soon as they are assigned to a few lines later. They are also domain checked: the only members they will ever be able to have must also be members of the set item. The first assignment not only makes the set subitem1 dynamic, it also has the effect that its superset item becomes a static set and from then on its membership is frozen. The first two assignments each add one new element to subitem1. Note that both are also elements of item, as required. The third assignment is an example of the familiar indexed assignment: subitem2 is assigned all the members of item. The last assignment removes the label 'perfume' from the dynamic set subitem2. The output generated by the display statement is shown below:
3.25 Dynamic Sets

---
9 SET subitem1 first subset of item
ink , lipstick, pen , pencil

---
9 SET subitem2 second subset of item
dish , ink , lipstick, pen , pencil

Note that even though the labels 'pen' and 'pencil' were declared to be members of the set subitem1 before the assignment statements that added the labels 'ink' and 'lipstick' to the set, they appear in the listing above at the end. The reason is that elements are displayed in the internal order, which in this case is the order specified in the declaration of the set item.

Alternatively, the elements of the set subitem2 could be assigned in the following way:

subitem2(item) = no;
subitem2(subitem1) = yes;
subitem2('dish') = yes;

The first statement removes all elements from the set subitem2. The second statement adds all elements of the set subitem1. Note that this assignment is permitted since the set subitem1 is a proper subset of the set item (which is the domain of subitem2). The third statement adds one additional element.

3.25.2.3 Dynamic Sets with Multiple Indices

As mentioned earlier, dynamic sets may be multi-dimensional. The following lines continue the example above and illustrate assignments for multi-dimensional sets.

Sets sold(item) "items sold" / pencil, pen /
sup "suppliers" / bic, parker, waterman /
supply(sold,sup) ;
supply('pencil','bic') = yes ;
supply('pen',sup) = yes ;

Note that supply is a two-dimensional dynamic set. It links sold items with their respective suppliers. Other examples with multi-dimensional dynamic sets are in subsections Dynamic Sets in Conditional Assignments and Conditional Indexed Operations with Dynamic Sets below.

All the mechanisms using asterisks and parenthesized lists that were introduced in section Multi-Dimensional Sets in chapter Set Definition are available for dynamic sets as well.
3.25.2.4 Equations Defined over the Domain of Dynamic Sets

Generally, dynamic sets are not permitted as domains in declarations of sets, variables, parameters and equations. However, they may be referenced and sometimes it is necessary to define an equation over a dynamic set.

Note

The trick is to declare the equation over the entire domain but define it over the dynamic set.

For example, defining an equation over a dynamic set can be necessary in models that will be solved for arbitrary groupings of regions simultaneously. We assume there are no explicit links between regions, but that we have a number of independent models with a common data definition and common logic. We illustrate with an artificial example, leaving out lots of details.

Set allr "all regions" / N, S, W, E, N-E, S-W /
r(allr) "region subset for particular solution"
type "set for various types of data";
Scalar price /10/;
Parameter revenue(allr);
Table data(allr,type) "all other data ...";
Variables activity1(allr) "first activity"
activity2(allr) "second activity"
revenue(allr) "revenue";
Equations resource1(allr) "first resource constraint ..."
prodbal1(allr) "first production balance ...";
resource1(r).. activity1(r) =l= data(r,'resource-1');
prodbal1(r).. activity2(r)*price =e= revenue(r);

To repeat the important point: the equation is declared over the set allr, but defined over r, a subset.
Note that the variables and data are declared over allr but referenced over r. Then the set r may be assigned arbitrary combinations of elements of the set allr, and the model may be solved any number of times for the chosen groupings of regions.

3.25.2.5 Assigning Membership to Singleton Sets

Singleton sets have only one element. Hence any assignment to a singleton set first clears or empties the set, no explicit action to clear the set is necessary. This is illustrated with the following example:

Set i "Static Set" / a, b, c /
ii(i) "Dynamic Set" / b /;
Singleton Set si(i) "Dynamic Singleton Set" / b /;
ii('c') = yes;
si('c') = yes;
display ii, si;

Note that both ii and si are subsets of the set i, but only si is declared as a singleton set. The assignment statements assign to both sets the element 'c'. While 'c' is added to the set ii, it replaces the original element in the singleton set si. The output from the display statement confirms this:
3.25 Dynamic Sets

---

8 SET ii Dynamic Set
b, c

8 SET si Dynamic Singleton Set
c

For more information on singleton sets in GAMS, see section Singleton Sets.

Attention

That an assignment to a singleton set first clears the set always, means that it is even cleared if there would be no change at all for a regular set:

Singleton Set s / 1 /;
s(s)$0 = yes;
display s;

Here is the output from the display statement in the listing file:

---

3 SET s

( EMPTY )

The assignment behavior can be changed with the option and command line parameter strictSingleton which affects the behavior of a membership assignment to a Singleton Set. With strictSingleton=0 GAMS does not complain about an assignment with more than one element on the right hand side but takes the first one. With strictSingleton=1 (default), such an assignment raises an error. Consider the following example:

Set i "Static Set" / a, b, c /
Singleton Set si(i) "Dynamic Singleton Set";
si(i) = ord(i) > 1;
display si;

By default, the above code will trigger an error as an assignment to a singleton set with more than one element on the right hand side is forbidden:

*** Error at line 3: Multiple assignment to Singleton Set not allowed (see option strictSingleton)

However, with option (or command line parameter) strictSingleton=0 GAMS does not complain about such an assignment with more than one element on the right hand side but takes the first one:

Set i "Static Set" / a, b, c /
Singleton Set si(i) "Dynamic Singleton Set";
online strictSingleton = 0;
si(i) = ord(i) > 1;
display si;

The output from the display statement confirms this:

---

5 SET si Dynamic Singleton Set
b

3.25.3 Set Operations

GAMS provides symbols for arithmetic set operations that may be used with dynamic sets. An overview of the set operations in GAMS is given in Table 1. Examples and alternative formulations for each operation follow. Note that in the table below the set i is the static superset and the sets j and k are dynamic sets.
<table>
<thead>
<tr>
<th>Set Operation</th>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set Union</td>
<td>( j(i) + k(i) )</td>
<td>Returns a subset of ( i ) that contains all the elements of the sets ( j ) and ( k ).</td>
</tr>
<tr>
<td>Set Intersection</td>
<td>( \bar{j}(i) \ast \bar{k}(i) )</td>
<td>Returns a subset of ( i ) that contains the elements of the set ( j ) that are also elements of the set ( k ).</td>
</tr>
<tr>
<td>Set Complement</td>
<td>( \neg j(i) )</td>
<td>Returns a subset of ( i ) that contains all the elements of the set ( i ) that are not elements of the set ( j ).</td>
</tr>
<tr>
<td>Set Difference</td>
<td>( j(i) - k(i) )</td>
<td>Returns a subset of ( i ) that contains all the elements of the set ( j ) that are not elements of the set ( k ).</td>
</tr>
</tbody>
</table>

**Table 1:** Set Operations with Dynamic Sets

The following examples draw on the database model [ZLOOF] that we introduced above. Recall that the set \( \text{item} \) is the superset of the dynamic sets \( \text{subitem1} \) and \( \text{subitem2} \). We add new dynamic sets for the results of the respective set operations. The following example illustrates that the dynamic set operations are equivalent to the following alternative ways of representation.

Sets \( \text{union1(item)} \), \( \text{intersection1(item)} \), \( \text{complement1(item)} \), \( \text{difference1(item)} \)

\[
\text{union2(item)} = \text{subitem1(item)} + \text{subitem2(item)}; \quad \text{display union1;}
\]
\[
\text{union2(subitem1)} = \text{yes}; \quad \text{union2(subitem2)} = \text{yes}; \quad \text{display union2;}
\]
\[
\text{intersection1(item)} = \text{subitem1(item)} \ast \text{subitem2(item)}; \quad \text{display intersection1;}
\]
\[
\text{intersection2(item)} = \text{yes}(\text{subitem1(item)} \text{ and } \text{subitem2(item)}); \quad \text{display intersection2;}
\]
\[
\text{complement1(item)} = \neg \text{subitem1(item)}; \quad \text{display complement1;}
\]
\[
\text{complement2(item)} = \text{yes}; \quad \text{complement2(subitem1)} = \text{no}; \quad \text{display complement2;}
\]
\[
\text{difference1(item)} = \text{subitem2(item)} - \text{subitem1(item)}; \quad \text{display difference1;}
\]
\[
\text{difference2(item)} = \text{yes}(\text{subitem2(item)}); \quad \text{difference2(subitem1)} = \text{no}; \quad \text{display difference2;}
\]

The display statements will show that the above assignment statements for each operation result in the same dynamic set like using the set operator. Observe that the alternative formulations for the set intersection and set difference involve conditional assignments. Conditional assignments in the context of dynamic sets are discussed in depth in the next section.

**Note**

The indexed operation \( \text{sum} \) may be used for set unions. Similarly, the indexed operation \( \text{prod} \) may be used for set intersections. For examples see section Conditional Indexed Operations with Dynamic Sets below.

### 3.25.4 Using Dollar Controls with Dynamic Sets

The remainder of this chapter assumes familiarity with the dollar condition that is introduced in chapter Conditional Expressions, Assignments and Equations. All the dollar control machinery is available for use with dynamic sets. In fact, the full power of dynamic sets can be exploited using these dollar controls.

Recall that set membership of subsets and dynamic sets may be used as a logical condition; see subsection Logical Conditions: Set Membership and Set Functions for details. Set membership may also be a building block in complex logical conditions that are constructed using the logical operators not, and, or, xor, imp and eqv. Moreover, the set operations introduced in the previous section may also be used in logical conditions. Like other dollar conditions, dollar conditions with dynamic sets are used in the context of assignments, indexed operations and equations. We will discuss in detail each of these in the following subsections.

Apart from being part of logical conditions, dynamic sets may be assigned members with conditional assignments. Examples are given in the next subsection.
3.25 Dynamic Sets

3.25.4.1 Dynamic Sets in Conditional Assignments

Dynamic sets may be used in two ways in conditional assignments: they may be the item on the left-hand side that is assigned to and they may be part of the logical condition. Below we present examples for both. The examples are again based on the database model [ZLÖOF] that we introduced above.

```plaintext
Set  item         "all items" / dish, ink, lipstick, pen, pencil, perfume /  
    subitem1(item) "first subset of item" / ink, lipstick, pen, pencil /  
    subitem2(item) "second subset of item";

subitem2(item)$subitem1(item) = yes;
display subitem2;
```

The conditional assignment adds the members of dynamic set `subitem1` to the dynamic set `subitem2`. Thus `subitem2` will have the following elements:

```
---- 6 SET subitem2 second subset of item
   ink , lipstick, pen , pencil
```

Note that instead of using `subitem1` in a dollar condition we could also write:

```plaintext
subitem2(subitem1) = yes;
```

In the next example of a conditional assignment, a dynamic set features in the logical condition on the right-hand side. The first statement clears the set `subitem2` of any previously assigned members and the second statement assigns all members of `subitem1` to `subitem2`. The following conditional assignment will have the same result:

```plaintext
subitem2(item) = no;
subitem2(item) = yes$subitem1(item);
```

The logical condition in this assignment is `subitem1(item)`. It is satisfied for all members of the set `subitem1`. Hence the statement assigns all elements of the domain `item` that are members of the set `subitem1` to the dynamic set `subitem2`. Note that in this assignment the dollar operator is on the right.

In the section Dollar on the Right we show that conditional assignments with the dollar operator on the right-hand side imply an `if-then-else` structure where the `else` case is automatically zero. Unlike parameters, dynamic sets cannot be assigned the value of zero, they are assigned the value `no` instead. Therefore a more explicit formulation of the conditional assignment above would be:

```plaintext
subitem2(item) = no;
subitem2(item) = yes$subitem1(item) + no$(not subitem1(item));
```

For more on sets in logical conditions, see section Logical Conditions: Set Membership and Set Functions. For more on conditional assignments, see section Conditional Assignments.
### 3.25.4.2 Conditional Indexed Operations with Dynamic Sets

Indexed operations in GAMS are introduced in section **Indexed Operations**. They may be controlled by dollar conditions as discussed in section **Conditional Indexed Operations**. The domain of conditional indexed operations is often restricted by a set, called the conditional set. Dynamic sets may be used as conditional sets or they may be assigned to with a statement that features a conditional indexed operation on the right-hand side. We will illustrate both cases with examples.

Suppose we have a set of origins, a set of destinations and a table specifying the flight distance between them:

Set i "origins" / Chicago, Philadelphia /  
  j "destinations" / Vancouver, Bogota, Dublin, Rio, Marrakech / ;  

Table d(i,j) "distance (miles)"  
      | Vancouver | Bogota | Dublin | Rio   | Marrakech |
|-----|-----------|--------|--------|-------|-----------|
| Chicago | 1777      | 2691   | 3709   | 5202  | 4352      |
| Philadelphia | 2438      | 2419   | 3306   | 4695  | 3757      ;

We wish to find the longest distance that we can travel given that we have a limit of 3500 miles.

Set can_do(i,j) "connections with less than 3500 miles";  
can_do(i,j)$(d(i,j) < 3500) = yes;  
display can_do;  
Scalar maxd "longest distance possible"  
maxd = smax((i,j)$can_do(i,j), d(i,j));  
display maxd;

The dynamic set can_do contains all connections that are less than 3500 miles. The scalar maxd is defined by a conditional assignment where the indexed operation smax scans all entries of the parameter d whose label combinations are members of the set can_do and chooses the largest value. The output generated by the display statements is shown below:

```
---- 11 SET can_do connections with less than 3500 miles
      | Vancouver | Bogota | Dublin |
|-----|-----------|--------|--------|
| Chicago | YES       | YES    |        |
| Philadelphia | YES      | YES    | YES    |

---- 15 PARAMETER maxd = 3306.000 longest distance possible
```

There is a shorter alternative formulation for this assignment; see subsection **Filtering through Dynamic Sets** below for details.

Finally, we also wish to know which flight connection is linked to the longest possible distance. Consider the following two lines:

Singleton set maxc(i,j) "maximum distance connection";  
maxc(i,j) = yes$can_do(i,j) and (d(i,j) = maxd);
The dynamic singleton set is assigned the member of the dynamic set `can_do` whose distance equals the maximum distance.

The full power of indexed operators becomes apparent with multi-dimensional dynamic sets. As earlier in this chapter, we illustrate with fragments of code adapted from the relational database model [ZLOOF].

```plaintext
Set dep "departments" / cosmetics, hardware, household, stationary, toy /
sup "suppliers" / bic, dupont, parker, revlon /
item "items sold" / dish, ink, lipstick, pen, pencil, perfume /
sales(dep,item) "departments and items sold" /
   cosmetics. (lipstick,perfume)
   hardware. ink
   household. (dish,pen)
   stationary. (dish,ink,pen,pencil)
   toy. (ink,pen,pencil) /
supply(item,sup) "items and suppliers" /
   dish.(bic,dupont) , ink.(bic,parker) , lipstick.revlon
   pen.(parker,revlon) , pencil.(bic,parker) , perfume.revlon /
Set g03(dep) "departments selling items supplied by Parker";
g03(dep) = sum(item$supply(item,'parker'), sales(dep,item));
display g03;
```

The assignment above is used to create the set of departments that sell items supplied by 'parker'. Note that the set `g03` is a subset of the set `dep`. Its members are specified by assignment, hence it is a dynamic set. Note that the assignment is made to a set, therefore the indexed operator `sum` refers to a set union (and not to an addition as would be the case if the assignment were made to a parameter). The indexed operation is controlled by the two-dimensional set `supply` with the label 'parker' in the second index position. This logical condition is TRUE for all members of the set `supply` where the second index is 'parker'. Hence the summation is over all items sold, provided that the supplier is 'parker'. Given the declaration of the set `supply`, this means 'ink', 'pen' and 'pencil'. The associated departments are thus all departments except for 'cosmetics':

```plaintext
---- 19 SET g03 departments selling items supplied by Parker

hardware , household , stationary, toy
```

Now suppose we are interested in the departments that are selling only items supplied by 'parker'. We introduce a new dynamic set `g11` and the following assignment adds the desired departments:

```plaintext
Set g11(dep) "departments only selling items supplied by parker";
g11(dep) = prod(sales(dep,item), supply(item,"parker"));
display g11;
```

Note that the indexed operation `prod` refers to set intersections in the context of assignments to dynamic sets. From all departments linked with items only those are included where all items sold are supplied by 'parker'. This means that departments that additionally sell items that are not supplied by 'parker' are excluded. Hence, only 'hardware' and 'toy' are added to `g11`.

```plaintext
```
3.25.4.3 Conditional Equations with Dynamic Sets

Recall that dollar conditions in the context of equations may restrict the domain of the equation and they may also feature in the algebraic formulation of the equation; see section Conditional Equations for more information. In both instances dynamic sets may be used as part of the logical condition. Dollar conditions with dynamic sets in the algebra of equations are similar to conditional assignments with dynamic sets; see section Dynamic Sets in Conditional Assignments above. The example that follows illustrates the use of a dynamic set to restrict the domain of definition of an equation. In section Equations Defined over the Domain of Dynamic Sets above we had the following equation definition:

\[
\text{prodbal1}(r) \quad \text{activity2}(r) \cdot \text{price} = \text{revenue}(r)
\]

Recall that \( r \) is a dynamic set and a subset of the set \( \text{allr} \). Hence this equation may be rewritten in the following way:

\[
\text{prodbal1}(\text{allr}) \quad \text{activity2}(\text{allr}) \cdot \text{price} = \text{revenue}(\text{allr})
\]

Note that both formulations achieve the same result: restricting the domain of definition to those elements that belong to the dynamic set \( r \). While in the second formulation the condition is specified explicitly, in the first formulation the domain is filtered through the dynamic set \( r \). This is the topic of the next subsection.

3.25.4.4 Filtering through Dynamic Sets

The filtering process is introduced and explained in section Filtering Sets in chapter Conditional Expressions, Assignments and Equations. In certain circumstances it is an alternative to the dollar condition to restrict the domain of equations, sets, variables, parameters and indexed operations. We already saw an example for restricting the domain of definition of an equation in the previous subsection. The next example refers to restricting the domain in an indexed operation. In section Conditional Indexed Operations with Dynamic Sets we had the following assignment:

\[
\text{maxd} = \text{smax}(\text{i}, \text{j}) \quad \text{can\_do}(\text{i}, \text{j}), \text{d}(\text{i}, \text{j}))
\]

Recall that \( \text{maxd} \) is a scalar, \( \text{i} \) and \( \text{j} \) are sets, \( \text{can\_do} \) is a dynamic set and \( \text{d} \) is a two-dimensional parameter. Note that the conditional set is the dynamic set \( \text{can\_do} \). The assignment may be rewritten in the following way:

\[
\text{maxd} = \text{smax}(\text{can\_do}(\text{i}, \text{j}), \text{d}(\text{i}, \text{j}))
\]

Here the indexed operation is filtered through the dynamic set \( \text{can\_do} \), a dollar condition is not necessary.
3.26 Sets as Sequences: Ordered Sets

3.26.1 Introduction

Sets are introduced in chapter Set Definition. There we state that in general, sets in GAMS are regarded as an unordered collection of labels. However, in some contexts, say, multi-period planning models, some sets need to be treated as if they were sequences. In this chapter we will establish the notion of ordered sets and we will cover their special features and the associated operations.

Examples where ordered sets are needed include economic models that explicitly represent conditions in different time periods that are linked, location problems where the formulation may require a representation of contiguous areas, as in a grid representation of a city, scheduling problems and programs that model stocks of capital with equations of the form ‘stocks at the end of period \( n \) are equal to stocks at the end of period \( n - 1 \) plus net gains during period \( n \).’

Note

Models involving sequences of time periods are often called dynamic models, because they describe how conditions change over time. This use of the word dynamic unfortunately has a different meaning from that used in connection with dynamic sets, but this is unavoidable.

3.26.2 Ordered and Unordered Sets

Certain one-dimensional sets may be treated as if they were a sequence. Those sets need to be ordered and static. A one-dimensional set is ordered if the definition or initialization of the elements in the set corresponds to the order of the labels in the GAMS Entry order.

Note

- The GAMS entry order is the order in which the individual labels first appear in the GAMS program, either explicitly or as a result of using the shorthand asterisk notation.
- For the sake of simplicity, sets that are static and ordered are often just referred to as ordered sets.

GAMS maintains a unique element list where all labels that are used as elements in one or more sets are listed. The order of the elements in any one set is the same as the order of those elements in the unique element list. This means that the order of a set may not be what it appears to be if some of the labels were used in an earlier definition. The internal GAMS order of the labels can be made visible with the dollar control option $onUELlist. This directive generates a map that is shown in the compilation output of the listing file. For details on the listing file and GAMS output in general, see chapter GAMS Output.

A good rule of thumb is that if the user wants a set to be ordered and the labels in the set have not been used already, then they will be ordered.

In the example below we show ordered and unordered sets and the map showing the order. The input is:

```
$onUELlist
```

```
Note that the label "1987" is the first label seen by GAMS. It appears again as the last label in the initialization list for the set t2. This means that the set t2 is not ordered and any attempt to use t2 in a context implying order, such as the operations introduced later in this chapter, will cause error messages. Observe that the set t3 is ordered, as all the members of t3 have appeared in the GAMS program before, and in the same order that they are listed in the definition of t3.

The unique element listing map below shows the entry order (the important one) and the sorted order, obtained by sorting the labels into dictionary order. The single digits on the left are the sequence numbers of the first label on that line.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>1984</td>
<td>1985</td>
<td>1986</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>1989</td>
<td>1990</td>
<td>1991</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A set can always be made ordered by moving its declaration closer to the beginning of the program. With these restrictions in mind, we will continue in the next section with the operations that may be used with ordered sets.

### 3.26.3 Sorting a Set

Note that besides the entry order of unique elements there is also a sorted (alphabetical) order. To obtain the sorted order (of an ordered or unordered set) the special predefined two-dimensional set `SortedUELs(,*)` can be used. Consider the following example where set j is reported in an alphabetically sorted format:

```gams
set j / c, a, b, 1, 2, 11 /;
display j;
alias(*,u);
file ordered /ordered.txt/;
loop(SortedUELs(u,j), put ordered j.tl:0 ' ');
putclose ordered;
```

The output generated by the display statement follows:

```
---- 2 SET j
 c , a , b , 1 , 2 , 11
```

Note that, as expected, the display statement shows the elements of set j in the entry order not in alphabetical order. However, the elements are listed in alphabetical order in the file `ordered.txt`. Note furthermore, that alphabetical sorting leads to an order where e.g. 11 precedes 2.

```
1 11 2 a b c
```

In the example above u is aliased with the Universal Set. For an introduction to writing external files with `put`, see chapter The Put Writing Facility.
3.26 Sets as Sequences: Ordered Sets

3.26.4 Ord and Card Operators

As stated in section Labels in chapter GAMS Programs, labels in GAMS do not have a numerical value. The examples used were that the label '1986' does not have a numerical value of 1986 and the label '01' is different from the label '1'. This section introduces two operators - ord and card - that return integer values when applied to sets. While the integer values returned do not represent the numerical value of the label, they can be used for the same purpose.

Note

GAMS provides some string manipulation capability by extending the card and ord operators to also work on strings.

3.26.4.1 The Ord Operator

The operator ord returns the relative position of a member in a set.

Attention

By default the operator ord may be used only with one-dimensional sets that are static and ordered.

Some examples show the usage.

Set t "time periods" / 1985*1995 /;
Parameter val(t);
val(t) = ord(t);

Note that as a result of the statements above, the value of val('1985') will be 1, val('1986') will be 2 and so on.

A common use of ord is in setting up vectors that represent quantities growing in some analytically specified way. For example, suppose a country has 56 million people in the base period and the population is growing at the rate of 1.5 percent per year. Then the population in succeeding years can be calculated as follows:

\[
\text{population}(t) = 56 \times (1.015^{(\text{ord}(t) - 1)})
\]

It is often useful to simulate general matrix operations in GAMS. The first index of a two dimensional parameter can conveniently represent the rows, the second the columns and order is necessary. The example below shows how to set the upper triangle of a matrix equal to the row index plus the column index, and the diagonal and lower triangle to zero.

Set i "row and column labels" / x1*x10 /;
alias (i,j);
Parameter a(i,j) "a general square matrix";
a(i,j) $(\text{ord}(i) < \text{ord}(j)) = \text{ord}(i) + \text{ord}(j)$;
Note that in the assignment statement the logical condition \((\text{ord}(i) < \text{ord}(j))\) restricts the assignment to the entries of the upper triangle. For more information on logical conditions and conditional assignments in GAMS, see sections Logical Conditions and Conditional Assignments respectively.

Note that the strict requirement that the set needs to be ordered for the operator \(\text{ord}\) to be used may be relaxed with a dollar control option called \texttt{offOrder}. Consider the following lines where we revisit the example from the previous section.

```plaintext
$\texttt{offOrder}
Parameter p(t2);
p(t2) = \text{ord}(t2);
display p;
```

Note that, as we explained above, the set \(t2\) is not ordered. Therefore using \(\text{ord}(t2)\) somewhere in the model will usually cause the program to be terminated with an error message. However, with the dollar control option \texttt{offOrder} active, the set \(t2\) is treated as if it were ordered and the display statement will generate the following output:

```
---- 6 PARAMETER p
1987 1.000, 1983 2.000, 1984 3.000, 1985 4.000, 1986 5.000
```

While this may be useful in some circumstances, the option comes with a price, since the system will not be able to diagnose odd and incorrect formulations and data sets. The strict requirement that the set needs to be ordered for the \(\text{ord}\) operator can be turned on again via \texttt{onOrder}.

### 3.26.4.2 The Card Operator

The operator \texttt{card} returns the number of elements in a set.

Note

The operator \texttt{card} may be used with any set: static and dynamic sets, ordered and unordered sets.

The following example illustrates its use:

```plaintext
Set t "time periods" / 1985*1995 /;
Scalar s;
s = \text{card}(t);
Display s;
```

Note that \(s\) will be assigned the value 11 since the set \(t\) has 11 elements.

A common use of \texttt{card} is to specify some condition only for the final period, for example to fix a variable. Consider the following artificial example:

```
c.fx(t)$\text{(ord}(t) = \text{card}(t)) = \text{demand}(t);
```

Note that the logical condition \((\text{ord}(t) = \text{card}(t))\) restricts the assignment to the last element of the set \(t\): no assignment is made for other members of \(t\). The advantage of this way of fixing the variable \(c\) is that the membership of \(t\) can be changed safely and this statement will always fix \(c\) for the last element.

For more information on logical conditions and conditional assignments in GAMS, see sections Logical Conditions and Conditional Assignments respectively.

### 3.26.5 Lag and Lead Operators

Lag and lead operators are used to relate the current member of an ordered set to the previous or next member of the set. GAMS provides two forms of lag and lead operators (linear and circular), they are summarized in Table 1. Note that in the table below \(t\) is a member of an ordered set and \(n\) is a positive integer.
3.26 Sets as Sequences: Ordered Sets

<table>
<thead>
<tr>
<th>Operation</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linear Lag</td>
<td>$t - n$</td>
<td>Refers to the element of the ordered set whose relative position in the set is $\text{ord}(t)-n$.</td>
</tr>
<tr>
<td>Linear Lead</td>
<td>$t + n$</td>
<td>Refers to the element of the ordered set whose relative position in the set is $\text{ord}(t)+n$.</td>
</tr>
<tr>
<td>Circular Lag</td>
<td>$t -- n$</td>
<td>Same as $t - n$, only here the first element of the set is assumed to be preceded by the last element of the set, thus forming a circle of elements.</td>
</tr>
<tr>
<td>Circular Lead</td>
<td>$t ++ n$</td>
<td>Same as $t + n$, only here the last element of the set is assumed to be followed by the first element of the set, thus forming a circle of elements.</td>
</tr>
</tbody>
</table>

**Table 1: Linear and Circular Lag and Lead Operators**

Note that the only difference between linear and circular lag and lead operators is how endpoints are treated. Linear operators assume that there are no members preceding the first and following the last member of the ordered set. This assumption may result in elements of the set being referenced that actually do not exist. Therefore the user must think carefully about the treatment of endpoints: models with linear lag and lead operators will need special exception handling logic to deal with them. The next two sections will describe how this issue is handled in GAMS in the context in which these operators are typically used: assignments and equations. Linear lag and lead operators are useful for modeling time periods that do not repeat, like a set of years (say 1990 to 1997).

Circular lag and lead operators assume that the first and last members of the set are adjacent, so as to form a circular sequence of members. This means that 'first--1' is a reference to 'last' and 'last++2' is the same as 'first++1'. All references and assignments are defined. The assumption of circularity is useful for modeling time periods that repeat, such as months of the year or hours in the day. It is quite natural to think of January as the month following December. Agricultural farm budget models and workforce scheduling models are examples of applications where circular leads occur naturally.

**Note**

- GAMS is able to distinguish the linear lag and lead operators '-' and '+' from arithmetic operators by context. To avoid ambiguity, GAMS does not allow to mix lag and lead operators with arithmetic operators. For example, $i+1+1$ is not allowed, but writing $i+(1+1)$ would work.
- Observe that the lag (or lead) value $n$ does not have to be an explicit constant: it can be an arbitrary expression, provided that it evaluates to an integer. If it does not, error messages will be produced. A negative result causes a switch in sense (from lag to lead, for example).

Note that if lag and lead operators are used with an unordered set, the program will terminate with an error message. The strict requirement that the set be ordered may be relaxed with the dollar control option offOrder. If the directive $\text{offOrder}$ is added, in the lines that follow unordered sets are treated as if they were ordered and therefore lag and lead operators may be used with them. While this may be advantageous in some circumstances, the option comes with a price, since the system will not be able to diagnose odd and incorrect formulations and data sets. The strict requirement that the set needs to be ordered for the use of lag and lead operators can be turned on again via onOrder.

The next two subsections will give some illustrative examples on the use of lag and lead operators in assignment statements and in equations respectively.

### 3.26.5.1 Lags and Leads in Assignments

Lag and lead operators may be used in assignment statements. The use of a lag or lead operator on the right-hand side of an assignment is called a reference, while their use on the left-hand side is called an assignment and involves the definition of a domain of the assignment. The concepts behind reference and assignment are equally valid for the linear and circular forms of the lag and lead operators. However, the importance of the distinction between reference and assignment is not pronounced for circular lag and lead operators, because non-existent elements are not referred to in this case.
Note

A reference to a non-existent element causes the default value zero to be used, whereas an attempt to assign to a non-existent element results in no assignment being made.

We will first illustrate linear lag and lead operators for reference and assignment. Then we will turn to the circular form of the operators.

3.26.5.1.1 Linear Lag and Lead Operators in Assignments - Reference

Consider the following example, where the lag operator is used on the right-hand side of an assignment statement:

```
Set t "time sequence" / y-1987*y-1991 /
Parameter a(t), b(t);
a(t) = 1986 + ord(t);
b(t) = -1;
b(t) = a(t-1);
option decimals = 0;
display a, b;
```

Note that the option statement suppresses the decimal places from the display statement.

```
---- 7 PARAMETER a
---- 7 PARAMETER b
```

Note that, as expected, the values for the parameter a are 1987, 1988 up to 1991 corresponding to the labels "y-1987", "y-1988" and so on. Observe that the parameter b is initialized to −1 so that the result of the next assignment can be seen clearly. Note that in the last assignment the lag operator '−' is used on the right-hand side, resulting in the values for b equal to the values for a from the previous period. If there is no previous period, as with the first element, "y-1987", the value zero is assigned, replacing the previous value of −1 (values of zero for parameters are not displayed).

3.26.5.1.2 Linear Lag and Lead Operators in Assignments - Assignment

Consider the following variation of the previous example. Here the lead operator is used on the left-hand side of an assignment statement:

```
Set t "time sequence" / y-1987*y-1991 /;
Parameter a(t), c(t);
a(t) = 1986 + ord(t);
c(t) = -1;
c(t+2) = a(t);
option decimals = 0;
display a, c;
```

Note that, as before, the option statement suppresses the decimal places from the display statement.

```
---- 7 PARAMETER a
---- 7 PARAMETER c
```
The assignment to \( a \) is explained in the previous subsection. Note that the parameter \( c \) is initialized to \(-1\). The assignment to \( c \) involving the lead operator on the left-hand side needs special attention. It is best to spell out step by step how this assignment is made. For each member of \( t \) in sequence, find the member of \( c \) associated with \( t+2 \). If it exists, replace its value with the value of \( a(t) \). If not (as with labels "y-1990" and "y-1991") make no assignment. The first member of the set \( t \) is "y-1987", therefore the first assignment is made to \( c("y-1989") \) which takes the value of \( a("y-1987") \), that is 1987. No assignments at all are made to \( c("y-1987") \) and \( c("y-1988") \): these two retain their previous values of \(-1\).

3.26.5.1.3 Circular Lag and Lead Operators in Assignments

The following example illustrates the use of circular lag and lead operators in assignment statements.

```plaintext
Set s "seasons" / spring, summer, autumn, winter /;
Parameter val(s) / spring 10, summer 15, autumn 12, winter 8 /
     lagval(s)
     leadval(s);
lagval(s) = -1;
lagval(s) = val(s--2);
leadval(s) = -1;
leadval(s++1) = val(s);
option decimals = 0;
display val, lagval, leadval;
```

Note that, as before, the option statement suppresses the decimal places from the display statement. The results are shown below.

```
----- 10 PARAMETER val
spring 10, summer 15, autumn 12, winter 8

----- 10 PARAMETER lagval
spring 12, summer 8, autumn 10, winter 15

----- 10 PARAMETER leadval
spring 8, summer 10, autumn 15, winter 12
```

In the example parameter \( \text{lagval} \) is used for reference while \( \text{leadval} \) is used for assignment. Notice that the case of circular lag and lead operators does not refer to any non-existent elements. The difference between reference and assignment is therefore not important. Note that the following two statements from the example above,

\[
\text{lagval}(s) = \text{val}(s--2); \\
\text{leadval}(s++1) = \text{val}(s);
\]

are equivalent to

\[
\text{lagval}(s++2) = \text{val}(s); \\
\text{leadval}(s) = \text{val}(s--1);
\]

The use of reference and assignment have been reversed with no difference in effect.
3.26.5.2 Lags and Leads in Equations

The principles established in the previous section follow quite naturally into equation definitions. A lag or lead to the left of the ‘.’ symbol is a modification of the domain of definition of the equation. The linear form may cause one or more individual equations to be suppressed. A lag or lead operation in the body of an equation (to the right of the ‘.’ symbol) is a reference. If the associated label is not defined, the term vanishes.

Note

All lag and lead operands must be *exogenous*. For more information, see section Functions in Equation Definitions.

In the next two subsections we will provide examples illustrating the use of the linear form of the lag and lead operators in equations to modify the domain of definition and for reference respectively. In the last subsection we will turn to *circular* lag and lead operators in equations.

3.26.5.2.1 Linear Lag and Lead Operators in Equations - Domain Control

Consider the following simple artificial multi-period example. We specify a complete model and encourage users to solve it and further explore it.

```
Sets 
  t / t1*t5 /
  tfirst(t);
Parameter 
  i(t) / #t 1 /;
Scalar 
  k0 / 3.00 /;

 tfirst(t) = yes$(ord(t) = 1);

Variables 
  k(t), z;

k.fx(tfirst) = k0;

Equations 
  kk(t), dummy;

 dummy.. z =e= 0;
 kk(t+1) .. k(t+1) =e= k(t) + i(t);

model m /all/;
option limrow = 10;
solve m using lp min z;
```

Note that the equation `kk` is declared over the set `t`, but it is defined over the domain `(t+1)`. Therefore the first equation that will be generated is the following:

```
k('t2') =e= k('t1') + i('t1');
```

Note that the value of the variable `k('t1')` is fixed at the value of scalar `k0`. Observe that for the last element of `t`, the term `k(t+1)` is not defined and therefore the equation will not be generated. If lag or lead operators are used in the domain of definition of an equation, the equation listing can be a useful tool to verify whether the equations that have been generated are those that were intended:

```
kk(t2).. - k(t1) + k(t2) =E= 1 ; (LHS = 0, INFES = 1 *****)
kk(t3).. - k(t2) + k(t3) =E= 1 ; (LHS = 0, INFES = 1 *****)
kk(t4).. - k(t3) + k(t4) =E= 1 ; (LHS = 0, INFES = 1 *****)
kk(t5).. - k(t4) + k(t5) =E= 1 ; (LHS = 0, INFES = 1 *****)
```

To summarize, the lead operator in the domain of definition has restricted the number of constraints generated so that there are no references to non-existent variables.

For a more realistic model that illustrates the usage of linear lag operators in equations, see for example the optimal economic growth model [RAMSEY].
3.26.5.2.2 Linear Lag and Lead Operators in Equations - Reference

In the previous subsection we showed how to write the equation \( kk \) using the lead operator for domain control in combination with fixing the variable \( k(t_{\text{first}}) \) to \( k_0 \). An alternative formulation could neglect the fixing of \( k(t_{\text{first}}) \) and use a lag operator and a dollar condition in the body of the equation while the domain of definition is unrestricted:

\[
kk(t) \cdot k(t) = e= k(t-1) + i(t-1) + k0\$tfirst(t);
\]

Note that for the first element of the set \( t \) the terms \( k(t-1) \) and \( i(t-1) \) are not defined and therefore vanish. Without the conditional term, the resulting equation would be:

\[
k('t1') = e= 0;
\]

However, this would lead to different results as \( k('t1') \) would not be set to the value of \( k0 \) anymore. Therefore the conditional expression \( k0\$tfirst(t) \) is added. Observe that in this formulation equations are generated for all time periods, no equation is suppressed.

In general, the choice between using lag and lead operators as reference like in the last example or in domain control is often a matter of taste.

3.26.5.2.3 Circular Lag and Lead Operators in Equations

In the case of circular lag and lead operators, the difference between their use in domain control and as reference is not important because it does not lead to any equations or terms being suppressed. Consider the following artificial example.

Set \( s \) "seasons" / spring, summer, autumn, winter /;

Variablerodu(s) "amount of goods produced in each season"
avail(s) "amount of goods available in each season"
sold(s) "amount of goods sold in each season";

Equation matbal(s);
matbal(s) .. avail(s++) = e = avail(s) + produ(s) - sold(s);

In this example four individual equations are generated. They are listed below.

\[
\begin{align*}
\text{avail('summer')} & = e = \text{avail('spring')} + \text{produ('spring')} - \text{sold('spring')} ; \\
\text{avail('autumn')} & = e = \text{avail('summer')} + \text{produ('summer')} - \text{sold('summer')} ; \\
\text{avail('winter')} & = e = \text{avail('autumn')} + \text{produ('autumn')} - \text{sold('autumn')} ; \\
\text{avail('spring')} & = e = \text{avail('winter')} + \text{produ('winter')} - \text{sold('winter')} ;
\end{align*}
\]

Note that for the last element of the set \( s \) the term \( \text{avail(s++)} \) is evaluated to \( \text{avail('spring')} \). This term is well defined and therefore it does not vanish. Similarly, using the circular lead operator in the domain of definition like in the following line will result in the same four equations being generated as above and no equation being suppressed.

\[
\text{matbal(s++) .. avail(s++)} = e = \text{avail(s)} + \text{produ(s)} - \text{sold(s)} ;
\]
3.26.6 Summary

This chapter introduced the concept of ordered sets. All the features in GAMS that dealt with this issue including the ord and card functions, as well as the linear and circular forms of the lag and lead operators were described in detail.

3.27 Data Manipulations with Parameters

3.27.1 Introduction

In this chapter we explicitly cover only parameter manipulation, including all aspects of data handling. Much of this material is relevant elsewhere (e.g. to sets), but for specifics related to assignment to sets, to conditions, and to assignments within flow control constructs such as the loop statement, see chapters Dynamic Sets, Conditional Expressions, Assignments and Equations and Programming Flow Control Features respectively.

Once initialized, data often requires manipulation in order to bring it into a form most suitable for use in a model or an application. The assignment statement is the way to do this. All the possible components of the assignment statement except conditions are introduced and discussed in this chapter.

3.27.2 The Assignment Statement

The assignment statement is the fundamental data manipulation statement in GAMS. It may be used to define or alter values associated with sets, parameters, variables or equations.

A simple assignment is written in the style associated with many other computer languages. GAMS uses the traditional symbols for addition (+), subtraction (−), multiplication (∗) and division (/). We will use them in the examples that follow, and give more details in section Expressions.

3.27.2.1 Scalar Assignments

Consider the following artificial sequence:

```gams
scalar x / 1.5 /
  x = 1.2;
  x = x + 2;
```

The scalar x is initialized to be 1.5. The second statement changes the value to 1.2, and the third changes it to 3.2. The second and third statements are assignments: each replaces the current value of x with a new one.

Note that the same symbol can be used on the left and right of the = sign. The new value is not available until the calculation is complete, and the operation gives the expected result.

Note

An assignment cannot start with a reserved word. A semicolon is therefore required as a delimiter before all assignments.

Note that extended range identifiers (e.g. INF) and acronyms may also be used in assignment statements. For specific details, see sections Extended Range Arithmetic and Acronym Usage respectively.
3.27.2.2 Indexed Assignments

The GAMS syntax for performing indexed assignments is extremely powerful. This operation offers what may be thought of as simultaneous or parallel assignments and provides a concise way of specifying large amounts of data. Consider the mathematical statement $DJ_d = 2.75 \cdot DA_d$ for all elements of $d$. This means that for every member of the set $d$, a value is assigned to $DJ$. This can be written in GAMS as follows:

\[
dj(d) = 2.75 \cdot da(d);
\]

This assignment is known technically as an indexed assignment and set $d$ as the controlling index or controlling set.

Attention

The index set(s) on the left hand side of an indexed assignment are referred to synonymously as the controlling indices, controlling sets, or controlling domain of the assignment.

The extension to two or more controlling indices should be obvious. There will be an assignment made for each label combination that can be constructed using the indices inside the parentheses. Consider the following example of an assignment to all 100 data elements of the parameter $a$.

```
sets row / r-1*r-10 /  
col / c-1*c-10 /  
sro(row) / r-7*r-10 / ;
parameters r(row) / r-1*r-7 4, r-8*r-10 5/  
c(col) / c-1*c-5 3, c-6*c-10 2/;
parameters a(row,col);
a(row,col) = 13.2 + r(row)*c(col);  
```

The calculation in the last statement is carried out for each of the 100 unique two-label combinations that can be formed from the elements of $row$ and $col$. An explicit formulation of the first of these assignments follows:

\[
a('r-1','c-1') = 13.2 + r('r-1') \cdot c('c-1');
\]

Note that for indexed assignments a copy of the symbols on the right hand side is installed before the assignment is carried out. That means it does not work "in-place" or recursively. Consider the following example where we compute the first ten Fibonacci numbers and store them in parameter $f$ using a loop. The example also illustrates how such a recursive calculation does not work with a parallel assignment statement for parameter $g$.

```
set i / i1*i10 /  
parameter  
f(i) / i1 1 /  
g(i) / i1 1 /;  
loop(i$(ord(i)>=2),  
f(i) = f(i-2) + f(i-1);  
);  
g(i)$$(ord(i)>=2) = g(i-2) + g(i-1)  
display f,g;
```
The display statement results in the following output.

```
----  9 PARAMETER f
  i1  1.000,  i2  1.000,  i3  2.000,  i4  3.000,  i5  5.000
  i6  8.000,  i7 13.000,  i8 21.000,  i9 34.000,  i10 55.000
----  9 PARAMETER g
  i1  1.000,  i2  1.000,  i3  1.000
```

### 3.27.2.3 Restricting the Domain in Assignments

Sometimes it is necessary to make assignments over selected elements of a set instead of over the entire domain. There are several ways to accomplish this: using explicit labels, subsets, conditionals and tuples.

#### 3.27.2.3.1 Restricting the Domain: Explicit Labels

The strongest restriction of the domain is assigning a value to just one element. Labels may be used explicitly in the context of assignments to accomplish this. The following example illustrates:

```
a('r-7','c-4') = -2.36 ;
```

This statement assigns a constant value to just one element of the parameter \( a \). All other elements of \( a \) remain unchanged. Labels must be quoted when used in this way.

#### 3.27.2.3.2 Restricting the Domain: Subsets

In general, wherever a set name may occur in an indexed assignment, a subset may be used instead. Consider the following example:

```
a(sro,'col-10') = 2.44 -33*r(sro) ;
```

Since the set \( sro \) was declared as a subset of the set \( row \), we can use \( sro \) as a controlling index in the assignment above to make the assignment only for the elements of \( sro \).

#### 3.27.2.3.3 Restricting the Domain: Conditionals

Conditional assignments are discussed in detail in section Conditional Assignments in chapter Conditional Expressions, Assignments and Equations. For details on the types of logical conditions, see section Logical Conditions. Here we present a simple example to illustrate:

```
a(row,col)$[a(row,col) >= 100] = INF ;
```

This assignment has the following effect: all elements of the parameter \( a \) whose value was at least 100 are assigned the value INF, while all other elements of \( a \) remain unchanged.
3.27.2.3.4 Restricting the Domain: Tuples

Tuples or multi-dimensional sets are introduced in section Many-to-Many Mapping. In this simple example we show how they may be used to restrict the domain. The example builds on the first example in this section. We repeat the whole code here for clarity.

sets row / r-1*r-10 /
col / c-1*c-10 /
sro(row) / r-7*r-10 /;
set tuple(row,col) /r-1.c-1, r-1.c-10, r-10.c-1, r-10.c-10/;
parameters r(row) /r-1*r-7 4, r-8*r-10 5/
c(col) /c-1*c-5 3, c-6*c-10 2/;
parameters a(row,col), b(row,row);
a(row,col) = 13.2 + r(row)*c(col) ;
a(tuple(row,col)) = 7 + r(row)*c(col) ;
a(tuple) = 0.25 * a(tuple) ;

Note that we have introduced the new set tuple. It is two-dimensional and contains just four elements. As before, the parameter a is first assigned values for all its 100 elements. We then change some of these values using the set tuple as domain. The values of the elements of the parameter a that are not elements of the set tuple remain unchanged.

For a more elaborate example involving tuples, see section Filtering Sets in Assignments.

3.27.2.4 Issues with Controlling Indices

Attention

The number of controlling indices on the left of the = sign should be at least as large as the number of indices on the right. There should be no index on the right-hand side of the assignment that is not present on the left unless it is operated on by an indexed operator. For more on indexed operators, see section Indexed Operations.

Consider the following statement:

a(row,'col-2') = 22 - c(col) ;

GAMS will flag this statement as an error since col is an index on the right-hand side of the equation but not on the left.

Note that there would be no error here if col were a singleton set. Since there is only one element in a singleton set, the intent and behavior is well-defined even when col is not under control.

Attention

Each set is counted only once to determine the number of controlling indices. If the intent is for a set to appear independently more than once within the controlling domain, the second and subsequent occurrences of the set should be aliases of the original set, so that the number of controlling indices is equal to the number of indices. For details on aliases, see section The Alias Statement: Multiple Names for a Set.

Consider the following statement as an illustration:

b(row,row) = 7.7 - r(row) ;
This statement has only one controlling index, namely \textit{row}. One element (on the diagonal of \textit{b}) is assigned for each element of \textit{row}, for a total of 10 assigned values. None of the off-diagonal elements of \textit{b} will be changed!

If the intent is to assign values to each element of \textit{b}, this can be done by introducing an alias \textit{rowp} for \textit{row} and using this alias in the second index position. There will then be two controlling indices and GAMS will make assignments over all 100 values of the full Cartesian product. The following example illustrates this method:

\begin{verbatim}
alias(row,rowp) ;
b(row,rowp) = 7.7 - (r(row) + r(rowp))/2 ;
\end{verbatim}

3.27.3 Expressions

An expression is an arbitrarily complicated specification for a calculation, with parentheses nested as needed for clarity and intent. In this section the discussion of parameter assignments will continue by showing in more detail the expressions that may be used on the right of the $=$ sign. We will cover standard arithmetic operations and indexed operations here, and functions and extended range arithmetic in the next two sections.

3.27.3.1 Standard Arithmetic Operations

The standard arithmetic symbols and operations and their order of precedence are given in Table 1. Note that 1 denotes the highest order of precedence and 3 denotes the lowest order of precedence. Parentheses can be used to override the default precedence order in the usual way. Operators (including exponentiation) on the same level are evaluated from left to right.

\begin{table}[h]
\centering
\begin{tabular}{|l|c|c|}
\hline
Operation & Symbol & Order of Precedence \\
\hline
Exponentiation & $^{**}$ & 1 \\
Multiplication & $*$ & 2 \\
Division & $/$ & 2 \\
Addition & $+$ & 3 \\
Subtraction & $-$ & 3 \\
\hline
\end{tabular}
\caption{Standard Arithmetic Operations}
\end{table}

Note that the full GAMS operator precedence hierarchy also includes logical operators; it is given in section Mixed Logical Conditions. Note further that the symbols for addition, subtraction and multiplication have a different meaning if they are used in the context of sets. For details see sections Set Operations and Lag and Lead Operators.

Attention

The operation $x^{**}y$ is equivalent to the function \texttt{rPower(x,y)} and is calculated internally as $e^{y \times \log(x)}$. This operation is not defined if \texttt{x} has a negative value; an error will result in this case. If the possibility of negative values for \texttt{x} is to be admitted \textit{and} the exponent is known to be an integer, then the function \texttt{power(x,u)} may be used.
Note

As usual, operations within parentheses or brackets are evaluated before other numerical calculations, where the innermost parentheses are resolved first. Any of the pairs (), [], and {} are allowed.

Consider for example:

\[ x = 5 + 4*3**2; \]

For clarity, this could have been written as follows:

\[ x = 5 + (4*[3**2]) ; \]

In both cases the result is 41.

Note

It is often better to use parentheses than to rely on the order of precedence of operators, since this prevents errors and clarifies intentions.

Note that expressions may be freely continued over many lines: an end of line is permissible at any point where a blank may be used. Blanks may be used for readability around identifiers, parentheses and operation symbols. Blanks are not allowed within identifiers or numbers, and are significant inside the quotes used to delimit labels.

3.27.3.2 Indexed Operations

In addition to the simple operations in Table 1, GAMS also provides the following four indexed operations.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>Summation</td>
<td>sum</td>
</tr>
<tr>
<td>Product</td>
<td>prod</td>
</tr>
<tr>
<td>Minimum value</td>
<td>smin</td>
</tr>
<tr>
<td>Maximum value</td>
<td>smax</td>
</tr>
</tbody>
</table>

Table 2: Indexed Operations

These four operations are performed over one or more controlling indices. The syntax in GAMS for these operations is:

\[
\text{indexed_op( (index_list), expression);}
\]

Indexed_op is one of the four keywords for indexed operations, index_list is the list of the controlling indices and expression is the expression to be evaluated. If there is only one controlling index, the parentheses around it may be removed. Consider the following simple example adapted from [ANDEAN]:

---
sets i plants / cartagena, callao, moron /
       m product / nitr-acid, sulf-acid, amm-sulf /;

parameter capacity(i,m) capacity in tons per day
       totcap(m) total capacity by process ;

totcap(m) = sum(i, capacity(i,m));

The index over which the summation is done, i, is separated from the reserved word sum by a left
parenthesis and from the data term capacity(i,m) by a comma. The set i is called the controlling
index for this operation. The scope of the control is the pair of parentheses () that start immediately
after the sum. Note that using normal mathematical representation the last line could be written as:
totCm = \sum_i C_{im}.

It is also possible to sum simultaneously over the domain of two or more sets as in the first assignment
that follows. The second assignment demonstrates the use of a less trivial expression than an identifier
within the indexed operation.

count = sum((i,j), a(i,j)) ;
emp = sum(t, l(t)*m(t)) ;

The equivalent mathematical forms are:

\[ count = \sum_i \sum_j A_{ij} \quad \text{and} \quad emp = \sum_t L_t M_t. \]

Note that the following alternative notation may be used for the first assignment above:

count = sum(i, sum(j, a(i,j)));

In the context of sets the sum operator may be used to compute the number of elements in a set and for
projections. For details see section Projection and Aggregation of Sets.

The smin and smax operations are used to find the largest and smallest values over the domain of the
index set or sets. The index for the smin and smax operators is specified in the same manner as in the
index for the sum operator. In the following example we want to find the largest capacity:

lrgunit = smax((i,m),capacity(i,m));

Attention

The indexed operations smin and smax may be used in equation definitions only if the corresponding
model is of type DNLP. For more on GAMS model types, see GAMS Model Types.

Note

● In the context of assignment statements, the attributes of variables and equations (e.g.
x.up(i,j)) may be used in indexed operations just as scalars and parameters are used.
For more on variable and equations attributes, see sections Variable Attributes and Equation
Attributes respectively.
● In the context of equation definitions, scalars, parameters and variables may appear freely in
indexed operations. For more on equation definitions, see section Defining Equations.

Sometimes it is necessary to restrict the domain of indexed operations. This may be done with the same
techniques as in indexed assignments, see section Restricting the Domain in Assignments for details. See
also section Conditional Indexed Operations for more details on conditions in the context of indexed
operations.

We now turn to two additional capabilities that are available in GAMS to add power and flexibility to
expression calculations: functions and extended range arithmetic.
3.27.4 Functions

Functions play an important role in the GAMS language, especially for nonlinear models. Like other programming languages, GAMS provides a number of built-in or intrinsic functions. GAMS is used in an extremely diverse set of application areas and this creates frequent requests for the addition of new and quite sophisticated or specialized functions. There is a trade-off between satisfying these requests and avoiding a complexity not needed by most users. The GAMS Function Library Facility provides the means for managing this trade-off, see subsection Extrinsic Functions below.

3.27.4.1 Intrinsic Functions

GAMS provides many functions, ranging from commonly used standard functions like exponentiation, logarithms, and trigonometric functions to utility functions for controlling and querying the running GAMS job or process. The complete list of available functions is given in the following tables: Mathematical Functions, String Manipulation Functions, Logical Functions, Time and Calendar Functions, and GAMS Utility and Performance Functions. For details specific to using these functions in equations, see the section on Expressions in Equation Definitions.

Some of the tables that follow contain an endogenous classification column "End. Classif." that specifies in which models the function may legally appear. In order of least to most restrictive, the choices are DNLP, NLP, any, none. See section Classification of Models for details on model types in GAMS. Note well: functions classified as any are only permitted with exogenous (constant) arguments.

Functions are typically used in assignment statements and equations. In these cases, they are only evaluated at execution time. Some functions can also be used at compile time, e.g. to compute the factorial or square root of a scalar. Some of the tables below contain a column "Compile Time" indicating which functions can be used at compile time.

A word on the notation in the tables below: for function arguments, lower case indicates that an endogenous variable is allowed. For details on endogeneous variables, see section Functions in Equation Definitions. Upper case function arguments indicate that a constant is required. Arguments in square brackets may be omitted: the default values used in such cases are specified in the function description provided.

3.27.4.1.1 Mathematical Functions

Mathematical functions may be used as expressions in assignment statements and in equation definitions. We start with some simple examples to illustrate. A list with all mathematical functions available in GAMS is given in Table 3.

**Exp(x)**

\[
a = \exp(t);
b = \exp(t+2);
\]

The GAMS function \( \exp(x) \) returns the exponential \( e^x \) of its argument. The assignments above set \( a = e^t \) and \( b = e^{t+2} \) respectively.

**Log(x)**

\[
z(j) = \log(y(j));
\]

The GAMS function \( \log(x) \) returns the natural logarithm of its argument. The assignment above evaluates the logarithm once for each element of the controlling domain \( j \).

**Max(x1,x2,x3,...)**
\[ x = \max(y+2, t, t\cdot t); \]

The function \texttt{max} returns the maximum of a set of expressions or terms. In the assignment above, \( x \) will be assigned the maximum of \( y + 2 \), \( t \), and \( t \cdot t \).

**Round\((x[\text{DECPL}])\)**

The function \texttt{round} rounds its argument \( x \) to the specified number \texttt{DECPL} of places, where positive values of \texttt{DECPL} indicating rounding to the right of the decimal point. If the argument \texttt{DECPL} is not specified, it defaults to zero, and the function rounds its argument to the nearest integer value. For example,

\[
\begin{align*}
x &= \text{round}(q); \\
y &= \text{round}(q,d); \\
z &= \text{round}(12.432,2); \\
h &= \text{round}(515.5,-1);
\end{align*}
\]

In the first assignment \( q \) is rounded to the nearest integer value, while in the second \( q \) is rounded to the number of decimals specified by \( d \). The result of the third assignment is 12.43, while the final assignment results in a value of 520.

**Table 3: Mathematical Functions**

### 3.27.4.1.2 String Manipulation Functions

GAMS provides some string manipulation capability by extending the `card` and `ord` functions to work on strings as well as sets. In Table 4 the extended behavior is described. In this context, the functions take `strings` and `places` as arguments, and the numeric `places` argument must be a constant. This behavior only applies to execution-time usage of these functions.

**Table 4: String Manipulation Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>card(STRING)</td>
<td><strong>Returns the number of characters</strong> in the string.</td>
</tr>
<tr>
<td>ord(STRING[,PLACE])</td>
<td><strong>Returns the ASCII code number of a character</strong> in a position in a string. The optional place entry defaults to 1 if omitted and identifies the character position within the string to be examined (1 for the first, 2 for the second, etc.)</td>
</tr>
</tbody>
</table>

There are four types or sources of strings in this context. A string may be a string literal, i.e. a
concatenation of letters and blanks as in "drink it" in the example that follows. It may be the symbol text (aka the explanatory text) associated with any symbol. Or it may be the labels or text associated with the elements of a set. The following table gives an overview:

Table 5: String Types

<table>
<thead>
<tr>
<th>Notation</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>characters</td>
<td>A concatenation of characters and blanks: all legal GAMS characters are allowed, see section Characters for details.</td>
<td>The characters must be surrounded by double or single quotes.</td>
</tr>
<tr>
<td>symbol_name.ts</td>
<td>The string is the explanatory text associated with a symbol name.</td>
<td>If the explanatory text is missing, the value of card is 0.</td>
</tr>
<tr>
<td>set_name.tl</td>
<td>The string is the label for a set element.</td>
<td>This string type may be used only when set_name is part of the controlling domain.</td>
</tr>
<tr>
<td>set_name.te</td>
<td>The string is the explanatory text associated with a set element.</td>
<td>This string type may be used only when set_name is part of the controlling domain. If the explanatory text is missing, the value of card is 0.</td>
</tr>
</tbody>
</table>

The string types are illustrated in the following example. Note that the directive in the first line activates the end-of-line comment option, see eolCom.

```
$oneolcom
variable z 'any symbol can have explanatory text';
set teas "teas available to order" / black "English Breakfast", green, peppermint /;
scalar p;
p = card("drink it");        !! result: p=8
p = card(z.ts);              !! result: p=36
p = card(teas.ts);           !! result: p=23
loop{teas,
    p = card(teas.tl)       !! length of set element label from the set "teas": "teas" is the controlling set
    display "length of set element label", p;
    p = card(teas.te)       !! length of set element explanatory text: "teas" is the controlling set
    display "length of set element explanatory text", p;
};
```

Note that the strings teas.tl and teas.te are used in the context of a loop statement (see section The Loop Statement). This is a typical usage pattern.

### 3.27.4.1.3 Logical Functions

Logical functions may be used as expressions in assignment statements as in the following example.

```
x = ifthen(tt=2, 3, 4+y);
```

Here \( x = 3 \) if \( tt = 2 \), otherwise \( x = 4 + y \).

The logical functions available in GAMS are given in Table 6. Note that logical functions may also be used in conditions and logic equations, see sections Logical Conditions and Logic Equations respectively.
Most of the logical functions can also be indicated using the familiar operator notation, e.g. \( (x \text{ and } y) \), \( (x \geq y) \), etc. In such cases, the operator notation is allowed at compile time. Further, note that the inputs and outputs of these functions are often logical/Boolean values, so GAMS does implicit conversions as necessary. As expected, false becomes 0 and true becomes 1 when converting logical values to numeric, and 0 becomes false and nonzero becomes true when numeric values are converted to logicals. For details on behavior when the inputs are special values, see sections Extended Range Arithmetic and Acronym Usage, but note that EPS, +INF, -INF, and acronyms become true when converted to logicals.

Table 6: Logical Functions

<td>DNLP</td>
<td>yes</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rel_eq(x,y)</td>
<td>( x \text{ eq } y )</td>
<td>Numeric Relation: Equal</td>
<td>Returns true iff ( x = y )</td>
<td>DNLP</td>
<td>alt</td>
<td></td>
</tr>
<tr>
<td>rel_ge(x,y)</td>
<td>( x \geq y )</td>
<td>Numeric Relation: Greater Equal</td>
<td>Returns true iff ( x \geq y )</td>
<td>DNLP</td>
<td>alt</td>
<td></td>
</tr>
</tbody>
</table>
3.27.4.1.4 Time and Calendar Functions  GAMS offers several functions that relate to time and dates. The fundamental measurement of time in GAMS is the serial day number beginning with January 1, 1900. This serial day number is a real number whose integer part contains a unique number for each day and whose fractional part contains information about hours, minutes, and seconds. We can think of the serial day number as being a date.time pair. The day information extracted from serial day numbers is based on the Gregorian calendar.

Note  
In all functions given in Table 7, serial day 1 is January 1, 1900.

All of the functions in Table 7 can be used at compile time.

Table 7: Time and Calendar Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

### 3.27.4.2 Extrinsic Functions

Using the GAMS Function Library Facility, functions may be imported from an external library into a GAMS model. Apart from the import syntax, the imported functions may be used in the same way as intrinsic functions. In particular, they may be used in equation definitions. Some function libraries are included with the standard GAMS software distribution, but GAMS users can also create their own libraries using an open programming interface. The GAMS Test Library instances [TRILIB01], [TRILIB02], [TRILIB03], and [CPPLIB00] are simple examples (in the programming languages C, Delphi, Fortran and C++, respectively) that come with every GAMS system.

For details on using and creating extrinsic function libraries, and on the extrinsic function libraries that are provided with GAMS, see the chapter on Extrinsic Functions.

### 3.27.4.3 Function Suffixes

Up to this point, this section has described and discussed functions without mentioning their derivatives. These derivatives are very important, though: most of the nonlinear solvers integrated with GAMS will
require first derivatives to solve models, and many will also use or require second derivatives as well. It is sometimes useful (e.g. when testing an extrinsic function) to evaluate the derivatives of GAMS functions instead of the functions themselves. This can be done via function suffixes.

Function suffixes can specify the evaluation of a gradient (i.e. first derivative), a Hessian (i.e. second derivative), a minimum or maximum value of the function over a given range, or the minimum or maximum value of the gradient over a given range. A full list of function suffixes is given in Table 9. For functions whose arguments are constant, the derivatives are zero, so typically func is a mathematical function listed in Table 3 above. Note that function suffixes are not defined for functions without arguments (for example, pi), so specifying something like pi.grad results in a compilation error.

Table 9: Function Suffixes

<table>
<thead>
<tr>
<th>Function Suffix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>func.value(x)</td>
<td>Value of the function func at x, equals func(x).</td>
</tr>
<tr>
<td>func.grad(x)</td>
<td>Value of the gradient of the function func at x.</td>
</tr>
<tr>
<td>func.gradn(x)</td>
<td>Value of the gradient of the function func at x, computed numerically.</td>
</tr>
<tr>
<td>func.hess(x)</td>
<td>Value of the Hessian of the function func at x.</td>
</tr>
<tr>
<td>func.hessn(x)</td>
<td>Value of the Hessian of the function func at x, computed numerically.</td>
</tr>
<tr>
<td>func.low(x1:x2)</td>
<td>Lower bound of the function func(x) on the interval [x1,x2].</td>
</tr>
<tr>
<td>func.high(x1:x2)</td>
<td>Upper bound of the function func(x) on the interval [x1,x2].</td>
</tr>
<tr>
<td>func.gradL(x1:x2)</td>
<td>Lower bound of the gradient of the function func(x) on the interval [x1,x2]</td>
</tr>
</tbody>
</table>
| func.gradH(x1:x2)   | Upper bound of the gradient of the function func(x) on the interval [x1,x2]|}

Consider the following simple example:

```gams
scalars g, l, h, gl, gh;

g = sin.grad(0);
l = sin.low(pi/3:pi/2);
h = sin.high(pi/3:pi/2);
gl = sin.gradL(pi/3:pi/2);
gh = sin.gradH(pi/3:pi/2);

display g, l, h, gl, gh;
```

For univariate functions like sine or cosine, there is no need to specify a variable index when evaluating derivatives. For multivariate functions, the default is to take partial derivatives w.r.t. the first variable. To specify other variables, the colon syntax in the example below is used.

```gams
scalars x / 1 /
ylo / -1 /
yup / 2 /
e0, e1, elo, ehi
     e_1, e_2
     e_11, e_22, e_21
     ;
```
\begin{verbatim}
e0 = edist(x,ylo);
e1 = edist(x,yup);
e0 = edist.low(x,ylo:x,yup);
ehi = edist.high(x,ylo:x,yup);

\textbf{e}_1 = edist.grad(x,yup);
\textbf{e}_1 = edist.grad(1:x,yup); \textit{same as above}
e_2 = edist.grad(2:x,yup);
e_11 = edist.hess(x,yup);
\textbf{e}_11 = edist.hess(1:1:x,yup); \textit{same as above}
e_22 = edist.hess(2:2:x,yup);
e_21 = edist.hess(2:1:x,yup);

display x, ylo, yup, e0, e1, elo, ehi, e_1, e_2, e_11, e_22, e_21;
\end{verbatim}

For more examples, see model [FUNCS4] in the GAMS Test Library.

Note

- The function suffixes \textit{value}, \textit{grad}, \textit{gradn}, \textit{hess} and \textit{hessn} are also defined for extrinsic functions. When implementing an extrinsic function, be aware that missing derivatives will be computed numerically: see model [TRILIB01] for an example.

To compute derivatives numerically, GAMS uses finite difference approximations. This computation can be controlled with two options: the \textit{FDOpt} option controls which variant of the finite difference method is used, while the \textit{FDDelta} option controls the step size.

### 3.27.5 Extended Range Arithmetic and Error Handling

GAMS uses an \textit{extended range} arithmetic to handle missing data, the results of undefined operations, infinite values, and zeros that are stored explicitly. The \textit{special values} used in this arithmetic are listed and described in Table 10 below, along with the value of the \textit{mapVal} function that corresponds to these values. We can think of special values as any value for which \textit{mapVal} does not return 0.

<table>
<thead>
<tr>
<th>Special value</th>
<th>Description</th>
<th>\textit{mapVal}</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{INF}</td>
<td>Plus infinity. Similar to IEEE plus infinity. Behaves in the expected way in computations, so that e.g. \texttt{min(x,INF)} = x unless x is also special.</td>
<td>6</td>
</tr>
<tr>
<td>\texttt{-INF}</td>
<td>Minus infinity. Similar to IEEE minus infinity. Behaves in the expected way in computations, so that e.g. \texttt{max(x,INF)} = x unless x is also special.</td>
<td>7</td>
</tr>
<tr>
<td>\texttt{NA}</td>
<td>Not available - used to indicate missing data. It is a sticky value: e.g. \texttt{max(x,NA)} = NA even for \texttt{x = INF}</td>
<td>5</td>
</tr>
<tr>
<td>\texttt{UNDF}</td>
<td>Undefined - indicates the result of an undefined or illegal operation. Similar to IEEE NaN. A user cannot directly set a value to \texttt{UNDF} unless the dollar control option \texttt{onUNDF} is active. For details, see the chapter on Dollar Control Options.</td>
<td>4</td>
</tr>
<tr>
<td>\texttt{EPS}</td>
<td>A stored zero value. If the dollar control option \texttt{onEPS} is active, zeros in a parameter or table statement are treated as \texttt{EPS}. For details on dollar control options, see chapter Dollar Control Options.</td>
<td>8</td>
</tr>
</tbody>
</table>

\textbf{Table 10:} Special Values for Extended Range Arithmetic
Attention

Avoid creating or using numbers with very large (1.0e299 or above) or very small (1.0e-299 or below) magnitudes. Large numbers may be treated by GAMS as undefined (UNDF) or other special values, leading to unpredictable and unusable results. Always use INF (or -INF) explicitly for arbitrarily large (or small) numbers.

GAMS has defined the results of all arithmetic operations and all function evaluations that use these special values. The behavior is designed to both maximize utility and minimize surprise, and is illustrated in the library model [CRAZY]. For example: 1+INF evaluates to INF, 1-EPS to 1, NA * 2 to NA, and EPS*INF to UNDF.

The following table shows a selection of results for exponentiation and division for a variety of input parameters including NA and INF.

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a**b</th>
<th>power(a,b)</th>
<th>a/b</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
<td>4</td>
<td>4</td>
<td>1</td>

</tbody>
</table>

Table 11: Extended Range Arithmetic in Exponentiation and Division

Note that most extended range identifiers may be used in assignment statements, as illustrated below.

```gams
a(row,'col-3') = NA;
a(row,'col-4') = INF;
a(row,'col-5') = -INF;
```

The values most often used in assignments are NA in incomplete tables and INF for variable bounds.

The special value EPS is numerically equal to zero, so when used in the context of numerical comparisons, it behaves as zero. For example, the logical expressions x > 0 and x > EPS have the same result. However, EPS is a stored zero, so setting a parameter to zero (e.g. a(row,col)=0) results in no values being stored for a, while setting a parameter to EPS (e.g. a(row,col)=EPS) results in the value EPS being stored for every (row,col) tuple. This is sometimes useful, especially if a is used later in loops (see Programming Flow Control Features) or dollar conditions (see Conditional Expressions, Assignments and Equations).

For example, consider the statement

```gams
a(row,col)$[a(row,col)] = INF ;
```

In the case where a was originally assigned to be zero, the dollar-condition is always false so no infinities are assigned. If a was originally assigned the value EPS, the dollar-condition is always true and every tuple in a will be set to infinity.

When an attempted arithmetic operation is illegal or has undefined results because of the value of arguments (division by zero is the normal example), an error is reported and the result is set to undefined (UNDF). The error is marked on the output file with a row of four asterisks "****" making this sequence a good search target in the editor. GAMS will also report the line number of the offending statement and give as much detail as possible about the cause. From there on, the resulting UNDF is treated as a proper data value and does not trigger additional error messages. For more on error messages, see chapter GAMS Output.
Note

GAMS will not solve a model if an error has been detected, and it will terminate with an error condition.

It is therefore wise to anticipate and avoid operations like division by zero that will cause errors. This is most easily done with the dollar control, and is discussed in section The Dollar Condition.

3.27.6 Predefined Symbols

GAMS offers several predefined symbols including: sameAs, diag, sortedUels, solvers, licenseCodes, solverCapabilities, componentEDate, componentMDate, and ComponentLicenseOptions. With the exception of sameAs, diag, and sortedUels these predefined symbols are for very special (and mostly internal) purposes, but the way they work is identical.

These symbols can be used in a GAMS program without being declared but work in an idiosyncratic way. For example, the complete program

display solvers, sameAs;

compiles and executes without error and produces the following result in the listing file:

```
---- 1 SET Solvers Available Solvers  ( EMPTY )
---- 1 SET SameAs Set Element Comparison Without Checking  ( EMPTY )
```

However, if labels have been declared (in any set) that corresponds to a solver name, then set solvers will contain this label. Consider the following example:

Set titles / Lord, Baron, Duke /;
Set greeks / Euclid, Pythagoras, Antigone /;
display solvers, sameAs;

Note that Antigone and Baron are the names of solvers in GAMS and therefore they will be displayed as a member of the set solvers. Also note that the set sameAs contains the diagonal elements for both sets:

```
---- 3 SET Solvers Available Solvers
   Baron , Antigone
```

```
---- 3 SET SameAs Set Element Comparison Without Checking

  Лорд  Барон  Дуки  Еуclid  Питагорас  Антигона

  Лорд  YES
  Барон  YES
  Дуки  YES
  Еуclid  YES
  Питагорас  YES
  Антигона  YES
```
User defined symbols can have the same name as a predefined symbol. In this case the user symbol hides the predefined symbols as demonstrated in the following example:

```gams
Set diag / 1*3 /;
$if setType diag $log diag is a set
$if preType diag $log diag is a predefined type
```

The log will only contain the line `diag is a set`. The test `$if preType diag` fails.

The list of all predefined symbols can be retrieved by declaring and displaying a set using some system data:

```gams
data set pre /system.predefinedSymbols/; display pre;
```

which results in

```
---- 1 SET pre
   SameAs , Diag , Solvers
   LicenseCodes , SolverCapabilities , SortedUvs
   ComponentEDate , ComponentMDate , ComponentLicenseOptions
```

### 3.27.7 Summary

GAMS provides powerful facilities for data manipulation with parallel assignment statements, built-in functions and extended range arithmetic.

### 3.28 Data Entry: Parameters, Scalars and Tables

#### 3.28.1 Introduction

Data handling is of crucial importance in all modeling applications. The quality of the numbers and the intelligence with which they are used is likely to be at least as important as the logic of the model in determining if an application is successful or not. GAMS has been designed to have a complete set of facilities for entering information, manipulating it and reporting on the results. In this chapter we will concentrate on data entry. Chapter Data Manipulations with Parameters introduces and discusses data manipulations. For details on reporting, see chapters GAMS Output, The Display Statement, The Put Writing Facility, and GAMS Data eXchange (GDX).

One very important principle will motivate all our discussions on data:

**Note**

Data should be entered in its most basic form and each data item should be entered only once.

There are two reasons for adopting this principle. Numbers are almost certain to change, and when they do we want to be able to make the process of changing them as easy and safe as possible. We also want to make our model easy for others to read and understand. Keeping the amount of data as small as possible will certainly help. All the data transformations are shown explicitly in the GAMS representation, which makes it possible to reproduce the results of a study and shows the reader all the assumptions made during data manipulation. Another advantage is that everything needed to run or change the model is included in one program that can easily be moved from place to place or from one machine to another.

This chapter deals with the data type *parameter*. For other data types, see section Data Types and Definitions. Data for *parameters* can be entered in three basic formats: scalar, list oriented, or tables of two or more dimensions. For each of these formats, GAMS offers a separate keyword:
### Table 1: Parameters, Scalars and Tables

Note that the term *parameter* is used in two ways: as data type and as keyword, so one could also see *scalars* and *tables* as special formats of *parameters*. Each of the data input formats will be introduced and discussed in the following sections. At the end of the chapter the special data type *acronym* is introduced.

Note

- By default, parameters in all input formats may only be initialized once, thereafter data must be modified with assignment statements. This can be changed using the dollar control option `$onMulti`.
- This chapter explains the complete syntax to declare *parameters* which includes the optional initialization. So, while it is possible to initialize the data at declaration, often the data is read from other sources like databases or spreadsheets. More information about this can be found in the chapter *Data Exchange with Other Applications*.

#### 3.28.2 Scalars

The *scalar* statement is used to declare and (optionally) initialize a GAMS parameter of dimensionality zero. This means that there are no associated sets, so there is exactly one number associated with the parameter.

##### 3.28.2.1 The Syntax

In general, the syntax for a *scalar* declaration in GAMS is as follows:

```plaintext
scalar[s] scalar_name [text] [/numerical_value/]
{ scalar_name [text] [/numerical_value/]} ;
```

The keyword *scalar[s]* indicates that this is a *scalar* statement and *scalar_name* is the internal name of the scalar in GAMS, it is an *identifier*. The optional *explanatory text* is used to describe the scalar and the optional *numerical value* is assigned to be the value of *scalar_name*. *Numerical_value* can be given as fixed number or as *constant evaluation*. Alternatively, the special data type *acronym* may be used as value. For details on acronyms, see section *Acronyms*.

Note that more than one scalar may be declared in one scalar statement. The entries have to be separated by commas or by end of line. For advice on explanatory text and how to choose a *scalar_name*, see the tutorial *Good Coding Practices*.

Note that scalars may be declared but not initialized in the scalar statement. A value can also be assigned later as illustrated in the example that follows.
3.28 Data Entry: Parameters, Scalars and Tables

3.28.2.2 An Illustrative Example

An example of a scalar definition in GAMS is shown below.

Scalar
rho  "discount rate"           /  .15  /
  irr  "internal rate of return"
  life "financial lifetime of productive units" / 20 /;

The statement above initializes rho and life, but not irr. Later on another scalar statement can be used to initialize irr or an assignment statement could be used to provide the value:

irr = 0.07;

For more on scalar assignments and parameter assignments in general, see section Data Entry by Assignment.

3.28.3 Parameters

The parameter format is used to enter list oriented data which can be indexed over one or several sets.

3.28.3.1 The Syntax

In general, the syntax for a parameter declaration in GAMS is as follows:

parameter[s] param_name[(index_list)] [text] [/ element [=] numerical_value
  {,element [=] numerical_value} /]
  {,param_name[(index_list)] [text] [/ element [=] numerical_value
  {,element [=] numerical_value} /]};

The keyword parameter[s] indicates that this is a parameter statement and param_name is the internal name of the parameter in GAMS, it is an identifier. A parameter may be defined over one or more sets that may be specified in the index_list. Note that the specification of the index list in the declaration is optional. However, mostly it is advisable to specify it for reasons of clarity and to enable domain checking. For more on domain checking, see section Domain Checking. The optional explanatory text is used to describe the parameter.

Parameter initialization requires a list of data elements, each consisting of a label or label-tuple and a value. Element is an element of the defining set or - if there is more than one defining set - a combination of the elements of the defining sets. The referenced set elements must belong to the set that the parameter is indexed over. Finally, numerical_value is the value assigned to the record defined by the set element or element tuple. It can be given as fixed number or as constant evaluation. Alternatively, the special data type acronym may be entered as value. For details on acronyms, see section Acronyms.

Note

The default value of a parameter is 0.

Slashes must be used at the beginning and end of the list, and commas must be used if several data elements are listed in one line. An equals sign or a blank separates the label tuple from its associated value. A parameter can be defined in a similar syntax to that used for a set. For advice on explanatory text and how to choose a parameter name, see the tutorial Good Coding Practices.

Note

Several parameters may be declared in one parameter statement.
3.28.3.2 Illustrative Examples

The following example illustrates the parameter statement. It is adapted from [MEXSS]. We also show the set definitions because they make the example clearer. For more on sets definitions, see chapter Set Definition.

Set i "steel plants" / hylsa monterrey hylsap puebla /
       j "markets" / mexico-df, monterrey, guadalaja /;

Parameter
dd(j) "distribution of demand"
      / mexico-df 55, guadalaja 15 /;

The index specification for the parameter dd means that there will be a vector of data associated with it, one number corresponding to every member of the set j. The numbers are specified along with the declaration in a format very reminiscent of the way we specify sets: in this simple case a label followed by a blank separator and then a value. Any of the legal number entry formats are allowable for the value. For details on number formats in GAMS, see subsection Numbers. The default data value is zero. Since monterrey has been left out of the data list, the value associated with dd('monterrey') is zero. As with sets, commas are optional at end of line.

We may also list several data elements on a line, separated by commas as in the following example:

Parameter
    a(i) / seattle = 350, san-diego = 600 /
    b(i) / seattle 2000, san-diego 4500 /;

If a parameter is defined over a set and all elements of the set are assigned the same value, then the following notation may be used as a shortcut:

parameter param_name[(set_name)] [text] /(#|set.)set_name numerical_value/;

Here set is a reserved word and set_name is the name of the set as it has been declared in a previous set declaration statement. Instead of set, one could also use the # sign. The following artificial example illustrates this notation:

Set j /j1, j2/;
Parameter hh(j) /set.j 10/
       gg /#j 10/;

This resolves in hh('j1') = hh('j2') = gg('j1') = gg('j2') = 10.

Note

By default it is not possible to define an empty parameter at declaration. This may be changed using the dollar control option $onEmpty, as shown in the following example:

Set i / seattle, san-diego /;
$onEmpty Parameter a(i) / /;

That initializes a('seattle') and a('san-diego') to 0. So it is not the same as this:

Set i / seattle, san-diego /;
Parameter a(i);

Here, a is declared, but not initialized (so, it is not defined yet) and one would get an error when trying to read it.
3.28.3.3 Parameter Data for Higher Dimensions

A parameter may have several dimensions. For the current maximum number of permitted dimensions, see Dimensions. The list oriented data initialization through the parameter statement can be easily extended to data of higher dimensionality. The label that appears on each line in the one-dimensional case is replaced by a label tuple for higher dimensions. The elements in the \( n \)-tuple are separated by dots (\( . \)) just like in the case of multi-dimensional sets.

The following example illustrates the use of parameter data for higher dimensions:

```gams
Parameter
salaries(employee,manager,department)
   / anderson .murphy .toy = 6000
   hendry .smith .toy = 9000
   hoffman .morgan .cosmetics = 8000 /;
```

All the mechanisms using asterisks and parenthesized lists that we introduced in our discussion of sets are available here as well. For details see section Multi-Dimensional Sets. Below is an artificial example, in which a very small fraction of the total data points are initialized. GAMS will mark an error if the same label combination (or label-tuple) appears more than once in a data list.

```gams
Set row / row1*row10 /
   col / col1*col10 /;
Parameter
   a(row, col)
      / (row1,row4) . col2*col7 12
      row10 . col10 17
      row1*row7 . col10 33 /;
```

In this example the twelve elements \( row1 . col2 \) to \( row1 . col7 \) and \( row4 . col2 \) to \( row4 . col7 \) are all initialized at 12, the single element \( row10 . col10 \) at 17, and the seven elements \( row1 . col10 \) to \( row7 . col10 \) at 33. The other 80 elements (out of a total of 100) remain at their default value, which is 0. This example shows the ability of GAMS to provide a concise initialization or definition for a sparse data structure.

3.28.4 Tables

Tabular data can be declared and initialized in GAMS using a table statement. For two and higher-dimensional parameters this provides an easier and more concise method of data entry than the list based approach, since - at least in smaller tables - each label appears only once.

3.28.4.1 The Syntax

In general, the syntax for a table declaration in GAMS is as follows:

```gams
table table_name[(index_list)] [text] EOL
   element { element } EOL
   element numerical_value { numerical_value} EOL
{element numerical_value} EOL} ;
```

The keyword `table` indicates that this is a `table` declaration and `table_name` is the internal name of the table in GAMS, it is an `identifier`. The name of the parameter can be followed by the `index_list`. In the `index_list` the sets are specified over which the table is defined. Note that the specification of the index list in the declaration is optional. However, mostly it is advisable to specify it for reasons of clarity and to enable domain checking. For more on domain checking, see section Domain Checking. The optional `explanatory text` is used to describe the table, followed by `EOL` which means "end of line", a line break. `Element` is an element of one of the driving sets. More details follow below. `Numerical_value` is the value of the entry associated with the corresponding element combination. It can be given as fixed number or as constant evaluation. Alternatively, the special data type `acronym` may be used as value. For details on acronyms, see section Acronyms. For advice on explanatory text and how to choose a `table_name`, see the tutorial Good Coding Practices.

Attention

By default, the table statement is the only statement in the GAMS language that is not free format. This may be changed using the dollar control option `$onDelim`.

The following rules apply:

- The relative positions of all entries in a table are significant. This is the only statement where end of line (EOL) has meaning. The character positions of the numeric table entries must overlap the character positions of the column headings.
- The column section has to fit on one line.
- The sequence of values forming a row must be on the same line.
- The element definition of a row can span more than one line.
- A specific column can appear only once in the entire table.

The rules for building simple tables are straightforward. The components of the header line are

```
keyword - identifier - index_list - text
```

Note that the `index_list` and the `text` are optional. Labels are used on the top and the left to map out a rectangular grid that contains the data values. The order of labels is unimportant, but if domain checking has been specified (i.e. the `index_list` has been given in the first line of the table declaration) each label must match one in the associated set. Labels must not be repeated, but can be left out if the corresponding numbers are all zero or not needed. At least one blank must separate all labels and data entries. Blank entries imply that the default value (zero) will be associated with that label combination.

Note

- Tables must have at least two dimensions. For the current maximum number of permitted dimensions, see Dimensions.
- In contrast to the `set`, `scalar`, and `parameter` statements, only one identifier may be declared and initialized in a `table` statement.
### 3.28.4.2 An Illustrative Example

In the following example a simple table is presented. It is adapted from [KORPET], the relevant set definitions are also given.

```plaintext
Set i "plants" / inchon, ulsan, yosu /
   m "productive units" / atmos-dist "atmospheric distillation unit"
                     steam-cr "steam cracker"
                     aromatics "aromatics unit"
                     hydrodeal "hydrodealkylator" /;

Table ka(m,i) "initial cap. of productive units (100 tons per yr)"
   inchon  ulsan  yosu
atmos-dist  3702  12910 9875
steam-cr    517   1207
aromatics   181   148
hydrodeal   180

;
```

In this example the row labels are drawn from the set `m` and those on the column from the set `i`. Note that the data for each row is aligned under the corresponding column headings. Entries that are not specified are assigned the default value zero.

Note

If there is any uncertainty about which column a number belongs to, GAMS will protest with an error message and mark the ambiguous entry.

Attention

Special care has to be taken, if tabs are used. The GAMS command line option `TabIn` controls the tab spacing. Note that this spacing might be different from the spacing that the editor is showing, hence the visible alignment might be different from the alignment that GAMS is actually using.

### 3.28.4.3 Continued Tables

If a table has too many columns to fit nicely on a single line, then the columns that don't fit may be continued on additional lines. We use the same example to illustrate:

```plaintext
Table ka(m,i) "initial cap. of productive units (100 tons per yr)"
   inchon  ulsan
atmos-dist  3702  12910
steam-cr    517   1207
aromatics   181   148
hydrodeal   180

+ yosu
atmos-dist  9875
steam-cr    1207
aromatics   148

;
```

The crucial item is the plus '+' sign above the row labels and to the left of the column labels in the continued part of the table. The row labels have been duplicated, except that `hydrodeal` has been left out, since it does not have any associated data. Tables may be continued as many times as necessary.
3.28.4.4 Tables with more than Two Dimensions

Tables may have more than two dimensions. For the current maximum number of permitted dimensions, see Dimensions. As usual, dots are used to separate adjacent labels and may be used in the row or column position. The label on the left of the row corresponds to the first set in the index list, and that on the right of each column header to the last. Obviously, there must be the same number of labels associated with each number in the table, as there are sets in the index list.

The best layout depends on the size of the defining sets and the amount of data. It should provide the most intuitively satisfactory way of organizing and inspecting the data. For most people it is easier to look down a column of numbers than across a row. However, putting extra labels on the row has the advantage of greater density of information.

The following example, adapted from [MARCO], illustrates the use of tables with more than two dimensions.

Set ci "commodities : intermediate" / naphtha "naphtha" dist "distillate" gas-oil "gas-oil" / cr "commodities : crude oils" / mid-c "mid-continent" w-tex "west-texas" / q "attributes of intermediate products" / density, sulfur /;

Table attrib(ci, cr, q) "blending attributes"
    density sulfur
         naphtha. mid-c 272 .283
         naphtha. w-tex 272 1.48
         dist . mid-c 292 .526
         dist . w-tex 297 2.83
         gas-oil. mid-c 295 .98
         gas-oil. w-tex 303 5.05
;

The table attrib could also be laid out as shown below:

Table attrib (ci,cr,q) "blending attributes"
    w-tex.density mid-c.density w-tex.sulfur mid-c.sulfur
         naphtha 272 272 1.48 .283
         dist 297 292 2.83 .526
         gas-oil 303 295 5.05 .98
;

3.28.4.5 Condensing Tables

All the mechanisms using asterisks and parenthesized lists that were introduced in the discussion of sets are available here as well. For details on these mechanisms, see section Multi-Dimensional Sets. The following example shows how repeated columns or rows can be condensed with asterisks and lists in parentheses. The set membership is not shown, but can easily be inferred.
Table upgrade\(\text{(strat, size, tech)}\)

</tr>
<tr>
<td>strategy-2*strategy-3. (small, medium)</td>
</tr>
<tr>
<td>strategy-4. medium</td>
</tr>
</tbody>
</table>

### 3.28.4.6 Handling Long Row Labels

It is possible to continue the row labels in a table on a second, or even third line in order to accommodate a reasonable number of columns. The break must come after a dot, and the rest of each line containing an incomplete row label-tuple must be blank.

The following example, adapted from [INDUS], is used to illustrate. This table actually has nine columns and many rows, here we have reproduced just a small part to show continued row label-tuples.

Table yield \((c, t, s, w, z)\) "crop yield (metric tons per acre)"

<table>
<thead>
<tr>
<th>nwpf</th>
<th>pmw</th>
</tr>
</thead>

### 3.28.5 Constant Evaluation

Instead of fixed numerical values, one can also use constant expressions to assign values to parameters in a data statement. The syntax of constant expressions used in data statements follows the GAMS syntax as described in Data Manipulations with Parameters, but is restricted to scalar values and a subset of the GAMS intrinsic functions, as summarized below:

- Real numbers only
- Evaluation left to right
- Operator precedence:
  - `^`, `**`
  - `/`, `*`
  - `+`, `-` binary and unary
  - `<`, `<=`, `>=`, `>`, `LE`, `GE`, `EQ`, `NE`, `GT`
  - `NOT`
  - `AND`, `XOR`, `EQV`, `IMP`
• See Functions for list of supported functions

When used in a data statement, the constant expressions have to be enclosed in a pair of square brackets [ ] or curly brackets { }. Spaces can be used freely inside those brackets. Here is a little examples:

Scalars x "PI half" / [pi/2] / 
e "famous number" / [ exp( 1 ) ] /;

Parameter y "demo" / USA.(high,low) [1/3] 
   USA.medium {1/4} /;

3.28.6 Data Entry by Assignment

Data may also be entered using assignment statements. Assignments are introduced and discussed in detail in section The Assignment Statement. This section here is a short outlook and shows how parameters that have already been declared may be assigned values. The general assignment statement has the following form:

parameter_name[(index_list)] = expression;

Here parameter_name is the name of a parameter that has been declared previously in a scalar, parameter or table statement, index_list indicates the controlling indices and may either contain a set or sets, a label or label tuple or a combination of those, and expression may be a number, a numerical expression or an acronym. For details on numerical expressions, see section Expressions.

The following examples illustrate how assignments may be used for data entry.

Set j /j1, j2, j3/;
Scalar a1;
Scalars a2 /11/;
Parameter cc(j),
   bc(j) /j2 22/;
a1 = 10;
a2 = 5;
cc(j) = bc(j)+10;
cc("j1") = 1;

The scalar a1 is declared but not initialized in the first scalar statement. It is assigned the value of 10 in the first assignment. The scalar a2 is initialized in the second scalar statement and this value is changed to 5 in the second assignment. Note that the original data is not retained. In the parameter statement the parameter cc(j) is declared but not initialized and the parameter bc(j) is only initialized for j2. This means that bc('j2') = 22 and bc('j1') = bc('j3') = 0, the default value. Now, the third assignment sets the parameter cc(j) and assigns to all elements of the set j the value of the parameter bc(j) plus 10. So we have cc('j2') = 32 and cc('j1') = cc('j2') = 10. Note that in this example the set j has only three elements so only 3 assignments are made simultaneously. However, suppose that the number of set elements is large, say 100,000, then to each element a value is assigned with just one assignment statement. Finally, the value of cc('j1') is changed to 1.

Observe that in the examples above assignments either refer to one specific set element or to the whole set. It is also possible to make assignments to only a part of the set. The mechanisms for partial set references are discussed in section Restricting the Domain in Assignments. Set elements that are not assigned new values in an assignment with a partial set reference retain their previous values. Recall that these may be the default value, values from the parameter or table statement, or values resulting from previous calculations.
3.28.7 Acronyms

An acronym is a special data type that allows the use of strings as values. Note that acronyms have no numeric values and are treated as character strings only.

3.28.7.1 The Syntax

The declaration for an acronym is similar to a set or parameter declaration. The basic format is as follows:

\[
\text{Acronym} \{\text{ acronym\_name } \{\text{ text }\} , \text{ acronym\_name } \{\text{ text }\} \};
\]

The keyword \texttt{acronym[s]} indicates that this is an acronym statement and \texttt{acronym\_name} is the internal name of the acronym in GAMS, it is an identifier. The optional explanatory text is used to describe the acronym. For advice on explanatory text and how to choose an \texttt{acronym\_name}, see the tutorial Good Coding Practices.

Note that more than one acronym may be declared in one acronym statement. The entries have to be separated by commas or by end of line. A simple example illustrates this:

\[
\text{Acronym Monday, Tuesday, Wednesday, Thursday, Friday;}
\]

3.28.7.2 Acronym Usage

Acronyms may be used as data in scalar, parameter and table statements. An example for acronyms in a parameter statement follows.

\[
\text{Set machines / m-1*m-5 / ;}
\text{Acronym Monday, Tuesday, Wednesday, Thursday, Friday;}
\text{Parameter shutdown(machines) / m-1 Tuesday m-2 Wednesday m-3 Friday m-4 Monday m-5 Thursday / ;}
\]

Acronyms may also be used in assignments as in the example below. For more on assignments, see section The Assignment Statement.

\[
\text{Acronym Monday, Tuesday, Wednesday, Thursday, Friday;}
\text{Scalar dayOfWeek;}
\text{dayOfWeek = Wednesday;}
\]

Note that \textit{numerical} operations like addition or subtraction are not allowed with acronyms. Such operations would be meaningless since acronyms do not have numeric values.

Another context where acronyms may be used is in logical conditions. For more on logical conditions, see chapter Conditional Expressions, Assignments and Equations. This is shown in the following example:
Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
Scalar dayOfWeek
    workHours /6/;
dayOfWeek = Wednesday;
workHours$(dayOfWeek <> Friday) = 8;

Note that only the equality and inequality operators may be used with acronyms. Other operations like addition and division are meaningless since acronyms do not have numeric values.

Acronyms are specific to GAMS and hence difficult to deal with when exchanging data with other systems. Users often replace parameters that contain acronyms with dynamic sets that have an additional index whose values correspond to the acronyms found in the original parameter. The machine shutdown data from above can be represented via a two-dimensional set as follows:

Set machines / m-1*m-5 /;
    weekdays / Monday, Tuesday, Wednesday, Thursday, Friday /;
    shutdown(machines,weekdays) /
        m-1.Tuesday
        m-2.Wednesday
        m-3.Friday
        m-4.Monday
        m-5.Thursday /;

3.28.8 Summary

In this chapter, the declaration and initialization of parameters with the Scalar, Parameter, and Table statement have been discussed. Chapter Data Manipulations with Parameters will describe how this data can be changed with assignment statements.

3.29 Variables

3.29.1 Introduction

This chapter covers the declaration and manipulation of GAMS variables. Many of the concepts covered in the previous chapters are directly applicable here.

A variable is the GAMS name for what are called endogenous variables by economists, columns or activities by linear programming experts, and decision variables by industrial Operations Research practitioners. They are the entities whose values are generally unknown until after a model has been solved. A crucial difference between GAMS variables and columns in traditional mathematical programming terminology is that one GAMS variable is likely to be associated with many columns in the traditional formulation.

3.29.2 Variable Declarations

A GAMS variable, like all other identifiers, must be declared before it may be referenced.
3.29 Variables

3.29.2.1 The Syntax

The declaration of a variable is similar to a set or parameter declaration, in that domain lists and explanatory text are allowed and recommended, and several variables may be declared in one statement. The syntax is given below.

```
[var_type] variable[s] var_name [(index_list)] [text] [/var_data/] {, var_name [(index_list)] [text]}
```

The keyword `var_type` denotes the optional variable type that is explained in detail in the next subsection. `Variable[s]` is the keyword that indicates that this is a variable statement. `Var name` is the internal name of the variable in GAMS, it is an identifier. In the optional `index_list` the set or sets may be specified over which an indexed variable is declared. The optional explanatory text may be used to describe the variable for future reference and to ease readability. Specifying variable data is another optional element in the variable statement. Variable data allows to initialize variable attributes at compile time. For an example and details on variable attributes, see section Variable Attributes.

A typical variable statement adapted from the model [RAMSEY] is shown below for illustration:

```
Variables
  k(t) capital stock (trillion rupees)
  c(t) consumption (trillion rupees per year)
  i(t) investment (trillion rupees per year)
  utility utility measure;
```

The declaration of `k` above implies, as usual, that references to `k` are restricted to the domain of the set `t`. A model that includes `k` will probably have several corresponding variables in the associated mathematical programming problem: most likely one for each member of `t`. In this way, very large models can be constructed using a small number of variables. (It is quite unusual for a model to have as many as 50 distinct variables.) It is still unclear from the declaration whether `utility` is not domain checked or whether it is a scalar variable, i.e., one without associated sets. Later references will be used to settle the issue. For more details on domain checking, see section Domain Checking.

As the syntax indicates, the explanatory text is optional. However, it is important that variable declarations include explanatory text and that this be as descriptive as possible, since the text is used to annotate the solution output. Note the use of 'per' instead of '/' in the text above: slashes are illegal in all unquoted text.

Note
- Variable names, the contained set element names plus the explanatory text must obey the general rules for language items.
- Variables can be defined over from 0 up to 20 sets
- The sets over which variables are declared indicate that these variables are potentially defined for every element of the defining sets. However the actual definition of variables does not occur until variables appear in an equation definition where the equation needs to be part of a model that in turn occurs in a solve statement.

3.29.2.2 Variable Types

There are nine basic types of variables that may be used in variable statements. These are shown in table Table 1.
<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
<th>Default Lower Bound</th>
<th>Default Upper Bound</th>
</tr>
</thead>
<tbody>
<tr>
<td>free (default)</td>
<td>No bounds on variable. Both bounds may be changed from the default values by the user.</td>
<td>-inf</td>
<td>+inf</td>
</tr>
<tr>
<td>positive or nonnegative</td>
<td>No negative values are allowed for variable. The user may change both bounds from the default value.</td>
<td>0</td>
<td>+inf</td>
</tr>
<tr>
<td>negative</td>
<td>No positive values are allowed for variables. The user may change both bounds from the default value.</td>
<td>-inf</td>
<td>0</td>
</tr>
<tr>
<td>binary</td>
<td>Discrete variable that can only take values of 0 or 1. For details see section Types of Discrete Variables. In relaxed Model types the integrality requirement is relaxed.</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>integer</td>
<td>Discrete variable that can only take integer values between the bounds. The user may change both bounds from the default value. The default upper bound inside GAMS is +inf but when the variable is passed on to the solver, the option or command line parameter IntVarUp decides what upper bound (by default 100) is passed on to the solver in case GAMS has upper bound +inf. In relaxed Model types the integrality requirement is relaxed.</td>
<td>0</td>
<td>+inf</td>
</tr>
<tr>
<td>sos1</td>
<td>A set of variables, such that at most one variable within a group may have a non-zero value. For details see section Types of Discrete Variables.</td>
<td>0</td>
<td>+inf</td>
</tr>
<tr>
<td>Keyword</td>
<td>Description</td>
<td>Default Bound</td>
<td>Lower Bound</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>sos2</td>
<td>A set of variables, such that at most two variables within a group may have non-zero values and the two non-zero values are adjacent. For details see section Types of Discrete Variables.</td>
<td>0</td>
<td>+inf</td>
</tr>
<tr>
<td>semicont</td>
<td>Semi-continuous, must be zero or above a given minimum level. For details see section Types of Discrete Variables.</td>
<td>1</td>
<td>+inf</td>
</tr>
<tr>
<td>semiint</td>
<td>Semi-integer, must be zero or above a given minimum level and integer. For details see section Types of Discrete Variables. The default upper bound inside GAMS is +inf but when the variable is passed on to the solver, the option or command line parameter IntVarUp decides what upper bound (by default 100) is passed on to the solver in case GAMS has upper bound +inf. In relaxed Model types the integrality requirement is relaxed.</td>
<td>1</td>
<td>+inf</td>
</tr>
</tbody>
</table>

**Table 1:** Variable types and default bounds

The default type is **free**, which means that if the type of the variable is not specified, it will not be bounded at all. The most frequently used types are **free** and **positive**. The type **positive variables** is used for variables for which negative values are meaningless, such as capacities, quantities or prices. Note that bounds may be changed using variable attributes and assignment statements, see section **Variable Attributes**.

**Note**

- Every optimization model must contain at least one unrestricted named variable (i.e. one declared with the keywords **Variable** or **Free Variable**). This variable is the objective variable. Even an objective variable can have lower and upper bounds assigned via the .lo and .up variable attribute.
- If a model is unbounded, a frequent cause for the unboundedness is that the modeler forgot to make a variable positive.
3.29.2.3 Styles for Variable Declaration

Two styles are commonly used to declare variable types. The first is to list all variables with domain specifications and explanatory text as a group, and later to group them separately as to type. The example shown below is adapted from [MEXSS]. The default type is free, so phi and phipsi will be free variables in the example below. Note the use of variable names derived from the original mathematical representation.

**Variables**

```plaintext
Positive Variables u, v, e;
```

The commas in the list of positive variables are required separators.

**Attention**

It is possible to declare an identifier more than once. However, the second and any subsequent declarations should only add new information that does not contradict what has already been entered.

The second popular way of declaring variables is to list them in groups by type. We rewrite the example above using this second method:

**Free Variables**

```plaintext
phi "total cost (mill us$)"
phipsi "raw material cost (mill us$)"
```

**Positive Variables**

```plaintext
u(c,i) "purchase of domestic materials (mill units per yr)"
v(c,j) "imports (mill tpy)"
e(c,i) "exports (mill tpy)"
```

The choice between the two approaches is best based on clarity.

3.29.3 Variable Attributes

While a GAMS parameter has one number associated with each unique label combination, a variable has several. They represent:

<table>
<thead>
<tr>
<th>Variable Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lower bound</td>
<td>.lo</td>
<td>Lower bound for the variable. Set by the user either explicitly or through default values associated with the variable type.</td>
</tr>
<tr>
<td>Upper bound</td>
<td>.up</td>
<td>Upper bound for the variable. Set by the user either explicitly or through default values associated with the variable type.</td>
</tr>
<tr>
<td>Fixed value</td>
<td>.fx</td>
<td>A fixed value for the variable. If set it results in the upper and lower bounds of the variable to be set to the value of the .fx attribute.</td>
</tr>
</tbody>
</table>
3.29 Variables

<table>
<thead>
<tr>
<th>Variable Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activity level</td>
<td>.l</td>
<td>Activity level for the variable, also the current value or starting point. This attribute is reset to a new value when a model containing the variable is solved. The activity level is used to construct a basis for the model.</td>
</tr>
<tr>
<td>Marginal</td>
<td>.m</td>
<td>The marginal value (or reduced cost) for the variable. This attribute is reset to a new value when a model containing the variable is solved. The activity level is used to construct a basis for the model.</td>
</tr>
<tr>
<td>Scale factor</td>
<td>.scale</td>
<td>Numerical scaling factor for all coefficients associated with the variable if the model attribute scaleopt is set to 1. For more on scaling, see section Model Scaling - The Scale Option. Only applicable for continuous variables.</td>
</tr>
<tr>
<td>Branching priority</td>
<td>.prior</td>
<td>Branching priority value used in mixed integer programming models if the model attribute prioropt is set to 1. For details see section Setting Priorities for Branching. It can also be used to relax discrete restrictions by setting .prior = +inf regardless of the prioropt setting. Only applicable for discrete variables.</td>
</tr>
<tr>
<td>Stage</td>
<td>.stage</td>
<td>This attribute allows to assign variables to stages in a stochastic program or other block structured model. Its current use is limited to 2-stage stochastic programs solved with DECIS and other exotic features, e.g. the Benders partition in CplexD.</td>
</tr>
</tbody>
</table>

Table 2: Variable Attributes

Users distinguish between these values when necessary by appending the suffix to the variable name. Examples are given below.

It is possible to specify initial values for these variable attributes at compile time. This can be done within the variable declaration statement as illustrated in the following example or during execution time as explained in section Assigning Values to Variable Attributes.

```
Variable x1(j) my first / j1.up 10 , j1.lo 5, j1.l 7, j1.m 0, j1.scale 20 /;
```

The upper bound of the variable x1("j1") is set to 10, the lower bound is set to 5, the starting value for the activity level is set to 7 and the starting value for the marginal is set to 0. The variable is also scaled by the factor 20, which means it is multiplied by 20.

Note that it is also possible to use a table structure to assign values to variable attributes. The following example is adapted from model [TRNSPORT].

```
Variable Table x(i,j) initial values
     1   m
seattle. new-york  50
seattle. chicago  300
san-diego.new-york  275
san-diego.chicago  0.009;
```

Note

- `.fx` and attributes `.lo` and `.up` on the same variable cannot be in a data statement. `.fx` sets both `.lo` and `.up` and hence we would have a double definition of the same attribute. Since attribute `.scale` is applicable for continuous variables and attribute `.prior` for discrete variables, they share the same internal space in a GAMS variable. Some solvers can make use of priorities even for continuous variables (e.g. BARON). Such priorities need to be supplied via a solver option file.

- The attribute `.stage` uses the same internal space as `.scale` and `.prior`. So a model cannot specify scale factor and branching priorities together with stages.

In addition to the variable attributes introduced above, there are a number of variable attributes that cannot be assigned but may be used in computations. They are given in Table 3.

<table>
<thead>
<tr>
<th>Variable Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td><code>.range</code></td>
<td>The difference between the lower and upper bounds for a variable. It becomes zero if the lower equals the upper bound, e.g. if the <code>.fx</code> attribute is set.</td>
</tr>
<tr>
<td>Slack upper bound</td>
<td><code>.slackup</code></td>
<td>Slack from variable upper bound. This is defined as the greater of two values: zero or the difference between the upper bound and the level value of a variable.</td>
</tr>
<tr>
<td>Slack lower bound</td>
<td><code>.slacklo</code></td>
<td>Slack from variable lower bound. This is defined as the greater of two values: zero or the difference between the level value and the lower bound of a variable.</td>
</tr>
<tr>
<td>Slack</td>
<td><code>.slack</code></td>
<td>Minimum slack from variable bound. This is defined as the minimum of two values: the slack from the variable lower bound and the slack from the variable upper bound.</td>
</tr>
<tr>
<td>Infeasibility</td>
<td><code>.infeas</code></td>
<td>Amount by which a variable is infeasible falling below its lower bound or above its upper bound. This is defined as the smallest of three values: zero, the difference between the lower bound and the level value, the difference between the level value and the upper bound of a variable, i.e. <code>max(0, lower-level, level-upper)</code>.</td>
</tr>
</tbody>
</table>

Table 3: Additional Variable Attributes that Cannot Be Assigned but May Be Used in Computations.

3.29.3.1 Bounds on Variables

All default bounds set at declaration time may be changed using assignment statements.

Attention

For discrete variable types, the consequences of the type declaration cannot be completely undone (e.g. the `.scale` attribute is not available) but their value domain can be changed to continuous by setting attribute `.prior` to infinity.

Bounds on variables are the responsibility of the user. After variables have been declared, default bounds have already been assigned: for many purposes, especially in linear models, the default bounds are sufficient. In nonlinear models, however, bounds play a far more important role. It may be necessary to provide bounds to prevent undefined operations, such as division by zero. In nonlinear programming it is often necessary to define a 'reasonable' solution space that will assist in efficiently finding a solution.
3.29 Variables

Attention

The lower bound cannot be greater than the upper bound: if you happen to impose such a condition, GAMS will generate an execution error, namely "**** Matrix error - lower bound > upper bound" when executing a solve statement.

Note that the upper bound on integer and semi-integer variables needs special consideration. The default upper bound is +\text{inf} and the option or command line parameter IntVarUp controls what upper bound is sent to the solver. With the current default value (1) of IntVarUp, an upper bound of 100 is sent to the solver. Setting IntVarUp to zero will pass +\text{inf} as the default upper bound to the solver. The other available values for IntVarUp work like zero, but enable special reports/execution errors in case the solution reports a level value greater than 100 for any integer variable with a default bound of +\text{inf}.

3.29.3.2 Fixing Variables

GAMS allows the user to fix variables through the .\text{fx} variable suffix. This is almost equivalent to setting the lower bound and upper bound equal to the fixed value. The attribute .\text{fx} also resets the activity level .\text{l} to the fixed value. When setting .\text{lo} and .\text{up} the activity level remains unchanged. A solve statement will project the activity level within the active bounds. Fixed variables can subsequently be freed by changing the lower and upper bounds.

3.29.3.3 Activity Levels of Variables

GAMS allows the user to set the activity levels of variables through the .\text{l} variable suffix. These activity levels of the variables prior to the solve statement serve as initial value for the solver. This is particularly important for nonlinear programming problems. For discrete models in many cases the solver needs an additional indicator to interpret the activity levels as a feasible integer solution via a solver option (e.g. Cplex' \text{mipstart}).

Attention

- GAMS only stores variables with non-default values (similar to storing only non-zero values of parameters). Non-default variables can be accidentally created by using harmlessly looking assignments like

\[ \text{x.up}(i,j,k,l) = 0; \]

Even if the equations only reference such variables over a small subset of \((i,j,k,l)\) this statement creates \text{card}(i)*\text{card}(j)*\text{card}(k)*\text{card}(l) variable records in the GAMS database. Such fixings of \(x(i,j,k,l)\) to 0 can be avoided by using dynamic sets or dollar conditions in the equation algebra to only reference tuples of \((i,j,k,l)\) for which \(x(i,j,k,l)\) can possibly have a non-zero value.

- In order to filter only necessary tuples for an equation the filtering conditions needs to be provided only once when defining the equation (equ\((i,j,k)\)). This is different for variables because they appear in many equations and the filtering condition needs to be potentially repeated many time. Therefore it is good practice and reduces GAMS model generation time if the filtering of the variables is governed by a dynamic set:

\[ \text{sum}((i,j)$(\text{ord}(i)>\text{ord}(j) \text{ and } \text{cap}(i,j)>0), x(i,j)) \]

versus

\[ \text{set net}(i,j); \text{net}(i,j) = \text{ord}(i)>\text{ord}(j) \text{ and } \text{cap}(i,j)>0; \]
\[ \text{sum}(\text{net}(i,j), x(i,j)) \]
3.29.4 Variables in Display and Assignment Statements

GAMS allows the modeler to use the values associated with the various attributes of each variable in assignment and display statements. The next two subsections explain the use of variables on the left and right-hand sides of assignment statements respectively. Then we will explain the use of variables in display statements.

3.29.4.1 Assigning Values to Variable Attributes

Assignment statements operate on one variable attribute at a time, and require the suffix to specify which attribute is being used. Any index list comes after the suffix.

The following code snippets are from models [MEXSS] and [RAMSEY]. The first example illustrates the use of assignment statements to set upper and lower bounds on variables.

```gams
x.up(c,i,j) = 1000 ; phi.lo = inf ;
```

A very common use is to bound one particular entry individually:

```gams
p.up('pellets', 'ahmsa', 'mexico-df') = 200 ;
```

Or to put small lower bounds on a variable identifier used as a divisor in a nonlinear program:

```gams
c.lo(t) = 0.01 ;
```

Or to provide initial values for a nonlinear problem:

```gams
c.l(t) = 4*cinit(t) ;
```

Remember that the order is important in assignments, and notice that the two pairs of statements below produce very different results. In the first case, the lower bound for \( c('1985') \) will be 0.01, but in the second, the lower bound is 1.

```gams
c.fx('1985') = 1; c.lo(t) = 0.01 ;
c.lo(t) = 0.01 ; c.fx ('1985') = 1 ;
```

Everything works as described in the previous chapter, including the various mechanisms described there of indexed operations, dollar operations, subset assignments and so on. An example from model LOCATION follows.

```gams
ship_sm.lo(sl,m)$\{$ord(sl) = 1 and ord(m) = 1\} = 1;
```

The lower bound of the variable \( \text{ship}_\text{sm}(sl,m) \) is set to 1 and this assignment is only valid for \( \text{ship}_\text{sm}('s1', 'd1') \), the realization of the variable where both indices are the first members of their respective sets.
3.29.4.2 Variable Attributes in Assignments

Using variable attributes on the right-hand side of assignment statements is important for a variety of reasons. Two common uses are for generating reports and for generating initial values for some variables based on the values of other variables. For more on variable attributes in report writing, see section Displaying Variable Attributes below and especially chapter The Put Writing Facility.

The following examples adapted from model [CHENERY] illustrate the use of variable attributes on the right-hand side of assignment statements:

* initial values for variables

\[
y.l(i) = 250 \; ; \; x.l(i) = 200 \; ; \\
e.l(t) = 0 \; ; \; m.l(t) = 0 \; ; \\
g.l(t) = mew(t) + xsi(t)*m.l(t) \; ; \\
h.l(t) = gam(t) - alp(t)*e.l(t) \; ;
\]

* generating report after solve

Scalar

\[
cva \quad \mbox{"total value added at current prices"} \\
rva \quad \mbox{"real value added"} \\
cli \quad \mbox{"cost of living index"} \\
\]

\[
cva = \sum (i, v.l(i)*x.l(i)) \; ; \\
cli = \sum (i, p.l(i)*ynot(i))/\sum (i, ynot(i)) \; ; \\
rva = cva/cli \; ;
\]

Display cli, cva, rva ;

As with parameters, a variable must have some non-default data values associated with it before it can be used in a display statement or on the right-hand side of an assignment statement. After a solve statement has been processed or if non-default values have been set with an assignment statement, this condition is satisfied. Solve statements are introduced and discussed in chapter Model and Solve Statements.

Attention

The .fx suffix is mostly just a shorthand for .lo and .up and can therefore only be used only on the left-hand side of an assignment statement.

Note

In general, the variable level needs to be specified via the attribute .l for assignment statements. However, the dollar control option $on/offDotL allows the implicit use of the attribute .l in assignment statements, thus it facilitates using the same algebra in model definitions and assignment statements. This is especially useful in the context of macros.
3.29.4.3 Displaying Variable Attributes

The display statement is introduced and discussed in detail in chapter The Display Statement. Here we demonstrate how variable attributes are used in display statements.

Since several values are associated with each variable, the user must specify which attribute should be displayed when using variables in display statements. As before, appending the appropriate suffix to the variable name does this and no domain specification may appear. As an example, we show how to display the level of phi and the level and the marginal values of v from [MEXSS]:

```plaintext
display phi.l, v.l, v.m;
```

The output looks similar, except that (of course) the listing shows which of the values is being displayed. Because zeroes, and especially all zero rows or columns, are suppressed, the patterns seen in the level and marginal displays will be quite different, since non-zero marginal values are often associated with activity levels of zero.

```
Mexico Steel - Small Static (MEXSS,SEQ=15)

     Execution
     ---- 203 VARIABLE PHI.L = 538.811 total cost (mill us$)
     ---- 203 VARIABLE V.L imports (mill tpy)
           ( ALL 0.000 )
     ---- 203 VARIABLE V.M imports (mill tpy)
           mexico-df monterrey guadalaja
                          steel 7.018 18.822 6.606
```

We should mention here a clarification of our previous discussion of displays. It is actually the default values that are suppressed on display output. For parameters and variable levels and marginals, the default is zero, and so zero entries are not shown. For bounds, however, the defaults can be non-zero. The default value for the upper bound of a positive variable is +INF, and if we would also display v.up above, for example, we would see:

```plaintext
     ---- 203 VARIABLE V.UP imports (mill tpy)
           ( ALL +INF )
```

If any of the bounds have been changed from the default value, then only the entries for the changed elements will be shown. This may sound confusing, but since few users display bounds it has not proved troublesome in practice.

Note

The attribute .range may be used in display statements. It provides a convenient way to check whether a variable is fixed as it lists the 0 values explicate because the default for range (which won’t be displayed) is +inf.
3.29.5 Summary

Remember that wherever a parameter may appear in a display or an assignment statement, a variable may also appear - provided that it is qualified with one of the suffixes. The only places where a variable name may appear without a suffix is in a variable declaration, as has been shown in this chapter, in an equation definition, which is discussed in chapter Equations, or in a $on/offDotL$ block.

3.30 Equations

3.30.1 Introduction

The keyword equation defines GAMS names that may be used in the model statement. A GAMS equation name is associated with the symbolic algebraic relationships that will be used to generate the constraints in a model. The algebraic relationships are defined by using constants, mathematical operators, functions, sets, parameters and variables. As with variables, one GAMS equation may be defined over a group of sets and in turn map into several individual constraints associated with the elements of those sets. Most of the example code in this chapter is from the model location.

This chapter is organized as follows. First, we introduce how equations are declared and defined, then we discuss expressions in equation definitions, followed by a section on equation attributes. A summary and quick reference conclude the chapter.

3.30.2 Declaring Equations

An equation must be declared before it can be defined and used in a model.

3.30.2.1 The Syntax

The declaration of an equation is similar to a set or parameter declaration. The syntax is given below.

Equation[s] eqn_name [(index_list)] [explanatory text] [/eqn_data/] {, eqn_name [(index_list)] [explanatory text] [/eqn_data/]}

Equation[s] is the reserved word that indicates that one or more blocks of equations are about to be declared. A block of equations may initiate one or more individual constraints. Eqn_name is the internal name of the equation, an identifier in GAMS. In the optional index_list the set or sets are specified over which an indexed equation is declared. The optional explanatory text may be used to describe the equation for future reference and to ease readability. Specifying equation data is another optional element in the equation declaration. Equation data allows to initialize equation attributes at compile time. For an example see the next section. For more on equation attributes see section Equation Attributes.

One or more equations may be declared in one equation statement. The equation names have to be separated by commas or by a line break as in the example that follows. The end of the declaration statement is indicated by a semicolon.

Note

It is good practice to end the equation declaration with a semicolon, even though it is not mandatory if the next statement starts with a GAMS keyword.

For advice on choosing equation names and phrasing the explanatory text see chapter Good Modeling Practices.
3.30.2.2 An Illustrative Example

The following example is from the model location. In addition to the equation declarations the relevant set definitions are given.

Sets
- sl 'supply locations' /s1, s2/
- wh 'warehouse locations' /a, b, c/;

Equations
- tcost_eq 'total cost accounting equation'
- supply_eq(sl) 'limit on supply available at supply location'
- capacity_eq(wh) 'warehouse capacity' /a.scale 50, a.l 10, b.m 20/;

The keyword Equations marks the beginning of the equation declaration. Each equation name is optionally followed by its domain (associated set or sets) unless it is a scalar equation. It is possible but not good practice to declare indexed equations without their domains. The name of the first equation is tcost_eq and it is followed by the explanatory text 'total cost accounting equation'. The name of the equation tcost_eq is not followed by any associated sets. Since we follow good practice here we assume that tcost_eq is a scalar equation. Scalar equations do not have any associated sets and will generally produce one equation in the model. For more on scalar equations see subsection Scalar Equations.

The other two equations are indexed equations, they are declared over a set. The equation supply_eq is declared over the set sl and the equation capacity_eq is declared over the set wh. In typical circumstances an indexed equation declaration implies that a block of constraints will be generated. For example, equation supply_eq(sl) implies that two constraints will be generated, one for each element of the set sl. For more on indexed equations see subsection Indexed Equations.

The declaration of the equation capacity_eq specifies some equation attributes. The first entry indicates that the equation capacity_eq('a') is scaled by a factor of 50, which means division of all entries in that equation by 50 upon model passage to the solver. For more on scaling see section Model Scaling - The Scale Option. The second entry sets the initial value of the equation capacity_eq('a') to 10 and b.m means that the initial marginal value of the equation capacity_eq('b') is set to 20. Alternatively, a table structure may be used to specify the values of equation attributes. The following table may replace the notation above.

```
Equation Table capacity_eq(wh) 'warehouse capacity'
      scale  l    m
        a  50   10
        b  20 ;
```

For more on equation attributes see section Equation Attributes.

Note

An equation may be declared over more than one set.

3.30.3 Defining Equations

After declaring equations they have to be defined. The definition of an equation specifies the algebraic structure of the equation in GAMS. The syntax is given first, an illustrative example follows and in the remainder of this section some of the key components of equation definitions are discussed.
### 3.30.3.1 The Syntax

The syntax for defining an equation is as follows:

\[
\text{eqn\_name(index\_list)[\$logical\_condition(s)].. expression eqn\_type expression ;}
\]

**Eqn\_name** is the name of the equation as introduced in the equation declaration, that may be followed by an **index\_list** for indexed equations. In the **index\_list** the set or sets are specified over which an indexed equation is defined. These sets are also called **domain of definition** of the equation. One or more logical conditions are optional. For an example see Indexed Equations. For more on logical conditions in equation definitions see Dollar Control over the Domain of Definition. The two dots '..' are mandatory and indicate the start of the algebra. It is good practice to end the definition of an equation with a semicolon, even though it is not mandatory if the next statement starts with a GAMS keyword.

**Attention**

An equation must be declared before it is defined.

**Expression** refers to an algebraic expression which may include variables, parameters, functions, and constants among other items. For details on expressions in GAMS, see section Expressions.

**Attention**

Only variables that appear at least once with a nonzero coefficient in an equation definition will appear in a model.

**Eqn\_type** refers to the equation type denoted by the symbol between the right-hand side and left-hand side expressions that form the equation. The symbols that are allowed are given in **Table 1**.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(=e=)</td>
<td>Equality: right-hand side must equal left-hand side.</td>
</tr>
<tr>
<td>(=g=)</td>
<td>Greater than: left-hand side must be greater than or equal to right-hand side.</td>
</tr>
<tr>
<td>(=l=)</td>
<td>Less than: left-hand side must be less than or equal to right-hand side.</td>
</tr>
<tr>
<td>(=n=)</td>
<td>No relationship implied between left-hand side and right-hand side. This equation type is ideally suited for use in MCP models and in variational inequalities.</td>
</tr>
<tr>
<td>(=x=)</td>
<td>Equation is defined by external programs. See External Equations.</td>
</tr>
<tr>
<td>(=c=)</td>
<td>Conic constraint. See Conic Programming in GAMS.</td>
</tr>
<tr>
<td>(=b=)</td>
<td>Boolean equations. See Logic Equations.</td>
</tr>
</tbody>
</table>

**Table 1**: Equation Types

Equation definitions may be carried over as many lines of input as needed. Blanks may be inserted to improve readability, and expressions may be arbitrarily complicated.

Note that an equation can only be defined once. By using logical conditions it is possible to control which constraints are generated. In addition, the components of an equation may be modified by changing the data it uses. However, if the logic of the equation needs to be changed then a new equation with a new name has to be declared and defined.
3.30.3.2 An Illustrative Example

Consider the following example adapted from the model [mexss]. The associated variable and equation declarations are also included.

Variables phi, phipsi, philam, phi, phi p, phi eps;
Equations obj;
obj.. phi =e= phipsi + philam + phi p - phi eps;

The name of the equation being defined is obj and the symbol =e= indicates that this is an equality. Any of the following forms of the equation are mathematically equivalent.

obj.. phipsi + philam + phi p - phi eps =e= phi;
obj.. phi - phieps =e= philam - phi + phi p;
obj.. phi + phi p - phi e p - phi eps - philam =e= 0;
obj.. 0 =e= phi + phi p - phi e p - phi eps - philam - phi p;

Note
The arrangement of the terms in the equation is a matter of choice, but often a particular one is chosen because it makes the model easier to understand.

3.30.3.3 Scalar Equations

A scalar equation will produce one equation in the associated optimization problem. The equation obj defined above is an example of a scalar equation which contains only scalar variables. Note that scalar equations may contain indexed variables. However, they must occur with an indexed operator such as sum or prod, unless the indexed variables refer to a singleton set (a set with only one element). Consider the following example from the model location. Note that the set wh has three elements.

configure_eq.. sum(wh, build(wh)) =l= 1;

The variable build is defined over the set wh, it is an indexed variable. It may be used in the scalar equation configure_eq since it occurs in conjunction with the indexed operator sum.

3.30.3.4 Indexed Equations

All the set references in scalar equations are within the scope of indexed operators or they refer to singleton sets; thus many variable, set and parameter references can be included in one equation. In addition, GAMS also allows for equations to be defined over a domain, thereby developing a compact representation for constraints. The index sets to the left of '...' are called the domain of definition of the equation.
3.30 Equations

Note

- Domain checking ensures that the domain over which an equation is defined is the set (or the sets) or a subset of the set (or the sets) over which the equation was declared.
- As a corollary, domain checking also catches the error of the indices being listed in an inconsistent order. For example, declaring an equation as myequation(s,t) and then naming it in the definition as myequation(t,s) causes an error (unless s and t are aliases of the same set). For more information, see section Domain Checking.

The following indexed equation with a single index generates a separate constraint for each member of the driving (or controlling) set. It is taken from the model [chenery]. In this example, t is a set with three members, mew and xsi are parameters and m and g are variables.

\[
dg(t) .. g(t) = e= mew(t) + xsi(t) \times m(t) ;
\]

As the set t has three members, three constraints will be generated, one for each member of t specifying the dependence of g on m. The data associated with the parameters mew and xsi are used to build the individual constraints. This data does not have to be known when the equation is defined, but it has to be populated before a model containing the equation is solved.

The extension to two or more indices on the left of '..' is obvious. There will be one constraint generated for each combination of set elements that can be constructed using the indices inside the parenthesis. Here are two examples from the model [aircraft], a scheduling model.

\[
bd(j,h) .. b(j,h) = e= dd(j,h) - y(j,h) ;
\]
\[
yd(j,h) .. y(j,h) = l= \text{sum}(i, p(i,j) \times x(i,j)) ;
\]

The domain of definition of both equations is the Cartesian product of j and h: constraints will be generated for every set element pair that can be constructed from the members of these two sets.

The next example illustrates the use of the optional logical conditions in the definition of equations. It is taken from the production and distribution model [ferts].

\[
CC(m,i) \text{\$mpos(m,i)} .. \text{\text{sum}}(p \text{\$ppos(p,i)}, b(m,p) \times z(p,i)) = l= \text{util} \times k(m,i) ;
\]

CC is a capacity constraint defined for elements of the sets m and i. However, in this case not all cases of m exist at each location i, and the mapping set mpos(m,i) tells the cases where m exists at i and thus is used to restrict the domain cases for which the constraints are actually generated. The control of the summation over p with ppos(p,i) is an additional logical condition, and is required because not all processes p are possible at all locations i.

The equation may alternatively written in the following way:

\[
CC(\text{mpos}(m,i)) .. \text{\text{sum}}(\text{ppos}(p,i), b(m,p) \times z(p,i)) = l= \text{util} \times k(m,i) ;
\]

Instead of defining the equation over the indices (m,i) the equation is defined over the set mpos that is itself defined over the indices (m,i). A similar logic applies to restricting the summation.

Conditional expressions are introduced and discussed in the section Conditional Expressions, Assignments and Equations. See specifically Dollar Control over the Domain of Definition for logical conditions in equation definitions.
3.30.3.5 Using Labels Explicitly in Equations

Sometimes it can be necessary to refer to specific set elements in equations. This can be done as with parameters - by using quotes or double quotes around the label. Consider the following example from the model location:

\[ \text{sum}(m, \text{ship}_wm(wh,m)) = l = \text{build}(wh) \times \text{data}(wh, "capacity") ; \]

3.30.3.6 Logic Equations

Logic equations use Boolean algebra and have to evaluate to TRUE (or 1) to be feasible. The Boolean functions available in GAMS and the default order of precedence of the operators are given in Table 2. Note that 1 denotes the highest order of precedence or the most binding operator and 3 denotes the lowest order of precedence or the least binding operators. As usual, the default order of precedence holds only in the absence of parentheses and operators on the same level are evaluated from left to right.

<table>
<thead>
<tr>
<th>Function</th>
<th>Operator</th>
<th>Alternative Notation</th>
<th>Return Values</th>
<th>Order of precedence</th>
</tr>
</thead>
<tbody>
<tr>

<td>3</td>
</tr>
<tr>
<td>Material equivalence</td>
<td>x eqv y or x &lt;= y</td>
<td>bool_eqv(x,y)</td>
<td>returns 0 if exactly one argument is 0, else returns 1</td>
<td>3</td>
</tr>
</tbody>
</table>

Table 2: Boolean Functions and Operator Precedence

Note that in the table above \( x \) and \( y \) are binary variables.

There are three ways to declare and define logic equations:

1. The logic equation is declared using the keyword Logic Equation and the definition contains only Boolean algebra symbols.
2. The logic equation is declared like any other equation using the keyword Equation and in the definition the symbol \( =b= \) appears indicating that it is a logic equation.
3. This is a combination of the first two options: the equation is declared with the keyword Logic Equation and defined using the symbol \( =b= \).

The following example demonstrates the first way to declare and define a logic equation. It is adapted from the food manufacturing problem [foodemp]. In this problem the blending of oils is modeled.
Sets
  m  "planning period (month)" / m1*m6 /
p  "raw oils" / v1*v2, o1*o3 /

Variables
  induse(m,p) "indicator for usage of raw oil per month" ;
Binary variable induse;

Logic Equation
  deflogic(m) "if some vegetable raw oil is used we also need to use the non-vegetable oil o3" ;
  deflogic(m).. induse(m,'v1') or induse(m,'v2') -> induse(m,'o3');

The variable induse is a binary variable, it can only take the values 0 and 1. The equation ensures that in an optimal solution if either vegetable oil v1 or vegetable oil v2 is blended in a product, then non-vegetable oil o3 is also blended in that product.

An alternative formulation of the equation deflogic using the =b= notation is given below.

  deflogic(m).. induse(m,'v1') or induse(m,'v2') -> induse(m,'o3') =b= 1;

Note that the value of 1 on the right-hand side means that the logic expression on the left-hand side must evaluate to TRUE in a feasible solution. To illustrate further, we could negate the left-hand side expression using the logic operator not and then the right-hand side would have to evaluate to zero or FALSE to yield the same result as above. The respective equation definition follows.

  deflogic(m).. not (induse(m,'v1') or induse(m,'v2') -> induse(m,'o3')) =b= 0;

Note that currently logic equations are allowed only in models of the GAMS model type EMP. For more on GAMS model types see section Classification of Models.

3.30.4 Expressions in Equation Definitions

The arithmetic operators and some of the functions that are described in section Expressions may be used in equation definitions.

Consider the following example adapted from the model [chenery] demonstrating the use of parentheses and exponentiation.

  dem(i) ..  y(i) =e= ynot(i)*(pd*p(i))**thet(i) ;

A list of arithmetic operators is given in subsections Standard Arithmetic Operations and Indexed Operations.
3.30.4.1 Functions in Equation Definitions

All available GAMS functions are listed in the section Functions. Some functions are not allowed at all in equation definitions. They include random distribution functions and are marked with none in the third column of the tables listing all functions.

Attention

Some functions like uniform and normal are not allowed in equation definitions.

The use of the other functions is determined by the type of arguments in the model. There are two types of arguments:

1. Exogenous arguments: The arguments are known. Parameters and variable attributes (for example, .l and .m attributes) are used as arguments. The expression is evaluated once when the model is being set up and most mathematical functions as well as time and calendar functions are allowed.

2. Endogenous arguments: The arguments are variables and therefore unknown at the time of model setup. The function will be evaluated many times at intermediate points while the model is being solved. Note that the occurrence of any function with endogenous arguments implies that the model is not linear.

Functions that are allowed only with exogenous arguments are marked with any in the tables listing all functions.

There are two types of functions allowing endogenous arguments: smooth functions and discontinuous functions. Smooth functions are continuous functions with continuous derivatives (like sin, exp, log). Discontinuous functions include continuous functions with discontinuous derivatives (like max, min, abs) and discontinuous functions (like ceil, sign). Smooth functions may be used routinely in nonlinear models. However, discontinuous functions may cause numerical problems and should be used only if unavoidable, and only in a special model type called DNLP. For more details on model types see section Classification of Models.

Attention

The best way to model discontinuous functions is with binary variables. The result is a model of the type MINLP. The model [ABSMIP] demonstrates this formulation technique for the functions abs, min, max and sign. See also section Reformulating DNLP Models. We strongly discourage the use of the DNLP model type.

In Table 3 the use of functions in equation definitions is summarized.

<table>
<thead>
<tr>
<th>Functions are allowed ...</th>
<th>Description of Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>not at all</td>
<td>Functions that are marked none in the third column of the tables listing all functions in section Functions.</td>
</tr>
<tr>
<td>only with exogenous arguments</td>
<td>Functions that are marked any in the third column of the tables listing all functions in section Functions.</td>
</tr>
<tr>
<td>with endogenous arguments</td>
<td>Smooth functions. They are marked NLP in the third column of the tables listing all functions in section Functions.</td>
</tr>
<tr>
<td>with endogenous arguments</td>
<td>Discontinuous functions. They are marked DNLP in the third column of the tables listing all functions in section Functions.</td>
</tr>
</tbody>
</table>
3.30 Equations

Table 3: Functions in Equation Definitions

3.30.4.2 Preventing Undefined Operations in Equations

Some operations are not defined at particular values of the arguments. Two examples are division by 0 and the \( \log \) of 0. While this can easily be identified at model setup for exogenous functions and expressions, it is a lot more difficult when the terms involve variables. The expression may be evaluated many times when the problem is being solved and the undefined result may arise only under certain cases. One way to avoid an expression becoming undefined is adding bounds to the respective variables. Consider the following example from the model \texttt{[ramsey]}:

\[
c\.lo(t) = 0.01 \\
util .. utility =e= \text{sum(t, beta(t)*log(c(t)))} 
\]

Specifying a lower bound for \( c(t) \) that is slightly larger than 0 prevents the \( \log \)-function from becoming undefined.

3.30.5 Equation Attributes

Equation attributes may be specified in a similar way as variable attributes. Five values are associated with each unique label combination of every equation. They are denoted by the suffixes \texttt{.l}, \texttt{.m}, \texttt{.lo}, \texttt{.up} and \texttt{.scale}. A list of the attributes and their description is given in Table 4.

<table>
<thead>
<tr>
<th>Equation Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lower bound</td>
<td>.lo</td>
<td>Negative infinity or zero for a ( \text{=g=}, \text{=e=}, \text{=c=} ) or ( \text{=b=} ) equation.</td>
</tr>
<tr>
<td>Upper bound</td>
<td>.up</td>
<td>Positive infinity or zero for an ( \text{=l=}, \text{=e=} ) or ( \text{=b=} ) equation.</td>
</tr>
<tr>
<td>Equation level</td>
<td>.l</td>
<td>Level of the equation in the current solution, equal to the level of all terms involving variables.</td>
</tr>
<tr>
<td>Marginal</td>
<td>.m</td>
<td>Marginal value for equation. This attribute is reset to a new value when a model containing the equation is solved. The marginal value for an equation is also known as the shadow price for the equation and in general not defined before solution but if present it can help to provide a basis for the model.</td>
</tr>
<tr>
<td>Scale factor</td>
<td>.scale</td>
<td>Numerical scaling factor that scales all coefficients in the equation. This is only used when the model attribute \texttt{scaleopt} is set to 1. For more on scaling, see section Model Scaling - The Scale Option.</td>
</tr>
<tr>
<td>Stage</td>
<td>.stage</td>
<td>This attribute allows to assign equations to stages in a stochastic program or other block structured model. Its current use is limited to 2-stage stochastic programs solved with DECIS.</td>
</tr>
</tbody>
</table>

Table 4: Equation Attributes

Note that all attributes except for \texttt{.scale} and \texttt{.stage} contain the attribute values of equations after a solution of the model has been obtained. For some solvers it can be useful to specify marginal values \texttt{.m} and level values \texttt{.l} on input to provide starting information. Also note that the marginal value is also known as the \textit{dual} or \textit{shadow price}. Roughly speaking, the marginal value \texttt{.m} of an equation is the amount by which the value of the objective variable would change if the equation level were moved one unit.
Equation attributes may be referenced in expressions and be can be used to specify starting values (see section Declaring Equations). In addition, they serve for scaling purposes and for reporting after a model was solved. For example, they may be displayed using the display statement. The following example is from the model location.

Model warehouse 'warehouse location model' /all/;
solve warehouse using mip min tcost;
display supply_eq.l;

The display statement generates the following output at the end of the listing file:

```
---- 108 EQUATION supply_eq.L limit on supply available at supply location
s1 50.000, s2 75.000
```

The level values of the equation supply_eq are displayed. As expected, there are two level values, one for each member of the set s1 over which the equation supply_eq was defined.

Note

By default, all equation attributes introduced above except for .scale are echoed to the solution report that is part of the listing file.

In addition to the equation attributes introduced above, there are a number of equation attributes that cannot be assigned but may be used in computations. They are given in Table 5.

<table>
<thead>
<tr>
<th>Equation Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>.range</td>
<td>The difference between the lower and upper bounds of an equation.</td>
</tr>
<tr>
<td>Slack lower bound</td>
<td>.slacklo</td>
<td>Slack from equation lower bound. This is defined as the greater of two values: zero or the difference between the level value and the lower bound of an equation.</td>
</tr>
<tr>
<td>Slack upper bound</td>
<td>.slackup</td>
<td>Slack from equation upper bound. This is defined as the greater of two values: zero or the difference between the upper bound and the level value of an equation.</td>
</tr>
<tr>
<td>Slack</td>
<td>.slack</td>
<td>Minimum slack from equation bound. This is defined as the minimum of two values: the slack from equation lower bound and the slack from equation upper bound.</td>
</tr>
<tr>
<td>Infeasibility</td>
<td>.infeas</td>
<td>Amount by which an equation is infeasible falling below its lower bound or above its upper bound. This is defined as max(0, lower bound - level, level - upper bound).</td>
</tr>
</tbody>
</table>

Table 5: Additional Equation Attributes that Cannot Be Assigned but May Be Used in Computations.

3.30.6 Summary and Quick Reference

In this chapter we have covered the declaration and definition of equations in GAMS, arithmetic operations and functions that may be used in equations and equation attributes. A list summarizing the main points to keep in mind follows.
• Equations must be declared before they may be defined. [1]

• It is good practice to add an explanatory text to the declaration. [2]

• More than one equation may be declared at once. The equation names have to be separated by commas or by a line break. [3]

• Equations may be declared and defined over sets which are called the domain of definition of the equation. [4]

• One indexed equation may generate many constraints depending on the size of the set(s) over which it is defined. [5]

• Equations may be defined over subsets. The dollar condition may be used to filter the members of a set so that only a subset of the members are considered. [6]

• The set(s) over which an equation is defined must be consistent with the set(s) over which the equation was declared, being the set(s) themselves or a subset of the set(s). [7]

• The arrangement of terms in an equation is up to the other. Variables can appear on both sides of an equation. [8]

• Labels of specific set elements may be used explicitly in equations. [9]

• All arithmetic operations that may be used to evaluate expressions are also allowed in equations. [10]

• Many functions that are defined in GAMS may be used in equations. [11]

• It is good practice to set bounds for variables to avoid undefined operations if equations contain operations that are undefined at certain values. [12]

• Equations have attributes similar to variables (.l, .m, .lo, .up and .scale). [13]

3.31 Model and Solve Statements

3.31.1 Introduction

This chapter brings together all the concepts discussed in previous chapters by explaining how to specify a model and solve it.

3.31.2 The Model Statement

The model statement is used to collect equations into groups and to label them so that they can be solved. The simplest form of the model statement uses the keyword all: the model consists of all equations declared before the model statement is entered. For most simple applications this is all the user needs to know about the model statement.
3.31.2.1 The Syntax

In general, the syntax for a model declaration in GAMS is as follows:

```
model[s] model_name [text] [/ all | eqn_name {, eqn_name} /]
  {,model_name [text] [/ all | eqn_name {, eqn_name} /]} ;
```

The keyword `model[s]` indicates that this is a model statement and `model_name` is the internal name of the model in GAMS, it is an identifier. The optional explanatory text is used to describe the model, `all` is a keyword as introduced above and `eqn_name` is the name of an equation that has been declared prior to the model statement. For advice on explanatory text and how to choose a `model_name`, see the tutorial Good Coding Practices.

Note
Model statements for Mixed Complementarity Problem (MCP) and Mathematical Program with Equilibrium Constraints (MPEC) models require a slightly different notation, since complementarity relationships need to be included. For details see subsections Mixed Complementarity Problem (MCP) and Mathematical Program with Equilibrium Constraints (MPEC).

An example of a model definition in GAMS is shown below.

```
Model transport "a transportation model" / all /;
```

The `model` is called `transport` and the keyword `all` is a shorthand for all known (declared) equations.

Several models may be declared (and defined) in one model statement. This is useful when experimenting with different ways of writing a model, or if one has different models that draw on the same data. Consider the following example, adapted from [PROLOG], in which different groups of the equations are used in alternative versions of the problem. Three versions are solved: the linear, nonlinear, and 'expenditure' versions. The model statement to define all three is:

```
Model nortonl "linear version" / cb,rc,dfl,bc,obj /
nortonn "nolinear version" / cb,rc,dfn,bc,obj /
nortone "expenditure version" / cb,rc,dfe,bc,obj / ;
```

Here `cb`, `rc`, etc. are the names of the equations. We will describe below how to obtain the solution to each of the three models.

Note
If several models are declared and defined with one model statement, the models have to be separated by commas or linefeeds and a semicolon terminates the entire statement.

If several models are declared then it is possible to use one previously declared model in the declaration of another. The following examples illustrate this:

```
Model one  "first model" / tcost_eq, supply_eq, demand_eq /
two  "second model that nests first" / one, balance_eq /
three "third model that nests first and second" / two, capacity_eq, configure_eq /;
```
Model one is declared and defined using the general syntax, model two contains all the equations of model one and the equation balance_eq, and model three contains all of model two and the equations capacity_eq and configure_eq.

In addition to nesting models as illustrated above, it is also possible to use the symbols + and - to augment or remove items relative to models that were previously defined. The following examples serve as illustration:

Model four "fourth model: model three minus model one" / three-one / 
    five "fifth model: model three without eqn configure_eq" / three-configure_eq / 
    six "sixth model: model four plus model two" / four+two /;

Model four contains the equations from model three except for those that belong to model one. Model five contains all equations from model three except for equation configure_eq. Model six contains the union of the equations in model four and two. Note that both model names and equation names may be used in association with the symbols + and -.

### 3.31.2.2 Classification of Models

Various types of problems can be solved with GAMS. Note that the type of the model must be known before it may be solved. The model types are briefly discussed in this section. GAMS checks that the model is in fact the type the user thinks it is, and issues explanatory error messages if it discovers a mismatch - for instance, that a supposedly linear model contains nonlinear terms. Some problems may be solved in more than one way, and the user has to choose which way to use. For instance, if there are binary or integer variables in the model, it can be solved either as a MIP or as a RMIP.

The model types and their identifiers, which are needed in the a solve statement, are given in Table 1. For details on the solve statement, see section The Solve Statement.

</tbody>
</table>

**Table 1:** GAMS Model Types

**Note**

- The relaxed model types RMIP, RMINLP, RMIQCP, and RMPEC solve the problem as the corresponding model type (e.g. MIP for RMIP) but relax the discrete requirement of the discrete variables. This means that integer and binary variables may assume any values between their bounds. SemiInteger and SemiCont variables may assume any values between 0 and their upper bound. For SOS1 and SOS2 variables the restriction of the number of non-zero values is removed.
- Many "LP" solvers like Cplex offer the functionality of solving convex quadratic models. So the Q matrices in the model need to be positive semidefinite. An extension to this are the second-order cone programs (SOCP) with either symmetric or rotated cones. See the solver manuals (e.g. on MOSEK) for details.
- Unlike other checks on the model algebra (e.g. existence of discrete variables or general non-linear terms), the GAMS compiler does not enforce a quadratic model to only consist of
quadratic and linear terms. This requirement is enforced at runtime for a particular model instance.

3.31.2.2.1 Linear Programming (LP) Mathematically, the Linear Programming (LP) problem looks like:

\[
\text{Minimize or maximize } \quad cx \\
\text{subject to } \quad Ax \leq b \\
L \leq x \leq U,
\]

where \( x \) is a vector of variables that are continuous real numbers, \( cx \) is the objective function, and \( Ax \leq b \) represents the set of constraints. For details on the equation types allowed in GAMS, see Equation Types. \( L \) and \( U \) are vectors of lower and upper bounds on the variables.

GAMS supports free (unrestricted) variables, positive variables, and negative variables. Note that users may customize lower and upper bounds, for details see section Bounds on Variables.

For information on LP solvers that can be used through GAMS see the Solver/Model type Matrix.

3.31.2.2.2 Nonlinear Programming (NLP) Mathematically, the Nonlinear Programming (NLP) problem looks like:

\[
\text{Minimize or Maximize } \quad f(x) \\
\text{subject to } \quad g(x) \leq 0 \\
L \leq x \leq U,
\]

where \( x \) is a vector of variables that are continuous real numbers, \( f(x) \) is the objective function, and \( g(x) \leq 0 \) represents the set of constraints. For details on the equation types allowed in GAMS, see Equation Types. Note that the functions \( f(x) \) and \( g(x) \) have to be differentiable. \( L \) and \( U \) are vectors of lower and upper bounds on the variables.

For information on NLP solvers that can be used through GAMS see the Solver/Model type Matrix. See also the tutorial Good NLP Formulations.

Note

NLP models may have the nonlinear terms inactive. In this case setting the model attribute TryLinear to 1 causes GAMS to check the model and use the default LP solver if possible. For details on model attributes, see subsection Model Attributes.

3.31.2.2.3 Quadratically Constrained Programs (QCP) Mathematically, the Quadratically Constrained Programming (QCP) problem looks like:

\[
\text{Maximize or Minimize } \quad cx + x'Qx \\
\text{subject to } \quad Aix + x'Rix \leq bi \quad \text{for all } i \\
L \leq x \leq U,
\]

where \( x \) denotes a vector of variables that are continuous real numbers, \( cx \) is the linear part of the objective function, \( x'Qx \) is the quadratic part of the objective function, \( Aix \) represents the linear part of the \( i \)th constraint, \( x'Rix \) represents the quadratic part of the \( i \)th constraint, \( bi \) is the right-hand side if the \( i \)th constraint, and \( \alpha \) is an equation operator. For details on the equation types allowed in GAMS, see Equation Types". Further, \( L \) and \( U \) are vectors of lower and upper bounds on the variables.

Note that a QCP is a special case of the NLP in which all the nonlinearities are required to be quadratic. As such, any QCP model can also be solved as an NLP. However, most "LP" vendors provide routines to solve LP models with a quadratic objective. Some allow quadratic constraints as well. Solving a model using the QCP model type allows these "LP" solvers to be used to solve quadratic models as well as linear ones. Some NLP solvers may also take advantage of the special (quadratic) form when solving QCP models.
Attention

In case a model with quadratic constraints is passed to a QCP solver that only allows a quadratic objective, a capability error will be returned (solver status 6 CAPABILITY PROBLEMS). Some solvers will fail when asked to solve a non-convex quadratic problems as described above.

Note

Using the model attribute TryLinear causes GAMS to see if the problem can be solved as an LP problem. For details on model attributes, see subsection Model Attributes.

For information on QCP solvers that can be used through GAMS see the Solver/Model type Matrix.

3.31.2.2.4 Nonlinear Programming with Discontinuous Derivatives (DNLP) Mathematically, the Nonlinear Programming with Discontinuous Derivatives (DNLP) problem looks like:

\[
\begin{align*}
\text{Minimize} & \quad f(x) \\
\text{subject to} & \quad g(x) \leq 0 \\
& \quad L \leq x \leq U,
\end{align*}
\]

where \(x\) is a vector of variables that are continuous real numbers, \(f(x)\) is the objective function, \(g(x) \leq 0\) represents the set of constraints, and \(L\) and \(U\) are vectors of lower and upper bounds on the variables. For details on the equation types allowed in GAMS, see Equation Types. Note that this is the same as NLP, except that non-smooth functions, like \(\text{abs}, \text{min}, \text{max}\) may appear in \(f(x)\) and \(g(x)\).

For information on DNLP solvers that can be used through GAMS see the Solver/Model type Matrix.

Attention

- We strongly advise against using the model type DNLP. The best way to model discontinuous functions is with binary variables, which results in a model of the type MINLP. The model [ABSMIP] demonstrates this formulation technique for the functions \(\text{abs}, \text{min}, \text{max}\) and \(\text{sign}\). See also section Reformulating DNLP Models.
- Solvers may have difficulties when dealing with the discontinuities, since they are really NLP solvers and the optimality conditions and the reliance on derivatives may be problematic. Using the global solvers ANTIGONE, BARON, COUENNE, LINDO or SCIP may alleviate this problem.

3.31.2.2.5 Mixed Integer Programming (MIP) Mathematically, the Mixed Integer Linear Programming (MIP) problem looks like:

Maximize or Minimize \[c_1 t + c_2 u + c_3 v + c_4 w + c_5 x + c_6 y + c_7 z\]
subject to \[A_1 t + A_2 u + A_3 v + A_4 w + A_5 x + A_6 y + A_7 z \alpha b\]
\[t \in \mathbb{R}\]
\[u \geq 0 \quad \text{and} \quad u \leq L_2 \quad \text{and} \quad u \in \mathbb{Z}\]
\[v \in (0,1)\]
\[w \in \text{SOS1}\]
\[x \in \text{SOS2}\]
\[y = 0 \quad \text{or} \quad L_6 \leq y\]
\[z = 0 \quad \text{or} \quad L_7 \leq z \quad \text{and} \quad z \in \mathbb{Z},\]

where
3.31 Model and Solve Statements

- $c_1 t + c_2 u + c_3 v + c_4 w + c_5 x + c_6 y + c_7 z$ is the objective function,
- $A_1 t + A_2 u + A_3 v + A_4 w + A_5 x + A_6 y + A_7 z \alpha b$ represents the set of constraints of various equality and inequality forms,
- $t$ is a vector of variables that are continuous real numbers,
- $u$ is a vector of variables that can only take integer values smaller than $L_2$,
- $v$ is a vector of binary variables,
- $w$ is a vector of variables that belong to SOS1 sets; this means that at most one variable in the set is nonzero,
- $x$ is a vector of variables that belong to SOS2 sets; this means that at most two adjacent variables in the set are nonzero,
- $y$ is a vector of variables that are semi-continuous; they are either zero or larger than $L_6$,
- $z$ is a vector of variables that are semi-integer; they are integer and either zero or larger than $L_7$.

For details on the equation types allowed in GAMS, see Equation Types. For more details on MIPs in GAMS, especially the use of SOS and semi variables, see section Special Mixed Integer Programming (MIP) Features.

For information on MIP solvers that can be used through GAMS, see the Solver/Model type Matrix.

Attention

Not all MIP solvers cover all the cases associated with SOS and semi variables. Please consult the solver manuals for details on capabilities.

3.31.2.2.6 Mixed Integer Nonlinear Programming (MINLP)  

Mathematically, the Mixed Integer Nonlinear Programming (MINLP) problem looks like:

Maximize or Minimize \[ f(x) + Dy \]
subject to \[ g(x) + Hy \alpha 0 \]
\[ L \leq x \leq U \]
\[ y = \{0, 1, 2, \ldots\} \]

where $x$ is a vector of variables that are continuous real numbers, $y$ denotes a vector of variables that can only take integer values, $f(x) + Dy$ is the objective function, $g(x) + Hy \alpha 0$ represents the set of constraints, and $L$ and $U$ are vectors of lower and upper bounds on the variables. For details on the equation types allowed in GAMS, see Equation Types. Further, $y = \{0, 1, 2, \ldots\}$ is the integrality restriction on $y$.

For information on MINLP solvers that can be used through GAMS see the Solver/Model type Matrix.

Note

- SOS and semi variables can also be accommodated by some solvers. Please consult the solver manuals for details on capabilities.
- The model attribute TryLinear causes GAMS to examine whether the problem may be solved as a MIP problem. For details on model attributes, see subsection Model Attributes.
3.31.2.2.7 Mixed Integer Quadratically Constrained Programs (MIQCP)  A Mixed Integer Quadratically Constrained Program (MIQCP) is a special case of the MINLP in which all the nonlinearities are required to be quadratic. For details see the description of the QCP, a special case of the NLP.

For information on MIQCP solvers that can be used through GAMS, see the Solver/Model type Matrix.

Note
The model attribute TryLinear causes GAMS to examine whether the problem may be solved as a MIP problem. For details on model attributes, see subsection Model Attributes.

3.31.2.2.8 Mixed Complementarity Problem (MCP) Unlike the other model types we have introduced so far, the Mixed Complementarity Problem (MCP) does not have an objective function. An MCP is specified by three pieces of data: a function \( F(z) : \mathbb{R}^n \mapsto \mathbb{R}^n \), lower bounds \( l \in \{ \mathbb{R} \cup \{-\infty\} \}^n \) and upper bounds \( u \in \{ \mathbb{R} \cup \{\infty\} \}^n \). A solution is a vector \( z \in \mathbb{R}^n \) such that for each \( i \in \{1, \ldots, n\} \), one of the following three conditions hold:

\[
\begin{align*}
F_i(z) &= 0 \quad \text{and} \quad l_i \leq z_i \leq u_i \quad \text{or} \\
F_i(z) &> 0 \quad \text{and} \quad z_i = l_i \quad \text{or} \\
F_i(z) &< 0 \quad \text{and} \quad z_i = u_i.
\end{align*}
\]

This problem can be written compactly as

\[ F(z) \perp L \leq z \leq U, \]

where the symbol \( \perp \) (which means “perpendicular to”, shortened to “perp to”) indicates pair-wise complementarity between the function \( F \) and the variable \( z \) and its bounds.

The following special case is an important and illustrative example:

\[ F(z) \perp z \geq 0. \]

In this example, the unstated but implied upper bound \( u \) is infinity. Since \( z \) is finite, we cannot have \( z_i = u_i \) and the third condition above cannot hold: this implies \( F_i(z) > = 0 \). The remaining two conditions imply pair-wise complementarity between \( z \geq 0 \) and \( F(z) \geq 0 \). This is exactly the Nonlinear Complementarity Problem, often written as

\[ F(z) \geq 0, \quad z \geq 0, \quad \langle F(z), z \rangle = 0. \]

None of this rules out the degenerate case (i.e. \( F_i(z) \) and \( z_i \) both zero). In practice, these can be difficult models to solve.

Another special case arises when the bounds \( L \) and \( U \) are infinite. In this case, the second and third conditions above cannot hold, so we are left with \( F(z) = 0 \), a square system of nonlinear equations. And finally, we should mention a special case that occurs frequently in practice: if \( l_i = u_i \) (i.e. \( z_i \) is fixed) then we have a complementary pair: one of the three conditions will hold as long as \( F_i(z) \) is defined. Essentially, fixing a variable removes or obviates the matching equation. This is often useful when modeling with MCP.

The definition above describes the canonical MCP model as it exists when GAMS passes it to an MCP solver. Some models have exactly this form even in the GAMS code, but usually some processing is done by the GAMS system to arrive at a model in this form. Here we’ll describe the steps of this process and illustrate with an example from the model library.

1. The process starts with the list of rows (aka single equations) and columns (aka single variables) that make up the MCP model, and potentially some matching information.
The usual rules apply: rows are part of the model because their associated equations are included in the model statement, but columns only become part of the model by use; a column enters the model only if it is used in some row of the model. Therefore including a variable symbol as part of a match in the model statement will not influence the set of columns belonging to the model.

Matches (where they exist) are pointers from rows to columns.

Technically, the MCP is defined via a function $F$ while a model contains constraints. Given a constraint, we define an associated function as $\text{LHS} - \text{RHS}$, so e.g. $F_i \geq 0$ is consistent with a $\geq$ constraint.

1. The model \texttt{P2R3_MCP} includes the rows from equations \texttt{dem}, \texttt{sup}, \texttt{in\_out.p}, and \texttt{dom\_trad.x} and exactly the columns used by these rows. Checking the listing file, we see columns for \texttt{Qd}, \texttt{Qs}, \texttt{x}, and \texttt{p}. In addition, the model statement specifies two matches: \texttt{in\_out.p} and \texttt{dom\_trad.x}. These matches always take the form of an \texttt{equation\_variable} pair, with no indices or domains included.

2. In this example, the rows corresponding to the equation \texttt{in\_out} match up perfectly with the columns from the variable \texttt{p}: there are no holes in the set of rows or columns because of some dollar conditions in the equation definition. We have a one-to-one match so all the rows of \texttt{in\_out} and columns of \texttt{p} are consumed by the match in the model statement. The same holds for the \texttt{dom\_trad.x} pair, so what is left are the rows of \texttt{dem} and \texttt{sup} and the columns of \texttt{Qd} and \texttt{Qs}, all of which are unmatched.

3. Any fixed columns remaining are ignored: these columns can be treated like exogenous variables or parameters.

4. If what remains is a set of $\leq$ rows and an \textit{equal number} of unbounded columns, these can be matched up in any order and we have a well-defined MCP. If this is not what remains, an error is triggered.

To illustrate how this works, consider the spatial equilibrium model \texttt{SPATEQU} with the following model statement:

```
Model P2R3_MCP / dem, sup, in\_out.p, dom\_trad.x /;
```

1. The model \texttt{P2R3_MCP} includes the rows from equations \texttt{dem}, \texttt{sup}, \texttt{in\_out} and \texttt{dom\_trad} and exactly the columns used by these rows. Checking the listing file, we see columns for \texttt{Qd}, \texttt{Qs}, \texttt{x}, and \texttt{p}. In addition, the model statement specifies two matches: \texttt{in\_out.p} and \texttt{dom\_trad.x}. These matches always take the form of an \texttt{equation\_variable} pair, with no indices or domains included.

2. In this example, the rows corresponding to the equation \texttt{in\_out} match up perfectly with the columns from the variable \texttt{p}: there are no holes in the set of rows or columns because of some dollar conditions in the equation definition. We have a one-to-one match so all the rows of \texttt{in\_out} and columns of \texttt{p} are consumed by the match in the model statement. The same holds for the \texttt{dom\_trad.x} pair, so what is left are the rows of \texttt{dem} and \texttt{sup} and the columns of \texttt{Qd} and \texttt{Qs}, all of which are unmatched.

3. There are no fixed variables to remove.

4. Since \texttt{dem} and \texttt{sup} are $\leq$ constraints and \texttt{Qd} and \texttt{Qs} are free variables, we can match them in any order without changing the solution set for this model. The counts of these unmatched equality rows and unmatched free variables are equal, so we get a well-defined MCP.

When rows are matched explicitly to columns, some care must be taken to match them consistently. For example, consider a row-column match $g.y$. The row $g$ can be of several types: $\leq$, $\geq$, $\leq =$, or $\geq =$. An $\leq$ row can be matched to any sort of variable: the $\leq$ doesn’t imply any sort of relationship, which works perfectly with our definition of $\perp$ above: the allowed sign or direction of $g$ is determined completely by the bounds on the complementary variable $y$. If $g$ is an $\leq$ row, this is consistent with a free variable $y$, but what if $y$ has an active lower bound? By definition we allow $g$ to be positive at solution, but this violates the declaration as an $\leq$ row. Such cases can be handled by marking the row with a \texttt{redef}. The
The total number of redefs for a given model is available via the NumRedef model attribute and is shown in the report summary. Note that the set of rows marked depends on the solution: in the example above, if $g$ is zero at solution it will not be marked as a redef, regardless of what the bounds are on $y$. Finally, some combinations are simply not allowed: they will result in a model generation error. The table below lists the outcome for all possible combinations.

### Table 2: MCP Matching

<table>

</tbody>
</table>

The definition, process, and rules above have several implications for valid MCP models:

- It is always acceptable to use the =N= notation when defining the equations in an MCP model, provided these equations are matched explicitly. In this case the bounds on $F(z)$ are implied by the bounds on the matching columns, and redefs will never occur.
- Variables that are known to be lower-bounded (no upper bound) will match consistently with =G= equations.
- Variables that are known to be upper-bounded (no lower bound) will match consistently with =L= equations.
- Variables that are known to be unbounded will match consistently with =E= equations.
- Where the bound structure is not known in advance, or both upper and lower bounds exist, a match with an =N= equation will always be consistent. Other equation types will result in errors or redefs.
- The model may initially have fewer rows than columns, as long as the "extra" columns are unmatched fixed columns that ultimately get removed from the MCP passed to the solver.
- Any bounded-but-not-fixed column must be matched explicitly to a row.
- The only rows that may be unmatched are =E= rows.

- It is customary to re-use the constraints of an LP or NLP model when formulating the MCP corresponding to the Karush-Kuhn-Tucker (KKT) conditions. If the original model is a minimization, the LP/NLP marginals .m and the variables for these marginals in the MCP will use the same sign convention, and the orientation for the constraints will be consistent between the two models, making re-use easier.

As mentioned above, it is typical to use the same equations in both NLP and MCP models. Sometimes, it is not the original equation that is wanted for the MCP, but rather the reoriented (aka negated or flipped) equation. For example, the flipped version of $x^{+1.5} = L = y$ is $y = G = x^{+1.5}$, while $sqr(u) - sqr(v) = E = 5$ becomes $-sqr(u) + sqr(v) = E = -5$. Instead of re-implementing the equation in flipped form, the same result can be achieved by prefixing the equation name with a - in the model statement. See the [mcp10] model for an example of such usage. When equations are used in flipped form, they are marked with a `redir` in the listing file’s solution listing.

An example of complementarity that should be familiar to many is the relationship between a constraint and its associated dual multiplier: if the constraint is non-binding, its dual multiplier must be zero (i.e. at bound) while if a dual multiplier is nonzero the associated constraint must be binding. In fact, the KKT or first-order optimality conditions for LP and NLP models can be expressed and solved as an MCP.
These complementarity relationships found in optimization problems are useful in understanding the marginal values assigned to rows and columns in the GAMS solution for MCP. With no objective function, the usual definition for marginal values and their interpretation isn't useful. Instead, the GAMS MCP convention for the marginal values of columns is to return the slack of the associated row (i.e. its value when interpreted and evaluated as a function). For the marginal values of rows, the level value (not the slack) of the associated column is returned. When we apply this convention to the NCP \( F(z) \geq 0, z \geq 0, \langle F(z), z \rangle = 0 \) we see pairwise complementarity between the levels and marginals returned for each of the rows and columns in the model. This is also the case if we take the KKT conditions of an LP in a suitable standard form: minimization, \( x \geq 0, Ax \geq b \).

MCPs arise in many application areas including applied economics, game theory, structural engineering and chemical engineering. For further details on this class of problems, see http://www.neos-guide.org/content/complementarity-problems.

For information on MCP solvers that can be used through GAMS, see Solver/Model type Matrix.

3.31.2.2.9 Constrained Nonlinear System (CNS) The Constrained Nonlinear System (CNS) is the second GAMS model type that does not have an objective function. Mathematically, a CNS model looks like:

\[
\begin{align*}
\text{Find} & \quad x \\
\text{subject to} & \quad F(x) = 0 \\
& \quad L \leq x \leq U \\
& \quad G(x) \propto b,
\end{align*}
\] (3.1)

where \( x \) is a set of continuous variables and \( F \) is a set of nonlinear equations of the same dimension as \( x \). This is a key property of this model type: the number of equations equals the number of variables, so we have a square system. The (possibly empty) constraints \( L \leq x \leq U \) are not intended to be binding at the solution, but instead are included to constrain the solution to a particular domain, to avoid regions where \( F(x) \) is undefined, or perhaps just to give the solver a push in the right direction. The (possibly empty) constraints \( G(x) \propto b \) are intended to serve the same purpose as the variable bounds and are silently converted to equations with bounded slacks.

Note that since there is no objective in a CNS model, there are no marginal values for variables and equations. Any marginal values already stored in the GAMS database will remain untouched. CNS models also make use of some model status values that allow a solver to indicate if the solution is unique (e.g. for a non-singular linear system) or if the linearization is singular at the solution. For singular models (solved or otherwise), the solver can mark one or more dependent rows with a depnd. The total number of rows so marked for a given model is available via the NumDepnd model attribute and is shown in the report summary.

The CNS model is a generalization of a square system of equations \( F(x) = 0 \). Such a system could also be modeled as an NLP with a dummy objective. However, there are a number of advantages to using the CNS model type, including:

- A check by GAMS that the model is really square,
- solution/model diagnostics by the solver (e.g. singular at solution, (locally) unique solution),
- CNS-specific warnings if the side constraints \( L \leq x \leq U \) or \( G(x) \propto b \) are active at a solution,
- and potential improvement in solution times, by taking better advantage of the model properties.

For information on CNS solvers that can be used through GAMS, see the Solver/Model type Matrix.
Mathematical Program with Equilibrium Constraints (MPEC)  
Mathematically, the Mathematical Program with Equilibrium Constraints (MPEC) problem looks like:

\[
\begin{align*}
\text{Maximize or Minimize} & \quad f(x, y) \\
\text{subject to} & \quad g(x, y) \leq 0 \\
& \quad L_x \leq x \leq U_x \\
& \quad F(x, y) \perp L_y \leq y \leq U_y,
\end{align*}
\]

where \(x\) and \(y\) are vectors of continuous real variables. The variables \(x\) are often called the \textit{control} or \textit{upper-level} variables, while the variables \(y\) are called the \textit{state} or \textit{lower-level} variables. \(f(x, y)\) is the objective function, \(g(x, y) \leq 0\) represents the set of traditional (i.e. NLP-type) constraints; some solvers may require that these constraints only involve the control variables \(x\). The function \(F(x, y)\) and the bounds \(L_y\) and \(U_y\) define the equilibrium constraints. If \(x\) is fixed, then \(F(x, y)\) and the bounds \(L_y\) and \(U_y\) define an MCP; the discussion of the "perp to" symbol \(\perp\) in that section applies here as well. From this definition, we see that the MPEC model type contains NLP and MCP models as special cases of MPEC.

A simple example of an entire MPEC model is given below.

```plaintext
variable z, x1, x2, y1, y2;
positive variable y1;
y2.lo = -1;
y2.up = 1;
equations cost, g, h1, h2;

cost.. z =E= x1 + x2;
g.. sqr(x1) + sqr(x2) =L= 1;
h1.. x1 =G= y1 - y2 + 1;
h2.. x2 + y2 =N= 0;

model example / cost, g, h1.y1, h2.y2 /;
solve example using mpec min z;
```

Note that as in the MCP, the complementarity relationships in an MPEC are specified in the model statement via equation-variable pairs: the \(h1.y1\) specifies that the equation \(h1\) is perpendicular to the variable \(y1\) and the \(h2.y2\) specifies that the equation \(h2\) is perpendicular to the variable \(y2\). For details on the solve statement, see section \textit{The Solve Statement}.

While the MPEC model formulation is very general, it also results in problems that can be very difficult to solve. The state-of-the-art for MPEC solvers is not nearly as advanced as that for other model types. As a result, you should expect the MPEC solvers to be more limited by problem size and/or robustness issues than solvers for other model types.

For information on MPEC solvers that can be used through GAMS, see the \textit{Solver/Model type Matrix}. For more details on MPECs and solver development, see [http://gamsworld.org/mpec/index.htm](http://gamsworld.org/mpec/index.htm) and [http://www.neos-guide.org/content/complementarity-problems](http://www.neos-guide.org/content/complementarity-problems).

Extended Mathematical Programs (EMP)  
Extended Mathematical Programming (EMP) is an (experimental) framework for automated mathematical programming reformulations. Using EMP, model formulations that GAMS cannot currently handle directly or for which no robust and mature solver technology exists can be automatically and reliably reformulated or transformed into models for which robust and mature solver technology does exist within the GAMS system. For more details, see the chapter on EMP. Currently EMP supports:

- Equilibrium problems including variational inequalities, Nash games, and Multiple Optimization Problems with Equilibrium Constraints (MOPECs).
Hierarchical optimization problems such as bilevel programs.

Disjunctive programs for modeling discrete choices with binary variables.

Stochastic programs including two-stage and multi-stage stochastic programs, chance constraints and risk measures such as Variance at Risk (VaR) and Conditional Variance at Risk (CVaR).

Apart from the disjunctive and stochastic programming models mentioned above, EMP models are typically processed (aka solved) via the JAMS solver: this solver does the work of reformulation/transformation, calling GAMS to solve this reformulation, and post-processing the solution that results to bring it back in terms of the original EMP model.

Examples demonstrating how to use the EMP framework and the JAMS and DE solvers are available in the GAMS EMP Library. These solvers require no license of their own to run but can and do call subsolvers that do require a license.

3.31.2.3 Model Attributes

Models have attributes that hold a variety of information, including

- information about the results of a solve performed, a solve statement, the solution of a model,
- information about certain features to be used by GAMS or the solver,
- information passed to GAMS or the solver specifying various settings that are also subject to option statements.

Model attributes are accessed in the following way:

```
model_name.attribute
```

Here model_name is the name of the model in GAMS and .attribute is the specific attribute that is to be accessed. Model attributes may be used on the left-hand side and the right-hand side of assignments. Consider the following example:

```
transport.resLim = 600;
x = transport.modelStat;
```

In the first line the attribute .resLim of the model transport is specified to be 600 (seconds). In the second line the value of the attribute .modelStat of the model transport is assigned to the scalar x. Note that model attributes may also be used in display statements.

Some of the attributes are mainly used before the solve statement to provide information to GAMS or the solver link. Others are set by GAMS or the solver link and hence are mainly used after a solve statement.

Moreover, some of the attributes used before the solve may also be set via an option statement or the command line. Consider the following example:

```
option ResLim=10;
```
This line is an option statement and applies to all models. One can set the model attribute .ResLim to overwrite the global ResLim option. In order to revert the individual .ResLim to the global ResLim option, one needs to set the model attribute to NA. For more on option statements, see chapter The Option Statement.

```
gams mymodel ResLim=10
```

This sets the global ResLim option when invoking the gams run (e.g. from the command line). For more on command line parameters, see chapter The GAMS Call and Command Line Parameters.

Note that a model-specific option takes precedence over the global setting specified with an option statement and that a setting via an option statement takes precedence over a setting via the command line parameter.

The complete list of model attributes is given below. Observe that each entry is linked to a detailed description of the respective attribute, including information of whether the attribute is also available as command line parameter or option statement. Note that detailed descriptions of all GAMS command line parameters, options and model attributes are given in section Detailed Descriptions of All Options.

### 3.31.3.2 Model Attributes Mainly Used After Solve

### 3.31.3 The Solve Statement

Once a model has been defined using the model statement, the solve statement prompts GAMS to call one of the available solvers for the particular model type. This section introduces and discusses the solve statement in detail. For a list of GAMS model types, see Table 1. For information on how to specify desired solvers, see section Choosing a Solver.

**Note**

It is important to remember that GAMS does *not* solve the problem, but passes the problem definition to one of a number of separate solver programs that are integrated with the GAMS system.

#### 3.31.3.1 The Syntax of the Solve Statement

In general, the syntax for a solve statement is as follows. Note that there are two alternatives that are equally valid:

```plaintext
solve model_name using model_type maximizing|minimizing var_name;
solve model_name maximizing|minimizing var_name using model_type ;
```

The keyword `solve` indicates that this is a `solve` statement. `Model_name` is the name of the model as defined by a `model` statement. Note that the `model` statement must be placed before the `solve` statement in the program. The keyword `using` is followed by `model_type`, which is one of the GAMS model types described above, see Table 1. The keywords `maximizing` or `minimizing` indicate the direction of the optimization. `Var_name` is the name of the objective variable that is being optimized. An example of a `solve` statement in GAMS is shown below.

```plaintext
Solve transport using lp minimizing cost ;
```

`Solve` and `using` are reserved words, `transport` is the name of the model, `lp` is the model type, `minimizing` is the direction of optimization, and `cost` is the objective variable. Note that an objective variable is used instead of an objective row or function.
Attention

The objective variable must be scalar and of type free, and must appear in at least one of the equations in the model.

Recall that some model types (e.g. the Constrained Nonlinear System (CNS) or the Mixed Complementarity Problem (MCP)) do not have an objective variable. So their solve statement syntax is slightly different:

```
solve model_name using model_type;
```

As before, solve and using are keywords, model_name is the name of the model as defined by a model statement and model_type is the GAMS model type CNS or MCP. There is no objective variable and consequently no direction of optimization. An example from the spatial equilibrium model [SPATEQU] illustrates this solve statement:

```
Solve P2R3_MCP using mcp;
```

P2R3_MCP is the model name, the model type is MCP and as expected, there is no objective variable.

The EMP model type serves many purposes including some experimental ones. The solve statement with model type EMP can be with or without the objective variable and optimization direction. For more information, see chapter Extended Mathematical Programming (EMP).

### 3.31.3.2 Actions Triggered by the Solve Statement

When GAMS encounters a solve statement during compilation (the syntactic check of the input file) or execution (actual execution of the program), it initiates a number of special actions. The purpose is to prevent waste that would be caused by solving a model that has apparently been incorrectly specified. During compilation the following are verified:

1. All symbolic equations have been defined and the objective variable is used in at least one of the equations.
2. The objective variable is scalar and of type free (even though lower and upper bounds may have been specified)
3. MCP models are checked for appropriate complementarity and squareness.
4. Each equation fits into the specified problem class (linearity for LP, continuous derivatives for NLP, as outlined above).
5. All sets and parameters in the equations have values assigned.
Note

GAMS issues explanatory error messages if it discovers that the model is not according to type; for example, the presence of nonlinear terms in a supposedly LP model. For details on error messages, see chapter GAMS Output.

At execution time the solve statement triggers the following sequence of steps:

1. The model is translated into the representation required by the solution system to be used.

2. Debugging and comprehension aids that the user wishes to see are produced and written to the output file (EQUATION LISTING, etc). For customizing options (e.g. LimRow and LimCol), see chapter The Option Statement.

3. GAMS verifies that there are no inconsistent bounds or unacceptable values (for example, NA or UNDF) in the problem.

4. Any errors detected at this stage cause termination with as much explanation as possible, using the GAMS names for the identifiers causing the trouble.

5. GAMS designs a solution strategy based on the possible availability of level values or basis information from a previous solution: all available information is used to provide efficiency and robustness of operation. Any specifications provided by the user (Iteration limits etc.) are incorporated. A solver is chosen which is either the default solver for that problem type, the solver specified on the command line or the solver chosen by an option statement. For details see section Choosing a Solver.

6. GAMS passes control to the solution subsystem and waits while the problem is being solved.

7. GAMS reports on the status of the solution process and loads solution values back into the GAMS database. This causes new values to be assigned to the .l and .m fields for all individual equations and variables in the model. In addition, the post solution model attributes are assigned. The procedure for loading back the data associated with level and marginal values may be customized using the SolveOpt model attribute and option. A row by row and column by column listing of the solution is provided by default. It may be suppressed by the SolPrint model attribute or option. Any apparent difficulty with the solution process will cause explanatory messages to be displayed. Errors caused by forbidden nonlinear operations are reported at this stage.

Note

When the solver does not provide a dual solution (.m), then GAMS does not print the marginal column in the solution listing and set the marginal field in variables and equations to NA.

The outputs from these steps, including any possible error messages, are discussed in detail in chapter GAMS Output.

3.31.4 Programs with Several Solve Statements

Several solve statements can be processed in the same program. The next few subsections discuss various instances where several solve statements may be needed in the same file. If sequences of expensive or difficult models are to be solved, it might be useful to interrupt program execution and continue later. For details on this topic, see chapter The Save and Restart Feature.
3.31.4.1 Several Models

If there are different models then the solves may be sequential, as below. Each of the models in [PROLOG] consists of a different set of equations, but the data are identical, so the three solves appear in sequence with no intervening assignments:

Solve nortonl using nlp maximizing z;
Solve nortonn using nlp maximizing z;
Solve nortone using nlp maximizing z;

When there is more than one solve statement in the program, GAMS uses as much information as possible from the previous solution to provide a starting point or basis in the search for the next solution.

3.31.4.2 Loop: One Model, Different Data

Multiple solves may also occur as a result of a solve statement within a loop statement. Loop statements are introduced and discussed in detail in chapter Programming Flow Control Features; here we show that they may contain a solve statement and thus lead to multiple solves within one model. The example from [MEANVAR] computes the efficient frontier for return and variance for a portfolio selection problem at equidistance points.

```plaintext
loop(p(pp),
    v.fx = vmin + (vmax-vmin)/(card(pp)+1)*ord(pp) ;
    Solve var1 maximizing m using nlp ;
    xres(i,p) = x.l(i);
    xres('mean',p) = m.l;
    xres('var',p) = v.l;
);
```

The set p is a set of point between the minimum and maximum variance, it is the driving set of the loop. A variance variable v is fixed at a equidistance points. With each iteration through the loop another variance level is used, the NLP model var1 is solved for each iteration and the outputs are stored in the parameter xres(*,pp), to be used later for reporting. As often for reporting purposes, the universal set * is used.

This example demonstrates how to solve the same model (in terms of variables and equations) multiple times with slightly different data. For such situations the Gather-Update-Solve-Scatter (GUSS) facility improves on the loop implementation by saving generation time and minimizing the communication with the solver. GUSS is activated by the additional keyword scenario in the solve statement followed by a set name that provides mapping information between parameters in the model and the scenario containers. A GUSS implementation of the loop would look as follows:

```plaintext
parameter vfx(p), px(p,i), pm(p);
set dict / p .scenario.''
    v .fixed .vfx
    x .level .px
    m .level .pm /;
vfx(p(pp)) = vmin + (vmax-vmin)/(card(pp)+1)*ord(pp);
Solve var1 maximizing m using nlp scenario dict;
xres(i,p) = px(p,i);
xres('mean',p) = pm(p);
xres('var',p) = vfx(p);
```
3.31.4.3 Customizing Solution Management: SolveOpt

It is important to consider how GAMS manages solutions if multiple models are solved. By default, GAMS merges subsequent solutions with prior solutions. This is not an issue if all models operate over the same set of variables. However, recursive procedures, different equation inclusions or logical conditions may cause only part of the variables or different variables to appear in the models to be solved. In such a case it might be useful to modify the solution management procedure using the model attribute or option SolveOpt.

3.31.4.4 Sensitivity or Scenario Analysis

Multiple solve statements can be used not only to solve different models, but also to conduct sensitivity tests, or to perform case (or scenario) analyses of models by changing data or bounds and then solving the same model again. While some commercial LP systems allow access to “sensitivity analysis” through GAMS it is possible to be far more general and not restrict the analysis to either solver or model type. This facility is even more useful for studying many scenarios since no commercial solver will provide this information.

An example of sensitivity testing is in the simple oil-refining model [MARCO]. Because of pollution control, one of the key parameters in oil refinery models is an upper bound on the sulfur content of the fuel oil produced by the refinery. In this example, the upper bound on the sulfur content of fuel oil was set to 3.5 percent in the original data for the problem. First, the model is solved with this value. Next, a slightly lower value of 3.4 percent is used and the model is solved again. Finally, the considerably higher value of 5 percent is used and the model is solved for the last time. Key solution values are saved for later reporting after each solve. This is necessary because a following solve replaces any existing values. The key solution values are the activity levels of the process level variable, which is defined over a set of processes and a set of crude oils. The complete sequence is:

```gams
parameter report(*,*,*) "process level report";
qs('upper','fuel-oil','sulfur') = 3.5 ;
Solve oil using lp maximizing phi;
report(cr,p,'base') = z.l(cr,p) ;
report('sulfur','limit','base') = qs('upper','fuel-oil','sulfur');
qs ('upper','fuel-oil','sulfur') = 3.4 ;
Solve oil using lp maximizing phi ;
report(cr,p,'one') = z.l(cr,p) ;
report('sulfur','limit','one') = qs ('upper','fuel-oil','sulfur');
qs('upper','fuel-oil','sulfur') = 5.0 ;
Solve oil using lp maximizing phi ;
report(cr,p,'two') = z.l(cr,p) ;
report('sulfur','limit','two') = qs('upper','fuel-oil','sulfur');
Display report ;
```

Note that the parameter report is defined over the universal set or short universe. In general, the universe is useful when generating reports, otherwise it would be necessary to provide special sets containing the labels used in the report. Any mistakes made in spelling labels used only in the report should be immediately apparent, and their effects should be limited to the report. The parameter qs is used to set the upper bound on the sulfur content in the fuel-oil, and the value is retrieved for the report. Note that the display statement in the final line is introduced and discussed in detail in chapter The Display Statement. This example shows not only how simply sensitivity analysis can be done, but also how the associated multi-case reporting can be handled.

The output from the display statement is shown below. Observe that there is no production at all if the permissible sulfur content is lowered. The case attributes have been listed in the row SULFUR.LIMIT.

Section Global Display Controls contains more details on how to arrange reports in a variety of ways.
3.31.4.5 Iterative Implementation of Non-Standard Algorithms

Another use of multiple solve statements is to permit iterative solution of different blocks of equations, most often using solution values from the first solve as data for the next solve. These decomposition methods are useful for certain classes of problems because the subproblems being solved are smaller, and therefore more tractable. One of the most common examples of such a method is the Dantzig-Wolfe decomposition.

An example of a problem that is solved in this way is a multi-commodity network flow problem in [DANWOLFE].

3.31.5 Choosing a Solver

After a model has been checked and prepared as described above, GAMS passes the model to a solver. When the GAMS system is installed default solvers for all model types are specified and these solvers are used if the user doesn't specify anything else. It is easy to switch to other appropriate solvers provided the user has the corresponding license. There are multiple ways to switch solvers:

1. Using a command line parameter of the following form:

   gams mymodel model_type=solver name

   For example,

   gams mymodel lp=cbc

2. With an option command of the following form that is placed before the solve statement:

   Option model_type=solver_name;

   Here option is a keyword, model_type is the same model type that is used in the solve statement and solver_name is the name of one of the available solvers. For example,

   Option LP=cbc, NLP=conopt, MIP=cbc, MINLP=default;
The MINLP=default switchs back to the default solver for the MINLP model type.

3. Instead of providing a particular solver for a model type, the option Solver can be used to use a given solver for all model types this solver can handle.

Option Solver=cbc;

4. (Re)running gamsinst at any time and altering the choice of default solver as described in the installation notes.

Note
A list of all solvers and current default solvers may be generated in the listing file with Option SubSystems;

3.31.6 Making New Solvers Available with GAMS

This short section is to encourage those of you who have a favorite solver not available through GAMS. Linking a solver program with GAMS requires some programming skills and the use of libraries provided by GAMS. There is a collection of open source solver links to GAMS at the COIN-OR project GAMSLinks. The benefits of a link with GAMS to the developer of a solver are several. They include:

- Immediate access to a wide variety of test problems.
- An easy way of making performance comparisons between solvers.
- The guarantee that a user has not somehow provided an illegal input specification.
- Elaborate documentation, particularly of input formats, is not needed.
- Access to the existing community of GAMS users, for marketing or testing.

This completes the discussion of the model and solve statements.

3.32 Conditional Expressions, Assignments and Equations

3.32.1 Introduction

This chapter deals with the way in which conditional assignments, expressions and equations are made in GAMS. The index operations already described are very powerful, but it is necessary to allow for exceptions of one sort or another. For example, heavy trucks may not be able to use a particular route because of a weak bridge, or some sectors in an economy may not produce exportable products. Exceptions such as these may easily be modeled with a logical condition combined with the dollar operator ‘$’, a very powerful feature of GAMS introduced in this chapter.

This chapter is organized as follows: We will introduce the general form of the dollar condition first and then we will focus on the various types of logical conditions. Next, we will discuss how dollar conditions are used to build conditional assignments, conditional indexed operations and conditional equations. We will conclude the chapter by showing that in certain cases conditions may be modeled using filtering sets instead of the dollar operator. Programming flow control features such as the if statement, the loop, the while statement, and the for statement are not covered in this chapter. These can be found in the chapter Programming Flow Control Features.
3.32 The Dollar Condition

The dollar operator is one of the most powerful features in GAMS. The general syntax for a conditional expression is:

\[ \text{term} \; \$ \; \text{logical\_condition} \]

Here, \text{term} can be a number, a (indexed) symbol, and also a complex expression. The dollar operator may be read as \textit{under the condition that} the following \text{logical\_condition} evaluates to \texttt{TRUE} (or is unequal 0).

Consider the following simple condition, where \( a \) and \( b \) are scalars.

\[
\text{if} \; (b > 1.5), \; \text{then} \; a = 2
\]

This can be written in GAMS using the dollar operator as follows.

\[
a \; \$(b > 1.5) = 2 ;
\]

Note that the \text{term} is the scalar \( a \) and the \text{logical\_condition} is the expression \((b > 1.5)\). If the condition is not satisfied, no assignment is made. To make it clear, this conditional assignment may be read as: \textit{‘given that \( b \) is greater than 1.5, \( a \) equals 2’}.

Logical conditions may take various forms, they are introduced in the next section. Conditional expressions may be used in the context of assignments, indexed operations and equations. These topics are covered in later sections of this chapter.

Note

Logical conditions used with the dollar operator cannot contain variables. However, \texttt{variable attributes} are allowed.

3.32.3 Logical Conditions

Logical conditions are special expressions that evaluate to a value of either \texttt{TRUE} or \texttt{FALSE}. Logical conditions may be numerical expressions and numerical relations, they may refer to set membership and they may also contain acronyms. In the following subsections this is shown in the context of simple conditional assignments with the dollar operator on the left-hand side (compare section Dollar on the Left).

In this section we use many examples to illustrate the concepts that are being introduced. In all these examples \( a \) and \( b \) are scalars, \( s, t, u \) and \( v \) are parameters, and \( i \) and \( j \) are sets.
3.32.3.1 Logical Conditions: Numerical Expressions

Numerical expressions may serve as logical conditions: a result of zero is treated as the logical value FALSE and a non-zero result is treated as the logical value TRUE. The following example illustrates this point.

\[
b \begin{array}{l}
(2a - 4) = 7;
\end{array}
\]

Here the numerical expression \((2a - 4)\) is the logical condition. The numerical expression is zero if \(a\) equals 2, and non-zero otherwise. Hence the logical value of the expression is FALSE for \(a = 2\) and TRUE for all other values of \(a\). The assignment is only made if the numerical expression evaluates to TRUE, otherwise no assignment is made.

Attention

Values of the extended range arithmetic such as \(\text{inf}\) are also allowed in logical conditions. If the result of a numerical expression used as a logical condition takes any of these values, the logical value is TRUE, even for e.g. \(\text{eps}\), which is numerically 0.

Observe that functions are also allowed in logical conditions. If they evaluate to zero, the logical condition is FALSE, otherwise it is TRUE. Consider the following example:

\[
b \begin{array}{l}
\cos(a) = 7;
\end{array}
\]

Note that the assignment is only made if the cosine of \(a\) does not equal zero.

3.32.3.2 Logical Conditions: Numerical Relational Operators

Numerical relational operators compare two numerical expressions and return a logical value. For completeness, all numerical relational operators are listed in Table 1.

<table>
<thead>
<tr>
<th>Relation</th>
<th>Operator</th>
<th>Alternative Notation</th>
<th>Return Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strictly less than</td>
<td>(x &lt; y)</td>
<td>x lt y</td>
<td>Returns TRUE if (x &lt; y), else returns FALSE.</td>
</tr>
<tr>
<td>Less than or equal to</td>
<td>(x \leq y)</td>
<td>x le y</td>
<td>Returns TRUE if (x \leq y), else returns FALSE.</td>
</tr>
<tr>
<td>Equal to</td>
<td>(x = y)</td>
<td>x eq y</td>
<td>Returns TRUE if (x = y), else returns FALSE.</td>
</tr>
<tr>
<td>Not equal to</td>
<td>(x \neq y)</td>
<td>x ne y</td>
<td>Returns TRUE if (x \neq y), else returns FALSE.</td>
</tr>
<tr>
<td>Greater than or equal to</td>
<td>(x \geq y)</td>
<td>x ge y</td>
<td>Returns TRUE if (x \geq y), else returns FALSE.</td>
</tr>
<tr>
<td>Strictly greater than</td>
<td>(x &gt; y)</td>
<td>x gt y</td>
<td>Returns TRUE if (x &gt; y), else returns FALSE.</td>
</tr>
</tbody>
</table>

Table 1: Numerical Relational Operators

Consider the following examples.

\[
b \begin{array}{l}
(a < 0) = 10;
\end{array}
\]
b \(\$: (sqr(a) > a) = 12\);
a \(\$: (\sum(i, s(i)) > 0 ) = 7\);
t(i) \(\$: (a <> 0) = t(i) + 1\);

In the first line the logical condition is the relational expression \((a < 0)\). The assignment is only made if this expression is \textsc{true}, that is, if the scalar \(a\) is negative. The logical condition in the second line is a bit more complex. It evaluates to \textsc{false} if \(0 \leq a \leq 1\). For all other values of \(a\), it evaluates to \textsc{true}. So the assignment is made for all values of \(a\), except for those values of \(a\) that are in the closed interval \([0, 1]\). Note that if \(a = -3\), then the logical condition in the first line will be \textsc{true}, so \(b\) will become 10. In addition, the logical condition in the second line will be \textsc{true}, so \(b\) will change to 12. The logical condition in the third line evaluates to \textsc{true} if the sum of all values of the parameter \(a\) is strictly positive. Then \(a\) is assigned the value of 7. The assignment in the last line depends on whether \(a\) is non-zero. If \(a\) is zero no assignment is made, otherwise all entries of the parameter \(t\) are updated.

Note that acronyms may also be used with relational operators to build logical conditions. However, only the equality operator \(=\) and inequality operator \(<>\) are allowed in the context of acronyms, since they have no numerical values and the other operators would be meaningless. For an example, see section Acronym Usage.

### 3.32.3.3 Logical Conditions: Logical Operators

GAMS offers standard logical operators that may combine two or more logical conditions to build complex logical expressions. For example, if several expressions are required to be \textsc{true} simultaneously, they may be connected with the operator \texttt{and}. The logical operators available in GAMS are listed in Table 2 and Table 3. Another way to construct complex logical conditions is by nesting them. For details, see subsection Nested Dollar Conditions below.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Operator</th>
<th>Alternative Notation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Negation</td>
<td>not x</td>
<td>x (\neq) y</td>
<td>The logical condition (x) has to be \textsc{false}, in order for the expression to be \textsc{true}.</td>
</tr>
<tr>
<td>Logical conjunction</td>
<td>x and y</td>
<td>x (\land) y</td>
<td>Two logical conditions are \textsc{true} simultaneously.</td>
</tr>
<tr>
<td>Logical disjunction</td>
<td>x or y</td>
<td>x (\lor) y</td>
<td>At least one of two logical conditions applies.</td>
</tr>
<tr>
<td>Exclusive disjunction</td>
<td>x xor y</td>
<td>x (\oplus) y</td>
<td>Exactly one of two logical conditions applies.</td>
</tr>
<tr>
<td>Logical implication</td>
<td>x imp y</td>
<td>x (\Rightarrow) y</td>
<td>If the logical condition (x) is \textsc{true} but at the same time the logical condition (y) is \textsc{false}, then the whole expression is \textsc{false}, in all other cases the expression evaluates to \textsc{true}.</td>
</tr>
<tr>
<td>Logical equivalence</td>
<td>x eqv y</td>
<td>x (\equiv) y</td>
<td>Both logical conditions are either \textsc{true} simultaneously or \textsc{false} simultaneously for the whole expression to be \textsc{true}.</td>
</tr>
</tbody>
</table>

**Table 2: Logical Operators**

The logical values of these operators are summarized in the following truth table.

<table>
<thead>
<tr>
<th>(x)</th>
<th>(y)</th>
<th>not (x)</th>
<th>x and y</th>
<th>x or y</th>
<th>x xor y</th>
<th>x imp y</th>
<th>x eqv y</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>FALSE</td>
<td>TRUE</td>
<td>FALSE</td>
<td>FALSE</td>
<td>FALSE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
</tbody>
</table>
x | y | not x | x and y | x or y | x xor y | x imp y | x eqv y
---|---|-------|---------|--------|--------|--------|--------
FALSE | TRUE | TRUE | FALSE | TRUE | TRUE | TRUE | FALSE
TRUE | FALSE | FALSE | FALSE | TRUE | TRUE | FALSE | FALSE
TRUE | TRUE | FALSE | TRUE | TRUE | TRUE | TRUE | TRUE

Table 3: Truth Table of Logical Operators

The following somewhat artificial examples serve as illustration.

```
Set i / i1*i5 /;
Parameter s(i) / i1 3, i2 5, i4 8 /
  t(i) / i1*i4 13 /
  u(i) / i2 1 /
  v(i) / i1 7, i3 2 /;

u(i) $ (not s(i)) = v(i);
u(i) $ (s(i) and u(i) and t(i)) = s(i);
u(i) $ (s(i) or v(i) or t(i)) = 4;
```

Note that there are three conditional assignments for the parameter u. In the first assignment the logical condition is \(\text{not } s(i)\). This condition holds for all entries of \(s\) that are not specified and therefore zero by default: \(s('i3')\) and \(s('i5')\). Hence \(u('i3')\) and \(u('i5')\) are assigned the values of \(v('i3')\) and \(v('i5')\) respectively. The value of \(v('i3')\) is 2 and the value of \(v('i5')\) is zero by default. After the first assignment we have \(u('i2') = 1\) and \(u('i3') = 2\), all other values of \(u\) are zero. Note that the logical condition failed for \(u('i2')\) and therefore its value remained unchanged. The logical condition in the second assignment is \(\text{TRUE}\) for those labels of the set \(i\) that have non-zero entries in the parameters \(s\), \(u\) and \(t\) simultaneously. This condition holds only for \(i2\). Therefore \(u('i2') = s('i2') = 5\) and all other values of \(u\) remain unchanged, resulting in non-zero values only for \(u('i2')\) and \(u('i3')\). The logical condition in the last assignment evaluates to \(\text{TRUE}\) for all labels of the set \(i\) that have at least one non-zero entry in the parameters \(s\), \(v\) and \(t\). This holds for all labels except for \(i5\). Therefore \(u('i5')\) stays zero and all other values of \(u\) are changed to 4. These examples demonstrate the power of the dollar operator combined with logical operators. Even more complex logical conditions are possible; see subsection Mixed Logical Conditions below for details.

### 3.32.3.4 Logical Conditions: Set Membership and Set Functions

Apart from numerical and relational expressions, set membership and functions referencing set elements may be used as a logical condition. Consider the following example as illustration for set membership as logical condition.

```
Set i / i1*i5 /;
  j(i) / i1*i3 /;
Parameter s(i) / i1 3, i2 5, i3 11, i4 8, i5 1 /
  t(i);
  t(i) $ j(i) = s(i) + 3;
```

Note that the set \(j\) is a subset of the set \(i\) and that the parameter \(t\) is declared but not defined. The conditional expression \(t(i) \&\& j(i)\) in the last line restricts the assignment to the members of the subset \(j\) since only they satisfy the condition \(j(i)\). The values for \(t('i4')\) and \(t('i5')\) remain unchanged. In this case this means that they are zero (by default). Note that there is an alternative formulation for this type of conditional assignment; for details see subsection Filtering Sets in Assignments below.
Note

Only the membership of subsets and dynamic sets may be used as logical conditions.

The use of set membership as a logical condition is an extremely powerful feature of GAMS, see section Conditional Equations below for more examples.

Logical conditions may contain functions that return particular values depending on the position of elements in sets, the size of sets or the comparison of set elements to each other or text strings. These functions are presented in Table 4.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description and Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>sameAs(element1,element2)</td>
<td>Returns TRUE if element1 is identical to element2, and FALSE otherwise.</td>
</tr>
<tr>
<td>sameAs(&quot;text&quot;,element2)</td>
<td>Same as function sameAs, but returns numerical value 1 for TRUE and 0 for FALSE.</td>
</tr>
<tr>
<td>diag(element1,element2)</td>
<td>Returns the number of elements in a set. Note that this can also be called with a quoted text and returns the number of characters of that text in that case. For more details, see section The Card Operator.</td>
</tr>
<tr>
<td>ord(set_name)</td>
<td>Returns the relative position of an element in a set. Note that ord may be used only with one-dimensional, static, ordered sets. For more details, see section The Ord Operator.</td>
</tr>
</tbody>
</table>

Table 4: Functions Referencing Sets

In the following example we have two sets of cities and we want to know how many of them feature in both sets.

Set i / Beijing, Calcutta, Mumbai, Sydney, Johannesburg, Cairo /;
Set j / Rome, Paris, Boston, Cairo, Munich, Calcutta, Barcelona /;
Scalar b;
b = sum((i,j)$sameAs(i,j),1);

Note that in the assignment statement we sum over both sets and we use the function sameAs to restrict the domain of the indexed operation to those label combinations (i,j) where the function sameAs evaluates as TRUE. Thus only identical elements are counted.

Note that in this example the function diag could have been used with the same result.

The functions ord and card are frequently used to single out the first or last element of an ordered set. For example, we may want to fix a variable for the first and last elements of a set:

\[ x.fx(i) \text{ $ (ord(i) = 1) \} = 3; \]
\[ x.fx(i) \text{ $ (ord(i) = \text{card}(i)) \} = 7; \]

In the first assignment the variable \( x \) is fixed for the first element of the set \( i \) and in the second assignment \( x \) is fixed for the final element of \( i \).

Note

As an alternative to the formulation above, one could also use the set attributes first and last to get the same result:

\[ x.fx(i) \text{ $ (i.first) = 3; \}
\[ x.fx(i) \text{ $ (i.last) = 7; \]
### 3.32.3.5 Numerical Values of Logical Conditions

We have seen that logical conditions may take the form of numerical expressions, expressions with relational operators, complex expressions using logical operators, set membership and set functions. However, GAMS does not have a Boolean data type.

**Attention**

GAMS follows the convention that the result of a relational operation is zero if the assertion is \textsc{false}, and 1 if it is \textsc{true}.

Consider the following example as illustration.

\[ x = (1 < 2) + (2 < 3); \]

The expression to the right of the assignment evaluates to 2 since both logical conditions within parentheses are \textsc{true} and therefore assume a value of 1. Note that this is different from the assignment below:

\[ x = (1 < 2) \text{ or } (2 < 3) \]

This assignment evaluates to 1, since both statements to the left and right of \textsc{or} are \textsc{true} and therefore the whole expression is \textsc{true}.

### 3.32.3.6 Mixed Logical Conditions

The building blocks introduced in the subsections above may be combined to generate more complex logical conditions. These may contain standard arithmetic operations, numerical relational operations and logical operations. All operations, their symbols and their order of precedence are given in Table 5. Note that 1 denotes the highest order of precedence and 7 denotes the lowest order of precedence. As usual, the default order of precedence holds only in the absence of parentheses and operators (symbols) on the same level are evaluated from left to right.

<table>
<thead>
<tr>
<th>Type of Operation</th>
<th>Operation</th>
<th>Operator</th>
<th>Order of precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard arithmetic operation</td>
<td>Exponentiation</td>
<td>**</td>
<td>1</td>
</tr>
<tr>
<td>Standard arithmetic operation</td>
<td>Multiplication, Division</td>
<td>* , /</td>
<td>2</td>
</tr>
<tr>

<td>or, xor, imp, eqv</td>
<td>7</td>
</tr>
</tbody>
</table>

**Table 5:** Complete Hierarchy for Operator Precedence in GAMS
Note

We recommend to use parentheses rather than relying on the order of precedence of operators. Parentheses prevent errors and make the intention clear.

Consider the following example:

\[ x - 5y \text{ and } z - 5 \]

\[ (x - (5y)) \text{ and } (z-5) \]

These two complex logical conditions are equivalent. However, the parentheses make the second expression easier to understand.

Some simple examples of complex logical conditions, their numerical values and their logical values are given in Table 6.

<table>
<thead>
<tr>
<th>Logical Condition</th>
<th>Numerical Value</th>
<th>Logical Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>((1 &lt; 2) + (3 &lt; 4))</td>
<td>2</td>
<td>TRUE</td>
</tr>
<tr>
<td>((2 &lt; 1) \text{ and } (3 &lt; 4))</td>
<td>0</td>
<td>FALSE</td>
</tr>
<tr>
<td>((4+5 - 3) + (10/8))</td>
<td>18.25</td>
<td>TRUE</td>
</tr>
<tr>
<td>((4+5 - 3) \text{ or } (10 - 8))</td>
<td>1</td>
<td>TRUE</td>
</tr>
<tr>
<td>((4 \text{ and } 5) + (2+3 &lt;= 6))</td>
<td>2</td>
<td>TRUE</td>
</tr>
<tr>
<td>((4 \text{ and } 0) + (2+3 &lt; 6))</td>
<td>0</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Table 6: Examples of Complex Logical Conditions

3.32.3.7 Nested Dollar Conditions

An alternative way to model complex logical conditions is by nesting them. The syntax is:

\[ \text{term}\; $ (\text{logical\_condition1}$$(\text{logical\_condition2}$$(\ldots))$) \]

Note that in nested dollar conditions all succeeding expressions after the dollar operator must be enclosed in parentheses. The nested expression is equivalent to the following conditional expression that uses the logical operator \text{and} instead of the nesting:

\[ \text{term}\; $ (\text{logical\_condition1 \text{ and } logical\_condition2 \text{ and } \ldots})$ \]

Consider the following example. Note that \(i, j(i)\) and \(k(i)\) are sets, and \(u(i)\) and \(v(i)\) are parameters.

\[ u(i)\; $ (j(i)$k(i)) = v(i) \; ; \]

The assignment will be made only for those members of the set \(i\) that are members of both sets \(j\) and \(k\). Note the position of the parentheses in the dollar condition. The assignment statement above can be rewritten in the following way.

\[ u(i)\; $ (j(i) \text{ and } k(i)) = v(i) \; ; \]

Note

We recommend to use the logical \text{and} operator instead of nesting dollar operators, because this formulation is easier to read.
3.32.4 Conditional Assignments

A conditional assignment is an assignment statement with a dollar condition on the left-hand side or on the right-hand side. Most examples until now were conditional assignments with the dollar operator on the left.

Attention

The effect of the dollar condition is significantly different depending on which side of the assignment it is located.

The next two subsections describe the use of the dollar condition on each side of the assignment. Note that in many cases it may be possible to use either of the two forms of the dollar condition to describe an assignment. We recommend to choose the clearer formulation.

Note that if the logical condition in an assignment statement refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section Filtering Sets in Assignments below.

3.32.4.1 Dollar on the Left

If the dollar condition is on the left-hand side of an assignment, an assignment is made only in case the logical condition is satisfied. If the logical condition is not satisfied then no assignment is made and the previous content of the parameter on the left will remain unchanged. In case the parameter on the left-hand side of the assignment has not previously been initialized or assigned any values, zeros will be used for any label for which the assignment was suppressed.

Consider the following example adapted from [CHENERY]. Note that the parameter sig has been previously defined in the model.

\[ \text{rho}(i) \$ (\text{sig}(i) \neq 0) = (1./\text{sig}(i)) - 1. ; \]

In this assignment \( \text{rho}(i) \) is calculated and the dollar condition on the left protects against dividing by zero. If any of the values associated with the parameter \( \text{sig} \) turns out to be zero, no assignment is made and the previous values of \( \text{rho}(i) \) remain. As it happens, \( \text{rho}(i) \) was not previously initialized, and therefore all the labels for which \( \text{sig}(i) \) is zero will result in a value of zero.

Now recall the convention that non-zero implies TRUE and zero implies FALSE. The assignment above could therefore be written as:

\[ \text{rho}(i) \$ \text{sig}(i) = (1./\text{sig}(i)) - 1. ; \]

In the following examples \( i \) is a set and \( s \) and \( t \) are parameters.

\[ s(i) \$ t(i) = t(i) ; \]
\[ s(i) \$ ((t(i)-1) > 0) = t(i)**0.5 ; \]

Note that the first assignment is suppressed if the value of the parameter \( t \) equals zero. The second assignment is suppressed for values of the parameter \( t \) that are smaller or equal to 1.

Note

The first of the last two examples is special in the way that the logical condition used with the dollar on the left and the expression on the right hand side of the assignment are actually the same. This allows to use a shorter notation using the combined \$= \) assignment. That assignment is equivalent to the following one (which called sparse assignment):

\[ s(i) \$= t(i) ; \]
3.32.4.2 Sparse Assignments

Sparse assignments will assign a value to the left-hand side of the = sign only if the right-hand side is nonzero. This behavior is triggered using the $= notation as in the following example.

Set   i /a,b,c/
Parameter d1(i) "Initial data" /a 1, b 1, c 1/
   d2(i) "Data to be used to overwrite d1" /a 0, b -2 /
   d3(i) "Empty data parameter";

* Initialize d3 to d1
   d3(i) = d1(i);
* Use dollar on the left to overwrite d3 with non-zero values from d2
   d3(i)$d2(i) = d2(i);
* Result: d3('a')=1; d3('b')=-2; d3('c')=1;

* Re-Initialize d3 to d1
   d3(i) = d1(i);
* Use sparse assignment to overwrite d3 with non-zero values from d2
   d3(i) $= d2(i);
* Result: d3('a')=1; d3('b')=-2; d3('c')=1;

Note that in the final assignments above, the values of the parameter d3(i) is replaced with values from parameter d2(i) only if the entry in d2(i) is non-zero, the other values are left untouched. Both assignments are equivalent.

3.32.4.3 Dollar on the Right

If the dollar condition is on the right-hand side of an assignment statement, an assignment will always be made. In case the logical condition is not satisfied the value of zero is assigned.

Above we had the following simple conditional assignment:

\[ a \ (b > 1.5) = 2; \]

Now we move the dollar condition to the right-hand side:

\[ a = 2 \ (b > 1.5) \ ; \]

This is equivalent to:

\[ \text{if } (b > 1.5) \text{ then } (a = 2), \text{ else } (a = 0) \]

Note that an if-then-else type of construct is implied, but the else operation is predefined and never made explicit. The else could be made explicit with the following formulation:

\[ a = 2 \ (b > 1.5) + 0 \ (b \leq 1.5) \ ; \]
The use of this feature is more apparent in instances when an else condition needs to be made explicit. Consider the next example adapted from the fertilizer model [FERTD]. The set i is the set of plants, and we are calculating mur(i), the cost of transporting imported raw materials. In some cases a barge trip must be followed by a road trip because the plant is not alongside the river and we must combine the separate costs. The assignment is:

\[
\text{mur}(i) = (1.0 + 0.0030 \times \text{ied}(i, \text{'barge'})) \times \text{ied}(i, \text{'barge'}) + (0.5 + 0.0144 \times \text{ied}(i, \text{'road'}) \times \text{ied}(i, \text{'road'});
\]

This means that if the entry in the distance table ied is not zero, then the cost of shipping using that link is added to the total cost. If there is no distance entry, there is no contribution to the cost, presumably because that mode is not used.

Consider another example for a conditional assignment with the dollar operator on the right:

\[
\text{b} = \text{sum}(i, t(i)) \times (a > 0) + 4;
\]

Here a and b are scalars, i is a set and t is a parameter. If the scalar a is positive, the scalar b is assigned the sum of all values of the parameter t plus 4. If a is zero or negative, b becomes just 4. Note that the sum is only computed if the condition holds, this potentially makes the program faster.

### 3.32.5 Conditional Indexed Operations

We have seen how exceptions in assignments are modeled with dollar conditions. Dollar conditions are also used in indexed operations, where they control the domain of operation. This is conceptually similar to the conditional assignment with the dollar on the left.

Consider the following example adapted from [GTM], a gas trade model for interrelated gas markets. Here the set i contains supply regions and the parameter supc models supply capacities. The scalar tsupc is computed with the following statement:

\[
\text{tsupc} = \text{sum}(i \times (\text{supc}(i) \neq \text{inf}), \text{supc}(i));
\]

This assignment restricts the sum to the finite values of the parameter supc.

In indexed operations the logical condition is often a set. This set is called the conditional set and assignments are made only for labels that are elements of the conditional set. This concept plays an important role in dynamic sets.

Multi-dimensional sets are introduced in section Multi-Dimensional Sets. In the example used there a two-dimensional set is used to define the mapping between countries and ports. Another typical example for a multi-dimensional set is a set-to-set mapping that defines the relationship between states and regions. This is useful for aggregating data from the state to the regional level. Consider the following example:

Sets r "regions" / north, south /
s "states" / florida, texas, vermont, maine /
corr(r,s) / north.(vermont,maine) 
south.(florida,texas) /;

Parameter y(r) "income for each region"
income(s) "income of each state"

/ florida 4.5, vermont 4.2
texas 6.4, maine 4.1 / ;
The set $corr$ links the states to their respective regions, the parameter $income$ is the income of each state. The parameter $y$ is computed with the following assignment statement:

$$y(r) = \sum(s \mid corr(r,s), income(s)) ;$$

The conditional set $corr(r,s)$ restricts the domain of the summation: for each region $r$ the summation over the set $s$ is restricted to the label combinations $(r,s)$ that are elements of the set $corr(r,s)$. Conceptually, this is analogous to the Boolean value TRUE or the arithmetic value non-zero. The effect is that only the contributions of vermont and maine are included in the total for north, and south is the sum of the incomes from only texas and florida.

Note that the summation above can also be written as:

$$y(r) = \sum(s,income(s) \mid corr(r,s)) ;$$

In this formulation the parameter income is controlled by the conditional set $corr$ instead of the index $s$. Note that both formulations yield the same result, but the second alternative is more difficult to read.

In the next example the logical condition on the right-hand side appears in the context of an indexed operation, but it does not refer to the index. Thus it is treated similarly to a dollar on the right logical condition. Note that $a$ and $b$ are scalars, $i$ is a set and $s$ is a parameter.

$$b = \sum(i \mid a, s(i)) ;$$

Here the scalar $b$ is assigned the sum of the values of the parameter $s$ only if $a$ does not equal zero. Otherwise $b$ will be assigned the value zero. Observe that the following alternative formulation will generally be faster than the assignment above:

$$b = \sum(i, s(i)) \mid a ;$$

Note that if the logical condition in the context of indexed operations refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section Filtering Controlling Indices in Indexed Operations below.

3.32.6 Conditional Equations

The dollar operator is also used for exception handling in equations. The next two subsections discuss the two main uses of dollar operators in the context of equations: in the body of an equation and over the domain of definition.
3.32.6.1 Dollar Operators within the Algebra of Equations

A dollar operator in the algebraic formulation of an equation is analogous to the dollar control on the right of assignments, as presented in section Dollar on the Right. Assuming that "the right" means the right of the '...' then the analogy is even closer. As in the context of assignments, an if-else operation is implied. It is used to exclude parts of the definition from some of the generated constraints.

Consider the following example adapted from the production model [CHENERY].

Set i "sectors" / light-ind, food+agr, heavy-ind, services /
t(i) "tradables" / light-ind, food+agr, heavy-ind /;
Variables x(i) "quantity of output"
y(i) "final consumption"
e(i) "quantity of exports"
m(i) "quantity of imports";
Equations mb(i) "material balance";
mb(i).. x(i) =g= y(i) + (e(i) - m(i)) $ t(i) ;

Note that in the equation definition in the last line, the term \((e(i) - m(i))\) on the right-hand side of the equation is added only for those elements of the set \(i\) that also belong to the subset \(t(i)\), so that the element services is excluded.

Further, conditional indexed operations may also feature in expressions in equation definitions. The supply balance equation from the gas trade model [GTM] is an example. Note that the set \(i\) contains the supply regions, the set \(j\) contains the demand regions, and the two-dimensional set \(ij\) is the set of feasible links; the variable \(x\) denotes the shipment of natural gas and the variable \(s\) denotes the regional supply.

\[
\text{sb}(i) .. \sum(j \text{ sij}(i,j), x(i,j)) =l= s(i) ;
\]

Similar to the assignment example seen before, the conditional set \(ij(i,j)\) restricts the domain of the summation: for each supply region \(i\) the summation over the demand regions \(j\) is restricted to the label combinations \((i,j)\) that are elements of the set of feasible links \(ij(i,j)\).

3.32.6.2 Dollar Control over the Domain of Definition

In case constraints should only be included in the model if particular conditions are met, a dollar condition in the domain of definition of an equation may be used to model this restriction. Such a dollar condition is analogous to the dollar control on the left of assignments. Assuming that "the left" means the left of the symbols '...' then the analogy is even closer.

Note

The dollar control over the domain of definition of equations restricts the number of constraints generated to less than the number implied by the domain of the defining sets.

Consider the following example adapted from the Andean fertilizer model [ANDEAN]:

\[
gple(w,wp,te) \text{ s ple}(w,wp) .. yw(w,te) - yw(wp,te) =l= dpack;
\]
Here $w$, $wp$ and $te$ are sets, $ple$ is a two-dimensional parameter, $yw$ is a variable and $dpack$ is a scalar. Note that the dollar condition restricts the first two indices of the domain of the equation to those label combinations that have non-zero entries in the two-dimensional parameter $ple$.

Sometimes the desired restriction of an equation may be achieved either way: through a condition in the algebra or a condition in the domain of definition. Compare the following two lines, where $eq1$ and $eq2$ are equations, $i$ and $j$ are sets, $b$ is a scalar, $s$ is a parameter and $x$ is a two-dimensional variable.

\[
\begin{align*}
    eq1(i) & \text{ $b.. \sum(j, x(i,j)) \text{=g=} -s(i)$;} \\
    eq2(i) & \text{ $\sum(j, x(i,j)) \text{ $b =g=} -s(i) \text{ $b$;} }
\end{align*}
\]

In the first line the dollar condition is in the domain of definition, in the second line the dollar conditions are in the algebraic formulation of the equation. If $b$ is non-zero, the generated equations $eq1$ and $eq2$ will be identical. However, if $b$ is 0, no equation $eq1$ will be generated, but for each $i$ we will see a trivial equation $eq2$ of the form $0 \text{=g=} 0$.

Note that if the logical condition in the domain of definition of an equation refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section Filtering the Domain of Definition below.

### 3.32.7 Filtering Sets

If the logical condition refers to set membership, the restriction modeled with a dollar condition may sometimes be achieved without the dollar operator. Consider the following statement, where $i$ and $j(i)$ are sets, and $u$ and $s$ are parameters:

\[
    u(i) \text{ $j(i) = s(i)$ ;}
\]

Note that the assignment is made only for those elements of the set $i$ that are also elements of the subset $j$. This conditional assignment may be rewritten in a shorter way:

\[
    u(j) = s(j);
\]

In this statement the assignment has been filtered through the condition without the dollar operator by using the subset $j$ as the domain for the parameters $u$ and $s$. This formulation is cleaner and easier to understand. It is particularly useful in the context of multi-dimensional sets (tuples), and it may be used in assignments, indexed operations and the domain of definition of equations.

#### 3.32.7.1 Filtering Sets in Assignments

Suppose we want to compute the transportation cost between local collection sites and regional transportation hubs for a fictional parcel delivery service. We define sets for the collection sites and transportation hubs and a two-dimensional set where the collection sites are matched with their respective hubs:
Set \( i \) "local collection sites" / miami, boston, chicago, houston, phoenix / 
\( j \) "regional transportation hubs" / newyork, detroit, losangeles, atlanta / ;

Set \( r(i,j) \) "regional transportation hub for each local collection site" /
boston .newyork  
miami .atlanta  
houston .atlanta  
chicago .detroit  
phoenix .losangeles / ;

Table distance\((i,j)\) "distance in miles"
\begin{tabular}{lcccc}
\hline
 & newyork & detroit & losangeles & atlanta \\
miami & 1327 & 1387 & 2737 & 665 \\
boston & 216 & 699 & 3052 & 1068 \\
chicago & 843 & 275 & 2095 & 695 \\
houston & 1636 & 1337 & 1553 & 814 \\
phoenix & 2459 & 1977 & 398 & 1810 \\
\end{tabular}

Parameter factor "cost estimate per unit mile"  

\begin{align*}
\text{factor} &= 0.009 \\
\text{shipcost}(i,j) &= \text{factor}\times\text{distance}(i,j)
\end{align*}

The distance between collection sites and transportation hubs is given in the table. The last line is a conditional assignment for the parameter \( \text{shipcost} \). This assignment is only made if the label combination \((i,j)\) is an element of the set \( r \). Note that in each instance the indices \( i \) and \( j \) appear together. Thus the assignment may be simply written as:

\[ \text{shipcost}(r) = \text{factor}\times\text{distance}(r) ; \]

Note that the assignment is explicitly restricted to the members of the set \( r \); the dollar operator is not necessary. Observe that if the indices \( i \) or \( j \) appear separately in any assignment, the above simplification cannot be made. For example, consider the case where the shipping cost depends not only on the parameter \( \text{factor} \) and the distance between collection sites and regional hubs, but also on the congestion at the regional hub. We introduce a new parameter \( \text{congestfac} \) that models the congestion at each regional hub and is indexed only over the set \( j \):

Parameter \( \text{congestfac}(j) \) "congestion factor" /
\begin{align*}
\text{newyork} &= 1.5 \\
\text{detroit} &= 0.7 \\
\text{losangeles} &= 1.2 \\
\text{atlanta} &= 0.9
\end{align*}

The new cost of shipment is computed as follows:

\begin{align*}
\text{shipcost}(i,j) &= \text{factor}\times\text{congestfac}(j)\times\text{distance}(i,j) \\
\end{align*}

Note that this conditional assignment cannot be reformulated as:

\[ \text{shipcost}(r) = \text{factor}\times\text{congestfac}(j)\times\text{distance}(r) ; \]

In the representation above the index \( j \) appears on the right-hand side, but not on the left-hand side. GAMS will flag this assignment as an error. However, the following representation will work:

\begin{align*}
\text{shipcost}(r(i,j)) &= \text{factor}\times\text{congestfac}(j)\times\text{distance}(r) \\
\end{align*}

In this formulation the set \( r \) is explicitly denoted as a tuple of the sets \( i \) and \( j \). The set \( j \) may then appear on the right-hand side.
3.32.7.2 Filtering Controlling Indices in Indexed Operations

Similarly, the controlling indices in indexed operations may be filtered through the conditional set without the use of the dollar operator. We continue with the shipping cost example from the last subsection. The total cost of shipment is obtained through the equation that follows. We also include the variable definitions for clarity.

Variable shipped(i,j), totcost;
Equation costequ;

costequ.. totcost =e= sum((i,j) $ r(i,j), shipcost(i,j)*shipped(i,j));

Here the variable shipped is the number of parcels shipped from the local collection site i to the regional transportation hub j, and the variable totcost is the total cost of all shipments. Note that she summation in the equation is restricted to the label combinations that are elements of the set r. Alternatively, the equation above may be written as:

costequ.. totcost =e= sum(r, shipcost(r)*shipped(r));

In this formulation the summation is performed explicitly only over the elements of the set r, no dollar condition is necessary. However, if the expression in the equation included a term dependent only on index j, then we would have to reformulate differently. Suppose the equation included also the congestion factor congestfac that is indexed only over j:

cost.. totcost =e= sum((i,j) $ r(i,j), factor*congestfac(j)*distance(i,j)*shipped(i,j));

In this case the equation needs to be simplified in the following way:

cost.. totcost =e= sum(r(i,j), factor*congestfac(j)*distance(r)*shipped(r));

Like before, the domain of the indexed operation sum is the set r. But this time the domain of r has to be named explicitly, so that the parameter congestfac which is indexed only over the set j is permitted in the scope of the indexed operation. Note that this reasoning is analogous to the reasoning for filtering sets in assignments in the subsection above.

3.32.7.3 Filtering the Domain of Definition

The rules for filtering sets that we have introduced in subsections Filtering Sets in Assignments and Filtering Controlling Indices in Indexed Operations also apply in the context of equation domains. We continue with the parcel transport example introduced above and add a binary variable bin, the parameter bigM and the equation connect to the model. Recall that shipped(i,j) is a variable and r(i,j) is a set.

Parameter bigM(i,j);
Binary variable bin(i,j);
Equation connect(i,j);
connect(i,j) $ r(i,j).. shipped(i,j) =l= bigM(i,j)*bin(i,j);
The dollar condition restricts the domain of definition of the equation `connect` to those label combinations of the sets `i` and `j` that are elements of the set `r`. The equation relates the continuous variable `shipped(i,j)` to the binary variable `bin(i,j)`. Note that each domain in the equation is the index pair `(i,j)`. So the equation may be simplified as follows:

```
connect(r).. shipped(r) =l= bigM(r)*bin(r) ;
```

In this formulation the domain of the equation is explicitly restricted to the members of the set `r`, without the use of a dollar condition. Note that if the right-hand side of the equation contained any term that was indexed over `i` or `j` separately, then the domain of definition of the equation would have to be simplified as:

```
connect(r(i,j))
```

The reasoning is the same as in the case of assignments and indexed operations.

### 3.33 The Display Statement

#### 3.33.1 Introduction

The `display` statement in GAMS is a quick way to write data into the listing file. It does not provide a publication quality reporting function, but is instead aimed at functionality that is easy to use and provides graceful defaults. These defaults may be modified by the user to control the layout and appearance of the output. Both, defaults and customization options are presented in this chapter. For information on the listing file, see chapter GAMS Output. In addition to the `display` statement, GAMS offers the put writing facility, a more sophisticated way to generate reports, where the user has much more flexibility and control over the output of individual items.

#### 3.33.2 The Syntax

In general, the syntax for the `display` statement in GAMS is as follows:

```
display ident | quoted text {, ident | quoted text};
```

The keyword `display` indicates that this is a display statement. It is followed by an `identifier`. If the identifier is a set or a parameter, only the name of the set or parameter itself is specified. If the identifier is a variable, an equation or a model, it must be followed by a suffix, i.e. a variable attribute, equation attribute or model attribute respectively. As usual, quoted text must be surrounded by single or double quotes. The identifiers and the text may be mixed and matched in any order, and the whole statement may be continued over several lines. For conditional displays a dollar condition may follow the keyword `display`.

The output produced by a display statement consists of labels and data. For multi-dimensional sets the keyword `yes` (indicating membership) is used instead of values.
3.33 The Display Statement

Note

Only the non-default values are displayed for all data types.

The default value is generally zero. Exceptions are some upper and lower bounds of variables and equations (the attributes .lo and .up). Their default values are listed in sections Variable Attributes and Equation Attributes respectively.

The syntax of the display statement is illustrated by the following example:

Sets
s / s1*s4 /
t / t5*t7 /
st(s,t) / s1.t5, s1.t7, s2.t6, s3.t7, s4.t5 /

Parameters
p(s) / s1 0.33, s3 0.67 /
q(t) / t5 0.33, t7 0.67 /

Variable
v(s,t) ;
v.l(s,t) = p(s)*q(t);

display 'first a simple set', s, 'then a two-dimensional set', st, 'then a parameter', p, 'then the activity level of a variable', v.l;

The display statement will generate the following lines in the listing file:

----  8 first a simple set
----  8 SET s
    s1, s2, s3, s4

----  8 then a two-dimensional set
----  8 SET st
    t5 t6 t7
    s1 YES YES
    s2 YES
    s3 YES
    s4 YES

----  8 then a parameter
----  8 PARAMETER p
    s1 0.330, s3 0.670

----  8 then the activity level of a variable
----  8 VARIABLE v.l
    t5 t7
    s1 0.109 0.221
    s3 0.221 0.449

Note that only the non-default values are displayed. In the case of multi-dimensional identifiers like the set st and the level values of the variable v, the data is by default reported in a tabular form that is easy to read.
3.33.3 Displaying Multi-Dimensional Identifiers: Label Order

We have seen that two-dimensional identifiers are displayed in table format. The default layout for displaying multi-dimensional identifiers is summarized in Table 1. Note that the default format may be modified with the local display control. The figures in the table refer to the index position in the domain list of the identifier. For example, if we display \( x \), where \( x \) has been declared as \( x(i,j,k,l) \), then the \( i \) labels (the first index) will by default be associated with the individual subtables, the \( j \) and \( k \) with the row labels and the \( l \) (the fourth and last index) with the column headings.

<table>
<thead>
<tr>
<th>Number of Indices</th>
<th>Subtable</th>
<th>Index Position(s) on the Row</th>
<th>Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>list format</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>-</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>-</td>
<td>1,2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>2,3</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>1,2</td>
<td>3,4</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>1,2,3</td>
<td>4,5</td>
<td>6</td>
</tr>
</tbody>
</table>

Table 1: Default Layout for Displaying Multi-Dimensional Identifiers

For 7 to the maximum number of indices the natural progression is followed. For the current maximum number of indices, see Dimensions. The labels vary slowest for the first index position and quickest for the highest. Within each index position the order of the label is the GAMS entry order of the labels. Some users may need to manipulate the order of the labels.

Note

The only way to change the order in which the labels for each index position appear in the display output is to change the order of appearance of the labels in the GAMS program.

This is most easily done by declaring a set whose only purpose is to list all the labels in the order that is needed. Make this set the very first declaration in the GAMS program.

Note that the order of the indices in an identifier is always as the order in the declaration statement. One can declare them in the order that is found appealing, or make an assignment to a new identifier with a different order, as illustrated in the example below.

3.33.3.1 Example for Multi-Dimensional Displays

Consider the following example. The parameter \( x \) has four dimensions or index positions. It is initialized using parameter format and then displayed as shown below.

Set i first index / first, second /
   j second index / one, two, three /
   k third index / a, b /
   l fourth index / i, ii / ;

Parameter

\[
x(i,j,k,l) \text{ a four dimensional structure /}
\]

\[
\begin{align*}
\text{second.one.a.i} & = 0.00013, & \text{first.three.b.i} & = -6.3161 \\
\text{first.one.b.i} & = 5.63559, & \text{second.two.b.i} & = 20000.00 \\
\text{second.one.b.ii} & = -17.29948, & \text{first.two.b.ii} & = 10.3457 \\
\text{first.two.a.ii} & = 0.02873, & \text{second.one.a.ii} & = 1.0037 \\
\text{second.two.a.ii} & = +\text{inf}, & \text{first.two.a.i} & = -2.9393 \\
\text{first.one.a.ii} & = 0.00000 \\
\end{align*}
\]

\[
y(k,l,i,j) \text{ a four dimensional structure with changed index order;}
\]

\[
y(k,l,i,j) = x(i,j,k,l);
\]

display x, y;
3.33 The Display Statement

For variable \( x \) the code fragment produces the following output:

```plaintext
---- 16 PARAMETER x a four dimensional structure
INDEX 1 = first
       i    ii
  one .b    5.636
  two .a   -2.939   0.029
  two .b    10.346
 three.b   -6.316

INDEX 1 = second
       i    ii
  one .a  1.300000E-4   1.004
  one.b  -17.299
  two .a   +INF
  two .b   20000.000
```

Notice that there are two subtables, one for each label in the first index position. Note further that the order of the labels is not the same as in the input data list of the parameter \( x \), but is according to the label order in the driving sets. Observe that the numbers are rounded, three decimals are displayed by default. This default may be modified with display controls, which is the topic of the next section. Note that the zero in the list for \( x(\text{first}, \text{one}, \text{a}, \text{ii}) \) has vanished, since default values are not shown. Similarly, rows and columns containing only zero values are suppressed in each subtable separately. Note further that the especially small value appears in E-format.

Notice furthermore how parameter \( y \) can be used to display the same data with a different index order.

### 3.33.4 Display Controls

GAMS allows the user to modify the number of row and column labels in the display listing as well as the accuracy of the data being displayed. There are global and local display controls. Global display controls allow the user to affect more than one display statement. The local display control may be used to override the global controls if specific data need to be listed in a particular format. Both controls are expressed with option statements.

#### 3.33.4.1 Global Display Controls

The first option for global display controls specifies the number of digits shown after the decimal point. It affects the numbers appearing in all display output following the option statement, unless it is changed for a specific identifier as shown below. The general form of this option statement is:

```plaintext
option decimals = value;
```

The keyword `option` indicates that this is an option statement, `decimals` is the specific option and `value` is an integer between 0 and 8. The value 0 supresses decimals as well as the decimal point. Note that the default is 3. Note further that the width of the number field does not change, just the number of decimals. This may cause numbers which would normally be displayed in fixed format to appear in E-format, that is with the exponent represented explicitly.

Consider the following extension to the example discussed in the previous section.
GAMS will round or convert numbers to E-format where necessary and the output is as follows:

---- 14 PARAMETER x  a four dimensional structure

INDEX 1 = first

<table>
<thead>
<tr>
<th></th>
<th>i</th>
<th>ii</th>
</tr>
</thead>
<tbody>
<tr>
<td>one .b</td>
<td>5.6</td>
<td></td>
</tr>
<tr>
<td>two .a</td>
<td>-2.9 2.873000E-2</td>
<td></td>
</tr>
<tr>
<td>two .b</td>
<td>10.3</td>
<td></td>
</tr>
<tr>
<td>three .b</td>
<td>-6.3</td>
<td></td>
</tr>
</tbody>
</table>

INDEX 1 = second

<table>
<thead>
<tr>
<th></th>
<th>i</th>
<th>ii</th>
</tr>
</thead>
<tbody>
<tr>
<td>one .a</td>
<td>1.300000E-4</td>
<td></td>
</tr>
<tr>
<td>one .b</td>
<td>-17.3</td>
<td></td>
</tr>
<tr>
<td>two .a</td>
<td>+INF</td>
<td></td>
</tr>
<tr>
<td>two .b</td>
<td>20000.0</td>
<td></td>
</tr>
</tbody>
</table>

Note that GAMS overrode the decimal choice for x('first','two','a','ii') to ensure that small numbers are not displayed as zeroes.

Another option for global display control modifies the width of the display. This is particularly important for longer label names. Label names that are headers of columns are cut off after 9 characters when data is displayed in table format. The following option may be used to display longer names in full:

```
option dispwidth = value;
```

The name of the option is `dispwidth` and `value` is a positive integer smaller or equal to 31. An illustrative example follows.

```
Set i 'South African cities' / Johannesburg, Cape_Town /
    j 'other African cities' / Maputo, Dar_es_Salaam /
    f(i,j) 'direct flight connections' / Johannesburg.Maputo, Johannesburg.Dar_es_Salaam, Cape_Town.Maputo /

display f ;
```

The display statement generates the following output:

```
---- 4 SET f  direct flight connections

   Maputo       Dar_es_Salaam
Johannesburg  YES  YES
Cape_Town     YES

```

Note that only the label 'Dar_es_Salaam' is cut off since it is heading a column. The label 'Johannesburg' is not cut off as it is the label for a row. Now we add the following line to change the width of the display statement:

```
option dispwidth = value;
```
option dispwidth = 15; display f;

As expected, the output changes and the label 'Dar_es_Salaam' is no longer cut off:

```
---- 5 SET f direct flight connections

<table>
<thead>
<tr>
<th></th>
<th>Maputo</th>
<th>Dar_es_Salaam</th>
</tr>
</thead>
<tbody>
<tr>
<td>Johannesburg</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>Cape_Town</td>
<td>YES</td>
<td></td>
</tr>
</tbody>
</table>
```

### 3.33.4.2 Local Display Control

It is often useful to control the number of decimals for specific identifiers separately. The following option statement accomplishes this:

```latex
option ident:d-value;
```

Ident denotes the name of the identifier and d-value is an integer in the range 0 to 8. The number of decimal places shown on all displays of ident that follow will be d-value.

This option statement can be extended to control the layout of the data in addition to the decimal places. The general form is as follows:

```latex
option ident:d-value:r-value:c-value ;
```

Here r-value denotes the number of index positions that are combined to form the row label and c-value means the number of indices on the column headers.

The example discussed in the previous section is further extended in order to illustrate the local display control.

```latex
option x:5:3:1; display x;
```

These two statements generate the following output:

```
---- 17 PARAMETER x a four dimensional structure

<table>
<thead>
<tr>
<th></th>
<th>i</th>
<th>ii</th>
</tr>
</thead>
<tbody>
<tr>
<td>first.one</td>
<td>.b</td>
<td>5.63559</td>
</tr>
<tr>
<td>first.two</td>
<td>.a</td>
<td>-2.93930</td>
</tr>
<tr>
<td>first.two</td>
<td>.b</td>
<td>10.34570</td>
</tr>
<tr>
<td>first.three</td>
<td>.b</td>
<td>-6.31610</td>
</tr>
<tr>
<td>second.one</td>
<td>.a</td>
<td>0.00013</td>
</tr>
<tr>
<td>second.one</td>
<td>.b</td>
<td>-17.29948</td>
</tr>
<tr>
<td>second.two</td>
<td>.a</td>
<td>+INF</td>
</tr>
<tr>
<td>second.two</td>
<td>.b</td>
<td>20000.00000</td>
</tr>
</tbody>
</table>
```
Note that five decimal places are shown, three labels are used to mark the rows and one label acts as head of the column. Since this is a four-dimensional structure, all indices are accounted for.

The next example places two indices on each of the row and column labels and retains five decimal places:

option x:5:2:2; display x;

The output is:

---- 18 PARAMETER x a four dimensional structure

<table>
<thead>
<tr>
<th></th>
<th>a.i</th>
<th>a.ii</th>
<th>b.i</th>
<th>b.ii</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td>5.63559</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>-2.93930</td>
<td>0.02873</td>
<td>10.34570</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>-6.31610</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>second</td>
<td>0.00013</td>
<td>1.00370</td>
<td>-17.29948</td>
<td></td>
</tr>
<tr>
<td>second</td>
<td>+INF</td>
<td>20000.00000</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If in the option statement less dimensions are specified than the number of indices in the domain, then subtables will be generated for the labels of the beginning indices. Observe how the display layout will change if we use the following statement:

option x:0:1:1; display x;

The output follows.

---- 19 PARAMETER x a four dimensional structure

INDEX 1 = first  INDEX 2 = one

<table>
<thead>
<tr>
<th>i</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
</tr>
</tbody>
</table>

INDEX 1 = first  INDEX 2 = two

<table>
<thead>
<tr>
<th>i</th>
<th>ii</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>-3</td>
</tr>
<tr>
<td>b</td>
<td>10</td>
</tr>
</tbody>
</table>

INDEX 1 = first  INDEX 2 = three

<table>
<thead>
<tr>
<th>i</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
</tr>
</tbody>
</table>

INDEX 1 = second  INDEX 2 = one

<table>
<thead>
<tr>
<th>i</th>
<th>ii</th>
</tr>
</thead>
</table>
The option statement for local display controls may be used to generate data in list format by setting the r-value to zero:

```
option ident:d-value:0:c-value;
```

In this case the c-value specifies the maximum number of items displayed on a line. The actual number will depend on the page width and the number and length of the labels.

Using the same example as in the previous sections, we change the r-value to zero in the option statement:

```
option x:5:0:1; display x;
option x:5:0:2; display x;
```

Note that we specified one and two columns to illustrate the impact of different c-value settings. These statements will generate the following output:

```
---- 20 PARAMETER x a four dimensional structure
first .one .b.i  5.63559
first .two .a.i -2.93930
first .two .a.ii 0.02873
first .two .b.ii 10.34570
first .three .b.i -6.31610
second .one .a.i 0.00013
second .one .a.ii 1.00370
second .one .b.ii -17.29948
second .two .a.ii +INF
second .two .b.i 20000.00000

---- 21 PARAMETER x a four dimensional structure
first .one .b.i  5.63559, first .two .a.i -2.93930
first .two .a.ii 0.02873, first .two .b.ii 10.34570
first .three .b.i -6.31610, second .one .a.i 0.00013
second .one .a.ii 1.00370, second .one .b.ii -17.29948
second .two .a.ii +INF, second .two .b.i 20000.00000
```

This output nicely illustrates the label order used. The first index varies the slowest, the last the fastest, and each one runs from beginning to end before the next one to the left advances. This ordering scheme is also used in equation and column lists and in the solution report which are all generated by the solve statement.
### 3.33.5 Conditional Displays

This section assumes familiarity with the *if statement* and the *dollar condition*.

The display statement may be controlled by conditional expressions. Conditionals have the effect that the items are displayed only if a logical condition is satisfied. There are two ways to express conditional displays in GAMS: with dollar conditions and using *if* statements. The syntax using a dollar condition is as follows:

\[
\text{display$logical\_condition \ ident \mid quoted\_text \{, \ ident \mid quoted\_text};
\]

Note that the dollar condition is inserted after the keyword *display*. For details on the various forms of conditional expressions in GAMS, see sections **Logical Conditions** and **Filtering Sets**. Consider the following simple example:

```plaintext
Scalars x, y;
x = 7;
y = 3;
display$(x-y < 0) "display if x minus y is less than 0", x, y;
```

The logical condition \((x-y < 0)\) controls the display statement. In this case it is not satisfied, hence there will be no display output. If the value of \(y\) is changed to, say 10, then the logical condition will be satisfied and the display statement will generate the following output:

```
---- 4 display if x minus y is less than 0
PARAMETER x = 7.000
PARAMETER y = 10.000
```

The syntax for conditional displays using an *if* statement is as follows:

```plaintext
if( logical\_condition, display statement );
```

The simple example above may be reformulated as follows:

```plaintext
Scalars x, y;
x = 7;
y = 3;
if( x-y < 0,
   display "display if x minus y is less than 0", x, y;
);
```

### 3.34 Programming Flow Control Features

#### 3.34.1 Introduction

In this chapter we will describe the programming flow control features available in GAMS. The *if statement* facilitates expressing complex conditional statements (see also chapter **Conditional Expressions, Assignments and Equations**). In addition, GAMS offers four loop constructs to handle looping requirements: the loop statement, the while statement, the for statement and the repeat statement. At the end of this chapter we will introduce the break, and continue statements, which give additional control over the execution of loop structures, and the abort statement, a statement that may be used to terminate the execution of a program.

Note that this chapter deals with programming flow control features at execution time. In addition, GAMS provides a dollar control option that allows for *conditional processing of input files at compile time*. For more information, see the detailed description of the option $if. For details on dollar control options in general, see chapter **Dollar Control Options**.
3.34.2 The If Statement

The if statement is useful to branch conditionally around a group of statements. In some cases this can also be written as a set of dollar conditions, but the if statement may make the GAMS code more readable. An optional else and/or elseif part allows the user to formulate traditional if-then-else constructs.

3.34.2.1 The If Statement: Syntax

The syntax for an if statement in GAMS is as follows:

```gams
if (logical_condition,
    statement; {statement;})
{ elseif logical_condition,
    statement; {statement;} } ]
[ else
    statement; {statement;} ]
);
```

The keyword if indicates that this is an if statement. The logical condition is followed by one or more statements that are executed if the logical condition is satisfied. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. The if statement may end at this point, without any specifications for cases when the logical condition is FALSE and no action is taken in these cases. However, GAMS also allows further specifications: optional alternative if tests and optional statements for cases when all previous if tests have failed. The keyword elseif introduces an alternative if test with a logical condition and one or more statements. Note that the elseif case is optional and may be repeated multiple times. Note further that the elseif case implies that the logical condition of the if case has not been satisfied. The keyword else introduces the final part of the construct. It is optional and allows specification for cases when the logical condition of the if case (and possibly the elseif case(es)) has not been satisfied.

Attention

Only execution statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside an if statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.

3.34.2.2 The If Statement: Examples

Consider the following set of conditional assignment statements that use dollar conditions:

```gams
p(i)$(f <= 0) = -1 ;
p(i)$((f > 0) and (f < 1)) = p(i)**2 ;
p(i)$(f >= 1) = p(i)**3 ;
q(j)$(f <= 0) = -1 ;
q(j)$((f > 0) and (f < 1)) = q(j)**2 ;
q(j)$(f >= 1) = q(j)**3 ;
```
They may be expressed using an if-elseif-else statement:

```plaintext
if (f <= 0,
   p(i) = -1 ;
   q(j) = -1 ;
elseif ((f > 0) and (f < 1)),
   p(i) = p(i)**2 ;
   q(j) = q(j)**2 ;
else
   p(i) = p(i)**3 ;
   q(j) = q(j)**3 ;
)
```

Note that the body of the if statement may contain solve statements. For instance, consider the bit of GAMS code that follows. Note that ml is a GAMS model, z is a free variable, j is a set and x is a variable.

```plaintext
solve ml using lp minimizing z;
if (ml.modelstat = 4,
   display "model ml was infeasible, relax bounds on x and solve again";
   x.up(j) = 2*x.up(j) ;
   solve ml using lp minimizing z ;
else
   if (ml.modelstat <> 1,
      abort "error solving model ml" ;
   );
);
```

First the model ml is solved. For details on solve statements in GAMS, see section The Solve Statement. Then a post solution analysis is done with the if statement. If the model is infeasible, the upper bound on the variable x is relaxed and the model is solved again. If the original model is not infeasible and it is not optimal either, then the compilation is aborted and the error message above is reported. For more information on GAMS output, see chapter GAMS Output, particularly subsection Model Status for a list of all GAMS model statuses. The display statement is introduced in chapter The Display Statement. For details on the abort command, see abort.

The following GAMS code is illegal since it is not permitted to define equations inside an if statement.

```plaintext
if (s > 0,
   eq.. sum(i,x(i)) =g= 2 ;
);
```

The following GAMS code is also illegal since declarations inside an if statement are not allowed.

```plaintext
if (s > 0,
   scalar y ; y = 5 ;
);
```

### 3.34.3 The Loop Statement

The loop statement facilitates executing a group of statements for each member of a set. Loop statements are particularly useful for cases when parallel assignments are not sufficient. This is the case most often when there is no analytic relationship between the values to be assigned to a parameter. It is, of course, also useful to have a looping statement for general programming.
3.34.3.1 The Loop Statement: Syntax

The syntax for the `loop` statement in GAMS is as follows:

```gams
loop(index_list[$(logical_condition)],
    statement; {statement;}
) ;
```

The keyword `loop` indicates that this is a loop statement. The `index_list` is the controlling domain of the loop. Note that loops may be controlled by more than one set. In this case parentheses are required around the index list, which is also called the `loop set(s)`. Observe that dynamic sets are allowed as loop sets. The loop set(s) may be restricted by a logical condition. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. For an introduction to dollar conditions in general, see chapter Conditional Expressions, Assignments and Equations. The index list is followed by one or more statements. Except for the final statement, each statement must end with a semicolon `;`. The loop statements are executed for each member of the controlling domain in turn. The order of evaluation is the entry order of the labels. A loop is thus another, more general, type of indexed operation.

Attention

- Only `execution` statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `loop` statement.
- It is illegal to modify any controlling set inside the body of the loop.

Loop statements in GAMS are often used for iterative calculations, generating reports with `put statements` and doing scenario based studies with `solve statements`. Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option `onEnd`.

3.34.3.2 The Loop Statement: Examples

Consider a hypothetical case when a growth rate is empirical:

```plaintext
Set        t / 1985*1990 /
Parameter  pop(t) / 1985 3456 /
```

The `loop` statement is then used to calculate the cumulative sums iteratively:

```gams
loop(t, pop(t+1) = pop(t) + growth(t) ) ;
```

In this example the driving set is `t` and we have just one statement in the scope of the loop.

The following small artificial examples illustrate the effects of a dollar condition in a `loop` statement.
In the first loop statement the controlling domain is the set pair (i,j). It is restricted to those label combinations whose values associated with the parameter q are greater than zero. The logical condition in the second loop statement is $c(i) + c(i)^2$. This is shorthand for $c(i) + c(i)^2 \neq 0$. The domain in the third loop statement is restricted to those elements of the set i where the sum over j of the absolute values of the parameter q does not equal zero. Note that this condition is satisfied only for the label "i1". Observe that i and j are both ordered sets. In the fourth loop statement the first and the last element of the set j are excluded. For more on the set operators ord and card, see sections The Ord Operator and The Card Operator respectively. The dollar control in the last loop statement excludes all label combinations that are not members of the set k. For further details on dollar conditions, see chapter Conditional Expressions, Assignments and Equations.

A loop is often used to perform iterative calculations. Consider the following example, which finds square roots by Newton's method. This example is purely for illustration - in practice, the function sqrt should be used. Newton's method is based on the assertion that if $x$ is an approximation to the square root of $v$, then $(x + v/x)/2$ is a better approximation.

```
Set i "set to drive iterations" / i-1*i-100 /;
Parameter value(i) "used to hold successive approximations";
Scalars target "number whose square root is needed" / 23.456 /
sqrtval "final approximation to sqrt(target)" curacc "accuracy of current approximation" reltol "required relative accuracy" / 1.0e-06 /;
```

In the first statement some data in the model is updated in accordance with the $i^{th}$ element of the parameter g. In the second statement the model is solved. For details on the solve statement, see section The Solve Statement. The objective value for each iteration is saved in the parameter d in the third statement.
3.34 Programming Flow Control Features

abort$(target <= 0) "argument to newton must be positive";
value("i-1") = target/2 ;
curacc = 1 ;
loop(i$(curacc > reltol),
   value(i+1) = 0.5*(value(i) + target/value(i));
   sqrtval = value(i+1);
   curacc = abs (value(i+1)-value(i))/(1+abs(value(i+1)))
);
abort$(curacc > reltol) "square root not found"
option decimals=8;
display "square root found within tolerance", sqrtval, value;

Note that in this example the dollar condition in the loop does not restrict the driving set $i$, but it is used to terminate the loop procedure. The scalar $curacc$ is updated in every iteration. As soon as it becomes equal to or smaller than the required relative accuracy $reltol$ the loop stops. As the output below shows, this is the case after seven iterations. The body of the loop statement consists of three statements. The first statement calculates the current approximation and assigns it to the parameter $value$. The second statement updates the scalar $sqrtval$, and the third statements computes the accuracy of the current approximation in each iteration. Note that before and after the loop statement we added lines to account for special cases. For details on the abort statement, see section The Abort Statement at the end of this chapter. The output generated by the display statement is given below.

---- 19 square root found within tolerance
---- 19 PARAMETER SQRTVAL = 4.84313948 final approximation to sqrt(target)
---- 19 PARAMETER VALUE used to hold successive approximations
   i-1 11.72800000, i-2 6.86400000, i-3 5.14062471, i-4 4.85174713
   i-5 4.84314711, i-6 4.84313948, i-7 4.84313948

Note that a statement within the body of a loop may be an if statement (or any other programming flow control statement). Moreover, the logical condition in a loop statement may be expressed with an if statement instead of a dollar condition. The following example serves as illustration. Observe that $k$ is a set and $s$, $t$, $u$ and $a$ are parameters.

loop (k, 
   if((s(k) < 0 and t(k)),
      u(k) = a(k);
   );
);

Note that if the logical condition is not satisfied the assignment is not made and the parameter $u$ remains unchanged.

Recall that subsets are connected with their supersets by arcs thus building a domain tree where the root node is the universal set. The following example demonstrates how the domain tree may be used in a loop statement.
Set i / i1*i10 /  
i(i)  
j(i) / i1*i9 /  
jjj(j) / i1*i8 /  
jjj(jj) / i1*i7 /;

loop(i(jjj), ii(i) = yes;);
display ii;

Observe that the looping set is i(jjj). This means that we loop over those elements of i that are also elements of the set j jj. This construct is permitted since i is in the domain tree on the path from j jj to the universe or universal set. It is allowed to go up the domain tree on one path and go down on another path. Therefore all the elements of j jj are assigned to ii. The outcome of the display statement confirms this:

---- 8 SET ii
i1, i2, i3, i4, i5, i6, i7

3.34.4 The While Statement

The while statement facilitates the repeated execution of one or more statements as long as a logical condition is satisfied.

3.34.4.1 The While Statement: Syntax

The syntax for the while statement in GAMS is as follows:

while(logical_condition,  
statement; 
{statement;}
);

The keyword while indicates that this is a while statement. Inside the while statement a logical condition is followed by one or more statements. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. The statements are executed as long as the logical condition is TRUE.

Attention

Only execution statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a while statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.
3.34 Programming Flow Control Features

3.34.4.2 The While Statement: Examples

Consider the following simple example:

Scalar x; x = 1;
while ( round(x,2) < 10,
    x = x + 0.01;
);
display x;

Note that the scalar x is increased in each iteration until it equals 10. Note further, that to ensure an exact result, in numerical comparisons we need a stable check like we have above (round(x,2) < 10), otherwise rounding errors may occur. As soon as x reaches 10, the logical condition is no longer satisfied and therefore there will be no further passes. Hence the final value of x equals 10.

Note that the number of passes in a while statement may be restricted using the command line parameter or option forlim. For details on command line parameters and options, see section Specifying Options Through the Command Line and chapter The Option Statement respectively.

While statements may be used to control the solve statement. For instance, consider the following implementation of a random multi-start method for non-convex optimization.

scalar count / 1 /;
scalar globmin / inf /;
option bratio = 1 ;
while(count <= 1000,
    x.l(j) = uniform(x.lo(j),x.up(j)) ;
solve ml using nlp minimizing obj ;
if (obj.l < globmin,
    globmin = obj.l ;
    bestsol(j) = x.l(j) ;
) ;
    count = count+1 ;
);  

Note that we start from a random starting point by setting the initial level values randomly between the upper and lower bounds. This assumes that the bounds have been previously specified and are not infinity. When the method improves, that is, if the logical condition (obj.l < globmin) is satisfied, the best known solution is stored in the scalar globmin. The level values associated with the best known solution so far are then saved in the parameter bestsol. This procedure is repeated 1000 times. The model [PRIME] is another example where the use of the while statement is illustrated. In this model the set of all prime numbers smaller than 200 is generated.

The following GAMS code is illegal since equation definitions inside a while statement are not permitted.

while(s > 0,
    eq.. sum(i,x(i)) =g= 2 ;
);

The following GAMS code is also illegal since declarations inside a while statement are not allowed.

while(s > 0,
    scalar y ; y = 5 ;
);
3.34.5 The For Statement

The for statement provides a compact way to iterate over a range of values and execute one or more statements each time.

3.34.5.1 The For Statement: Syntax

The syntax for the for statement in GAMS is as follows:

```gams
for (a = start_value to|downto end_value [by incr],
    statement; {statement;})
);
```

The keyword for indicates that this is a for statement. The scalar a begins with the real number start_value and is changed after each pass of the loop by the increment incr until it reaches the real number end_value. Note that the specification of an increment is optional, the default is 1. If the increment is given, it has to be a positive real number. Note further that to indicates that the scalar a is increased and downto indicates that it is decreased. In each iteration one or more statements are executed.

Attention

Only execution statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a for statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.

3.34.5.2 The For Statement: Examples

Consider the following simple example:

```gams
Scalar s;
for (s = -3.8 to -0.1 by 1.4,
    display s ;
);
```

Note that negative real numbers are possible for the start and end values. The resulting listing file will contain the following lines:

```
---- 3 PARAMETER s = -3.800
---- 3 PARAMETER s = -2.400
---- 3 PARAMETER s = -1.000
```

Observe that the value of s was increased by 1.4 with each pass of the loop as long as it did not exceed -0.1. In the next example the value of s is decreased:
Scalar s;
for (s = 3 downto -0.1 by 1.4,
    display s ;
);  

Note that the number of passes in a for statement may be restricted using the command line parameter or option forlim. For details on command line parameters and options, see section Specifying Options Through the Command Line and chapter The Option Statement respectively.

Like while statements, for statements may be used to control the solve statement. The following example illustrates the use of the for statement by replicating the random search for a global optimum of a non-convex model that we discussed above.

scalar i ;
scalar globmin / inf / ;
option bratio = 1 ;
for (i = 1 to 1000,
    x.l(j) = uniform(x.lo(j),x.up(j)) ;
    solve ml using nlp minimizing obj ;
    if (obj.l < globmin,
        globmin = obj.l ;
        bestsol(j) = x.l(j) ;
    );
);  

Note that the logical condition in the while loop (count <= 1000) is replaced by the specification of the range of values for the scalar i. The body of the for loop is identical to the body of the while loop, except for the statement to update the scalar count that we needed in the while loop. This demonstrates the similarities and differences between the two loops.

The following GAMS code is illegal since it is not allowed to define equations inside a for statement.

for (s = 1 to 5,
    eq.. sum(i,x(i)) =g= 2 ;
);  

The following GAMS code is also illegal since declarations inside a for statement are not permitted.

for (s = 1 to 5,
    scalar y ; y = 5 ;
);  

### 3.34.6 The Repeat Statement

The repeat statement facilitates the repeated execution of one or more statements. This is done unconditionally at least once and stopped when a logical condition is satisfied.
3.34.6.1 The Repeat Statement: Syntax

The syntax for the repeat statement in GAMS is as follows:

```gams
repeat(
    statement; {statement;}
until logical_condition );
```

The keyword `repeat` indicates that this is a `repeat` statement. One or more statements are executed in each iteration. The keyword `until` introduces the termination criterion: if the logical condition is satisfied, the `repeat` loop is terminated. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

Note that the `repeat` statement is similar to the `while` statement, but a `repeat` loop is guaranteed to be executed at least one time since the logical condition is stated after the statements.

Attention

Only execution statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `repeat` statement.

Examples are given in the next subsection.

3.34.6.2 The Repeat Statement: Examples

Consider the following simple example:

```gams
Scalar a / 1 /;
repeat(
    a = a + 1;
    display a;
until a = 5 );
```

The scalar `a` is increased in each iteration by 1. If `a` equals 5, the termination criterion is satisfied and the loop stops. Note that this example works nicely since both, the scalar and the increment, are integer. In case the entity on the right-hand side of the termination condition is not an integer or the increment is not an integer, we recommend a formulation of the check that is more stable to avoid rounding errors. An example for a stable termination condition follows.

```gams
Scalar a / 1 /;
repeat(
    a = a + 0.1;
    display a;
until abs(a-5) < 1e-6 );
```

Observe that in the next example the termination condition is `TRUE` from the start. In this case the statement in the body of the `repeat` statement is executed once and then the loop is terminated. Hence the final value of `a` will be 5.
Scalar a / 4 /;
repeat (  
a = a + 1;
display a;
until a >= 3 );

Note that the number of passes in a while statement may be restricted using the command line parameter or option forlim. For details on command line parameters and options, see section Specifying Options Through the Command Line and chapter The Option Statement respectively.

Here is a little more complex example. A repeat statement is used to narrow the interval where a quadratic function passes through zero. Note that, as is often the case, one of the statements in the repeat loop is another programming flow control statement, in this case an if statement.

Scalar max "current upper boundary of interval" /10/
min "current lower boundary of interval" /-10/
root "value where function equals zero"
function_value1 "function value at min"
function_value2 "function value at max"
tolerance "tolerance for root" /0.00000001/
signswitch "indicates that sign switch was found" /0/
inc "increment to try to find sign switch" ;

function_value1 = 6 - 5*min + sqr(min);
inc = (max - min)/37;
root = min;
repeat (  
root = root + inc;
function_value2 = 6 - 5*root + sqr(root);

if( ( sign(function_value1) <> sign(function_value2)
and abs(function_value1) > 0 
and abs(function_value2) > tolerance ),
max = root;
signswitch = 1;
else
 if(abs(function_value2) > tolerance,
 function_value1 = function_value2;
 min = root;
 );
);  
until (signswitch > 0) or (root > max );
display min, max, function_value1, function_value2;

The result of the display statement shows that the value of min is 1.892 and the value of max is 2.432, the interval was narrowed to 0.54, which is just a little less than the value of inc. As expected, function_value1 and function_value2 differ in sign, confirming that the root of the quadratic function is indeed in the interval.

### 3.34.7 The Break Statement

The break statement gives additional control over the execution of loop structures, namely the loop statement, the while statement, the for statement and the repeat statement. It allows to break the execution of a loop structure prematurely.
3.34.7.1 The Break Statement: Syntax

The syntax for the `break` statement is as follows:

```
break [n];
```

The keyword `break` indicates that this is a break statement. It terminates the n inner most control structures. n is optional and if it is omitted, it is set to 1.

Most often `break` statements are used in the context of if statements or with dollar conditions. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

3.34.7.2 The Break Statement: Examples

This is a simple, artificial example using the `break` statement to exit a loop statement:

```
Set  i / i1*i10 /;
Scalar cnt / 0 /;
loop(i,
   break$sameas('i6',i);
   cnt = cnt+1;
);
display cnt;
```

The `break` statement in combination with the dollar condition terminates the execution of the loop body in the 6th iteration. This can be seen looking at the value of `cnt` after the loop, which will be 5.

Here is a little more complex example which uses the optional argument n to terminate more than one loop structure at once:

```
Set  i / i1*i10 /;
Scalar x, y, cant / 0 /;
for(x = 1 to 10,
   y = 0;
   while(y < 10,
      y = y+1;
      loop(i,
         break$sameas('i6',i) 2;
         cant = cant+1;
      );
   );
);
display cant;
```

In this example, `cnt` will be 50 at the end. As in the previous example, it is increased 5 times in the inner most loop, before the `break` statement is executed. This time `break` is called with the argument 2, which causes the two inner most control structures (namely the `loop` and the `while`) to be terminated. The outer most control structure (the `for`) is not influenced, so that its body gets executed 10 times, which results in a total of 50 increments for the scalar `cnt`.

Note, if `break` would be called with the argument 3 instead of 2, also the `for` loop would be terminated, so that `cnt` would be 5 at the end. If `break` would be called with 1 (or without additional argument) instead of 2, only the inner most `loop` would be terminated so that `cnt` would be 500 at the end.
3.34 Programming Flow Control Features

3.34.8 The Continue Statement

The *continue* statement gives additional control over the execution of loop structures, namely the *loop statement*, the *while statement*, the *for statement* and the *repeat statement*. It allows to jump to the end of the inner most loop structure without executing the remaining statements in the body.

3.34.8.1 The Continue Statement: Syntax

The syntax for the *continue* statement is as follows:

```
continue;
```

The keyword *continue* indicates that this is a continue statement. It jumps to the end of the inner most control structure.

Most often *continue* statements are used in the context of *if statements* or with *dollar conditions*. For details on the various forms of logical conditions in GAMS, see sections *Logical Conditions* and *Filtering Sets*.

3.34.8.2 The Continue Statement: Examples

This is a simple, artificial example using the *continue* statement to skip parts of a *loop* body:

```
Set i / i1*i10 /;
Scalar cnt / 0 /;
loop(i,
  continue$(mod(ord(i),2)=0);
  cnt=cnt+1
);
display cnt;
```

In that example, every 2nd iteration of the *loop* statement is skipped. Therefore, *cnt* will be 5 at the end of the *loop*.

3.34.9 The Abort Statement

The *abort* statement is used to terminate the *execution* of a program. Most often the abort statement is used in the context of conditionals. Examples are given below. Also it may be used to display a text or an identifier in the listing file similar to the *display statement* but mostly to present the reason for the termination of the execution.

Note that the *abort* statement is to be distinguished from the dollar control option *$abort* which may be used to terminate the *compilation* of a program.
3.34.9.1 The Abort Statement: Syntax

The syntax for the `abort` statement is as follows:

```
abort [ ident | quoted text {, ident | quoted text} ];
```

The keyword `abort` indicates that this is an abort statement, all other elements of the statement are optional. `Ident` denotes an identifier. If the identifier is a set or a parameter, only the name of the set or parameter itself is specified, without any domains. If the identifier is a variable, an equation or a model, it must be followed by a suffix, since only attributes of variables, equations and models can be displayed. For more on variable and equation attributes including full lists, see sections Variable Attributes and Equation Attributes respectively. For details on set attributes, see section Model Attributes. Recall that sets also have attributes, they may also be displayed using the suffix notation. For details on set attributes, see section Set Attributes. As usual, `quoted text` must be surrounded by single or double quotes. The identifiers and the text may be mixed and matched in any order, and the whole statement may be continued over several lines.

An abort statement causes the termination of the execution with an execution error and the information in the statement will be displayed.

There is also a variant with the extension `.noError` that terminates the execution and displays the information, but does not cause an execution error. The syntax is as follows:

```
abort.noError [ ident | quoted text {, ident | quoted text} ];
```

Most often `abort` statements are used in the context of if statements or with dollar conditions. The syntax is as follows:

```
if (logical_condition, abort [ ident | quoted text {, ident | quoted text} ]; );
```

or

```
abort$logical_condition [ ident | quoted text {, ident | quoted text} ];
```

For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

3.34.9.2 The Abort Statement: Examples

Consider the following artificial example:

```
Set       i   / i1*i5 /;
Parameter p(i) / i1 1, i2 2, i3 3, i4 5, i5 8 /;
loop(i,
    if (p(i) > 3, abort "Parameter larger than 3", p);
    p(i) = p(i) + 2;
);
```
Note that the abort statement is part of an if statement which is part of a loop statement. The execution of this program will be terminated with the following display and error message:

```
---- 4 Parameter larger than 3
---- 4 PARAMETER p
i1 3.000, i2 4.000, i3 5.000, i4 5.000, i5 8.000
**** Exec Error at line 4: Execution halted: abort 'Parameter larger than 3'
```

Observe that the values of \( p('1') \), \( p('2') \) and \( p('3') \) were updated, but the values of \( p('4') \) and \( p('5') \) are equal to the initialization values since the program was terminated before they could be updated.

If the extension `.noError` is used in the example above, the following lines will appear in the listing file:

```
---- 4 Parameter larger than 3
---- 4 PARAMETER p
i1 3.000, i2 4.000, i3 5.000, i4 5.000, i5 8.000
**** Execution halted from line 4: abort.noError 'Parameter larger than 3'
****
```

Note that the execution of the program is aborted as before, but there is no execution error in this case.

Instead of an if statement we may use a dollar condition in the loop:

```gams
Set i / i1*i5 /;
Parameter p(i) / i1 1, i2 2, i3 3, i4 5, i5 8 /;
loop(i,
    abort$(p(i) > 3) "Parameter larger than 3", p;
    p(i) = p(i) + 2;
);
```

Observe that this alternative formulation has the same outcome as above.

### 3.35 The Option Statement

#### 3.35.1 Introduction

The option statement is used to set various global system parameters to control among other things output detail, the solution process and the layout of displays. GAMS provides default values for global system parameters that are adequate for the most purposes. However, there are always cases when the user would like to maintain control of some aspects of the run. In addition, the option statement provides an efficient and compact syntax to perform powerful operations on identifiers. Observe that option statements are processed at execution time unlike dollar control options that are processed at compile time.

This chapter is organized as follows. We will first introduce the general syntax of the option statement, then we will continue with a list of all available options that may be used with option statements and provide links to their detailed explanations in the GAMS Call chapter. Finally we turn to the special options that involve identifiers.
3.35.1.1 The Syntax of the Option Statement

The general form of an option statement is as follows:

```
option(s) key1 [= value1] { ,|EOL key2 [= value2] };
```

The keyword `option` or `options` indicates that this is an option statement. It is followed by `key1`, which is one of the options that are listed in this chapter. Consider the following simple example:

```
option reslim=800;
```

Here the keyword `option` is followed by the key `reslim`. The option `reslim` specifies the maximum time in seconds that a solver may run before it terminates. Thus, in this example we give the solver 800 seconds to come up with a solution (which is slightly less than the default value of 1000).

Note

Option names are not reserved words and therefore they do not conflict with other uses of their names.

Observe that it depends on the respective option whether a value is expected and if so, what type of value. There are six different cases. An overview is given in Table 1.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Type of Value</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>yes</td>
<td>no</td>
<td>-</td>
<td>dmpOpt, eject, memoryStat</td>
</tr>
<tr>
<td>yes</td>
<td>yes</td>
<td>integer number</td>
<td>decimals, limcol, seed</td>
</tr>
<tr>
<td>yes</td>
<td>yes</td>
<td>real number</td>
<td>FDDelta, optCR, resLim</td>
</tr>
<tr>
<td>yes</td>
<td>yes</td>
<td>text string</td>
<td>LP, solprint, sysout</td>
</tr>
<tr>
<td>yes</td>
<td>yes</td>
<td>identifier</td>
<td>See identifier options.</td>
</tr>
<tr>
<td>no</td>
<td>no</td>
<td>-</td>
<td>See identifier operations.</td>
</tr>
</tbody>
</table>

**Table 1:** Types of Options

Note that the last type is special: it does not involve a named option or key, but the keyword `option` is followed by identifiers and identifier operators. These special option statements are discussed in detail in section Special Options: Identifier Operations.

Observe that the value of an option may be reset as often as necessary, the new value will replace the previous value each time. Further, more than one option may be specified with one option statement and commas or end-of-line characters are both legal separators between options.

We will demonstrate with the following example how several options may be used. The code snippet may be added to the model `[DICE]`.

```
option measure, limcol = 100
        optcr = 0.00, mip = xpress;
solve xdice using mip max wnx;
option clear = comp;
```
Note that in the first option statement four options are specified: option measure has no associated value, option limcol expects an integer value, option optcr expects a real value and option MIP expects a text string as value. The second option statement specifies just one identifier option: clear, which has the variable comp as value.

Attention

Option statements are executed in sequence with other instructions. Therefore, if an option statement is located between two solve statements, the new values will be assigned between the solves and thus they will apply only to the second solve statement.

### 3.35.2 List of Options

The options available through the option statement are grouped into the following functional categories:

- Options that affect output details
- Solver specific parameters
- Options that control choice of solver
- Options that affect input program control
- Other options
- Special options that involve identifiers

In the following subsections we will offer brief descriptions of the options in the first five categories. Note that each entry is linked to a detailed description of the respective option. Observe that detailed descriptions of all GAMS command line parameters, options and model attributes are given in section Detailed Descriptions of All Options. The options that belong to the last category are special, they are introduced and discussed in section Special Options that Involve Identifiers below.

### 3.35.2.1 Options that Control Output Details

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asyncSolLst</td>
<td>Print solution listing when asynchronous solve (Grid or Threads) is used</td>
</tr>
<tr>
<td>decimals</td>
<td>Decimal places for display statements</td>
</tr>
<tr>
<td>dispWidth</td>
<td>Number of characters to be printed in the column labels of all subsequent display statements</td>
</tr>
<tr>
<td>eject</td>
<td>Inject a page break into the LST file</td>
</tr>
<tr>
<td>limCol</td>
<td>Maximum number of columns listed in one variable block</td>
</tr>
<tr>
<td>limRow</td>
<td>Maximum number of rows listed in one equation block</td>
</tr>
<tr>
<td>MCPRHoldFx</td>
<td>Print list of rows that are perpendicular to variables removed due to the holdfixed setting</td>
</tr>
<tr>
<td>profile</td>
<td>Execution profiling</td>
</tr>
<tr>
<td>profileTol</td>
<td>Minimum time a statement must use to appear in profile generated output</td>
</tr>
<tr>
<td>solPrint</td>
<td>Solution report print option</td>
</tr>
<tr>
<td>solSlack</td>
<td>Causes the equation output in the listing file to contain slack variable values instead of level values</td>
</tr>
<tr>
<td>sysOut</td>
<td>Solver Status file reporting option</td>
</tr>
</tbody>
</table>
### 3.35.2.2 Options that Control Solver-Specific Parameters

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bRatio</td>
<td>Basis acceptance threshold</td>
</tr>
<tr>
<td>domLim</td>
<td>Domain violation limit solver default</td>
</tr>
<tr>
<td>intVarUp</td>
<td>Set default upper bound on integer variables</td>
</tr>
<tr>
<td>iterLim</td>
<td>Iteration limit of solver</td>
</tr>
<tr>
<td>optCA</td>
<td>Absolute Optimality criterion solver default</td>
</tr>
<tr>
<td>optCR</td>
<td>Relative Optimality criterion solver default</td>
</tr>
<tr>
<td>reform</td>
<td>Reformulation level</td>
</tr>
<tr>
<td>resLim</td>
<td>Wall-clock time limit for solver</td>
</tr>
<tr>
<td>savePoint</td>
<td>Save solver point in GDX file</td>
</tr>
<tr>
<td>solveLink</td>
<td>Solver link option</td>
</tr>
<tr>
<td>sys12</td>
<td>Pass model with generation errors to solver</td>
</tr>
<tr>
<td>threads</td>
<td>Number of threads to be used by a solver</td>
</tr>
</tbody>
</table>

### 3.35.2.3 Options that Control the Choice of Solver

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CNS</td>
<td>Constrained Nonlinear Systems - default solver</td>
</tr>
<tr>
<td>DNLP</td>
<td>Non-Linear Programming with Discontinuous Derivatives - default solver</td>

</tr>
<tr>
<td>MPEC</td>
<td>Mathematical Programs with Equilibrium Constraints - default solver</td>
</tr>
<tr>
<td>NLP</td>
<td>Non-Linear Programming - default solver</td>
</tr>
<tr>
<td>QCP</td>
<td>Quadratically Constrained Programs - default solver</td>
</tr>
<tr>
<td>RMINLP</td>
<td>Relaxed Mixed-Integer Non-Linear Programming - default solver</td>
</tr>
<tr>
<td>RMIP</td>
<td>Relaxed Mixed-Integer Programming - default solver</td>
</tr>
<tr>
<td>RMIQCP</td>
<td>Relaxed Mixed Integer Quadratically Constrained Programs - default solver</td>
</tr>
<tr>
<td>RMPEC</td>
<td>Relaxed Mathematical Programs with Equilibrium Constraints - default solver</td>
</tr>
<tr>
<td>solver</td>
<td>Default solver for all model types that the solver is capable to process</td>
</tr>
</tbody>
</table>

### 3.35.2.4 Options that Affect Input Program Control

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fdDelta</td>
<td>Step size for finite differences</td>
</tr>
<tr>
<td>fdOpt</td>
<td>Options for finite differences</td>
</tr>
<tr>
<td>gdxUels</td>
<td>Unload labels or UELs to GDX either squeezed or full</td>
</tr>
<tr>
<td>seed</td>
<td>Random number seed</td>
</tr>
<tr>
<td>solveOpt</td>
<td>Multiple solve management</td>
</tr>
<tr>
<td>strictSingleton</td>
<td>Error if assignment to singleton set has multiple elements</td>
</tr>
</tbody>
</table>
3.35.2.5 Other Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dmpOpt</td>
<td>Debugging option: causes GAMS to echo the runtime option settings</td>
</tr>
<tr>
<td>dmpSym</td>
<td>Debugging option: causes GAMS to echo the symbol table to the listing file</td>

<tr>
<td>dualCheck</td>
<td>Output on the reduced cost condition</td>
</tr>
<tr>
<td>forLim</td>
<td>GAMS looping limit</td>
</tr>
<tr>
<td>integer1..5</td>
<td>Integer communication cells</td>
</tr>
<tr>
<td>measure</td>
<td>Output of time and memory use since the last measure statement or the program beginning</td>
</tr>
<tr>
<td>memoryStat</td>
<td>Show memory statistics in the LST file</td>
</tr>
<tr>
<td>real1..5</td>
<td>Real communication cells</td>
</tr>
<tr>
<td>subSystems</td>
<td>Lists all solvers available as well as the current default and active solvers in the LST file</td>
</tr>
<tr>
<td>sys10</td>
<td>Changes rpower to ipower when the exponent is constant and within 1e-12 of an integer</td>
</tr>
<tr>
<td>sys11</td>
<td>Dynamic resorting if indices in assignment/data statements are not in natural order</td>
</tr>
<tr>
<td>threadsAsync</td>
<td>Number of threads to be used for asynchronous solve (solveLink=6)</td>
</tr>
</tbody>
</table>

3.35.2.6 Special Options that Involve Identifiers

Several options involve identifiers: they either take identifiers as values or have no key and value, but perform an operation on an identifier. In the following two subsections we will introduce and discuss these special options.

3.35.2.6.1 Special Options: Identifier Options  The value of identifier options is not a string or a number, but an identifier. In this subsection we will describe these options in detail.

clear

This option resets an identifier to its default value to free memory. The syntax is as follows:

```
option clear = identifier;
```

The following identifier types may be reset: sets, parameters, equations and variables. The option will free up memory to the GAMS heap manager, thus the memory may be used by GAMS but not by the operating system. To force the memory to be freed up to the operating system, the GAMS process needs to be terminated. One way to do this is to restart the execution system by solving a dummy model with the option SolveLink set to zero.

kill

This option is a synonym to option clear. Observe that the dollar control option $kill is not a synonym to $clear.

shuffle

This option rearranges the values of a parameter in a random order. The syntax is as follows:

```
option shuffle = itemname;
```

Here itemname is a one-dimensional parameter. One-dimensional parameters may be declared (and defined) in four different ways, depending on the domain and the data. The following table gives an overview of the effect of the option shuffle in the four cases.
<table>
<thead>
<tr>
<th>Domain Type</th>
<th>No Data</th>
<th>Has Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Universal set as domain</td>
<td>Use the universal set to initialize the data (case 1 in the example below).</td>
<td>Use the universal set to add zero values before shuffling the data (case 3 in the example below).</td>
</tr>
<tr>
<td>Specific set as domain</td>
<td>Use the domain to initialize the data (case 2 in the example below).</td>
<td>Use the domain to add zero values before shuffling the data (case 4 in the example below).</td>
</tr>
</tbody>
</table>

If the parameter was declared without data (the second column in the table above), the domain or the universal set will be used to assign the numbers 1 to N, where N is the number of elements in the domain or the universal set. If the parameter was declared with data (the third column in the table above), the domain or the universal set will be used to add zeroes for possibly missing entries. These zero values will participate in the random shuffle, but they will not be stored in the parameter. The following example serves as illustration:

```plaintext
Set i / i1*i5 / j / j1*j5 /;
option decimals = 0;

*Case 1: universal set as domain and no data
Parameter A(*) "The universe is used to fill the parameter";
  option shuffle = A;
  display A;

*Case 2: set j as domain and no data
Parameter B(j) "The set j is used to fill the parameter";
  option shuffle = B;
  display B;

*Case 3: universal set as domain and has data
Parameter C(*) "The universe is used to add zeroes" / j2 2, j4 4 /;
  option shuffle = C;
  display C;

*Case 4: set i as domain and has data
Parameter D(i) "The set i is used to add zeroes" / i1 10, i3 30, i5 50 /;
  option shuffle = D;
  display D;
```

The code above will generate the output that follows. Observe that in this example, the universal set is the union of the sets i and j, which means that all elements of the sets i and j are members of the universal set. Note that we use random numbers, therefore the outcomes from a different run may vary.
3.35 The Option Statement

--- 19 PARAMETER C The universe is used to add zeroes

j1 2, j2 4

--- 24 PARAMETER D The set i is used to add zeroes

i2 30, i4 50, i5 10

In the next example we will demonstrate how to generate a random mapping of a set:

Set i / i1*i6 /

rmi(i,i) "random mapping"

Parameter A(i);

option shuffle = A;

rmi(i, i + (- Ord(i) + A(i))) = yes;

display rmi;

A display of the set rmi follows. Note that there is exactly one element in each row and each column:

--- 7 SET rmi random mapping

<table>
<thead>
<tr>
<th></th>
<th>i1</th>
<th>i2</th>
<th>i3</th>
<th>i4</th>
<th>i5</th>
<th>i6</th>
</tr>
</thead>
<tbody>
<tr>
<td>i1</td>
<td>YES</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>i2</td>
<td>YES</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>i3</td>
<td>YES</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>i4</td>
<td>YES</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>i5</td>
<td>YES</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>i6</td>
<td>YES</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Observe that each use of the option shuffle will generate a new random data rearrangement.

3.35.2.6.2 Special Options: Identifier Operations In some cases the keyword option in an option statement is followed by an identifier and one or more operators to perform identifier operations like display control, index matching and projection and aggregation of sets and parameters.

3.35.2.6.2.1 Display Control The display statement is introduced and discussed in chapter The Display Statement. While GAMS provides defaults for the displayed identifiers that suffice in most cases, the print format may be customized with the following option statement:

option ident:d;
option ident:d:r:c;

The keyword option is followed by the name of an identifier ident, a colon and an integer value d. Note that d may be between 0 and 8 and specifies the number of decimal places that will be displayed for the respective identifier. The specifications r and c are optional. They denote the number of index positions printed as row labels and the number of index positions printed as column labels respectively. Note that if r is zero, a list format will be used. For more information and examples, see sections Local Display Control and Display Statement to Generate Data in List Format.
3.35.2.6.2.2  **Index Matching**  Index matching is a very compact way to define multi-dimensional sets. The general syntax is as follows:

```plaintext
option set_name(index1:index2[:index3:...]);
```

The keyword `option` is followed by the name of the set, `set_name`, and two (or more) indices in parentheses that are linked with the matching operator `:`. Note that the set must have been declared earlier in the program. If the set has also been defined earlier in the program, it will be cleared first and then the matching operation will be processed. Note furthermore that the list of identifiers may be expanded to more than two and that besides the matching operator `:` also `,` may be used and will be interpreted as product operator. Consider the following example which also makes use of display control:

```plaintext
Set i / i1,i2/
   j / j1,j2,j3 /
   k / k1,k5 /
   ij(i,j), ijk(i,j,k), kij(k,i,j);
* index matching
Option ij(i:j), ijk(i,j:k), kij(k:i,j);
* display control
Option ij:0:0:1, ijk:0:0:1, kij:0:0:1;
Display ij, ijk, kij;
```

In its simplest form the matching operator is used to create the two dimensional set `ij`.

```plaintext
---- 9 SET ij
i1.j1
i2.j2
```

Note that each member of the index `i` has been matched with a member of the index `j` until one of the indices ran out of members.

The index matching operations to define the three-dimensional sets `ijk` and `kij` illustrate a more sophisticated usage of the index operator. The sets `ijk` and `kij` are built with the indices from left to right using the product operator when a `,` is encountered or the matching operator when a `:` is found.

For `ijk` the first operator is the `,`, which is interpreted as product operator for the sets `i` and `j` and hence builds the Cartesian product of the two sets which has six 2-tuples as elements (`i1.j1, i1.j2, i1.j3, i2.j1, i2.j2, i2.j3`). The matching operator `:` is then applied to match those 2-tuples with the five set elements in `k`. The resulting sets are:

```plaintext
---- 9 SET ijk
i1.j1.k1
i1.j2.k2
i1.j3.k3
i2.j1.k4
i2.j2.k5
```

```plaintext
---- 9 SET kij
k1.i1.j1
k1.i1.j2
k1.i1.j3
k2.i2.j1
k2.i2.j2
k2.i2.j3
```
The previous example can be extended to define sets of even higher dimension in the following way:

```plaintext
set h / h1*h4 / 
   hijk_1(h,i,j,k) 
   hijk_2(h,i,j,k); 
* index matching
Option hijk_1(h:ijk);
Option hijk_2(h:i,j:k);
* display control
Option hijk_1:0:0:1, hijk_2:0:0:1;
Display hijk_1, hijk_2;
```

Note that sets \(hijk_1\) and \(hijk_2\) will be different even though \(hijk_1\) uses set \(ijk\) and \(hijk_2\) uses the same matching and product operation used at definition of \(ijk\) but spelled out. As already mentioned above, the matching operator builds up the sets with the indices from left to right. Hence, as set \(ijk\) is build first and then used on the right of the matching operator the two sets are built up differently.

```plaintext
---- 19 SET hijk_1
h1.i1.j1.k1 
  h2.i1.j2.k2 
  h3.i1.j3.k3 
  h4.i2.j1.k4

---- 19 SET hijk_2
h1.i1.j1.k1 
  h1.i1.j2.k2 
  h1.i1.j3.k3 
  h2.i2.j1.k4 
  h2.i2.j2.k5
```

### 3.35.2.6.2.3 Projection and Aggregation of Sets and Parameters

In GAMS, projection and aggregation operations on sets may be performed in two different ways: with an assignment and the `sum` operator, and with an option statement.

Using an assignment and the `sum` operator is the slower but more intuitive way. Assignments and the `sum` operator are introduced and discussed in detail in chapter Data Manipulations with Parameters and section Indexed Operations respectively. Here we only show how they may be used in the context of sets to perform projections and aggregations. The following example serves as illustration.

```plaintext
Sets i / i1*i3 / 
  j / ji*j2 / 
  k / k1*k4 / 
  ijk(i,j,k) / #i.#j.#k / 
  ij1a(i,j) 
  ij1b(i,j); 

Scalars Count_1a, Count_1b, Count_2a, Count_2b;

* Method 1: Using an assignment and the sum operator for a projection 
  ij1a(i,j) = sum(k,ij1(i,j,k));

* Method 1: Using an assignment and the sum operator for aggregations 
  Count_2a = sum(ijk(i,j,k),1); 
  Count_1a = sum(ij1a(i,j),1); 
```
Note that the set $ijk$ is a three-dimensional set, its elements are 3-tuples and all permutations of the elements of the three sets $i$, $j$ and $k$ are in its domain. Thus the number of elements of the set $ijk$ is $3 \times 2 \times 4 = 24$. The sets $ij1a$ and $ij1b$ are two-dimensional sets that are declared in the set statement, but not defined. The first assignment statement defines the members of the set $ij1a$. This is a projection from the set $ijk$ to the set $ij1a$ where the three-tuples of the first set are mapped onto the pairs of the second set, such that the dimension $k$ is eliminated. This means that the four elements "$i1.j1.k1", "i1.j1.k2", "i1.j1.k3" and "i1.j1.k4" of the set $ijk$ are all mapped to the element "$i1.j1" of the set $ij1a$. Note that in this context, the result of the sum operation is not a number but a set. The second and third assignments are aggregations, where the number of elements of the two sets are computed. As already mentioned, the result of the first aggregation is 24 and the result of the second aggregation is $6 = 24 / 4$.

The second way to perform projections and aggregations is faster and more compact, it uses an option statement. The general syntax of this option statement is as follows.

\begin{verbatim}
option ident1 < ident2 ;
option ident1 <= ident2 ;
\end{verbatim}

The keyword option is followed by the identifiers $ident1$ and $ident2$ which are linked by the symbol '<' or '<='. Observe that in most cases the two symbols have the same effect. The exception is the special case when both identifiers are defined over domains that use at least one shared index set more than once, see the example below. Note that in general the dimension of the item on the left has to be equal or less than the dimension of the item on the right. Further, the index space of the two identifiers must be matchable. If the dimensions of the two identifiers are equal, then the same indices must appear in both, albeit the order may differ. If the dimension of the left item is less than the dimension of the right item, then the indices on the left must also appear on the right.

Observe that if both identifiers are sets, the operation will be a projection. However, if the identifier on the left-hand side is a scalar or a parameter and the identifier on the right-hand side is a set it will be an aggregation. The example that follows shows how the projection and the two aggregations above are accomplished with the option statement.

* Method 2: Option statement performs a projection
Option $ij1b < ijk$;

* Method 2: Option statements performs aggregations (counting of elements)
Option Count_2b < $ijk$;
Option Count_1b < $ij1b$;

display $ijk$, $ij1a$, $ij1b$, Count_1a, Count_1b, Count_2a, Count_2b;

In the example above, the set on the left-hand side, $ij1b$, has fewer indices than the set on the right-hand side, $ijk$. Observe that if the two sets differ only in the order of the indices then a projection will have the effect of a permutation of the tuple.

Note

The option statement for projection and aggregation operations may also be applied to parameters.

Until now the indices in the domain of the sets were unique. A special case arises when sets are defined over a domain with the same indices, for example the set $s(i,i,i)$. In this case, a projection always has the effect of a permutation. Users may choose whether they wish to perform the permutation from left to right or from right to left. The option statement

\begin{verbatim}
Option item1 < item2 ;
\end{verbatim}
The Option Statement

means a right-to-left permutation, while the option statement

```
Option item1 <= item2 ;
```

entails a left-to-right permutation. The following example clarifies the difference:

```
Set i / i1*i3 /
   s(i,i,i) "Set members" / i1.i2.i3, i3.i3.i1/
   pR1(i,i) "projection right to left with assignment"
   pR2(i,i) "projection right to left with option statement"
   pL1(i,i) "projection left to right with assignment"
   pL2(i,i) "projection left to right with option statement";
Alias (i,ii,iii);

* Right-to-left permutation, two ways
   pR1(i,ii) = sum(s(iii,ii,i),1);
   option pR2 < s;

* Left-to-right permutation, two ways
   pL1(i,ii) = sum(s(i,ii,iii),1);
   option pL2 <= s;

option s:0:0:1, pR1:0:0:1, pR2:0:0:1, pL1:0:0:1, pL2:0:0:1;
display s, pR1, pR2, pL1, pL2 ;
```

Note that in the right-to-left permutation, the element "i1.i2.i3" is projected to "i3.i2" and the element "i3.i3.i1" is projected to "i1.i3". In the left-to-right permutation however, the the element "i1.i2.i3" is projected to "i1.i2" and the element "i3.i3.i1" is projected to "i3.i3". Hence, the left-to-right permutation (<=) might be more intuitive.

Our examples so far involved only sets. As mentioned above, projections and aggregations may also be performed with parameters. However, there are some subtle differences. The first difference refers to the terminology: we aggregate sets, but we count parameters. The second difference is the result of the operation if the domain of the left symbol is just a permuted version of the domain of the right symbol. Consider the following example:

```
Set i / i1*i3 /
   j / j1*j2 /;
Table p(i,j)
   j1  j2
   i1  1  2
   i2  3  4
   i3  5  6;

parameter pperm(j,i);
option pperm < p;
option decimals = 0;
display p, pperm;
```

The output generated by the display statement follows:
### 3.36 System Attributes

#### 3.36.1 Introduction

System attributes give access to string constants in the GAMS system environment. We will refer to these string constants as system suffixes. Moreover, there are attributes that can be used as data elements for user symbols. This way one can get access e.g. to the solvers (as set elements) in the system. We will refer to these data elements as system data. Two special system data attributes, namely `powerSetLeft` and `powerSetRight`, for a three dimensional set `setName(n,s,b)` create data which can be interpreted as a numbering system with base `b` and `s` digits. Finally, a system attribute can provide access to a system function that was hidden by the compiler because of a name conflict with a user symbol.

#### 3.36.2 System Suffixes

System suffixes contain information about the GAMS system environment during a run. There are two ways to reference them: `system.suffix` and `%system.suffix%`. Here `system` is a keyword and `.suffix` is the name of the system suffix. A full list is given in section List of all System Suffixes below. Note that `system.suffix` references the execution-time version of the system suffix and `%system.suffix%` references the compile-time version resulting in a textual replacement. The execution-time system suffix can only be used in the context of put files. Consider the following example where both versions are used:

```plaintext
file fx;
put fx 'lp:' system.LP;
option lp=gurobi;
put / 'lp:' system.LP
put / 'lp:%system.LP%';
```

Observe that the compile-time string `%system.LP%` is evaluated at compile time and does not change. However, the execution-time system suffix `system.LP` is evaluated at execution time and it does change. It is first CPLEX, since CPLEX is the default LP solver. Then it changes to GUROBI as a result of the execution-time command `option LP=gurobi;`. The resulting put file `fx.put` follows:

```
lp:CPLEX
lp:GUROBI
lp:CPLEX
```

In the following two subsection we will discuss execution-time suffix in more detail.
3.36 System Attributes

3.36.2.1 Execution-Time System Suffixes

Execution-time system suffixes are only used in the context of the put writing facility with commands like put, putclose and put utility. Consider the following simple example. We have the files x.gms and dummy.gms, where x.gms contains just the following line:

file fx; put fx system.version;

The file dummy.gms contains the following:

$exit;

We run these files with the following calls:

> c:\gams\win64\24.7\gams x.gms action=c s=putVersion

Note that the value c for the command-line parameter action causes the first input file to be compiled only. The result is saved in the work file putVersion. Then we restart and execute dummy.gms. Now, depending on the GAMS release version, the put file fx will have a different content:

- c:\gams\win64\24.7\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 247"
- c:\gams\win64\24.8\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 248"

In contrast, the value of the compile-time system suffix %system.version% is determined at compile time. Suppose we change the file x.gms to contain the following line:

file fx; put fx "%system.version%";

The file dummy.gms is not changed and we use the same calls as above. Note that the put file will have the same content for both versions of GAMS:

- c:\gams\win64\24.7\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 247"
- c:\gams\win64\24.8\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 247"

3.36.2.2 Compile-Time System Suffixes

Compile-time system suffixes may be placed anywhere a compile-time variables makes sense, including code for conditional compilation. The quoting of these compile-time system suffixes depends on their use in the code. Consider the following example:

$set systemDATE %system.date%
display "system.date", "%system.date%";
$ifi %system.LP% == Xpress $log "LP solver is Xpress."

The resulting output generated by the display statement follows:

---- 3 system.DATE
11/07/16

3.36.2.3 List of all System Suffixes

In the following table all system suffixes are listed.
<table>
<thead>
<tr>
<th>System Suffix</th>
<th>Description</th>

</table>
A model that prints all system suffixes with its current values to a put file can be found in model [SSUFFIX].

### 3.36.3 System Data

Some of the system relevant information does not fit into a single string. Such system data can be stored in GAMS symbols. The system data for this symbol can be accessed in the data statement of the symbol, e.g. set allSolvers / system.solverNames /; Now you can work with the solver names as you can work with any set. The system data can be viewed as an internal set, so it can be you can to create more complex GAMS symbols with this information. For example:

```gams
set seq / 1*1000 /;
set solvermap(seq,*) / set.seq:system.solverNames /;
parameter solverpar(*) / system.solverNames 1 /;
```

Here is the list and dimensionality of the system data:

</tr>
</tbody>
</table>

### 3.36.3.1 Power Set

The very special system attribute powerSetLeft and powerSetRight do not provide access to static data relevant to the system but produce data based on existing sets \( b \) and \( s \). This system data produced can be interpreted as a numbering system with base \( b \) and \( s \) digits. The total number of tuples created is \( \text{power}(\text{card}(b),\text{card}(s)) \). The first index of the resulting set has to have at least this size. The following small example demonstrates the functionality of powerSetRight:

```plaintext
$set digits 3
set s / s1*s%digits% /, b / 0,1 /;
$eval nMax power(card(b),card(s))
set n / n1*n%nMax% /
   x(n,s,b) / system.powerSetRight /;
option x:0:0:%digits%; display x;
```

With 3 digits the display results in the following output:

```
---- 6 SET x
 n1.s1.0, n1.s2.0, n1.s3.0
 n2.s1.0, n2.s2.0, n2.s3.1
 n3.s1.0, n3.s2.1, n3.s3.0
 n4.s1.0, n4.s2.1, n4.s3.1
 n5.s1.1, n5.s2.0, n5.s3.0
 n6.s1.1, n6.s2.0, n6.s3.1
 n7.s1.1, n7.s2.1, n7.s3.0
 n8.s1.1, n8.s2.1, n8.s3.1
```

Changing powerSetRight to powerSetLeft reassigns the order of the digits. So the lowest digit is on the left:

```
---- 6 SET x
 n1.s1.0, n1.s2.0, n1.s3.0
 n2.s1.1, n2.s2.0, n2.s3.0
 n3.s1.0, n3.s2.1, n3.s3.0
 n4.s1.1, n4.s2.1, n4.s3.0
 n5.s1.0, n5.s2.0, n5.s3.1
 n6.s1.1, n6.s2.0, n6.s3.1
 n7.s1.0, n7.s2.1, n7.s3.1
 n8.s1.1, n8.s2.1, n8.s3.1
```
3.36.4 Access to Hidden Functions

Intrinsic functions are not keywords but they are stored in a list of predefined names. If a user program uses such a predefined name of a function for a user symbol, GAMS will hide the original function. For example,

```gams
set uniform 'School Uniform' / skirt, blouse, blazer, socks, shoes /;
scalar randomNumber;
randomNumber = uniform(0,1);
```

will result in a compilation error in the second line because GAMS expects `uniform` to be a set. The function `uniform` is hidden for this GAMS program. Renaming the user symbol that hides a function is often the best solution for this, but there are a few cases (including GAMS code already compiled and stored in a restart file) where renaming is not an option. A hidden function can be accessed via the system attribute `system.functionName`. So the following will successfully compile and execute:

```gams
set uniform 'School Uniform' / skirt, blouse, blazer, socks, shoes /;
scalar randomNumber;
randomNumber = system.uniform(0,1);
```

3.37 The Grid and Multi-Threading Solve Facility

3.37.1 Introduction

The GAMS Grid facility allows to take advantage of High Performance Computing Grids and systems with multiple CPUs. This language feature facilitates the management of asynchronous submission and collection of model solution tasks in a platform independent fashion. A simple architecture, relying on existing operating system functionality allows for rapid introduction of new environments and provides for an open research architecture.

A typical application uses a coarse grain approach involving hundreds or thousands of model solutions tasks which can be carried out in parallel. Examples include but are not limited to scenario analysis, Monte Carlo simulations, Lagrangian relaxation, decomposition algorithms and advanced solution approaches.

The grid features work on all GAMS platforms and have been tailored to many different environments, like the Condor Resource Manager, a system for high throughput computing from the University of Wisconsin-Madison, or the SUN Grid Engine. Researchers using Condor reported a delivery of 5000 CPU hours in 20 hours wall clock time.

Similarly, the GAMS Multi-Threading Solve Facility allows the asynchronous submission and collection of model solution tasks on a single, multi-threaded machine while using efficient in-memory communication between GAMS and the solver.

Disclaimer: The use of the term grid computing may be offensive to some purists in the computer science world. We use it very loosely to refer to a collection of computing components that allow us to provide high throughput to certain applications. One may also think of it as a resurrection of the commercial service bureau concept of some 30 years ago.

Caution: Although these features have been tested on all platforms and are part of our standard release we may change the approach and introduce alternative mechanisms in the future.

Acknowledgments: Prof. Monique Guignard-Spielberg from the Wharton School at the University of Pennsylvania introduced us to parallel Lagrangian relaxation on the SUN Grid Environment. Prof. Michael Ferris from the University of Wisconsin-Madison adopted our original GAMS grid approach to the high throughput system Condor and helped to make this approach a practical proposition.
3.37.2 The Grid Facility: Basic Concepts

The Grid facility separates the solution process into several steps which then can be controlled separately. First we will review the steps taken during synchronous solution and then we will introduce the asynchronous or parallel solution steps.

When GAMS encounters a solve statement during execution it proceeds in three basic steps:

1. **Generation**: The symbolic equations of the model are used to instantiate the model using the current state of the GAMS data base. This instance contains all information and services needed by a solution method to attempt a solution. This representation is independent of the solver and computing platform.

2. **Solution**: The model instance is handed over to a solver and GAMS will wait until it terminates.

3. **Update**: The detailed solution and statistics are passed to GAMS from the solver to update the GAMS data base.

In most cases, the time taken to generate the model and update the data base with the solution will be much smaller than the actual time spent in a specific solver. The model generation will take a few seconds, whereas the time to obtain an optimal solution may take a few minutes to several hours or even longer. If sequential model solutions do not depend on each other, we can solve in parallel and update the data base in a random order. All we need is a facility to generate models, submit them for solution and continue. At a convenient point in our GAMS program we will then look for the completed solutions and update the data base accordingly. To summarize, solving in parallel entails two steps:

1. **Submission Loop**: In this phase we will generate and submit models for solutions that can be solved independently.

2. **Collection Loop**: The solutions of the previously submitted models are collected as soon as a solution is available. It may be necessary to wait for some solutions to complete by pausing the execution for some time.

Note that we have assumed that there will be no errors in any of these steps. Of course, this will not always be the case and elaborate mechanisms are in place to make the operation fail-safe.

Note

For scenario analysis the solver GUSS might be of particular interest. The model [GUSSGRID] demonstrates how GUSS is used together with the Grid facility.

3.37.3 The Grid Facility: A First Example

In this section we will illustrate the use of the basic grid facility with the model [QMEANVAR]. This model traces an efficiency frontier for restructuring an investment portfolio. Each point on the frontier requires the solution of independent quadratic mixed integer models. The original solution loop is shown below:

```gams
loop(p(pp),
    ret.fx = rmin + (rmax-rmin)/(card(pp)+1)*ord(pp) ;
    solve minvar min var using miqcp ;
    xres(i,p) = x.l(i);
    report(p,i,'inc') = xi.l(i);
    report(p,i,'dec') = xd.l(i);
);  
```

This loop will save the solutions of the model minvar for different returns ret. As the solutions do not depend on the order in which they are carried out, we can rewrite this loop to operate in parallel.
### 3.37.3.1 The Submission Loop

The first step for solving in parallel using the Grid facility is to write the submission loop:

```gams
Parameter h(pp)   'model handles';
minvar.solveLink = 3;
loop(p(pp),
    ret.fx = rmin + (rmax-rmin)/(card(pp)+1)*ord(pp)
    solve minvar min var using miqcp;
    h(pp) = minvar.handle;
);
```

The model attribute `solveLink` controls the behavior of the `solve` statement. The value of 3 (which is equivalent to the compile-time constant `%solveLink.Async Grid%`) directs GAMS to generate the model and submit it for solution and then continue without waiting for the completion of the solution step. Thus with setting `minvar.solveLink` to 3 we activate grid computing.

A **handle** in the grid environment identifies the particular model and data instances available. The model attribute `handle` contains a unique identification of each submitted solution request and is typically stored in a parameter defined over a set that covers all model instances. The specific numerical values of handles are assigned by GAMS and may be used to recover solutions and manage models that are solved on the grid. In our example, the handle parameter is `h` and the set of all model instances is `pp`. The handle values that are stored in `h` are later used to collect the solutions once the solution processes are completed.

### 3.37.3.2 The Collection Loop

We collect the solutions with the following collection loop:

```gams
loop(pp$handleCollect(h(pp)),
    xres(i,pp) = x.l(i);
    report(pp,i,'inc') = xi.l(i);
    report(pp,i,'dec') = xd.l(i);
);
```

Note that the dollar condition restricts the looping set `pp` to those elements which return a nonzero value to the function `handleCollect(h(pp))`. The function `handleCollect` tests the solution status for each element of the set `pp`. And if the solution is available, it is read into the GAMS data base. In this case the function returns a value of 1. If the solution is not ready to be retrieved, the value zero will be returned.

Observe that the collection loop above has one big flaw. If a solution has not been ready (that is if `handleCollect` equaled zero), it will not be retrieved. We need to call this loop several times until all solutions have been retrieved or we get tired of it and quit. We will use a `repeat until construct` and the handle parameter `h` to control the loop to look only for the solutions that have not been loaded yet. The code follows:

```gams
repeat
    loop(pp$handleCollect(h(pp)),
        xres(i,pp) = x.l(i);
        report(pp,i,'inc') = xi.l(i);
        report(pp,i,'dec') = xd.l(i);
        display$handleDelete(h(pp)) 'trouble deleting handles' ;
        h(pp) = 0;
    ) ;
    display$readyCollect(h, 100) 'Problem waiting for next instance to complete';
until card(h) = 0 or timeelapsed > 100;
xres(i,pp)$h(pp) = na;
```
Once we have extracted a solution we will set the handle parameter \( h \) to zero. In addition, we want to remove the instance from the system by calling the function \texttt{handleDelete} which returns zero if successful. No harm is done if it fails but we want to be notified via the conditional display statement. Before running the collection loop again, we may want to wait a while to give the system time to complete more solution steps. This is done with the function \texttt{readyCollect} which waits until another model instance with a handle in \( h \) is ready to be collected (or the optionally defined number of seconds has passed). The final wrinkle is to terminate if all model instances have been deleted from the system since their solutions were retrieved or after 100 seconds have elapsed, even if we did not get all solutions. This is accomplished with the function \texttt{timeElapsed} and is important, because if one of the solution steps fails our program would never terminate. Recall that the handle parameter \( h \) equals zero for all elements of the set \( pp \) whose related models have been solved and their solutions have been extracted. The last statement in the code above sets the results of the \textit{missed} solves to \texttt{na} to signal the failed solve. The parameter \( h \) will now contain the handles of the failed solves for later analysis.

Alternatively, we could use the function \texttt{handleStatus} and collect the solutions that are stored in a GDX file. For example, we could write:

\begin{verbatim}
loop(pp$(handleStatus(h(pp)) = 2),
   minvar.handle = h(pp);
   execute_loadhandle minvar;
   xres(i,pp) = x.l(i);
   report(pp,i,'inc') = xi.l(i);
   report(pp,i,'dec') = xd.l(i);
);
\end{verbatim}

The function \texttt{handleStatus} tests the solution process and returns the value 2 if the solution process has been completed and the results can be retrieved. The solution is stored in a GDX file which can be loaded in a way similar to other GDX solution points. First, we need to specify which solution to retrieve by setting the the model attribute \texttt{minvar.handle} to the appropriate value. Then we can use the statement \texttt{execute_loadhandle minvar;} to load the solution for the model \texttt{minvar} back into the GAMS data base.

Note

Except for the requirement of a model with a previously specified handle, the command \texttt{execute_loadhandle} operates like the procedure \texttt{execute_loadpoint}.

Using the function \texttt{handleStatus} and the command \texttt{execute_loadhandle} instead of the simpler \texttt{handleCollect}, adds one more layer of control to the final collection loop. Now we need one additional \texttt{if} statement inside the collection loop above:

\begin{verbatim}
repeat
   loop(pp$h(pp),
      if(handleStatus(h(pp)) = 2,
         minvar.handle = h(pp);
         execute_loadhandle minvar;
         xres(i,pp) = x.l(i);
         report(pp,i,'inc') = xi.l(i);
         report(pp,i,'dec') = xd.l(i);
         display$handleDelete(h(pp)) 'trouble deleting handles' ;
         h(pp) = 0;
      );
   display$readyCollect(h, 100) 'Problem waiting for next instance to complete';
until card(h) = 0 or timeelapsed > 100;
xres(i,pp)$h(pp) = na;
\end{verbatim}

Finally, we are ready to run the modified model.
3.37.3.3 The Execution Log

The execution log will contain some new information that may be useful for more advanced applications:

--- LOOPS pp = p1
--- 46 rows 37 columns 119 non-zeroes
--- 311 nl-code 7 nl-non-zeroes
--- 14 discrete-columns
--- Submitting model minvar with handle grid137000002
--- Executing after solve
... --- \texttt{GDXin=C:\answersv5\gams_srcdev\225j\grid137000003\gmsgrid.gdx}
--- Removing handle grid137000003

Note that the log contains some additional information about the submission, retrieval and removal of the solution instance. In the following sections we will make use of this additional information.

For a complete example for grid computing, see the grid enabled transport model \([\text{TRNSGRID}]\).

Observe that we have made no assumptions about what kind of solvers and what kind of computing environment we will operate. The example above is completely platform and solver independent and it runs on a Windows laptop or on a massive grid network like the Condor system without any changes in the GAMS source code.

3.37.4 Advanced Use of Grid Features

In this section we will describe a few special application requirements and show how this can be handled with the current system. Some of those applications may involve thousands of model instances with solution times of many hours each. Some may fail and require resubmission. More complex examples require communication and the use of GAMS facilities like the Branch-and-Cut-and-Heuristic Facility (BCH), which submit other models from within a running solver.

Imagine a situation with thousands of model instances each taking between minutes and many hours to solve. We will break the master program into a submitting program, an inquire program and a final collection program. We will again use the model \([\text{QMEANVAR}]\) to demonstrate the principle. We will split the code of the modified \([\text{QMEANVAR}]\) GAMS code into three components: \texttt{qsubmit}, \texttt{qcheck} and \texttt{qreport}.

3.37.4.1 Very Long Job Durations: The Submitting Program

The file \texttt{qsubmit.gms} will include everything up to and including the new submission loop. To save the instances we will need a unique grid directory \texttt{gdir} and to restart the problem we will have to create a save file. For details on the save and restart facility in GAMS, see chapter The Save and Restart Feature. When running the first job, we will use the command line parameter save or its synonym \texttt{s} to create the required save file:

> gams qsubmit s=submit gdir=c:\test\grid
### 3.37.4.2 Very Long Job Durations: The Inquire Program

The solution of all the model instances may take hours. From time to time we may run a quick inquiry job to learn about the status. The following program `qcheck.gms` will list the current status:

```gams
Parameter status(pp,*);
Scalar   handle;
Acronym  BadHandle, Waiting, Ready;
loop(pp,
    handle = handleStatus(h(pp));
    if(handle=0,
       handle = BadHandle;
    elseif handle=2,
       handle = Ready;
       minvar.handle = h(pp);
       execute_loadhandle minvar;
       status(pp,'solvestat') = minvar.solvestat;
       status(pp,'modelstat') = minvar.modelstat;
       status(pp,'seconds') = minvar.resusd;
    else
       handle = Waiting;
    );
    status(pp,'status') = handle;
);display status;
```

For details on the model attributes referenced in the code above, see `handle`, `solveStat`, `modelStat` and `resUsd`. To run the program above, we will restart from the previous save file by using the command line parameter `restart` or its synonym `r`.

```
> gams qcheck r=submit gdir=c:\test\grid
```

The output generated by the display statement may look like the following:

```
-----  173 PARAMETER status

solvestat   modelstat  seconds   status
  p1  1.000  1.000   0.328    Ready
  p2  1.000  1.000   0.171    Ready
  p3       Waiting
  p4       Waiting
  p5  1.000  1.000   0.046    Ready
```

We may want to do some more detailed analysis on one of the solved model instances. The respective program, called `qanalyze.gms`, may include the following lines of code:

```gams
$if not set instance $abort --instance is missing
if(not handleStatus(h('%instance%')),
   abort$yes 'model instance %instance% not ready');
minvar.handle = h('%instance%');
execute_loadhandle minvar;
display x.l,xi.l,xd.l;
...
```

For information on dollar control options, see chapter Dollar Control Options, especially the detailed descriptions of the options `$if` and `$abort`. Note that `instance` is a compile-time variable. The program may be called using a double dash parameter, which defines and sets a GAMS compile-time variable:

```
> gams qanalyze r=submit gdir=c:\test\grid --instance=p4
```
3.37.4.3 Very Long Job Durations: The Collection Program

Once all jobs are completed we are ready for the collection loop. For simplicity, we will not include the repeat loop, because we would not run the final collection program unless we were satisfied that we got most of the solutions that we wanted. The file qreport.gms could look like the following:

```plaintext
loop(pp$handleStatus(h(pp)),
    minvar.handle = h(pp);
    execute_loadhandle minvar;
    xres(i,pp) = x.l(i);
    report(pp,i,'inc') = xi.l(i);
    report(pp,i,'dec') = xd.l(i);
    h(pp) = 0;
);
```

We will restart the program above from the save file that was created earlier:

```plaintext
> gams qreport r=submit gdir=c:\test\grid
```

Note that it is not necessary to run the job from the same directory that we have used for the initial submission; it is even possible to use a different operating system.

3.37.5 Summary of Grid Features

We introduced several GAMS features to facilitate the asynchronous or parallel execution of the solve statement. These GAMS features are summarized in the following subsections.

In addition to the features described below, the option or command line parameter ThreadsAsync was introduced. ThreadsAsync controls the number of threads or CPU cores that are used in multi-threading computing.

3.37.5.1 Grid Handle Functions

The grid handle functions are listed in Table 1. For details on functions in GAMS in general and complete lists of all GAMS functions, see section Functions. Note that the desired return values - the return values that indicate that no error has occurred - are marked with bold letters.
### Function | Description | Return Values
--- | --- | ---
handleCollect(HANDLE) | Tests if the solve of the model instance identified by HANDLE is done; if so, it loads the solution into the GAMS data base. If the option asyncSolLst is active the solution listing is printed to the listing file. **Note** that handleCollect ignores the setting of the option SolveOpt and always uses the default value merge. | 0: The model instance was not ready or could not be loaded. 
>0: The model instance solution has been loaded. (When using the Grid facility, this is always 1; when using the multi-threading option, this returns the thread ID used.)

handleStatus(HANDLE) | Tests if the solve of the model instance identified by HANDLE is done. **Note** that there are compile-time constants that are related to this function. | 0: The model instance is not known to the system. 
1: The model instance exists but the solution process is incomplete. 
2: The solution process has terminated and the solution is ready for retrieval. 
3: The solution process signaled completion but the solution cannot be retrieved.

handleDelete(HANDLE) | Deletes the model instance identified by HANDLE and returns a numerical indicator of the status of the deletion. If the HANDLE given is not valid, an execution error is triggered. | 0: The model instance has been removed. 
1: The argument HANDLE is not a legal handle. 
2: The model instance is not known to the system. 
3: The deletion of the model instance encountered errors.

handleSubmit(HANDLE) | Resubmits the model instance identified by HANDLE for solution. In case of a nonzero return an execution error is triggered. | 0: The model instance has been resubmitted for solution. 
1: The argument HANDLE is not a legal handle. 
2: The model instance is not known to the system. 
3: The completion signal could not be removed. 
4: The resubmit procedure could not be found. 
5: The resubmit process could not be started.
Table 1: Grid Handle Functions

Note that GAMS might issue execution errors which could give additional information that may help to identify the source of problems. The function execError may be used to get and set the number of execution errors.

3.37.5.2 Grid Model Attributes

Model attributes are introduced in section Model Attributes. The following three model attributes are particularly relevant for grid computing:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>solveLink</td>
<td>Specifies the solver linking conventions. The following values direct the solve statement to use grid computing or multi-thread computing: 3, 4, 6 and 7. Note that the default for this model attribute can be set as command line parameter and option statement. For more information, see the detailed description.</td>
</tr>
<tr>
<td>handle</td>
<td>Specifies the current instance handle. This is used to identify a specific model instance and to provide additional information needed for the process signal management (compare subsections The Submission Loop and The Collection Loop above).</td>
</tr>
<tr>
<td>number</td>
<td>Specifies the current instance number. Any time a solve is attempted for a model, the instance number is incremented by one and the handle is update accordingly. The instance number can be reset by the user which then resynchronizes the handle.</td>
</tr>
</tbody>
</table>

Table 2: Grid Handle Attributes

3.37.5.3 Grid Solution Retrieval

As an alternative to the function handleCollect a solution may be retrieved with the following statement:

```
execute_loadhandle mymodel;
```

This statement will update the GAMS data base with the status and solution for the current instance of `mymodel`. Note that the underlying mechanism is a GDX file. Except for the requirement of a model with a previously specified handle, this command operates like the procedure `execute_loadpoint`. If the option `asyncSolLst` is active the solution listing is printed to the listing file.
3.37.5.4 The Grid Directory

The instantiated (generated) models and their corresponding solutions are kept in unique directories that may be reached from the submitting system. Each GAMS job may have only one grid directory. By default, the grid directory is assumed to be the scratch directory. This may be overwritten by using the GAMS command line parameter GridDir, or short $GD$. An example follows.

```bash
> gams myprogram ... GDir=gridpath
```

If `gridpath` is not a fully qualified name, the name will be completed using the current directory. If the grid path does not exist, an error will be issued and the GAMS job will be terminated. A related GAMS parameter is ScrDir or short $SD$.

Recall the following default mechanism: When a GAMS job is started a unique process directory is created in the current directory. These directories are named `zzzz` to `zzzz`. When a GAMS job terminates, the system will remove the process directory at the completion of a GAMS job. Any file that has not been created by the GAMS core system will be flagged. If the call `gamskeep` instead of `gams` is used, another exit script will be activated that results in the process directory to be kept.

Note that if we do not specify a scratch directory, the scratch directory will be the same as the process directory. If we do not specify a grid directory, the grid directory will be the same as the scratch directory.

Observe that if we assume that some of the model instances may fail or we want to break the GAMS program into several pieces to run as separate jobs, we need to be careful not to remove the model instance we have not completely processed. In such cases we have to use the parameter GridDir, so that we may access previously created model instances.

3.37.6 The Grid Facility: Architecture and Customization

The current Grid facility relies on very basic operating system features and does not attempt to offer real and direct job or process control. The file system is used to signal the completion of a submitted task and GAMS has currently no other way to interact with the submitted process directly, like forcing termination or change the priority of a submitted task. This approach has its obvious advantages and disadvantages. There are a number of attempts to use grid computing to provide value added commercial remote computing services.

When GAMS executes a solve with the option solveLink set to 3 it will perform the following steps:

1. Create a subdirectory in the GridDir with the name `gridnnn`. Here `nnn` stands for the numeric value of the handle. The handle value is the internal symbol ID number x 1e6 + the model instance number. For example, in the `[QMEANVAR]` example the first grid subdirectory was `grid137000002`.
2. Remove the completion signal in case the file already exists. Currently the signal is a file called `finished`. For example, grid137000002/finished.
3. Create or replace a GDX file called `gmsgrid.gdx` which will contain a dummy solution with failed model and solver status. This file will be overwritten by the final step of the solution process and will be read when calling `executeLoadhandle`.
4. Place all standard GAMS solver interface files into the above instance directory.
5. Execute the submission wrapper called `gmsgrid.cmd` under Windows or `gmsgrid.run` under Unix. These submission scripts are usually located in the GAMS system directory, they may be located via the current path if they are not found in the GAMS system directory.
The grid submission script `gmsgrid.cmd` or `gmsgrid.run` is called with four arguments that are needed to make a standard GAMS solver call: the solver executable file name, the solver control file name, the solver scratch directory, and the solver name. The submission script then does the final submission to the operating system. This final script will perform the following steps:

1. call the solver,
2. call a utility that will create the final GDX file `gmsgrid.gdx`,
3. set the completion signal `finished`.

If we want to use the function `handleSubmit` we will also have to create the script `gmsrerun.cmd` or `gmsrerun.run`. This script could later be used to resubmit the job.

For example, the default submission script for Windows is shown below:

```bash
@echo off
: gams grid submission script
:
: arg1 solver executable
: 2 control file
: 3 scratch directory
: 4 solver name
:
: gmscr_nx.exe processes the solution and produces 'gmsgrid.gdx'
:
: note: %3 will be the short name, this is needed because
: the START command cannot handle spaces or "...
: before we use %~3 will strip surrounding "...
: makes the name short
:
: gmsrerun.cmd will resubmit runit.cmd

echo @echo off > %3runit.cmd
echo %1 %2 %4 >> %3runit.cmd
echo gmscr_nx.exe %2 >> %3runit.cmd
echo echo OK >%3finished & exit >> %3runit.cmd

echo @start /b /belownormal %3runit.cmd ~> nul > %3gmsrerun.cmd

start /b /belownormal %3runit.cmd > nul

exit
```

### 3.37.6.1 Grid Submission Testing

The grid submission process can be tested on any GAMS program without having to change the source text. The option `solveLink=4` instructs the solve statement to use the grid submission process and then wait until the results are available. Note that the option `solveLink` may be set via a GAMS command line parameter, a GAMS option statement or via assignment to the model attribute. Once the model instance has been submitted for solution, GAMS will check if the job has been completed. It will keep checking twice the `reslim` seconds allocated for this optimization job and report a failure if this limit has been exceeded. After successful or failed retrieval of the solution, GAMS will remove the grid directory, unless we have used the call `gamskeep` or have set the GAMS command line parameter `keep`.
3.37.7 Multi-Threading

Note: This feature is in beta status.

As we have described in this chapter, each solve is handled in its own process space with the Grid facility. Recall that the Grid facility is activated by setting the option or model attribute solveLink to 3 or 4. If solveLink is set to 6 (or the compile-time constant %solveLink.Async Threads%) instead, a separate thread is used. This allows efficient in-memory communication between GAMS and the solver, like it is done if the option solveLink is set to 5 (or the compile-time constant %solveLink.Load Library%).

Apart from this, the multi-threading facility works in the same way as the Grid facility. The solve statement generates the model and passes it to the solver in a separate thread, then a handle of the model instance may be stored using the model attribute handle and the grid handle functions may be used to collect the solution and deal with the model instance, namely handleCollect, handleDelete, handleStatus and readyCollect.

Note that the option or command line parameter ThreadsAsync sets the maximum number of threads that should be used for the asynchronous solves.

The following matrix shows which solvers may be used with solveLink = 6 on which platform:

<table>
<thead>
<tr>
<th>Solver</th>
<th>x86 32bit MS Windows</th>
<th>x86 64bit MS Windows</th>
<th>x86 64bit Linux</th>
<th>x86 64bit Mac OS X</th>
<th>Sparc 64bit SOLARIS</th>
<th>IBM Power 64bit AIX</th>
</tr>
</thead>
<tbody>
<tr>
<td>GUROBI</td>

<td>x</td>
<td>x</td>
<td>x</td>
</tr>
</tbody>
</table>

If a solver is selected for which solveLink = 6 is not supported on the corresponding platform, solveLink = 3 will be used instead and it will be noted in the log.

3.37.7.1 Multi-threading Submission Testing

The multi-threading submission process may be tested on any GAMS program without having to change the source text. The option solveLink = 7 (or, equivalently, the compile-time constant %solveLink.Threads Simulate%) instructs the solve statement to use the multi-threading submission process, wait until the results are available and then load the solution into the GAMS data base. Once the model instance has been submitted for solution, GAMS will check if the job has been completed. It will keep checking twice the reslim seconds allocated for this optimization job and report a failure if this limit has been exceed. After successful or failed retrieval of the solution GAMS will remove the thread handle.
3.38 Special Features for Mathematical Programs

3.38.1 Introduction

In this chapter we will introduce special GAMS features that are useful for specific model types. The features include model scaling, conic programming and features that facilitate mixed integer as well as indicator constraints, a feature that does not translate across solvers.

3.38.2 Special Mixed Integer Programming (MIP) Features

Some special features have been added to GAMS to help simplifying the modeling of Mixed Integer Programming (MIP) problems. In GAMS MIP is the model type for mixed integer linear programs, this section used MIP more generally, we consider model with discrete variables, including non-linear expressions and pure discrete problem. We will first present details on discrete variables in GAMS, then we will discuss how to customize priorities for the branching process. Next, we will cover the model attributes that are important for MIPs and we will conclude with some hints that will make mixed integer programming with GAMS easier.

3.38.2.1 Types of Discrete Variables

Variables and variable types are introduced in chapter Variables. GAMS provides six discrete variable types: binary, integer, sos1, sos2, semicont and semiint. In the following subsections we will present details and examples for each of these discrete variable types. Note that if any discrete variables feature in a model, it has to be a mixed integer model or one of the related model types, like MINLP or MIQCP. See section Classification of Models for a full listing of all GAMS model types.

3.38.2.1.1 Binary Variables

Binary variables can take values of 0 (zero) and 1 (one) only. They are declared as follows:

Binary Variable var_name [(index_list)] [text];

The keyword binary indicates that this is a binary variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as binary later. Consider the following code snippets from the orthogonal Latin Square model [LATIN]:

```plaintext
Sets k "rows" / row1*row4 /
   l "columns" / col1*col4 /
   v "values" / val1*val4 /;
alias (i,j,v);
Variables x(i,j,k,l) "pairs (i,j) allocated to cell(k,l)"
   z "some objective";
Binary Variable x;
Equations c1(i,j) "for each cell pick only one item pair";
c1(i,j).. sum((k,l), x(i,j,k,l)) =e= 1;
```
Note that the binary variable $x$ is used in equation $c_1$ to model the restriction that in each cell only one item pair is allowed. Binary variables are often used to model logical conditions such as imposing mutual exclusivity or complementarity.

Note that the default lower bound is 0 (zero) and the default upper bound is 1 (one). If the relaxed versions of the discrete models is solved, binary variables are treated like positive variables with the upper bound of 1. In addition, an infinite priority may be used to override binary specifications, see section Setting Priorities for Branching below for more information.

Even though the only possible values are 0 and 1, a solver might return a value for binary variable that is only close to 0 or 1. Every solver works with tolerances and also uses a tolerance to determine if a value is close enough to an integer values. So it is unwise to use code as $a(i)$(b.l(i)=1) = yes; because one will potentially miss some elements. A safe way to write such code is: $a(i)$(b.l(i)>0.5) = yes;.

Rounding the level of a binary variable after the solve is also possible, but it is not done by the solver or the solver link because even small rounding can lead to infeasibilities.

A binary variable can also have a true fractional value after a solver if the model status does not indicate a feasible integer solution (model status 1 or 8).

### 3.38.2.1.2 Integer Variables

Integer variables are discrete variables that can take only values between their bounds. The user may change both bounds from the default value. The default lower bound is 0 (zero) and the default upper bound inside GAMS is $+\text{inf}$, but when the variable is passed on to the solver, the option or command line parameter IntVarUp decides what upper bound (by default 100) is passed on to the solver in case GAMS has upper bound $+\text{inf}$. This has some historic reason. Early MIP solvers only worked with binary variables. Integer variables could be modeled by in a base-2 system using binary variables. In order to limit the number of binary variable per integer variable a small interval of numbers was required and hence a small number (100) was picked.

Note that in relaxed model types the integrality requirement is relaxed. In addition, an infinite priority may be used to override integer specifications, see section Setting Priorities for Branching below for more information. Integer variables are declared as follows:

```
Integer Variable var_name [(index_list)] [text];
```

The keyword `integer` indicates that this is an integer variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as `integer` later. Consider the following code snippets from the power scheduling model [MAGIC]:

```
Sets t "demand blocks" / 12pm-6am, 6am-9am, 9am-3pm, 3pm-6pm, 6pm-12pm /
g "generators" / type-1, type-2, type-3 /;
Variables x(g,t) "generator output (1000mw)"
      n(g,t) "number of generators in use"
      cost "total operating cost (1)";
Integer Variable n;
```

The integer variable $n$ models the number of generators of various types that are in use at any of the time blocks.
3.38.2.1.3 Special Order Sets of Type 1 (SOS1)  
SOS1 variables are a set of variables, such that at most one variable within the group may have a nonzero value. This variable may take any positive value. Special ordered sets of type 1 are defined as follows:

SOS1 Variable var_name (index_list) [text];

The keyword SOS1 indicates that this is a SOS1 variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as SOS1 later. Consider the following example:

SOS1 Variable s1(i), t1(k,j), w1(i,j,k);

Note that the members of the innermost (the right-most) index belong to the same SOS set. For example in the sets defined above, s1 represents one special ordered set of type 1 with i elements, t1 defines k sets with j elements each and w1 defines (i,j) sets with k elements each.

The default bounds for SOS1 variables are zero and +inf. As with any other variable, the user may change these bounds. Further, the user may explicitly provide whatever convexity row that the problem may need through an equation that requires the members of the SOS1 set to be less than a certain value. Any such convexity row will implicitly define bounds on each of the variables.

Consider the following example:

SOS1 Variable s1(i); Equation defsoss1;
defsoss1.. sum(i,s1(i)) =l= 3.5;

The equation defsoss1 implicitly defines the nonzero value that one of the elements of the SOS1 variable s1 may take as equal to or smaller than 3.5. Note that it is also possible that all variables s1 equal zero.

A special case arises when one of the elements of the set has to be nonzero and equal to a number, say 3.5. In this case equation defsoss1 will be:

defsoss1.. sum(i,s1(i)) =e= 3.5;

Frequently the nonzero value equals 1. As a result, the SOS1 variable is effectively a binary variable. It is only treated differently by the solver at the level of the branch and bound algorithm. For example, consider the following example where we want to model that one out of n options has to be selected. This is expressed as:

SOS1 Variable x(i); Equation defx;
defx.. sum(i, x(i)) =e= 1;

The variable x can be made binary without any change in meaning and the solution provided by the solver will be indistinguishable from the SOS1 case.

The use of special ordered sets may not always improve the performance of the branch and bound algorithm. If there is no natural order the use of binary variables may be a better choice. A good example of this is the classical assignment problem (see [H.P. Williams (2013) Model Building in Mathematical Programming], Wiley, Section 9.3.

Note that any model with SOS1 variables requires a MIP solver, because the solution process needs to impose the restrictions of at most one nonzero level values may be present.

For an example where SOS1 variables are used, see the production scheduling model [PRODSCHX].
3.38 Special Features for Mathematical Programs

3.38.2.1.4 Special Order Sets of Type 2 (SOS2)  
SOS2 variables are a set of variables, such that at most two variables within the set may have nonzero values and these variables have to be adjacent. This requirement implies that the set is ordered, see chapter Sets as Sequences: Ordered Sets for details on ordered sets in GAMS. Note that the nonzero variables may take any positive value. Special ordered sets of type 2 are defined as follows:

SOS2 Variable var_name [(index_list)] [text];

The keyword SOS2 indicates that this is a SOS2 variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as SOS2 later. Consider the following example:

Set i / i1*i5 /;
SOS2 Variable s2(i), t2(k,j), w2(i,j,k);

The members of the innermost (the right-most) index belong to the same set. For example, in the sets defined above, s2 represents one special ordered set of type 2 with elements for each member of the set i. At most two variables s2 may be nonzero and they must reference adjacent elements of the set i. Note that the variables s2('i1') and s2('i2') are adjacent, but the variables s2('i1') and s2('i3') are not. Further, t2 defines k sets of SOS2 variables with j elements each and the adjacency requirement refers to the set j which must be ordered. Similarly, w2 defines (i,j) sets with k elements each and the adjacency requirement refers to the set k which must be ordered.

The default bounds for SOS2 variables are zero and +inf. As with any other variable, the user may change these bounds. SOS2 variables are most often used to model piece-wise linear approximations to nonlinear functions. The production scheduling model [PRODSCHX] shows SOS type formulations with binary, SOS1 and SOS2 sets.

Note that any model with SOS2 variables requires a MIP solver, because the solution process needs to impose the restrictions of adjacency and that no more than two nonzero level values may be present.

3.38.2.1.5 Semi-Continuous Variables  
Semi-continuous variables are either zero or above a given minimum level. This can be expressed algebraically as: either $x = 0$ or $L \leq x \leq U$. By default, the lower bound $L$ is 1 and the upper bound $U$ is +inf. As usual, these bounds may be changed with the variable attributes .lo and .up. Semi-continuous variables are defined as follows:

SemiCont Variable var_name [(index_list)] [text];

The keyword semicont indicates that this is a semi-continuous variable and then the usual conventions for variable declarations” are followed. Alternatively, the variable may be declared first and specified as semicont later. Consider the following example:

SemiCont Variable x;
x.lo = 1.5; x.up = 23.1;

The slice of code above declares the variable x to be a semi-continuous variable that may either be zero or behave as a continuous variable between 1.5 and 23.1.

Note that any model with semi-continuous variables requires a MIP solver, because the solution process needs to impose the discontinuous jump between zero and the threshold value.
Note

- Not all MIP solvers allow semi-continuous variables. We recommend users to verify how the solver they are interested in handles semi-continuous variables by checking the relevant section of the respective solver manual.
- The lower bound has to be less than the upper bound, and both bounds have to be greater than zero, otherwise GAMS will report an error.
- The variable solution listing might show the level outside the lower and upper bound which for other variables indicates an infeasible variable, but not so for semi-continuous variables.
- Semi-continuous variables are especially helpful if the upper bound is \(+\text{inf}\) and no implicit bound can be easily derived. If a finite upper bound is available it can be computational more efficient to replace the semi-continuous variable \(sc\) with lower bound \(scLow\) by a continuous variable \(x\) and binary variable \(b\) and the following equations:

\[
\text{Equation xForceLowerBnd "Force x to be greater than scLow if b is 1"}
\]
\[
xForceLowerBnd.. x \geq scLow * b;
\]
\[
xForceZero.. x \leq x.up * b;
\]

3.3.8.2.1.6 Semi-Integer Variables

Semi-integer variables are either zero or integer and above a given minimum value. This can be expressed algebraically as: either \(x = 0\) or \(x \in \{L,...,U\}\). By default, the lower bound \(L\) is 1 and the upper bound \(U\) inside GAMS is \(+\text{inf}\). However, when the variable is passed on to the solver, the option or command line parameter \text{IntVarUp}\) decides what upper bound (by default 100) is passed on to the solver in case GAMS has upper bound \(+\text{inf}\). As usual, these default bounds may be changed with the variable attributes \text{.lo}\) and \text{.up}\). Note that in relaxed model types the integrality requirement is relaxed. In addition, an infinite priority may be used to override integer specifications, see section Setting Priorities for Branching below for more information.

Semi-integer variables are defined as follows:

\[
\text{SemiInt Variable var\_name [\text{[(index\_list)]} [\text{[text]}]};\]

The keyword \text{semiint}\) indicates that this is a semi-integer variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as \text{semiint}\) later. Consider the following example:

\[
\text{SemiInt Variable x;}
\]
\[
x.lo = 2; x.up = 25;
\]

The slice of code above declares the variable \(x\) to be a semi-integer variable that may either be zero or take any integer value between 2 and 25. Note that the bounds for \text{semiint}\) variables have to take integer values, otherwise GAMS will flag an error during model generation. Note further, that any model with semi-integer variables requires a MIP solver.

Note

- Not all MIP solvers allow semi-integer variables. We recommend users to verify how the solver they are interested in handles semi-integer variables by checking the relevant section of the respective solver manual.
- The lower bound has to be less than the upper bound, and both bounds have to be greater than zero, otherwise GAMS will report an error.
- The variable solution listing might show the level outside the lower and upper bound which for other variables indicates an infeasible variable, but not so for semi-integer variables.
Semi-integer variables are especially helpful if the upper bound is $+\infty$ and no implicit bound can be easily derived (together with the appropriate IntVarUp setting). If a finite upper bound is available it can be computational more efficient to replace the semi-integer variable $s_i$ with lower bound $s_i\text{Low}$ by an integer variable $i$ and binary variable $b$ and the following equations:

\[
\begin{align*}
\text{Equation } & \text{iForceLowerBnd } \quad \text{"Force } i \text{ to be greater than } s_i\text{Low if } b \text{ is 1"} \\
& \text{iForceZero } \quad \text{"Force } i \text{ to be zero if } b \text{ is zero"} \\
\text{iForceLowerBnd} & \quad i = \geq s_i\text{Low} \cdot b; \\
\text{iForceZero} & \quad i = \leq i\text{.up} \cdot b;
\end{align*}
\]

### 3.38 Setting Priorities for Branching

By setting priorities users may specify an order for choosing variables to branch on during a branch and bound search for MIP models. Without priorities the MIP algorithm will internally determine which variable is the most suitable to branch on. Priorities for individual variables may be used only if the model attribute .prioropt is set to 1; the respective GAMS statement is:

```gams
mymodel.prioropt = 1;
```

Here `mymodel` is the name of the model specified in the model statement. The default value is NA.

If the model attribute .prioropt is set to 1, the variable attribute .prior may be used to set the priorities of individual discrete variables. Note that there is one .prior value for each individual component of a multidimensional variable. Priorities may be set to any real value; the default value is 1. As a general rule, the most important variables should be given the highest priority. The highest priority is denoted by the lowest nonzero value in the .prior attribute. Functionally, the attribute .prior establishes in what order variables are to be branched on in the branch-and-bound algorithm while searching for a solution. Variables with a specific .prior value will be branched on earlier until all fractional variables with higher .prior values have been branched on.

**Note**

The variable attribute .prior of a discrete variable may be used to relax the discrete restriction on that variable: setting the .prior value to $+\infty$ will relax a variable permanently (or until .prior gets a finite value assigned). This relaxation is done independently of the model attribute .prioropt.

Consider the following example:

```gams
z.prior(i,'small') = 3;
z.prior(i,'medium') = 2;
z.prior(i,'large') = 1;
```

In this example the variables $z(i, \text{large})$ are branched on before the variables $z(i, \text{medium})$, which in turn are branched on before the variables $z(i, \text{small})$.

Note that knowledge about the problem may help to determine which variables should be considered first. For example, consider a problem with a binary variable $u$ representing a yes/no decision whether to build a factory and other binary variables representing equipment selections within that factory. We would naturally want to explore whether or not the factory should be built before considering what specific equipment to be purchased within the factory. Therefore we would set the priority values lower for $u$. By assigning a higher priority - a lower value of the attribute .prior - to the build/nobuild decision variable $u$, we can force this logic into the tree search and thus speed up computation time since uninteresting portions of the tree are left unexplored.
Note

- The lower the value given to the .prior suffix, the higher the priority for branching.
- All members of any SOS1 or SOS2 set should be given the same priority value since it is the set itself which is branched upon rather than the individual members of the set.
- While any value is accepted for .prior many solvers scale all giving priorities in the integer range of 0,...,1000.
- Branching priorities were a very important feature in the early days of mixed integer programming. Nowadays, it is not easy to find branching priorities that improve on the solvers default selection.
- Global non-linear optimization solvers branch on continuous variables too (see, for example BARON). In GAMS one cannot set the branching priority of a continuous variable. Such branching priorities need to be communicated via a solver option file.

3.38.2.3 Miscellaneous Hints

We will conclude the discussion of mixed integer models in GAMS with this section where we offer a variety of hints that are meant to make special facilities of mixed integer programming solvers more accessible.

3.38.2.3.1 Model Attributes for Mixed Integer Programming in GAMS

GAMS offers several model attributes that may be used to influence MIP solver performance or report on results of MIPs. These model attributes include Cheat, CutOff, NodLim, ObjEst, OptCA, OptCR, PriorOpt and TryInt.

3.38.2.3.2 The Branch and Cut and Heuristic Facility

Hard MIP problems can be solved faster with the help of user supplied routines that generate cutting planes and good integer feasible solutions. The GAMS Branch-and-Cut-and-Heuristic (BCH) automates all major steps necessary to define, execute and control the use of user defined routines within the framework of general purpose branch-and-cut codes. It is documented in Branch-and-Cut-and-Heuristic Facility (BCH).

3.38.2.3.3 Branch and Bound Output

While the log output for each solver differs, some key figures are usually displayed for branch-and-bound based solvers. For example, solving a linear mixed integer model with CPLEX will yield output like the following:

<table>
<thead>
<tr>
<th>Nodes</th>
<th>Objective</th>
<th>Best Integer</th>
<th>Cuts/</th>
<th>ItCnt</th>
<th>Gap</th>
</tr>
</thead>
<tbody>
<tr>
<td>* 0+ 0</td>
<td>0.0000</td>
<td>5.05646e+08</td>
<td>---</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Found incumbent of value 0.000000 after 0.01 sec. (0.73 ticks)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0 0</td>
<td>2.23031e+07</td>
<td>12</td>
<td>2.23031e+07</td>
<td>17</td>
<td></td>
</tr>
<tr>
<td>0 0</td>
<td>2.23031e+07</td>
<td>7</td>
<td>0.0000</td>
<td>Cuts: 8</td>
<td></td>
</tr>
<tr>
<td>* 0+ 0</td>
<td>2.23031e+07</td>
<td>2.23031e+07</td>
<td>0.00%</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Found incumbent of value 2.2303094e+07 after 0.02 sec. (1.08 ticks)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Solution satisfies tolerances.

MIP Solution: 22303093.628684 (23 iterations, 0 nodes)
Final Solve: 22303093.628684 (0 iterations)

Best possible: 22303113.950091
Absolute gap: 20.321407
Relative gap: 0.000001
A brief explanation of the columns follows:

- **Node** is the number of branch and bound nodes so far.
- **Nodes Left** is the number of problems created during the branching process that are yet to be examined.
- **Objective** gives the current objective function value of the relaxes node problem.
- **IInf** gives the number of discrete variables with fractional solution levels.
- **Best Integer** gives the incumbent solution. Note the last solution in that column is not necessarily the global best solution.
- **Cuts/Best Bound** gives the current lower bound on the solution.
- **ItCnt** gives the accumulated LP iteration count
- **Gap** gives the maximum percentage difference from the theoretical optimum.

Note that it is common that solves of mixed integer models end with a gap between the solution found and the best possible solution. This may be controlled by limits (e.g. time), solver options and model attributes like .OptCR and .OptCA.

### 3.38.2.3.4 Nonlinear MIPs

Modelers may wish to impose integer restrictions on nonlinear formulations combining two hard model types: MIP and NLP. Such MINLP models can be solved with a selection of solvers. Many solvers, e.g. DICOPT and SBB, provide a local optimum where others, e.g. ANTIGONE and BARON provide a global optimum. In most cases both types of MINLP solver make use of MIP and NLP solvers to calculate a solution. Such **subsolvers** need to be licensed for the solver to succeed.

### 3.38.2.3.5 Model Termination Conditions and Recommended Actions

Recall that the termination condition of the model after the solution process has been completed is stored in the model attribute .modelStat. A list of all possible model statuses is given in section Model Status. We can easily check for the existence of a feasible solution (status 1 and 8). Linear models and MINLP problems solved with global solvers can achieve the "OPTIMAL" status, given sufficient resources (time) and a setting of OptCR and OptCA to 0. All other cases do not yield a feasible integer solution. If a problem is reported as infeasible (status 4,5,10, and 19), it might be a good idea to see if the relaxed version of the model is already infeasible. Debugging models that are relaxed feasible but integer infeasible is very difficult.

### 3.38.2.3.6 Frequent Problems

There are some problems users frequently encounter either due to GAMS settings or problem characteristics:

#### Default bounds

One needs to be aware that while the GAMS upper bound for integer and semi-integer variables is +inf, the bound that is passed to the solver can be different, namely 100 (see the discussion about integer variables). This can lead to unexpected results (e.g. infeasibilities or suboptimal solutions declared as optimal).

#### Ending with a gap – large default for optCR (10%)

MIP solves often end with a gap between the solution found and the best possible solution. This is controlled by OptCR or OptCA or by non-convergence. Note that the default value of 0.1 for optCR is relatively large. Users may want to reduce this to a smaller value. We will discuss the other cause of a gap next.

#### The nonending quest
Integer programming is a quite desirable formulation technique. However, integer problems are theoretically hard and the solution process (in the worst case) of exponential complexity. There are many ways that focus on improving the solution time of the solver. As with all models scaling is important (especially when using bigM formulations). For particular problems many different formulations exist and the literature about a particular problem together with the ability of GAMS to rapidly prototype and experiment is the best constellation to get the best results for the problem at hand. For fine tuning, some MIP solvers provide automated tuning tools (see e.g. Cplex tuning) that tweak the solver options to get the best performance.

3.38.3 Model Scaling - The Scale Option

The rules for good scaling are exclusively based on algorithmic needs. GAMS has been developed to increase the efficiency of modelers, and one of the best ways seems to be to encourage modelers to write their models using a notation that is as natural as possible. The units of measurement are one part of this natural notation. However, there is a potential conflict between what the modeler thinks is a good unit and what constitutes a well-scaled model.

3.38.3.1 The Scale Option

To facilitate the translation between a natural model and a well scaled model, GAMS has introduced the concept of a scale factor, both for variables and equations. The notations and definitions are quite simple. Scaling is turned off by default. Setting the model attribute .scaleopt to 1 turns on the scaling feature. For example,

```plaintext
model mymodel /all/ ;
mymodel.scaleopt = 1 ;
solve mymodel using nlp maximizing dollars ;
```

The statement should be inserted somewhere after the model statement and before the solve statement. To turn scaling off again, mymodel.scaleopt has to be set to zero before the next solve.

In most respects GAMS scaling is hidden from the user. The solution values reported back from a solution algorithm are always reported in the notation of the user. The algorithm’s internal representation of the equations and variables are only reflected in the derivatives in the equation and column listings in the GAMS output if the values of the options limrow and limcol are positive. In addition, the internal representations will appear in the debugging output from the solution algorithm if the option sysout is set to on.

3.38.3.2 Scaling Variables

The scale factor of a variable is defined using the variable attribute .scale in the following way:

```plaintext
myvar.scale(i,j) = c;
```

The scale factor c is a number or a numerical expression that evaluates to a number. Note that the default scale factor is 1.

Note that there is one scale value for each individual component of a multidimensional variable.

Assume that c is the scale factor of a variable V_u. Assume further, that the variable seen by the algorithm is V_a. Then we have: V_a = V_u/c. This means that each variable as seen by the user is divided by the scale factor.

For example, consider the following code snippet:
Positive Variables x1, x2;
Equation eq;
eq.. 200*x1 + 0.5*x2 =l= 5;
x1.up = 0.01;
x2.up = 10;
x1.scale = 0.01;
x2.scale = 10;

By setting x1.scale to 0.01 and x2.scale to 10, the model seen by the solver is:

Positive Variables xPrime1, xPrime2;
Equation eq;
eq.. 2*xPrime1 + 5*xPrime2 =l= 5;
xPrime1.up = 1;
xPrime2.up = 1;

Note that the solver does not see the variables x1 or x2, but rather the scaled (and better-behaved) variables xPrime1 and xPrime2. Note further, that upper and lower bounds on variables are automatically scaled in the same way as the variable itself.

Attention

- **Discrete variables** cannot be scaled.
- **Expert Note.** Internally, GAMS stores with each variable and equation one additional attribute or field (besides fields for level, marginal and lower and upper bound). Depending on the type of variable and sometimes even model type or solver, this field has different names in the GAMS language. For continuous variables, the field is called *scale*, while for discrete variable it is called *prior*. For stochastic 2-stage linear program models solved with DECIS, this field is called *stage*. The field .stage can lead to confusing results. Consider the following example:

```gams
Variable x;
x.scale = 0.1;
display x.stage;
```

The output is:

```
---- 3 VARIABLE x.scale = 0.100
```

The field .scale has to be in a certain range ( >1e-20 and no special value), but this is only checked at model generation time. The field .prior can be any number and even +inf (but no other special values). For further information on .prior, see section Setting Priorities for Branching. For an introduction to variable and equation fields, see sections Variable Attributes and Equation Attributes respectively.

### 3.38.3.3 Scaling Equations

The scale factor of an equation is defined using the equation attribute .scale in the following way:

```gams
mzeqn.scale(i,j) = d;
```
The scale factor $d$ is a number or a numerical expression that evaluates to a number. Note that the default scale factor is 1.

Assume that $d$ is the scale factor of an equation $G_u$. Assume further, that the equation seen by the algorithm is $G_a$. Then we have: $G_a = G_u / d$. This means that each equation as seen by the user is divided by the scale factor.

For example, consider the following equations:

Positive Variables $y_1$, $y_2$;
Equations eq1, eq2;
eq1..  200*y1 + 100*y2 =l= 500;
eq2..  3*y1 - 4*y2 =g= 6;

By setting $eq1.scale$ to 100, the model seen by the solver is:

Positive Variables $y_1$, $y_2$;
Equations eqPrime1, eq2;
eqprime1..  2*y1 + 1*y2 =l= 5;
eq2..  3*y1 - 4*y2 =g= 6;

Note
The user may have to perform a combination of equation and variable scaling to obtain a well-scaled model.

Consider the following example:

Positive variables $x_1$, $x_2$;
Equations eq1, eq2;
eq1..  100*x1 + 5*x2 =g= 20;
eq2..  50*x1 - 10*x2 =l= 5;
x1.up = 0.2;
x2.up = 1.5;

Setting the following scale values:

$x1.scale = 0.1;$
eq1.scale = 5;
eq2.scale = 5;

will result in the solver seeing the following well-scaled model:

Positive Variables $xPrime1$, $x2$;
Equations eqPrime1, eqPrime2;
eqPrime1..  2*xPrime1 + x2 =g= 4;
eqPrime2..  xPrime1 - 2*x2 =l= 1;
xPrime1.up = 2;
x2.up = 1.5;
3.38.3.4 Scaling Derivatives

In nonlinear models the derivatives also need to be well-scaled. Assume that the derivatives in the model of the user are denoted by \( \frac{d(G_u)}{d(V_u)} \). Assume further, that the derivatives in the scaled model seen by the algorithm are denoted by \( \frac{d(G_a)}{d(V_a)} \). Then we have: \( \frac{d(G_a)}{d(V_a)} = \frac{d(G_u)}{d(V_u)} \cdot \frac{c}{d} \), where \( c \) is the scale factor for the variable and \( d \) is the scale factor for the equation.

The user may affect the scaling of derivatives by scaling both the equation and variable involved.

3.38.3.5 Scaling Data

Scaling input data is independent of the model attribute .scaleopt and may contribute considerably towards achieving a well-scaled model. We recommend users to try to define the units of the input data such that the largest values expected for decision variables and their marginals is under a million, if possible.

For example, in US agriculture about 325 million acres are cropped and the corn crop is 9-10 billion bushels per year. When defining production data, we could enter land in 1000's of acres and all other resources in 1000's of units. We could also define the corn crop in millions of bushels. The data will be simultaneously scaled, hence if resource endowments are quoted in 1000's, corn yields are divided by 1000. This scaling results in a corn production variable in the units of millions. Consumption statistics would need to be scaled accordingly. Money units could also be in millions or billions of dollars. Such data scaling generally greatly reduces the disparity of coefficients in the model.

3.38.4 Conic Programming in GAMS

Conic programming models minimize a linear function over the intersection of an affine set and the product of nonlinear cones. The problem class involving second order (quadratic) cones is known as Second Order Cone Programs (SOCP). These are nonlinear convex problems that include linear and (convex) quadratic programs as special cases.

Conic programs allow the formulation of a wide variety of application models, including problems in engineering and financial management. Examples are portfolio optimization, Truss topology design in structural engineering, Finite Impulse Response (FIR) filter design and signal processing, antenna array weight design, grasping force optimization, quadratic programming, robust linear programming and norm minimization problems.

For more information, see References and Links at the end of this section.

3.38.4.1 Introduction to Conic Programming

Conic programs can be thought of as generalized linear programs with the additional nonlinear constraint \( x \in C \), where \( C \) is required to be a convex cone. The resulting class of problems is known as conic optimization and has the following form:

\[
\begin{align*}
\text{minimize} & \quad c^T x \\
\text{subject to} & \quad Ax \leq r^c, \\
& \quad x \in [l^x, u^x] \\
& \quad x \in C
\end{align*}
\]

where \( A \in \mathbb{R}^{m \times n} \) is the constraint matrix, \( x \in \mathbb{R}^n \) the decision variable and \( c \in \mathbb{R}^n \) the objective function cost coefficients. The vector \( r^c \in \mathbb{R}^m \) represents the right-hand side and the vectors \( l^x, u^x \in \mathbb{R}^n \) are lower and upper bounds on the decision variable \( x \).
Now partition the set of decision variables $x$ into sets $S^t$, $t = 1, \ldots, k$, such that each decision variable $x$ is a member of at most one set $S^t$. For example, we could have

$$S^1 = (x_1, x_4, x_7) \quad \text{and} \quad S^2 = (x_6, x_5, x_3, x_2).$$

Let $x_{S^t}$ denote the variables $x$ belonging to set $S^t$. Then define

$$C := \{ x \in \mathbb{R}^n : x_{S^t} \in C_t, t = 1, \ldots, k \},$$

where $C_t$ must have one of the following forms:

- **Quadratic cone** (also referred to as Lorentz or ice cream cone):

  $$C_t = \left\{ x \in \mathbb{R}^{n^t} : x_1 \geq \sqrt{\sum_{j=2}^{n^t} x_j^2} \right\}.$$

- **Rotated quadratic cone** (also referred to as hyperbolic constraints):

  $$C_t = \left\{ x \in \mathbb{R}^{n^t} : 2x_1x_2 \geq \sum_{j=3}^{n^t} x_j^2, x_1, x_2 \geq 0 \right\}.$$

These two types of cones allow the formulation of quadratic, quadratically constrained and many other classes of nonlinear convex optimization problems.

### 3.38.4.2 Implementation of Conic Constraints in GAMS

The recommended way to write conic constraints is by using a quadratic formulation. Many solvers have the capability to identify the conic constraints in a QCP model even if it is not in perfect form but can be easily reformulated to fit in the described form. However, some solvers (namely MOSEK) expect the conic constraints to be precisely in the form given above. In earlier versions this form was enforced by a special type of equation, the $=c=$ equation type. Moreover, such solvers have other requirements (e.g. disjunctive cones) that can be easily fulfilled by simple reformulation steps. Much progress is expected on the solver side in the coming years, so we don’t go into much detail here.

Observe that we could formulate conic problems as regular NLPs using the following constraints:

- **Quadratic cone:**

  $$x(‘1’) = \text{g} = \text{sqrt}[ \text{sum(i}[\text{not sameas(i,‘1’)}], \text{sqr}[x(i)]) ];$$

- **Rotated quadratic cone:**

  $$2*x(‘1’)*x(‘2’) = \text{g} = \text{sum(i}[\text{not sameas(i,‘1’)} \text{ and not sameas(i,‘2’)}], \text{sqr}[x(i)]) ;$$

  Here $x(‘1’)$ and $x(‘2’)$ are positive variables.

The following example illustrates the different formulations for conic programming problems. Note that a conic optimizer usually outperforms a general NLP method for the reformulated (NLP) cone problems.
3.38.4.3 Example

Consider the following example, which illustrates the use of rotated conic constraints. We will give reformulations of the original problem in regular NLP form and in conic form (with conic constraints).

The original problem is:

\[
\begin{align*}
\text{minimize} & \quad \sum_{i=1}^{n} \frac{d_i}{x_i} \\
\text{subject to} & \quad a x \leq b \\
& \quad x_i \in [l_i, u_i], \quad i = 1, \ldots, n
\end{align*}
\]

where \( x \in \mathbb{R}^n \) is the decision variable, \( d, a, l, u \in \mathbb{R}^n \) are parameters with \( l_i > 0 \) and \( d_i \geq 0 \) and \( b \in \mathbb{R} \) is a scalar parameter. The original model may be written in GAMS using the equations:

\[
\begin{align*}
\text{defobj..} & \quad \sum(n, d(n)/x(n)) =e= \text{obj}; \\
\text{e1..} & \quad \sum(n, a(n)*x(n)) =l= b; \\
\text{Model orig /defobj, e1/;}
\end{align*}
\]

\[
\begin{align*}
x.\text{lo}(n) & = l(n); \\
x.\text{up}(n) & = u(n);
\end{align*}
\]

We can write an equivalent QCP formulation by using the substitution \( t_i = 1/x_i \) in the objective function and adding a constraint. As we are dealing with a minimization problem, \( d_i \geq 0 \) and \( x_i \geq l_i > 0 \), we can relax the equality \( t_i x_i = 1 \) into an inequality \( t_i x_i \geq 1 \), which results in an equivalent problem with a convex feasible set:

\[
\begin{align*}
\text{minimize} & \quad \sum_{i=1}^{n} d_i t_i \\
\text{subject to} & \quad a x \leq b \\
& \quad t_i x_i \geq 1, \quad i = 1, \ldots, n \\
& \quad x \in [l, u], \\
& \quad t \geq 0
\end{align*}
\]

where \( t \in \mathbb{R}^n \) is a new decision variable. The GAMS formulation of this QCP is:

\[
\begin{align*}
\text{defobjc..} & \quad \sum(n, d(n)*t(n)) =e= \text{obj}; \\
\text{e1..} & \quad \sum(n, a(n)*x(n)) =l= b; \\
\text{Model cqcp /defobjc, e1, coneqcp/;}
\end{align*}
\]

\[
\begin{align*}
t.\text{lo}(n) & = 0; \\
x.\text{lo}(n) & = l(n); \\
x.\text{up}(n) & = u(n);
\end{align*}
\]

We note that the constraints \( t_i x_i \geq 1 \) are almost in rotated conic form. If we introduce a variable \( z \in \mathbb{R}^n \) with \( z_i = \sqrt{2} \), then we can reformulate the problem using conic constraints as:

\[
\begin{align*}
\text{minimize} & \quad \sum_{i=1}^{n} d_i t_i \\
\text{subject to} & \quad a x \leq b \\
& \quad z_i = \sqrt{2}, \quad i = 1, \ldots, n \\
& \quad 2t_i x_i \geq z_i^2, \quad i = 1, \ldots, n \\
& \quad x \in [l, u], \\
& \quad t \geq 0
\end{align*}
\]
The GAMS formulation using conic equations is:

\[
\text{defobjc..} \quad \sum(n, d(n)*t(n)) =e= \text{obj}; \\
\text{e1..} \quad \sum(n, a(n)*x(n)) =l= b; \\
\text{e2(n)..} \quad z(n) =e= \sqrt{2}; \\
\text{coneperfect(n)..} \quad 2*x(n)*t(n) =g= \sqrt{2*(n)}; \\
\]

Model cperfect /defobjc, e1, e2, coneperfect/;
\[t.l(n) = 0;\]
\[x.l(n) = l(n);\]
\[x.l(n) = u(n);\]

The complete model is listed below:

\[
\text{Set} \quad n / n1*n10 /; \\
\text{Parameter} \quad d(n), a(n), l(n), u(n); \\
\text{Scalar} \quad b; \\
\]
\[d(n) = \text{uniform}(1,2);\]
\[a(n) = \text{uniform}(10,50);\]
\[l(n) = \text{uniform}(0.1,10);\]
\[u(n) = l(n) + \text{uniform}(0,12-l(n));\]

\[
\text{Variables}\ x(n); \\
\quad x.l(n) = \text{uniform}(l(n), u(n)); \\
\quad b = \sum(n, x.l(n)*a(n)); \\
\]

\[
\text{Variables}\ t(n), z(n), \text{obj}; \\
\text{Equations}\ \text{defobjc, defobj, e1, e2(n), coneqcp(n), coneperfect(n), conenlp(n)}; \\
\]
\[
\text{defobjc..} \quad \sum(n, d(n)*t(n)) =e= \text{obj}; \\
\text{defobj..} \quad \sum(n, d(n)/x(n)) =e= \text{obj}; \\
\text{e1..} \quad \sum(n, a(n)*x(n)) =l= b; \\
\text{coneqcp(n)..} \quad t(n)*x(n) =g= 1; \\
\text{e2(n)..} \quad z(n) =e= \sqrt{2}; \\
\text{coneperfect(n)..} \quad 2*x(n)*t(n) =g= \sqrt{2*(n)}; \\
\]

3.38.4.4 Sample Conic Models in GAMS

Conic models in the GAMS model library and on \texttt{gamsworld} include:
3.38 Special Features for Mathematical Programs

- [EMFL]: a multiple facility location problem,
- [QP7]: a portfolio investment model using rotated quadratic cones (quadratic program using a Markowitz model),
- fir_socp.gms: a linear phase lowpass filter design model,
- springs.gms: an equilibrium of system with piecewise linear springs,
- trussm.gms: a Truss topology design problem with multiple loads.

3.38.4.5 References and Links

- Seventh *Dimacs Implementation Challenge* on Semidefinite and Related Optimization Problems.

3.38.5 Indicator Constraints

An indicator constraint is a way of expressing relationships between variables by specifying a binary variable to control whether or not a constraint takes effect. For example, indicator constraints are useful in problems where there are fixed charges to express only if a given variable comes into play.

So-called Big M formulations require to estimate an upper bound of an expression in a model. In most cases the model data can be used to determine relatively small number for such coefficients. In some cases it is not possible to find small Big M values and a resulting solution may exhibit trickle flow and have other unwanted side-effects. The main purpose of indicator constraints is to overcome these limitations of Big M formulations. Generally, the use of indicator constraints is not warranted when the unwanted side-effects of Big M formulations are not present.

Consider the following example:

```
constr01.. x1 + x2 + x3 =l= 1e+9*y; // may cause problems
```

Here we use a Big M formulation, that relies on the $x$ values to sum to less than one billion. Note that this formulation may cause numeric instability or undesirable solutions in some situations. Alternatively, we could use an indicator constraint:

```
constr01$(y=0).. x1 + x2 + x3 =l= 0; // alternative
```
Note that $y$ is a binary variable; the logical condition makes sure that the constraint is only active if $y = 0$. Unfortunately, the $\$()$ expressions do not allow endogenous variables and we need a different way to specify such implications. Indicators are supported by CPLEX, GUROBI, LOCALSOLVER, SCIP, and XPRESS.

We should mention a formulation of indicators without the explicit indicator constraints. We can use a SOS1 constraint to express that a constraint holds or not based on a binary variable by having a SOS1 set of a slack variable and the binary variable $\text{SOS1}(\text{slack}, 1-y)$:

```
Positive variable slack;
constr01.. x1 + x2 + x3 =l= slack; // alternative
```

Recall that only one of the variables in a SOS1 constraint can be non-zero, so if $1-y$ is non-zero (i.e. $y=0$) then $\text{slack}$ must be zero, i.e. the constraint holds. If $1-y=0$ is non-zero, i.e. $y=1$ then $\text{slack}$ can be used to make the constraint feasible for any setting of $x1$, $x2$, and $x3$. Here two unrelated variable, $\text{slack}$ and $y$ are part of an SOS1 constraint and some tricks are required to formulate this properly in GAMS:

Set oo / slack, yExpr /
SOS1 variable indic(oo);
Equation iOn, iOff;
Positive variable slack;
constr01.. x1 + x2 + x3 =l= slack;
iOn.. indic('slack') =e= slack;
iOff.. indic('yExpr') =e= 1-y;

### 3.38.5.1 Indicator Constraints with GAMS

In the remainder of this section we will describe how to specify indicator constraints when using GAMS. Please consult the corresponding solver manual for information on whether indicator constraints are supported and possible differences in their specification.

The example from above will be implemented with a constraint in combination with additional information in a solver option file, e.g. CPLEX: `cplex.opt`:

```
constr01.. x1 + x2 + x3 =l= 0;
```

and the following entry in the option file:

```
indic constr01$y 0
```

This has the following effect: equation `constr01` will become an indicator constraint and becomes active in a solution where the binary variable takes the value 0. If the value of $y$ in a solution is 1, the constraint is not active.

Note that this way of entering an indicator constraint is dangerous since the option files changes the model (usually an option file has some effect on the performance of the algorithm). Therefore, the solver will abort if there is a problem processing the indicator options in the solver option file.
Attention

If the model is given to a solver without the option file containing the indicator mapping (or to a solver that does not understand the `indic` keyword, a very different model will be solved. The current implementation of indicator constraints requires a significant amount of caution from the user.

There are two ways of entering the equation/binary variable mapping in a solver option file: with an indexed format and using labels.

The *indexed format* is a convenient shorthand notation which borrows its syntax from the GAMS syntax. It requires that the indices for the binary variable are already present in the index set of the equation.

Consider the following example of an invalid GAMS syntax with an endogenous variable in the dollar condition:

```plaintext
equ1(i,j,k)$(ord(i) < ord(j) and bin1(i,k)=1).. lhs =l= rhs;
```

This may be specified with the following equation in the GAMS file:

```plaintext
equ1(i,j,k)$(ord(i) < ord(j)).. lhs =l= rhs;
```

plus a solver option file with the following entry:

```plaintext
indic equ1(i,j,k)$bin1(i,k) 1
```

The *label format* is used in cases where the binary variable indices are not present in the equation indices or the binary variable is adjusted with lags or leads. In these cases the mapping of all individual equations and variables of the indicator constraints need to be specified. An example follows.

```plaintext
Set i /i1*i3/, j /j1*j2/;
Binary variable bin1(j);
Equation equ1(i,j);
equ1(i,j)$(bin1(j++)=0).. lhs =e= 0;
```

Note that the example above is not valid GAMS code. Instead, we will combine a valid GAMS equation and a solver option file using the label format as follows:

```plaintext
equ1(i,j).. lhs =e= 0;
```

and the solver option file

```plaintext
indic equ1('i1','j1')$bin1('j2') 0
indic equ1('i1','j2')$bin1('j1') 0
indic equ1('i2','j1')$bin1('j2') 0
indic equ1('i2','j2')$bin1('j1') 0
indic equ1('i3','j1')$bin1('j2') 0
indic equ1('i3','j2')$bin1('j1') 0
```
Note that the lines in such option files need not be entered manually. They may be easily generated using the GAMS The Put Writing Facility. For example, the lines above may be generated as follows:

```gams
file fcpx / cplex.opt /;
fcpx.pc=8;
loop((i,j), put fcpx 'indic' equ1(i,j) '$' bin1(j++1) '0'/);
putclose fcpx;
```

There are situations where the indicator binary variable exist in the indicator constraint only and hence will not be generated by GAMS to be passed on to the solver. In such cases the solver will issue the following error message:

**Error: Column is not of type Variable**

There is an easy way to fix this problem: adding the binary indicator variable artificially to the model. For example, it may be added with the coefficient $\epsilon$ to the objective:

```gams
defobj.. z =e= ... + \epsilon*sum(j, bin1(j));
```

### 3.38.5.2 An Example for Indicator Constraints with GAMS

In this subsection we will comment on parts of the model [TRNSINDIC]. This model uses big M formulations and indicator constraints to solve the same problem. In addition, a formulation that makes it easy to switch between these two is presented. It is a fixed-charge network example based on the well-known model [TRNSPORT].

Recall that $i$ is the set of canning plants and $j$ is the set of markets where cases of some product are to be shipped. First, the basic model is reformulated to a MIP by introducing the binary variable $use(i,j)$ and two new equations:

**Binary Variable $use(i,j)$** is 1 if arc is used in solution;

**Equations**

- **minship(i,j)** ensure minimum shipping
- **maxship(i,j)** ensure zero shipping if use variable is 0;

```gams
minship(i,j).. x(i,j) =g= minshipping*use(i,j);
maxship(i,j).. x(i,j) =l= bigM*use(i,j);
```

Note that $minshipping$ is a scalar denoting the minimum amount of cases that may be shipped and $bigM$ is a sufficiently large number, as usual.

Next, the same problem is solved with indicator constraints: the two new equations are reformulated and a CPLEX option file with information on indicator constraints is added:

**Equations**

- **iminship(i,j)** ensure minimum shipping using indicator constraints
- **imaxship(i,j)** ensure zero shipping if use variable is 0 using indicator constraints;

```gams
iminship(i,j).. x(i,j) =g= minshipping;
imaxship(i,j).. x(i,j) =e= 0;
```

Model indicatorModel /cost, supply, demand, iminship, imaxship/ ;

```gams
file fcpx Cplex Option file / cplex.opt /;
putclose fcpx 'indic iminship(i,j)$use(i,j) 1' / 'indic imaxship(i,j)$use(i,j) 0';
indicatorModel.optfile = 1;
Solve indicatorModel using mip minimizing z ;
```
Note that the option file contains an entry for each of the two equations. Note further, that the binary variable `use` moved from the equations to the option file. However, it also features in the objective equation of the model, therefore this is not problematic. Observe that the indexed format for the equation/binary variable mapping was used in the option file. Alternatively, the label format may be used:

```gams
loop((i,j),
    put fcp 'indic ' iminship.tn(i,j) '$' use.tn(i,j) yes / 'indic ' imaxship.tn(i,j) '$' use.tn(i,j) no / );
putclose fcp;
```

In a final step the model is reformulated again such that the same problem may be solved with and without indicator constraints. This can be especially useful for debugging a model with indicator constraints. For details, see [TRNSINDIC].

Another example of a model with indicator constraints is the model [BILINEAR] where various formulations to represent bilinear product terms are demonstrated.

## 3.39 GAMS Output

### 3.39.1 Introduction

The output from GAMS contains many components in support for checking and comprehending a model. This chapter discusses the components of the GAMS output file generated from a GAMS run as well as ways to control the amount of diagnostic output produced.

The output file generated from a GAMS run is called listing file. The listing file has the file extension .lst and can be read using any text editor. By default the listing file has the same file name as the input file, but this can be changed using the command line parameter `Output`. See chapter The GAMS Call and Command Line Parameters for more information. The main components in the listing file are:

1. **Compilation.** The compilation output contains an echo print of the input file, possibly error messages, along with lists of GAMS objects and cross reference maps.

2. **Execution.** The execution output contains the results of display statements and possibly execution error messages.

3. **Model Generation.** The output generated during model generation contains listings of equations and variable listings as well as model statistics and possibly generation execution error messages.

4. **Solution.** The output generated when an external solver program processes the model is the solution report including the solve summary, the solver report, the solution listing and the report summary.

5. **Post-Solution.** The final components added to the listing file are the final execution summary and the file summary.

A small nonlinear program [ALAN] will be used to illustrate every component of the listing file. The possibilities for extension to large models with voluminous output (which is when the diagnostics are really useful) should be apparent. After covering all the components of the listing file we will discuss error reporting and conclude the chapter with a compiled list of how to customize the output file.

This chapter does not cover the output that can be generated by the user through display statements and put statements. This output is covered in the chapters The Display Statement and The Put Writing Facility respectively.
3.39.2 An Illustrative Model

[ALAN] is a portfolio selection model whose objective is to choose a portfolio of investments whose expected return meets a target while minimizing the variance. We will discuss a simplified version of this model. The input file is listed for reference.

3.39 GAMS Output

3.39.3 Compilation Output

The compilation output is the output produced during the initial check of the program, often referred to as compilation. It contains the following parts: the echo print of the input file, the symbol reference map, the symbol listing map, the unique element listing map, and the include file summary.

By default only the echo print and the include file summary is shown, the other parts are suppressed and may be turned on with dollar control options. See also section Customizing the Output File on how to control the appearance and amount of detail in the output file produced by the GAMS compiler.

3.39.3.1 The Echo Print of the Input File

The *echo print* of the program is always the first part of the output file. It is a listing of the input with added line numbers. It is possible to control the listing output using $offlisting to suppress the echo print and $onlisting to turn the echo print on again. The first few lines of the echo print of the Illustrative Model follow:

A Quadratic Programming Model for Portfolio Analysis (ALAN, SEQ=124a)

Compilation

2
4

This is a mini mean-variance portfolio selection problem described in 'GAMS/MINOS: Three examples' by Alan S. Manne, Department of Operations Research, Stanford University, May 1986.

10
11 * This model has been modified for use in the documentation

The default header of the GAMS listing file is General Algebraic Modeling System. This may be replaced using the $title at the start of a line. The text on that line will be the new header, as demonstrated above. After the header the compilation output is announced with the title Compilation.

The first three line numbers refer to empty lines in the input and line 11 is a comment line. If the lines on the input file are counted, it can be seen that this comment line appears after ten lines of dollar directives, comments and empty lines.

The dollar control options that follow in the model are used to display more information in the output file than the default and will be discussed in the subsections below.

Note

By default, dollar control option lines are not listed in the echo print. The $onDollar and $offDollar controls the echoing of Dollar Control Options lines in the listing file. Dollar control option lines are also listed if they contain errors.

The block comment enclosed by $onText and $offText is listed without line numbers, while single line comments starting with asterisks (*) are listed with the respective line numbers. Observe that line numbers always refer to the physical line number in the input file. The remainder of the echo print follows:
Set i securities /hardware, software, show-biz, t-bills/;
alias (i,j);
Scalar target mean annual return on portfolio % /10/,
lowyield yield of lowest yielding security,
highrisk variance of highest security risk ;

Lines in the echo print can be set to double space using $double and then reset to single space with $single. If errors were detected, the explanatory messages would be found at the end of the echo print. All discussions of error messages have been grouped together in the section Error Reporting below.

3.39.3.2 The Symbol Reference Map

The other parts of the compilation outputs are maps. They are extremely useful for users looking at a model written by someone else or trying to make changes in their own model after spending some time away from it. By default all maps are suppressed and can be turned on with dollar control options that are specified below.

The first map is the symbol cross reference. It can be turned on with the dollar control option $onSymXRef at the beginning of the program. The symbol cross reference map lists all identifiers (symbols) from the model in alphabetical order, identifies them as to data type, shows the line numbers where the symbols appear and classifies each appearance. The map that was generated as part of the output of our Illustrative Model is shown below:
Symbol Listing

<table>

<td>model</td>
</tr>
<tr>
<td>PARAM</td>
<td>parameter</td>
</tr>
<tr>
<td>SET</td>
<td>set</td>
</tr>
<tr>
<td>VAR</td>
<td>variable</td>
</tr>
</tbody>
</table>

For further details on data types in GAMS, see section Data Types and Definitions.

The symbol \textit{highrisk} was declared as a \textit{scalar}, but is listed as a \textit{parameter} in the map above. Recall that \textit{parameters}, \textit{scalars}, and \textit{tables} are three \textit{input formats} for the data type \textit{parameter}. For more information, see the overview Parameters, Scalars and Tables.

After the name and type of the identifier, a list of references to the symbol is given. References are grouped by reference type and identified by the line number in the output file. The actual reference can be found by referring to the echo print of the program, which has line numbers on it. In the case of the symbol \( x \) in the example above, the list of references as shown in the symbol reference map are as follows:

| declared | 37 |
| impl-asn | 50 |
| ref      | 39 45 46 2*47 51 |

This means that \( x \) is declared on line 37, implicitly assigned through a solve statement on line 50 and referenced on lines 39, 45, 46, 47, and 51. The entry 2*47 means that there are two references to \( x \) on line 47 of the input file.

The complete list of reference types and their shorthand symbols in GAMS Output is given below:
<table>
<thead>
<tr>
<th>Shorthand Symbol</th>
<th>Reference Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>declared</td>
<td>Declaration</td>
<td>The identifier is declared as to type. This must be the first appearance of the identifier.</td>
</tr>
<tr>
<td>defined</td>
<td>Definition</td>
<td>An initialization (for a table or a data list between slashes) or symbolic definition (for an equation) starts for the identifier.</td>
</tr>
<tr>
<td>assigned</td>
<td>Assignment</td>
<td>Values are replaced because the identifier appears on the left-hand side of an assignment statement.</td>
</tr>
<tr>
<td>impl-asn</td>
<td>Implicit Assignment</td>
<td>An equation or variable will be updated as a result of being referred to implicitly in a solve statement.</td>
</tr>
<tr>
<td>control</td>
<td>Control</td>
<td>A set is used as (part of) the driving index in an assignment, equation, loop or indexed operation.</td>
</tr>
<tr>
<td>ref</td>
<td>Reference</td>
<td>The symbol has been referenced on the right-hand side of an assignment or in a display, equation, model, solve statement or put statement.</td>
</tr>
<tr>
<td>index</td>
<td>Index</td>
<td>Like control, but used only for set labels. Appears only in the cross reference map of unique elements. See section The Unique Element Listing Map for details.</td>
</tr>
</tbody>
</table>

Note that the symbol reference map may be useful in model development, documentation preparation, and to make sure that all declared items are actually used in the model (by checking that they all have reference symbols in addition to declared and defined).

3.39.3.3 The Symbol Listing Map

The second optional map is the symbol listing. In the symbol listing map all identifiers are grouped alphabetically by data type and listed with their explanatory texts. This is another very useful aid for trying to understand a large model prepared by someone else. Note that expressive explanatory text is particularly helpful here. The symbol listing map can be turned on by entering a line containing the dollar control option $onSymList at the beginning of the program. The symbol listing map generated from our illustrative model follows:

SETS

i securities
j Aliased with i

PARAMETERS

highrisk variance of highest security risk
lowyield yield of lowest yielding security
mean mean annual returns on individual securities (%)
target target mean annual return on portfolio %
v variance-covariance array (%-squared annual return)

VARIABLES

variance variance of portfolio
x fraction of portfolio invested in asset i

EQUATIONS

dmean definition of mean return on portfolio
dvar definition of variance
fsum fractions must add to 1.0

MODELS
portfolio

3.39.3.4 The Unique Element Listing Map

The last optional map is the Unique Element Listing (UEL). The unique element listing map can be turned on by entering a line containing the dollar control option $onUELList at the beginning of the program. All unique elements are first grouped in entry order and then in sorted order with their explanatory texts:

Unique Element Listing

Unique Elements in Entry Order
1 hardware software show-biz t-bills

Unique Elements in Sorted Order
1 hardware show-biz software t-bills

In addition, a map with references for every label is given if the dollar control option $onUELXRef appears at the beginning of the program.

ELEMENT REFERENCES

<table>
<thead>
<tr>
<th>ELEMENT</th>
<th>REFERENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>hardware</td>
<td>13 ref 21 27 28</td>
</tr>
<tr>
<td>show-biz</td>
<td>13 ref 23 27 30</td>
</tr>
<tr>
<td>software</td>
<td>13 ref 22 27 29</td>
</tr>
<tr>
<td>t-bills</td>
<td>13 ref 24 27 31</td>
</tr>
</tbody>
</table>

The unique element list is important in the context of ordered sets. For details see section Ordered and Unordered Sets.

3.39.3.5 The Include File Summary

Often the GAMS program includes a text file specified by the dollar control option $include. Consider the following example:

$include 'file1.inc'
Set i / i1*i10 /;
Scalar a; a = 7;
$include 'file2.inc'

The file file1.inc contains the following two lines:
The file file2.inc contains the following line:

\[ a = a + 3; \]

The echo print follows:

```
INCLUDE C:\models\file1.inc
  2 Set j / j1*j5 /;
  3 Parameter k(j);
  4 Set i / i1*i10 /;
  5 Scalar a; a = 7;
INCLUDE C:\models\file2.inc
  7 a = a + 3;
```

Note that the contents of the two include files are expanded in the echo print and the include file names and their path is echoed in the lines with the dollar control option `$include`. If we insert the dollar control option `$offinclude` in the first line of the code, the echo print will not include the lines with the names of the include files any more, but the contents will still be echoed:

```
#include C:\models\file1.inc
  2 Set j / j1*j5 /;
  3 Parameter k(j);
  4 Set i / i1*i10 /;
  5 Scalar a; a = 7;
#include C:\models\file2.inc
  7 a = a + 3;
```

If the program contains include files, there will be an Include File Summary at the end of the compilation output. The include file summary of the simple example above (without the line `$offinclude`) follows:

```
Include File Summary

<table>
<thead>
<tr>
<th>SEQ</th>
<th>GLOBAL</th>
<th>TYPE</th>
<th>PARENT</th>
<th>LOCAL</th>
<th>FILENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>INPUT</td>
<td>0</td>
<td>0</td>
<td>C:\models\test.gms</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>INCLUDE</td>
<td>1</td>
<td>1</td>
<td>.C:\models\file1.inc</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>INCLUDE</td>
<td>1</td>
<td>4</td>
<td>.C:\models\file2.inc</td>
</tr>
</tbody>
</table>
```

In the first column the sequence number of the input files is given. Note that the parent file called by the GAMS call is always listed first. The second column gives the global (expanded) line number which contains the respective option `include` or one of its variants. The third column indicates the type of the respective file. An overview of the file types is given below:

<table>
<thead>
<tr>
<th>File Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INPUT</td>
<td>The GAMS input file that was called with the GAMS call.</td>
</tr>
<tr>
<td>INCLUDE</td>
<td>A file that was inserted with the dollar command option <code>$include</code>.</td>
</tr>
<tr>
<td>BATINCLUDE</td>
<td>A file that was inserted with the dollar command option <code>$batinclude</code>.</td>
</tr>
<tr>
<td>LIBINCLUDE</td>
<td>A file that was inserted with the dollar command option <code>$libinclude</code>.</td>
</tr>
<tr>
<td>SYSINCLUDE</td>
<td>A file that was inserted with the dollar command option <code>$sysinclude</code>.</td>
</tr>
</tbody>
</table>
3.39 GAMS Output

The next column, named PARENT, provides the sequence number of the respective parent file. The column with the header LOCAL gives the local line number in the parent file where the file was included. The last column shows the path and the name of the respective file.

Note that compilation error messages in include files have additional information about the name of the include file and the local line number. For information on compilation errors, see section Compilation Errors below.

3.39.4 Execution Output

The execution output follows the compilation output in the GAMS listing file. It is introduced with the title Execution. The execution output is the output generated while GAMS is performing data manipulations and results from display statements. The output from the display statement on line 33 of our Illustrative Model is shown below.

Execution

---- 33 PARAMETER lowyield = 7.000 yield of lowest yielding security
PARAMETER highrisk = 10.000 variance of highest security risk

If errors are detected because of illegal data operations, a brief message indicating the cause and the line number of the offending statement will appear. For further information on execution errors, see section Execution Errors below.

Note

In case there is no display statement before The Solve Statement in the model and there are no execution errors, there will be no execution output in the GAMS listing file.

3.39.5 Model Generation Output

The model generation output, the solution report, and the post-solution Output are produced when a solve statement is executed. The actions that are initiated by a solve statement are presented in section Actions Triggered by the Solve Statement. All output generated as a result of a solve is labeled with a subtitle identifying the model, its type and the line number of the solve statement.

The output generated during model generation includes equations listing, variable listing, and model statistics.

3.39.5.1 The Equation Listing

The equation listing is the first part of the output generated by a solve statement. It is marked with the subtitle Equation Listing. By default, the first three equations in every block are listed. This can be modified with the option limrow. If there are three or fewer single equations in any equation block, then all the single equations are listed.

Note that by studying the equation listing the user may determine whether the model generated by GAMS is the the model that the user has intended - an extremely important question. This component of the output shows the specific equations generated within the model when the current values of the sets and parameters are plugged into the general algebraic form of the model.

The equation listing from our Illustrative Model is given below. In our case we have three equation blocks, each producing one single equation.
A Quadratic Programming Model for Portfolio Analysis (ALAN, SEQ=124a)

Equation Listing

SOLVE portfolio Using NLP From line 50

---- fsum =E= fractions must add to 1.0

fsum.. x(hardware) + x(software) + x(show-biz) + x(t-bills) =E= 1 ; (LHS = 0, INFES = 1 ****)

---- dmean =E= definition of mean return on portfolio

dmean.. 8*x(hardware) + 9*x(software) + 12*x(show-biz) + 7*x(t-bills) =E= 10 ; (LHS = 0, INFES = 10 ****)

---- dvar =E= definition of variance

dvar.. (0)*x(hardware) + (0)*x(software) + (0)*x(show-biz) - variance =E= 0 ; (LHS = 0)

Note

The equation listing is an extremely useful debugging aid. It shows the variables that appear in each constraint. In addition, it shows what the individual coefficients and right-hand side values evaluate to after the data manipulations have been done.

Each equation block is marked with four dashes which are useful for mechanical searching. The name, type of equation and explanatory text is shown, followed by the individual equations.

Note

All the terms that depend on variables are collected on the left-hand side and all the constant terms are combined into one number on the right-hand side, any necessary sign changes being made.

Four places of decimals are shown if necessary, but trailing zeroes following the decimal point are suppressed. E-format is used to prevent small numbers to be displayed as zeros.

Note

Nonlinear equations are treated differently. If the coefficient of a variable in the equation listing is enclosed in parentheses, then the corresponding constraint is nonlinear, and the value of the coefficient depends on the activity levels of one or more of the variables. The listing is not algebraic, but shows the partial derivative of each variable evaluated at their current level values.

Note that in the equation listing from our example the equation dvar is nonlinear. A simpler example will help to clarify the point. Consider the following equation and associated level values.

eq1.. 2*sqr(x)*power(y,3) + 5*x - 1.5/y =e= 2; x.l = 2; y.l = 3 ;

This equation will appear in the equation listing as:

eq1.. (221)*x + (216.1667)*y =E= 2 ; (LHS = 225.5 ****)
The coefficient of $x$ is determined by first differentiating the equation above with respect to $x$. This results in $2 \times (2 \times x.l) \times (y.l)^3 + 5$, which evaluates to 221, given that $x.l$ equals 2 and $y.l$ equals 3. Similarly, the coefficient of $y$ is obtained by differentiating the equation above with respect to $y$, which results in $2 \times (x.l)^2 \times 3 \times (y.l)^2 + \frac{1}{(y.l)^2}$, giving 216.1667. Observe that the coefficient of $y$ could not have been determined if its level had been left at zero. The attempted division by zero would have produced an error and premature termination. For further information on modeling NLP problems with GAMS, see the tutorial Good NLP Formulations.

The result of evaluating the left-hand side of the equation at the initial point is shown at the end of each individual equation listing. In the example above it is 225.5, and the three asterisks(∗∗∗) are a warning that the constraint is infeasible at the starting point.

Note

The order in which the equations are listed depends on how the model was defined. If it was defined with a list of equation names, then the listing will be in the order of that list. If it was defined as /all/, then the list will be in the order of declaration of the equations. The order of the entries for the individual constraints is determined by the label entry order.

3.39.5.2 The Column Listing

The column listing or variable listing is the next part of the output. It is marked with the title Column Listing and contains a list of the individual coefficients sorted by column rather than by row (like in the equation listing). By default the first three entries for each variable are shown, along with their lower bound .lo, upper bound .up and current level values .l. Note that the default number of entries shown may be modified with the option limcol.

The format for the coefficients is exactly as in the equation listing, with the nonlinear coefficients enclosed in parentheses and the trailing zeroes dropped. The column listing from our Illustrative Model follows.

\]

**Note**

The order in which the variables appear is the order in which they were declared.

#### 3.39.5.3 The Model Statistics

The final information generated while a model is being prepared for solution is the statistics block. It is marked with the title *Model Statistics*. Its most obvious use is to provide details on the size and nonlinearity of the model. The model statistics of our *Illustrative Model* follow:

```plaintext
A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Model Statistics SOLVE portfolio Using NLP From line 50

MODEL STATISTICS

BLOCKS OF EQUATIONS 3 SINGLE EQUATIONS 3
BLOCKS OF VARIABLES 2 SINGLE VARIABLES 5
NON ZERO ELEMENTS 12 NON LINEAR N-Z 3
DERIVATIVE POOL 20 CONSTANT POOL 17
CODE LENGTH 25

GENERATION TIME = 0.004 SECONDS 4 MB
EXECUTION TIME = 0.005 SECONDS 4 MB
```

The *BLOCK* counts refer to GAMS *equations* and *variables*, the *SINGLE* counts to individual rows and columns in the problem generated. The *NON ZERO ELEMENTS* entry refers to the number of nonzero coefficients in the problem matrix.

There are four entries that provide additional information about nonlinear models. The *NON LINEAR N-Z* entry refers to the number of nonlinear matrix entries in the model. Nonlinear models may differ in the level of complexity. For example, \(x \times y\) is a simpler form of nonlinearity than \(\exp(x \times y)\). Even though both these terms count as 1 nonlinear entry in the matrix, additional information is required to provide the user with a feel for the complexity of the nonlinearity. GAMS provides the *CODE LENGTH* entry as a good yardstick for this purpose. There are two other entries - *DERIVATIVE POOL* and *CONSTANT POOL* - that provide some more information about the nonlinearity. In general, the more nonlinear a problem is, the more difficult it is to solve.

The times that follow statistics are also useful. The *GENERATION TIME* is the time used since compilation (syntax check) is finished. This includes the time spent in generating the model. The measurement units are given and represent ordinary clock time on personal computers or central processor usage (CPU) time on other machines. Memory use is given in megabytes.
3.39.6 The Solution Report

The solution report is the next part of the output. It is marked with the title Solution Report and includes the solve summary, the solver report, the solution listing, and the report summary.

3.39.6.1 The Solve Summary

The solve summary contains details about the solution process and is marked with the title SOLVE SUMMARY. The first part of the solve summary is common to all solvers and is discussed in this subsection. The second part of the solve summary is solver specific, it is covered in the subsection Solver Report below. The first part of the solve summary for our Illustrative Model follows.

A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Solution Report SOLVE portfolio Using NLP From line 50

**SOLVE SUMMARY**

<table>
<thead>
<tr>
<th>MODEL</th>
<th>portfolio</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE</td>
<td>NLP</td>
</tr>
<tr>
<td>SOLVER</td>
<td>MINOS</td>
</tr>
<tr>
<td>OBJECTIVE</td>
<td>variance</td>
</tr>
<tr>
<td>DIRECTION</td>
<td>MINIMIZE</td>
</tr>
<tr>
<td>FROM LINE</td>
<td>50</td>
</tr>
</tbody>
</table>

**** SOLVER STATUS 1 Normal Completion
**** MODEL STATUS 2 Locally Optimal
**** OBJECTIVE VALUE 2.8990

RESOURCE USAGE, LIMIT 0.188 1000.000
ITERATION COUNT, LIMIT 5 2000000000
EVALUATION ERRORS 0 0

The entry MODEL contains the name of the model being solved, TYPE provides the model type of the model, SOLVER shows the name of the solver used to solve the model, OBJECTIVE gives the name of the objective variable being optimized, DIRECTION shows the direction of optimization being performed and the entry FROM LINE provides the line number of the solve statement the solve summary refers to.

Note that the four asterisks make it easy to find the solve summary if it is searched for mechanically.

The entries SOLVER STATUS and MODEL STATUS contain the solver and model status for the problem respectively. Their possible values are given in Model Status table and Solver Status tables below. The entry OBJECTIVE VALUE provides the value of the objective function at the termination of the solve. This value is the optimum value for the problem provided the solver and model have the right status.

The entry RESOURCE USAGE, LIMIT reports the amount of wall clock time (in seconds) taken by the solver and the upper limit allowed for the solver. Note that the solver will stop as soon as the limit on time usage has been reached. The default limit may be changed with the option reslim. Observe that the option statement option reslim = x; - where x is the desired limit in wall clock seconds - must be entered in the model before the solve statement.

The entry ITERATION COUNT, LIMIT provides the number of iterations used by the solver and the upper limit allowed for the solver. The solver will stop as soon as this limit is reached. The default limit on iterations used is practically infinity. This limit may be changed with the option iterlim. Observe that the option statement option iterlim = n; - where n is the desired limit of the iterations used - must be entered in the model before the solve statement.

Finally, the entry EVALUATION ERRORS reports the number of numerical errors encountered by the solver and the upper limit allowed for the solver. These errors result from numerical problems like division by zero. Note that this is suppressed for LP, RMIP and MIP models since evaluation errors are not applicable for these model types. The default limit on evaluation errors used is zero. This limit may be changed with the option domlim. Observe that the option statement option domlim = n; - where n is the desired limit of the evaluation errors allowed - must be entered in the model before the solve statement.

</tr>
</tbody>
</table>
### Model Status
Note that the model status is stored in the model attribute `modelStat`. For details on model attributes, see section Model Attributes. Observe that there are compile-time constants that are related to this model attribute.

#### Model Status

<table>
<thead>
<tr>
<th>Value</th>
<th>Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>NORMAL COMPLETION</td>
<td>The solver terminated in a normal way: it was not interrupted by a limit (resource, iterations, nodes or other) or by internal difficulties. The model status describes the characteristics of the accompanying solution.</td>
</tr>
<tr>
<td>2</td>
<td>ITERATION INTERRUPT</td>
<td>The solver was interrupted because it used too many iterations. The option <code>iterlim</code> may be used to increase the iteration limit if everything seems normal.</td>
</tr>
<tr>
<td>3</td>
<td>RESOURCE INTERRUPT</td>
<td>The solver was interrupted because it used too much time. The option <code>reslim</code> may be used to increase the time limit if everything seems normal.</td>
</tr>
<tr>
<td>4</td>
<td>TERMINATED BY Solver</td>
<td>The solver encountered some difficulty and was unable to continue. More details will appear following the message.</td>
</tr>
<tr>
<td>5</td>
<td>EVALUATION INTERRUPT</td>
<td>Too many evaluations of nonlinear terms at undefined values. We recommend to use variable bounds to prevent forbidden operations, such as division by zero. The rows in which the errors occur are listed just before the solution.</td>
</tr>
<tr>
<td>6</td>
<td>CAPABILITY PROBLEMS</td>
<td>The solver does not have the capability required by the model. For example, some solvers do not support certain types of discrete variables or support a more limited set of functions than other solvers.</td>
</tr>
<tr>
<td>7</td>
<td>LICENSING PROBLEMS</td>
<td>The solver cannot find the appropriate license key needed to use a specific subsolver.</td>
</tr>
<tr>
<td>8</td>
<td>USER INTERRUPT</td>
<td>The user has sent a message to interrupt the solver via the interrupt button in the IDE or sending a Control+C from a command line.</td>
</tr>
<tr>
<td>9</td>
<td>ERROR SETUP FAILURE</td>
<td>The solver encountered a fatal failure during problem set-up time.</td>
</tr>
<tr>
<td>10</td>
<td>ERROR SOLVER FAILURE</td>
<td>The solver encountered a fatal error.</td>
</tr>
</tbody>
</table>

### Solver Status

- **ERROR INTERNAL SOLVER FAILURE**: The solver encountered an internal fatal error.
- **SOLVE PROCESSING SKIPPED**: The entire solve step has been skipped. This happens if execution errors were encountered and the GAMS parameter `ExecErr` has been set to a nonzero value or the property `MaxExecError` has a nonzero value.
- **ERROR SYSTEM FAILURE**: This indicates a completely unknown or unexpected error condition.
Note that the solver status is stored in the model attribute `solveStat`. For details on model attributes, see section Model Attributes. Observe that there are compile-time constants that are related to this model attribute.

### 3.39.6.2 Solver Report

The next section in the listing file is the part of the solve summary that is particular to the solver program that has been used. This section normally begins with a message identifying the solver and its authors: MINOS and QUADMINOS was used in the example here. There will also be diagnostic messages in plain language if anything unusual was detected and specific performance details, some of them probably technical. The solver manual of the respective solver will help explain these. In case of serious trouble, the GAMS listing file will contain additional messages printed by the solver. This may help identify the cause of the difficulty. If the solver messages do not help, a perusal of the solver documentation or help from a more experienced user is recommended. The solver report from our Illustrative Model follows.

```
GAMS/MINOS
MINOS 5.6 (Nov 2014)

GAMS/MINOS 5.6, Large Scale Nonlinear Solver
B. A. Murtagh, University of New South Wales
P. E. Gill, University of California at San Diego,
W. Murray, M. A. Saunders, and M. H. Wright,
Systems Optimization Laboratory, Stanford University

Work space allocated -- 0.77 Mb

EXIT - Optimal Solution found, objective: 2.899038
```

Note that the line `Work space allocated -- 0.77 MB` provides the amount of memory used by the solver for the problem. The solver estimates the amount of memory it will need to solve the problem. If this amount is not available on the machine used, GAMS will return a message saying that not enough memory was allocated. In addition, GAMS will return the maximum amount of memory available on the machine. The user may direct the solver to use less memory with the model attribute `.workspace`:

```
mymodel.workspace = x;
```

Here `mymodel` is the name of the model being solved as specified by the model statement and `x` is the amount of memory in Megabytes. Note that the solver will attempt to solve the problem with `x` MB of memory. However, it is not guaranteed to succeed since the problem may require more memory.

Note that more information for a successful run may be obtained using the option `sysout`. As usual, the respective option statement should be placed before the solve statement.

### 3.39.6.3 The Solution Listing

The solution listing is a row-by-row then column-by-column listing of the solutions returned to GAMS by the solver program. Each individual equation and variable is listed with four pieces of information. The solution listing may be suppressed with the option `solprint`:

```
option solprint = off ;
```
This option statement should be placed before the solve statement. The solution listing generated from our Illustrative Model is shown below.

</tr>
</tbody>
</table>

The order of the equations and variables is the same as in the symbol listing map.

The four columns associated with each entry correspond to the equation and variable attributes and have the following meaning:

- **LOWER** lower bound (.lo)
- **LEVEL** level value (.l)
- **UPPER** upper bound (.up)
- **MARGINAL** marginal (.m)

For variables, the values in the **LOWER** and **UPPER** columns refer to the lower and upper bounds. For equations, they are obtained from the (constant) right-hand side value and from the relational type of the equation. For details see section Variable Attributes and Equation Attributes. Note that instead of level values, slack values may be shown in equations. For more information, see section Customizing the Output File below.

Note

The **LEVEL** and **MARGINAL** values have been determined by the solver and the values shown are used to update the GAMS values. In the list they are shown with fixed precision, but the values are returned to GAMS with full machine accuracy. The single dots '.' on the list represent zeros.

**EPS** is the GAMS extended value used for a stored zero. It is common to see a marginal value given as **EPS**, since GAMS uses the convention that marginals are necessarily zero for basic variables and typically non-zero for other variables.
Note

EPS is used to indicate non-basic variables whose marginal values are at or close to zero, and for nonlinear problems to indicate superbasic variables whose marginals are at or close to zero. A superbasic variable is one between its bounds at the final point but not in the basis.

Note that in the Glossary there are brief explanations of technical terms that were used in this section.

For models that are not solved to optimality or for models types without an objective, some constraints may additionally be marked with certain flags. The list of these flags and their description is given in the following table.

<table>
<thead>
<tr>
<th>Shorthand Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INFES</td>
<td>The row or column is <strong>infeasible</strong>. This mark is made for any entry where the level value is not between the upper and lower bounds.</td>
</tr>
<tr>
<td>NOPT</td>
<td>The row or column is <strong>non-optimal</strong>. This mark is made for any non-basic entries for which the marginal sign is incorrect, or superbasic ones for which the marginal value is too large.</td>
</tr>
<tr>
<td>UNBND</td>
<td>The row or column can increase without limit (e.g. in an unbounded ray) or has an excessively large magnitude.</td>
</tr>
<tr>
<td>REDEF</td>
<td>The equation type has been ignored or redefined for this solution point, e.g. because this is an MCP</td>
</tr>
<tr>
<td>REDIR</td>
<td>The equation has been flipped (i.e. negated or reoriented) in the model statement: useful for MCP and EMP</td>
</tr>
<tr>
<td>DEPND</td>
<td>The row or column is dependent on other rows or columns in the system: see CNS</td>
</tr>
</tbody>
</table>

### 3.39.6.4 Report Summary

The final section of the solution report is the report summary, marked with four asterisks (as are all important components of the output) followed by the title REPORT SUMMARY. It shows the count of rows or columns that have been marked INFES, NOPT or UNBND in the solution listing. For model types like MCP where REDEFs and REDIRs are possible, the counts for these markers may also be shown. The sum of infeasibilities will be shown if the reported solution is infeasible. The domain error count is only shown if the problem is nonlinear. If there are variables or equations where the levels were projected to one of the bounds, the count of those is also shown here.

A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a) Solution Report SOLVE portfolio Using NLP From line 50

```
**** REPORT SUMMARY : 0 NONOPT 0 INFEASIBLE 0 UNBOUNDED 0 ERRORS 42 PROJECTED
```

### 3.39.7 Post-Solution Output

The final part of the listing file is the post-solution output. It contains Final Execution Summary and the File Summary.
3.39.7.1 Final Execution Summary

The final execution summary is marked with the title Execution and contains the output from display statements that were placed after the solve statement in the model, allowing simple reporting. In addition, it shows the final execution time and memory use. The respective output from our Illustrive Model follows.

A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)

Execution

----  51 VARIABLE x.L  fraction of portfolio invested in asset i
     hardware 0.303,  software 0.087, show-biz 0.505,  t-bills 0.106

----  51 VARIABLE variance.L   =     2.899 variance of portfolio

EXECUTION TIME   =     0.001 SECONDS 3 MB

For further information on this output and ways to customize it, see chapter The Display Statement.

3.39.7.2 File Summary

The file summary is the very last part of the output file. If output has been written to put files, there will be a REPORT FILE SUMMARY that is marked with four asterisks. The report will list the put files with their internal names and the full paths of their external names.

All listing files have a FILE SUMMARY that is marked with four asterisks and that reports the names of the input and output (listing) files.

**** FILE SUMMARY

Input   C:\PROGRAM FILES\gamsIDE\ALAN.GMS
Output  C:\PROGRAM FILES\gamsIDE\ALAN.LST

If work files (save or restart) have been used, they will be listed in the file summary as well.

3.39.8 Error Reporting

All comments and descriptions about errors have been collected in this section for easy reference when disaster strikes.

Effective error detection and recovery are important parts of any modeling system. GAMS is designed around the assumption that the error state is the normal state of modeling. Experience shows that most compilations during the early stages of development will produce errors. Not to worry! The computer is much better at checking details than the human mind and should be able to provide positive feedback and suggestions about how to correct errors or avoid ambiguities. Developing a model is like writing a paper or an essay; many drafts and rewrites are required until the arguments are presented in the most effective way and meet all the requirements of proper English. GAMS acts like a personal assistant with knowledge of mathematical modeling and of the syntactic and semantic details of the language.
Errors are detected at various stages in the modeling process. Most of them are caught at the compilation stage, which behaves like the proofreading stage of the modeling process. Once a problem has passed through the rigorous test of this stage, the error rate drops to almost zero. Most of the execution runs, which are much more expensive than compilation, proceed without difficulties because GAMS knows about modeling and has anticipated problems. Many of the typical errors made with conventional programming languages are associated with concepts that do not exist in GAMS. Those error sources – like address calculations, storage assignment, subroutine linkages, input-output and flow control – create problems at execution time, are difficult to locate, often lead to long and frustrating searches, and leave the computer user intimidated. GAMS takes a radically different approach. Errors are spotted as early as possible, they are reported in a way that is comprehensible to the user, including clear suggestions for how to correct the problem and a presentation of the source of the error in terms of the problem of the user.

Note

All errors are marked with four asterisks '****' at the beginning of a line in the output listing.

As soon as an error is detected, processing will be stopped at the next convenient opportunity. A model will never be solved after an error has been detected. The only remedy is to fix the error and repeat the run.

Errors are grouped into the three phases of GAMS modeling: compilation, execution and model generation (which includes the solution that follows). In the following subsections we will discuss the errors that may occur in each of these phases.

3.39.8.1 Compilation Errors

Compilation errors are discussed in some detail in the tutorial A GAMS Tutorial by Richard E. Rosenthal and the tutorial Fixing Compilation Errors. Note that there is some overlap between the material in the tutorials and this section. Several hundred different types of errors can be detected during compilation and can often be traced back to just one specific symbol in the GAMS input. Most of the errors are caused by simple mistakes: forgetting to declare an identifier, putting indices in the wrong order, leaving out a necessary semicolon or misspelling a label. For errors that are not caused by such simple mistakes, the explanatory error message text will help diagnose the problem and correct it.

Note

When a compilation error is discovered, a dollar symbol and error number are printed below the offending symbol (usually to the right) on a separate line that begins with four asterisks.

If more than one error is encountered on a line (possibly because the first error caused a series of other spurious errors) the dollar signs may be suppressed and error number squeezed. GAMS will not list more than 10 errors on any one line.

Note

A list of all error numbers encountered and a description of the probable cause of each error is printed at the end of the echo print of the program. The error messages are self-explanatory. For further information on compilation errors and advice on how to resolve them, see the tutorial Fixing Compilation Errors.

It is worth noting that it is easy to produce a model that does not do what you want it to do, but does not contain errors in the sense that the term is being used in this section. The best precaution is to check your work carefully and build in as many automatic consistency checks as possible.

Note that if a GAMS reserved word is accidentally used for the name of a label or an identifier it is impossible to provide helpful error messages for technical reasons. This may cause confusion. We recommend users to familiarize themselves with the reserved words.
Attention

In some cases an error may not be detected until the statement following its occurrence, where it may produce a number of error conditions whose explanations seem quite silly. We recommend to always check carefully for the cause of the first error in such a group. If nothing obvious is wrong, look at the previous statement and particularly watch out for missing semicolons.

The following example illustrates the general reporting format for compilation errors.

```
1 Set c crops / wheat, corn, wheat, longaname /
   **** $172
2 Parameter price(c) / wheat 200, cotton 700 /
   **** $170
3 Error Messages
170 Domain violation for element
172 Element is redefined

**** 2 ERROR(S) 0 WARNING(S)

**** USER ERROR(S) ENCOUNTERED
```

3.39.8.2 Compilation Time Errors

The reporting format for errors found while analyzing solve statements is more complicated than for normal compilation errors, mainly because many things must be checked. All identifiers referenced must be defined or assigned, the mathematics in the equations must match the model class, and so on. More elaborate reporting is required to accurately describe any problems found. The solve statement is only checked if the model has been found to be error free up to this point. This is not only because the check is comparatively expensive, but also because many erroneous and confusing messages can be produced while checking a solve in a program containing other errors.

Attention

Compiler error messages related to a solve statement are reported in two places and in two formats:

1. They are shown immediately after the solve statement with a short text including the name of any offending identifier and the type of model involved. This will be sufficient in most cases.

2. A longer message with some hints appears with the other error messages at the end of the compilation.

The example below illustrates the general reporting format for compiler errors associated with a solve statement.

```
1 Variables x, y, z ;
2 Equations eq1, eq2 ;
3
4 eq1.. x**2 - y =e= z ;
5 eq2.. min(x,y) =l= 20 ;
6
7 Model silly / all / ;
8 solve silly using lp maximizing z ;
   **** $54,51,256
```
**** THE FOLLOWING LP ERRORS WERE DETECTED IN MODEL SILLY:
**** 54 IN EQUATION EQ1 . ENDG OPERANDS FOR **
**** 51 IN EQUATION EQ2 . ENDG ARGUMENT(S) IN FUNCTION

Error Messages

51 Endogenous function argument(s) not allowed in linear models
54 Endogenous operands for ** not allowed in linear models
256 Error(s) in analyzing solve statement. More detail appears
   Below the solve statement above

**** 3 ERROR(S) 0 WARNING(S)
**** USER ERROR(S) ENCOUNTERED

3.39.8.3 Execution Errors

Execution time errors are usually caused by illegal arithmetic operations such as division by zero or taking
the log of a negative number. GAMS prints a message on the output file with the line number of the
offending statement and continues execution. A GAMS program should never abort with an unintelligible
message from the computer's operating system if an invalid operation is attempted. GAMS has rigorously
defined an extended algebra that contains all operations including illegal ones. Note that the model
[CRAZY] contains all non-standard operations and should be executed to study for its exceptions. For
advice on detecting and resolving execution errors, see the tutorial Finding and Fixing Execution Errors
and Performance Problems.

Recall that the GAMS arithmetic is defined over the closed interval [-INF, +INF] and contains the extended
range arithmetic values EPS (small but not zero), NA (not available) and UNDF (the result of an illegal
operation). The results of illegal operations are propagated through the entire system and can be displayed
with standard display statements. However, observe that, if errors have been previously detected, a model
cannot be solved and a work file cannot be saved.

3.39.8.4 Solve Errors

The execution of a solve statement can trigger additional errors called matrix errors. They report on
problems encountered during transformation of the model into a format required by the solver. Problems
are most often caused by illegal or inconsistent bounds, or by an extended range value that is used as a
matrix coefficient. The example below shows the general format of these errors:

1 Variable x;
2 Equation eq1;
3
4 eq1.. x =l= 10 ;
5 x.lo = 10 ;
6 x.up = 5 ;
7 Model wrong /eq1/;
8 solve wrong using lp maximizing x ;
9
**** Matrix error - lower bound > upper bound
x (.LO, .L, .UP = 10, 0, 5)
...
**** SOLVE from line 8 ABORTED, EXECERROR = 1
...
**** USER ERROR(S) ENCOUNTERED
Some solve statements require the evaluation of nonlinear functions and the computation of derivatives. Since these calculations are not carried out by GAMS but by other subsystems not under the direct control of GAMS, errors associated with these calculations are reported in the solution report. Note that by default the subsystems will interrupt the solution process if arithmetic exceptions are encountered. This may be changed with the option domlim. They are then reported on the listing as shown in the following example:

```gams
1 Variable x, y;
2 Equation one;
3
4 one.. y =e= sqrt(10/x);
5 x.l = 10;
6 x.lo = 0;
7
8 Model divide / all /;
9 solve divide maximizing y using nlp;
```

**SOLVE SUMMARY**

MODEL divide

SOLVER MINOS FROM LINE 9

**** SOLVER STATUS 5 Evaluation Interrupt
**** MODEL STATUS 7 Feasible Solution
**** OBJECTIVE VALUE 3.1622776602E+0149

RESOURCE USAGE, LIMIT 0.182 1000.000
ITERATION COUNT, LIMIT 0 2000000000
EVALUATION ERRORS 2 0

EXIT - Function evaluation error limit exceeded.

**** ERRORS/WARNINGS IN EQUATION one
  2 error(s): div: FUNC SINGULAR: x/y, |y| <= 1e-150 (RETURNED 1E299)

**** REPORT SUMMARY :

1 NONOPT ( NOPT)
0 INFEASIBLE
0 UNBOUNDED
1 ERRORS ( ****)

Note that the solver status returned with a value of 5, meaning that the solver has been interrupted because more than domlim evaluation errors have been encountered. The type of evaluation error and the equation causing the error are also reported.

In case the solver returns an intermediate feasible solution because of evaluation errors, the following solve will still be attempted. The only fatal GAMS error that can be caused by a solver program, is the failure to return any solution at all. If this happens all possible information is listed on the GAMS output file and any solves that follow will not be attempted.

### 3.39.9 Customizing the Output File

This section reviews the most commonly used dollar control options, options, and command line parameters to customize output in the listing file. Table 1 lists dollar control options, options, and command line parameters that are used in the input file to control the amount of detail in the output file produced by the
GAMS compiler. Table 2 lists dollar control options and command line parameters that can change the layout and appearance of the output. The first column of the two tables shows the purpose of customizing the output that differs from the GAMS default behavior.

The output generated by display statements can also be customized. This topic is covered in section Display Controls from chapter The Display Statement. See also the complete list of dollar control options that affect the output format in section Dollar Control Options Affecting the Output Format.

3.40 The GAMS Call and Command Line Parameters

There are multiple ways to trigger the run of a GAMS model: Running a model via F9 from the IDE, executing `GAMSJob.Run` method in the object-oriented APIs or calling the `gams` executable from a command line. In all cases the same GAMS engine runs the user’s model. Several options are available to customize the GAMS run. Depending on the particular way GAMS is triggered these options are supplied in different ways. For example, in the IDE via the parameter field in the main window, in the object-oriented API through the GAMSOptions class, and from the command line via command line arguments. In order to avoid confusion with the often used word `option` we refer to these entities as `command line parameters` and demonstrate its with the `gams` executable from the command line. Although details will vary with the type of computer and operating system used, the general operating principles are the same on all machines.

In this chapter we will introduce how GAMS is called from the command line and how parameters may be specified on the command line or in other ways. In addition, we will discuss user-defined command line parameters, compile-time variables and compile-time constants, which are GAMS specialties, and environment variables in GAMS. Moreover, most of the chapter is dedicated to the detailed description of all GAMS options (i.e. options available via command line parameters, option statement, and model attribute).

In almost all cases such a run continues from start to end without any user interaction. A GAMS run usually consists of two phases: the compilation and execution phase.

3.40.1 The Generic GAMS Call

The simplest way to start GAMS from a command shell is to enter the following command from the system prompt:

```bash
> gams myfile
```

GAMS will compile and execute the GAMS statements in the file `myfile`. If a file with this name cannot be found, GAMS will look for a file with the extended name `myfile.gms`. During the run GAMS will print a log to the console and create a listing file that is written by default to the file `myfile.lst`. For example, the following statements retrieves and runs the model `[TRNSPORT]` from the GAMS model library with the responds from the GAMS system:

```bash
> gamslib trnsport
Copy ASCII : trnsport.gms
> gams trnsport
--- Job trnsport Start 06/21/17 06:23:45 24.8.4 r60966 WEX-WEI x86 64bit/MS Windows

Observe that some GAMS options may be specified on the command line as part of the GAMS call. In
addition, command line parameters may be set by specifying a secondary customization parameter file
and by modifying the GAMS system parameter file. As command line parameters may be specified in
several different ways, there are rules of precedence in case of conflicting instructions. We will discuss
these topics in the next four subsections.

3.40.1.1 Specifying Options Through the Command Line

GAMS permits certain options to be passed through the command line. The syntax of the simple GAMS
call is extended as follows:

> gams myfile key1=value1 key2=value2 ...

Here key1 is the name of the option that is being set on the command line and value1 is the value to
which the option is set. Depending on the option, value1 could be a character string, an integer number
or a real number. Note that the options that may be set on the command line are called GAMS command
line parameters.

For example, consider the following commands to run the transportation model [TRNSPORT]:

> gams trnsport  o myrun.lst logOption 2
> gams trnsport -o myrun.lst -logOption 2
> gams trnsport /o myrun.lst /logOption 2
> gams trnsport o=myrun.lst logOption=2
> gams trnsport -o=myrun.lst -logOption=2
> gams trnsport /o=myrun.lst /logOption=2

All six commands above are equivalent: each directs the output listing to the file myrun.lst. Note that o
is the synonym of the command line parameter output and it is set to the value myrun.lst. In addition,
the parameter LogOption is set to 2, which has the effect that the log output is redirected to the file
trnsport.log. Please also note that the option name can be specified without consideration of the
casing of the option. Hence logoption works as well as LogOption or any other casing. The way options
are specified can vary with each option. So a mixed alternative, e.g. gams trnsport -o=myrun.lst
/logoption 3 is valid too.

In addition to predefined command line parameters, GAMS also allows user-defined command line
parameters which work in tandem with compile-time variables. User-defined parameters, also called
double dash parameters, and compile-time variables are introduced in section Double Dash Parameters,
Compile-Time Variables and Environment Variables below.
3.40.1.2 Specifying Options Through a Secondary Parameter File

Command line parameters may also be set by specifying a secondary customization parameter file. For example, we will create a file with the following two lines, call it moreOptions.txt and save it in the current working directory.

```
limCol=0
limRow=0
```

Note that setting `limcol` and `limrow` to zero will suppress the column listing and equation listing respectively. Moreover, note that we can specify the option in different ways in this secondary parameter file, even have multiple options on one line. In the next step we will use the following command to run the transportation model [TRNSPORT]:

```
> gams trnsport parmFile=moreOptions.txt
```

Note that this call has the same effect as the following specification:

```
> gams trnsport limCol=0 limRow=0
```

Observe that command line parameter include files are particularly useful if modelers wish to use the same set of command line parameters repeatedly.

If options are listed multiple times on the command line, the last specification sets the option. This is important in particular in combination with a secondary parameter file. In the following example, GAMS will operate with `limRow=0`:

```
> gams trnsport limRow=10 parmFile=moreOptions.txt
```

while with the order reversed, GAMS operates with `limrow=10`:

```
> gams trnsport parmFile=moreOptions.txt limRow=10
```

3.40.1.3 Specifying Options Through the GAMS System Parameter File

A third way to specify command line parameters is by modifying the GAMS system parameter file, which is part of the GAMS system. It has different names depending on the operating system: `.gmsprmnt.txt` for Windows and `gmsprmun.txt` for UNIX/Linux and Mac OS X. The parameter file may be modified in the following way:

```
******************************************************************
* GAMS 2.50 default Unix parameter file *
* Gams Development Corp. *
* Date : 4 May, 1998 *
******************************************************************
* entries required by CMEX, put in by the gams script *
* SYSDIR *
* SCRDIR *
* SCRIPTNEXT *
* INPUT *
PageWidth 95
ParmFile "c:\some\central\location\moreOptions.txt"
```

Note that the last two lines were added to the standard GAMS system parameter file. As a consequence, each GAMS run will have a print width of 95 columns on the pages of the listing file. In addition, the command line parameters specified in the file `moreOptions.txt` will now apply to each GAMS run.
3.40.1.4 Order of Precedence for Options

The order of precedence for command line parameters including customization specifications in the GAMS IDE is as follows:

1. Command line parameters that are specified on the command line or in the IDE command line field.
2. Command line specifications in the IDE options window Execute (this is reached through File|Options|Execute).
3. Command line specifications in the specific IDE dialogs, e.g. Output (this is reached through File|Options|...).
4. Entries in the GAMS system parameter file.

Many command line parameters initialize the default for a GAMS Option also accessible inside the GAMS program. For example, the system default for option MIQCP is SBB. If the command line parameter MIQCP has been set, e.g. to DICOPT, DICOPT will be new default MIQCP solver. Inside the GAMS program, one can reset the MIQCP via option MIQCP=BonMin; but setting it back to the default will result in DICOPT (not SBB) being the default solver: option MIQCP=default.;

3.40.2 Double Dash Parameters, Compile-Time Variables and Environment Variables

In this section we will cover double-dash parameters that enable users to set values for specific variables on the command line. These variables are substituted with their respective specified values at compile time. We will also discuss how operating system specific environment variables may be accessed and modified from a GAMS program.

3.40.2.1 Double Dash Parameters and Compile-Time Variables: A Simple Example

We will introduce double dash parameters and compile-time variables using as an example the well-known transportation model [TRNSPORT]. Assume we wish to explore how the solution changes if the demand assumes various values. To model this, we will introduce the compile-time variable DMULT, a multiplier for the demand b:

\[
\$set \text{DMULT 1} \\
\ldots \\
demand(j) \ldots \text{sum}(i, \text{x}(i,j)) = \text{g= } \%\text{DMULT}\% \ast \text{b}(j) ;
\]

Note that DMULT is defined with the dollar control option $set and its value is set to 1, which corresponds to the base line. Observe that the compile-time variable is referenced in the equation with the '%...%' notation. %DMULT% will be replaced at compile time by its value, in this case 1. We are now in the position to run the program multiple times by just changing the value of DMULT in the first line, which will automatically change the multiplier in the equation to the respective value.

GAMS offers a more convenient way for setting a compile-time variable like DMULT to a variety of values:

\[
\$if not set \text{DMULT}$set \text{DMULT 1} \\
\ldots \\
demand(j) \ldots \text{sum}(i, \text{x}(i,j)) = \text{g= } \%\text{DMULT}\% \ast \text{b}(j) ;
\]
Note that we set a default value for \texttt{DMULT} using conditional compilation. We may change this default on the command line when calling GAMS by specifying \texttt{DMULT} as a double dash parameter as follows:

\begin{verbatim}
> gams trnsport.gms --DMULT=0.9
\end{verbatim}

Observe that with the specification \texttt{--DMULT=0.9} the compile-time variable \texttt{DMULT} is set and therefore the default does not apply. Thus the double dash parameter facilitates changing the value of a compile-time variable directly on the command line as part of the GAMS call while the respective GAMS file remains unchanged.

Assume that the model contains a second compile-time variable called \texttt{METHOD} that acts as a switch for various methods of solving the model and it may take the values 1, 2 and 3. In this case both compile-time variables may be set on the command line as follows:

\begin{verbatim}
> gams trnsport.gms --DMULT=1.12 --METHOD=3
\end{verbatim}

In the next two subsections we will discuss double dash parameters and compile-time variables in more detail.

### 3.40.2.2 Double Dash Parameters

Double dash parameters are user-defined command line parameters that are used to define scoped compile-time variables or to assign values to scoped compile-time variables. The general syntax is:

\begin{verbatim}
> gams myfile --NAME=value
\end{verbatim}

Here \texttt{NAME} is the name of the double dash parameter and \texttt{value} is its assigned value that may be any string. If the string contains spaces or other token terminating characters, the string value should be quoted. Consider the following simple example:

\begin{verbatim}
> gams myfile --keycity=Boston --myvalue=7.6 --dothis="display x;"
\end{verbatim}

Suppose that \texttt{myfile.gms} contains the following lines with the scoped compile-time variables \texttt{keycity}, \texttt{myvalue} and \texttt{dothis}:

\begin{verbatim}
x("%keycity%")=%myvalue%;
%dothis%
\end{verbatim}

Note that the compile-time variables are referenced using the notation \%...\%. The GAMS call above has the effect that at compile time the compile-time variables are substituted with the values specified through the double dash parameters resulting in the following:

\begin{verbatim}
x("Boston")=7.6;
display x;
\end{verbatim}

GAMS offers three alternative syntax variants for defining double dash parameters:
> gams myfile //NAME=value
> gams myfile /-NAME=value
> gams myfile --NAME=value

Note that the four syntax variants may be used interchangeably and have the same effect.

Double dash parameters are particularly useful for specifying granularity when modeling a discretization of time and or space. For example, in the model [CHAIN] the problem is to find the chain with minimal potential energy, assuming the chain has uniform density, is suspended between two points and has a given length $L$. Consider the following code snippet:

```gams
$if not set nh $set nh 50
Set nh / i0*i%nh% /
```

The first two lines use conditional compilation to set a default value for the compile-time variable `nh`. Note that the value of `nh` determines the cardinality of the set `nh`, which is used for the discretization. The value of `nh` may be easily set on the command line to any desired value using `nh` as a double dash parameter:

```gams
> gams chain --nh=100
```

Note that the double dash functionality supersedes the command line parameters `user1, ..., user5` which are accessible in the source file via `%gams.user1%, ..., %gams.user5%`. The example above would work with `user1` in the following way:

```gams
$set nh 50
$if not "%gams.user1"=="" $set nh %gams.user1%
Set nh / i0*i%nh% /
```

The modified code could be called with:

```gams
> gams chain user1=100
```

Note that the double dash parameters facilitate using meaningful names instead of the generic names `user1, ..., user5`. This is especially useful if there are multiple parameters to pass on to the GAMS program.

Observe that the dollar control option `$setDDList` may be used to ensure that a model can only be run with the listed double dash parameters:

```gams
$setDDList nh
$if not errorFree $log *** Only allowed double dash options is: --nh=value
```

### 3.40.2.3 Compile-Time Variables

Compile-time variables are special variables that are substituted with their values at compile-time. They are not declared and defined with regular declaration statements like standard symbols (sets, parameters, ...), but they are defined with the dollar control option `$set` and its variants. There are three kinds of compile-time variables that differ in their scope level: local, scoped and global. An overview is given in Table 1.
### Scope Levels for Compile-Time Variables in GAMS

<table>
<thead>
<tr>
<th>Scope</th>
<th>Availability</th>
<th>Defined with</th>
<th>Removed from the system with</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local</td>
<td>Available only in the input file where they are defined</td>
<td>$setLocal.</td>
<td>$dropLocal</td>
</tr>
<tr>
<td>Scoped</td>
<td>Available in the input file where they are defined and in all include files of the input file.</td>
<td>$set</td>
<td>$drop</td>
</tr>
<tr>
<td>Global</td>
<td>Available in the input file where they are defined, in all parent files and in all include files.</td>
<td>$setGlobal</td>
<td>$dropGlobal</td>
</tr>
</tbody>
</table>

#### Table 1: Scope Levels for Compile-Time Variables in GAMS

Note that *scoped* compile-time variables may also be defined on the command line with *double dash parameters*. For example, in the example above the compile-time variable DMULT may be referenced in the equation demand without being defined with the dollar control option $set$ as long as it is defined and set on the command line. Note further, that *global* compile-time variables are saved in work files.

While the scope of a compile-time variable cannot be directly changed, but dropping and adding variables in different scopes accomplishes the same. Consider the following example:

```gams
$set MYVAR xxx

* From scoped to global
$ifThen set MYVAR
    $ setGlobal MYVAR %MYVAR%
    $ show
    $ drop MYVAR
    $ show
$endIf

* From global to local
$ifThen setGlobal MYVAR
    $ setLocal MYVAR %MYVAR%
    $ show
    $ dropGlobal MYVAR
    $ show
$endIf
```

Note that the compile-time variable MYVAR is first defined as a scoped variable with the value xxx. The dollar control option ifThen tests whether MYVAR was defined with $set$ and since this is TRUE the next four dollar control statements are processed: a new global compile-time variable called MYVAR is defined and is set to the value of the scoped compile-time variable MYVAR, the resulting compile-time variables are shown, the scoped compile-time variable is removed from the system with the option $drop$ and the resulting compile-time variables are shown again. A similar procedure is followed to change the global compile-time variable MYVAR to a local compile-time variable with the same name and value.

The output generated by the four dollar control options $show$ follows:

<table>
<thead>
<tr>
<th>Level</th>
<th>SetVal</th>
<th>Type</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>MYVAR</td>
<td>SCOPED</td>
<td>xxx</td>
</tr>
<tr>
<td>0</td>
<td>MYVAR</td>
<td>GLOBAL</td>
<td>xxx</td>
</tr>
</tbody>
</table>
Observe that this report is called Environment Report. This name is unfortunate, since the variables reported are in fact compile-time variables. Environment variables in GAMS are discussed in section Environment Variables in GAMS below.

Note that if a compile-time variable is referenced with `%MYVAR%`, it could reference a global, scoped or local compile-time variable called MYVAR. GAMS will always access the compile-time variable MYVAR with the most local scope. Thus if all three scopes are defined, the local compile-time variable is accessed first, then the scoped and then the global, as demonstrated in the following example:

\[
\begin{align*}
\$set &\ XXX \text{ scoped} \\
\$setLocal &\ XXX \text{ local} \\
\$setGlobal &\ XXX \text{ global} \\
\$log &\ %XXX% \\
\$dropLocal &\ XXX \\
\$log &\ %XXX% \\
\$drop &\ XXX \\
\$log &\ %XXX% \\
\$dropGlobal &\ XXX \\
\$log &\ %XXX% \\
\end{align*}
\]

The resulting log output will be:

```
local
scoped
global
%XXX%
```

Note that how `%XXX%` will be handled if no compile-time variable XXX is defined, is determined by the command line parameter stringChk.

For a full list of dollar control options that affect compile-time variables, see section Dollar Control Options for Compile-Time Variables and Environment Variables.

### 3.40.2.4 Environment Variables in GAMS

GAMS programs have access to operating system s via `%sysEnv.NAME%`. Operating system environment variables may be modified or new environment variables may be defined with the dollar control option `$setEnv`. Consider the following artificial example:
Note that the dollar control option $\text{dropEnv}$ removes an environment variable. The log output follows:

\begin{verbatim}
$\text{sysEnv.GEORGE}$
Dantzig
$\text{sysEnv.GEORGE}$
\end{verbatim}

There are two environment variables in GAMS that are specific to the GDX facility: $\text{GDXCONVERT}$ and $\text{GDXCOMPRESS}$. Since GDX is used by utilities and other programs some general customization can be achieved via these environment variables. Their values determine the type of GDX files that are written. These environment variables may be overwritten through the command line parameters $\text{gdxConvert}$ and $\text{gdxCompress}$ or inside the GAMS file with the dollar control option $\text{setEnv}$. Consider the following example that uses the latter functionality:

\begin{verbatim}
Scalar x /1/;
$\text{log sysEnv.GDXCONVERT}$
$\text{log sysEnv.GDXCOMPRESS}$
$\text{gdxOut x.gdx}$
$\text{unLoad x}$
$\text{gdxOut}$
$\text{call gdxdump x.gdx -v | grep "File format\|Compression"}$

$\text{setEnv GDXCONVERT v6}$
$\text{setEnv GDXCOMPRESS 1}$
$\text{gdxOut x.gdx}$
$\text{unLoad x}$
$\text{gdxOut}$
$\text{call gdxdump x.gdx -v | grep "File format\|Compression"}$

$\text{setEnv GDXCONVERT v7}$
$\text{setEnv GDXCOMPRESS 0}$
$\text{gdxOut x.gdx}$
$\text{unLoad x}$
$\text{gdxOut}$
$\text{call gdxdump x.gdx -v | grep "File format\|Compression"}$
\end{verbatim}

Note that $\text{gdxdump}$ is a GDX utility that writes the contents of a GDX file as a GAMS formatted text file. The switch $\text{-v}$ lets $\text{gdxdump}$ print the file version information. With the $\text{grep}$ utility we filter the lines that contain either File format or Compression. This code is run with the following call that initializes GDXCOMPRESS and GDXCONVERT:

\begin{verbatim}
> gams gdxenv.gms gdxCompress=0 gdxConvert=v6 lo=3
\end{verbatim}

The output follows:
3.40.3 Compile-Time Constants

Compile-time constants are constants that are related to some functions, model attributes or options. They have a fixed value and are referenced as \%prefix.constant\%. Here *prefix* is the name of the respective function, model attribute or option and *constant* is the name of the constant.

For example, the function handleStatus is used in the context of grid computing. Typically, a collection loop may take the following form:

```
loop(pp$(handleStatus(h(pp)) = 2), ... );
```

Alternatively, the following formulation may be used:

```
loop(pp$(handleStatus(h(pp)=\%handleStatus.ready\%), ... );
```

Observe that the compile-time constant \%handleStatus.ready\% equals the value of 2. See the table below for other compile-time constants that are related to the function handleStatus.

Note

Compile-time constants are replaced at compile time and cannot be manipulated or reassigned.

Though compile-time constants are most often used in the context of the function, model attribute or option indicated with the prefix, they are in fact context free and may be used anywhere where an integer is expected. Consider the following example:

```
Scalar x / \%solPrint.on\% /; display x;
```

A complete list of the compile-time constants is given in Table 2.

Table 2: Compile-Time Constants
<table>
<thead>
<tr>

</table>
### 3.40.4 GAMS Compile Time and Execution Time Phase

The GAMS log indicates different phases of a job run in the log file:

```plaintext
...  --- Starting compilation
...  --- Starting execution: elapsed 0:00:00.056
...
```

During compilation GAMS converts the GAMS user program into lower-level instructions that are executed during execution time. Before the user program is converted into lower-level instructions the compiler processes the input: the compile time variables and macros are substituted and comments are removed. Moreover, during compilation any dollar control option present in the user code is executed. Many of these dollar control options impact the behavior of the compilation phase (e.g. `$include` instructs the compiler to process a file before continuing processing the remaining part of the current file). The code the compiler actually converts into lower-level instructions is echoed (by default) to the listing file. The compiler also assembles the list of user symbols (sets, parameters, variables, ...) and the list of labels. These lists become immutable after the compiler finishes. So during execution time, for example, no new labels can be added. The only exception from this is during a continued compilation/execution using the save and restart facility. The separation between compile time and execution time is confusing especially for novice users and mistakes as the following are frequent:

```plaintext
file fInput / data.txt /;
scalar iCnt; for (iCnt=1 to 100, put fInput iCnt:0:0 /); putClose fInput;
set i /
  $include data.txt
/;
```

The intention of the code, that does not work, is clear: The put facility is used to create the input file `data.txt` that is included via the `$include` instruction. The problem with this code is that the `$include` instruction is executed at compile time while the code using the put statement is executed at execution time, i.e. after the compilation phase is over. Hence, the compiler tries to include this file before the put instructions are executed. If the file `data.txt` is not present, the compiler will terminate with a compilation error, but if a file with name `data.txt` is present this one will be processed by the `$include` and a mistake like this might remain undiscovered for a long time.

Most of the time GAMS performs compilation and execution in one GAMS job which makes it even harder to grasp the concept of compile and execution time. The command line parameter `action` can be used to separate the compilation and execution phase into multiple jobs.
3.40.5 List of Command Line Parameters

In the following two subsections we will present an overview of the command line parameters with brief descriptions. Detailed descriptions of all command line parameters follow in section Detailed Descriptions of All Options below.

3.40.5.1 General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>GAMS processing request</td>
</tr>
<tr>
<td>appendExpand</td>
<td>Expand file append option</td>
</tr>
<tr>
<td>appendLog</td>
<td>Log file append option</td>
</tr>
<tr>
<td>appendOut</td>
<td>Output file append option</td>
</tr>
<tr>
<td>asyncSolLst</td>
<td>Print solution listing when asynchronous solve (Grid or Threads) is used</td>
</tr>
<tr>
<td>case</td>
<td>Output case option for LST file</td>
</tr>
<tr>
<td>cErr</td>
<td>Compile time error limit</td>
</tr>
<tr>
<td>charSet</td>
<td>Character set flag</td>
</tr>
<tr>
<td>curDir</td>
<td>Current directory</td>
</tr>
<tr>
<td>dFormat</td>
<td>Date format</td>
</tr>
<tr>
<td>dumpOpt</td>
<td>Writes preprocessed input to the file input.dmp</td>
</tr>
<tr>
<td>dumpParms</td>
<td>GAMS parameter logging</td>
</tr>
<tr>
<td>dumpParmsLogPrefix</td>
<td>Prefix of lines triggered by DumpParms&gt;1</td>
</tr>
<tr>
<td>eolOnly</td>
<td>Single key-value pairs (immediate switch)</td>
</tr>
<tr>
<td>errMsg</td>
<td>Placing of compilation error messages</td>
</tr>
<tr>
<td>errNam</td>
<td>Name of error message file</td>
</tr>
<tr>
<td>error</td>
<td>Force a compilation error with message</td>
</tr>
<tr>
<td>errorLog</td>
<td>Max error message lines written to the log for each error</td>
</tr>
<tr>
<td>etLim</td>
<td>Elapsed time limit in seconds</td>
</tr>
<tr>
<td>execErr</td>
<td>Execution time error limit</td>
</tr>
<tr>
<td>execMode</td>
<td>Limits on external programs that are allowed to be executed</td>

<tr>
<td>expand</td>
<td>Expanded (include) input file name</td>
</tr>
<tr>
<td>fdDelta</td>
<td>Step size for finite differences</td>
</tr>
<tr>
<td>fdOpt</td>
<td>Options for finite differences</td>
</tr>
<tr>
<td>fErr</td>
<td>Alternative error message file</td>
</tr>
<tr>
<td>fileCase</td>
<td>Casing of new file names (put, gdx, ref etc.)</td>
</tr>
<tr>
<td>fileStem</td>
<td>Sets the file stem for output files which use the input file name as stem</td>
</tr>
<tr>
<td>fileStemApFromEnv</td>
<td>Append a string read from an environment variable to the &quot;FileStem&quot;</td>
</tr>
<tr>
<td>forceWork</td>
<td>Force GAMS systems to process save files for example with an execution error</td>
</tr>
<tr>
<td>forLim</td>
<td>GAMS looping limit</td>
</tr>
<tr>
<td>freeEmbeddedPython</td>
<td>Free external resources at the end of each embedded Python code blocks</td>
</tr>
<tr>
<td>G205</td>
<td>Use GAMS version 2.05 syntax</td>
</tr>
<tr>
<td>GDX</td>
<td>GAMS data exchange file name</td>
</tr>
<tr>
<td>gdxCompress</td>
<td>Compression of generated GDX file</td>
</tr>
<tr>
<td>gdxConvert</td>
<td>Version of GDX files generated (for backward compatibility)</td>
</tr>
<tr>
<td>gdxUels</td>
<td>Unload labels or UELs to GDX either squeezed or full</td>

<tr>
<td>interactiveSolver</td>
<td>Allow solver to interact via command line input</td>
</tr>
<tr>
<td>jobTrace</td>
<td>Job trace string to be written to the trace file at the end of a GAMS job</td>
</tr>
<tr>
<td>keep</td>
<td>Controls keeping or deletion of process directory and scratch files</td>
</tr>
<tr>
<td>libIncDir</td>
<td>LibInclude directory</td>
</tr>
<tr>
<td>license</td>
<td>Use alternative license file</td>
</tr>
<tr>
<td>logFile</td>
<td>Log file name</td>
</tr>
<tr>
<td>logLine</td>
<td>Amount of line tracing to the log file</td>
</tr>
<tr>
<td>logOption</td>
<td>Log option</td>
</tr>
<tr>
<td>lstTitleLeftAligned</td>
<td>Write title of LST file all left aligned</td>
</tr>
<tr>
<td>maxProcDir</td>
<td>Maximum number of 225+ process directories</td>
</tr>
<tr>
<td>MCPRHoldFx</td>
<td>Print list of rows that are perpendicular to variables removed due to the holdfixed setting</td>
</tr>
<tr>
<td>multiPass</td>
<td>Multipass facility</td>
</tr>
<tr>
<td>noNewVarEqu</td>
<td>Triggers a compilation error when new equations or variable symbols are introduced</td>
</tr>
<tr>
<td>on115</td>
<td>Generate errors for unknown unique element in an equation</td>
</tr>
<tr>
<td>output</td>
<td>Listing file name</td>
</tr>
<tr>
<td>pageContr</td>
<td>Output file page control option</td>
</tr>
<tr>
<td>pageSize</td>
<td>Output file page size (=0 no paging)</td>
</tr>
<tr>
<td>pageWidth</td>
<td>Output file page width</td>
</tr>
<tr>
<td>parmFile</td>
<td>Command Line Parameter include file</td>
</tr>
<tr>
<td>pLicense</td>
<td>Privacy license file name</td>
</tr>
<tr>
<td>prefixLoadPath</td>
<td>Prepend GAMS system directory to library load path</td>
</tr>
<tr>
<td>procDir</td>
<td>Process Directory</td>
</tr>
<tr>
<td>procDirPath</td>
<td>Directory to create process directory in</td>
</tr>
<tr>
<td>profile</td>
<td>Execution profiling</td>
</tr>
<tr>
<td>profileFile</td>
<td>Write profile information to this file</td>
</tr>
<tr>
<td>profileTol</td>
<td>Minimum time a statement must use to appear in profile generated output</td>
</tr>
<tr>
<td>putDir</td>
<td>Put file directory</td>
</tr>
<tr>
<td>pyMultInst</td>
<td>GAMS/Python Multiple Instance Interpreter</td>
</tr>
<tr>
<td>pySetup</td>
<td>GAMS/Python Setup</td>
</tr>
<tr>
<td>reference</td>
<td>Symbol reference file</td>
</tr>
<tr>
<td>scrDir</td>
<td>Scratch directory</td>
</tr>
<tr>
<td>scrExt</td>
<td>Scratch file extension to be used with temporary files</td>
</tr>
<tr>
<td>scrNam</td>
<td>Work file names stem</td>
</tr>
<tr>
<td>seed</td>
<td>Random number seed</td>
</tr>
<tr>
<td>showOSMemory</td>
<td>Show the memory usage reported by the Operating System instead of the internal counting</td>
</tr>
<tr>
<td>stepSum</td>
<td>Summary of computing resources used by job steps</td>
</tr>
<tr>
<td>strictSingleton</td>
<td>Error if assignment to singleton set has multiple elements</td>
</tr>
<tr>
<td>stringChk</td>
<td>String substitution options</td>
</tr>
<tr>
<td>suppress</td>
<td>Compiler listing option</td>

### 3.40.6 Detailed Descriptions of All Options

In this section we will give detailed descriptions of all options that may be used as command line parameters, in option statements or as model attributes. Note that we indicate for each entry the context in which
the option is available. Observe that the options are listed in alphabetical order for easy reference.

**action** *(string)*: GAMS processing request

Synonym: A

Available: Command line

This option controls the way GAMS processes the input file. In particular GAMS currently processes the input file in multiple phases and this allows one to restrict the phases used. The two phases in order are:

- *Compilation* During this pass, the file is compiled, and syntax errors are checked for. Data initialization statements like scalar, parameter, and table statements are also processed during this stage.
- *Execution* During this stage, all execution time statements including assignments, loops, and solves are executed.

The special action GT is related to processing trace records. See option `traceLevel` for details.

Default: CE

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Restart After Solve</td>
</tr>
<tr>
<td>C</td>
<td>CompileOnly</td>
</tr>
<tr>
<td>E</td>
<td>ExecuteOnly</td>
</tr>
<tr>
<td>CE</td>
<td>Compile and Execute</td>
</tr>
<tr>
<td>GT</td>
<td>Trace Report</td>
</tr>
</tbody>
</table>

**appendExpand** *(boolean)*: Expand file append option

Synonym: AE

Available: Command line

This option controls the manner of file opening of the option `expand`.

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reset expand file</td>
</tr>
<tr>
<td>1</td>
<td>Append to expand file</td>
</tr>
</tbody>
</table>

**appendLog** *(boolean)*: Log file append option

Synonym: AL

Available: Command line

This option is used in conjunction with the setting of `logOption` to 2 and 4, where the log from the GAMS run is redirected to a file. Setting this option to 1 will ensure that the log file is appended to and not overwritten (replaced).

Default: 0
### appendOut (boolean): Output file append option

**Meaning**
- **0**: Reset log file
- **1**: Append to logfile

**Default**: 0

### asyncSolLst (boolean): Print solution listing when asynchronous solve (Grid or Threads) is used

**Meaning**
- **0**: Do not print solution listing into lst file for asynchronous solves
- **1**: Print solution listing into lst file for asynchronous solves

**Default**: 0

### bRatio (real): Basis acceptance threshold

**Meaning**
- **bRatio** accepts any basis and forces GAMS to construct a basis using whatever information is available.
- A **bRatio** of 0 accepts any basis and forces GAMS to construct a basis using whatever information is available.
- Setting **bRatio** to 1 will cause all existing basis information to be discarded, which is sometimes needed with nonlinear problems. A **bRatio** of 0 accepts any basis and forces GAMS to construct a basis using whatever information is available. If **bRatio** has been set to 0 and there was no previous solve, an all slack (sometimes called all logical) basis will be provided. This option has no effect for most MIP solvers because MIP presolve destroys a basis.

**Default**: 0.25

### case (boolean): Output case option for LST file
Available: Command line

This option controls the case of the text in the listing file.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Write listing file in mixed case</td>
</tr>
<tr>
<td>1</td>
<td>Write listing file in upper case only</td>
</tr>
</tbody>
</table>

cErr (integer): Compile time error limit

Available: Command line

The compilation will be aborted after n errors have occurred. By default, there is no error limit and GAMS compiles the entire input file and collects all the compilation errors that occur. If the file is too long and the compilation process is time consuming, cerr could be used to set to a low value while debugging the input file.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error limit (default)</td>
</tr>
<tr>
<td>n</td>
<td>Stop after n errors</td>
</tr>
</tbody>
</table>

charSet (boolean): Character set flag

Available: Command line

This option specifies whether foreign language characters are permitted in comments and text items. For a list of standard GAMS characters, see table Legal Characters.

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use limited GAMS characters set</td>
</tr>
<tr>
<td>1</td>
<td>Accept any character in comments and text items (foreign language characters)</td>
</tr>
</tbody>
</table>

cheat (real): Cheat value, i.e. minimum solution improvement threshold

Available: Attribute statement (use before solve)

For a branch-and-bound based solver, each new feasible solution must be at least the value of cheat better than the current best feasible solution. Note that this may speed up the search, but may cause some solutions, including optimal ones, to be missed. If a model has been solved with a nonzero cheat value, then the optimal solution will be within the cheat value or less of the found solution. Observe that the option cheat is specified in absolute terms (like the option optCA), therefore non-negative values are appropriate for both minimization and maximization models. Note that using this option will invalidate any reporting of the dual bound or optimality gaps. Further, certain solver options can override the cheat setting, e.g., the Cplex option objDif, and some solvers may ignore the cheat option.

Default: 0
**CNS** *(string):* Constrained Nonlinear Systems - default solver

Available: Command line, Option statement

The default solver for models of the type *Constrained Nonlinear Systems* is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

**curDir** *(string):* Current directory

Synonym: CDir

Available: Command line

This option sets the current working directory. It is useful when GAMS is called from an external system like Visual Basic. If it is not specified, it will be set to the directory the GAMS module is called from.

**cutOff** *(real):* Cutoff value for branch and bound

Available: Attribute statement (use before solve, reset by solve statement)

Within a branch-and-bound based solver, the parts of the tree with an objective value worse than the cutoff value are ignored. Note that this may speed up the initial phase of the branch and bound algorithm (before the first integer solution is found). However, the true optimum may be beyond the cutoff value. In this case the true optimum will be missed and moreover, no solution will be found.

Observe that this option is specified in absolute terms (like the option `optCA`).

Default: 0

**decimals** *(integer):* Decimal places for display statements

Available: Option statement

This option specifies the number of decimals that will be printed for numeric values that do not have a specific print format attached. The range is $[0, 8]$.

Default: 3

**defPoint** *(integer):* Indicator for passing on default point

Available: Attribute statement (use before solve, reset by solve statement)

This option determines the point that is passed to the solver as a basis. By default, the levels and marginals from the current basis are passed to the solver. In some circumstances (mostly during debugging), it can be useful to pass a standard default input point, i.e. with all levels set to 0 or lower bound.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Pass user defined levels and marginals to solver</td>
</tr>
<tr>
<td>1</td>
<td>Pass default levels and marginals to solver</td>
</tr>
<tr>
<td>2</td>
<td>Pass default marginals to solver</td>
</tr>
</tbody>
</table>
**dFormat (integer):** Date format

Synonym: DF

Available: Command line

This option controls the date format in the listing file. The three date formats correspond to various conventions used around the world. For example, the date December 2, 1996 will be written as 12/02/96 with the default df value of 0, as 02.12.96 with df=1, and as 96-12-02 with df=2.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Date as mm/dd/yy</td>
</tr>
<tr>
<td>1</td>
<td>Date as dd.mm.yy</td>
</tr>
<tr>
<td>2</td>
<td>Date as yy-mm-dy</td>
</tr>
</tbody>
</table>

**dictFile (real):** Force writing of a dictionary file if dictfile > 0

Available: Attribute statement (use before solve, reset by solve statement)

If this option is set to a value that is larger than zero, it will instruct GAMS to make the GAMS names of variables and equations that have been generated by the solve statement available to the solver. In many solver links these names are registered with the solver and hence messages from the solver that involve variables and equations (e.g. an infeasible row or duplicate columns) can be easily interpreted by the user. Consider the following example:

Row 'demand(new-york)' infeasible, all entries at implied bounds.

Duplicate columns x(san-diego.new-york) and x(san-diego.chicago) make problem unbounded.

If we have `modelname.dictfile=0` the same messages will read as follows:

Row 'c4' infeasible, all entries at implied bounds.

Duplicate columns x4 and x5 make problem unbounded.

Sometimes a dictionary is required for a successful run. Some solver option use the original GAMS names and need to be matched with the variables 1..n and equations 1..m in the solver. The dictionary file with its API allows to calculate such a mapping. Note that this is done automatically inside the solver links, so users do not need to be concerned with it.

For example, in the indicator constraints implementation a binary indicator variable is matched to a constraint. In the model [INDIC01] from the GAMS test library, this matching is done in the following GAMS/Cplex option file `cplex.opt`:

```
indic eq3(dice,f,fp)$comp(dice,f,fp) 1
```

Observe that if no dictionary is available, we will get an error:

```
**** Unable to read dictionary file required for indicator constraints
```
However, the dictionary comes at a price. Generating the names and calculating and storing
the map takes time and space. In addition, GAMS names take up space in the solver. Thus, if
the user needs very fast generation and does not need names, setting dictFile to zero is a
good option.

Further, note that some solvers allow to suppress the loading of names (using the solver option
names=no). Suppressing the loading of names facilitates to use the name mapping features
required for models like INDIC01 above, but does not load the names into the solver name
space for better reporting (and hence saves some space).

dispWidth (integer): Number of characters to be printed in the column labels of all subsequent display
statements

Available: Option statement

This option controls the number of characters that are shown for a label in a column in the
context of the display statement. Consider the following example:

Set i / thislabelhas24characters /;
Parameter p(i,i) / thislabelhas24characters.thislabelhas24characters 2/;
display p;

option dispWidth=24;
display p;

The two display statements in this code will generate the following output:

---- 3 PARAMETER p

thislabel~
thislabelhas24characters 2.000

---- 6 PARAMETER p

thislabelhas24characters
thislabelhas24characters 2.000

Observe that in the first display, the label in the column is cut off after 10 characters, while in
the second display it is shown in full.

Note that the default value is 10 and the range is [10,31].

Default: 10

dmpOpt (no value): Debugging option: causes GAMS to echo the runtime option settings

Available: Option statement

This debugging option has the effect that all available option statements and their current
values are listed in the listing file.

dmpSym (no value): Debugging option: causes GAMS to echo the symbol table to the listing file

Available: Option statement

This debugging option is especially useful for diagnosing memory problems. It has the effect
that GAMS will report the number of elements that are stored for each identifier at the point
in the program where this option is inserted. The report that is generated in this way is called
a memory dump. For details, see section Finding the Causes for Excessive Memory Use.
DNLP (string): Non-Linear Programming with Discontinuous Derivatives - default solver

Available: Command line, Option statement

The default solver for models of the type Nonlinear Programs with Discontinuous Derivatives is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

domLim (integer): Domain violation limit solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the maximum number of domain errors (undefined operations like division by zero) a nonlinear solver will perform, while calculating function and derivative values, before it terminates the run and returns solver status 5 EVALUATION ERROR LIMIT. Nonlinear solvers have difficulties recovering after attempting an undefined operation. Note that some solvers operate in a mode where trial function evaluations are performed. These solvers will not move to points at which evaluation errors occur, thus the evaluation errors at trial points are not counted against the limit.

Default: \( \infty \)

domUsd (integer): Number of domain violations

Available: Attribute statement (use after solve)

This model attribute returns the number of domain violations after a solve.

dualCheck (integer): Output on the reduced cost condition

Available: Option statement

If this option is set to 1, the reduced cost condition for each variable in the column listing will be evaluated using the equation marginals. The default value is zero, which means that the calculation will be omitted.

Default: 0

dumpOpt (integer): Writes preprocessed input to the file input.dmp

Available: Command line

This option with value larger than 9 creates a GAMS input file of that will reproduce results encapsulating all include files into one GAMS file. If activated, a file will be written containing GAMS source code for the entire problem. The file name is the input file name with the extension .dmp. For values smaller than 10, this option tries to encapsulate all the items from a restart file that are needed to execute a solve.

For the values smaller than 10, consider the following example. We will split the transportation model [TRNSPORT] into two files and run them with the save and restart feature. Then we will illustrate the option dumpOpt. The first file called trans1.gms contains the first part of the model up to and including the model statement:
Sets
   i    canning plants / seattle, san-diego /
   j    markets       / new-york, chicago, topeka / ;

Parameters
   a(i) capacity of plant i in cases
      / seattle  350
         san-diego 600 / 
   b(j) demand at market j in cases
      / new-york 325
         chicago 300 
         topeka  275 / ;

Table d(i,j) distance in thousands of miles
      new-york   chicago   topeka
   seattle         2.5       1.7       1.8
   san-diego       2.5       1.8       1.4 ;

Scalar f freight in dollars per case per thousand miles /90/ ;

Parameter c(i,j) transport cost in thousands of dollars per case 
   c(i,j) = f * d(i,j) / 1000 ;

Variables
   x(i,j) shipment quantities in cases
   z    total transportation costs in thousands of dollars ;
Positive Variable x ;

Equations
   cost        define objective function
   supply(i)   observe supply limit at plant i
   demand(j)   satisfy demand at market j ;

   cost ..      z   =e=   sum((i,j), c(i,j)*x(i,j)) ;
   supply(i) .. sum(j, x(i,j)) =l= a(i) ;
   demand(j) .. sum(i, x(i,j)) =g= b(j) ;

model transport /all/ ;

Note that we removed all comments for brevity. The second file called transport.gms contains the solve statement and the display statement:

solve transport using lp minimizing z ;
display x.l, x.m ;

We run the first file with the command line parameter save and thus generate a work file. For details on work files, see chapter The Save and Restart Feature. Then we run trans2.gms restarting from the saved work file. The result will be equivalent to running the original model [TRANSPORT].

Note

The option dumpOpt can only be used effectively, if the first line in the second file, trans2.gms, is the solve statement.

Now, we will illustrate the use of the option dumpOpt, by running the second file with the following command:

Here trans is the name of the saved files generated from the file trans1.gms. As a result of this call, a new file will be created. It is called trans2.dmp and has the following content:

* This file was written with DUMPOPT=1 at 11/30/11 08:43:06
* INPUT = C:\Fred\GAMS options\test\transport2.gms
* DUMP = C:\Fred\GAMS options\test\transport2.dmp
* RESTART = C:\Fred\GAMS options\test\trans1.gms

* with time stamp of 11/30/11 08:40:41
* You may have to edit this file and the input file.
* There are 5 labels

Set WorkFileLabelOrder dummy set to establish the proper order /
  seattle, san-diego, new-york, chicago, topeka /;

Model transport;

Variable z total transportation costs in thousands of dollars;

Set i(*) canning plants /
  seattle, san-diego /;

Set j(*) markets /
  new-york, chicago, topeka /;

Parameter c(i,j) transport cost in thousands of dollars per case /
  seattle.new-york 0.225, seattle.chicago 0.153, seattle.topeka 0.162, san-diego.new-york 0.225, san-diego.chicago 0.162, san-diego.topeka 0.126 /

Positive Variable x(i,j) shipment quantities in cases;

Parameter a(i) capacity of plant i in cases /
  seattle 350, san-diego 600 /

Parameter b(j) demand at market j in cases /
  new-york 325, chicago 300, topeka 275 /

Equation demand(j) satisfy demand at market j;

Equation supply(i) observe supply limit at plant i;

Equation cost define objective function;

* *** EDITS FOR INPUT FILE ***

*** END OF DUMP ***

Note that all the data that enters the model in the solve statement has been regenerated. Observe that the parameter d has not been regenerated since it does not appear in the model. Changing the value of the parameter dumpopt will have the effect that other names are used for the identifiers in the regenerated file, see table below.
Note

If $\texttt{Verbatim}$ is active, $\texttt{DumpOpt} = 11$ behaves like $\texttt{DumpOpt} = 21$ (comments are kept)

Default: 0
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No dumpfile</td>

<td>Extract referenced data from the restart file using new set element names and drop symbol text</td>
</tr>
<tr>
<td>4</td>
<td>Extract referenced symbol declarations from the restart file</td>
</tr>
<tr>
<td>11</td>
<td>Write processed input file without comments</td>
</tr>
<tr>
<td>21</td>
<td>Write processed input file with all comments</td>
</tr>
</tbody>
</table>

**dumpParms** (*integer*): GAMS parameter logging

Synonym: DP

Available: Command line

This option lists the settings of all command line parameters that were changed or set by the user, GAMS or the IDE during the current run. Note that with \( dp=2 \) all file operations are listed, including the full path of each file on which any operation is performed.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No logging</td>
</tr>
<tr>
<td>1</td>
<td>Lists accepted/set parameters</td>
</tr>
<tr>
<td>2</td>
<td>Log of file operations plus list of accepted/set parameters</td>
</tr>
</tbody>
</table>

**dumpParmsLogPrefix** (*string*): Prefix of lines triggered by DumpParms>1

Synonym: DPLP

Available: Command line

This option prefixes in the log file the list of all command line parameters that were changed or set by the user, GAMS or the IDE during the current run. Note that the option dumpParms must be greater than 1 for dumpParmsLogPrefix to have an effect.

Default: ***

**eject** (*no value*): Inject a page break into the LST file

Available: Option statement

This option has the effect that a page break is inserted in the listing file.

**EMP** (*string*): Extended Mathematical Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Extended Mathematical Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.
3.40 The GAMS Call and Command Line Parameters

**eolOnly (integer):** Single key-value pairs (immediate switch)

Synonym: EY

Available: Command line

This option controls formatting of parameters on the command line and is useful in conjunction with the option parmFile.

This option acts as an immediate switch that forces only one option-value pair to be read on a line. Note that by default, any number of option-value pairs may be present on the same line and termination characters and quoting is necessary to determine the end of key/value pair. With this option active the remainder after the key is used as the value independent of quoting or termination characters.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Any number of keys or values</td>
</tr>
<tr>
<td>1</td>
<td>Only one key-value pair on a line</td>
</tr>
</tbody>
</table>

**errMsg (integer):** Placing of compilation error messages

Available: Command line

This option controls the position of the compilation error messages in the listing file. To illustrate the option, consider the following slice of GAMS code:

```gams
Set      i   / 1*10  /  ;
Set      j(i) / 10*11  /  ;
Parameter a(jj) / 12 25.0 /  ;
```

After running this code, the listing file will contain the following lines:

1 Set i / 1*10 /  ;
2 Set j(i) / 10*11 /  ;
***** $170
3 Parameter a(jj) / 12 25.0 /  ;
***** $120
4
120 Unknown identifier entered as set
170 Domain violation for element

***** 2 ERROR(S) 0 WARNING(S)

Note that numbers $170 and $120 flag the two errors as they occur, but the errors are explained only at the end of the compilation output. However, if the code is run using the option errmsg=1, the resulting listing file will contain the following:

1 Set i / 1*10 /  ;
2 Set j(i) / 10*11 /  ;
***** $170
***** 170 Domain violation for element
3 Parameter a(jj) / 12 25.0 /  ;
***** $120
***** 120 Unknown identifier entered as set
4
***** 2 ERROR(S) 0 WARNING(S)
Observe that the explanation for each error is provided immediately following the error marker.

Default: 0
3.40 The GAMS Call and Command Line Parameters

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Place error messages at the end of compiler listing</td>
</tr>
<tr>
<td>1</td>
<td>Place error messages immediately following the line with the error</td>
</tr>
<tr>
<td>2</td>
<td>Suppress error messages</td>
</tr>
</tbody>
</table>

**errNam (string):** Name of error message file

Available: Command line

This option specifies the name of a file defining the internally used compiler error messages. It is used to change the name from the default name `gamserrs.txt`.

**error (string):** Force a compilation error with message

Available: Command line

This option forces a parameter error with a specified message. It is useful in the context of incorporating a GAMS file within another batch file where the user needs to have control over the conditions when GAMS is called. See also section Conditional Compilation.

To illustrate, the default GAMS log file from running a model with the option `error=Hallo` will look as follows:

```
gams: **** Error: Parameter error(s)
    :         Reading parameter(s) from "command line"
    :         *** Error Hallo
    :         Finished reading from "command line"
```

**errorLog (integer):** Max error message lines written to the log for each error

Synonym: ER

Available: Command line

This option controls the number of error message lines that are written to the log file.

Under the IDE, the default is reset to 99.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error messages to LOG file</td>
</tr>
<tr>
<td>n</td>
<td>Number of lines for each error that will be written to LOG file</td>
</tr>
</tbody>
</table>

**etAlg (real):** Elapsed time it took to execute the solve algorithm

Available: Attribute statement (use after solve)

This model attribute returns the elapsed time it took to execute the solve algorithm. The time does not include the time to generate the model, the time to read and write files etc. The time is expressed in seconds of wall-clock time.

**etLim (real):** Elapsed time limit in seconds
Synonym: ETL

Available: Command line

This option controls the time limit for a GAMS job. The system will terminate with a compilation or execution error if the limit is reached. A GAMS job will terminate if the elapsed time in seconds exceeds the value of etLim.

Default: $\infty$

**etSolve** *(real)*: Elapsed time it took to execute a solve statement in total

Available: Attribute statement (use after solve)

This model attribute returns the elapsed time it took to execute a solve statement in total. This time includes the model generation time, the time to read and write files, the time to create the solution report and the time taken by the actual solve. The time is expressed in seconds of wall-clock time.

**etSolver** *(real)*: Elapsed time taken by the solver only

Available: Attribute statement (use after solve)

This model attribute returns the elapsed time taken by the solver only. This does not include the GAMS model generation time and the time taken to report and load the solution back into the GAMS database. The time is expressed in seconds of wall-clock time.

**execErr** *(integer)*: Execution time error limit

Available: Command line

This option puts an upper limit on the number of errors that may be found during execution or preprocessing associated with a solve statement. If more than execErr errors have been found GAMS will abort.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No errors allowed limit</td>
</tr>
<tr>
<td>n</td>
<td>Max number allowed</td>
</tr>
</tbody>
</table>

**execMode** *(integer)*: Limits on external programs that are allowed to be executed

Available: Command line

A higher value denotes a more restrictive alternative. If the restriction level n is chosen, then the restriction levels less than n will also be active. For example, if restriction level 3 is chosen, then restrictions 2 and 1 will apply too.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Everything allowed</td>
</tr>
<tr>
<td>1</td>
<td>Interactive shells in $\text{call}$ and execute commands are prohibited</td>
</tr>
<tr>
<td>2</td>
<td>Embedded Code and all $\text{call}$ and execute commands are prohibited</td>
</tr>
<tr>
<td>3</td>
<td>$\text{echo}$ or put commands can only write to directories in or below the working or scratchdir</td>
</tr>
<tr>
<td>4</td>
<td>$\text{echo}$ and put commands are not allowed</td>
</tr>
</tbody>
</table>
expand (string): Expanded (include) input file name

Synonym: EF

Available: Command line

This option generates a file that contains information about all the input files processed during a particular compilation. By default, the names of the input files are composed by completing the name with the current directory.

Consider the following example:

```
$call rm expfile.txt
$onecho > file1.inc
a = a*2; display a;
$include file2.inc
$offecho
$onecho > file2.inc
a = a+1; display a;
$include file3.inc
$offecho
$onecho > file3.inc
a = a**2; display a;
$offecho
parameter a / 1 /;
$include file3.inc
$include file2.inc
$include file1.inc
```

If the model is run with the command line parameter `ef=expfile.txt`, a file called `expfile.txt` will be generated. This file will contain the following lines:

```
1 INPUT 0 0 0 1 29 C:\GAMS\Examples\expand.gms
2 CALL 0 1 1 1 1 rm expfile.txt
3 INCLUDE 1 1 1 14 14 15 C:\GAMS\Examples\file3.inc
4 INCLUDE 1 1 15 16 19 C:\GAMS\Examples\file2.inc
5 INCLUDE 2 4 2 18 19 C:\GAMS\Examples\file3.inc
6 INCLUDE 1 1 16 20 25 C:\GAMS\Examples\file1.inc
7 INCLUDE 2 6 2 22 25 C:\GAMS\Examples\file2.inc
8 INCLUDE 3 7 2 24 25 C:\GAMS\Examples\file3.inc
9 EXIT 0 1 20 29 29 C:\GAMS\Examples\expand.gms
```

Note that the first row always refers to the parent file, in this case the file `expand.gms`. The first column gives the sequence number of the input files that were encountered. The second column refers to the type of file that is referenced. The following file types are possible:

0 INPUT
1 INCLUDE
2 BATINCLUDE
3 LIBINCLUDE
4 SYSINCLUDE

Observe that `$call` is also listed. The third column describes the depth for nested include files. The fourth column provides the sequence number of the parent file for the file being referenced. The fifth column gives the local line number in the parent file where the dollar control option `$include` appeared. The sixth column gives the global (expanded) line number which contained `$include`. The seventh column provides the total number of lines in the file after it is processed. The last column provides the name of the file.

Note that the listing in the expand file is similar to the `include file summary` in the listing file of the model.
**fdDelta** (real): Step size for finite differences

Available: Command line, Option statement, Attribute statement (use before solve)

This option allows users to control the step size while the numerical Hessian and numerical derivatives are computed in the context of the function suffixes `.hessn` and `.gradn`. For functions with one argument, GAMS evaluates the function at $f(x-d)$ and $f(x+d)$ for the numerical gradient. If function values are used for the numerical Hessian, GAMS will evaluate at $f(x-2d)$, $f(x)$ and $f(x+2d)$. For functions with multiple arguments, the same calculations are performed for the components of the input argument vector.

Default: $1.0E^{-05}$

**fdOpt** (integer): Options for finite differences

Available: Command line, Option statement, Attribute statement (use before solve)

This option allows users to control how numerical derivatives are computed. The values provide choice regarding the scaling of steps, Hessian calculation method and the use of numerical first derivatives.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>All derivatives analytically, for numerical Hessian use gradient values, scale delta</td>
</tr>
<tr>

<td>Same as 2, but no scale of delta</td>
</tr>
<tr>
<td>13</td>
<td>Same as 3, but no scale of delta</td>
</tr>
<tr>
<td>14</td>
<td>Same as 4, but no scale of delta</td>
</tr>
</tbody>
</table>

**fErr** (string): Alternative error message file

Available: Command line

This option redirects the compilation error messages to a file and names the file. By default, the file name is composed by completing the name with the scratch directory and the scratch extension. Note that under default settings such a file with compilation error messages is not generated. This option can be used when GAMS is being integrated into other environments like Visual Basic. The error messages that are reported in the listing file may be extracted with this option and their display may be controlled from the environment that is calling GAMS.

To illustrate, consider the slice of GAMS code that we used to explain the option `errMsg`. If we call this code with the command line parameter `ferr=myfile.err`, a file called `myfile.err` will be created in the scratch directory. This file will contain the following lines:

```
0 0 0 0 D:\GAMS\NEW.LST
1 1 170 31 D:\GAMS\NEW.GMS
2 2 120 14 D:\GAMS\NEW.GMS
```
Note that the first column refers to the global row number of the error in the listing file. The second column refers to the row number of the error in the individual file where the problem occurred. This will be different from the first column only if the error occurred in an include file. In this case, the second column will contain the line number in the include file where the error occurred, while the first number will contain the global line number (as reported in the listing file) where the error occurred. The number in the third column refers to the error number of the compilation error. The fourth number refers to the column number of the error in the source file. The last column contains the individual file in which the error occurred.

**fileCase** *(integer)*: Casing of new file names (put, gdx, ref etc.)

Available: Command line

This option facilitates modifying the case of file names for files like put files, GDX files, reference files. It only works with new file names. However, note that it won’t create `transport.REF` if `TRNSPORT.ref` already exists.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Causes GAMS to use default casing</td>
</tr>
<tr>
<td>1</td>
<td>Causes GAMS to upper case file names</td>
</tr>
<tr>
<td>2</td>
<td>Causes GAMS to lower case file names</td>
</tr>
</tbody>
</table>

**fileStem** *(string)*: Sets the file stem for output files which use the input file name as stem by default

Available: Command line

By default, some output files use the input file name as base. If the names of these output files were not set explicitly, then this option may be used to set another name than the input file name as base for these output files. In particular, the names for the following files may be set with `fileStem`: dump files (see option `dumpOpt`), GDX files (if the option `GDX` was set to `default`), log files (see option `logFile`), lst files (see option `output`), reference files (if the option `reference` was set to `default`) and trace summary files (see option `trace`).

**fileStemApFromEnv** *(string)*: Append a string read from an environment variable to the ”FileStem”

Available: Command line

This option for users that submit GAMS job via `mpirun/mpiexec`. Such commands will spawn multiple instances of GAMS (the precise number is an argument to `mpirun/mpiexec`). Each invocation of GAMS will run the identical job and only the contents of an environment variable (`PMI_RANK`) will differentiate the run. Since GAMS will normally write to `modelname.log/lst` if we run the GAMS file `modelname.gms` we will have many jobs writing to the same file. Therefore we use this option to append the content of a particular environment variable (name given by this option) to the default file names (see `fileStem`). Hence GAMS will create `modelname0.log/lst, modelname1.log/lst, and so forth when started with mpirun/mpiexec and `fileStemApFromEnv` is set to the environment variable that provides the MPI rank of the invocation. We allow to specify the name of the environment variable because different MPI implementations use different variable names (e.g. `PMI_RANK` or `OMPI_COMM_WORLD_RANK`).

**forceOptFile** *(integer)*: Overwrites other option file section mechanism

Available: Command line

Default: 0
**forceWork** *(boolean)*: Force GAMS systems to process save files for example with an execution error

Synonym: FW

Available: Command line

Most of the work files generated by GAMS using the command line parameter save are saved in binary format. The information inside these files will change from one GAMS version to another GAMS version. GAMS makes every attempt to be backward compatible and ensure that all new GAMS systems are able to read save files generated by older GAMS systems. However, at certain versions, we are forced to concede default incompatibility (regarding save files, not source files) in order to protect efficiency. The option `forceWork` may be used to force newer GAMS systems into translating and reading save files generated by older systems.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No translation</td>
</tr>
<tr>
<td>1</td>
<td>Try translation</td>
</tr>
</tbody>
</table>

**forLim** *(integer)*: GAMS looping limit

Available: Command line, Option statement

This option specifies the maximum number of permitted executions of control structures with a for statement, a while statement or a repeat statement before GAMS signals an execution error and terminates the control structure.

Default: \( \infty \)

**freeEmbeddedPython** *(boolean)*: Free external resources at the end of each embedded Python code blocks

Available: Command line

This parameter changes the behavior of \$offEmbeddedCode and endEmbeddedCode. When set to 1, internal resources get freed and with the next start of an embedded Python code section, the Python environment has to be reinitialized. This is not the case when this parameter is set to 0. In that case also the interpreter stays “alive”, which allows to access Python symbols defined in one embedded code block in a following block.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Keep resources to reuse them potentially</td>
</tr>
<tr>
<td>1</td>
<td>Free resources</td>
</tr>
</tbody>
</table>

**fSave** *(boolean)*: Creates a forced work file, i.e., the file is saved even if execution errors or other errors occured

Available: Command line

This option allows to save a file even in the face of execution or other errors. How it works depends on the command line parameter save.
Note that the option value of 1 is mainly used by solvers that can be interrupted from the terminal.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Workfile only written to file specified by SAVE if no errors occur</td>
</tr>
<tr>
<td>1</td>
<td>Workfile always written to file specified by SAVE or if SAVE is not present to a name made up by GAMS</td>
</tr>
</tbody>
</table>

**G205 (integer):** Use GAMS version 2.05 syntax

Available: Command line

This option sets the level of the GAMS syntax and is mainly used to ensure backward compatibility. New keywords have been introduced in the GAMS language since Release 2.05. Models developed earlier that use identifiers that have since become keywords will cause errors when they are run with the latest version of GAMS. This option enables users to run such old models.

For example, the word "if" is a keyword in GAMS that was introduced with the first version of Release 2.25. Setting the option \texttt{g205=1} allows the word "if" to be used as an identifier since it was not a keyword in Release 2.05. As another example, the word "for" is a keyword in GAMS that was introduced with the later versions of Release 2.25. Setting the option \texttt{g205=2} allows "for" to be used as an identifier since it was not a keyword in the first version of Release 2.25.

Note

If the values 1 or 2 are specified for option \texttt{g205}, then it will not be permitted to use enhancements of the GAMS language that were introduced in later versions.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use only latest syntax</td>
</tr>
<tr>
<td>1</td>
<td>Allow version 2.05 syntax only</td>
</tr>
<tr>
<td>2</td>
<td>Allow version 2.25 syntax only</td>
</tr>
</tbody>
</table>

**GDX (string):** GAMS data exchange file name

Available: Command line

This option specifies the name of the GAMS data exchange file and causes a GDX file to be written that contains all data in the model at the end of the job. Setting \texttt{gdx} to the string 'default' causes GAMS to create a GDX file with the gms file root name and a gdx extension. Thus the call

```bash
gams transport gdx=default
```

will cause GAMS to write the GDX file \texttt{transport.gdx}.

**gdxCompress (boolean):** Compression of generated GDX file

Available: Command line

This option specifies whether the GDX files are compressed or not.

Default: 0
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not compress GDX files</td>
</tr>
<tr>
<td>1</td>
<td>Compress GDX files</td>
</tr>
</tbody>
</table>

**gdxConvert (string):** Version of GDX files generated (for backward compatibility)

Available: Command line

This option specifies in which format the GDX files will be written.

Default: v7

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>v5</td>
<td>Version 5 GDX file, does not support compression</td>
</tr>
<tr>
<td>v6</td>
<td>Version 6 GDX file</td>
</tr>
<tr>
<td>v7</td>
<td>Version 7 GDX file</td>
</tr>
</tbody>
</table>

**gdxUels (string):** Unload labels or UELs to GDX either squeezed or full

Available: Command line, Option statement

This option specifies the UEL export mode. The UEL table may be written to a GDX file in two different modes. In **squeezed** mode, only the UELs that are required by the exported symbols are exported. In **full** mode, all UELs are exported. The following code snippet illustrates the difference:

```
Set   i / i1*i5 /;
Parameter p(i) / i3 3 /;

option gdxuels = squeezed;
execute_unload 'squeezed' p;
execute 'gdxdump squeezed UelTable=i';

option gdxuels = full;
execute_unload 'full' p;
execute 'gdxdump full UelTable=i';
```

The file **squeezed.gdx** will contain the following lines:

```
Set   i / 'i3' /;
Parameter p(*) / 'i3' 3 /;
```

The file **full.gdx** on the other hand, will contain the following lines:

```
Set   i / 'i1', 'i2', 'i3', 'i4', 'i5' /;
Parameter p(*) / 'i3' 3 /;
```

Default: **squeezed**
3.40 The GAMS Call and Command Line Parameters

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Squeezed</td>
<td>Write only the UELs to Universe, that are used by the exported symbols</td>
</tr>
<tr>
<td>Full</td>
<td>Write all UELs to Universe</td>
</tr>
</tbody>
</table>

**gridDir** *(string)*: Grid file directory

Synonym: GDir

Available: Command line

This option sets the grid file directory. Note that each GAMS job has only one grid file directory.

**gridScript** *(string)*: Grid submission script

Synonym: GScript

Available: Command line

This option provides the name of a script file that is used to submit grid computing jobs. If only the file name is given the file is assumed to be located in the system directory. A fully qualified name can be given as well. The script needs to be similar to the file `gmsgrid.cmd` on Windows machines with arguments that give name and location of the solver executable, the solver control file name and the name of the scratch directory. For an example of such a script, see section The Grid Facility: Architecture and Customization. However, note that advanced knowledge of how GAMS sets up and calls solvers is needed for successful use.

Default: `gmsgrid`

**handle** *(real)*: Unique handle number of SOLVE statement

Available: Attribute statement (use after solve)

The model attribute handle contains a unique identification of each submitted solution request and is typically stored in a parameter defined over a set that covers all model instances. The handle number may be used by the functions handleCollect, handleStatus, handleDelete, handleSubmit and readyCollect. For details see chapter The Grid and Multi-Threaded Solve Facility.

**heapLimit** *(real)*: Maximum Heap size allowed in MB

Synonym: HL

Available: Command line

This option allows to limit the amount of memory a GAMS job may use during compilation and execution. If the needed data storage exceeds this limit, the job will be terminated.

Default: $\infty$

**holdFixed** *(boolean)*: Treat fixed variables as constants

Available: Command line, Attribute statement (use before solve)

This option facilitates treating fixed variables as constants. Thus the problems size may be reduced.

Default: 0
### IDE (boolean): Integrated Development Environment flag

Available: Command line

This option instructs GAMS to write special instructions to the log file that are in turn read by the IDE.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Fixed variables are not treated as constants</td>
</tr>
<tr>
<td>1</td>
<td>Fixed variables are treated as constants</td>
</tr>
</tbody>
</table>

### input (string): Input file

Synonym: I

Available: Command line

Completing the input file name with the current directory composes the final name. If such a file does not exist and the extension was not specified, the standard input extension will be attached and a second attempt will be made to open an input file.

### inputDir, inputDir1..40 (string): Input file directories

Synonym: IDIR

Available: Command line

In general, GAMS searches for input and include files in the current working directory only. This option allows the user to specify additional directories for GAMS to search for include and batinclude files. A maximum of 40 separate directories may be included. The directories are separated by Operating System specific symbols. For example, on a PC the separator is a semicolon (;) character and under Unix it is the colon (:) character. Note that libinclude and sysinclude files are handled differently. Their paths are specified with the command line parameters libIncDir and sysIncDir respectively.

Consider the following illustration:

```bash
> gams myfile idir \mydir;\mydir2
```

Note that the search order for the file `myfile.gms` and all included files in PC systems will be as follows: (1) the current directory, (2) the directories specified by `inputdir` in their respective order (here the directories: `\mydir` and `\mydir2`). Under Unix, the corresponding GAMS call will be:

```bash
> gams myfile idir \mydir:\mydir2
```
Note that the information in the option inputDir may be also transferred to GAMS by entering the individual directories separately. A maximum of 40 directories may be passed on in this manner. The number appended to InputDir is important since the earlier InputDir directories will be searched first.

The example above may alternatively be formulated in the following way:

```
> gams myfile idir1 mydir1 idir2 mydir2
```

Note that in this case the search order will be as follows:

1. current directory
2. mydir1
3. mydir2

Observe that we could modify the command in the following way:

```
> gams myfile idir3 \mydir1 idir2 \mydir2
```

Note that in this case the search order will be as follows:

1. current directory
2. mydir2
3. mydir1

Thus it is not the order in which the directories are specified that matters, but the number of the option inputDir that they have been assigned to.

**integer1..5 (integer):** Integer communication cell N

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies an integer communication cell that may contain any integer number.

**interactiveSolver (boolean):** Allow solver to interact via command line input

Available: Command line

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interaction with solvelfink 0 is not supported</td>
</tr>
<tr>
<td>1</td>
<td>Interaction with solvelfink 0 is supported</td>
</tr>
</tbody>
</table>

**intVarUp (integer):** Set default upper bound on integer variables

Available: Command line, Option statement

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Set default upper bound for integer variables to +INF</td>
</tr>
<tr>
<td>Value</td>
<td>Meaning</td>
</tr>
<tr>
<td>-------</td>
<td>---------</td>
</tr>
<tr>
<td>1</td>
<td>Pass a value of 100 instead of +INF to the solver as upper bound for integer variables</td>
</tr>
<tr>
<td>2</td>
<td>Same as 0 but writes a message to the log if the level of an integer variable is greater than 100</td>
</tr>
<tr>
<td>3</td>
<td>Same as 2 but issues an execution error if the level of an integer variable is greater than 100</td>
</tr>
</tbody>
</table>

**iterLim (integer):** Iteration limit of solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies the maximum number of permitted solver iterations, before the solver terminates the run. If this limit is reached, the solver will terminate and will return solver status 2 ITERATION INTERRUPT. Note that the definition of what constitutes an iteration depends on the solver. For LP solvers, *iterlim* often refers to the number of simplex iterations (i.e., pivots). For MIP solvers, *iterlim* often refers to the cumulative number of simplex iterations over all solves of LP relaxations. Observe that *iterlim* does not apply to all iterations. For example, it does not apply to barrier iterations and major iterations in nonlinear solvers. For these iterations solver-specific options need to be set.

Default: 2000000000

**iterUsd (integer):** Number of iterations used

Available: Attribute statement (use after solve)

This model attribute returns the number of iterations used after a solve.

**jobTrace (string):** Job trace string to be written to the trace file at the end of a GAMS job

Synonym: JT

Available: Command line

This option specifies a string that is written to the trace file at the end of a GAMS job.

**keep (boolean):** Controls keeping or deletion of process directory and scratch files

Available: Command line

This option controls whether to keep the process directory. In the process directory the temporary/scratch files are located, unless the options scrDir or procDir were used.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Delete process directory</td>
</tr>
<tr>
<td>1</td>
<td>Keep process directory</td>
</tr>
</tbody>
</table>

**libIncDir (string):** LibInclude directory

Synonym: LDIR

Available: Command line
This option specifies the name of the directory to be used by GAMS for libinclude files that do not have a full path specification. An absolute or relative path may be specified. If the option lDir is not set, it will be set to the subdirectory inclib of the GAMS system directory. A relative path is relative to the GAMS system directory.

Note that if the option ldir parameter is set, the default library include directory will not be searched.

Attention

Only one directory may be set with the option lDir. Thus the string specified will be treated as one directory. If additional directories are added, errors will be reported.

Consider the following example:

> gams myfile ldir mydir

Note that GAMS will search for any referenced libinclude file in the directory <GAMS System Directory>/mydir.

license (string): Use alternative license file

Available: Command line

This option specifies the name the file that contains the GAMS license. It may be used to change the name from the default gamslice.txt that is located in the system directory. This option should only be used by advanced users attempting to override internal license information.

limCol (integer): Maximum number of columns listed in one variable block

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of columns that are listed for each variable in the column listing in the listing file. Note that the value of zero will suppress the column listing.

Default: 3

limRow (integer): Maximum number of rows listed in one equation block

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of rows that are listed for each equation in the equation listing in the listing file. Note that the value of zero will suppress the equation listing.

Default: 3

line (integer): Line number of last solve of the corresponding model

Available: Attribute statement (use after solve)

This model attribute returns the line number of the last solve of the respective model.

linkUsed (integer): Integer number that indicates the value of SolveLink used for the last solve

Available: Attribute statement (use after solve)

logFile (string): Log file name
**Synonym:** LF  
**Available:** Command line

**logLine** *(integer)*: Amount of line tracing to the log file  
**Synonym:** LL  
**Available:** Command line

This option may be used to limit the number of line tracing sent out to the log file during the compilation phase of a GAMS run. Note that setting this option to zero will cause the line tracing to be suppressed for all phases of the GAMS processing.

The log file that results from running the model [TRNSPORT] with the option `ll=0` is shown below.

```plaintext
--- Starting compilation
--- Starting execution: elapsed 0:00:00.018
--- Generating LP model transport
--- 6 rows 7 columns 19 non-zeroes
--- Executing CPLEX: elapsed 0:00:00.060

IBM ILOG CPLEX 24.8.2 r59988 Released Jan 3, 2017 DEG x86 64bit/Mac OS X
Cplex 12.7.0.0

Reading data...
Starting Cplex...
Space for names approximately 0.00 Mb
Use option 'names no' to turn use of names off
Tried aggregator 1 time.
LP Presolve eliminated 1 rows and 1 columns.
Reduced LP has 5 rows, 6 columns, and 12 nonzeros.
Presolve time = 0.01 sec. (0.00 ticks)

If we compare this output to the output shown in the example of option logFile, we will observe that the line numbers are missing from this log file.

Default: 2
3.40 The GAMS Call and Command Line Parameters

### logOption (integer): Log option

**Synonym:** LO  
**Available:** Command line

This option controls the location of the output log of a GAMS run. By default, GAMS directs the log of the run to the screen/console. If `logOption` is set to 2, the log will be redirected to a file. With `logOption=3` all the output goes to the standard output. Note that if no file name is provided for the log through the option `logFile`, the file name will be the input file name with the extension `.log`. Observe that the settings zero and 2 may be used to permit jobs to run in the background.

To illustrate, consider the following call:

```
> gams trnsport lo=2
```

Note that the resulting log file, `trnsport.log`, will be identical to the file `myfile.log` that is shown as part of the description of the option `logFile`.

**Default:** 1

### LP (string): Linear Programming - default solver

**Available:** Command line, Option statement

The default solver for models of the type Linear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

### lstTitleLeftAligned (boolean): Write title of LST file all left aligned

**Available:** Command line

**Default:** 0  

<table>
<thead>
<tr>

</table>
marginals (integer): Indicator for marginals present

Available: Attribute statement (use after solve)

maxInfes (real): Maximum of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the maximum number of infeasibilities after a solve.

maxProcDir (integer): Maximum number of 225* process directories

Available: Command line

This option controls the maximum number of work file directories that may be generated by GAMS. By default they are called 225a, 225b, ..., 225aa, 225ab ... Note that the label 225 may be changed with the option procDir.

Default: 700

MCP (string): Mixed Complementarity Problems - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Complementarity Problems is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

MCPRHoldFx (boolean): Print list of rows that are perpendicular to variables removed due to the holdfixed setting

Available: Command line, Option statement, Attribute statement (use before solve)

Default: 0

meanInfes (real): Mean of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the mean of the infeasibilities after a solve.

measure (no value): Output of time and memory use since the last measure statement or the program beginning

Available: Option statement

This option has the effect that three measurements will be displayed: the memory and time usage since the last option statement measure and the total time used. See also the related option profile.

memoryStat (no value): Show memory statistics in the LST file

Available: Option statement

This option has the effect that memory statistics will be shown in the listing file.
MINLP (string): Mixed-Integer Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Integer Nonlinear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

MIP (string): Mixed-Integer Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Integer Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

MIQCP (string): Mixed Integer Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Integer Quadratically Constrained Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

modelStat (integer): Integer number that indicates the model status

Available: Attribute statement (use after solve)

This model attribute returns the model status after a solve. Observe that there are compile-time constants that are related to modelStat. Note that additional information to the values given in the table below is provided in section Model Status.

MPEC (string): Mathematical Programs with Equilibrium Constraints - default solver

Available: Command line, Option statement

The default solver for models of the type Mathematical Program with Equilibrium Constraints is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

multiPass (boolean): Multipass facility

Synonym: MP

Available: Command line

This option may be used to instruct GAMS to use a quick syntax checking compilation facility which does not require all items to be declared. This alternative is useful when a large model is assembled from smaller pieces. It allows slices of GAMS code to be independently checked for syntax errors.

Consider the following example:

\[
a(i) = b(i) * 5 ; \\
b(i) = c(j) ;
\]

By default, running a file containing just these two statements will generate the following listing file:

1 a(i) = b(i) * 5 ;
**** $140,120,140
2 b(i) = c(j) ;
**** $140,120,149
120 Unknown identifier entered as set
140 Unknown symbol
149 Uncontrolled set entered as constant

**** 6 ERROR(S) 0 WARNING(S)

Note that both sets \( i \) and \( j \) have not been defined or initialized. In addition, the identifiers \( a \), \( b \) and \( c \) have not been defined either. Further, an assignment cannot be made without the right-hand side of the assignment being known. However, in both assignments there is no data available for the right-hand side. If we run the same two lines with the option \( mp=1 \), we will get the following listing file:

1 a(i) = b(i) * 5 ;
2 b(i) = c(j) ;
**** $149
149 Uncontrolled set entered as constant

**** 1 ERROR(S) 0 WARNING(S)

Observe that the statements have now been processed independently of their context. They are now checked only for consistency. GAMS now assumes that the sets \( i \) and \( j \), as well as the identifiers \( a \), \( b \), and \( c \) have been defined and, if necessary, initialized elsewhere. The only error that is reported is the inconsistency of indices in the second statement.

Default: 0
### Value | Meaning
---|---
0 | Standard compilation
1 | Check-out compilation
2 | As 1, and skip $call and ignore missing file errors with $include and $gdxin

**NLP** (*string*): Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Nonlinear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

**nodLim** (*integer*): Node limit in branch and bound tree

Available: Command line, Attribute statement (use before solve)

This option specifies the maximum number of nodes that are to be processed in the branch and bound tree search for a MIP problem. Note that setting `nodLim` can stop solutions that are exhibiting ”excessive” iterations: if the limit is reached the algorithm will terminate, without obtaining optimality. In this case the solver status will be 4 TERMINATED BY SOLVER. Observe that a value of zero is interpreted as 'not set'.

Default: 0

**nodUsd** (*integer*): Number of nodes used by the MIP solver

Available: Attribute statement (use after solve)

This model attribute returns the number of nodes used by the MIP solver after a solve.

**noNewVarEqu** (*integer*): Triggers a compilation error when new equations or variable symbols are introduced

Available: Command line

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>AllowNewVarEqu</td>
</tr>
<tr>
<td>1</td>
<td>DoNotAllowNewVarEqu</td>
</tr>
</tbody>
</table>

**number** (*real*): Model instance serial number

Available: Attribute statement (use after solve)

This model attribute returns the model instance serial number. Note that the first model solved is assigned number 1, the second number 2 etc. The user may also set a value \(n\) and the next model solved will be assigned the number \(n+1\).

**numDepnd** (*integer*): Number of dependencies in a CNS model
Available: Attribute statement (use after solve)

This model attribute returns the number of dependencies identified in a CNS model after a solve.

\textbf{numDVar} \hspace{1em} (\textit{integer}): Number of discrete variables

Available: Attribute statement (use after solve)

This model attribute returns the number of discrete variables after a solve.

\textbf{numEqu} \hspace{1em} (\textit{integer}): Number of equations

Available: Attribute statement (use after solve)

This model attribute returns the number of equations after a solve.

\textbf{numInfes} \hspace{1em} (\textit{integer}): Number of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the number of infeasibilities after a solve.

\textbf{numNLIns} \hspace{1em} (\textit{integer}): Number of nonlinear instructions

Available: Attribute statement (use after solve)

This model attribute returns the number of nonlinear instructions after a solve.

\textbf{numNLNZ} \hspace{1em} (\textit{integer}): Number of nonlinear nonzeros

Available: Attribute statement (use after solve)

This model attribute returns the number of nonlinear nonzeros after a solve.

\textbf{numNOpt} \hspace{1em} (\textit{integer}): Number of nonoptimalities

Available: Attribute statement (use after solve)

This model attribute returns the number of nonoptimalities after a solve.

\textbf{numNZ} \hspace{1em} (\textit{integer}): Number of nonzero entries in the model coefficient matrix

Available: Attribute statement (use after solve)

This model attribute returns the number of nonzero entries in the model coefficient matrix after a solve.

\textbf{numRedef} \hspace{1em} (\textit{integer}): Number of MCP redefinitions

Available: Attribute statement (use after solve)

This model attribute returns the number of MCP equation-type redefinitions after a solve.

\textbf{numVar} \hspace{1em} (\textit{integer}): Number of variables

Available: Attribute statement (use after solve)

This model attribute returns the number of variables after a solve.
**numVarProj** *(integer)*: Number of bound projections during model generation

Available: Attribute statement (use after solve)

This model attribute returns the number of bound projections during model generation.

**objEst** *(real)*: Estimate of the best possible solution for a mixed-integer model

Available: Attribute statement (use after solve)

This model attribute returns the estimate of the best possible solution for a MIP or other models with discrete variables. The model attribute is mainly used after solve.

Some GAMS solvers implement algorithms (e.g. branch-and-bound) that generate a bound on the objective function value for the best possible solution. Users may access this bound by using the model attribute **objEst**. Note that this is mainly used for models with discrete variables (e.g. MIP and MINLP), but some global solvers implement spatial branch-and-bound algorithms that also provide such a bound for purely continuous problems. In case the solver does not set the attribute, its value is `na`.

**objVal** *(real)*: Objective function value

Available: Attribute statement (use after solve)

This model attribute returns the objective function value after a solve.

**on115** *(boolean)*: Generate errors for unknown unique element in an equation

Available: Command line

This option generates errors for unknown unique elements in an equation.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error messages</td>
</tr>
<tr>
<td>1</td>
<td>Issue error messages</td>
</tr>
</tbody>
</table>

**optCA** *(real)*: Absolute Optimality criterion solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies an absolute termination tolerance for a global solver. General problems are often extremely difficult to solve and proving that a solution that was found for a nonconvex problem is indeed the best possible solution can use enormous amounts of resources. The absolute gap is defined to be \(|PB-DB|\). Here the primal bound \(PB\) is the objective function value of the best feasible solution found thus far and the dual bound \(DB\) is the current bound on the optimal value of the problem (i.e., lower bound in case of minimization and upper bound in case of maximization).

If the absolute gap is not greater than **optCA**, the solver will terminate and return solver status 1 NORMAL COMPLETION and model status 8 INTEGER SOLUTION (for a problem with discrete variables) or 2 LOCAL OPTIMAL or 7 FEASIBLE SOLUTION (for a problem without discrete variables). Note that this is a termination test only; setting this option should not change the global search.
Note

As this is an absolute criterion, setting the value to 100 means that the objective value will be within the 100 units of the true objective value.

Observe that a nonzero value for **optCA** will reduce solution time. However, it may cause the true integer optimum to be missed. This will be the case if at the time the solution algorithm stops, the value of the true integer optimum is within the tolerance specified by **optCA** of the best current solution. Therefore the reported solution could be the best, but it is guaranteed only to be within the tolerance of the true optimal solution.

Default: 0

**optCR** *(real)*: Relative Optimality criterion solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies a relative termination tolerance for a global solver. General problems are often extremely difficult to solve and proving that a solution that was found for a nonconvex problem is indeed the best possible solution can use enormous amounts of resources. The precise definition of **optCR** depends on the solver. GAMS and some solvers use the following formula to compute the optimality gap:

\[ \frac{|PB-DB|}{\max(|PB|,|DB|)} \]

Here the primal bound **PB** is the objective function value of the best feasible solution found thus far and the dual bound **DB** is the current bound on the optimal value of the problem (i.e., lower bound in case of minimization and upper bound in case of maximization). However, two other formulas are also widely used, namely

\[ \frac{|PB-DB|}{|PB|} \]

and

\[ \frac{|PB-DB|}{|DB|} \]

Different adjustments when the denominator approaches zero or bounds are of different signs will be applied. The solver will stop as soon as it has found a feasible solution proven to be within **optCR** of optimal, that is, the optimality gap falls below **optCR**.

Note

As **optCR** is specified in proportional terms relative to the objective value, a value of 0.1 means that the objective value will be within 10% of the true objective value.

Observe that the solver will stop after finding a solution proven to be optimal within the tolerance specified with **optCR** and thus the solution time may be reduced. However, setting this option may cause the true integer optimum to be missed. This will be the case if at the time the solution algorithm stops, the value of the true integer optimum is within the tolerance specified by **optCR** of the best current solution. Therefore the reported solution could be the best, but it is guaranteed only to be within the tolerance of the true optimal solution.

Default: 0.10

**optDir** *(string)*: Option file directory

Available: Command line

This option may be used to specify the name of the directory for solver option files. By default, the directory will be set to the current working directory.
**optFile (integer):** Default option file

Available: Command line, Attribute statement (use before solve)

This option instructs the solver to read an option file. The value of `optFile` determines which option file is used (see table below). Solver options allow users to manipulate the way solvers work. This may affect various solver functions including the choice of the branch and bound tree handling strategies. Please consult the solver manuals for options for each solver.

Note that this option is available as model attribute and command line parameter. Consider the following GAMS call:

```
> gams myfile optfile=1
```

Observe that the value of 1 for `optFile` means that the option file with the name `solverName.opt` will be used. Here `solverName` is the name of the respective solver. For example, if the solver CONOPT is used, the name of the respective option file is `conopt.opt`.

Note

If `optFile` is set with the model attribute in the GAMS input file, the value of the model attribute will override any `optFile` specifications on the command line.

Different values for `optFile` allow access to different option files for the same solver. Note that the following rule is used: if we specify `optfile = n`, then `solvername.opt` will be used for `n=1`, otherwise `solvername.opX`, `solvername.oXX` or `solvername.XXX` will be used, where `X`'s are the characters representing the value of `n`, for `n > 1`. Observe that no option file will be used if the value of `optFile` is zero.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>

</tbody>
</table>

**output (string):** Listing file name

Synonym: OO

Available: Command line

By default, the name of the output file (or listing file) is automatically created by combining the name of the input file with the current directory and applying the standard output file extension `.lst`. This option may be used to specify an alternative name for the output file. If the value is a file name without an absolute path, the current directory will compose the final name. If the absolute path is included in the file name, then the name is used as specified.

Consider the following examples:
gams transport
gams transport o=transport.out
gams transport o=c:\test\transport.out

Note that the first call will create an output file called transport.lst (for PC and Unix platforms) in the current directory. The second call will create a file called transport.out in the current directory. The last call will create the file as listed. If the directory c:\test does not exist, GAMS will exit with a parameter error.

**pageContr (integer):** Output file page control option

   Synonym: PC

   Available: Command line

   This option affects the page control in the listing file.

   Default: 3

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No page control, with padding</td>
</tr>
<tr>
<td>1</td>
<td>FORTRAN style line printer format</td>
</tr>
<tr>
<td>2</td>
<td>No page control, no padding</td>
</tr>
<tr>
<td>3</td>
<td>Formfeed character for new page</td>
</tr>
</tbody>
</table>

**pageSize (integer):** Output file page size (=0 no paging)

   Synonym: PS

   Available: Command line

   This option specifies the number of lines that are used on a page for printing the listing file. The lower bound is zero, which is interpreted as +inf. That means that everything is printed to one page.

   Default: 58

**pageWidth (integer):** Output file page width

   Synonym: PW

   Available: Command line

   This option sets the print width on a page in the listing file with a possible range from 72 to 32767. Note that under the IDE, the default is set to 80. If the value is outside the allowed range, the default value will be used.

   Note that .pw is also a put file attribute. In the context of the put writing facility, it may be used to set the page width of a put file. See page width for further details.

   Default: 255

**parmFile (string):** Command Line Parameter include file
### 3.40 The GAMS Call and Command Line Parameters

Synonym: PF

Available: Command line

This option specifies the name of a secondary customization parameter file to use. It is used to augment the command line adding more command line parameters from a file. It is read from the current directory unless a path is specified. For an example, see section Specifying Options Through a Secondary Parameter File.

**pLicense** *(string)*: Privacy license file name

Available: Command line

This option gives the name of a privacy license file that contains file encryption codes. A full path should be used. For more information, see Encrypting Files.

**prefixLoadPath** *(boolean)*: Prepend GAMS system directory to library load path

Available: Command line

The OS environment variable to locate shared libraries used to be prefixed with the GAMS system directory. The option controls if this done or not. For the platforms Windows and AIX setting of this option has no impact.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not set GAMS system directory at beginning of library load path</td>
</tr>
<tr>
<td>1</td>
<td>Set GAMS system directory at beginning of library load path</td>
</tr>
</tbody>
</table>

**priorOpt** *(real)*: Priority option for variable attribute .prior

Available: Attribute statement (use before solve)

Instructs the solver to use the priority branching information passed by GAMS through variable suffix values variable.prior. If and how priorities are used is solver-dependent.

Default: 0

**procDir** *(string)*: Process Directory

Available: Command line

This option specifies the name of the process directory. If specified, the directory must already exist and it will not be deleted when GAMS cleans up. By default, the process directory name is chosen automatically from the list 225a, 225b, ..., 225aa, 225ab ..., by skipping over existing entries, and the directory will be deleted during cleanup if the option keep is not used. Very little is written to the process directory, but the scratch directory is used more, and the option scrDir takes its default from the process directory.

**procDirPath** *(string)*: Directory to create process directory in

Available: Command line

This option specifies the directory where the process directory should be created. If specified, the directory must already exist. While the process directory does not get cleaned automatically if the option procDir is set, this is not the case if the option procDirPath is used instead. Thus it allows to conveniently change the location of the process directory without changing the GAMS cleanup behavior. Note that if the location of the process directory is changed, the location of the default scratch directory will be changed accordingly (see option scrDir).
**procUsed (integer):** Integer number that indicates the used model type

Available: Attribute statement (use after solve)
profile (integer): Execution profiling

Available: Command line, Option statement

The execution profile of a GAMS run contains the individual and cumulative time required to execute the sections of the GAMS model, as well as information on memory use. The option profile controls whether an execution profile will be generated in the listing file. Observe that profile is available as command line parameter and option statement.

Note

The value for profile that is specified with an option statement in the GAMS input file overrides the value of profile that is passed through the command line.

Observe that an execution profile will be generated if the option profile is assigned a value larger than zero (zero is the default). Setting profile to 1 has the effect that execution times for each statement and the number of set elements over which the particular statement is executed will be reported. However, statements in programming flow control structures like loops will be omitted. Information on the execution of these statements will be included in the profile if the value is $n$, with $n > 1$. Note that an overview of the values for profile is given in the table at the end of this description.

Consider the following GAMS call:

```gams
> gams trnsport profile=1
```

This call causes the following additional lines to appear in the listing file:

<table>

</tr>
</tbody>
</table>

```
```
Observe that the first column provides the line number in the input file of the statement that is executed.

The second column reports the type of the respective statement. For an overview of all GAMS statements, see section Classification of GAMS Statements. In addition, ExecInit denotes the beginning of the execution phase of the GAMS input file and GAMS Fini denotes the end of this phase. Note that as soon as a solve statement is processed, GAMS will pass control to the solver system. Once the solver has completed its task, GAMS will restart. Thus we have two ExecInit/GAMS Fini pairs in our example. Note that only equations are listed, and not variables. This reflects the fact that GAMS uses an equation based scheme to generate a model.

The third and fourth columns show the individual time needed to execute the statement and the cumulative time taken by the GAMS system so far.

The last column gives the number of assignments that were generated in the specified line.

In addition to the lines above, a profile summary is created at the end of the listing file. This summary contains (up to) ten of the slowest execution steps. The profile summary from transport.lst follows:

```
---- Profile Summary (17 records processed)
  0.011  0.004GB  44 Assignment c (6)
  0.009  0.004GB  65 Solve Fini transport (19)
  0.002  0.002GB  65 Solve Read transport
  0.001  0.004GB  65 GAMS Fini
  0.001  0.003GB  57 Equation cost (1)
  0.001  0.003GB  69 GAMS Fini
```

Note that execution profiles and profile summaries are particularly useful for detecting the sources of performance problems. For further details, see section Finding the Causes for Slow Program Execution.

Default: 0

</table>

**profileFile (string):** Write profile information to this file

**Synopsis:** PFILE

**Available:** Command line

This option causes profiling information to be written to a file. Note that profiling information is only created with the setting `profile=1` or `profile=2`. For example such a file may have the following content:
3.40 The GAMS Call and Command Line Parameters

profileTol *(real)*: Minimum time a statement must use to appear in profile generated output

Synonym: PTOL

Available: Command line, Option statement

This option sets the profile tolerance in seconds. All statements that take less time to execute than this tolerance are not reported in the listing file. Note that this option is only effective if the value of the option profile is larger than zero.

Default: 0

putDir *(string)*: Put file directory

Synonym: PDir

Available: Command line

By default, put files are generated and saved in the current working directory. This option may be used to specify an alternative directory. Note that this option does not work if an absolute file name is provided through the file statement.

pyMultInst *(integer)*: GAMS/Python Multiple Instance Interpreter

Available: Command line

This option controls the setup of the Python interpreter for use in embedded Python code sections. If this option is set to 1 the embedded Python code can work with multiple independent Python sessions. If pyMultInst is set to 0 there is a single interpreter even with multiple parallel embedded Python sessions that all share the same data space. With pyMultInst set to 0 or 1, the environment variable GMSPYTHONMULTINST is set by GAMS to this value. If the option is not set the value will be taken from the user environment variable GMSPYTHONMULTINST. Note that setting this to 1 might cause problems when using third party modules and packages (e.g. numpy or modules that make use of it) and might also impact the performance.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use a single-session Python interpreter</td>
</tr>
<tr>
<td>1</td>
<td>Use a multi-session Python interpreter</td>
</tr>
</tbody>
</table>

pySetup *(integer)*: GAMS/Python Setup
This option controls the setup of Python for use in embedded Python code sections. If this option is set to 1 GAMS will use the Python installation that comes with the GAMS installation (sysdir/GMSPython) for Windows, Linux, and Mac OS X. With pySetup set to 0 an alternative Python installation will be used for embedded code. See section Porting to a Different Version of Python for details.

Default: 1

<table>

**QCP (string): Quadratically Constrained Programs - default solver**

The default solver for models of the type Quadratically Constrained Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

**realI..5 (real): Real communication cell N**

This option specifies a real communication cell that may contain any real number.

**reference (string): Symbol reference file**

Synonym: RF

If this option is specified, all symbol references will be written to the specified file. Setting rf or Reference to the string 'default' will cause GAMS to create a reference file with the file root name of the GAMS input file and the extension ref. Thus the call

```
> gams trnsport rf=default
```

will generate the reference file trnsport.ref.

**reform (integer): Reformulation level**

This option triggers an objective function reformulation. The interpretation depends on the solver. The solvers MINOS and SNOPT support this option. Note that the default value is zero and the range is [-2147483647,2147483647 ].

**resCalc (real): Time spent in function and derivative calculations (deprecated)**

Available: Attribute statement (use after solve)
resDeriv (real): Time spent in derivative calculations (deprecated)

   Available: Attribute statement (use after solve)

resGen (real): Time GAMS took to generate the model in CPU seconds (deprecated)

   Available: Attribute statement (use after solve)

   This model attribute returns the time GAMS took to generate the model in CPU seconds.

resIn (real): Time to import model (deprecated)

   Available: Attribute statement (use after solve)

resLim (real): Wall-clock time limit for solver

   Available: Command line, Option statement, Attribute statement (use before solve)

   This option specifies the time in seconds that the solver can run before it can terminate and return the solver status 3 RESOURCE INTERRUPT. The solver should start the clock soon after it starts, so the time required to read in the problem and do any reformulations, preprocessing or presolving is included in the time limit. Where possible, the time limit applies to the wall-clock time: this behavior translates well to multi-threaded solves.

   Default: 1000

resOut (real): Time to export solution (deprecated)

   Available: Attribute statement (use after solve)

restart (string): Name of a restart file, see The Save and Restart Feature

   Synonym: R

   Available: Command line

   This option specifies the name of a work file that was written with the option save that will be used to restart the GAMS program. The work file is also called restart file. For more information including examples, see chapter The Save and Restart Feature.

restartNamed (string): Name of another matching restart file, see Obfuscated Work Files

   Synonym: RN

   Available: Command line

resUsd (real): Time the solver used to solve the model in CPU seconds

   Available: Attribute statement (use after solve)

   This model attribute returns the time in seconds used by the solver. Wherever possible, the units used (wall-clock time vs. CPU time) will be the same as used by the reslim option.

RMINLP (string): Relaxed Mixed-Integer Non-Linear Programming - default solver
Available: Command line, Option statement

The default solver for models of the type Relaxed Mixed Integer Nonlinear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

RMIP (string): Relaxed Mixed-Integer Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mixed Integer Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

RMIQCP (string): Relaxed Mixed Integer Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mixed Integer Quadratically Constrained Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

RMPEC (string): Relaxed Mathematical Programs with Equilibrium Constraints - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mathematical Program with Equilibrium Constraints is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

rObj (real): Objective function value from the relaxed solve of a mixed-integer model when the integer solver did not finish

Available: Attribute statement (use after solve)

This model attribute returns the objective function value from the relaxed solve of a MIP when the integer solver did not finish.

save (string): Creates a work file, see The Save and Restart Feature
Synonym: S

Available: Command line

This option specifies the name of a work file to be written. The work file is intended to be used later to restart the GAMS program and it is also called save file. Note that save files are platform-independent.

The final name is composed by completing the specified save file name with the current directory and the standard work file extension. By default, GAMS will generated eight save files. Therefore the name of the save file should be such that GAMS can generate eight names from it. GAMS distinguishes file names from their extensions. If no extension is provided by the user, GAMS will add the extensions g01 through g08 to name the eight saved work files. Note that the character ? in the name of the save file will be replaced by GAMS with the numbers 1 to 8.

The following table illustrates which names GAMS will generate given the name provided by the user with the option save.
Note

On Unix platforms the character ? is a special character and may require a backslash character \ before it in order to be interpreted correctly. For example, the name myfile? should be written as myfile\? on this platform.

For further information including examples, see chapter The Save and Restart Feature.

saveObfuscate (string): Creates an obfuscated work file, see Obfuscated Work Files

Synonym: SO

Available: Command line

savePoint (integer): Save solver point in GDX file

Synonym: SP

Available: Command line, Option statement, Attribute statement (use before solve)

This option instructs GAMS to save a point format GDX file that contains the information on the current solution point.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No point GDX file is to be saved</td>
</tr>
<tr>
<td>1</td>
<td>A point GDX file from the last solve is to be saved</td>
</tr>
<tr>
<td>2</td>
<td>A point GDX file from every solve is to be saved</td>
</tr>
</tbody>
</table>

scaleOpt (boolean): Employ user specified variable and equation scaling factors

Available: Attribute statement (use before solve)

This option determines whether GAMS will employ user-specified variable and equation scaling factors. It must be set to a nonzero value if scaling factors are to be used. For more details on scaling, see section Model Scaling - The Scale Option.

Default: 0

scrDir (string): Scratch directory

Synonym: SD

Available: Command line

This option specifies the name of the scratch directory. The scratch directory is used by GAMS for intermediate files that are generated during execution. The scratch directory and all its
contents are usually deleted at the end of the GAMS run. By default, the scratch directory takes its value from the process directory that is specified with the option procDlr. If neither the scratch directory nor the process directory are specified, the scratch directory will be set to a subdirectory of the current working directory with an internally generated name. If the scratch directory is specified, the respective directory must already exist and neither the content nor the directory itself will be deleted by GAMS at the end of the run.

Note that the option solveLink may be used to reduce or eliminate the need for intermediate files.

**scrExt** *(string)*: Scratch file extension to be used with temporary files

- **Synonym**: SE
- **Available**: Command line
- This option specifies the name of the extension for the temporary files that GAMS is generating during execution.
- **Default**: dat

**scriptExit** *(string)*: Program or script to be executed at the end of a GAMS run

- **Available**: Command line
- By default, GAMS does not call an exit script anymore. If this is required, the option scriptExit has to be set explicitly to the script that should be called after GAMS terminates. Note that an empty template of an exit script is in the GAMS system directory: it is called gmsxitnt.cmd for Windows and gmsxitus.run for Unix.

**scriptFrst** *(string)*: First line to be written to GAMSNEXT file.

- **Synonym**: SF
- **Available**: Command line
- This option specifies the first line written to gamsnext. The default is an empty string and the first line is not written.

**scrNam** *(string)*: Work file names stem

- **Synonym**: SN
- **Available**: Command line
- This option specifies the name stem that is used to complete the names of intermediate work files. Note that the name stem must have at least one ‘?’. The name will be completed with the scratch directory and the standard scratch name extension.

**seed** *(integer)*: Random number seed

- **Available**: Command line, Option statement
- This option specifies the seed that is used for the pseudo random number generator.
- **Default**: 3141

**showOSMemory** *(integer)*: Show the memory usage reported by the Operating System instead of the internal counting

- **Available**: Command line
- **Default**: 0
### solPrint *(int or string)*: Solution report print option

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the printing of the solution listing to the listing file.

Note that the numeric values plus some compile-time constants are deprecated (off: 0 and solprint.Summary, on: 1 and solprint.Report, and silent: 2 and solprint.Quiet) they are only relevant for backward compatibility. Note further, that there are compile-time constants that are associated with this option. The table below offers an overview of the different types of values and a description of the associated meaning.

<table>
<thead>
<tr>
<th>String Value</th>
<th>Compile-Time Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>solprint.Off</td>
<td>Remove solution listings following solves</td>
</tr>
<tr>
<td>on</td>
<td>solprint.On</td>
<td>Include solution listings following solves</td>
</tr>
<tr>
<td>silent</td>
<td>solprint.Silent</td>
<td>Suppress all solution information</td>
</tr>
</tbody>
</table>

Default: off

### solSlack *(boolean)*: Causes the equation output in the listing file to contain slack variable values instead of level values

Available: Option statement

If the value of this option is set to 1, the equation output in the listing file will contain slack variable values instead of level values.

Default: 0

### solveLink *(integer)*: Solver link option

Synonym: SL

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies the solver linking conventions. Note that values 3, 4, 6 and 7 are relevant for grid computing. Observe that there are compile-time constants that are associated with this option.

Default: 0
### Value | Meaning
--- | ---
1 | Solver is called from a shell and GAMS remains open
2 | Solver is called with a spawn (if possible) or a shell (if spawn is not possible) and GAMS remains open
3 | GAMS starts the solution and continues in a Grid computing environment
4 | GAMS starts the solution and wait (same submission process as 3) in a Grid computing environment
5 | The problem is passed to the solver in core without use of temporary files
6 | The problem is passed to the solver in core without use of temporary files, GAMS does not wait for the solver to come back
7 | The problem is passed to the solver in core without use of temporary files. GAMS waits for the solver to come back but uses same submission process as 6

**solveOpt** (*int or string*): Multiple solve management

Available: Option statement, Attribute statement (use before solve)

This option will instruct GAMS how to manage the model solution if only part of the variables and equations in the particular problem are solved.

Observe that this option is available as model attribute and option statement. The values for model attributes are numeric, while the values for option statements are text strings. In addition, there are compile-time constants that are associated with this option. The first of the two tables below offers an overview of how the different types of values are related and the second table gives the values in numerical terms and a description of the associated meaning.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Compile-Time Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>replace</td>
<td>solveOpt.Replace</td>
</tr>
<tr>
<td>1</td>
<td>merge</td>
<td>solveOpt.Merge</td>
</tr>
<tr>
<td>2</td>
<td>clear</td>
<td>solveOpt.Clear</td>
</tr>
</tbody>
</table>

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The solution information for all equations appearing in the model is completely replaced by the new model results; variables are only replaced if they appear in the final model</td>
</tr>
<tr>
<td>1</td>
<td>The solution information for all equations and variables is merged into the existing solution information</td>
</tr>
<tr>
<td>2</td>
<td>The solution information for all equations appearing in the model is completely replaced; in addition, variables appearing in the symbolic equations but removed by conditionals will be removed</td>
</tr>
</tbody>
</table>

**solver** (*string*): Default solver for all model types that the solver is capable to process

Available: Command line, Option statement

The command line parameter `solver=abc` initializes the default solver for the model types the solver "abc" is capable of to abc. This initialization is done before the default solvers of individual model types are set via command line parameters. Consider the following example:

```plaintext
> gams trnsport lp=conopt solver=bdmlp
```
Note that this GAMS call will first set the solver BDMLP as the solver for the model types LP, RMIP and MIP, since these are the model types that BDMLP can handle. Then Conopt will be reset as the default solver for LPs. Observe that the order of these parameters on the command line is irrelevant. If multiple occurrences of the option `solver` appear, the last entry will set value of the option.

In addition, the solver for multiple model types may be set in the GAMS model source code via the following statement:

```gams
option solver = abc;
```

This statement sets the solver for the model types the solver abc can handle to abc. Note that in such an option statement the order of other solver setting options is significant. Consider the following example:

```gams
option lp=conopt, solver=bdmlp;
```

This statement will first set the solver for LPs to Conopt and in the next step to BDMLP because BDMLP is capable of handling the model type LP. In some cases it makes sense to set a solver twice. Consider the following example:

```gams
option solver=conopt, solver=cbc;
```

This option statement has the effect that models of the types CNS, DNLP, NLP, QCP, RMIQCP or RMINLP will be solved with Conopt and models of the types LP, RMIP or MIP will be solved with CBC.

Note that as usual, a specification of an option through the command line takes precedence over a specification with an option statement.

**solverCntr (string):** Solver control file name

- Synonym: SCNTR
- Available: Command line

This option specifies the solver control file name. Note that the name is completed with the scratch directory and the scratch extension.

**solverDict (string):** Solver dictionary file name

- Synonym: SDICT
- Available: Command line

This option specifies the solver dictionary file name. Note that the name completed with the scratch directory and the scratch extension.

**solverInst (string):** Solver instruction file name

- Synonym: SINST
- Available: Command line

This option specifies the solver instruction file name. Note that the name is completed with the scratch directory and the scratch extension.

**solverMatr (string):** Solver matrix file name

- Available: Command line

This option specifies the solver matrix file name. Note that the name is completed with the scratch directory and the scratch extension.
Synonym: SMATR

Available: Command line

This option specifies the solver matrix file name. Note that the name is completed with the scratch directory and the scratch extension.

**solverSolu** *(string)*: Solver solution file name

Synonym: SSOLU

Available: Command line

This option specifies the solver solution file name. Note that the name is completed with the scratch directory and the scratch extension.

**solverStat** *(string)*: Solver status file name

Synonym: SSTAT

Available: Command line

This option specifies the solver status file name. Note that the name is completed with the scratch directory and the scratch extension.

**solveStat** *(integer)*: Indicates the solver termination condition

Available: Attribute statement (use after solve)

This model attribute indicates the solver termination condition. Observe that there are compile-time constants that are related to **solveStat**. Note that additional information to the values given in the table below is provided in section *Solver Status*.

<table>
<thead>

</tbody>
</table>

**stepSum** *(boolean)*: Summary of computing resources used by job steps

Available: Command line

This option controls the generation of a step summary of the processing times taken by GAMS during a given run.
For example, the call

   > gams trnsport stepsum=1

will generate the following step summaries in the listing file:

STEP SUMMARY: 0.016 0.016 STARTUP
              0.005 0.005 COMPILATION
              0.065 0.065 EXECUTION
              0.001 0.001 CLOSEDOWN
              0.087 0.087 TOTAL SECONDS
              0.089 0.089 ELAPSED SECONDS
              3.942 3.942 MAX HEAP SIZE (MB)

Note that this step summary will be printed before the model is sent to the solver, thus it may be found before the solve summary. The second step summary will be printed after solution, it will appear at the very end of the listing file:

STEP SUMMARY: 0.004 0.020 STARTUP
              0.000 0.005 COMPILATION
              0.003 0.068 EXECUTION
              0.000 0.001 CLOSEDOWN
              0.007 0.094 TOTAL SECONDS
              0.239 0.328 ELAPSED SECONDS
              2.899 3.942 MAX HEAP SIZE (MB)

Observe that the first column reports the time for the individual section of the run, while the second column reports accumulated times including previous sections.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No step summary</td>
</tr>
<tr>
<td>1</td>
<td>Step summary printed</td>
</tr>
</tbody>
</table>

**strictSingleton** (boolean)  
Error if assignment to singleton set has multiple elements

Available: Command line, Option statement

This option affects the behavior of a membership assignment to a singleton set. If the value is set to zero, GAMS will not complain about a singleton set with more than one element, but will take only the first element. However, if the value is set to 1, a singleton set definition with more than one element will cause an error.

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Take first record if assignment to singleton set has multiple elements</td>
</tr>
<tr>
<td>1</td>
<td>Error if assignment to singleton set has multiple elements</td>
</tr>
</tbody>
</table>

**stringChk** (integer):  
String substitution options

Available: Command line
This option affects the result of the check for \%xxx\% symbols. Note that \%xxx\% symbols may be environment variables or compile-time variables.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No substitution if symbol undefined and no error</td>
</tr>
<tr>
<td>1</td>
<td>Error if symbol undefined</td>
</tr>
<tr>
<td>2</td>
<td>Remove entire symbol reference if undefined and no error</td>
</tr>
</tbody>
</table>

subSys (string): Name of subsystem configuration file

Available: Command line

This option specifies the name of the configuration file that contains solver defaults and other information. This option should be used only by advanced users who attempt to override internal subsystem information.

subSystems (no value): Lists all solvers available as well as the current default and active solvers in the LST file

Available: Option statement

This option has the effect that all available subsystems will be displayed in the listing file. Note that a solver is considered a subsystem.

sumInfeas (real): Sum of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the sum of infeasibilities after a solve.

suppress (boolean): Compiler listing option

Available: Command line

If set to 1, this option will suppress the echoing of the contents of the input file(s) to the listing file. Note that this option is similar in functionality to the dollar control option $on/offlisting.

Note

The dollar control options $on/offlisting will affect the echo print in the listing file only if suppress is set to zero. If suppress is set to 1, the input file(s) will not be echoed to the listing file and the dollar control options will not have any effect on the listing file.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>

</tr>
<tr>
<td>1</td>
<td>Suppress compiler listing</td>
</tr>
</tbody>
</table>

symbol (string): Symbol table file

Available: Command line
This option specifies the name of a partial symbol table that may be written in conjunction with reference files.

**symPrefix (string):** Prefix all symbols encountered during compilation by the specified string in work file

Available: Command line

**sys10 (boolean):** Changes rpower to ipower when the exponent is constant and within 1e-12 of an integer

Available: Command line, Option statement

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disable conversion</td>
</tr>
<tr>
<td>1</td>
<td>Enable conversion</td>

<tr>
<td>1x</td>
<td>Print additional information in lst file</td>
</tr>
</tbody>
</table>

**sys16 (integer):** Disable search record memory (aka execute this as pre-GAMS 24.5)
sys17 *(integer)*: Disable sparsity trees growing with permutation (aka execute this as pre-GAMS 24.5)

Available: Command line

Default: 0

**sysDir** *(string)*: GAMS system directory where GAMS executables reside

Available: Command line

This option sets the GAMS system directory. It is useful if there are multiple systems installed on the machine or when GAMS is called from an external system like Visual Basic.

**sysIdent** *(real)*: Solver identification number

Available: Attribute statement (use after solve)

**sysIncDir** *(string)*: SysInclude directory

Synonym: SDIR

Available: Command line

This option specifies the name of the directory to be used by GAMS for *sysinclude* files that do not have a full path specification. An absolute or relative path may be specified. If this option is not set, it will be set to the GAMS system directory.

Note that if this option is set, the default system include directory will not be searched.

Attention

Only one directory may be set with the option **sDir**. Thus the string specified will be treated as one directory. If additional directories are added, errors will be reported.

Consider the following example:

```gams
> gams myfile sdir mydir
```

Note that GAMS will search for any referenced *sysinclude* file in the directory **mydir**.

**sysOut** *(bool or string)*: Solver Status file reporting option

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls whether additional solver generated output (the solver status file) is included in the listing file. Note that the contents of the solver status file are useful for debugging or to get additional information about a solver run. Normally, only those messages flagged by the solver as destined for the listing file will be listed. If the solver crashes or encounters any unexpected difficulties, the contents of the solver status file will be automatically sent to the listing file.

Note that the boolean values (off: 0 and off: 1) are deprecated, they are only relevant for backward compatibility. The table below gives the boolean values and the associated meaning.
<table>
<thead>
<tr>
<th>String</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Suppress additional solver generated output</td>
</tr>
<tr>
<td>on</td>
<td>Include additional solver generated output</td>
</tr>
</tbody>
</table>

Default: off

**sysVer** *(real)*: Solver version

Available: Attribute statement (use after solve)

**tabIn** *(integer)*: Tab spacing

Available: Command line

This option sets the tab spacing. By default, tabs are not allowed in GAMS. However, the most common setting is 8. As a result, the tabs are at columns 1, 9, 17, ... and the intermediate columns are replaced by blanks.

Default: 8

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Tabs are not allowed</td>
</tr>
<tr>
<td>1</td>
<td>Tabs are replaced by blanks</td>
</tr>
<tr>
<td>n</td>
<td>Tabs are 1, n+1, 2n+1,... (default: n=8)</td>
</tr>
</tbody>
</table>

**tFormat** *(boolean)*: Time format

Synonym: TF

Available: Command line

This option controls the time format in the listing file. The three date formats correspond to the various conventions used around the world. For example, the time 7:45 PM will be written as 19:45:00 with the default tf value of zero and as 19.45.00 with tf=1.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Time as hh:mm:ss</td>
</tr>
<tr>
<td>1</td>
<td>Time as hh.mm.ss</td>
</tr>
</tbody>
</table>

**threads** *(integer)*: Number of threads to be used by a solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of threads or CPU cores to be used by a solver. If the number is greater than the number of available CPU cores, it will be reduced to the number of cores available. Note that the value of zero means that all available cores will be used.

Default: 1
### 3.40 The GAMS Call and Command Line Parameters

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use number of available cores</td>
</tr>
<tr>
<td>n</td>
<td>Use n threads</td>
</tr>
<tr>
<td>minus _n</td>
<td>Number of cores to leave free for other tasks</td>
</tr>
</tbody>
</table>

**threadsAsync** *(integer)*: Number of threads to be used for asynchronous solve (solveLink=6)

Available: Command line, Option statement

Default: -1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use number of available cores</td>
</tr>
<tr>
<td>n</td>
<td>Use n threads</td>
</tr>
<tr>
<td>minus _n</td>
<td>Number of cores to leave free for other tasks</td>
</tr>
</tbody>
</table>

**timer** *(integer)*: Instruction timer threshold in milli seconds

Available: Command line

This option specifies an instruction timer threshold in milli seconds. That means that only details about internal GAMS instructions that took more than n milli seconds are echoed to the log.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interpreted as +inf, no details echoed</td>
</tr>
<tr>
<td>n</td>
<td>Echo all details about internal GAMS instructions that took more than n milli seconds to the log</td>
</tr>
</tbody>
</table>

**tolInfeas** *(real)*: Infeasibility tolerance for an empty row of the form a.. 0*x =e= 0.0001;

Available: Attribute statement (use before solve)

This option specifies the infeasibility tolerance for an empty row of the following form:

a.. 0*x =e= 0.0001;

If the option is not set, a tolerance of 10 times the machine precision will be used. Empty rows that fail this infeasibility check will be flagged with the listing file message **Equation infeasible due to rhs value**.

**tolInfRep** *(real)*: This attribute sets the tolerance for marking infeasible in the equation listing

Available: Attribute statement (use before solve)

This option sets the tolerance for marking an equation **infeasible** in the equation listing.

Note that the default value is 1.0E-6.

Default: 1.0E-06

**tolProj** *(real)*: Tolerance for setting a variable level to its bound and filtering marginals when reading a solution
Available: Attribute statement (use before solve)

This option controls the tolerance for filtering marginals (i.e. setting marginals within the tolerance to zero) and projecting levels to the lower or upper bound that are within the tolerance when reading a solution. Note that the default value is 1e-8.

Default: 1.0E-08

**trace (string):** Trace file name

Available: Command line

This option specifies the trace file name and causes a trace file to be written. Note that if a previous trace file of the same name already exists, then all new data output will be appended. Therefore, users should be careful to delete all old versions of the trace file if the a file name is reused and they do wish the new data to be appended.

**traceLevel (integer):** Solvestate threshold used in conjunction with action=GT

Synonym: TL

Available: Command line

Default: 0

**traceOpt (integer):** Trace file format option

Available: Command line

This option specifies the format of the trace file. Note that several different types of trace files may be created, depending on what output information is desired.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver and GAMS step trace without headers</td>
</tr>
<tr>
<td>1</td>
<td>Solver and GAMS step trace</td>
</tr>
<tr>
<td>2</td>
<td>Solver step trace only</td>
</tr>
<tr>
<td>3</td>
<td>Trace file format used for GAMS performance world</td>
</tr>
<tr>
<td>5</td>
<td>Trace file with all available trace fields</td>
</tr>
</tbody>
</table>

**tryInt (real):** Whether solver should make use of a partial integer-feasible solution

Available: Attribute statement (use before solve, reset by solve statement)

Signals the solver to make use of a partial or near-integer-feasible solution stored in current variable values to get a quick integer-feasible point. The exact form of implementation depends on the solver and may be partly controlled by solver settings or options. See the solver manuals for details.

**tryLinear (real):** Examine empirical NLP model to see if there are any NLP terms active. If there are none the default LP solver will be used

Available: Attribute statement (use before solve)
If this option is set to 1, empirical NLP models will be examined to determine if there are any active NLP terms. If there are none, the default LP solver will be used. The procedure also checks to see if QCP and DNLP models can be reduced to an LP; MIQCP and MINLP can be solved as a MIP; RMIQCP and RMINLP can be solved as an RMIP. Note that the default value is zero.

**user1..5 (string):** User string N

Synonym: U1

Available: Command line

This option permits users to enter a text for up to 5 user-defined options. The double dash parameters supersede these parameters.

**warnings (integer):** Number of warnings permitted before a run terminates

Available: Command line

This option specifies the maximum number of allowable warnings, before the run terminates.

Default: $\infty$

**workDir (string):** Working directory

Synonym: WDir

Available: Command line

This option sets the working directory. This option is useful when GAMS is called from an external system like Visual Basic. If it is not specified, the working directory will be set to the directory curDir.

**workFactor (real):** Memory Estimate multiplier for some solvers

Available: Command line, Attribute statement (use before solve)

This option instructs the solver how much workspace to allocate for problem solution relative to the solver-computed estimate. For example, setting the value to 2 will double the memory estimate. In cases where a solver allocates memory dynamically as it is needed, this option will have no effect. Note that in cases where both options `workfactor` and `workSpace` are specified, the value for `workSpace` will take precedence.

Default: 1

**workSpace (real):** Work space for some solvers in MB

Available: Command line, Attribute statement (use before solve)

This option instructs the solver how much workspace in Megabytes to allocate. If it is not specified by the user, the solver will estimate the size. In cases where a solver allocates memory dynamically as it is needed, this option will have no effect, or it may be used as a memory limit.

**xSave (string):** Creates a compressed work file
Synonym: XS

Available: Command line

This option specifies the name of a save file written in ASCII format in older GAMS systems (versions older than 21.7), in order for the save file to be platform dependent and may be moved to machines with different operating systems.

In GAMS systems from release 22.3 and newer this option has the effect that compressed save files are written.

```
xSaveObfuscate (string): Creates a compressed obfuscated work file
```

Synonym: XSO

Available: Command line

```
zeroRes (real): The results of certain operations will be set to zero if abs(result) LE ZeroRes
```

Available: Command line

This option specifies the threshold value for internal rounding to zero in certain operations.

Default: 0

```
zeroResRep (boolean): Report underflow as a warning when abs(results) LE ZeroRes and result set to zero
```

Available: Command line

This option causes GAMS to issue warnings whenever a rounding occurs because of the setting of the option zeroRes.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No warning when a rounding occurs because of ZeroRes</td>
</tr>
<tr>
<td>1</td>
<td>Issue warnings whenever a rounding occurs because of ZeroRes</td>
</tr>
</tbody>
</table>

3.40.7 Executing an External Program

External programs may be run during a GAMS job either using the `$call`, `Execute` or `Put_utility` syntax. The `$call` procedure is executed at the moment that is encountered during compilation. The `Execute` and `Put_utility` commands causes the external program to be run during GAMS program execution. The contrast between these statements is important in two ways:

- Influence on results that can be included in a GAMS program – Anything run with `$call` can generate files that can be included in the subsequent compilation. On the other hand files generated with `Execute` and `Put_utility` cannot be included because `$Include` operates only at compile time (unless you use `Save and Restart`).

- Influence on results that can be fed into the external program – Obviously when one is running an external program there is the desire to pass it data depicting results of the GAMS execution. `$call` cannot do this as the data passed have to exist at compile time and cannot use the result of any
GAMS calculations and solves in the current program. Execute commands on the other hand can use any data generated during a run which arise before the Execute and Put_utility command’s position in the file through passage via put files or other mechanisms.

The big difference between the $call and execute is

- **$call**
  - can generate results to be immediately incorporated back into GAMS
  - cannot use GAMS results generated within this run because the $Call is executed at compile time.

- **execute and put_utility**
  - can cause a program to be started using results generated by the GAMS program (note such results do have to have been saved in an external file using a command like put)
  - cannot generate results which can be immediately reincluded into the GAMS program because new material can only be added compile time.

### 3.40.7.1 Execute

This command uses the syntax

```
execute[.async[NC]] "[=]command_to_execute"
```

to execute a program specified by command_to_execute. The execution occurs during the GAMS execution phase.

- The = will call the program directly, while without the = GAMS calls a shell that executes the program. When a program is executed in a shell, mechanisms like redirection (>) and pipe (|) will work.
- The .async suffix makes GAMS go ahead without waiting.
- The .asyncNC option tells the operating system to start the run a new console rather than sharing the console of the parent process allowing use of multiple processors. This is available under Windows only.
- Since this occurs during execution one cannot use the compile time $Include to incorporate the results of that external run into the GAMS code except through a GAMS from GAMS approach as discussed below or through save and restart use (see the Save Restart chapter).

### 3.40.7.2 Asynchronous Execution

The .async variant of $call and execute start a job without waiting for the result. One can continue in the GAMS program and collect the return code of the job later. There are three ways to start a job asynchronously:

- **$call.async ...** (compile phase)
- **execute.async ...**; (execution phase)
- ‘put_utility fx ’exec.async" / '...'; / put_utility fx 'shell.async" / '...';‘; (execution phase)
After each of those the function `JobHandle` can be used to get the Process ID (pid) of the last job started. With `jobStatus(pid)` one could check for the status of a job. Possible return values are:

- 0: error (input is not a valid PID or access is denied)
- 1: process is still running
- 2: process is finished with return code which could be accessed by `errorLevel`
- 3: process not running anymore or was never running, no return code available

With `jobTerminate(pid)` a interrupt signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.

With `jobKill(pid)` a kill signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.

The model `[ASYNCEXEC]` from the GAMS Test Library demonstrates the use of this feature.

### 3.41 Dollar Control Options

#### 3.41.1 Introduction

Dollar control options are used to indicate compiler directives and options. Dollar control options are not part of the GAMS language and must be entered on separate lines marked with the symbol `$` in the first column. A dollar control option line may be placed anywhere within a GAMS program and it is processed during the compilation of the program. The symbol `$` is followed by one or more options separated by spaces. Since the dollar control options are not part of the GAMS language, they do not appear on the compilation output in the listing file unless an error has been detected or the user has requested them to be shown (with the option `$onDollar`). Note that dollar control option lines are not case sensitive and a continued compilation uses the previous settings.

This chapter is organized as follows. First an overview of the dollar control options will be given in section List of Dollar Control Options, where the options will be presented in groups reflecting their major functional categories. Section Detailed Description of Dollar Control Options will contain a reference list of all dollar control options in alphabetical order with detailed description for each.

We will conclude this chapter with separate sections for two important topics: Conditional Compilation, Macros in GAMS, Compressing and Decompressing Files, and Encrypting Files.

#### 3.41.1.1 Syntax

In general, the syntax in GAMS for dollar control statements is as follows:

```
$option_name argument_list {option_name argument_list}
```

The symbol `$` in the first column indicates that this is a dollar control statement. It is followed by the name of the dollar control option `option_name` and the list of arguments `argument_list` of the option. Depending on the particular option, the number of arguments required can vary from 0 to many. More than one dollar control option may be activated in one statement. Note that in this case the symbol `$` is not repeated. Observe that some dollar control options require that they be the first option on a line.
3.41 Dollar Control Options

Note

- No blank space is permitted between the character $ and the first option that follows.
- The effect of the dollar control option is felt immediately after the option is processed.
- Dollar control options are not part of the GAMS language they instruct the compiler to perform some task. Therefore, dollar control options are not terminated with a semicolon as real GAMS language statements.

A simple example of a list of dollar control options is shown below:

```gams
$title Example to illustrate dollar control options $onsymxref onsymlist
```

Note that there is no blank space between the character $ and the option that follows. The first dollar control option $title sets the title of the pages in the listing file to the text that follows the option name. In the second line of the example above, two options are set: $onSymXRef and $onSymList. These options turn on the echoing of the symbol cross reference table and symbol listing in the compilation output in the listing file.

Observe that it is also permitted to place a dollar control statement in a column other than column 1. However, in this case the statement must begin with the symbols $$, like in this example

```gams
$$title Example showing that dollar control option can start in any column with an extra $ added
```

3.41.2 List of Dollar Control Options

The dollar control options are grouped into nine major functional categories affecting

- the input comment format
- the input data format
- the output format
- reference maps
- program control
- GDX operations
- compile-time variables and environment variables
- macro definitions
- compressing and encrypting source files

The following subsections briefly describe the options in each of the categories.

3.41.2.1 Dollar Control Options Affecting the Input Comment Format
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comment</td>
<td>Set the comment character</td>
</tr>
<tr>
<td>eolCom</td>
<td>Set the end-of-line comment character(s)</td>
</tr>
<tr>
<td>inlineCom</td>
<td>Set the in-line comment characters</td>
</tr>
<tr>
<td>maxCol</td>
<td>Set the right-hand margin of the input file</td>
</tr>
<tr>
<td>minCol</td>
<td>Set left-hand margin of the input file</td>
</tr>
<tr>
<td>offEolCom</td>
<td>Turn end-of-line comments off</td>
</tr>
<tr>
<td>offInline</td>
<td>Turn in-line comments off</td>
</tr>
<tr>
<td>offMargin</td>
<td>Turn margin marking off</td>
</tr>
<tr>
<td>offNestCom</td>
<td>Turn nested comments off</td>
</tr>
<tr>
<td>offText</td>
<td>Turn text mode off</td>
</tr>
<tr>
<td>onEolCom</td>
<td>Turn end-of-line comments on</td>
</tr>
<tr>
<td>onInline</td>
<td>Turn in-line comments on</td>
</tr>
<tr>
<td>onMargin</td>
<td>Turn margin marking on</td>
</tr>
<tr>
<td>onNestCom</td>
<td>Turn nested comments on</td>
</tr>
<tr>
<td>onText</td>
<td>Turn text on: the following lines are comment</td>
</tr>
</tbody>
</table>

Note that comments in GAMS are introduced in section Comments.

### 3.41.2.2 Dollar Control Options Affecting the Input Data Format

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dollar</td>
<td>Set the 'dollar' character</td>

</tbody>
</table>
### 3.41.2.5 Dollar Control Options Affecting Program Control

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abort[.noError]</td>
<td>Issue an (error) message and abort compilation</td>
</tr>
<tr>
<td>batInclude</td>
<td>Include file with substitution arguments</td>
</tr>
<tr>
<td>call</td>
<td>Execute another program during compilation</td>
</tr>
<tr>
<td>call.Async[NC]</td>
<td>Execute another program asynchronously during compilation</td>
</tr>
<tr>
<td>clear</td>
<td>Reset all data for an identifier to its default value</td>
</tr>
<tr>
<td>clearError[s]</td>
<td>Clear compilation errors</td>
</tr>
<tr>
<td>else</td>
<td>Else clause</td>
</tr>
<tr>
<td>elseIf</td>
<td>ElseIf structure with case sensitive comparison</td>
</tr>
<tr>
<td>elseIfE</td>
<td>ElseIf structure with expression evaluation</td>
</tr>
<tr>
<td>elseIfI</td>
<td>ElseIf structure with case insensitive comparison</td>
</tr>
<tr>
<td>endif</td>
<td>Close ifThen/ifThenE/ifThenI control structure</td>
</tr>
<tr>
<td>error</td>
<td>Issue an error message</td>
</tr>
<tr>
<td>exit</td>
<td>Exit from compilation</td>
</tr>
<tr>
<td>funcLibIn</td>
<td>Load extrinsic function library</td>
</tr>
<tr>
<td>goto</td>
<td>Go to line with given label name</td>
</tr>
<tr>
<td>hiddenCall</td>
<td>Execute another program (hidden) during compilation</td>
</tr>
<tr>
<td>hiddenCall.Async[NC]</td>
<td>Execute another program (hidden) asynchronously during compilation</td>
</tr>
<tr>
<td>if</td>
<td>Conditional processing, case sensitive</td>
</tr>
<tr>
<td>ifE</td>
<td>If statement with expression evaluation</td>
</tr>
<tr>
<td>iff</td>
<td>Conditional processing, case insensitive</td>
</tr>
<tr>
<td>ifThen</td>
<td>IfThen-elseIf structure with case sensitive comparison</td>
</tr>
<tr>
<td>ifThenE</td>
<td>IfThen-elseIf structure with expression evaluation</td>
</tr>
<tr>
<td>ifThenI</td>
<td>IfThen-elseIf structure with case insensitive comparison</td>
</tr>
<tr>
<td>include</td>
<td>Include file</td>
</tr>
<tr>
<td>kill</td>
<td>Kill data connected with identifier</td>
</tr>
<tr>
<td>label</td>
<td>Label name as entry point from $goto .</td>
</tr>
<tr>
<td>libInclude</td>
<td>Include file from library directory</td>
</tr>
<tr>
<td>offEmbeddedCode</td>
<td>Ends embedded code section</td>
</tr>
<tr>
<td>offMulti</td>
<td>Turn redefinition of data off</td>
</tr>
<tr>
<td>offOrder</td>
<td>Allow lag and lead operations on dynamic or unordered sets</td>
</tr>
<tr>
<td>offRecurse</td>
<td>Disable recursive include files</td>
</tr>
<tr>
<td>offStrictSingleton</td>
<td>Take first label if data statement for singleton set has multiple elements</td>
</tr>
<tr>
<td>onEmbeddedCode</td>
<td>Starts embedded code section with substitution</td>
</tr>
<tr>
<td>onEmbeddedCodeS</td>
<td>Starts embedded code section with substitution</td>
</tr>
<tr>
<td>onEmbeddedCodeV</td>
<td>Starts embedded code section without substitution</td>
</tr>
<tr>
<td>onMulti</td>
<td>Turn redefinition of data on (merging into existing data)</td>
</tr>
<tr>
<td>onMultiR</td>
<td>Turn redefinition of data on (replacing existing data)</td>
</tr>
<tr>
<td>onOrder</td>
<td>Lag and lead operations on constant and ordered sets only</td>
</tr>
<tr>
<td>onRecurse</td>
<td>Enable recursive include files</td>
</tr>
<tr>
<td>onStrictSingleton</td>
<td>Error if data statement for singleton set has multiple elements</td>
</tr>
<tr>
<td>maxGoTo</td>
<td>Maximum number of jumps to the same label</td>
</tr>
<tr>
<td>phantom</td>
<td>Define a phantom element</td>
</tr>
<tr>
<td>shift</td>
<td>bat/lib/sysInclude argument shift operation</td>
</tr>
<tr>
<td>stop</td>
<td>Stop compilation</td>
</tr>
<tr>
<td>sysInclude</td>
<td>Include file from system directory</td>
</tr>
</tbody>
</table>
### Dollar Control Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>terminate</td>
<td>Terminate compilation and execution</td>
</tr>
<tr>
<td>warning</td>
<td>Issue compilation warning</td>
</tr>
</tbody>
</table>

Note that conditional compilation in GAMS is discussed in section Conditional Compilation below.

#### 3.41.2.6 Dollar Control Options for GDX Operations

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdxIn</td>
<td>Open GDX file for input</td>
</tr>
<tr>
<td>gdxOut</td>
<td>Open GDX file for output</td>
</tr>
<tr>
<td>load</td>
<td>Load symbols from GDX file - domain filtered</td>
</tr>

</tbody>
</table>

3.41.3 Detailed Description of Dollar Control Options

In this section we will describe each dollar control option in detail. Note that the dollar control options are listed in alphabetical order for easy reference. Note further, that in each entry the default value, if applicable, is given in parentheses.

$\text{abort\.noError}$

Syntax:

$\text{abort\.noError} \ [\text{text}]$

If used as $\text{abort}$, this option will issue a compilation error and abort the compilation. It may be followed by a text.

Example:

$\text{if not } \%\text{system.fileSys}\% \ == \ \text{UNIX}  \\
\text{abort} \ \text{We only do UNIX}$
This stops compilation if the operating system is not Unix. Running the example above on Windows will result in the compilation being aborted and the following lines in the listing file:

```
2  $abort We only do UNIX
****    $343
```

Error Messages
343 Abort triggered by above statement

This option has a variant: `$abort.noError`. If the extension `.noError` is used the compilation will be aborted as well, but there will be no error. If a save file is written, all remaining unexecuted code will be flushed. This allows effective reuse of the save file.

Note that there is also an `abort statement` in GAMS, it is used to terminate the execution of a program.

See also `$exit`, `$error`, `$stop`, and `$terminate`.

### $batInclude

**Syntax:**

```
$batInclude external_file {arg}
```

The `$batInclude` facility performs the same task as the `$include` facility: it inserts the contents of the specified file `external_file` at the location of the call. However, in addition, the option `$batInclude` also passes on arguments `arg` which may be used inside the include file. `External_file` is the name of the batch include file, it may be quoted or unquoted. The arguments `arg` are passed on to the batch include file. These arguments are treated as character strings that are substituted by numbers inside the included file. The arguments may be single unbroken strings (quoted or unquoted) or quoted multi-part strings.

Note that the syntax has been modeled after the DOS batch facility. Inside the batch file, a parameter substitution is indicated by using the character `%` followed immediately by an integer value corresponding to the order of parameters on the list where `%1` refers to the first argument, `%2` to the second argument, and so on. If an integer value is specified that does not correspond to a passed parameter, then the parameter flag is substituted with a null string. The parameter flag `%0` is a special case that will substitute a fully expanded file name specification of the current batch included file. The flag `%$` is the current `$` symbol (see `$dollar`). Observe that parameters are substituted independent of context and the entire line is processed before it is passed to the compiler. There is one exception: parameter flags that appear in comments are not substituted.

**Attention**

- GAMS requires that processing the substitutions must result in a line of less than or equal to the maximum input line length.
- The case of the passed parameters is preserved, thus it may be used in string comparisons.

**Example:**

```
$batInclude "file1.inc" abcd "bbbb" "cccc dddd"
```

Note that `file1.inc` is included with `abcd` as the first parameter, `bbbb` as the second parameter and `cccc dddd` as the third parameter.
Parameter a,b,c ;
  a = 1 ; b = 0 ; c = 2 ;
$batInclude inc2.inc b a
display b ;
$batInclude inc2.inc b c
display b ;
$batInclude inc2.inc b "a+5"
display b ;

The external file inc2.inc contains the following line:

%1 = sqr(%2) - %2 ;

The echo print in the corresponding listing file follows:

1 Parameter a,b,c ;
2 a = 1 ; b = 0 ; c = 2 ;
BATINCLUDE C:\tmp\inc2.inc
4 b = sqr(a) - a ;
5 display b ;
BATINCLUDE C:\tmp\inc2.inc
7 b = sqr(c) - c ;
8 display b ;
BATINCLUDE C:\tmp\inc2.inc
10 b = sqr(a+5) - a+5 ;
11 display b ;

Note that the option $batInclude appears three times with different arguments. GAMS is
interprets the contents of the batch include file in turn as:

b = sqr(a) - a ;
b = sqr(c) - c ;
b = sqr(a+5) - a+5 ;

Note that the third call is not interpreted as $sqr(a+5)-(a+5)$, but instead as $sqr(a+5)-a+5$.
The results of the display statement are shown at the end of the listing file are given below:

<table>
<thead>
<tr>
<th></th>
<th>5 PARAMETER b</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>0.000</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>2.000</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>40.000</td>
<td></td>
</tr>
</tbody>
</table>

Observe that the third call leads to $b = sqr(6)-1+5$, thus the final value of $b$ is 40. Suppose
the statement in the batch include file is modified to read as follows:

%1 = sqr(%2) - (%2) ;

With this modification the output generated by the display statement will be as follows:

<table>
<thead>
<tr>
<th></th>
<th>5 PARAMETER b</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>0.000</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>2.000</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>30.000</td>
<td></td>
</tr>
</tbody>
</table>

Note that the third call leads to $b = sqr(6)-6$ which results in $b$ taking a value of 30.
Note

The option $batInclude without any arguments is equivalent to the option $include.

See also $include, $libInclude, $sysInclude.

$call

Syntax:

$call [=]command

This option passes a command to the current operating system command processor and interrupts compilation until the command has been completed. If the command string is empty or omitted, a new interactive command processor will be loaded.

Example:

$call dir

This command creates a directory listing on a PC.

Note that the command string may be passed to the system and executed directly without using a command processor by prefixing the command with an '=' sign. Compilation errors will be issued if the command or the command processor cannot be loaded and executed properly.

$call gams trnsport
$call =gams trnsport

The first call will run the model [TRNSPORT] in a new command shell. The DOS command shell does not send any return codes from the run back to GAMS. Therefore any errors in the run are not reported back. The second call, however, will send the command directly to the system. The return codes from the system will be intercepted correctly and they will be available to the GAMS system through the errorLevel function.

Attention

Some commands (like copy on a PC and cd in Unix) are shell commands and cannot be spawned off to the system. Using these in a system call will create a compilation error.

$call 'copy myfile.txt mycopy.txt'
$call '=copy myfile.txt mycopy.txt'

The first call will work on a PC, but the second will not. The copy command may be used only from a command line shell. The system is not aware of this command (Try this command after clicking Run under the Start menu in Windows. You will find that it does not work).

See also $call.Async, $hiddenCall.

$call.Async[NC]

Syntax:

$call.Async[NC] command

$call.Async works like $call but allows asynchronous job handling. This means users may start a job command without having to wait for the result, they may continue in their model and collect the return code of the job later. The function jobHandle may be used to get the process ID (pid) of the last job started. The status of the job may be checked using the function jobStatus(pid). An interrupt signal to a running job may be sent with the function jobTerminate(pid). With the function jobKill(pid) a kill signal may be sent to a running job.

The difference between $call.Async and $call.AsyncNC is, that the latter starts processes in a new console, rather than sharing the console of the parent process.
Note

On non-Windows platforms $\texttt{call.AsyncNC}$ and $\texttt{call.Async}$ are synonyms.

$\texttt{clear}$

**Syntax:**

$\texttt{clear}$ ident {ident}

This option resets all data for the identifiers ident to their default values. Note that only the following data types may be reset: sets, parameters, variables and equations. Note further, that the clearing is carried out during compile time and not when the GAMS program executes.

**Example:**

```gams
Set i / 1*20 /;
Scalar a / 2 /;
$clear i a
display i, a;
```

The option $\texttt{clear}$ resets i and a to their default values: an empty set for i and zero for a. The output generated by the display statement follows:

```
---- 4 SET i
       ( EMPTY )
---- 4 PARAMETER a = 0.000
```

**Attention**

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Both the dollar control options and the data initialization is done in the first pass, and assignments in the second, irrespective of their relative locations. This is an issue particularly with $\texttt{clear}$ since data can be both initialized and assigned.

```gams
Scalar a / 12 /;
a = 5;
$clear a
display a;
```

Note that the scalar data initialization statement is processed during compilation and the assignment statement $a = 5$; during execution. In the order that it is processed, the example above is read by GAMS as:

```
* compilation step
Scalar a /12/ ;
$clear a
* execution step
a = 5;
display a ;
```

Therefore the result is that a takes the value of 5. The output from the display statement is as follows:

```
---- 4 PARAMETER a = 5.000
```

Compare also $\texttt{kill}$ and the execution time option $\texttt{clear}$.

$\texttt{clearError}[s]$
Syntax:

$clearError[s]

This option ($clearError and $clearErrors are synonyms) clears GAMS awareness of compiler errors and turn them into warning messages instead.

Example:

Scalar z / 11 /;
$eval x sqrt(-1)
$clearError
$log \%x\%
Display z;

Note that without the use of $clearError the program above would not continue with the execution after line 2.

$comment (\ast)

Syntax:

$comment char

This option changes the symbol indicating a single line comment from the default \ast to the single character char. Note that after this option is used, the new comment character char cannot be used in column 1 as before, since it got a special meaning. Note further, that the case of the character does not matter if it is used as a comment character. This option should be used with great care and we recommend to reset the symbol quickly to the default.

Attention

The case of the start-of-line comment character does not matter when being used.

Example:

$comment c
c now we use a FORTRAN style comment symbol
$comment *
* now we are back to the default

See also section Comments.

$compress

Syntax:

$compress source target

This option causes the file source to be compressed into the packed file target.

Example: Consider the following example where the well-known model [TRNSPORT] is used:

$call gamslib trnsport
$compress trnsport.gms t2.gms
$include t2.gms
The first command retrieves the file `trnsport.gms` and the second command compresses it. Note that a compressed GAMS file is treated like any other GAMS file, therefore it may be included and executed as usual. Large data files that do not change often can be compressed this way to save disk space.

The following example serves as a little utility to compress and decompress files:

```
$ifthen set decompress
$ if not set input $set input file_c.gms
$ if not exist %input% $abort No file input file %input% exist
$ if not set output $set output file.gms
$ log Decompressing %input% into %output%
$ decompress %input% %output%
$else
$ if not set input $set input file.gms
$ if not exist %input% $abort No file input file %input% exist
$ if not set output $set output file_c.gms
$ log Compressing %input% into %output%
$ compress %input% %output%
$endif
```

The program (saved to a file called `compress.gms`) can be used as follows:

```
> gams compress.gms --input myfile.gms --output myfile_c.gms
> gams compress.gms --decompress=1 --input myfile_c.gms --output myfile.gms
```

See also `$decompress`. Further details are given in chapter Compressing and Decompressing Files.

$decompress

Syntax:

```
$decompress source target
```

This option causes the compressed file `source` to be decompressed into the unpacked file `target`.

Example: Consider the following example where the well-known model [TRNSPORT] is used:

```
$call gamslib trnsport
$compress trnsport.gms t2.gms
$decompress t2.gms t3.gms
$call diff t3.gms trnsport.gms
$if errorlevel 1 $abort t3.gms and trnsport.gms are not identical!
```

The first command retrieves the file `trnsport.gms`, the second command compresses it and the third command decompresses the compressed file. Note that the resulting file, `t3.gms`, is identical to the original file `trnsport.gms` which is tested via the `diff` program.

See also `$compress`. Further details are given in chapter Compressing and Decompressing Files.

$dollar ($)

Syntax:

```
$dollar char
```

This option changes the current 'dollar' symbol to the single character `char`.
Note

The special $\%$ substitution symbol can be used to get the current 'dollar' symbol.

Example:

$dollar$

#log now we can use '$\%$' as the '$$' symbol

$double$

Syntax:

$double$

The lines following this option will be echoed double spaced to the echo print in the listing file.

Example:

Set i /1*2/ ;
Scalar a /1 / ;
$double$
Set j /10*15/ ;
Scalar b /2 / ;

The resulting echo print in the listing file looks as follows:

1 Set i /1*2/ ;
2 Scalar a /1/ ;
4 Set j /10*15/ ;
5 Scalar b /2/ ;

Note that lines before the option $double$ are listed single spaced, while the lines after the option are listed with double space.

See also $single$.

$drop$

Syntax:

$drop VARNAME$

This option destroys (removes from the program) the scoped compile-time variable VARNAME that was defined with the dollar control option $set$.

Example:

$set NAME my name
$if set NAME $log Scoped compile-time variable NAME is set to "%NAME%"
$drop NAME
$if not set NAME $log Scoped compile-time variable NAME is not available anymore

See also $set$, $dropGlobal$, and $dropLocal$.

$dropEnv$

Syntax:
$\textit{dropEnv} VARNAME

This dollar control option destroys (removes from the program) the operating system environment variable \textit{VARNAME}. For detailed information, see the dollar control option.

Example:

$\texttt{if setEnv GDXCOMPRESS \textit{dropEnv} GDXCOMPRESS}$

See also $\texttt{setEnv}$, and $\texttt{if setEnv}$.

$\textit{dropGlobal}$

\textbf{Syntax:}

$\texttt{dropGlobal} VARNAME$

This option destroys (removes from the program) the global compile-time variable \textit{VARNAME} that was defined with the dollar control option $\texttt{setGlobal}$.

Example:

$\texttt{setGlobal NAME my name}$$\texttt{if setGlobal NAME \log Global compile-time variable NAME is set to "\%NAME\%"}$

$\texttt{dropGlobal NAME}$$\texttt{if not setGlobal NAME \log Global compile-time variable NAME is not available anymore}$

See also $\texttt{setGlobal}$, and $\texttt{drop}$.

$\textit{dropLocal}$

\textbf{Syntax:}

$\texttt{dropLocal} VARNAME$

This option destroys (removes from the program) the local compile-time variable \textit{VARNAME} that was defined with the dollar control option $\texttt{setLocal}$.

$\texttt{setLocal NAME my name}$$\texttt{if setLocal NAME \log Local compile-time variable NAME is set to "\%NAME\%"}$

$\texttt{dropLocal NAME}$$\texttt{if not setLocal NAME \log Local compile-time variable NAME is not available anymore}$

See also $\texttt{setLocal}$, and $\texttt{drop}$.

$\textit{echo}$

\textbf{Syntax:}

$\texttt{echo} text \{\texttt{>} \texttt{>}\} external\_file$

This option allows to write the text \texttt{text} to a file \texttt{external\_file}. The text and the file name may both be quoted or unquoted. The file name is expanded using the working directory. The option $\texttt{echo}$ tries to minimize file operations by keeping the file open in anticipation of another $\texttt{echo}$ to be appended to the same file. The file will be closed at the end of the compilation or when an option $\texttt{call}$ or any variant of the option $\texttt{include}$ is encountered. The redirection symbols $\texttt{>}$ and $\texttt{>>}$ have the usual meaning of starting at the beginning or appending to an existing file respectively.

Example:
$echo  The message written goes from the first non blank
$echo ' to the first > or >> symbol unless the text is' >> echo.txt
$echo "is quoted. The input File is %gams.input%. The" >> echo.txt
$echo 'file name "echo.txt" will be completed with' >> echo.txt
$echo %gams.workdir%. >> echo.txt
$echo >> echo.txt

The content of the resulting file echo.txt is the following:

The message written goes from the first non blank
to the first > or >> symbol unless the text is
is quoted. The input File is C:\tmp\echoTest.gms. The
file name "echo.txt" will be completed with
C:\tmp\.

See also $on/offEcho, and $echoN.

$echoN

Syntax:
$echoN text >[>] external_file

This option sends a text message text to an file external_file like $echo but writes no end
of line marker so the line is repeatedly appended to by subsequent commands. The redirection
symbols > and >> have the usual meaning of starting at the beginning or appending to an
existing file respectively. Note that the text and the file name may be quoted or unquoted. By
default the file will be saved in the working directory.

Example:
$echoN 'Text to be sent' > 'aaa.txt'
$echoN 'More text' >> aaa.txt
$echo This was entered with $echo >> 'aaa.txt'
$echo This too >> aaa.txt

The created file aaa.txt contains the following text:

Text to be sentMore textAnd more and more and moreThis was entered with $echo
This too

See also $on/offEcho, and $echo.

$eject

Syntax:
$eject

This option advances the echo print to the next page.

Example:
$eject
Set   i,j ;
Parameter Data(i,j) ;
$eject
Scalar a;
a = 7;
The statements following the first `eject` will be listed on one page in the echo print of the listing file and the statements following the second `eject` will be listed on the next page.

$else

Syntax:

```text
$ifThen[E|I] cond
...
{ $elseif[E|I] cond
  ...
} $else
...
$endif
```

This option always appears together with the option $ifThen[E|I]. It is followed by an instruction which is executed if the conditional expression of the matching option $ifThen[E|I] is not true. For an example, see section Conditional Compilation with $ifThen and $else.

See also $ifThen, $elseIf and section Conditional Compilation.

$elseIf

Syntax:

```text
$ifThen[E|I] cond
...
{ $elseif[E|I] cond
  ...
} $else
...
$endif
```

This option always appears together with the option $ifThen[E|I]. It is followed by another condition and instruction. For an example, see section Conditional Compilation with $ifThen and $else.

See also $ifThen, $else, $elseIfE, $elseIfI and section Conditional Compilation.

$elseIfE

Syntax:

```text
$ifThen[E|I] cond
...
{ $elseif[E|I] cond
  ...
} $else
...
$endif
```

This option does the same as $elseIf but evaluates numerical values of the control variables.

See also $elseIf and section Conditional Compilation.

$elseIfI
$ifThen[E|I] cond
...
{ $elseif[E|I] cond
... 
}[ $else
... ]
$endif

This option does the same as $elseif but it is case insensitive.

See also $elseif and section Conditional Compilation.

$encrypt

Syntax:
$encrypt source target

This option causes a file to be converted into an encrypted file. Here source is the name of the source file to be encrypted and target is the name for the resulting encrypted file. Note that encryption requires the secure option to be licensed and is available for commercial licenses only. The command line parameter pLicense specifies the target license to be used for encryption. The encrypted file can only run on a system licensed with the license file used for encryption. No special action is required on the executing system since GAMS recognizes whether a file is encrypted and will process it accordingly. There is no option to decrypt an encrypted file, so better keep the original unencrypted file.

Further details and examples are given in chapter Encrypting Files.

$endIf

Syntax:
$ifThen[E|I] cond
...
{ $elseif[E|I] cond
... 
}[ $else
... ]
$endif

This must option must be matched with one of the options $ifThen, $ifThenE or $ifThenI. For an example, see section Conditional Compilation with $ifThen and $else.

See also $ifThen and section Conditional Compilation.

$eolCom (!!)

Syntax:
$eolCom char[char]

This option redefines and activates the end-of-line comment symbol, which may be one character or a sequence of two characters. By default, this is initialized to !!, but is not active. The option $onEolCom is used to activate the end-of-line comments. If $eolCom is used, $onEolCom is set automatically.

Example:
$eolCom //
Set i /1*2/ ; // set declaration
Parameter a(i) ; // parameter declaration

Here the character sequence // serves as the end-of-line-comment indicator.
Attention

It is not allowed to reset the end-of-line comment symbol to the current end-of-line comment symbol. This would cause a compilation error as in the following example:

```gams
$eolCom //
$eolCom //
```

Some end of line character settings can cause confusion. The widely used end of line character sequence `//` is also legal GAMS syntax in put statement to indicate two line breaks:

```gams
file fx; put fx;
put 'first line' // 'second line' //;
$eolCom //
put 'third line' // 'fourth line';
```

results in a put file with the following content:

```
first line
second line
third line
```

This can also confuse syntax highlighting in editors (or on this web page). Other popular end of line characters like `#` and `@` are also used as GAMS syntax, see Controlling the Cursor On a Page.

See also section Comments for more about comments in GAMS.

$err

Syntax:

```
$err [text]
```

This option will issue a compilation error and will continue with the next line.

Example:

```gams
$if not exist myfile
$err File myfile not found - will continue anyway
```

Note that the first line checks if the file `myfile` exists. If the file does not exist, it will generate an error with the comment `File myfile not found - will continue anyway` and then the compilation will continue with the next line.

See also $abort, $exit, $terminate, and $stop.

$escape

Syntax:

```
$escape character
```
This option allows users to work with text sequences containing \% without substitution.

This causes all subsequent commands of the form \%symbol\% to not have parameter substitution done for them. As a consequence, no parameter substitutions are performed in GAMS statements (mostly useful in display and put statements) and the outcome of such statements where \%symbol\% is used is just \%symbol\%.

Note that the effect of the option $\text{escape}$ may be reversed with the option $\text{escape } \%$.

**Example:**

```gams
$set tt DOIT
file it; put it;

display "first \%tt\%";
display "second \%tt\%&";
put "display one ", "\%system.date\%" /;
put "display two " "\%&system.date\%&"/;

$\text{escape } \&$
display "third \%tt\%";
display "fourth \%tt\%&";
put "display third ", "\%system.date\%" /;
put "display fourth " "\%&system.date\%&"/;

$\text{escape } \%$
display "fifth \%tt\%";
display "sixth \%tt\%&";
put "display fifth ", "\%system.date\%" /;
put "display sixth " "\%&system.date\%&"/;
```

The output generated by the display statements follows:

```
---- 6 first DOIT
---- 7 second \%tt\%&
---- 12 third DOIT
---- 13 fourth \%tt\%
---- 18 fifth DOIT
---- 19 sixth \%tt\%&
```

The file `it.put` will contain the following lines:

```gams
display one 08/10/17
display two \%system.date\%
display third 08/10/17
display fourth \%system.date\%
display fifth 08/10/17
display sixth \%&system.date\%
```

Note that this option was introduced to facilitate writing GAMS code (or command.com/cmd.exe batch scripts) from GAMS including unsubstituted compile-time variables. Text can also be written at compile-time without parameter substitution via option $\text{on/offEchoV}$ and at run-time via $\text{on/offPutV}$. 
Note

In GAMS the escape character follows the character (%) that needs to be escaped. In many other languages the escape character precedes the to be escaped character.

$eval

Syntax:

$eval VARNAME expression

This option evaluates a numerical expression at compile time and places it into a scoped compile-time variable. In turn the option $ifE may be used to do numeric testing on the value of this variable.

VARNAME is the name of a compile-time variable and expression is an expression that consists of constants, functions, operators and other compile-time variables with numerical values. Note that no whitespace is allowed in the expression which can be overcome by additional parentheses.

Example:

$eval b1 ifthen(uniform(0,1)<0.5,0,1)
$eval b2 ifthen(uniform(0,1)<0.5,0,1)
$eval b3 (%b1%)xor(%b2%)
$log b1=%b1% b2=%b2% b1 xor b2=%b3%

The first two lines use the uniform function to generate a random number between 0 and 1 and assign 0 if this number is less than 0.5 otherwise 1 via the ifthen function to the scoped compile-time variable b1 and b2. In the third line we apply the logical xor operator to b1 and b2 and store the result in b3. The parentheses are required because the more natural expression b1% xor b2% contains spaces. In the forth line we print the values and result to the log.

b1=1 b2=1 b1 xor b2=0

The expression are evaluated using IEEE nonstop arithmetic, so no evaluation errors are triggered as demonstrated in the following example:

$eval OneDividedByZero 1/0
$log 1/0=%OneDividedByZero%

This produces the following log:

1/0=+INF

The $eval and related dollar control options give access to a reduced set of GAMS functions: abs, card, ceil, cos, errorlevel, exp, fact, floor, frac, gamsrelease, gamsversion, gday, gdow, ghour, glep, gmillsec, gminute, gmonth, gsecond, gyear, ifthen, jdate, jnow, jobhandle, jobkill, jobstatus, jobterminate, jstart, jtime, log, log10, log2, max, min, mod, numcores, pi, power, round, sameas, sign, sin, sleep, sqrt, sqrt2, tan, trunc, and uniform. The available operators are: +, -, *, /, ** and even ^ (integer power) which is not available in regular GAMS expression and requires the use of the function ipower. The comparison relations are <, >, <=, >=, <>, and =. The logical operators are not, and, or, xor, imp, and eqv.

The expression also allows the use of dollar on the right. In the following example we replace the ifthen function by a dollar one the right:
Moreover, the $eval has access to data available at compile time. The expression can access the value of scalars and for other symbols we can use the card function to access the cardinality (at this point) of the symbol. Here is an example:

Scalar ac 'Avogadro constant' / 6.0221409e+23 /;
$eval log_ac round(log10(ac))
$log round(log10(ac))=%log_ac%
Set d / d0*d%log_ac% /;
$eval card_d card(d)
$log card(d)=%card_d%

Access to individual records of symbols is not possible. The embedded code facility allows access to symbol records at compile time.

See also $evalGlobal, $evalLocal, $ifE, and $set.

$evalGlobal

Syntax:

$evalGlobal VARNAME expression

This option evaluates a numerical expression at compile time and places it into a global compile-time variable. The syntax and behavior otherwise is identical to $eval.

$evalLocal

Syntax:

$evalLocal VARNAME expression

This option evaluates a numerical expression at compile time and places it into a local compile-time variable. The syntax and behavior otherwise is identical to $eval.

$exit

Syntax:

$exit

This option will cause the compiler to exit (stop reading) from the current file. This is equivalent to having reached the end of file.

Example:

Scalar a ;
a = 5 ;
display a ;
$exit
a = a+5 ;
display a ;
Note that the lines following the option $exit will not be compiled.

Observe that there is a difference to the dollar control option $stop. If there is only one input file, $stop and $exit will have the same effect. If the option $exit occurs within an include file, it acts like an end-of-file on the include file. However, if the option $stop occurs within an include file, GAMS will stop reading all input.

See also $abort, $error, $terminate, and $stop.

$expose

Syntax:

$expose all | ident1 ident2 ...

This option removes all privacy restrictions from identifiers.

With explicit identifiers the privacy restrictions are removed only for the listed identifiers and with all the restrictions are removed for all identifiers. The privacy restrictions may be set with the dollar control options $hide or $protect. Note that a special license file is needed for this feature to work and that the expose only takes effect in subsequent restart files. For further information, see chapter Secure Work Files.

$funcLibIn

Syntax:

$funcLibIn InternalLibName ExternalLibName

This makes extrinsic function libraries available to a model. InternalLibName is the internal name of the library in the GAMS code and ExternalLibName is the name of the shared library in the file system. See Using Function Libraries for more information.

$gdxIn

Syntax:

$gdxIn [GDXFileName]

This option is used in a sequence to load specified items from a GDX file. Here GDXFileName denotes the name of the GDX file (with or without the extension .gdx) and the command opens the specified GDX file for reading. The use of $gdxIn without a file name closes the currently open GDX file. The command is used in conjunction with the option $load or one of its variants.

Example:

set i,j; parameters a(i), b(j), d(i,j), f;
$gdxIn mydata.gdx
$load i j a b d f
$gdxIn

See also $load, and $gdxOut.

$gdxOut

Syntax:

$gdxOut [GDXFileName]
This option is used in a sequence to unload specified items to a GDX file at compile time. Here GDXFileName denotes the name of the GDX file (with or without the extension GDX) and the command opens the specified GDX file for writing. The use of $gdxOut without a file name closes the currently open output GDX file. The command is used in conjunction with the dollar control option $unLoad.

Example:

```gams
set i /i1*i3/; parameters a(i) /i1 3, i2 87, i3 1/;
$gdxOut mydata.gdx
$unLoad i a
$gdxIn
```

See also $unLoad, and $gdxIn.

### $goto

**Syntax:**

```gams
$goto id
$label id
```

This option will cause GAMS to search for a line starting with $label id and then continue reading from there. This option can be used to skip over or repeat sections of the input files. In $batinclude files the target labels or label arguments can be passed as parameters because of the manner in which parameter substitution occurs in such files. In order to avoid infinite loops, jumps to the same label are restricted to a maximum of 100 times by default. This maximum may be changed with the option $maxGoto.

Example:

```gams
Scalar a ;
a = 5;
display a ;
$goto next
a = a+5 ;
display a ;
$label next
a = a+10 ;
display a ;
```

Note that GAMS will continue from line $label next after reading line $goto next. Observe that all lines in between are ignored. Therefore the final value of a in the example above will be 15.

**Attention**

The lines $goto and $label have to be in the same file. If the target label is not found in the current file an error will be issued.

See also $label, $maxGoto.

### $hidden

**Syntax:**

```gams
$hidden text
```
A line starting with this option will be ignored and will not be echoed to the listing file. This option is used to enter information only relevant to the person manipulating the file.

**Example:**

```
$hidden You need to edit the following lines if you want to:
$hidden
$hidden 1. Change form a to b
$hidden 2. Expand the set
```

The lines above serve as comments to the person who wrote the file. However, these comments will not be visible in the listing file and are therefore hidden from view.

**Note**

This option is particularly useful when the input file is encrypted.

**$hiddenCall**

**Syntax:**

```
$hiddenCall [=]command
```

This option does the same as `$call` but the statement is neither shown on the log nor the listing file.

**$hiddenCall.Async[NC]**

**Syntax:**

```
$hiddenCall.Async[NC] command
```

This option does the same as `$call.Async[NC]` but the statement is neither shown on the log nor the listing file.

**$hide**

**Syntax:**

```
$hide all | ident1 ident2 ...
```

This option hides identifiers so they cannot be displayed or computed, but they may still be used in model calculations (i.e. commands when the solve statement is executed).

With explicit identifiers the listed identifiers are hidden and with `all` all identifiers are hidden. These restrictions may be removed with the dollar control options `expose` or `purge`. Note that a special license file is needed for this feature to work.

For further information, see chapter **Secure Work Files**.

**$if**

**Syntax:**

```
$if [not] conditional_expression new_input_line
```
This dollar control option provides the greatest amount of control over conditional processing of the input file(s).

For more information on the conditional expressions allowed, details on the new_input_line and examples, see section Conditional Compilation below.

See also $ifE, $ifI, $ifThen.

$ifE

Syntax:

$ifE [not] conditional_expression new_input_line

This dollar control option does the same as the option $if but allows constant expression evaluation. The conditional_expression may take two different forms:

expr1 == expr2 TRUE if (expr1-expr2)/(1+abs(expr2)) < 1e-12
expr TRUE if expr1 <> 0

Example:

Scalar a;
$ifE (log2(16)^2)=16 a=0; display a;
$ifE log2(16)^2 == 16 a=1; display a;
$ifE NOT round(log2(16)^2-16) a=2; display a;
$ifE round(log2(16)^2-16) a=3; display a;
$ifE round(log2(16)^2-17) a=4; display a;

This will create the following output:

---- 3 PARAMETER a = 1.000
---- 4 PARAMETER a = 2.000
---- 6 PARAMETER a = 4.000

See also $if and section Conditional Compilation.

$ifI

Syntax:

$ifI [not] conditional_expression new_input_line

This option is working like the option $if. The only difference is that $if makes comparisons involving text in a case sensitive fashion while $ifI is case insensitive.

See also $if and section Conditional Compilation.

$ifThen

Syntax:

$ifThen[E|I] cond
...
{ $elseIf[E|I] cond
  ...
} [$else
  ...
] $endIf
This option is a form of the option $if$ that controls whether a number of statements are active. The syntax for the condition is generally the same as for the option $if$. Like $if$, it is case sensitive. Often it is followed by one or more of the following dollar control options: $else$, $elsif$, $elseIf$, $elseIfE$. The option $ifThen$ must be matched with the option $endif$ that marks the end of the construct. An example is given in section Conditional Compilation with $ifThen$ and $endif$.

Note that users may add a tag to the $ifThen$ and $endif$. For example, $ifThen.tagOne$ has to match with $endif.tagOne$.

Example:

```
$ifThen.one x == y
  display "it1";
$elsif.one a == a
  display "it2";
$ifThen.two c == c
  display "it3";
$endif.two
$elsif.one b == b
  display "it4";
$endif.one
```

The resulting listing file will contain the following lines:

```
---- 2 it2
---- 4 it3
```

Note that the first condition ($x == y$) is obviously not true and the fourth condition ($b == b$) is not tested because the second condition ($a == a$) was already true.

See also $if$, $ifThenE$, $ifThenI$, $else$, $elsif$ and section Conditional Compilation.

$ifThenE$

Syntax:

```
$ifThen[E|I] cond
...
{ $elsif[E|I] cond
  ...
} [ $else
  ...
] $endif
```

This option does the same as the option $ifThen$ but evaluates numerical values of the control variables.

See also $ifThen$ and section Conditional Compilation.

$ifThenI$

Syntax:
$ifThen[E|l] \ cond
...
{ $elseif[E|l] \ cond
... }
[ $else
...
]$endif

This option does the same as the option $ifThen but it is case insensitive.

See also $ifThen and section Conditional Compilation.

$include

Syntax:

$include external_file

This option inserts the contents of a specified text file at the location of the call. External_file
is the name of the file that is included. It can be quoted or unquoted. Note that include files
may be nested.

The include file names are processed in the same way like the input file. The names are
expanded using the working directory. If the file cannot be found and no extension is given,
the standard GAMS input extension is tried. However, if an incomplete path is given, the
file name is completed using the include directory. By default, the library include directory
is set to the working directory. The default directory search path may be extended with the
command line parameter InputDir.

Note that the start of the include file is marked and the include file is echoed to the echo
print in the listing file. This reference to the include file may be omitted by using the option
$offInclude.

Example:

$include myfile
$include "myfile"

Both statements above are equivalent and the search order for the include file is as follows:

1. myfile in current working directory
2. myfile.gms in current working directory
3. myfile and myfile.gms (in that order) in directories specified by the command line
   parameter InputDir.

Attention

The current settings of the dollar control options are passed on to the lower level include
files. However, the dollar control options set in the lower level include file are passed on
to the parent file only if the option $onGlobal is set.

Note that details on the compilation output of include files are given in section The Include
File Summary.

See also $batInclude, $libInclude, $sysInclude.

$inlineCom (/ * * /)
Syntax:

\$inlineCom char[char] char[char]

This option redefines and activates the in-line comment symbols. These symbols are placed at the beginning and the end of the in-line comment and are one character or a two character sequence at the beginning and the end. By default, the system is initialized to '/*' and '*/', but is not active. The option \$onInline is used to activate the in-line comments. If \$inlineCom is used, \$onInline is set automatically.

Example:

\$inlineCom {{ }}
Set {{ this is an inline comment }} i / 1*2 / ;

Note that the character pairs {{ }} serve as the indicator for in-line comments.

Attention

It is not allowed to reset the option \$inlineCom to the current symbol for in-line comments. This would cause an compilation error as in the following example:

\$inlinecom {{ }}
\$inlinecom {{ }}

Note

The option \$onNestCom enables the use of nested comments.

See also section Comments.

\$kill

Syntax:

\$kill ident {ident}

This option removes all data for the identifiers ident, only the type and dimension are retained (this means that these identifiers will be declared but not defined anymore). Note that only the data of the following data types may be removed: sets, parameters, variables and equations. Note further that the data removal is carried out during compile time and not when the GAMS program executes.

Example:

Set i / 1*20 /;
Scalar a /2/;
\$kill i a

Note that the effect of the third line above is that all data from a and i is removed, so the set i and the scalar a are declared, but not initialized or assigned to. Note that after i and a have been killed, a display statement for them will trigger an error. However, new data may be assigned to identifiers that were previously killed. Thus the following statements are valid if appended to the code above:

Set i / i1 *i3 /;
a = 7;

Observe that this option needs to be distinguished from the dollar control option \$clear, that resets the data to the default values.
$label

Syntax:

$goto id
$label id

This option marks a line to be jumped to by a dollar control option $goto. Any number of labels may be used in files and not all of them need to be referenced. Re-declaration of a label identifier will not generate an error and only the first occurrence encountered by the GAMS compiler will be used for future $goto references.

Example:

Scalar a;
a = 5;
display a;
$goto next
a = a+5;
display a;
$label next
a = a+10;
display a;

When GAMS reaches the line $goto next, it continues from the line $label next. All lines in between are ignored. Therefore in the example above, the final value of a is 15.

Attention

If several dollar control options appear in one line and label is one of them, then label must be listed first.

See also $goto, $maxGoto.

$libInclude

Syntax:

$libInclude external_file {arg}

This option is mostly equivalent to the option $batInclude. However, if an incomplete path is given, the file name is completed using the library include directory. By default, the library include directory is set to the directory inclib in the GAMS system directory. Note that the default directory may be reset with the command line parameter ldir.

Example:

$libInclude abc x y

This call will first look for the include file [GAMS System Directory]/inclib/abc. If this file does not exist GAMS will looks for the file [GAMS System Directory]/inclib/abc.gms. The arguments x and y are passed on to the include file and are interpreted as explained in the detailed description of the option $batInclude.

See also $include, $batInclude, $sysInclude.
$lines n
This option starts a new page in the listing file if less than n lines are available on the current page.

Example:
$hidden Never split the first few lines of the following table
$lines 5
Table io(i,j) Transaction matrix
... ;
This will ensure that if there are less than five lines available on the current page in the listing file before the next statement (in this case, the table statement) is echoed to it, the contents of this statement are echoed to a new page.

$load
Syntax:
$load [sym1[, sym2=gdxSym2[, sym3<gdxSym3[.dim1][,] ...]]
This option is preceded and succeeded by the option $gdxIn that open the GDX file for reading. The option $load loads specified items from the GDX file. Note that more than one instance of $load may occur. A listing of the GDX file contents will be created if the option $load is not followed by arguments.

Examples
Consider the following example, where transsol is the GDX file of the transportation model [TRANSPORT]
$gdxIn transsol
$load
Sets i, j; Parameters a(i), b(j), d(i,j), f;
$load i j a b d f
$gdxIn
A comma between the symbols is optional. The follow example works identically:
$gdxIn transsol
$load
Sets i, j; Parameters a(i), b(j), d(i,j), f;
$load i, j, a, b, d, f
$gdxIn
The $load without any arguments produces a table of contents of the GDX container in the listing file:
Content of GDX C:\Users\default\Documents\gmsdir\projdir\transsol.gdx
5 UELs

<table>
<thead>

</tbody>
</table>
Symbols may be loaded with new names with the following syntax: $\texttt{load i=gdx.i j=j.gdx}$. The universal set may be loaded using $\texttt{load uni=*.}$

\$\texttt{gdxIn transsol}$
Sets $i$, $jj$, $uni$; Parameters $a(i)$, $bb(jj)$, $d(i,jj)$, $f$;
\$\texttt{load i jj=j uni=** a bb=b d f}$
\$\texttt{gdxIn}$
\texttt{display uni;} \\
This results in a display of all used labels:

---

5 SET uni
Seattle, San-Diego, New-York, Chicago, Topeka

The syntax $\texttt{sym<[>]GDXSym.[dimI]}$ allows to load a one dimensional set from a symbol in the GDX file that has even a higher dimensionality. GAMS tries to find the set $\texttt{sym}$ as a domain in the symbol $\texttt{GDXSym}$ and uses the labels from this index position (with $<$ the first domain set from the right and with $<=$ from the left). If no domain information is stored in the GDX file or the domain information does not match the suffix $\texttt{.dimI}$ allows to pick a fixed index position.

In the following we work with a GDX file created by the following code:

set $i$ / $i1*i3$ /, $ii(i,i)$ / $i1.i2$, $i2.i3$ /;
\$\texttt{gdxOut ii}$
\$\texttt{unLoad i ii}$
\$\texttt{gdxOut}$

Now use use this GDX file to load the first and second index from $ii$:

set $i$, $i1$;
\$\texttt{gdxIn ii}$
* Load first index from $ii$ as $i$
\$\texttt{load i<ii i1<ii.dim1}$
\texttt{display i, i1;} \\
the display lists all labels from the first index of $ii$:

---

5 SET $i$ Domain loaded from $ii$ position 1
$i1$, $i2$

---

5 SET $i1$ Domain loaded from $ii$ position 1
$i1$, $i2$

Now we match from the right and get the second index of $ii$:

set $i$, $i2$;
\$\texttt{gdxIn ii}$
* Load second index from $ii$ as $i$
\$\texttt{load i<ii i2<ii.dim2}$
\texttt{display i, i2;} \\
The resulting listing file will contain the following lines:

---

5 SET $i$ Domain loaded from $ii$ position 2
$i2$, $i3$

---

5 SET $i2$ Domain loaded from $ii$ position 2
$i2$, $i3$

This type of projection loading can be useful to extract the domain sets from a single parameter that is stored in a GDX file:

set $i,j,k$; parameter $data(i,j,k)$;
\$\texttt{gdxIn data}$
\$\texttt{load i<data.dim1 j<data.dim2 k<data.dim3 data}$
Attention

Loading an item that was already initialized will cause a compilation error.

For example, the following code snippet will cause a compilation error:

```gams
Set j / 1*5 /;
$gdxIn transsol
$load j
$gdxIn
```

Note that GAMS offers variants of `$load` that do not cause a compilation error in such a case: `$loadM` and `$loadR`.

### `$loadDC`

**Syntax:**

```gams
$loadDC [sym1[,] sym2=gdxSym2[,] sym3<=[=]gdxSym3[.dimI][,] ...]
```

This option is an alternative form of `$load`. It performs domain checking when items are loaded. Any domain violations will be reported and flagged as compilation errors. All other features are the same as discussed under `$load`.

**Example:** Consider the following example where `transsol` is the GDX file of the transportation model `[TRNSPORT]`.

```gams
Set i, j;
Parameter b(i), a(j);
$gdxIn transsol
$load i b
$loadDC j a
$gdxIn
```

Note that in contrast to the example above, the parameter `a` is indexed over the set `i` and the parameter `b` is indexed over the set `j` in the file `transsol`. While `$load i b` does not generate an error and `b` is just empty, the option `$loadDC j a` triggers a domain violation error because in `transsol a` is indexed over `i` and produces a list of errors in the listing file:

```
--- LOAD a = 3:a
**** Unique domain errors for symbol a
  Dim  Elements
  i  seattle, san-diego

  5  $loadDC j a
**** $649
```

### `$loadDCM`

**Syntax:**

```gams
$loadDCM [sym1[,] sym2=gdxSym2[,] sym3<=[=]gdxSym3[.dimI][,] ...]
```

This option combines the functionality of merging as in `$loadM` and domain checking as in `$loadDC`.

**Example:**

Consider the following example where `transsol` is the GDX file of the transportation model `[TRNSPORT]`.

```
--- LOAD a = 3:a
**** Unique domain errors for symbol a
  Dim  Elements
  i  seattle, san-diego

  5  $loadDC j a
**** $649
```
Set i, uni 'all labels';
Parameter abFail(i), ab(uni) 'capacity and demand';
$gdxIn transsol
$load i abFail=a
$loadDCM abFail=b
$loadDCM uni=i uni=j ab=a ab=b
$gdxIn
display uni, ab;

Here we try to merge parameters a and b together into one parameter. The first attempt (to merge it into parameter abFail) would fail because of line 5 and result into a domain violation report as described with dollar control option $loadDC. In the second attempt we first merge the sets i and j into set uni and then merge the parameters a and b into ab. If one comments line 5 the resulting display looks as follows:

    ---- 8 SET uni all labels
    seattle, san-diego, new-york, chicago, topeka

    ---- 8 PARAMETER ab capacity and demand
    seattle 350.000, san-diego 600.000, new-york 325.000
    chicago 300.000, topeka 275.000

$loadDCR

Syntax:

$loadDCR [sym1[,] sym2=gdxSym2[,] sym3<[^=]gdxSym3[.dimI][,] ...) 

This option combines the functionality of replacing data as in $loadR and domain checking as in $loadDC.

Example:

Consider the following example where transsol is the GDX file of the transportation model [TRNSPORT].

Set uni 'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadM uni=i uni=j ab=a
$loadDCR ab=b
$gdxIn
display uni, ab;

Here we try to read twice into the parameter ab. First GDX symbol a and b are read into ab. GDX symbol b is read with replace and hence the parameter ab contains the elements of b only.

$loadM

Syntax:

$loadM [sym1[,] sym2=gdxSym2[,] sym3<[^=]gdxSym3[.dimI][,] ...) 

This option is an alternative form of $load. Instead of replacing an item or causing a symbol redefined error if the item was already initialized it merges the contents. Records that would result in domain violations will be ignored.

Example:

Consider the following example where transsol is the GDX file of the transportation model [TRNSPORT].
Set i, uni 'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadM uni=i uni=j ab=a ab=b
$gdxIn
display uni, ab;

Here we merge parameters a and b together into one parameter ab. We first merge the sets i and j into set uni and then merge the parameters a and b into ab. The resulting display looks as follows:

---- 6 SET uni all labels
    seattle , san-diego, new-york , chicago , topeka
---- 6 PARAMETER ab capacity and demand
    seattle 350.000, san-diego 600.000, new-york 325.000
    chicago 300.000, topeka 275.000

$loadR

Syntax:

$loadR [sym1[,] sym2=gdxSym2[,] sym3<=[=]gdxSym3[.dimI][,] ...]

This option is a variant of the option $load. With $loadR we can have multiple loads into the same symbols and the data stored in GAMS will be replaced with the one from the GDX container.

Example:

Consider the following example, where transsol is the GDX file of the transportation model [TRNSPORT]:

Sets i / 1*3 /    
    j / 1*2 /;
$gdxIn transsol
$loadR i j
$gdxIn
display i, j;

The resulting listing file will contain the following lines:

---- 6 SET i canning plants
    Seattle , San-Diego
---- 6 SET j markets
    New-York, Chicago , Topeka

$log

Syntax:

$log text

This option will send a message text to the log file. Recall that by default, the log file is the console. The default log file may be reset with the command line parameters logOption and logFile.
Attention

- Leading blanks are ignored when the text is written out to the log file as a result of using the $\log$ option.
- All special [%] symbols will be substituted before the text passed through the $\log$ option is sent to the log file.

Example:

$\log$

$\log$ The following message will be written to the log file
$\log$ with leading blanks ignored. All special [%] symbols will
$\log$ be substituted before this text is sent to the log file.
$\log$ This was line [%system.incLine%] of file [%system.incName%]
$\log$

The log file that results by running the lines above will contain the following lines:

The following message will be written to the log file
with leading blanks ignored. All special [%] symbols will
be substituted before this text is sent to the log file.
This was line 5 of file C:\\tmp\\logTest.gms

Note that [%system.incLine%] is replaced by 5 which is the line number where the string replacement was requested. Note further that [%system.incName%] is substituted with the name of the file completed with the absolute path. Observe that the leading blanks on the second line of the example are ignored.

$\text{macro}$

Syntax:

$\text{macro name(arg1,arg2,arg3,...) macro_body}$

This option defines a macro in GAMS. Here name is the name of the macro, arg1,arg2,arg3,... are the arguments and macro_body defines what the macro should do. The macro names follow the rules for identifiers. The macro name cannot be used for other symbols. For further details and examples, see section Macros in GAMS below.

$\text{maxCol (80001)}$

Syntax:

$\text{maxCol n}$

This option restricts the valid range of input columns at the right margin. Note that all input after column n is treated as comment, therefore it is ignored.

Example:

$\text{maxCol 30}$

Set i / vienna, rome /; set definition
Scalar a / 2.3 /; scalar definition

Observe that the text strings set definition and scalar definition are treated as comments and are ignored since they begin on or after column 31.

Any changes in the margins via $\text{maxCol}$ or $\text{minCol}$ will be reported in the listing file with the message that gives the valid range of input columns. For example, the dollar control option $\text{minCol 20 maxCol 110}$ will trigger the following message:

NEW MARGINS: 20-110
Note

- GAMS requires that the right margin set by $\text{maxCol}$ is greater than 15.
- GAMS requires that the right margin set by $\text{maxCol}$ is greater than the left margin set by $\text{minCol}$.

See also $\text{on/offMargin}$ and section Comments.

$\text{maxGoto 100}$

Syntax:

$\text{maxGoto } n$

This option sets the maximum number of jumps to the same label and is used in the context of the options $\text{goTo}$ and $\text{label}$. Once the maximum number is reached a compilation error is triggered. Such a limit has been implemented to avoid infinite loops at compile time.

Example:

Scalar a / 1 /;
$\text{maxGoto 5}$
$\text{label label1}$
a = a+10;
display a ;
$\text{goTo label1}$

Note that a compilation error is triggered if $\text{goTo label1}$ is called for the fifth time.

$\text{minCol} \ (1)$

Syntax:

$\text{minCol } n$

This option restricts the valid range of input columns at the left margin. Note that all input before column $n$ is treated as comment, therefore it is ignored.

Example:

$\text{minCol 30}$

Set definition    Set i / vienna, rome /;
Scalar definition  Scalar a / 2.3 /;

Observe that the text strings set definition and scalar definition are treated as comments and are ignored since they are placed before column 30.

Any changes in the margins via the option $\text{maxCol}$ or $\text{minCol}$ will be reported in the listing file with the message that gives the valid range of input columns. For example, the dollar control option $\text{minCol 20 maxCol 110}$ will trigger the message:

NEW MARGINS: 20–110
Attention

GAMS requires that the left margin set by the option $\text{minCol}$ is smaller than the right margin set by the option $\text{maxCol}$.

See also $\text{on/offMargin}$ and section Comments.

$\text{[on][off]Delim}$ ($\text{offDelim}$)

Syntax:

$\text{onDelim}$
$\text{offDelim}$

This option controls whether data in table statements may be entered in comma delimited format.

Example:

Sets plant 'plant locations' / NEWYORK, CHICAGO, LOSANGELES /
market 'demands' / MIAMI, HOUSTON, PORTLAND /

Table dist(plant,market)
$\text{onDelim}$
,MIAMI,HOUSTON,PORTLAND
NEWYORK,1300,1800,1100
CHICAGO,2200,1300,700
LOSANGELES,3700,2400,2500
$\text{offDelim}$

Display dist;

The resulting listing file will contain the following output:

```
----   12 PARAMETER dist

MIAMI   HOUSTON   PORTLAND

NEWYORK  1300.000  1800.000  1100.000
CHICAGO  2200.000  1300.000   700.000
LOSANGELES  3700.000  2400.000  2500.000
```

$\text{[on][off]Digit}$ ($\text{onDigit}$)

Syntax:

$\text{onDigit}$
$\text{offDigit}$

This option controls the precision check on numbers. Computers work with different internal precision. To have the same behavior on all supported platforms, GAMS does not accept numbers with more than 16 significant digits on input. Sometimes one needs to work with input values with more digits, e.g., if the data is generated from some source, which is out if the users control. Instead of changing numbers with too much precision, the option $\text{offDigit}$ instructs GAMS to use as much precision as possible and ignore the rest of the number.

Example:
Parameter y(*) / toolarge 12345678901234.5678
$offDigit
       ignored 12345678901234.5678 /

The resulting listing file will contain the following lines:

1       Parameter y(*) / toolarge 12345678901234.5678
       **** $103
3       ignored 12345678901234.5678 /

Error Messages
103    Too many digits in number
       ($offdigit can be used to ignore trailing digits)

Note that the error occurs in the 17th significant digit of y("toolarge"). However, after the line containing the option $offDigit, y("ignored") is accepted without any errors even though there are more than 16 significant digits.

$[on][off]Dollar  ($offDollar)

Syntax:

$onDollar
$offDollar

This option controls the echoing of dollar control option lines in the listing file.

Example:

$hidden This line will not be displayed
$onDollar
$hidden This line will be displayed
$offDollar
$hidden This line will not be displayed

The compilation output of the resulting listing file will contain the following lines:

2       $onDollar
3       $hidden This line will be displayed

Note that all lines between the option $onDollar and the option $offDollar are echoed in the listing file. Note further that the effect of this option is immediate: the line $onDollar is echoed in the listing file, while the line $offDollar is not.

$[on][off]DotL ($offDotL)

Syntax:

$onDotL
$offDotL

This option activates or deactivates the automatic addition of the attribute .L to variables on the right-hand side of assignments. It is most useful in the context of macros. For further information, see section Macros in GAMS below.

$[on][off]DotScale ($offDotScale)

Syntax:
3.41 Dollar Control Options

This option activates or deactivates the automatic addition of the attribute .Scale to variables and equations on the right-hand side of assignments. As with on|offDotL It is most useful in the context of macros. For further information, see section Macros in GAMS below.

$[on][off]Echo[S][V]

Syntax:

$onEcho[S|V] >[>] external_file
text
{text}
$offEcho

This option is used to send one or more lines of text to an file external_file. The text and the file name may be quoted or unquoted. The external file is not closed until the end of the compilation or when the option $call or any variant of the option $include is encountered. Note that the redirection symbols > and >> have the usual meaning: > creates a new file and writes to it or - in case there exists already a file with the respective name - overwrites the existing file and >> appends to a file. Note further that parameter substitutions are permitted with $onEcho. The option $onEcho has two more variants: $onEchoS and $onEchoV. $onEchoS allows parameter substitutions like $onEcho, so it is just a synonym which makes it more obvious that parameter substitution is allowed with the appended S. The option $onEchoV does not allow parameter substitutions but writes the text verbatim.

Example:

$set it TEST
$onEchoS > externalfile1.txt
send %it% to external file
line 2 to send
$offEcho

$onEchoV > externalfile2.txt
send %it% to external file
line 2 to send
$offEcho

The externalfile1.txt will contain the following lines:

send TEST to external file
line 2 to send

The externalfile2.txt will contain these lines:

send %it% to external file
line 2 to send

Observe that in the first case %it% is substituted with TEST, but in the second case there is no substitution.

Note that by default the external file will be placed in the current working directory if there is no path specified.

See also options $echo, and $echoN.

$[on][off]Embedded ($offEmbedded)
Syntax:

$onEmbedded
$offEmbedded

This option enables or disables the use of embedded values in parameter and set data statements. If enabled, the explanatory text for set elements is concatenated with blank separators. For parameters, the embedded values get multiplied.

Example:

```gams
Set k / a,b /
   l / a /
Set      i(k,l) / a.a 'aaaa cccc dddd'
         b.a 'bbbb cccc dddd' /;
Parameter m(k,l) / a.a 12
         b.a 24 /;
$onEmbedded
Set      j(k,l) / (a aaaa, b bbbb).(a cccc) dddd /;
Parameter n(k,l) / (a 1, b 2) .(a 3) 4 /;
```

Note that the explanatory text of the set elements in i and j as well as the values of the parameters m and n are identical.

$[on][off]EmbeddedCode[S|V]

Syntax:

$onEmbeddedCode[S|V] Python: [arguments]
{Python code}
$offEmbeddedCode {symbol[<[=]embSymbol[.dimX]]}

This option is used to execute one or more lines of Python code while GAMS stays alive. The Python code has access to GAMS symbols and can read and change them.

Note that parameter substitutions are permitted with $onEmbeddedCode. The option $onEmbeddedCode has two more variants: $onEmbeddedCodeS and $onEmbeddedCodeV. $onEmbeddedCodeS allows parameter substitutions like $onEmbeddedCode, so it is just a synonym which makes it more obvious that parameter substitution is allowed with the appended S. The option $onEmbeddedCodeV does not allow parameter substitutions but passes the code verbatim to the Python interpreter. The optional arguments given to $onEmbeddedCode[S|V] can be accessed in the Python code.

$offEmbeddedCode can be followed by a GAMS symbol or a list of GAMS symbols. If GAMS symbols are specified they get updated in the GAMS database after the Python code got executed. The syntax `symbol<[=]embSymbol[.dimX]` allows to load a one dimensional set from a symbol which was set in the embedded code that has even a higher dimensionality (here we call `<[=]` the projection operator). GAMS tries to find the set `symbol` as a domain in the symbol `embSymbol` and uses the labels from this index position (with `<` the first domain set from the right and with `<=` from the left). If no domain information is stored in the GDX file or the domain information does not match the suffix `.dimX` allows to pick a fixed index position (`X` needs to be replaced by the desired index position).

Example:
Set cc / "France - Paris", "France - Lille", "France - Toulouse"
   "Spain - Madrid", "Spain - Cordoba", "Spain - Seville", "Spain - Bilbao"
   "USA - Washington DC", "USA - Houston", "USA - New York",
   "Germany - Berlin", "Germany - Munich", "Germany - Bonn" /
country / system.empty /
city / system.empty /
mccCountry(cc,country)
mccCity(cc,city);

$onEmbeddedCode Python:
mccCountry = []
mccCity = []
country = set()
city = set()
for cc in gams.get("cc"):
r = str.split(cc, " - ", 1)
mccCountry.append((cc,r[0]))
mccCity.append((cc,r[1]))
country.add(r[0])
city.add(r[1])
gams.set("country",list(country))
gams.set("city",list(city))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
$offEmbeddedCode country city mccCountry mccCity

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry ,mccCity;

This will be in the listing file:

---- 28 SET country

Spain , USA , France , Germany

---- 28 SET city

Washington DC, Toulouse , Berlin , Munich
Houston , Madrid , New York , Seville
Paris , Bilbao , Lille , Bonn
Cordoba

---- 28 SET mccCountry

France - Paris .France
France - Lille .France
France - Toulouse .France
Spain - Madrid .Spain
Spain - Cordoba .Spain
Spain - Seville .Spain
Spain - Bilbao .Spain
USA - Washington DC .USA
USA - Houston .USA
USA - New York .USA
Germany - Berlin .Germany
Germany - Munich .Germany
Germany - Bonn .Germany
Using the *projection* operator the same task could be done like this:

```gams
Set cc  / "France - Paris", "France - Lille", "France - Toulouse"
        "Spain - Madrid", "Spain - Cordoba", "Spain - Seville", "Spain - Bilbao"
        "USA - Washington DC", "USA - Houston", "USA - New York",
        "Germany - Berlin", "Germany - Munich", "Germany - Bonn" /
    country / system.empty /
    city / system.empty /
    mccCountry(cc,country)
    mccCity(cc,city);
```

```python
mccCountry = []
mccCity = []
for cc in gams.get("cc"):
    r = str.split(cc, " - ", 1)
    mccCountry.append((cc,r[0]))
    mccCity.append((cc,r[1]))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
```

See also chapter *Embedded Code Facility* for more details.

### $onEmpty/OffEmpty

**Syntax:**

- `$onEmpty`
- `$offEmpty`

Setting `$onEmpty` allows empty data statements for list or table formats. Note that by default, empty data statements will cause a compilation error.

**Example:**
Set i / 1,2,3 /;
Set j(i) / / ;
Parameter x(i) "empty parameter" / / ;
Table y(i,i) "headers only"
   1 2 3 ;
$onEmpty
Set k(i) / / ;
Parameter xx(i) "empty parameter" / / ;
Table yy(i,i) "headers only"
   1 2 3 ;

The resulting listing file will contain the following lines:

1 Set i / 1,2,3 / ;
2 Set j(i) / / ;
3 Parameter x(i) "empty parameter" / / ;
4 Table y(i,i) "headers only"
5   1 2 3
6 ;
7 Parameter xx(i) "empty parameter" / / ;
8 Table yy(i,i) "headers only"
9   1 2 3
10 ;

Error Messages

460 Empty data statements not allowed. You may want to use $ON/OFFEMPTY
462 The row section in the previous table is missing

Empty data statements are most likely to occur when data is being entered into the GAMS model by an external program. This problem may be overcome with the option $onEmpty.

Note

The empty data statement may only be used with symbols which have a known dimension. If the dimension is also derived from the data, the option $phantom should be used to generate 'phantom' set elements.

The option $onEmpty in conjunction with the option $onMulti and the save and restart feature may be used to set up a model and add data later.

$[on][off]End ($offEnd)

Syntax:

$onEnd
$offEnd

This option offers an alternative syntax for flow control statements. The option $onEnd causes the following words to be regarded as keywords: do, endLoop, endIf, endFor and endWhile. They are used to close the language constructs loop, if, for and while respectively.

Example:
Note

The standard syntax is given as an end-of-line comment.

Set i / 1*3 /;
Scalar cond / 0 /;
Parameter a(i) / 1 1.23, 2 2.65, 3 1.34/;

$eolCom //
$onEnd

loop i do // loop (i,
    display a; // display a;
endLoop; // );

if (cond) then // if (cond,
    display a; // display a;
else // else
    a(i) = a(i)/2; // a(i) = a(i)/2;
    display a; // display a;
endif; // );

for cond = 1 to 5 do // for (cond = 1 to 5,
    a(i) = 2 * a(i); // a(i) = 2 * a(i);
endFor; // );

while cond > 3 do // while (cond > 3,
    a(i) = a(i) / 2; // a(i) = a(i) / 2;
    cond = cond-1; // cond = cond-1;
endWhile; // );

Observe that the alternative syntax is more in line with the syntax used in some of the popular programming languages.

Attention

Setting the option $onEnd will make the alternative syntax valid, and at the same time it will make the standard syntax invalid. Therefore the two forms of the syntax will never be valid simultaneously.

$[on][off]EolCom ($offEolCom)

Syntax:

$onEolCom
$offEolCom

This option acts as a switch to control the use of end-of-line comments. Note that by default, the end-of-line comment symbol is set to !! but the processing is disabled.

Example:

$onEolCom
Set i /1*2/ ; !! set declaration
Parameter a(i) ; !! parameter declaration

Observe that after the option $onEolCom has been specified, comments may be entered on the same line as GAMS code.
Note
The option $eolCom automatically sets $onEolCom.

See also section Comments.

$[on][off]Eps ($offEps)

Syntax:

$onEps
$offEps

This option is used to treat zero as EPS in a parameter or table data statement. This can be useful if the value of zero is overloaded with existence interpolation.

Example:

Set i / one, two, three, four /;
Parameter a(i) /
$oneps
  one 0
$offeps
  two 0
  three EPS /;
Display a ;

The outcome generated by the display statement follows:

---- 8 PARAMETER a
   one EPS, three EPS

Note that only those entries specifically entered as 0 are treated like EPS.

$[on][off]Expand ($offExpand)

Syntax:

$onExpand
$offExpand

This option changes the processing of macros that appear in the arguments of a macro call. The default operation is not to expand macros in the arguments. The switch $onExpand enables the recognition and expansion of macros in the macro argument list and $offExpand will restore the default behavior.

Example:

variable x(*,*);
$macro f(i) sum(q, x(i,q))
$macro equ(x) equation equ_&x; equ_&x.. &x =e= 0;
equ(f(i))

The macro expansion of the code above will result in an equation definition that reads as follows:

equation equ_f(I); equ_f(i).. f(i) =e= 0;
If we compile the code under $onExpand the argument f(i) is expanded before the macro equ() gets expanding resulting in the following (incorrect) code:

    equation equ_sum(q, x(i,q)); equ_sum(q, x(i,q)).. sum(q, x(i,q)) =e= 0;

For further information, see section Macros in GAMS below.

$[on][off]Global  ($offGlobal)

Syntax:

$onGlobal
$offGlobal

When an include file is inserted, it inherits the dollar control options from the higher level file. However, the dollar control option settings specified in the include file do not affect the higher level file. This convention is common among most scripting languages or command processing shells. In some cases, it may be desirable to break this convention. This option allows an include file to change the options of the parent file as well.

Example:

$include 'inc.inc'
$hidden after first call to include file
$onGlobal
$include 'inc.inc'
$hidden after second call to include file

The file inc.inc contains the following lines:

$onDollar
$hidden text inside include file

The the echo print of the resulting listing file follows:

    INCLUDE D:\GAMS\INC.INC
    2 $onDollar
    3 $hidden text inside include file
    INCLUDE D:\GAMS\INC.INC
    7 $onDollar
    8 $hidden text inside include file
    9 $hidden after second call to include file

Note that the dollar control option $onDollar inside the include file does not affect the parent file until $onGlobal is set. The text following the option $hidden is then echoed to the listing file.

$[on][off]Include  ($onInclude)

Syntax:

$onInclude
$offInclude

This option controls the listing of the expanded include file name in the listing file.

Example:
We assume that the file \texttt{inc.inc} contains the following lines:

\$onDollar
\textbf{hidden} Text inside include file
\$offInclude

The resulting listing file will contain the following lines:

\begin{verbatim}
INCLUDE C:\tmp\inc.inc
  2 \$onDollar
  3 \textbf{hidden} Text inside include file
  6 \$onDollar
  7 \textbf{hidden} Text inside include file
\end{verbatim}

Note that the include file name is echoed the first time the include file is used. However, the include file name is not echoed after \$offInclude has been set.

\section{$\texttt{[on][off]Inline}$ ($\texttt{offInline}$)}

\textbf{Syntax:}

\begin{verbatim}
$onInline
$offInline
\end{verbatim}

This option acts as switch to control the use of in-line comments. Note that by default, the in-line comment symbols are set to the two character pairs /\* and */\* but the processing is disabled. In-line comments may span several lines till the end-of-comment characters are encountered.

\textbf{Example:}

\begin{verbatim}
$onInline
Set i /* The default comment symbols are now active. These comments can continue
to additional lines till the closing comments are found. */ / i1*i3 / ;
\end{verbatim}

\textbf{Note}

- The option \texttt{inlineCom} automatically sets \$onInline.
- \textit{Nested} in-line comments are illegal unless the option \$onNestCom is set.

See also section Comments.

\section{$\texttt{[on][off]Listing}$ ($\texttt{onListing}$)}

\textbf{Syntax:}

\begin{verbatim}
$onListing
$offListing
\end{verbatim}

This option controls the echoing of input lines to the compilation output of the listing file. Note that suppressed input lines do not generate entries in the symbol and reference sections that appear at the end of the compilation output. Lines with errors will always be listed.

\textbf{Example:}
Set i /0234*0237/  
j /a,b,c/  ;
Table x(i,j) "very long table"  
a b c  
0234 1 2 3  
0235 4 5 6  
0236 5 6 7  
0237 1 1 1  

The resulting listing file will contain the following lines:

1 Set i /0234*0237/  
2 j /a,b,c/  ;
3 Table x(i,j) very long table  
4 a b c  
5 0234 1 2 3  
10 0237 1 1 1  

Note that the lines in the source file between the options $offListing and $onListing are not echoed to the listing file.

Note

For some projects the listing file can become huge and can take significant time to be written. This time can be saved by setting $offListing at the beginning of the input file and $onListing just before the parts one is interested in, or not at all, if one does not look at the listing file anyway.

$[on][off]Local ($onLocal)

Syntax:

$onLocal
$offLocal

The suffix .local attached to the name of a controlling set will use an implicit alias within the scope of the indexed operation or on the left-hand side of an assignment statement. This feature is particularly useful in the context of nested macros.

Example:

Set i /1*3/; alias(i,j);
Parameter xxx(i,j) / 1.1 1, 2.2 2, 3.3 3, 1.3 13, 3.1 31 /;
display xxx;

Parameter p(i);
p(i.local) = sum(j, xxx(i,j));
display p;

Note that in the assignment statement the set i on the right-hand side is controlled by i.local on the left-hand side. Thus we have the following values for the two parameters:
3.41 Dollar Control Options

---  3 PARAMETER xxx
     1     2     3
     1 1.000 13.000
     2   2.000
     3 31.000  3.000

---  7 PARAMETER p
     1  14.000,  2   2.000,  3  34.000

In the example above, the suffix .local appeared one time on the left-hand side. The option $onLocal allows the suffix .local to appear more than one time attached to the same symbol. Consider the following example that extends the example above:

Parameter g(i,i);
g(i.local-1,i.local) = xxx(i,i);
display g;

Note that in the assignment statement of g the suffix .local attached to the set i appears two times on the left-hand side. The question arises whether the reference to the set i on the right-hand side refers to the first or the second instance of .local on the left-hand side. The assignment statement may alternatively be written in the following way using an explicit alias statement:

alias (i,i1,i2);
g(i1-1,i2) = xxx(i2,i2);

Thus becomes clear that the symbol on the right-hand side refers to the controlling index that enters last (here the second one). The output generated by the display statement follows:

---  10 PARAMETER g
     1     2     3
     1 1.000  2.000  3.000
     2 1.000  2.000  3.000

Observe that the multiple use of the suffix .local on the same symbol is considered an error with the option $offLocal.

Note that it is also allowed to combine the original index with an index suffixed with .local. Consider the following alternative formulation:

g(i.local-1,i) = xxx(i,i);

Note that in this case the index suffixed with .local takes precedence and the reference of i on the right-hand side refers to the index i.local even though i is entered last. Observe that this statement even works with $offLocal as the suffix .local appears only once.

See also section Macros in GAMS below.

$[on][off]Log  ($onLog)

Syntax:

$onLog
$offLog

This option acts as a switch that controls logging information about the line number and memory consumption during compilation. This is scoped like the option $on/offListing applying only to included files and any subsequent included files but reverting to the setting $onLog in the parent files (if it was not changed there as well).

Example:
Set i /i1*i20000000/;
$include inc.inc
Set l /l1*l20000000/;

The file inc.inc looks like this:

Set j /j1*j20000000/;
$offLog
Set k /k1*k20000000/;

The generated log will contain the following lines:

--- test.gms(1) 1602 Mb 5 secs
--- test.gms(2) 1602 Mb
--- .inc.inc(1) 3122 Mb 6 secs
--- test.gms(3) 6161 Mb 14 secs

Note that the first line of both the parent and the include file got logged, but not the third line of the include file, after $offLog was set. The last line of the parent file got logged again.

$[on][off]Macro ($onMacro)

Syntax:
$onMacro
$offMacro

Enables or disables the expansion of macros defined by $macro.

Example:

$macro oneoverit(y) 1/y
$offMacro
y = oneoverit(x1);
display y;

causes an error because the macro oneoverit in line 3 can not be expanded.

$[on][off]Margin ($offMargin)

Syntax:
$onMargin
$offMargin

This option controls margin marking, that means if margins set by the options $minCol and $maxCol, should be marked in the lst file.

Example:

$onmargin mincol 20 maxcol 51
Now we have Set i "plant" / US, UK /; This defines I
turned on the Scalar x / 3.145 /; A scalar example.
margin marking. Parameter a, b; Define some
parameters.
$offmargin

The lst file will contain this:
Now we have |Set i "plant" / US, UK /; |This defines I
3 turned on the |Scalar x / 3.145 /; |A scalar example.
4 margin marking. |Parameter a, b; |Define some
5 | |parameters.

Note that any statements between columns 1 and 19 and any input beyond column 52 are treated as comments. These margins are marked with | on the left and right.

See also section Comments.

$[on][off]Multi ($[offMulti])

Syntax:

$onMulti
$offMulti

This option controls multiple data statements or tables. By default, GAMS does not allow data statements to be redefined. If this option is activated the second or subsequent data statements are merged with entries of the previous ones. Note that all multiple data statements are performed before any other statement is executed.

Note
• There is also $onMultiR, which behaves similarly, but replaces existing data instead of merging into it. Compare the example here and there to see the difference.
• When $onMulti is active $load behaves like a $loadM.

Example:

Consider the following slice of code. The list after the end of line comment describes the complete content of the symbol x after the data statement has been processed:

$eolCom //
Set i / i1*i10 /;
Parameter x(i) / i1*i3 1 / // /i1 1,i2 1,i3 1/
$onMulti
Parameter x(i) / i7*i9 2 / // /i1 1,i2 1,i3 1,i7 2,i8 2,i9 2/
Parameter x(i) / i2*i6 3 / // /i1 1,i2 3,i3 3,i4 3,i5 3,i6 3,i7 2,i8 2,i9 2/
Parameter x(i) / i3*i5 0 / // /i1 1,i2 3,i6 3,i7 2,i8 2,i9 2/
$offMulti
display x;

Note that the repeated parameter statements would have resulted in a compilation error without the presence of the option $onMulti. The result of the display statement in the listing file follows:

---- 8 PARAMETER x
1 1.000, 2 3.000, 6 3.000, 7 2.000, 8 2.000, 9 2.000

Note that x("i1") is assigned the value of 1 with the first data and is not affected by any of the subsequent data statements. x("i3") on the other hand is reset to 3 by the third data statement and wiped out with 0 in the fourth data statement.
Attention

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Dollar control options and data initialization are both done in the first pass and assignments in the second, irrespective of their relative locations. This is an issue particularly with the option $onMulti since it allows data initializations to be performed more than once. See section GAMS Compile Time and Execution Time Phase for details.

Consider the following example:

Scalar a /12/;
a=a+1;
$onMulti
Scalar a /20/;
display a;

Note that the two scalar data initialization statements and the option $onMulti are processed before the assignment statement a=a+1. As a result, the final value of a will be 21. The output of the display statement follows:

---- 5 PARAMETER a = 21.000

Observe that the option $onEmpty in conjunction with the option $onMulti and the save and restart feature may be used to set up a model and add data later. See example in section Advanced Separation of Model and Data for details.

$onMultiR/offMulti ($offMulti)

Syntax:

$onMultiR
$offMulti

This option controls multiple data statements or tables. By default, GAMS does not allow data statements to be redefined. If this option is activated the second or subsequent data statements replace the previous ones. Note that all multiple data statements are performed before any other statement is executed.

Note

• There is also $onMulti, which behaves similarly, but merges into existing data instead of replacing it. Compare the example here and there to see the difference.

• In contrast to $onMulti, $onMultiR also allows to redefine an equation.

Example:

Consider the following slice of code. The list after the end of line comment describes the complete content of the symbol x after the data statement has been processed:

$eolCom //
Set i / i1*i10 /;
Parameter x(i) / i1*i3 1 / // /i1 1,i2 1,i3 1/
$onMultiR
Parameter x(i) / i7*i9 2 / // /i7 2,i8 2,i9 2/
Parameter x(i) / i2*i6 3 / // /i2 3,i3 3,i4 3,i5 3,i6 3/
Parameter x(i) / i3*i5 0 / // ( ALL 0.000 )
$offMulti
display x;

Note that the repeated parameter statements would have resulted in a compilation error without the presence of the option $onMultiR. The result of the display statement in the listing file follows:

---- 9 PARAMETER x

( ALL 0.000 )
Note

- When using a redefinition with $onMultiR to remove elements from a set, which was used as domain of another symbol, also the dependent symbol gets reduced. This can happen through data statements, but also with $clear and $load/$loadDC.
- When $onMultiR is active $load behaves like a $loadR.

Example:

Set i / i1*i5 /;
Parameter p(i) / #i 3 /;
$onMultiR
Set i / i3*i6 /;
Display p;

Looking at the output from the Display statement one can see, that the entries for i1 and i2 were removed by the second definition of i:

---- 7 PARAMETER p
i3 3.000, i4 3.000, i5 3.000

Attention

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Dollar control options and data initialization are both done in the first pass and assignments in the second, irrespective of their relative locations. This is an issue particularly with the option $onMultiR since it allows data initializations to be performed more than once. See section GAMS Compile Time and Execution Time Phase for details.

Consider the following example:

Scalar a /12/;
a=a+1;
$onMultiR
Scalar a /20/;
display a;

Note that the two scalar data initialization statements and the option $onMultiR are processed before the assignment statement a=a+1. As a result, the final value of a will be 21. The output of the display statement follows:

---- 5 PARAMETER a = 21.000

Observe that the option $onEmpty in conjunction with the option $onMultiR and the save and restart feature may be used to set up a model and add data later. See example in section Advanced Separation of Model and Data for details.

$[on][off]NestCom  ($offNestCom)

Syntax:

$onNestCom
$offNestCom
This option controls nested in-line comments. It makes sure that the open-comment and close-comment characters match.

Example:

```gams
$inlineCom { } onNestCom
{ nesting is now possible in comments { braces have to match }}
```

See also $inlineCom, $onInline and section Comments.

$[on][off]Order ($onOrder)

Syntax:

```gams
$onOrder
$offOrder
```

**Lag and lead operations** and the `ord` function require the referenced set to be **ordered** and constant. In some special cases users might want to use those operations on dynamic and/or unordered sets. The option `$on/offOrder` has been added to locally relax the default requirements. The use of this option comes with a price, the system will not be able to diagnose odd and incorrect formulations and data sets.

Example:

```gams
Parameter p(t2);
$offOrder
p(t2) = ord(t2);
display t2, p;
```

Without the `$offOrder` the compilation of the line `p(t2) = ord(t2);` would have triggered a compilation error. The ordinal numbers assigned here are probably not what one expects. The element 1987 gets ordinal number 1 although it seems to be last last in the set. The ordinal numbers are assigned in the order the set is stored internally in GAMS. This order is also used when displaying the set `t2`:

```gams
---- 6 SET t2
---- 6 PARAMETER p
1987 1.000, 1983 2.000, 1984 3.000, 1985 4.000, 1986 5.000
```

$[on][off]Put[S][V]

Syntax:

```gams
File myputfile;
put myputfile;
$onPut[S|V]
text
{text}
$offPut
```
The pair $\texttt{onPut[SV]}$ - $\texttt{offPut}$ causes a block of text to be placed in a put file at run-time. The is one of the few dollar control options that operate at run time. The $\$ in the first column usually indicates action at compile time.

Note that parameter substitutions are not permitted with $\texttt{onPut}$. The option $\texttt{onPut}$ has two more variants: $\texttt{onPutS}$ and $\texttt{onPutV}$. $\texttt{onPutS}$ allows parameter substitutions while the option $\texttt{onPutV}$ does not allow parameter substitutions, like $\texttt{onPut}$, so it is just a synonym which makes it more obvious that the text is written verbatim with the appended V.

**Example:**

```gams
$set it TEST
File myputfile;
put myputfile;
$onPutS
Line 1 of text "\%it\%"
Line 2 of text \%it\%
$offPut
```

This code generates the put file myputfile.put with the following content:

```
Line 1 of text "TEST"
Line 2 of text TEST
```

Note that the compile-time variable \%it\% was replaced by TEST. However, if the option $\texttt{onPutV}$ is used instead, then \%it\% will not be substituted:

```gams
$set it TEST
File myputfile
put myputfile
$onPutV
Line 1 of text "\%it\%"
Line 2 of text \%it\%
$offPut
```

The resulting file myputfile.put will contain the following lines:

```
Line 1 of text "\%it\%"
Line 2 of text \%it\%
```

$\texttt{[on][off]Upper}$ ($\texttt{offUpper}$)

**Syntax:**

```gams
$onUpper
$offUpper
```

GAMS code echoed to the listing file is written in upper case after $\texttt{onUpper}$. The default of mixed code echoing is restored with $\texttt{offUpper}$. 
Note

The default case of the echo print can be set using the command line option case.

Example:

Set
    i 'Canning plants' / seattle, san-diego /
    j 'Markets'       / new-york, chicago, topeka /;

$onupper
Parameter
    a(i) 'Capacity of plant i in cases'
    / seattle 350
    san-diego 600 /

$offupper
    b(j) 'Demand at market j in cases'
    / new-york 325
    chicago 300
    topeka  275 /;

The generated listing file looks like this:

```gams
1 Set
2 i 'Canning plants' / seattle, san-diego /
3 j 'Markets'       / new-york, chicago, topeka /;
4
5 PARAMETER
6 A(I) 'CAPACITY OF PLANT I IN CASES'
7    / SEATTLE 350
8          SAN-DIEGO 600 /
9
10 b(j) 'Demand at market j in cases'
11    / new-york 325
12          chicago 300
13              topeka 275 /;
```

$[on][off]Recurse ($offRecurse)

Syntax:

$onRecurse
$offRecurse

This option controls whether it is permitted for a file to include itself.

Example:

The following GAMS program result in a recursive inclusion of the program itself:

```
$onRecurse
$include "%gams.input%"
```

Note that the maximum include nesting level is 40 and if it is exceeded an error is triggered.

In the following example that prints a string and then the reverse string the nesting level is less that 40 and one get some kind of recursion at compile time:
3.41 Dollar Control Options

$onEchoV > reverse.gms
$ifthen $1=$3+1
  put ' ';
$exit
$endif
loop(map(chars,code)$(code.val=ord(%2,%1)), put chars.tl:0);
$eval posPlus1 %1+1
$batInclude reverse %posPlus1% %2 %3
loop(map(chars,code)$(code.val=ord(%2,%1)), put chars.tl:0);
$offEcho

set chars / A*Z /, code / 65*90 /, map(chars,code) / #chars:#code /;
file fx /''/; put fx;
$onRecurse
$batInclude reverse 1 RACECAR 7
put /;
$batInclude reverse 1 LAGER 5

The log will print the following lines:

--- Starting execution: elapsed 0:00:00.067
RACECAR RACECAR
LAGER REGAL
*** Status: Normal completion

$on[off]StrictSingleton ($onStrictSingleton)

Syntax:

$onStrictSingleton
$offStrictSingleton

If the option $onStrictSingleton is active, a compilation error is triggered if a data statement for a singleton set contains more than one element. After activating the option $offStrictSingleton GAMS will take the first element of a singleton set that was declared with multiple elements as the valid element, the other elements are disregarded and there is no error. The option to control this behavior at runtime is strictSingleton.

Example:

The first element is not always the one that appears in the data statement first as the following example shows:

set i /1,2/
$offStrictSingleton
singleton set ii(i) /2,1/;
display ii;

The set ii contains the element 1 because it is the first in the GAMS label order as the display statements shows:

---- 4 SET ii
1

$on[off]SymList ($offSymList)

Syntax:
$\text{onSymList}$

$\text{offSymList}$

This option controls whether the symbol listing map appears in the compilation output of the listing file. The symbol listing map contains the complete listing of all symbols that have been defined and their explanatory text. The entries are in alphabetical order and grouped by symbol type.

**Example:**

The symbol listing map generated by running $\text{[TRNSPORT]}$ with $\text{$\text{onSymList}$}$ is as follows:

**Symbol Listing**

**SETS**

i  canning plants

j  markets

**PARAMETERS**

a  capacity of plant i in cases

b  demand at market j in cases

c  transport cost in thousands of dollars per case

d  distance in thousands of miles

f  freight in dollars per case per thousand miles

**VARIABLES**

x  shipment quantities in cases

z  total transportation costs in thousands of dollars

**EQUATIONS**

cost  define objective function

demand  satisfy demand at market j

supply  observe supply limit at plant i

**MODELS**

transport

This serves as a simple description of the symbols used in a model and may be used in reports and other documentation. For further information, see section The Symbol Listing Map.

$\text{[$on]}\text{[off]}\text{SymXRef}  \quad (\text{$\text{offSymXRef}$})$

**Syntax:**

$\text{[$onSymXRef]}$

$\text{[$offSymXRef]}$

This option controls the following:

- Collection of cross references for symbols like sets, parameters, variables, acronyms, equations, models and put files.
• Symbol cross reference report of all collected symbols in the compilation output of the listing file. For details, see section The Symbol Reference Map.

• Listing of all referenced symbols and their explanatory text by symbol type in listing file. This listing may also be activated with the option $onSymList.

Example:

$onSymXRef
Set i / 1*6 /, k;
$offSymXRef
Set j(i) "will not show" / 1*3 /;
$onSymXRef
k('1') = yes;

The resulting listing file will contain the following symbol reference map and symbol listing map:

<table>
<thead>
<tr>
<th>SYMBOL</th>
<th>TYPE</th>
<th>REFERENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>i</td>
<td>SET</td>
<td>declared</td>
</tr>
<tr>
<td>k</td>
<td>SET</td>
<td>declared</td>
</tr>
</tbody>
</table>

SETS

i
k

Note that the set j does not appear in these listings because the listing was deactivated with the option $offSymXRef in line 3 of the code above.

$[on][off]Text

Syntax:

$onText
$offText

The pair $onText - $offText encloses comment lines. Line numbers in the compiler listing are suppressed to mark skipped lines.

Example:

* Standard comment line
$onText
Everything here is a comment
until we encounter the closing $offText
like the one below
$offText
* Another standard comment line

The echo print of the resulting listing file will contain the following lines:

1  * Standard comment line
   Everything here is a comment
   until we encounter the closing $offText
   like the one below
7  * Another standard comment line
Attention

GAMS requires that every $onText has a matching $offText and vice versa.

See also section Comments.

$[on][off]UEILList ($offUEILList)

Syntax:

$onUEILList
$offUEILList

This option controls the complete listing of all set elements that have been entered in the compilation output of the listing file. For details see section The Unique Element Listing Map.

Example:

The unique element listing in the listing file generated by running the model [TRNSPORT] with $onUEILList follows:

Unique Element Listing

Unique Elements in Entry Order
1 seattle san-diego new-york chicago topeka

Unique Elements in Sorted Order
1 chicago new-york san-diego seattle topeka

Note that the sorted order is not the same as the entry order. For more information, see section Ordered and Unordered Sets.

$[on][off]UEIXRef ($offUEIXRef)

Syntax:

$onUEIXRef
$offUEIXRef

This option controls the collection and listing of cross references of set elements in the compilation output. For more information, see section The Unique Element Listing Map.

Example:

Set i "set declaration" / one, two, three /, k(i);
$onUEIXRef
k('one') = yes;
$offUEIXRef
k('two') = yes;
$onUEIXRef
k('three') = yes;

The resulting listing file will contain the following unique element reference report:
3.41 Dollar Control Options

Unique Element Listing

ELEMENT REFERENCES

one index 3
three index 7

Note that the element two does not appear in this listing because the listing was deactivated with the option $offUE1xRef in line 4 of the code above.

$[on][off]UNDF  ($offUNDF)

Syntax:

$onUNDF
$offUNDF

This option controls the use of the special value UNDF which indicates a result is undefined. For details see section Extended Range Arithmetic. By default, UNDF is not permitted to be used in assignments. This may be changed with the option $onUNDF.

Example:

Scalar x;
$onUNDF
x = UNDF;
Display x;

The output of the display statement follows:

---- 4 PARAMETER x = UNDF

Note that an error would have been triggered without the use of $onUNDF. The option $offUNDF will return the system to the default, where UNDF may not be used in assignments.

$[on][off]Uni  ($offUni)

Syntax:

$onUni
$offUni

This controls whether the compiler checks the referential integrity (see section Domain Checking) of the code. This is an essential part of good GAMS programming and it is highly recommend to declare symbols with proper domains. With the universe as a domain the compiler does not help the user with easy-to-make mistakes, like swapping indexes, a(i,j) versus a(j,i). By default something like this would generate an error, if a was declared as a(i,j). Such an error could be ignored, by setting $onUni, which can be useful in few situations, when accessing a symbol with a set that is not the domain or a subset of the domain. For example, we could read data of a union of sets that already exist. We could use the universe as the domain for that symbol, but perhaps we need to protect the referential integrity of this symbol too.

Example:
Set       fruit / apple, pear / 
          veggie / carrot, pea / 
          produce / #fruit, #veggie /;
Parameter produceCalories(produce) "per 100g" / apple 52, pear 57, carrot 41, pea 81 / 
fc(fruit) "calories per 100g" 
vc(veggie) "calories per 100g"

$onUni 
fcc(fruit) = produceCalories(fruit); 
vc(veggie) = produceCalories(veggie); 
$offUni 
display fc, vc;

So when assigning fc we only access produceCalories with fruit. We could reverse the order of declaration of fruit, veggie and produce and use a proper subdomain, but sometimes data flow and input don't allow that.

Attention

When the GAMS compiler operates under $onUni it treats all symbols as being declared over the universe. So all domain checking is gone. We can set elements in a symbols that normally can't be entered. This can also lead to strange effects:

set       i / 1*2 / 
          j / a,b /;
parameter pi(i);
$onuni 
pi(j) = 1; 
$offuni * We will see elements from j in pi
Display pi;
* The following should only clear the i-elements from pi, but it clears the entire symbol, because GAMS knows it's doing this to the entire domain and 
* takes a shortcut.
pi(i) = no; 
Display pi;

$[on][off]Verbatim

Syntax:

$onVerbatim
$offVerbatim

These options are used in conjunction with the GAMS command line parameter DumpOpt to suppress the input preprocessing for input lines that are copied to the dmp file. This feature is mainly used to maintain different versions of related models in a central environment.

Note

- The options $on/offVerbatim are only recognized for DumpOpt ≥ 10 and apply only to lines in the file between the two options
- If $onVerbatim is active, DumpOpt = 11 behaves like DumpOpt = 21 (comments are kept)

Observe that the use of the options $goto and $on/offVerbatim are incompatible and may produce unexpected results.

Example:
$set f 123
$log %f%
$onVerbatim
$log %f%
$offVerbatim
$log %f%

The corresponding dmp file will contain the following lines:

$log 123
$onVerbatim
$log %f%
$offVerbatim
$log 123

See also command line parameter DumpOpt.

$[on][off]Warning ($offWarning)

Syntax:

$onWarning
$offWarning

This option acts as a switch for data domain checking. In some cases it may be useful to accept
domain errors in data statements that are imported from other systems and report warnings
instead of errors. Data will be accepted and stored, even though it is outside the domain.

Attention

- This switch effects three types of domain errors usually referred to as error numbers
  116, 170 and 171, see example below.
- This may have serious side affects and we recommend to exercise great care when
  using this feature.

Example:

Set i / one, two, three /
$onWarning
   j(i) / four, five /
   k / zero /;
Parameter x(i) "Messsed up Data" / one 1.0, five 2.0 /;
x('six') = 6;
x(j) = 10;
x('two') = x('seven');
j(k) = yes;
$offWarning
display i,j,x;

Note that the set j, although specified as a subset of i, contains elements not belonging to
its domain. Similarly, the parameter x contains data elements outside the domain of i. The
skeleton listing file that results from running this code follows:
Set i  / one, two, three /;
j(i)   / four, five /;
**** $170 $170
k      / zero /;
Parameter x(i) "Messsed up Data" / one 1.0, five 2.0 /;
**** $170
x('six') = 6; x(j) = 10; x('two') = x('seven');
**** $170 $116,170
j(k) = yes;
**** $171
display i,j,x;

Error Messages

116  Label is unknown
170  Domain violation for element
171  Domain violation for set

**** 0 ERROR(S)  7 WARNING(S)

Execution

----  9 SET i
one , two , three

----  9 SET j
four, five, zero

----  9 PARAMETER x Messsed up Data
one 1.000, four 10.000, five 10.000, six 6.000

Observe that the domain violations are marked like normal compilation errors but are only treated as warnings and it is permitted to execute the code.

For an introduction to domain checking in GAMS, see section Domain Checking.

$phantom id

Syntax:

$phantom id

This option is used to designate id as a phantom set element. Syntactically, a phantom element is handled like any other set element. Semantically, however, it is handled like it does not exist. This is sometimes used to specify a data template that initializes the phantom records to default values.

Example:

$phantom null
Set i  / null /
   j / a, b, null /;
display i,j;

The output generated by the display statement is shown below:
3.41 Dollar Control Options

Note that null does not appear in the listing file.

Attention

Statements that assign values to phantom labels are ignored.

Consider the following extension to the previous example:

```
Parameter p(j) / a 1, null 23 /;
display p;
```

The output generated by the display statement is shown below:

```
---- 6 PARAMETER p
     a 1.000
```

The system attribute system.empty is an implicitly defined phantom element. The following code works even without specifying $phantom:

```
Set i / system.empty /;
j / a, b, system.empty /;
display i,j;
```

Another way to specify empty data statements makes use of on/offEmpty. The following example produces the same data as the data statement with the phantom label. In contrast to the example we $phantom we need to provide the dimensionality of the symbol i explicitly via the (*):

```
$onEmpty
Set i(*) / /
j / a, b /;
display i,j;
```

$suffixPath

Syntax:

```
$suffixPath directoryPath
```

This option augments the search path in PATH environment variable. The effect is that the text directoryPath is added to the beginning of the search path.

Example:

```
$log %sysenv.\PATH% $suffixPath C:\somewhereelse\anotherpath $log %sysenv.\PATH%
```

The log contains the following two relevant lines:

```
C:\Windows\system32;C:\Windows;C:\Windows\System32\Wbem;C:\Windows\System32\WindowsPowerShell\v1.0;C:\somewhereelse\anotherpath;C:\Windows\system32;C:\Windows;C:\Windows\System32\Wbem;C:\Windows\sys
The option `setEnv` and `sysEnv.VARNAME` allow to modify system environment variables but the length of the environment variable value is limited in GAMS to 255 characters. The `PATH` environment variable is often much longer and therefore this special `$prefixPath` option exists.

This works on all platforms but the path separator depends on the operating system (; for Windows and : for Unix).

### $protect

**Syntax:**

```
$protect all | ident1 ident2 ...
```

This option creates a privacy setting: it freezes all values of identifiers with the result that modifications are no longer allowed but the parameters may still be used in model calculation (for example, equation definitions). Here `ident1` and `ident2` are specific GAMS identifiers previously defined in the program and the keyword `all` denotes all identifiers.

Note that this option is mainly used in the context of secure work files. The privacy restrictions may be removed with the options `$expose` or `$purge`.

### $purge

**Syntax:**

```
$purge all | ident1 ident2 ...
```

This option removes the identifiers and all associated data in a privacy setting. With explicit identifiers the listed identifiers are removed, and with `all` all identifiers are removed.

Note that this option is used in the context of secure work files. A special license file is needed for this feature to work, the removal only takes effect in the restart files.

### $remark

**Syntax:**

```
$remark text
```

This option performs a parameter substitution and writes a comment `text` to the compilation output of the listing file. Note that the line numbers of the comment are suppressed.

**Example:**

```
$set it TEST
$remark Write %it% to the listing file
```

The resulting listing file will contain the following line:

`Write TEST to the listing file`

### $set

**Syntax:**

```
$set VARNAME text
```

These options allow to modify system environment variables but the length of the environment variable value is limited in GAMS to 255 characters. The `PATH` environment variable is often much longer and therefore this special `$prefixPath` option exists.
This option establishes or redefines contents of a scoped compile-time variable that is accessible in the code where the command appears and all code included therein. Here VARNAME is any user chosen variable name; text is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that scoped compile-time variables may be destroyed (removed from the program) with the option $drop.

Note that in contrast to the option $eval the option $set does not evaluate the expression at compile time.

Note that GAMS allows scoped, local and global compile-time variables to be defined with the same name and therefore in some cases needs to prioritize. When referencing a compile-time variable via VARNAME, a local variable hides scoped and global variables and a scoped variables hides the global variable as the following example demonstrates.

Example:

```gams
$setLocal myvar this is a local variable
$set myvar this is a scoped variable
$setGlobal myvar this is a global variable
$log %myvar%
$droplocal myvar
$log %myvar%
$drop myvar
$log %myvar%
```

The log will look as follows:

```
this is a local variable
this is a scoped variable
this is a global variable
```

If one wants to set a compile-time variable in an include file that is visible to the program after the $include one need to use $setglobal:

```gams
$onEchoV > setvar.gms
$setArgs varname varvalue
$setglobal %varname% %varvalue%
$offEcho
$batInclude setvar MYVAR one
$log %MYVAR%
```

The log will show

```
one
```

An inventory of all defined compile-time variables and their type (local, scoped, and global) is available with the option $show.

See also $setGlobal, $setLocal, and section Compile-Time Variables.

$setArgs

Syntax:

```
$setArgs id1 id2 id3 ...
```
With this option parameters that may be substituted are defined as GAMS compile-time variables. Note that $setArgs may only be used in external files that are included with the option $batInclude, $libInclude, and $sysInclude.

Example:

Scalar a /2/, b /4/, c /5/;
$batInclude test3 a b c

The file test3.gms contains the following lines:

Scalar x;
x = %1 + %2 * %3;
display x;
$setArgs aa bb cc
x = %aa% - %bb% * %cc%;
display x;
x = %1 + %2 * %3;
display x;

The option $setArgs allows the batInclude file to use the more descriptive compile-time variables aa%, bb% instead of %1, %2 and cc% instead of %3. Note that the use of %1, %2 etc. is still allowed. The program listing looks as follows:

    1 Scalar a /2/, b /4/, c /5/;
    3 Scalar x;
    4 x = a + b * c;
    5 display x;
    7 x = a - b * c;
    8 display x;
    9 x = a + b * c;
   10 display x;

and the output generated by the display statements follows:

    ---- 5 PARAMETER x = 22.000
    ---- 8 PARAMETER x = -18.000
    ---- 10 PARAMETER x = 22.000

See also $set, $batInclude.

$setComps

Syntax:

$setComps perioddelimstring id1 id2 id3 ...

This option establishes or redefines compile-time variables so they contain the components of a period delimited string.

Here perioddelimstring is any period delimited string like the set specification of a multi-dimensional parameter, id1 is the name of a scoped compile-time variable that will contain the name of the set element in the first position, id2 is the name of a scoped compile-time variable that will contain the name of the set element in the second position and id3 is the name of a scoped compile-time variable that will contain the name of the set element in the third position. The items may be recombined back into the original filename string by using %id1%, %id2%, %id3%.

Example:
3.41 Dollar Control Options

```plaintext
$setComps period.delim.string id1 id2 id3
$log id1=%id1%
$log id2=%id2%
$log id3=%id3%
$set name %id1%.%id2%.%id3%
$log name=%name%
```

The resulting log file will contain the following lines:

```plaintext
id1=period
id2=delim
id3=string
name=period.delim.string"
```

See also `$set`.

**$setDDList**

**Syntax:**

```
$setDDList id1 id2 id3 ...
```

This option causes GAMS to look for misspelled or undefined double dash GAMS parameters.

**Example:** Consider the following example where three double dash GAMS parameters are defined on the command line:

```plaintext
> gams mymodel.gms --one=11 --two=22 --three=33 --four=44
```

The corresponding GAMS file follows:

```plaintext
$log %one%
$log %two%
$setDDList three
$log %three%
$log %four%
```

Note that the option `$setDDList three` checks if all double dash parameters have been used so far except for `three`. An error is triggered because `four` has not been used so far, the log file will contain the following:

```plaintext
*** 1 double dash variables not referenced
   --four=44
```

See also section Double Dash Parameters.

**$setEnv**

**Syntax:**

```
$setEnv VARNAME value
```

This option defines an operating system environment variable. Here `VARNAME` is a user chosen environment variable name and `value` may contain text or a number. Note that system environment variables are destroyed (removed from the program) with the option `$dropEnv` or when GAMS terminates.

**Example:**
$ondollar
$set env this is very silly
$log %env%
$setenv verysilly %env%
$log %sysenv.verysilly%
$if not "%env%"="%sysenv.verysilly%" $error "$setEnv did not work"
$dropenv verysilly
$if setenv verysilly $error should not be true

The following output is echoed to the log file:

--- Starting compilation
this is very silly
this is very silly

See also $dropEnv and section Environment Variables in GAMS.

$setGlobal

Syntax:

$setGlobal VARNAME text

This option establishes or redefines contents of a global compile-time variable that is accessible in the code where the command appears and all code included therein and all parent files. Here VARNAME is any user chosen variable name; text is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that global compile-time variables may be destroyed (removed from the program) with the option $dropGlobal.

The difference between local, scoped, and global compile-time variable is explained with the option $set.

See also $set, $setLocal, $dropGlobal and section Compile-Time Variables.

$setLocal

Syntax:

$setLocal VARNAME text

This option establishes or redefines contents of a local compile-time variable that is accessible only in the code module (source file) where it is defined. Here VARNAME is any user chosen variable name; text is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that local compile-time variables may be destroyed (removed from the program) with the option $dropLocal.

The difference between local, scoped, and global compile-time variable is explained with the option $set.

See also $set, $setGlobal, $dropLocal and section Compile-Time Variables.

$setNames

Syntax:

$setNames file filepath filename fileextension
This option establishes or redefines three scoped compile-time variables so they contain the drive subdirectory, filename and extension of a file named with full path. Here file is any filename, filepath is the name of a scoped compile-time variable that will contain the name of the subdirectory where the file is located, filename is the name of a scoped compile-time variable that will contain the root name of the file and fileextension is the name of a scoped compile-time variable that will contain the extension of the file.

Example:

```
$setNames "%gams.input%" filepath filename fileextension
$set name %filepath%%filename%%fileextension%
$log %name%
```

The log will show

```
C:\Users\default\Documents\gamside\projdir\
Untitled_1.gms
```

Note that file is separated into its three components placing C:\Users\default\Documents\gamside\projdir\ into filepath, Untitled_1 into filename and .gms into fileextension. The three items may be recombined back into the original filename by using filepath%filename%fileextension% as shown in the example.

If the file is missing a path, name, or extension the corresponding variable is defined but remains empty as demonstrated in the following example:

```
$onEchoV > showfileparts.gms
$setNames "%1" filepath filename fileextension
$log path=%filepath%
$log name=%filename%
$log ext=%fileextension%
$offEcho
$batInclude showfileparts "C:\tmp\"
$batInclude showfileparts "Untitled_1"
$batInclude showfileparts "Untitled_1.gms"
$batInclude showfileparts "Untitled_1.gms.txt"
```

The log shows:

```
--- Untitled_1.gms(7) 2 Mb
  path=C:\tmp\
  name=
  ext=
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(8) 2 Mb
  path=
  name=Untitled_1
  ext=
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(9) 2 Mb
  path=
  name=Untitled_1
  ext=.gms
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(10) 2 Mb
  path=
  name=Untitled_1
  ext=.txt
```
Note that if a file contains multiple . files, the last one will be assigned to the file extension as shown in the example with Untitled1.gms.txt.

$shift

Syntax:

$shift

This option is similar to the command.com/cmd.exe shift operator (see en.wikipedia.org/wiki/COMMAND.COM::Batch file commands). It shifts the order of all parameters passed once to the left. This effectively drops the lowest numbered parameter in the list.

Example:

Scalar a, b, c ; a = 1 ;
$batInclude inc.inc a b c
display a, b, c ;

The batch include file inc.inc follows:

%2 = %1 + 1 ;
$shift
%2 = %1 + 1 ;

The resulting listing file will contain the following echo print:

1 Scalar a, b, c ; a = 1 ;
BATICCLUDE C:\Users\default\Documents\gamsdir\projdir\inc.inc
3 b = a + 1 ;
5 c = b + 1 ;
6 display a, b, c ;

Note that in the first statement in the include file, %1 is the first argument in the $batInclude call and in this case it is interpreted as a. %2 is the second argument in the $batInclude call and is interpreted as b. This leads to the overall assignment being interpreted as b=a+1. The dollar control option $shift shifts the arguments to the left. As a result, %1 is interpreted as b, and %2 is interpreted as c. This leads to the second assignment being interpreted as c=b+1.

Therefore the outcome generated by the display statement in the input file is as follows:

----
6 PARAMETER a = 1.000
PARAMETER b = 2.000
PARAMETER c = 3.000

See also $batInclude.

$show

Syntax:

$show

This option causes current values of the compile-time variables plus a list of the macros and active input and include files to be shown in the compilation output.

Example:
3.41 Dollar Control Options

$set it 1
$setLocal yy
$setGlobal gg what
$include myinclude
$show

The file myinclude.gms follows:

$set inincs
$setLocal inincsl
$setGlobal inincsg
$show

The resulting listing file will contain the following environment reports in the compilation output:

---- Begin of Environment Report
LEVEL TYPE LINE FILE NAME
----------------------------------
1 INCLUDE 5 C:\Users\default\Documents\gamside\projdir\myinclude.gms
0 INPUT 4 C:\Users\default\Documents\gamside\projdir\\Untitled_1.gms
Level SetVal Type Text
-----------------------------------------------------
1 inincsl LOCAL
1 inincs SCOPED
0 yy LOCAL
0 it SCOPED 1
0 gg GLOBAL what
0 inincsg GLOBAL
---- macro definitions
$macro multx(x) x*x
---- End of Environment Report

and

---- Begin of Environment Report
LEVEL TYPE LINE FILE NAME
----------------------------------
0 INPUT 6 C:\Users\default\Documents\gamside\projdir\\Untitled_1.gms
Level SetVal Type Text
-----------------------------------------------------
0 yy LOCAL
0 it SCOPED 1
0 gg GLOBAL what
0 inincsg GLOBAL
---- macro definitions
$macro multx(x) x*x
$macro addx(x) x+x
---- End of Environment Report

Note that only the macros and the item defined with the option $setGlobal in the included file carries over. Observe that the name "Environment Report" is unfortunate since the reported values are for compile-time variables, not environment variables.

See also section Compile-Time Variables.

$single
Syntax:

$single

The lines following this option will be echoed single spaced in the compilation output. Note that this is the default. The option is only useful as a switch to deactivate the option $double.

Example:

Set i / 1*2 / ;
Scalar a / 1 / ;
$double
Set j / 10*15 / ;
Scalar b / 2 / ;
$single
Set k / 5*10 / ;
Scalar c / 3 / ;

The echo print in the resulting listing file will look as follows:

1 Set i / 1*2 / ;
2 Scalar a /1/ ;
4 Set j / 10*15 / ;
5 Scalar b /2/ ;
7 Set k / 5*10 / ;
8 Scalar c /3/ ;

Note that lines between the options $double and $single are listed double spaced, while the lines after the option $single revert back to being listed single spaced.

See also $double.

$splitOption

Syntax:

$splitOption KEYVALPAIR optname optvalue

Establishes or redefines two scoped compile-time variables so they contain the name and value of an option key/value pair specified in various formats. KEYVALPAIR is a string formatted as -opt=val or -opt val (instead of - one can also use /). optname is the name of a scoped compile-time variable that will contain the name of the option and optvalue is the name of a scoped compile-time variable that will contain the value of the option. This is useful in particular in combination with batInclude files.

Example:

$onechoV > myinclude.gms
* Default values for named arguments
setqGlobal a1 1
setqGlobal a2 2
setqGlobal a3 3
setqGlobal positionalArgs
$label ProcessNamedArguments
$ splitOption "%1" key val
$ if x%key%==a1 $goto FinishProcessNamedArguments
$ ifThenI.NamedArguments %key%==a1

$ setGlobal a1 %val%
$ elseNamedArguments %key%==a2
$ setGlobal a2 %val%
$ elseNamedArguments %key%==a3
$ setGlobal a3 %val%
$ elseNamedArguments
$ error Unknown named argument "%key%"
$ endifNamedArguments
$ shift
$ goTo ProcessNamedArguments
$ label FinishProcessNamedArguments
$ setGlobal positionalArgs %1 %2 %3
$ offEcho
$ batInclude myinclude -a3=0 -a2=3.14 i j k
$ log Using named arguments -a1=%a1% -a2=%a2% -a3=%a3% positionalArgs=%positionalArgs%

Now when calling this piece of code as a _batInclude_ one can specify optionally some named arguments (in any order) right after the name of the _batInclude_ file and before the positional arguments as demonstrated by the log output:

Using named arguments -a1=1 -a2=3.14 -a3=0 positionalArgs=i j k

stars (****)

**Syntax:**

$stars char[char][char][char]

This option is used to redefine the **** marker in the GAMS listing file. By default, important lines like those that denote errors and the solver and model status are prefixed with ****. A new marker consists of one to four characters.

**Example:**

$stars *##*
garbage

The resulting listing file follows:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>garbage</td>
<td></td>
</tr>
<tr>
<td>***</td>
<td>$140</td>
<td></td>
</tr>
<tr>
<td>***</td>
<td>$36,299</td>
<td>UNEXPECTED END OF FILE (1)</td>
</tr>
</tbody>
</table>

**Error Messages**

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>36</td>
<td>'=' or '..' or ':=' or '$=' operator expected rest of statement ignored</td>
<td></td>
</tr>
<tr>
<td>140</td>
<td>Unknown symbol</td>
<td></td>
</tr>
<tr>
<td>299</td>
<td>Unexpected end of file</td>
<td></td>
</tr>
</tbody>
</table>

$sTitle

**Syntax:**

$sTitle text

This option sets the subtitle in the page header of the listing file to _text_. Note that the next output line will appear on a new page in the listing file.

**Example:**
Data tables for input/output

See also title.

$stop

Syntax:

$stop [text]

This option stops program compilation without creating an error. Note there is a difference to the option $exit. If there is only one input file, $stop and $exit will have the same effect. In an include file the option $exit acts like an end-of file on the include file. However, the option $stop in an include file will cause GAMS to stop reading all input but continue the execution phase of the so far compiled program. The text followed by $stop is ignored.

Example:

$ifthen not set EXPORTEXCEL
$ stop No export to Excel
$else
$ call gdxxrw ...
$endif

See also $abort, $error, $exit, and $terminate.

$sysInclude

The syntax of this dollar control option is equivalent to the syntax of $batinclude:

Syntax:

$sysinclude external_file arg1 arg2 ...

However, if an incomplete path is given, the file name is completed using the system include directory. By default, the system include directory is set to the GAMS system directory. Note that the default directory may be reset with the command line parameter sysIncDir.

Example:

The only relevant include file in the GAMS system directory is mpsgeset for MPSGE models, see for example [HARMGE]:

$sysInclude mpsgeset KAMIYA

Note that this call will first look for the include file [GAMS System Directory]/mpsgeset. If this file does not exist, it will looks for [GAMS System Directory]/mpsgeset.gms. The argument KAMIYA is passed on to the include file and are interpreted as explained for the dollar control option $batInclude.

Consider the following example:

$sysInclude C:\Users\default\Documents\mpsgeset KAMIYA

This call will first look specifically for the include file C:\Users\default\Documents\mpsgeset and next for C:\Users\default\Documents\mpsgeset.gms.

See also $batInclude.
$terminate
Syntax:
$terminate [text]
This option terminates compilation and also does not execution to program compiled so far without giving an error.
Example:
$if set JUSTTERMINATE $terminate
See also $abort, $error, $exit, and $stop.
$title
Syntax:
$title text
This option sets the title in the page header of the listing file to text. Note that the next output line will appear on a new page in the listing file.
Example:
$title Production Planning Model
$title Set Definitions
See also $setTitle.
$unLoad
Syntax:
$unLoad sym1[,] sym2=gdxSym2[,] ...]
This option unloads specified items to a GDX file. Note that $unLoad must be used in conjunction with the option $gdxOut: $gdxOut must precede $unLoad. More than one option $unLoad may appear in between. Symbols can be renamed via the sym=GDXSym syntax. A $unLoad without arguments unloads the entire GAMS database into the GDX file.
Example: Consider the following slice of code:
Sets i 'canning plants' / seattle, san-diego /
   j 'markets' / new-york, chicago, topeka / ;
Parameters
   a(i) 'capacity of plant i in cases'
   / seattle 350
   san-diego 600 /
   b(j) 'demand at market j in cases'
   / new-york 325
   chicago 300
   topeka 275 /
Table d(i,j) 'distance in thousands of miles'
   new-york chicago topeka
   seattle 2.5 1.7 1.8
   san-diego 2.5 1.8 1.4 ;
$gdxOut tran
$unLoad i j
$unLoad b=dem a=sup
$unLoad d
$gdxout tranX
$unLoad
Note that the last lines will create a file named `tran.gdx` that contains `i`, `j` and `d` and the parameters `a` and `b` which are now named `dem` and `sup`. The `$unLoad` in the very last line creates a GDX file `tranX.gdx` with all symbols (with their original names). The table of content (via `$gdxIn` and `$load` without parameters) of these two files looks as follows:

Content of GDX C:\Users\default\Documents\gamsdir\projdir\tran.gdx
5 UELs

<table>
<thead>
<tr>
<th>Number</th>
<th>Type</th>
<th>Dim</th>
<th>Count</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set</td>
<td>1</td>
<td>2</td>
<td>i</td>
</tr>
<tr>
<td>2</td>
<td>Set</td>
<td>1</td>
<td>3</td>
<td>j</td>
</tr>
<tr>
<td>3</td>
<td>Parameter</td>
<td>1</td>
<td>3</td>
<td>dem(j)</td>
</tr>
<tr>
<td>4</td>
<td>Parameter</td>
<td>1</td>
<td>2</td>
<td>sup(i)</td>
</tr>
<tr>
<td>5</td>
<td>Parameter</td>
<td>2</td>
<td>6</td>
<td>d(i,j)</td>
</tr>
</tbody>
</table>

Content of GDX C:\Users\default\Documents\gamsdir\projdir\tranX.gdx
5 UELs

<table>
<thead>
<tr>
<th>Number</th>
<th>Type</th>
<th>Dim</th>
<th>Count</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set</td>
<td>1</td>
<td>2</td>
<td>i</td>
</tr>
<tr>
<td>2</td>
<td>Set</td>
<td>1</td>
<td>3</td>
<td>j</td>
</tr>
<tr>
<td>3</td>
<td>Parameter</td>
<td>1</td>
<td>2</td>
<td>a(i)</td>
</tr>
<tr>
<td>4</td>
<td>Parameter</td>
<td>1</td>
<td>3</td>
<td>b(j)</td>
</tr>
<tr>
<td>5</td>
<td>Parameter</td>
<td>2</td>
<td>6</td>
<td>d(i,j)</td>
</tr>
</tbody>
</table>

Both listings show domain information for the various symbols but only the file `tranX.gdx` created with `$unLoad` without arguments has the real domain sets that can be used for domain matching when loading with the `$load sym<=[=]symGDX`, see `$load` for details.

$use205

Syntax:

$use205

This option sets the GAMS syntax to the syntax of Release 2.05. This is mainly used for backward compatibility. New keywords have been introduced in the GAMS language since Release 2.05. Models developed earlier that use identifiers that have since become keywords will cause errors when run with the latest version of GAMS. This option will allow to run such models.

Example:

$use205
Set if /1.2.3/;
Scalar x ;

The word "if" is a keyword in GAMS that was introduced with the first version of Release 2.25. Setting option `$use205` allows "if" to be used as an identifier since it was not a keyword in Release 2.05.

$use225

Syntax:

$use225
This option sets the GAMS syntax to the syntax of the first version of Release 2.25. This is mainly used for backward compatibility. New keywords have been introduced in the GAMS language since the first version of Release 2.25. Models developed earlier that use identifiers that have since become keywords will cause errors when run with the latest version of GAMS. This option will allow to run such models.

**Example:**

```
$use225
Set for /1.2.3/;
Scalar x ;
```

The word "for" is a keyword in GAMS that was introduced with the later versions of Release 2.25. Setting option $use225 allows "for" to be used as an identifier since it was not a keyword in the first version of Release 2.25.

$use999

**Syntax:**

```
$use999
```

This option sets the GAMS syntax to the syntax of the latest version of the compiler. Note that this setting is the default.

**Example:**

```
$use225
Set for /1.2.3/;
Scalar x ;
$use999
for (x=1 to 3, display x) ;
```

Note that the word "for" is used as a set identifier after setting the option $use225 and later the keyword for is used in a looping construct after having set the language syntax to that of the latest version using the option $use999.

$version

**Syntax:**

```
$version n
```

This issues a compilation error if n is greater than the current GAMS version. This can be useful to ensure that a model is run only with new versions of GAMS, because, e.g., a particular feature which did not exist in older versions is needed.

**Example:**

```
* With GAMS 24.8.1 the function numCores was added to the system.
* Make sure, that we use this GAMS version or newer.
$version 248
```

```
Scalar nc "Number of cores";
nc = numCores;
Display nc;
```

$warning
Syntax:

$warning text

This dollar control option issues a compilation warning to the log and listing but continues compilation and execution.

Example

$ifthen not set INPUTFILE
$ set INPUTFILE default.txt
$ warning Using default INPUTFILE "default.txt". Use --INPUTFILE=myfile.txt to overwrite default.
$endif

The GAMS log file will issue a warning:

*** Error 332 in C:\Users\default\Documents\gamsdir\projdir\myinput.gms
$Warning encountered - see listing for details

with the details in the listing file:

3  $ warning Using default INPUTFILE "default.txt". Use --INPUTFILE=myfile.txt to overwrite default.
**** $332

3.4.1.4 Conditional Compilation

GAMS offers several dollar control options that facilitate conditional compilation. In this section we will first introduce the general syntax, present an overview of all relevant options and list the conditional expressions that may be used to perform tests. Then we will give several examples to illustrate how these options are used and to demonstrate their power. This section is meant as an introduction to conditional compilation in GAMS and complements the detailed descriptions of the dollar control options listed in Table 1 below.

3.4.1.4.1 Conditional Compilation: General Syntax and Overviews

The dollar control option $if and its variants provide a great amount of control over conditional processing of the input file(s). The syntax in GAMS is similar to the IF statement of the DOS Batch language:

$if [not] <conditional expression> new_input_line

The dollar control statement begins with $if. Note that $if may be replaced by one of its variants that are listed in Table 1 below. The operator not is optional and makes it possible to negate the conditional expression that follows. The conditional expression may take various forms, a complete list is given in Table 2. The result of the conditional test is used to determine whether to process or not the remainder of the line, new_input_line, which may be any valid GAMS input line.

Attention

The first non-blank character on the line following the conditional expression is considered to be the first column position of the GAMS input line. Therefore, if the first character encountered is a comment character the remainder of the line is treated as a comment line. Likewise, if the first character encountered is the dollar control character, the line is treated as a dollar control line.

Alternatively, the new_input_line may be placed in the next line. The corresponding syntax follows:

$if [not] <conditional expression>
new_input_line

Note that in this version the space after the conditional expression is left blank. If the conditional is found to be false, either the remainder of the line (if any) will be skipped or the next line will not be processed.

The overviews in Table 1 and Table 2 conclude this subsection. Examples are given in the next subsection.

Table 1: $if and Related Dollar Control Options
### Dollar Control Options

<table>
<thead>
<tr>
<th>Dollar Control Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$if</td>
<td>This option is used to do case sensitive comparisons. Several examples are given in the next subsection.</td>
</tr>
<tr>
<td>$ifE</td>
<td>This variant does the same as $if but allows numerical constant expression evaluation. For an example, see the detailed description of this option.</td>
</tr>
<tr>
<td>$ifI</td>
<td>This variant is the same as $if, but it is case insensitive.</td>
</tr>
<tr>
<td>$ifThen</td>
<td>This variant controls whether a block of statements will be processed or not. It is used to do case sensitive comparisons. Most often it is followed by one or more of the following dollar control options: $else, $elseIf, $elseIfE, $elseIfI. The option $ifThen must be matched with the option $endIf that marks the end of the block. An example is given below.</td>
</tr>
<tr>
<td>$ifThenE</td>
<td>This is a variant of $ifThen and is used for numerical comparisons. Like $ifThen, it is often followed by the option $else or one of its variants and must be matched with the option $endIf that marks the end of the block.</td>
</tr>
<tr>
<td>$ifThenI</td>
<td>This is a variant of $ifThen and is used to do case insensitive comparisons. Like $ifThen, it is often followed by the option $else or one of its variants and must be matched with the option $endIf that marks the end of the construct.</td>
</tr>
<tr>
<td>$endIf</td>
<td>This option must be matched with a preceding option $ifThen, $ifThenE or $ifThenI and marks the end of the if - then construct. Note that the option $endIf is not followed by a conditional expression, but it may be followed by a new input line. This GAMS input is restricted to other dollar control statements. An example is given below.</td>
</tr>
<tr>
<td>$else</td>
<td>This option follows the option $ifThen, $ifThenE or $ifThenI. It is followed by an instruction which is executed if the conditional expression of the matching $ifThen statement is not true. Note that therefore this dollar control statement does not contain a conditional expression. An example is given below.</td>
</tr>
<tr>
<td>$elseIf</td>
<td>This option follows the option $ifThen, $ifThenE or $ifThenI. It is followed by another conditional expression and instruction. Note that this option is case sensitive. An example is given below.</td>
</tr>
<tr>
<td>$elseIfE</td>
<td>This is a variant of $elseIf that evaluates numerical values.</td>
</tr>
<tr>
<td>$elseIfI</td>
<td>This is a variant of $elseIf that is case insensitive.</td>
</tr>
</tbody>
</table>

### Table 2: Conditional Expressions in Conditional Compilation

<table>
<thead>
<tr>
<th>Conditional Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acrType id</td>
<td>True if id is an acronym.</td>
</tr>
<tr>
<td>decla_OK</td>
<td>True if a declaration statement is permitted in the current line. Note that declaration statements are not permitted within programming flow control structures like if statements or loop statements. An example is given below.</td>
</tr>
<tr>
<td>declared id</td>
<td>True if id was declared.</td>
</tr>
<tr>
<td>defined id</td>
<td>True if id was defined. An example is given below.</td>
</tr>
<tr>
<td>dExist directoryname</td>
<td>True if a directory with the name directoryname exists.</td>
</tr>
<tr>
<td>dimension n id</td>
<td>True if id has n dimensions. Note that n may take values from 0 to maximum number of possible indexes (see Dimensions).</td>
</tr>
<tr>
<td>equType id</td>
<td>True if id is an equation.</td>
</tr>
<tr>
<td>errorFree</td>
<td>True if compilation up to this point has been free of errors.</td>
</tr>
<tr>
<td>errorLevel n</td>
<td>True if the return code of a program called via $call is equal to or larger than n. For lists of GAMS return codes, see chapter GAMS Return Codes. An example is given below.</td>
</tr>
<tr>
<td>Conditional Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>exist filename</code></td>
<td>True if a file with the name <code>filename</code> exists. An example is given below.</td>
</tr>
<tr>
<td><code>filType id</code></td>
<td>True if <code>id</code> is the name of a put file.</td>
</tr>
<tr>
<td><code>funType id</code></td>
<td>True if <code>id</code> is a GAMS function.</td>
</tr>
<tr>
<td><code>gamsVersion n</code></td>
<td>True if current GAMS version equals <code>n</code>. For example, if the current GAMS version is 24.7, then <code>gamsVersion</code> will equal 247. Minor version numbers, e.g. 24.7.4 do not count</td>
</tr>
<tr>
<td><code>gdxDimension n id</code></td>
<td>True if <code>id</code> exists in a GDX file previously opened with <code>$gdxIn</code> and has <code>n</code> dimensions. Note that <code>n</code> may take values from 0 to maximum number of possible indexes (see Dimensions).</td>
</tr>
<tr>
<td><code>gdxEquType id</code></td>
<td>True if <code>id</code> exists in a GDX file previously opened with <code>$gdxIn</code> and is an equation.</td>
</tr>
<tr>
<td><code>gdxParType id</code></td>
<td>True if <code>id</code> exists in a GDX file previously opened with <code>$gdxIn</code> and is a parameter.</td>
</tr>
<tr>
<td><code>gdxSetType id</code></td>
<td>True if <code>id</code> exists in a GDX file previously opened with <code>$gdxIn</code> and is a set.</td>
</tr>
<tr>
<td><code>gdxSymExist id</code></td>
<td>True if <code>id</code> exists in a GDX file previously opened with <code>$gdxIn</code>.</td>
</tr>
<tr>
<td><code>gdxVarType id</code></td>
<td>True if <code>id</code> exists in a GDX file previously opened with <code>$gdxIn</code> and is a variable.</td>
</tr>
<tr>
<td><code>macType id</code></td>
<td>True if <code>id</code> is a macro.</td>
</tr>
<tr>
<td><code>modType id</code></td>
<td>True if <code>id</code> is a model.</td>
</tr>
<tr>
<td><code>parType id</code></td>
<td>True if <code>id</code> is a parameter.</td>
</tr>
<tr>
<td><code>preType id</code></td>
<td>True if <code>id</code> is a one of the predefined symbols in GAMS. Details are given below.</td>
</tr>
<tr>
<td><code>putOpen</code></td>
<td>True if both a file statement and at least one put statement have been compiled. Note that this does not guarantee that a file will be open at runtime.</td>
</tr>
<tr>
<td><code>readable id</code></td>
<td>True if <code>id</code> was correctly initialized, i.e. the symbol has a data statement or appeared on the left-hand side of an assignment statement, and may therefore be used on the right-hand side of an assignment statement. An example is given below.</td>
</tr>
<tr>
<td><code>set varname</code></td>
<td>True if the scoped compile-time variable <code>varname</code> was set with the dollar control option <code>$set</code>, <code>$setGlobal</code> or <code>$setLocal</code>.</td>
</tr>
<tr>
<td><code>setEnv varname</code></td>
<td>True if the environment variable <code>varname</code> was set in the systems environment, e.g. with the dollar control option <code>$setEnv</code>.</td>
</tr>
<tr>
<td><code>setGlobal varname</code></td>
<td>True if the control variable <code>varname</code> was set with the dollar control option <code>$setGlobal</code>.</td>
</tr>
<tr>
<td><code>setLocal var_name</code></td>
<td>True if the control variable <code>var_name</code> was set with the dollar control option <code>$setLocal</code>.</td>
</tr>
<tr>
<td><code>setType id</code></td>
<td>True if <code>id</code> is a set.</td>
</tr>
<tr>
<td><code>solver solver_name</code></td>
<td>True if a solver named <code>solver_name</code> exists in the GAMS system. An example is given below.</td>
</tr>
<tr>
<td><code>uelExist id</code></td>
<td>True if unique element <code>id</code> exists in current GAMS database.</td>
</tr>
<tr>
<td><code>varType id</code></td>
<td>True if <code>id</code> is a variable.</td>
</tr>
<tr>
<td><code>warnings</code></td>
<td>True if the compilation until this point has been free of warnings.</td>
</tr>
<tr>
<td><code>xxxType id</code></td>
<td>True if <code>id</code> is an unknown type. For more information, see below.</td>
</tr>
</tbody>
</table>
### 3.41 Dollar Control Options

<table>
<thead>
<tr>
<th>Conditional Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>string1 == string2</code></td>
<td>True only if <code>string1</code> matches <code>string2</code> exactly. Note that the strings may be quoted or unquoted. Null (empty) strings may be indicated by an empty quote: &quot;&quot; or &quot;. The case of the strings provided either explicitly or, more likely, through a parameter substitution, is preserved and therefore will affect the string comparison. Quoted strings with leading and trailing blanks are not trimmed and the blanks are considered part of the string. Note that the string may have the form %VARNAME%, where VARNAME refers to a compile-time variable including GAMS command line parameters and system attribute. An example for a string comparison with a command line parameter is given below. An example for a string comparison with a system attribute is given below.</td>
</tr>
</tbody>
</table>

### 3.41.4.2 Conditional Compilation: Examples

#### 3.41.4.2.1 File Operation Test
The operator `exist` may be used to test whether a given file name exists. Consider the following example:

```gams
$if exist myfile.dat $include myfile.dat
```

Observe that the effect of this dollar control statement is that the file `myfile.dat` is included if it exists. Note that the character $ at the beginning of the option $include is the first non-blank character after the conditional expression `exist myfile.dat` and therefore it is treated as the first column position. The statement above may also be written as follows:

```gams
$if exist myfile.dat
$include myfile.dat
```

#### 3.41.4.2.2 Conditional Compilation and Batch Include Files
In the next example we will illustrate how the option `$if` is used inside a batch include file where parameters are passed through the option `$batInclude` from the parent file:

```gams
$if not "%1a" == a $goto labelname
$if exist %1 file.ap=1;
```

Note that in the first line the `$if` condition uses the string comparison "%1a" == a to check if the parameter is empty. This test may also be done in the following way: %1 == "". If the parameter is not empty, the option `$goto` is processed.

Note

The option `$label` cannot be part of the conditional input line. However, if the option `$label` appears on the next line, the condition decides once if the label is placed or not and subsequent instances of `$goto` will find the label without reevaluating the condition.

The second line illustrates the use of standard GAMS statements if the conditional expression is valid. If the file name passed as a parameter through the `$batInclude` call exists already, the GAMS will execute the `file.ap=1;` statement which will append to the file.

The next example demonstrates how an unknown number of file specifications may be passed on to a batch include file that will include each of them if they exist. The batch include file could look as follows:
* Batch Include File - inclproc.gms
  * include and process an unknown number of input files
  $label nextfile
  * Quote everything because file name might have blanks
  $if exist "%1" $include "%1"
  $shift
  $if not "%ia" == a $goto nextfile

The call to this file in the parent file could take the following form:

$batInclude inclproc "file 1.inc" file2.inc file3.inc file4.inc

3.41.4.2.3 Testing Whether an Item Has Been Defined

The next example shows how to test if a named item was declared and/or defined.

Set i;
$if defined i $log First: set i is defined
$if declared i $log First: set i is declared
Set i /seattle/;
$if defined i $log Second: set i is defined
$if declared i $log Second: set i is declared

Note that after the first declaration of i only declared i evaluates to true when after the second declaration with a data statement both defined i and declared i are true.

3.41.4.2.4 Testing Whether an Item May Be Used in an Assignment

The expression readable id tests whether data were assigned to an item and therefore he item may be used on the right-hand side of an assignment statement. Consider the following example:

Scalar f;
$if not readable f $log f cannot be used on the right
Scalar f /1/;
$if readable f $log f can be used on the right
$kill f
$if not readable f $log f cannot be used on the right after clear
f = 1;
$if readable f $log f can be used on the right after assignment

Note that in the first test the set f was declared, but there was no data statement, hence it is not readable. After a declaration with a data statement the test readable f evaluates to TRUE. With $kill we can revert f to a data less state and hence not readable f is TRUE after the "$kill". The assignment statement f = 1; make the scalar f readable again.

3.41.4.2.5 Testing Whether an Identifier May Be Declared

In programming flow control structures, like if statements or loop statements declaration statements are not permitted. The test decla_ok may be used to test whether the current environment allows declaration statements. Consider the following example:

$if decla_ok $log declarations are possible
if(1,
 $ if not decla_ok $log declarations are not allowed
);

Note that the conditional expression in the both $if tests will evaluate to TRUE. However, the second test of decla_ok itself will be FALSE because it is processed while compiling an if statement, but with the not the entire expression evaluated to TRUE. For more information, see chapter Programming Flow Control Features.
3.41.4.2.6 Comments in the Context of Conditional Compilation

In-line and end-of-line comments are stripped out of the input file before processing the new input line. If either of these forms of comments appear, they will be treated as blanks. Consider the following example:

```plaintext
Parameter a ;
a=10 ;
$eolCom // inlineCom /* */
$if exist myfile.dat /* in line comments */ // end of line comments
a = 4 ;
display a;
```

Note that the comments on line 3 are ignored and the fourth line with the assignment statement will be processed if the conditional expression is true. Hence the outcome generated by the display statement will list `a` with a value of 4 if the file `myfile.dat` exists and a value of 10 if the file does not exist.

3.41.4.2.7 Error Level Test

Consider the following example:

```plaintext
$call gams mymodel.gms lo=2
$if errorlevel 1 $abort one or more errors encountered
```

Note that the errorlevel is retrieved from the previous system call via `$call`. The conditional statement `errorlevel 1` is true if the returned errorlevel is equal to or larger than 1. In case of calling GAMS this means that something was not quite right with the execution of GAMS (either a compilation or execution error or other more exotic errors, see GAMS return codes. If this is the case, this GAMS program will be aborted immediately at compilation time.

Usually programs return 0 on success and non-zero on failure. The `$if errorlevel 1` checks for strictly positive return codes. There are rare cases with failures and negative return codes (e.g. on Windows if some DLL dependencies of the program can't be resolved). In such a case `$if errorlevel 1` will evaluate to false and not continue with the `$abort` instruction. It might be better to access the program return code via the `errorLevel` function in the following way:

```plaintext
$call gams mymodel.gms lo=2
$ifE errorLevel<>0 $abort one or more errors encountered
```

3.41.4.2.8 Solver Test

The following example illustrates how to check if a solver exists.

```plaintext
$if solver ZOOM
```

Note that the conditional expression is false since the solver named `ZOOM` does not exist in the GAMS system (anymore).
3.41.4.2.9 Command Line Parameters in String Comparison Tests

Assume we include the following dollar control statements in a GAMS file called myfile.gms:

```gams
$if not '%gams.ps%'=='' $log Page size set to %gams.ps%
$if not '%gams.pw%'=='' $log Page width set to %gams.pw%
$if not '%gams.mip%'=='' $log MIP solver default is %gams.mip%
```

Then we run the program with the following call:

```bash
> gams myfile pageSize=60 pageWidth=85 mip=cbc
```

Note that we specified values for the command line parameters pageSize, pageWidth, and MIP. We can either use the short or long name on the command line and in the compile-time variable. If we do not specify the option on the command line we will get the default value for option page size and page width. The MIP solver line will not show because gams.mip% remains empty. The log with option setting on the command line will include the following lines:

Page size set to 60
Page width set to 85
MIP solver default is cbc

Command line parameters are introduced in chapter The GAMS Call and Command Line Parameters.

3.41.4.2.10 System Attributes in String Comparison Tests

Compile-time system attributes may also be used in string comparison tests. The system attribute that is most useful in this context is .fileSys. It identifies the name of the operating system being used. Consider the following example:

```gams
$ifthen not %gams.logOption%==3
$  ifi %system.fileSys%==UNIX  $set nullFile > /dev/null
$  ifi %system.fileSys%==MSNT  $set nullFile > nul
$  if not set nullFile $abort %system.fileSys% not recognized
$else
$  set nullFile
$endif
$call gamslib trnsport %nullFile%
```

These dollar control statements allow the definition of a NULL file destination that is dependent on the operating system that is being used. Note that the control variable nullfile is set to the operating system dependent name. This makes it useful to make an external program that writes to STDOUT quiet in case the GAMS log does not go to STDOUT (logOption=3). This example could also use the system attribute system.nullFile which is sets the operating system dependent NULL file destination:

```gams
=set nullFile
$if not %gams.logOption%==3 $set nullfile > %system.nullFile%
$call gamslib trnsport %nullfile%
```

System attributes in general are introduced in chapter System Attributes.
### 3.41.4.2.11 Conditional Compilation with $ifThen and $else

Consider the following example which illustrates the use of $ifThen, $elseif, $else and $endif:

```gams
$set x a
$label test
$ifThen %x% == a $set x 'c' $log $ifThen with x=%x%
$elseif %x% == b $set x 'k' $log $elseif 1 with x=%x%
$elseif %x% == c $set x 'b' $log $elseif 2 with x=%x%
$else $set x 'e' $log $else with x=%x%
$endif $if not %x% == e $goTo test
```

Note that the resulting log file will contain the following lines:

```gams
$ifthen with x=a
$elseif 2 with x=c
$elseif 1 with x=b
$else with x=k
```

Observe that the options $else and $endif are not followed by conditional expressions and the instruction following the option $endif contains a dollar control statement. Moreover, note that the $set x 'c' has the text to be set in quotes. GAMS needs to know where the text ends and the next dollar control option (in this case $log) starts.

### 3.41.4.2.12 Type of Identifiers

The type of a symbol can be retrieved via $if ...Type. Consider the following example:

```gams
Set diag / 1*3 /;
Parameter p(diag) / 1 1, 2 4, 3 8 /;
$if setType diag $log diag is a set
$if not varType diag $log diag is not a variable
$if preType diag $log diag is a predefined type
$if parType p $log p is a parameter
$if setType sameAs $log sameAs is a set
$if preType sameAs $log sameAs is a predefined type
```

Note that for predefined symbols more than one type applies (e.g. sameAs is of set and predefined type). Please also note that diag is a set even though there is a predefined symbol named diag but that becomes invisible with a user defined symbols with the same name.

Normally there is no way to get a symbol into the GAMS symbols table without a proper type. However, if the dollar command line parameter `multiPass` is set to a value larger than zero, then the compiler will just check for some integrity and will try to deduce the symbol type from the context. If it is not able to do so, the symbol type will remain unknown. For example, compiling the following lines with `multiPass=1`

```gams
display x;
$if xxxType x $log x is of unknown type
```

result in the line `x is of unknown type` in the GAMS log.
3.41.5 Macros in GAMS

Macros are widely used in computer science to define and automate structured text replacements. The GAMS macro processors function similarly to the popular C/C++ macro preprocessor. Note that the GAMS macro facility has been inspired by the GAMS-F preprocessor for function definition developed by Michael Ferris, Tom Rutherford and Collin Starkweather, 1998 and 2005. The GAMS macro facility incorporates the major features of the GAMS-F preprocessor into the standard GAMS release as of version 22.9. GAMS macros act like a standard macro when defined. However, their recognition for expansion is GAMS syntax driven.

3.41.5.1 Syntax and Simple Examples

The definition of a macro in GAMS takes the following form:

```
$macro name    macro_body
$macro name(arg1,arg2,arg3,...) macro_body with tokens arg1, ...
```

The dollar symbol $ followed by macro indicate that this line is a macro definition. The name of the macro has to be unique, similar to other GAMS identifiers like sets and parameters. The macro name is immediately followed by a list of replacement arguments arg1, arg2, arg3,... that are enclosed in parentheses. The macro body is not further analyzed after removing leading and trailing spaces.

The recognition and following expansion of macros is directed by GAMS syntax. The tokens in the macro body to be replaced by the actual macro arguments follow the standard GAMS identifier conventions. Consider the following simple example of a macro with one argument:

```
$macro reciprocal(y) 1/y
```

Here the name of the macro is `reciprocal`, `y` is the argument and the macro body is `1/y`. This macro may be called in GAMS statements as follows:

```
$macro reciprocal(y) 1/y
scalar z, x1 /2/, x2 /3/;
z = reciprocal(x1) + reciprocal(x2);
```

As GAMS recognizes `reciprocal(x1)` and `reciprocal(x2)` as macros, the assignment statement will expand to:

```
z = 1/x1 + 1/x2;
```

The next example illustrates macros with multiple arguments:

```
$macro ratio(x,y) x/y
scalar z, x1 /2/, x2 /3/;
z = ratio(x1,x2);
```

The assignment above will expand to:
$z = x_1/x_2;

Note that the macro definition may extend over several lines with the symbol \ acting as a continuation string. Consider the following example:

\begin{verbatim}
$macro myxor(a,b) (a or b) \n    and (not a or not b)
scalar z;
    z = myxor(1,0);
    display z;
\end{verbatim}

The $z$ assignment expands to

\begin{verbatim}
z = (x_1 or x_2) and (not x_1 or not x_2);
\end{verbatim}

Note that although the macro has been defined over two lines, the expansion happens by combining the lines after stripping leading white spaces of the second line as demonstrated in the next example (because and has a higher precedence than or we can omit the parenthesis):

\begin{verbatim}
$macro myxor(a,b) not a and b \n    or a and not b
scalar z;
    z = myxor(1,0);
    display z;
\end{verbatim}

The $z$ assignment expands to this:

\begin{verbatim}
z = not 1 and 0 or 1 and not 0;
\end{verbatim}

The & can be used to preserve (some of the) leading white spaces (but not the line breaks) if that is desired:

\begin{verbatim}
$macro myxor(a,b) not a and b \n    & or a and not b
\end{verbatim}

3.41.5.2 Nested Macros

Macros may be nested. Consider the following example:

\begin{verbatim}
$macro product(a,b) a*b
$macro addup(i,x,z) sum(i,product(x(i),z))
set j /j1*j10/;
Parameter a1(j) / #j 1 /, z, x1 /5/;
    z = addup(j,a1,x1);
\end{verbatim}

Observe that the macro product is nested in the macro addup. The assignment will expand to:

\begin{verbatim}
z = sum(j,a1(j)*x1);
\end{verbatim}

Note that nested macros may result in an expansion of infinite length. An example follows.

\begin{verbatim}
$macro a b,a
display a;
\end{verbatim}

This will expand into:

\begin{verbatim}
display b,b,b,b,b,b,b,b,b,b,b,b,b,...
\end{verbatim}

In such a case GAMS will eventually refuse to do more substitutions and will issue a compilation error:

732 Too many edits on one single line - possible recursion in macro calls
    compilation will be terminated
3.41.5.3 Ampersands in Macro Definitions

The expansion of arguments may be more carefully controlled by the use of ampersands & in the macro body. A single ampersand & is used as a concatenation or separation symbol to indicate tokens that are to be replaced. Consider the following example:

```
$macro f(i) sum(j, x(i,j))
$macro equ(q) equation equ_&_q; \
    equ_&_q.. q =e= 0;
set i /i/, j /j/;
variable x(i,j);
equ(f(i))
```

This will expand into:

```
equation equ_f(i);equ_f(i).. sum(j, x(i,j)) =e= 0;
```

Note that without the ampersand notation, GAMS would have recognized only the third occurrence of q and hence the expansion would have been:

```
equation equ_q;equ_q.. sum(j, x(i,j)) =e= 0;
```

Two ampersands && immediately preceding a token will drop the most outer matching single or double quotes of the replacement argument. This makes it possible to include expressions with spaces, commas and unbalanced parentheses. The latter one is something users should really avoid doing. An example follows.

```
$macro d(q) display &&q;
$macro ss(q) &&q)
set i /i/, k /k/;
parameter a1(i) / i 1/, z;
d('"here it is" , i,k')
d('"(zz")')
z=ss('sum(i,a1(i)');
z=ss('prod(i,a1(i)');
```

Note that the expressions d contain quotes, spaces and commas and the expression ss has unbalanced parentheses within the quoted parts. In turn these expand to become:

```
display "here it is" , i,k;
display "(zz";
z=sum(i,a1(i));
z=prod(i,a1(i));
```
3.41.5.4 Additional Macro Features

Deeply nested macros may require aliased sets in indexed operations like `sum` and `prod`. A minor syntax extension allows the implicit use of aliases. The suffix `.local` on a controlling set will use an implicit alias within the scope of the indexed operation. Consider the following example:

```plaintext
$macro ratio(a, b) a/b
$macro total(q) sum(i,q(i))
set i /i1*i15/;
parameter a(i) / #i 1 /, b(i) / #i 2 /, r(i), asum;
asum = total(a);
r(i) = ratio(total(a), b(i));
```

The assignment statement will expand to:

```plaintext
asum = sum(i,a(i));
r(i) = sum(i,a(i))/b(i);
```

The second line will not compile because the `i` in the sum is already controlled from the `i` on the left. The intention was the `total` macro is to add up the elements of a parameter indexed over `i`. As in the `r(i)` assignment the macro might be used in a statement where `i` is already controlled hence when doing the `sum` in the macro we want to use an alias of `i`. If we change the macro definition to

```plaintext
$macro total(q) sum(i.local,q(i))
```

The code works as expected because the `i` in the sum refers to the `i.local` and not the outside `i`.

Note that the modifier `.local` is not limited to macros and may be used in any context. For further details and more examples, see the detailed description of the dollar command option `$on/offLocal`.

Another feature of macros is the implicit use of the suffix `.L` in report writing and other data manipulation statements. This allows using the same algebra in model definitions and assignment statements. The following code illustrates this feature:

```plaintext
$macro sumIt(i,term) sum(i,term)
cost ..   z  =e=  sumIt((i,j), (c(i,j)*x(i,j))) ;
supply(i) ..  sumIt(j, x(i,j)) =l=  a(i) ;
demand(j) ..  sumIt(i, x(i,j)) =g=  b(j) ;
Model transport /all/ ;
solve transport using lp minimizing z ;
Parameter tsupply(i) total demand for report
  tdemand(j) total demand for report
$onDotL
  tsupply(i)=sumIt(j, x(i,j));
  tdemand(j)=sumIt(i, x(i,j));
```

The option $onDotL enables the implicit suffix .L for variables. This feature was introduced for macros with variables to be used in equation definitions as well as assignment statements. The matching option $offDotL will disable this feature. Similarly, $offDotScale will access the .scale suffix of a variable or equation in an assignment statement.

Three more switches are relevant to macros. The option $show will list any GAMS macros defined. The option $on/$offMacro will enable or disable the expansion of macros; the default is $onMacro. Finally, the option $on/offExpand will change the processing of macros appearing in the arguments of a macro call. The default operation is not to expand macros in the arguments. The switch $onExpand enables the recognition and expansion of macros in the macro argument list. The option $offExpand will restore the default behavior.

Note that macro definitions are preserved in a save/restart file and are available again for a continued compilation.

Summarizing, macros shares the name space of GAMS symbols, like sets, parameters, variables, etc. Macros are recognized and expanded anywhere a proper GAMS identifier may be used. This may be suppressed with the option $on/offMacro. The body of macros is only used during expansion. Hence, macro definitions are not order dependent. Variables in macro bodies will have an implicit suffix .L when they are used in assignment statements. This GAMS feature needs to be activated with the option $onDotL.

### 3.41.6 Compressing and Decompressing Files

GAMS provides two dollar control options for compressing and decompressing GAMS input files:

<table>
<thead>
<tr>
<th>Dollar Control Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$compress &lt;source&gt; &lt;target&gt;</td>
<td>The file source is compressed into the packed file target.</td>
</tr>
<tr>
<td>$decompress &lt;source&gt; &lt;target&gt;</td>
<td>The compressed file source is decompressed into the unpacked file target.</td>
</tr>
</tbody>
</table>

**Attention**

Spaces are interpreted as separators between the source and target file names, hence quotes (single or double) have to be used if the file names contain spaces.

Note that GAMS will recognize whether a file is compressed and will processes it accordingly.

**Note**

Like any other GAMS input files, all compressed files are platform-independent.

### 3.41.6.1 Compressing and Decompressing Files: A Simple Example

We use the well-known transportation model [TRNSPORT] to illustrate. First we copy the model from the GAMS Model Library and then we create a compressed version of the original:

```
> gamslib trnsport
> echo $compress trnsport.gms t1.gms > t2.gms
> gams t2
```
Alternatively, the following code snippet may be used from within a GAMS file:

```gams
$call 'gamslib trnsport'
$compress trnsport.gms t1.gms
$include t1.gms
```

Note that the compressed input file `t1.gms` can be treated like any other GAMS input file. If it is executed, the listing file will be identical to the listing file of the original input file `trnsport.gms`, since a decompressed input is reported in the echo print. As usual, the parts of the model that are marked with the dollar control option `$on/offListing` will not appear in the echo print.

The compressed file `t1.gms` can be decompressed as follows:

```bash
> echo $decompress t1.gms. t3.gms > t4.gms
> gams t4
```

Alternatively, from within a GAMS file:

```gams
$decompress t1.gms t3.gms
```

Observe that the decompressed file `t3.gms` is identical to the original file `trnsport.gms`. This can easily be tested with the following command:

```bash
> diff trnsport.gms t3.gms
```

### 3.41.6.2 Compressing and Decompressing Files: The Model CEFILES

The following more elaborate example is self-explanatory. It is adapted from model [CEFILES](#) and can easily be modified to test the use of compressed files.

```gams
* --- get model
$call gamslib -q trnsport

* --- compress and run model
$compress trnsport.gms t1.gms
$decompress t1.gms t3.gms
$call diff trnsport.gms t1.org > %system.nullFile%
$if errorLevel 1 $abort files trnsport and t1 are different

* --- check to see if we get the same result
$call gams trnsport gdx=trnsport lo=%gams.lo%
$if errorLevel 1 $abort model trnsport failed
$call gams t1 gdx=t1 lo=%gams.lo%
$if errorLevel 1 $abort model t1 failed
$call gdxdiff trnsport t1 %system.reDirLog%
$if errorLevel 1 $abort results for trnsport and t1 are not equal

* --- also works with include files
$echo $include t1.gms > t2.gms
$call gams t2 gdx=t2 lo=%gams.lo%
$if errorLevel 1 $abort model t2 failed
$call gdxdiff trnsport t2 %system.reDirLog%
$if errorLevel 1 $abort results for trnsport and t2 are not equal
$terminate
```
3.41.7 Encrypting Files

When models are distributed to users other than the original developers, issues of privacy, security, data integrity and ownership arise. To address these concerns, secure work files may be used and GAMS input files may be encrypted. Note, that the encryption follows the work file security model and requires special licensing.

Note

Like any other GAMS input files, all compressed and encrypted files are platform-independent.

Encryption is only available if a system is licensed for secure work files and usually requires a target license file which will contain the user or target encryption key. Note that once a file has been encrypted it cannot be decrypted any more. GAMS provides the following dollar control option to encrypt an input file:

```
$encrypt <source> <target>
```

Here the name of the input file to be encrypted is `source` and the name of the resulting encrypted file is `target`.

3.41.7.1 Encrypting Files: A Simple Example

We use again the transportation model [TRNSPORT] to illustrate. First we copy the model from the GAMS Model Library and then we create an encrypted version of the original:

```
> gamslib -q trnsport
> echo $encrypt trnsport.gms t1.gms > t2.gms
> gams t2 pLicense=target lo=%gams.logOption%
```

Note that the first two lines are similar to the directives that we have used to compress the model above. In the third line, the command line parameter `pLicense` specifies the target or privacy license to be used as a user key for encrypting. Thus the new encrypted file `t1.gms` is locked to the license key `target` and it can only be executed with the license file `target`:

```
> gams t1 license=target dumpOpt=11
```

Note that the command line parameter `license` is used to override the default GAMS license file `gamslice.txt` that is located in the system directory. Note further that the command line parameter `dumpOpt` is usually used for debugging and maintenance. The value 11 causes a clean copy of the input to be written to the file `t1.dmp`, where all include files and macros are expanded. Observe that if some lines have been marked with the dollar control options $on/offListing in the original file, then these lines will be suppressed in the file `t1.dmp`.

Note

Once a file has been encrypted, it cannot be decrypted any more. There is no inverse mechanism to recover the original file from the encrypted file. An attempt to decompress it using $decompress will fail.

Observe that encrypting is done on the fly into memory when the GAMS system files are read. GAMS will recognize if a file is just plain text or compressed and/or encrypted and will validate and process the files accordingly.
3.41.7.2 Encrypting Files: The Model ENCRYPT

The following more elaborate example is self-explanatory; it is model [ENCRYPT] from the GAMS Model Library.

Note that the option license=demo is used. This overrides the license that is currently installed with a demo license that has the secure file option enabled.

$ontext
To create an encrypted file, we need a license file which has the security option enabled. To allow easy testing and demonstration a special temporary demo license can be created internally and will be valid for a limited time only, usually one to two hours.

In the following example we will use the GAMS option license=demo to use a demo license with secure option instead of our own license file. Also note that we use the same demo license file to read the locked file by specifying the GAMS parameter pLicense=license.
$offtext

* --- get model
$ondollar
$call gamslib -q trnsport

* --- encrypt and try to decrypt
$call rm -f t1.gms
$echo $encrypt trnsport.gms t1.gms > s1.gms
$call gams s1 license=demo pLicense=license lo=%gams.logOption%
$if errorLevel 1 $abort encryption failed

$eolCom //
$if not errorFree $abort decompress did not fail
$call gams t1 license=demo gdx=t1 lo=%gams.logOption%
$if errorLevel 1 $abort model t1 failed
$call gdxdiff trnsport t1 %system.reDirLog% $if errorLevel 1 $abort results for trnsport and t1 are not equal

* --- use the encrypted file as an include file
$onEcho > t2.gms
$offListing
* this is hidden
option limRow=0,limCol=0,solPrint=off;
$include t1.gms
$onListing
* this will show
$offEcho
$call gams t2 license=demo lo=%gams.logOption%
$if errorLevel 1 $abort model t2 failed

* --- protect against viewing
* now we will show how to protect parts of an input
* file from viewing and extracting original source
* via the gams DUMPOPT parameter. We just need to
* encrypt again

* --- encrypt new model
$call rm -f t3.gms
$echo $encrypt t2.gms t3.gms > s1.gms
$call gams s1 license=demo pLicense=license lo=%gams.logOption%
$if errorLevel 1 $abort encryption failed
$call gams t3 license=demo gdx=t3 dumpOpt=11 lo=%gams.logOption%
$if errorLevel 1 $abort model t3 failed
$call gdxdiff transport t3 %system.reDirLog%
$if errorLevel 1 $abort results for transport and t3 are not equal

* --- check for hidden output
$call grep "this is hidden" t3.lst > %system.nullFile%
$if not errorLevel 1 $abort did not hide in listing
$call grep "this is hidden" t3.dmp > %system.nullFile%
$if not errorLevel 1 $abort did not hide in dump file

3.42 The Put Writing Facility

3.42.1 Introduction

While the GDX facility is widely used to exchange bulk GAMS data with other programs the put writing
facility allows to generate sophisticated reports in GAMS. The result are external ASCII files that are
structured using information that is stored by the GAMS system. The put writing facility offers users
numerous ways to control three format layers: the format of the external file that is written to, the format
of the pages of the external files and the format of output items. Hence the structure of the put writing
facility is more complex and requires more programming than the display statement, but there is much
more flexibility and control over the output. The put writing facility generates external files automatically
when the GAMS program is executed. The files are written sequentially, a single page at a time. The
current page is stored in a buffer, which is automatically written to an external file when the page is full.
Thus, the put writing facility has only control over the current page and does not have the ability to go
back to alter former pages. However, while a particular page is current, information placed on it may be
overwritten or removed at will.

This chapter is organized as follows. We will first introduce the file statement and the put statement,
which are at the core of the put writing facility. Then we will present a simple example that will serve
as illustration. We will also introduce some widely used features as we comment on the example. The
remainder on the chapter will cover in detail the external report files, also called put files, the structure
of put file pages and ways to control their format, types of output items and their formatting controls,
and the put utility statement, a variant of the put statement that allows to special communication of
formatted elements with the outside world. In addition, we will briefly discuss exception handling in the
context of put statements and GAMS errors that are specific to put statements. We will conclude the
chapter with an elaborate example. Note that put file attributes play a crucial role, since they are used
for most formatting controls. A complete list of all file attributes is given in section Put File Attributes.
3.42.2 The Syntax

The basic structure of the put writing facility in its simplest form is as follows:

File file_name {,file_name};
put file_name;
put item {,item};

Note that the first line is a file statement. File statements define one or more external files that will be written to and specify internal names for them. These internal names will be used in the GAMS model to reference the external files when they are written to. The second line is a put statement that assigns the file with the name file_name as the current file. The third line is a put statement that writes one or more items to the current file. Items are any type of output like explanatory text, set labels, parameters, and variable, equation values and model attributes.

Next, we will present more details on the file statement and the put statement in the following two subsections and then we will turn to a first example that will illustrate how the put writing facility works.

3.42.2.1 The File Statement: Defining Put Files

External files that are written to with the put writing facility are called put files. They are defined with a file statement. The syntax for a file statement is as follows:

File[s] file_name ["text"] [external_file_name]
{,file_name ["text"] [external_file_name] } ;

The keyword file or files indicates that this is a file statement. It is followed by the internal name for the put file, file_name. The internal file name is a handle for the put file, it is used in the GAMS model to refer to the put file. The optional explanatory text may be used to describe the put file for future reference and to ease readability. The final part of the file statement is the actual name of the put file. Naming the external file is optional. In case it is omitted, by default, GAMS will create a name by appending the extension .put to the internal name. Consider the following example:

File results;

Note that in this statement no external file name is specified. Thus GAMS will create the external file results.put in the current working directory. Observe that by default, all put files are stored in the current working directory. There are several ways to specify alternative directories for put files. For details see section Choosing Where Put Files are Saved below.

Note

Multiple put files may be defined with one file statement.

Consider the following example:

File  class1
    class2  "this defines a specific external file" /report.txt/
    log    "this defines access to the GAMS log file" /''/;

Observe that the internal name of the first file is class1. As no external name is specified, GAMS will assign the absolute name class1.put to this file. The second file will be referenced in the model with the name class2 and it corresponds to the external file report.txt. The third file is special: the internal name '' is reserved for writing output to the GAMS log. Note that writing to the GAMS log can be useful to monitor how the solution process of the model is progressing.

For further details on put files, see section Put Files below.
The Put Statement

The put statement is at the core of the put writing facility. It has two different functions: it specifies which of the previously defined put files is the current file and it writes output to that file. The syntax for the first function is simple:

```
put file_name;
```

The keyword `put` indicates that this is a put statement, `file_name` is the internal name of a put file that was previously defined with a `file statement`. This put statement has the effect that the specified file is now ready to be written to. Note that this put statement is necessary even if only one put file has been previously defined. For an example of how it is used when output is written to several different files, see the next section.

The basic syntax for a put statement that is used to write output to a file is as follows:

```
put item {,item};
```

The statement begins with the keyword `put` followed by one or more items. Items may be a text (like a quoted text, an explanatory text, the name of a set element), a numerical value (like the value of a parameter, the value of an attribute, the solution status of the model) or a set value (`YES` or `NO` indicating whether a label is an element of a specific set). These items are discussed in detail in section Output Items below. In addition, GAMS facilitates writing a text block to a put file and including the content of an external file in a put file. For details see sections Text Items: Text Blocks and The Put Utility Statement respectively.

Note that it is also allowed to use only one put statement to assign one file as the current file and write to it. The syntax follows:

```
put file_name item {,item};
```

In addition, it is permitted to use just one put statement to write to multiple files sequentially. Thus the most general form of a put statement is as follows:

```
put file_name item {,item} {,file_name item {,item}};
```

Note that only one file is current at a time. When a file is current, the output items following the name of this file will be written to the file. After this has been completed, the current file is reassigned to the next internal file name in the statement. The last internal file name used in a put statement continues to be the current file until a subsequent put statement uses an internal file name.

Observe that the keyword `put` has several variants: `putclose`, `puttl`, `puthd`, `putpage` and `put_utility`.
3.42 The Put Writing Facility

3.42.3 A First Example

We will use a small example to introduce the basic features of the put writing facility. The example is based on the well-known transportation model [TRNSPORT]. The following code segment could be placed at the end of the transportation model to create a report:

```gams
File factors /factors.dat/,
    results /results.dat/;
put factors;
put 'Transportation Model Factors' / /
    'Freight cost ', f, 
    @1#6, 'Plant capacity'/;
loop(i, put @3, i.tl, @15, a(i)/);
put '/Market demand'/;
loop(j, put @3, j.tl, @15, b(j)/);

put results;
put 'Transportation Model Results' / /;
loop((i,j), put i.tl, @12, j.tl, @24, x.l(i,j):8:4 /);
```

In the first line, the file statement defines the internal file names factors and results and connects them to the external files factors.dat and results.dat respectively. These internal file names are used inside the model to reference files which are external to the model.

In the second line, the put statement assigns the file factors as the current file, that is the file which is currently available to be written to.

In the third line, the put statement starts the actual writing to the put file. The first item that is written is the quoted text string 'Transportation Model Factors'. The item is followed by two slashes. A slash instructs the cursor to move to the first column of the next line. Two slashes have the effect that the cursor is moved to the first column of the second line, thus introducing a blank line.

Attention

Two slashes // are a popular end of line comment character sequence. So an intended blank line can result in a comment in the GAMS code. A safe way to use slashes in put statement is to separate the slashes by a space.

The next item is the string 'Freight cost ' followed by the value of the scalar f. Note that these output items are separated by commas. Blanks and commas serve as delimiters for separating different output items. These delimiters leave the cursor at the next column position in the file following the last item written. In most cases, a blank and a comma may be used interchangeably. However, the comma is the stronger form and will eliminate any ambiguities.

In the fifth line, the code above starts with the instruction @1#6. In the context of put statements, the symbols @ and # serve to reposition the cursor to a specific column and row respectively. Thus in our case, the cursor is repositioned to column 1 of row 6 of the put file. Then another text string is written and a new line is started. The semicolon terminates the put statement. More details on cursor positioning are given in section Controlling the Cursor On a Page.

In line 6, the next put statement is embedded within a loop statement. Note that the set i is the looping set. The put statement writes at column position 3 the set label name and at column position 15 the value of the parameter a(i) for each element of the set i. Observe that set element labels are referenced with the name of the set and the suffix .te. For more information on identifier suffixes, see section Text Items below. Note that the put statement has to be placed within a looping structure, since only one element of the index set may be written with a put statement.
In line 7, the first symbol after the keyword put is a slash, that has the effect that a blank line is inserted before the text string 'Market demand' is written.

In line 8, we have again a put statement within a loop structure: the values of the parameter b are written in a similar way to those of parameter a in line 6.

After execution, the put file factors.dat will look as follows:

Transportation Model Factors

Freight cost 90.00

Plant capacity
Seattle 350.00
San-Diego 600.00

Market demand
New-York 325.00
Chicago 300.00
Topeka 275.00

Note that this output has been formatted using the default file format values. GAMS offers several ways to customize the format, see sections Global Item Formatting Controls and Local Item Formatting Controls below for further information.

In the last three lines of the code above, the file results.dat is made current and the level values associated with the variable x along with their corresponding set element index labels are written line by line. Note that the format of the output results of the variable x is customized by specifying a field width of 8 spaces with 4 of these spaces reserved for decimal places. This is an example of local formatting. The put file results.dat will contain the following lines:

Transportation Model Results

Seattle New-York 50.0000
Seattle Chicago 300.0000
Seattle Topeka 0.0000
San-Diego New-York 275.0000
San-Diego Chicago 0.0000
San-Diego Topeka 275.0000

This small example has demonstrated the main features of the put writing facility. However, its surface has just barely been scratched. In the remainder of this chapter we will describe in detail the many features of the put writing facility. Observe that in section Creating a Report for the Model MEXSS at the end of this chapter we will present a more elaborate report.

3.42.4 Put Files

As mentioned earlier, external files that are written to with the put writing facility are called put files. They are defined with a file statement and are made current with a put statement. Once they are current, they may be written to. By default, put files are saved in the current working directory. In this section we will cover more details on put files. We will discuss ways to specify other directories for put files, introduce the putclose statement, a variant of the put statement that closes the current file, and we will show how to append to an existing external file instead of replacing (overwriting) it. In addition, we will introduce the notion of put file attributes including a list of all attributes.
3.42.4.1 Choosing Where Put Files are Saved

Recall that by default, put files are saved in the current working directory. GAMS offers several ways to specify other directories for put files. The easiest way to specify another directory is by including the absolute or relative path in the file statement. Consider the following example:

File report / C:\Documents\GAMS\Output\report.dat /;

Note that the put file report.dat with the internal name report will be stored in the directory specified in the file statement instead of the current working directory.

An alternative directory for all put files in a model may be specified with the command line parameter PutDir. Assume we wish to write some output from running the well-known transportation model [TRNSPORT] to the file results defined above. Consider the following GAMS call:

> gams trnsport PutDir=c:\output

Note that the file results.put will be stored in the directory specified in the GAMS call. Observe that storing put files in the directory specified with PutDir is applies to all file that are not specified via an absolute file name. For more information on command line parameters, see chapter The GAMS Call and Command Line Parameters. scratchdir as putdir option (.pdir) lets GAMS write put files into the scratch directory.

The content of a put file will be sent to the GAMS log file if the put file is specified in the following way:

File name / '' /;

For example, the following code snippet may be added to the transportation model [TRNSPORT]:

File name / '' /;
pname ;
put 'instructions that will go to the GAMS log' /;
put 'more instructions that will go to the GAMS log' /

As a result, the respective GAMS log will contain the following lines:

...instructions that will go to the log file
more instructions that will go to the log file
*** Status: Normal completion
--- Job trnsport.gms Stop 01/25/17 15:46:09 elapsed 0:00:00.320
3.42.4.2 The Putclose Statement: Closing a Put File

Recall that the file statement and the put statement are at the core of the put writing facility. The putclose statement is a variant of the put statement, it is used to close a put file. The syntax is as follows:

```
putclose [file_name] {item} {file_name item {item}};
```

If the file_name is missing, putclose will close the current file. Often the putclose statement is used in this simple form. Consider the following example:

```plaintext
File report;
put report;
put "This is a report."
putclose;
```

Note that the last line has the effect that the file report.put is closed. The file may be used again later. As usual, it has to be assigned as the current file and then it may be written to. By default, an existing file is overwritten (replaced). Alternatively, it may be appended to. For details see section Writing to an Existing Put File below. The briefest version of the above code is

```plaintext
File report; putclose report "This is a report."
```

Closing a put file is useful for example when writing a solver option file from within the GAMS model. Consider the following example, where we will create and close an option file for the solver MINOS.

```plaintext
File opt 'Minos option file' / minos.opt /;
put opt 'Iteration limit 500'/
     'Feasibility tolerance 1.0E-7'/ ;
putclose opt;
```

Note that the file minos.opt is closed with a simple putclose statement. This will make the file available to be used by the solver. Observe that the code snippet above has to be placed before the respective solve statement.

Now, the last three lines in the example above may be reduced to two lines in the following way:

```plaintext
putclose opt 'Iteration limit 500'/
     'Feasibility tolerance 1.0E-7'/ ;
```

In this formulation, the putclose statement makes the file minos.opt current, writes to it and then closes the file after the last item has been written. Even though this is shorter, many users prefer the first formulation, since it is clearer.

Similarly to the put statement, the putclose statement may also be used to write to several files subsequently. The only difference to the put statement is, that the last current file will be closed after is has been written to.

Observe that GAMS automatically closes the put files of a model when it exits, even without a putclose statement.
3.42.4.3 Writing to an Existing Put File

When the put writing facility is used to write to a file that is not empty, by default, the existing content is overwritten (replaced). However, GAMS provides the option to append to the file instead via the file attribute append option (.ap). Consider the following example:

```plaintext
File append /append.dat/
put append;
put "This is the first line." /;
putclose;
append.ap = 1;
put append;
put "This is the second line.";
```

Note that the putclose statement in line 4 closes the file `append.dat`. The assignment in the next line instructs the put writing facility to append to the file if the file is opened again and written to. Thus the following output is generated:

This is the first line.
This is the second line

For information on file attributes in general, see section Put File Attributes below.

3.42.4.4 Put File Attributes

Put files have attributes that are mainly used to customize the format of put files, put file pages and output items. Put file attributes are accessed in the following way:

```plaintext
file_name.attribute
```

Here `file_name` is the internal name of the put file and `.attribute` is the specific attribute that is to be accessed. We can also access the specific attribute of the current file by `file.attribute`. This useful in particular in `batincludes` that are used for multiple put files. Put file attributes may be used on the left-hand side and right-hand side of assignments. Consider the following example:

```plaintext
factors.nw = 10;
scalar x; x = factors.nw;
```

In the first line, the attribute numeric field width (.nw) of the put file with the internal name `factors` is assigned the value of 10. In the second line, the value of the attribute .nw is assigned to a scalar parameter x. In addition, put file attributes may be used as output items. For an example, see section Controlling the Cursor with File Attributes below. A complete list of put file attributes is given in Table 1.

Table 1: Put File Attributes
<table>
<thead>
<tr>
<th>Put File Attribute</th>
<th>Symbol</th>
<th>Description</th>
<th>Default Value</th>
<th>Optional Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Append option</td>
<td>.ap</td>
<td>Allows to append to an existing file, instead of replacing (overwriting) it. For more information, see section Writing to an Existing Put File.</td>
<td>0</td>
<td>0: Overwrite 1: Append</td>
</tr>
<tr>
<td>Bottom margin</td>
<td>.bm</td>
<td>Number of blank lines to be placed in the bottom margin of the page. The bottom margin lines are in addition to the lines specified with the file attribute page size (.ps). Note that this attribute is functional only if the value of the suffix print control (.pc) is zero.</td>
<td>0</td>
<td>0: Mixed case 1: Upper case 2: Lower case</td>
</tr>
<tr>
<td>Alphabetic case</td>
<td>.case</td>
<td>Specifies the case in which alphabetic characters are displayed in the put file, regardless of the input. Note that the meaning of 1 and 2 differs from the one for lcase.</td>
<td>0</td>
<td>0: Mixed case 1: Upper case 2: Lower case</td>
</tr>
<tr>
<td>Current column</td>
<td>.cc</td>
<td>This attribute may be used to return or set the current cursor column in the main window. For more information, see Current Cursor Column.</td>
<td>0</td>
<td>Value may be between 1 and the page width.</td>
</tr>
<tr>
<td>Current row</td>
<td>.cr</td>
<td>This attribute may be used to return or set the current cursor row in the main window. For more information, see Current Cursor Row.</td>
<td>1</td>
<td>Value may be between 1 and the page size minus any header rows, title rows and margins.</td>
</tr>
<tr>
<td>Number of put errors</td>
<td>.errors</td>
<td>See section Put Errors for details and an example.</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Header current column</td>
<td>.hdcc</td>
<td>This attribute may be used to return or set the current cursor column in the header block. For more information, see Current Cursor Column.</td>
<td>0</td>
<td>Value may be between 1 and the page width.</td>
</tr>
<tr>
<td>Put File Attribute</td>
<td>Symbol</td>
<td>Description</td>
<td>Default Value</td>
<td>Optional Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------</td>
<td>-------------</td>
<td>---------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Header current row</td>
<td>.hdcr</td>
<td>This attribute may be used to return or set the current cursor row in the header block. For more information, see Current Cursor Row.</td>
<td>1</td>
<td>Value may be between 1 and the size of the header.</td>
</tr>
<tr>
<td>Header last line</td>
<td>.hdll</td>
<td>This attribute may be used to return the number of the last line of the page header or reset the last row written in the page header. For more information, see Last Line Control.</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Alphabetic label case</td>
<td>.lcase</td>
<td>Specifies the case in which alphabetic characters of a label are displayed in the put file, regardless of the original casing.</td>
<td>0</td>
<td>0: Mixed case 1: Lower case 2: Upper case</td>
</tr>
<tr>
<td>Label justification</td>
<td>.lj</td>
<td>Alignment of set labels.</td>
<td>2</td>
<td>1: Right, 2: Left, 3: Center</td>
</tr>
<tr>
<td>Last line</td>
<td>.ll</td>
<td>This attribute may be used to return the number of the last line of the main window or reset the last row written in the main window. For more information, see Last Line Control.</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Left margin</td>
<td>.lm</td>
<td>Number of empty columns to be placed on the left of the page.</td>
<td>0</td>
<td></td>

<td>Value may be 0 or larger.</td>
</tr>
<tr>
<td>Window size</td>
<td>.ws</td>
<td>Returns the number of rows that may be written to the main window given the number of rows in the title and header blocks and the page size. Note that this attribute is computed by GAMS and cannot be changed by the user.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 3.42.5 Put File Pages

In this section we will discuss the structure of put file pages, in particular how to write titles and headers. In addition, we will give details on how users may control many aspects of the format of a put file page.

#### 3.42.5.1 Adding Titles and Headers

Titles and headers are widely used when there are sections of a page that remain relatively constant throughout a document. There are three independent writing areas on each page of a put file: the title block, the header block and the main window. The layout of a page is shown in the following diagram.

```
+-----------------+
| Title Block     |
+-----------------+
| Header Block    |
+-----------------+
| Main Window     |
```

3.42 The Put Writing Facility

Note that the put statement writes to the main window. There are two variants of the put statement that write to the title block and header block respectively: the puttl statement and the puthd statement.

Observe that every page must have an entry in the main window. If a page has no output in its main window, the page will not written, regardless of whether there are output items in the title or header blocks. To force a page that has an empty window out to file, we recommend to simply write something innocuous to the window, like the following:

```
put ''; // space
```

This will initiate the main window of the page and thus the page will be written.

Further, note that the size of any area of a page is based on the number of lines written to it and the total number of lines has to be smaller than the specified page size. A new page is started automatically whenever a page is full. For details on manual pagination, see section The Putpage Statement: Controlling Paging. Each area of a page is maintained independently. For example, we may write to the title block first, then to the header block and then again to the title block. However once we have written to the main window, all subsequent entries to the title and header are written to the next page, not the current page.

3.42.5.1.1 The Puttl Statement: Writing to the Title Block

The puttl (or putTitle which can be used as a synonym) statement is a variant of the put statement that writes to the title block of a page. The syntax is as follows:

```
puttl [file_name] item {item};
```

The keyword puttl indicates that this is a puttl statement. The internal name of the file, file_name, may be omitted if the desired file is already current. Like in the put statement, the content that is written is one or more items, that may be a text string, a numerical value or a set value. For more information on items, see section Output Items below. Consider the following example:

```
puttl factors 'GAMS Put Example';
```

If this line is placed before the put statement that writes to the main window in the example above, then GAMS Put Example will be written to the title block.

Observe that title blocks often contain the name of the model and the number of the put page. Once content is placed in the title block, it will be repeated on every page unless it is modified or deleted. For details on how to write output like the page number to a put file, see section System Suffixes as Output Items below.

Note

If content has already been written to the main window of a page, the items in the puttl statement will appear in the title block starting from the next page. Thus the title has to be written before any entries in the main window if it is to appear on the current page.

Observe that if the title and header blocks contain too many lines given the page size, the page will overflow resulting in a put error.
3.42.5.1.2 The puthd Statement: Writing to the Header Block  Like the puttl statement, the puthd (or putHeader which can be used as a synonym) statement is a variant of the put statement. Puthd statements write to the header block of a page. The syntax is as follows:

```plaintext
puthd [file_name] item {item};
```

The keyword puthd indicates that this is a puthd statement. The internal name of the file, file_name, may be omitted if the desired file is already current. Like in the put statement, the content that is written is one or more items. See section Output Items below for more information on items.

Observe that title blocks often contain a disclaimer or an instruction that is meant to be repeated on every page. Once content is placed in the header block, it will be repeated on every page unless it is modified or deleted.

**Note**

If content has already been written to the main window of a page, the items in the puthd statement will appear in the header block starting from the next page. Thus the header has to be written before any entries in the main window if it is to appear on the current page.

Observe that if the title and header blocks contain too many lines given the page size, the page will overflow resulting in a put error.

3.42.5.1.3 The putclear Statement: Deleting Title and Header Blocks  The putclear (or putfmcl which can be used as a synonym) statement may be used to delete the title and header blocks. The syntax is simple:

```plaintext
putclear;
```

If the keyword putclear is inserted after a title and/or header block has been written, but before the main window has been written to, then the title and/or header blocks of the current page will be deleted. If the main window has already been written to, the the title and/or header block of the next and all subsequent pages will be deleted. Note that if the user wishes to delete either only the title or only the header block, the put file attributes .tlll and .hdll respectively may be set to zero. For more information, see Last Line Control.

3.42.5.2 The putpage Statement: Controlling Paging

A new page is started automatically if the bottom of a page is reached. Alternatively, a new page may be started early using a variant of the put statement: the putpage statement. The syntax is as follows:

```plaintext
putpage [file_name] {item};
```

The keyword putpage indicates that this is a putpage statement. In its simplest form, the putpage statement consists of just the keyword. If only the keyword is used, the current page will be terminated. The optional file_name makes the put file with the internal name file_name current. If output items follow, they will be written to the current page and a new page will be made available for the next put statement.

Consider the following example:

```plaintext
File example / example.txt /;
putpage example "This text is placed in the main window and the page ends here.";
put "Here starts a new page in the same putfile."
```

Observe that three file attributes are helpful for manual paging: last page (.lp), window size (.ws) and last line (.ll).
3.42 The Put Writing Facility

3.42.5.3 Controlling the Format of a Put File Page

While GAMS established gracious defaults, there are numerous ways to customize the format of a put file page. In this section we will present the put file attributes that facilitate the control of various aspects of page formatting and ways to control the position of the cursor.

3.42.5.3.1 Controlling Page Size, Page Width and Margins

By default, 60 rows (lines) may be written on a put file page. At any point in the program the file attribute page size (.ps) may be used to reset this value. Note that the upper limit is 130. Note further, that a put error will result if the attribute is set to a value that is smaller than the number of rows which have already been written to the current page. Observe that the specification of .ps is only effective if the attribute print control (.pc) has a value other than its default value.

By default, 255 characters (columns) may be written to each line of a put file page. Like the page size, the page width may be reset at any point. GAMS provides the file attribute page width (.pw) to do this. Note that the upper limit is 32767. Note further, that a put error will result if the attribute is set to a value that is smaller than the number of columns which have already been written to the current page.

By default, put file pages do not have top, bottom and left margins. However, it is easy to specify blank lines for the margins with the file attributes top margin (.tm) and bottom margin (.bm). Note that the lines reserved for the margins are in addition to the value specified for the page size (.ps). Observe that the file attribute .bm is only functional if the value of the file attribute print control (.pc) is set to zero.

3.42.5.3.2 Controlling the Print Format and the Use of Capital and Lower Case Letters

By default, GAMS prints continuous pages. However, the file attribute print control (.pc) offers several alternative options. For a full list, see the respective entry in Table Put File Attributes above. Note in particular that the options 4, 5, 6 and 8 create delimited files, which are useful for importing output to other applications like spreadsheets. For an example, see section Creating a Report for the Model MEXSS.

By default, alphabetic characters are displayed in the case they were inputted. Note that the value of 1 for the file attribute alphabetic case (.case) will display all output in capital letters, regardless of the input, and the value of 2 will result in only lower case letters being displayed.

Assume that we wish a put file report.txt to have pages with 72 characters to a row and 58 lines, ASCII page control characters to be inserted at the end of every page, an additional top margin of 6 lines and all output displayed in upper case. The following assignments will implement these specifications:

File report /report.txt/;
report.pw = 72; report.ps = 58; report.pc = 3;
report.tm = 6; report.case = 1;

3.42.5.3.3 Controlling the Cursor On a Page

There are three ways to control the position of the cursor: with cursor control characters, with the system attribute system.tab and with file attributes. In this section we will give details on cursor control characters, while inserting tabs and file attributes that are relevant for cursor control will be discussed in the next two sections.

By default, the cursor is moved to the space immediately following the last character written. GAMS provides the control characters listed in Table 2 to specify another position for the cursor.
<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#n</td>
<td>Move cursor position to row n of current page.</td>
</tr>
<tr>
<td>@n</td>
<td>Move cursor position to column n of current line.</td>
</tr>
<tr>
<td>/</td>
<td>Move cursor to first column of next line.</td>
</tr>
</tbody>
</table>

**Table 2:** Cursor Control Characters

Note that the numeric value n that follows the characters # and @ may be any expression or symbol with a numeric value. An example is given below. Note further, that the character @ is commonly used to align columns if the column headings have different widths. For an example, see section Creating a Report for the Model MEXSS. Observe that the character @ may be used to overwrite output items that were written earlier. Consider the following example:

```plaintext
File out /out.dat/;
put out;
put 'Good' @3 'morning everybody!';
```

This code snippet will generate the following output:

*Good morning everybody!*

Observe that cursor control characters are also used and discussed in the example at the beginning of this chapter.

### 3.42.5.3.4 Controlling the Cursor with a System Attribute: Inserting Tabs

The system attribute `system.tab` may be used to insert tabs. Consider the following example:

```plaintext
File test / test.dat /;
put test;
put "1" system.tab "2" system.tab "3" ;
```

The put file will contain the following line, separating 1, 2, and 3 by tabs.

*1 2 3*

### 3.42.5.3.5 Controlling the Cursor with File Attributes

In addition to cursor control characters and tabs, the position of the cursor may be controlled using the file attributes that will be discussed in this section. These file attributes refer to the current column, the current row and the last line in the title block, the header block and the main window.

**Current Cursor Column**

As there are three independent writing areas on each put file page, there are three file attributes that refer to the current column. They are listed in Table 3.
3.42 The Put Writing Facility

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.cc</td>
<td>Current cursor column in the main window.</td>
</tr>
<tr>
<td>.hdcc</td>
<td>Current cursor column in the header block</td>
</tr>
<tr>
<td>.tlcc</td>
<td>Current cursor column in the title block</td>
</tr>
</tbody>
</table>

Table 3: File Attributes for the Column Position of the Cursor

Note that the values for these attributes are numeric and they are updated only at the end of a put statement. Consequently, their values will remain constant during a put statement, even if multiple items or lines are displayed. Observe that the attributes may be used on the left-hand side and on the right-hand side of an assignment statement to set the current column position and return it respectively.

The following example illustrates the updating of the cursor control suffixes and the use of cursor control characters. The example is trivial but instructive:

Scalar lmarg 'left margin' /6/;
File out; put out;
put @(lmarg+2) 'out.cc = ', out.cc:0:0 ' ';
put @out.cc 'x'/ @out.cc 'y'/ @out.cc 'z' ;
put 'out.cc = ' out.cc:0:0;

The resulting file out.put will contain the following lines:

```
out.cc = 1 x
y
z out.cc = 23
```

Note that the scalar lmarg is set to a specific value that will be used as an alignment tab. Symbols which hold common alignment values such as margins or tabs are often useful for large structured documents. The first put statement uses the cursor control character @ to relocate the cursor to column 8 where the text item out.cc and the respective value for the file attribute .cc are displayed. Note that the numerical value of the file attribute is formatted locally with the effect that only integers are displayed. We observe that at the start of the first put statement the file attribute out.cc equals 1.

The second put statement illustrates the updating of the cursor control suffixes by writing the letters x, y and z on three different lines. Each is preceded by moving the cursor to the value of the file attribute .cc. Note that at the end of the first put statement the value of out.cc is updated to 20. Hence, out.cc is 20 at the start of the second put statement. As a single put statement is used to write all three letters, the value of out.cc remains constant and thus the letters are written in the same column. At the end of the second put statement the value of out.cc value is updated to 23 (observe that there are two blank spaces after the letter z).

The third put statement writes the current value of the file attribute out.cc, which is the value at the start of the put statement.

Current Cursor Row

As there are three independent writing areas on each put file page, there are three file attributes that refer to the current row. They are listed in Table 4.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.cr</td>
<td>Current cursor row in the main window</td>
</tr>
<tr>
<td>.hdcr</td>
<td>Current cursor row in the header block</td>
</tr>
<tr>
<td>.tlcr</td>
<td>Current cursor row in the title block</td>
</tr>
</tbody>
</table>
Table 4: File Attributes for the Row Position of the Cursor

Note that the values for these attributes are numeric and they updated only at the end of a put statement. Consequently, their values will remain constant during a put statement regardless of how many rows are displayed. Observe that the attributes may be used on the left-hand side and on the right-hand side of an assignment statement to set the current row and return it respectively. The file attributes for the row position of the cursor behave similarly to those for the column position.

Last Line Control

Like the file attributes for the current column and row position, the file attributes for the last line have three variants, one for each writing area. They are given in Table 5.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.ll</td>
<td>Last line in the main window</td>
</tr>
<tr>
<td>.hdll</td>
<td>Last line in the header block</td>
</tr>
<tr>
<td>.tlll</td>
<td>Last line in the title block</td>
</tr>
</tbody>
</table>

Table 5: File Attributes for the Last Line

Note that unlike the row and column controls, the last line attributes are updated continuously. Last line attributes are especially useful for modifying the three writing areas of a page. They may be used on the left-hand side and on the right-hand side of an assignment statement to set the current last line and return it respectively. Rows will be deleted if the last line attribute is set to a value that is lower than the current row.

Attention

The file attributes .tlll and .hdll may not hold values applicable to the current page, because when the title or header blocks are modified, they will correspond to the title or header blocks of the next page if the main window has been written to on the current page.

As mentioned above, in addition to determining the last line in a writing area, these file attributes may be used to delete lines within a writing area. In the following example, the header block will be completely deleted by resetting the attribute .hdll to zero.

```plaintext
File out;
puthd out 'This header statement will be eliminated';
out.hdll = 0;
```

Note that a header is written initially. However, by changing the attribute .hdll to zero, the cursor is reset to the top of the header block. As a result, the header will not be written unless something new is added to the header block.

3.42.6 Output Items

Output items are the items in the put statement that are written to the put file. They may be a text, a numerical value or a set value. In this section we will provide more information on these three types of items. Observe that system suffixes and command line parameters are either text strings or have a numerical value. They may also be used as output items.
3.42.6.1 Text Items

Text items may be a quoted text, an explanatory text of identifiers and labels or names of set elements. In this section we will give details on each of these text items. In addition, text items may be system attributes or command line parameters. For these text items, see sections System Suffixes as Output Items and Command Line Parameters as Output Items respectively. Details on default field widths and alignments for text items and global and local customizing controls are given in section Customizing the Format of Output Items.

3.42.6.1.1 Text Items: Quoted Text  The simplest text output item is a quoted text. A quoted text is any combination of characters or numbers set apart by a pair of single ('') or double (""") quotes with each the items needing to use a matching pair. Thus the following three lines are all exactly equivalent.

```
put 'Run on ' system.date ' using source file ' system.ifile;
put "Run on " system.date " using source file " system.ifile;
put 'Run on ' system.date " using source file " system.ifile;
```

Note that there is a limit on the length of all output items: output items may not exceed the page width. In case this limit is exceeded, a put error will be reported in the listing file. Put errors are introduced and discussed in section Put Errors.

3.42.6.1.2 Text Items: Identifier Attributes  Text items like the explanatory text of an identifier, the name of a set element and the explanatory text of a set element are specified with identifier attributes. The identifier attributes are listed in Table 6.

<table>
<thead>
<tr>
<th>Identifier Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explanatory text of an identifier</td>
<td>.ts</td>
<td>Displays the descriptive text associated with any identifier (like a set, a parameter, a variable, an equation, a model).</td>
</tr>
<tr>
<td>Name of a set element</td>
<td>.tl</td>
<td>Displays the names of the individual elements of a set. Observe that the put statement must be embedded in a loop statement, where the respective set is the looping set or the set is a singleton set.</td>
</tr>
<tr>
<td>Identifier Attribute</td>
<td>Symbol</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Explanatory text of a set element</td>
<td>.te(index_list)</td>
<td>Displays the explanatory text associated with a set element. Note that this attribute requires the specification of a driving index. If the set is a simple set, the set name itself will have to be specified as index (see example below). If the set is defined over an index, then the index or a subset of the index may be specified. A special case arises in case users wish to gain access to the explanatory text that appears in the definition of another set (see example below). Observe that if there is no explanatory text for a set element in the set definition, then either the name of the set element (default) or a blank will be displayed, depending on the value of the file attribute text fill (.tf). Note that with .tf=3 even if an explanatory text exists, the name of the element will be displayed. Observe that the put statement must be embedded in a loop statement, where the respective set is the looping set or the set is a singleton set.</td>
</tr>
</tbody>
</table>

Indexed identifier with label combination | .tn            | Displays the name of the identifier with all individual label combinations. Observe that the put statement must be embedded in a loop statement, where the respective index is the looping set or the set is a singleton set. See example below. |

Table 6: Identifier Attributes

Consider the following example:

```
Set  i master set of sites / i1 Seattle, i2 Portland
    i3 San Francisco, i4 Los Angeles, i5 /
   j subset of sites    / i3 * i5 / ;

File out; put out i.ts /;
loop(i, put i.tl, i.te(i) /);
```

The resulting put file `out.put` will contain the following output:

```
master set of sites
i1 Seattle
i2 Portland
i3 San Francisco
i4 Los Angeles
i5 i5
```
Note that the explanatory text of the set $i$ is written first, followed by the label names of the set $i$ and their respective explanatory texts. Note further that even though the set $i$ does not have an index (it is a simple set), an index is required for the attribute .te. In this case we specify as index the set itself. Observe that the set element $i5$ was defined without an explanatory text. By default, GAMS inserts the name of the element instead. This may be changed by altering the code in the following way:

```plaintext
put out i.ts /;
out.tf = 0;
loop(i, put i.tl, i.te(i) /);
```

Note that we assign the value of zero to the file attribute text fill (.tf) before the put statement where one of the items refers to the explanatory text of a set element. As a result, a blank will be displayed where the explanatory text of the set element $i5$ is supposed to appear:

```plaintext
master set of sites
i1  Seattle
i2  Portland
i3  San Francisco
i4  Los Angeles
i5
```

Assume we also wish to display the elements of the set $j$ and their explanatory texts. We could just adapt the code above for the set $j$ and add the following two lines:

```plaintext
put / j.ts /;
loop(j, put j.tl, j.te(j) /);
```

These lines will result in the following output to be appended to the put file:

```plaintext
subset of sites
i3
i4
i5
```

Note that the explanatory text associated with the set elements is missing, since there is no explanatory text for the elements in the definition of the set $j$ and the value of zero for text fill is still valid. However, we may gain access to the explanatory text of the set elements in the definition of the set $i$ in the following way:

```plaintext
put / j.ts /;
loop(j, put j.tl, i.te(j) /);
```

Note that the specification $i.te(j)$ singles out the explanatory texts of the elements of the set $i$ that are also elements of the set $j$. Hence we will obtain the desired output:

```plaintext
subset of sites
i3  San Francisco
i4  Los Angeles
i5
```
The following example illustrates the use of the identifier attribute .tn. The model [MEXSS] is a simplified representation of the Mexican steel sector, where five steel plants have to satisfy the demand for steel in three markets. Each steel plant i has several productive units m and the capacity of every unit in every plant is specified with the parameter k(m,i). Assume we wish to write to a put file a list of all nonzero capacities. We could add the following code to the model:

```
File out /out.dat/;
put out 'Capacity (in metric tons)' / /;
loop((m,i)$k(m,i),
   put k.tn(m,i), @30 '=' k(m,i) /;
)
```

Note that we restrict the loop statement with a logical condition to exclude entries of zero. The put file out.dat will contain the following lines:

```
Capacity (in metric tons)

k('blast-furn','ahmsa')  = 3.25
k('blast-furn','fundidora')  = 1.40
k('blast-furn','sicartsa')  = 1.10
k('openhearth','ahmsa')  = 1.50
k('openhearth','fundidora')  = 0.85
k('bof','ahmsa')  = 2.07
k('bof','fundidora')  = 1.50
k('bof','sicartsa')  = 1.30
k('direct-red','hylsa')  = 0.98
k('direct-red','hylsap')  = 1.00
k('elec-arc','hylsa')  = 1.13
k('elec-arc','hylsap')  = 0.56
```

Observe that a more elaborate report for the model [MEXSS] is given in section Creating a Report for the Model MEXSS at the end of this chapter. The identifier attribute .tn is particularly useful when creating scalar EMP info files.

#### 3.42.6.1.3 Text Items: Text Blocks
The easiest way to write blocks of text to a put file is with the dollar control options $onPut and $offPut. Consider the following example:

```
File fx; put fx;
$onPut
We will write four
lines of text to the put file,
including a blank line.
$offPut
```

The put file fx.put will contain the following lines:

```
We will write four
lines of text to the put file,
including a blank line.
```

Note that these dollar control options have a variant that allows the substitution of compile-time variables. For details see the description of $on/offPut.
3.42.6.2 Numeric Items

Numeric items may be values of parameters, variable and equation attributes or model attributes and expressions of such elements. These numeric items will be discussed in this section. In addition, numeric items may be command line parameters. For these numeric items, see section Command Line Parameters as Output Items. Details on default field widths and alignments for numeric items and global and local customizing controls are given in section Customizing the Format of Output Items.

3.42.6.2.1 Numeric Items: Parameters and Functions

In our first example in this chapter, one of the output items was the parameter \( \mathbf{f} \). For convenience, we repeat the respective code below:

```plaintext
put 'Freight cost ', f;
```

Note that the simple name of the parameter is sufficient. In the same example we also had two parameters that were defined over an index: \( \mathbf{a}(i) \) and \( \mathbf{b}(i) \). The respective lines of code follow:

```plaintext
loop(i, put @3, i.tl, @15, a(i)/);
* ... loop(j, put @3, j.tl, @15, b(j)/);
```

Note that indexed parameters must be specified with their index and a put statement with an indexed parameter has to be embedded within a loop structure.

3.42.6.2.2 Numeric Items: Variable and Equation Attributes

Recall that data associated with variables and equations is stored in variable attributes and equation attributes respectively. A full list is given in sections Variable Attributes and Equation Attributes.

Suppose we wish to generate a report with the demand for each market in the transportation model [TRNSPORT], the satisfied demand after solution of the model and the marginal cost of meeting the demand. Recall that the demand data for each market is saved in the parameter \( \mathbf{b}(j) \) and the relationship between shipment quantities and demand is encoded in equation \( \text{demand}(j) \). The following code will generate the desired report:

```plaintext
File report /report.dat/; put report;
loop(j, put 'Report for ' j.tl /  
   'Demand'  @35 b(j):10:0  / 
   'Demand satisfied'  @35 demand.l(j):10:0 / 
   'Marginal Cost of meeting demand'  @35 demand.m(j):10:2 / ;
);
```

Note that we use three numeric output items: the parameter \( \mathbf{b}(j) \), the level value of the equation \( \text{demand.l}(j) \) and the marginal value of the equation \( \text{demand.m}(j) \). Note further, that all three items are indexed over the set \( j \) and thus the put statement has to be placed within a loop statement. Observe that we customize the formatting of the items. For details see section Local Item Formatting Controls. The put file report.dat will contain the following output:
Report for New-York
Demand 325
Demand satisfied 325
Marginal Cost of meeting demand 0.23

Report for Chicago
Demand 300
Demand satisfied 300
Marginal Cost of meeting demand 0.15

Report for Topeka
Demand 275
Demand satisfied 275
Marginal Cost of meeting demand 0.13

3.42.6.2.3 Numeric Items: Model Attributes  GAMS models have many model attributes. An introduction and a complete list is given in section Model Attributes. While in principle all model attributes may be used as output items, the attributes .modelstat and .sollvestat with their string valued counter parts .TModStat and .TSolStat are used most frequently. They refer to the model status and solver termination condition after solution respectively. For a complete list of their values, see sections Model Status and Solver Status.

3.42.6.3 Set Value Items

There are only two set values: YES and NO. The set value will be YES if a label is an element of a specific set and NO otherwise. Consider the following example which is adapted from the example in section Text Items: Identifier Attributes above:

Set i master set of sites / i1 Seattle, i2 Portland, i3 San Francisco, i4 Los Angeles, i5 /
    j subset of sites / i3 * i5 / ;

File out2 / out2.dat /;
put out2 j.ts /;
out2.tf = 0;
loop(i, put i.tl, j(i), ', ', i.te(i) /);

Note that within the loop structure, the put statement writes each element of the set i, determines whether it is a member of the set j and displays the respective set value, and adds the explanatory text for the label. Hence the resulting put file out2.dat will look as follows:

subset of sites
i1   NO Seattle
i2   NO Portland
i3   YES San Francisco
i4   YES Los Angeles
i5   YES

Observe that the set values in the second column reflect set membership of the set j. Observe further, that the missing explanatory text for label i5 is displayed as a blank, since the value of the file suffix text fill (.tf) equals zero.
System Suffixes as Output Items

System suffixes contain information about a GAMS run, they are introduced and discussed in chapter System Attributes. System suffixes may be used as output items in the context of put statements. They are accessed in the following two ways:

\[ \text{system.attribute} \]
\[ \%\text{system.attribute}\% \]

Here \text{system} is a keyword and \text{.suffix} is a specific system suffixes. Note that \text{system.suffix} references the execution-time version (which can be of type string or numeric) of the system suffixes and \%\text{system.suffix}\% (which is interpreted by the compiler as part of the input string) references the compile-time version. For further details on the difference between execution-time and compile-time system suffixes, see chapter System Attributes. A complete list of all system suffixes is given in section List of all System Suffixes, in Table 7 we present a list of the most common system suffixes.

<table>
<thead>
<tr>
<th>System Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.date</td>
<td>Program execution date</td>
</tr>
<tr>
<td>.ifile</td>
<td>Input file name</td>
</tr>
<tr>
<td>.ofile</td>
<td>Output file name</td>
</tr>
<tr>
<td>.rdate</td>
<td>Restart file date</td>
</tr>
<tr>
<td>.rfile</td>
<td>Restart file name</td>
</tr>
<tr>
<td>.sfile</td>
<td>Save file name</td>
</tr>
<tr>
<td>.title</td>
<td>Title of the model as specified by $title</td>
</tr>
</tbody>
</table>

Table 7: A Selection of System Suffixes

To illustrate how system suffixes are used, assume we wish to include the program execution date, the name of the input (GAMS) file, and the page number of the current put statement in the input file to the report results.dat in section A First Example above. We will modify the code in the following way:

File factors /factors.dat/, results /results.dat/;
* ...
put results;
puthd 'Program Execution Date:', @26, system.date /
   'Source File:', @26, system.ifile /;
   'Page Number:', @26, system.page /
   put 'Transportation Model Results' / /
loop((i,j), put i.tl, @12, j.tl, @24, x.l(i,j):8:4 /);

The file results.dat will then contain the following lines:

Program Execution Date: 01/13/17
Source File: C:\Documents\GAMS\Models\trnsport.gms
Page Number: 1

Transportation Model Results

Seattle New-York 50.0000
Seattle Chicago 300.0000
Seattle Topeka 0.0000
San-Diego New-York 275.0000
San-Diego Chicago 0.0000
San-Diego Topeka 275.0000
Note that the date is given in the American format: month/day/year and can be reset via the command line parameter DFormat. Also note that including the page number in the header block of a put file will have the effect that the pages of the put file will be numbered. Of course, this is especially useful for longer put files.

3.42.6.5 Command Line Parameters as Output Items

Command line parameters may also be used as output items. They are introduced and discussed in chapter The GAMS Call and Command Line Parameters. For an overview of all GAMS command line parameters, see section List of Command Line Parameters. In the context of a put statement, command line parameters are referenced as compile-time strings as follows:

```gams
put "%gams.parameter%";
```

Here parameter is a GAMS command line parameter. To illustrate how command line parameters are used, assume we wish to include the page size of the input file, the name of the input file and the name of the restart file in the report results.dat in section A First Example above. We will modify the code in the following way:

```gams
File factors /factors.dat/, results /results.dat/ ;
* ...
put results;
put 'Transportation Model Results' // ;
loop((i, j), put i.tl, @12, j.tl, @24, x.l(i, j):8:4 //);
put / "Page size = %gams.ps%"
    / "GAMS input file = %gams.input%"
    / "GAMS restart file = %gams.restart%";
```

The last three lines of the put file results.dat follow:

```
Page size = 58
GAMS input file = C:\Documents\GAMS\Models\transport.gms
GAMS restart file =
```

Note that there was no restart file in the GAMS run, thus the value for gams.restart% is the empty string.

3.42.6.6 Customizing the Format of Output Items

GAMS provides global and local controls to modify the default format of output items. Global controls are set with file attributes and apply to all output items in a put file that follow the assignment of a file attribute. Local controls are used to change the format of only one specific output item.

3.42.6.6.1 Global Item Formatting Controls

The alignment (justification) of the field and the width of the field may be modified for all types of output items. The attributes that control field alignment are listed in Table 8. Note that possible values are 1 (right), 2 (left) and 3 (center).
### Table 8: File Attributes for Field Alignment

The width of the field is specified with the number of spaces to be allocated. The attributes that control field width are listed in Table 9.

<table>
<thead>
<tr>
<th>Type of Output Item</th>
<th>Symbol</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text items: set labels</td>
<td>.lj</td>
<td>2: Left</td>
</tr>
<tr>
<td>Text items: quoted and explanatory text</td>
<td>.tj</td>
<td>2: Left</td>
</tr>
<tr>
<td>Numeric values</td>
<td>.nj</td>
<td>1: Right</td>
</tr>
<tr>
<td>Set values</td>
<td>.sj</td>
<td>1: Right</td>
</tr>
</tbody>
</table>

### Table 9: File Attributes for Field Width

Note that the value of zero signifies a *variable* field width, matching the exact size of the item being displayed. If a text output item does not fit within the specified field, truncation will occur to the right. For numeric output items, the decimal portion of a number is rounded or scientific notation is used to fit the number within the given field. If a number is still too large, asterisks will replace the value in the output file.

For example, the following assignment will set the field width for numeric items in the file `out.put` globally to 4:

```
out.nw = 4;
```

In addition to field alignment and field width, there are further global controls that apply to numeric output items only. They are given in Table 10.

<table>
<thead>
<tr>
<th>File Attribute</th>
<th>Symbol</th>
<th>Description</th>
<th>Default Value</th>
<th>Optional Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of decimals</td>
<td>.nd</td>
<td>Sets the number of decimals that are displayed for numeric items. A value of zero entails that only the integer part of a number is displayed.</td>
<td>2</td>
<td>Values may be between 0 and 10.</td>
</tr>
<tr>
<td>File Attribute</td>
<td>Symbol</td>
<td>Description</td>
<td>Default Value</td>
<td>Optional Values</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------</td>
<td>--------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Numeric round format</td>
<td>.nr</td>
<td>Offers the option to display a numeric value in scientific notation. This is especially useful if a value is smaller than the number of decimals specified with the suffix number of decimals (.nd). Note that by default, a number that is smaller than the number of decimals specified with .nd, but larger than the zero tolerance level set with .nz is displayed as zero. In many situations, it is important to be aware that such small values exist.</td>
<td>1</td>
<td>0: Item is displayed in F or E format. 1: Item is rounded to fit fields. 2: Item is displayed in scientific notation.</td>
</tr>
<tr>
<td>Numeric zero tolerance</td>
<td>.nz</td>
<td>Sets the tolerance level for which a number will be rounded to zero for display purposes. Note that in case this attribute is set to zero, rounding is determined by the field width.</td>
<td>1.0e-10</td>
<td></td>
</tr>
</tbody>
</table>

Table 10: File Attributes for Global Format Control Specific to Numeric Items

Note that the maximum size of a displayed number must fit within 20 spaces using at most 15 significant digits. The remaining spaces are used for the sign, exponential notation or padding with zeros.

The following example illustrates the result of different combinations of numeric file attributes. Note that we will use five combinations of the file attributes .nd, .nz, .nr and .nw to display three numerical values.

Set c suffix combinations / comb1 * comb6 / v value indices / value1 * value3 / ;

Table suffix(c,*) numeric suffix combinations

<table>
<thead>
<tr>
<th></th>
<th>nd</th>
<th>nz</th>
<th>nr</th>
<th>nw</th>
</tr>
</thead>
<tbody>
<tr>
<td>comb1</td>
<td>3</td>
<td>0</td>
<td>0</td>
<td>12</td>
</tr>
<tr>
<td>comb2</td>
<td>3</td>
<td>1e-5</td>
<td>0</td>
<td>12</td>
</tr>
<tr>
<td>comb3</td>
<td>3</td>
<td>1e-5</td>
<td>1</td>
<td>12</td>
</tr>
<tr>
<td>comb4</td>
<td>8</td>
<td>0</td>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>comb5</td>
<td>6</td>
<td>1e-5</td>
<td>1</td>
<td>12</td>
</tr>
<tr>
<td>comb6</td>
<td>0</td>
<td>1e-5</td>
<td>1</td>
<td>12</td>
</tr>
</tbody>
</table>

Parameter value(v) test values / value1 123.4567 value2 0.1234567
3.42 The Put Writing Facility

```plaintext
value3  0.0001234567 /;

File out; put out;
out.nj=2; out.lw=10; out.cc=11;
loop (v, put v.tl:21);
loop (c,
    out.nd=suffix(c,"nd");
    out.nz=suffix(c,"nz");
    out.nr=suffix(c,"nr");
    out.nw=suffix(c,"nw");
    put / c.tl;
    loop (v,
        put @(ord(v)*21-10), value(v)
    )
);)

Observe that we have chosen to align the values to the left. This will enhance readability as the model loops through the suffix combinations that entail different field widths. The resulting output file `out.put` follows:

<table>
<thead>
<tr>
<th></th>
<th>value1</th>
<th>value2</th>
<th>value3</th>
</tr>
</thead>
<tbody>
<tr>
<td>comb1</td>
<td>123.457</td>
<td>0.123</td>
<td>1.2345670E-4</td>
</tr>
<tr>
<td>comb2</td>
<td>123.457</td>
<td>0.123</td>
<td>1.2345670E-4</td>
</tr>
<tr>
<td>comb3</td>
<td>123.457</td>
<td>0.123</td>
<td>0.000</td>
</tr>
<tr>
<td>comb4</td>
<td>1.23457E+2</td>
<td>0.123457</td>
<td>0.00012346</td>
</tr>
<tr>
<td>comb5</td>
<td>123.456700</td>
<td>0.123457</td>
<td>0.000123</td>
</tr>
<tr>
<td>comb6</td>
<td>123</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Note that in `comb1` the display of values switches to the exponential notation when the value becomes smaller than the number of decimal places allowed. This is a result of `.nr=0`. Note further, that `value3` is greater than the zero tolerance level (`.nz`), but smaller than the number of decimals allowed (`.nd`) in both, `comb2` and `comb3`. However, `.nr=0` results in the exponential notation in the display of `comb2`, while `.nr=1` has the effect that this small value is rounded to zero. Observe that in `comb6` all values are rounded to integers because `.nd` is set to zero.

3.42.6.6.2 Local Item Formatting Controls

The local item formatting controls allow to format specific output items. Note that local formatting overrides global format settings. The syntax is as follows:

```plaintext
item:{<>}width:decimals;
```

Here `item` is the output item, followed by a colon, an alignment (justification) symbol, the field width, a colon and the number of decimals to be displayed. Note that the specification of the number of the decimal places is only valid for numeric output. Note further, that if a component of the local formatting feature is omitted, then the respective global formatting settings will be used. The local alignment symbols are listed in Table 11.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Alignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;</td>
<td>Right</td>
</tr>
<tr>
<td>&lt;</td>
<td>Left</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>Center</td>
</tr>
</tbody>
</table>

**Table 11**: Local Alignment Symbols
Observe that similar to global formatting, a field width of zero means that the field width will be variable, depending on the item to be displayed.

The following example serves as illustration. Observe that we use end-of-line comments to annotate the code.

File out; put out;

$eolCom //
Set i / i1*i3 /;
Parameter d(i) / i1 1426, i2 1347, i3 900 /;
Scalar f / 17.6745 /;

loop(i, put d(i):0:0 /); // default justification and a field width
/// of variable size with no decimals

put / 'Right Justified Comment':>50
    / 'Center Justified Truncated Comment':<>20;

put / / f:<6:2; // left aligned scalar with 6 spaces for field width
    // and two decimals

3.42.7 The Put_Utility Statement

The put_utility statement is a variant of the put statement that may be used to execute external programs. The syntax is as follows:

put_utility [file_name] 'command' / 'arguments' {/ 'command' / 'arguments'};

The keyword put_utility and its synonym put_utilities indicate that this is a put_utility statement. The keyword is followed by the internal name of an external file, file_name. Note that file_name may be omitted. It is not required for the put_utility statement but might be used to activate a file to be used with following put statements. Command denotes one of the commands listed in Table 12 below. Commands are followed by a slash and their respective arguments. Observe that a put_utility statement may contain multiple command / argument pairs. An example is given below.

The following simple example illustrates the put_utility statement:

File test / test.txt /;
put test "This is the original file."

put_utility 'ren' / 'test.dat';
putclos "This is the renamed file."

This is the original file.

The file test.dat will have the following content:

This is the renamed file.
Write to the renamed file.
Note

If Put File Attributes are specified, they are also considered for the put_utility commands and arguments. This could lead to surprising results in some cases, like in this example:

```plaintext
File test / test.txt /;
  test.pc = 5;
  put test "This is the original file."

put_utility 'ren' / 'test.dat';
putclose "This is the renamed file."
```

This will trigger the following errors:

```plaintext
*** Error at line 5: Put_Utilities: Unknown request "'ren'"
*** Error at line 5: Put_Utilities: Unknown request "'test.dat'"
```

The problem is, that `test.pc = 5;` puts quotes around non-numeric output, and thus "ren" (including the quotes) is not recognized as command anymore. To overcome this issue `test.pc` should be set back to default for the `ren` command like this:

```plaintext
File test / test.txt /;
  test.pc = 5;
  put test "This is the original file."

  test.pc = 2;
  put_utility 'ren' / 'test.dat';
  test.pc = 5;
  putclose "This is the renamed file."
```

We will present a list of all commands and their arguments in Table 12 and give examples for most commands below.

**Table 12: List of Commands and their Arguments**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description of Command</th>
<th>Description of Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>assignText</td>
<td>Allows to set the explanatory or label text of a singleton set element. See example below.</td>
<td>Name of singleton set symbol and text.</td>
</tr>
<tr>
<td>click</td>
<td>Adds a clickable file reference to the process window of the IDE. See example below.</td>
<td>File name of the file to which the reference will point.</td>
</tr>
<tr>
<td>exec</td>
<td>Passes a command to the operating system for execution. GAMS will wait until the command is executed. See example below. Note that the distinction between exec and shell is technical and may be operating system specific. Typically, the ability to use redirect of standard input output and the error console is involved.</td>
<td>Command to be executed with arguments.</td>
</tr>
<tr>
<td>exec.aSync</td>
<td>Passes a command to the operating system for execution. However, GAMS will not wait until the command is executed. Job control is handled identical to jobs spawned via execute.async.</td>
<td>Command to be executed with arguments.</td>
</tr>
<tr>
<td>exec.aSyncNC</td>
<td>Passes a command to the operating system for execution using a different console than the parent process (Windows only). GAMS will not wait until the command is executed, thus using multiple processors is possible. Job control is handled identical to jobs spawned via execute.async.</td>
<td>Command to be executed with arguments.</td>
</tr>
<tr>
<td>Command</td>
<td>Description of Command</td>
<td>Description of Arguments</td>
</tr>
<tr>
<td>---------</td>
<td>------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>gdxIn</td>
<td>Accesses the GDX file specified in the argument. A subsequent directive <code>execute_load</code> or <code>execute_loadpoint</code> without a specified file name will unload data from the GDX file thus accessed. See example below.</td>
<td>Name of the GDX file that data will be loaded from.</td>
</tr>
<tr>
<td>gdxOut</td>
<td>Creates a new GDX file or accesses an existing GDX file specified in the argument. A subsequent directive <code>execute_unload</code> without a specified file name will write to the GDX file thus created or accessed. Note that if an existing GDX file is accessed, it will be overwritten. See example below.</td>
<td>Name of the GDX file to which data will be unloaded.</td>
</tr>
<tr>
<td>glb</td>
<td>Used by GAMS to facilitate building the model library - not intended for users.</td>
<td>–</td>
</tr>
<tr>
<td>htm</td>
<td>Used by GAMS to facilitate building the model library - not intended for users.</td>
<td>–</td>
</tr>
<tr>
<td>inc</td>
<td>Includes the contents of an external file in the currently active put file. See example below.</td>
<td>File name of external file.</td>
</tr>
<tr>
<td>log</td>
<td>Sends a message to the log file (also process window). See example below.</td>
<td>Text of message.</td>
</tr>
<tr>
<td>msg</td>
<td>Sends a message to the listing file. See example below.</td>
<td>Text of message.</td>
</tr>
<tr>
<td>msgLog</td>
<td>Sends a message to both, the log file and the listing file. See example below.</td>
<td>Text of message.</td>
</tr>
<tr>
<td>ren</td>
<td>Creates a new external name for the current put file. The internal name will reference the new external file. Any subsequent put statements will write to the new file. See the simple example above and a more complex example below.</td>
<td>External file name.</td>
</tr>
<tr>
<td>save</td>
<td>Writes a save file of the current state of execution.</td>
<td>Name of save file.</td>
</tr>
<tr>
<td>shell</td>
<td>Passes a command to the command shell processor, where it is processed. The processed form of the command is then passed to the operating system for execution. See example below. Note that the distinction between shell and exec is technical and may be operating system specific. Typically, the ability to use redirect of standard input output and the error console is involved.</td>
<td>Command.</td>
</tr>
<tr>
<td>solver</td>
<td>Selects a solver for a given or all model types (use *) by name. See example below.</td>
<td>Model type or * and solver name.</td>
</tr>
<tr>
<td>title</td>
<td>Changes the title on the DOS window.</td>
<td>New name for window.</td>
</tr>
<tr>
<td>winMsg</td>

<td>Window name and message.</td>
</tr>
</tbody>
</table>
In the remainder of this section we will present examples.

**Exec: Creating Empty Files by Executing External Program `touch`**

Consider the following example:

```plaintext
Set i / 1*3 /;
loop(i, put_utility 'exec' / 'touch ' i.tl:0 '.txt');
```

Note that the command to be executed is `touch`. Thus this code snippet will create three empty files called `1.txt`, `2.txt`, and `3.txt`.

**Exec and Ren: Creating Directories and Renaming Files**

Consider the following example:

```plaintext
File test / test.txt /; put test;
Set i / i01*i07 /;
loop(i, put_utilities 'exec' / 'mkdir ' 'test-':0 i.tl:0;
    put_utilities 'ren' / 'test-':0 i.tl:0 '%system.dirSep%test-':0 i.tl:0 '.txt':0 ;
    put 'this should be ' i.tl );
```

Observe that as the loop is executed, the first `put_utility` statement will create seven subdirectories called `test-i01`, ..., `test-i07`. The second `put_utility` statement will create a text file for each of the new subdirectories. The text file in subdirectory `test-i01` is called `test-i01.txt`, the text file in subdirectory `test-i02` is called `test-i02.txt`, etc. The `put` statement in the last line will write to each text file. For example, the following line will be generated for the text file `test-i01.txt`:

```plaintext
this should be i01
```

Note that at the end of the loop, the external file associated with the internal file name `test` is the put file `test-i07.txt`, since this file was the last current put file.

**Inc: Including the Content of a File**

In this example, we first create the external file `recall.txt`, write to it and close it. Then we create a new external file called `report.dat`. In a third step we include the content of the first file in the second file.

```plaintext
File recall /recall.txt/;
putclose recall "I am the external content."

File report /report.dat/;
put report "Here we include content from an external file."
put_utility 'inc' / 'recall.txt' ;
```

Note that the file `report.dat` will contain the following lines:

```plaintext
Here we include content from an external file.
I am the external content.
```
Msg, log and Msglog: Writing to the Log File and Listing file

Consider the following example:

```
put_utility 'msg' / 'This message is for the lst file.'
    / 'log' / 'This message is for the log file.'
    / 'msgLog' / 'And this message is for the lst and the log file.';
```

Note that the following two lines will be generated in the log file:

This message is for the log file.
And this message is for the lst and the log file.

In addition, the listing file will contain the following two lines just before the report file summary.

This message is for the lst file.
And this message is for the lst and the log file.

Gdxout: Creating GDX Files and Unloading Data to them

Consider the following example:

```
Set j / 2005*2007 /;
Scalar random;
loop(j,
    put_utility 'gdxOut' / 'data' j.tl:0;
    random = uniform(0,1);
    execute_unload random;
);
```

This code will create the GDX files data2005.gdx, data2006.gdx and data2007.gdx. Note that each GDX file will contain a value between zero and 1 for the scalar random. For example, the file data2005.gdx (exported to an ASCII via gdxdump) will have the following content:

```
Scalar random / 0.171747132 /;
```

Gdxin: Loading Data from GDX Files

Note that the following example is an extension of the previous example that demonstrated the use of the command gdxout.

```
loop(j,
    put_utility 'gdxIn' / 'data' j.tl:0 ;
    execute_load random;
    display random;
);
```

This code loads the values of the scalar random from the GDX files data2005.gdx, data2006.gdx and data2007.gdx and displays them in the listing file of the GAMS input file:
3.42 The Put Writing Facility

---- 19 PARAMETER random = 0.172
---- 19 PARAMETER random = 0.843
---- 19 PARAMETER random = 0.550

Shell: Writing to Various Files

Consider the following example:

Set j / j1*j5 /;
Scalar random;

loop(j,
  random = uniformint(0,100);
  put_utility 'shell' / 'echo ' random:0:0 ' > ' j.tl:0;
);

Observe that the shell script command echo outputs an integer between zero and 100 to the files j1, ..., j5.

Click: Adding a Clickable Link

Assume that there is a file called sets.html in our working directory. Consider the following code snippet:

put_utility 'click' / 'sets.html' ;

If we run this code snippet with the GAMS IDE, the following clickable link will appear in the IDE process window:

>>> File sets.html

Solver: Select a solver by name at execution time

The solver keyword allows to select a solver at execution time by name. Normally, the option statement
option solver=xpress, lp=cplex; is used to select the current solver, but in case where you want to
programmatically change the solver as in this example, this put_utility keyword can be useful. Consider the
following code snippet which extends the [DICE] model:

... set slv 'MIP solvers to run' / cplex, gurobi, mosek, scip, xa, xpress /;
parameter rep 'report status, time, objective value, and more';
option bratio=1;
loop(slv,
  put_utility 'solver' / 'mip' / slv.tl:0;
  solve xdice using mip max wnx;
  rep(slv,'sstat') = xdice.solveStat;
  rep(slv,'mstat') = xdice.modelStat;
  rep(slv,'obj') = xdice.objVal;
  rep(slv,'time') = xdice.etSolve;
  rep(slv,'solver id') = xdice.sysIdent;
);
display rep;
If we run this code we get a report like this:

--- 82 PARAMETER rep report status, time, objective value, and more

<table>
<thead>
<tr>
<th>solver</th>
<th>status</th>
<th>time</th>
<th>objective</th>
<th>solver id</th>
</tr>
</thead>
<tbody>
<tr>
<td>cplex</td>
<td>1.000</td>
<td>21.000</td>
<td>0.385</td>
<td>24</td>
</tr>
<tr>
<td>cbc</td>
<td>1.000</td>
<td>21.000</td>
<td>2.547</td>
<td>10</td>
</tr>
<tr>
<td>gurobi</td>
<td>1.000</td>
<td>21.000</td>
<td>1.077</td>
<td>36</td>
</tr>
<tr>
<td>mosek</td>
<td>1.000</td>
<td>21.000</td>
<td>2.372</td>
<td>56</td>
</tr>
<tr>
<td>scip</td>
<td>1.000</td>
<td>21.000</td>
<td>7.346</td>
<td>76</td>
</tr>
<tr>
<td>xa</td>
<td>3.000</td>
<td>21.000</td>
<td>20.061</td>
<td>80</td>
</tr>
<tr>
<td>xpress</td>
<td>1.000</td>
<td>21.000</td>
<td>1.460</td>
<td>81</td>
</tr>
</tbody>
</table>

If one wants to set a solver for all possible model types (similar to `option solver=xpress;`) specific model type has to be replaced by `*`: `put_utility 'solver' / 'xpress';`.

**AssignText: Assigns label text to an element of a singleton set**

GAMS has no string data type. The explanatory or label text of an element can serve in several situations as a poor man's string type and used in `put` and `put_utility` statements. The example below extends the `[TRNSPORT]` model and disables flow on a particular connection. The solution point file created by `savePoint` gets renamed to e.g. `sol.seattle.new-york.gdx`. The filename is assembled using the `assignText` keyword. This has been packaged for better readability in some `STRING` macros:

```gams
$macro STRINGDEF(sym) singleton set sym / sym /
$macro STRING(sym) sym.te(sym)
$macro STRINGASSIGN(sym,text) put_utility 'assignText' / 'sym' / text
$macro STRINGAPPEND(sym,text) put_utility 'assignText' / 'sym' / sym.te(sym) text
alias (i,ii), (j,jj);
transport.savePoint = 1;
STRINGDEF(fname);
loop((ii,jj),
  x.up(ii,jj) = 0;
  solve transport min z using lp;
  x.up(ii,jj) = inf;
  STRINGASSIGN(fname,'sol');
  STRINGAPPEND(fname,'_' ii.tl:0);
  STRINGAPPEND(fname,'_' jj.tl:0 '.gdx');
  put_utility 'shell' / 'mv transport_p.gdx ' STRING(fname);
);
```

3.42.8 Conditional Put Statements

In GAMS, shorthand notation for conditional statement are `dollar conditions`, as introduced in chapter Conditional Expressions, Assignments and Equations. Dollar conditions may also be used in the context of a `put` statement and its variants. The syntax in its most general form is as follows:

```
put $ logical_condition [file_name] item {item} {file_name item {item}};
```
Note that like all put statements, the *conditional* put statement begins with the keyword `put`. The keyword is followed by the dollar operator and a logical condition. If the logical condition is `TRUE` the put statement will be executed, otherwise the put statement will be ignored. For details on logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. Observe that the remainder of the conditional put statement is identical to the regular put statement introduced in section The Put Statement.

The following example demonstrates how dollar conditions are used in the context of put statements.

```plaintext
put$(a > 10) 'Some output items';
```

Note that the quoted text will only be written to the put file if the scalar or variable `a` is greater than 10.

### 3.42.9 Errors Associated with Put Statements

There are two types of errors that may occur when the put writing facility is used: **syntax errors** and **put errors**. In this section we will discuss these errors.

#### 3.42.9.1 Syntax Errors in Put Statements

Syntax errors are caused by the incorrect usage of the GAMS language, including unmatched parentheses, undefined identifiers, uncontrolled sets or the incorrect use of a keyword. These errors are detected during program compilation and are always fatal to program execution. For more information on compilation errors, see section Compilation Errors and the tutorials A GAMS Tutorial by Richard E. Rosenthal and Fixing Compilation Errors.

#### 3.42.9.2 Put Errors

Put errors are unique to the put writing facility. They are detected during program execution and are caused when the specifications of file attributes are violated. Typical errors include assigning inappropriate values to file attributes and attempts to write outside a page, like moving the cursor with the cursor control character `@` to a location beyond the page width. Consider the following example:

```plaintext
File out /out.dat/;
out.pw = 8;
put out "Let's try this.";
```

Note that we specify the page width (`.pw`) to be just 8 characters. However, the quoted text has clearly more than 8 characters. In such a case the GAMS code will be compiled and the log file will report "Normal completion". At the appropriate position in the listing file the following error will be reported:

```
**** PUT ERROR FOR FILE out AT LINE 5: PUT LINE OVERFLOW - LOOK FOR **** ON PUTFILE, YOU CAN RESET .PW UP TO 32767
```

The put file `out.dat` will contain the following line:

```
Let’****
```

As put errors are not fatal and are not emphasized in the log file, they may be easily overlooked. Especially in large put files, put errors may go undetected. GAMS provides the file attribute `.errors` that facilitates the display of the numer of put errors. Consider the following example:

```plaintext
File out /out.dat/;
out.pw = 8;
put out "Let's try this.";
abort$(out.errors) "Put errors in out:", out.errors;
```

Users may choose to output the number of put errors in a put file or display statement or even trigger an execution error as in the example above.
### 3.42.10 Creating a Report for the Model MEXSS

We started this chapter with a simple example and we will complete it with a more elaborate example. In this section we will show how the put writing facility may be used to create a report for the model [MEXSS]. The code for the report may be inserted at the end of the original model and is shown below in its entirety.

The model [MEXSS] analyzes the relative efficiency of five different plants for meeting the product requirements of ingot steel in three different markets. The model may be used to identify the major bottlenecks that constrain production in the system of plants. It will find the production levels in the steel mills and shipments from the mills to the markets that will meet the market requirements at least cost. We will create a report for this model that will present details on the productive units at the five plants, the unused capacities and the marginal values of the capacities. This report may be extended to include other data and results and the code may be reused to create new reports if the data in the model is changed. For models that are run periodically, say, weekly or monthly, reusable reports can be invaluable.

We will start the code for the report with defining the put file, setting the file attributes print control and page size and making the the put file current. Then we will specify some global formatting settings. We will continue with writing a title block and finally turn to the core of the report: a table with three subtables. Note that we will use in-line comments to annotate the code. The code follows:

```gams
$eolcom //
File out /out.dat/;
out.pc=3; out.ps=54; // print control, page size
put out;

* Global Format Settings:
Scalars indent1 indent to first column of units display
indent2 indent to first column of field labels
indent3 indent to first column of first numeric field
textwide wide text / 80 /
textnarr narrow text / 30 / ;

out.nr = 0.01; // numeric round format
out.tw = textwide; // width of text field
out.lw = 11; // width of label field
out.nw = 11; // width of numeric field
out.nd = 2; // number of decimals displayed
indent1 = 3;
indent2 = 30;
indent3 = 27;

* Title Block
puttl 'MEXICO STEEL - SMALL STATIC MODEL':<> /
   system.date:<>/ / /;

* Main Window
out.tj = 3; // alignment of text: center
put
   'This report is based on selected data and results from the model'/
   'MEXSS in the GAMS Library. This model analyzes the relative efficiency'/
   'of five different plants in meeting the product requirements for ingot'/
   'steel in three different markets. The model aims to find the pattern '/
   'of production levels in the mills and shipments from the mills to the '/
   'markets that will meet the market requirements at the least cost. '/
/

Note that we set print control (.pc) to ASCII formfeed. Below we illustrate how to use one of the print control settings that generate a delimited file. Observe that we group all global format parameters and settings near the top of the code. This way of organizing the code will make it easy to modify the structure of the report in the future as needed. Observe further, that the output items in the title block are locally formatted to be center aligned.

In the remainder of the code the actual report is written in the main window. The block of text at the beginning serves as a brief introduction to the report. Note that the core of the report is a table consisting
of three subtables, where the subtables share the column headings. Before writing the table, we insert a test - the conditional putpage statement - to determine whether there is a sufficient number of lines on the current page to accommodate the size of the first subtable. Thus the put writing facility would start a new page if there were not enough rows. We repeat similar tests before the code for the other two subtables. Observe that we insert a header block with the column headings. If a new page had to be started since there were not enough rows for the second or the third subtable, the header block would contain the column headings of the table. (Users might want to experiment by reducing the file attribute page size (.ps) to say, 30.) The report that will be generated follows:

MEXICO STEEL - SMALL STATIC MODEL  
01/31/17

This report is based on selected data and results from the model MEXSS in the GAMS Library. This model analyzes the relative efficiency of five different plants in meeting the product requirements for ingot steel in three different markets. The model aims to find the pattern of production levels in the mills and shipments from the mills to the markets that will meet the market requirements at the least cost.

<td>138.03</td>
<td>140.00</td>
<td>0.00</td>
<td>94.28</td>
</tr>
</tbody>
</table>

Assume we need the data reported in the first subtable above in a delimited file format in order to import it to other applications, like spreadsheets or databases. Consider the following code:

```
file out2 / 'out2.csv' /;
```
Note that we set the file attribute page control (\texttt{.pc}) to 5. This means that non-numeric output items will be quoted and each output item will be delimited with commas. Observe that field widths, alignments and horizontal cursor relocations were completely avoided. The put file \texttt{out2.put} will contain the following lines:

\begin{verbatim}
"capacity (metric tons)","ahmsa","fundidora","sicartsa","hylsa","hylsap"
bblast furnaces",3.25,1.40,1.10,0.00,0.00,0.00
"open hearth furnaces",1.50,0.85,0.00,0.00,0.00,0.00
"basic oxygen converters",2.07,1.50,1.30,0.00,0.00,0.00
"direct reduction units",0.00,0.00,0.00,0.98,1.00
"electric arc furnaces",0.00,0.00,0.00,1.13,0.56
\end{verbatim}

While a comma is the most commonly used delimiting character, other delimiters like a blank space (\texttt{.pc=4}) and a tab (\texttt{.pc=6}) may also be used.

For other examples of code that uses the put writing facility, see the various models in the GAMS Model Library.

### 3.43 Solver Usage

For the novice GAMS user, solver usage can be very simple: one runs the model and inspects the listing file to see what the solution is. No knowledge of solver options or solver specific return codes is required. While this is enough for some users, most will quickly find they need some basic knowledge of how to control the solver and interpret the results. Section \textbf{Controlling a Solver via GAMS Options} describes how to set the GAMS options that control a solver. Further, most solvers allow the user to set additional, solver-specific options. These can be set via a solver specific options file, which will be discussed in Section \textbf{The Solver Options File}. However, use of generic GAMS options should be preferred, since a GAMS option setting applies to all solvers and is interpreted by the solvers in a consistent way.

A number of solvers can make use of an initialization of variable and equation values. This will be discussed in \textbf{Starting Point and Initial Basis}.

Further solver specific topics, which are more interesting for advanced users, are discussed in the Sections \textbf{Solve trace} and \textbf{Branch-and-Cut-and-Heuristic Facility (BCH)}.

For some hints on how to select a solver, see \textbf{Choosing an appropriate Solver}.
3.43.1 Controlling a Solver via GAMS Options

GAMS options can be set on the GAMS command line, e.g.,

\$ gams trnsport iterlim = 100

Additionally, they can be set by an option statement within a GAMS model, e.g.,

\texttt{option iterlim = 100;}

Finally, a model attribute can set a GAMS option for an individual model:

\texttt{mymodel.iterlim = 100;}

The model suffix takes precedence over the option statement, which takes precedence over the command line parameters. If none of these methods is used to set an option, default values apply.

Further, one can unset any model-specific option by assigning it the value \texttt{NA}:

\texttt{mymodel.iterlim = NA;}

Unfortunately, not every option can be via as command line parameter, option statement, and model attribute. We refer to

- **Solver-Related Options** for the list of solve-related options that can be set via the command line,
- **Options that Control Solver-Specific Parameters and Options that Control the Choice of Solver** for the list of solve-related options that can be set via the option statement, and
- **Model Attributes Mainly Used Before Solve** for the list of solve-related model attributes.

3.43.2 The Solver Options File

To specify solver-specific options, it is necessary to use a solver option file. Two things are required to do this: one must create an option file having a proper name, and one must tell the solver to read and use this option file.

To tell a solver to use an option file, one can set the \texttt{optfile} model attribute or the \texttt{optfile} option to a positive value. For example,

\begin{verbatim}
model mymodel /all/;
   mymodel.optfile = 1;
   solve mymodel using nlp maximizing dollars;
\end{verbatim}

The option file takes its name from the solver being used: \texttt{solvername.XYZ}, where \texttt{solvername} is the name of the solver that is specified, and the suffix \texttt{XYZ} depends on the value to which \texttt{optfile} has been set. If its value is 1, the suffix is \texttt{opt}. For example, the option file when calling CONOPT would be called \texttt{conopt.opt}. See the documentation on \texttt{optfile} for more information.

The format of the options file can change marginally from solver to solver. The following illustrates some frequent features of the option file format. However, solvers may vary from this format. Thus, the solver-specific documentation should be checked before using an option file.
Blank lines in an option file are ignored.

A comment line might begin with an asterisk (*) in the first column, is not interpreted by either GAMS or the solver, and is used purely for documentation.

Each non-comment line contains only one option specification.

The format for specifying options is as follows:

```
keyword(s) [modifier] [value]
```

The keyword may consist of one or more words and is not case sensitive. The value might be an integer, a real, or a string. Real numbers can be expressed in scientific format, e.g., 1e-6. Note that not all options require modifiers or values.

Any errors in the spelling of keyword(s) or modifiers will lead to that option being misunderstood and therefore ignored. Errors in the value of an option can result in unpredictable behavior. When detected, errors are either ignored or pushed to a default or limiting value, but not all can or will be detected.

Consider the following CPLEX options file,

```
* CPLEX options file
barrier
crossover 2
```

The first line begins with an asterisk and therefore contains comments. The first option specifies the use of the barrier algorithm to solve the linear programming problem, while the second option specifies that the crossover option 2 is to be used. Details of these options can be found in Summary of CPLEX Options.

Consider the following MINOS options file,

```
* MINOS options file
scale option 2
completion partial
```

The first option sets the scale option to a value of 2. In this case, the keyword 'scale option' consists of two words. In the second line, the completion option is set to partial. Details of these options can be found in Summary of MINOS Options.

### 3.43.2.1 Dot Options

Dot options in a solver option file allow users to associate values to variables and equations using the GAMS name of the variables and equations. The general syntax of a dot option in the option file is as follows:

```
(variable/equation name).optionname (value)
```

Dot options can be specified for all, a block, a slice, and a single variable and equation. Please note that a specific dot option may only apply to variables or equations (e.g. the GAMS/Gurobi dot option prior applies to variables only). The following example makes the use of the dot option clear.

For example, suppose one has a GAMS declaration:

```gams
Set i /i1*i5/;
Set j /j2*j4/;
Variable v(i,j);
Equation e(i,j);
```

Consider the following lines in an option file with the imaginary option name dotopt:

```
Set i /i1*i5/;
Set j /j2*j4/;
Variable v(i,j);
Equation e(i,j);
```
<table>
<thead>
<tr>
<th>Line in option file</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>variables.dotopt 1</td>
<td>Sets the value of all variables to 1</td>
</tr>
<tr>
<td>equations.dotopt 2</td>
<td>Sets the value of all equations to 2</td>
</tr>
<tr>
<td>v.dotopt 3</td>
<td>Sets the value of the variables in block v to 3</td>
</tr>
<tr>
<td>e.dotopt(∗,∗) 4</td>
<td>Sets the value of the equations in block e to 4</td>
</tr>
<tr>
<td>v.dotopt(∗,’j2’) 5</td>
<td>Sets the value of the variables v that have j2 in the second index position (slice) to 5</td>
</tr>
<tr>
<td>e.dotopt(‘i3’,∗) 6</td>
<td>Sets the value of the equations e that have i3 in the first index position (slice) to 6</td>
</tr>
<tr>
<td>w.dotopt(‘i2’) 7</td>
<td>Sets the value of the single variables v(‘i2’) to 7</td>
</tr>
<tr>
<td>e.dotopt(‘i3’,’j3’) 8</td>
<td>Sets the value of the single equations e(‘i3’,’i3’) to 8</td>
</tr>
</tbody>
</table>

The values of the dot option are applied in correspondence to the sequence in which they appear in the option file. In the current example, the values of dotopt for the equation e would be as follows:

<table>
<thead>
<tr>
<th>e.dotopt</th>
<th>i1</th>
<th>i2</th>
<th>i3</th>
</tr>
</thead>
<tbody>
<tr>
<td>j2</td>
<td>4</td>
<td>4</td>
<td>6</td>
</tr>
<tr>

### 3.43.3 Starting Point and Initial Basis

#### 3.43.3.1 Starting Point

NLP solvers that search for a locally optimal solution of a NLP require an initial point to start their search. Further, as closer this initial point is to a local optimum, the less effort the solver may have to spend. The latter can also be true for solvers that search for global optimal solutions, such as most LP or MIP solver or global MINLP solvers.

Because of this immense importance of a starting point, GAMS always passes a starting point to a solver. By default, the point passed on by GAMS is given by the level and marginal attributes of variables and equations. If these values have not been set yet, default values are used. This default value is zero, except for variables which bounds would forbid this value. In this case, the bound closest to zero is used.

Next to setting these values explicitly in a GAMS model, a user can also load them from a save file or a GDX point file via execute_loadpoint. The latter may have been generated by running a related model and using option savepoint. Further, in models with several solve statements, the solution from one solve, if any, is used to initialize the starting point for a succeeding solve. This happens automatically since solutions from a solve statements are also stored in the level and marginal values of variables and equations. Finally, note that model attribute defpoint can be used to force sending the default starting point to a solver.

For some solvers, in particular for MIP or MINLP, an option may have to be set to make use of the starting point. Further, some solvers offer the possibility to make use of a partial starting point or use the starting point as a guide for the search. For details, see the specific solver manuals and look for parameters like mipstart and the use of the GAMS parameter tryint.
3.43.3.2 Initial Basis

While for some solvers, the values of a starting point are sufficient to initialize the search, active-set based algorithms make use of a different form of starting information. An active-set based algorithms tries to identify which constraints are active (or binding) in a feasible or optimal solution, that is, which variable are at one of their bounds (if any) and for which equations the activity equals to the right-hand-side. For linear programs, the simplex algorithm is such an algorithm. The classifications of constraints into active and inactive ones is called a basis. Active constraints are called nonbasic and inactive constraint are called basic. A basis that specifies the active constraints in an optimal solution is called an optimal basis.

Active-set based algorithms may start by guessing an initial basis and then iteratively update this basis by switching the basic-status of constraints until an optimal basis is found. Therefore, solution time may be reduced substantially if one can identify a priori a good approximation of an optimal basis. Such a user-provided initial basis is also called an advanced basis. However, provision of an advanced basis does not always help. Especially presolving algorithms in a solver may cause that a user provided initial basis is ignored. Further, solvers may perform poorly when the given basis is "worse" than what the solver would otherwise have constructed with its own heuristics. Finally, it is needless to say that only active-set based algorithms are amenable to the use of an initial basis.

If sufficient information is available in the starting point, then GAMS uses these values to automatically form an initial basis for a solver. This basis is formed as follows:

- Variables with a zero level value are suggested to be nonbasic, if and only if they have a non-zero marginal value.
- Variables with a non-zero level value are suggested to be nonbasic, if and only if the level value equals to one of the variable bounds. As a variable at one of their bounds indicates that the bound may be binding, nonbasic variables should also have non-zero marginal.
- Equations with non-zero marginal are suggested to be nonbasic. Otherwise, they are suggested to be basic.

Next, GAMS decides whether the so formed basis contains sufficiently many nonbasic entries. It does so by checking whether the number of nonbasic entries in the basis exceeds the number of equations times the value of GAMS option bratio. Thus in a problem with 1000 equations and with the default value of bratio (0.25), GAMS will not suggest a basis unless it could find at least 250 nonbasic constraints.

Note, that the default starting point is usually not sufficient for the construction of an initial basis. If the automatic transfer of a basis from one solve statement to the next leads to poor behavior in the solver, setting the option bratio to 1 or the model attribute defpoint to 1 can suppress the use of an initial basis.

A user can also attempt to explicitly provide an initial basis by setting a corresponding starting point. That is, one can set a guess for an initial basis by specifying

- non-zero marginals for equations that are felt to be active in a solution
- non-zero marginals for variables that are felt to be at their bound in a solution
- non-zero levels for the variables that are felt to be non-zero in a solution
3.43.4 Solve trace

In order to do accurate performance evaluations it may be useful to obtain more detailed information about a solve than the "end data" that the trace file provides. E.g., for a branch-and-bound based solver, one may want to have intermediate information about the values of primal and dual bounds at the root node and subsequent nodes within the search.

The solve trace option that is implemented in some of the GAMS solver interfaces allows users to output solve information, e.g., primal and dual bounds, for every n nodes or at every time step. For example, the user may be interested in the objective value of the incumbent solution or the best dual bound on the optimal value every 50 nodes and every five seconds of the solve.

Note

The solve trace file format and options may change in a future GAMS release.

The solve trace option is invoked via a GAMS solver options file. Usually, options to specify a filename of the trace file to be created and options to specify time and node intervals are available. Please refer to the GAMS solver manuals for the exact names of these options (search for solvetrace or miptrace).

The solve trace file is written in comma-separated-value (CSV) format, where the entries in each line have the following meaning:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>lineNum</td>
<td>a line index</td>
</tr>
<tr>
<td>seriesID</td>
<td>indicator why the line was written: S = start of search, N = node frequency, T = time frequency, E = end of search</td>
</tr>
<tr>
<td>node</td>
<td>number of enumerated branch-and-bound nodes</td>
</tr>
<tr>
<td>seconds</td>
<td>time since the solving started</td>
</tr>
<tr>
<td>bestFound</td>
<td>primal bound, i.e., objective value of incumbent solution</td>
</tr>
<tr>
<td>bestBound</td>
<td>dual bound, i.e., bound on optimal value</td>
</tr>
</tbody>
</table>

A sample solve trace file is miptrace.mtr where the file includes statistics of a GAMS run using the MIP model blend2 from the Performance Library and the solver Xpress. See also the slides for the presentation Advanced Use of GAMS Solver Links (2013) for some ideas on what to do with the solve trace functionality.

3.43.5 Branch-and-Cut-and-Heuristic Facility (BCH)

Global search algorithms can sometimes significantly benefit from user supplied routines that support the solution process of an hard optimization problem. For example, branch-and-cut solvers (e.g., CPLEX, Gurobi, SCIP, Xpress) can profit from user-supplied cutting planes or good feasible solutions. GAMS users could supply these as part of the model given to the solver, by adding a set of constraints representing likely to be violated cuts and an initial solution (possibly in combination with GAMS parameters like tryint and solver-specific options like mipstart in CPLEX). However, this does not allow a dynamic interaction between a running solver and user supplied routines that, for example, use a current relaxation solution to construct cutting planes or feasible solutions. The GAMS Branch-and-Cut-and-Heuristic (BCH) facility attempts to automate all major steps necessary to make callbacks that certain solvers provide for such usage available to the GAMS user. This allows GAMS users to apply complex solution strategies without having to have intimate knowledge about the inner workings of a specific solver.

Currently, only two solvers support the BCH facility: CPLEX and SBB. With GAMS/CPLEX, user supplied GAMS programs that implement primal heuristics and cut generation can be used. With SBB, only primal heuristics are possible.
As the name indicates, the BCH facility has been designed with the solving process of a branch-and-cut solver (e.g., CPLEX, Gurobi, SCIP, Xpress) in mind. Such solvers often allow to call a user supplied routine after a node in the branch-and-bound (B&B) tree has been processed. Within that routine, available information like the solution of a relaxation (often an LP or NLP) at that node and the current incumbent, if any, is exported by the BCH facility into a GDX file using the original GAMS namespace. Next, different user supplied GAMS programs can be called, e.g., for finding cuts which are violated by the relaxation solution (cut generator) or to find new incumbents (primal heuristic). These GAMS programs should import the information from the GDX file and do their computations. After termination, the BCH facility resumes control, reads the findings from the GAMS program and passes them to the solver.

A relaxation solution may be exported into a file `bchout.gdx` by the BCH facility. This GDX file does not only contain the variable values as level values (.l), but also variable bounds (.lo and .up). For a B&B solver, these are the local bounds at this node. Hence, they reflect branching decisions made in the B&B tree and bound tightenings that were deduced by the solver. In a similar way, the BCH facility may export an incumbent solution to the GDX file `bchout_i.gdx`. The bounds for the incumbent solution reflect global bounds, i.e., the original bounds, possibly tightened by the solver. GDX files can be imported by the GAMS program using the compile time `$load` or run time `execute_load`.

The BCH facility is activated and controlled by setting certain options in the solvers options file. The precise names and meanings of the options may vary from one solver to another. Therefore, also the corresponding GAMS solver manual should be checked. The options that come with the BCH facility can be used to define the calls of the users GAMS programs, to determine when they should be called, and to overwrite the filenames for the GDX files (to avoid name clashes). General BCH related options are the following:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserGDXIn</td>
<td>The name of the GDX file read back into the solver.</td>
<td>bchin.gdx</td>
</tr>
<tr>
<td>UserGDXName</td>
<td>The name of the GDX file exported from the solver with the solution at the node.</td>
<td>bchout.gdx</td>
</tr>
<tr>
<td>UserGDXNameInc</td>
<td>The name of the GDX file exported from the solver with the incumbent solution.</td>
<td>bchout_i.gdx</td>
</tr>
<tr>
<td>UserGDXPrefix</td>
<td>Prefix to add to UserGDXIn, UserGDXName, and UserGDXNameInc</td>
<td>empty</td>
</tr>
<tr>
<td>UserJobID</td>
<td>Postfix to add to listing and log filenames and to UserGDXIn, UserGDXName, and UserGDXNameInc. Further, --UserJobID is added to calls to users GAMS programs.</td>
<td>empty</td>
</tr>
<tr>
<td>UserKeep</td>
<td>Calls users GAMS programs with <code>gamskeep</code> instead of <code>gams</code>.</td>
<td>0</td>
</tr>
</tbody>
</table>

In the following, the interface for the available callbacks are explained in more detail and corresponding options are listed.

### 3.43.5.1 Primal Heuristics

In the primal heuristic callback, the user can provide a GAMS program which tries to construct a feasible solution based on the information provided by the solver, e.g., a current relaxation solution and the current incumbent. Thus, the GAMS program could attempt to repair infeasibilities in the relaxation solution or try to improve the incumbent from the solver.

If the GAMS program finds a new solution, it should store it in the level values of variables that correspond to the original variables. For example, if the original model uses binary variable `open(i,t)`, then at the end of the GAMS program `open.l(i,t)` should contain a 0 (zero) or a 1 (one). The BCH facility calls the GAMS program and instructs GAMS to store the results in a GDX file at termination. This GDX file is then read in again by the BCH facility and the solution is passed back to the solver. The solver checks this solution for infeasibilities and in case this check is passed and the solution is better than the best known solution, the solver updates it's incumbent.
If the GAMS program cannot find a feasible solution, it can terminate with an execution error triggered by an `abort` statement to prevent the BCH facility from reading the results from the heuristic run.

BCH parameters to control the primal heuristic call are typically the following:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserHeurFreq</td>
<td>Determines the frequency of the heuristic call.</td>
<td>10</td>
</tr>
<tr>
<td>UserHeurMult</td>
<td>Determines the multiplier for the frequency of the heuristic call.</td>
<td>2</td>
</tr>
<tr>
<td>UserHeurInterval</td>
<td>Determines the interval when to apply the multiplier for the frequency of the heuristic call. For example, for the first 100 (UserHeurInterval) nodes, the solver calls the heuristic every 10th (UserHeurFreq) node. After 100 nodes, the frequency gets multiplied by 10 (UserHeurMult), so that for the next 100 nodes the solver calls the heuristic every 20th node. For nodes 200-300, the heuristic get called every 40th node, for nodes 300-400 every 80th node and after node 400 every 100th node.</td>
<td>100</td>
</tr>
<tr>
<td>UserHeurFirst</td>
<td>For how many of the first nodes the heuristic should be called.</td>
<td>10</td>
</tr>
<tr>
<td>UserHeurObjFirst</td>
<td>Similar to UserHeurFirst, but specifies for how many of the first nodes the heuristic should be called if the optimal value of the current nodes relaxation promises a significant improvement of the current incumbent, i.e., the optimal value of the relaxation at the node has to be closer to the current dual bound than the current primal bound.</td>
<td>solver dependent</td>
</tr>
<tr>
<td>UserHeurNewInt</td>
<td>Whether to call the heuristic when the solver found a new feasible solution.</td>
<td>no</td>
</tr>
<tr>
<td>UserHeurCall</td>
<td>Arguments to the GAMS call to invoke the heuristic GAMS program.</td>
<td>empty</td>
</tr>
</tbody>
</table>

As an example, for the Oil Pipeline Network Design problem, the BCH options to invoke the primal heuristic in the GAMS program `bchoil_h.inc` when using GAMS/CPLEX could be

```
userheurcall   bchoil_h.inc mip cplex optcr 0 reslim 10
userheurfirst  5
userheurfreq   20
userheurinterval 1000
```

### 3.43.5.2 Cutting Planes

In the cut generator callback, the user can provide a GAMS program which tries to find a linear cut (that is, a linear inequality) that is violated by the relaxation solution. The solver would then add these cuts to its cut pool. Typically, it then resolves the relaxation at the node and calls the cut generator again. If no cutting planes are found, the solver will continue, e.g., by processing the next node. Please note that the solver cannot perform validity checks on the provided cuts. Hence, it is possible to cut off areas of the feasible region, including optimal solutions.

Exporting cuts is a little more complicated than a solution because next to the cut coefficients, also the sense and the right-hand-side of the cut inequality needs to be exported. Further, exporting several cuts with one call should be possible. For this purpose, the GAMS program has to define and fill a set `cc` and parameters `numcuts`, `rhs_c(cc)`, and `sense_c(cc)` appropriately. The set `cc` is used as a cut index. It can be larger than the number of actually generated cuts. Parameter `numcuts` should specify the number of added cuts. `rhs_c(cc)` should store the right-hand-side of each cut. Finally, `sense_c(cc)` should store the sense of each cut, which must be 1 for lower-equal (\(\leq\)), 2 for equal (\(=\), rather unusual for cuts), and 3 for greater-equal (\(\geq\)). The corresponding declaration in GAMS code may be
The only thing missing are the cut coefficients. As it should be possible to return more than one cut, using variable attributes like level values is not sufficient. Therefore, for each variable that is part of a cut, a new parameter must be added in the GAMS program. The name of the parameter must be the name of the corresponding variable with an additional \texttt{c} at the end. Further, the parameter must be indexed like the variable, but with the cut index set \texttt{cc} added at the beginning. For example, assume variable \texttt{open(i,t)} should be part of a cut. Then the cut coefficients should be stored in a parameter \texttt{open.c(cc,i,t)}, e.g.,

Parameter \texttt{open.c(cc,i,t) \textquote{coefficients of variable open(i,t) in cut cc'}};

The BCH facility reads all parameters that end in \texttt{c}, takes the base name and looks for a variable with that name and indices and builds up the cut matrix. A cut cannot introduce a new variable into the model. All cuts added to the model are assumed to be \textit{global cuts}, that is, they need to be valid for the entire problem, not just for the current node.

**BCH parameters to control the cut generation call are typically the following:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserCutFreq</td>
<td>Determines the frequency of the cut generator call.</td>
<td>10</td>
</tr>
<tr>
<td>UserCutMult</td>
<td>Determines the multiplier for the frequency of the cut generator call.</td>
<td>2</td>
</tr>
<tr>
<td>UserCutInterval</td>
<td>Determines the interval when to apply the multiplier for the frequency of the cut generator call. See UserHeurInterval for details.</td>
<td>100</td>
</tr>
<tr>
<td>UserCutFirst</td>
<td>Calls the cut generator for the first n nodes.</td>
<td>10</td>
</tr>
<tr>
<td>UserCutNewInt</td>
<td>Whether to call the cut generator if the solver found a new integer feasible solution.</td>
<td>no</td>
</tr>
<tr>
<td>UserCutCall</td>
<td>Arguments to the GAMS call to invoke the cut generator GAMS program.</td>
<td>empty</td>
</tr>
</tbody>
</table>

As an example, for the Oil Pipeline Network Design problem, the BCH options to invoke the cut generator in the GAMS program \texttt{bchoil.c.inc} when using GAMS/CPLEX could be

```bash
usercutcall  bchoil_c.inc mop cplex
usercutfirst 0
usercutfreq 0
usercutnewint yes
```

### 3.43.5.3 Incumbent Callbacks

The incumbent callbacks can be used to execute a GAMS program when the solver found a new feasible solution that improves the incumbent. Additionally, the incumbent check callback \texttt{UserIncbCall} can be used to notify the solver whether the given feasible solution should be accepted by the solver. This allows to implement a filtering mechanism that forces a solver to search for additional solutions even though an optimal solution might have been found already.

The following parameters control the incumbent callbacks:
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserIncbCall</td>
<td>Arguments to the GAMS call to invoke the incumbent checking GAMS program. The incumbent is rejected if the GAMS program terminates normally. In case of a compilation or execution error, the incumbent is accepted.</td>
<td>empty</td>
</tr>
<tr>
<td>UserIncbICall</td>
<td>Arguments to the GAMS call to invoke the incumbent reporting GAMS program.</td>
<td>empty</td>
</tr>
</tbody>
</table>

### 3.43.5.4 Examples

The GAMS model library contains a few examples to show how to use the BCH facility:

- **bchtlbas.gms**: Trim Loss Minimization with Heuristic using BCH Facility This model implements a very simple LP/MIP-based primal heuristic for the trimloss minimization problem.
- **bchfcnet.gms**: Fixed Cost Network Flow Problem with Cuts using BCH Facility This model implements simple but difficult to separate cuts for a network design problem. The global solver BARON is used to find violated cuts by solving a non-convex MINLP.
- **bchmknap.gms**: Multi knapsack problem using BCH Facility This model implements simple cover inequalities for the multi-knapsack problem.
- **bchoil.gms**: Oil Pipeline Design Problem using BCH Facility This is the most complex example. It implements three different primal heuristics: an initial heuristic based on a simplified cost structure, a rounding heuristic, and a local branching heuristic. In addition, complex cuts are generated by solving regionalized versions of the original problem.
- **dicegrid.gms**: MIP Decomposition and Parallel Grid Submission - DICE Example This example uses many of the UserJobID option to rename files, since running multiple jobs in parallel requires the use of different filenames. This example also uses the incumbent reporting call UserIncbICall.
- **solnpool.gms**: Cplex Solution Pool for a Simple Facility Location Problem This example uses the incumbent checking call UserIncbCall as an advanced filter for accepting or rejecting solutions found by CPLEX.

### 3.43.6 Choosing an appropriate Solver

For any of the GAMS problem classes (LP, MCP, MINLP, ...), there is no solver that is best on every problem instance. Below, we provide some links to rules of thumb on choosing a solver or solver comparisons.

- M. Bussieck and S. Vigerske, MINLP Solver Software.
- H. Mittelmann: Decision Tree for Optimization Software and Benchmarks for Optimization Software
3.43.6.1 Relative Merits of MINOS and CONOPT

3.43.6.1.1 How to choose between MINOS and CONOPT
It is almost impossible to predict how difficult it is to solve a particular model. The best and most reliable way to find out which solver to use is to try out both. However, there are a few rules of thumb:

CONOPT is well suited for models with very non-linear constraints. If you experience that MINOS has problems achieving feasibility during the optimization, you should try CONOPT. On the other hand, if your model has few nonlinearities outside the objective function, MINOS and QUADMINSOS is probably the best solver.

CONOPT is has a fast method for finding a first feasible solution that is particularly well suited for models with few degrees of freedom (this means: the number of variables is approximately the same as the number of constraints - in other words, models that are almost square). In these cases CONOPT is likely to outperform MINOS while for models with many more variables than equations MINOS is probably more suited.

CONOPT has a preprocessing step in which recursive equations and variables are solved and removed from the model. If you have a model where many equations can be solved one by one, CONOPT will take advantage of this property. Similarly, intermediate variables only used to define objective function terms are eliminated from the model and the constraints are moved into the objective function.

CONOPT has many built-in tests (e.g. tests for detecting poor scaling). Many models that can be improved by the modeler are rejected with a constructive message. CONOPT is therefore a useful diagnostic tool during model development even if another solver is used for the production runs.

3.43.6.1.2 Why serious NLP modelers should have both MINOS and CONOPT
It is almost impossible to predict how difficult it is to solve a particular model. However, if you have two solvers, you can try both. The overall reliability is increased and the expected solution time will be reduced.

On a test set of 196 large and difficult models, many poorly scaled or without initial values, both MINOS and CONOPT failed on 14 models. However only 4 failed on both MINOS and CONOPT. So the reliability of the combined set of solvers is much better than any individual solver.

Many examples of poorly formulated models were observed on which MINOS failed. CONOPT rejected many of the models, but with diagnostic messages pinpointing the cause of the problem. After incorporating the changes suggested by CONOPT, both MINOS and CONOPT could solve the model. Switching between the two solvers during the initial model building and debugging phase can often provide useful information for improving the model formulation.

3.43.6.1.3 Special Offer for two NLP Solvers
In order to encourage modelers to have two NLP solvers, GAMS offers a 50% discount on the second solver when both MINOS and CONOPT are purchased together.

3.43.6.2 PATH versus MILES

This document describes some of the differences between the MCP solvers PATH 4.7 and MILES. MILES is a free solver, that comes with the GAMS/BASE module, while PATH is an optional solver, that is charged for separately.

PATH and MILES are two GAMS solvers capable of solving mixed nonlinear complementarity problems (MCP). Both solvers are based on the sequential linear complementarity algorithm, i.e., they both solve a sequence of linear mixed complementarity problems whose solutions typically converge to the solution of the MCP. To solve each of the linear subproblems (major iterations), both codes use a generalization
of an algorithm due to Lemke that is based on a sequence of pivots (minor iterations) similar to those
generated by the simplex method for linear programming. To do these pivots efficiently, both codes use
the same sparse linear algebra package.

As a result of the above similarities, the performance of the two codes is comparable for many "easy"
models. Viewed over a broad range of problems, however, PATH is typically faster and more robust
than MILES. While both codes solve all the MCP and MPSGE models in GAMSlib, PATH significantly
outperforms MILES on the MCPLIB test collection found at CPNET.

Most sophisticated MCP and MPSGE modelers prefer to use PATH over MILES. PATH has a crashing
scheme that allows it to quickly improve the user given starting point before starting to solve the linear
subproblems. This frequently speeds up solution time. PATH automatically attempts to fix "singular"
models using a technique based on proximal perturbations. In many cases, this enables the linear
subproblems to be solved, leading to a model solution. This typically helps modelers at model development
time.

PATH has many more solution options to enable it solve difficult models. The code automatically tries
useful options on difficult problems using a restart procedure. PATH has a much more sophisticated
"globalization" procedure that typically improves speed and robustness. PATH implements a nonmonotone
 watchdog technique. Stalling is frequently circumvented by allowing larger steps to be taken toward
solutions.

PATH has many more diagnostic features that help uncover problems in a model. In particular, singularities
in the model, zero rows and columns and several measures of optimality are returned to the user.
Theoretically, PATH has better convergence properties than MILES. In particular, new merit functions
are known to allow more reliable and faster convergence.

3.44 The Save and Restart Feature

GAMS saves the information provided in input files in intermediate - mostly binary - files, called work
files or scratch files. Some of these files are used to exchange information between GAMS and the solvers.
They are usually deleted just before a GAMS run is complete. However, these intermediate files may be
used to process an input file, save the result and later reload this file and continue with processing another
input file. Thus, input files may be processed sequentially through the use of the intermediate files. This
is a useful feature that can help to reduce the required time when, e.g., several runs of similar models are
being made, all of them sharing an equal large initialization part.

The same process may be described in a different way. Assume a large GAMS program is run and an
output file is generated, as usual. Suppose the large program is split in two parts. The first part is run
and the resulting work file is saved along with the resulting listing file. Then the second part is run after
reading in the data from the work file saved previously and a new listing file is generated for the second
part. The content of the two listing files will be the same as the content of the output from the very first
run when the large program was processed without interruption. Only the arrangement of the content will
slightly differ. Splitting the files makes it possible to interrupt a GAMS task and restart it later without
loss of information. Furthermore, changes could be made or errors corrected in the later parts.

Note

The work file preserves all information (including declarations, values, option settings and dollar
command line parameters) known to GAMS at the end of the run.
The work file is not machine specific and thus is portable between platforms. However, a work file
that has been generated with one version of GAMS cannot be used for a restart with an older GAMS
version.

This chapter illustrates the basics of the save and restart feature in Section Basic Usage and presents some
use cases in Section Use Cases. Preventing unauthorized access to and obfuscating the content of work
files is discussed in Sections Secure Work Files and Obfuscated Work Files, respectively. An overview of
all command line parameters for saving and restarting in GAMS is given in Section Solve and Restart
Options (chapter The GAMS Call and Command Line Parameters).
3.44 The Save and Restart Feature

3.44.1 Basic Usage

The mechanism to break up the compilation of a large input file into many components and stages is provided by the command line parameters `save` and `restart`.

The following demonstrates saves and restarts with the well known transportation model `[TRNSPORT]`. First, the code is split into three parts, resulting in the files `tranmodel.gms`, `transolve.gms`, and `tranreport.gms`. The file `tranmodel.gms` contains the first part of the model up to and including the model statement:

Sets
  i "canning plants" / seattle, san-diego /
  j "markets" / new-york, chicago, topeka / ;

Parameters
  a(i) "capacity of plant i in cases"
    / seattle 350
    san-diego 600 /
  b(j) "demand at market j in cases"
    / new-york 325
    chicago 300
    topeka 275 /

Table d(i,j) "distance in 1000 miles"
  new-york   chicago topeka
  seattle    2.5     1.7     1.8
  san-diego  2.5     1.8     1.4 ;

Scalar f "freight in dollars/case per 1000 miles" /90/ ;

Parameter c(i,j) "transport cost in $1000/case";
c(i,j) = f * d(i,j) / 1000 ;

Variables
  x(i,j) "shipment quantities in cases"
  z "total transportation costs in 1000$" ;

Positive Variable x ;

Equations
  cost "define objective function"
  supply(i) "observe supply limit at plant i"
  demand(j) "satisfy demand at market j" ;

  cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;
  supply(i) .. sum(j, x(i,j)) =l= a(i) ;
  demand(j) .. sum(i, x(i,j)) =g= b(j) ;

Model transport /all/ ;

The file `transolve.gms` contains the solve statement:

  solve transport using lp minimizing z;

And the third file, `tranreport.gms`, contains the display statement:

  display x.l, x.m ;

Observe that concatenating the three files (in the right order) results in the original model `[TRNSPORT]`. 
3.44.1.1 Saving The Work File

The information in `tranmodel.gms` may be stored by using the following call to GAMS:

> gams tranmodel save=s1

This command line statement creates the output file `tranmodel.lst` and the work file `s1.g00` in the current working directory. Observe that actually eight save files are created by GAMS. For information on the names of these save files, see the detailed description of the command line parameter `save`.

Note that the command line parameter `s` is a synonym to `save`.

3.44.1.2 Restarting from the Work File

Consider the following call:

> gams transolve restart=s1

GAMS reads the work file named `s1.g00` and regenerates the information stored in `tranmodel.gms`. Then `transolve.gms` is run and the result is as if the a concatenation of `tranmodel.gms` and `transolve.gms` had been executed. Note, that the output file `tranmodel.lst` will contain the echo print of the model and `transolve.lst` will contain the echo print of the solve statement and all the output generated by the solve.

Note that the command line parameter `r` is a synonym of `restart`.

Observe that a restarted run always requires a GAMS input file to continue with. The restart does not alter work files. They may be used repeatedly to continue a particular run many times, possibly with many different continuation input files.

3.44.1.3 A Sequence of Saves and Restarts

In case there are more than two files that should be run sequentially, the second and any other non-final run will have to generate input files for a following restart. Therefore, their workfiles need to be saved.

Following the splitup of model [TRNSPORT] into the three files `tranmodel.gms`, `transolve.gms`, and `tranreport.gms`, a sequence of GAMS calls that would run the whole `trnsport` model could be as follows:

> gams tranmodel     s=s1
> gams transolve     r=s1 s=s2
> gams tranreport     r=s2

The listing file of `tranreport.gms` will contain the compilation output with the echo print of the display statement, the final execution summary with the output generated from the display statement and the file summary. The listing files of all three input files together will have the same content as `trnsport.lst` (generated by a run of `trnsport.gms`).

Observe that the three files could also have been processed with a sequence of `$include` file statements. The advantages of using the `save` and `restart` feature instead are given in section Use Cases below.
3.44 The Save and Restart Feature

3.44.1.4 Avoiding Common Mistakes

A common mistake that occurs when using the save and restart feature is running GAMS on the same file twice, e.g.,

```gams
> gams transport s=trans
> gams transport r=trans
```

In this case all the data and equation definitions are repeated, which will cause compilation errors for the second run as in GAMS each data item may be defined only once.

Further, it is the responsibility of the modeler to ensure that the contents of the input file matches that of the work file, although the compiler will issue errors if it detects any inconsistencies, such as references to symbols not previously declared.

3.44.1.5 Prefixing Symbols in the Work File

Assume writing some reporting code that works off a restart file and new symbol names that have not been used in the previous program are required. GAMS offers a convenient and systematic way to achieve this by prefixing all symbols in the work file with a specified string. Consider the following example, again using the transportation model [TRANSPORT]:

```gams
> gams transport s=prefix symPrefix=aa_
```

This solves the model and saves the work file prefixed.g00. The command line parameter symPrefix has the effect that all symbols in the work file are prefixed with aa_. For the next step, consider the following simple reporting code, saved in a file called report.gms:

Scalar i / 0 /;
loop(aa_i, i = i+1);
display 'number of canning plants', i;

Note that this code will be run with a restart from the work file prefixed.g00. Therefore, the looping set aa_i is identical to the set i in the model [TRANSPORT]. Since all symbols from the original model have been prefixed, convenient symbol names can be used for reporting purposes. The run of report.gms is achieved by the following call:

```gams
> gams report r=prefix
```

The resulting listing file contains the following output:

```
---- 76 number of canning plants
      PARAMETER i = 2.000
```

3.44.2 Use Cases

The basic function of a work file is to preserve information that has been expensive to produce. The following discusses several use cases for work files.
### 3.44.2.1 Separation of Model and Data

The separation of model and data is one of the core principles of the GAMS modeling paradigm. Using the save and restart feature helps to exploit this separation.

Separation of model and data will be illustrated on the transportation model [TRNSPORT]. First, consider a GAMS file `transportmodel.gms` which contains only the algebraic representation of the transportation problem, obtained by removing all data and execution statements from [TRNSPORT]:

Sets

- `i` canning plants
- `j` markets

Parameters

- `a(i)` "capacity of plant i in cases"
- `b(j)` "demand at market j in cases"
- `c(i,j)` "transport cost in 1000$/case"
- `d(i,j)` "distance in 1000 miles"

Scalar `f` "freight in $/case per 1000 miles"

Variables

- `x(i,j)` "shipment quantities in cases"
- `z` "total transportation costs in 1000$

Positive Variable `x`;

Equations

- `cost` "define objective function"
- `supply(i)` "observe supply limit at plant i"
- `demand(j)` "satisfy demand at market j"

`cost` .. `z =e=` sum((i,j), `c(i,j)`*`x(i,j)`)) ;

`supply(i)` .. sum(j, `x(i,j)`) =l= `a(i)` ;

`demand(j)` .. sum(i, `x(i,j)`) =g= `b(j)` ;

Model `transport /all/` ;

Second, consider a GAMS file `transportdata.gms` that contains the data of the model as well as the solve and display statements:

Sets

- `i` / seattle, san-diego /
  - `j` / new-york, chicago, topeka /;

Parameters

- `a(i)` / seattle 350
  - san-diego 600 /
- `b(j)` / new-york 325
  - chicago 300
  - topeka 275 /

Table `d(i,j)`

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

Scalar `f` / 90 /;

`c(i,j)` = `f` * `d(i,j)` / 1000 ;

Solve `transport` using lp minimizing `z` ;

Display `x.l`, `x.m` ;
3.44 The Save and Restart Feature

The second file (transportdata.gms) cannot be run alone as the definition of model transport is missing. However, one may first run the first file (transportmodel.gms) and save its work file. Then one can restart from this work file to run the second file:

> gams transportmodel.gms s=transmod
> gams transportdata.gms r=transmod

3.44.2.2 Advanced Separation of Model and Data

In the previous example some execution time statements namely the assignment of c, the solve, and the display where performed in the data file. If the model execution logic is more complex we do not want to add this to the data file. Hence we create in this example a restart file from this first file but will only compile, but not execute (see difference between compile and execute phases in section GAMS Compile Time and Execution Time Phase):

$onEmpty

Sets i(*) canning plants / /
    j(*) markets / /
Parameters a(i) "capacity of plant i in cases" / /
    b(j) "demand at market j in cases" / /
    c(i,j) "transport cost in 1000$/case"
    d(i,j) "distance in 1000 miles" / /;
Scalar f "freight in $/case per 1000 miles" / 0 /;

c(i,j) = f * d(i,j) / 1000 ;

Variables x(i,j) "shipment quantities in cases"
    z "total transportation costs in 1000$" ;
Positive Variable x ;

Equations cost "define objective function"
    supply(i) "observe supply limit at plant i"
    demand(j) "satisfy demand at market j" ;

cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;
supply(i) .. sum(j, x(i,j)) =l= a(i) ;
demand(j) .. sum(i, x(i,j)) =g= b(j) ;

Model transport /all/ ;

Solve transport using lp minimizing z ;
Display x.l, x.m ;

Second, we consider a file that contains the data of the model but no other execution time statements. Because we already have empty data statements (/ /) for the data items in the first file, we need to instruct the compiler to allow a second data statement with the real data using $onMulti:

$onMulti
Sets i / seattle, san-diego /
    j / new-york, chicago, topeka / ;
Parameters a(i) / seattle 350
In order to run the model we first compile, but not execute the first model (see command line parameter `action=c`) and create a save file. Next, we run the second model. This does a continued compilation, it compiles the data statements from the second files and then executes the execution time statements from the first (`c(i,j) = ...`, `solve ...`, and `display ...`) and second (here there are none).

```
> gams transportmodel.gms action=c s=transmod
> gams transportdata.gms r=transmod
```

### 3.44.2.3 Generating Concise Listing Files

By default a GAMS listing file has many components, see chapter GAMS Output for details. In case a more concise listing file is needed, the save and restart feature may be used to generate such a file.

Recall the reorganization of the transportation model `[TRNSPORT]` into a model file `transportmodel.gms` and a data-and-solve file `transportdata.gms` from the previous section. Now consider the addition of two further files. The first one, called `transportreport.gms`, contains post-solution computations for reporting:

```gams
Parameter m(*,*) 'movement of commodities in cases';
   m(i,j) = x.l(i,j);
   m('total',j) = sum(i, x.l(i,j));
   m(i,'total') = sum(j, x.l(i,j));
   m('total','total') = sum(j, m('total',j));
```

The second one, called `transportdisplay.gms`, contains only a display statement:

```gams
Option decimals = 0;
Display m;
```

Using these four files, the following save and restart sequence can be called:

```
> gams transportmodel s=trans1
> gams transportdata r=trans1 s=trans2
> gams transportreport r=trans2 s=trans3
> gams transportdisplay r=trans3
```

The output file `transportdisplay.lst` is brief. Apart from the echo print, the execution time and the file summary, it contains only the output generated by the display statement:
#### 3.44 The Save and Restart Feature

---

```plaintext
52 PARAMETER m movement of commodities in cases

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
<th>total</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>50</td>
<td>300</td>
<td></td>
<td>350</td>
</tr>
<tr>
<td>san-diego</td>
<td>275</td>
<td>275</td>
<td></td>
<td>550</td>
</tr>
<tr>
<td>total</td>
<td>325</td>
<td>300</td>
<td>275</td>
<td>900</td>
</tr>
</tbody>
</table>
```

In this way it is possible to create output files that are concise and contain only the information needed, while at the same time the more detailed output is stored in other listing files and may be inspected if needed.

#### 3.44.2.4 Incremental Program Development

GAMS programs are often developed in stages. A typical approach is to start with set statements, tables and data manipulations, then equations are declared and defined, followed by model and solve statements and finally assignments for generating reports. As each piece of the model is built, it should be run and checked for errors by inserting diagnostic display and abort statements. As confidence grows that the parts of the model are correct, it is useful to save the completed parts in a work file. Subsequently, it is possible to work only on the piece under active development by restarting from the saved work file and thus reducing running time and the amount of output produced in each of the development runs.

This approach is especially useful when working on the results report part, since the setup and solution of a model instance is typically dominating the computing time, while the report part has to be run often to get all details of setting up content and layout into a satisfying form. Thus, the model may be generated and solved and the result saved in a work file. One may then restart from the work file while developing the report.

#### 3.44.2.5 Tracking a Sequence of Difficult Solve Statements

In many cases where solves are known to be difficult and expensive, it may be too risky to let GAMS process a job containing many solve statements. The risk is that if one solve does not proceed to normal completion, then the following solve will not be possible or will start from a bad initial point and much time and effort will be wasted.

An alternative is to request one solve at a time and save the work file. By doing so, the output of each solve can be carefully inspected before proceeding. If everything is as expected, the job can be restarted and the next solve be executed. If an error has occurred, the previous solve may be repeated, maybe with a different initial point or modified working limits such as iteration or time limits.

#### 3.44.2.6 What-If Analysis

Many modeling exercises involve a 'what if' analysis, in which a base case is defined and the point of the study is to see how the system changes when circumstances change, either naturally or by design. Often, the effect of many different changes to the base case are considered separately.

The save and restart feature facilitates such analyses. The base case may be saved using a work file and then all desired scenarios may be run separately by restarting from the same work file. Each scenario probably involves only doing some changes to the data (e.g., coefficients in equations or variable bounds), solving the changed model (the solution of the base case will then automatically be used as a starting point), and reporting.
3.44.2.7 The GAMS Runtime License

A GAMS runtime license can be used to restrict users to run an existing model with their own data without the possibility to modify the model itself.

For example, recall the separation of model [TRNSPORT] from Section Separation of Model and Data above into a model file trnsportmodel.gms and a data and solve file trnsportdata.gms. The developer of the model may run trnsportmodel.gms with the command

> gams trnsportmodel s=trans

to generate a work file trans.g00. She then distributes this work file and the data and solve file trnsportdata.gms to end users. If the end users have a run-time license for GAMS, they are not able to see the model or change it by adding any new variables or equations, but they can run the model by the command

> gams trnsportdata r=trans

Observe that the end users have full control of the data, e.g., are able to manipulate the elements of sets or the values of the various parameters.

3.44.3 Secure Work Files

When models are distributed to users other than the original developers or embedded in applications to be deployed by other developers, issues of privacy, security, data integrity and ownership arise. One may have to hide, protect or purge some parts of the model before it can be released. The information to be protected can be of numeric or symbolic nature. Examples include the following:

Privacy

A Social Accounting Matrix supplied by a statistical office is required in a general equilibrium model to be used by the Ministry of Finance. The data from the statistical office needs to be protected for obvious privacy reasons and the model experiments are used to evaluate policy options that are highly confidential. Most of the model structure is public, most of the data however is private and model results need to be transformed in such a way as to prohibit the discovery of the original data.

Security

Components of a model contain proprietary information that describes mathematically a chemical reaction. The associated algebra and some of the data are considered of strategic importance and need to be hidden completely. However, the final model will be used at different locations around the world.

Integrity

Data integrity safeguards are needed to assure the proper functioning of a model. Certain data and symbolic information need to be protected from accidental changes that would compromise the operation of the model.

To address these issues, so called secure work files have been introduced to GAMS. Such a work file behaves like any other work file but it is locked to a specific user’s license file. The content of a secure work file protected against unauthorized access via the GAMS license mechanism.

Attention

A special GAMS license is required to create secure work file, see also Usage. The security features of secure work files are not extended to the solver level. As a consequence, full information about a model instance can be extracted on the GAMS solver level by a user that is authorized to solve the model. See Limitations for more information.
3.44 The Save and Restart Feature

3.44.3 An Introductory Example

The well-known transportation model [TRNSPORT] will be used again to illustrate the creation and deployment of a secure work file. Assume one wants to distribute this model but there are concerns about proprietary formulations and data. In addition, one would like to prevent that the user does unintentional modifications to the model. It is assumed that the objective function and the supply constraints are to be hidden from other users and only the demand figures should be allowed to be changed. Data that is not needed any more will be purged as well.

First, a copy of the model from the model library is created, the model is run and a normal work file t1 is created:

> gamslib trnsport
> gams trnsport s=t1

Next, a file t2.gms with access control commands is created,

```
$eolcom //
$protect all // make all symbols read only
$purge d f // remove items d and f
$hide cost supply a // make objective invisible
$expose transport b // allow changes to b
```

and a secure work file t2.g00 is created by executing t2.gms with a restart from t1.g00:

> gams t2 r=t1 s=t2 plicense=target

The newly created work file is secure since the access control commands were activated with the privacy GAMS license option PLicense. This command line parameter specifies the name of the target user’s license file. The effect is that the work file t2.g00 can now only be read with the target license file.

The log output will contain the following lines:

```
GAMS Rev 124 Copyright (C) 1987-2001 GAMS Development...
Licensee: Source User Name
   Source Company Name
*** Creating a Secure Restart File for:
***   Target User Name
***   Target Company Name
--- Starting continued compilation
--- T2.GMS(6) 1 Mb
--- Starting execution
*** Status: Normal completion
```

The three lines starting with *** are a recap of the content of the target license file. From now on, the source and the target licenses are 'burned into' this file and all its descendants. One can now send the restart file to the target user or system.

The target user may run the model with new data, add new GAMS statements and create new work files. However, there are two restrictions: some of the symbols are hidden and this model can only be executed using the target license file.

For example, the target user may want to half the demand and compare the original solution with the new one. The following file, called t3.gms, will accomplish this:
Parameter rep 'summary report';
rep(i,j,'base') = x.l(i,j);
b(j) = b(j)*0.5;

solve transport minimizing z using lp;

rep(i,j,'half') = x.l(i,j);
display rep;

This new file may be executed on the target system, restarting from the work file t2.g00:

> gams t3 r=t2

The resulting log file will contain the following lines:

GAMS Rev 124 Copyright (C) 1987-2001 GAMS Development...
Licensee: Target User Name
       Target User Company
*** Restarting from a Secure Restart File created by:
***     Source User Name
***     Source Company Name
--- Starting continued compilation
--- T3.GMS(5) 1 Mb
...

Note that the originator/owner of the secure work file is mentioned by name. A similar message will be contained in the listing file:

... EXECUTION TIME = 0.000 SECONDS 1.1 Mb WIN201-124
**** Secure Save/Restart File Source:
       Source User Name
       Source Company Name
**** Secure Save/Restart File Target:
       Target User Name
       Target User Company
...

A more detailed inspection of the listing file shows that the hidden variables and equations do not appear in the usual equation and variable listings and the solution print. The hidden items can only be accessed via a public (exposed) model and a solve statement. However, note that the full model instance may still be accessed by the target user, see Limitations.

In the following, secure work files and the access control commands are described in more detail.
3.44.3.2 Usage

Secure work files control access to symbolic and numeric information and can only be read by a specific GAMS user. The initial creation or additions to access control requires a special GAMS license. Saving secure work files without new access controls does not require a special GAMS license. The creation or addition of access control is signaled by the use of the GAMS command line parameter PLicense, which gives the name of a privacy license file. The shortcut PLICENSE=LICENSE sets the privacy license to the current license file. This is convenient when experimenting with access controls.

When a secure work file is written for the first time, the first and second lines of the current license file and the privacy license file are inserted into the work file. This information cannot be changed any more and the original source and the intended target users are locked into the work file.

A secure work file may be used just like any other work file and new work files may be derived from secure files. However, their use is restricted to the target user specified with the command line parameter PLicense. The target user can, if licensed, add access controls to an existing secure file by using the parameter PLICENSE=LICENSE but cannot change the original information about source and target users.

There are four access control commands (ACCs) that are processed during the compilation phase. These commands can be inserted anywhere in the program. They are processed in chronological order and have the following syntax:

\$acc ident1 ident2 ...
$acc all

Here ident1 and ident2 are GAMS identifiers previously defined in the program and acc denotes one of the four access control commands:

<table>
<thead>
<tr>
<th>Dollar Control Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>purge</td>
<td>Removes the objects and all data associated.</td>
</tr>
<tr>
<td>hide</td>
<td>Hides the objects but allows them to be used in model calculations.</td>
</tr>
<tr>
<td>protect</td>
<td>The objects cannot be modified but they may be used in model calculations.</td>
</tr>
<tr>
<td>expose</td>
<td>Removes all privacy restrictions, the symbols will be reverted to their original state.</td>
</tr>
</tbody>
</table>

The keyword all applies the ACCs to all identifiers defined up to this point in the GAMS source code. Note that ACCs may be changed and redefined within the same GAMS program. However, identifiers inherited from a restart file cannot be changed.

3.44.3.3 A Practical Example

This section uses the transportation model [TRNSPORT] to show how to hide input data and results from the target user. The target user will be allowed to view percentage changes from an unknown base case only. In addition to the original model, a data initialization and a report model will be introduced.

First, a method to calculate input data is defined. As the GAMS language does not offer the definition of methods (or functions), here a model is used to define algebraically the desired correspondence between the input and output of the method we wish to emulate. Execution of the method will then correspond to solving the model. The model is the following:
Variable newc(i,j)  'new transport data';
Equation defnewc(i,j) 'definition of new transport data';
defnewc(i,j).. newc(i,j) =e= f*d(i,j)/1000;

Model getc  'compute new transport data' / defnewc /;
Solve getc using cns;

By solving model getc (see Constrained Nonlinear System (CNS) for details on problem type CNS), the variable newc(i,j) will obtain the value of f*d(i,j)/1000 in the variable level attributes. Thus, newc.l corresponds to parameter c in the original model.

Next, the objective function of the original model is changed to reflect economies of scale. Furthermore, a base case value basex is computed for later use in the reporting model:

Scalar beta 'scaling exponent' / 1.1 /;
Equation newcost 'economies of scale objective function';
newcost.. z =e= sum((i,j), newc.l(i,j) * x(i,j)**beta);

Model estrans / newcost, supply, demand /;
solve estrans using nlp minimizing z;

Parameter basex(i,j) 'base values of x'; basex(i,j) = x.l(i,j);

Finally, a method to transform the results of model estrans to the relative change with respect to the base case is defined. As for the computation of the input data (newc), a model is used to emulate this method:

Variable delta(i,j)  'percentage change from base values';
Equation defdelta(i,j) 'definition of delta';
defdelta(i,j)$basex(i,j).. delta(i,j) =e= 100*(x.l(i,j)-basex(i,j))/basex(i,j);

Model rep / defdelta /;
solve rep using cns;

Assume the GAMS code above has been saved in a file p1.gms. Running GAMS on this file,

> gams p1 s=p1

creates a work file with the name p1.g00.

In the following, some test runs similar to those that are expected to be defined by the target user are made. Three scenarios to be solved in a loop are defined in file u1.gms:
Set s / one, two, three /;
Parameter sbeta(s) / one 1.25, two 1.5, three 2.0 /
    sf(s) / one 85, two 75, three 50 /;
Parameter report 'summary report';

loop(s,
    beta = sbeta(s);
    f = sf(s);
    solve getc using cns;
    solve estrans using nlp minimizing z;
    solve rep using cns;
    report(i,j,s) = delta.l(i,j);
    report('','beta',s) = beta;
    report('','f',s) = f;
    report('obj','z',s) = z.l
);

display report;

File u1.gms can be executed with a restart from the work file p1.g00:

> gams u1 r=p1

The display statement generates the following output:

---- 109 PARAMETER report summary report

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle .new-york</td>
<td>-4.050</td>
<td>-6.967</td>
<td>-8.083</td>
</tr>
<tr>
<td>seattle .topeka</td>
<td>233.958</td>
<td>348.468</td>
<td>404.187</td>
</tr>
<tr>
<td>san-diego.new-york</td>
<td>3.605</td>
<td>6.201</td>
<td>7.194</td>
</tr>
<tr>
<td>san-diego.chicago</td>
<td>28.138</td>
<td>40.719</td>
<td>47.228</td>
</tr>
<tr>
<td>.beta</td>
<td>1.250</td>
<td>1.500</td>
<td>2.000</td>
</tr>
<tr>
<td>.f</td>
<td>85.000</td>
<td>75.000</td>
<td>50.000</td>
</tr>
<tr>
<td>obj .z</td>
<td>526.912</td>
<td>1652.963</td>
<td>13988.774</td>
</tr>
</tbody>
</table>

Note that all symbols are still completely exposed. Access controls need to be added to the model p1.gms before it can be made available to the target client. The information to be protected is the original distance matrix and derived information. A recommended procedure is to first hide everything and then enable access to only selected parts of the model. The access control information is collected in the file s1.gms:

$hide all
$expose getc estrans rep
$expose i j z delta
$expose f beta a b

Using the initial workfile p1, a secure work file s1.g00 is created by executing

> gams s1 r=p1 s=s1 plicense=license
To test the system from the target users point of view, the license of the current GAMS system is used also for the target user.

To test the secure work file, problem u1.gms is run again, restarting from the work file s1:

> gams u1 r=s1

Inspecting the resulting listing file, one observes that equation, variable and solution listings related to the hidden variables are not shown anymore. Any attempt to reference a hidden variable will cause a compilation error.

### 3.4.4.3.4 Limitations

One of the design goals for secure work files has been to minimize the impact on other components of the GAMS system. Solvers used within a secure environment should work as if called within a normal environment. This implies that certain information about a model can easily be recovered by using solvers like CONVERT or solver options like writelp for CPLEX, writemps for CBC, or gams/interactive for SCIP.

For example, consider the secure work file t2.g00 from Section An Introductory Example. The target user could now reproduce the complete model instance, including the hidden equation supply or the objective function cost by running the following GAMS code, restarting from t2.g00:

```gams
option mip = scip;
transport.optfile = 1;
$echo gams/interactive = "display prob quit" > scip.opt
solve transport min z using mip;
```

This produces the log output:

```
...
original problem has 6 variables (0 bin, 0 int, 6 cont) and 5 constraints
STATISTICS
  Problem name : r
  Variables    : 6 (0 binary, 0 integer, 0 implicit integer, 6 continuous)
  Constraints  : 0 initial, 5 maximal

3.44 The Save and Restart Feature

Note, that this approach is only possible for the target user, since its license is required to unlock the work file. Further, the original algebra of the model is still protected by GAMS, only the generated model instance (with original variable and equation names) and variable and equation symbols can be made available this way.

A further limitation of secure work files is that the source and target license files are locked to the secure work file and cannot be changed. If the target user receives a new license file (due to a system upgrade, for example), the secure work file cannot be read any more by the target user and must be recreated.

3.44.4 Obfuscated Work Files

GAMS offers a limited set of facilities to change all the names and other documentation related to a specific model run in a work file. This can be useful if the model has to be solved in an untrusted computing environment, e.g., a public cloud facility. When the results are back in the secure environment, the changed names can be transformed back to their original.

A work file that has all strings for symbols, set elements and explanatory text replaced with obfuscated names is called an obfuscated work file. GAMS obfuscates by keeping the original length of the symbol name or label name, but replaces them by a sequence of strings. For example, for symbols of length 3 it creates A00, A01, A02, ..., Z00. The method used for explanatory text is similar, but here GAMS always uses the single quote character and thus may create many weird looking labels. In addition to item names, labels and explanatory text, titles and subtitles in the listing file are obfuscated. Observe that other strings that have some meaning in the execution of GAMS, e.g., file names, cannot be changed. Despite of the changes in the string pool, an obfuscated work file has all the capabilities of a normal work file.

Recall from Section Saving The Work File that work files are created with the command line parameter save. Obfuscated work files are created with the variant saveobfuscate. The creation of an obfuscated work file is often combined with the creation of a regular work file, as the latter will be necessary to translate information from an obfuscated work file back to the name space of the original model.

In the following, the intended use of obfuscated work files is illustrated. First, a GAMS model (here [TRNSPORT]) is compiled into a regular and an obfuscated work file:

> gamslib trnsport
> gams trnsport action=compile s=0named so=0obfuscated

Note, that the command line parameter action=compile is used to only compile, but not execute, the model. Observe that the name of the regular work file is 0named.g00 and the name of obfuscated work file is 0obfuscated.g00.

In the next step, the obfuscated work file is moved to a non-secure machine and GAMS is restarted from this work file on an empty GAMS model file. This executes the original model (here trnsport), but with all names obfuscated. The outcome of this execution is saved in another, still obfuscated, work file 1obfuscated.g00.

> echo *Empty > empty.gms
> gams empty r=0obfuscated s=1obfuscated

The work file 1obfuscated.g00 is now brought back to a trusted machine. To obtain the results, say the marginal values of the supply equation, in a non-obfuscated form, GAMS is executed again on a model that writes out values of supply.m to a GDX file supply.gdx. This model is restarted from the obfuscated work file 1obfuscated.g00, but additionally the originally created non-obfuscated work file 0named.g00 is passed in via the command line parameter RestartNamed (short: rn):
Recall, that the work file `named.gdx` resulted from the initial compilation and contains the names from the original namespace. It never left the trusted environment. The effect of combining options `r` and `rn` is that all content from the obfuscated work file is taken, except for the names of symbols and labels, the explanatory texts, and the listing file titles and subtitles, which are read from the work file specified via `rn`.

GAMS automatically performs the following three checks to ensure that the named and obfuscated work files are consistent:

1. The number of labels and symbols must be identical.
2. The size of the string pool must be identical.
3. The first 10 labels point to the same addresses in the string pool.

The first two checks imply that the execution in the obfuscated name space cannot introduce new symbols or labels or even new strings (e.g., from `display 'this is a new string'`). Therefore, the empty GAMS program that was used to execute from the obfuscated work file above can hardly be replaced by any useful code since the obfuscated symbols and labels are not known.

### 3.45 Embedded Code Facility

**Note**

This feature is currently in beta status.

#### 3.45.1 Motivation

GAMS uses relational data tables as a basic data structure. With these, GAMS code for parallel assignment and equation definition is compact, elegant, and efficient. However, traditional data structures (arrays, lists, dictionaries, trees, graphs, …) are not natively or easily available in GAMS. Though it is possible to represent such data structures in GAMS, the GAMS code working with such structures can easily become unwieldy, obfuscating, or inefficient. Also, in the past it was not easy to connect libraries from other systems for special algorithms (e.g. graph algorithms, matrix operations, …) to GAMS without some data programming knowledge and a deep understanding of internal representation of GAMS data (e.g. the GDX API).

The Embedded Code Facility addresses this need and extends the connectivity of GAMS to other programming languages. It allows the use of external code (e.g. Python) during compile and execution time. GAMS symbols are shared with the external code, so no communication via disk is necessary. It utilizes an API (this API will be published in one of the next releases so users can extend the embedded code to other languages/systems) and additional source code for common tasks so that the user can concentrate on the task at hand and not the mechanics of moving data in and out of GAMS.
3.45 Embedded Code Facility

3.45.2 Concept

As pointed out in section Motivation, the main idea of the Embedded Code Facility is to enable the use of external code in GAMS and give this code direct in-memory access to the GAMS database (or better: to GAMS symbols, namely sets, parameters, variables, and equations). This can be done by defining sections in the GAMS code which contain no GAMS code, but code written in a defined external code. These sections can be used at both GAMS compile and execution time (compare section GAMS Compile Time and Execution Time Phase). Details about how to do this can be found in the Syntax section.

Note

It is planned to extend this feature to different programming languages. However, at the moment only Python is supported.

Also, the system provides some help to develop and debug the external code independent of GAMS first. More about this topic can be found in section Troubleshooting Embedded Python Code.

The communication of the data between the GAMS part of the program and the embedded code part was inspired by the existing interface to GDX in many ways. So the system allows to access specific symbol records by both labels and label indices. Also, it is possible to decide if data changed in the embedded code should replace the GAMS data or get merged with it and just like loading data from GDX, one can decide if data from embedded code should change the GAMS database filtered or domain checked. How to do these things is explained in detail in section Python.

3.45.3 Simple Example

In a very first example we look into some Python code that helps to split some label names that are already present in GAMS. We do this at compile time in order to read the broken up pieces as individual sets (country and city) into GAMS plus some mapping sets (mccCountry and mccCity) between the original labels and the new labels. The compile-time embedded code starts with a $onEmbeddedCode followed by the type of code to expect (Python:). Python is currently the only code that works. GAMS plans to add other (even compiled) languages in the future. The lines between $onEmbeddedCode and $offEmbeddedCode is Python code. We do not want to go into Python details, but the first few lines initialize some empty Python list objects (mccCountry and mccCity) as well as some empty Python set objects. In the Python for loop that follows we iterate over all individual labels of the GAMS set cc. Python gets access to the GAMS set cc via the member function get of the implicitly defined Python object gams. get returns an object that is iterable and can be used in a Python for loop. The type of the records one gets depend on the dimensionality and type of the GAMS symbol. In the loop body we use the Python split function to extract the first (r[0] is country) and second (r[1] is city) part of the label. The three strings cc, r[0], r[1] are used to build up the Python list objects that store the information for the maps mccCountry and mccCity and the Python set objects that store the labels for the new sets country and city. The Python set has the advantage to store a label just once even if we add it multiple times. Python prepares to send items back to GAMS via the gams member function set that can deal with both Python list and Python set objects. The command $offEmbeddedCode is followed by a list (without separating commas) of GAMS symbols that instructs the GAMS compiler to read these symbols back.

Note that GAMS syntax is case insensitive while Python is case sensitive. Hence, the strings that represent the GAMS symbol names in the Python code can have any casing (e.g. gams.get("cc") or gams.get("CC")), while the corresponding Python objects need to have consistent casing throughout the Python code.

The following code presents the entire embeddedSplit example from the GAMS Data Utilities Library:
Set cc  / "France - Paris", "France - Lille", "France - Toulouse"
        , "USA - Washington DC", "USA - Houston", "USA - New York",
        , "Germany - Berlin", "Germany - Munich", "Germany - Bonn" /
  country
city
mccCountry(cc,country<) Mapping between country and related elements in set cc
mccCity(cc,city<) Mapping between city and related elements in set cc;

$onEmbeddedCode Python:
mccCountry = []
mccCity = []
for cc in gams.get("cc"):
    r = str.split(cc, " - ", 1)
mccCountry.append((cc,r[0]))
mccCity.append((cc,r[1]))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
$offEmbeddedCode mccCountry mccCity

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry ,mccCity;

The display in the listing file looks as follows:

---- 25 SET country
Spain , USA , Germany, France

---- 25 SET city
Berlin , Bilbao , Cordoba , Madrid
New York , Washington DC, Paris , Houston
Munich , Lille , Seville , Bonn
Toulouse

---- 25 SET mccCountry
France - Paris .France
France - Lille .France
France - Toulouse .France
Spain - Madrid .Spain
Spain - Cordoba .Spain
Spain - Seville .Spain
Spain - Bilbao .Spain
USA - Washington DC .USA
USA - Houston .USA
USA - New York .USA
Germany - Berlin .Germany
Germany - Munich .Germany
Germany - Bonn .Germany

---- 25 SET mccCity
France - Paris .Paris
France - Lille .Lille
France - Toulouse .Toulouse
Spain - Madrid .Madrid
Spain - Cordoba .Cordoba
Spain - Seville .Seville
Spain - Bilbao .Bilbao
The second example demonstrates the use of embedded code at execution time. The syntax for the execution time embedded code in this example is identical to the compile time variant with the exception of the keywords that start and end the embedded code section: embeddedCode and endEmbeddedCode. It is important to understand that the execution of the code happens at GAMS execution time, so e.g. no new labels can be produced and send back to GAMS. In this example we use some Python code to generate a random permutation of set elements of set i and store this in a two dimensional set p. In this example we do not use a loop to iterate through the elements of a GAMS system but make use of the fact that the Python object returned by gams.get("i") is iterable and can in its entirety be stored in the Python list with name i with the short and powerful command i = list(gams.get("i")). The permutation of elements in list p which is a copy of list i is created by the Python statement random.shuffle(p). The following code presents the entire example:

Set i /i1*i10/
  p(i,i) "permutation";

embeddedCode Python:
  import random
  i = list(gams.get("i"))
  p = list(i)
  random.shuffle(p)
  for idx in range(len(i)):
      p[idx] = (i[idx], p[idx])
  gams.set("p", p)
endEmbeddedCode

option p:0:0:1;
display p;

The display in the listing file looks as follows:

```
    11 SET p permutation
     i1 .i1
     i2 .i7
     i3 .i5
     i4 .i2
     i5 .i10
     i6 .i6
     i7 .i9
     i8 .i4
     i9 .i8
     i10.i3
```

### 3.45.4 Syntax

This section explains the GAMS functions/keywords which were introduced to enable the Embedded Code Facility. The first subsection deals with the syntax for compile time, the second with the syntax for execution time (compare section GAMS Compile Time and Execution Time Phase).
3.45.4.1 Compile Time

There are three dollar control options to start an embedded code section for Python at compile time:

\$onEmbeddedCode Python: [arguments]
\$onEmbeddedCodeS Python: [arguments]
\$onEmbeddedCodeV Python: [arguments]

Lines following one of the above statements are passed on to a Python interpreter until this dollar control option, which ends the embedded code section at compile time, is hit:

\$offEmbeddedCode \{symbol[<=]embSymbol[.dimX]\}

These dollar control options are explained here in more detail. An example which uses them can be seen above.

Note

- The optional arguments from the \$onEmbeddedCode[S|V] statement can be accessed as gams.arguments in the Python code.
- The optional output symbols from the \$offEmbeddedCode statement need to be set using the function gams.set in the Python code.
- More about the specific GAMS Python syntax can be found below.

3.45.4.2 Execution Time

At execution time an embedded code section is started with one of these statements:

embeddedCode Python: [arguments]
embeddedCodeS Python: [arguments]
embeddedCodeV Python: [arguments]

Similar to the compile time alternatives \$onEmbeddedCode[S|V], the first two variants are synonyms which allow parameter substitution in the Python code that follows, while the last variant does not allow this but passes the code verbatim to the Python interpreter. The optional arguments in all three variants can be accessed in the Python code that follows as gams.arguments (see section Python for more details). Lines following one of the above statements are passed on to the Python interpreter until one of the following two statements, which end the embedded code section at execution time, is hit:

endEmbeddedCode \{output symbols\}
pauseEmbeddedCode \{output symbols\}

Both statements end the embedded code section and switch back to GAMS syntax in the following lines. Also, both statements can be followed by a GAMS symbol or a list of GAMS symbols which would get updated in the GAMS database after the Python code got executed. If output symbols are specified, they need to be set in the embedded code before using the function gams.set (see section Python for more details). And by default, they really behave exactly the same. However, when the command line parameter freeEmbeddedPython is set to 1, there is a difference between the two statements: Then, as the names suggest, endEmbeddedCode ends the embedded code section, while pauseEmbeddedCode pauses it. If it ends, it cannot be continued at a later point, because some internal resources get freed, it could just be re-initiated (e.g. by another embeddedCode statement). If the embedded code section got paused, it could also be continued at a later stage in the GAMS program, which means that no reinitialization is needed and Python symbols which were defined before the pause are still available when continuing. With the default of freeEmbeddedPython set to 0 endEmbeddedCode behaves like pauseEmbeddedCode (and pauseEmbeddedCode always behaves the same, so it is independent of the setting of freeEmbeddedPython). Note that since GAMS does not stay in memory under the default settings that continuing any Python code after GAMS executes a solve causes the code to fail with the following error message:
This happens because under default conditions GAMS passes out of memory when the solver starts up. This causes the loss of the state of the embedded code environment. Whether GAMS is retained in memory is controlled by SolveLink (default=0). By using a different value (e.g. SolveLink=2 (solveLink.callModule%) or SolveLink=5 (solveLink.loadLibrary%)), GAMS stays in memory and a paused embedded code environment can be continued after the solve statement has carried out.

To continue a previously paused embedded code section one of the following statements is used:

```
continueEmbeddedCode [handle]: [arguments]
continueEmbeddedCodeS [handle]: [arguments]
continueEmbeddedCodeV [handle]: [arguments]
```

As seen before, the first two variants are synonyms which allow parameter substitution in the embedded code that follows, while the last variant does not allow this but passes the code verbatim to the interpreter. Also as seen above when discussing `EmbeddedCode[S|V]`, the optional arguments in all three variants can be accessed in the embedded code that follows as `gams.arguments` (see section Python for more details). New in these statements is the optional handle. If omitted, the last code section that was paused will be continued. However, sometimes one might need to maintain different embedded code sections active in parallel and independent of each other. In order to use this facility, it is required to set PyMultiInst to 1. Note that this setting might cause problems when using third party modules and packages (e.g. numpy or modules that make use of it) and might also impact the performance. There is a new function to store a handle of the last embedded code section that was executed which could then later be used to continue a specific paused code section:

```
handle = embeddedHandle;
```

An example of how this can be used can be seen in the GAMS Datalib model `[embeddedMultiInstance]`. A simplified use of just `embeddedCode` and `endEmbeddedCode` can also be seen in a simple example above.

Note

Keeping the Python environment alive with `pauseEmbeddedCode` and `continueEmbeddedCode[S|V]` or `endEmbeddedCode` and `freeEmbeddedPython=0` can be particularly useful, when there is an expensive initialization (e.g. to import other code parts) which can be done only once but further execution needs to be done many times (e.g. inside a loop).

3.45.5 Python

The Python class `ECGamsDatabase` is the interface between GAMS and Python. An instance of this class is automatically created when an embedded code section is entered and can be accessed using the identifier `gams`. The following methods can be used in order to interact with GAMS:

```
gams.get(symbolName, keyType=KeyType.STRING, keyFormat=KeyFormat.AUTO, valueFormat=ValueFormat.AUTO, recordFormat=RecordFormat.AUTO)
```

This method retrieves an iterable object representing the symbol identified with `symbolName`. Typically there are two possibilities to access the records. Iterating using e.g. a for loop provides access to the individual records. By calling `list()` on the iterable object, a list containing all the data is created. Several optional parameters can be used in order to modify the format of the retrieved data:
• **keyType**: Determines the data type of the keys. It can be either `KeyType.STRING` (labels) or `KeyType.INT` (label indexes). The default setting is `KeyType.STRING`.

• **keyFormat**: Specifies the representation of the keys. Possible values are as follows:
  - `KeyFormat.TUPLE`: Encapsulate keys in a tuple
  - `KeyFormat.FLAT`: No encapsulation
  - `KeyFormat.SKIP`: Keys are skipped and do not appear in the retrieved data
  - `KeyFormat.AUTO` (default): Depending on the dimension of the GAMS symbol, a default format is applied:
    * Zero dimensional/scalar: `KeyFormat.SKIP`
    * One dimensional: `KeyFormat.FLAT`
    * Multi dimensional: `KeyFormat.TUPLE`

• **valueFormat**: Specifies the representation of the values. Possible values are as follows:
  - `ValueFormat.TUPLE`: Encapsulate values in a tuple
  - `ValueFormat.FLAT`: No encapsulation
  - `ValueFormat.SKIP`: Values are skipped and do not appear in the retrieved data
  - `ValueFormat.AUTO` (default): Depending on the type of the GAMS symbol, a default format is applied:
    * Set: `ValueFormat.SKIP`
    * Parameter: `ValueFormat.FLAT`
    * Variable/Equation: `ValueFormat.TUPLE`

• **recordFormat** Specifies the encapsulation of records into tuples. Possible values are as follows:
  - `RecordFormat.TUPLE`: Encapsulates every record in a tuple
  - `RecordFormat.FLAT`: No encapsulation. Throws an exception if it can not be applied. It is guaranteed that the length of a retrieved Python list is equal to the number of records of the corresponding GAMS symbol. This principle leads to an incompatibility of `RecordFormat.FLAT` whenever a record consists of more than one item (e.g. multi dimensional symbols, variables and equations which have five numeric values).
  - `RecordFormat.AUTO` (default): Depending on the number of items that represent a record, a default format is applied. If possible this is always `RecordFormat.FLAT`.

GAMS special values NA, INF, and -INF will be mapped to IEEE special values `float('nan')`, `float('inf')`, and `float('-inf')`. GAMS special value EPS will be either mapped to 0 or to the small numeric value 4.94066E-324 depending on the setting of flag `gams.epsAsZero`.

The following Python code shows some examples of `gams.get` and illustrates the use of different formats:

```python
Set i / i1 text 1, i2 text 2 /
  j / j1*j2 /
Scalar p0 /3.14/;
Parameter p1(i) / #i 3.14 /
  p2(i,j) / i1.#j 3.14 /
Variable v0 / fx 3.14 /;
equation e1(i) / #i.fx 3.14 /
  e2(i,j) / i1.#j.fx 3.14 /;
$onEmbeddedCode Python:
# scalar parameter
l = list(gams.get('p0'))
assert l == [3.14], "error"
l = list(gams.get('p0', recordFormat=RecordFormat.TUPLE))
assert l == [(3.14,)], "error"
```

3.45 Embedded Code Facility

# one dimensional parameters:
l = list(gams.get('p1'))
assert l == ["i1", 3.14], "error"
l = list(gams.get('p1', keyFormat=KeyFormat.TUPLE))
assert l == ["i1", (3.14,)], "error"
l = list(gams.get('p1', valueFormat=ValueFormat.TUPLE))
assert l == [("i1",), 3.14], "error"
l = list(gams.get('p1', keyFormat=KeyFormat.TUPLE, valueFormat=ValueFormat.TUPLE))
assert l == [(["i1"], (3.14,)), (["i2"], (3.14,))], "error"

# two dimensional parameter:
l = list(gams.get('p2'))
assert l == [(["i1", "j1"], 3.14), (["i1", "j2"], 3.14)], "error"
l = list(gams.get('p2', keyFormat=KeyFormat.FLAT))
assert l == [(["i1", "j1"], 3.14), (["i1", "j2"], 3.14)], "error"

# one dimensional sets:
l = list(gams.get('i'))
assert l == ['i1', 'i2'], "error"
l = list(gams.get('i', valueFormat=ValueFormat.FLAT))
assert l == [(["i1", "text 1"], (["i2", "text 2"]), "error"

# scalar variables/equations
l = list(gams.get('v0'))
assert l == [(3.14, 0, 3.14, 3.14, 1)], "error"

# one dimensional variables/equations:
l = list(gams.get('e1'))
assert l == [(["i1", (3.14, 0, 3.14, 3.14, 1)], (["i2", (3.14, 0, 3.14, 3.14, 1))], "error"
l = list(gams.get('e1', valueFormat=ValueFormat.FLAT))
assert l == [(["i1", (3.14, 0, 3.14, 3.14, 1), (["i2", (3.14, 0, 3.14, 3.14, 1))], "error"
l = list(gams.get('e1', keyFormat=KeyFormat.TUPLE))
assert l == [(["i1"], (3.14, 0, 3.14, 3.14, 1)), (["i2", (3.14, 0, 3.14, 3.14, 1))], "error"

# two dimensional variables/equations:
l = list(gams.get('e2'))
assert l == [(["i1", "j1"], (3.14, 0, 3.14, 3.14, 1), (["i1", "j2"], (3.14, 0, 3.14, 3.14, 1))], "error"
l = list(gams.get('e2', keyFormat=KeyFormat.FLAT, valueFormat=ValueFormat.FLAT))
assert l == [(["i1", "j1", (3.14, 0, 3.14, 3.14, 1), (["i1", "j2", (3.14, 0, 3.14, 3.14, 1))], "error"

# using label indexes instead of labels
l = list(gams.get('p1', keyType=KeyType.INT))
assert l == [(1, 3.14), (2, 3.14)], "error"
l = list(gams.get('i', keyFormat=KeyFormat.TUPLE, valueFormat=ValueFormat.TUPLE, keyType=KeyType.INT))
assert l == [([1,], ("text 1"), ([2,], ("text 2"))], "error"
l = list(gams.get('e2', keyType=KeyType.INT))
assert l == [([1, 3, (3.14, 0, 3.14, 3.14, 1), ([1, 4, (3.14, 0, 3.14, 3.14, 1))], "error"

This method sets the data for the GAMS symbol identified with symbolName. The parameter data takes a Python list or set containing items that represent the records of the symbol. It is also possible to pass an instance of a subclass of _GamsSymbol (e.g. GamsParameter or GamsSet) when using the Object-oriented GAMS Python API in an embedded code section. In case of a Python list or set, depending on the type and the dimension of the symbol, different formats can be used in order to specify the data. Different formats cannot be mixed within one list. In general
each record needs to be represented as a tuple containing the keys and the value field(s). Keys and/or values can also be enclosed in a tuple. Keys can be entered as labels (string) or label indexes (int). Value fields depend on the type of the symbol:

- **Parameters**: One numerical value
- **Sets**: explanatory text (optional)
- **Variable/Equations**: Five numerical values: level, marginal, lower bound, upper bound, scale/prior/stage

IEEE special values `float('nan')`, `float('inf')`, and `float('-inf')` will be remapped to GAMS special values `NA`, `INF`, and `-INF`. The small numeric value `4.94066E-324` will be mapped into GAMS special value `EPS`.

The following Python code gives some examples on different valid formats for different symbol types and dimensions:

```python
$onEmbeddedCode Python:
# scalar parameter
data = [3.14]
data = [(3.14,)]

# one dimensional parameters:
data = ["i1", 3.14], ("i2", 3.14)]
data = [(["i1"], 3.14), (["i2"], 3.14)]
data = [(["i1"], (3.14,)), (["i2"], (3.14,))]
data = [(["i1"],), (3.14,)), (["i2"],), (3.14,))]

# two dimensional parameter:
data = ["i1", 'j1', 3.14], ('i1', 'j2', 3.14)]
data = [(["i1", 'j1'], (3.14,)), ('i1', 'j2'), (3.14,))]

# one dimensional sets:
data = ['i1', 'i2']
data = [('i1',), ('i2',)]

# one dimensional sets with explanatory text
data = ["i1", "text 1"], ('i2", "text 2")]
data = [(["i1",), ("text 1",)), ('i2",), ("text 2",))]

# scalar variables/equations
data = [3.14, 0, 0, 10, 1)]

# one dimensional variables/equations:
data = ["i1", 3.14, 0, 0, 10, 1], ("i2", 3.14, 0, 0, 10, 1)]
data = [(["i1", (3.14, 0, 0, 10, 1)), ("i2", (3.14, 0, 0, 10, 1))]
data = [(["i1",), (3.14, 0, 0, 10, 1)), (["i2",), (3.14, 0, 0, 10, 1))]

# two dimensional variables/equations:
data = ["i1", "j1", 3.14, 0, 0, 10, 1], ("i1", "j2", 3.14, 0, 0, 10, 1)]
data = [(["i1", "j1"), (3.14, 0, 0, 10, 1)), (["i1", "j2"), (3.14, 0, 0, 10, 1))]

# using label indexes instead of labels
data = [[(1,), (3.14,)], ((2,), (3.14,))] # one dimensional parameter
data = [[(1,), ("text 1",)], ((2,), ("text 2",))] # one dimensional set
data = [[(1, 3), (3.14, 0, 0, 10, 1)), ((1, 4), (3.14, 0, 0, 10, 1))]] # two dimensional equation

$offEmbeddedCode
The optional parameter `mergeType` specifies if data in a GAMS symbol is merged (`MergeType.MERGE`) or replaced (`MergeType.REPLACE`). If left at `MergeType.DEFAULT` it depends on the setting of `$on/offmulti[R]$` if GAMS does a merge, replace, or trigger an error during compile time. During execution time `MergeType.DEFAULT` is the same as `MergeType.REPLACE`. The optional parameter `domCheck` specifies if Domain Checking is applied. Possible values are `True` and `False`.

Note

When calling `gams.set()` in an embedded code section during execution time, new labels that are not known to the current GAMS program can not be added. The attempt will result in an execution error.

`gams.getUel(idx)`

Returns the label corresponding to the label index `idx`

`gams.mergeUel(label)`

Adds `label` to the GAMS universe if it was unknown and returns the corresponding label index.

Note

When calling `gams.mergeUel()` in an embedded code section during execution time, new labels that are not known to the current GAMS program can not be added. The attempt will result in an execution error.

`gams.getUelCount()`

Returns the number of labels.

`gams.printLog(msg)`

Print `msg` to log.

`gams.arguments`

Contains the command line that was passed to the Python interpreter of the embedded code section. The syntax for passing arguments to the Python interpreter can be seen above.

`gams.epsAsZero`

Flag to read GAMS EPS as 0 (`True`) or as a small number, 4.94066E-324, when set to `False`. Default is `True`.

`gams.ws`

Property to retrieve an instance of `GamsWorkspace` that allows to use the Object-oriented GAMS Python API. The instance is created when the property is read for the first time using a temporary working directory. A different working directory can be specified using `gams.wsWorkingDir`. For debug output, the property `gams.debug` can be set to a value from `DebugLevel`

`gams.wsWorkingDir`
Property that can be specified before accessing gams.ws for the first time in order to set the working directory. Setting the property after the first call to gams.ws will have no effect of the created GamsWorkspace.

\texttt{gams.db}

Property to retrieve an instance of \texttt{GamsDatabase}. The instance is created when the property is read for the first time and allows to access the GAMS symbols using the methods of the Object-oriented GAMS Python API.

\texttt{gams.debug}

Property that can be set to a value from \texttt{DebugLevel} for debug output. Default is \texttt{DebugLevel.Off} (0). Setting this property affects both the debug output from embedded code and the debug output from the Object-oriented API. The property needs to be changed before accessing gams.ws for the first time in order to take effect in the Object-oriented API. Setting the property after the first call to gams.ws will have no effect on the GamsWorkspace.

For more examples on how to use the interface in Python see the following examples and tests:

- \texttt{embeddedSplit} (GAMS Data Utilities Library)
- \texttt{embeddedSort} (GAMS Data Utilities Library)
- \texttt{embeddedMultiInstance} (GAMS Data Utilities Library)
- \texttt{EMBPY01} (GAMS Test Library)
- \texttt{EMBPY02} (GAMS Test Library)

3.45.5.1 Using the Object-oriented API

The ECGamsDatabase class provides mechanisms for using the Object-oriented GAMS Python API in an embedded code section. The property \texttt{gams.ws} can be used to get an instance of GamsWorkspace. The property \texttt{gams.db} allows to access an instance of GamsDatabase that can be used to read and write data from the internal GAMS database like it can be done using \texttt{gams.get} and \texttt{gams.set} but using the access mechanisms of the GamsDatabase class.

3.45.5.2 Exchange via Files and Environment Variables

The Python class ECGamsDatabase provides read and write access to GAMS symbols. There are two other communication methods that can be used at GAMS compile time: files and environment variables. At compile time the Python code can produce a text file that can be included into GAMS via \texttt{$include} as in the following example:

\begin{verbatim}
$onEmbeddedCode Python: 10
  f = open('i.txt', 'w')
  for i in range(int(gams.arguments)):
    f.write('i'+str(i+1)+'\n')
  f.close()
$offEmbeddedCode

Set i /
  $include i.txt
  /
  display i;
\end{verbatim}
Here the Python code received the number of elements to write to a text file via the argument after Python: This text file is then included in the data statement of the GAMS set i. The display in the listing file looks as follows:

```
---- 20 SET i
i1, i2, i3, i4, i5, i6, i7, i8, i9, i10
```

Python provides many packages to read input files for many different formats and hence can be used to transform such formats to a GAMS compatible input format, as an alternative to providing the data via list objects and the `gams.set` functionality.

The second alternative to exchange information at compile time are environment variables. GAMS and Python allow to get and set environment variables and hence can be conveniently used to exchange small pieces of information. The following code provides an example where the maximum value of a parameter b is needed to build a set k:

```
Set i / i1*i5 /;
Parameter b(i) / i1 2, i2 7, i3 59, i4 2, i5 47 /;
$onEmbeddedCode Python:
  import os
  kmax = int(max([b[1] for b in list(gams.get("b"))]))
  gams.printLog('max value in b is ' + str(kmax))
o.environ["MAXB"] = str(kmax)
$offEmbeddedCode
$if x%sysEnv.MAXB%==x $abort MAXB is not set
Set k "from 0 to max(b)" / k0*k%sysEnv.MAXB% /;
Scalar card_k;
card_k = card(k);
Display card_k;
```

Alternatively in this example, we could build the GAMS set k in Python and send to GAMS via `gams.set`:

```
Set i / i1*i5 /;
Parameter b(i) / i1 2, i2 7, i3 59, i4 2, i5 47 /;
Set k "from 0 to max(b)" / system.empty /;
$onEmbeddedCode Python:
  kmax = int(max([b[1] for b in list(gams.get("b"))]))
  gams.printLog('max value in b is ' + str(kmax))
  gams.set("k", list(map(lambda k: 'k'+str(k), range(kmax + 1))))
$offEmbeddedCode
Scalar card_k;
card_k = card(k);
Display card_k;
```

In both cases the resulting GAMS symbol k is the same and the display in the listing file looks as follows:

```
---- 10 PARAMETER card_k = 60.000
```
3.45.5.3 Multiple Independent Python Sessions

At execution time the user has the ability to pause and continue an embedded code segment. Besides some performance aspects this also allows to work with multiple independent Python sessions. Due to some Python module incompatibilities (e.g. numpy) the independent Python sessions have to be enabled with a command line option pyMultInst set to 1. After the pauseEmbeddedCode we can obtain and store the handle of the last embedded code execution via function embeddedHandle. The handle needs to be supplied when we continue the Python session via continueEmbeddedCode. The different Python sessions are fairly separate as shown in the example below. Here we save the GAMS scalar ord_i in a Python object i five times. The value for i that we store in the five different Python sessions is 1 to 5. In the subsequent loop we activate the Python session with the appropriate handle and print the value of i:

```bash
if not %sysEnv.GMSPYTHONMULTINST%==1 $abort.noError Start with command line option pyMultInst=1
Set i / i1*i5 /;
Parameter h(i)
  ord_i / 0 /;
loop(i,
  ord_i = ord(i);
  embeddedCode Python:
    i = int(list(gams.get("ord_i"))[0])
    gams.printLog(str(i))
  pauseEmbeddedCode
  h(i) = embeddedHandle;
);
loop(i,
  continueEmbeddedCode h(i):
    gams.printLog(str(i))
  endEmbeddedCode
);
```

The GAMS log shows the value of i in the different Python sessions:

```
--- Starting execution: elapsed 0:00:00.002
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
--- 1
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
--- 2
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
--- 3
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
--- 4
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
--- 5
--- Execute embedded library embpycclib64.dll
--- 1
--- Execute embedded library embpycclib64.dll
--- 2
--- Execute embedded library embpycclib64.dll
--- 3
--- Execute embedded library embpycclib64.dll
--- 4
--- Execute embedded library embpycclib64.dll
--- 5
*** Status: Normal completion
```
3.45.5.4 Troubleshooting Embedded Python Code

The GAMS compiler ensures that the number of errors during execution time is minimized. While the logic of the GAMS program might be flawed there is nothing (with a few exceptions) that the GAMS system cannot execute. This is different if we embed foreign code in a GAMS program. The GAMS compiler does not understand the foreign code syntax and just skips over it. Only when the code is executed we will find out if everything works as expected. If the embedded code contains some (Python) syntax errors the Python parser will inform us about this and the message will appear in the GAMS log. For example, the following Python code using the gams.printLog function two times will generate a syntax error:

```python
$onEmbeddedCode Python:
  gams.printLog('hello')
  gams.printLog('world...')
$offEmbeddedCode
```

The GAMS log will provide some guidance:

```plaintext
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll File "C:\tmp\gamsdir\225a\myPy.dat.dat", line 8
  gams.printLog('world...')

IndentationError: unexpected indent
```

```plaintext
--- Python error! Return code from Python execution: -1
*** Error executing Python embedded code section:
*** Check log above
```

Moreover, if the Python code raises an exception which is not handled within the code this will also lead to a compilation or execution error in GAMS depending at what phase the embedded code is executed.

```python
embeddedCode Python:
  raise Exception('something is wrong')
endEmbeddedCode
```

will produce the following GAMS log and an execution time error:

```plaintext
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
--- Exception from Python: something is wrong
*** Error at line 1: Error executing "embeddedCode" section: Check log above
```
Note

It is good practice to raise a Python exception if an error occurs. In any case using `exit()` needs to be avoided since it terminates the executable in an uncontrolled way.

The Python code is executed as part of the GAMS process and GAMS gives control to the Python interpreter when executing the embedded code. So in the worst case if the Python interpreter crashes, the entire GAMS process will crash. Therefore, it is important to be able to test and debug the embedded Python code independent of GAMS. In the following examples we call the Python interpreter executable as part of a GAMS job. In principle this can be tested and debugged completely independent of GAMS where a GDX file represents the content of the GAMS database.

In the first example we mimic the embedded code facility at compile time by exporting the entire GAMS database to a GDX file `debug.gdx`. With `on/offEcho` we write the embedded code with a few extra lines at the top and bottom surrounded by a try/except block and execute the Python interpreter via `call`. One of the extra lines at the end of the embedded code triggers the creation of a GDX result file `debugOut.gdx` which can be imported in subsequent `$gdxin/$load` commands.

```python
Set i /i1*i10/
  p(i,i) permutation;

$gdxOut debug.gdx
$unload
$gdxOut

$onEcho > debug.py
from gamsemb import *
gams = ECGAMSDatabase('debug.gdx')
try:
  import random
  i = list(gams.get("i"))
  p = list(i)
  random.shuffle(p)
  for idx in range(len(i)):
    p[idx] = (i[idx], p[idx])
  gams.set("p", p)
  gmdWriteGDX(gams._gmd, 'debugOut.gdx', 1);
except Exception as e:
  print(str(e))
$offEcho

$call ="%gams.sysdir%GMSPython/python" debug.py
$if errorlevel 1 $abort Problems running Python

$gdxIn debugOut.gdx
$loadDC p

Option p:0:0:1;
Display p;
```

In the second example we mimic the embedded code facility at execution time by exporting the entire GAMS database to a GDX file `debug.gdx` via `execute_unload 'debug.gdx';`. We write the embedded code with a few extra lines at the top and bottom surrounded by a try/except block via the `put` facility and execute the Python interpreter via `execute`. Identical to the compile time example, we export the result to the GDX file `debugOut.gdx` which can be imported via the `execute_load` statement.
Set i /i1*i10/  
   p(i,i) permutation;

execute_unload 'debug.gdx';
file fpy / 'debug.py' /; put fpy;

$onPutS
from gamsemb import *
gams = ECGAMSDatabase(r'\%gams.sysdir% \
[:2],’debug.gdx’)
gams.arguments = ’-a c -b -db abc’
try:
    import random
    i = list(gams.get("i"))
    p = list(i)
    random.shuffle(p)
    for idx in range(len(i)):
        p[idx] = (i[idx], p[idx])
geamset("p", p)
gmdWriteGDX(gams._gmd,'debugOut.gdx',1);
ext except Exception as e:
    print(str(e))
$offPut

putClose fpy;
execute ‘=%gams.sysdir%GMSPython/python” debug.py’;
abort$errorlevel ’problems running python’;

execute_load ’debugOut.gdx’, p;
Option p:0:0:1;
Display p;

3.45.5.5 Performance Considerations of Embedded Python Code

If the same embedded code section (e.g. in a loop) is executed many times there are a few considerations
 to be taken into account in order to get the best performance. For this we will experiment with the
 example from the introduction. We look for a random permutation of a set i. In addition we have a
 cost matrix c(i,ii) and we are looking for the least cost permutation. We should just formulate this
 as matching in a bi-partite graph but in order to demonstrate some performance considerations we will
 repeatedly call the Python code that provides a random permutation and we will evaluate the cost of the
 permutation in GAMS and store the value of the cheapest one. Here is the naive implementation using
 embedded code:

Set i /i1*i50/  
   p(i,i) permutation;
Alias (i,ii);
Parameter c(i,i) cost of permutation;
c(i,ii) = uniform(-50,50);
Set iter / 1*100 /;
Scalar tcost
   minTCost / +inf /;
loop(iter,
    embeddedCode Python:
        import random
        i = list(gams.get("i"))
        p = list(i)
random.shuffle(p)
for idx in range(len(i)):
    p[idx] = (i[idx], p[idx])
gams.set("p", p)
endEmbeddedCode
p
tcost = sum(p, c(p));
if (tcost < minTCost, minTCost = tcost);
);
Display minTCost;

In the code we start and stop the Python interpreter and with every execution of the embedded code we need to make the setup and initialization which takes a significant amount of time. The entire GAMS job executes in about 16 seconds. We can avoid the repeated setup and initialization by using pause and continue:

Set i / i1*i50 /  
p(i,i) permutation;
Alias (i,ii);
Parameter c(i,i) cost of permutation;
c(i,ii) = uniform(-50,50);

embeddedCode Python:
import random
pauseEmbeddedCode
Set iter / 1*1000 /;
Scalar tcost
minTCost / +inf /;
loop(iter,
    continueEmbeddedCode:
    i = list(gams.get("i"))
    p = list(i)
    random.shuffle(p)
    for idx in range(len(i)):
        p[idx] = (i[idx], p[idx])
    gams.set("p", p)
    pauseEmbeddedCode
    p
tcost = sum(p, c(p));
    if (tcost < minTCost, minTCost = tcost);
    );
    continueEmbeddedCode:
    pass
endEmbeddedCode
Display minTCost;

The last embedded code execution of the Python pass statement is to clean up and terminate the Python session. As you can see from the set iter we had to increase this from 100 to 1000 to measure the timing properly. This run takes about 1.179 secs (we ran this 20 times and build the average). This is the biggest improvement, the other two following enhancements are just icing on the cake. We can actually extract the set i and store this in Python list i just once:

Set i / i1*i50 /  
p(i,i) permutation;
Alias (i,ii);
Parameter c(i,i) cost of permutation;
c(i,ii) = uniform(-50,50);

embeddedCode Python:
  import random
  i = list(gams.get("i"))
pauseEmbeddedCode

set iter / 1*1000 /;
scalar tcost
  minTCost / +inf /;
loop(iter,
  continueEmbeddedCode:
    p = list(i)
    random.shuffle(p)
    for idx in range(len(i)):
      p[idx] = (i[idx], p[idx])
    gams.set("p", p)
    pauseEmbeddedCode p
    tcost = sum(p, c(p));
    if (tcost < minTCost, minTCost = tcost);
  );
continueEmbeddedCode:
pass
endEmbeddedCode
Display minTCost;

The total running time of this is 1.005 secs. In addition, we can work with label indexes rather than the labels itself. Indexes are integers and are often faster than labels that are stored as strings. The only difference to the code above is the extraction method of the Python list i by i = list(gams.get("i",keyType=KeyType.INT)). The resulting running time is 0.993 secs.

3.45.5.6 Porting to a Different Version of Python

GAMS comes with a Python 3.6 interpreter that is used as default interpreter in the Embedded Code Facility. It is located in [GAMS directory]/GMSPython and comes with the usual tools for e.g. installing further Python modules and packages like pip and easy_install. These tools need to be executed in the directory in which they are located since they are referencing the Python interpreter using a relative path. In order to make them work from arbitrary locations as well one can either change the so-called Shebang (#!) line manually or run the script fixPath.py which does the work for a list of specific programs.

cd [GAMS directory]/GMSPython/bin
./python3.6 fixPath.py

The Embedded Code Facility using the Python programming language is implemented for Python 3.6. Instead of using the default Python interpreter that comes with GAMS (for platforms Windows, Linux, and Mac OS X), it is possible to use another Python installation instead. The command line parameter pySetup has to be set to 0. In addition, on Linux and Mac OS X it is required to prevent Embedded Code from finding the directory GMSPython. For these platforms one needs to rename or delete the directory GMSPython located in the GAMS system directory. Next, the system needs to be made aware of the alternative Python installation. GAMS needs to find the Python run-time library (python36.dll, libpython3.6m.dylib, or libpython3.6m.so). The location of the library (usually somewhere in Python installation directory) needs to be added to the search path for libraries. This is operating system specific. Adding the location to the PATH (Windows), LD_LIBRARY_PATH (Linux), or DYLD_LIBRARY_PATH (Mac OS X) environment variable will let GAMS find the required library. Moreover, PYTHONHOME or
GMSPYTHONHOME (the latter takes precedence) environment variable should point to the alternative Python installation.

In order for the Embedded Code Facility to work, one needs to make the alternative Python interpreter aware of the required modules provided by GAMS. This can be done by installing them or setting PYTHONPATH appropriately. See the Getting started of the GAMS Python API for further instructions on installing the Python API. Note that the supported Python version for embedded code is Python 3.6 and that beside the GAMS Python API, the module gamsemb.py is required which is located in [GAMS directory]/apifiles/Python/api_36 only. If the setup.py script is used for installation, gamsemb.py will only be installed if the Python version is 3.6. Note that if a different version of Python is used in an experimental setup, it might be required to build the embedded code library manually. How to do this is explained in the paragraph below.

Although the Embedded Code Facility and its binary components are part of the GAMS distribution, it is possible to build it manually from source using the following commands. The exact command line might change depending on the compiler and the operating system in use:

- **Windows (32 bit):**
  ```
  cd [GAMS directory]/apifiles/C/api
  cl.exe -Feembpycclib.dll -I./include -I. embpyoo.c emblib.c gmdcc.c ..././GMSPython/libs/python36.lib -LD -link -def:emblib.def
  ```

- **Windows (64 bit):**
  ```
  cd [GAMS directory]/apifiles/C/api
  icl.exe -Feembpycclib64.dll -I./include -I. embpyoo.c emblib.c gmdcc.c ..././GMSPython/libs/python36.lib -LD -link
  ```

- **Linux (64 bit):**
  ```
  cd [GAMS directory]/apifiles/C/api
  gcc -o libembpycclib64.so -nostartfiles -shared -Wl,-Bsymbolic -m64 -pthread -Wl,-rpath,$ORIGIN/GMSPython/lib -fPIC -I ../../../GMSPython/include/python3.6m -I. embpyoo.c emblib.c gmdcc.c -L./include -L./GMSPython/lib -ldl python3.6m -l -ldl
  ```

- **Mac OS X:**
  ```
  cd [GAMS directory]/apifiles/C/api
  gcc -o libembpycclib64.dylib -dynamiclib -m64 -shared -Wl,-rpath,$ORIGIN/GMSPython/lib -fPIC -I ../../../GMSPython/include/python3.6m -I. embpyoo.c emblib.c gmdcc.c -L./include -L./GMSPython/lib -ldl python3.6m -l -ldl
  ```

### 3.46 Extrinsic Functions

#### 3.46.1 Introduction

Mathematical functions play an important role in the GAMS language, especially for nonlinear models. Like other programming languages, GAMS provides a number of built-in or intrinsic functions. GAMS is used in an extremely diverse set of application areas and this creates frequent requests for the addition of new and often sophisticated and specialized functions. There is a trade-off between satisfying these requests and avoiding complexity not needed by most users. The GAMS Function Library Facility provides the means for managing this trade-off, since it allows users to import functions from an external library into a GAMS model. However, these external libraries can currently only provide functionality for the evaluation of functions (incl. their first and second derivatives) in a point. Solvers that need to analyze the algebraic structure of the model instance are therefore not able to work with extrinsic functions. This includes the class of deterministic global solvers, see column "Global" in this table, while, for example, stochastic global solvers can work with extrinsic functions.

In this chapter we will demonstrate how to access functions from an extrinsic function library in a GAMS model and we will describe the extrinsic function libraries that are included in the GAMS distribution. In addition, we will provide some pointers for users who wish to build their own extrinsic function library.
3.46 Extrinsic Functions

3.46.2 Using Function Libraries

Function libraries are made available to a model with the following compiler directive:

\[ \$\text{FuncLibIn} \ <\text{InternalLibName}> \ <\text{ExternalLibName}> \]

Here \text{InternalLibName} is a handle that will be used to refer to the library inside the model source code, \text{ExternalLibName} is the file name of the shared library that implements the extrinsic functions. To access libraries included with the GAMS distribution, the name of the library may be used with no path prefix. GAMS will look for the library in the GAMS system directory. To access a library that does not reside in this standard place, the external name should include a relative or absolute path to the location of the library. GAMS will then search for the specified library using the mechanisms specific to the host operating system. When processing the directive \$\text{FuncLibIn}, GAMS will validate the library, make the included functions available for use and add a table of the included functions to the listing file.

Note

The function library facility gives users complete control over naming so that potential name conflicts between libraries can be avoided.

Before the individual functions may be used, they have to be declared in the following way:

Function \(<\text{InternalFuncName}> /<\text{InternalLibName}>.\ <\text{FuncName}>/; \]

Here \text{InternalFuncName} is the name of the individual function that will be used in the GAMS code. The user may choose this internal name freely and thus avoid potential naming conflicts. \text{InternalLibName} is the name of the function library as defined by the \$\text{FuncLibIn} directive and \text{Func.Name} is the name of the individual function in the external function library. Once functions have been declared in this way they may be used like intrinsic functions.

Consider the following simple example:

\$\text{FuncLibIn} \ myLib \ triclib

Function myCos /myLib.Cosine/
    mySin /myLib.Sine/
    myPi /myLib.Pi/;

Scalar d;
  d = myCos(myPi/3);
  display d;

Note that in the first line the external trigonometric library \text{triclib} is activated and the internal name \text{myLib} is specified for it. Then the functions are declared. Observe that \text{Cosine}, \text{Sine} and \text{Pi} are functions in the trigonometric library. After the library has been loaded and the functions have been declared, the functions may be used as usual. The trigonometric library is discussed in section Example: Trigonometric Library below.
3.46.3 Libraries that are included in the GAMS Distribution

In this section we will present the libraries that are included in the GAMS distribution: the Fitpack Library, the Piecewise Polynomial Library and the Stochastic Library. In addition, we will provide details on the LINDO Sampling Library. However, note that the LINDO Sampling Library is only available for LINDO license holders.

In the tables that follow, the "Endogenous Classification" (last column) specifies in which models the function may legally appear. In order of least to most restrictive, the choices are any, DNLP, NLP, none. See section Classification of Models for details on model types in GAMS. Note well that functions classified as any are only permitted with exogenous (constant) arguments.

A word on the notation in the tables below: for function arguments, lower case indicates that an endogenous variable is allowed. For details on endogeneous variables, see section Functions in Equation Definitions. Upper case function arguments indicate that a constant is required. Arguments in square brackets may be omitted: the default values used in such cases are specified in the function description provided.

3.46.3.1 The Fitpack Library

FITPACK by Paul Dierckx [65] is a Fortran-based library for one-dimensional and two-dimensional spline interpolations. This library has been repackaged to work with the GAMS Function Library Facility. The model [FITLIB01] from the GAMS Test Library is an example of the use of the library FITPACK inside GAMS.

Note that the supporting points to which the function will be fit need to be stored in a three-dimensional parameter, fitdata, in a GDX file fit.gdx. The first dimension is a function index, the second dimension is the index of the supporting point and the third dimension takes one of the following four values: "w" (weight), "x" (x-value), "y" (y-value) or "z" (z-value).

The FITPACK library is made available with the following directive:

```
$FuncLibIn <InternalLibName> fitfclib
```

It provides the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>fitFunc(FUNIND,x[,y])</td>
<td>Evaluate spline</td>
<td>DNLP</td>
</tr>
<tr>
<td>fitParam(FUNIND,PARAM[,VALUE])</td>
<td>Read or set parameters</td>
<td>none</td>
</tr>
</tbody>
</table>

The function FitParam may be used to change certain parameters that are used for the evaluation. The following values are defined:

- 1: Smoothing factor (S)
- 2: Degree of spline in direction x (Kx)
- 3: Degree of spline in direction y (Ky)
- 4: Lower bound of function in direction x (LOx)
- 5: Lower bound of function in direction y (LOY)
- 6: Upper bound of function in direction x (UPx)
- 7: Upper bound of function in direction y (UPy)
3.46 Extrinsic Functions

3.46.3.2 The Piecewise Polynomial Library

The Piecewise Polynomial Library may be used to evaluate piecewise polynomial functions. An example is given in the model [PWPLIB01] in the GAMS Test Library. Note that the functions that are to be evaluated need to be defined and stored in a GDX file. The following code snippet serves as illustration:

* Define two piecewise polynomial functions
Table pwpdata(*,*,*) '1st index: function number, 2nd index: segment number, 3rd index: degree'
 leftBound 0 1 2
 1.1 1 2.4 -2.7 0.3
 1.2 4 5.6 -4.3 0.5
 2.1 0 0 -6.3333 0
 2.2 0.3333 1.0370 -12.5554 9.3333
 2.3 0.6667 9.7792 -38.7791 29;
* Write pwp data to gdx file, which will be read by external library (pwpcclib)
$gdxout pwp.gdx
$unload pwpdata
$gdxout

Observe that on each row of the table pwpdata we have the following entries:

FuncInd.SegInd  leftBound  Coef0  Coef1  Coef2

Here FuncInd sets a function index and SegInd defines the index of the segment (or interval) which is described. Further, LeftBound gives the lower bound of the segment. The upper bound will be taken from the lower bound on the following segment, or set to infinity in case it is the last segment. Finally, CoefX defines the X-th degree coefficient of the polynomial corresponding to this segment.

The Piecewise Polynomial Library is made available with the following directive:

$FuncLibIn <InternalLibName> pwpcclib

It provides the following function:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwpFunc(FUNIND,x)</td>
<td>Piecewise polynomials</td>
<td>DNLP</td>
</tr>
</tbody>
</table>

3.46.3.3 The Stochastic Library

The Stochastic Library provides random deviates, probability density functions, cumulative density functions and inverse cumulative density functions for certain continuous and discrete distributions. This library is made available with the following directive:

$FuncLibIn <InternalLibName> stodclib

The continuous distributions that are available with this library are the following:
<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{beta}(\text{SHAPE}_1, \text{SHAPE}_2) )</td>
<td>Beta distribution with shape parameters ( \text{SHAPE}_1 ) and ( \text{SHAPE}_2 ), see MathWorld</td>
</tr>
<tr>
<td>( \text{cauchy}(\text{LOCATION}, \text{SCALE}) )</td>
<td>Cauchy distribution with location parameter ( \text{LOCATION} ) and scale parameter ( \text{SCALE} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{ChiSquare}(\text{DF}) )</td>
<td>Chi-squared distribution with degrees of freedom ( \text{DF} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{exponential}(\text{LAMBDA}) )</td>
<td>Exponential distribution with rate of change ( \text{LAMBDA} ), see MathWorld</td>
</tr>
<tr>
<td>( f(\text{DF}_1, \text{DF}_2) )</td>
<td>F-distribution with degrees of freedom ( \text{DF}_1 ) and ( \text{DF}_2 ), see MathWorld</td>
</tr>
<tr>
<td>( \text{gamma}(\text{SHAPE}, \text{SCALE}) )</td>
<td>Gamma distribution with shape parameter ( \text{SHAPE} ) and scale parameter ( \text{SCALE} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{gumbel}(\text{LOCATION}, \text{SCALE}) )</td>
<td>Gumbel distribution with location parameter ( \text{LOCATION} ) and scale parameter ( \text{SCALE} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{invGaussian}(\text{MEAN}, \text{SHAPE}) )</td>
<td>Inverse Gaussian distribution with mean ( \text{MEAN} ) and scale parameter ( \text{SHAPE} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{laplace}(\text{MEAN}, \text{SCALE}) )</td>
<td>Laplace distribution with mean ( \text{MEAN} ) and scale parameter ( \text{SCALE} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{logistic}(\text{LOCATION}, \text{SCALE}) )</td>
<td>Logistic distribution with location parameter ( \text{LOCATION} ) and scale parameter ( \text{SCALE} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{logNormal}(\text{LOCATION}, \text{SCALE}) )</td>
<td>Lognormal distribution with location parameter ( \text{LOCATION} ) and scale parameter ( \text{SCALE} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{normal}(\text{MEAN}, \text{STD_DEV}) )</td>
<td>Normal distribution with mean ( \text{MEAN} ) and standard deviation ( \text{STD_DEV} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{pareto}(\text{SCALE}, \text{SHAPE}) )</td>
<td>Pareto distribution with scale parameter ( \text{SCALE} ) and shape parameter ( \text{SHAPE} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{rayleigh}(\text{SIGMA}) )</td>
<td>Rayleigh distribution with parameter ( \text{SIGMA} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{studentT}(\text{DF}) )</td>
<td>Student’s t-distribution with degrees of freedom ( \text{DF} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{triangular}(\text{LOW}, \text{MID}, \text{HIGH}) )</td>
<td>Triangular distribution between ( \text{LOW} ) and ( \text{HIGH} ), where ( \text{MID} ) is the most probable number, see MathWorld</td>
</tr>
<tr>
<td>( \text{uniform}(\text{LOW}, \text{HIGH}) )</td>
<td>Uniform distribution between ( \text{LOW} ) and ( \text{HIGH} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{weibull}(\text{SHAPE}, \text{SCALE}) )</td>
<td>Weibull distribution with shape parameter ( \text{SHAPE} ) and scale parameter ( \text{SCALE} ), see MathWorld</td>
</tr>
</tbody>
</table>

Further, the following discrete distributions are available:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{binomial}(N, P) )</td>
<td>Binomial distribution with number of trials ( N ) and success probability ( P ) in each trial, see MathWorld</td>
</tr>
<tr>
<td>( \text{geometric}(P) )</td>
<td>Geometric distribution with success probability ( P ) in each trial, see MathWorld</td>
</tr>
<tr>
<td>( \text{hyperGeo}(\text{TOTAL}, \text{GOOD}, \text{TRIALS}) )</td>
<td>Hypergeometric distribution with total number of elements ( \text{TOTAL} ), number of good elements ( \text{GOOD} ) and number of trials ( \text{TRIALS} ), see MathWorld</td>
</tr>
<tr>
<td>( \text{logarithmic}(P\text{-FACTOR}) )</td>
<td>Logarithmic distribution with parameter ( P\text{-FACTOR} ), also called log-series distribution, see MathWorld</td>
</tr>
<tr>
<td>( \text{negBinomial}(\text{FAILURES}, P) )</td>
<td>Negative Binomial distribution with ( \text{FAILURES} ) being the number of failures until the experiment is stopped and success probability ( P ) in each trial. The generated random number describes the number of successes until the defined number of failures is reached, see MathWorld</td>
</tr>
<tr>
<td>( \text{poisson}(\text{LAMBDA}) )</td>
<td>Poisson distribution with mean ( \text{LAMBDA} ), see MathWorld</td>
</tr>
</tbody>
</table>
### 3.46 Extrinsic Functions

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uniformint(LOW,HIGH)</td>
<td>Integer Uniform distribution between LOW and HIGH, see MathWorld</td>
</tr>
</tbody>
</table>

Note that for each distribution the library offers the following four functions, where DistributionName is the name of the distribution as listed in the tables above, parameters are the parameters associated with each distribution, and x is the point at which the function is to be evaluated. Note that x may be an endogenous variable.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif. for Continuous Distributions</th>
<th>End. Classif. for Discrete Distributions</th>
</tr>
</thead>
<tbody>
<tr>
<td>d&lt;DistributionName&gt;</td>
<td>Generate a random variable (sample from the distribution)</td>
<td>none</td>
<td>none</td>
</tr>
<tr>
<td>pdf&lt;DistributionName&gt;</td>
<td>Probability density function</td>
<td>DNLP</td>
<td>none</td>
</tr>
<tr>
<td>cdf&lt;DistributionName&gt;</td>
<td>Cumulative distribution function</td>
<td>DNLP</td>
<td>none</td>
</tr>
<tr>
<td>icdf&lt;DistributionName&gt;</td>
<td>Inverse cumulative distribution function</td>
<td>DNLP</td>
<td>none</td>
</tr>
</tbody>
</table>

For example, the functions for the Normal distribution are

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>dNormal(MEAN,STD_DEV)</td>
<td>Samples a random number from the Normal distribution</td>
<td>none</td>
</tr>
<tr>
<td>pdfNormal(x,MEAN,STD_DEV)</td>
<td>Probability density function for Normal distribution</td>
<td>DNLP</td>
</tr>
<tr>
<td>cdfNormal(x,MEAN,STD_DEV)</td>
<td>Cumulative distribution function for Normal distribution</td>
<td>DNLP</td>
</tr>
<tr>
<td>icdfNormal(x,MEAN,STD_DEV)</td>
<td>Inverse cumulative distribution function for Normal distribution</td>
<td>DNLP</td>
</tr>
</tbody>
</table>

Finally, the seed for the various random number generators can be set by using the following function:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>SetSeed(SEED)</td>
<td>Defines the seed for random number generator</td>
<td>none</td>
</tr>
</tbody>
</table>

In the following example, a sample of size 20 is generated from the Normal, Binomial, Cauchy, and Lognormal distributions each:

```bash
$funclib stolib stodclib
Functions randnorm /stolib.dnormal /
   randbin /stolib.dbinomial /
   randcauchy /stolib.dcauchy /
   randlognorm /stolib.dlognormal /;
Set i / i1*i20 /;
Set j / norm, binomial, cauchy, lognorm /;
Parameter randx(i,j) "distribution sample";
```
randx(i,“norm”) = randnorm(5,2);
randx(i,“binomial”) = randbin(10,0.5);
randx(i,“cauchy”) = randcauchy(5,1);
randx(i,“lognorm”) = randlognorm(1.2,0.3);
display randx;

In the example, first the stochastic library is made available in GAMS, then the functions that will be
used from the library are declared, giving them names under which to refer to them in the GAMS model.

The output generated by the display statement is the following:

<table>
<thead>
<tr>
<th>i</th>
<th>norm</th>
<th>binomial</th>
<th>cauchy</th>
<th>lognorm</th>
</tr>
</thead>
<tbody>
<tr>
<td>i1</td>
<td>4.373</td>

</tbody>
</table>

3.46.3.4 The LINDO Sampling Library

The LINDO Sampling Library provides samples of random numbers for certain distributions.

It is made available by the following directive:

$FuncLibIn <InternalLibName> lsadclib

Observe that a LINDO license is required to use this library.

The following table list the LINDO sampling functions.
### 3.46 Extrinsic Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sampleLS&lt;DistributionName&gt;(parameters)</code></td>
<td>Creates a sample using the distribution <code>DistributionName</code>, according to the distribution parameters, and returns a <code>HANDLE</code> that references the sample, as illustrated in the example below.</td>
<td>none</td>
</tr>
<tr>
<td><code>getSampleValues(HANDLE)</code></td>
<td>Retrieves sampling created by the function <code>sampleLS</code>. See example below.</td>
<td>none</td>
</tr>
<tr>
<td><code>induceCorrelation(CORTYPE)</code></td>
<td>Induces the correlation that was set with the function <code>setCorrelation</code> before. <code>CORTYPE</code> describes the correlation type: 0 (Pearson), 1 (Kendall) or 2 (Spearman). See example below.</td>
<td>none</td>
</tr>
<tr>
<td><code>setCorrelation(SAMPLE1,SAMPLE2,COR)</code></td>
<td>Defines correlation between two samplings. See example below.</td>
<td>none</td>
</tr>
<tr>
<td><code>setSeed(SEED)</code></td>
<td>Specifies the seed for the random number generator.</td>
<td>none</td>
</tr>
<tr>
<td><code>setRNG(RNG)</code></td>
<td>Specifies the random number generator that will be used. Possible values are -1 (FREE), 0 (SYSTEM), 1 (LINDO1), 2 (LINDO2), 3 (LIN1), 4 (MULT1), 5 (MULT2), and 6 (MERSENNE).</td>
<td>none</td>
</tr>
</tbody>
</table>

The following tables list the available continuous and discrete distributions, respectively. Note that the parameter `SAMSIZE` must be specified and describes the size of the sample. However, the parameter `VARRED` is optional and facilitates choosing a variance reduction method. The values are 0 (meaning "none"), 1 (meaning "Latin Hyper Square") and 2 (meaning "Antithetic"). The default is Latin Hyper Square sampling, it will be used if no variance reduction method is specified.

#### Continuous Distribution

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>beta(SHAPE_1,SHAPE_2,SAMSIZE[,VARRED])</code></td>
<td><strong>Beta distribution</strong> specified by two shape parameters.</td>
</tr>
<tr>
<td><code>cauchy(LOCATION,SCALE,SAMSIZE[,VARRED])</code></td>
<td><strong>Cauchy distribution</strong> specified by the location and the scale parameter.</td>
</tr>
<tr>
<td><code>chisquare(DF,SAMSIZE[,VARRED])</code></td>
<td><strong>Chi-Squared</strong> distribution specified by degrees of freedom.</td>
</tr>
<tr>
<td><code>exponential(RATE,SAMSIZE[,VARRED])</code></td>
<td><strong>Exponential distribution</strong> specified by rate of change.</td>
</tr>
<tr>
<td><code>f(DF_1,DF_2,SAMSIZE[,VARRED])</code></td>
<td><strong>F distribution</strong> specified by degrees of freedom. Note that the function <code>sampleLSf</code> uses another version of the F distribution than the function <code>dF</code> from the Stochastic Library.</td>
</tr>
<tr>
<td><code>gamma(SHAPE,SCALE,SAMSIZE[,VARRED])</code></td>
<td><strong>Gamma distribution</strong> specified by shape and scale parameter. Note that the function <code>sampleLSgamma(A,B)</code> is equivalent to the function <code>dGamma(B,A)</code> from the Stochastic Library.</td>
</tr>
<tr>
<td><code>gumbel(LOCATION,SCALE,SAMSIZE[,VARRED])</code></td>
<td><strong>Gumbel distribution</strong> specified by location and scale parameter.</td>
</tr>
<tr>
<td><code>laplace(LOCATION,SCALE,SAMSIZE[,VARRED])</code></td>
<td><strong>Laplace distribution</strong> specified by location and scale parameter.</td>
</tr>
<tr>
<td><code>logistic(LOCATION,SCALE,SAMSIZE[,VARRED])</code></td>
<td><strong>Logistic distribution</strong> specified by location and scale parameter.</td>
</tr>
</tbody>
</table>
### Continuous Distribution

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lognormal(LOCATION,SCALE,SAMSIZE[,VARRED])</td>
<td>Log Normal distribution specified by location and scale parameter.</td>
</tr>
<tr>
<td>normal(MEAN,STD_DEV,SAMSIZE[,VARRED])</td>
<td>Normal distribution specified by given mean and standard deviation.</td>
</tr>
<tr>
<td>pareto(SCALE,SHAPE,SAMSIZE[,VARRED])</td>
<td>Pareto distribution specified by shape and scale parameter.</td>
</tr>
<tr>
<td>studentt(DF,SAMSIZE[,VARRED])</td>
<td>Student's t-distribution specified by degrees of freedom.</td>
</tr>
<tr>
<td>triangular(LOW,MID,HIGH,SAMSIZE[,VARRED])</td>
<td>Triangular distribution specified by lower and upper limit and mid value.</td>
</tr>
<tr>
<td>uniform(LOW,HIGH,SAMSIZE[,VARRED])</td>
<td>Uniform distribution specified by the given bounds.</td>
</tr>
<tr>
<td>weibull(SCALE,SHAPE,SAMSIZE[,VARRED])</td>
<td>Weibull distribution specified by scale and shape parameter. Note that the function sampleLSweibull(A,B) is equivalent to the function dWeibull(B,A) from the Stochastic Library.</td>
</tr>
</tbody>
</table>

### Discrete Distribution

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binomial(N,P,SAMSIZE[,VARRED])</td>
<td>Binomial distribution specified by number of trials N and success probability P in each trial.</td>
</tr>
<tr>
<td>hypergeo(TOTAL,GOOD,TRIALS,SAMSIZE[,VARRED])</td>
<td>Hypergeometric distribution specified by total number of elements, number of good elements, and number of trials.</td>
</tr>
<tr>
<td>logarithmic(P-FACTOR,SAMSIZE[,VARRED])</td>
<td>Logarithmic distribution specified by P-Factor. Note that the function sampleLSlogarithmic uses another version of the logarithmic distribution than dLogarithmic from the Stochastic Library.</td>
</tr>
<tr>
<td>negbinomial(SUCC,P,SAMSIZE[,VARRED])</td>
<td>Negative Binomial distribution specified by the number of successes and the probability of success. The generated random number describes the number of failures until the defined number of successes is reached. Note that the function sampleLSnegbinomial(R,P) is equivalent to the function dNegBinomial(R,P-1) from the Stochastic Library.</td>
</tr>
<tr>
<td>poisson(MEAN,SAMSIZE[,VARRED])</td>
<td>Poisson distribution specified by mean.</td>
</tr>
</tbody>
</table>

The following example illustrates the use of the sample generator and shows the effect of the functions setCorrelation and induceCorrelation:

```
$funclibin lsalib lsadclib

Functions normalSample / lsalib.SampleLSnormal /
        getSampleVal / lsalib.getSampleValues /
        setCor    / lsalib.setCorrelation /
        indCor    / lsalib.induceCorrelation ;

Scalars d "dummy"
       h "handle for first sample"
```
k "handle for second sample";

Set i "sample index" / i01*i12 /;

Parameters sv_h(i) "sample values for handle h"
    sv_k(i) "sample values for handle k";

* generate two handles for 12 samples from normal distribution with mean 5 and std.dev. 2 each
  h = normalSample(5,2,12);
  k = normalSample(5,2,12);

* retrieve sample values from Lindo library
  loop(i, sv_h(i) = getSampleVal(h) );
  loop(i, sv_k(i) = getSampleVal(k) );
  display sv_h, sv_k;

* set and induce a correlation between samples h and k
  d = setCor(h,k,-1);
  d = indCor(1);

* retrieve sample values again from correlated distribution
  loop(i, sv_h(i) = getSampleVal(h) );
  loop(i, sv_k(i) = getSampleVal(k) );
  display sv_h, sv_k;

The resulting output shows that the values of sv_k are reordered according to the desired correlation:

---- 25 PARAMETER sv_h sample values for handle h
  i01 2.079,  i02 6.454,  i03 4.437,  i04 2.747,  i05 5.339,  i06 4.059,  i07 6.311,  i08 7.512,  i09 8.280,  i10 3.380,  i11 4.596,  i12 5.752
---- 25 PARAMETER sv_k sample values for handle k
  i01 7.550,  i02 3.021,  i03 9.474,  i04 6.442,  i05 4.592,  i06 0.704,  i07 3.890,  i08 6.002,  i09 3.311,  i10 5.084,  i11 4.227,  i12 5.509

---- 35 PARAMETER sv_h sample values for handle h
  i01 2.079,  i02 6.454,  i03 4.437,  i04 2.747,  i05 5.339,  i06 4.059,  i07 6.311,  i08 7.512,  i09 8.280,  i10 3.380,  i11 4.596,  i12 5.752
---- 35 PARAMETER sv_k sample values for handle k
  i01 7.550,  i02 3.021,  i03 9.474,  i04 6.442,  i05 4.592,  i06 0.704,  i07 3.890,  i08 6.002,  i09 3.311,  i10 5.084,  i11 4.227,  i12 5.509

3.46.4 Build Your Own Library

This section discusses the creation of a custom extrinsic function library. Before attempting to implement such a library, we suggest to study the example libraries for which source code and test models are available. These libraries are studied below.
Attention

Building extrinsic function libraries requires the knowledge of a regular programming language (like C/C++, Fortran, ...) and experience with handling compilers and linkers to build dynamically linked libraries. In some situation, it may be easier to use the simpler GAMS macros or batinclude files to define own functions.

Note

Extrinsic functions are limited to 20 scalar arguments and return a scalar value.

An extrinsic function library consists of a specification part and a number of callbacks to evaluate the defined functions at an input point.

The specification part is implemented by a callback `querylibrary`. It returns information about the library itself, available functions, their arguments, endogenous classification, etc. to the GAMS execution system. C, Delphi, or Fortran source code for this callback can be generated automatically by using the Python helper script `ql.py`. The script processes a specification file `*.spec`, which is specified as first argument. The format of this file is documented in the file `tri.spec`. Both `ql.py` and `tri.spec` are contained in the source of the trigonometric library examples in the GAMS test library, obtainable via

```
$ testlib trilib01
$ unzip trisource.zip
```

If an extrinsic function will be used within equations of a GAMS model, next to the function value evaluation callback, also callbacks that compute first and second derivatives with respect to all endogenous arguments at an input point should be provided. Occasionally, this can be inconvenient. Observe that GAMS can use the function values at points close to the input point to estimate the derivative values using finite differences. However, this method is not as accurate as analytic derivatives and requires a number of function evaluations, thus the convenience comes at a price. The attribute `MaxDerivative` in the specification of a function signals GAMS the highest derivatives this function will provide. For higher order derivatives, GAMS will use finite differences to approximate the derivative values. However, a better alternative is often the use of automatic differentiation when implementing the function evaluation. This is demonstrated in the CPP Library Example, see section Automatic Differentiation for more details.

GAMS offers some support to check the implementation of derivatives for extrinsic functions via the function suffixes `grad`, `gradn`, `hess` and `hessn`. These function suffixes are defined for intrinsic and extrinsic functions. For example, for an extrinsic function `userfunc`, the gradient evaluation that the user implemented may be called with `userfunc.grad`. Further, an approximation of the gradient by finite differences is available by calling `userfunc.gradn`. Comparing the results of these two calls can often help to check the implementation of the gradient. The same principle applies for the Hessian and the function suffixes `hess` and `hessn`. The GAMS options `FDDelta` and `FDOpt` can be used to influence the finite difference calculations. For more details, see model [DERIVTST] in the GAMS Model Library.

### 3.46.4.1 Example: Trigonometric Library

The Trigonometric Library serves as an example of how to code and build an extrinsic function library. The library is included in the GAMS distribution in binary form. In addition, the source code in C, Delphi, and Fortran is available in the include files of the models [TRILIB01], [TRILIB02] and [TRILIB03] respectively. The library implements the following extrinsic functions:
### 3.46 Extrinsic Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>setMode(MODE)</td>
<td>Sets mode globally. Possible values are 0 for radian and 1 for degree. May be overwritten by the optional argument MODE in the functions cosine and sine.</td>
<td>none</td>
</tr>
<tr>
<td>cosine(x[,MODE])</td>
<td>Returns the cosine of the argument x. Note that the argument MODE is optional, default setting: MODE = 0.</td>
<td>NLP</td>
</tr>

The C implementation of this extrinsic function library can be found in the files triccli.c and triccliqlc. Together with the API specification file extrfunc.h, these files document the callbacks that need to be implemented by a GAMS extrinsic function library. The file triccliqlc implements the querylibrary callback, which provides information about the library itself and the extrinsic functions it implements. For example, the information that the function cosine has an endogenous required first argument and an exogenous optional second argument is available from the querylibrary callback. The file triccliqlc (and also the Delphi and Fortran90 equivalents tridcli.inc and triifortlibql.f90) has been generated by the script ql.py by processing the specification file tri.spec.

### 3.46.4.2 Example: Reading a GAMS Parameter File

This library serves as an example of how to code and build an extrinsic function library that reads the information from a GAMS parameter file. The library is included in the GAMS distribution in binary form and also as source code written in C, which comes along with the GAMS Test Library model [parlib01].

This example library implements the following extrinsic function:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>LogOption</td>
<td>Returns the value for the command line parameter LogOption in the parameter file.</td>
<td>any</td>
</tr>
</tbody>
</table>

The C implementation of this extrinsic function library may be found in the files parcclib.c and parcclibqlc. The API specification file is called par.spec. The LibInit function in the extrinsic function library is responsible to read the GAMS parameter file. The LogOption function then only has to return the value of the LogOption parameter from the parameter file. If the option hasn’t been specified, the default value will be returned. For further details, see the comments in the file parcclib.c.

### 3.46.4.3 Example: The CPP Library

The CPP library serves both as an example of how to use C++ to obtain gradients and Hessians “for free” and as a source of functions based on the multivariate Normal distribution. The library is available in compiled form and as C++ source. Test Library model [CPPLIB00] exercises the process of building a shared library from C++ source and doing some basic tests, while models [CPPLIB01], [CPPLIB02], [CPPLIB03], [CPPLIB04], and [CPPLIB05] are more thorough tests for the CPP library extrinsics shipped with the distribution. These functions are listed and described in the following table. Note that in keeping with the language conventions of statistics, PDF is shorthand for “probability density function” and CDF is shorthand for “cumulative distribution function”.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pdfUVN(x)</td>
<td>PDF of uni-variate Normal distribution, see MathWorld or R</td>
<td>NLP</td>
</tr>
</tbody>
</table>
### 3.46.4.3.1 Automatic Differentiation

Often, extrinsic functions are created in order to be used with endogenous arguments. In such cases it is necessary to provide first and second derivatives with respect to these arguments in addition to the function values themselves. One way to compute these derivatives is via automatic differentiation techniques (see the article in Wikipedia for details).

Note that with C++ it is possible to overload the usual arithmetic operators (assignment, addition, multiplication, etc.) so that automatic differentiation occurs with little or no change to the function-only source code. This is the technique used to compute the derivatives in the CPP Library. Observe that the Test Library model [CPPLIB00] includes all the source code for the CPP Library and illustrates the steps needed to build the library from this source. The source is a working self-documentation of how the process of automatic differentiation works.

### 3.46.4.3.2 Multi-Variate Normal Distributions

As shown in the table above, the CPP Library implements the PDF and CDF for the univariate, bivariate and trivariate standard Normal distributions. We use the standard Normal (mean of 0, standard deviation of 1) since intrinsic functions are limited to 20 arguments. The functions for the univariate case are included as convenient examples and should give results (nearly) identical to the functions pdfNormal and cdfNormal from the stochastic library. For the multivariate cases, the implementation is based on TVPACK from Alan Genz, with some modifications to allow for proper computation of derivatives. Note that we chose to implement the functions taking correlation coefficients as arguments, not a covariance matrix. The conversion from a covariance matrix to correlation coefficients is straightforward. The following R code describes this conversion. Here the package mnormt is used that computes the multivariate CDF with similar code to Genz:

```r
# start with a mean mu and variance-covariance matrix S1
x <- c(1.0,3.0,3.0)
mu <- c(0.0,1.0,-1.0)
S1 <- matrix(c(1.0,1.0,1.5, 1.0,4.0,1.5, 1.5,1.5,9.0),3,3)
v1 <- pmnorm(x=x, mean=mu, varcov=S1)

# convert to std normal with 3 correlation coeffs
R <- cov2cor(S1)
sd <- sqrt(diag(S1))
xm <- (x-mu) / sd
v2 <- pmnorm(x=xm, mean=0, varcov=R)
```

Note that for the bivariate case there is one correlation coefficient $r$. The CDF implementation is not quite accurate to machine precision, it has 14 or 15 digits of accuracy. The trivariate case includes 3 correlation coefficients, the 3 off-diagonal elements from the lower triangle of $R$ above. The accuracy of the CDF depends on the inputs: it is higher when the correlation is nearly zero and lower as the condition number of $R$ increases. Typically, an accuracy of $10^{-11}$ is all that can be achieved. In both multivariate cases, we recommend to avoid evaluating at or near points where the correlation matrix is degenerate. At nearly degenerate points, the accuracy of the distribution and density functions suffers. As the correlation matrix becomes degenerate, the distribution becomes degenerate too.
3.46.4.4 Remark: Stateful Libraries

While GAMS intrinsic functions are \textit{stateless}, users may implement \textit{stateful} extrinsic functions, i.e., functions that have some memory. There are two ways to achieve stateful extrinsic functions:

1. Library initialization (\texttt{LibInit}): at initialization time, the function library reads some data that is required to evaluate the provided functions. An example is the Piecewise Polynomial Library.

2. Previous function calls: function calls that alter the execution of successive function calls. An example is the function \texttt{SetMode} from the Trigonometric Library.

Attention

Altering the state of an extrinsic function library by function evaluation calls is problematic, since different parts of the GAMS system potentially use different instances of the function library.

For example, consider that the function \texttt{SetMode} of the Trigonometric Library is called via \texttt{SetMode(1)} before a solve statement. Unless option \texttt{solvelink} is set to 5, the solver will run in a separate process with a new instance of the function library and therefore will use the default \texttt{mode}, which is zero. Further, if \texttt{solvelink} is set to zero, the GAMS process will terminate in order to execute the solve statement and will restart a new GAMS process after the solve. The restarted GAMS process will load a fresh instance of the extrinsic function library, which has no memory of the value of \texttt{mode} from before the solve statement. This problem is demonstrated in the GAMS Test Library model \cite{TRILIB04}.

3.46.5 Extrinsic Functions vs. External Equations

In addition to extrinsic functions, GAMS offers another facility to include additional mathematical functions in GAMS: external equations. These equations are denoted by \texttt{equation type} \texttt{=} \texttt{x=} \texttt{.} A feasible solution for a model instance must satisfy all internal and external equations. External equations are introduced and discussed in chapter \textit{External Equations}.

Similar to extrinsic functions, it is the users responsibility to provide routines that evaluates the external equation. Further, both facilities are especially pertinent to nonlinear models.

An overview of some characteristics of extrinsic functions and external equations is given in the following table:

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Extrinsic Function</th>
<th>External Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of arguments</td>
<td>20</td>
<td>No limit</td>
</tr>
<tr>
<td>Available in statements</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Debugging support</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Returns Hessian to solver</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Consider the following example, which demonstrates how an equation \( z = \int_{x_2}^{x_1} x \, dx \) may be formulated using either an extrinsic function and an external equation:

* using an extrinsic function  
e1.. integralx(x1,x2) =e= z;

* using an external equation  
e1.. 1*x1 + 2*x2 + 3*z =x= 1;
Note that the function integralx is assumed to be a user-defined extrinsic function, probably implemented as \( \text{integralx}(x_1, x_2) = \frac{1}{2}(x_2^2 - x_1^2) \).

Note further, that the integers 1 to 3 in the external equation are mapped to indices for variables that are used in external functions inside an external module. The right-hand side of the external equation denotes the external equation number. It is assumed that the user-defined external equation implements the function \((x_1, x_2, z) \mapsto \int_{x_1}^{x_2} x \, dx - z\).

As a simple example for the use of an extrinsic function in a statement, consider the following assignment, which sets the level of variable \( y \) to the value of \((\int_0^2 x \, dx)^2\):

\[
y.l = \text{sqr} \left( \text{integralx}(0, 2) \right);
\]

### 3.47 External Equations

GAMS provides a number of built-in or intrinsic functions for use in equations. Still, the extremely diverse set of application areas in which GAMS is used can create demand for the addition of new and often sophisticated and specialized functions. There is a trade-off between satisfying these requests and avoiding complexity not needed by most users. The GAMS External Equations Facility provides one means for managing this trade-off, since it allows users to import functions from an external library to define equations in a GAMS model. However, these external libraries can currently only provide functionality for the evaluation of functions (incl. their first derivatives) in a point. Solvers that need to analyze the algebraic structure of the model instance are therefore not able to work with external equations. This includes the class of deterministic global solvers, see column "Global" in this table, while, for example, stochastic global solvers can work with external equations.

**Note**

Both external equations and extrinsic functions aim to provide possibilities to extend GAMS by user-provided mathematical functions. However, there are fundamental differences in the use and implementation of both. For most situations, extrinsic functions should be preferred over external equations. See also Extrinsic Functions vs. External Equations.

**Attention**

Building external equation libraries requires the knowledge of a regular programming language (like C/C++, FORTRAN, ...) and experience with handling compilers and linkers to build dynamically linked libraries.

**Note**

The external equation interface is not intended as a way to bypass some of the very useful model checking done by GAMS for models that are solved with NLP solvers. External equations are still assumed to be continuous with accurate and smooth first derivatives. The continuity assumption implies that external equations must have very low noise levels, considerably below the feasibility tolerance used by the solver. The assumption about accurate derivatives implies that derivatives must be computed more accurately than can be done with standard finite differences. If these assumptions are not satisfied, then there is no guarantee that the NLP solver can find a solution that has the mathematical properties of a local optimum, i.e., a solution that satisfies the Karush-Kuhn-Tucker conditions within the standard tolerances used by the solver.
In the following, connecting code written in FORTRAN, C, Delphi, or some other programming language to equations and variables in a GAMS model is described. These GAMS equations will be referred to as external equations and the compiled version of the programming routines will be referred to as the external module that defines the external functions. The form of the external module depends on the operating system that is used. The external module under Windows is a Dynamic Link Library (.dll) and the external module under Unix is a shared object (.so or .dylib). In principle, any language or system may be used to build the DLL or shared object that defines the external module, as long as the interface conventions are not changed.

The GAMS Test Library provides examples of external equations consisting of GAMS models and C, Delphi, Java, and FORTRAN code. For more details, see Section Examples in the GAMS Test Library.

The basic mechanism of external equations is to declare all the equations and variables using the usual GAMS syntax. The interpretation of the external equations is done in a special way. Instead of the usual semantic content, the external equations specify the mapping between the equation and variable names used in GAMS and the function and variable indices used in the external module. This mapping is described in Section Model Interface. The external module may be written in C, FORTRAN, or most other programming languages. Section Programming Interface describes the general definitions for an external module for C, Delphi, and FORTRAN from a programming language perspective. Note that the way the program is compiled and converted into an external module is system and compiler specific. The following Section Implementation gives detailed advice on various aspects of the implementation of the external module.

### 3.47.1 Examples in the GAMS Test Library

Model [TESTEXEQ] gives an overview of all examples in the GAMS Test Library and may be used to compile and run them. Note that the remainder of this chapter will reference examples that are listed in this model. Further, model [COMPLINK] may be used as a script to compile and link external equation libraries. Note that these models hardcore the path to the Java compiler and libraries and these paths will need to be adapted by the user when running the Java examples.

Observe that regardless of how external libraries are built, the examples (e.g. [EX1]) will by default solve a model without using external equations. To solve the example models with all kinds of different external equation libraries, they may be run with the argument

```
--runall=1
```

Alternatively, only selected libraries may be used by using one or more of the following command line parameters:

```
--runC=1
--runC_cb=1
--runD=1
--runD_cb=1
--runF=1
--runF_cb=1
--runJ=1
```
3.47.2 Model Interface

3.47.2.1 External Equation Syntax

External equations that are used to specify the interface to the external module are declared in GAMS like any other equation. The syntax for the external equation definition statement is as follows:

\[ \text{eqn\_name(index\_list)[logical\_condition(s)].. expression =x= expression ;} \]

Note that the only difference to the usual equation definition is the use of the equation type \( =x= \).

The equations defined by an external module are always interpreted as equality constraints with zero right-hand sides. Thus inequalities have to be converted to equalities by adding explicit slack variables, which will serve as additional external variables. A nonzero right-hand side need to be taken care of in the external equation implementation.

3.47.2.2 Mapping of external equations and variables to indices

Some mappings must be specified to link an external module to a GAMS model. External equations are assumed to be defined in terms of indices \( i = 1 \ldots m \). These indices must be mapped to GAMS equation names. Similarly, the variables used inside the external functions are assumed to be defined in terms of indices \( j = 1 \ldots n \). These indices must be mapped to GAMS variable names. Finally, the name of the external module must be specified. Note that GAMS solvers are typically designed for large models and rely on sparsity. The last part of the specification of a set of external equations is therefore the sparsity pattern of the external equations, i.e., which variables appear in which equations.

The value of the constant term of the external equation must be an integer, since the value of the constant maps the row of the GAMS equation to the index (in \( 1 \ldots m \)) of the external equation. Several blocks of GAMS equations may be mapped to external equations using the \( =x= \) notation. The mapping between GAMS equations of type \( =x= \) and indices \( 1 \ldots m \) must be bijective (one-to-one). This means that two GAMS equations may not be mapped into the same external equation index and that there may not be any holes in the list of external equation indices. Although there may be any number of blocks of GAMS external equations, they must all map into and be implemented by one single external module.

The variable part of each external equation defines both the sparsity pattern of the external equation and the mapping from GAMS variables to the indices of the external variables. The variable part must be a sum of terms where each term is an integer times a variable. The existence of the term indicates that the variable involved is used in the external equation and that there is a corresponding derivative. The value of the coefficient defines the index of the external variable (in \( 1 \ldots n \)) that the GAMS variable is mapped to. For example, the term \( 5\times Y \) indicates that the external equation depends on the GAMS variable \( Y \) and that \( Y \) is mapped to the 5th element in the vector of external variables. Clearly, if a variable appears in more than one external equation, then the value of its coefficient must be the same in each case.

Note that several blocks of GAMS variables may be used in external equations. In contrast to equations, where all rows in an equation block are either external or not, some columns in a variable block may be external while others are not. The mapping between GAMS variables that appear in equations of type \( =x= \) and external variable indices \( 1 \ldots n \) must be bijective (one-to-one). This means that two GAMS columns may not be mapped into the same external variable index and that there may not be any holes in the list of external variable indices. Although there may be any number of blocks of GAMS variables mapped to external variables, they must all map into one single vector passed to the subroutine in the external module.

Observe that while some GAMS variables are external, there is no syntax provided to mark them as external variables. They may be used in non-external GAMS equations as well as external equations. Indeed, without this capability the model would be separable and the external equations and the functions they map to would be of little use.
3.47 External Equations

Note

- As the coefficients and right-hand sides in the GAMS definition of external equations are interpreted as indices, users are not allowed to scale external equations and variables.
- External equations are treated in a special way, therefore the command line parameter and model attribute HoldFixed will not treat any fixed external variables as constants.

3.47.2.3 Name of external module

The name of the external module in which the external equations are implemented may be defined in a number of ways. By default, the external module is assumed to have the same name as the GAMS model with an extension that is operating system dependent. The extension is .dll for Windows, .dylib for MacOS X, and .so for any other Unix.

A custom name for the external module may be specified with a file statement. In this case the file name has to be listed as an additional item in the model statement. If the library extension is omitted in the file statement, GAMS will add the system-dependent extension automatically. This helps to make the model portable between different operating systems.

Consider the following simple example:

File myextfile / extern /;
Model mymodel / all, myextfile /;

When model mymodel is solved, GAMS will try to load the an external module file named extern.so, extern.dylib, or extern.dll, depending on the current operating system.

By default, the external module is assumed to be located in the directory from which GAMS is called. A different location may be specified with an added path in the file statement.

3.47.3 Programming Interface

This section discusses C, Delphi, and FORTRAN interfaces to the GAMS external equations facility.

The external equation module need to provide a function called GEFUNC. The beginning of the external equation module typically looks as follows:

C:

```c
#define GE_EXPORT
#include "geheader.h"

GE_API int GE_CALLCONV gefunc(int* icntr, double* x, double* f, double* d, msgcb_t msgcb)
```

The header file geheader.h can be found in the testlib.ml subdirectory of the GAMS distribution. It defines the preprocessor defines GE_API and GE_CALLCONV and the signature of function gefunc. GE_API is used to indicate to the compiler whether the function should be exported or imported. Due to defining GE_EXPORT before including geheader.h, GE_API is defined such that the function will be marked for export (__declspec(dllexport) on Windows and __visibility__("default") with GCC). Further, GE_CALLCONV indicates the calling convention that should be used on Windows. Currently, this is defined to be __stdcall. On other operating systems, it is empty.

FORTRAN:
Integer Function gefunc (icntr, x, f, d, msgcb)

C Control Buffer:
   Integer icntr(*)
C Numerical Input and Output:
   Double Precision x(*), f, d(*)
C Message Callback Routine
   External msgcb

Delphi:

uses
gerheader_d;

Function GeFunc(var Icntr: ticntr;
   var x: tarray;
   var F: double;
   var D: tarray;
   MsgFunc: tMsgCallBack): integer; stdcall;

The unit file geheader_d.pas can be found in the testlib_ml subdirectory of the GAMS distribution.

In the following, the arguments of GEFUNC are described in detail.

3.47.3.1 Control vector icntr

The array icntr is a control vector that is used to pack and communicate control information between GAMS and the external module. Some helpful definitions to work with the icntr array are provided by the files geheader.h (C), geheader_d.pas (Delphi), and gehelper.f90 (Fortran 90). The array elements are the following:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>icntr[1_Length]</td>
<td>Holds the length of array icntr in number of elements. This is provided by GAMS.</td>
</tr>
<tr>
<td>icntr[1_Neq]</td>
<td>Number of external equation rows seen in the GAMS model. This is provided by GAMS.</td>
</tr>
<tr>
<td>icntr[1_Nvar]</td>
<td>Number of external variables seen in the GAMS model. This is provided by GAMS.</td>
</tr>
<tr>
<td>icntr[1_Nz]</td>
<td>Number of nonzero derivatives or Jacobian elements seen in the GAMS model. This is provided by GAMS.</td>
</tr>
<tr>
<td>icntr[1_Mode]</td>
<td>Current mode of operation. This is provided by GAMS. The following values are possible:</td>
</tr>
<tr>
<td></td>
<td>DOINIT: Initialize. This will be the first call of GEFUNC, where initializations needed by the external module may be performed.</td>
</tr>
<tr>
<td></td>
<td>DOTERM: Terminate. This will be the last call of GEFUNC, where cleanup tasks needed by the external module may be performed.</td>
</tr>
<tr>
<td></td>
<td>DOEVAL: Function evaluation. External equations should be evaluated.</td>
</tr>
<tr>
<td></td>
<td>DOCONSTDERIV: Constant Derivatives. Information about constant derivatives should be provided.</td>
</tr>
<tr>
<td></td>
<td>DOHVPROD: Hessian-Vector product. The product between the Hessian of an external equation and a vector should be computed. See Second Derivatives: Hessian times Vector for details.</td>
</tr>
<tr>
<td>icntr[1_Eqno]</td>
<td>Index of the external equation to be evaluated during this call to GEFUNC. This is provided by GAMS in function evaluation mode (icntr[1_Mode]=DOEVAL) and is a number between 1 and icntr[1_Neq], inclusive. Note that the external equation interface allows to communicate information about only one function at a time.</td>
</tr>
<tr>
<td>icntr[1_Dofunc]</td>
<td>Flag whether function value should be computed. icntr[1_Dofunc] is provided by GAMS in function evaluation mode (icntr[1_Mode]=DOEVAL). If set to 1, then GEFUNC must return the numerical value of the function indexed by icntr[1_Eqno] in the scalar f.</td>
</tr>
</tbody>
</table>
### Element Description

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>icntr[I_Dodrv]</td>
<td>Flag whether derivative should be computed. icntr[I_Dodrv] is provided by GAMS in function evaluation mode (icntr[I_Mode]=DOEVAL). If set to 1, then GEFUNC must return the numerical values of the derivatives of the function indexed by icntr[I_Eqno] in the array d.</td>
</tr>
<tr>
<td>icntr[I_Newpt]</td>
<td>Flag for new point. icntr[I_Newpt] is provided by GAMS in function evaluation mode (icntr[I_Mode]=DOEVAL). If set to 1, then the point x may be different from the previous call of GEFUNC. If set to 0, then x will not have changed since the previous call.</td>
</tr>
<tr>
<td>icntr[I_Debug]</td>
