<td>As 1 but the terms are computed based on a moving average of the squares X and Jac. The purpose of the moving average is to keep the scale factor more stable. This is often an advantage, but for models with very large terms (large variables and in particular large derivatives) in the initial point the averaging process may not have enough time to bring the scale factors into the right region.</td>
</tr>
<tr>
<td>3</td>
<td>Rows are first scaled by dividing by the largest term in the row, then columns are scaled by dividing by the maximum of the largest term and the value of the variable. A term is here defined as abs(X)*abs(Jac) where X is the value of the variable and Jac is the value of the derivative (Jacobian element). The scale factors are then projected on the interval between Rtmins and Rtmaxs.</td>
</tr>
</tbody>
</table>

**LMUSDF (integer):** Method used with defined variables

When defined variables are identified (see LSUSDF) they can be used in two ways, controlled by LMUSDF:

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Defined variables are only used in the initial point and for the initial basis (default).</td>
</tr>
<tr>
<td>1</td>
<td>Defined variables are kept basic and the defining constraints are used to recursively assign values to the defined variables in all trial points.</td>
</tr>
</tbody>
</table>

**LS2NDI (boolean):** Flag for approximating Hessian information for incoming superbasics. If Ls2ndi is turned on (1) CONOPT will try to estimate second order Hessian information for incoming superbasic variables based on directional second derivatives. This is more costly than the standard method described under LMNDIA.

Default: 0

**LS2PTJ (boolean):** Flag for use of perturbations to compute 2nd derivatives in SQP method. If on (1) CONOPT may use perturbations of the Jacobian to compute directional 2nd derivatives if they are not provided with other cheaper and more accurate methods. With GAMS it is only relevant for models with functions defined in external function libraries or models with external equations defined with the =X= equation type.

Default: 1
<table>
<thead>
<tr>
<th>Flag Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSANRM (boolean)</td>
<td>Flag for turning Steepest Edge on.</td>
</tr>
<tr>
<td></td>
<td>Flag used to turn steepest edge pricing on (1) or off (0). Steepest edge pricing makes the individual iterations more expensive but it may decrease their number. Only experimentation can show if it is worth while.</td>
</tr>
<tr>
<td></td>
<td>Default: 0</td>
</tr>
<tr>
<td>LSCRSH (boolean)</td>
<td>Flag for crashing an initial basis without fixed slacks</td>
</tr>
<tr>
<td></td>
<td>When turned on (1) CONOPT will try to crash a basis without fixed slacks in the basis. Fixed slacks are only included in a last round to fill linearly dependent rows. When turned off, large infeasible slacks will be included in the initial basis with preference for variables and slacks far from bound.</td>
</tr>
<tr>
<td></td>
<td>Default: 1</td>
</tr>
<tr>
<td>LSESLP (boolean)</td>
<td>Flag for enabling SLP mode.</td>
</tr>
<tr>
<td></td>
<td>If Lseslp is on (the default) then the SLP (sequential linear programming) sub-solver can be used, otherwise it is turned off.</td>
</tr>
<tr>
<td></td>
<td>Default: 1</td>

<td>When turned on (the default) CONOPT will try to identify post-triangular equations. Otherwise this phase is ignored.</td>
</tr>
<tr>
<td></td>
<td>Default: 1</td>
</tr>
<tr>
<td>LSPRET (boolean)</td>
<td>Pre-processor flag for identifying and using pre-triangular equations.</td>
</tr>
<tr>
<td></td>
<td>When turned on (the default) CONOPT will try to identify pre-triangular equations. Otherwise this phase is ignored.</td>
</tr>
<tr>
<td></td>
<td>Default: 1</td>
</tr>
</tbody>
</table>
**LSSCAL** *(boolean)*: Flag for dynamic scaling. 

When Lsscal is on (the default) CONOPT will use dynamic scaling of equations and variables. See also **LMSCAL**.

Default: 1

**LSSQRS** *(boolean)*: Flag for Square System. Alternative to defining modeltype=CNS in GAMS

When turned on the modeler declares that this is a square system, i.e. the number of non-fixed variables must be equal to the number of constraints, no bounds must be active in the final solution, and the basis selected from the non-fixed variables must always be nonsingular.

Default: 0

**LSTCRS** *(boolean)*: Flag for using the triangular crash method.

When turned on CONOPT will try to crash a triangular basis using ideas by Gould and Reid. The procedure relies on identifying and using good initial values provided by the modeler and only assigning values to variables that are not initialized. Should only be used when several important variables have been given reasonable initial values. The sum of infeasibilities may for some models grow during the crash procedure, so modelers are advised that the option should be used with caution. The option will be ignored if defined variables are forced into the bases **LSUSDF**.

Default: 0

**LSTRIA** *(boolean)*: Flag for triangular or recursive system of equations.

If turned on the equations must form a recursive system. Equations that depend on known variables are allowed as long as they are consistent, e.g. \( x = 1 \) and \( 2 \times x = 2 \). If the equations are not recursive the model is considered infeasible, and the equations with minimum row count are flagged together with the columns they intersect. See also **LSISMP**.

Default: 0

**LSTRID** *(boolean)*: Flag for turning diagnostics on for the post-triangular equations.

If turned on certain diagnostic messages related to the post-triangular equations will be printed. The messages are mainly related to unusual modeling constructs where linear variables for example only appear in the objective or where certain constraints are guaranteed redundant.

Default: 0

**LSUQDF** *(boolean)*: Flag for requiring defined variables to be unique

When turned on (1) CONOPT will not allow defined variables unless they are unique. We exclude a variable if it can be defined from more than one equation, and we exclude equations if they can be used to define more than one variable.

Default: 1

**LSUSDF** *(boolean)*: Flag for forcing defined variables into the basis

When turned on (1) CONOPT will identify defined variables from constraints of the type \( x(i) = f(x) \) where \( x(i) \) is free or implied free. The largest number of defined variables possible will be made basic and will be assigned initial values that are consistent with their defining constraint. When turned off (0) defined variables and their defining constraints are treated like all other variables and constraints. When turned on the triangular crash (**LSTCRS**) will not be used.

Default: 1
**PRDEF** *(boolean)*: Flag for printing the defined variables and their defining constraints.

When turned on (1) CONOPT will print a list of the defined variables and their defining constraints in the order in which they can be evaluated.

Default: 0

**pretri2log** *(boolean)*: Send messages about the pre-triangular analyser to the log

Default: 0

**PRPOST** *(boolean)*: Flag for printing the post-triangular part of the model

When turned on (1) CONOPT will print a list of the post-triangular constraints and the variables they are solved for in the order in which they can be evaluated.

Default: 0

**PRPREC** *(boolean)*: Flag for printing the variables changed by the pre-processor

When turned on (1) CONOPT will print a list of the variables that are changed by the pre-processor. The list includes pre-triangular variables, variables changed by implied bounds, and definitional variables. The three lists can for some models be very long and you can limit the list to variables that are changed by more than *(RTPREC)*

Default: 0

**PRPRET** *(boolean)*: Flag for printing the pre-triangular part of the model

When turned on (1) CONOPT will print a list of the pre-triangular constraints and the variables they are solved for, including the solution values, in the order in which they are solved.

Default: 0

**RTBND1** *(real)*: Bound filter tolerance for solution values close to a bound.

A variable is considered to be at a bound if its distance from the bound is less than Rtbnd1 Max(1,ABS(Bound)). If you need a very small value then your model is probably poorly scaled.

Range: [3.e-13, 1.e-5]

Default: 1.e-7

**RTBNDT** *(real)*: Bound tolerance for defining variables as fixed.

A variable is considered fixed if the distance between the bounds is less than Rtbndt * Max(1,Abs(Bound)). The tolerance is also used on implied bounds (from converted inequalities) and these implied bounds may be infeasible up to Rtbndt.

Range: [3.e-13, 1.e-5]

Default: 1.e-7

**RTIPVA** *(real)*: Absolute Pivot Tolerance for building initial basis.
**CONOPT**

Absolute pivot tolerance used during the search for a first logically non-singular basis. The default is fairly large to encourage a better conditioned initial basis.

Range: $[3 \cdot 10^{-13}, 1 \cdot 10^{-3}]$  
Default: $1 \cdot 10^{-7}$

**RTIPVR (real):** Relative Pivot Tolerance for building initial basis

Relative pivot tolerance used during the search for a first logically non-singular basis.

Range: $[1 \cdot 10^{-4}, 0.9]$  
Default: $1 \cdot 10^{-3}$

**RTMAXJ (real):** Upper bound on the value of a function value or Jacobian element.

Very large values of variables, function value, and derivatives and in particular large variations in the absolute value of the variables, functions, and derivatives makes the model harder to solve and poses problems for both feasibility and optimality tests. CONOPT will usually try to scale the model (see LSSCAL) to remove these problems. However, scaling can also make important aspects of a model appear un-important and there is therefore a limit to how aggressively we can scale a model (see RTMAXS and RTMINS). To avoid serious scaling problems CONOPT poses upper bounds on all variables (see RTMAXV) and all function value and derivatives, RTMAXJ.

Range: $[1 \cdot 10^{4}, 1 \cdot 10^{30}]$  
Default: $1 \cdot 10^{10}$

**RTMAXS (real):** Upper bound on scale factors.

Scale factors are projected on the interval from Rtmins to Rtmaxs. It is used to prevent very large or very small scale factors due to pathological types of constraints. RTMAXS is silently increased to $\max(\text{RTMAXV}, \text{RTMAXS})/100$ if RTMAXV or RTMAXJ have large non-default values.

Range: $[1, 1 \cdot 10^{20}]$  
Default: $1 \cdot 10^{9}$

**RTMAXV (real):** Upper bound on solution values and equation activity levels

See RTMAXJ for a discussion of why CONOPT poses upper bounds on variables and derivatives. If the value of a variable, including the objective function value, exceeds RTMAXV then the model is considered to be unbounded and the optimization process returns the solution with the large variable flagged as unbounded.

Range: $[1 \cdot 10^{5}, 1 \cdot 10^{30}]$  
Default: $1 \cdot 10^{10}$

**RTMINA (real):** Zero filter for Jacobian elements and inversion results.

Contains the smallest absolute value that an intermediate result can have. If it is smaller, it is set to zero. It must be smaller than RTPIVA/10.

Range: $[1 \cdot 10^{-30}, \infty]$  
Default: $1 \cdot 10^{-20}$
**RTMINJ** *(real)*: Filter for small Jacobian elements to be ignored during scaling.  
A Jacobian element is considered insignificant if it is less than Rtminj. The value is used to select which small values are scaled up during scaling of the Jacobian.

Range: \([1.e-7, 1.e-3]\]
Default: \(1.e-5\)

**RTMINS** *(real)*: Lower bound for scale factors computed from values and 1st derivatives.  
Scale factors used to scale variables and equations are projected on the range Rtmins to Rtmaxs. The limits are used to prevent very large or very small scale factors due to pathological types of constraints. The default value for Rtmins is 1 which means that small values are not scaled up. If you need to scale small value up towards 1 then you must define a value of Rtmins \(< 1\).

Range: \([1.e-10, 1]\]
Default: 1

**RTMNS2** *(real)*: Lower bound for scale factors based on large 2nd derivatives.  
Scaling of the model is in most cases based on the values of the variables and the first derivatives. However, if the scaled variables and derivatives are reasonable but there are large values in the Hessian of the Lagrangian (the matrix of 2nd derivatives) then the lower bound on the scale factor can be made smaller than Rtmins. CONOPT will try to scale variables with large 2nd derivatives by one over the square root of the diagonal elements of the Hessian. However, the revised scale factors cannot be less than Rtmns2.

Range: \([1.e-9, 1]\]
Default: \(1.e-6\)

**RTMXJ2** *(real)*: Upper bound on second order terms.  
The function and derivative debugger (see LKDEBG) tests if derivatives computed using the modelers routine are sufficiently close to the values computed using finite differences. The term for the acceptable difference includes a second order term and uses Rtmxj2 as an upper bound on second order derivatives in the model. Larger Rtmxj2 values will allow larger deviations between the user-defined derivatives and the numerically computed derivatives.

Range: \([1, \infty]\]
Default: \(1.e4\)

**RTNWMA** *(real)*: Maximum feasibility tolerance (after scaling).  
The feasibility tolerance used by CONOPT is dynamic. As long as we are far from the optimal solution and make large steps it is not necessary to compute intermediate solutions very accurately. When we approach the optimum and make smaller steps we need more accuracy. RTNWMA is the upper bound on the dynamic feasibility tolerance and RTNWMI is the lower bound.

Range: \([1.e-10, 1.e-3]\]
Default: \(1.e-7\)

**RTNWMI** *(real)*: Minimum feasibility tolerance (after scaling).  

See `RTNWMA` for a discussion of the dynamic feasibility tolerances used by CONOPT.

Range: \([4.0\times10^{-11}, 1.0\times10^{-5}]\)

Default: \(4.0\times10^{-10}\)

**RTNWTR** *(real)*: Feasibility tolerance for triangular equations. 

Triangular equations are usually solved to an accuracy of `RTNWMI`. However, if a variable reaches a bound or a constraint only has pre-determined variables then the feasibility tolerance can be relaxed to `Rtnwtr`.

Range: \([3.0\times10^{-13}, 1.0\times10^{-4}]\)

Default: \(2.0\times10^{-8}\)

**RTOBJL** *(real)*: Limit for relative change in objective for well-behaved iterations. 

The change in objective in a well-behaved iteration is considered small and the iteration counts as slow progress if the change is less than `Rtobjl \times \text{Max}(1, \text{Abs}(\text{Objective}))`. See also `LFNICR`.

Range: \([3.0\times10^{-13}, 1.0\times10^{-5}]\)

Default: \(3.0\times10^{-12}\)

**RTOBJR** *(real)*: Relative accuracy of the objective function.

It is assumed that the objective function can be computed to an accuracy of `Rtobjr \times \text{max}(1, \text{abs}(\text{Objective}))`. Smaller changes in objective are considered to be caused by round-off errors.

Range: \([3.0\times10^{-14}, 1.0\times10^{-6}]\)

Default: \(3.0\times10^{-13}\)

**RTONED** *(real)*: Accuracy of One-dimensional search.

The onedimensional search is stopped if the expected decrease in then objective estimated from a quadratic approximation is less than `Rtoned` times the decrease so far in this onedimensional search.

Range: \([0.05, 0.8]\)

Default: 0.2

**RTPIVA** *(real)*: Absolute pivot tolerance.

During LU-factorization of the basis matrix a pivot element is considered large enough if its absolute value is larger than `Rtpiva`. There is also a relative test, see `RTPIVR`.

Range: \([2.2\times10^{-16}, 1.0\times10^{-7}]\)

Default: \(1.0\times10^{-10}\)

**RTPIVR** *(real)*: Relative pivot tolerance during basis factorizations.
During LU-factorization of the basis matrix a pivot element is considered large enough relative to other elements in the column if its absolute value is at least $R_{tpivr} \times$ the largest absolute value in the column. Small values or $R_{tpivr}$ will often give a sparser basis factorization at the expense of the numerical accuracy. The value used internally is therefore adjusted dynamically between the users value and 0.9, based on various statistics collected during the solution process. Certain models derived from finite element approximations of partial differential equations can give rise to poor numerical accuracy and a larger user-value of $R_{tpivr}$ may help.

Range: $[1.e^{-3}, 0.9]$

Default: 0.05

$R_{tpivt}$ (real): Absolute pivot tolerance for nonlinear elements in pre-triangular equations.

The smallest pivot that can be used for nonlinear or variable Jacobian elements during the pre-triangular solve. The pivot tolerance for linear or constant Jacobian elements is $R_{tpiva}$. The value cannot be less that $R_{tpiva}$.

Range: $[2.2e^{-16}, 1.e^{-3}]$

Default: 1.e-5

$R_{tpivu}$ (real): Relative pivot tolerance during basis updates.

During basis changes CONOPT attempts to use cheap updates of the LU-factors of the basis. A pivot is considered large enough relative to the alternatives in the column if its absolute value is at least $R_{tpivu} \times$ the other element. Smaller values of $R_{tpivu}$ will allow sparser basis updates but may cause accumulation of larger numerical errors.

Range: $[1.e^{-3}, 0.9]$

Default: 0.05

$R_{tprec}$ (real): Tolerance for printing variables changed by the pre-processor

The list of variables changed by the pre-processor (see (PRPREC)) can be limited to the variables that are changed by more than $R_{tprec}$, defined as $\delta X > R_{tprec} \times \max(1, \text{abs}(X))$.

Range: $[0.0, \infty]$

Default: 0.0

$R_{tprel}$ (real): Tolerance for defining large changes in variables in pre-processor

The statistics for the number of variables that are changed in the pre-processor are classified as small and large changes. The change, $\delta X$, is defined as large if $\delta X > R_{tprel} \times \max(1, \text{abs}(X))$.

Range: $[0.0, \infty]$

Default: 0.01

$R_{tredg}$ (real): Optimality tolerance for reduced gradient.
The reduced gradient is considered zero and the solution optimal if the largest superbasic component of the reduced gradient is less than $R_{\text{tredg}}$.

Range: $[3.0 \times 10^{-13}, 1]$  

Default: $1.0 \times 10^{-7}$

**RTZERN (real):** Zero-Noise in external equations

By default CONOPT will debug the derivatives returned from External functions in GAMS in the initial point (see `LKDEBG`). If external functions have constant derivatives then the constant terms are still part of the external function and this can give rise to small inaccuracies in the contribution of the constant derivatives to the function value. This noise can cause the debugger to incorrectly state that a the external equation depend on the variable with the constant derivative. A larger value of Rtzern should remove the error.

Range: $[0.0, 1]$  

Default: 0.0

**RVFILL (real):** Fill in factor for basis factorization.

Rvfill is used in the initial allocation of memory for the factorization of the basis. The fill-in (number of new nonzeros) is assumed to be Rvfill-1 times the initial number of nonzeros in the basis. The default is 5 but you may experiment with a smaller value (down to 1.0) for models that use too much memory to get started. If Rvfill is small you may get slower execution due to increased memory movement. And you may still run out of memory later in the optimization.

Range: $[1.00, 20]$  

Default: 5

**RVHESS (real):** Memory factor for Hessian generation: Skip if #Hessian elements $> \#\text{Jacobian elements} \times R_{\text{vhes}}, 0 \text{ means unlimited}$.

The Hessian of the Lagrangian is considered too dense and is not passed on to CONOPT if the number of nonzero elements in the Hessian of the Lagrangian is greater than the number of nonlinear Jacobian elements multiplied by Rvhes. The assumption is that a very dense Hessian is expensive both to compute and use. If Rvhes = 0.0 then there is no limit on the number of Hessian elements.

Default: 10

**RVTIME (real):** Time Limit. Overwrites the GAMS Reslim option.

Synonym: reslim

The upper bound on the total number of seconds that can be used in the execution phase. There are only tests for time limit once per iteration. The default value is 10000. Rvtime is overwritten by Reslim when called from GAMS. Rvtime is defined in ProbSize and/or UpdtSize when used as a subroutine library.

Default: GAMS ResLim
5.7.10 APPENDIX C: References

5.8 CONOPT4

Author
Arne Drud, ARKI Consulting and Development A/S, Bagsvaerd, Denmark

5.8.1 Introduction

CONOPT4 is an NLP solver derived from CONOPT3 but with many changes. This initial note will describe some of the more important changes from CONOPT3 to CONOPT4 and some of the new options that control these changes. Selected parts of the log-file are also shown and explained. The note is fairly technical and the casual user does not have to understand the details.

More self-contained documentation for CONOPT4 without numerous references to CONOPT3 will appear later.

5.8.2 When should you use CONOPT4?

CONOPT3 is a mature solver with a lot of built-in heuristics developed over years of experimentation and CONOPT3 works well for a large class of models. Initially, CONOPT4 is being developed and tuned for models where CONOPT3 has problems or where small adjustments have given a better solver. Our initial recommendations are:

- CONOPT4 should be tried on models that take more than a few minutes to solve. CONOPT3 is probably your best guess for small and medium sized models, i.e. models with less than 1,000 to 10,000 variables and constraints.
- CONOPT4 should be tried for large CNS models, i.e. models with more than 100,000 variables and constraints.
- CONOPT4 should be tried for models where CONOPT3 runs out of memory. However, note that models of this size under all circumstances are very large and good behavior cannot be guaranteed.
- CONOPT4 should be tried on models where CONOPT3 ends in a locally infeasible solution. CONOPT4 has several new components that avoid obviously infeasible areas and let CONOPT4 move away from saddle points.
- CONOPT4 should be tried on models where CONOPT3 finds a large number of definitional constraints.
5.8.3 Memory Management

CONOPT3 has a limit on the amount of memory that can be used of 8 GBytes. The way memory is allocated and used has been completely rewritten and there is no longer a logical limit in CONOPT4.

5.8.4 Revised Preprocessor

The preprocessor in CONOPT3 identifies pre- and post-triangular variables and constraints, and it handles these variables and constraints in a special way so some internal routines can run more efficiently. The triangular variables are for example always basic. CONOPT3 does not include these variables in tests for entering and leaving the basis. And triangular variables are processed before other variables in the inversion routine. Despite the special status of some variables and constraints, they are all part of the model to be solved.

CONOPT4 distinguished between a 'user model' as defined by the user via the GAMS language, and an 'internal model'. Pre-triangular variables and constraints are simply removed from the user model. Post-triangular variables and constraints are collapsed into a single condensed objective function. And definitional constraints are eliminated. After the internal model has been solved CONOPT4 translates the internal solution back into the solution for the user model and reports this solution to the user. Because CONOPT4 uses these two different models it is no longer possible to turn the preprocessor off.

In addition to the simple pre- and post-triangular variables and constraints from CONOPT3, the preprocessor in CONOPT4 looks at more possibilities for simplifying the model. Some of the new features are:

- Fixed variables are removed completely.
- Constraints that represent simple inequalities are identified and changed into simple bounds on the variables and the constraints are removed.
- Simple monotone constraints such as \( \exp(x) \leq c_1 \) or \( \log(y) \leq c_2 \) are converted into simple bounds on the variables and then removed.
- Forcing constraints such as \( x_1 + x_2 \leq 0 \) with \( x_1.l = 0 \) and \( x_2.l = 0 \) are identified, the variables are fixed, and the constraints are removed. If a forcing constraint is identified then other constraints may become pre-triangular so they also can be removed.
- Linear and monotone constraints are used to compute 'implied bounds' on many variables and these bounds can help CONOPT4 get a better starting point for finding an initial feasible solution.
- Some non-monotone constraints such as \( \text{sqr}(x_1) + \text{sqr}(x_2) \leq 1 \) can also be used to derive implied bounds (here \(-1 \&lt; x_1 \&lt; +1 \) and \(-1 \&lt; x_2 \&lt; +1 \)) that both can improve the starting point and can be used to determine that other terms are monotone.
- Constraints with exactly two variables, e.g. simple linear identities such as \( x_1 = a \cdot x_2 + b \) or simple monotone identities such as \( x_3 = \exp(x_4) \), are used to move bounds between the two variables and this may result in more variables being included in the post-triangle.
- Linear constraints that are identical or proportional to others are identified and removed.
- Pairs of constraints that define a lower and an upper bound on the same linear expression or proportional linear expressions, e.g. \( 1 \leq x_1 + x_2 \) and \( 2 \cdot x_1 + 2 \cdot x_2 \leq 4 \), are turned into a single ranged constraint implemented with a double-bounded slack variable.
- Nonlinear constraints that become linear when the pre-triangular variables are fixed are recognized as being linear with the resulting simplifications.
Some of the new preprocessing steps are useful when solving sub-models in a Branch and Bound environment. A constraint like \( x = \leq M \cdot y \) where \( y \) is a binary variable fixed at either 0 or 1 is turned into a simple bound on \( x \). And a constraint like \( \sum(i, x(i)) \leq Cap \cdot y \) (with \( x\text{.lo}(i) = 0 \)) combined with \( y \) fixed at zero will force all \( x(i) \) to zero.

The preprocessor also identifies constructs that are easy to make feasible. There are currently two types:

- **Penalty terms**: We define a penalty constraint as a constraint of the form \( f(x_1, x_2, \ldots) + p - n = E = 0 \), where \( p \) and \( n \) are positive variables, and where \( p \) and \( n \) only appear in post-triangular constraints or in previously identified penalty constraint. For any feasible values of the \( x \)-variables it is easy to find values of \( p \) and \( n \) that makes the penalty constraint feasible: \( p = \max(0, -f(x)) \) and \( n = \max(0, f(x)) \). The definition is easily generalized to constraints where \( p \) and \( n \) have coefficients different from one and nonzero bounds; the essence is the presence of two linear unbounded terms of opposite sign.

- **Minimax terms**: We define a minimax group as a group of constraints of the form \( \text{eq}(i) \cdot f_i(x_1, x_2, \ldots) = E = z \) where \( z \) is common to the group and otherwise only appear in post-triangular constraints, and \( z \) is unbounded from above. For any feasible value of the \( x \)-variables it is easy to find a value of \( z \) that makes the minimax group feasible: \( z = \text{smin}(i: f_i(x)) \). The definition is easily generalized to groups of constraints where \( z \) has coefficients different from one and where the direction of the inequality is reversed.

The preprocessor will also recognize definitional equations: constraints of the form \( x = E = f(y) \), where \( x \) is a free variable or the bounds on \( x \) cannot be binding, are called definitional equations and \( x \) is called a defined variable. If there are many potential defined variable the preprocessor will select a recursive set and logically eliminate them from the internal model: The values of the defined variables are easily derived from the values of all other variables by evaluating the definitional equations in their recursive order, and these values are substituted into the remaining constraints before their residuals are computed. The matrix of derivatives of the remaining constraints is computed from the overall matrix of derivatives via an elimination of the triangular definitional equations.

The procedure used to recognize definitional equation is similar to the one used in CONOPT3. However, the actual use of the definitional equations is quite different in CONOPT4. The definitional equations are eliminated from the internal model and they are not present in the internal operations used to solve this model. For some models this can make a big difference.

We will show a few examples of log files where the output from the preprocessor is shown. The first is from the *otpop.gms* model in the GAMS Library:

The pre-triangular part of the model has 32 constraints and 43 variables.
The post-triangular part of the model has 9 constraints and variables.
There are 13 definitional constraints and defined variables.
```
Preprocessed model has 39 variables and 23 constraints with 88 Jacobian elements, 22 of which are nonlinear.

</table>

The first few lines define the size of the user model. Usually there will also be information on the Hessian of the Lagrangian; these two lines are missing from models where the Hessian is not generated, usually because it is very large and dense (or because the generation has been turned off with the option Flg_Hessian = false).

After the description of the initial sum of infeasibilities there are three lines with statistics from the preprocessor. Note that the pre-triangular part of the model has more variables than constraints, in this case because there are fixed variables. The post-triangular part will always have the same number of constraints as variables, and the same is true for definitional constraints and defined variables.

After the statistics from the preprocessor the size of the resulting internal model is shown. There is no Hessian information; it is costly to derive the Hessian for the internal model and it will in most cases be very dense so all use of 2nd order information in the internal model is computed by mapping data to the user model and using the real Hessian.

The next lines show the change in the sum of infeasibilities during the initial stages. The first line is after the preprocessor has changed some variables and removed many constraints. The second line is after the internal model has been scaled. And last line is after some variables have been adjusted as described in the next section.

The second example is from the prolog.gms model in the GAMS Library:

<table>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The post-triangular part of the model has 1 constraints and variables. There are 17 penalty and minimax constraints with 3 variables.

Reduced model without penalty components has 17 variables and 5 constraints with 46 Jacobian elements, 0 of which are nonlinear.

</tbody>
</table>

There are no pre-triangular variables and constraints and the pre-triangular line is therefore missing, just like the line describing definitional constraints. On the other hand, there is a line telling that the model has 17 penalty and minimax constraints involving a total of 3 variables.

The internal model that is generated is here without the penalty and minimax constraints. This particular sub-model and other internal sub-models are described in more detail later in this note.
5.8.5 Phase 0 - Finding an Initial Feasible Solution

Phase 0 is started with a new 'Adjust Initial Point' procedure that tries to minimize the sum of infeasibilities by changing individual variables one at a time. The procedure is very cheap since each change of a single variable only involve a small part of the overall model, and it will as a by-product produce a large part of a good initial basis and many constraints will become feasible. As the log file examples above shows, the procedure can in some cases reduce the sum of infeasibilities significantly.

Phase 0 in CONOPT3 is based on Newton's method with a heuristic for taking some constraints out if they do not behave well for Newton. The method can be very fast if a good initial basis is found, but for larger models it can also use a large number of basis changes without any real improvement and can therefore be very slow. CONOPT4 has replaced the heuristic with a rigorous LP framework that iteratively finds a better basis for Newton's method. CONOPT4 can therefore be slower for very easy models but the variability in solution time is smaller and it should never be very slow.

The new Phase 0 procedure replaces the Triangular Crash procedure from CONOPT3.

The following example shows the relevant part of the log file for GAMS Library model otpop.gms:

```
Iter  Phase  Ninf  Infeasibility  RGmax  NSB  Step  InItr  MX OK
      1.0510968588E+03 (Full preprocessed model)
      4.5063072017E+01 (After scaling)
      5.0023365462E+00 (After adjusting individual variables)
1  0  0  2.2657221820E+00  1.0E+00  3  T  T
2  0  0  1.8510537501E+00  1.0E+00  2  T  T
3  0  0  1.8243868306E+00  1.0E+00  1  T  T
4  0  0  1.8239239188E+00  1.0E+00  1  T  T
5  0  0  1.8239236521E+00  1.0E+00  1  T  T
** Feasible solution. Value of objective = 323.670194144
```

The InItr column shows the number of LP-like inner iterations for each outer iteration and Step = 1 indicates that the full solution from the LP was be used.

The next example is from GAMS Library model mathopt3.gms:

```
Iter  Phase  Ninf  Infeasibility  RGmax  NSB  Step  InItr  MX OK
      1.7198687345E+03 (Full preprocessed model)
      7.9643177481E+00 (After scaling)
      1.2674164214E-01 (After adjusting individual variables)
1  S0  0  2.6763223208E+00  1.2E-01  2  F  F
2  0  0  1.3292743354E+00  1.0E+00  2  T  T
3  S0  0  4.9371333807E+00  2.5E-01  1  F  F
4  S0  0  2.3899063615E+00  1.0E+00  2  T  T
5  S0  0  3.2207192474E+00  5.0E-01  1  F  F
6  0  0  3.2206913182E+00  6.2E-02  1  F  F
7  1  3  6.8573593504E-01  1.7E+00  1  1.2E+00  1  T  T
```

For some of the iterations Step is less than 1 indicating that the direction found by the inner linear model could not be used in full due to nonlinearities. Also note the lines with 'S0' in the Phase column. The S tells that the model was scaled before the iteration and the sum of infeasibilities was increased during this scaling procedure. The sum of infeasibilities is therefore not monotone decreasing even if each outer iteration does decrease them.
5.8.6 Transition between SLP and SQP

The transition from SLP to SQP and back again is in CONOPT3 based on monitoring failure. The logic has been changed in CONOPT4 so transition is based on continuous measurements of curvature, both in the general constraints and in the objective function, combined with estimates of computational costs and progress for SLP and SQP.

The continuation of the log file for GAMS Library model otpop.gms shows some of this:

<table>

** Optimal solution. Reduced gradient less than tolerance.**

Iterations 6 to 9 are SLP iterations (Phase 3) and iterations 10 to 14 are SQP iterations (Phase 4). The SLP iterations have Step less than 1 due to nonlinear objective terms and CONOPT4 jumps directly from SLP to SQP. CONOPT3 needed some steepest descend and some Quasi-Newton iterations as a transition, and although these iterations are fast, the transition could sometimes be slow.

5.8.7 Bad Iterations

Bad iterations (for both solvers flagged with “F” in the “OK” column of the log file) are an important problem for both CONOPT3 and CONOPT4. They appear if the output from the SLP or SQP procedure is a search direction where CONOPT cannot move very far because it is difficult to make the nonlinear constraints feasible again. The efforts spend in solving the SLP or SQP procedure is therefore partially wasted. The problem is usually associated with a basis that is ill-conditioned or changes very fast.

CONOPT3 has some heuristics for changing the basis in these cases. For models with many basic and superbasic variables this can be a slow and not very reliable procedure.

CONOPT4 uses a more rigorous procedure based on monitoring the size of some intermediate terms. It can be the size of elements of the tangent for basic variables relative to similar elements for superbasic variables. Or it can be intermediate results from the computation of the reduced costs. The monitoring procedure is cheap and it is used to maintain a well-conditioned basis throughout the optimization instead of waiting until something does not work well.

5.8.8 Saddle Points and Directions of Negative Curvature

CONOPT is based on moving in a direction derived from the gradient (or the reduced gradient for models with constraints). If the reduced gradient (projected on the bounds) is zero then the solution satisfies the first-order optimality conditions and it is standard procedure to stop. Unfortunately, this means that we can stop in a saddle-point.

It is not very common to move towards a saddle-point and get stuck in it. However, it is not uncommon that the initial point, provided by a user or by default, is a saddle point. A simple example is the
constraint $xy = 1$ started with $x.l = y.l = 0$ that easily can end with a locally infeasible solution. Or minimize $z$, $z = xy$ with the same starting point that could end locally optimal without moving even though better points exist in the neighborhood.

CONOPT4 has an added procedure that tries to find a direction of negative curvature that can move the solution point away from a saddle-point. The procedure is only called in points that satisfy the first order optimality conditions and it is therefore a cheap safeguard. The theory behind the method is developed for models without degeneracy and it works very well in practice for these models. Models with some kind of degeneracy (basic variables at bound or nonbasic variables with zero reduced cost) use the same procedure, but it is in this case only a heuristic that cannot be guaranteed to find a direction of negative curvature, even if one exists.

If you know that there are no directions of negative curvature you can turn the procedure of by setting the logical option Flg_NegCurve to false. If the model is known to be convex you can set the logical option Flg_Convex to true and it will also turn this procedure off. The saving is usually very small, except for models that solve in very few iterations and for model with a large number of superbasics.

There is no output in the log file for negative curvature. If a useful direction is found CONOPT4 will follow it and the optimization continues. Otherwise, the solution is declared locally optimal.

### 5.8.9 Use of Alternative Sub-Models

During the course of an optimization CONOPT4 can work with up to three different internal sub-models. These models are:

- Full Model: This model consists of the constraints in the user's model excluding all pre- and post-triangular constraints and with the definitional variables eliminated by their defining constraints.
- No-Penalty Model: This model consists of the Full Model excluding all penalty and mini-max constraints. This model does not have an objective function.
- Linear Feasibility Model: This model consists of the linear constraints of the Full Model. The Linear Feasibility model is either solved without an objective function or minimizing a quadratic distance measure; this is discussed below.

The pre-triangular variables are considered fixed and they do not appear in any of the sub-models. Their influence comes through their contribution to coefficients and constant terms. The post-triangular variables are considered intermediate variables in the definition of the objective function. They do not appear in the last two models that only are concerned with feasibility, and they only appear indirectly via the objective in the Full Model. The defined variables are considered intermediate variables in the definition of the remaining constraints in the same way as post-triangular variables are intermediate in the objective. The variables in the Full Model are all variables excluding pre- and post-triangular variables and excluding defined variables; this set can include variables that do not appear in any constraints. The constraints of the full models are all constraints excluding pre- and post-triangular constraints and with the definitional equations logically eliminated. The variables in the Linear Feasibility Model and in the No-Penalty Model are the variables that appear in the constraints of these models (excluding pre-triangular variables).

CONOPT always starts by searching for a feasible solution and the sub-models only play a role in this part of the optimization so if the initial point provided by the modeler is feasible then these sub-models are irrelevant. If there are many penalty and/or minimax constraints then the No-Penalty Model will be much smaller than the Full Model and it is more efficient to use the smaller model while searching for feasibility. So the No-Penalty model is only introduced for efficiency reasons. It is by default solved before the Full Model if all of the following conditions are satisfied:

- The Flg_NoPen options is true (the default value)
• The model is not a CNS model
• The user did not provide an initial basis
• Some of the constraints in the No-Penalty Model are infeasible.
• The number of penalty and minimax constraints is more than the number of constraints in the Full Model multiplied by the value of option Rat\_NoPen. The default value of Rat\_NoPen is 0.1, i.e. the No-Penalty Model is only defined and solved if it is at least 10% smaller than the Full Model.

The GAMS Library model prolog.gms used earlier has many penalty and minimax constraints. The relevant part of the log file is:

```
Iter    Phase  Ninf  Infeasibility  RGmax  NSB  Step  InItr  MX  OK
0       0       1.2977431398E+03 (Input point)
The post-triangular part of the model has 1 constraints and variables.
There are 17 penalty and minimax constraints with 3 variables.

Reduced model without penalty components has 17 variables and 5 constraints with 46 Jacobian elements, 0 of which are nonlinear.

Iter Phase Ninf Infeasibility RGmax NSB Step InItr MX OK
1 0 1.2960000000000E+03 (Model without penalty constraints)
5.0625000000000E+00 (After scaling)
0.0000000000000E+00 (After adjusting individual variables)

Previous model terminated and penalty components are added back in. Full preprocessed model has 20 variables and 22 constraints with 120 Jacobian elements, 8 of which are nonlinear.

Iter Phase Ninf Infeasibility RGmax NSB Step InItr MX OK
0.00000000000000E+00 (After adjusting penalty variables)

** Feasible solution. Value of objective = -1147.54681404
```

The No-Penalty model is small with only 5 constraints and 17 variables and it solves already in the 'Adjust Individual Point' procedure. The Full Model is significantly larger with 22 constraints and 20 variables, and it is feasible when started from the solution to the No-Penalty model.

The Linear Feasibility Model is introduced to help avoid locally infeasible solutions. It produces a starting point to the nonlinear models (No-Penalty Model or Full Model) that satisfies all linear constraints. If the Linear Feasibility Model is infeasible then the overall model is proved to be infeasible (independent of nonlinearities) and there is no reason to proceed with the nonlinear part of the model.

The Linear Feasibility Model is only useful if the model has some linear constraints and if the initial point provided by the modeler does not satisfy these constraints. If a feasible solution to the linear constraints is found there are several possible ways to continue before the No-Penalty Model and/or the Full Model are started:

A. Use the solution point as is.

B. Perform an approximate minimization of the weighted distance from the user's initial point. Include only the variables that have non-default initial values, i.e. variables with an initial value (xini) that is different from zero projected on the bounds, i.e. xini ne \( \min(\max(0,x._{lo}),x._{up}) \). The distance measure is \( \sqrt{\frac{(x-xini)}{\max(1,\text{abs}(xini))}} \).

C. As in B, but include all variables in the distance measure.

D. As in C, but define xini to 1 projected on the bounds for all variables with default initial value.
Possibility A is fast but may give a starting point for the nonlinear model far from the initial point provided by the user, B is slower but gives a starting point for the nonlinear model that is close to the point provided by the user, and C and D are also slower but may provide reasonably good and different starting points for the nonlinear model.

The order in which the sub-models are solved depends on a Linear Feasibility Model strategy option, \texttt{Lin\_Method}:

1. If \texttt{Lin\_Method} has the default value 1 then the initial point and basis is assumed to be fairly good and CONOPT4 will start with the No-Penalty Model (only if the conditions mentioned above are satisfied) followed by the Full Model. If the model terminates locally optimal, unbounded, or on some resource limit (time, iterations, function evaluations) then we are done and CONOPT terminates. But if the model is locally infeasible then we build and solve the Linear Feasibility Model. If this model is infeasible, the overall model is infeasible and we are again done. If it is feasible we minimize objective B and use the solution point as a second starting point for the nonlinear model. If this attempt also terminates locally infeasible we try to generate an alternative initial point with objective C and then with objective D. If all fails, the model is labeled locally infeasible.

2. With \texttt{Lin\_Method} = 2 CONOPT will start with the Linear Feasibility Model with objective A before looking at the No-Penalty and Full models. If they are locally infeasible from this starting point we followed the procedure from above with objective B, C, and then D.

3. \texttt{Lin\_Method} = 3 is similar to \texttt{Lin\_Method} = 2 except that the first objective A is skipped.

An example where all Linear Feasibility objectives are used is taken from \texttt{ex5\_3\_2.gms} in the GlobalLib collection of test models. It shows the repeated starts of the Linear Feasibility Model followed by the Full Preprocessed model:

Preprocessed model has 22 variables and 16 constraints
with 59 Jacobian elements, 24 of which are nonlinear.

\begin{verbatim}
Iter Phase Ninf Infeasibility RGmax NSB Step InItr MX OK
4.1200000000E+02 (Full preprocessed model)
8.4843750000E+00 (After scaling)
6.2500000000E-01 (After adjusting individual variables)
1 1 1 6.2500000000E-01 0.0E+00 5 0.0E+00 T T
4 1 1 6.2500000000E-01 0.0E+00 4
** Infeasible solution. Reduced gradient less than tolerance.
\end{verbatim}

Initial linear feasibility model has 22 variables and 7 constraints
with 22 linear Jacobian elements.
Objective: Distance to initial point (nondefault variables)

\begin{verbatim}
Iter Phase Ninf Infeasibility RGmax NSB Step InItr MX OK
3.0200000000E+02 (Linear feasibility model)
3.1718750000E+00 (After scaling)
** Linear constraints feasible. Distance = 0.0000000000
\end{verbatim}

Restarting preprocessed model from a new starting point.

** Feasible solution. Value of objective = 1.86415945946

Iter Phase Ninf Objective RGmax NSB Step InItr MX OK
40 4 1.8641594595E+00 0.0E+00 0

** Optimal solution. There are no superbasic variables.
The Full Model is infeasible when started directly from the values provided by the user. The Linear Feasibility model is then solved to get a different starting point for the Full model where the linear part is feasible. The Full Model is also infeasible from this point and it is necessary to solve the Linear Feasibility model three times with different objective functions before the full model becomes feasible.

The number of submodels that are solved is limited by the option, Num_Rounds. The default value is 4, i.e. we will try very hard to find a feasible point as shown in the example above. The value 1 will make CONOPT terminate immediately when a locally infeasible point is found. You can use Num_Rounds if you are not interested in spending a lot of time on a model that is likely to be infeasible. It can be particularly relevant if CONOPT4 is used as the sub-solver inside SBB where infeasible sub-problems are fairly likely.

If the model is defined to be convex with the option Flg_Convex = true then a locally infeasible solution is labeled (globally) infeasible and the Linear Feasibility Model will not be used. (A locally optimal solution is also labeled (globally) optimal.)

5.8.10 Multiple Threads

CONOPT4 can use multiple threads for some internal computations and in collaboration with GAMS for function and derivative evaluations. Multiple threads are currently only used for certain fairly large and dense computations and there are not so many of these in the types of model usually build with GAMS. In addition, multiple threads have quite high overhead and they are therefore only useful for fairly large models. Currently the best improvements have been for very large models with more than 100,000 variables or constraints, in particular for CNS models if this size.

It is the intention to implement multiple threads into more parts of CONOPT4 in the future.

Threads can be turned on with the GAMS command-line option Threads=n or with the CONOPT4 option threads.

5.8.11 Solving CNS Models

CONOPT4 is a general NLP (Nonlinear Programming) solver, but it also has some specialized routines for solving CNS (Constrained Nonlinear System) models. Due to the specialized routines, it is in general possible to solve much larger CNS models than NLP models, and there are users that solve models with more than 1 million variables and equations, mainly in the area of Economic General Equilibrium models.

5.8.11.1 Basic CNS Theory

CONOPT4’s CNS procedure is based on Newton’s method: The constraints are linearized around the starting point and the suggested change in variables is computed by solving a square set of linear equations where the right-hand-side is the vector of residuals:

\[ g(x_0 + dx) = 0 \] (5.1)

is approximated by

\[ g(x_0) + J \cdot dx = 0 \iff dx = J^{-1}g(x_0) \] (5.2)

The matrix \( J \) is the Jacobian or the matrix of first derivatives of the constraint functions \( g \). For a CNS model \( J \) will be a square matrix. In the optimization part of CONOPT4 we work with a sub-matrix selected from a subset of columns of the Jacobian and this matrix is called a Basis and we will therefore sometimes use the term basis and inverse basis when referring to \( J \) and \( J^{-1} \). If the starting point is close to the solution, Newton’s method is known to converge very quickly. We may even use the same \( J^{-1} \) for several iterations. The rate of convergence, defined as the norm of \( g \) after the iteration relative to the
norm of $g$ before the iteration, using a fixed $J^{-1}$ is approximately equal to the largest eigenvalue in the matrix

$$ I - J_I^{-1} J_F $$

(5.3)

where $J_I$ is the initial Jacobian matrix, that is used in the inversion, and $J_F$ is the final Jacobian matrix, computed the final solution point. Approximating $J_F = J_I + dJ$ we get an approximation of the rate of convergence, $\rho$, as

$$ \rho = \max_{\text{eigenvalue}} \left( I - J_I^{-1} (J_I + dJ) \right) = \max_{\text{eigenvalue}} \left( J_I^{-1} dJ \right) $$

(5.4)

When the change in Jacobian, $dJ$, is small, the largest eigenvalue will also be small and we will get fast convergence. If the starting point is far from the final point, then the linearization may not be very good with a large $dJ$ and the suggested change in variables may give rise to growing residuals. The procedure used inside CONOPT4's CNS solver is to find a step in the suggested direction, $dx$, where the residuals are approximately minimized and use this step. The solution will gradually come closer, the linearization will become better, $dJ$ will become smaller, the optimal step will come closer to one, and the procedure will (usually) terminate with fast convergence.

### 5.8.11.2 Evaluating External Chocks using CNS

Economic General Equilibrium / CNS models are often used to evaluate the effect of policies changes or external chocks. The setup in GAMS is often of this type:

* Define model and initialize data
Solve M using CNS;
* Store the base solution
* Define the chock by changing some exogenous variables
Solve M using CNS;
* Compare the new solution with base solution.

The second `Solve` will start from the base solution and this point will in many cases be a very good starting point and the second `Solve` will therefore run quickly. However, for large chocks and very complex models, the second `Solve` may converge very slowly and it may not solve at all, because the new solution is too far from the base solution. For these cases it is not unusual to break the large chock down into a sequence of smaller chocks and solve the model several times. With smaller chocks each `Solve` will start from a point that is not too far away from the final solution for this chock. The GAMS model with smaller chocks will look like this:

* Define model and initialize data
Solve M using CNS;
* Store the base solution
Parameter ExoDiff(indx) The change in exogenous variables;
ExoDiff(indx) = ExoTarget(indx) - ExoBase(indx);
Set Iter / Iter1*Iter5 /
Parameter Step(Iter); Step(Iter) = ord(Iter)/card(Iter);
Loop(Iter,
   Exo(indx) = ExoBase(indx) + Step(Iter)*ExoDiff(indx);
   Solve M using CNS;
);
* Compare new solution with base solution.

The number of iterations and the way the `Step`-parameter is defined may vary and there is often no good a-priori rule for deciding. The smaller chocks will give $dJ$-matrices with smaller value and therefore smaller (equal to better) rates of convergence. Easy experiments can be solved with few steps while difficult experiments require more steps to converge. More iterations will give smaller steps and the individual `Solve` will be faster, but the overhead in model generation and extra solves can be large. For some chocks there is no solution to the model: some of the model variables may go outside their bounds, some may move towards infinity, or the model may no longer be well-defined because the basis matrix becomes singular. In practice, one of the `Solve` in the `Loop` will violate a bound or it will converge extremely slowly, but it is often not possible to pinpoint exactly how large the chock should be before the model breaks down.
5.8.11.3 Evaluating External Chocks using NLP

The theoretical solution to avoiding the choice of iteration steps is to change the model to an NLP and maximize the chock:

* Define model and initialize data
Solve M using CNS;
* Store the base solution

Parameter ExoDiff(indx) The change in exogenous variables
ExoDiff(indx) = ExoTarget(indx) - ExoBase(indx);

* Define the chock using variables and equations
Variable Exov(indx) Exogenous variables as a function of step;
Variable Step Share of the chock;
Equation Exod(indx) Define Exov;
Exod(indx).. Exov(indx) =E= ExoBase(indx)+Step*ExoDiff(indx);
Model m1 / M + Exod /
Step.lo = 0; Step.up = 1; Step.l = 0;
Exov.l(indx) = ExoBase(indx) + Step.l*ExoDiff(indx);
Solve M1 using NLP maximizing Step;
* Compare new solution with base solution.

The NLP approach follows the solution from the feasible solution at Step = 0 through solutions for larger and larger steps and the change in Step is determined by how easy it is to maintain feasibility of the constraints. This NLP works well for small or simple models. However, for very large models such as the 1 million plus models mention above, the overhead associated with NLP can be very large because the specialized CNS routines no longer are used. Some statistics using CONOPT 4.26 on a 6 million model shows the problems:

- Pre-processor: The special CNS version locates pre- and post-triangular variables in 5 seconds; the NLP version used another 25 second to derive bounds and find defined variables. Analysing the 2 mill defined variables took 4000 seconds; it is now reduced to 8 seconds in CONOPT 4.27.
- Initial Basis: The special CNS version assigns all non-fixed variables to the basis and this is very fast; the NLP version makes sure that the basis is non-singular and it takes 1000 seconds, and the basis is not complete and many hours are needed to repair it.

5.8.11.4 Option TraceCNS

The NLP model defined above is not a general NLP. It has exactly one degree of freedom, namely the Step variable (the objective variable in the model), and the rest of the model, including the extra Exod-equations and Exov variables, is a CNS model. To take advantage of the specialized CNS routines CONOPT 4.27 introduced a new logical option, FlgTraceCNS or just TraceCNS. If FlgTraceCNS is defined as true (default is false), then CONOPT will use the special CNS pre-processor, it will define the initial CNS basis, it will fix the objective variable (here Step) to its initial value and find an initial feasible solution using the old CNS procedure. When a feasible solution has been found, the bounds on the objective variable are reset and the standard optimization routine is started from a feasible solution and a good basis. There are a few adjustments in the optimization routine; some are related to the iteration output, and some take advantage of the special properties of the TraceCNS model.

An example of the log-file for a large model can explain some of the key aspects. The chock is a tax-rate that is changed from a base value of 500 to the target of 1250:
5.8 CONOPT4 version 4.27

** TraceCNS terminates with objective at optimal bound.

The original CNS model had 6285822 equations. We have added 159042 equations to define the 159042
exogenous variables, that have been made endogenous (representing the Exod equations and Exov variables
above). Since these extra equations have a very simple structure, they will not add much complexity to
the solution process.

In this case we do not start from a feasible solution. The first iterations down to the line Feasible
solution to a square system are CNS iterations. Each line represents an inversion of the basis and
the numbers in the InItr column are the number of Newton iterations that use the same basis.

Starting TraceCNS .. identifies the start of the NLP procedure and the Objective defines the starting
step. The numbers in the Objective column represent the progress of the step or here the tax rate.
There are two types of iteration lines. The lines without a number in the Iter column represents a
re-computation of the Jacobian and inversion of the basis inside the linesearch and the numbers in the
InItr column are the number of Newton iterations using this basis. The lines with a number in the Iter
column are the standard output from CONOPT4's NLP procedure and the number in the InItr column
are the number of LP or QP iterations used to define the search direction, usually just 1. The last line without a value in the Iter column will have the same Objective value as the line with a value in the Iter column. The new iteration lines with a number in the Iter column have been added to show that the solution process is alive and the InItr numbers show how much work is done. In very large CNS models each inversion may take more than one minute, and one linesearch or NLP iteration with several inversion may take much longer. Because progress may be slow, CONOPT4 will check for time or resource limit and for user interrupt (Cntrl-C) after each of these lines.

Inside the linesearch CONOPT4 will use Newton iterations to restore feasibility as discussed in Basic CNS Theory. The change in Jacobian, \( dJ \), will approximately grow with the size of the step, \( dJ = M \cdot \text{Step} \), where \( M \) is a matrix of 2nd derivatives in the direction we are moving. The rate of convergence can therefore be approximated by

\[
\rho(\text{Step}) = \max_{\text{eigenvalue}} (J^{-1}M \cdot \text{Step}) = \max_{\text{eigenvalue}} (J^{-1}M) \cdot \text{Step} = \rho(1) \cdot \text{Step}
\]  

(5.5)

CONOPT4 will approximate \( \rho(1) \) and use it to decide on the largest Step that will lead to convergence. Once we have moved this step the Jacobian has changed so much that further progress is impossible with the current Jacobian and its inverse, and it is necessary to recompute the Jacobian and its inverse. Since this process is the most expensive part of the optimization procedure, often accounting for more than 75% of the overall time for large models, we use the steps where the Jacobian is recomputed and reinverted to identify the overall progress.

The final line **TraceCNS terminates with objective at the optimal bound** tells us that the tax rate has been changed to the target value and that the model is solved with this value. Since the model is considered a special case of a CNS model the solution returned to GAMS will not have any dual variables, just as for regular CNS models.

The particular case was originally solved using four CNS Solve statements. The total time was 12.43 minutes with 5.23 minutes in the four CONOPT4 runs and 7.20 minutes in GAMS where most of the time was used for the four model generations.

With the NLP model and the Flg_TraceCNS option the total time was 6.47 minutes; CONOPT4 used 5.20 minutes and since there is only one model generation, GAMS only used 1.27 minutes. Notice that the time spend in CONOPT4 is about the same, but there is a big saving in the time spend in GAMS. It should be mentioned that the same NLP model without the Flg_TraceCNS option ran for 36 hours without reaching a solution.

5.8.11.5 Option Trace_MinStep

A more difficult case was also originally solved using four CNS Solve statements. The two first CNS models solved in 2 min 23 seconds and 1 min 31 seconds, respectively. The third CNS had problems; it used 1 hour 5 minutes and the last part of the iteration log was:

<table>

** Domain error(s) in nonlinear functions. Check bounds on variables.

The long time is caused by the many small steps, and the solution process finally terminates because a variable, \( x \), that appears in an \( x^{p} \) expression with \( p < 1 \) becomes negative. The same model solved as an NLP model with Flg_TraceCNS solved in 28 min 10 sec. The first part of the iteration log is similar to the one shown above. The last part of the iteration log is:
The objective or the step changes more and more slowly between the reinversions. This indicates that the Jacobian changes faster and faster so the change, dJ, is about the same size as the initial Jacobian after smaller and smaller steps.

Unfortunately, it is not easy to identify where and why the Jacobian changes too much. It requires knowledge of the actual model, and an expert user must combine this knowledge with the final solution reported in GAMS. The problem is often some variables that become very large or very small.

By default, CONOPT4 will stop when the change in objective between reinversions is less than 0.1% of the target step for three consecutive reinversions. This tolerance can be changed with option TraceMinStep to get a more or less accurate solution. A smaller value will seldom change much but it can be costly in time.

**TraceMinStep = 0** forces CONOPT4 to move as far as possible. For this model the final step changes from 653.2 to 657.9 compared to the start at 500 and the target at 1250, and the solution time changes from 28 minutes to 3 hours 20 minutes.

### 5.8.11.6 Termination Messages from TraceCNS

The first example showed the ideal termination message

**TraceCNS terminates with objective at optimal bound.**

Sometimes the objective cannot be moved all the way to the target value. There are several different cases:
• We saw the slow convergence message in the previous section.

CONOPT may terminate with messages like:

```
3 3 5.475253047E-01 3.6E-02 1 1.0E+00 1 T T
4 4 5.475253047E-01 0.0E+00 0
```

** TraceCNS: An endogenous variable has reached its bound.

The solution process is stopped because a variable has reached a bound. The offending bound will be shown in the listing file with a message like:

```
**** ERRORS/WARNINGS IN VARIABLE x(i2)
  1 error(s): The variable has reached its bound
```

In this case the solution will include dual variables.

• Another termination message is:

```
20 4 5.8578628609E-01 1.5E-07 1 1.2E+00 1 F F
21 4 5.8578628609E-01 7.6E-08 1
```

** TraceCNS: The basis has become singular.

The basis has become singular at the final step and it is not possible to move further. Unfortunately, it is not possible to give a detailed description of a variable or equation that causes the problem; detailed knowledge of the actual model must be combined with the solution. The solution returned to GAMS will include dual variables that may help in the analysis. Most models that could terminate with a singular basis will in practice terminate with a slow convergence message because the path to the final singular basis often will require a large number of small steps.

• CONOPT4 may also terminate due to functions evaluation error with a message like this:

```
29 4 2.0000000000E+00 1.0E+00 1 3.9E-11 1 F F
```

** Domain error(s) in nonlinear functions.
Check bounds on variables.

The equation(s) with function evaluation errors will be shown in the listing file with a message like:

```
**** ERRORS/WARNINGS IN EQUATION e(i1)
  2 error(s): sqrt: FUNC DOMAIN: x < 0 (RETURNED 0)
```

• Finally, CONOPT4 may terminate due to an unbounded variable with a message like this:

```
21 4 1.999999947E+10 3.2E-06 1
```

** Unbounded solution. A variable has reached 'Infinity'.
Largest legal value (Lim_Variable) is 1.00E+15

The variable that has become too large will be shown in the listing file with a message like:

```
**** ERRORS/WARNINGS IN VARIABLE x(i3)
  1 error(s): The variable has reached 'infinity'
```
5.8.11.7 Error Messages from TraceCNS

Flg_TraceCNS can only be used on a very special type of model and if the requirements are not satisfied you may see some of the following messages.

First of all, the model must be an optimization model with an objective variable. This is tested by GAMS during compile time and an error message will come from GAMS.

Flg_TraceCNS requires that the objective variable is bounded in the optimization direction. If this is not satisfied you will get this message:

** Error in TraceCNS: The objective must be bounded.

after the pre-processor.

There must only be one degree of freedom represented by the objective variable. If there are extra free variables you will get this message:

** Error in TraceCNS: The number of non-fixed variables excluding the objective (nn) is not equal to the number of equations (mm).

also right after the pre-processor.

5.8.12 APPENDIX A - Options

The options that ordinary GAMS users can access are listed below.

5.8.12.1 Algorithmic options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>

</tbody>
</table>

cooptfile (string): ↔

Flg_2DDir (boolean): Flag for computing and using directional 2nd derivatives. ↔

If turned on, make directional second derivatives (Hessian matrix times directional vector) available to CONOPT. The default is on, but it will be turned off of the model has external equations (defined with =X=) and the user has not provided directional second derivatives. If both the Hessian of the Lagrangian (see Flg_Hessian) and directional second derivatives are available then CONOPT will use both: directional second derivatives are used when the expected number of iterations in the SQP sub-solver is low and the Hessian is used when the expected number of iterations is large.

Default: auto

Flg_AdjIniP (boolean): Flag for calling Adjust Initial Point ↔

If Flg_AdjIniP is on (the default) then the Adjust Initial Point routine is called after the pre-processor. Can be turned off if the routine is very slow.

Default: 1

Flg_Convex (boolean): Flag for defining a model to be convex ↔

When turned on (the default is off) CONOPT knows that a local solution is also a global solution, whether it is optimal or infeasible, and it will be labeled appropriately. At the moment, Flg_NegCurve will be turned off. Other parts of the code will gradually learn to take advantage of this flag.

Default: 0
**Flg_Crash_Slack** *(boolean)*: Flag for pre-selecting slacks for the initial basis. 

When turned on (1) CONOPT will select all infeasible slacks as the first part of the initial basis.

Default: 0

**Flg_Dbgs_Intv** *(boolean)*: Flag for debugging interval evaluations. 

Flg_Dbgs_Intv controls whether interval evaluations are debugged. Currently we check that the lower bound does not exceed the upper bound for all intervals returned, both for function values and for derivatives.

Default: 0

**Flg_Hessian** *(boolean)*: Flag for computing and using 2nd derivatives as Hessian of Lagrangian. 

If turned on, compute the structure of the Hessian of the Lagrangian and make it available to CONOPT. The default is usually on, but it will be turned off if the model has external equations (defined with =X=) or cone constraints (defined with =C=) or if the Hessian becomes too dense. See also **Flg_2DDir** and **HessianMemFac**.

Default: auto

**Flg_Interv** *(boolean)*: Flag for using intervals in the Preprocessor 

If turned on (default), CONOPT will attempt to use interval evaluations in the preprocessor to determine if functions are monotone or if intervals for some of the variables can be excluded as infeasible.

Default: 1

**Flg_NegCurve** *(boolean)*: Flag for testing for negative curvature when apparently optimal 

When turned on (the default) CONOPT will try to identify directions with negative curvature when the model appears to be optimal. The objective is to move away from saddlepoints. Can be turned off when the model is known to be convex and cannot have negative curvature.

Default: 1

**Flg_NoDefc** *(boolean)*: Flag for turning definitional constraints off. The default is false. 

If Flg_NoDefc is on, the Preprocessor will not look for definitional constraints and variables.

Default: 0

**Flg_NoPen** *(boolean)*: Flag for allowing the Model without penalty constraints 

When turned on (the default) CONOPT will create and solve a smaller model without the penalty constraints and variables and the minimax constraints and variables if the remaining constraints are infeasible in the initial point. This is often a faster way to start the solution process.

Default: 1

**Flg_Prep** *(boolean)*: Flag for using the Preprocessor
If turned on (default), CONOPT will use its preprocessor to try to determine pre- and post-triangluar components of the model and find definitional constraints.

Default: 1

**Flg.Range (boolean):** Flag for identifying sets of ranged constraints

If turned on (default), CONOPT will as part of its preprocessor look for sets of parallel linear constraints and turn each set into a single ranged constraints. There is currently a potential problem with the duals on these constraints and if duals are important ranges can be turned off with this flag.

Default: 1

**Flg.SLPMode (boolean):** Flag for enabling SLP mode.

If Flg.SLPMode is on (the default) then the SLP (sequential linear programming) sub-solver can be used, otherwise it is turned off.

Default: 1

**Flg.SQPMode (boolean):** Flag for enabling of SQP mode.

If Flg.SQPMode is on (the default) then the SQP (sequential quadratic programming) sub-solver can be used, otherwise it is turned off.

Default: 1

**Flg.Square (boolean):** Flag for Square System. Alternative to defining modeltype=CNS in GAMS

When turned on the modeler declares that this is a square system, i.e. the number of non-fixed variables must be equal to the number of constraints, no bounds must be active in the final solution, and the basis selected from the non-fixed variables must always be nonsingular.

Default: 0

**Flg.TraceCNS (boolean):** Flag for tracing a CNS solution.

When turned on the model must, for fixed value of the objective variable, be a CNS model and must satisfy the conditions of a CNS. The model is first solved as a CNS with the initial value of the objective fixed and the objective is then minimized or maximized subject to the CNS constraints.

Default: 0

**Frq.Log.Simple (integer):** Frequency for log-lines for non-SLP/SQP iterations.

Frq.Log.Simple and Frq.Log.SlpSqp can be used to control the amount of iteration send to the log file. The non-SLP/SQP iterations, i.e. iterations in phase 0, 1, and 3, are usually fast and writing a log line for each iteration may be too much, especially for smaller models. The default value for the log frequency for these iterations is therefore set to 10 for small models, 5 for models with more than 500 constraints or 1000 variables and 1 for models with more than 2000 constraints or 3000 variables.

Default: auto

**Frq.Log.SlpSqp (integer):** Frequency for log-lines for SLP or SQP iterations.
Frq_Log_Simple and Frq_Log_SlpSqp can be used to control the amount of iteration send to the log file. Iterations using the SLP and/or SQP sub-solver, i.e. iterations in phase 2 and 4, may involve several inner iterations and the work per iteration is therefore larger than for the non-SLP/SQP iterations and it may be relevant to write log lines more frequently. The default value for the log frequency is therefore 5 for small models and 1 for models with more than 500 constraints or 1000 variables.

Default: auto

Frq_Rescale (integer): Rescaling frequency. ↔

The row and column scales are recalculated at least every Frq_Rescale new point (degenerate iterations do not count), or more frequently if conditions require it.

Default: 5

HEAPLIMIT (real): Maximum Heap size in MB allowed ↔

Range: $[0, \infty]$ 

Default: 1e20

HessianMemFac (real): Memory factor for Hessian generation: Skip if Hessian elements > Nonlinear Jacobian elements * HessianMemFac, 0 means unlimited. ↔

The Hessian of the Lagrangian is considered too dense therefore too expensive to evaluate and use, and it is not passed on to CONOPT if the number of nonzero elements in the Hessian of the Lagrangian is greater than the number of nonlinear Jacobian elements multiplied by HessianMemFac. See also Flg_Hessian. If HessianMemFac = 0.0 (the default value) then there is no limit on the number of Hessian elements.

The following cells are used to count calls of various routines and the time spend in them. The timing is usually only turned on if some debugging level is on and the statistics is only printed in these cases.

Default: 0

Lim_Dbg_1Drv (integer): Flag for debugging of first derivatives ↔

Lim_Dbg_1Drv controls how often the derivatives are tested. Debugging of derivatives is only relevant for user-written functions in external equations defined with =X=. The amount of debugging is controlled by Mtd_Dbg_1Drv. See Lim_Hess_Est for a definition of when derivatives are considered wrong.

Default: 0

<table>
<thead>
<tr>
<th>value</th>

<td>The derivatives are tested in all iterations that can be divided by Lim_Dbg_1Drv, provided the derivatives are computed in this iteration. (During phase 0, 1, and 3 derivatives are only computed when it appears to be necessary.)</td>
</tr>
</tbody>
</table>

Lim_Err_2DDir (integer): Limit on errors in Directional Second Derivative evaluation. ↔

If the evaluation of Directional Second Derivatives (Hessian information in a particular direction) has failed more than Lim_Err_2DDir times CONOPT will not attempt to evaluate them any more and will switch to methods that do not use Directional Second Derivatives.
Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: 10

**Lim_Err_Fuc_Drv** *(integer)*: Limit on number of function evaluation errors. Overwrites GAMS Domlim option ←

Function values and their derivatives are assumed to be defined in all points that satisfy the bounds of the model. If the function value or a derivative is not defined in a point CONOPT will try to recover by going back to a previous safe point (if one exists), but it will not do it more than at most Lim_Err_Fuc_Drv times. If CONOPT is stopped by functions or derivatives not being defined it will return with a intermediate infeasible or intermediate non-optimal model status.

Default: GAMS DomLim

**Lim_Err_Hessian** *(integer)*: Limit on errors in Hessian evaluation. ←

If the evaluation of Hessian information has failed more than Lim_Err_Hessian times CONOPT will not attempt to evaluate it any more and will switch to methods that do not use the Hessian. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: 10

**Lim_Hess_Est** *(real)*: Upper bound on second order terms. ←

The function and derivative debugger (see **Lim_Dbgs_1Drv**) tests if derivatives computed using the modelers routine are sufficiently close to the values computed using finite differences. The term for the acceptable difference includes a second order term and uses Lim_Hess_Est as an estimate of the upper bound on second order derivatives in the model. Larger Lim_Hess_Est values will allow larger deviations between the user-defined derivatives and the numerically computed derivatives.

Default: 1.e4

**Lim_Iteration** *(integer)*: Maximum number of iterations. Overwrites GAMS Iterlim option. ←

The iteration limit can be used to prevent models from spending too many resources. You should note that the cost of the different types of CONOPT iterations (phase 0 to 4) can be very different so the time limit (GAMS Reslim or option **Lim_Time**) is often a better stopping criterion. However, the iteration limit is better for reproducing solution behavior across machines.

Default: GAMS IterLim

**Lim_Msg_Dbgs_1Drv** *(integer)*: Limit on number of error messages from function and derivative debugger. ←

The function and derivative debugger (see **Lim_Dbgs_1Drv**) may find a very large number of errors, all derived from the same source. To avoid very large amounts of output CONOPT will stop the debugger after Lim_Msg_Dbgs_1Drv error(s) have been found.

Default: 10

**Lim_Msg_Large** *(integer)*: Limit on number of error messages related to large function value and Jacobian elements. ←
Very large function value or derivatives (Jacobian elements) in a model will lead to numerical difficulties and most likely to inaccurate primal and/or dual solutions. CONOPT is therefore imposing an upper bound on the value of all function values and derivatives. This bound is 1.e30. If the bound is violated CONOPT will return with an intermediate infeasible or intermediate non-optimal solution and it will issue error messages for all the violating Jacobian elements, up to a limit of Lim_Msg_Large error messages.

Default: 10

**Lim_NewSuper (integer):** Maximum number of new superbasic variables added in one iteration.

When there has been a sufficient reduction in the reduced gradient in one subspace new non-basics can be selected to enter the superbasis. The ones with largest reduced gradient of proper sign are selected, up to a limit. If Lim_NewSuper is positive then the limit is \( \min(500, \text{Lim}_\text{NewSuper}) \). If Lim_NewSuper is zero (the default) then the limit is selected dynamically by CONOPT depending on model characteristics.

Default: auto

**Lim_Pre_Msg (integer):** Limit on number of error messages related to infeasible pre-triangle.

If the pre-processor determines that the model is infeasible it tries to define a minimal set of variables and constraints that define the infeasibility. If this set is larger than Lim_Pre_Msg elements the report is considered difficult to use and it is skipped.

Default: 25

**Lim_RedHess (integer):** Maximum number of superbasic variables in the approximation to the Reduced Hessian.

CONOPT uses and stores a dense lower-triangular matrix as an approximation to the Reduced Hessian. The rows and columns correspond to the superbasic variable. This matrix can use a large amount of memory and computations involving the matrix can be time consuming so CONOPT imposes a limit on on the size. The limit is Lim_RedHess if Lim_RedHess is defined by the modeler and otherwise a value determined from the overall size of the model. If the number of superbasics exceeds the limit, CONOPT will switch to a method based on a combination of SQP and Conjugate Gradient iterations assuming some kind of second order information is available. If no second order information is available CONOPT will use a quasi-Newton method on a subset of the superbasic variables and rotate the subset as the reduced gradient becomes small.

Default: auto

**Lim_SlowPrg (integer):** Limit on number of iterations with slow progress (relative less than Tol_Obj_Change).

The optimization is stopped if the relative change in objective is less than Tol_Obj_Change for Lim_SlowPrg consecutive well-behaved iterations.

Default: 20

**Lim_StallIter (integer):** Limit on the number of stalled iterations.

An iteration is considered a stalled iteration if there is no change in objective because the linesearch is limited by nonlinearities or numerical difficulties. Stalled iterations will have Step = 0 and F in the OK column of the log file. After a stalled iteration CONOPT will try various heuristics to get a better basis and a better search direction. However, the heuristics may not work as intended or they may even return to the original bad basis, especially if the model does not satisfy standard constraints qualifications and does not have a KKT point. To prevent cycling CONOPT will therefore stop after Lim_StallIter stalled iterations and returns an Intermediate Infeasible or Intermediate Nonoptimal solution.

Default: 100
**Lim_Start_Degen** *(integer)*: Limit on number of degenerate iterations before starting degeneracy breaking strategy.

The default CONOPT pivoting strategy has focus on numerical stability, but it can potentially cycle. When the number of consecutive degenerate iterations exceeds Lim_Start_Degen, CONOPT will switch to a pivoting strategy that is guaranteed to break degeneracy but with slightly weaker numerical properties.

Default: 100

**Lim_Time** *(real)*: Time Limit. Overwrites the GAMS Reslim option.

The upper bound on the total number of seconds that can be used in the execution phase. There are only tests for time limit once per iteration. The default value is 10000. Lim_Time is overwritten by Reslim when called from GAMS.

Range: $[0, \infty]$  
Default: GAMS ResLim

**Lim_Variable** *(real)*: Upper bound on solution values and equation activity levels

If the value of a variable, including the objective function value and the value of slack variables, exceeds Lim_Variable then the model is considered to be unbounded and the optimization process returns the solution with the large variable flagged as unbounded. A bound cannot exceed this value.

Range: $[1.e5, 1.e30]$  
Default: 1.e15

**Lin_Method** *(integer)*: Method used to determine if and/or which Linear Feasibility Models to use

The Linear Feasibility Model can use different objectives: Objective 1 is no objective, i.e. the first point that satisfies the Linear Feasibility Model is used as a starting point for the Full Model. Objective 2 minimizes a scaled distance from the initial point for all variables defined by the modeler. Objective 3 minimizes a scaled distance from the initial point for all variables including those not defined by the modeler. Objective 4 minimizes a scaled distance from random a point selected away from bounds.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Ignore Linear Feasibility Model in the first round and use objective 2, 3, and 4 (see above) in the following rounds as long as model is locally infeasible. This is the default method.</td>
</tr>

<td>Use Linear Feasibility Model with objective 1 in the first round and continue with objective 2, 3, and 4 in the following rounds as long as model is locally infeasible.</td>
</tr>
<tr>
<td>3</td>
<td>Use Linear Feasibility Model with objective 2 in the first round and continue with objective 3 and 4 in the following rounds as long as model is locally infeasible.</td>
</tr>
</tbody>
</table>

**Mtd_dbg_1Drv** *(integer)*: Method used by the function and derivative debugger.

The function and derivative debugger (turned on with **Lim_dbg_1Drv**) can perform a fairly cheap cheap test or a more extensive test, controlled by Mtd_dbg_1Drv. See **Lim_Hess_Est** for a
5.8 CONOPT4

Definition of when derivatives are considered wrong. All tests are performed in the current point found by the optimization algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform tests for sparsity pattern and tests that the numerical values of the derivatives appear to be correct. This is the default.</td>
</tr>
<tr>
<td>1</td>
<td>As 0 plus make extensive tests to determine if the functions and their derivatives are continuous around the current point. These tests are much more expensive and should only be used if the cheap test does not find an error but one is expected to exist.</td>
</tr>
</tbody>
</table>

Mtd_RedHess (integer): Method for initializing the diagonal of the approximate Reduced Hessian

Each time a nonbasic variable is made superbasic a new row and column is added to the approximate Reduced Hessian. The off-diagonal elements are set to zero and the diagonal to a value controlled by Mtd_RedHess:

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The new diagonal element is set to the geometric mean of the existing diagonal elements. This gives the new diagonal element an intermediate value and new superbasic variables are therefore not given any special treatment. The initial steps should be of good size, but build-up of second order information in the new sub-space may be slower. The larger diagonal element may also in bad cases cause premature convergence.</td>
</tr>
<tr>
<td>1</td>
<td>The new diagonal elements is set to the minimum of the existing diagonal elements. This makes the new diagonal element small and the importance of the new superbasic variable will therefore be high. The initial steps can be rather small, but better second order information in the new sub-space should be build up faster.</td>
</tr>
</tbody>
</table>

Mtd_Scale (integer): Method used for scaling.

CONOPT will by default use scaling of the equations and variables of the model to improve the numerical behavior of the solution algorithm and the accuracy of the final solution (see also Frq_Rescale.) The objective of the scaling process is to reduce the values of all large primal and dual variables as well as the values of all large first derivatives so they become closer to 1. Small values are usually not scaled up, see Tol_Scale_Max and Tol_Scale_Min. Scaling method 3 is recommended. The others are only kept for backward compatibility.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Scaling is based on repeatedly dividing the rows and columns by the geometric means of the largest and smallest elements in each row and column. Very small elements less than Tol_Jac_Min are considered equal to Tol_Jac_Min.</td>
</tr>
<tr>
<td>1</td>
<td>Similar to 3 below, but the projection on the interval [Tol_Scale_Min,Tol_Scale_Max] is applied at a different stage. With method 1, abs(X)*abs(Jac) with small X and very large Jac is scaled very aggressively with a factor abs(Jac). With method 3, the scale factor is abs(X)*abs(Jac). The difference is seen in models with terms like Sqrt(X) close to X = 0.</td>
</tr>
</tbody>
</table>
As 1 but the terms are computed based on a moving average of the squares X and Jac. The purpose of the moving average is to keep the scale factor more stable. This is often an advantage, but for models with very large terms (large variables and in particular large derivatives) in the initial point the averaging process may not have enough time to bring the scale factors into the right region.

.Rows are first scaled by dividing by the largest term in the row, then columns are scaled by dividing by by the maximum of the largest term and the value of the variable. A term is here defined as \( \text{abs}(X) \times \text{abs}(\text{Jac}) \) where X is the value of the variable and Jac is the value of the derivative (Jacobian element). The scale factor are then projected on the interval between Tol_Scale_Min and Tol_Scale_Max.

**Mtd_step_phase0 (integer):** Method used to determine the step in Phase 0.

The steplength used by the Newton process in phase 0 is computed by one of two alternative methods controlled by Mtd_step_phase0:

Default: **auto**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this method. It is the default method for optimization models.</td>
</tr>
<tr>
<td>1</td>
<td>A method based on bending (projecting the target values of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum. Linear constraints that initially are feasible may become infeasible due to bending.</td>
</tr>
</tbody>
</table>

**Mtd_step_tight (integer):** Method used to determine the maximum step while tightening tolerances.

The steplength used by the Newton process when tightening tolerances is computed by one of two alternative methods controlled by Mtd_step_tight:

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this default method.</td>
</tr>
<tr>
<td>1</td>
<td>A method based on bending (projecting the target value of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum.</td>
</tr>
</tbody>
</table>

**Num_rounds (integer):** Number of rounds with Linear Feasibility Model

Lin Method defined which Linear Feasibility Model are going to be solved if the previous models end Locally Infeasible. The number of rounds is limited by Num_rounds.

Range: \([1, \ldots, 4]\)

Default: 4
**Rat\_NoPen** *(real): Limit on ratio of penalty constraints for the No\_Penalty model to be solved*  

The No-Penalty model can only be generated and solved if the number of penalty and minimax constraints exceed Rat\_NoPen times the constraints in the Full Model.

Default: 0.1

**THREAD2D** *(integer): Number of threads used for second derivatives*  

Range: \{0, ..., \infty\}

Default: 1

**THREADC** *(integer): Number of compatibility threads used for comparing different values of THREADS*  

Range: \{0, ..., \infty\}

Default: 1

**THREADF** *(integer): Number of threads used for function evaluation*  

Range: \{0, ..., \infty\}

Default: 1

**threads** *(integer): Number of threads used by Conopt internally*  

Range: \{0, ..., \infty\}

Default: GAMS Threads

**Tol\_Bound** *(real): Bound filter tolerance for solution values close to a bound.*  

A variable is considered to be at a bound if its distance from the bound is less than Tol\_Bound \times \text{Max}(1,|\text{Bound}|). The tolerance is used to build the initial bases and is used to flag variables during output.

Range: [3.e-13, 1.e-5]

Default: 1.e-7

**Tol\_BoxSize** *(real): Initial box size for trust region models for overall model*  

The new Phase 0 methods solves an LP model based on a scaled and linearized version of the model with an added trust region box constraint around the initial point. Tol\_BoxSize defines the size of the initial trust region box. During the optimization the trust region box is adjusted based on how well the linear approximation fits the real model.

Range: [0.01, 1.e6]

Default: 10

**Tol\_BoxSize\_Lin** *(real): Initial box size for trust region models for linear feasibility model*  

Similar to Tol\_BoxSize but applied to the linear feasibility model. Since this model has linear constraints the default initial box size is larger.

Range: [0.01, 1.e8]

Default: 1000
**Tol_Box_LinFac** *(real)*: Box size factor for linear variables applied to trust region box size

The trust region box used in the new Phase 0 method limits the change of variables so 2nd order terms will not become too large. Variables that appear linearly do not have 2nd order terms and the initial box size is therefore larger by a factor Tol_Box_LinFac.

Parameters related to growth factors and initial values in the definitional constraints

Range: *[1, 1.e4]*

Default: 10

**Tol_Def_Mult** *(real)*: Largest growth factor allowed in the block of definitional constraints

The block of definitional constraints form a triangular matrix. This triangular matrix can hide large accumulating growth factors that can lead to increases in the initial sum of infeasibilities and to numerical instability. Tol_Def_Mult is an upper bound on these growth factors. If it is exceeded some critical chains of definitional constraints will be broken leading to a larger internal model, that should be numerically better behaved.

Parameters related to scaling

Range: *[1.01, ∞]*

Default: 1.e4

**Tol_Feas_Max** *(real)*: Maximum feasibility tolerance (after scaling).

The feasibility tolerance used by CONOPT is dynamic. As long as we are far from the optimal solution and make large steps it is not necessary to compute intermediate solutions very accurately. When we approach the optimum and make smaller steps we need more accuracy. Tol_Feas_Max is the upper bound on the dynamic feasibility tolerance and **Tol_Feas_Min** is the lower bound. It is NOT recommended to use loose feasibility tolerances since the objective, including the sum of infeasibility objective, will be less accurate and it may prevent convergence.

Range: *[1.e-10, 1.e-3]*

Default: 1.e-7

**Tol_Feas_Min** *(real)*: Minimum feasibility tolerance (after scaling).

See **Tol_Feas_Max** for a discussion of the dynamic feasibility tolerances used by CONOPT.

Range: *[3.e-13, 1.e-5]*

Default: 4.e-10

**Tol_Feas_Tria** *(real)*: Feasibility tolerance for triangular equations.

Triangular equations are usually solved to an accuracy of **Tol_Feas_Min**. However, if a variable reaches a bound or if a constraint only has pre-determined variables then the feasibility tolerance can be relaxed to Tol_Feas_Tria.

Range: *[3.e-13, 1.e-4]*

Default: 1.0e-8

**Tol_Fixed** *(real)*: Tolerance for defining variables as fixed based on initial or derived bounds.
A variable is considered fixed if the distance between the bounds is less than $\text{Tol}_{\text{Fixed}} \times \max(1, \text{Abs(Bound)})$. The tolerance is used both on the users original bounds and on the derived bounds that the preprocessor implies from the constraints of the model.

Accuracies for linesearch and updates

Range: $[3.\text{e}-13, 1.\text{e}-8]$

Default: $4.\text{e}-10$

$\text{Tol}_{\text{Jac}_\text{Min}}$ (real): Filter for small Jacobian elements to be ignored during scaling.

A Jacobian element is considered insignificant if it is less than $\text{Tol}_{\text{Jac}_\text{Min}}$. The value is used to select which small values are scaled up during scaling of the Jacobian. It is only used with scaling method $\text{Mtd}_{\text{Scale}} = 0$.

Range: $[1.\text{e}-7, 1.\text{e}-3]$

Default: $1.\text{e}-5$

$\text{Tol}_{\text{Linesearch}}$ (real): Accuracy of One-dimensional search.

The onedimensional search is stopped if the expected decrease in the objective estimated from a quadratic approximation is less than $\text{Tol}_{\text{Linesearch}} \times$ the decrease so far in this onedimensional search.

Range: $[0.05, 0.8]$

Default: $0.2$

$\text{Tol}_{\text{Obj}_{\text{Acc}}}$ (real): Relative accuracy of the objective function.

It is assumed that the objective function can be computed to an accuracy of $\text{Tol}_{\text{Obj}_{\text{Acc}}} \times \max(1, \text{abs(Objective)})$. Smaller changes in objective are considered to be caused by round-off errors.

Range: $[3.0\text{e}-14, 10.\text{e}-6]$

Default: $3.0\text{e}-13$

$\text{Tol}_{\text{Obj}_{\text{Change}}}$ (real): Limit for relative change in objective for well-behaved iterations.

The change in objective in a well-behaved iteration is considered small and the iteration counts as slow progress if the change is less than $\text{Tol}_{\text{Obj}_{\text{Change}}} \times \max(1, \text{Abs(Objective)})$. See also $\text{Lim}_{\text{SlowPrg}}$.

Range: $[3.0\text{e}-13, 1.0\text{e}-5]$

Default: $3.0\text{e}-12$

$\text{Tol}_{\text{Optimality}}$ (real): Optimality tolerance for reduced gradient when feasible.

The reduced gradient is considered zero and the solution optimal if the largest superbasic component of the reduced gradient is less than $\text{Tol}_{\text{Optimality}}$.

Range: $[3.\text{e}-13, 1]$

Default: $1.\text{e}-7$
**Tol\_Opt\_Infeas** *(real)*: Optimality tolerance for reduced gradient when infeasible.

The reduced gradient is considered zero and the solution infeasible if the largest superbasic component of the reduced gradient is less than Tol\_Opt\_Infeas.

Range: [3.e-13, 1]

Default: 1.e-7

**Tol\_Opt\_LinF** *(real)*: Optimality tolerance when infeasible in Linear Feasibility Model

This is a special optimality tolerance used when the Linear Feasibility Model is infeasible. Since the model is linear the default value is smaller than for nonlinear submodels.

Pivot tolerances

Range: [3.e-13, 1.e-4]

Default: 1.e-10

**Tol\_Piv\_Abs** *(real)*: Absolute pivot tolerance.

During LU-factorization of the basis matrix a pivot element is considered large enough if its absolute value is larger than Tol\_Piv\_Abs. There is also a relative test, see **Tol\_Piv\_Rel**.

Range: [2.2e-16, 1.e-7]

Default: 1.e-10

**Tol\_Piv\_Abs\_Ini** *(real)*: Absolute Pivot Tolerance for building initial basis.

Absolute pivot tolerance used during the search for a first logically non-singular basis. The default is fairly large to encourage a better conditioned initial basis.

Range: [3.e-13, 1.e-3]

Default: 1.e-7

**Tol\_Piv\_Abs\_NLTr** *(real)*: Absolute pivot tolerance for nonlinear elements in pre-triangular equations.

The smallest pivot that can be used for nonlinear or variable Jacobian elements during the pre-triangular solve. The pivot tolerance for linear or constant Jacobian elements is Tol\_Piv\_Abs. The value cannot be less than Tol\_Piv\_Abs.

Range: [2.2e-16, 1.e-3]

Default: 1.e-5

**Tol\_Piv\_Ratio** *(real)*: Relative pivot tolerance during ratio-test

During ratio-tests, the lower bound on the slope of a basic variable to potentially leave the basis is Tol\_Piv\_Ratio + the largest term in the computation of the tangent.

Range: [1.e-10, 1.e-6]

Default: 1.e-8

**Tol\_Piv\_Rel** *(real)*: Relative pivot tolerance during basis factorizations.
During LU-factorization of the basis matrix a pivot element is considered large enough relative
to other elements in the column if its absolute value is at least $Tol_{Piv\_Rel} \times$ the largest
absolute value in the column. Small values or $Tol_{Piv\_Rel}$ will often give a sparser basis
factorization at the expense of the numerical accuracy. The value used internally is therefore
adjusted dynamically between the users value and 0.9, based on various statistics collected
during the solution process. Certain models derived from finite element approximations of
partial differential equations can give rise to poor numerical accuracy and a larger user-value
of $Tol_{Piv\_Rel}$ may help.

Range: $[1.e^{-3}, 0.9]$

Default: 0.05

$Tol_{Piv\_Rel\_Ini}$ (real): Relative Pivot Tolerance for building initial basis

Relative pivot tolerance used during the search for a first logically non-singular basis.

Range: $[1.e^{-4}, 0.9]$

Default: 1.e-3

$Tol_{Piv\_Rel\_Updt}$ (real): Relative pivot tolerance during basis updates.

During basis changes CONOPT attempts to use cheap updates of the LU-factors of the basis.
A pivot is considered large enough relative to the alternatives in the column if its absolute
value is at least $Tol_{Piv\_Rel\_Updt} \times$ the other element. Smaller values of $Tol_{Piv\_Rel\_Updt}$
will allow sparser basis updates but may cause accumulation of larger numerical errors.

Range: $[1.e^{-3}, 0.9]$

Default: 0.05

$Tol_{Scale2D\_Min}$ (real): Lower bound for scale factors based on large 2nd derivatives.

Scaling of the model is in most cases based on the values of the variables and the first derivatives.
However, if the scaled variables and derivatives are reasonable but there are large values in
the Hessian of the Lagrangian (the matrix of 2nd derivatives) then the lower bound on the
scale factor can be made smaller than $Tol_{Scale\_Min}$. CONOPT will try to scale variables
with large 2nd derivatives by one over the square root of the diagonal elements of the Hessian.
However, the revised scale factors cannot be less than $Tol_{Scale2D\_Min}$.

Range: $[1.e^{-9}, 1]$

Default: 1.e-6

$Tol_{Scale\_Max}$ (real): Upper bound on scale factors.

Scale factors are projected on the interval from $Tol_{Scale\_Min}$ to $Tol_{Scale\_Max}$. Is used to
prevent very large or very small scale factors due to pathological types of constraints. The
upper limit is selected such that $\text{Square}(X)$ can be handled for $X$ close to $\text{Lim\_Variable}$. More
nonlinear functions may not be scalable for very large variables.

Range: $[1, 1.e30]$

Default: 1.e25

$Tol_{Scale\_Min}$ (real): Lower bound for scale factors computed from values and 1st derivatives.
Scale factors used to scale variables and equations are projected on the range Tol\_Scale\_Min to Tol\_Scale\_Max. The limits are used to prevent very large or very small scale factors due to pathological types of constraints. The default value for Tol\_Scale\_Min is 1 which means that small values are not scaled up. If you need to scale small value up towards 1 then you must define a value of Tol\_Scale\_Min < 1.

Range: [1.e-10, 1]
Default: 1

Tol\_Scale\_Var (real): Lower bound on x in x*Jac used when scaling.

Rows are scaled so the largest term x*Jac is around 1. To avoid difficulties with models where Jac is very large and x very small a lower bound of Tol\_Scale\_Var is applied to the x-term.

Largest Jacobian element and tolerance in 2nd derivative tests:

Range: [1.e-8, 1]
Default: 1.e-5

Contains the smallest absolute value that an intermediate result can have. If it is smaller, it is set to zero. It must be smaller than Tol\_Piv\_Abs/10.

Default: 1.e-20

Trace\_MinStep (real): Minimum step between Reinversions when using TraceCNS.

The optimization is stopped with a slow convergence message if the change in trace variable or objective is less than this tolerance between reinversions for more than two consecutive reinversions. The step is scaled by the distance from the initial value to the critical bound.

Range: [0, 1]
Default: 0.001

5.9 CONVERT

5.9.1 Introduction

CONVERT is a utility which transforms a GAMS model instance into a scalar model where all confidential information has been removed or into formats used by other modeling and solution systems. CONVERT is designed to achieve the following goals:

- Permit users to convert a confidential model into GAMS scalar format so that any identifiable structure is removed. It can then be passed on to others for investigation without confidentiality being lost.
- A way of sharing GAMS test problems for use with other modeling systems or solvers.

CONVERT comes free of charge with any licensed GAMS system and can convert GAMS models into a number of formats, see Section Target languages and formats for a list.
5.9 CONVERT

5.9.2 How to use CONVERT

CONVERT is run like any other GAMS solver. From the command line this is:

```
>> gams modelname modeltype=convert
```

where `modelname` is the GAMS model name and `modeltype` the solver indicator for a particular model type (e.g. LP, MIP, RMIP, QCP, MIQCP, RMIQCP, NLP, DNLP, CNS, MINLP, or MCP). CONVERT can also be specified via the option statement within the model itself before the solve statement:

```
option modeltype=convert;
```

5.9.3 The GAMS Scalar Format

By default, CONVERT generates a scalar GAMS model (`gams.gms`) from the input model. The scalar model exhibits the following characteristics:

- A model without sets or indexed parameters. It does not exhibit any of the advanced characteristics of modeling systems and is easily transformable.
- A model with a new set of individual variables, depicting each variable in the GAMS model as one of 3 types: positive, integer or binary. Each variable is numbered sequentially, i.e. all positive GAMS variables are mapped into n single variables $x_1, x_2, \ldots, x_n$.
- A model with individual equations depicting each variable in the GAMS model. All equations are also numbered sequentially, that is equations $e_1, e_2, \ldots, e_m$.

Equation and variable bounds, as well as variable starting values are preserved from the original GAMS formulation.

As an example, suppose the user wishes to translate the GAMS Model Library model `trnsport` into scalar format, One would run

```
gams trnsport.gms lp=convert
```

which would generate the following scalar model `gams.gms`:

```
* LP written by GAMS Convert at 11/19/20 15:28:05
*
* Equation counts
*    Total   E   G   L   N   X   C   B
*       6   1   3   2   0   0   0   0
* *
* Variable counts
*       x   b   i   s1s  s2s   sc   si
*    Total   cont binary integer sos1 sos2 scont sint
*       7    7    0    0    0    0    0    0
*  FX   0
* *
* Nonzero counts
*    Total   const      NL
*        6       6       0
```
Variables
x1,x2,x3,x4,x5,x6,x7;

Positive Variables
x1,x2,x3,x4,x5,x6;

Equations
e1,e2,e3,e4,e5,e6;

e1.. -0.225 * x1 - 0.153 * x2 - 0.162 * x3 - 0.225 * x4 - 0.162 * x5 - 0.126 * x6 + x7 =E= 0;
e2.. x1 + x2 + x3 =L= 350;
e3.. x4 + x5 + x6 =L= 600;
e4.. x1 + x4 =G= 325;
e5.. x2 + x5 =G= 300;
e6.. x3 + x6 =G= 275;

Model m / all /;

m.limrow = 0;
m.limcol = 0;

Solve m using LP minimizing x7;

Note that the resulting scalar model does not contain any of the descriptive information about the data or the context of the constraints.

Additionally, a dictionary file (dict.txt) is created by default which specifies a mapping between the variable and equation names in the scalar model and their corresponding names in the original model.

For the above example, the dictionary file is

LP written by GAMS Convert at 11/19/20 15:28:05

Equation counts

|x| E | G | L | N | X | C | B |
---|---|---|---|---|---|---|---|
6 | 1 | 3 | 2 | 0 | 0 | 0 | 0 |

Variable counts

|x| cont | binary | integer | sos1 | sos2 | scont | sint |
---|------|--------|---------|------|------|--------|------|
7 | 7 | 0 | 0 | 0 | 0 | 0 | 0 |

Nonzero counts

| Total | const | NL |
---|------|----|
19 | 19 | 0 |

Equations 1 to 6

e1 cost
e2 supply(seattle)
e3 supply-san-diego
e4 demand(new-york)
Variables 1 to 7
  x1 x(seattle,new-york)
  x2 x(seattle,chicago)
  x3 x(seattle,topeka)
  x4 x(san-diego,new-york)
  x5 x(san-diego,chicago)
  x6 x(san-diego,topeka)
  x7 z

Conversion of a GAMS model to a scalar one may be handy for model debugging. However, in this case, it may be good to retain the original variable and equation names. The following simple sed command attempts to achieve this:

```
sed -n -e "s:^ *\([exbi][0-9][0-9]*\) \(.\)*:s/\1/\2/g:gp" dict.txt | sed -n '1!G;h;$p' > mod.txt
gams.gms
```

For the above example, this outputs:

Variables
  x(seattle,new-york),x(seattle,chicago),x(seattle,topeka),x(san-diego,new-york),x(san-diego,chicago),x(san-diego,topeka),z;

Positive Variables
  x(seattle,new-york),x(seattle,chicago),x(seattle,topeka),x(san-diego,new-york),x(san-diego,chicago),x(san-diego,topeka);

Equations
  cost,supply(seattle),supply(san-diego),demand(new-york),demand(chicago),demand(topeka);

```
cost.. -0.225 * x(seattle,new-york) - 0.153 * x(seattle,chicago) - 0.162 * x(seattle,topeka) - 0.225 * x(san-diego,new-york) - 0.162 * x(san-diego,chicago) - 0.126 * x(san-diego,topeka) + z =E= 0;
supply(seattle).. x(seattle,new-york) + x(seattle,chicago) + x(seattle,topeka) =L= 350;
supply(san-diego).. x(san-diego,new-york) + x(san-diego,chicago) + x(san-diego,topeka) =L= 600;
demand(new-york).. x(seattle,new-york) + x(san-diego,new-york) =G= 325;
demand(chicago).. x(seattle,chicago) + x(san-diego,chicago) =G= 300;
demand(topeka).. x(seattle,topeka) + x(san-diego,topeka) =G= 275;
```

Of course, this is not a valid GAMS code and cannot be compiled, but it may be sufficient to view the model algebra as generated by the GAMS compiler.

By using

```
sed -n -e "y/((),-/__,/" -e "s:~*([exbi][0-9][0-9]*$) \(.\)*:s/\1/\2/g:gp" dict.txt | sed -n '1!G;h;$p' > mod.txt
gams.gms
```

one gets for this example

Variables
  x_seattle_new_york_,x_seattle_chicago_,x_seattle_topeka_,x_san_diego_new_york_,x_san_diego_chicago_,x_san_diego_topeka_,z;

Positive Variables
  x_seattle_new_york_,x_seattle_chicago_,x_seattle_topeka_,x_san_diego_new_york_,x_san_diego_chicago_,x_san_diego_topeka_.
Equations
\[
\begin{align*}
\text{cost} & \text{, supply\_seattle\_} , \text{supply\_san\_diego\_}, \text{demand\_new\_york\_}, \text{demand\_chicago\_}, \text{demand\_topeka\_}; \\
\text{cost}.. & -0.225 \times \text{x\_seattle\_new\_york\_} - 0.153 \times \text{x\_seattle\_chicago\_} - 0.162 \times \text{x\_seattle\_topeka\_} - 0.225 \times \text{x\_san\_diego\_new\_york\_} - 0.162 \times \text{x\_san\_diego\_chicago\_} - 0.126 \times \text{x\_san\_diego\_topeka\_} + z = & E = 0; \\
\text{supply\_seattle\_}.. & \quad \text{x\_seattle\_new\_york\_} + \text{x\_seattle\_chicago\_} + \text{x\_seattle\_topeka\_} = \underline{L} = 350; \\
\text{supply\_san\_diego\_}.. & \quad \text{x\_san\_diego\_new\_york\_} + \text{x\_san\_diego\_chicago\_} + \text{x\_san\_diego\_topeka\_} = \underline{L} = 600; \\
\text{demand\_new\_york\_}.. & \quad \text{x\_seattle\_new\_york\_} + \text{x\_san\_diego\_new\_york\_} = \overline{G} = 325; \\
\text{demand\_chicago\_}.. & \quad \text{x\_seattle\_chicago\_} + \text{x\_san\_diego\_chicago\_} = \overline{G} = 300; \\
\text{demand\_topeka\_}.. & \quad \text{x\_seattle\_topeka\_} + \text{x\_san\_diego\_topeka\_} = \overline{G} = 275;
\end{align*}
\]

This can even be compiled by GAMS and gives the correct solution.

The proposed commands come with several limitations and may not produce in all cases the desired output. For example, wrong results would be printed if the original model contains variable or equation names that start with \{b, i, e, x\}digit. Also semicontinuous or semiinteger variables or special ordered sets are not supported by the above. We leave it to the experienced user to extend the command appropriately.

5.9.4 The OSiL Format

The Optimization Services Instance Language (OSIL) [70] specifies an XML-based format to represent optimization problem instances. GAMS/CONVERT can write MINLP model instances in OSiL format. Expression trees are written in OSnL format.

Next to the indexed operations for sum, product, minimum, and maximum, and the operations for subtraction and division, the following intrinsic functions are mapped to their OSnL counterparts: \text{sqr}, \text{sqrt}, \text{exp}, \text{log}, \text{log2}, \text{log10}, \text{abs}, \text{cos}, \text{sin}, \text{tan}, \text{arccos}, \text{arcsin}, \text{arctan}, \text{sinh}, \text{cosh}, \text{tanh}, \text{pi}, \text{gamma}, \text{loggamma}, \text{floor}, \text{ceil}, \text{round}, \text{trunc}, \text{sign fact}, \text{binomial}. The functions \text{cvPower}, \text{power}, \text{rpower}, \text{vcpower} are all mapped to OSnL’s \text{power} operator, thus conditions on arguments are not preserved. Functions \text{arctan2}, \text{centropy}, \text{edist}, \text{errorf}, and \text{poly} are represented by an expression according to their algebraic definition. The intrinsic functions \text{signpower}, \text{entropy}, \text{sigmoid}, \text{gammareg}, \text{beta}, \text{logbeta}, and \text{betareg} are also written to OSiL files, but do not follow the OSnL standard (as it currently does not offer these functions). Thus, OsiL readers may reject XML files that use these functions. Finally, also the logical functions are written to OSiL by using their OSnL counterpart.

5.9.5 User-Specified Options

CONVERT options are passed on through option files. If you specify \langle\text{modelname}\rangle.\text{optfile} = 1; before the SOLVE statement in your GAMS model, CONVERT will look for and read an option file with the name \text{convert.opt} (see The Solver Options File for general use of solver option files). The syntax for the CONVERT option file is

\text{optname value}

with one option on each line. For example,

\text{ampl}

This option file would tell CONVERT to produce an AMPL input file. For file format options, the user can specify the filename for the file to be generated. For example, the option file entry

\text{lingo myfile.lng}

would generate a LINGO input file format called \text{myfile.lng}. Using the option \text{lingo} by itself, would produce the default output file for that option (\text{lingo.lng}).

All available options are listed in the following tables.

5.9.5.1 Target languages and formats
<table>
<thead>
<tr>

5.10 COPT

Cardinal Optimizer by Cardinal Operations is a solver for mixed-integer linear and convex quadratic programming problems.

5.10.1 Usage

A GAMS/COPT or GAMS/COPT-Link license is required to use the GAMS/COPT interface that is distributed with GAMS. If only a GAMS/COPT-Link license is available, also a separate COPT license needs to be installed on the system, see the "Cardinal Operations User Guide" for details.

The following statement can be used inside your GAMS program to specify using COPT

```gams
Option MIP = COPT;  { or LP, QCP, MIQCP, ... }
```

The above statement should appear before the Solve statement. If COPT was specified as the default solver during GAMS installation, the above statement is not necessary.

COPT supports special ordered sets (SOS), but no semicontinuous or semiinteger variables.

5.10.1.1 Specification of COPT Options

The following GAMS parameters are currently supported by GAMS/COPT: reslim, iterlim, nodlim, optcr, optca, tryint, and threads.

Further options can be set via a solver options file, see Section The Solver Option File for further information. Following is an example options file `copt.opt`:

```plaintext
TreeCutLevel 0
SimplexThreads 4
```

It will cause COPT to use cut generators only in the root node (for a MI(QC)P solve) and specifies to use 4 threads in the simplex algorithm.

5.10.1.2 Specification of Indicators

Indicators are a modeling tool to specify that certain equations in a model must only be satisfied if certain binary variables take a specified value. Indicators are not supported by the GAMS language, but can be passed to COPT via a GAMS/COPT solver options file, see Indicator Constraints for more details on its syntax.
5.10.1.3 MIP Starting Point

When solving a MIP, by default all values that are specified as variable levels in the GAMS model are passed as starting point to COPT (unless MipStartMode = 0). However, if GAMS option tryint is set to a nonzero value or MipStartMode = 2, then only values of binary and integer variables which fractionality is at most the value tryint are passed as starting point to COPT (possible fractional values are rounded to integers). COPT will then try to complete this partial solution to a feasible solution.

5.10.1.4 Solution Pool

When COPT solves a problem, it may find several solutions, whereof only the best one is available to the GAMS user via the variable level values in the GAMS model. If the option solnpool is specified, then all alternative solutions found by COPT are written into GDX files and an index file with the name given by the this option is written. If the option solnpoolmerge is specified, then all alternative solutions found by COPT are written into a single GDX file, which name is given by the this option.

The GAMS testlib model dumpsol shows an example use for this option.

5.10.1.5 Infeasible and unbounded LPs

If an LP is found infeasible by COPT, a primal infeasibility certificate in form of a Farkas proof (see also Mosek manual) is computed. The GAMS/COPT link returns the values of this certificate in the equations marginal values and sets the INFES markers (see solution listing) for those equations that are included in the Farkas proof.

If an LP is found unbounded by COPT, a dual infeasibility certificate in form of a primal ray is computed. If the problem is feasible, then the primal ray gives a direction in which the objective function can be infinitely improved. The GAMS/COPT link returns the values of the primal ray in the variable level values and sets UNBND markers (see solution listing) for those variables that are included in the ray.

COPT option ReqFarkasRay can be used to disable the calculation of these infeasibility certificates.

5.10.1.6 Finding an Irreducible Inconsistent Subsystem (IIS) of Constraints

If an LP or MIP is infeasible, COPT has the capability to identify a subset of the constraints that are infeasible and become feasible once any one of them is eliminated. Option iis can be used to enable finding an IIS.

As an example, consider a GAMS model containing

Positive Variables x, y;
Equation el;
el.. x + y =l= -1;

The corresponding COPT output when iis has been set to 1 will look like
Starting the simplex solver using 1 thread

Method | Iteration | Objective | Primal.NInf | Dual.NInf | Time  
--- | --- | --- | --- | --- | ---  
Dual | 0 | 0.0000000000e+00 | 1 | 0 | 0.00s  

Solving finished
Status: Infeasible Objective: - Iterations: 0 Time: 0.00s

Start the IIS computation for an LP

| Iteration | Min RowBnd | Max RowBnd | Min ColBnd | Max ColBnd | Time  
--- | --- | --- | --- | --- | ---  
0 | 0 | 1 | 0 | 2 | 0.00s  
1 | 0 | 1 | 0 | 2 | 0.00s  
2 | 1 | 1 | 0 | 2 | 0.00s  
3 | 1 | 1 | 1 | 2 | 0.00s  
4 | 1 | 1 | 2 | 2 | 0.00s  

IIS summary: 1 rows, 2 bounds of columns
IIS computation finished (0.000s)
IIS is minimal
Number of equations in IIS: 1
  Upper: e1 <= -1
Number of variables in IIS: 2
  Lower: x >= 0
  Lower: y >= 0

That is, COPT finds the problem infeasible. Then the IIS computation is started and an IIS is found. The IIS is then printed to the log and listing file. It consists of the lower bounds of variables $x$ and $y$ and equation $e1$. This suggests that the entire model can be made feasible by lowering the lower bound of $x$ or $y$ or by increasing the right-hand side of $e1$.

If one knows in advance that the problem is infeasible, then option iis can be set to 2 to skip the initial solve.

### 5.10.1.7 Using the Feasibility Relaxation

The feasibility relaxation is enabled by the FeasRelax parameter in a COPT solver option file.

With the FeasRelax option COPT selectively relaxes the variable bounds and constraint sides of an infeasible model instance in a way that a weighted penalty function is minimized. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

Attention

At the moment, COPT can only relax sides of linear constraints. Indicator and quadratic constraints are not considered for relaxation.

By default all equation sides are candidates for relaxation and weighted equally but none of the variable bounds can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the dot option feaspref. A zero preference means that the associated bound or constraint side is not to be modified. The weighted penalty function is constructed from these preferences. The larger the preference, the more likely it will be that a given variable bound or constraint side will be relaxed. However, it is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a COPT solver option file. The syntax is:
For example, suppose we have a GAMS declaration:

```plaintext
Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);
```

Then, the relaxation preference in the `copt.opt` file can be specified by:

```plaintext
feasrelax 1
v.feaspref 1
v.feaspref('i1','*') 2
v.feaspref('i1','j2') 0
e.feaspref('j1','*') 0
e.feaspref('i5','j4') 2
```

First we turn the feasible relaxation on. Furthermore, we specify that all variables `v(i,j)` have preference of 1, except variables over set element `i1`, which have a preference of 2. The variable over set element `i1` and `j2` has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords `variables` or `equations` instead of the individual variable and equations names (e.g. `variables.feaspref 1`).

The parameter `FeasRelaxMode` allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter `FeasRelaxMode` indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a sum of required relaxations; as the number of constraints and bounds required to be relaxed; as a sum of the squares of required relaxations).

Also check model `feasopt1` in the GAMS model library.

### 5.10.1.8 Parameter Tuning Tool

The COPT tuning tool performs multiple solves on a model instance, choosing different parameter settings for each run, in a search for settings that improve runtime or other quality measures. The longer it is run, the more likely it is to find a significant improvement. For notes on the limitation of parameter tuning tools, see also the GAMS/Gurobi manual.

A number of tuning-related parameters allow to control the operation of the tuning tool. To enable tuning, option `Tuning` needs to be set. The value of `Tuning` will be used as a prefix for the name of option files written by the solver link. The amount of time spend for tuning can be controlled by option `TuneTimeLimit`. Options `TuneMode` and `TuneMeasure` allow to specify whether solving time or bounds on the optimal value should be used as quality measure for the tuning time.

Options that are set in a GAMS/COPT options file are considered as fixed parameters and are not changed by the tuning tool. Since the GAMS/COPT link changes the default for a few COPT options, please check the log for the fixed parameters.

Using option `TuneParams`, a COPT options file with parameters that should be tuned can be specified. Note that this parameter file is read by COPT directly, so that its syntax may deviate from the one of GAMS/COPT solver option files. The file allows multiple values for each parameter name. For example,
if the file contains the lines `RootCutLevel 0 1 2 3` and `TreeCutLevel 0 1 2 3`, then the tuner will optimize only the amount of cutting plane generation for the given instance. If `TuneParams` is not set, the tuner will generate tuning parameter sets automatically.

If the tuning tool found one or several parameter sets that improve performance, then these will be written into files named `<Tuning>..<idx>`, where `Tuning` is the value of option `Tuning` and `idx` the index of the parameter set. The parameter set that yields best performance has index 000. GAMS/COPT does not return a solution if the tuning tool is used. Tuning cannot be used at the same time as other advanced features, like feasibility relaxation.

### 5.10.2 List of COPT Options

In the following, we give a detailed list of available COPT options.

#### 5.10.2.1 Limits and Tolerances

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>AbsGap</td>
<td>The absolute gap for MIP</td>
<td>GAMS optca</td>
</tr>
<tr>
<td>BarIterLimit</td>
<td>Barrier iteration limit</td>
<td>GAMS iterlim</td>
</tr>
<tr>
<td>DualTol</td>
<td>The tolerance for dual solutions and reduced cost</td>
<td>1e-06</td>
</tr>
<tr>
<td>FeasTol</td>
<td>The feasibility tolerance</td>
<td>1e-06</td>
</tr>
<tr>
<td>IntTol</td>
<td>The integer feasibility tolerance</td>
<td>1e-06</td>
</tr>
<tr>
<td>MatrixTol</td>
<td>The input matrix coefficient tolerance</td>
<td>1e-10</td>
</tr>
<tr>
<td>NodeLimit</td>
<td>Limit of nodes for MIP</td>
<td>GAMS nodlim</td>
</tr>
<tr>
<td>RelGap</td>
<td>The relative gap for MIP</td>
<td>GAMS optcr</td>
</tr>
<tr>
<td>SolTimeLimit</td>
<td>Time limit that is only effective after a primal feasible solution has been found</td>
<td>1e+20</td>
</tr>
<tr>
<td>TimeLimit</td>
<td>Time limit of the optimization</td>
<td>GAMS reslim</td>
</tr>
</tbody>
</table>

#### 5.10.2.2 Presolving and Scaling

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dualize</td>
<td>Whether to dualize a problem before solving it</td>
<td>-1</td>
</tr>
</tbody>
</table>

-1: Choose automatically.
0: No dualizing.
1: Dualizing the problem.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Presolve</td>
<td>Level of presolving performed before solving a problem</td>
<td>-1</td>

5.11 CPLEX

5.11.1 Introduction

GAMS/Cplex is a GAMS solver that allows users to combine the high level modeling capabilities of GAMS with the power of Cplex optimizers. Cplex optimizers are designed to solve large, difficult problems quickly and with minimal user intervention. Access is provided (subject to proper licensing) to Cplex solution algorithms for linear, quadratically constrained and mixed integer programming problems. While numerous solving options are available, GAMS/Cplex automatically calculates and sets most options at the best values for specific problems.

All Cplex options available through GAMS/Cplex are summarized at the end of this document.

5.11.2 How to Run a Model with Cplex

The following statement can be used inside your GAMS program to specify using Cplex

\[
\text{Option LP = Cplex;} \quad \{ \text{or QCP, MIP, MIQCP, RMIP or RMIQCP } \}
\]

The above statement should appear before the Solve statement. If Cplex was specified as the default solver during GAMS installation, the above statement is not necessary.

Attention

The free bare-bone link mode (previously GAMS/OSICPLEX) that allowed to solve LP and MIP when the user had a separate CPLEX license has been removed. If you relied on using this bare-bone link option, then do not hesitate to contact sales@gams.com to arrange for a GAMS/CPLEX Solver Link license.

5.11.3 Overview of Cplex

5.11.3.1 Linear Programming

Cplex solves LP problems using several alternative algorithms. The majority of LP problems solve best using Cplex's state of the art dual simplex algorithm. Certain types of problems benefit from using the primal simplex algorithm, the network optimizer, the barrier algorithm, or the sifting algorithm. The concurrent option will allow solving with different algorithms in parallel. The solution is returned by the first to finish.

Solving linear programming problems is memory intensive. Even though Cplex manages memory very efficiently, insufficient physical memory is one of the most common problems when running large LPs. When memory is limited, Cplex will automatically make adjustments which may negatively impact performance. If you are working with large models, study the section entitled Physical Memory Limitations carefully.

Cplex is designed to solve the majority of LP problems using default option settings. These settings usually provide the best overall problem optimization speed and reliability. However, there are occasionally reasons for changing option settings to improve performance, avoid numerical difficulties, control optimization run duration, or control output options.

Some problems solve faster with the primal simplex algorithm rather than the default dual simplex algorithm. Very few problems exhibit poor numerical performance in both the primal and the dual. Therefore, consider trying primal simplex if numerical problems occur while using dual simplex.

Cplex has a very efficient algorithm for network models. Network constraints have the following property:
• each non-zero coefficient is either a +1 or a -1
• each column appearing in these constraints has > exactly 2 nonzero entries, one with a +1 coefficient and one with a -1 coefficient

Cplex can also automatically extract networks that do not adhere to the above conventions as long as they can be transformed to have those properties.

The barrier algorithm is an alternative to the simplex method for solving linear programs. It employs a primal-dual logarithmic barrier algorithm which generates a sequence of strictly positive primal and dual solutions. Specifying the barrier algorithm may be advantageous for large, sparse problems.

Cplex provides a sifting algorithm which can be effective on problems with many more variables than equations. Sifting solves a sequence of LP subproblems where the results from one subproblem are used to select columns from the original model for inclusion in the next subproblem.

GAMS/Cplex also provides access to the Cplex Conflict Refiner previously known as IIS (Irreducibly Inconsistent Set). The conflict refinder takes an infeasible program and produces a set of conflicting constraints. Such a set consists of constraints and variable bounds which is infeasible but becomes feasible if any one member of the set is dropped. GAMS/Cplex reports the conflict in terms of GAMS equation and variable names and includes the conflict report as part of the normal solution listing.

5.11.3.2 Quadratically Constrained Programming

Cplex can solve models with quadratic constraints. These are formulated in GAMS as models of type QCP. QCP models are solved with the Cplex Barrier method.

QP models are a special case that can be reformulated to have a quadratic objective function and only linear constraints. Those are automatically reformulated from GAMS QCP models. When such problems are convex, Cplex normally solves them efficiently in polynomial time. Nonconvex QPs, however, are known to be quite hard. Cplex applies various approaches to those problems, such approaches as barrier algorithms or branch and bound algorithms. Notably, in the branch and bound approach, there is no theoretical guarantee about the complexity of such a problem. Consequently, solution of such a problem (that is, a nonconvex QP) can take many orders of magnitude longer than the solution of a convex QP of comparable dimensions. Therefore, the default is to reject such model. The parameter OptimalityTarget allows to change this behavior.

For QCP models Cplex returns a primal and in most cases also dual values.

5.11.3.3 Mixed-Integer Programming

The methods used to solve pure integer and mixed integer programming problems require dramatically more mathematical computation than those for similarly sized pure linear programs. Many relatively small integer programming models take enormous amounts of time to solve.

For problems with integer variables, Cplex uses a branch and cut algorithm which solves a series of LP subproblems. Because a single mixed integer problem generates many subproblems, even small mixed integer problems can be very compute intensive and require significant amounts of physical memory.

GAMS and GAMS/Cplex support Special Order Sets of type 1 and type 2 as well as semi-continuous and semi-integer variables.

Cplex can also solve problems of GAMS model type MIQCP. As in the continuous case, if the base model is a QP the Simplex methods can be used and duals will be available at the solution. If the base model is a QCP, only the Barrier method can be used for the nodes and only primal values will be available at the solution.
5.11.3.4 Feasible Relaxation

The Conflict Refiner identifies the causes of infeasibility by means of inconsistent set of constraints. However, you may want to go beyond diagnosis to perform automatic correction of your model and then proceed with delivering a solution. One approach for doing so is to build your model with explicit slack variables and other modeling constructs, so that an infeasible outcome is never a possibility. An automated approach offered in GAMS/Cplex is known as FeasOpt (for Feasible Optimization) and turned on by parameter FeasOpt in a CPLEX option file. More details can be found in the section entitled Using the Feasibility Relaxation.

5.11.3.5 Solution Pool: Generating and Keeping Multiple Solutions

This section introduces the solution pool for storing multiple solutions to a mixed integer programming problem (MIP and MIQCP). The chapter also explains techniques for generating and managing those solutions.

The solution pool stores multiple solutions to a mixed integer programming (MIP and MIQCP) model. With this feature, you can direct the algorithm to generate multiple solutions in addition to the optimal solution. For example, some constraints may be difficult to formulate efficiently as linear expressions, or the objective may be difficult to quantify exactly. In such cases, obtaining multiple solutions will help you choose one which best fits all your criteria, including the criteria that could not be expressed easily in a conventional MIP or MIQCP model. For example,

- You can collect solutions within a given percentage of the optimal solution. To do so, apply the solution pool gap parameters SolnPoolAGap and SolnPoolGap.
- You can collect a set of diverse solutions. To do so, use the solution pool replacement parameter SolnPoolReplace to set the solution pool replacement strategy to 2. In order to control the diversity of solutions even more finely, apply a diversity filter.
- In an advanced application of this feature, you can collect solutions with specific properties. To do so, see the use of the incumbent filter.
- You can collect all solutions or all optimal solutions to model. To do so, set the solution pool intensity parameter SolnPoolIntensity to its highest value.

Please note, that the value for best possible can exceed the optimal solution value if CPLEX has already solved the model to optimality but continues to search for additional solutions.

5.11.3.5.1 Filling the Solution Pool

There are two ways to fill the solution pool associated with a model: You can accumulate successive incumbents or generate alternative solutions by populating the solution pool. The method is selected with the parameter SolnPoolPop:

- The regular optimization procedure automatically adds incumbents to the solution pool as they are discovered (SolnPoolPop = 1).
- Cplex also provides a procedure specifically to generate multiple solutions. You can invoke this procedure by setting option SolnPoolPop = 2. You can also invoke this procedure many times in a row in order to explore the solution space differently. In particular, you may invoke this procedure multiple times to find additional solutions, especially if the first solutions found are not satisfactory. This is done by specifying a GAMS program (option SolnPoolPopRepeat) that inspects the solutions. In case this GAMS program terminates normally, i.e. no execution or compilation error, the exploration for alternative solutions proceeds.
The option `SolnPoolReplace` designates the strategy for replacing a solution in the solution pool when the solution pool has reached its capacity. The value 0 replaces solutions according to a first-in, first-out policy. The value 1 keeps the solutions with the best objective values. The value 2 replaces solutions in order to build a set of diverse solutions.

If the solutions you obtain are too similar to each other, try setting `SolnPoolReplace` to 2.

The replacement strategy applies only to the subset of solutions created in the current call of populate. Solutions already in the pool are not affected by the replacement strategy. They will not be replaced, even if they satisfy the criterion of the replacement strategy. So with every repeated call of the populate procedure the solution pool will be extended by the newly found solution. After the GAMS program specified in `SolnPoolPopRepeat` determined to continue the search for alternative solutions, the file specified by option `SolnPoolPopDel` option is read in. The solution numbers present in this file will be delete from the solution pool before the populate routine is called again. The file is automatically deleted by the GAMS/Cplex link after processing.

### 5.11.3.5.2 Enumerating All Solutions

With the solution pool, you can collect all solutions to a model. To do so, set the solution pool intensity parameter `SolnPoolIntensity` to its highest value, 4 and set `SolnPoolPop = 2`.

You can also enumerate all solutions that are valid for a specific criterion. For example, if you want to enumerate all alternative optimal solutions, do the following:

- Set the pool absolute gap parameter `SolnPoolAGap = 0.0` (for models with potential numerical issues, better use a small non-zero like 1e-6).
- Set the pool intensity parameter `SolnPoolIntensity` = 4.
- Set the populate limit parameter `PopulateLim` to a value sufficiently large for your model; for example, 2100000000.
- Set the pool population parameter `SolnPoolPop` = 2.

Beware, however, that, even for small models, the number of possible solutions is likely to be huge. Consequently, enumerating all of them will take time and consume a large quantity of memory.

There may be an infinite number of possible values for a continuous variable, and it is not practical to enumerate all of them on a finite-precision computer. Therefore, populate gives only one solution for each set of binary and integer variables, even though there may exist several solutions that have the same values for all binary and integer variables but different values for continuous variables.

Likewise, for the same reason, the populate procedure does not generate all possible solutions for unbounded models. As soon as the proof of unboundedness is obtained, the populate procedure stops.

Cplex uses numerical methods of finite-precision arithmetic. Consequently, the feasibility of a solution depends on the value given to tolerances. Two parameters define the tolerances that assess the feasibility of a solution:

- the integrality tolerance `EpInt`
- the feasibility tolerance `EpRHS`

A solution may be considered feasible for one pair of values for these two parameters, and infeasible for a different pair. This phenomenon is especially noticeable in models with numeric difficulties, for example, in models with BigM coefficients.

Since the definition of a feasible solution is subject to tolerances, the total number of solutions to a model may vary, depending on the approach used to enumerate solutions, and on precisely which tolerances are used. In most models, this tolerance issue is not problematic. But, in the presence of numeric difficulties, Cplex may create solutions that are slightly infeasible or integer infeasible, and therefore create more solutions than expected.
5.11.3.5.3 Filtering the Solution Pool Filtering allows you to control properties of the solutions generated and stored in the solution pool. Cplex provides two predefined ways to filter solutions.

If you want to filter solutions based on their difference as compared to a reference solution, use a **diversity filter**. This filter is practical for most purposes. However, if you require finer control of which solutions to keep and which to eliminate, use the **incumbent filter**.

5.11.3.5.4 Diversity Filter A diversity filter allows you to generate solutions that are similar to (or different from) a set of reference values that you specify for a set of binary variables using dot option **DivFlt** and lower and upper bounds **DivFltLo** and **DivFltUp**. In particular, you can use a diversity filter to generate more solutions that are similar to an existing solution or to an existing partial solution. If you need more than one diversity filter, for example, to generate solutions that share the characteristics of several different solutions, additional filters can be specified through a Cplex Filter File using parameter **ReadFLT**. Details can be found in the example model **solnpool** in the GAMS model library.

5.11.3.5.5 Incumbent Filter If you need to enforce more complex constraints on solutions (e.g. if you need to enforce nonlinear constraints), you can use the incumbent filtering. The incumbent checking routine is part of the GAMS BCH Facility. It will accept or reject incumbents independent of a solution pool. During the populate or regular optimize procedure, the incumbent checking routine specified by the parameter **UserIncbCall** is called each time a new solution is found, even if the new solution does not improve the objective value of the incumbent. The incumbent filter allows your application to accept or reject the new solution based on your own criteria. If the GAMS program specified by **UserIncbCall** terminates normally, the solution is rejected. If this program returns with a compilation or execution error, the incumbent is accepted.

5.11.3.5.6 Accessing the Solution Pool The solutions are stored in GAMS Data eXchange (GDX) file and can be loaded by your GAMS program. Details can be found in the model **solnpool** in the GAMS model library and in . If you instruct Cplex to generate thousands of solution this becomes inefficient. The option **SolnPoolMerge** triggers the creation of a single GDX file containing all solutions.

The GAMS/Cplex link produces, if properly instructed, a GAMS Data eXchange(GDX) file with name specified in **SolnPool** that contains a set **Index** with elements **file1**, **file2**, ... The associated text of these elements contain the file names of the individual GDX solution file. The name is constructed using the prefix **soln** (which can be specified differently by option **SolnPoolPrefix**), the name of the model and a sequence number. For example **soln_loc.p1.gdx**. GAMS/Cplex will overwrite existing GDX files without warning. The set **Index** allows us to conveniently walk through the different solutions in the solution pool. A complete model can be found in the model **solnpool** in the GAMS model library.

```plaintext
solve mymodel min z using mip;
set soln possible solutions in the solution pool /file1*file1000/
   solnpool(soln) actual solutions;
file fsol;
execute_load 'solnpool.gdx', solnpool=Index;
loop(solnpool(soln),
   put_utility fsol 'gdxin' / solnpool.te(soln):0:0;
   execute_loadpoint;
   display z.l;
);
```

If you instruct Cplex to generate thousands of solution this method becomes inefficient. The option **SolnPoolMerge** triggers the creation of a single GDX file containing all solutions. Details on usage of this option can be found in the model **solmpool** in the GAMS model library.
5.11.3.6 Benders Algorithm

CPLEX implements Benders algorithm.

Given a formulation of a problem, CPLEX can decompose the model into a single master and (possibly multiple) subproblems. To do so, CPLEX makes use of annotations that you supply for your model. This approach can be applied to mixed-integer linear programs (MILP). For certain types of problems, this approach can offer significant performance improvements.

The parameter, BendersStrategy, specifies to CPLEX how you want to apply Benders algorithm as a strategy to solve your model. By default, if you did not annotate your model to specify a decomposition, CPLEX executes conventional branch and bound. If you annotated your model, CPLEX attempts to refine your decomposition and applies Benders algorithm. With this parameter, you can direct CPLEX to decompose your model and to apply its implementation of Benders algorithm in one of these alternative ways:

- **1**: CPLEX attempts to decompose your model strictly according to your annotations.
- **2**: CPLEX decomposes your model by using your annotations as hints and refining the decomposition where it can. CPLEX initially decomposes your model according to your annotation and then attempts to refine that decomposition by further decomposing the specified subproblems. This approach can be useful if you annotate certain variables to go into master, and all others to go into a single subproblem, which CPLEX can then decompose further for you.
- **3**: CPLEX automatically decomposes your model, ignoring any annotations you may have supplied. CPLEX puts all integer variables into the master, puts all continuous variables into a subproblem and decomposes that subproblem, if possible.

If you want to specify a decomposition to CPLEX, you need to annotate your model and specify a Benders partition of your variable space. These Benders partition can be conveniently specified with the dot option BendersPartition or through the .stage variable suffix.

These Benders partition values specify to CPLEX whether certain variables belong to the master or to one of the subproblems assigned to workers (where the subproblems are numbered from 1 (one) to N, the number of subproblems). If you annotate a given variable with the value 0 (zero), CPLEX assigns that variable to the master. If you annotate a given variable with the value i, where i is greater than or equal to 1 (one), CPLEX assigns that variable to subproblem i. If a variable is not specified, the default will be to go into the master problem. Note that with variable.BendersPartition 1 you can assign all variables to the subproblem and then selectively assign the master variables with varname.BendersPartition 0.

If you want to communicate the Benders partition values via the .stage variable suffix, the partition numbers are off by one compared to the partition number via the dot option. So the master variables have stage 1, and the subproblems start with stage 2. If you want to leave a variable unassigned you can either make the stage 0 or fractional (e.g. 1.5). Discrete variables are automatically put into the master problem and don’t need to be set. In addition to specifying the Benders partition values via the .stage variable suffix the link option BendersPartitionInStage needs to be set to 1.

CPLEX produces an error if the annotated decomposition does not yield disjoint subproblems. For example, if your annotations specify that two (or more) variables belong in different subproblems, yet your model specifies that these variables participate in the same constraint, then these variables are linked. Consequently, the subproblems where these variables appear according to your annotations are not disjoint with respect to the partition.
5.11.3.7 Multiple Objectives

While typical optimization models have a single objective function, real-world optimization problems often have multiple, competing objectives. For example, in a production planning model, you may want to both maximize profits and minimize late orders, or in a workforce scheduling application, you may want to both minimize the number of shifts that are short-staffed while also respecting worker's shift preferences.

The main challenge you face when working with multiple, competing objectives is deciding how to manage the tradeoffs between them. Cplex provides tools that simplify the task: Cplex allows you to blend multiple objectives, to treat them hierarchically, or to combine the two approaches. In a blended approach, you optimize a weighted combination of the individual objectives. In a hierarchical or lexicographic approach, you set a priority for each objective, and optimize in priority order. When optimizing for one objective, you only consider solutions that would not degrade the objective values of higher-priority objectives. Cplex allows you to enter and manage your objectives, to provide weights for a blended approach, or to set priorities for a hierarchical approach. Cplex will only solve multi-objective models with strictly linear objectives. Moreover, for continuous models, Cplex will report a primal only solution (not dual information).

Following the workforce application the specifications of the objectives would be done as follows:

```plaintext
 equations defObj, defNumShifts, defSumPreferences;
 variables obj, numShifts, sumPreferences;

 defObj.. obj =e= numShifts - 1/100*sumPreferences;
 defNumShifts.. numShifts =e= ...;
 defSumPreferences.. sumPreferences =e= ...;

 model workforce /all/;
 solve workforce minimizing obj using mip;
```

With the default setting Cplex will solve the blended objective. Using the parameter MultObj Cplex will use a hierarchical approach. A hierarchical or lexicographic approach assigns a priority to each objective, and optimizes for the objectives in decreasing priority order. At each step, it finds the best solution for the current objective, but only from among those that would not degrade the solution quality for higher-priority objectives. The priority is specified by the absolute value of the objective coefficient in the blended objective function (defObj). In the example, the numShifts objective with coefficient 1 has higher priority than the sumPreferences objective with absolute objective coefficient 1/100. The sign of the objective coefficient determines the direction of the particular objective function. So here numShifts will be minimized (same direction as on the solve statement) while sumPreferences will be maximized.

GAMS needs to identify the various objective functions, therefore the objective variables can only appear in the blended objective functions and in the particular objective defining equation.

By default, the hierarchical approach won't allow later objectives to degrade earlier objectives. This behavior can be relaxed through a pair of attributes: ObjNRelTol and ObjNAbsTol. Their meaning differs for continuous and discrete models:

- **Discrete models**: By setting one of the two tolerances for a particular objective, you can indicate that later objectives are allowed to degrade this objective by the specified relative or absolute amount, respectively. In our earlier example, if the optimal value for numShifts is 100, and if we set ObjNAbsTol for this objective to 20, then the second optimization step maximizing sumPreferences would find the best solution for the second objective from among all solutions with objective 120 or better for numShifts. Note that if you modify both tolerances, later optimizations would use the looser of the two values (i.e., the one that allows the larger degradation).

- **Continuous Models**: ObjNAbsTol does not include a hard constraint for previous objective functions in subsequent solves. Instead, ObjNAbsTol defines a threshold for the reduced costs above which nonbasic variables in the associated LP solve will be fixed at the bound at which they reside. The option ObjNRelTol has no effect here. In order to apply the above discrete strategy for continuous models, set MultObjTolMip to 1.
5.11.4 GAMS Options

The following GAMS options are used by GAMS/Cplex:

- **Option BRatio = x;**
  
  Determines whether or not to use an advanced basis. A value of 1.0 causes GAMS to instruct Cplex not to use an advanced basis. A value of 0.0 causes GAMS to construct a basis from whatever information is available. The default value of 0.25 will nearly always cause GAMS to pass along an advanced basis if a solve statement has previously been executed.

- **Option IterLim = n;**
  
  Sets the simplex iteration limit. Simplex algorithms will terminate and pass on the current solution to GAMS.

  Cplex handles the iteration limit for MIP problems differently than some other GAMS solvers. The iteration limit is applied per node instead of as a total over all nodes. For MIP problems, controlling the length of the solution run by limiting the execution time (ResLim) is preferable.

  Similarly, when using the sifting algorithm, the iteration limit is applied per sifting iteration (ie per LP). The number of sifting iterations (LPs) can be limited by setting Cplex parameter SiftItLim. It is the number of sifting iterations that is reported back to GAMS as iterations used.

- **Option ResLim = x;**
  
  Sets the time limit in seconds. In case resLim assumes its default value (1e+10) Cplex will use its own default (1e+75). The algorithm will terminate and pass on the current solution to GAMS.

- **Option SysOut = On;**
  
  Will echo Cplex messages to the GAMS listing file. This option may be useful in case of a solver failure.

- **ModelName.Cheat = x;**
  
  Cheat value: each new integer solution must be at least x better than the previous one. Can speed up the search, but you may miss the optimal solution. The cheat parameter is specified in absolute terms (like the OptCA option). The Cplex option ObjDif overrides the GAMS cheat parameter.

- **ModelName.Cutoff = x;**
  
  Cutoff value. When the branch and bound search starts, the parts of the tree with an objective worse than x are deleted. This can sometimes speed up the initial phase of the branch and bound algorithm.

- **ModelName.NodLim = x;**
  
  Maximum number of nodes to process for a MIP problem.

- **Option OptCA = x;**
  
  Absolute optimality criterion for a MIP problem. The OptCA option asks Cplex to stop when

  \[ |BP - BF| < \text{OptCA} \]

  where BF is the objective function value of the current best integer solution while BP is the best possible integer solution.

  Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

- **ModelName.OptCR = x;**
5.11 CPLEX

Relative optimality criterion for a MIP problem. Notice that Cplex uses a different definition than GAMS normally uses. The OptCR option asks Cplex to stop when

\[
\frac{|BP - BF|}{(1.0e - 10 + |BF|)} < \text{OptCR}
\]

where BF is the objective function value of the current best integer solution while BP is the best possible integer solution. The GAMS definition is:

\[
\frac{|BP - BF|}{|BP|} < \text{OptCR}
\]

Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

- **ModelName.OptFile= 1;**
  Instructs Cplex to read the option file. The name of the option file is `cplex.opt`.

- **ModelName.PriorOpt= 1;**
  Instructs Cplex to use priority branching information passed by GAMS through the `variable.prior` parameters.

- **ModelName.TryInt= x;**
  Causes GAMS/Cplex to make use of current variable values when solving a MIP problem. If a variable value is within x of a bound, it will be moved to the bound and the preferred branching direction for that variable will be set toward the bound. The preferred branching direction will only be effective when priorities are used. Priorities and tryint are sometimes not very effective and often outperformed by GAMS/CPLEX default settings. Supporting GAMS/CPLEX with knowledge about a known solution can be passed on by different means, please read more about this in section entitled Starting from a MIP Solution.

GAMS/Cplex also sets many model attributes that can be used in your GAMS program by accessing `ModelName.suffix`. A list of model attributes available after the solve can be found here [Model Attributes Mainly Used After Solve](#).

Cplex has the concept of deterministic time i.e. a measure of time that respects the same solution path to arrive at the same values in the solution while it yields the same level of performance for repeated solving of the same model with the same parameter settings, on the same computing platform. The length of a deterministic time tick may vary by platform. Nevertheless, ticks are normally consistent measures for a given platform (combination of hardware and software) carrying the same load. In other words, the correspondence of ticks to clock time depends on the hardware, software, and the current load of the machine. For the same platform and same load, the ratio of ticks per second stays roughly constant, independent of the model solved. However, for very short optimization runs, the variation of this ratio is typically high. GAMS/Cplex reports the deterministic time ticks spend inside Cplex in the model attribute `ETA1g`. Normally `ETA1g` is reporting the seconds.

### 5.11.5 Summary of CPLEX Options

The various Cplex options are listed here by category, with a few words about each to indicate its function. The options are listed again, in alphabetical order and with detailed descriptions, in the last section of this document.

5.11.5.13 The GAMS/Cplex Options File

The GAMS/Cplex options file consists of one option or comment per line. An asterisk (*) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by any amount of white space (blanks or tabs).

Following is an example options file cplex.opt.

```
    scaind 1
    simdisplay 2
```

It will cause Cplex to use a more aggressive scaling method than the default. The iteration log will have an entry for each iteration instead of an entry for each refactorization.

5.11.6 Special Notes

5.11.6.1 Physical Memory Limitations

For the sake of computational speed, Cplex should use only available physical memory rather than virtual or paged memory. When Cplex recognizes that a limited amount of memory is available it automatically
makes algorithmic adjustments to compensate. These adjustments almost always reduce optimization speed. Learning to recognize when these automatic adjustments occur can help to determine when additional memory should be added to the computer.

On virtual memory systems, if memory paging to disk is observed, a considerable performance penalty is incurred. Increasing available memory will speed the solution process dramatically. Also consider option MemoryEmphasis to conserve memory where possible.

When solving LPs, the Simplex algorithm (lpmethod 1 or 2) usually consumes less memory than the Barrier algorithm (lpmethod 2). During the Simplex algorithm, Cplex performs an operation called refactorization at a frequency determined by the ReInv option setting. The longer Cplex works between refactorizations, the greater the amount of memory required to complete each iteration. Therefore, one means for conserving memory is to increase the refactorization frequency. Since refactorization is an expensive operation, increasing the refactorization frequency by reducing the ReInv option setting generally will slow performance. Cplex will automatically increase the refactorization frequency if it encounters low memory availability. This can be seen by watching the iteration log. The default log reports problem status at every refactorization. If the number of iterations between iteration log entries is decreasing, Cplex is increasing the refactorization frequency. Since Cplex might increase the frequency to once per iteration, the impact on performance can be dramatic. Providing additional memory should be beneficial.

GAMS/Cplex also provides the option FreeGAMSModel to free some memory allocated by the GAMS link and making it available to Cplex. This only works when the GAMS parameter solveLink is set 0 which should be always done when memory is tight because GAMS completely vacates memory.

The Threads options also has a significant impact on memory consumption. The concurrent solvers keep multiple copies of the problem in memory which double or even triples the amount of memory consumed. If memory tight, set the Threads parameter to 1.

Not loading GAMS names into CPLEX can also help in saving some memory. This can be done by setting the model attribute dictFile or by using CPLEX option names.

5.11.6.2 Using Special Ordered Sets

For some models a special structure can be exploited. GAMS allows you to declare SOS1 and SOS2 variables (Special Ordered Sets of type 1 and 2).

In Cplex the definition for SOS1 variables is:

- A set of variables for which at most one variable may be non-zero.

The definition for SOS2 variables is:

- A set of variables for which at most two variables may be non-zero. If two variables are non-zero, they must be adjacent in the set.

5.11.6.3 Using Semi-Continuous and Semi-Integer Variables

GAMS allows the declaration of semi-continuous and semi-integer variables. These variable types are directly supported by GAMS/Cplex. For example:

```plaintext
SemiCont Variable x;
  x.lo = 3.2;
  x.up = 8.7;

SemiInt Variable y;
  y.lo = 5;
  y.up = 10;
```

Variable x will be allowed to take on a value of 0.0 or any value between 3.2 and 8.7. Variable y will be allowed to take on a value of 0 or any integral value between 5 and 10.
5.11 CPLEX

5.11.6.4 Running Out of Memory for MIP Problems

The most common difficulty when solving MIP problems is running out of memory. This problem arises when the branch and bound tree becomes so large that insufficient memory is available to solve an LP subproblem. As memory gets tight, you may observe frequent warning messages while Cplex attempts to navigate through various operations within limited memory. If a solution is not found shortly the solution process will be terminated with an unrecoverable integer failure message.

The tree information saved in memory can be substantial. Cplex saves a basis for every unexplored node. When utilizing the best bound method of node selection, the list of such nodes can become very long for large or difficult problems. How large the unexplored node list can become is entirely dependent on the actual amount of physical memory available and the actual size of the problem. Certainly increasing the amount of memory available extends the problem solving capability. Unfortunately, once a problem has failed because of insufficient memory, you can neither project how much further the process needed to go nor how much memory would be required to ultimately solve it.

Memory requirements can be limited by using the WorkMem, option with the NodeFileInd option. Setting NodeFileInd to 2 or 3 will cause Cplex to store portions of the branch and bound tree on disk whenever it grows to larger than the size specified by option WorkMem. That size should be set to something less than the amount of physical memory available.

Another approach is to modify the solution process to utilize less memory.

- Set option NodeSel to use a best estimate strategy or, more drastically a depth-first-search. Depth first search rarely generates a large unexplored node list since Cplex will be diving deep into the branch and bound tree rather than jumping around within it.
- Set option VarSel to use strong branching. Strong branching spends extra computation time at each node to choose a better branching variable. As a result it generates a smaller tree. It is often faster overall, as well.
- On some problems, a large number of cuts will be generated without a correspondingly large benefit in solution speed. Cut generation can be turned off using option Cuts.
- Use the Simplex algorithm instead of the Barrier algorithm using options StartAlg and SubAlg.
- Use option solvefinal to avoid solving the final LP.

See also Physical Memory Limitations.

5.11.6.5 Failing to Prove Integer Optimality

One frustrating aspect of the branch and bound technique for solving MIP problems is that the solution process can continue long after the best solution has been found. Remember that the branch and bound tree may be as large as $2^n$ nodes, where $n$ equals the number of binary variables. A problem containing only 30 binary variables could produce a tree having over one billion nodes! If no other stopping criteria have been set, the process might continue ad infinitum until the search is complete or your computer's memory is exhausted.

In general you should set at least one limit on the optimization process before beginning an optimization. Setting limits ensures that an exhaustive tree search will terminate in reasonable time. Once terminated, you can rerun the problem using some different option settings.
5.11.6.6 Starting from a MIP Solution

You can provide a known solution (for example, from a MIP problem previously solved or from your knowledge of the problem) to serve as the first integer solution. When you provide such a starting solution, you may invoke relaxation induced neighborhood search (RINS heuristic) or solution polishing to improve the given solution. This first integer solution may include continuous and discrete variables of various types, such as semi-continuous variables or special ordered sets.

If you specify values for all discrete variables, GAMS/CPLEX will check the validity of the values as an integer-feasible solution; if you specify values for only a portion of the discrete variables, GAMS/CPLEX will attempt to fill in the missing values in a way that leads to an integer-feasible solution. If the specified values do not lead directly to an integer-feasible solution, GAMS/CPLEX will apply a quick heuristic to try to repair the MIP Start. The number of times that GAMS/CPLEX applies the heuristic is controlled by the repair tries parameter (RepairTries). If this process succeeds, the solution will be treated as an integer solution of the current problem.

A MIP start will only be used by GAMS/CPLEX if the MipStart parameter is set to 1. The starting values must be set via the .L variable attribute in the GAMS model before the solve statement.

5.11.6.7 Using the Feasibility Relaxation

The feasibility relaxation is enabled by the FeasOpt parameter in a CPLEX solver option file.

With the FeasOpt option CPLEX accepts an infeasible model and selectively relaxes the bounds and constraints in a way that minimizes a weighted penalty function. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

By default all equations are candidates for relaxation and weighted equally but none of the variables can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the dot option FeasPref. A negative or zero preference means that the associated bound or constraint is not to be modified. The weighted penalty function is constructed from these preferences. The larger the preference, the more likely it will be that a given bound or constraint will be relaxed. However, it is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a CPLEX solver option file. The syntax is:

\[(\text{variable or equation})\text{.feaspref} \ (\text{value})\]

For example, suppose we have a GAMS declaration:

\[
\begin{align*}
\text{Set} \ i /i1*i5/; \\
\text{Set} \ j /j2*j4/; \\
\text{variable} \ v(i,j); \ \text{equation} \ e(i,j);
\end{align*}
\]

Then, the relaxation preference in the cplex.opt file can be specified by:

```
feasopt 1
v.feaspref 1
v.feaspref('i1','*') 2
v.feaspref('i1','j2') 0
e.feaspref('*,j1') 0
e.feaspref('i5','j4') 2
```
First we turn the feasible relaxation on. Furthermore, we specify that all variables \( v(i,j) \) have preference of 1, except variables over set element \( i1 \), which have a preference of 2. The variable over set element \( i1 \) and \( j2 \) has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords \texttt{variables} or \texttt{equations} instead of the individual variable and equations names (e.g. \texttt{variables.feaspref 1}).

The parameter \texttt{FeasOptMode} allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter \texttt{FeasOptMode} indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a \textit{sum} of required relaxations; as the \textit{number} of constraints and bounds required to be relaxed; as a \textit{sum of the squares} of required relaxations). Please check description of parameters \texttt{FeasOpt} and \texttt{FeasOptMode} for details. Also check example models \texttt{feassopt*} in the GAMS Model library.

### 5.11.6.8 Sensitivity Analysis

Sensitivity analysis (post-optimality analysis) in linear programming allows one to find out more about an optimal solution for a problem. In particular, objective ranging and right-hand-side ranging give information about how much an objective coefficient or a right-hand-side value can change without changing the optimal basis. In other words, they give information about how sensitive the optimal basis is to a change in the objective function or a right-hand-side.

Although not so much used for practical large scale problems and not available for mixed-integer or nonlinear models, ranging information can still be of use in some circumstances. This section describes how to produce ranging information with GAMS/CPLEX.

To obtain objective ranging information for a particular variable, the name of the GAMS variable should be specified with the \texttt{ObjRng} option. For example, to obtain ranging information for a variable \texttt{prod}, add the line

```
objrng prod
```

to a CPLEX options file. The \texttt{ObjRng} option can be repeated to specify ranging for more than one variable. To specify ranging for all variables, use the keyword \texttt{all}, i.e.,

```
objrng all
```

Similarly, to obtain right-hand-side ranging information for a particular equation, the name of the equation should be specified with the \texttt{RhsRng} option. Also this option can be repeated to obtain right-hand-side ranging information for several equations. To specify ranging for all equations use the keyword \texttt{all}.

As an example, consider solving the model [TRNSPORT] from the GAMS model library with CPLEX and options file

```
objrng all
rhsrng all
```

This gives the following table in the listing file:
If obtaining ranging information in a listing file is not sufficient, option `RngRestart` can be used to specify a file to which to write ranging information in GAMS syntax. For example, using an options file containing

```
rhsrng supply
rhsrng demand
rngrestart ranges.inc
```

will result in a file named `ranges.inc` being written with the following content:

```plaintext
* Include file with ranging information
* The set RNGLIM /LO,UP/ is assumed to be
* declared.
PARAMETER supplyRNG(i,RNGLIM) /  
seattle.LO 300  
seattle.UP 625  
san-diego.LO 550  
san-diego.UP +INF  
/;  
PARAMETER demandRNG(j,RNGLIM) /  
new-york.LO 50  
new-york.UP 375  
chicago.LO 25  
chicago.UP 350  
topeka.LO 0  
topeka.UP 325  
/;
```

For each equation specified, the ranging information is stored in a newly declared corresponding GAMS parameter. The name of the parameter is based on the name of the equation, but with `RNG` appended. The user is responsible for ensuring that the new name does not exceed the maximum symbol name length of GAMS identifiers. Further, the domain list of the new parameter is the same as the domain list for the corresponding equation with an additional dimension added to the end. The user is responsible for ensuring that the new parameter does not exceed the maximum number of index positions.
5.11 CPLEX

5.11.7 GAMS/Cplex Log File

Cplex reports its progress by writing to the GAMS log file as the problem solves. Normally the GAMS log file is directed to the computer screen.

The log file shows statistics about the presolve and continues with an iteration log.

For the primal simplex algorithm, the iteration log starts with the iteration number followed by the scaled infeasibility value. Once feasibility has been attained, the objective function value is listed instead. At the default value for option simdisplay there is a log line for each refactorization. The screen log has the following appearance:

```
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time = 0.01 sec.
Using conservative initial basis.
Iteration log . . .
Iteration:  1  Scaled infeas =  193998.067174
Iteration:  29  Objective =  -3484.286415
Switched to devex.
Iteration:  98  Objective =  -1852.931117
Iteration: 166  Objective =  -349.706562
Optimal solution found.
Objective :  901.161538
```

The iteration log for the dual simplex algorithm is similar, but the dual infeasibility and dual objective are reported instead of the corresponding primal values:

```
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time = 0.01 sec.
Iteration log . . .
Iteration:  1  Scaled dual infeas =  3.890823
Iteration:  53  Dual objective =  4844.392441
Iteration: 114  Dual objective =  1794.360714
Iteration: 176  Dual objective =  1120.183325
Iteration: 238  Dual objective =  915.143030
Removing shift (1).
Optimal solution found.
Objective :  901.161538
```

The log for the network algorithm adds statistics about the extracted network and a log of the network iterations. The optimization is finished by one of the simplex algorithms and an iteration log for that is produced as well.
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time = 0.02 sec.

Extracted network with 25 nodes and 116 arcs.
Extraction time = 0.01 sec.
Iteration log . . .
Iteration: 0 Infeasibility = 1232.378800 (-1.32326e+12)

Network - Optimal: Objective = 1.5716820779e+03
Network time = 0.01 sec. Iterations = 26 (24)

Iteration log . . .
Iteration: 1 Scaled infeas = 212696.154729
Iteration: 62 Scaled infeas = 10020.401232
Iteration: 142 Scaled infeas = 4985.200129
Switched to devex.
Iteration: 217 Objective = -3883.782587
Iteration: 291 Objective = -1423.126582

Optimal solution found.

Objective : 901.161538

The log for the barrier algorithm adds various algorithm specific statistics about the problem before starting the iteration log. The iteration log includes columns for primal and dual objective values and infeasibility values. A special log follows for the crossover to a basic solution.

Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time = 0.02 sec.

Number of nonzeros in lower triangle of A*A' = 6545
Using Approximate Minimum Degree ordering
Total time for automatic ordering = 0.01 sec.

</table>
For MIP problems, during the branch and bound search, Cplex reports the node number, the number of nodes left, the value of the Objective function, the number of integer variables that have fractional values, the current best integer solution, the best relaxed solution at a node and an iteration count. The last column show the current optimality gap as a percentage. CPLEX logs an asterisk (∗) in the left-most column for any node where it finds an integer-feasible solution or new incumbent. The + denotes an incumbent generated by the heuristic.
### Detailed Descriptions of CPLEX Options

These options should be entered in the options file after setting the GAMS ModelName.OptFile parameter to 1. The name of the options file is `cplex.opt`. The options file is case insensitive and the keywords should be given in full.

#### advind (integer): advanced basis use

Use an Advanced Basis. GAMS/Cplex will automatically use an advanced basis from a previous solve statement. The GAMS `BRatio` option can be used to specify when not to use an advanced basis. The Cplex option `AdvInd` can be used to ignore a basis passed on by GAMS (it overrides `BRatio`).

Default: determined by GAMS `Bratio`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use advanced basis</td>
</tr>
<tr>
<td>1</td>
<td>Use advanced basis if available</td>
</tr>
<tr>
<td>2</td>
<td>Crash an advanced basis if available (use basis with presolve)</td>
</tr>
</tbody>
</table>

#### aggcutlim (integer): aggregation limit for cut generation

Limits the number of constraints that can be aggregated for generating flow cover and mixed integer rounding cuts. For most purposes, the default will be satisfactory.

Default: 3

#### aggfill (integer): aggregator fill parameter

Aggregator fill limit. If the net result of a single substitution is more non-zeros than the setting of the `AggFill` parameter, the substitution will not be made.

Default: 10
**aggind (integer): aggregator on/off**

This option, when set to a nonzero value, will cause the Cplex aggregator to use substitution where possible to reduce the number of rows and columns in the problem. If set to a positive value, the aggregator will be applied the specified number of times, or until no more reductions are possible. At the default value of -1, the aggregator is applied once for linear programs and an unlimited number of times for mixed integer problems.

Default: -1

<table>
<thead>
<tr>
<th>value</th>

</thead>
<tbody>
<tr>
<td>-1</td>
<td>Once for LP, unlimited for MIP</td>
</tr>
<tr>
<td>0</td>
<td>Do not use</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Aggregator will be applied the specified number of times</td>
</tr>
</tbody>
</table>

**auxrootthreads (integer): number of threads for auxiliary tasks at the root node**

Partitions the number of threads for CPLEX to use for auxiliary tasks while it solves the root node of a problem. On a system that offers $N$ processors or $N$ global threads, if you set this parameter to $n$, where $N>n>0$ then CPLEX uses at most $n$ threads for auxiliary tasks and at most $N-n$ threads to solve the root node. See also the parameter Threads.

You cannot set $n$, the value of this parameter, to a value greater than or equal to $N$, the number of processors or global threads offered on your system. In other words, when you set this parameter to a value other than its default, that value must be strictly less than the number of processors or global threads on your system. Independent of the auxiliary root threads parameter, CPLEX will never use more threads than those defined by the global default thread count parameter. CPLEX also makes sure that there is at least one thread available for the main root tasks. For example, if you set the global threads parameter to 3 and the auxiliary root threads parameter to 4, CPLEX still uses only two threads for auxiliary root tasks in order to keep one thread available for the main root tasks. At its default value, 0 (zero), CPLEX automatically chooses the number of threads to use for the primary root tasks and for auxiliary tasks. The number of threads that CPLEX uses to solve the root node depends on several factors: 1) the number of processors available on your system; 2) the number of threads available to your application on your system (for example, as a result of limited resources or competition with other applications); 3) the value of the global default thread count parameter Threads.

Default: 0

<table>
<thead>
<tr>

<td>$N&gt;n&gt;0$</td>
<td>Use $n$ threads for auxiliary root tasks</td>
</tr>
</tbody>
</table>

**baralg (integer): algorithm selection**

Selects which barrier algorithm to use. The default setting of 0 uses the infeasibility-estimate start algorithm for LPs and MIP subproblems and the standard barrier algorithm, option 3, for other cases. The standard barrier algorithm is almost always fastest. The alternative algorithms, options 1 and 2, may eliminate numerical difficulties related to infeasibility, but will generally be slower.

Default: 0
<table>

<td>Infeasibility-constant start</td>
</tr>
<tr>
<td>3</td>
<td>standard barrier algorithm</td>
</tr>
</tbody>
</table>

**barcolnz (integer):** dense column handling

Determines whether or not columns are considered dense for special barrier algorithm handling. At the default setting of 0, this parameter is determined dynamically. Values above 0 specify the number of entries in columns to be considered as dense.

Default: 0

**barcrossalg (integer):** barrier crossover method

Selects which crossover method is used at the end of a barrier optimization. To turn off crossover set SolutionType to 2.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>Primal crossover</td>
</tr>
<tr>

**bardisplay (integer):** progress display level

Determines the level of progress information to be displayed while the barrier method is running.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No progress information</td>
</tr>
<tr>
<td>1</td>
<td>Display normal information</td>
</tr>
<tr>
<td>2</td>
<td>Display diagnostic information</td>
</tr>
</tbody>
</table>

**barepcomp (real):** convergence tolerance

Determines the tolerance on complementarity for convergence of the barrier algorithm. The algorithm will terminate with an optimal solution if the relative complementarity is smaller than this value.

Default: 1.0e–08

**bargrowth (real):** unbounded face detection

Used by the barrier algorithm to detect unbounded optimal faces. At higher values, the barrier algorithm will be less likely to conclude that the problem has an unbounded optimal face, but more likely to have numerical difficulties if the problem does have an unbounded face.

Default: 1.0e+12
baritlim (integer): iteration limit

Determines the maximum number of iterations for the barrier algorithm. When set to 0, no Barrier iterations occur, but problem setup occurs and information about the setup is displayed (such as Cholesky factorization information). When left at the default value, there is no explicit limit on the number of iterations.

Default: large

barmaxcor (integer): maximum correction limit

Specifies the maximum number of centering corrections that should be done on each iteration. Larger values may improve the numerical performance of the barrier algorithm at the expense of computation time. The default of -1 means the number is automatically determined.

Default: -1

barobjrng (real): maximum objective function

Determines the maximum absolute value of the objective function. The barrier algorithm looks at this limit to detect unbounded problems.

Default: 1.0e+20

barorder (integer): row ordering algorithm selection

Determines the ordering algorithm to be used by the barrier method. By default, Cplex attempts to choose the most effective of the available alternatives. Higher numbers tend to favor better orderings at the expense of longer ordering run times. The automatic option includes additional processing and may yield results that differ from the explicit choice.

Default: 0

barqcpepcomp (real): convergence tolerance for the barrier optimizer for QCPs

Range: [1.0e-12, 1.0e+75]

Default: 1.0e-07

barstartalg (integer): barrier starting point algorithm

This option sets the algorithm to be used to compute the initial starting point for the barrier solver. The default starting point is satisfactory for most problems. Since the default starting point is tuned for primal problems, using the other starting points may be worthwhile in conjunction with the PreDual parameter.

Default: 1
<table>

</tr>
<tr>
<td>4</td>
<td>primal average, estimate dual</td>
</tr>
</tbody>
</table>

**bbinterval** *(integer)*: best bound interval \(\leftarrow\)

Set interval for selecting a best bound node when doing a best estimate search. Active only when **NodeSel** is 2 (best estimate). Decreasing this interval may be useful when best estimate is finding good solutions but making little progress in moving the bound. Increasing this interval may help when the best estimate node selection is not finding any good integer solutions. Setting the interval to 1 is equivalent to setting **NodeSel** to 1.

Default: 7

**bendersfeascuttol** *(real)*: Tolerance for whether a feasibility cut has been violated in Benders decomposition \(\leftarrow\)

Default: 1.0e-06

**bendersoptcuttol** *(real)*: Tolerance for optimality cuts in Benders decomposition \(\leftarrow\)

Default: 1.0e-06

**.benderspartition** *(integer)*: Benders partition \(\leftarrow\)

Default: 0

**benderspartitioninstage** *(boolean)*: Benders partition through stage variable suffix \(\leftarrow\)

Default: 0

**bendersstrategy** *(integer)*: Benders decomposition algorithm as a strategy \(\leftarrow\)

Given a formulation of a problem, CPLEX can decompose the model into a single master and (possibly multiple) subproblems. To do so, CPLEX can make use of annotations that you supply for your model. The strategy can be applied to mixed-integer linear programs (MILP). For certain types of problems, this approach offers significant performance improvements as subproblems can be solved in parallel.

For mixed integer programs (MIP), under certain conditions, CPLEX can apply Benders algorithm to improve the search to find more feasible solutions more quickly.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Off</td>
</tr>
<tr>
<td></td>
<td>Execute conventional branch and bound; ignore any Benders annotations. That is, do not use Benders algorithm even if a Benders partition of the current model is present.</td>
</tr>
</tbody>
</table>
If annotations specifying a Benders partition of the current model are available, CPLEX attempts to decompose the model. CPLEX uses the master as given by the annotations, and attempts to partition the subproblems further, if possible, before applying Benders algorithm to solve the model. If the user supplied annotations, but the annotations supplied do not lead to a complete decomposition into master and disjoint subproblems (that is, if the annotations are wrong in that sense), CPLEX produces an error.

Apply user annotations
CPLEX applies Benders algorithm to a decomposition based on annotations supplied by the user. If no annotations to decompose the model are available, this setting produces an error. If the user supplies annotations, but the supplied annotations do not lead to a complete partition of the original model into disjoint master and subproblems, then this setting produces an error.

Apply user annotations with automatic support for subproblems
CPLEX accepts the master as given and attempts to decompose the remaining elements into disjoint subproblems to assign to workers. It then solves the Benders decomposition of the model. If no annotations to decompose the model are available, this setting produces an error. If the user supplies annotations, but the supplied annotations do not lead to a complete partition of the original model into disjoint master and subproblems, then this setting produces an error.

Apply automatic decomposition
CPLEX ignores any annotation supplied with the model; CPLEX applies presolve; CPLEX then automatically generates a Benders partition, putting integer variables in master and continuous linear variables into disjoint subproblems. CPLEX then solves the Benders decomposition of the model. If the problem is a strictly linear program (LP), that is, there are no integer-constrained variables to put into master, then CPLEX reports an error. If the problem is a mixed integer linear program (MILP) where all variables are integer-constrained, (that is, there are no continuous linear variables to decompose into disjoint subproblems) then CPLEX reports an error.

### bndrng (string): do lower / upper bound ranging

Calculate sensitivity ranges for the specified GAMS lower and upper bounds. Unlike most options, bndrng can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS lower and upper bound named. Specifying all will cause range information to be produced for all lower and upper bounds. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option RngRestart is specified.

### bndstrenind (integer): bound strengthening

Use bound strengthening when solving mixed integer problems. Bound strengthening tightens the bounds on variables, perhaps to the point where the variable can be fixed and thus removed from consideration during the branch and bound algorithm. This reduction is usually beneficial, but occasionally, due to its iterative nature, takes a long time.

Default: -1
bqpcuts (integer): boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

brdir (integer): set branching direction

Used to decide which branch (up or down) should be taken first at each node.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Down branch selected first</td>
</tr>
<tr>
<td>0</td>
<td>Algorithm decides</td>
</tr>
<tr>
<td>1</td>
<td>Up branch selected first</td>
</tr>
</tbody>
</table>

bttol (real): backtracking limit

This option controls how often backtracking is done during the branching process. At each node, Cplex compares the objective function value or estimated integer objective value to these values at parent nodes; the value of the bttol parameter dictates how much relative degradation is tolerated before backtracking. Lower values tend to increase the amount of backtracking, making the search more of a pure best-bound search. Higher values tend to decrease the amount of backtracking, making the search more of a depth-first search. This parameter is used only once a first integer solution is found or when a cutoff has been specified.

Range: $[0.0, 1.0]$  

Default: 1.0

calcqcpduals (integer): calculate the dual values of a quadratically constrained problem

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not calculate dual values</td>
</tr>
<tr>
<td>1</td>
<td>Calculate dual values as long as it does not interfere with presolve reductions</td>
</tr>
<tr>
<td>2</td>

</tr>
<tr>
<td>3</td>
<td>Generate clique cuts very aggressively</td>
</tr>
</tbody>
</table>

**clocktype (integer):** clock type for computation time

Decides how computation times are measured for both reporting performance and terminating optimization when a time limit has been set. Small variations in measured time on identical runs may be expected on any computer system with any setting of this parameter.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>CPU time</td>
</tr>
<tr>
<td>2</td>
<td>Wall clock time</td>
</tr>
</tbody>
</table>

**clonelog (integer):** enable clone logs

The clone logs contain information normally recorded in the ordinary log file but inconvenient to send through the normal log channel in case of parallel execution. The information likely to be of most interest to you are special messages, such as error messages, that result from calls to the LP optimizers called for the subproblems. The clone log files are named cloneK.log, where $K$ is the index of the clone, ranging from 0 (zero) to the number of threads minus one. Since the clones are created at each call to a parallel optimizer and discarded when it exits, the clone logs are opened at each call and closed at each exit. The clone log files are not removed when the clones themselves are discarded.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Clone log files off</td>
</tr>
<tr>
<td>0</td>
<td>Automatic</td>

<tr>
<td>3</td>
<td>Generate cover cuts very aggressively</td>
</tr>
</tbody>
</table>

**cpumask (string):** switch and mask to bind threads to processors (Linux only)

The value of this parameter serves as a switch to turn on (or to turn off) CPLEX binding of multiple threads to multiple processors on platforms where this feature is available. Hexadecimal values of this parameter serve as a mask to specify to CPLEX which processors (or cores) to use in binding multiple threads to multiple processors. CPU binding is also sometimes known as *processor affinity*. CPU binding reduces the variability of CPLEX runs. On some occasions, running the same CPLEX on the same (non trivial) models would produce a big variation in runtime, e.g. 1000 seconds versus 900 seconds on a 12 core machine. These differences happen
while CPLEX still gets exactly the same results and executes the exact same path, thanks to its completely deterministic algorithms. Running the same tests with CPU binding enabled reduced this variability in running time significantly.

If not set to off or auto CPLEX treats the value of this parameter as a string that resembles a hexadecimal number without the usual 0x prefix. A valid string consists of these elements: a) any digit from 0 (zero) through 9 (inclusive), b) any lower case character in the range a through f (inclusive), and c) any upper case character in the range A through F (inclusive). CPLEX rejects a string containing any other digits or characters than those.

When the value of this parameter is a valid string, each bit of this string corresponds to a central processing unit (CPU), that is, to a processor or core. The lowest order bit of the string corresponds to the first logical CPU, and the highest order corresponds to the last logical CPU. For example, 00000001 designates processor #0, 00000003 designates processors #0 and #1, FFFFFFFF designates all processors #0 through #31. CPLEX uses the ith CPU if and only if the ith bit of this string is set to 1 (one). Tip: For GNU/Linux users, this parameter behaves like the taskset command (except that this parameter lacks the prefix 0x).

If this CPU mask parameter is set to a valid string that designates a hexadecimal number, but global Threads count is set to 0 (zero), then CPLEX still starts as many threads as the number of cores on the machine, but only the cores enabled in the mask will be used.

For example, if a user sets this CPU mask parameter to the hexadecimal value ”f” on a 16-core machine, and the user sets the global Threads count to 0 (zero), the result is 16 threads. These 16 threads will be bound to the first four cores in a round-robin way: threads 1,5,9,13 to core 1, threads 2,6,10,14 to core 2 and so on. This situation is probably not what the user intended. Therefore, if you set this CPU mask parameter, then you should also set global threads count; indeed, you should set the threads parameter to the number of active cores designated by the mask.

For example, on a 16 core machine, consider the difference between the value ”off” and the value ffff. If the value of this parameter is ”off” CPLEX does no binding. If the value of this parameter is ffff, CPLEX binds threads to cores.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>CPLEX decides whether to bind threads to cores (or processors)</td>
</tr>
<tr>
<td>off</td>
<td>CPLEX performs no binding</td>
</tr>
<tr>
<td>hex</td>
<td>CPLEX binds the threads in round-robin fashion to the cores specified by the mask</td>
</tr>
</tbody>
</table>

**craind (integer):** crash strategy (used to obtain starting basis) ←

The crash option biases the way Cplex orders variables relative to the objective function when selecting an initial basis.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Primal: alternate ways of using objective coefficients. Dual: aggressive starting basis</td>
</tr>
<tr>
<td>0</td>
<td>Primal: ignore objective coefficients during crash. Dual: aggressive starting basis</td>
</tr>
<tr>
<td>1</td>
<td>Primal: alternate ways of using objective coefficients. Dual: default starting basis</td>
</tr>
</tbody>
</table>
**cutlo (real):** lower cutoff for tree search

Sets the lower cutoff tolerance. When the problem is a maximization problem, CPLEX cuts off or discards solutions that are less than the specified cutoff value. If the model has no solution with an objective value greater than or equal to the cutoff value, then CPLEX declares the model infeasible. In other words, setting the lower cutoff value c for a maximization problem is similar to adding this constraint to the objective function of the model: \( \text{obj} \geq c \).

This option overrides the GAMS Cutoff setting.

This parameter is not effective with FeasOpt. FeasOpt cannot analyze an infeasibility introduced by this parameter. If you want to analyze such a condition, add an explicit objective constraint to your model instead.

Default: \(-1.0 \times 10^{+75}\)

**cutpass (integer):** maximum number of cutting plane passes

Sets the upper limit on the number of passes that will be performed when generating cutting planes on a mixed integer model.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>None</td>
</tr>
<tr>
<td>0</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Maximum passes to perform</td>
</tr>
</tbody>
</table>

**cuts (string):** default cut generation

Allows generation setting of all optional cuts at once. This is done by changing the meaning of the default value (0: automatic) for the various Cplex cut generation options. The options affected are Cliques, Covers, DisjCuts, FlowCovers, FlowPaths, FracCuts, GUBCovers, ImplBd, LiftProjCuts, MCFcuts, MIRCuts, and Symmetry.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Do not generate cuts</td>
</tr>
<tr>
<td>0</td>
<td>Determined automatically</td>
</tr>
<tr>

<td>Generate cuts moderately</td>
</tr>
<tr>
<td>2</td>
<td>Generate cuts aggressively</td>
</tr>
<tr>
<td>3</td>
<td>Generate cuts very aggressively</td>
</tr>
<tr>
<td>4</td>
<td>Generate cuts highly aggressively</td>
</tr>
<tr>
<td>5</td>
<td>Generate cuts extremely aggressively</td>
</tr>
</tbody>
</table>

**cutsfactor (real):** cut limit

This option limits the number of cuts that can be added. For values between zero and one inclusive (that is, in the range \([0.0, 1.0]\), CPLEX generates no cuts.

For values strictly greater than 1.0 (one), CPLEX limits the number of rows in the model with cuts added.
The limit on this total is the product of *CutsFactor* times the original number of rows. If CPLEX has presolved the model, the *original number of rows* is the number of rows in the presolved model. (This behavior with respect to a presolved model is unchanged.)

CPLEX regards negative values of this parameter as equivalent to the default value -1.0. That is, a negative value specifies no particular limit on the number of cuts. CPLEX computes and dynamically adjusts such a limit automatically.

Default: -1.0

**cutup** *(real): upper cutoff for tree search ←*

Sets the upper cutoff tolerance. When the problem is a minimization problem, CPLEX cuts off or discards any solutions that are greater than the specified upper cutoff value. If the model has no solution with an objective value less than or equal to the cutoff value, CPLEX declares the model infeasible. In other words, setting an upper cutoff value \( c \) for a minimization problem is similar to adding this constraint to the objective function of the model: \( \text{obj} < c \).

This option overrides the GAMS Cutoff setting.

This parameter is not effective with FeasOpt. FeasOpt cannot analyze an infeasibility introduced by this parameter. If you want to analyze such a condition, add an explicit objective constraint to your model instead.

Default: \( 1.0e+75 \)

**datacheck** *(integer): controls data consistency checking and modeling assistance ←*

When the value of this parameter is set to level 2, CPLEX turns on both data consistency checking and modeling assistance. At this level, CPLEX issues warnings at the start of the optimization about disproportionate values (too large, too small) in coefficients, bounds, and right-hand sides (RHS).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Data checking off</td>
</tr>
<tr>
<td>1</td>
<td>Data checking on</td>
</tr>
<tr>

</tr>
<tr>
<td>2</td>
<td>Turn on only at the end of preprocessing</td>
</tr>
<tr>
<td>3</td>
<td>Turn on at the beginning and at the end of preprocessing</td>
</tr>
</tbody>
</table>

**dettilim** *(real): deterministic time limit ←*

Sets a time limit expressed in ticks, a unit to measure work done deterministically.

The length of a deterministic tick may vary by platform. Nevertheless, ticks are normally consistent measures for a given platform (combination of hardware and software) carrying the same load. In other words, the correspondence of ticks to clock time depends on the hardware, software, and the current load of the machine. For the same platform and same load, the ratio of ticks per second stays roughly constant, independent of the model solved. However, for very short optimization runs, the variation of this ratio is typically high.

Default: $1.0e+75$

disjcuts (integer): disjunctive cuts generation ←

Determines whether or not to generate disjunctive cuts during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Do not generate disjunctive cuts</td>
</tr>
<tr>
<td>0</td>
<td>Determined automatically</td>
</tr>
<tr>

<td>Probing dive</td>
</tr>
<tr>
<td>3</td>
<td>Guided dive</td>
</tr>
</tbody>
</table>

.divflt (real): solution pool range filter coefficients ←

A diversity filter for a solution pool (see option SolnPool) allows you generate solutions that are similar to (or different from) a set of reference values that you specify for a set of binary variables. In particular, you can use a diversity filter to generate more solutions that are similar to an existing solution or to an existing partial solution.

A diversity filter drives the search for multiple solutions toward new solutions that satisfy a measure of diversity specified in the filter. This diversity measure applies only to binary variables. Potential new solutions are compared to a reference set. This reference set is specified with this dot option. If no reference set is specified, the difference measure will be computed relative to the other solutions in the pool. The diversity measure is computed by summing the pair-wise absolute differences from solution and the reference values.

Default: 0
**divfltlo** *(real)*: lower bound on diversity $\leftarrow$

Please check option DivFlt for general information on a diversity filter.

If you specify a lower bound on the diversity using DivFltLo, Cplex will look for solutions that are different from the reference values. In other words, you can say, Give me solutions that differ by at least this amount in this set of variables.

Default: *mindouble*

**divfltu** *(real)*: upper bound on diversity $\leftarrow$

Please check option DivFlt for general information on a diversity filter.

If you specify an upper bound on diversity DivFltUp, Cplex will look for solutions similar to the reference values. In other words, you can say, Give me solutions that are close to this one, within this set of variables.

Default: *maxdouble*

**dpriind** *(integer)*: dual simplex pricing $\leftarrow$

Pricing strategy for dual simplex method. Consider using dual steepest-edge pricing. Dual steepest-edge is particularly efficient and does not carry as much computational burden as the primal steepest-edge pricing.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>4</td>
<td>Steepest-edge pricing, unit initial norms</td>
</tr>
<tr>
<td>5</td>
<td>Devex pricing</td>
</tr>
</tbody>
</table>

**dynamicrows** *(integer)*: switch for dynamic management of rows $\leftarrow$

This parameter specifies how CPLEX should manage rows in the current model during dual simplex optimization. More specifically, this parameter controls the use of the kernel simplex method (KSM) for the dual simplex algorithm. That is, CPLEX dynamically adjusts the dimensions of the basis matrix during execution of the dual simplex algorithm, according to the settings of this parameter.

When the value of this parameter is -1, its default value, this parameter specifies that the user wants CPLEX to manage rows dynamically, adjusting the dimensions of the basis matrix during dual simplex optimization. When it is set to 0, this parameter specifies that CPLEX must keep all rows. When it is set to 1, this parameter specifies that CPLEX can keep or discard rows according to its internal calculations.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic</td>
</tr>
<tr>
<td>0</td>
<td>Keep all rows</td>
</tr>
<tr>
<td>1</td>
<td>Manage rows</td>
</tr>
</tbody>
</table>
**eachcutlim** *(integer)*: sets a limit for each type of cut

This parameter allows you to set a uniform limit on the number of cuts of each type that Cplex generates. By default, the limit is a large integer; that is, there is no effective limit by default.

Tighter limits on the number of cuts of each type may benefit certain models. For example, a limit on each type of cut will prevent any one type of cut from being created in such large number that the limit on the total number of all types of cuts is reached before other types of cuts have an opportunity to be created. A setting of 0 means no cuts.

This parameter does not influence the number of Gomory cuts. For means to control the number of Gomory cuts, see also the fractional cut parameters: FracCand, FracCuts, and FracPass.

Default: 2100000000

**epagap** *(real)*: absolute stopping tolerance

Synonym: optca

Absolute tolerance on the gap between the best integer objective and the objective of the best node remaining. When the value falls below the value of the epagap setting, the optimization is stopped. This option overrides GAMS OptCA which provides its initial value.

Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

Default: GAMS OptCA

**epgap** *(real)*: relative stopping tolerance

Synonym: optcr

Relative tolerance on the gap between the best integer objective and the objective of the best node remaining. When the value falls below the value of the epgap setting, the mixed integer optimization is stopped. Note the difference in the Cplex definition of the relative tolerance with the GAMS definition. This option overrides GAMS OptCR which provides its initial value.

Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

Range: [0.0, 1.0]

Default: GAMS OptCR

**epint** *(real)*: integrality tolerance

Integrality Tolerance. This specifies the amount by which an integer variable can be different than an integer and still be considered feasible.

Range: [0.0, 0.5]

Default: 1.0e-05

**eplin** *(real)*: degree of tolerance used in linearization

Default: 0.001
epmrk (real): Markowitz pivot tolerance

The Markowitz tolerance influences pivot selection during basis factorization. Increasing the Markowitz threshold may improve the numerical properties of the solution.

Range: \([1.0e-04, 1.0]\]
Default: 0.01

eopt (real): optimality tolerance

The optimality tolerance influences the reduced-cost tolerance for optimality. This option setting governs how closely Cplex must approach the theoretically optimal solution.

Range: \([1.0e-09, 0.1]\]
Default: 1.0e-06

epper (real): perturbation constant

Perturbation setting. Highly degenerate problems tend to stall optimization progress. Cplex automatically perturbs the variable bounds when this occurs. Perturbation expands the bounds on every variable by a small amount thereby creating a different but closely related problem. Generally, the solution to the less constrained problem is easier to solve. Once the solution to the perturbed problem has advanced as far as it can go, Cplex removes the perturbation by resetting the bounds to their original values.

If the problem is perturbed more than once, the perturbation constant is probably too large. Reduce the epper option to a level where only one perturbation is required. Any value greater than or equal to 1.0e-8 is valid.

Default: 1.0e-06

eprhs (real): feasibility tolerance

Feasibility tolerance. This specifies the degree to which a problem’s basic variables may violate their bounds. This tolerance influences the selection of an optimal basis and can be reset to a higher value when a problem is having difficulty maintaining feasibility during optimization. You may also wish to lower this tolerance after finding an optimal solution if there is any doubt that the solution is truly optimal. If the feasibility tolerance is set too low, Cplex may falsely conclude that a problem is infeasible.

Range: \([1.0e-09, 0.1]\]
Default: 1.0e-06

exactkappa (boolean): report exact condition number in quality report

Default: 0

feasopt (boolean): computes a minimum-cost relaxation to make an infeasible model feasible

With Feasopt turned on, a minimum-cost relaxation of the right hand side values of constraints or bounds on variables is computed in order to make an infeasible model feasible. It marks the relaxed right hand side values and bounds in the solution listing.

Several options are available for the metric used to determine what constitutes a minimum-cost relaxation which can be set by option FeasOptMode.

Feasible relaxations are available for all problem types with the exception of quadratically constraint problems.

Default: 0
The parameter `FeasOptMode` allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter `FeasOptMode` indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the minimality of the relaxation (as a sum of required relaxations; as the number of constraints and bounds required to be relaxed; as a sum of the squares of required relaxations).

Default: 0

`feaspref (real)`: feasibility preference

You can express the costs associated with relaxing a bound or right hand side value during a `FeasOpt` run through the `.feaspref` option. The input value denotes the user’s willingness to relax a constraint or bound. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed.

Default: 1

`fixoptfile (string)`: name of option file which is read just before solving the fixed problem

`flowcovers (integer)`: flow cover cut generation

Determines whether or not flow cover cuts should be generated during optimization.

Default: 0
flowpaths (integer): flow path cut generation

Determines whether or not flow path cuts should be generated during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

freegamsmodel (boolean): preserves memory by dumping the GAMS model instance representation temporarily to disk

In order to provide the maximum amount of memory to the solver this option dumps the internal representation of the model instance temporarily to disk and frees memory. This option only works with SolveLink=0 and only for models without quadratic constraints.

Default: 0

gubcovers (integer): GUB cover cut generation

Determines whether or not GUB (Generalized Upper Bound) cover cuts should be generated during optimization. The default of 0 indicates that the attempt to generate GUB cuts should continue only if it seems to be helping.

Default: 0

<table>
<thead>
<tr>
<th>value</th>

</tbody>
</table>

heurfreq (integer): heuristic frequency

This option specifies how often to apply the node heuristic. Setting to a positive number applies the heuristic at the requested node interval. A value of 100, for example, means that heuristics are invoked every hundredth node in the tree.
Default: 0
<table>
<thead>
<tr>
<th>value</th>

</tr>
</tbody>
</table>

**heuristic** *(real)*: the effort that CPLEX spends on heuristics during a MIP solve

The value is used to increase (if >1) or decrease (if <1) the effort that CPLEX spends on heuristics during a MIP solve. If set to 0, no heuristic will run.

Default: 1.0

**iafile** *(string)*: secondary option file to be read in interactive mode triggered by iatriggerfile

If in interactive mode and this option is set, options will be read from the file specified by this option instead of direct user input (as described in interactive). This option file read can be triggered by interrupting Cplex with a Control-C or using the option iatriggerfile. If defined, GAMS/CPLEX looks for this file (content irrelevant) all iatriggerfile seconds and if found, reads the option file iafile. The iatriggerfile is removed afterwards so it does not trigger twice.

**iatriggerfile** *(string)*: file that triggers the reading of a secondary option file in interactive mode

See iafile.

**iatriggerfile** *(real)*: time interval in seconds the link looks for the trigger file in interactive mode

See iafile.

Default: 60

**iis** *(integer)*: run the conflict refiner also known as IIS finder if the problem is infeasible

Find an set of conflicting constraints or IIS (Irreducibly Inconsistent Set) and write an conflict report to the GAMS solution listing if the model is found to be infeasible.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>

</tr>
</tbody>
</table>
indicoptstrict (boolean): abort in case of an error in indicator constraint in solver option file

If enabled and a variable or equation specified in an indicator constraint is not present in the model, model generation will abort with an error message. Otherwise, if this option is disabled, erroneous indicator constraints are ignored and a warning is printed.

Default: 1

interactive (boolean): allow interactive option setting after a Control-C

When set to yes, options can be set interactively after interrupting Cplex with a Control-C. Options are entered just as if they were being entered in the cplex.opt file. Control is returned to Cplex by entering continue. The optimization can be aborted by entering abort. This option can only be used when running from the command line. Moreover, the GAMS option InteractiveSolver needs to be set to 1.

Default: 0

intsollim (integer): maximum number of integer solutions

This option limits the MIP optimization to finding only this number of mixed integer solutions before stopping.

Default: large

itlim (integer): iteration limit

Synonym: iterlim

The iteration limit option sets the maximum number of iterations before the algorithm terminates, without reaching optimality. This Cplex option overrides the GAMS IterLim option. Any non-negative integer value is valid.

Default: GAMS IterLim

.lazy (boolean): Lazy constraints activation

Determines whether a linear constraint is treated as a lazy constraint. At the beginning of the MIP solution process, any constraint whose Lazy attribute is set to 1 (the default value is 0) is removed from the model and placed in the lazy constraint pool. Lazy constraints remain inactive until a feasible solution is found, at which point the solution is checked against the lazy constraint pool. If the solution violates any lazy constraint, the solution is discarded and one or more of the violated lazy constraints are pulled into the active model.

Lazy constraints are only active if option LazyConstraints is enabled and are specified through the option .lazy. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: 0

lazyconstraints (boolean): Indicator to use lazy constraints

Default: 0

lbheur (boolean): local branching heuristic

This parameter lets you control whether Cplex applies a local branching heuristic to try to improve new incumbents found during a MIP search. By default, this parameter is off. If you turn it on, Cplex will invoke a local branching heuristic only when it finds a new incumbent. If Cplex finds multiple incumbents at a single node, the local branching heuristic will be applied only to the last one found.

Default: 0
**liftprojcuts** (*integer*): lift-and-project cuts

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>

<tr>
<td>3</td>
<td>Generate locally valid implied bound cuts very aggressively</td>
</tr>
</tbody>
</table>

**lowerobjstop** (*real*): in a minimization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value lower than or equal to the specified value

Default: $-1e75$

**lpmethod** (*integer*): algorithm to be used for LP problems

Specifies which LP algorithm to use. If left at the default value (0 for automatic), and a primal-feasible basis is available, primal simplex will be used. If no primal-feasible basis is available, and Threads is equal to 1, dual simplex will be used. If Threads is greater than 1 and no primal-feasible basis is available, the concurrent option will be used.

Sifting may be useful for problems with many more variables than equations.

The concurrent option runs multiple methods in parallel. The first thread uses dual simplex. The second thread uses barrier. The next thread uses primal simplex. Remaining threads are used by the barrier run. If the aspect ratio (number of columns versus number of rows) is large, and if more than 10 threads are available, then concurrent optimization also invokes sifting on the LP. The solution is returned by first method to finish.

Default: 0

<table>

</tbody>
</table>

**ltol (real):** basis identification primal tolerance

Default: 0

**mcfcuts (integer):** multi-commodity flow cut generation

 Specifies whether Cplex should generate multi-commodity flow (MCF) cuts in a problem where Cplex detects the characteristics of a multi-commodity flow network with arc capacities. By default, Cplex decides whether or not to generate such cuts. To turn off generation of such cuts, set this parameter to -1. Cplex is able to recognize the structure of a network as represented in many real-world models. When it recognizes such a network structure, Cplex is able to generate cutting planes that usually help solve such problems. In this case, the cuts that Cplex generates state that the capacities installed on arcs pointing into a component of the network must be at least as large as the total flow demand of the component that cannot be satisfied by flow sources within the component.

Default: 0

<table>
<thead>

<td>Generate MCF cuts aggressively</td>
</tr>
</tbody>
</table>

**memoryemphasis (boolean):** reduces use of memory

This parameter lets you indicate to Cplex that it should conserve memory where possible. When you set this parameter to its non default value, Cplex will choose tactics, such as data compression or disk storage, for some of the data computed by the barrier and MIP optimizers. Of course, conserving memory may impact performance in some models. Also, while solution information will be available after optimization, certain computations that require a basis that has been factored (for example, for the computation of the condition number Kappa) may be unavailable.

Default: 0

<table>

</tr>
<tr>
<td>5</td>
<td>Same as 3 but adds LP display for all nodes</td>
</tr>
</tbody>
</table>

### mipinterval (integer): progress display interval

Controls the frequency of node logging when the parameter MIPDisplay is set higher than 1 (one). Frequency must be an integer; it may be 0 (zero), positive, or negative. By default, CPLEX displays new information in the node log during a MIP solve at relatively high frequency during the early stages of solving a MIP model, and adds lines to the log at progressively longer intervals as solving continues. In other words, CPLEX logs information frequently in the beginning and progressively less often as it works. When the value is a positive integer n, CPLEX displays new incumbents, plus it displays a new line in the log every n nodes. When the value is a negative integer n, CPLEX displays new incumbents, and the negative value determines how much processing CPLEX does before it displays a new line in the node log. A negative value close to zero means that CPLEX displays new lines in the log frequently. A negative value far from zero means that CPLEX displays new lines in the log less frequently. In other words, a negative value of this parameter contracts or dilates the interval at which CPLEX displays information in the node log.

Default: 0

### mipkappastats (integer): MIP kappa computation

MIP kappa summarizes the distribution of the condition number of the optimal bases CPLEX encountered during the solution of a MIP model. That summary may let you know more about the numerical difficulties of your MIP model. Because MIP kappa (as a statistical distribution) requires CPLEX to compute the condition number of the optimal bases of the subproblems during branch-and-cut search, you can compute the MIP kappa only when CPLEX solves the subproblem with its simplex optimizer. In other words, in order to obtain results with this parameter, you can not use the sifting optimizer nor the barrier without crossover to solve the subproblems. See the parameters StartAlg and SubAlg.

Computing the kappa of a subproblem has a cost. In fact, computing MIP kappa for the basis matrices can be computationally expensive and thus generally slows down the solution of a
problem. Therefore, the setting 0 (automatic) tells CPLEX generally not to compute MIP kappa, but in cases where the parameter NumericalEmphasis is turned on, CPLEX computes MIP kappa for a sample of subproblems. The value 1 (sample) leads to a negligible performance degradation on average, but can slow down the branch-and-cut exploration by as much as 10% on certain models. The value 2 (full) leads to a 2% performance degradation on average, but can significantly slow the branch-and-cut exploration on certain models. In practice, the value 1 (sample) is a good trade-off between performance and accuracy of statistics. If you need very accurate statistics, then use value 2 (full).

In case CPLEX is instructed to compute a MIP kappa distribution, the parameter Quality is automatically turned on.

Default: 0

<td>2</td>
<td>Compute MIP kappa for all subproblems</td>
</tr>
</tbody>
</table>

mipordind (boolean): priority list on/off

Synonym: prioropt

Use priorities. Priorities should be assigned based on your knowledge of the problem. Variables with higher priorities will be branched upon before variables of lower priorities. This direction of the tree search can often dramatically reduce the number of nodes searched. For example, consider a problem with a binary variable representing a yes/no decision to build a factory, and other binary variables representing equipment selections within that factory. You would naturally want to explore whether or not the factory should be built before considering what specific equipment to purchased within the factory. By assigning a higher priority to the build/no build decision variable, you can force this logic into the tree search and eliminate wasted computation time exploring uninteresting portions of the tree. When set at 0 (default), the MPOrdInd option instructs Cplex not to use priorities for branching. When set to 1, priority orders are utilized.

Note: Priorities are assigned to discrete variables using the .prior suffix in the GAMS model. Lower .prior values mean higher priority. The .prioropt model suffix has to be used to signal GAMS to export the priorities to the solver.

Default: GAMS PriorOpt

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

</tr>
<tr>
<td>1</td>
<td>Priority orders are utilized</td>
</tr>
</tbody>
</table>

mipordtype (integer): priority order generation

This option is used to select the type of generic priority order to generate when no priority order is present.

Default: 0
mipsearch (integer): search strategy for mixed integer programs

Sets the search strategy for a mixed integer program. By default, Cplex chooses whether to apply dynamic search or conventional branch and cut based on characteristics of the model.

Default: 0

<table>
<thead>
<tr>
<th>value</th>

<td>increasing bound range</td>
</tr>
<tr>
<td>3</td>
<td>increasing cost per coefficient count</td>
</tr>
</tbody>
</table>

mipstart (integer): use mip starting values

This option controls the use of advanced starting values for mixed integer programs. A setting of 2 indicates that the values should be checked to see if they provide an integer feasible solution before starting optimization. For mipstart equals 1, 2, 3 or 4 fractional values are rounded to the nearest integer value if the integrality violation is larger than CPLEX’s integer tolerance and smaller or equal to tryint. A partial MIP start is applied for mipstart equals 1, 3 or 4. Here, for discrete variables only integer values (after possible rounding) are added to the advanced starting values.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>do not use the values</td>
</tr>
<tr>
<td>1</td>

<td>6</td>
<td>set discrete variable values and use no checks at all. Warning: CPLEX may accept infeasible points as solutions!</td>
</tr>
</tbody>
</table>

mipstopexpr (string): stopping expression for branch and bound

If the provided logical expression is true, the branch-and-bound is aborted. Supported values are: etalg, resusd, nodusd, objest, objval. Supported operators are: +, -, *, /, ^, %, !=, ==, <, <=, >, >=, !, &&, ||, ( ), abs, ceil, exp, floor, log, log10, pow, sqrt. Example: nodusd >= 1000 && abs(objest - objval) / abs(objval) < 0.1

miptrace (string): filename of MIP trace file

For a description of this feature, see chapter Solve trace.

Note: In contrast to other solvers, GAMS/CPLEX doesn’t append the MIP trace file after a certain time or node count, but when CPLEX reports global progress. In order to indicate this, the MIP trace file will show X instead of N or T.
**miqcpstrat (integer):** MIQCP relaxation choice

This option controls how MIQCPs are solved. For some models, the setting 2 may be more effective than 1. You may need to experiment with this parameter to determine the best setting for your model.

Default: 0

<table>

</tr>
<tr>
<td></td>
<td>Cplex will solve a LP relaxation of the model at each node.</td>
</tr>
</tbody>
</table>

**mircuts (integer):** mixed integer rounding cut generation

Determines whether or not to generate mixed integer rounding (MIR) cuts during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Do not generate MIR cuts</td>
</tr>
<tr>
<td>0</td>
<td>Determined automatically</td>

<td>Generate MIR cuts moderately</td>
</tr>
<tr>
<td>2</td>
<td>Generate MIR cuts aggressively</td>
</tr>
</tbody>
</table>

**mpslongnum (boolean):** MPS file format precision of numeric output

Determines the precision of numeric output in the MPS file formats. When this parameter is set to its default value 1 (one), numbers are written to MPS files in full-precision; that is, up to 15 significant digits may be written. The setting 0 (zero) writes files that correspond to the standard MPS format, where at most 12 characters can be used to represent a value. This limit may result in loss of precision.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use limited MPS precision</td>
</tr>
<tr>
<td>1</td>
<td>Use full-precision</td>
</tr>
</tbody>
</table>

**mtol (real):** basis identification dual tolerance

Default: 0

**multimipstart (string):** use multiple mipstarts provided via gdx files

Specifies (multiple) GDX files with values for the variables. Each file is treated as one initial guess for the MIP start. These MIP starts are added in addition to the initial guess provided by the level attribute. A MIP start GDX file can be created, for example, by using the command line option `savepoint`.
**multobj** *(boolean)*: controls the hierarchical optimization of multiple objectives

Default: 0

**multobjdisplay** *(integer)*: level of display during multiobjective optimization

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No display</td>
</tr>
<tr>
<td>1</td>
<td>Summary display after each subproblem</td>
</tr>
<tr>
<td>2</td>
<td>Summary display after each subproblem, as well as subproblem logs</td>
</tr>
</tbody>
</table>

**multobjmethod** *(integer)*: method used for multi-objective solves

When solving a continuous multi-objective model using a hierarchical approach, the model is solved once for each objective. The algorithm used to solve for the highest priority objective is controlled by the LPMethod parameter. This parameter determines the algorithm used to solve for subsequent objectives.

Default: 0

**multobjoptfiles** *(string)*: List of option files used for individual solves within multi-objective optimization

The options given by the option files in multobjoptfiles are applied on top of the default GAMS/CPLEX options. This includes options set by the user via the standard option file.

If the list of option files in multobjoptfiles is less than the number of objective functions, the default GAMS/CPLEX options (incl. user options as before) are used to solve the remaining instances. Additional option files (i.e. more than objective functions) are ignored.

Applied options can be verified by setting multobjdisplay to 2.

**multobjtolmip** *(boolean)*: enables hard constraints for hierarchical optimization objectives based on degradation tolerances

CPLEX supports two different strategies to handle the degradation tolerances objnabstol and objnreltol depending on the problem type (continuous or discrete), see objnabstol. This setting enables the discrete strategy for continuous models. Note that objnreltol has no effect for discrete models. Enabling this option can lead to higher solution times.

Default: 1

**names** *(boolean)*: load GAMS names into Cplex

This option causes GAMS names for the variables and equations to be loaded into Cplex. These names will then be used for error messages, log entries, and so forth. Setting names to no may help if memory is very tight.

Default: 1

**netdisplay** *(integer)*: network display level

This option controls the log for network iterations.

Default: 2
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No network log.</td>
</tr>
<tr>
<td>1</td>
<td>Displays true objective values</td>
</tr>
<tr>
<td>2</td>
<td>Displays penalized objective values</td>
</tr>
</tbody>
</table>

**netepopt (real):** optimality tolerance for the network simplex method

This optimality tolerance influences the reduced-cost tolerance for optimality when using the network simplex method. This option setting governs how closely Cplex must approach the theoretically optimal solution.

Range: \([1.0e^{-11}, 0.1]\)

Default: \(1.0e^{-06}\)

**neteprhs (real):** feasibility tolerance for the network simplex method

This feasibility tolerance determines the degree to which the network simplex algorithm will allow a flow value to violate its bounds.

Range: \([1.0e^{-11}, 0.1]\)

Default: \(1.0e^{-06}\)

**netfind (integer):** attempt network extraction

Specifies the level of network extraction to be done.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Extract pure network only</td>
</tr>
<tr>
<td>2</td>
<td>Try reflection scaling</td>
</tr>
<tr>
<td>3</td>
<td>Try general scaling</td>
</tr>
</tbody>
</table>

**netitlim (integer):** iteration limit for network simplex

Iteration limit for the network simplex method.

Default: \(\text{large}\)

**netppriind (integer):** network simplex pricing

Network simplex pricing algorithm. The default of 0 (currently equivalent to 3) shows best performance for most problems.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>

</tr>
<tr>
<td>3</td>
<td>Multiple partial pricing with sorting</td>
</tr>
</tbody>
</table>
**nodecuts (integer):** decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree

Default: 0

**nodefileind (integer):** node storage file indicator

Specifies how node files are handled during MIP processing. Used when parameter WorkMem has been exceeded by the size of the branch and cut tree. If set to 0 when the tree memory limit is reached, optimization is terminated. Otherwise a group of nodes is removed from the in-memory set as needed. By default, Cplex transfers nodes to node files when the in-memory set is larger than 128 MBytes, and it keeps the resulting node files in compressed form in memory. At settings 2 and 3, the node files are transferred to disk. They are stored under a directory specified by parameter WorkDir and Cplex actively manages which nodes remain in memory for processing.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No node files</td>
</tr>
<tr>
<td>1</td>
<td>Node files in memory and compressed</td>
</tr>
<tr>
<td>2</td>
<td>Node files on disk</td>
</tr>
<tr>
<td>3</td>
<td>Node files on disk and compressed</td>
</tr>
</tbody>
</table>

**nodelim (integer):** maximum number of nodes to solve

Synonym: nodlim

The maximum number of nodes solved before the algorithm terminates, without reaching optimality. This option overrides the GAMS NodLim model suffix. When this parameter is set to 0 (this is only possible through an option file), Cplex completes processing at the root; that is, it creates cuts and applies heuristics at the root. When this parameter is set to 1 (one), it allows branching from the root; that is, nodes are created but not solved.

Default: GAMS NodLim

**nodesel (integer):** node selection strategy

This option is used to set the rule for selecting the next node to process when backtracking.

Default: 1

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**numericalemphasis (boolean):** emphasizes precision in numerically unstable or difficult problems
5.11 CPLEX

This parameter lets you indicate to Cplex that it should emphasize precision in numerically difficult or unstable problems, with consequent performance trade-offs in time and memory.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Exercise extreme caution in computation</td>
</tr>
</tbody>
</table>

**objdif (real)**: overrides GAMS Cheat parameter

Synonym: cheat

A means for automatically updating the cutoff to more restrictive values. Normally the most recently found integer feasible solution objective value is used as the cutoff for subsequent nodes. When this option is set to a positive value, the value will be subtracted from (added to) the newly found integer objective value when minimizing (maximizing). This forces the MIP optimization to ignore integer solutions that are not at least this amount better than the one found so far. The option can be adjusted to improve problem solving efficiency by limiting the number of nodes; however, setting this option at a value other than zero (the default) can cause some integer solutions, including the true integer optimum, to be missed. Negative values for this option will result in some integer solutions that are worse than or the same as those previously generated, but will not necessarily result in the generation of all possible integer solutions. This option overrides the GAMS Cheat parameter.

Default: 0.0

**objllim (real)**: objective function lower limit

Setting a lower objective function limit will cause Cplex to halt the optimization process once the minimum objective function value limit has been exceeded.

Default: \(-1.0e+75\)

**objnabstol (string)**: allowable absolute degradation for objective

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is \(\text{ObjNAbsTol}\ ObjVarName\ value\).

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. For MIPs (or if MultObjTolMip is enabled), if it achieves objective value \(z\) when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most \(\text{ObjNAbsTol}\). For LPs, \(\text{ObjNAbsTol}\) defines a threshold for reduced costs above which nonbasic variables in the associated LP solve will be fixed at the bound at which they reside.

**objnrealtol (string)**: allowable relative degradation for objective

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is \(\text{ObjNRelTol}\ ObjVarName\ value\).

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. For MIPs (or if MultObjTolMip is enabled), if it achieves objective value \(z\) when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most \(\text{ObjNRelTol} \times |z|\). This option has no effect for continuous models.
objrng (string): do objective ranging

Calculate sensitivity ranges for the specified GAMS variables. Unlike most options, ObjRng can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS variable named. Specifying all will cause range information to be produced for all variables. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option RngRestart is specified.

Default: no objective ranging is done

objulim (real): objective function upper limit

Setting an upper objective function limit will cause Cplex to halt the optimization process once the maximum objective function value limit has been exceeded.

Default: 1.0e+75

optimalitytarget (integer): type of optimality that Cplex targets

This parameter specifies the type of solution that CPLEX attempts to compute with respect to the optimality of that solution when CPLEX solves a continuous (QP) or mixed integer (MIQP) quadratic model. In other words, the variables of the model can be continuous or mixed integer and continuous; the objective function includes a quadratic term, and perhaps the objective function is not positive semi-definite (non PSD). This parameter does not apply to quadratically constrained mixed integer problems (MIQCP); that is, this parameter does not apply to mixed integer problems that include a quadratic term among the constraints.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic CPLEX first attempts to compute a provably optimal solution. If CPLEX cannot compute a provably optimal solution because the objective function is not convex, CPLEX will return with an error (Q is not PSD).</td>
</tr>
<tr>
<td>1</td>
<td>Search for a globally optimal solution to a convex model CPLEX searches for a globally optimal solution to a convex model. In problems of type QP or MIQP, this setting interacts with linearization switch QToLin for QP, MIQP</td>
</tr>
<tr>
<td>2</td>
<td>Search for a solution that satisfies first-order optimality conditions no optimality guarantee CPLEX first attempt to compute a provably optimal solution. If CPLEX cannot compute a provably optimal solution because the objective function is not convex, CPLEX searches for a solution that satisfies first-order optimality conditions but is not necessarily globally optimal.</td>
</tr>
<tr>
<td>3</td>
<td>Search for a globally optimal solution regardless of convexity If the problem type is QP, CPLEX first changes the problem type to MIQP. CPLEX then solves the problem (whether originally QP or MIQP) to global optimality. In problems of type QP or MIQP, this setting interacts with with linearization switch QToLin for QP, MIQP. With this setting information about dual values is not available for the solution.</td>
</tr>
</tbody>
</table>

parallelmode (integer): parallel optimization mode

Sets the parallel optimization mode. Possible modes are automatic, deterministic, and opportunistic.
In this context, deterministic means that multiple runs with the same model at the same parameter settings on the same platform will reproduce the same solution path and results. In contrast, opportunistic implies that even slight differences in timing among threads or in the order in which tasks are executed in different threads may produce a different solution path and consequently different timings or different solution vectors during optimization executed in parallel threads. When running with multiple threads, the opportunistic setting entails less synchronization between threads and consequently may provide better performance.

In deterministic mode, Cplex applies as much parallelism as possible while still achieving deterministic results. That is, when you run the same model twice on the same platform with the same parameter settings, you will see the same solution and optimization run.

More opportunities to exploit parallelism are available if you do not require determinism. In other words, Cplex can find more opportunities for parallelism if you do not require an invariant, repeatable solution path and precisely the same solution vector. To use all available parallelism, you need to select the opportunistic parallel mode. In this mode, Cplex will utilize all opportunities for parallelism in order to achieve best performance.

However, in opportunistic mode, the actual optimization may differ from run to run, including the solution time itself and the path traveled in the search.

Parallel MIP optimization can be opportunistic or deterministic.

Parallel barrier optimization is only deterministic.

A GAMS/Cplex run will use deterministic mode unless explicitly specified.

If `ParallelMode` is explicitly set to 0 (automatic) the settings of this parallel mode parameter interact with settings of the `Threads` parameter. Let the result number of threads available to Cplex be \( n \) (note that negative values for the threads parameter are possible to exclude work on some cores).

Here is a list of possible value:

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Enable opportunistic parallel search mode</td>
</tr>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>Enable deterministic parallel search mode</td>
</tr>
</tbody>
</table>

`perind` (boolean): force initial perturbation

Perturbation Indicator. If a problem automatically perturbs early in the solution process, consider starting the solution process with a perturbation by setting `PerInd` to 1. Manually perturbing the problem will save the time of first allowing the optimization to stall before activating the perturbation mechanism, but is useful only rarely, for extremely degenerate problems.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>not automatically perturbed</td>
</tr>
<tr>
<td>1</td>
<td>automatically perturbed</td>
</tr>
</tbody>
</table>
**perlim** (*integer*): number of stalled iterations before perturbation

Perturbation limit. The number of stalled iterations before perturbation is invoked. The default value of 0 means the number is determined automatically.

Default: 0

**polishafterdett ime** (*real*): deterministic time before starting to polish a feasible solution

Default: $1.0 \times 10^7$

**polishafterepgap** (*real*): absolute MIP gap before starting to polish a feasible solution

Solution polishing can yield better solutions in situations where good solutions are otherwise hard to find. More time-intensive than other heuristics, solution polishing is actually a variety of branch-and-cut that works after an initial solution is available. In fact, it requires a solution to be available for polishing, either a solution produced by branch-and-cut, or a MIP start supplied by a user. Because of the high cost entailed by solution polishing, it is not called throughout branch-and-cut like other heuristics. Instead, solution polishing works in a second phase after a first phase of conventional branch-and-cut. As an additional step after branch-and-cut, solution polishing can improve the best known solution. As a kind of branch-and-cut algorithm itself, solution polishing focuses solely on finding better solutions. Consequently, it may not prove optimality, even if the optimal solution has indeed been found. Like the RINS heuristic, solution polishing explores neighborhoods of previously found solutions by solving subMIPs.

Sets an absolute MIP gap (that is, the difference between the best integer objective and the objective of the best node remaining) after which CPLEX stops branch-and-cut and begins polishing a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: 0.0

**polishafterepgap** (*real*): relative MIP gap before starting to polish a solution

Sets a relative MIP gap after which CPLEX will stop branch-and-cut and begin polishing a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: 0.0

**polishafterintsol** (*integer*): MIP integer solutions to find before starting to polish a feasible solution

Sets the number of integer solutions to find before CPLEX stops branch-and-cut and begins to polish a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: 2,147,483,647

**polishafternode** (*integer*): nodes to process before starting to polish a feasible solution

Sets the number of nodes processed in branch-and-cut before CPLEX starts solution polishing, if a feasible solution is available.

Default: 2,147,483,647

**polishaftertime** (*real*): time before starting to polish a feasible solution

Tells CPLEX how much time in seconds to spend during mixed integer optimization before
CPLEX starts polishing a feasible solution. The default value is such that CPLEX does not
start solution polishing by default.

Default: 1.0e+75

**populatelim (integer):** limit of solutions generated for the solution pool by populate method

Limits the number of solutions generated for the solution pool during each call to the populate
procedure. Populate stops when it has generated *PopulateLim* solutions. A solution is counted
if it is valid for all filters (see DivFlt and consistent with the relative and absolute pool gap
parameters (see *SolnPoolGap* and *SolnPoolAGap*), and has not been rejected by the incumbent
checking routine (see UserIncbCall), whether or not it improves the objective of the model.
This parameter does not apply to MIP optimization generally; it applies only to the populate
procedure.

If you are looking for a parameter to control the number of solutions stored in the solution
pool, consider the parameter *SolnPoolCapacity* instead.

Populate will stop before it reaches the limit set by this parameter if it reaches another limit,
such as a time or node limit set by the user.

Default: 20

**ppriind (integer):** primal simplex pricing

Pricing algorithm. Likely to show the biggest impact on performance. Look at overall solution
time and the number of Phase I and total iterations as a guide in selecting alternate pricing
algorithms. If you are using the dual Simplex method use *DPriInd* to select a pricing algorithm.
If the number of iterations required to solve your problem is approximately the same as the
number of rows in your problem, then you are doing well. Iteration counts more than three
times greater than the number of rows suggest that improvements might be possible.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| -1    | Reduced-cost pricing  
This is less compute intensive and may be preferred if the problem is small or easy. This option may also be advantageous for dense problems (say 20 to 30 nonzeros per column). |
| 0     | Hybrid reduced-cost and Devex pricing |
| 1     | Devex pricing  
This may be useful for more difficult problems which take many iterations to complete Phase I. Each iteration may consume more time, but the reduced number of total iterations may lead to an overall reduction in time. Tenfold iteration count reductions leading to threefold speed improvements have been observed. Do not use devex pricing if the problem has many columns and relatively few rows. The number of calculations required per iteration will usually be disadvantageous. |
| 2     | Steepest edge pricing  
If devex pricing helps, this option may be beneficial. Steepest-edge pricing is computationally expensive, but may produce the best results on exceptionally difficult problems. |
| 3     | Steepest edge pricing with slack initial norms  
This reduces the computationally intensive nature of steepest edge pricing. |
| 4     | Full pricing |
**predual** *(integer)*: give dual problem to the optimizer

Solve the dual. Some linear programs with many more rows than columns may be solved faster by explicitly solving the dual. The `PreDual` option will cause Cplex to solve the dual while returning the solution in the context of the original problem. This option is ignored if presolve is turned off.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>do not give dual to optimizer</td>
</tr>
<tr>
<td>0</td>
<td>automatic</td>
</tr>
<tr>
<td>1</td>
<td>give dual to optimizer</td>
</tr>
</tbody>
</table>

**preind** *(boolean)*: turn presolver on/off

Perform Presolve. This helps most problems by simplifying, reducing and eliminating redundancies. However, if there are no redundancies or opportunities for simplification in the model, it may be faster to turn presolve off to avoid this step. On rare occasions, the presolved model, although smaller, may be more difficult than the original problem. In this case turning the presolve off leads to better performance. Specifying 0 turns the aggregator off as well.

Default: 1

**prepass** *(integer)*: number of presolve applications to perform

Number of MIP presolve applications to perform. By default, Cplex determines this automatically. Specifying 0 turns off the presolve but not the aggregator. Set `PreInd` to 0 to turn both off.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Determined automatically</td>
</tr>
<tr>
<td>0</td>
<td>No presolve</td>
</tr>
<tr>

<td>Perform aggressive node probing</td>
</tr>
</tbody>
</table>
**pricelim (integer):** pricing candidate list

Size for the pricing candidate list. Cplex dynamically determines a good value based on problem dimensions. Only very rarely will setting this option manually improve performance. Any non-negative integer values are valid.

Default: 0, in which case it is determined automatically

**printoptions (boolean):** list values of all options to GAMS listing file

Write the values of all options to the GAMS listing file. Valid values are no or yes.

Default: 0

**probe (integer):** perform probing before solving a MIP

Determines the amount of probing performed on a MIP. Probing can be both very powerful and very time consuming. Setting the value to 1 can result in dramatic reductions or dramatic increases in solution time depending on the particular model.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>No probing</td>
</tr>
<tr>

<tr>
<td>2</td>
<td>DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.</td>
</tr>
<tr>
<td>3</td>
<td>Concurrent: Uses ThreePass and DoubleForward in parallel. As soon as one finishes, the other one stops.</td>
</tr>
</tbody>
</table>

**qpmakepsdind (boolean):** adjust MIQP formulation to make the quadratic matrix positive-semi-definite
Determines whether Cplex will attempt to adjust a MIQP formulation, in which all the variables appearing in the quadratic term are binary. When this feature is active, adjustments will be made to the elements of a quadratic matrix that is not nominally positive semi-definite (PSD, as required by Cplex for all QP formulations), to make it PSD, and will also attempt to tighten an already PSD matrix for better numerical behavior. The default setting of 1 means yes but you can turn it off if necessary; most models should benefit from the default setting.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

**qpmethod (integer):** algorithm to be used for QP problems

Specifies which QP algorithm to use.

At the default of 0 (automatic), barrier is used for QP problems and dual simplex for the root relaxation of MIQP problems.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tbody>
</table>

**qtolin (integer):** linearization of the quadratic terms in the objective function of a QP or MIQP model

This parameter switches on or off linearization of the quadratic terms in the objective function of a quadratic program or of a mixed integer quadratic program.

In a convex mixed integer quadratic program, this parameter controls whether Cplex linearizes the product of binary variables in the objective function during presolve. In a nonconvex quadratic program or mixed integer quadratic program solved to global optimality according to OptimalityTarget, this parameter controls how Cplex linearizes the product of bounded variables in the objective function during presolve.

This parameter interacts with the existing parameter OptimalityTarget: When the solution target type is set to 1 (that is, Cplex searches for a globally optimal solution to a convex model), then in a convex MIQP, this parameter tells Cplex to replace the product of a binary variable and a bounded linear variable by a linearly constrained variable. When the solution target type is set to 3, then in a nonconvex QP or nonconvex MIQP, this parameter controls the initial relaxation.

Default: -1
5.11 CPLEX

</tbody>
</table>

Condition number of the scaled basis matrix = 9.000e+00

Default: 0

**randomseed** *(integer)*: sets the random seed differently for diversity of solutions ⇔

Default: changes with each Cplex release

**readflt** *(string)*: reads Cplex solution pool filter file ⇔

The GAMS/Cplex solution pool options cover the basic use of diversity and range filters for producing multiple solutions. If you need multiple filters, weights on diversity filters or other advanced uses of solution pool filters, you could produce a Cplex filter file with your favorite editor or the GAMS Put Facility and read this into GAMS/Cplex using this option.

**readparams** *(string)*: read Cplex parameter file ⇔

**reduce** *(integer)*: primal and dual reduction type ⇔

Determines whether primal reductions, dual reductions, or both, are performed during preprocessing. It is occasionally advisable to do only one or the other when diagnosing infeasible or unbounded models.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No primal or dual reductions</td>
</tr>
<tr>
<td>1</td>

</tr>
<tr>
<td>2</td>
<td>Only dual reductions</td>
</tr>
<tr>
<td>3</td>
<td>Both primal and dual reductions</td>
</tr>
</tbody>
</table>
\textbf{reinv} \textit{(integer): refactoring frequency} \leftrightarrow

Refactorization Frequency. This option determines the number of iterations between refactorizations of the basis matrix. The default should be optimal for most problems. Cplex's performance is relatively insensitive to changes in refactorization frequency. Only for extremely large, difficult problems should reducing the number of iterations between refactorizations be considered. Any non-negative integer value is valid.

Default: 0, in which case it is determined automatically

\textbf{relaxfixedinfeas} \textit{(boolean): accept small infeasibilities in the solve of the fixed problem} \leftrightarrow

Sometimes the solution of the fixed problem of a MIP does not solve to optimality due to small (dual) infeasibilities. The default behavior of the GAMS/Cplex link is to return the primal solution values only. If the option is set to 1, the small infeasibilities are ignored and a full solution including the dual values are reported back to GAMS.

Default: 0

<table>

</table>

\textbf{relobjdif} \textit{(real): relative cheat parameter} \leftrightarrow

The relative version of the \textit{ObjDif} option. Ignored if \textit{ObjDif} is non-zero.

Default: 0.0

\textbf{repairtries} \textit{(integer): try to repair infeasible MIP start} \leftrightarrow

This parameter lets you indicate to Cplex whether and how many times it should try to repair an infeasible MIP start that you supplied. The parameter has no effect if the MIP start you supplied is feasible. It has no effect if no MIP start was supplied.

Default: 0

<table>
<thead>
<tr>

<tr>
<td>3</td>
<td>Represolve with cuts and allow new root cuts</td>
</tr>
</tbody>
</table>

rerun (string): rerun problem if presolve infeasible or unbounded →

The Cplex presolve can sometimes diagnose a problem as being infeasible or unbounded. When this happens, GAMS/Cplex can, in order to get better diagnostic information, rerun the problem with presolve turned off. The GAMS solution listing will then mark variables and equations as infeasible or unbounded according to the final solution returned by the simplex algorithm. The IIS option can be used to get even more diagnostic information. The rerun option controls this behavior. Valid values are auto, yes, no and nono. The value of auto is equivalent to no if names are successfully loaded into Cplex and option IIS is set to no. In that case the Cplex messages from presolve help identify the cause of infeasibility or unboundedness in terms of GAMS variable and equation names. If names are not successfully loaded, rerun defaults to yes. Loading of GAMS names into Cplex is controlled by option Names. The value of nono only affects MIP models for which Cplex finds a feasible solution in the branch-and-bound tree but the fixed problem turns out to be infeasible. In this case the value nono also disables the rerun without presolve, while the value of no still tries this run. Feasible integer solution but an infeasible fixed problem happens in few cases and mostly with badly scaled models. If you experience this try more aggressive scaling (ScaInd) or tightening the integer feasibility tolerance EPInt. If the fixed model is infeasible only the primal solution is returned to GAMS. You can recognize this inside GAMS by checking the marginal of the objective defining constraint which is always nonzero.

Default: nono

<table>
<thead>
<tr>

<tr>
<td>no</td>
<td>Do not rerun infeasible models</td>
</tr>
<tr>
<td>nono</td>
<td>Do not rerun infeasible fixed MIP models</td>
</tr>
</tbody>
</table>

rhsrng (string): do right-hand-side ranging →

Calculate sensitivity ranges for the specified GAMS equations. Unlike most options, RHSRng can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS equation named. Specifying all will cause range information to be produced for all equations. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option RngRestart is specified.

Default: no right-hand-side ranging is done

rinsheur (integer): relaxation induced neighborhood search frequency →
Cplex implements a heuristic known a Relaxation Induced Neighborhood Search (RINS) for MIP and MIQCP problems. RINS explores a neighborhood of the current incumbent to try to find a new, improved incumbent. It formulates the neighborhood exploration as a MIP, a subproblem known as the subMIP, and truncates the subMIP solution by limiting the number of nodes explored in the search tree.

Parameter **RINSHeur** controls how often RINS is invoked. A value of 100, for example, means that RINS is invoked every hundredth node in the tree.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Disable RINS</td>
</tr>
<tr>
<td>0</td>
<td>Automatic</td>

</tr>
</tbody>
</table>

**rltcuts (integer)**: Reformulation Linearization Technique (RLT) cuts

This parameter controls the addition of cuts based on the Reformulation Linearization Technique (RLT) for nonconvex quadratic programs (QP) or mixed integer quadratic programs (MIQP) solved to global optimality. That is, the OptimalityTarget parameter must be set to 3. The **RLTCuts** option is not controlled by the option **Cuts**.

Default: 0

<table>
<thead>
<tr>

</tr>
<tr>
<td>3</td>
<td>Generate RLT cuts very aggressively</td>
</tr>
</tbody>
</table>

**rngrestart (string)**: write GAMS readable ranging information file

Write ranging information, in GAMS readable format, to the file named. If the file extension is GDX, the ranging information is exported as GDX file. Options **ObjRng** and **RHSRng** are used to specify which GAMS variables or equations are included.

Default: ranging information is printed to the listing file

**scaind (integer)**: matrix scaling on/off

This option influences the scaling of the problem matrix.

Default: 0

<table>

</tbody>
</table>

sifting (boolean): switch for sifting from simplex optimization

Default: 1

siftitlim (integer): limit on sifting iterations

Sets the maximum number of sifting iterations that may be performed if convergence to optimality has not been reached.

Default: large

simdisplay (integer): simplex display level

This option controls what Cplex reports (normally to the screen) during optimization. The amount of information displayed increases as the setting value increases.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No iteration messages are issued until the optimal solution is reported</td>
</tr>
<tr>
<td>1</td>

<tr>
<td>2</td>
<td>An iteration log message will be issued after each iteration</td>
</tr>
<tr>
<td></td>
<td>The variables, slacks and artificials entering and leaving the basis will also be reported.</td>
</tr>
</tbody>
</table>

singlim (integer): limit on singularity repairs
The singularity limit setting restricts the number of times Cplex will attempt to repair the basis when singularities are encountered. Once the limit is exceeded, Cplex replaces the current basis with the best factorizable basis that has been found. Any non-negative integer value is valid.

Default: 10

**solnpool (string): solution pool file name**

The solution pool enables you to generate and store multiple solutions to a MIP problem. The option expects a GDX filename. This GDX file name contains the information about the different solutions generated by Cplex. Inside your GAMS program you can process the GDX file and read the different solution point files. Please check the GAMS/Cplex solver guide document and the example model `solnpool.gms` from the GAMS model library.

**solnpoolagap (real): absolute tolerance for the solutions in the solution pool**

Sets an absolute tolerance on the objective bound for the solutions in the solution pool. Solutions that are worse (either greater in the case of a minimization, or less in the case of a maximization) than the objective of the incumbent solution according to this measure are not kept in the solution pool.

Values of the solution pool absolute gap and the solution pool relative gap `SolnPoolGap` may differ: For example, you may specify that solutions must be within 15 units by means of the solution pool absolute gap and also within 1% of the incumbent by means of the solution pool relative gap. A solution is accepted in the pool only if it is valid for both the relative and the absolute gaps.

The solution pool absolute gap parameter can also be used as a stopping criterion for the populate procedure: if populate cannot enumerate any more solutions that satisfy this objective quality, then it will stop. In the presence of both an absolute and a relative solution pool gap parameter, populate will stop when the smaller of the two is reached.

Default: 1.0e+75

**solnpoolcapacity (integer): limits of solutions kept in the solution pool**

Limits the number of solutions kept in the solution pool. At most, `SolnPoolCapacity` solutions will be stored in the pool. Superfluous solutions are managed according to the replacement strategy set by the solution pool replacement parameter `SolnPoolReplace`.

The optimization (whether by MIP optimization or the populate procedure) will not stop if more than `SolnPoolCapacity` are generated. Instead, stopping criteria are regular node and time limits and `PopulationLim`, `SolnPoolGap` and `SolnPoolAGap`.

Default: 2100000000

**solnpoolgap (real): relative tolerance for the solutions in the solution pool**

Sets a relative tolerance on the objective bound for the solutions in the solution pool. Solutions that are worse (either greater in the case of a minimization, or less in the case of a maximization) than the incumbent solution by this measure are not kept in the solution pool.

Values of the solution pool absolute gap `SolnPoolAGap` and the solution pool relative gap may differ: For example, you may specify that solutions must be within 15 units by means of the solution pool absolute gap and within 1% of the incumbent by means of the solution pool relative gap. A solution is accepted in the pool only if it is valid for both the relative and the absolute gaps.

The solution pool relative gap parameter can also be used as a stopping criterion for the populate procedure: if populate cannot enumerate any more solutions that satisfy this objective quality, then it will stop. In the presence of both an absolute and a relative solution pool gap parameter, populate will stop when the smaller of the two is reached.

Default: 1.0e+75
**solnpoolintensity (integer):** solution pool intensity for ability to produce multiple solutions

Controls the trade-off between the number of solutions generated for the solution pool and the amount of time or memory consumed. This parameter applies both to MIP optimization and to the populate procedure.

Values from 1 to 4 invoke increasing effort to find larger numbers of solutions. Higher values are more expensive in terms of time and memory but are likely to yield more solutions.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic. Its default value, 0, lets Cplex choose which intensity to apply.</td>
</tr>
<tr>
<td>1</td>
<td>Mild: generate few solutions quickly. For value 1, the performance of MIP optimization is not affected. There is no slowdown and no additional consumption of memory due to this setting. However, populate will quickly generate only a small number of solutions. Generating more than a few solutions with this setting will be slow. When you are looking for a larger number of solutions, use a higher value of this parameter.</td>
</tr>
<tr>
<td>2</td>
<td>Moderate: generate a larger number of solutions. For value 2, some information is stored in the branch and cut tree so that it is easier to generate a larger number of solutions. This storage has an impact on memory used but does not lead to a slowdown in the performance of MIP optimization. With this value, calling populate is likely to yield a number of solutions large enough for most purposes. This value is a good choice for most models.</td>
</tr>
<tr>
<td>3</td>
<td>Aggressive: generate many solutions and expect performance penalty. For value 3, the algorithm is more aggressive in computing and storing information in order to generate a large number of solutions. Compared to values 1 and 2, this value will generate a larger number of solutions, but it will slow MIP optimization and increase memory consumption. Use this value only if setting this parameter to 2 does not generate enough solutions.</td>
</tr>
<tr>
<td>4</td>
<td>Very aggressive: enumerate all practical solutions. For value 4, the algorithm generates all solutions to your model. Even for small models, the number of possible solutions is likely to be huge; thus enumerating all of them will take time and consume a large quantity of memory.</td>
</tr>
</tbody>
</table>

**solnpoollmerge (string):** solution pool file name for merged solutions

Similar to **solnpool**, this option enables you to generate and store multiple solutions to a MIP problem. The option expects a GDX filename. This GDX file contains all variables with an additional first index (determined through **SolnPoolPrefix**) as parameters (Cplex only reports the primal solution). Inside your GAMS program, you can process the GDX file and read all solutions in one read operation. Please check the GAMS/Cplex solver guide document for further solution pool options and the example model **solnpool.gms** from the GAMS model library.

**solnpooldumpsym (integer):** maximum number of variable symbols when writing merged solutions

Default: 10

**solnpoolpop (integer):** methods to populate the solution pool
Regular MIP optimization automatically adds incumbents to the solution pool as they are discovered. Cplex also provides a procedure known as populate specifically to generate multiple solutions. You can invoke this procedure either as an alternative to the usual MIP optimizer or as a successor to the MIP optimizer. You can also invoke this procedure many times in a row in order to explore the solution space differently (see option SolnPoolPopRepeat). In particular, you may invoke this procedure multiple times to find additional solutions, especially if the first solutions found are not satisfactory.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Just collect the incumbents found during regular optimization</td>
</tr>
<tr>
<td>2</td>
<td>Calls the populate procedure</td>
</tr>
</tbody>
</table>

**solnpoolpopdel** (string): file with solution numbers to delete from the solution pool →

After the GAMS program specified in SolnPoolPopRepeat determined to continue the search for alternative solutions, the file specified by this option is read in. The solution numbers present in this file will be delete from the solution pool before the populate routine is called again. The file is automatically deleted by the GAMS/Cplex link after processing.

**solnpoolpoprepeat** (string): method to decide if populating the solution should be repeated →

After the termination of the populate procedure (see option SolnPoolPop). The GAMS program specified in this option will be called which can examine the solutions in the solution pool and can decide to run the populate procedure again. If the GAMS program terminates normally (not compilation or execution time error) the search for new alternative solutions will be repeated.

**solnpoolprefix** (string): file name prefix for GDX solution files →

Default: soln

**solnpoolreplace** (integer): strategy for replacing a solution in the solution pool →

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Replace the first solution (oldest) by the most recent solution; first in, first out</td>
</tr>
<tr>
<td>1</td>
<td>Replace the solution which has the worst objective</td>
</tr>
<tr>
<td>2</td>
<td>Replace solutions in order to build a set of diverse solutions</td>
</tr>
</tbody>
</table>

**solutiontype** (integer): type of solution (basic or non basic) for an LP or QP →

Specifies the type of solution (basic or non basic) that CPLEX attempts to compute for a linear program (LP) or for a quadratic program (QP). In this context, basic means having to do with the basis, and non basic applies to the variables and constraints not participating in the basis.

By default (that is, when the value of this parameter is 0 (zero) automatic), CPLEX seeks a basic solution (that is, a solution with a basis) for all linear programs (LP) and for all quadratic programs (QP).

When the value of this parameter is 1 (one), CPLEX seeks a basic solution, that is, a solution that includes a basis with a basic status for variables and constraints. In other words, CPLEX behaves the same way for the values 0 (zero) and 1 (one) of this parameter.
When the value of this parameter is 2, CPLEX seeks a pair of primal-dual solution vectors. This setting does not prevent CPLEX from producing status information, but in seeking a pair of primal-dual solution vectors, CPLEX possibly may not produce basic status information; that is, it is possible that CPLEX does not produce status information about which variables and constraints participate in the basis at this setting.

Do not use the deprecated value -1 (minus one) of the parameter barrier crossover algorithm to turn off crossover of the barrier algorithm but use this parameter to indicate that a primal-dual pair is sufficient.

Default: 0

\texttt{solvefinal (boolean):} switch to solve the problem with fixed discrete variables

Sometimes the solution process after the branch-and-cut that solves the problem with fixed discrete variables takes a long time and the user is interested in the primal values of the solution only. In these cases, \texttt{solvefinal} can be used to turn this final solve off. Without the final solve no proper marginal values are available and only NAs are returned to GAMS.

Default: 1

<table>

<tr>
<td>4</td>
<td>Highly aggressive level of symmetry breaking</td>
</tr>
<tr>
<td>5</td>
<td>Extremely aggressive level of symmetry breaking</td>
</tr>
</tbody>
</table>

### threads (integer): global default thread count

Synonym: gthreads

Default number of parallel threads allowed for any solution method. Negative values are interpreted as the number of cores to leave free so setting threads to -1 leaves one core free for other tasks. Cplex does not understand negative values for the threads parameter. GAMS/Cplex will translate this into a positive number by applying the following formula: \(\max(1,\text{number of cores}-|\text{threads}|)\). Setting threads to 0 lets Cplex use at most 32 threads or the number of cores of the machine, whichever is smaller.

Default: GAMS Threads

### tilm (real): overrides the GAMS ResLim option

Synonym: reslim

The time limit setting determines the amount of time in seconds that Cplex will continue to solve a problem. This Cplex option overrides the GAMS ResLim option. Any non-negative value is valid.

Default: GAMS ResLim
trelim (real): maximum space in memory for tree

Sets an absolute upper limit on the size (in megabytes) of the branch and cut tree. If this limit is exceeded, Cplex terminates optimization.

Default: $1.0e+75$

**tuning** (string): invokes parameter tuning tool

Invokes the Cplex parameter tuning tool. The mandatory value following the keyword specifies a GAMS/Cplex option file. All options found in this option file will be used but not modified during the tuning. A sequence of file names specifying existing problem files may follow the option file name. The files can be in LP, MPS or SAV format. Cplex will tune the parameters either for the problem provided by GAMS (no additional problem files specified) or for the suite of problems listed after the GAMS/Cplex option file name without considering the problem provided by GAMS. Due to technical reasons a single option input line is limited by 256 characters. If the list of model files exceeds this length you can provide a second, third, ... line starting again with keyword **tuning** and a list of model instance files.

The result of such a tuning run is the updated GAMS/Cplex option file with a tuned set of parameters. The solver and model status returned to GAMS will be **NORMAL COMPLETION** and **NO SOLUTION**. More details on Cplex tuning can be found on IBM’s web page. Tuning is incompatible with the BCH facility and other advanced features of GAMS/Cplex.

**tuningdettlim** (real): tuning deterministic time limit per model or suite

Default: $1.0e+75$

**tuningdisplay** (integer): level of information reported by the tuning tool

Specifies the level of information reported by the tuning tool as it works.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Turn off display</td>
</tr>
<tr>
<td>1</td>
<td>Display standard minimal reporting</td>
</tr>
<tr>
<td>2</td>
<td>Display standard report plus parameter settings being tried</td>
</tr>
<tr>
<td>3</td>
<td>Display exhaustive report and log</td>
</tr>
</tbody>
</table>

**tuningmeasure** (integer): measure for evaluating progress for a suite of models

Controls the measure for evaluating progress when a suite of models is being tuned. Choices are mean average and minmax of time to compare different parameter sets over a suite of models.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>mean average</td>
</tr>
<tr>
<td>2</td>
<td>minmax</td>
</tr>
</tbody>
</table>

**tuningrepeat** (integer): number of times tuning is to be repeated on perturbed versions
Specifies the number of times tuning is to be repeated on perturbed versions of a given problem. The problem is perturbed automatically by Cplex permuting its rows and columns. This repetition is helpful when only one problem is being tuned, as repeated perturbation and re-tuning may lead to more robust tuning results. This parameter applies to only one problem in a tuning session.

Default: 1

**tuningtilim (real):** tuning time limit per model or suite

Sets a time limit per model and per test set (that is, suite of models).

As an example, suppose that you want to spend an overall amount of time tuning the parameter settings for a given model, say, 2000 seconds. Also suppose that you want Cplex to make multiple attempts within that overall time limit to tune the parameter settings for your model. Suppose further that you want to set a time limit on each of those attempts, say, 200 seconds per attempt. In this case you need to specify an overall time limit of 2000 using GAMS option reslim or Cplex option TiLim and tuningtilim to 200.

Default: 0.2\*GAMS ResLim

**upperobjstop (real):** in a maximization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value greater than or equal to the specified value

Default: 1e75

**usercallparmfile (string):** Command-line parameter include file used in GAMS command-line calls triggered by BCH

**.usercut (boolean):** User cut activation

Determines whether a linear constraint is treated as a user cut. At the beginning of the MIP solution process, any constraint whose usercut attribute is set to 1 (the default value is 0) is removed from the model and placed in the user cut pool. User cuts may be used by CPLEX at any time to improve the solution process. There is no guarantee that they are actually used. The user cut pool is only active if option usercutpool is enabled and are specified through the option .usercut. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: 0

**usercutcall (string):** the GAMS command line to call the cut generator

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**usercutfirst (integer):** calls the cut generator for the first n nodes

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

**usercutfreq (integer):** determines the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10
usercutinterval (integer): determines the interval when to apply the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 100

usercutmult (integer): determines the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 2

usercutnewint (boolean): calls the cut generator if the solver found a new integer feasible solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 1

usercutpool (boolean): Indicator to use user cuts

Default: 0

usergdxin (string): the name of the GDX file read back into Cplex

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchin.gdx

usergdxname (string): the name of the GDX file exported from the solver with the solution at the node

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchout.gdx

usergdxnameinc (string): the name of the GDX file exported from the solver with the incumbent solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchout_i.gdx

usergdxprefix (string): prefixes usergdxin, usergdxname, and usergdxnameinc

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

usergdxsol (string): the name of the GDX file exported by Cplex to store the solution of extra columns

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchsol.gdx

userheurcall (string): the GAMS command line to call the heuristic

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userheurfirst (integer): calls the heuristic for the first n nodes

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.
More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**Default:** 10

**userheurfreq (integer):** determines the frequency of the heuristic model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**Default:** 10

**userheurinterval (integer):** determines the interval when to apply the multiplier for the frequency of the heuristic model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**Default:** 100

**userheurmult (integer):** determines the multiplier for the frequency of the heuristic model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**Default:** 2

**userheurnewint (boolean):** calls the heuristic if the solver found a new integer feasible solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**Default:** 1

**userheurobjfirst (integer):** Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**Default:** 0

**userincbcall (string):** the GAMS command line to call the incumbent checking program

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**userincbicall (string):** the GAMS command line to call the incumbent reporting program

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**userjobid (string):** postfixes lf, o on call adds –userjobid to the call. Postfixes gdxname, gdxnameinc and gdxin

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**userkeep (boolean):** calls gamskeep instead of gams

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

**Default:** 0

**userlazyconcall (string):** the GAMS command line to call the lazy constraint generator

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Note: There is no guarantee that CPLEX will use all of the added violated lazy constraints provided due to technical and/or efficiency reasons. It may thus happen that a later candidate solution violates previously provided lazy constraints. In this case consider passing the constraint again.

**varsel (integer):** variable selection strategy at each node

This option is used to set the rule for selecting the branching variable at the node which has been selected for branching. The default value of 0 allows Cplex to select the best rule based on the problem and its progress.

**Default:** 0
value | meaning
---|---
-1 | Branch on variable with minimum infeasibility
This rule may lead more quickly to a first integer feasible solution, but will usually be slower overall to reach the optimal integer solution.
0 | Branch variable automatically selected
1 | Branch on variable with maximum infeasibility
This rule forces larger changes earlier in the tree, which tends to produce faster overall times to reach the optimal integer solution.
2 | Branch based on pseudo costs
Generally, the pseudo-cost setting is more effective when the problem contains complex trade-offs and the dual values have an economic interpretation.
3 | Strong Branching
This setting causes variable selection based on partially solving a number of subproblems with tentative branches to see which branch is most promising. This is often effective on large, difficult problems.
4 | Branch based on pseudo reduced costs

**warninglimit** *(integer)*: determines how many times warnings of a specific type *(datacheck=2)* will be displayed

By default, when modeling assistance is turned on via the data consistency checking parameter, CPLEX will display 10 warnings for a given modeling issue and then omit the rest. This parameter controls this limit and allows the user to display all of the warnings if desired. In order to see all warnings change the value to its negative.

Default: 10

**workdir** *(string)*: directory for working files

The name of an existing directory into which Cplex may store temporary working files. Used for MIP node files and by out-of-core Barrier.

Default: current or project directory

**workeralgorithm** *(integer)*: set method for optimizing benders subproblems

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>Primal Simplex</td>
</tr>
<tr>
<td>2</td>
<td>Dual Simplex</td>
</tr>
<tr>
<td>3</td>
<td>Network Simplex</td>
</tr>
<tr>
<td>4</td>
<td>Barrier</td>
</tr>
<tr>
<td>5</td>
<td>Sifting</td>
</tr>
</tbody>
</table>

**workmem** *(real)*: memory available for working storage

Upper limit on the amount of memory, in megabytes, that Cplex is permitted to use for working files. See parameter **WorkDir**.

Default: 2048.0
writeannotation (string): produce a Cplex annotation file

writebas (string): produce a Cplex basis file

Write a basis file.

writeflt (string): produce a Cplex solution pool filter file

Write the diversity filter to a Cplex FLT file.

writelp (string): produce a Cplex LP file

Write a file in Cplex LP format.

writemps (string): produce a Cplex MPS file

Write an MPS problem file.

writemst (string): produce a Cplex MST file

Write a Cplex MST (containing the MIP start) file.

writeord (string): produce a Cplex ORD file

Write a Cplex ORD (containing priority and branch direction information) file.

writeparam (string): produce a Cplex parameter file with all active options

Write a Cplex parameter (containing all modified Cplex options) file.

writepre (string): produce a Cplex LP/MPS/SAV file of the presolved problem

Synonym: writepremps

Write a Cplex LP, MPS, or SAV file of the presolved problem. The file extension determines the problem format. For example, WritePre presolved.lp creates a file presolved.lp in Cplex LP format.

writeprob (string): produce a Cplex problem file and infers the type from the extension

Write a problem file in a format inferred from the extension. Possible formats are

- SAV: Binary matrix and basis file
- MPS: MPS format
- LP: CPLEX LP format with names modified to conform to LP format
- REW: MPS format, with all names changed to generic names
- RLP: LP format, with all names changed to generic names
- ALP: LP format, with generic name of each variable, type of each variable, bound of each variable. If the file name ends with .bz2 or .gz, a compressed file is written.

writesav (string): produce a Cplex binary problem file

Write a binary problem file.

zerohalfcuts (integer): zero-half cuts

Decides whether or not to generate zero-half cuts for the problem. The value 0, the default, specifies that the attempt to generate zero-half cuts should continue only if it seems to be helping. If the dual bound of your model does not make sufficient progress, consider setting this parameter to 2 to generate zero-half cuts more aggressively.

Default: 0
5.11.9 Setting up a GAMS/Cplex-Link license

The GAMS/Cplex-Link license requires that you have a valid license agreement with IBM for use of the current version of the Cplex library.

To add the Cplex-Link to your GAMS license, please write to sales@gams.com to confirm that you have such a license agreement and that your use of the GAMS solver will comply with the terms of that license agreement. Please reference your GAMS License ID, DCxxxx.

5.12 Deterministic Equivalent (DE)

Author
Martha Loewe

5.12.1 Introduction

DE is a solver for stochastic programs modeled with GAMS Extended Mathematical Programming for Stochastic Programming (EMP SP). DE can solve multi-stage LP, MIP, QCP, NLP and MINLP stochastic programming models. For details about EMP SP and the syntax to modify an existing GAMS model to be an stochastic programming model in GAMS EMP SP see Stochastic Programming. A list of DE solver options is given at the end of this document.

Stochastic programs are mathematical programs that include data that is not known with certainty, but is approximated by probability distributions. The simplest form of a stochastic program is the two-stage stochastic linear program with recourse. In mathematical terms it is defined as follows.

Let \( x \in \mathbb{R}^n \) and \( y \in \mathbb{R}^m \) be two variables and let the set of all realizations of the unknown data be given by \( \Omega, \Omega = \{ \omega_1, \ldots, \omega_S \} \subseteq \mathbb{R}^r \), where \( r \) is the number of the random variables representing the uncertain parameters. Then the stochastic program is given by

\[
\begin{align*}
\text{Min}_x & \quad z = c^T x + \mathbb{E}[Q(x, \omega)] \\
\text{s.t.} & \quad Ax = b, \quad x \geq 0,
\end{align*}
\]

where \( Q(x, \omega) = \text{Min}_y \)

\[
\begin{align*}
\text{s.t.} & \quad T_\omega x + W_\omega y(\omega) = h_\omega, \quad y(\omega) \geq 0, \quad \forall \omega \in \Omega.
\end{align*}
\]

The first two lines define the first-stage problem and the last two lines define the second-stage problem. In the first stage, \( x \) is the decision variable, \( c^T \) represents the cost coefficients of the objective function and \( \mathbb{E}[Q(x, \omega)] \) denotes the expected value of the optimal solution of the second stage problem. In addition, \( A \) denotes the coefficients and \( b \) the right-hand side of the first stage constraints. In the second stage, \( y \) is the decision variable, \( T \) represents the transition matrix, \( W \) the recourse matrix (cost of recourse) and \( h \)
the right-hand side of the second stage constraints. Note that all parameters and the decision variable of the second stage are dependent on \( \omega \). The objective variable \( z \) is also a random variable, since it is a function of \( \omega \). As a random variable cannot be optimized, DE automatically optimizes the expected value of the objective variable \( z \). DE is also able to optimize other risk measures, as will be discussed later.

In the first stage, a decision has to be made before the realization of the uncertain data is clear. The optimal solution of the first stage is fixed and only then the values that the uncertain parameters take will become known. Given the fixed solution of the first stage and the new data, in the second stage recourse action can be taken and the optimal solution determined. Each possible realization of the uncertain data is represented by an \( \omega_s \in \Omega \) and is called a scenario. The objective is to find a feasible solution \( x \) that minimizes the total cost, namely the sum of the first-stage costs and the expected second-stage costs.

One of the most common methods to solve a two-stage stochastic LP is to build and solve the deterministic equivalent. Assume that the uncertain parameters follow a (finite) discrete distribution and that each scenario \( \omega_s \) occurs with probability \( P(\omega_s) = p_s \) for all \( s = 1, \ldots, S \) and \( \sum_s p_s = 1 \). So \( E[Q(x, \omega)] = \sum_s p_s q^T y_s \), where \( y_s \) denotes the optimal second-stage decision for the scenario \( \omega_s \). Then the deterministic equivalent can be expressed as follows:

\[
\begin{align*}
    c^T x + p_1 q^T y_1 + p_2 q^T y_2 + \ldots + p_S q^T y_S \\
    \text{s.t.} \\
    A x + W_1 y_1 &= b \\
    T_2 x + W_2 y_2 &= h_2 \\
    \vdots \\
    T_S x + W_S y_S &= h_S \\
    x \in \mathbb{R}^n, & \quad y_1 \in \mathbb{R}^m, & \quad y_2 \in \mathbb{R}^m, & \quad \ldots \quad & \quad y_S \in \mathbb{R}^m
\end{align*}
\]

(5.7)

Note that for stochastic linear programs the deterministic equivalent is just a very large linear program.

The solver DE automatically generates the deterministic equivalent of a stochastic program and then hands it over for solution to a solver, termed the subsolver. The subsolver is the default solver for the type of model to be solved. The user may choose another subsolver with the option subsolver.

If modelers want to use DE, they may either add the option

\[
\text{option emp = de;}
\]

before the solve statement in the model or they may choose the solver DE on the command line, e.g.

\[
\text{gams mymodel.gms emp=de}
\]

5.12.2 Random Variables

Random variables and their distributions and stages determine the number of scenarios in the model and thus the number of equations that are generated for the deterministic equivalent. If there are two or more random variables in one stage they may be jointly distributed or not.

Assume that there is a two-stage stochastic model \( \mathcal{M}_2 \) that has two random variables \( a \) and \( b \) in the second stage. The random variables both follow a discrete distribution, the uncertain data for \( a \) is given by \( \Omega_a \) and the uncertain data for \( b \) is given by \( \Omega_b \). If the random variables are not jointly distributed, then \( |\Omega_a| \times |\Omega_b| \) scenarios are generated. If the random variables are jointly distributed, then we need to have \( |\Omega_a| = |\Omega_b| \) and the number of scenarios is \( |\Omega_a| \).
In addition to two-stage stochastic models, DE can also solve multi-stage stochastic models. Let $M_4$ be a stochastic model with four stages. In each of the stages after the first stage new data is revealed that was unknown in the previous stages. Assume that in each stage there is just one random variable. Let $\Omega_I$ denote the uncertain data in the second stage and $\Omega_{II}$ and $\Omega_{III}$ represent the uncertain data of the third and fourth stage respectively. Let $|\Omega_I| = n_1$, $|\Omega_{II}| = n_2$ and $|\Omega_{III}| = n_3$. DE builds the deterministic equivalent of this model by recursively generating a scenario tree. In the second stage the number of scenarios is $n_1$, in the third stage there are $n_1 \times n_2$ scenarios and in the fourth stage there are $n_1 \times n_2 \times n_3$ scenarios. Note that the number of scenarios in the model equals the number of scenarios in the last stage. However, the number of equations generated for the deterministic equivalent is the sum of the scenarios in each stage, so in this example it is $n_1 + n_1 \times n_2 + n_1 \times n_2 \times n_3 = n_1 \times (1 + n_2 \times (1 + n_3))$.

The following figure illustrates the scenario tree of a stochastic model with four stages.

Note that the structure of the scenario tree is limited: each node in a stage has exactly the same number of arcs.

If there is more than one random variable per stage, then the number of scenarios increases accordingly. Note that there is no absolute limit to the number of stages and random variables, but the model can become very large very quickly as the number of stages and random variables increases. Note further that the random variables are stagewise independent. The realization of the random variables in one stage does not influence the realization of the random variables in a later stage.

5.12.3 Sampling Procedures

DE can solve only stochastic programs with random variables that follow discrete probability distributions. If the random data follows a continuous probability distribution the set $\Omega$ has an infinite number of elements. Sampling is a process that generates a finite approximation $\Omega_N$ to $\Omega$. The size of $\Omega_N$ is $N$ and each element of $\Omega_N$ has the same probability $p = \frac{1}{N}$. Thus continuous probability distributions are approximated by discrete distributions. EMP SP provides the keyword `sample` to facilitate sampling. An example follows.

```plaintext
randvar d normal 45 10
sample d 100
```
These two lines are a portion of the emp.info file. In the first line d is defined as a random variable that follows a Normal distribution with mean 45 and standard deviation 10. In the second line it is specified that the continuous distribution is approximated by a sample of size 100. Note that the user determines the sample size $N$. Note further that the use of the keyword sample is mandatory for random variables with continuous distributions. Otherwise the following error message will appear:

*** Only random variables with sampled continuous distributions supported.

Observe that behind the scenes the sampling is performed by the LINDO system. So the modeler needs a LINDO licence for sample sizes larger than 10 (smaller sample sizes are included in the demo version). The LINDO system offers three variance reduction algorithms: the Antithetic algorithm, the Latin Square algorithm and the Monte Carlo algorithm. They may be enabled using either the option svr_ls_antithetic or svr_ls_latinsquare or svr_ls_montecarlo respectively.

Alternatively, the modeler may chose to generate a sample of the distribution first and then enter the sample as a discrete distribution in the emp.info file. There are two stochastic libraries that can be used for this procedure: the GAMS Stochastic Library and the LINDO Sampling Library. An example and details about the procedure using the LINDO library are given in section Sampling in the EMP manual.

5.12.4 The Expected Value Problem

Consider the special case where the sample size is 1 and the "sampled" value equals the expected value of the random variable. This entails that the random variable is replaced by its expected value. The resulting model is deterministic and is called the Expected Value Program. DE facilitates solving the Expected Value Problem through the option solveEVProb. If this option is specified in the option file (see example below) the Expected Value Problem is solved after the original stochastic model and the solution is reported. In addition, DE offers the option to choose a separate subsolver for the Expected Value Problem, the option evsubsolver.

In the following example the stochastic model is solved with the subsolver Conopt and the Expected Value Problem is solved with the subsolver Minos.

```
$onecho > de.opt
subsolver conopt
solveEVProb
evsusolver minos
$offecho
mymodel.optfile=1;
solve mymodel min obj using emp scenario dict;
```

Note that the option solveEVProb is not defined for models with chance constraints and models featuring VaR and CVaR. These model types are discussed in the next section.

5.12.5 What types of models can DE handle?

As mentioned earlier, DE can solve two-stage and multi-stage stochastic linear, quadratic and nonlinear models and the mixed-integer versions of all these models. There are two further classes of stochastic models that DE is equipped to solve: stochastic programs with chance constraints and stochastic programs with other risk measures such as Variance at Risk (VaR) and Conditional Variance at Risk (CVaR). CVaR is also called Expected Shortfall.
In stochastic programs with chance constraints the goal is to make an optimal decision prior to the realization of random data while allowing the constraints to be violated with a certain probability. Mathematically, a stochastic linear program with chance constraints can be expressed as follows:

$$\min_x c^T x$$
$$\text{s.t.} \quad P(Ax \leq b) \geq p$$
$$x \geq 0,$$

(5.8)

where $x \in \mathbb{R}^n$ is the decision variable and $c^T$ denotes the coefficients of the objective function, $A \in \mathbb{R}^{m \times n}$ is a random matrix and represents the coefficients and $b \in \mathbb{R}^m$ is a random vector and denotes the right-hand side of the constraints. The distinctive feature of stochastic programs with chance constraints is that the constraints (or some of them) may be violated with probability $\epsilon = 1 - p$, where $0 < p \leq 1$.

DE offers three reformulation options to solve stochastic programs with chance constraints: a reformulation using a mixed-integer program with big $M$ notation, a convex hull reformulation and the use of indicator variables and indicator constraints. Note that the default is the MIP reformulation (the default value of $M$ is set to 10000 and can be customized). With the option `ccreform` the reformulation method can be determined by the user.

For details on single and joint chance constraints and examples how to use the option `ccreform`, see the section Chance Constraints with EMP in the EMP manual. Note that random variables in programs with chance constraints may follow discrete or continuous probability distributions. Note further that there are no stages in stochastic programs with chance constraints.

As mentioned earlier, DE automatically optimizes the expected value of the objective function variable. DE also supports other risk measures, such as VaR and CVaR. In mathematical terms, DE is able to solve the following:

$$\min_x R(z),$$

(5.9)

where $z$ represents the objective function variable and $R$ denotes a risk measure such as the Expected Value, VaR and CVaR or a combination of risk measures (e.g., the weighted sum of Expected Value and CVaR). In addition, the modeler can also choose to trade off risk measures. For more details about risk measures see section Risk Measures with EMP in the EMP manual.

5.12.6 Reformulation Techniques

In this section some details are given about the reformulations that DE is performing behind the scenes.

5.12.6.1 Simple two-stage stochastic model

As mentioned previously, DE converts a stochastic model into its deterministic equivalent. Using the model `nbsimple.gms` from the GAMS EMP model library as an example, we show how exactly the deterministic equivalent is built. Note that this model is also discussed in detail in the section A Simple Example: The News Vendor Problem of the EMP manual.

The model is given by the following equations:

$$\max_x z(x) = -cx + E[Q(x, \omega)], \quad x \geq 0,$$

(5.10)
where

\[ Q(x, \omega) = \max_{s, i, l} vs(\omega) - hi(\omega) - pl(\omega) \]
\[ \text{s.t.} \quad x - s(\omega) - i(\omega) = 0 \]
\[ s(\omega), i(\omega), l(\omega) \geq 0 \quad \forall \omega \in \Omega. \]

Here \( c, v, h \) and \( p \) are some given parameters, the first-stage decision variable is \( x \), the second-stage decision variables are \( s, i \) and \( l \) and the uncertain data is represented by the random variable \( d(\omega) \).

We assume that the annotations specify that \( d \) follows a Normal distribution and the sample size to approximate this continuous distribution is 4 (where all scenarios are equally likely, so \( p(s) = 0.25 \)).

First, DE draws 4 values from the Normal distribution specified in the annotations. These 4 values are the basis for the 4 scenarios that are generated. For each scenario, a separate equation for the second-stage constraints is built (that are 8 equations). In the process, for each of the three decision variables of the second stage 4 variables are generated since the second-stage decision variables may take different values for each scenario. Next, an equation for the profit for each scenario is generated (4 equations) and finally, the equation to compute the average profit is built. So there are a total of 13 equations. They are given here:

\[
\begin{align*}
  x - s_1 - i_1 &= 0 \\
  x - s_2 - i_2 &= 0 \\
  x - s_3 - i_3 &= 0 \\
  x - s_4 - i_4 &= 0 \\
  s_1 + l_1 &= d_1 \\
  s_2 + l_2 &= d_2 \\
  s_3 + l_3 &= d_3 \\
  s_4 + l_4 &= d_4 \\
  z_1 &= -cx + vs_1 - hi_1 - pl_1 \\
  z_2 &= -cx + vs_2 - hi_2 - pl_2 \\
  z_3 &= -cx + vs_3 - hi_3 - pl_3 \\
  z_4 &= -cx + vs_4 - hi_4 - pl_4 \\
  z &= 0.25z_1 + 0.25z_2 + 0.25z_3 + 0.25z_4
\end{align*}
\] (5.11)

Note that there is only one realization of the first-stage decision variable \( x \) while for the second-stage decision variables there as many realizations as there are scenarios.

### 5.12.6.2 A multi-stage stochastic model

DE recursively builds a scenario tree to generate the deterministic equivalent of multi-stage models. We take the model inventory from the EMP manual to demonstrate how this is done. The 4-stage model is given by the following equations:

\[
\begin{align*}
  \max_{y_1, i_1} \quad & z = -\alpha y_1 - \gamma i_1 + \mathbb{E}[Q((y_1, i_1), \omega_1)] + \mathbb{E}[Q((y_1, i_1), \omega_1)] + \mathbb{E}[Q((y_1, i_1), \omega_1)] \\
  \text{s.t.} \quad & i_1 = y_1 \\
  & y_1, i_1 \geq 0,
\end{align*}
\]

where

\[
Q((y_1, i_1), \omega_1) = \max_{s_t, y_t, i_t} \beta s_t(\omega_1) - \alpha y_t(\omega_1) - \delta i_t(\omega_1) \\
\text{s.t.} \quad \begin{align*}
  i_{t-1} + y_t &= s_t + i_t \\
  s_t &\leq i_{t-1} \\
  s_t &\leq d_t(\omega_1) \\
  i_t &\leq \kappa \\
  s_t, y_t, i_t &\geq 0 \quad \text{for} \quad t = 2, 3, 4.
\end{align*}
\]
Here $y_1$ and $i_1$ are the first-stage decision variables and $y_t$, $i_t$ and $s_t$ are the decision variables of the later stages; $\alpha$, $\beta$, $\gamma$, $\delta$ and $\kappa$ denote fixed parameters. The uncertain data is represented by the random variable $d_t(\omega, \zeta)$, where $\omega, \zeta \in \Omega, \zeta = I, II, III$. Note that $s_t$, $y_t$ and $i_t$ depend on the realization of $d_t$. Now assume that $d_t$ follows a continuous distribution and the sample size to approximate this distribution is just 3 for stages 2 to 4. Note that in multi-stage models the sample size may vary for each stage. Note further that for all practical purposes this sample size is too small, it was chosen here for reasons of clarity of exposition. As usual, the distribution(s) and sample size(s) are specified in the annotations. Observe that the last constraint ($i_t \leq \kappa$) is implemented as a bound on the variable $i_t$, not as an equation. So, in addition to the objective equations, there is one equation in the first stage and three equations in each of the later stages.

This model is reformulated in the following way. First, an equation for the first stage constraint is generated. Secondly, three realizations of $d_2$ are chosen through a sampling procedure, so there are three scenarios at stage 2. For each of these three realizations of the random variable the equations for the second stage are generated (9 equations). Thirdly, three realizations of $d_3$ are sampled for stage 3. Each of these three realizations may follow one of the three scenarios of the second stage, so there are nine scenarios in stage 3 and hence $9 \times 3 = 27$ equations are generated for stage 3. The procedure is repeated in stage 4 where there are 27 scenarios and $27 \times 3 = 81$ equations. Next, the value of the objective variable for each scenario is computed by generating 27 equations for $z_s$ and finally, an equation to compute $z$ is built, where $z = \sum_s p(s)z_s$.

5.12.6.3 Chance Constraints

Models with chance constraints are reformulated as mixed integer problems by default. This reformulation is discussed in detail in the section Chance Constraints with EMP in the EMP manual. Reformulations using a convex hull or indicator variables and indicator constraints are also possible. The reformulation method may be determined by the user with the option ccreform.

5.12.6.4 Computing VaR

Models involving VaR are reformulated using mixed integer programs with big $M$ notation. By the example model portfolio.gms we demonstrate how this is done. This model is discussed in the section Value at Risk (VaR) in the EMP manual. The model is given by the following equations:

\[
\max \quad VaR_{\theta}[R] \\
\text{s.t} \quad R = \sum_j w_j v_j(\theta) \quad \forall \omega \in \Omega \\
\sum_j w_j = 1 \\
w_j \geq 0,
\]

where $VaR_{\theta}$ is the VaR at the lower $\theta$th percentile, the variable $R$ is the return (and is a function of the random variable $v_j(\omega)$), $w_j$ the weight associated with each asset $j$ and $v_j(\omega)$ is the (random variable) return of each asset $j$. The weights can also be interpreted as proportions of the amount to be invested, their sum must be 1. Note that $w_j$ is the decision variable in this problem.

Let $y(s)$ be a binary variable that acts as an indicator variable. For each scenario, it equals 1 if the return $R \geq VaR_{\theta}[R]$ and it is 0 otherwise. Then the model is reformulated to the following MIP:

\[
\max \quad VaR_{\theta}[R] \\
\text{s.t} \quad r(s) = \sum_j w_j v_j(s) \quad \forall s = 1, \ldots, S \\
r(s) \geq VaR_{\theta}[R] - M(1 - y(s)) \quad \forall s = 1, \ldots, S \\
cc = 1 - \sum_s p(s)y(s) \\
\sum_j w_j = 1 \\
0 \leq cc \leq \theta \\
w_j \geq 0.
\]
Here $r(s)$ denotes the return per scenario and $cc$ is a variable that represents the probability of violations (a violation occurs if in a scenario the return is smaller than $VaR_\theta[R]$). As usual, $p(s)$ is the probability that a scenario occurs and $M$ is the big $M$. The first three constraints together with the bounds on $cc$ ensure that the probability of violations is smaller than or equal to $\theta$.

Note that the default value for big $M$ for models with VaR is 1000 (and it is different from the default value for big $M$ for chance constraints). It may be customized with the option varbigm.

5.12.6.5 Computing CVaR

Models with CVaR are reformulated by converting the annotations into new variables and equations. Using the model portfolio.gms as an example we demonstrate how this is done. This model features in the GAMS EMP library and is also discussed in the section Conditional Value at Risk (CVaR) in the EMP manual. The model is given by:

$$\begin{align*}
\text{Max} & \quad CVaR_\theta[R] \\
\text{s.t} & \quad R = \sum_j w_j v_j(\omega) \quad \forall \omega \in \Omega \\
& \quad \sum_j w_j = 1 \\
& \quad w_j \geq 0,
\end{align*}$$

(5.14)

where $CVaR_\theta$ is the CVaR at the left tail of the distribution at the confidence level $\theta$ and all other variables are as defined above. Note that again, $w_j$ is the decision variable in this problem.

DE reformulates this model by introducing three new variables and three associated equations. Let $r(s)$ denote the return per scenario, $t$ the target return to be achieved with probability approximately $1 - \theta$ and $d(s)$, $d(s) \geq 0$, the lower deviation from $t$ per scenario. The equations follow.

$$\begin{align*}
    r(s) &= \sum_j w_j v_j(s) \\
    d(s) &\geq t - r(s) \\
    CVaR_\theta[R] &= t - \frac{1}{\theta} \sum p(s)d(s)
\end{align*}$$

(5.15)

Thus the model is reformulated to an LP and may be solved by an appropriate solver. It is easy to see that $t$ equals $VaR_\theta[R]$.

5.12.7 Logfile

The logfile gives much information about the solver progress. The following is the DE log output from running the nbdisjoint model from the GAMS EMP Model Library:

--- Starting compilation
--- nbdisjoint.gms(74) 3 Mb
--- Starting execution: elapsed 0:00:00.024
--- nbdisjoint.gms(72) 4 Mb
---
--- collecting and writing gdx file
---
--- Generating EMP model nb
--- nbdisjoint.gms(72) 6 Mb
--- 5 rows 9 columns 19 non-zeroes
--- 6 nl-code 2 nl-non-zeroes
First, the model in scalar form is generated. It has 5 equations, so the model statistics report 5 rows. Further, it has 6 positive variables, one free variable and 2 random variables, so there are 9 columns. A matrix form representation of the model with the variables as columns and the equations as rows has 19 non-zero entries. Next, DE generates the deterministic equivalent. The statistics for the deterministic equivalent indicate that there are 26 rows, 50 columns and 116 non-zero entries. The stochastic model has 6 scenarios, so for each second-stage equation there are 6 equations in the deterministic equivalent (i.e. a total of 24 equations). In addition, there is one first-stage equation and one equation to compute the expected value of the objective variable, which brings the sum total to 26 equations or rows. Similarly, for each second-stage variable in the stochastic model there are 6 variables in the deterministic equivalent (i.e. a total of 48 variables). In addition, there is the first-stage decision variable and a variable for the expected value of the objective variable adding up to a total of 50 variables or columns.

Note that the model type is identified as an LP and thus the default LP solver is invoked. In this case the subsolver is Cplex and most of the remainder of the logfile is output from the subsolver. At the end the mapping specified in the dictionary is performed.
The log file of solving stochastic models with VaR or CVaR is similar. It reports that the model type is being determined, the deterministic equivalent built and then handed over to the appropriate subsolver to be solved. However, when solving stochastic programs with chance constraints there is much more happening behind the scenes. DE automatically hands over the model to the subsolver JAMS. By default, JAMS reformulates the model and generates a scalar version of it. The scalar version of the reformulated model is then handed back to the GAMS system to be solved by an appropriate subsolver. The log file reports the progress of the subsolver until the model is solved. Then the solution from the GAMS subsolver is handed to JAMS and a list of disjunctions and their activity level is reported. (The equations in the scalar version of the reformulated model that may be left unsatisfied are called disjunctions. Active disjunctions refer to equations that are satisfied and not active disjunctions refer to equations that are not satisfied.)

Parts of the DE log file from running the simplechance model from the GAMS EMP Model Library are given below. These parts of the log file demonstrate the solution process for stochastic models with chance constraints that was just described.

#### 5.12.9 Detailed Descriptions of DE Options

**ccreform (string):** Reformulation option passed to JAMS

This option determines how to formulate the indicator contraints of the chance constraints in the deterministic equivalent. The model is passed to JAMS for the actual reformulation and solution with a subsolver. The possible reformulation options are `bigM` [big eps threshold], `chull` [big eps], and `indic`. The `indic` setting only works with solver that understand the indicator syntax in a GAMS option file.

Default: `bigM`

**correlationtype (integer):** Sample correlation type

Default: 0

empinfofile (string): Path and name of file containing additional EMP-SP information as randvar, jrandvar, stage etc.

evsubsolver (string): Subsolver to run on expected value problem

evsubsolveropt (integer): Optfile value to pass to the subsolver for expected value problem

Range: \{1, ..., 999\}

Default: 1

jamsopt (string): JAMS option file

maxnodes (integer): Tree size limit

Range: \{1000, ..., \infty\}

Default: 100000

solveEVProb (no value): Solve and report the expected value solution

Default: 0

subsolver (string): Subsolver to run

subsolveropt (integer): Optfile value to pass to the subsolver

Range: \{1, ..., 999\}

Default: 1

svr_ls_antithetic (string): Sample variance reduction map to Lindo Antithetic algorithm

svr_ls_latinsquare (string): Sample variance reduction map to Lindo Latin Square algorithm

svr_ls_montecarlo (string): Sample variance reduction map to Lindo Montecarlo algorithm

varbigm (real): Big M for Value at Risk reformulation

Default: 1000.0
5.13 DECIS

Author
Gerd Infanger; Vienna University of Technology; Stanford University

5.13.1 DECIS

5.13.1.1 Introduction

DECIS is a system for solving large-scale stochastic programs, i.e. programs that include parameters (coefficients and right-hand sides) that are not known with certainty, but are assumed to be known by their probability distribution. It employs Benders decomposition and advanced Monte Carlo sampling techniques. DECIS includes a variety of solution strategies, such as solving the universe problem, the expected value problem, Monte Carlo sampling within the Benders decomposition algorithm, and Monte Carlo pre-sampling. When using Monte Carlo sampling the user has the option of employing crude Monte Carlo without variance reduction techniques, or using as variance reduction techniques importance sampling or control variates, based on either an additive or a multiplicative approximation function. Pre-sampling is limited to using crude Monte Carlo only.

For solving linear and nonlinear programs (master and subproblems arising from the decomposition) DECIS interfaces with MINOS or CPLEX. MINOS, see Murtagh and Saunders (1983) [142], is a state-of-the-art solver for large-scale linear and nonlinear programs, and CPLEX is one of the fastest linear programming solvers available.

For details about the DECIS system consult the DECIS User’s Guide see Infanger (1997) [100]. It includes a comprehensive mathematical description of the methods used by DECIS. In this Guide we concentrate on how to use DECIS directly from GAMS, and especially on how to model stochastic programs using the GAMS/DECIS interface. First, however, in section What DECIS Can Do we give a brief description of what DECIS can do and what solution strategies it uses. This description has been adapted from the DECIS User’s Guide. In section GAMS/DECIS we discuss in detail how to set up a stochastic problem using GAMS/DECIS and give a description of the parameter setting and outputs obtained. In Appendix A - GAMS/DECIS Illustrative Examples we show the GAMS/DECIS formulation of two illustrative examples (APL1P and APL1PC) discussed in the DECIS User’s Guide. A list of DECIS error messages are represented in Appendix B - Error Messages.

5.13.1.2 What DECIS Can Do

DECIS solves two-stage stochastic linear programs with recourse:

\[
\begin{align*}
\min \ z &= cx + Ef^\omega y^\omega \\
\text{s.t} \quad Ax &= b \\
- B^\omega x + D^\omega y^\omega &= d^\omega \\
x, \quad y^\omega &\geq 0, \quad \omega \in \Omega.
\end{align*}
\]

where $x$ denotes the first-stage, $y^\omega$ the second-stage decision variables, $c$ represents the first-stage and $f^\omega$ the second-stage objective coefficients, $A$, $b$ represent the coefficients and right hand sides of the first-stage constraints, and $B^\omega$, $D^\omega$, $d^\omega$ represent the parameters of the second-stage constraints, where the transition matrix $B^\omega$ couples the two stages. In the literature $D^\omega$ is often referred to as the technology matrix or recourse matrix. The first stage parameters are known with certainty. The second stage parameters are random parameters that assume outcomes labeled $\omega$ with probability $p(\omega)$, where $\Omega$ denotes the set of all possible outcome labels.

At the time the first-stage decision $x$ has to be made, the second-stage parameters are only known by their probability distribution of possible outcomes. Later, after $x$ has already been determined, an actual outcome of the second-stage parameters will become known, and the second-stage decision $y^\omega$ is made based on knowledge of the actual outcome $\omega$. The objective is to find a feasible decision $x$ that minimizes the total expected costs, the sum of first-stage costs and expected second-stage costs.

For discrete distributions of the random parameters, the stochastic linear program can be represented by the corresponding equivalent deterministic linear program:

$$\begin{align*}
\min z &= cx + p^1fy^1 + p^2fy^2 + \cdots + p^Wfy^W \\
\text{s/t} & Ax = b \\
& -B^1x + Dy^1 = d^1 \\
& -B^2x + Dy^2 = d^2 \\
& \vdots \\
& -B^Wx + Dy^W = d^W \\
& x, y^1, y^2, \ldots, y^W \geq 0,
\end{align*}$$

which contains all possible outcomes $\omega \in \Omega$. Note that for practical problems $W$ is very large, e.g., a typical number could be $10^{20}$, and the resulting equivalent deterministic linear problem is too large to be solved directly.

In order to see the two-stage nature of the underlying decision making process the following representation is also often used:

$$\begin{align*}
\min cx + E z^\omega(x) \\
Ax &= b \\
x &\geq 0
\end{align*}$$

where

$$z^\omega(x) = \min f^\omega y^\omega$$

$$D^\omega y^\omega = d^\omega + B^\omega x$$

$$y^\omega \geq 0, \omega \in \Omega = \{1, 2, \ldots, W\}.$$
5.13.1.3 Representing Uncertainty

It is favorable to represent the uncertain second-stage parameters in a structure. Using \( V = (V_1, \ldots, V_h) \) an \( h \)-dimensional independent random vector parameter that assumes outcomes \( v^\omega = (v_1^\omega, \ldots, v_h^\omega) \) with probability \( p^\omega = p(v^\omega) \), we represent the uncertain second-stage parameters of the problem as functions of the independent random parameter \( V \):

\[
    f^\omega = f(v^\omega), \quad B^\omega = B(v^\omega), \quad D^\omega = D(v^\omega), \quad d^\omega = d(v^\omega).
\]

Each component \( V_i \) has outcomes \( v_i^\omega, \omega_i \in \Omega_i \), where \( \omega_i \) labels a possible outcome of component \( i \), and \( \Omega_i \) represents the set of all possible outcomes of component \( i \). An outcome of the random vector

\[
    v^\omega = (v_1^\omega, \ldots, v_h^\omega)
\]

consists of \( h \) independent component outcomes. The set

\[
    \Omega = \Omega_1 \times \Omega_2 \times \ldots \times \Omega_h
\]

represents the crossing of sets \( \Omega_i \). Assuming each set \( \Omega_i \) contains \( W_i \) possible outcomes, \( |\Omega_i| = W_i \), the set \( \Omega \) contains \( W = \prod W_i \) elements, where \( |\Omega| = W \) represents the number of all possible outcomes of the random vector \( V \). Based on independence, the joint probability is the product

\[
    p^\omega = p_1^{\omega_1} p_2^{\omega_2} \cdots p_h^{\omega_h}.
\]

Let \( \eta \) denote the vector of all second-stage random parameters, e.g., \( \eta = \text{vec}(f, B, D, d) \). The outcomes of \( \eta \) may be represented by the following general linear dependency model:

\[
    \eta^\omega = \text{vec}(f^\omega, B^\omega, d^\omega, d^\omega) = H v^\omega, \omega \in \Omega
\]

where \( H \) is a matrix of suitable dimensions. DECIS can solve problems with such general linear dependency models.

5.13.1.4 Solving the Universe Problem

We refer to the universe problem if we consider all possible outcomes \( \omega \in \Omega \) and solve the corresponding problem exactly. This is not always possible, because there may be too many possible realizations \( \omega \in \Omega \). For solving the problem DECIS employs Benders decomposition, splitting the problem into a master problem, corresponding to the first-stage decision, and into subproblems, one for each \( \omega \in \Omega \), corresponding to the second-stage decision. The details of the algorithm and techniques used for solving the universe problem are discussed in The DECIS User’s Manual.

Solving the universe problem is referred to as strategy 4. Use this strategy only if the number of universe scenarios is reasonably small. There is a maximum number of universe scenarios DECIS can handle, which depends on your particular resources.
5.13.1.5 Solving the Expected Value Problem

The expected value problem results from replacing the stochastic parameters by their expectation. It is a linear program that can also easily be solved by employing a solver directly. Solving the expected value problem may be useful by itself (for example as a benchmark to compare the solution obtained from solving the stochastic problem), and it also may yield a good starting solution for solving the stochastic problem. DECIS solves the expected value problem using Benders decomposition. The details of generating the expected value problem and the algorithm used for solving it are discussed in the DECIS User's Manual. To solve the expected value problem choose strategy 1.

5.13.1.6 Using Monte Carlo Sampling

As noted above, for many practical problems it is impossible to obtain the universe solution, because the number of possible realizations $|\Omega|$ is way too large. The power of DECIS lies in its ability to compute excellent approximate solutions by employing Monte Carlo sampling techniques. Instead of computing the expected cost and the coefficients and the right-hand sides of the Benders cuts exactly (as it is done when solving the universe problem), DECIS, when using Monte Carlo sampling, estimates the quantities in each iteration using an independent sample drawn from the distribution of the random parameters. In addition to using crude Monte Carlo, DECIS uses importance sampling or control variates as variance reduction techniques.

The details of the algorithm and the different techniques used are described in the DECIS User's Manual. You can choose crude Monte Carlo, referred to as strategy 6, Monte Carlo importance sampling, referred to as strategy 2, or control variates, referred to as strategy 10. Both Monte Carlo importance sampling and control variates have been shown for many problems to give a better approximation compared to employing crude Monte Carlo sampling.

When using Monte Carlo sampling DECIS computes a close approximation to the true solution of the problem, and estimates a close approximation of the true optimal objective value. It also computes a confidence interval within which the true optimal objective of the problem lies, say with 95% confidence. The confidence interval is based on rigorous statistical theory. An outline of how the confidence interval is computed is given in the DECIS User's Manual. The size of the confidence interval depends on the variance of the second-stage cost of the stochastic problem and on the sample size used for the estimation. You can expect the confidence interval to be very small, especially when you employ importance sampling or control variates as a variance reduction technique.

When employing Monte Carlo sampling techniques you have to choose a sample size (set in the parameter file). Clearly, the larger the sample size the better will be the approximate solution DECIS computes, and the smaller will be the confidence interval for the true optimal objective value. The default value for the sample size is 100. Setting the sample size too small may lead to bias in the estimation of the confidence interval, therefore the sample size should be at least 30.

5.13.1.7 Monte Carlo Pre-sampling

We refer to pre-sampling when we first take a random sample from the distribution of the random parameters and then generate the approximate stochastic problem defined by the sample. The obtained approximate problem is then solved exactly using decomposition. This is in contrast to the way we used Monte Carlo sampling in the previous section, where we used Monte Carlo sampling in each iteration of the decomposition.

The details of the techniques used for pre-sampling are discussed in the DECIS User's Manual. DECIS computes the exact solution of the sampled problem using decomposition. This solution is an approximate solution of the original stochastic problem. Besides this approximate solution, DECIS computes an estimate of the expected cost corresponding to this approximate solution and a confidence interval within which the true optimal objective of the original stochastic problem lies with, say, 95% confidence. The
A confidence interval is based on statistical theory, while its size depends on the variance of the second-stage cost of the stochastic problem and on the sample size used for generating the approximate problem. In conjunction with pre-sampling no variance reduction techniques are currently implemented.

Using Monte Carlo pre-sampling you have to choose a sample size. Clearly, the larger the sample size you choose, the better will be the solution DECIS computes, and the smaller will be the confidence interval for the true optimal objective value. The default value for the sample size is 100. Again, setting the sample size too small may lead to a bias in the estimation of the confidence interval, therefore the sample size should be at least 30.

To use Monte Carlo pre-sampling choose strategy 8.

5.13.1.8 Regularized Decomposition

When solving practical problems, the number of Benders iterations can be quite large. In order to control the decomposition, with the hope to reduce the iteration count and the solution time, DECIS makes use of regularization. When employing regularization, an additional quadratic term is added to the objective of the master problem, representing the square of the distance between the best solution found so far (the incumbent solution) and the variable $x$. Using this term, DECIS controls the distance between solutions in successive decomposition iterations.

To enable regularization you have to set the corresponding parameter. You also have to choose the value of the constant rho in the regularization term. The default is regularization disabled. Details of how DECIS carries out regularization are represented in the DECIS User's Manual.

Regularization is only implemented when using MINOS as the optimizer for solving subproblems. Regularization has proven to be helpful for problems that need a large number of Benders iteration when solved without regularization. Problems that need only a small number of Benders iterations without regularization are not expected to improve much with regularization, and may need even more iterations with regularization than without.

5.13.2 GAMS/DECIS

GAMS stands for General Algebraic Modeling Language, and is one of the most widely used modeling languages. Using DECIS directly from GAMS spares you from worrying about all the details of the input formats. It makes the problem formulation much easier but still gives you almost all the flexibility of using DECIS directly.

The link from GAMS to DECIS has been designed in such a way that almost no extensions to the GAMS modeling language were necessary for carrying out the formulation and solution of stochastic programs. In a future release of GAMS, however, additions to the language are planned that will allow you to model stochastic programs in an even more elegant way.

5.13.2.1 Setting up a Stochastic Program Using GAMS/DECIS

The interface from GAMS to DECIS supports the formulation and solution of stochastic linear programs. DECIS solves them using two-stage decomposition. The GAMS/DECIS interface resembles closely the structure of the SMPS (stochastic mathematical programming interface) discussed in the DECIS User's Manual. The specification of a stochastic problem using GAMS/DECIS uses the following components:

- the deterministic (core) model,
- the specification of the decision stages,
- the specification of the random parameters, and
- setting DECIS as the optimizer to be used.
5.13.2.2 Starting with the Deterministic Model

The core model is a deterministic linear program where all random parameters are replaced by their mean or by a particular realization. One could also see it as a GAMS model without any randomness. It could be a deterministic model that you have, that you intend to expand to a stochastic one. Using DECIS with GAMS allows you to easily extend a deterministic linear programming model to a stochastic one. For example, the following GAMS model represents a deterministic version of the electric power expansion planning illustrative example discussed in Infanger (1994).

```
* APL1P test model
* Dr. Gerd Infanger, November 1997
* Deterministic Program

set g generators / g1, g2/;
set dl demand levels /h, m, l/;

parameter alpha(g) availability / g1 0.68, g2 0.64 /;
parameter ccmin(g) min capacity / g1 1000, g2 1000 /;
parameter ccmax(g) max capacity / g1 10000, g2 10000 /;
parameter c(g) investment / g1 4.0, g2 2.5 /;

parameter f(g,dl) operating cost
g1 4.3 2.0 0.5
g2 8.7 4.0 1.0;

parameter d(dl) demand / h 1040, m 1040, l 1040 /;
parameter us(dl) cost of unserved demand / h 10, m 10, l 10 /;

free variable tcost total cost;
positive variable x(g) capacity of generators;
positive variable y(g, dl) operating level;
positive variable s(dl) unserved demand;

equations
cost total cost
cmin(g) minimum capacity
cmax(g) maximum capacity
omax(g) maximum operating level
demand(dl) satisfy demand;

cost .. tcost =e= sum(g, c(g)*x(g))
    + sum(g, sum(dl, f(g,dl)*y(g,dl)))
    + sum(dl,us(dl)*s(dl));

cmin(g) .. x(g) =g= ccmin(g);
cmax(g) .. x(g) =l= ccmax(g);
omax(g) .. sum(dl, y(g,dl)) =l= alpha(g)*x(g);
demand(dl) .. sum(g, y(g,dl)) + s(dl) =g= d(dl);

model apl1p /all/;

option lp=minos;
solve apl1p using lp minimizing tcost;

scalar ccost capital cost;
scalar ocost operating cost;
```
ccost = sum(g, c(g) * x.l(g));
ocost = tcost.l - ccost;
display x.l, tcost.l, ccost, ocost, y.l, s.l;

5.13.2.3 Setting the Decision Stages

Next in order to extend a deterministic model to a stochastic one you must specify the decision stages. DECIS solves stochastic programs by two-stage decomposition. Accordingly, you must specify which variables belong to the first stage and which to the second stage, as well as which constraints are first-stage constraints and which are second-stage constraints. First stage constraints involve only first-stage variables, while second-stage constraints involve both first- and second-stage variables. You must specify the stage of a variable or a constraint by setting the stage suffix ".STAGE" to either one or two depending on if it is a first or second stage variable or constraint. For example, expanding the illustrative model above by

* setting decision stages
x.stage(g) = 1;
y.stage(g, dl) = 2;
s.stage(dl) = 2;
cmin.stage(g) = 1;
cmax.stage(g) = 1;
omax.stage(g) = 2;
demand.stage(dl) = 2;
would make x(g) first-stage variables, y(g, dl) and s(dl) second-stage variables, cmin(g) and cmax(g) first-stage constraints, and omax(g) and demand(g) second-stage constraints. The objective is treated separately, you don’t need to set the stage suffix for the objective variable and objective equation.

Note that the use of the .stage variable and equation suffix causes the GAMS scaling facility (i.e. the .scale suffix) to be unavailable. Stochastic models have to be scaled manually.

5.13.2.4 Specifying the Stochastic Model

DECIS supports any linear dependency model, i.e., the outcomes of an uncertain parameter in the linear program are a linear function of a number of independent random parameter outcomes. DECIS considers only discrete distributions: you must approximate any continuous distributions by discrete ones. The number of possible realizations of the discrete random parameters determines the accuracy of the approximation. A special case of a linear dependency model arises when you have only independent random parameters in your model. In this case the independent random parameters are mapped one to one into the random parameters of the stochastic program. We will present the independent case first and then expand to the case with linear dependency. According to setting up a linear dependency model we present the formulation in GAMS by first defining independent random parameters and then defining the distributions of the uncertain parameters in your model.

5.13.2.4.1 Specifying Independent Random Parameters

There are of course many different ways you can set up independent random parameters in GAMS. In the following we show one possible way that is generic and thus can be adapted for different models. The set-up uses the set stoch for labeling outcome named "out" and probability named "pro" of each independent random parameter. In the following we show how to define an independent random parameter, say, v1. The formulation uses the set omegal1 as driving set, where the set contains one element for each possible realization the random parameter can assume. For example, the set omegal1 has four elements according to a discrete distribution of four possible outcomes. The distribution of the random parameter is defined as the parameter v1, a two-dimensional array of outcomes "out" and corresponding probability "pro" for each of the possible
realizations of the set omega1, "o11", "o12", "o13", and "o14". For example, the random parameter v1 has outcomes of $-1.0, -0.9, -0.5, -0.1$ with probabilities $0.2, 0.3, 0.4, 0.1$, respectively. Instead of using assignment statements for inputting the different realizations and corresponding probabilities you could also use the table statement. Always make sure that the sum of the probabilities of each independent random parameter adds to one.

* defining independent stochastic parameters
set stoch /out, pro /;
set omega1 / o11, o12, o13, o14 /;

\[
\begin{array}{cccc}
\text{out} & -1.0 & -0.9 & -0.5 & -0.1 \\
\text{pro} & 0.2 & 0.3 & 0.4 & 0.1 \\
\end{array}
\]

Random parameter v1 is the first out of five independent random parameters of the illustrative model APL1P, where the first two represent the independent availabilities of the generators g1 and g2 and the latter three represent the independent demands of the demand levels h, m, and l. We also represent the definitions of the remaining four independent random parameters. Note that random parameters v3, v4, and v5 are identically distributed.

set omega2 / o21, o22, o23, o24, o25 /;

\[
\begin{array}{cccc}
\text{out} & -1.0 & -0.9 & -0.7 & -0.1 & -0.0 \\
\text{pro} & 0.1 & 0.2 & 0.5 & 0.1 & 0.1 \\
\end{array}
\]

set omega3 / o31, o32, o33, o34 /;

\[
\begin{array}{cccc}
\text{out} & 900 & 1000 & 1100 & 1200 \\
\text{pro} & 0.15 & 0.45 & 0.25 & 0.15 \\
\end{array}
\]

set omega4 / o41, o42, o43, o44 /;

\[
\begin{array}{cccc}
\text{out} & 900 & 1000 & 1100 & 1200 \\
\text{pro} & 0.15 & 0.45 & 0.25 & 0.15 \\
\end{array}
\]

set omega5 / o51, o52, o53, o54 /;

\[
\begin{array}{cccc}
\text{out} & 900 & 1000 & 1100 & 1200 \\
\text{pro} & 0.15 & 0.45 & 0.25 & 0.15 \\
\end{array}
\]

5.13.2.4.2 Defining the Distributions of the Uncertain Parameters in the Model Having defined the independent stochastic parameters (you may copy the setup above and adapt it for your model), we next define the stochastic parameters in the GAMS model. The stochastic parameters of the...
model are defined by writing a file, the GAMS stochastic file, using the put facility of GAMS. The GAMS stochastic file resembles closely the stochastic file of the SMPS input format. The main difference is that we use the row, column, bounds, and right hand side names of the GAMS model and that we can write it in free format.

**Independent Stochastic Parameters**

First we describe the case where all stochastic parameters in the model are independent, see below the representation of the stochastic parameters for the illustrative example APL1P, which has five independent stochastic parameters.

First define the GAMS stochastic file "MODEL.STG" (only the exact name in uppercase letters is supported) and set up GAMS to write to it. This is done by the first two statements. You may want to consult the GAMS manual for how to use put for writing files. The next statement "INDEP DISCRETE" indicates that a section of independent stochastic parameters follows. We then write all possible outcomes and corresponding probabilities for each stochastic parameter by using loop statements. Of course one could also write each line separately, but the loops work nicely. Writing a "*" between the definitions of the independent stochastic parameters is merely for optical reasons and can be omitted.

```gams
* defining distributions (writing file MODEL.STG)
file stg /MODEL.STG/;
put stg;

put "INDEP DISCRETE" /;
loop(omega1,
    put "x g1 omax g1 ", v1("out", omega1), " period2 ", v1("pro", omega1)/;
    put "*" /;
)

loop(omega2,
    put "x g2 omax g2 ", v2("out", omega2), " period2 ", v2("pro", omega2)/;
    put "*" /;
)

loop(omega3,
    put "RHS demand h ", v3("out", omega3), " period2 ", v3("pro", omega3)/;
    put "*" /;
)

loop(omega4,
    put "RHS demand m ", v4("out", omega4), " period2 ", v4("pro", omega4)/;
    put "*" /;
)

loop(omega5,
    put "RHS demand l ", v5("out", omega5), " period2 ", v5("pro", omega5)/;
)
putclose stg;
```

In the example APL1P the first stochastic parameter is the availability of generator g1. In the model the parameter appears as the coefficient of variable x(g1) in equation omax(g1). The definition using the put statement first gives the stochastic parameter as the intersection of variable x(g1) with equation omax(g1), but without having to type the braces, thus `x g1 omax g1`, then the outcome `v1("out", omega1)` and the probability `v1("pro", omega1)` separated by "period2". The different elements of the statement must be separated by blanks. Since the outcomes and probabilities of the first stochastic parameters are driven by the set omega1 we loop over all elements of the set omega1. We continue and define all possible outcomes for each of the five independent stochastic parameters.

In the example of independent stochastic parameters, the specification of the distribution of the stochastic parameters using the put facility creates the following file "MODEL.STG", which then is processed by the GAMS/DECIS interface:
For defining stochastic parameters in the right-hand side of the model use the keyword `RHS` as the column name, and the equation name of the equation which right-hand side is uncertain, see for example the specification of the uncertain demands `RHS demand h`, `RHS demand m`, and `RHS demand l`. For defining uncertain bound parameters you would use the keywords `UP`, `LO`, or `FX`, the string `bnd`, and the variable name of the variable whose upper, lower, or fixed bound is uncertain.

Note all the keywords for the definitions are in capital letters, i.e., "INDEP DISCRETE", "RHS", and not represented in the example "UP", "LO", and "FX".

Note that in GAMS equations, variables may appear in the right-hand side, e.g. "EQ.. X+1 =L= 2*Y". When the coefficient 2 is a random variable, we need to be aware that GAMS will generate the following LP row `X - 2*Y =L= -1`. Suppose the probability distribution of this random variable is given by:

```plaintext
set s scenario /pessimistic, average, optimistic/;
parameter outcome(s) / pessimistic 1.5 average 2.0 optimistic 2.3 /;
parameter prob(s) / pessimistic 0.2 average 0.6 optimistic 0.2 /;
```

then the correct way of generating the entries in the stochastic file would be:

```plaintext
loop(s,
   put "Y EQ ",(-outcome(s))," PERIOD2 ",prob(s)/;
);
```

Note the negation of the outcome parameter. Also note that expressions in a PUT statement have to be surrounded by parentheses. GAMS reports in the row listing section of the listing file how equations are generated. You are encouraged to inspect the row listing to discover or confirm how coefficients appear in a generated LP row.
5.13.2.4.3 Dependent Stochastic Parameters  
Next we describe the case of general linear dependency of the stochastic parameters in the model, see below the representation of the stochastic parameters for the illustrative example APL1PCA, which has three dependent stochastic demands driven by two independent stochastic random parameters. First we give the definition of the two independent stochastic parameters, which in the example happen to have two outcomes each.

* defining independent stochastic parameters
set stoch /out, pro/;
set omega1 / o11, o12 /;
table v1(stoch,omega1)
  o11  o12
  out  2.1  1.0
  pro  0.5  0.5;
set omega2 / o21, o22 /;
table v2(stoch, omega2)
  o21  o22
  out  2.0  1.0
  pro  0.2  0.8;

We next define the parameters of the transition matrix from the independent stochastic parameters to the dependent stochastic parameters of the model. We do this by defining two parameter vectors, where the vector $hm1$ gives the coefficients of the independent random parameter $v1$ in each of the three demand levels and the vector $hm2$ gives the coefficients of the independent random parameter $v2$ in each of the three demand levels.

```plaintext
parameter hm1(dl) / h 300., m 400., l 200. /;
parameter hm2(dl) / h 100., m 150., l 300. /;
```

Again first define the GAMS stochastic file "MODEL.STG" and set GAMS to write to it. The statement BLOCKS DISCRETE indicates that a section of linear dependent stochastic parameters follows.

* defining distributions (writing file MODEL.STG)
file stg / MODEL.STG /;
put stg;
loop(omega1,
  put "BL v1 period2 ", v1("pro", omega1) /;
  loop(dl,
    h1 = hm1(dl) * v1("out", omega1);
    put "RHS demand ", dl.tl:1, " ", h1 /;
  );
);
loop(omega2,
  put "BL v2 period2 ", v2("pro", omega2) /;
  loop(dl,
    h1 = hm2(dl) * v2("out", omega2);
    put "RHS demand ", dl.tl:1, " ", h1 /;
  );
);
putclose stg;
```
Dependent stochastic parameters are defined as functions of independent random parameters. The keyword \texttt{BL} labels a possible realization of an independent random parameter. The name besides the \texttt{BL} keyword is used to distinguish between different outcomes of the same independent random parameter or a different one. While you could use any unique names for the independent random parameters, it appears natural to use the names you have already defined above, e.g., $v_1$ and $v_2$. For each realization of each independent random parameter define the outcome of every dependent random parameter (as a function of the independent one). If a dependent random parameter in the GAMS model depends on two or more different independent random parameters the contributions of each of the independent parameters are added. We are therefore in the position to model any linear dependency model. (Note that the class of models that can be accommodated here is more general than linear. The functions, with which an independent random variable contributes to the dependent random variables can be any ones in one argument. As a general rule, any stochastic model that can be estimated by linear regression is supported by GAMS/DECIS.)

Define each independent random parameter outcome and the probability associated with it. For example, the statement starting with \texttt{BL $v_1$ period2} indicates that an outcome of (independent random parameter) $v_1$ is being defined. The name \texttt{period2} indicates that it is a second-stage random parameter, and $v_1(”pro”, \omega_1)$ gives the probability associated with this outcome. Next list all random parameters dependent on the independent random parameter outcome just defined. Define the dependent stochastic parameter coefficients by the GAMS variable name and equation name, or "RHS" and variable name, together with the value of the parameter associated with this realization. In the example, we have three dependent demands. Using the scalar $h_1$ for intermediately storing the results of the calculation, looping over the different demand levels $dl$ we calculate $h_1 = h m_1(dl) \times v_1(”out$, $\omega_1)$ and define the dependent random parameters as the right-hand sides of equation $demand(dl)$.

When defining an independent random parameter outcome, if the block name is the same as the previous one (e.g., when \texttt{BL $v_1$} appears the second time), a different outcome of the same independent random parameter is being defined, while a different block name (e.g., when \texttt{BL $v_2$} appears the first time) indicates that the first outcome of a different independent random parameter is being defined. You must ensure that the probabilities of the different outcomes of each of the independent random parameters add up to one. The loop over all elements of $\omega_1$ defines all realizations of the independent random parameter $v_1$ and the loop over all elements of $\omega_2$ defines all realizations of the independent random parameter $v_2$.

Note that for the first realization of an independent random parameter, you must define all dependent parameters and their realizations. The values entered serve as a base case. For any other realization of an independent random parameter you only need to define the dependent parameters that have different coefficients than have been defined in the base case. For those not defined in a particular realization, their values of the base case are automatically added.

In the example of dependent stochastic parameters above, the specification of the distribution of the stochastic parameters using the put facility creates the following file "MODEL.STG", which then is processed by the GAMS/DECIS interface:

\begin{verbatim}
BLOCKS DISCRETE
BL v1 period2 0.50
RHS demand h  630.00
RHS demand m  840.00
RHS demand l  420.00
BL v1 period2 0.50
RHS demand h  300.00
RHS demand m  400.00
RHS demand l  200.00
BL v1 period2 0.50
RHS demand h  200.00
RHS demand m  300.00
RHS demand l  600.00
BL v2 period2 0.80
RHS demand h  100.00
RHS demand m  150.00
RHS demand l  300.00
\end{verbatim}
Again all the keywords for the definitions are in capital letters, i.e., "BLOCKS DISCRETE", "BL", "RHS", and not represented in the example "UP", "LO", and "FX".

Note that you can only define random parameter coefficients that are nonzero in your GAMS model. When setting up the deterministic core model put a nonzero entry as a placeholder for any coefficient that you wish to specify as a stochastic parameter. Specifying a random parameter at the location of a zero coefficient in the GAMS model causes DECIS to terminate with an error message.

5.13.2.5 Setting DECIS as the Optimizer

After having finished the stochastic definitions you must set DECIS as the optimizer. This is done by issuing the following statements:

* setting DECIS as optimizer
* DECISM uses MINOS, DECISC uses CPLEX

```
option lp=decism;
aplp.optfile = 1;
```

The statement `option lp = decism` sets DECIS with the MINOS LP engine as the optimizer to be used for solving the stochastic problem. Note that if you do not use DECIS, but instead use any other linear programming optimizer, your GAMS model will still run and optimize the deterministic core model that you have specified. The statement `apl1p.optfile = 1` directs GAMS to process the file `DECIS.OPT`, in which you may define any DECIS parameters.

5.13.2.5.1 Setting Parameter Options in the GAMS Model  The options iteration limit and resource limit can be set directly in your GAMS model file. For example, the following statements

```
option iterlim = 1000;
option reslim = 6000;
```

limit the number of decomposition iterations to be less than or equal to 1000, and the elapsed time for running DECIS to be less than or equal to 6000 seconds or 100 minutes.

5.13.2.5.2 Setting Parameters in the DECIS Options File  In the DECIS options file you can specify parameters regarding the solution algorithm used and control the output of the DECIS program. There is a record for each parameter you want to specify. Each record consists of the value of the parameter you want to specify and the keyword identifying the parameter, separated by a blank character or a comma. You may specify parameters with the following keywords: istrat, nsamples, nzrows, iwrite, ibug, iscratch, irog, rho, tolben, and tolw in any order. Each keyword can be specified in lower case or upper case text in the format (A10). Since DECIS reads the records in free format you don't have to worry about the format, but some computers require that the text is inputted in quotes. Parameters that are not specified in the parameter file automatically assume their default values. See details of these parameters from Section Description of GAMS/DECIS Options.

5.13.2.5.3 Example  In the following example the parameters istrat = 7, nsamples = 200, and nzrows = 200 are specified. All other parameters are set at their default values. DECIS first solves the expected value problem and then the stochastic problem using crude Monte Carlo sampling with a sample size of nsamples = 200. DECIS reserves space for a maximum of nzrows = 50 cuts.

```
7     "ISTRAT"
200   "NSAMPLES"
50    "NZROWS"
```
5.13.2.5.4 Setting MINOS Parameters in the MINOS Specification File  When you use MINOS as the optimizer for solving the master and the subproblems, you must specify optimization parameters in the MINOS specification file "MINOS.SPC". Each record of the file corresponds to the specification of one parameter and consists of a keyword and the value of the parameter in free format. Records having a "*" as their first character are considered as comment lines and are not further processed. For a detailed description of these parameters, see the MINOS Users' Guide (Murtagh and Saunders (1983) [142]). The following parameters should be specified with some consideration:

- **AIJ TOLERANCE** — Specifies the nonzero tolerance for constraint matrix elements of the problem. Matrix elements \(a_{ij}\) that have a value for which \(|a_{ij}|\) is less than "AIJ TOLERANCE" are considered by MINOS as zero and are automatically eliminated from the problem. It is wise to specify "AIJ TOLERANCE 0.0"

- **SCALE** — Specifies MINOS to scale the problem ("SCALE YES") or not ("SCALE NO"). It is wise to specify "SCALE NO".

- **ROWS** — Specifies the number of rows in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "ROWS" should be specified as the number of constraints in the core problem or greater.

- **COLUMNS** — Specifies the number of columns in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "COLUMNS" should be specified as the number of variables in the core problem or greater.

- **ELEMENTS** — Specifies the number of nonzero matrix coefficients in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "ELEMENTS" should be specified as the number of nonzero matrix coefficients in the core problem or greater.

5.13.2.5.5 Example  The following example represents typical specifications for running DECIS with MINOS as the optimizer.

```
BEGIN SPECS
PRINT LEVEL 1
LOG FREQUENCY 10
SUMMARY FREQUENCY 10
MPS FILE 12
ROWS 20000
COLUMNS 50000
ELEMENTS 100000
ITERATIONS LIMIT 30000
* FACTORIZATION FREQUENCY 100
AIJ TOLERANCE 0.0
* SCALE NO
END OF SPECS
```

5.13.2.5.6 Setting CPLEX Parameters Using System Environment Variables  When you use CPLEX as the optimizer for solving the master and the subproblems, optimization parameters must be specified through system environment variables. You can specify the parameters "CPLEXLICDIR", "SCALELP", "NOPRESOLVE", "ITERLOG", "OPTIMALITYTOL", "FEASIBILIITYTOL", and "DUALSIMPLEX".

- **CPLEXLICDIR** — Contains the path to the CPLEX license directory. For example, on a Unix system with the CPLEX license directory in /usr/users/cplex/cplexlicdir you issue the command `setenv CPLEXLICDIR /usr/users/cplex/cplexlicdir`. 
• SCALELP — Specifies CPLEX to scale the master and subproblems before solving them. If the environment variable is not set no scaling is used. Setting the environment variable, e.g., by issuing the command `setenv SCALELP yes`, scaling is switched on.

• NOPRESOLVE — Allows to switch off CPLEX’s presolver. If the environment variable is not set, presolve will be used. Setting the environment variable, e.g., by setting `setenv NOPRESOLVE yes`, no presolve will be used.

• ITERLOG — Specifies the iteration log of the CPLEX iterations to be printed to the file “MODEL.CPX”. If you do not set the environment variable no iteration log will be printed. Setting the environment variable, e.g., by setting `setenv ITERLOG yes`, the CPLEX iteration log is printed.

• OPTIMALITYTOL — Specifies the optimality tolerance for the CPLEX optimizer. If you do not set the environment variable the CPLEX default values are used. For example, setting `setenv OPTIMALITYTOL 1.0E-7` sets the CPLEX optimality tolerance to 0.0000001.

• FEASIBILITYTOL — Specifies the feasibility tolerance for the CPLEX optimizer. If you do not set the environment variable the CPLEX default values are used. For example, setting `setenv FEASIBILITYTOL 1.0E-7` sets the CPLEX optimality tolerance to 0.0000001.

• DUALSIMPLEX — Specifies the dual simplex algorithm of CPLEX to be used. If the environment variable is not set the primal simplex algorithm will be used. This is the default and works beautifully for most problems. If the environment variable is set, e.g., by setting `setenv DUALSIMPLEX yes`, CPLEX uses the dual simplex algorithm for solving both master and subproblems.

5.13.2.6 GAMS/DECIS Output

After successfully having solved a problem, DECIS returns the objective, the optimal primal and optimal dual solution, the status of variables (if basic or not), and the status of equations (if binding or not) to GAMS. In the case of first-stage variables and equations you have all information available in GAMS, as you would with any other solver, but instead of obtaining the optimal values for a deterministic core problem you actually have the optimal values for the stochastic problem. However, for second-stage variables and constraints the expected values of the optimal primal and optimal dual solution are reported. This saves space and is useful for the calculation of risk measures. However, the information as to what the optimal primal and dual solutions were in the different scenarios of the stochastic programs is not reported back to GAMS. In a future release of the GAMS/DECIS interface the GAMS language is planned to be extended to handle the scenario second-stage optimal primal and dual values at least for selected variables and equations.

While running, DECIS outputs important information about the progress of the execution to your computer screen. After successfully solving a problem, DECIS also outputs its optimal solution to the solution output file ”MODEL.SOL”. The debug output file ”MODEL.SCR” contains important information about the optimization run, and the optimizer output files ”MODEL.MO” (when using DECIS with MINOS) or ”MODEL.CPX” (when using DECIS with CPLEX) contain solution output from the optimizer used. In the DECIS User’s Guide you find a detailed discussion of how to interpret the screen output, the solution report and the information in the output files.

5.13.2.6.1 The Screen Output  The output to the screen allows you to observe the progress of a DECIS run. After the program logo and the copyright statement, you see four columns of output being written to the screen as long as the program proceeds. The first column (from left to right) represents the iteration count, the second column the lower bound (the optimal objective of the master problem), the third column the best upper bound (exact value or estimate of the total expected cost of the best solution found so far), and the fourth column the current upper bound (exact value or estimate of the total expected cost of current solution). After successful completion, DECIS quits with ”Normal Exit”, otherwise, if an error has been encountered, the programs stops with the message ”Error Exit”. 
5.13.2.6.2 Example  When solving the illustrative example APL1P using strategy 5, we obtain the following report on the screen:

```

```

Normal Exit

5.13.2.6.3 The Solution Output File  The solution output file contains the solution report from the DECIS run. Its name is "MODEL.SOL". The file contains the best objective function value found, the corresponding values of the first-stage variables, the corresponding optimal second-stage cost, and a lower and an upper bound on the optimal objective of the problem. In addition, the number of universe scenarios and the settings for the stopping tolerance are reported. In the case of using a deterministic strategy for solving the problem, exact values are reported. When using Monte Carlo sampling, estimated values, their variances, and the sample size used for the estimation are reported. Instead of exact upper and lower bounds, probabilistic upper and lower bounds, and a 95% confidence interval, within which the true optimal solution lies with 95% confidence, are reported. A detailed description of the solution output file can be found in the DECIS User's Guide.

5.13.2.6.4 The Debug Output File  The debug output file contains the standard output of a run of DECIS containing important information about the problem, its parameters, and its solution. It also contains any error messages that may occur during a run of DECIS. In the case that DECIS does not complete a run successfully, the cause of the trouble can usually be located using the information in the debug output file. If the standard output does not give enough information you can set the debug parameter ibug in the parameter input file to a higher value and obtain additional debug output. A detailed description of the debug output file can be found in the DECIS User's Guide.

5.13.2.6.5 The Optimizer Output Files  The optimizer output file "MODEL.MO" contains all the output from MINOS when called as a subroutine by DECIS. You can specify what degree of detail should be outputted by setting the appropriate "PRINT LEVEL" in the MINOS specification file. The optimizer output file "MODEL.CPX" reports messages and the iteration log (if switchwd on using the environment variable) from CPLEX when solving master and sub problems.

5.13.5 Appendix B - Error Messages

1. **ERROR in MODEL.STO: kwd, word1, word2 was not matched in first realization of block**
The specification of the stochastic parameters is incorrect. The stochastic parameter has not been specified in the specification of the first outcome of the block. When specifying the first outcome of a block always include all stochastic parameters corresponding to the block.

2. **Option word1 word2 not supported**
You specified an input distribution in the stochastic file that is not supported. Check the DECIS manual for supported distributions.

3. **Error in time file**
The time file is not correct. Check the file MODEL.TIM. Check the DECIS manual for the form of the time file.

4. **ERROR in MODEL.STO: stochastic RHS for objective, row name2**
The specification in the stochastic file is incorrect. You attempted to specify a stochastic right-hand side for the objective row (row name2). Check file MODEL.STO.

5. **ERROR in MODEL.STO: stochastic RHS in master, row name2**
The specification in the stochastic file is incorrect. You attempted to specify a stochastic right-hand side for the master problem (row name2). Check file MODEL.STO.

6. **ERROR in MODEL.STO: col not found, name1**
The specification in the stochastic file is incorrect. The entry in the stochastic file, name1, is not found in the core file. Check file MODEL.STO.

7. **ERROR in MODEL.STO: invalid col/row combination, (name1/name2)**
The stochastic file (MODEL.STO) contains an incorrect specification.

8. **ERROR in MODEL.STO: no nonzero found (in B or D matrix) for col/row (name1, name2)**
There is no nonzero entry for the combination of name1 (col) and name2(row) in the B-matrix or in the D-matrix. Check the corresponding entry in the stochastic file (MODEL.STO). You may want to include a nonzero coefficient for (col/row) in the core file (MODEL.COR).

9. **ERROR in MODEL.STO: col not found, name2**
The column name you specified in the stochastic file (MODEL.STO) does not exist in the core file (MODEL.COR). Check the file MODEL.STO.

10. **ERROR in MODEL.STO: stochastic bound in master, col name2**
You specified a stochastic bound on first-stage variable name2. Check file MODEL.STO.

11. **ERROR in MODEL.STO: invalid bound type (kwd) for col name2**
The bound type, kwd, you specified is invalid. Check file MODEL.STO.

12. **ERROR in MODEL.STO: row not found, name2**
The specification in the stochastic file is incorrect. The row name, name2, does not exist in the core file. Check file MODEL.STO.

13. **ERROR: problem infeasible**
The problem solved (master- or subproblem) turned out to be infeasible. If a subproblem is infeasible, you did not specify the problem as having the property of "complete recourse". Complete recourse means that whatever first-stage decision is passed to a subproblem, the subproblem will have a feasible solution. It is the best way to specify a problem, especially if you use a sampling based solution strategy. If DECIS encounters a feasible subproblem, it adds a feasibility cut and continues the execution. If DECIS encounters an infeasible master problem, the problem you specified is infeasible, and DECIS terminates. Check the problem formulation.

14. **ERROR: problem unbounded**
The problem solved (master- or subproblem) turned out to be unbounded. Check the problem formulation.
15. ERROR: error code: inform
   The solver returned with an error code from solving the problem (master- or subproblem). Consult
   the users' manual of the solver (MINOS or CPLEX) for the meaning of the error code, inform.
   Check the problem formulation.

16. ERROR: while reading SPECS file
   The MINOS specification file (MINOS.SPC) contains an error. Check the specification file. Consult
   the MINOS user's manual.

17. ERROR: reading mps file, mpsfile
   The core file mpsfile (i.e., MODEL.COR) is incorrect. Consult the DECIS manual for instructions
   regarding the MPS format.

18. ERROR: row 1 of problem is not a free row
   The first row of the problem is not a free row (i.e., is not the objective row). In order to make
   the first row a free row, set the row type to be 'N'. Consult the DECIS manual for the MPS specification
   of the problem.

19. ERROR: name not found = nam1, nam2
   There is an error in the core file (MODEL.COR). The problem cannot be decomposed correctly.
   Check the core file and check the model formulation.

20. ERROR: matrix not in staircase form
   The constraint matrix of the problem as specified in core file (MODEL.COR) is not in staircase
   form. The first-stage rows and columns and the second-stage rows and columns are mixed within
   each other. Check the DECIS manual as to how to specify the core file. Check the core file and
   change the order of rows and columns.
5.13.6   DECIS License and Warranty

5.14 DICOPT

5.14.1 Introduction

DICOPT is a program for solving mixed-integer nonlinear programming (MINLP) problems that involve
linear binary or integer variables and linear and nonlinear continuous variables. While the modeling
and solution of MINLP optimization problems has not yet reached the stage of maturity and reliability
achieved by linear, integer, or non-linear programming modeling, these problems still have rich areas
of application. For example, they often arise in engineering design, management sciences, and finance.
DICOPT (DIscrete and Continuous OPTimizer) was originally developed by Jagadisan Viswanathan, Ignacio
E. Grossmann, and Aldo Vecchietti at the Engineering Design Research Center (EDRC) at Carnegie
Mellon University. Currently, DICOPT is maintained by GAMS. The program is based on the extensions
of the outer-approximation algorithm for the equality relaxation strategy. The MINLP algorithm inside
DICOPT solves a series of NLP and MIP sub-problems. These sub-problems can be solved using any NLP
(Nonlinear Programming) or MIP (Mixed-Integer Programming) solver that runs under GAMS. The
performance will heavily depend on the choice of the selected subsolvers.

Although the algorithm has provisions to handle non-convexities, it does not necessarily obtain the global
optimum.

The GAMS/DICOPT system has been designed with two main goals in mind:

• to build on existing modeling concepts, introduce a minimum of extensions to the existing modeling
language, and provide upward compatibility to ensure easy transition from existing modeling
applications to nonlinear mixed-integer formulations

• to use existing optimizers to solve the DICOPT sub-problems. This allows one to match the best
algorithms to the problem at hand and guarantees that any new development and enhancements in
the NLP and MIP solvers become automatically and immediate available to DICOPT.

5.14.2 Requirements

In order to use DICOPT you will need to have access to a licensed GAMS BASE system as well as at least
one licensed MIP solver and one licensed NLP solver. For difficult models it is advisable to also have
access to multiple solvers.
5.14 DICOPT

5.14.3 How to Run a Model with GAMS/DICOPT

DICOPT is only able to solve MINLP and MIQCP models. If you did not specify DICOPT as the default solver you can use the following statement in your GAMS model:

```
option minlp = dicopt;
```

This should appear before the solve statement. DICOPT automatically uses the default MIP and NLP solver to solve its sub-problems. One can override this with GAMS statements like:

```
option nlp = conopt;  { or any other nlp solver }
option mip = gurobi;  { or any other mip solver }
```

These options can also be specified on the command line:

```
> gams mymodel minlp=dicopt nlp=conopt mip=gurobi
```

In the Integrated Development Environment (IDE) the command line option can be specified in the edit line in the right upper corner of the main window.

Possible NLP solvers include conopt, ipopt, knitro, minos, and snopt. Possible MIP solvers include cplex, gurobi, and xpress.

With an option file it is even possible to use alternate solvers in different cycles. Section DICOPT Options explains this is in detail.

5.14.4 Overview of DICOPT

DICOPT solves models of the form:

\[
\begin{align*}
\text{min or max} & \quad f(x, y) \\
\text{subject to} & \quad g(x, y) \sim b \\
& \quad \ell_x \leq x \leq u_x \\
& \quad y \in [\ell_y], \ldots, [u_y]
\end{align*}
\]

(MINLP)

where \(x\) are the continuous variables and \(y\) are the discrete variables. The symbol \(~\) is used to denote a vector of relational operators \({\leq, =, \geq}\). The constraints can be either linear or non-linear. Bounds \(\ell\) and \(u\) on the variables are handled directly. \([x]\) indicates the smallest integer, greater than or equal to \(x\). Similarly, \([x]\) indicates the largest integer, less than or equal to \(x\). The discrete variables can be either integer variables or binary variables.
5.14.5 The Algorithm

The algorithm in DICOPT is based on three key ideas:

- Outer Approximation
- Equality Relaxation
- Augmented Penalty

Outer Approximation refers to the fact that the surface described by a convex function lies above the tangent hyper-plane at any interior point of the surface. (In 1-dimension, the analogous geometrical result is that the tangent to a convex function at an interior point lies below the curve). In the algorithm outer-approximations are attained by generating linearizations at each iterations and accumulating them in order to provide successively improved linear approximations of nonlinear convex functions that underestimate the objective function and overestimate the feasible region.

Equality Relaxation is based on the following result from non-linear programming. Suppose the MINLP problem is formulated in the form:

\[
\begin{align*}
\text{minimize or maximize} & \quad f(x) + c^T y \\
\text{subject to} & \quad G(x) + H y \sim b \\
& \quad \ell \leq x \leq u \\
& \quad y \in \{0,1\}
\end{align*}
\]

i.e. the discrete variables are binary variables and they appear linearly in the model.

Let \( y^{(0)} \) be any fixed binary vector and let \( x^{(0)} \) be the solution of the corresponding NLP subproblem:

\[
\begin{align*}
\text{minimize} & \quad c^T y^{(0)} + f(x) \\
\text{subject to} & \quad A y^{(0)} + h(x) = 0 \\
& \quad B y^{(0)} + g(x) \leq 0 \\
& \quad \ell \leq x \leq u
\end{align*}
\]

Further let

\[
\begin{align*}
T^{(0)} &= \text{diag}(t_{i,i}) \\
t_{i,i} &= \text{sign}(\lambda_i)
\end{align*}
\]

where \( \lambda_i \) is the Lagrange multiplier of the \( i \)-th equality constraint.

If \( f \) is pseudo-convex, \( h \) is quasi-convex, and \( g \) is quasi-convex, then \( x^0 \) is also the solution of the following NLP:

\[
\begin{align*}
\text{minimize} & \quad c^T y^{(0)} + f(x) \\
\text{subject to} & \quad T^{(0)}(A y^{(0)} + h(x)) \leq 0 \\
& \quad B y^{(0)} + g(x) \leq 0 \\
& \quad \ell \leq x \leq u
\end{align*}
\]

In colloquial terms, under certain assumptions concerning the convexity of the nonlinear functions, an equality constraint can be relaxed to be an inequality constraint. This property is used in the MIP master problem to accumulate linear approximations.
Augmented Penalty refers to the introduction of (non-negative) slack variables on the right hand sides of the just described inequality constraints and the modification of the objective function when assumptions concerning convexity do not hold.

The algorithm underlying DICOPT starts by solving the NLP in which the 0-1 conditions on the binary variables are relaxed. If the solution to this problem yields an integer solution the search stops. Otherwise, it continues with an alternating sequence of nonlinear programs (NLP) called subproblems and mixed-integer linear programs (MIP) called master problems. The NLP subproblems are solved for fixed 0-1 variables that are predicted by the MIP master problem at each (major) iteration. For convex problems the master problem also provides a lower bound on the objective function. This lower bound (in the case of minimization) increases monotonically as iterations proceed due to the accumulation of linear approximations. Note that in the case of maximization this bound is an upper bound which can be used as a stopping criterion through a DICOPT option stop 1 (see section DICOPT Options). Another stopping criterion that tends to work very well for non-convex problems (and even for convex problems) is based on the heuristic: stop as soon as the NLP subproblems start worsening (i.e. the current NLP subproblem has an optimal objective function that is worse than the previous NLP subproblem). This stopping criterion relies on the use of the augmented penalty, and is used in the description of the algorithm below. This is also the default stopping criterion in the implementation of DICOPT. The algorithm can be stated briefly as follows:

1. Solve the NLP relaxation of the MINLP program. If \( y^{(0)} = y \) is integer, stop(integer optimum found). Else continue with step 2.

2. Find an integer point \( y^{(1)} \) with an MIP master problem that features an augmented penalty function to find the minimum over the convex hull determined by the half-spaces at the solution \( (x^{(0)}, y^{(0)}) \).

3. Fix the binary variables \( y = y^{(1)} \) and solve the resulting NLP. Let \( (x^{(1)}, y^{(1)}) \) be the corresponding solution.

4. Find an integer solution \( y^{(2)} \) with a MIP master problem that corresponds to the minimization over the intersection of the convex hulls described by the half-spaces of the KKT points at \( y^{(0)} \) and \( y^{(1)} \).

5. Repeat steps 3 and 4 until there is an increase in the value of the NLP objective function. (Repeating step 4 means augmenting the set over which the minimization is performed with additional linearizations - i.e. half-spaces - at the new KKT point).

In the MIP problems integer cuts are added to the model to exclude previously determined integer vectors \( y^{(1)}, y^{(2)}, ..., y^{(K)} \).

For a detailed description of the theory and references to earlier work, see [193] [110] [52].

The algorithm has been extended to handle general integer variables and integer variables appearing nonlinearly in the model.

### 5.14.6 Modeling

#### 5.14.6.1 Relaxed Model

Before solving a model with DICOPT, the user is strongly advised to experiment with the relaxed model where the integer restrictions are ignored. This is the RMINLP model. As the DICOPT will start solving the relaxed problem and can use an existing relaxed optimal solution, it is a good idea to solve the RMINLP always before attempting to solve the MINLP model, i.e., the following fragment is not detrimental with respect to performance:
model m /all/;
option nlp=conopt;
option mip=cplex;
option rminlp=conopt;
option minlp=dicopt;
*
* solve relaxed model
*
  solve m using rminlp minimizing z;
  abort$(m.modelstat > 2.5) "Relaxed model could not be solved";
 *
* solve minlp model
*
  solve m using minlp minimizing z;

The second SOLVE statement will only be executed if the first SOLVE was successful, i.e., if the model status was one (optimal) or two (locally optimal).

In general it is not a good idea to try to solve an MINLP model if the relaxed model cannot be solved reliably. As the RMINLP model is a normal NLP model, some obvious points of attention are:

- Scaling. If a model is poorly scaled an NLP solver may not be able find the optimal or even a feasible solution. Some NLP solvers have automatic scaling algorithms, but often it is better to attack this problem on the modeling level. The GAMS scaling facility can help in this respect.

- Starting point. If a poor starting point is used, the NLP solver may not be able to find a feasible or optimal solution. A starting point can be set by setting level values, e.g. \( \text{X.L} = 1 \). The GAMS default levels are zero, which is often not a good choice.

- Adding bounds. Add bounds so that all functions can be properly evaluated. If you have a function \( \sqrt{x} \) or \( \log(x) \) in the model, you may want to add a bound \( \text{X.LO}=0.001 \). If a function like \( \log(f(x)) \) is used, you may want to introduce an auxiliary variable and equation \( y = f(x) \) with an appropriate bound \( \text{Y.LO}=0.001 \).

In some cases the relaxed problem is the most difficult model. If more than one NLP solver is available you may want to try them in a sequence:

model m /all/;
option nlp=conopt;
option mip=cplex;
option rminlp=conopt;
option minlp=dicopt;
*
* solve relaxed model
*
  solve m using rminlp minimizing z;
  if (m.modelstat > 2.5,
      option rminlp=minos;
      solve m using rminlp minimizing z;
  );
  if (m.modelstat > 2.5,
      option rminlp=snopt;
      solve m using rminlp minimizing z;
  );
*
* solve minlp model
*
  solve m using minlp minimizing z;
In this fragment we first try to solve the relaxed model using CONOPT. If that fails we try MINOS, and if that solve also fails we try SNOPT.

It is worthwhile to spend some time getting the relaxed model to solve reliably and speedily. In most cases, modeling improvements in the relaxed model, such as scaling, will also benefit the subsequent NLP sub-problems. In general these modeling improvements turn out to be rather solver independent: changes that improve the performance with CONOPT will also help solving the model with MINOS.

5.14.6.2 OPTCR and OPTCA

The DICOPT algorithm assumes that the integer sub-problems are solved to optimality. The GAMS options for OPTCR and OPTCA are therefore ignored: subproblems are solved with both tolerances set to zero. If you want to solve a MIP sub-problem with an optimality tolerance you can use the DICOPT option file to set OPTCR or OPTCA. For more information see section DICOPT Options.

For models with many discrete variables, it may be necessary to introduce an OPTCR or OPTCA option in order to solve the model in acceptable time. For models with a limited number of integer variables the default to solve MIP sub-models to optimality may be acceptable.

5.14.6.3 Integer Formulations

A number of MIP formulations are not very obvious and pose a demand on the modeler’s knowledge and experience. A good overview of integer programming modeling is given in [202].

Many integer formulations use a so-called big- \( M \) construct. It is important to choose small values for those big- \( M \) numbers. As an example consider the fixed charge problem where \( y_i \in \{0,1\} \) indicate if facility \( i \) is open or closed, and where \( x_i \) is the production at facility \( i \). Then the cost function can be modeled as:

\[
\begin{align*}
C_i &= f_i y_i + v_i x_i \\
x_i &\leq M_i y_i \\
y_i &\in \{0,1\} \\
0 &\leq x_i \leq \text{cap}_i
\end{align*}
\]

where \( f_i \) is the fixed cost and \( v_i \) the variables cost of operating a facility \( i \). In this case the chosen \( M_i \) should be large enough that \( x_i \) is not restricted if \( y_i = 1 \). On the other hand, it should be as small as possible. This leads to a choice to have \( M_i \) equal to the (tight) upperbound of variable \( x_i \) (i.e. the capacity \( \text{cap}_i \) of facility \( i \)).

5.14.6.4 Non-smooth Functions

GAMS alerts NLP modelers against the use of non-smooth functions such as \texttt{min()}, \texttt{max()}, \texttt{smin()}, \texttt{smax()} and \texttt{abs()}. In order to use these functions, a non-linear program needs to be declared as a DNLP model instead of a regular NLP model:

```plaintext
option dnlp=conopt;
model m /all/;
solve m minimizing z using dnlp;
```
This construct will warn the user that problems may arise due to the use of non-smooth functions.

A possible solution is to use a smooth approximation. For instance, the function \( f(x) = |x| \) can be approximated by \( g(x) = \sqrt{x^2 + \varepsilon} \) for some \( \varepsilon > 0 \). This approximation does not contain the point \((0, 0)\).

An alternative approximation can be devised that has this property:
\[
 f(x) \approx \frac{2x}{1 + e^{-x/\theta}} - x
\]

MINLP models do not have such protection against non-smooth functions, but the use of such functions is just as problematic here. It is possible to use discrete variables with MINLP models in order to model if-then-else situations. For instance, in the case of the absolute value we can replace \( x \) by \( x^+ - x^- \) and \( |x| \) by \( x^+ + x^- \) by using:

\[
\begin{align*}
x &= x^+ - x^- \\
|x| &= x^+ + x^- \\
x^+ &\leq \delta M \\
x^- &\leq (1 - \delta)M \\
x^+, x^- &\geq 0 \\
\delta &\in \{0, 1\}
\end{align*}
\]

where \( \delta \) is a binary variable.

### 5.14.7 GAMS Options

GAMS options are specified in the GAMS model source, using either the `option` statement or a model suffix.

#### 5.14.7.1 The OPTION Statement

An option statement sets a global parameter. An option statement should appear before the `solve` statement, as in:

```gams
model m /all/;
option iterlim=100;
solve m using minlp minimizing z;
```

Option statements that affect the behavior of DICOPT are listed below:

- `option domlim = n;`
  
  This option sets a limit on the total accumulated number of non-linear function evaluation errors that are allowed while solving the NLP subproblems or inside DICOPT itself. An example of a function evaluation error or domain error is taking the square root of a negative number. This situations can be prevented by adding proper bounds. The default is zero, i.e. no function evaluation errors are allowed.
  
  In case a domain error occurs, the listing file will contain an appropriate message, including the equation that is causing the problem. For instance:

  **** ERRORS(S) IN EQUATION loss(cc,sw)
  2 instance(s) of - UNDEFINED REAL POWER (RETURNED 0.0E+00)
If such errors appear you can increase the DOMLIM limit, but often it is better to prevent the errors from occurring in the first place. In many cases this can be accomplished by adding appropriate bounds. Sometimes extra variables and equations need to be added to accomplish this. For instance, with an expression like \( \log(x - y) \), you may want to introduce a variable \( z > \varepsilon \) and an equation \( z = x - y \), so that the expression can be rewritten as \( \log(z) \).

- **option iterlim = n;**
  This option sets a limit on the total accumulated (minor) iterations performed in the MIP and NLP subproblems.

- **option minlp = dicopt;**
  This option selects DICOPT to solve MINLP problems.

- **option mip = s;**
  This option sets the MIP solver to be used for the MIP master problems. Note that changing from one MIP solver to another can lead to different results, and may cause DICOPT to follow a different path.

- **option nlp = s;**
  This option sets the NLP solver to be used for the NLP subproblems. Note that changing from one NLP solver to another can lead to different results, and may cause DICOPT to follow a different path.

- **option optca = x;**
  This option is ignored. MIP master problems are solved to optimality unless specified differently in the DICOPT option file.

- **option optcr = x;**
  This option is ignored. MIP master problems are solved to optimality unless specified differently in the DICOPT option file.

- **option reslim = x;**
  This option sets a limit on the total accumulated time (in seconds) spent inside DICOPT and the subsolvers.

- **option sysout = on;**
  This option will print extra information to the listing file.

In the list above (and in the following) \( n \) indicates an integer number. GAMS will also accept fractional values, which will be rounded. Options marked with an \( x \) parameter expect a real number. Options with an \( s \) parameter expect a string argument.

### 5.14.7.2 The Model Suffix

Some options are set by assigning a value to a model suffix, as in:

```plaintext
model m /all/
  m.optfile=1;
  solve m using minlp minimizing z;
```

Model suffixes that affect the behavior of DICOPT are listed below:

- **m.dictfile = 1;**
  This option tells GAMS to write a dictionary file containing information about GAMS identifiers (equation and variables names). Such information is needed when the DICOPT option \( nlptracelevel \) is used, otherwise the option can be ignored.
• \( m.\text{iterlim} = n; \)
  Sets the total accumulated (minor) iteration limit. This option overrides the global iteration limit set by an option statement, e.g.,

  ```gams
  model m /all/;
  m.iterlim = 100;
  option iterlim = 1000;
  solve m using minlp minimizing z;
  ```

  will cause DICOPT to use an iteration limit of 100.

• \( m.\text{optfile} = 1; \)
  This option instructs DICOPT to read an option file `dicopt.opt`. This file should be located in the current directory (or the project directory when using the GAMS IDE). The contents of the option file will be echoed to the listing file and to the screen (the log file):

  ```gams
  --- DICOPT: Reading option file D:\MODELS\SUPPORT\DICOPT.OPT
  > maxcycles 10
  --- DICOPT: Starting major iteration 1
  ```

  If the option file does not exist, the algorithm will proceed using its default settings. An appropriate message will be displayed in the listing file and in the log file:

  ```gams
  --- DICOPT: Reading option file D:\MODELS\SUPPORT\DICOPT.OPT
  --- DICOPT: File does not exist, using defaults...
  --- DICOPT: Starting major iteration 1
  ```

• \( m.\text{optfile} = n; \)
  If \( n > 1 \) then the option file that is read is called `dicopt.op n` (for \( n = 2, \ldots, 9 \)) or `dicopt.o n` (for \( n = 10, \ldots, 99 \)). E.g. `m.optfile=2;` will cause DICOPT to read `dicop.op2`.

• \( m.\text{prioropt} = 1; \)
  This option turns on the use of priorities on the discrete variables. Priorities influence the branching order chosen by the MIP solver during solution of the MIP master problems. The use of priorities can greatly impact MIP solver performance. The priorities themselves have to be specified using the `.prior` variables suffix, e.g. `x.prior(i,j) = ord(i);`. Contrary to intuition, variables with a lower value for their priority are branched on before variables with a higher priority, i.e., the most important variables should get lower priority values.

• \( m.\text{reslim} = x; \)
  Sets the total accumulated time limit. This option overrides the global time limit set by an option statement.

5.14.8 DICOPT Options

This sections describes the options that can be specified in the DICOPT option file. This file is usually called `dicopt.opt`. The `optfile` model suffix must be set to tell DICOPT to read this file:

```gams
model m /all/;
m.optfile=1;
solve m using minlp minimizing z;
```

The option file is searched for in the current directory, or in the project directory when the IDE is used.

The option file is a standard text file, with a single option on each line. All options are case-insensitive. A line is a comment line if it starts with an asterisk, * in column one. A valid option file can look like:
5.14 DICOPT

* stop only on infeasible MIP or hitting a limit
stop 0
* use minos to solve first NLP sub problem
* and conopt for all subsequent ones
nlpsolver minos conopt

A convenient way to write the option file from within a GAMS model is to use the following construct:

$onecho > dicopt.opt
stop 0
nlpsolver minos conopt
$offecho

This will make the model self-contained. Notice, however, that this overwrites an existing file dicopt.opt.

Available DICOPT options are listed below:

### 5.14.8.1 Algorithmic options

<table>
<thead>
<tr>

5.14.8.6 Detailed Options Description

continue (integer): How to proceed in case of NLP errors

This option can be used to let DICOPT continue in cases of NLP solver failure. The preferred approach is to fix the model so that NLP subproblems solve without problems. In some cases, however, (partial) failures of an NLP solver in solving the NLP subproblems can be ignored, as DICOPT may recover later on. Adding the option continue 0 during model debugging enables DICOPT to function in a more specific way.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stop on solver failure</td>
</tr>
<tr>
<td></td>
<td>Stop on solver failure. DICOPT will terminate when an NLP subproblem can not be solved to optimality. Some NLP solvers terminate with a status other than optimal if not all of the termination criteria are met. For instance, the change in the objective function is negligible (indicating convergence) but the reduced gradients are not within the required tolerance. Such a solution may or may not be close to the (local) optimum. Using continue 0 will prevent DICOPT from accepting such a solution.</td>
</tr>
<tr>
<td>1</td>
<td>Accept non-optimal feasible solutions</td>
</tr>
<tr>
<td></td>
<td>NLP subproblem failures resulting in a non-optimal but feasible solutions are accepted. Sometimes an NLP solver cannot make further progress towards meeting all optimality conditions, although the current solution is feasible. Such a solution can be accepted by this option.</td>
</tr>
<tr>
<td>2</td>
<td>Ignore infeasible solutions</td>
</tr>
<tr>
<td></td>
<td>NLP subproblem failures resulting in a non-optimal but feasible solution are accepted (as in option continue 1). NLP subproblem failures resulting in an infeasible solution are ignored. The corresponding configuration of discrete variables is forbidden to be used again. An integer cut to accomplish this is added to subsequent MIP master problems. Note that the relaxed NLP solution should be feasible. This setting is the default.</td>
</tr>
</tbody>
</table>

convex (boolean): If enabled, the defaults for a number of other options are set to values appropriate to convex MINLPs

If this option is enable, the default option values will be changed such that DICOPT will stop on crossover (stop set to 1), linearizations from infeasible NLP subproblems will be added to the MIP master problem (infeasder set to 1), penalty relaxation is no longer applied to linearizations (weight set to maxdouble), and the feasibility pump is run if there are no semicontinuous or semiinteger variables and no special ordered sets (feaspump set to 1).

Default: 0

domlim (string): List of allowed number of domain errors

domlim \( i_1, i_2, \ldots, i_n \). Sets a limit of the number of function and derivative evaluation errors for a particular cycle. A number of \(-1\) means that the global GAMS option \texttt{domlim} is used. The last number \( i_n \) sets a domain error limit for all cycles \( n, n + 1, \ldots \).

Example: \texttt{domlim 0 100 0}

The NLP solver in the second cycle is allowed to make up to 100 evaluation errors, while all other cycles must be solved without evaluation errors.

The default is to use the global GAMS \texttt{domlim} option.

\texttt{dumpsubprob (boolean):} Whether to dump MIP and NLP subproblems into GAMS files

For subproblems of the feasibility pump, use option \texttt{fp_dumps}.

Default: 0

\texttt{epsmip (real):} Tolerance on test on monotonic improvement of MIP master problem

This option can be used to relax the test on MIP objective functions. The objective function values of the MIP master problems should form a monotonic worsening curve. This is not the case if the MIP master problems are not solved to optimality. If the options \texttt{OPTCR} or \texttt{OPTCA} are set to a nonzero value, this test is bypassed. If the test fails, \texttt{DICOPT} will fail with a message:

The MIP solution became better after adding integer cuts. Something is wrong. Please check if your model is properly scaled. Also check your big M formulations -- the value of M should be relatively small. This error can also occur if you used a MIP solver option file with a nonzero OPTCR or OPTCA setting. In that case you may want to increase the EPSMIP setting using a DICOPT option file.

The value of

\[
\frac{\text{PreviousObj} - \text{CurrentObj}}{1 + |\text{PreviousObj}|}
\]

is compared against \texttt{epsmip}. In case the test fails but you want \texttt{DICOPT} to continue anyway, you may want to increase the value of \texttt{epsmip}. The current values used in the test (previous and current MIP objective, \texttt{epsmip}) are printed along with the above message to provide information about how much you should increase \texttt{epsmip} to pass the test. Normally, you should not have to change this value.

Default: \(1.0e-6\)

\texttt{epsx (real):} Tolerance for integer values when loading relaxed solution

This tolerance is used to distinguish integer variables that are set to an integer value by the user, or integer variables that are fractional. See the option \texttt{relaxed}.

Default: \(1.0e-3\)

\texttt{feaspump (integer):} Whether to run the Feasibility Pump

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not run the Feasibility Pump</td>
</tr>
<tr>
<td>1</td>
<td>Run the Feasibility Pump if there are no semicontinuous or semiinteger variables and no special ordered sets</td>

<tr>
<td>2</td>
<td>Always run the Feasibility Pump</td>
</tr>
</tbody>
</table>
**fp_acttol** (real): Tolerance on when to consider an equation as active

Default: 1E-6

**fp_cutoffdecr** (real): Additional relative decrement of cutoff value for the original objective function

Default: 0.1

**fp_dumpsubprob** (boolean): Whether to dump subproblems (NLPs and MIPs) into GAMS files

Default: 0

**fp_integercuts** (integer): Whether to add integer cuts after an NLP subproblem has been solved to optimality

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use integer cuts</td>
</tr>
<tr>
<td>1</td>
<td>Use integer cuts only for mixed-binary problems</td>
</tr>
<tr>
<td>2</td>
<td>Always use integer cuts</td>
</tr>
</tbody>
</table>

**fp_iterlimit** (integer): Major Iteration limit

Default: 20

**fp_mipgap** (real): Optimality tolerance (relative gap) to use for solving MIP projection problem

Default: 0.01

**fp_projectcuts** (boolean): Whether to add cut derived from projection of MIP solution onto NLP feasible set

Default: 1

**fp_projzerotol** (real): Tolerance on when to consider optimal value of projection problem as zero, which may trigger the solution of a Sub-NLP

Default: 1E-4

**fp_sollimit** (integer): Stop when a number of (improving) solutions has been bound

Default: `maxint`

**fp_stalllimit** (integer): Stop when no improving solution has been bound for a number of FP iterations, -1 to disable

Range: \{-1, ..., ∞\}

Default: 5

**fp_subsolverlog** (boolean): Whether to show the log of subsolvers

Default: 0

**fp_timelimit** (real): Time limit
Default: `maxdouble`

**fp_transercuts (boolean):** Whether to transfer cuts from the Feasibility Pump MIP to the DICOPT MIP (all except from the round in which the FP MIP became infeasible) ←

Default: 1

**infbnd (real):** Bound to use for unbounded integer variables in integer cuts ←

Value to use for missing bounds on discrete variables when constructing integer cuts.

Default: 10000

**infeasder (integer):** Use derivatives of infeasible nonlinear subproblems ←

This option is to determine whether linearizations of infeasible NLP subproblems are added or not added to the MIP master problem.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | No linearizations of infeasible NLP subproblems  
This is the default option in which no linearizations are added in the infeasible NLP subproblems. In this case a simple integer cut is added to remove from consideration the 0-1 vector that gave rise to the infeasible NLP. Since this may slow the convergence, it is recommended to reformulate the MINLP with "elastic" constraints (i.e., adding slacks to infeasible constraints and adding a penalty for them in the objective) to ensure that the NLP subproblems are mathematically feasible. |
| 1     | Add linearization for infeasible NLP subproblems  
This will add linearizations derived from the infeasible NLP subproblem to the master problem. This option is recommended to speed up convergence when the MINLP is known to be convex (i.e. its continuous relaxation is convex). The possibility of cutting-off the global optimum is increased if it is used for a nonconvex MINLP. |

**maxcycles (integer):** Maximum number of cycles ←

The maximum number of cycles or major iterations performed by DICOPT.

Default: 20

**mipiterlim (string):** List of iteration limits ←

mipiterlim $i_1 \ i_2 \ \ldots \ \ i_n$ sets an iteration limit on individual MIP master problems. The last number $i_n$ is valid for all subsequent cycles $n, n+1, \ldots$. A number of $-1$ indicates that there is no (individual) limit on the corresponding MIP master problem. A global iteration limit is maintained through the GAMS option `iterlim`.

Example: `mipiterlim 10000 \ -1`  
The first MIP master problem cannot use more than 10000 iterations, while subsequent MIP master problems are not individually restricted.

Example: `mipiterlim 10000`  
Sets an iteration limit of 10000 on all MIP master problems.
When this option is used it is advised to have the option `continue` set to its default of 2. The default for this option is not to restrict iteration counts on individual solves of MIP master problems. The default for this option is not to restrict iteration counts on individual solves of MIP master problems.

**mipoptfile (string):** List of option files for MIP solver

mipoptfile $s_1 \ s_2 \ldots \ s_n$ specifies the option file to be used for the MIP master problems. Several option files can be specified, separated by a blank. If a digit 1 is entered the default option file for the MIP solver in question is being used. The digit 0 indicates that no option file is to be used. The last option file is also used for subsequent MIP master problems.

Example: `mipoptfile mip.opt mip2.opt 0`

This option will cause the first MIP master problem solver to read the option file `mip.opt` and the second one to read the option file `mip2.opt`; subsequent MIP master problem solvers will not use any option file.

Option files are located in the current directory (or the project directory when using the IDE). The default is not to use an option file.

**mipreslim (string):** List of resource limits

mipreslim $x_1 \ x_2 \ldots \ x_n$ sets a resource (time) limit on individual MIP master problems. The last number $x_n$ is valid for all subsequent cycles $n, n+1, \ldots$. A number $\ -1.0$ means that the corresponding MIP master problem is not individually time restricted. A global time limit is maintained through the GAMS option `reslim`.

Example: `mipreslim -1 10000 -1`

The MIP master problem in cycle 2 cannot use more than 100 seconds, while subsequent MIP master problems are not individually restricted.

Example: `mipreslim 1000`

Sets a time limit on all MIP master problems of 1000 seconds.

When this option is used it is advised to have the option `continue` set to its default of 2. The default for this option is not to restrict individually the time a solver can spent on the MIP master problem.

**mipsolver (string):** List of MIP solvers

This option specifies with MIP solver to use for the MIP master problems.

Example: `mipsolver cplex xpress`

This instructs DICOPT to use Cplex for the first MIP and XPRESS for the second and subsequent MIP problems. The last entry may be used for more than one problem.

The names to be used for the solvers are the same as one uses in the GAMS statement `OPTION MIP=...;` The default is to use the default MIP solver. Note that changing from one MIP solver to another can lead to different results, and may cause DICOPT to follow a different path.

**nlpiterlim (string):** List of iteration limits
nlpiterlim \(i_1, i_2 \ldots i_n\) sets an iteration limit on individual NLP subproblems. The last number \(i_n\) is valid for all subsequent cycles \(n, n + 1, \ldots\). A number of \(-1\) indicates that there is no (individual) limit on the corresponding NLP subproblem. A global iteration limit is maintained through the GAMS option reslim.

Example: nlpiterlim 1000 -1
The first (relaxed) NLP subproblem cannot use more than 1000 iterations, while subsequent NLP subproblems are not individually restricted.

Example: nlpiterlim 1000
Sets an iteration limit of 1000 on all NLP subproblems.

When this option is used it is advised to have the option continue set to its default of 2. This default does not restrict the amount of iterations an NLP solver can spend on an NLP subproblem, other than the global iteration limit.

nlpoptfile (string): List of option files for NLP solver

nlpoptfile \(s_1, s_2 \ldots s_n\) specifies the option file to be used for the NLP subproblems. Several option files can be specified, separated by a blank. If a digit 1 is entered, the default option file for the NLP solver in question is being used. The digit 0 indicates that no option file is to be used. The last option file is also used for subsequent NLP subproblems.

Example: nlpoptfile nlp.opt nlp2.opt 0
This option will cause the first NLP subproblem solver to read the option file nlp.opt and the second one to read the option file nlp2.opt; subsequent NLP subproblem solvers will not use any option file.

Example: nlpoptfile 1
This will cause the NLP solver for all NLP subproblems to read a default option file (e.g. conopt.opt, minos.opt, snopt.opt etc.).

Option files are located in the current directory (or the project directory when using the IDE). The default is not to use an option file.

nlpreslim (string): List of resource limits

nlpreslim \(x_1, x_2 \ldots x_n\) sets a resource (time) limit on individual NLP subproblems. The last number \(x_n\) is valid for all subsequent cycles \(n, n + 1, \ldots\). A number \(-1.0\) means that the corresponding NLP subproblem is not individually time restricted. A global time limit is maintained through the GAMS option reslim.

Example: nlpreslim 100 -1
The first (relaxed) NLP subproblem can not use more than 100 seconds, while subsequent NLP subproblems are not individually restricted.

Example: nlpreslim 1000
Sets a time limit of 1000 seconds on all NLP subproblems.

When this option is used it is advised to have the option continue set to its default of 2. This default does not restrict the time an NLP solver can spend on an NLP subproblem (other than the global resource limit).

nlpsolver (string): List of NLP solvers

nlpsolver \(s_1, s_2 \ldots s_n\). This option specifies which NLP solver to use for the NLP subproblems.
Example: `nlp solver conopt minos snopt` tells DICOPT to use CONOPT for the relaxed NLP, MINOS for the second NLP subproblem, and SNOPT for the third and subsequent ones. The last entry is used for more than one subproblem: for all subsequent ones DICOPT will use the last specified solver.

The names to be used for the solvers are the same as those used in the GAMS statement `OPTION NLP=...;` The default is to use the default NLP solver. Note that changing from one NLP solver to another can lead to different results, and may cause DICOPT to follow a different path.

**nlptracefile (string):** Base name of trace files

Name of the files written if the option `nlptracelevel` is set. Only the stem is needed: if the name is specified as `nlptracefile nlptrace`, then files of the form `nlptrace.001`, `nlptrace.002`, etc. are written. These files contain the settings of the integer variables so that NLP subproblems can be investigated independently of DICOPT.

Default: `nlptrace`

**nlptracelevel (integer):** Trace level

This sets the level for NLP tracing, which writes a file for each NLP subproblem, so that NLP subproblems can be investigated outside the DICOPT environment. See also the option DICOPTnlptracefile “nlptracefile”.

By including a trace file in your original problem and changing it into an MINLP problem, the subproblem will be solved directly by an NLP solver. This option only works if the names in the model (names of variables and equations) are exported by GAMS. This can be accomplished by using the `m.dictfile` model suffix, as in `m.dictfile=1;`. In general it is more convenient to use the CONVERT solver to generate isolated NLP models (see section Model Debugging).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | No trace info is written  
       | No trace files are written. This is the default. |
| 1     | GAMS file with fixed integer variables  
       | A GAMS file for each NLP subproblem is written which fixes the discrete variables. |
| 2     | Include levels of continuous variables  
       | As `nlptracelevel` 1, but in addition level values of the continuous variables are written. |
| 3     | Include all levels and marginals  
       | As `nlptracelevel` 2, but in addition marginal values for the equations and variables are written. |

**optca (string):** List of OPTCA values

`optca x_1 x_2 ... x_n`. The absolute optimality criterion for the MIP master problems. The GAMS option `optca` is ignored, as, by default, DICOPT wants to solve MIP master problems to optimality. It is possible to stop the MIP solver earlier to allow it to solve a large problem, by specifying a value for `optca` or `optcr` in a DICOPT option file. With setting a value for `optca`, the MIP solver is instructed to stop as soon as the gap between the best possible integer solution and the best found integer solution is less than $x$, i.e. stop as soon as

$$|\text{BestFound} - \text{BestPossible}| \leq x$$
It is possible to specify a different **optca** value for each cycle. The last number $x_n$ is valid for all subsequent cycles $n, n+1, \ldots$.

Example: **optca** 10
Stop the search in all MIP problems as soon as the absolute gap is less than 10.

Example: **optca** 0 10 0
Sets a nonzero **optca** value of 10 for cycle 2, while all other MIP master problems are solved to optimality.

The default is zero.

**optcr** *(string)*: List of OPTCR values $\leftarrow$

**optcr** $x_1 \ x_2 \ \ldots \ x_n$. The relative optimality criterion for the MIP master problems. The GAMS option **optcr** is ignored, as by default DICOPT wants to solve MIP master problems to optimality. To allow it to solve a large problem it is possible to stop the MIP solver earlier by specifying a value for **optca** or **optcr** in a DICOPT option file. With setting a value for **optcr**, the MIP solver is instructed to stop as soon as the relative gap between the best possible integer solution and the best found integer solution is less than $x$, i.e., stop as soon as

$$\frac{|\text{BestFound} - \text{BestPossible}|}{|\text{BestPossible}|} \leq x$$

Note that the relative gap cannot be evaluated if the best possible integer solution is zero. In these cases the absolute optimality criterion **optca** can be used. It is possible to specify a different **optcr** value for each cycle. The last number $x_n$ is valid for all subsequent cycles $n, n+1, \ldots$.

Example: **optcr** 0.1
Stop the search in all the MIP problems as soon as the relative gap is smaller than 10%.

Example: **optcr** 0 0.01 0
Sets a nonzero **optcr** value of 1% for cycle 2, while all other MIP master problems are solved to optimality.

The default is zero.

**relaxed** *(integer)*: How to start DICOPT $\leftarrow$

In some cases it may be possible to use a known configuration of the discrete variables. Some users have very difficult problems, where the relaxed problem cannot be solved but where NLP sub-problems with the integer variables fixed are much easier. If a reasonable integer configuration is known in advance in these cases we can bypass the relaxed NLP and tell DICOPT to directly start with this integer configuration. The integer variables need to be specified by the user before the solve statement by assigning values to the levels, as in $Y.L(I) = \text{INITVAL}(I)$;

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Start with all integers fixed to the starting value. The first NLP sub-problem will be executed with all integer variables fixed to the values specified by the user. If you don't assign a value to an integer variable, it will retain it’s current value, which is zero by default.</td>
</tr>
<tr>
<td>1</td>
<td>Start with relaxed NLP. The first NLP problem is the relaxed NLP problem: all integer variables are relaxed between their bounds. This is the default.</td>
</tr>
<tr>
<td>2</td>
<td>Start with mixture of fixed and relaxed integers. The first NLP subproblem will be executed with some variables fixed and some relaxed. The program distinguishes the fixed from the relaxed variables by comparing the initial values against the bounds and the tolerance allowed EPSX. EPSX has a default value of 1.e-3. This can be changed through the option file.</td>
</tr>
</tbody>
</table>
**solvelink** *(integer):* Solvelink for NLP and MIP subsolver

This option defines the solvelink used for the NLP and MIP subsolver.

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Call NLP and MIP solver via script</td>
</tr>
<tr>
<td>2</td>
<td>Call NLP and MIP solver via module</td>
</tr>
<tr>
<td>5</td>
<td>Call NLP and MIP solver in memory</td>
</tr>
</tbody>
</table>

**stop** *(integer):* Stopping criterion

This option defines the stopping criterion to be used. The search is always stopped when the (minor) iteration limit (the `interlim` option), the resource limit (the `reslim` option), or the major iteration limit (see `maxcycles`) is hit or when the MIP master problem becomes infeasible.

Note: In general a higher number stops earlier, although in some cases stopping rule 2 may terminate the search earlier than rule 1. Section Modeling shows some experiments with these stopping criteria.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stop on <code>maxcycles</code></td>
</tr>
<tr>
<td></td>
<td>Do not stop unless an iteration limit, resource limit, or major iteration limit is hit or an infeasible MIP master problem becomes infeasible. This option can be used to verify that DICOPT does not stop too early when using one of the other stopping rules. In general it should not be used on production runs, as in general DICOPT will often find the optimal solution using one of the more optimistic stopping rules. Do not stop unless an iteration limit, resource limit, or major iteration limit is hit or an infeasible MIP master problem becomes infeasible. This option can be used to verify that DICOPT does not stop too early when using one of the other stopping rules. In general it should not be used on production runs, as in general DICOPT will often find the optimal solution using one of the more optimistic stopping rules.</td>
</tr>
<tr>
<td>1</td>
<td>Stop on crossover</td>
</tr>
<tr>
<td></td>
<td>Stop as soon as the bound defined by the objective of the last MIP master problem is worse or close (w.r.t. GAMS option <code>optcr</code>) to the best NLP solution found (a crossover occurred). For convex problems this gives a global solution, provided the weights are large enough and <code>optcr</code> is set to 0. This stopping criterion should only be used if it is known or it is very likely that the nonlinear functions are convex. In the case of non-convex problems the bounds of the MIP master problem are not rigorous. Therefore, the global optimum can be cut off with the setting <code>stop 1</code>.</td>
</tr>
<tr>
<td>2</td>
<td>Stop on worsening</td>
</tr>
<tr>
<td></td>
<td>Stop as soon as the NLP subproblems stop improving. This worsening criterion is a heuristic. For non-convex problems in which valid bounds can not be obtained the heuristic often works very well. Even on convex problems, in many cases it terminates the search very early while providing an optimal or a very good integer solution. The criterion is not checked before major iteration three.</td>
</tr>
<tr>
<td>3</td>
<td>Stop on crossover or worsening</td>
</tr>
<tr>
<td></td>
<td>Stop as soon as a crossover occurs or when the NLP subproblems start to worsen. (This is a combination of 1 and 2).</td>
</tr>
</tbody>
</table>
**usexinit** *(boolean)*: Use the user initial point as starting point for all NLP solves

Default: 0

**weight** *(real)*: Penalty parameter, set above 1e20 to disable penalty relaxation

The value of the penalty coefficients.

Default: 1000

### 5.14.9 DICOPT Output

DICOPT generates lots of output on the screen. DICOPT itself and also the NLP and MIP solvers that handle the sub-problems write messages to the screen. The most important part is the last part of the screen output.

In this section we will discuss the output DICOPT writes to the screen and the listing file using the model procsel.gms (this model is part of the GAMS model library). A DICOPT log is written and the reason why DICOPT terminated is explained.

```plaintext

--- DICOPT: Terminating...
--- DICOPT: Stopped on NLP worsening

The search was stopped because the objective function of the NLP subproblems started to deteriorate.

--- DICOPT: Best integer solution found: 1.923099
--- Reading solution for model process
*** Status: Normal completion

Notice that the integer solutions are provided by the NLP's except for major iteration one (the first NLP is the relaxed NLP). For all NLP's except the relaxed one the binary variables are fixed, according to a pattern determined by the previous MIP which operates on a linearized model. The integer solutions marked with a '<' are an improvement. We see that the NLP in cycle 4 starts to deteriorate, and DICOPT stops based on its default stopping rule.

Note that if the criterion stop 1 had been used the search would have been terminated at iteration 3. The reason is that the upper bound to the profit predicted by the MIP (1.42129) exceeds the best current NLP solution (1.9231). Since it can be shown that the MINLP involves convex nonlinear functions, 1.9231 is the global optimum and the criterion stop 1 is rigorous.

In case the DICOPT run was not successful, or if one of the subproblems could not be solved, the listing file will contain all the status information provided by the solvers of the subproblems. For each iteration the configuration of the binary variables will also be printed. This extra information can also be requested via the GAMS option:

```
option sysout = on ;
```
5.14 DICOPT

5.14.10 Special Notes

This section covers some special topics of interest to users of DICOPT.

5.14.10.1 Stopping Rule

Although the default stopping rule behaves quite well in practice there some cases where it terminates too early. In this section we discuss the use of the stopping criteria.

When we run the example procsel.gms with stopping criterion 0, we see the following DICOPT log:

--- DICOPT: Starting major iteration 10
--- DICOPT: Search terminated: infeasible MIP master problem
--- DICOPT: Log File:

<table>

--- Reading solution for model process
*** Status: Normal completion

This example shows some behavioral features that are not uncommon for other MINLP models. First, DICOPT often finds the best integer solution in the first few major iterations. Second, in many cases as soon as the NLP's start to give worse integer solution no better integer solution will be found. This observation is the motivation to make stopping option 2, where DICOPT stops as soon as the NLP's start to deteriorate, the default stopping rule. In this example DICOPT would have stopped in major iteration 4 (you can verify this in the previous section). In many cases this will give the best integer solution. For this problem, DICOPT has indeed found the global optimum.
Based on experience with other models, we find that the default stopping rule (stop when the NLP becomes worse) performs well in practice. In many cases it finds the global optimum solution for both convex and non-convex problems. In some cases, however, it may provide a sub-optimal solution. In those cases where you want more reassurance that no good integer solutions are missed you can use one of the other stopping rules.

Changing the MIP or NLP solver can change the path that DICOPT follows, since the sub-problems may have non-unique solutions. The optimum stopping rule for a particular problem depends on the MIP and NLP solvers used.

The bounds of the MIP master problem are not rigorous in the case of non-convex problems. Therefore, the global optimum can be cut-off with \texttt{stop 1}. However, this option is the best stopping criterion for convex problems.

5.14.10.2 Solving the NLP Problems

Using a combination of NLP solvers has been found effective in cases where the relaxed NLP and/or the other NLP sub-problems are very difficult. For example, MINOS has many more difficulties to establish if a model is infeasible, so one would like to use CONOPT for NLP subproblems that are either infeasible or barely feasible. The \texttt{nlpsolver} option can be used to specify the NLP solver to be used for each iteration.

Infeasible NLP sub-problems can be problematic for DICOPT. Those subproblems cannot be used to form a new linearization. Effectively only the current integer configuration is excluded from further consideration by adding appropriate integer cuts, but otherwise an infeasible NLP sub-problem provides no useful information to be used by the DICOPT algorithm. If your model shows many infeasible NLP sub-problems you can try to use the \texttt{infeasder} option. Otherwise a strategy that can help is to introduce explicit slack variables and add them with a penalty to the objective function.

Assume your model is of the form:

\[
\begin{align*}
\min & \quad f(x, y) \\
g(x, y) & \sim b \\
\ell & \leq x \leq u \\
y & \in \{0, 1\}
\end{align*}
\]

where \(\sim\) is a vector of relational operators \(\{\leq, =, \geq\}\). \(x\) are continuous variables and \(y\) are the binary variables. If many of the NLP subproblems are infeasible, we can try the following \texttt{elastic} formulation:

\[
\begin{align*}
\min & \quad f(x, y) + M \sum_i (s_i^+ + s_i^-) \\
y &= y^B + s^+ - s^- \\
g(x, y) & \sim b \\
\ell & \leq x \leq u \\
0 & \leq y \leq 1 \\
0 & \leq s^+, s^- \leq 1 \\
y^B & \in \{0, 1\}
\end{align*}
\]

I.e., the variables \(y\) are relaxed to be continuous with bounds \([0, 1]\), and binary variables \(y^B\) are introduced that are related to the variables \(y\) through a set of the slack variables \(s^+, s^-\). The slack variables are added to the objective with a penalty parameter \(M\). The choice of a value for \(M\) depends on the size of \(f(x, y)\), on the behavior of the model, etc. Typical values are 100 or 1000.
5.14.10.3 Solving the MIP Master Problems

MIP master problems may become expensive to solve when there are many discrete variables. One of the first things to try is to see if a different MIP solver can solve your particular problems more efficiently.

Different formulations can have dramatic impact on the performance of MIP solvers. Therefore it is advised to try out several alternative formulations. The use of priorities can have a big impact on some models. It is possible to specify a nonzero value for OPTCA and OPTCR in order to prevent the MIP solver from spending an unacceptable long time proving optimality of MIP master problems.

If the MIP master problem is infeasible the DICOPT solver will terminate. In this case you may want to try the same reformulation discussed in the previous paragraph.

5.14.10.4 Feasibility Pump

The feasibility pump is similar to the Outer-approximation, but its objective is to completely focus on finding good feasible solutions rather than optimal ones. The main idea of this algorithm is to decompose the original mathematical programming problem in two parts: integer feasibility and constraint feasibility. By solving an MIP subproblem its solution is an integer feasible solution, which may violate the constraints; and by solving a continuous relaxation of the original MINLP (NLP subproblem) the solution is constraint feasible but might not be integral. By minimizing in successive iterations the distance between these two types of solutions it is expected to achieve a solution that is both constraint and integral feasible.

The feasibility pump can be used as a standalone solver for convex MINLP problems. This is achieved by iteratively applying the method, while including a bound to the objective function. This bound is obtained by the best known solution and an epsilon improvement. This will result in the global optimum of a convex MINLP [28]. The drawback of this algorithm is that it may require many iterations, since each time the objective function is restricted to improve only by epsilon.

In DICOPT, the feasibility pump can be applied before the Outer-approximation method by setting option feaspump. In the feasibility pump, large improvements in the objective function are enforced at each iteration (option fp_cutoffdecr). After the method finishes, all the cuts and the best known solution are passed to the Outer-approximation method to prove optimality. More details on the implementation of the feasibility pump in DICOPT can be found in [19].

5.14.10.5 Model Debugging

In this paragraph we discuss a few techniques that can be helpful in debugging your MINLP model.

- Start with solving the model as an RMINLP model. Make sure this model solves reliably before solving it as a proper MINLP model. If you have access to different NLP solvers, make sure the RMINLP model solves smoothly with all NLP solvers. CONOPT, especially, can generate useful diagnostics such as Jacobian elements (i.e. matrix elements) that become too large.

- Try different NLP and MIP solvers on the subproblems. Example: use the GAMS statement OPTION NLP=KNITRO; to solve all NLP subproblem using the solver KNITRO.

- The GAMS option statement OPTION SYSOUT = ON; can generate extra solver information that can be helpful for diagnosing problems.

- If many of the NLP subproblems are infeasible, add slacks as described in section Solving the NLP Problems.

- Run DICOPT in pedantic mode by using the DICOPT option: CONTINUE 0. Make sure all NLP subproblems solve to optimality.
- Don't allow any nonlinear function evaluation errors, i.e. keep the DOMLIM limit at zero. See the discussion on DOMLIM in section The OPTION Statement.

- If you have access to another MINLP solver such as AlphaECP, SHOT, or SBB or even global solvers like Antigone or BARON, try to use a different solver on your model. To select another solver (here SBB) use the following GAMS option statement: OPTION MINLP=SBB;.

- Individual NLP or MIP subproblems can be extracted from the MINLP by using the CONVERT solver, which will write a model in scalar GAMS notation that can then be solved using any GAMS NLP or MIP solver. E.g., to generate the second NLP subproblem, you can use the following DICOPT option: NLPSOLVER CONOPT CONVERT. The model will be written to the file GAMS.GMS. A disadvantage of this technique is that some precision is lost due to the fact that files are being written in plain ASCII. The advantage is that you can visually inspect these files and look for possible problems such as poor scaling.

5.15 EXAMINER

5.15.1 Introduction

This document describes GAMS/Examiner, a tool for examining points and making an unbiased, independent assessment of their merit. In short, it checks if solutions are really solutions. As an example, it can take a solution point reported as optimal by a solver and examine it for primal feasibility, dual feasibility, and optimality. Examiner has a number of different modes, allowing it to check the input point from GAMS/Base as well as the solution passed by a solver back to GAMS.

Many of the tests done by Examiner (perhaps all of them!) are already being done by the GAMS solvers, so Examiner is in a sense redundant. However, the ability to make an independent, transparent check of a solver's solution is very useful in solver development, testing, and debugging. It is also useful when comparing the solutions returned by two different solvers. Finally, a tool like the Examiner allows one to examine solutions using different optimality tolerances and optimality criteria in a way that is not possible when working with the solvers directly.

GAMS/Examiner is installed automatically with your GAMS system. Without a full GAMS/Base license, examiner will run in student or demonstration mode (i.e. it will examine small models only).

5.15.2 Usage

Examiner can be used with all supported model types. Since Examiner doesn't really solve any problems, it is not a good choice for a default solver, and when installing GAMS it does not appear as an option in the list of possible solver defaults. However, you can choose Examiner via the command line:

```
gams transport LP=examiner;
```

or via a GAMS option statement

```
option LP=examiner;
```
somewhere before the `solve` statement.

Since Examiner is not really a solver, many of the usual GAMS options controlling solvers have no impact on it. However, the `sysout` option is interpreted in the usual way.

The optimality checks done in Examiner are first-order optimality checks done at a given point. A discussion here of these conditions and all they imply would be redundant: any good intro text in optimization will cover them. For linear programming, first-order optimality is all one needs to prove global optimality. For nonlinear programming, these conditions may or may not be necessary or sufficient for optimality; this depends on the convexity of the feasible set and objective and the form of the constraints. For integer programming models, these checks only make sense if we turn the global problem into a local one by adding bounds to the model, essentially fixing each discrete variable to its current value: these bounds are added automatically by Examiner.

Examiner runs in two basic modes of operation: it can examine the input point passed from GAMS/Base to the solver, and it can examine the point passed from the solver back to GAMS. Each mode can be used independent of the other. By default it will operate in the first mode, examining the initial "solution" passed to it by GAMS, but only if GAMS indicates it is passing an advanced basis to the solver (cf. the GAMS User Guide and the `bratio` option). If you wish to use the second `solver-check` mode, you may specify an appropriate subsolver using the `subsolver` option (see section Options). If no `subsolver` is selected, the default solver for the model type being solved is used. In most cases you will want to use an option file to specify exactly what type of examination you wish to perform. The rules for using an option file are described in The Solver Options File.

5.15.2.1 Solution Points: Definition

There are a number of different ways a solution point can be defined. Of course the different definitions will typically result in the same points being produced, but there are cases where this will not be precisely so. Since Examiner is intended to explore and analyze these cases, we must make these definitions precise. The following four points are defined and used in Examiner:

1. The `gamspoint` is the input point provided by GAMS to Examiner. The GAMS input point includes level & marginal values for the rows and columns: Examiner uses these exactly as given.

2. The `initpoint` is determined by the variable levels (primal vars) and equation marginals (dual vars) provided by GAMS to Examiner. These values are used to compute the equation levels and variable marginals / reduced costs using the function evaluator in Examiner, rather than using the values passed in by GAMS.

3. The `solupoint` is similar to the `initpoint`: it uses the variable levels (primal vars) and equation marginals (dual vars) to compute the equation levels and variable marginals. The variable levels and equation marginals used are those returned by the subsolver.

4. The `solvpoint` is the point returned by the subsolver. The subsolver returns both level and marginal values for the rows and columns: Examiner uses these, exactly as given.

5.15.2.2 Checks Performed

There are a number of checks that can be performed on any of the solution points. By default, Examiner tries to choose the appropriate checks. For example, if a primal simplex solver returns a model status of nonoptimal, the only checks that make sense are feasibility in the primal variables and constraints. However, this automatic choice of appropriate checks is not possible when checking points passed in from GAMS/Base.

1. **Primal variable feasibility**: check that all primal variables are within bounds.
2. **Primal constraint feasibility**: check that all primal constraints are satisfied.

3. **Dual variable feasibility**: check that all dual variables are within bounds.

4. **Dual constraint feasibility**: check that all dual constraints are satisfied.

5. **Primal complementary slackness**: check complementarity between the primal variables and the dual constraints/reduced costs.

6. **Dual complementary slackness**: check complementarity between the dual variables/equation marginals and the equation slacks.

7. **Equilibrium condition complementarity**: check complementarity of the equation/variable pairs in complementarity models (MCP, MPEC).

The checks above are implemented with default tolerances. These tolerances can be changed via an option file (see section Options).

Different ways exist to check the items mentioned above. For example, different norms can be used to measure the error of the residual when checking for primal feasibility. Currently, we have only implemented one way to make these checks.

For optimization models, it is possible to define a merit function that measures how well a given point satisfies conditions 1 through 6 above. Such a function is always nonnegative, and its value represents the error between the given point and a true solution. If such an input point is well-defined (e.g., if only one point is selected for examination) then Examiner will compute the merit function value at this point and return it in the RObj model attribute.

### 5.15.2.3 Scaling

By default, Examiner makes its checks on the original, unscaled model. In many cases, however, it is important to take scaling into account. Consider the effect of row scaling on the simple constraint $x^2 \leq 9$ where $x = 3.5$. Multiplying this constraint through by large or small constants changes the amount of the constraint violation proportionately, but the distance to feasibility is not changed. Applying row scaling to the original model eliminates this problem.

Most solvers scale a model before solving it, so any feasibility or optimality checks and tolerances are applied to the scaled model. The process of unscaling the model can result in a loss of feasibility or optimality. Even though we do not have access to the scales applied by the solver and cannot precisely construct the same scaled model, we can get a better idea of how the solver performed by looking at a model scaled by Examiner than by looking at the original.

It is also interesting to see what the model scaling looks like, even if we do not apply the scales to do the Examiner checks. If the row scales are in a nice range, say $[.1, 100]$, we can have some confidence that the model is well-scaled. In contrast, if the row scales are in the range $[1, 1e8]$ we may question the precision of the solution provided.

For each row, Examiner computes the true row scale as

$$\max_j (\|RHS_i\|, \max_j (\|A_{ij}\| \cdot \max(1, \|x_j\|)))$$

In this way variables with a large level value lead to large scale factors. To make the scale factor independent of the variable values, use an option file line of "AbsXScale 0". This replaces the term $\max(1, \|x_j\|)$ above with 1.

Since the user may wish to limit the size of the scale factors applied, the true row scales are projected onto the scale factor bounds to get the applied scale factors. The scale factors are applied when making a scaled check by dividing the rows by the scale factors and multiplying the corresponding Lagrange multipliers by these same factors. When making unscaled checks information about the true scales is still included in the output to give the user a hint about potential scaling issues.

Note that the scaled and unscaled checks are made independently. By default only the unscaled checks are performed. If you turn the scaled checks on via an option file line "scaled 1", this will not turn off the unscaled checks. You will need an option file line of "unscaled 0" to turn off unscaled checks.
5.15.3 Options

The following options control the behavior of GAMS/Examiner. Many of these are boolean (i.e. on/off) options. In this case, zero indicates off, nonzero on. For details on how to create and use an option file, see the section on the Solver Option File.

5.15.3.1 General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>absXScale</td>
<td>Whether to make scale factors dependent on x values. If on, the matrix coefficients are multiplied by max(1,abs(x)) when computing the scale factors. If off, the matrix coefficients are taken as is. See Section Scaling.</td>
<td>1</td>
</tr>
<tr>
<td>dumpGamsPoint</td>
<td>Whether to dump the GamsPoint to a basis file in GAMS source format.</td>
<td>0</td>
</tr>
<tr>
<td>dumpInitPoint</td>
<td>Whether to dump the InitPoint to a basis file in GAMS source format.</td>
<td>0</td>
</tr>
<tr>
<td>dumpSoluPoint</td>
<td>Whether to dump the SoluPoint to a basis file in GAMS source format.</td>
<td>0</td>

</table>

### 5.16 GAMSCHK

**Abridged GAMSCHK USER DOCUMENTATION - Version 1.1**
A System for Examining the Structure and Solution Properties of GAMS Model Instances

**Author**
Bruce A. McCarl, Professor, Department of Agricultural Economics, Texas A&M University

**Date**
April 2013
5.16 GAMSCHK

5.16.1 GAMSCHK USER DOCUMENTATION

This document describes procedures designed to aid users who wish to examine empirical GAMS models for possible flaws. The conceptual basis for many of the routines herein is supplied in McCarl and Spreen, and McCarl et.al.

The function of the specific components of GAMSCHK are to:

- List coefficients for user selected equations and/or variables using the DISPLAYCR procedure.
- List the characteristics of selected groups of variables and/or equations using MATCHIT.
- List the characteristics of equation and variable blocks using BLOCKLIST.
- Examine a GAMS model to see whether any variables and equations contain specification errors using ANALYSIS.
- Generate schematics depicting the characteristics of coefficients by variable and equation blocks using BLOCKPIC.
- Generate a schematic for small GAMS models or portions of larger models depicting the location of coefficients by sign and magnitude using PICTURE.
- Reconstruct the reduced cost of variables and the activity within equations after a model solution using POSTOPT.
- Help resolving problems with unbounded or infeasible models using NONOPT and ADVISORY.

5.16.2 General Notes on Package Usage

GAMSCHK must replace a solver. This is done using a GAMS option statement of the form:

OPTION LP= GAMSCHK;

or

OPTION NLP=GAMSCHK;

or

OPTION MIP=GAMSCHK;

which replaces either the solver of the particular model type with GAMSCHK. In turn, the user will invoke the solver using the statement:

SOLVE MODELNAME USING LP MINIMIZING OBJNAME;

where MODELNAME is the name used in the GAMS MODEL statement; OBJNAME is the objective variable name for the model; and the type of solver that GAMSCHK has replaced which must also be able to solve this type of problem (LP, NLP, MIP, ...) is identified. The following are examples of GAMS sequences which can be added to the GAMS file:

OPTION NLP=GAMSCHK;
SOLVE TRANSPORT USING NLP MINIMIZING Z;

or

OPTION LP=GAMSCHK;
SOLVE FEED USING LP MINIMIZING COST;

or

OPTION MIP=GAMSCHK;
SOLVE RESOURCE USING MIP MAXIMIZING PROFIT;
5.16.2.1 Selecting a Procedure and Providing Input - the *.GCK File

GAMSCHK requires that the user indicate which procedures are to be employed. This is specified through the use of the *.GCK file where the * refers to the filename from the GAMS execution instruction. The general form of that file is:

```
FIRST PROCEDURE NAME
   ITEM SELECTION INPUT
SECOND PROCEDURE NAME
   ITEM SELECTION INPUT
```

Spaces and capitalization are ignored in this input. For example, a *.GCK file could look like

```
DISPLAYCR
   variables
      SELL(*,*,FANCY)
   makeetable
   Invariables
      transport(plant2,*,fancy)
   Equations
      objT
      notthere
   inequations
      resourceq(plant1)
PICTURE
```

The first procedure name in this case is DISPLAYCR and the following 10 lines indicate the items to be selected. Then, we also request PICTURE. Selection entries are treated using several assumptions. In particular:

1. If the *.GCK file is empty then it is assumed that the BLOCKPIC procedure is selected.
2. Spaces maybe freely used in the GCK input file.
3. Upper, lower, or mixed case input is accepted.
4. GAMSCHK recognizes certain words. These words are listed in Appendix A: Reserved Names and cannot be used as variable or equation names.

5.16.2.2 The *.GCK file: General Notes on Item Selection

Some of the procedures permit selection of variables, equations or functions. Specifically, the DISPLAYCR, PICTURE, POSTOPT, and MATCHIT procedures accept input identifying the variables and equations to be utilized. Also NONOPT accepts limited input controlling its function. General observations about the selection requests are

1. Variables can be chosen by entering the word VARIABLE or VARIABLES possibly with a modifier, followed by variable selection statements.

---

2Thus, if the GAMS instructions are in the file called MYMODEL, and GAMS is invoked using the DOS command GAMS MYMODEL, then the GCK file would be called MYMODEL.GCK. If GAMS instructions are on the filename with a period in it then the name up to the period will be used, i.e., the GCK file associated with MYMODEL.IT would be MYMODEL.GCK.
2. Variables can also be selected using the INEQUATION or INEQUATIONS syntax followed by names of equations. Use of this syntax results in selection of variables with coefficients in the named equations.

3. Equations are selected by entering the keyword, EQUATION or EQUATIONS possibly with a modifier, followed by equation selection statements.

4. Equations can also be selected using the INVARIABLE or INVARIABLES syntax followed by names of variables. Use of this syntax results in selection of equations in which the named variables have coefficients.

5. Certain item selection modifier keywords can be used depending on procedure. The INTERSECT keyword works with procedures DISPLAYCR and POSTOPT. The INEQUATION and INVARIABLE keywords work with procedures DISPLAYCR, PICTURE and POSTOPT. LISTEQUATION and LISTVARIABLE keywords work with the MATCHIT procedure. INSOLUTION, NOTINSOLUTION, BINDING, and NOTBINDING keywords work with POSTOPT. The keywords VERBOSE and IDENTIFY work with NONOPT.

6. If variable or equation names do not follow the keyword, then usually all variables or equations are assumed selected.

When variables or equations are to be selected after an item selection keyword, a number of input conventions apply. These conventions are:

1. If a variable or equation name is entered without any following parentheses, then all cases for that variable or equation are selected.

2. The selection entries identify specific elements from among the sets over which the variables and equations are defined. In specifying these elements one can use various wild card entries as discussed below or an element name. Note GAMS set or subset names cannot be used. Set membership information is not available to the GAMSCHK routines.

3. Wild cards can be used to select items. An "*" will select any item. For example, "B*" will select anything starting with a B. "A?B" will select anything beginning with A, ending with B with one intervening alpha numeric character.

4. When individual elements are specified, you need not enclose them in quotes ("').

5. Quotes must be specified to include set item names with spaces, and special characters. In that case wild cards do not work and all input up to the next quote is simply copied.

6. When the selected item has more dimensions than specified, then all later dimensions are handled as if a wild card were specified. For example, when a variable X is defined with reference to 4 sets in the GAMS instructions, but only 3 parameters are specified in the GAMSCHK input, then the request is handled as if all elements of the 4th are desired.

7. When the selected item has less dimensions in GAMS than in the item selection input, then all additional dimensions are ignored. Thus, when a variable X is defined with reference to 3 sets in GAMS, but 4 parameters are specified in the item selection file, then the 4th specification is ignored.

8. Multiple selection statements can appear on successive lines of the *.GCK file. Output is ordered according to the way items are found in the GAMS file which is determined by the ordering of variables, equations, and set elements in the original GAMS input.

9. Error messages will be generated when an entry cannot be matched to a GAMS element.

10. Examples include
<table>
<thead>
<tr>
<th>Example</th>
<th>Explanation</th>

5.16.2.3 Procedure Output

In all cases the output generated by the procedure will be written to the *.LST file associated with the GAMS call. Thus, if the file is called MODEL with the *.GCK file (MODEL.GCK), then all output will be on MODEL.LST.

5.16.2.4 Nonlinear Terms

GAMS models examined with GAMSCHK may involve nonlinear terms. In such cases, GAMSCHK uses the value of the nonlinear term sent forth from GAMS which is an accurate marginal, not total value. GAMS develops this value based on the current level value of the variable. This will either be: a) the starting point selected by GAMS, if the model has not been solved, or b) the current solution value, if the model has been solved. The most accurate portrayals of the coefficients will be generated after the model has been solved through a GAMS SOLVE command before invoking GAMSCHK. Some cases may require a solution and/or the specification of a good starting point before using GAMSCHK. Also, nonlinear terms potentially cause misleading coefficients as those values are local marginal, not global, values determined by the current levels of the variables. Nonlinear terms are marked with *** in the DISPLAYCR, POSTOPT, and NONOPT output.

5.16.2.5 Entering Comments in the *.GCK File

The *.GCK file has been programmed so that users can enter comments. These comments can take one of two forms. Comments that begin with a hash mark are copied to the output when the program runs. Comments which begin with a question mark are simply overlooked. Thus, one can temporarily comment GAMSCHK selection statements making them inactive by putting in question marks. If multiple procedures are being run or if some sort of output is decided to screen in the computer output then the hash marks can be entered.

5.16.2.6 Controlling Page Width in the *.GCK File

When running multiple procedures, in particular the pictures with other procedures, it is often desirable to have some procedures run with wide page widths, but the rest with a narrower page width. The GCK file provides the option to narrow the page width using a PW= command. In particular, what one can do is run GAMS with a large page width, i.e. run GAMS BLOCK pw=200, then insert in the GCK file instructions which narrow that page width for selected procedures. Users should note that the page width can never be made any wider than the default page width when running with GAMS. Information in excess of the page width will be ignored. Thus, if the model is run under the default status which has a page width of 75 characters then GAMSCHK will reduce the page width down to the maximum page width allowed. Consequently, the pw= command can only be used to narrow the page width from the default page width, not increase it.
5.16.2.7 Running Multiple Procedures

GAMSCHK can run multiple procedures during one job. This is done by simply stacking the sequence of the commands in the .GCK file.

5.16.3 Use of the Procedures

The following section describes the procedures available in GAMSCHK and their input requirements.

5.16.3.1 DISPLAYCR

**Brief Purpose:** DISPLAYCR displays all coefficients from the empirical model for a set of user selected equations and variables. All nonzero coefficients under each selected variable or in each selected equation are displayed with the associated variable or equation name and coefficient value. The selection entries may refer to all terms in equations under variables or only those coefficients at the intersection of the selected variables and equations.

**Usage Notes:** This option mirrors the GAMS LIMCOL and LIMROW options, but allows the user to select the specific items to be displayed. Partial displays within a variable or equation are also allowed using INTERSECT. Use of VARIABLE and EQUATION keywords followed by selection statements allows one to select variables and equations. Use of the INVARIABLE command allows users to select the equations which are associated with a particular variable. For example, if one is having trouble with a particular variable and wants to look at competition in the equations in which it appears, then selecting the variable under the INVARIABLE command will display the complete contents of all the equations in which the selected variables have coefficients. Similarly, the INEQUATION command will display the complete contents of all variables which fall in a particular equation. Nonlinear terms are marked with 

Usage Notes: When the keyword INTERSECT is found then only the coefficients at the intersection of the specified equations and variables are selected. Use of INTERSECT with the INVARIABLE syntax results in the named variables and the equations in which they fall being selected. Similarly, use of INTERSECT with the INEQUATION syntax results in selection of the named equations and the variables which fall in those equations.

Note that when GAMS internal scaling features are employed the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

**Input File:** The keyword DISPLAYCR is entered followed by optional lines of item selection input identifying the variables and equations to be displayed. This file can contain the keywords VARIABLE, INVARIABLE, EQUATION, and INEQUATION, with each followed by a specification of the items to be selected using the procedure input specification conventions that were described above. The keyword INTERSECT can also be used. Several special cases are relevant:

- If none of the above keywords are found after DISPLAYCR and another procedure name does not follow, then the input is assumed to identify variables.

- If input is found but the VARIABLE or INEQUATION keyword cannot be found then no variables are assumed selected.

- If the VARIABLE keyword is entered, but is followed by the end of file or an Appendix A reserved word and INEQUATION does not appear, then all variables are assumed selected.

- If the EQUATION or INVARIABLE keyword cannot be found, then no equations are assumed selected.

- If the EQUATION keyword is entered, but is followed by the end of the file or a reserved word and the INVARIABLE command does not occur, then all equations are assumed selected.
• The keyword INVARIABLE is allowed. It should be followed by variable selection statements. In turn, DISPLAYCR selects all equations which have nonzero entries under the INVARIABLE selections.

• The keyword INEQUATION may be used. It should be followed by equation selection statements. In turn, DISPLAYCR selects all variables which have nonzero entries in the INEQUATION selections.

• The keyword INTERSECT causes only coefficients at the intersection of the specified equations and variables to be displayed. This occurs for all specifications in this run of DISPLAYCR. One should use DISPLAYCR again if some intersecting and some non-intersecting displays are desired.

• When INTERSECT appears along with INVARIABLE, the named variable is selected along with all the equations in which it falls. Similarly, when INTERSECT and INEQUATION appear then all the named equations and the variables appearing in them are selected.

5.16.3.2 MATCHIT

Brief Purpose: MATCHIT retrieves the names and characteristics of selected variables and equations. The characteristics reported tell whether the items are nonlinear as well as reporting scaling characteristics and counts of the coefficients. MATCHIT will summarize the items which match a request or list all the items individually.

Usage Notes: The input to MATCHIT can include the keywords VARIABLE and EQUATION along with those keywords with the prefix LIST attached. When the LIST prefix is not used, the procedure summarizes the characteristics of all items which match the item requests counting the number of matching items, the number of those items which are nonlinear, the total coefficients under or in those items, the number of positive, negative, and nonlinear coefficients that fall under or in those items. This does not list the names of the individual items which match. If the LIST prefix is used (entering LISTVARIABLE or LISTEQUATION) then the individual matching items are printed in the order in which they are encountered. For each matching item the information tells whether it is nonlinear, how many total coefficients it has, the count of positive, negative, and nonlinear coefficients falling under it, and the minimum and maximum absolute values of coefficients under it (excluding the objective function coefficient).

Note that when GAMS internal scaling features are employed then by default scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: This file contains the keyword MATCHIT, followed by optional item selection input data. The optional input identifies the variables and equations to be displayed. This input can contain the keywords VARIABLE or LISTVARIABLE followed by a specification of the variables to be selected using the procedure input specification conventions that were described above. This can be followed by the keyword EQUATION or LISTEQUATION and the specified entries.

Several special cases are relevant:

• If the procedure name is not followed by any selection input, then a count of all variables and equations appears.

• If the input is found, but the input does not begin with VARIABLE, EQUATION, LISTVARIABLE, or LISTEQUATION keywords, then the input is assumed to contain variable names.

• If the VARIABLE keyword is entered, but is not followed by variable selection statements, and LISTVARIABLE does not appear, then all variables are assumed selected.

• If the EQUATION or LISTEQUATION keyword cannot be found, then equations are assumed selected.
• If the EQUATION keyword is entered, but is not followed by equation selection statements or a LISTEQUATION entry, then all equations are assumed selected.

• The keyword LISTVARIABLE is allowed. It should be followed by variable selection statements. In turn, MATCHIT lists all variables which fall under the request.

• The keyword LISTEQUATION may also be used. It should be followed by equation selection statements. In turn, MATCHIT lists all equations which fall under the request.

5.16.3.3 ANALYSIS

Brief Purpose: Analyzes the structure of all variables and equations. Information is given on errors involving obvious model misspecifications causing redundancy, zero variable values, infeasibility, unboundedness, or obvious constraint relaxations in linear programs. The checks are those identified in Tables 1, 2 and 3.

Usage Notes: The analysis tests given in Tables 1 and 2 are utilized to determine if individual variables or equations in the model possess obvious specification errors. One test, for example, considers whether or not in a maximization problem a variable appears which has a positive return in the objective function, but no coefficients in the constraints indicating an obviously unbounded model. Similarly, information is provided on whether certain equations can never be satisfied. For example, tests examine whether an equality equation appears with a negative right hand side and all positives on the left hand side. Also tests see whether the bounds on variables preclude equation satisfaction or make equations redundant (Table 3). In ANALYSIS these tests are applied to each and every variable and equation. The BLOCKPIC and BLOCKLIST routines utilize the tests on a block by block basis. Thus, the messages will be triggered only if every variable or equation in that block has the same problem. Also interactions between variables and equations are not checked so ANALYSIS only finds flaws contained in individual variables/equations.

Input File: The keyword ANALYSIS is all that is accepted.

5.16.3.4 BLOCKLIST

Brief Purpose: The BLOCKLIST procedure displays the number and characteristics of the items in each GAMS variable and equation block.

Usage Notes: The characteristic information gives:

1. The variable sign restriction or equation inequality type.
2. The number of variables or equations in this block;
3. The number of variables or equations with at least one nonlinear term in this block.
4. The number of positive coefficients under the variables or in the equations.
5. The number of negative coefficients under the variables or in the equations.
6. The number of nonlinear coefficients under the variables or in the equations.
7. The largest coefficient in absolute value in this block;
8. The smallest coefficient in absolute value in this block. Analysis tests are also performed as discussed under the ANALYSIS procedure.

Note that when GAMS internal scaling features are employed, the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: No input other than the procedure name is needed.
5.16.3.5 BLOCKPIC

**Brief Purpose:** Generates model schematics and scaling information. The schematics depict coefficient signs, total and average number of coefficients within each GAMS equation and variable block.

**Usage Notes:** These schematics are designed to aid users in identifying flaws in coefficient placement and sign. The summary information on problem scaling characteristics is designed to help users in scaling data. The scaling information is usually reported after any GAMS scaling (using the variablename.scale and equationname.scale features) but before solver scaling. (The user can change whether descaling is done - see the options file). Analysis tests are done using the procedures in Tables 1 and 2.

Note that when GAMS internal scaling features are employed the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

**Input File:** The keyword BLOCKPIC is all that is recognized.

5.16.3.6 PICTURE

**Brief Purpose:** Generates a schematic depicting the location, sign and magnitude of coefficients for selected variables and equations. Users can use this schematic to help identify flaws in coefficient placement, magnitude, or sign. Reports are also generated on the number of individual elements in the pictured portions of each variable and equation.

**Usage Notes:** This output can be quite large, so PICTURE should only be used for small models or model components. Note that when GAMS internal scaling features are employed, the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

**Input File:** Optional input instructions may appear after the PICTURE keyword. This input selects the variables and equations to be included. Only coefficients at the intersection of the selected variables and equations are portrayed. The selected item in the .GCK file can contain the keywords VARIABLE, or INVariable followed by a specification of the selected variables using the procedure input specification conventions above. This can be followed by the keywords EQUATION or INEQUATION and the specified entries. Several special cases are also relevant:

- If the VARIABLE or INEQUATION keywords cannot be found, then all variables are assumed selected.
- If the EQUATION or INVARIABLE keywords cannot be found, then all equations are assumed to selected.
- If the none of the VARIABLE, INVARIABLE, EQUATION, or INEQUATION keywords are found, everything is pictured and all other input is ignored.
- When the INVARIABLE keyword is used, then all equations in which those variables have coefficients are selected along with the named variables.
- When the INEQUATION keyword is used, then all variables which have coefficients in the named equations are selected along with the named equations.
5.16.3.7 POSTOPT

**Brief Purpose:** Does post optimality computations. In that capacity POSTOPT either:

- Reconstructs the reduced cost of variables after a GAMS model solution. Modelers can use this information to discover why certain variables are nonbasic or why certain shadow prices take on particular values, or
- Reconstructs the usage and supply across an equation after a GAMS model solution. Modelers can use this information to discover why certain variables or slacks take on particular values, as well as to find out where items within equations are produced and/or used.

**Usage Notes:** POSTOPT uses essentially the same input conventions as does DISPLAYCR. Thus, the usage notes in that selection are also relevant here. In addition:

1. POSTOPT requires a solution has been obtained GAMSCHK will automatically cause a solver to be invoked unless suppressed by the options file;
2. Nonlinear terms may not be accurate in the row sums as their marginal value not their total value is used but GAMS will have adjusted the right-hand sides for their presence; and
3. Attention can be restricted to only certain types of variables or equations. Variables that are INSOLUTION (Nonzero or with Zero marginals), NOTINSOLUTION (zero with a nonzero marginal) can be requested, BINDING or NONBINDING equations can be focused on.

Note that when GAMS internal scaling features are employed, the default option is that the unscaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

**Input File:** An optional input file is read in, indicating the specific variables desired using the conventions explained under DISPLAYCR above. In addition:

- One can enter INSOLUTION to restrict attention to variables which are nonzero or have zero marginals.
- One can enter NOTINSOLUTION to restrict attention to zero variables.
- The above entries restrict alteration in all VARIABLE or INEQUATION selection statements in a POSTOPT run.
- One can enter BINDING to only consider equations with zero slack. Similarly, NONBINDING considers equations with nonzero slack.
- The above equation specifications restrict all sections by all EQUATION or INVARIABLES items in a POSTOPT run.

5.16.3.8 ADVISORY

**Brief Purpose:** To identify variables which could be unbounded or equations and variable bounds which could cause a model to be infeasible.

**Usage Notes:** The ADVISORY procedure causes a presolution report on the set of all: a) variables which could be unbounded and/or b) equations and variable bounds which could cause infeasibility. The tests used are summarized in Table 3. This procedure identifies all variables which would need to be bounded as well as all constraints which need artificial variables if one wishes to diagnose problems in a model. The same output is also generated by NONOPT but the ADVISORY version does not require a solution.

**Input file:** Just the word ADVISORY
5.16.3.9 NONOPT

Brief Purpose: To help diagnose unbounded and infeasible models.

Usage Notes: The NONOPT procedure can be used in either an informative mode or with models which terminate as unbounded or infeasible. NONOPT will look through an optimal model reporting all variables which may be potentially unbounded or infeasible and all equations which may be infeasible using the checks explained under the ADVISORY section. Also in an unbounded model NONOPT can report the names of unbounded or infeasible variables or equations as well as either budgeting or row summing them. NONOPT runs after a solution and causes a solve to occur.

Input File: NONOPT may be followed by optional keywords IDENTIFY or VERBOSE. The IDENTIFY keyword causes GAMSCHK to report potential unbounded variables and/or infeasible equations. VERBOSE causes full budgets and row summing as done by the POSTOPT procedure on infeasible equations, and/or variables as well as unbounded variables and/or equations. Only the last encountered of the VERBOSE or IDENTIFY keywords will be obeyed. The details on these options are as follows:

1. If the IDENTIFY keyword is used, then the rules in Table 3 are applied to the model. Identify also anticipates that large upper bounds and/or artificial variables may be present. In an optimal condition all variable and equation levels that have exponents greater than the user supplied level filter in the options file (or 6 by default) are identified as items which could be involved with an unbounded model. Similarly, all variables or equations with marginals greater in exponent than the user supplied marginal exponent filter will be identified as items potentially involved with an infeasible model.

2. When the VERBOSE keyword is read then all variables and equations which are listed as nonoptimal or infeasible are treated using the budgeting and row summing aspects of POSTOPT.

3. When no keyword is found and the model solution is not optimal then the nonoptimal equations, infeasible equations and/or nonoptimal variables automatically listed.

5.16.4 Options File

GAMSCHK accepts an option file controlling solver choice (when needed); descaling; and size of the nonoptimal filters; the number of variable and column blocks selection entries allowed. The file is called GAMSCHK.OPT

5.16.4.1 Solver Choice Options

GAMSCHK calls for the solution of the problem when the POSTOPT or NONOPT procedures are used. In doing this, GAMSCHK internally selects the default GAMS solver for a problem class. Users may override this choice using the solver options file. Users may also force or suppress the solution process.

There are 16 solver related keywords allowed in the options file. These are as follows:

<table>
<thead>
<tr>
<th>OPTION</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>LP</td>
<td>Gives name of solver for LP problems</td>
</tr>
<tr>
<td>MIP</td>
<td>Gives name of solver for MIP problems</td>
</tr>
<tr>
<td>RMIP</td>
<td>Gives name of solver for RMIP problems</td>
</tr>
<tr>
<td>NLP</td>
<td>Gives name of solver for NLP problems</td>
</tr>
<tr>
<td>MCP</td>
<td>Gives name of solver for MCP problems</td>
</tr>
<tr>
<td>MPEC</td>
<td>Gives name of solver for MPEC problems</td>
</tr>
</tbody>
</table>
### 5.16 GAMSCHK

<table>
<thead>
<tr>
<th>OPTION</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>RMPEC</td>
<td>Gives name of solver for RMPEC problems</td>
</tr>
<tr>
<td>CNS</td>
<td>Gives name of solver for CNS problems</td>
</tr>
<tr>
<td>DNLP</td>
<td>Gives name of solver for DNLP problems</td>
</tr>
<tr>
<td>MINLP</td>
<td>Gives name of solver for MINLP problems</td>
</tr>
<tr>
<td>RMINLP</td>
<td>Gives name of solver for RMINLP problems</td>
</tr>
<tr>
<td>SOLVERNAME</td>
<td>Gives name of solver to be used regardless of problem type</td>
</tr>
<tr>
<td>NOSOLVE</td>
<td>Suppresses solution of the problem</td>
</tr>
<tr>
<td>SOLVE</td>
<td>Forces solution of the problem</td>
</tr>
<tr>
<td>DESCALE</td>
<td>Controls treatment of scaling</td>
</tr>
<tr>
<td>OPTFILE</td>
<td>Solver options file number</td>
</tr>
</tbody>
</table>

In the first five cases, the option name is followed by the name of one of the licensed solvers. If the options file is empty, then the default solver will be used. If a solver name is given, then that solver will be used provided it matches the name of a solver GAMS recognizes.

#### 5.16.4.2 When Should I Use SOLVE or NOSOLVE

Ordinarily GAMSCHK will cause a solver to be used if either the POSTOPT or the NONOPT options are used. However, users can force solutions under other cases or suppress solutions if desired.

One should only force a solution (using the SOLVE option) when one wishes to use the solution information after GAMSCHK is done either to examine the solution output or do post optimality calculations. Forcing a solution will not cause GAMSCHK to have improved representations of nonlinear terms. That will only occur when a SOLVE statement is executed before the SOLVE statement involving GAMSCHK.

#### 5.16.4.3 Control of Number of Variable and Row Selections Allowed

The GAMSCHK program uses an upper estimate on the number of variable or equation blocks. In rare circumstances users may wish to override this choice. The options for this are:

<table>
<thead>
<tr>
<th>OPTION</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARBLOCK</td>
<td>Maximum number of variable blocks allowed</td>
</tr>
<tr>
<td>EQUBLOCK</td>
<td>Maximum number of equation blocks allowed</td>
</tr>
</tbody>
</table>

These options are followed by a number, but should not be routinely used.

#### 5.16.4.4 Scaling

GAMS users may be utilizing internal features which involve scaling through the Model-name.SCALEOPT=1, VariableName.SCALE, and EquationName.SCALE options. GAMSCHK can work with these options to create output which reflects scaled, unscaled or partially unscaled output. In particular, the command DESCALE can be entered with one of three options: NEVER, ALL, or PART. If you enter NEVER, then none of the model output will be descaled. If you enter ALL, then all of the model output will be descaled. The third option is to use PART. In that case the NONOPT and POSTOPT output will be descaled whereas scaled information will be displayed for PICTURE, BLOCKPIC, BLOCKLIST, MATCHIT and DISPLAYCR. The PART option allows investigation of scaling. If you do not enter a DESCALE option then all information will be reported as if the PART option was chosen.
5.16.4.5 NONOPT Filters

The NONOPT model in "IDENTIFY" mode checks through a model solution to identify large marginals and/or large variable values. The limits on these checks are provided by two options:

<table>
<thead>
<tr>
<th>OPTION</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEVELFILT</td>
<td>Numerical value of exponent on &quot;unbounded levels&quot;</td>
</tr>
<tr>
<td>MARGFILT</td>
<td>Numerical value of exponent on &quot;infeasible marginals&quot;</td>
</tr>
</tbody>
</table>

These options provide upper bounds on the exponents of the absolute values for the levels and marginals. They are followed by an integer which gives the exponent. Thus, entries like

```
LEVELFILT 7
MARGFILT 7
```

will cause the reporting of all marginals and levels which are greater in absolute value than $10^7$.

5.16.4.6 Example Options File

The GAMSCHK option file is called GAMSCHK.OPT. An example of a file could look like the following 6 lines:

```
LP SOPLEX
MIP CBC
VARIABLE 50
SOLVE
DESCALE PART
LEVELFILT 4
```

5.16.4.7 Solver Options File

One other important aspect regarding the options file involves the use of a problem solver options file when a solver such as SOPLEX, CBC, IPOPT etc. is also being used. As seen above the GAMSCHK.OPT does not recognize option commands such as those which would be submitted to the programming model solvers - SOPLEX for example. In all cases GAMSCHK will cause the default option file for the solver to be used when invoking the solver. Thus if SOPLEX and the options file is invoked is being used, SOPLEX options are controlled by the option file SOPLEX.OPT while GAMSCHK.OPT controls GAMSCHK operation. Users can change the number of the solver options file being used by using the OPTFILE parameter in the options file. OPTFILE 2 would cause use of solver options file .OP2.

5.16.5 Known Bugs

There are a few bugs that can cause GAMSCHK to report improper outputs or results. A list of the known bugs, their symptoms and a remedy is given below.
<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Remedy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zero Shadow Prices in POSTOPT</td>
<td>Old GAMS version or no Prior Solve</td>
<td>1) Make sure the model was solved, 2) if it was, do not suppress solve in option file, or 3) update to most recent GAMS version</td>
</tr>
<tr>
<td>Descaling Does Not Work</td>
<td>Old Version of GAMS</td>
<td>Update</td>
</tr>
<tr>
<td>GAMS Blows up after GAMSchk Runs</td>
<td>Old GAMS version</td>
<td>Ignore, *.LST file, results are fine, can be fixed by updating to the most recent version of GAMS</td>
</tr>
<tr>
<td>POSTOPT has error in budgets equal to twice objective function coefficient for nonlinear maximizations</td>
<td>Old GAMS MINOS version</td>
<td>Switch to a minimization formulation or update GAMS/MINOS</td>
</tr>
<tr>
<td>ROWSUM does not fully account for the value of nonlinear terms in POSTOPT</td>
<td>Value of nonlinear terms sent from GAMS are only a marginal value</td>
<td>None planned. GAMSCHK would need reprogramming</td>
</tr>
<tr>
<td>Error message about size of VARBLOCK or EQNBLOCK</td>
<td>exceeded maximum number of blocks</td>
<td>Modify option file, enlarging or eliminating parameters</td>
</tr>
<tr>
<td>GAMSCHK won’t run</td>
<td>Files are not properly installed</td>
<td>Recheck installation. If still doesn’t work report to author</td>
</tr>
<tr>
<td>Zero shadow prices when using NOSOLVE</td>
<td>Old version of GAMS solvers or Shadow prices suppressed</td>
<td>Try changing GAMSOMP.TXT lines 2 or 0 to 12 or 10, if that doesn’t work update GAMS.</td>
</tr>
</tbody>
</table>

5.16.6 Tables

Table 1: Conditions under which a modeler should be advised of potential difficulty for equations without nonlinear terms.

- **a/** The PS cases indicate, because the variables in this equation follow this pattern, that:
  1. The variables appearing with nonzeros in this equation are forced to equal zero.
  2. This equation can never be satisfied and is obviously infeasible.
  3. This equation is redundant. The nonnegativity conditions are a stronger restriction.

- **b/** In the examples x denotes indexed non-negative variables, y indexed non-positive variables, and z a single unrestricted variable.

- **c/** Here and in the cases below at least one nonzero must occur.

- **d/** These entries give examples of the problem covered by each warning. Namely, in the first case examining only the nonnegative variables suppose all those variables have signs $\geq 0$ but the right-hand-side is zero. Thus, we have $X \geq 0$ and $X \leq 0$ which implies $X = 0$. A warning is generated in that case.

- **e/** Only one coefficient is allowed.

5.17 Gurobi

Gurobi Optimization, [www.gurobi.com] (http://www.gurobi.com)

5.17.1 Introduction

The Gurobi suite of optimization products include state-of-the-art simplex and parallel barrier solvers for linear programming (LP) and quadratic programming (QP), parallel barrier solver for quadratically constrained programming (QCP), as well as parallel mixed-integer linear programming (MILP), mixed-integer quadratic programming (MIQP) and mixed-integer quadratically constrained programming (MIQCP) solvers.

The Gurobi MIP solver includes shared memory parallelism, capable of simultaneously exploiting any number of processors and cores per processor. The implementation is deterministic: two separate runs on the same model will produce identical solution paths.

While numerous solving options are available, Gurobi automatically calculates and sets most options at the best values for specific problems. All Gurobi options available through GAMS/Gurobi are summarized at the end of this chapter.

We offer a GAMS/Gurobi-Link license that works in combination with a Gurobi callable library license from Gurobi Optimization Inc.

Attention

The free bare-bone link mode (previously GAMS/OSIGUROBI) that allowed to solve LP and MIP when the user had a separate GUROBI license has been removed. If you relied on using this bare-bone link option, then do not hesitate to contact sales@gams.com to arrange for a GAMS/Gurobi-Link license.

5.17.2 How to Run a Model with Gurobi

The following statement can be used inside your GAMS program to specify using Gurobi

```
Option LP = Gurobi; { or MIP or RMIP or QCP or MIQCP or RMIQCP }
```

The above statement should appear before the `solve` statement. If Gurobi was specified as the default solver during GAMS installation, the above statement is not necessary.
5.17.3 Overview of GAMS/Gurobi

5.17.3.1 Linear, Quadratic and Quadratic Constrained Programming

Gurobi can solve LP and convex QP problems using several alternative algorithms, while the only choice for solving convex QCP is the parallel barrier algorithm. The majority of LP problems solve best using Gurobi’s state-of-the-art dual simplex algorithm, while most convex QP problems solve best using the parallel barrier algorithm. Certain types of LP problems benefit from using the parallel barrier or the primal simplex algorithms, while for some types of QP, the dual or primal simplex algorithm can be a better choice. If you are solving LP problems on a multi-core system, you should also consider using the concurrent optimizer. It runs different optimization algorithms on different cores, and returns when the first one finishes.

GAMS/Gurobi also provides access to the Gurobi infeasibility finder. The infeasibility finder takes an infeasible linear program and produces an irreducibly inconsistent set of constraints (IIS). An IIS is a set of constraints and variable bounds which is infeasible but becomes feasible if any one member of the set is dropped. GAMS/Gurobi reports the IIS in terms of GAMS equation and variable names and includes the IIS report as part of the normal solution listing. The infeasibility finder is activated by the option IIS. Another option for analyzing infeasible model the FeasOpt option which instructs GAMS/Gurobi to find a minimal feasible relaxation of an infeasible model. See section Feasible Relaxation for details.

GAMS/Gurobi supports sensitivity analysis (post-optimality analysis) for linear programs which allows one to find out more about an optimal solution for a problem. In particular, objective ranging and constraint ranging give information about how much an objective coefficient or a right-hand-side and variable bounds can change without changing the optimal basis. In other words, they give information about how sensitive the optimal basis is to a change in the objective function or the bounds and right-hand side. GAMS/Gurobi reports the sensitivity information as part of the normal solution listing. Sensitivity analysis is activated by the option Sensitivity.

The Gurobi presolve can sometimes diagnose a problem as being infeasible or unbounded. When this happens, GAMS/Gurobi can, in order to get better diagnostic information, rerun the problem with presolve turned off. The rerun without presolve is controlled by the option ReRun. In default mode only problems that are small (i.e. demo sized) will be rerun.

Gurobi can either presolve a model or start from an advanced basis or primal/dual solution pair. Often the solve from scratch of a presolved model outperforms a solve from an unpresolved model started from an advanced basis/solution. It is impossible to determine a priori if presolve or starting from a given advanced basis/solution without presolve will be faster. By default, GAMS/Gurobi will automatically use an advanced basis or solution from a previous solve statement. The GAMS BRatio option can be used to specify when not to use an advanced basis/solution. The GAMS/Gurobi option UseBasis can be used to ignore or force a basis/solution passed on by GAMS (it overrides BRatio). In case of multiple solves in a row and slow performance of the second and subsequent solves, the user is advised to set the GAMS BRatio option to 1.

5.17.3.2 Mixed-Integer Programming

The methods used to solve pure integer and mixed integer programming problems require dramatically more mathematical computation than those for similarly sized pure linear or quadratic programs. Many relatively small integer programming models take enormous amounts of time to solve.

For problems with discrete variables, Gurobi uses a branch and cut algorithm which solves a series of subproblems, LP subproblems for MILP, QP subproblems for MIQP, and QCP subproblems or LP outer approximation subproblems for MIQCP. Because a single mixed integer problem generates many subproblems, even small mixed integer problems can be very compute intensive and require significant amounts of physical memory. With option nonConvex Gurobi can also solve nonconvex (MI)QP and (MI)QCP problems using a spatial branch-and-bound method.
GAMS/Gurobi supports Special Order Sets of type 1 and type 2 as well as semi-continuous and semi-integer variables.

You can provide a known solution (for example, from a MIP problem previously solved or from your knowledge of the problem) to serve as the first integer solution.

If you specify some or all values for the discrete variables together with GAMS/Gurobi option MipStart, Gurobi will check the validity of the values as an integer-feasible solution. If this process succeeds, the solution will be treated as an integer solution of the current problem.

The Gurobi MIP solver includes shared memory parallelism, capable of simultaneously exploiting any number of processors and cores per processor. The implementation is deterministic: two separate runs on the same model will produce identical solution paths.

5.17.3.3 Nonlinear Programming

Gurobi is not a general purpose nonlinear programming solver, but it is able to handle certain nonlinear constraints by reformulating them into supported linear and/or quadratic constraints. These constraints are:

- MAX constraint:
  
eq 1.. r =e= \max(x_1,x_2,x_3,...,c);
  \eq z_2.. r =e= \max(i, x(i));

- MIN constraint:
  
eq 1.. r =e= \min(x_1,x_2,x_3,...,c);
  \eq z_2.. r =e= \min(i, x(i));

- AND constraint:
  
eq 1.. r =e= b_1 \text{ and } b_2 \text{ and } b_3 \text{ and } ...;
  \eq z_2.. r =e= \text{ and } (b(i));

- OR constraint:
  
eq 1.. r =e= b_1 \text{ or } b_2 \text{ or } b_3 \text{ or } ...;
  \eq z_2.. r =e= \text{ or } (b(i));

- ABS constraint:
  
eq r =e= \abs(x);

- EXP constraint:
  
eq 1.. r =e= \exp(x);
  \eq z_2.. r =e= x^a;
  \eq z_3.. r =e= a^x;

Here, \( a > 0 \) and for \eq 3 the lower bound of \( x \) must be nonnegative.

- LOG constraint:
  
eq 1.. r =e= \log(x);
  \eq z_2.. r =e= \log2(x);
  \eq z_3.. r =e= \log10(x);
• SIN / COS / TAN constraint:

    eq1.. r =e= sin(x);
    eq2.. r =e= cos(x);
    eq3.. r =e= tan(x);

• NORM constraint:

    eq1_1.. r =e= sum(i, abs(x(i)));
    eq1_2.. r =e= abs(x1) + abs(x2) + abs(x3) + abs(x4);
    eq2_1.. r =e= edist(x1,x2,x3,...);
    eq2_2.. r =e= sqrt(sum(i, sqr(x(i))));
    eq2_3.. r =e= sqrt(sqr(x1) + sqr(x2) + sqr(x3) + sqr(x4));
    eq3_1.. r =e= smax(i, abs(x(i)));
    eq3_2.. r =e= max(abs(x1), abs(x2), abs(x3), abs(x4));

    Note that a 2-norm constraint can lead to a non-convex quadratic model which is much harder to
    solve than a convex quadratic or linear model.

• POLY constraint:

    eq.. r =e= poly(x, a0, a1, a2, ...);

• SIGMOID constraint:

    eq1.. r =e= sigmoid(x);
    eq2.. r =e= 1 / (1 + exp(-x));

    Note
    Nonlinear constraints must perfectly match one of the above forms. Otherwise, GAMS/Gurobi
    will raise a capability error. For example, it is not possible to interchange left-hand-side and
    right-hand-side of the above constraints.

5.17.3.4 Feasible Relaxation

The Infeasibility Finder identifies the causes of infeasibility by means of inconsistent set of constraints
(IIS). However, you may want to go beyond diagnosis to perform automatic correction of your model
and then proceed with delivering a solution. One approach for doing so is to build your model with
explicit slack variables and other modeling constructs, so that an infeasible outcome is never a possibility.
An automated approach offered in GAMS/Gurobi is known as FeasOpt (for Feasible Optimization) and
turned on by parameter FeasOpt in a GAMS/Gurobi option file.

With the FeasOpt option GAMS/Gurobi accepts an infeasible model and selectively relaxes the bounds
and constraints in a way that minimizes a weighted penalty function. In essence, the feasible relaxation
tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS
and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the
listing file.

By default all equations are candidates for relaxation and weighted equally but none of the variables
can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable
bounds and constraints. These preferences can be conveniently specified with the .feaspref option. The
input value denotes the users willingness to relax a constraint or bound. The larger the preference, the
more likely it will be that a given bound or constraint will be relaxed. More precisely, the reciprocal of
the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed. It is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a GAMS/Gurobi solver option file using dot options. The syntax is:

\textit{(variable or equation).feaspref(value)}

For example, suppose we have a GAMS declaration:

\begin{verbatim}
Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);
\end{verbatim}

Then, the relaxation preference in the \textit{gurobi.opt} file can be specified by:

\begin{verbatim}
feasopt 1
v.feaspref 1
v.feaspref('i1',*) 2
v.feaspref('i1','j2') 0
e.feaspref(*,'j1') 0
e.feaspref('i5','j4') 2
\end{verbatim}

First we turn the feasible relaxation on. Furthermore, we specify that all variables \textit{v(i,j)} have preference of 1, except variables over set element \textit{i1}, which have a preference of 2. The variable over set element \textit{i1} and \textit{j2} has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords \textit{variables} or \textit{equations} instead of the individual variable and equations names (e.g. \textit{variables.feaspref 1}).

The parameter \textit{FeasOptMode} allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter \textit{FeasOptMode} indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a \textit{sum} of required relaxations; as the \textit{number} of constraints and bounds required to be relaxed; as a \textit{sum of the squares} of required relaxations). Please check description of parameter \textit{FeasOptMode} for details. Also check example models \textit{feasopt*} in the GAMS Model library.

### 5.17.3.5 Parameter Tuning Tool

The Gurobi Optimizer provides a wide variety of parameters that allow you to control the operation of the optimization engines. The level of control varies from extremely coarse-grained (e.g., the \textit{Method} parameter, which allows you to choose the algorithm used to solve continuous models) to very fine-grained (e.g., the \textit{MarkowitzTol} parameter, which allows you to adjust the precise tolerances used during simplex basis factorization). While these parameters provide a tremendous amount of user control, the immense space of possible options can present a significant challenge when you are searching for parameter settings that improve performance on a particular model. The purpose of the Gurobi tuning tool is to automate this search.
The Gurobi tuning tool performs multiple solves on your model, choosing different parameter settings for each, in a search for settings that improve runtime. The longer you let it run, the more likely it is to find a significant improvement.

A number of tuning-related parameters allow you to control the operation of the tuning tool. The most important is probably TuneTimeLimit, which controls the amount of time spent searching for an improving parameter set. Other parameters include TuneTrials (which attempts to limit the impact of randomness on the result), TuneResults (which limits the number of results that are returned), and TuneOutput (which controls the amount of output produced by the tool).

While parameter settings can have a big performance effect for many models, they aren’t going to solve every performance issue. One reason is simply that there are many models for which even the best possible choice of parameter settings won’t produce an acceptable result. Some models are simply too large and/or difficult to solve, while others may have numerical issues that can’t be fixed with parameter changes.

Another limitation of automated tuning is that performance on a model can experience significant variations due to random effects (particularly for MIP models). This is the nature of search. The Gurobi algorithms often have to choose from among multiple, equally appealing alternatives. Seemingly innocuous changes to the model (such as changing the order of the constraint or variables), or subtle changes to the algorithm (such as modifying the random number seed) can lead to different choices. Often times, breaking a single tie in a different way can lead to an entirely different search. We’ve seen cases where subtle changes in the search produce 100X performance swings. While the tuning tool tries to limit the impact of these effects, the final result will typically still be heavily influenced by such issues.

The bottom line is that automated performance tuning is meant to give suggestions for parameters that could produce consistent, reliable improvements on your models. It is not meant to be a replacement for efficient modeling or careful performance testing.

5.17.3.6 Compute Server

The Gurobi Compute Server allows you to use one or more servers to offload all of your Gurobi computations.

Gurobi compute servers support queuing and load balancing. You can set a limit on the number of simultaneous jobs each compute server will run. When this limit has been reached, subsequent jobs will be queued. If you have multiple compute servers, the current job load is automatically balanced among the available servers. By default, the Gurobi job queue is serviced in a First-In, First-Out (FIFO) fashion. However, jobs can be given different priorities. Jobs with higher priorities are then selected from the queue before jobs with lower priorities.

Gurobi Compute Server licenses and software are not included in GAMS/Gurobi. Contact Gurobi directly to inquire about the software and license.

5.17.3.7 Distributed Parallel Algorithms

Gurobi Optimizer implements a number of distributed algorithms that allow you to use multiple machines to solve a problem faster. Available distributed algorithms are:

- A distributed MIP solver, which allows you to divide the work of solving a single MIP model among multiple machines. A manager machine passes problem data to a set of worker machines in order to coordinate the overall solution process.

- A distributed concurrent solver, which allows you to use multiple machines to solve an LP or MIP model. Unlike the distributed MIP solver, the concurrent solver doesn’t divide the work associated with solving the problem among the machines. Instead, each machine uses a different strategy to solve the whole problem, with the hope that one strategy will be particularly effective and will finish much earlier than the others. For some problems, this concurrent approach can be more effective than attempting to divide up the work.
• **Distributed parameter tuning**, which automatically searches for parameter settings that improve performance on your optimization model. Tuning solves your model with a variety of parameter settings, measuring the performance obtained by each set, and then uses the results to identify the settings that produce the best overall performance. The distributed version of tuning performs these trials on multiple machines, which makes the overall tuning process run much faster.

These distributed parallel algorithms are designed to be almost entirely transparent to the user. The user simply modifies a few parameters, and the work of distributing the computation to multiple machines is handled behind the scenes by Gurobi.

### 5.17.3.7.1 Specifying the Worker Pool

Once you've set up a set of one or more distributed workers, you should list at least one of their names in the `WorkerPool` parameter. You can provide either machine names or IP addresses, and they should be comma-separated.

You can provide the worker access password through the `WorkerPassword` parameter. All servers in the worker pool must have the same access password.

### 5.17.3.7.2 Requesting Distributed Algorithms

Once you've set up the worker pool through the appropriate parameters, the last step to use a distributed algorithm is to set the `TuneJobs`, `ConcurrentJobs`, or `DistributedMIPJobs` parameter. These parameters are used to indicate how many distinct tuning, concurrent, or distributed MIP jobs should be started on the available workers.

If some of the workers in your worker pool are running at capacity when you launch a distributed algorithm, the algorithm won't create queued jobs. Instead, it will launch as many jobs as it can (up to the requested value), and it will run with these jobs.

These distributed algorithms have been designed to be nearly indistinguishable from the single machine versions. Our hope is that, if you know how to use the single machine version, you'll find it straightforward to use the distributed version. The distributed algorithms respect all of the usual parameters. For distributed MIP, you can adjust strategies, adjust tolerances, set limits, etc. For concurrent MIP, you can allow Gurobi to choose the settings for each machine automatically or specify a set of options. For distributed tuning, you can use the usual tuning parameters, including `TuneTimeLimit`, `TuneTrails`, and `TuneOutput`.

There are a few things to be aware of when using distributed algorithms, though. One relates to relative machine performance. Distributed algorithms work best if all of the workers give very similar performance. For example, if one machine in your worker pool were much slower than the others in a distributed tuning run, any parameter sets tested on the slower machine would appear to be less effective than if they were run on a faster machine. Similar considerations apply for distributed MIP and distributed concurrent. We strongly recommend that you use machines with very similar performance. Note that if your machines have similarly performing cores but different numbers of cores, we suggest that you use the `Threads` parameter to make sure that all machines use the same number of cores.

Logging for distributed MIP is very similar to the standard MIP logging. The main differences are in the progress section. The header for the standard MIP logging looks like this:

```
<table>
<thead>
<tr>
<th>Nodes</th>
<th>Current Node</th>
<th>Objective Bounds</th>
<th>Work</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expl</td>
<td>Unexpl</td>
<td>Obj Depth IntInf</td>
<td>Incumbent</td>
</tr>
</tbody>
</table>
```

By contrast, the distributed MIP header looks like this:

```
<table>
<thead>
<tr>
<th>Nodes</th>
<th>Current Node</th>
<th>Objective Bounds</th>
<th>Work</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expl</td>
<td>Unexpl</td>
<td>Obj Depth IntInf</td>
<td>Incumbent</td>
</tr>
</tbody>
</table>
```
Instead of showing iterations per node, the last field in the distributed log shows parallel utilization. Specifically, it shows the fraction of the preceding time period (the time since the previous progress log line) that the workers spent actively processing MIP nodes.

Here is an example of a distributed MIP progress log:

<table>
<thead>
<tr>
<th>Nodes</th>
<th>Utilization</th>
<th>Objective Bounds</th>
<th>Work</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Expl Unexpl</td>
<td>Obj Depth IntInf</td>
<td>Incumbent BestBd Gap</td>
</tr>
<tr>
<td>H 0</td>
<td>157344.6103</td>
<td>- -</td>
<td>0s</td>
</tr>
<tr>
<td>H 0</td>
<td>40707.72914</td>
<td>- -</td>
<td>0s</td>
</tr>
<tr>
<td>H 0</td>
<td>28468.53497</td>
<td>- -</td>
<td>0s</td>
</tr>
<tr>
<td>H 0</td>
<td>18150.08386</td>
<td>- -</td>
<td>0s</td>
</tr>
<tr>
<td>H 0</td>
<td>14372.87128</td>
<td>- -</td>
<td>0s</td>
</tr>
<tr>
<td>H 0</td>
<td>13725.47538</td>
<td>- -</td>
<td>0s</td>
</tr>
<tr>
<td>0</td>
<td>0 10543.761</td>
<td>19 13725.4754</td>
<td>10543.7611 23.2% 99% 0s</td>
</tr>
<tr>
<td>* 266</td>
<td>12988.46803</td>
<td>10543.7611</td>
<td>18.8% 0s</td>
</tr>
<tr>
<td>H 1503</td>
<td>12464.09984</td>
<td>10630.6187</td>
<td>14.7% 0s</td>
</tr>
<tr>
<td>* 2350</td>
<td>12367.60865</td>
<td>10632.7061</td>
<td>14.0% 1s</td>
</tr>
<tr>
<td>* 3360</td>
<td>12234.64180</td>
<td>10641.4586</td>
<td>13.0% 1s</td>
</tr>
<tr>
<td>H 3870</td>
<td>11801.18572</td>
<td>10641.4586</td>
<td>9.83% 99% 0s</td>
</tr>
</tbody>
</table>

Ramp-up phase complete - continuing with instance 2 (best bd 10661)

One thing you may find in the progress section is that node counts may not increase monotonically. Distributed MIP tries to create a single, unified view of node numbers, but with multiple machines processing nodes independently, possibly at different rates, some inconsistencies are inevitable.

Another difference is the line that indicates that the distributed ramp-up phase is complete. At this point, the distributed strategy transitions from a concurrent approach to a distributed approach. The log line indicates which worker was the winner in the concurrent approach. Distributed MIP continues by dividing the partially explored MIP search tree from this worker among all of the workers.

Another difference in the distributed log is in the summary section. The distributed MIP log includes a breakdown of how runtime was spent:

Runtime breakdown:
- Active: 37.85s (93%)
- Sync: 2.43s (6%)
- Comm: 0.34s (1%)

This is an aggregated view of the utilization data that is displayed in the progress log lines. In this example, the workers spent 93% of runtime actively working on MIP nodes, 6% waiting to synchronize with other workers, and 1% communicating data between machines.

The installation instructions for the Gurobi Remote Services can be found on Gurobi's web page [www.gurobi.com](http://www.gurobi.com).
5.17.3.7.3  Gurobi Instant Cloud  An alternative to setting up your own pool of machines is to use the Gurobi Instant Cloud. You only need a GAMS/Gurobi link license when you solve your problems in the Gurobi Instant Cloud. The cost for the Gurobi license is paid on a per use basis directly to Gurobi. If you follow through the steps on the Gurobi web site, you eventually get the names of the machines Gurobi has started for you in the cloud. In order to use these machines from GAMS/Gurobi, you need to provide a Gurobi license with access instructions for the Gurobi Instant Cloud (detailed instructions for configuring the client license file).

5.17.3.8  Solution Pool

While the default goal of the Gurobi Optimizer is to find one proven optimal solution to your model, with a possible side-effect of finding other solutions along the way, the solver provides a number of parameters that allow you to change this behavior.

By default, the Gurobi MIP solver will try to find one proven optimal solution to your model. It will typically find multiple sub-optimal solutions along the way, which can be retrieved later. However, these solutions aren't produced in a systematic way. The set of solutions that are found depends on the exact path the solver takes through the MIP search. You could solve a MIP model once, obtaining a set of interesting sub-optimal solutions, and then solve the same problem again with different parameter settings, and find only the optimal solution.

To store (some of the) solutions found along the way, you can enable the Solution Pool feature by setting option solnpool. If you'd like more control over how solutions are found and retained, the Gurobi Optimizer has a number of parameters available for this. The first and simplest is PoolSolutions, which controls the size of the solution pool. Changing this parameter won't affect the number of solutions that are found - it simply determines how many of those are retained.

You can use the PoolSearchMode parameter to control the approach used to find solutions. In its default setting (0), the MIP search simply aims to find one optimal solution. Setting the parameter to 1 causes the MIP search to expend additional effort to find more solutions, but in a non-systematic way. You will get more solutions, but not necessarily the best solutions. Setting the parameter to 2 causes the MIP to do a systematic search for the n best solutions. For both non-default settings, the PoolSolutions parameter sets the target for the number of solutions to find.

If you are only interested in solutions that are within a certain gap of the best solution found, you can set the PoolGap parameter. Solutions that are not within the specified gap are discarded.

Obtaining an OPTIMAL optimization return status when using PoolSearchMode=2 indicates that the MIP solver succeeded in finding the desired number of best solutions, or it proved that the model doesn't have that many distinct feasible solutions. If the solver terminated early (e.g., due to a time limit), you PoolObjBound attribute (printed to the log) to evaluate the quality of the solutions that were found. This attribute gives a bound on the objective of any solution that isn't already in the solution pool. The difference between this attribute and ObjBound is that the latter gives a bound on the objective for any solution, and which is often looser than PoolObjBound. The PoolObjBound attribute gives a bound on the objective of undiscovered solutions. Further tree exploration won't find better solutions. You can use this bound to get a count of how many of the n best solutions you found: any solutions whose objective values are at least as good as PoolObjBound are among the n best.

5.17.3.8.1  Solution Pool Example  Let's continue with a few examples of how these parameters would be used. Imagine that you are solving a MIP model with an optimal (minimization) objective of 100. Further imagine that, using default settings, the MIP solver finds four solutions to this model with objectives 100, 110, 120, and 130.

If you set the PoolSolutions parameter to 3 and solve the model again, the MIP solver would discard the worst solution and return with 3 solutions in the solution pool. If you instead set the PoolGap parameter
to value 0.2, the MIP solver would discard any solutions whose objective value is worse than 120 (which would also leave 3 solutions in the solution pool).

If you set the PoolSearchMode parameter to 2 and the PoolSolutions parameter to 10, the MIP solver would attempt to find the 10 best solutions to the model. An OPTIMAL return status would indicate that either (i) it found the 10 best solutions, or (ii) it found all feasible solutions to the model, and there were fewer than 10. If you also set the PoolGap parameter to a value of 0.1, the MIP solver would try to find 10 solutions with objective no worse than 110. While this may appear equivalent to asking for 10 solutions and simply ignoring those with objective worse than 110, the solve will typically complete significantly faster with this parameter set, since the solver does not have to expend effort looking for solutions beyond the requested gap.

5.17.3.8.2 Solution Pool Subtleties
There are a few subtleties associated with finding multiple solutions that we’ll cover now.

Continuous Variables
One subtlety arises when considering multiple solutions for models with continuous variables. Specifically, you may have two solutions that take identical values on the integer variables but where some continuous variables differ. By choosing different points on the line between these two solutions, you actually have an infinite number of choices for feasible solutions to the problem. To avoid this issue, we define two solutions as being equivalent if they take the same values on all integer variables (and on all continuous variables that participate in SOS constraints). A solution will be discarded if it is equivalent to another solution that is already in the pool.

Optimality Gap
The interplay between the optimality gap (MIPGap or MIPGapAbs) and multiple solutions can be a bit subtle. When using the default PoolSearchMode, a non-zero optimality gap indicates that you are willing to allow the MIP solver to declare a solution optimal, even though the model may have other, better solutions. The claim the solver makes upon termination is that no other solution would improve the incumbent objective by more than the optimality gap. Terminating at this point is ultimately a pragmatic choice - we’d probably rather have the true best solution, but the cost of reducing the optimality gap to zero can often be prohibitive.

This pragmatic choice can produce a bit of confusion when finding multiple optimal solutions. Specifically, if you ask for the n best solutions, the optimality gap plays a similar role as it does in the default case, but the implications may be a bit harder to understand. Specifically, a non-zero optimality gap means that you are willing to allow the solver to declare that it has found the n best solutions, even though there may be solutions that are better than those that were returned. The claim in this case is that any solution not among the reported n best would improve on the objective for the worst among the n best by less than the optimality gap.

If you want to avoid this source of potential confusion, you should set the optimality gap to 0 when using PoolSearchMode=2.

Logging
If you browse the log from a MIP solve with PoolSearchMode set to a non-default value, you may see the lower bound on the objective exceed the upper bound. This can’t happen with the default PoolSearchMode - if you are only looking for one optimal solution, the search is done as soon as the lower bound reaches the upper bound. However, if you are looking for the n best solutions, you have to prove that the model has no solution better than the n-th best. The objective for that n-th solution could be much worse than that of the incumbent. In this situation, the log file will include a line of the form:

Optimal solution found at node 123 - now completing solution pool...

Distributed MIP
One limitation that we should point out related to multiple solutions is that the distributed MIP solver has not been extended to support non-default PoolSearchMode settings. Distributed MIP will typically produce many more feasible solutions than non-distributed MIP, but there’s no way to ask it to find the n best solutions.
5.17 Gurobi

5.17.3.9 Multiple Objectives

While typical optimization models have a single objective function, real-world optimization problems often have multiple, competing objectives. For example, in a production planning model, you may want to both maximize profits and minimize late orders, or in a workforce scheduling application, you may want to both minimize the number of shifts that are short-staffed while also respecting worker’s shift preferences.

The main challenge you face when working with multiple, competing objectives is deciding how to manage the tradeoffs between them. Gurobi provides tools that simplify the task: Gurobi allows you to blend multiple objectives, to treat them hierarchically, or to combine the two approaches. In a blended approach, you optimize a weighted combination of the individual objectives. In a hierarchical or lexicographic approach, you set a priority for each objective, and optimize in priority order. When optimizing for one objective, you only consider solutions that would not degrade the objective values of higher-priority objectives. Gurobi allows you to enter and manage your objectives, to provide weights for a blended approach, or to set priorities for a hierarchical approach. Gurobi will only solve multi-objective models with strictly linear objectives. Moreover, for continous models, Gurobi will report a primal only solution (not dual information).

Following the workforce application the specifications of the objectives would be done as follows:

```plaintext
equations defObj, defNumShifts, defSumPreferences;
variables obj, numShifts, sumPreferences;

defObj.. obj =e= numShifts - 1/100*sumPreferences;
defNumShifts.. numShifts =e= ...;
defSumPreferences.. sumPreferences =e= ...;

model workforce /all/;
solve workforce minimizing obj using mip;
```

With the default setting GUROBI will solve the blended objective. Using the parameter MultObj GUROBI will use a hierarchical approach. A hierarchical or lexicographic approach assigns a priority to each objective, and optimizes for the objectives in decreasing priority order. At each step, it finds the best solution for the current objective, but only from among those that would not degrade the solution quality for higher-priority objectives. The priority is specified by the absolute value of the objective coefficient in the blended objective function (defObj). In the example, the numShifts objective with coefficient 1 has higher priority than the sumPreferences objective with absolute objective coefficient 1/100. The sign of the objective coefficient determines the direction of the particular objective function. So here numShifts will be minimized (same direction as on the solve statement) while sumPreferences will be maximized. GAMS needs to identify the various objective functions, therefore the objective variables can only appear in the blended objective functions and in the particular objective defining equation.

By default, the hierarchical approach won’t allow later objectives to degrade earlier objectives. This behavior can be relaxed through a pair of attributes: ObjNRelTol and ObjNAbsTol. By setting one of these for a particular objective, you can indicate that later objectives are allowed to degrade this objective by the specified relative or absolute amount, respectively. In our earlier example, if the optimal value for numShifts is 100, and if we set ObjNAbsTol for this objective to 20, then the second optimization step maximizing sumPreferences would find the best solution for the second objective from among all solutions with objective 120 or better for numShifts. Note that if you modify both tolerances, later optimizations would use the looser of the two values (i.e., the one that allows the larger degradation).
### 5.17.4 GAMS Options

The following GAMS options are used by GAMS/Gurobi:

**Option BRatio = x;**

Determines whether or not to use an advanced basis. A value of 1.0 causes GAMS to instruct Gurobi not to use an advanced basis. A value of 0.0 causes GAMS to construct a basis from whatever information is available. The default value of 0.25 will nearly always cause GAMS to pass along an advanced basis if a solve statement has previously been executed. This GAMS option is overridden by the GAMS/Gurobi option UseBasis.

**Option IterLim = n;**

Sets the simplex iteration limit. Simplex algorithms will terminate and pass on the current solution to GAMS. For MIP problems, if the number of the cumulative simplex iterations exceeds the limit, Gurobi will terminate. This GAMS option is overridden by the GAMS/Gurobi option IterationLimit.

**Option NodLim = x;**

Maximum number of nodes to process for a MIP problem. This GAMS option is overridden by the GAMS/Gurobi option NodeLimit.

**Option OptCA = x;**

Absolute optimality criterion for a MIP problem. The OptCA option asks Gurobi to stop when

\[ |BP - BF| < \text{OptCA} \]

where \( BF \) is the objective function value of the current best integer solution while \( BP \) is the best possible integer solution. This GAMS option is overridden by the GAMS/Gurobi option MipGapAbs.

**Option OptCR = x;**

Relative optimality criterion for a MIP problem. Notice that Gurobi uses a different definition than GAMS normally uses. The OptCR option asks Gurobi to stop when

\[ |BP - BF| < |BF| \times \text{OptCR} \]

where \( BF \) is the objective function value of the current best integer solution while \( BP \) is the best possible integer solution. The GAMS definition is:

\[ |BP - BF| < |BP| \times \text{OptCR} \]

This GAMS option is overridden by the GAMS/Gurobi option MipGap.

**Option ResLim = x;**

Sets the time limit in seconds. The algorithm will terminate and pass on the current solution to GAMS. Gurobi measures time in wall time on all platforms. Some other GAMS solvers measure time in CPU time on some Unix systems. In case ResLim assumes its default value \((1e+10)\) Gurobi will use its own default (infinity). This GAMS option is overridden by the GAMS/Gurobi option TimeLimit.

**Option SysOut = On;**
Will echo Gurobi messages to the GAMS listing file. This option may be useful in case of a solver failure.

\[\text{ModelName.\text{Cutoff}} = x;\]

Cutoff value. When the branch and bound search starts, the parts of the tree with an objective worse than \(x\) are deleted. This can sometimes speed up the initial phase of the branch and bound algorithm. This GAMS option is overridden by the GAMS/Gurobi option CutOff.

\[\text{ModelName.\text{OptFile}} = 1;\]

Instructs GAMS/Gurobi to read the option file. The name of the option file is \texttt{gurobi.opt}.

\[\text{ModelName.\text{PriorOpt}} = 1;\]

Instructs GAMS/Gurobi to use the priority branching information passed by GAMS through variable suffix values \texttt{variable.prior}.

### 5.17.5 Summary of GUROBI Options

#### 5.17.5.1 Termination options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{bariterlimit}</td>
<td>Barrier iteration limit</td>
<td>\text{infinity}</td>
</tr>
<tr>
<td>\texttt{bestbdstop}</td>
<td>Best objective bound to stop</td>
<td>\text{maxdouble}</td>
</tr>
<tr>
<td>\texttt{bestobjstop}</td>
<td>Best objective value to stop</td>
<td>\text{mindouble}</td>
</tr>
<tr>
<td>\texttt{cutoff}</td>
<td>Objective cutoff</td>
<td>\text{maxdouble}</td>
</tr>
<tr>
<td>\texttt{iterationlimit}</td>
<td>Simplex iteration limit</td>
<td>\text{infinity}</td>
</tr>
<tr>
<td>\texttt{memlimit}</td>
<td>Memory limit</td>
<td>\text{maxdouble}</td>
</tr>
<tr>
<td>\texttt{nodelimit}</td>
<td>MIP node limit</td>
<td>\text{maxdouble}</td>
</tr>
<tr>
<td>\texttt{softmenlimit}</td>
<td>Soft memory limit</td>
<td>\text{maxdouble}</td>
</tr>
<tr>
<td>\texttt{solutionlimit}</td>
<td>MIP feasible solution limit</td>
<td>\text{maxint}</td>
</tr>
<tr>
<td>\texttt{timelimit}</td>
<td>Time limit</td>
<td>GAMS reslim</td>
</tr>
<tr>
<td>\texttt{worklimit}</td>
<td>Work limit</td>
<td>\text{maxdouble}</td>
</tr>
</tbody>
</table>

#### 5.17.5.2 Tolerances options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{barconvtol}</td>
<td>Barrier convergence tolerance</td>
<td>\text{1e-08}</td>
</tr>
<tr>
<td>\texttt{barqcpconvtol}</td>
<td>Barrier QCP convergence tolerance</td>
<td>\text{1e-06}</td>
</tr>
<tr>
<td>\texttt{feasibilitytol}</td>
<td>Primal feasibility tolerance</td>
<td>\text{1e-06}</td>
</tr>
<tr>
<td>\texttt{intfeastol}</td>
<td>Integer feasibility tolerance</td>
<td>\text{1e-05}</td>
</tr>
<tr>
<td>\texttt{markowitztol}</td>
<td>Threshold pivoting tolerance</td>
<td>\text{0.0078125}</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>mipgap</td>
<td>Relative MIP optimality gap</td>
<td>GAMS optcr</td>
</tr>
<tr>
<td>mipgapabs</td>
<td>Absolute MIP optimality gap</td>
<td>GAMS optca</td>
</tr>
<tr>
<td>optimalitytol</td>
<td>Dual feasibility tolerance</td>
<td>1e-06</td>
</tr>
<tr>
<td>psdtol</td>
<td>Positive semi-definite tolerance</td>
<td>1e-06</td>
</tr>
</tbody>
</table>

### 5.17.5.3 Simplex options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>lpwarmstart</td>
<td>Warm start usage in simplex</td>
<td>1</td>
</tr>
<tr>
<td>networkalg</td>
<td>Network simplex algorithm</td>
<td>-1</td>
</tr>
<tr>
<td>normadjust</td>
<td>Simplex pricing norm</td>
<td>-1</td>
</tr>
<tr>
<td>perturbvalue</td>
<td>Simplex perturbation magnitude</td>
<td>0.0002</td>
</tr>
<tr>
<td>quad</td>
<td>Quad precision computation in simplex</td>
<td>-1</td>
</tr>
<tr>
<td>sifting</td>
<td>Sifting within dual simplex</td>
<td>-1</td>
</tr>
<tr>
<td>siftmethod</td>
<td>LP method used to solve sifting sub-problems</td>
<td>-1</td>
</tr>
<tr>
<td>simplexpricing</td>
<td>Simplex variable pricing strategy</td>
<td>-1</td>
</tr>
</tbody>
</table>

### 5.17.5.4 Barrier options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>barcorrectors</td>
<td>Central correction limit</td>
<td>-1</td>
</tr>
<tr>
<td>barhomogeneous</td>
<td>Barrier homogeneous algorithm</td>
<td>-1</td>
</tr>
<tr>
<td>barorder</td>
<td>Barrier ordering algorithm</td>
<td>-1</td>
</tr>
<tr>
<td>crossover</td>
<td>Barrier crossover strategy</td>
<td>-1</td>
</tr>
<tr>
<td>crossoverbasis</td>
<td>Crossover initial basis construction strategy</td>
<td>-1</td>
</tr>
<tr>
<td>qcpdual</td>
<td>Compute dual variables for QCP models</td>
<td>1</td>
</tr>
</tbody>
</table>

### 5.17.5.5 Scaling options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>objscale</td>
<td>Objective scaling</td>
<td>0</td>
</tr>
<tr>
<td>scaleflag</td>
<td>Model scaling</td>
<td>-1</td>
</tr>
</tbody>
</table>

### 5.17.5.6 MIP options
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branchdir</td>
<td>Branch direction preference</td>
<td>0</td>
</tr>
<tr>
<td>concurrentjobs</td>
<td>Enables distributed concurrent solver</td>
<td>0</td>
</tr>
<tr>
<td>concurrentmip</td>
<td>Enables concurrent MIP solver</td>
<td>1</td>

### 5.17.5.13 The GAMS/Gurobi Options File

The GAMS/Gurobi options file consists of one option or comment per line. An asterisk (*) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by any amount of white space (blanks or tabs).

Following is an example options file `gurobi.opt`.

```
simplexpricing 3
method 0
```

It will cause Gurobi to use quick-start steepest edge pricing and will use the primal simplex algorithm.

### 5.17.6 GAMS/Gurobi Log File

Gurobi reports its progress by writing to the GAMS log file as the problem solves. Normally the GAMS log file is directed to the computer screen.

The log file shows statistics about the presolve and continues with an iteration log.

For the simplex algorithms, each log line starts with the iteration number, followed by the objective value, the primal and dual infeasibility values, and the elapsed wall clock time. The dual simplex uses a bigM approach for handling infeasibility, so the objective and primal infeasibility values can both be very large during phase I. The frequency at which log lines are printed is controlled by the `DisplayInterval` option. By default, the simplex algorithms print a log line roughly every five seconds, although log lines can be delayed when solving models with particularly expensive iterations.

The simplex screen log has the following appearance:

```
Presolve removed 977 rows and 1539 columns
Presolve changed 3 inequalities to equalities
Presolve time: 0.078000 sec.
Presolved: 1748 Rows, 5030 Columns, 32973 Nonzeros

Iteration  Objective  Primal Inf.  Dual Inf.  Time
0  3.8929476e+31  1.200000e+31  1.485042e-04  0s
5624  1.1486966e+05  0.000000e+00  0.000000e+00  2s

Solved in 5624 iterations and 1.69 seconds
Optimal objective  1.148696610e+05
```

The barrier algorithm log file starts with barrier statistics about dense columns, free variables, nonzeros in $AA'$ and the Cholesky factor matrix, computational operations needed for the factorization, memory estimate and time estimate per iteration. Then it outputs the progress of the barrier algorithm in iterations with the primal and dual objective values, the magnitude of the primal and dual infeasibilities and the magnitude of the complementarity violation. After the barrier algorithm terminates, by default, Gurobi will perform crossover to obtain a valid basic solution. It first prints the information about pushing the dual and primal superbasic variables to the bounds and then the information about the simplex progress until the completion of the optimization.

The barrier screen log has the following appearance:
Presolve removed 2394 rows and 3412 columns
Presolve time: 0.09s
Presolved: 3677 Rows, 8818 Columns, 30934 Nonzeros

Ordering time: 0.20s

Barrier statistics:
Dense cols : 10
Free vars : 3
AA' NZ : 9.353e+04
Factor NZ : 1.139e+06 (roughly 14 MBytes of memory)
Factor Ops : 7.388e+08 (roughly 2 seconds per iteration)

Solved in 2043 iterations and 2.00 seconds
Optimal objective 1.126639605e+07

For MIP problems, the Gurobi solver prints regular status information during the branch and bound search. The first two output columns in each log line show the number of nodes that have been explored so far in the search tree, followed by the number of nodes that remain unexplored. The next three columns provide information on the most recently explored node in the tree. The solver prints the relaxation objective value for this node, followed by its depth in the search tree, followed by the number of integer variables with fractional values in the node relaxation solution. The next three columns provide information on the progress of the global MIP bounds. They show the objective value for the best known integer feasible solution, the best bound on the value of the optimal solution, and the gap between these lower and upper bounds. Finally, the last two columns provide information on the amount of work performed so far. The
first column gives the average number of simplex iterations per explored node, and the next column gives
the elapsed wall clock time since the optimization began.

At the default value for option DisplayInterval, the MIP solver prints one log line roughly every five
seconds. Note, however, that log lines are often delayed in the MIP solver due to particularly expensive
nodes or heuristics.

Presolve removed 12 rows and 11 columns
Presolve tightened 70 bounds and modified 235 coefficients
Presolve time: 0.02s
Presolved: 114 Rows, 116 Columns, 424 Nonzeros
Objective GCD is 1

5.17.7 Detailed Descriptions of GUROBI Options

aggfill (integer): Allowed fill during presolve aggregation

Controls the amount of fill allowed during presolve aggregation. Larger values generally lead
to presolved models with fewer rows and columns, but with more constraint matrix non-zeros.

The default value chooses automatically, and usually works well.

Default: -1

aggregate (integer): Presolve aggregation control

Default: 1

barconvtol (real): Barrier convergence tolerance
The barrier solver terminates when the relative difference between the primal and dual objective values is less than the specified tolerance.

Default: $1e^{-08}$

**barcorrectors** (*integer*): Central correction limit

The default value is chosen automatically, depending on problem characteristics.

Default: $-1$

**barhomogeneous** (*integer*): Barrier homogeneous algorithm

Determines whether to use the homogeneous barrier algorithm. At the default setting (-1), it is only used when barrier solves a node relaxation for a MIP model. Setting the parameter to 0 turns it off, and setting it to 1 forces it on. The homogeneous algorithm is useful for recognizing infeasibility or unboundedness. It is a bit slower than the default algorithm.

Default: $-1$

<table>

</tr>
<tr>
<td>1</td>
<td>Nested Dissection ordering</td>
</tr>
</tbody>
</table>

**barqcpconvtol** (*real*): Barrier QCP convergence tolerance

When solving a QCP model, the barrier solver terminates when the relative difference between the primal and dual objective values is less than the specified tolerance. Tightening this tolerance may lead to a more accurate solution, but it may also lead to a failure to converge.

Default: $1e^{-06}$

**bestbdstop** (*real*): Best objective bound to stop

Terminates as soon as the engine determines that the best bound on the objective value is at least as good as the specified value.

Default: $\text{maxdouble}$

**bestobjstop** (*real*): Best objective value to stop

Terminate as soon as the engine finds a feasible solution whose objective value is at least as good as the specified value.

Default: mindouble

**bqpcuts (integer):** BQP cut generation

Default: -1

<table>
<thead>

<td>Conservative</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

**branchdir (integer):** Branch direction preference

This option allows more control over how the branch-and-cut tree is explored. Specifically, when a node in the MIP search is completed and two child nodes, corresponding to the down branch and the up branch are created, this parameter allows you to determine whether the MIP solver will explore the down branch first, the up branch first, or whether it will choose the next node based on a heuristic determination of which sub-tree appears more promising.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

<td>Aggressive</td>
</tr>
</tbody>
</table>

**concurrentjobs (integer):** Enables distributed concurrent solver

Enables distributed concurrent optimization, which can be used to solve LP or MIP models on multiple machines. A value of $n$ causes the solver to create $n$ independent models, using different parameter settings for each. Each of these models is sent to a distributed worker for processing. Optimization terminates when the first solve completes. Use the WorkerPool parameter to provide a list of available distributed workers.

By default, Gurobi chooses the parameter settings used for each independent solve automatically. The intent of concurrent MIP solving is to introduce additional diversity into the MIP search.
By bringing the resources of multiple machines to bear on a single model, this approach can sometimes solve models much faster than a single machine.

Default: 0

**concurrentmip (integer):** Enables concurrent MIP solver

This parameter enables the concurrent MIP solver. When the parameter is set to value \( n \), the MIP solver performs \( n \) independent MIP solves in parallel, with different parameter settings for each. Optimization terminates when the first solve completes. Gurobi chooses the parameter settings used for each independent solve automatically. The intent of concurrent MIP solving is to introduce additional diversity into the MIP search. This approach can sometimes solve models much faster than applying all available threads to a single MIP solve, especially on very large parallel machines.

The concurrent MIP solver divides available threads evenly among the independent solves. For example, if you have 6 threads available and you set ConcurrentMIP to 2, the concurrent MIP solver will allocate 3 threads to each independent solve. Note that the number of independent solves launched will not exceed the number of available threads.

The concurrent MIP solver produces a slightly different log from the standard MIP solver. The log only provides periodic summary information. Each concurrent MIP log line shows the objective for the best feasible solution found by any of the independent solves to that point, the best objective bound proved by any of the independent solves, and the relative gap between these two values. Gurobi also includes node counts from one of the independent solves, as well as elapsed times, to give some indication of forward progress.

Default: 1

**covercuts (integer):** Cover cut generation

See the description of the global Cuts parameter for further information.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Conservative</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

**crossover (integer):** Barrier crossover strategy

Use value 0 to disable crossover; the solver will return an interior solution. Other options control whether the crossover algorithm tries to push primal or dual variables to bounds first, and then which simplex algorithm is used once variable pushing is complete. Options 1 and 2 push dual variables first, then primal variables. Option 1 finishes with primal, while option 2 finishes with dual. Options 3 and 4 push primal variables first, then dual variables. Option 3 finishes with primal, while option 4 finishes with dual. The default value of -1 chooses automatically.

Default: -1

**crossoverbasis (integer):** Crossover initial basis construction strategy

Default: -1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Chooses an initial basis quickly</td>
</tr>
<tr>
<td>1</td>
<td>Can take much longer, but often produces a more numerically stable start basis</td>
</tr>
</tbody>
</table>

**cutaggpasses** *(integer)*: Constraint aggregation passes performed during cut generation

A non-negative value indicates the maximum number of constraint aggregation passes performed during cut generation. See the description of the global Cuts parameter for further information.

Default: -1

**cutoff** *(real)*: Objective cutoff

Optimization will terminate if the engine determines that the optimal objective value for the model is worse than the specified cutoff. This option overwrites the GAMS cutoff option.

Default: maxdouble

**cutpasses** *(integer)*: Root cutting plane pass limit

Default: -1

**cuts** *(integer)*: Global cut generation control

The parameters, Cuts, CliqueCuts, CoverCuts, FlowCoverCuts, FlowPathCuts, GUBCoverCuts, ImpliedCuts, InrProofCuts, MIPIpCuts, MIRemoves, ModKCuts, NetworkCuts, GomoryPasses, StrongCGCuts, SubMIPCuts, CutAggPasses and ZeroHalfCuts, affect the generation of MIP cutting planes. In all cases except GomoryPasses and CutAggPasses, a value of -1 corresponds to an automatic setting, which allows the solver to determine the appropriate level of aggressiveness in the cut generation. Unless otherwise noted, settings of 0, 1, and 2 correspond to no cut generation, conservative cut generation, or aggressive cut generation, respectively. The Cuts parameter provides global cut control, affecting the generation of all cuts. This parameter also has a setting of 3, which corresponds to very aggressive cut generation. The other parameters override the global Cuts parameter (so setting Cuts to 2 and CliqueCuts to 0 would generate all cut types aggressively, except clique cuts which would not be generated at all. Setting Cuts to 0 and GomoryPasses to 10 would not generate any cuts except Gomory cuts for 10 passes).

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Conservative</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
<tr>
<td>3</td>
<td>Very aggressive</td>
</tr>
</tbody>
</table>

**degenmoves** *(integer)*: Degenerate simplex moves

Limits degenerate simplex moves. These moves are performed to improve the integrality of the current relaxation solution. By default, the algorithm chooses the number of moves to perform automatically.
Changing the value of this parameter can help performance in cases where an excessive amount of time is spent after the initial root relaxation has been solved but before the cut generation process or the root heuristics have started.

Default: -1

disconnected (integer): Disconnected component strategy

A MIP model can sometimes be made up of multiple, completely independent sub-models. This parameter controls how aggressively we try to exploit this structure. A value of 0 ignores this structure entirely, while larger values try more aggressive approaches. The default value of -1 chooses automatically. This only affects mixed integer programming (MIP) models.

Default: -1

displayinterval (integer): Frequency at which log lines are printed

Default: 5

distributedmipjobs (integer): Enables the distributed MIP solver

Enables distributed MIP. A value of \( n \) causes the MIP solver to divide the work of solving a MIP model among \( n \) machines. Use the WorkerPool parameter to provide the list of available machines.

Default: 0

.dofuncpieceerror (real): Error allowed for PWL translation of function constraints

Default: 1e-3

.dofuncpiecelength (real): Piece length for PWL translation of function constraints

The default length behavior for piecewise-linear approximation of a function constraint is controlled by funcPieceLength. This dot option .dofuncPieceError allows to overwrite the default behavior by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: 1e-2

.dofuncpieceratio (real): Control whether to under- or over-estimate function values in PWL approximation

The default ratio behavior for piecewise-linear approximation of a function constraint is controlled by funcPieceRatio. This dot option .dofuncPieceError allows to overwrite the default behavior by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: -1

.dofuncpieces (integer): Sets strategy for PWL function approximation
The default strategy for performing a piecewise-linear approximation of a function constraint is set by `funcPieces`. This dot option `.doFuncPieces` allows to overwrite the default strategy by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

dofuncpieceerror The default error behavior for piecewise-linear approximation of a function constraint is controlled by `funcPieceError`. This dot option `.doFuncPieceError` allows to overwrite the default behavior by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

**dualreductions** (boolean): Disables dual reductions in presolve

Default: 1

**dumpbcsol** (string): Dump incumbents to GDX files during branch-and-cut

The content of this string option is used as a file stem for GDX point files. The file name gets completed by the solution number. So if this option has been set to `mysol` then GDX files containing the new solution with the names `mysol0.gdx`, `mysol1.gdx`, ... will be created. The number of GDX files created depends on the number of solutions Gurobi finds during branch-and-cut.

**feasibilitytol** (real): Primal feasibility tolerance

All constrains must be satisfied to a tolerance of `FeasibilityTol`.

Range: [1e-09, 0.01]

Default: 1e-06

**feasopt** (boolean): Computes a minimum-cost relaxation to make an infeasible model feasible

With `Feasopt` turned on, a minimum-cost relaxation of the right hand side values of constraints or bounds on variables is computed in order to make an infeasible model feasible. It marks the relaxed right hand side values and bounds in the solution listing.

Several options are available for the metric used to determine what constitutes a minimum-cost relaxation which can be set by option `FeasOptMode`.

Feasible relaxations are available for all problem types.

Default: 0
### feaspref (real): feasibility preference

You can express the costs associated with relaxing a bound or right hand side value during a FeasOpt run through the `.feaspref` option. The syntax for dot options is explained in the Introduction chapter of the Solver Manual. The input value denotes the users willingness to relax a constraint or bound. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed.

Default: 1

#### feasrelaxbigm (real): Big-M value for feasibility relaxations

When relaxing a constraint in a feasibility relaxation, it is sometimes necessary to introduce a big-M value. This parameter determines the default magnitude of that value.

Default: 1e+06
**fixoptfile (string):** Option file for fixed problem optimization

**flowcovercuts (integer):** Flow cover cut generation

See the description of the global Cuts parameter for further information.

Default: -1

</tbody>
</table>

**freegamsmodel (boolean):** Preserves memory by dumping the GAMS model instance representation temporarily to disk

In order to provide the maximum amount of memory to the solver this option dumps the internal representation of the model instance temporarily to disk and frees memory. This option only works with SolveLink=0 and only for models without quadratic constraints.

Default: 0

**funcmaxval (real):** Maximum value for x and y variables in function constraints

Very large values in piecewise-linear approximations can cause numerical issues. This parameter limits the bounds on the variables that participate in function constraints. Specifically, if x or y participate in a function constraint, any bound larger than funcMaxVal (in absolute value) will be truncated.

Default: 1e+06

**funcpieceerror (real):** Error allowed for PWL translation of function constraint

If the funcPieces parameter is set to value -1 or -2, this parameter provides the maximum allowed error (absolute for -1, relative for -2) in the piecewise-linear approximation.

Default: 0.001

**funcpiece length (real):** Piece length for PWL translation of function constraint
If the `funcPieces` parameter is set to value 1, this parameter gives the length of each piece of the piecewise-linear approximation.

Default: 0.01

**funcpieceratio (real):** Controls whether to under- or over-estimate function values in PWL approximation

This option controls whether the piecewise-linear approximation of a function constraint is an underestimate of the function, an overestimate, or somewhere in between. A value of 0 will always underestimate, while a value of 1 will always overestimate. A value in between will interpolate between the underestimate and the overestimate. A special value of -1 chooses points that are on the original function.

Default: -1

**funcpieces (integer):** Sets strategy for PWL function approximation

<table>
<thead>

</tr>
</tbody>
</table>

**gomorypasses (integer):** Root Gomory cut pass limit

A non-negative value indicates the maximum number of Gomory cut passes performed. See the description of the global `Cuts` parameter for further information.

Default: -1

**gubcovercuts (integer):** GUB cover cut generation

See the description of the global `Cuts` parameter for further information.

Default: -1

<table>

</tr>
</tbody>
</table>

**heuristics (real):** Turn MIP heuristics up or down

Larger values produce more and better feasible solutions, at a cost of slower progress in the best bound.
Range: \([0, 1]\)

Default: 0.05

\textbf{iis (integer): Run the Irreducible Inconsistent Subsystem (IIS) finder if the problem is infeasible} ←

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No conflict analysis</td>

<td>Conflict analysis without previous solve</td>
</tr>
</tbody>
</table>

\textbf{iismethod (integer): IIS method} ←

Choose the IIS method to use. Method 0 is often faster, while method 1 can produce a smaller IIS. Method 2 ignores the bound constraints. Method 3 will return the IIS for the LP relaxation of a MIP model if the relaxation is infeasible, even though the result may not be minimal when integrality constraints are included. The default value of -1 chooses automatically.

Default: -1

\textbf{impliedcuts (integer): Implied bound cut generation} ←

See the description of the global \texttt{Cuts} parameter for further information.

Default: -1

<table>
<thead>
<tr>
<th>value</th>

<td>Aggressive</td>
</tr>
</tbody>
</table>

\textbf{improvestartgap (real): Trigger solution improvement} ←

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify an optimality gap at which the MIP solver will switch to this strategy. For example, setting this parameter to 0.1 will cause the MIP solver to switch once the relative optimality gap is smaller than 0.1.

Default: 0

\textbf{improvestartnodes (real): Trigger solution improvement} ←

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify the node count at which the MIP solver switches to a solution improvement strategy. For example, setting this parameter to 10 will cause the MIP solver to switch strategies once the node count is larger than 10.

Default: \texttt{maxdouble}
improvestarttime (real): Trigger solution improvement

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify a time limit when the MIP solver will switch to this strategy. For example, setting this parameter to 10 will cause the MIP solver to switch 10 seconds after starting the optimization.

Default: maxdouble

inproofcuts (integer): Infeasibility proof cut generation

Controls infeasibility proof cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the Cuts parameter.

Default: -1

integralityfocus (boolean): Set the integrality focus

One unfortunate reality in MIP is that integer variables don't always take exact integral values. While this typically doesn't create significant problems, in some situations the side-effects can be quite undesirable. The best-known example is probably a trickle flow, where a continuous variable that is meant to be zero when an associated binary variable is zero instead takes a non-trivial value. More precisely, given a constraint \( y = lb \cdot b \), where \( y \) is a non-negative continuous variable, \( b \) is a binary variable, and \( M \) is a constant that captures the largest possible value of \( y \), the constraint is intended to enforce the relationship that \( y \) must be zero if \( b \) is zero. With the default integer feasibility tolerance, the binary variable is allowed to take a value as large as \( 1e^{-5} \) while still being considered as taking value zero. If the \( M \) value is large, then the \( M \cdot b \) upper bound on the \( y \) variable can be substantial.

Reducing the value of the intFeasTol parameter can mitigate the effects of such trickle flows, but often at a significant cost, and often with limited success. The integralityFocus parameter provides a better alternative. Setting this parameter to 1 requests that the solver work harder to try to avoid solutions that exploit integrality tolerances. More precisely, the solver tries to find solutions that are still (nearly) feasible if all integer variables are rounded to exact integral values. We should say that the solver won’t always succeed in finding such solutions, and that this setting introduces a modest performance penalty, but the setting will significantly reduce the frequency and magnitude of such violations.

Default: 0

<table>
<thead>
<tr>

intfeastol (real): Integer feasibility tolerance

An integrality restriction on a variable is considered satisfied when the variable's value is less than IntFeasTol from the nearest integer value.

Range: \([1e^{-09}, 0.1]\]

Default: \(1e^{-05}\)

iterationlimit (real): Simplex iteration limit

\(1.0\)
Default: infinity

**kappa** *(boolean)*: Display approximate condition number estimates for the optimal simplex basis

<tr>
<td>1</td>
<td>Compute and display exact condition number</td>
</tr>
</tbody>
</table>

**.lazy** *(integer)*: Lazy constraints value

Determines whether a linear constraint is treated as a lazy constraint. At the beginning of the MIP solution process, any constraint whose Lazy attribute is set to 1, 2, or 3 (the default value is 0) is removed from the model and placed in the lazy constraint pool. Lazy constraints remain inactive until a feasible solution is found, at which point the solution is checked against the lazy constraint pool. If the solution violates any lazy constraint, the solution is discarded and one or more of the violated lazy constraints are pulled into the active model.

Larger values for this attribute cause the constraint to be pulled into the model more aggressively. With a value of 1, the constraint can be used to cut off a feasible solution, but it won’t necessarily be pulled in if another lazy constraint also cuts off the solution. With a value of 2, all lazy constraints that are violated by a feasible solution will be pulled into the model. With a value of 3, lazy constraints that cut off the relaxation solution are also pulled in.

Any constraint whose Lazy attribute is set to -1 is treated as a user cut; it is removed from the model and placed in the user cut pool. User cuts may be added to the model at any node in the branch-and-cut search tree to cut off relaxation solutions.

The main difference between user cuts and lazy constraints is that the former are not allowed to cut off integer-feasible solutions. In other words, they are redundant for the MIP model, and the solver is free to decide whether or not to use them to cut off relaxation solutions. The hope is that adding them speeds up the overall solution process. Lazy constraints have no such restrictions. They are essential to the model, and the solver is forced to apply them whenever a solution would otherwise not satisfy them.

Only affects MIP models. Lazy constraints are only active if option LazyConstraints is enabled and are specified through the option .lazy. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: 0

**lazyconstraints** *(boolean)*: Indicator to use lazy constraints

Default: 0

**liftprojectcuts** *(integer)*: Lift-and-project cut generation
Controls lift-and-project cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the Cuts parameter.

Default: -1

**lpwarmstart** (integer): Warm start usage in simplex

Controls whether and how Gurobi uses warm start information for an LP optimization. The non default setting of 2 is particularly useful for communicating advanced start information while retaining the performance benefits of presolve.

As a general rule, setting this parameter to 0 ignores any start information and solves the model from scratch. Setting it to 1 (the default) uses the provided warm start information to solve the original, unpresolved problem, regardless of whether presolve is enabled. Setting it to 2 uses the start information to solve the presolved problem, assuming that presolve is enabled. This involves mapping the solution of the original problem into an equivalent (or sometimes nearly equivalent) crushed solution of the presolved problem. If presolve is disabled, then setting 2 still prioritizes start vectors, while setting 1 prioritizes basis statuses. Taken together, the LPWarmStart parameter setting, the LP algorithm specified by Gurobi’s Method parameter, and the available advanced start information determine whether Gurobi will use basis statuses only, basis statuses augmented with information from start vectors, or a basis obtained by applying the crossover method to the provided primal and dual start vectors to jump start the optimization.

When Gurobi’s Method parameter requests the barrier solver, primal and dual start vectors are prioritized over basis statuses (but only if you provide both). These start vectors are fed to the crossover procedure. This is the same crossover that is used to compute a basic solution from the interior solution produced by the core barrier algorithm, but in this case crossover is started from arbitrary start vectors. If you set the LPWarmStart parameter to 1, crossover will be invoked on the original model using the provided vectors. Any provided basis information will not be used in this case. If you set LPWarmStart to 2, crossover will be invoked on the presolved model using crushed start vectors. If you set the parameter to 2 and provide a basis but no start vectors, the basis will be used to compute the corresponding primal and dual solutions on the original model. Those solutions will then be crushed and used as primal and dual start vectors for the crossover, which will then construct a basis for the presolved model. Note that for all of these settings and start combinations, no barrier algorithm iterations are performed.

The simplex algorithms provide more warm-starting options, with a parameter value of 1, simplex will start from a provided basis, if available. Otherwise, it uses a provided start vector to refine the crash basis it computes.

With a value of 2, simplex will use the crushed start vector on the presolved model to refine the crash basis. This is true regardless of whether the start is derived from start vectors or a starting basis from the original model. The difference is that if you provide an advanced basis, the basis will be used to compute the corresponding primal and dual solutions on the original model from which the primal or dual start on the presolved model will be derived.

Note: Only affects linear programming (LP) models.

Default: 1

**markowitztol** (real): Threshold pivoting tolerance

Used to limit numerical error in the simplex algorithm. A larger value may avoid numerical problems in rare situations, but it will also harm performance.

Range: [0.0001, 0.999]

Default: 0.0078125
**memlimit (real):** Memory limit

Limits the total amount of memory (in GB, i.e., $10^9$ bytes) available to Gurobi. If more is needed, Gurobi will fail with an OUT_OF_MEMORY error.

Default: `maxdouble`

**method (integer):** Algorithm used to solve continuous models

Synonyms: `ipmethod rootmethod`

Algorithm used to solve continuous models or the root node of a MIP model. Options are:
- `-1=automatic`, `0=primal simplex`, `1=dual simplex`, `2=barrier`, `3=concurrent`, `4=deterministic concurrent`, `5=deterministic concurrent simplex`.

In the current release, the default Automatic (-1) setting will typically choose non-deterministic concurrent (Method=3) for an LP, barrier (Method=2) for a QP or QCP, and dual (Method=1) for the MIP root node. Only the simplex and barrier algorithms are available for continuous QP models. Only primal and dual simplex are available for solving the root of an MIQP model. Only barrier is available for continuous QCP models.

Concurrent optimizers run multiple solvers on multiple threads simultaneously, and choose the one that finishes first. Method=3 and Method=4 will run dual simplex, barrier, and sometimes primal simplex (depending on the number of available threads). Method=5 will run both primal and dual simplex. The deterministic options (Method=4 and Method=5) give the exact same result each time, while Method=3 is often faster but can produce different optimal bases when run multiple times.

The default setting is rarely significantly slower than the best possible setting, so you generally won’t see a big gain from changing this parameter. There are classes of models where one particular algorithm is consistently fastest, though, so you may want to experiment with different options when confronted with a particularly difficult model.

Note that if memory is tight on an LP model, you should consider using the dual simplex method (Method=1). The concurrent optimizer, which is typically chosen when using the default setting, consumes a lot more memory than dual simplex alone.

Default: `-1`

**minrelnodes (integer):** Minimum relaxation heuristic control

Number of nodes to explore in the minimum relaxation heuristic. Note that this heuristic is only applied at the end of the MIP root, and only when no other root heuristic finds a feasible solution.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.
The default value automatically chooses whether to apply the heuristic. It will only rarely choose to do so.

Default: -1

\textbf{mipfocus} (integer): Set the focus of the MIP solver

Default: 0

<table>

\textbf{mipgap} (real): Relative MIP optimality gap

The MIP engine will terminate (with an optimal result) when the gap between the lower and upper objective bound is less than \texttt{MipGap} times the upper bound.

Range: \([0, \infty]\)

Default: \texttt{GAMS optcr}

\textbf{mipgaps} (real): Absolute MIP optimality gap

The MIP solver will terminate (with an optimal result) when the gap between the lower and upper objective bound is less than \texttt{MIPGapAbs}.

Range: \([0, \infty]\)

Default: \texttt{GAMS optca}

\textbf{mipsepcuts} (integer): MIP separation cut generation

See the description of the global \texttt{Cuts} parameter for further information.

Default: -1

mipstopexpr (string): Stop expression for branch and bound

If the provided logical expression is true, the branch-and-bound is aborted. Supported values are: resusd, nodusd, objest, objval. Supported operators are: +, -, *, /, ^, %, !=, ==, <=, >=, !!, &&, ||, ( ), abs, ceil, exp, floor, log, log10, pow, sqrt. Example: nodusd >= 1000 && abs(objest - objval) / abs(objval) < 0.1

miptrace (string): Filename of MIP trace file

More info is available in chapter Solve trace.

miptracenode (integer): Node interval when a trace record is written

Default: 100

miptracetime (real): Time interval when a trace record is written

Default: 1

miqcpmethod (integer): Method used to solve MIQCP models

Controls the method used to solve MIQCP models. Value 1 uses a linearized, outer-approximation approach, while value 0 solves continuous QCP relaxations at each node. The default setting (-1) chooses automatically.

Default: -1

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

modkcuts (integer): Mod-k cut generation

See the description of the global Cuts parameter for further information.

Default: -1

multimipstart (string): Use multiple (partial) mipstarts provided via gdx files

Specifies (multiple) GDX files with values for the variables. Each file is treated as one initial guess for the MIP start. These MIP starts are added in addition to the initial guess provided by
the level attribute. A MIP start GDX file can be created, for example, by using the command line option `savepoint`.

This option further allows to add partial MIP starts where some variable level records are not given. GUROBI will then try to construct a full MIP start out of it. In order to not provide a certain variable level record, simply not include that record in the GDX file or set the level value to NA or UNDEF.

This option requires `mipstart` enabled.

**multiobjmethod (integer):** Warm-start method to solve for subsequent objectives

When solving a continuous multi-objective model using a hierarchical approach, the model is solved once for each objective. The algorithm used to solve for the highest priority objective is controlled by the `Method` parameter. This parameter determines the algorithm used to solve for subsequent objectives. As with the `Method` parameters, values of 0 and 1 use primal and dual simplex, respectively. A value of 2 indicates that warm-start information from previous solves should be discarded, and the model should be solved from scratch (using the algorithm indicated by the `Method` parameter). The default setting of -1 usually chooses primal simplex.

Default: -1

**multiobjpre (integer):** Initial presolve on multi-objective models

Controls the initial presolve level used for multi-objective models. Value 0 disables the initial presolve, value 1 applies presolve conservatively, and value 2 applies presolve aggressively. The default -1 value usually applies presolve conservatively. Aggressive presolve may increase the chance of the objective values being slightly different than those for other options.

Default: -1

**multobj (boolean):** Controls the hierarchical optimization of multiple objectives

Default: 0

**names (boolean):** Indicator for loading names

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

<td>Aggressive</td>
</tr>
</tbody>
</table>
**nlpheur (boolean):** Controls the NLP heuristic for non-convex quadratic models

The NLP heuristic uses a non-linear barrier solver to find feasible solutions to non-convex quadratic models. It can often find solutions much more quickly than the alternative, but in some cases it can consume significant runtime without producing a solution.

Note: Only affects non-convex quadratic models.

Default: 1

**nodefiledir (string):** Directory for MIP node files

Determines the directory into which nodes are written when node memory usage exceeds the specified Nodestart value.

Default: .

**nodefilestart (real):** Memory threshold for writing MIP tree nodes to disk

Controls the point at which MIP tree nodes are written to disk. Whenever node storage exceeds the specified value (in GBytes), nodes are written to disk.

Default: maxdouble

**nodelimit (real):** MIP node limit

Default: maxdouble

**nodemethod (integer):** Method used to solve MIP node relaxations

Algorithm used for MIP node relaxations. Note that barrier is not an option for MIQP node relaxations.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tbody>
</table>

**nonconvex (integer):** Control how to deal with non-convex quadratic programs

Sets the strategy for handling non-convex quadratic objectives or non-convex quadratic constraints. With setting 0, an error is reported if the original user model contains non-convex quadratic constructs. With setting 1, an error is reported if non-convex quadratic constructs could not be discarded or linearized during presolve. With setting 2, non-convex quadratic problems are solved by means of translating them into bilinear form and applying spatial branching. The default -1 setting is currently equivalent to 1, and may change in future releases to be equivalent to 2.

Default: -1

**norelheurtime (real):** Limits the amount of time (in seconds) spent in the NoRel heuristic
Limits the amount of time (in seconds) spent in the NoRel heuristic. This heuristic searches for high-quality feasible solutions before solving the root relaxation. It can be quite useful on models where the root relaxation is particularly expensive. Note that this parameter will introduce non-determinism - different runs may take different paths. Use norelheurwork parameter for deterministic results.

Default: 0

**norelheurwork (real):** Limits the amount of work performed by the NoRel heuristic

This heuristic searches for high-quality feasible solutions before solving the root relaxation. It can be quite useful on models where the root relaxation is particularly expensive. The work metric used in this parameter is tough to define precisely. A single unit corresponds to roughly a second, but this will depend on the machine, the core count, and in some cases the model. You may need to experiment to find a good setting for your model.

Default: 0

**normadjust (integer):** Simplex pricing norm

Chooses from among multiple pricing norm variants. The default value of -1 chooses automatically.

Default: -1

**numericfocus (integer):** Set the numerical focus

The NumericFocus parameter controls the degree to which the code attempts to detect and manage numerical issues. The default setting makes an automatic choice, with a slight preference for speed. Settings 1-3 increasingly shift the focus towards being more careful in numerical computations. With higher values, the code will spend more time checking the numerical accuracy of intermediate results, and it will employ more expensive techniques in order to avoid potential numerical issues.

Default: 0

**obbt (integer):** Controls aggressiveness of Optimality-Based Bound Tightening

Default: -1

**objnabstol (string):** Allowable absolute degradation for objective

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is \( \text{ObjNAbsTol} \text{ ObjVarName value} \).

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value \( z \) when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most \( \text{ObjNAbsTol} \).

**objnreltol (string):** Allowable relative degradation for objective

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is \( \text{ObjNReI Tol} \text{ ObjVarName value} \).

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value \( z \) when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most \( \text{ObjNReI Tol} \ast |z| \).
**objscale (real):** Objective scaling

Divides the model objective by the specified value to avoid numerical errors that may result from very large objective coefficients. The default value of 0 decides on the scaling automatically. A value less than zero uses the maximum coefficient to the specified power as the scaling (so ObjScale=-0.5 would scale by the square root of the largest objective coefficient).

Range: [-1, ∞]

Default: 0

**optimalitytol (real):** Dual feasibility tolerance

Reduced costs must all be larger than OptimalityTol in the improving direction in order for a model to be declared optimal.

Range: [1e-09, 0.01]

Default: 1e-06

**partition (integer):** Variable partition value

The MIP solver can perform a solution improvement heuristic using user-provided partition information. The provided partition number can be positive, which indicates that the variable should be included when the correspondingly numbered sub-MIP is solved, 0 which indicates that the variable should be included in every sub-MIP, or -1 which indicates that the variable should not be included in any sub-MIP. Variables that are not included in the sub-MIP are fixed to their values in the current incumbent solution.

To give an example, imagine you are solving a model with 400 variables and you set the partition attribute to -1 for variables 0-99, 0 for variables 100-199, 1 for variables 200-299, and 2 for variables 300-399. The heuristic would solve two sub-MIP models: sub-MIP 1 would fix variables 0-99 and 300-399 to their values in the incumbent and solve for the rest, while sub-MIP 2 would fix variables 0-99 and 200-299.

The parameter PartitionPlace controls the use of the heuristic. The partition numbers are specified through the option .partition. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: 0

**partitionplace (integer):** Controls when the partition heuristic runs

This option works in combination with the Partition number for variables. Setting this option and providing some partitions enables the partitioning heuristic, which uses large-neighborhood search to try to improve the current incumbent solution.

This parameter determines where that heuristic runs. Options are:

- Before the root relaxation is solved (16)
- At the start of the root cut loop (8)
- At the end of the root cut loop (4)
- At the nodes of the branch-and-cut search (2)
- When the branch-and-cut search terminates (1)
The parameter value is a bit vector, where each bit turns the heuristic on or off at that place. The numerical values next to the options listed above indicate which bit controls the corresponding option. Thus, for example, to enable the heuristic at the beginning and end of the root cut loop (and nowhere else), you would set the 8 bit and the 4 bit to 1, which would correspond to a parameter value of 12.

The recommended value is 15 which indicates that every option except the first one listed above is enabled.

Default: 15

**perturbvalue (real):** Simplex perturbation magnitude ←

Range: \([0, \infty]\)

Default: 0.0002

**poolgap (real):** Relative gap for solutions in pool ←

Determines how large a gap to tolerate in stored solutions. When this parameter is set to a non-default value, solutions whose objective values exceed that of the best known solution by more than the specified (relative) gap are discarded. For example, if the MIP solver has found a solution at objective 100, then a setting of \(\text{PoolGap}=0.2\) would discard solutions with objective worse than 120 (assuming a minimization objective).

Default: \(\text{maxdouble}\)

**poolgapabs (real):** Absolute gap for solutions in pool ←

Determines how large a (absolute) gap to tolerate in stored solutions. When this parameter is set to a non-default value, solutions whose objective values exceed that of the best known solution by more than the specified (absolute) gap are discarded. For example, if the MIP solver has found a solution at objective 100, then a setting of \(\text{PoolGapAbs}=20\) would discard solutions with objective worse than 120 (assuming a minimization objective).

Default: \(\text{maxdouble}\)

**poolsearchmode (integer):** Choose the approach used to find additional solutions ←

With the default setting (\(\text{PoolSearchMode}=0\)), the MIP solver tries to find an optimal solution to the model. It keeps other solutions found along the way, but those are incidental. By setting this parameter to a non-default value, the MIP search will continue after the optimal solution has been found in order to find additional, high-quality solutions. With a setting of 2, it will find the \(n\) best solutions, where \(n\) is determined by the value of the \(\text{PoolSolutions}\) parameter. With a setting of 1, it will try to find additional solutions, but with no guarantees about the quality of those solutions. The cost of the solve will increase with increasing values of this parameter.

Once optimization is complete, the \(\text{PoolObjBound}\) attribute (printed to the log) can be used to evaluate the quality of the solutions that were found. For example, a value of \(\text{PoolObjBound}=100\) indicates that there are no other solutions with objective better 100, and thus that any known solutions with objective better than 100 are better than any as-yet undiscovered solutions.

Default: 0

**poolsolutions (integer):** Number of solutions to keep in pool ←
Determines how many MIP solutions are stored. For the default value of `PoolSearchMode`, these are just the solutions that are found along the way in the process of exploring the MIP search tree. For other values of `PoolSearchMode`, this parameter sets a target for how many solutions to find, so larger values will impact performance.

Default: 10

`precrush (boolean)`: Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model

Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model. This parameter is turned on when you use BCH with Gurobi.

Default: 0

`predeprow (integer)`: Presolve dependent row reduction

Controls the presolve dependent row reduction, which eliminates linearly dependent constraints from the constraint matrix. The default setting (-1) applies the reduction to continuous models but not to MIP models. Setting 0 turns the reduction off for all models. Setting 1 turns it on for all models.

Default: -1

`predual (integer)`: Presolve dualization

Depending on the structure of the model, solving the dual can reduce overall solution time. The default setting uses a heuristic to decide. Setting 0 forbids presolve from forming the dual, while setting 1 forces it to take the dual. Setting 2 employs a more expensive heuristic that forms both the presolved primal and dual models (on two threads), and heuristically chooses one of them.

Default: -1

`premiqcpform (integer)`: Format of presolved MIQCP model

Option 0 leaves the model in MIQCP form, so the branch-and-cut algorithm will operate on a model with arbitrary quadratic constraints. Option 1 always transforms the model into MISOCF form; quadratic constraints are transformed into second-order cone constraints. Option 2 always transforms the model into disaggregated MISOCF form; quadratic constraints are transformed into rotated cone constraints, where each rotated cone contains two terms and involves only three variables.

Default: -1

</tr>
</tbody>
</table>

`prepasses (integer)`: Presolve pass limit

Limits the number of passes performed by presolve. The default setting (-1) chooses the number of passes automatically.

Default: -1
preqlinearize (integer): Presolve Q matrix linearization

Options 1 and 2 attempt to linearize quadratic constraints or a quadratic objective, potentially transforming an MIQP or MIQCP model into an MILP. Option 1 focuses on getting a strong LP relaxation. Option 2 aims for a compact relaxation. Option 0 always leaves Q matrices unmodified. The default setting (-1) chooses automatically.

Default: -1

presos1bigm (real): Controls largest coefficient in SOS1 reformulation

Controls the automatic reformulation of SOS1 constraints into binary form. SOS1 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values increase the chances that an SOS1 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of -1 chooses a threshold automatically. You should set the parameter to 0 to shut off SOS1 reformulation entirely, or a large value to force reformulation.

Range: [-1, 1e+10]

Default: -1

presos1encoding (integer): Controls SOS1 reformulation

Controls the automatic reformulation of SOS1 constraints. Such constraints can be handled directly by the MIP branch-and-cut algorithm, but they are often handled more efficiently by reformulating them using binary or integer variables. There are several different ways to perform this reformulation; they differ in their size and strength. Smaller reformulations add fewer variables and constraints to the model. Stronger reformulations reduce the number of branch-and-cut nodes required to solve the resulting model.

Options 0 and 1 of this parameter encode an SOS1 constraint using a formulation whose size is linear in the number of SOS members. Option 0 uses a so-called multiple choice model. It usually produces an LP relaxation that is easier to solve. Option 1 uses an incremental model.
It often gives a stronger representation, reducing the amount of branching required to solve harder problems.

Options 2 and 3 of this parameter encode the SOS1 using a formulation of logarithmic size. They both only apply when all the variables in the SOS1 are non-negative. Option 3 additionally requires that the sum of the variables in the SOS1 is equal to 1. Logarithmic formulations are often advantageous when the SOS1 constraint has a large number of members. Option 2 focuses on a formulation whose LP relaxation is easier to solve, while option 3 has better branching behaviour.

The default value of -1 chooses a reformulation for each SOS1 constraint automatically.

Note that the reformulation of SOS1 constraints is also influenced by the PreSOS1BigM parameter. To shut off the reformulation entirely you should set that parameter to 0.

Default: -1

**presos2bigm (real):** Controls largest coefficient in SOS2 reformulation

Controls the automatic reformulation of SOS2 constraints into binary form. SOS2 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values increase the chances that an SOS2 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of 0 disables the reformulation. You can set the parameter to -1 to choose an automatic approach, or a large value to force reformulation.

Range: [-1, 1e+10]

Default: -1

**presos2encoding (integer):** Controls SOS2 reformulation

Controls the automatic reformulation of SOS2 constraints. Such constraints can be handled directly by the MIP branch-and-cut algorithm, but they are often handled more efficiently by reformulating them using binary or integer variables. There are several different ways to perform this reformulation; they differ in their size and strength. Smaller reformulations add fewer variables and constraints to the model. Stronger reformulations reduce the number of branch-and-cut nodes required to solve the resulting model.

Options 0 and 1 of this parameter encode an SOS2 constraint using a formulation whose size is linear in the number of SOS members. Option 0 uses a so-called multiple choice model. It usually produces an LP relaxation that is easier to solve. Option 1 uses an incremental model. It often gives a stronger representation, reducing the amount of branching required to solve harder problems.

Options 2 and 3 of this parameter encode the SOS2 using a formulation of logarithmic size. They both only apply when all the variables in the SOS2 are non-negative. Option 3 additionally requires that the sum of the variables in the SOS2 is equal to 1. Logarithmic formulations are often advantageous when the SOS2 constraint has a large number of members. Option 2 focuses on a formulation whose LP relaxation is easier to solve, while option 3 has better branching behaviour.

The default value of -1 chooses a reformulation for each SOS2 constraint automatically.

Note that the reformulation of SOS2 constraints is also influenced by the PreSOS2BigM parameter. To shut off the reformulation entirely you should set that parameter to 0.

Default: -1

**presparsify (integer):** Presolve sparsify reduction

This reduction can sometimes significantly reduce the number of nonzero values in the presolved model.

Default: -1
printoptions (boolean): List values of all options to GAMS listing file

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Do not list option values to GAMS listing file</td>

<tr>
<td>1</td>
<td>List option values to GAMS listing file</td>
</tr>
</tbody>
</table>

.prior (real): Branching priorities

GAMS allows to specify priorities for discrete variables only. Gurobi can detect that continuous variables are implied discrete variables and can utilize priorities. Such priorities can be specified through a GAMS/Gurobi solver option file. The syntax for dot options is explained in the Introduction chapter of the Solver Manual. The priorities are only passed on to Gurobi if the model attribute priorOpt is turned on.

Default: 1

projimpliedcuts (integer): Projected implied bound cut generation

Default: -1

<table>
<thead>
<tr>
<th>value</th>

</tr>
</tbody>
</table>

psdtol (real): Positive semi-definite tolerance

Positive semi-definite tolerance (for QP/MIQP). Sets a limit on the amount of diagonal perturbation that the optimizer is allowed to automatically perform on the Q matrix in order to correct minor PSD violations. If a larger perturbation is required, the optimizer will terminate stating the problem is not PSD.
Range: $[0, \infty]$
Default: $1e^{-06}$

**pumppasses (integer):** Feasibility pump heuristic control

Note that this heuristic is only applied at the end of the MIP root.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

Default: -1

**qcpdual (boolean):** Compute dual variables for QCP models

Determines whether dual variable values are computed for QCP models. Computing them can add significant time to the optimization, so you should turn this parameter to 0 if you do not need them.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not compute dual for QCP problem</td>
</tr>
<tr>
<td>1</td>
<td>Compute dual for QCP problem</td>

**qextractalg (integer):** quadratic extraction algorithm in GAMS interface

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.</td>
</tr>
<tr>
<td>2</td>
<td>DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.</td>
</tr>
<tr>
<td>3</td>
<td>Concurrent: Uses ThreePass and DoubleForward in parallel. As soon as one finishes, the other one stops.</td>
</tr>
</tbody>
</table>

**quad (integer):** Quad precision computation in simplex

Enables or disables quad precision computation in simplex. The -1 default setting allows the algorithm to decide.

Default: -1

**readparams (string):** Read Gurobi parameter file

**relaxliftcuts (integer):** Relax-and-lift cut generation

Default: -1
rerun (integer): Resolve without presolve in case of unbounded or infeasible

In case Gurobi reports *Model was proven to be either infeasible or unbounded*, this option decides about a resolve without presolve which will determine the exact model status. If the option is set to *auto*, which is the default, and the model fits into demo limits, the problems is resolved.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>

<td>Aggressive</td>
</tr>
</tbody>
</table>

rngrestart (string): Write GAMS readable ranging information file

If the extension specified is *gdx*, a GDX file is exported, and a GAMS file otherwise.

scaleflag (integer): Model scaling

Controls model scaling. By default, the rows and columns of the model are scaled in order to improve the numerical properties of the constraint matrix. The scaling is removed before the final solution is returned. Scaling typically reduces solution times, but it may lead to larger constraint violations in the original, unscaled model. Turning off scaling \( \text{ScaleFlag}=0 \) can sometimes produce smaller constraint violations. Choosing a more aggressive scaling option \( \text{ScaleFlag}=2 \) can sometimes improve performance for particularly numerically difficult models.

Default: -1

seed (integer): Modify the random number seed
Modifies the random number seed. This acts as a small perturbation to the solver, and typically leads to different solution paths.

Default: 0

*sensitivity* *(boolean)*: Provide sensitivity information

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not provide sensitivity information</td>
</tr>
<tr>
<td>1</td>
<td>Provide sensitivity information</td>
</tr>
</tbody>
</table>

*sifting* *(integer)*: Sifting within dual simplex

Enables or disables sifting within dual simplex. Sifting is often useful for LP models where the number of variables is many times larger than the number of constraints. With a *Moderate* setting, sifting will be applied to LP models and to the root node for MIP models. With an *Aggressive* setting, sifting will be also applied to the nodes of a MIP. Note that this parameter has no effect if you aren’t using dual simplex. Note also that sifting will be skipped in cases where it is obviously a worse choice, even when sifting has been selected.

Default: -1

<table>
<thead>

</tbody>
</table>
softmemlimit (real): Soft memory limit ←

Default: maxdouble

solfiles (string): Location to store intermediate solution files ←

During the MIP solution process, multiple incumbent solutions are typically found on the path to finding a proven optimal solution. Setting this parameter to a non-empty string causes these solutions to be written to files (in .sol format) as they are found. The MIP solver will append \_n.sol to the value of the parameter to form the name of the file that contains solution number n. For example, setting the parameter to value solutions/mymodel will create files mymodel\_0.sol, mymodel\_1.sol, etc., in directory solutions.

solnpool (string): Controls export of alternate MIP solutions ←

The GDX file specified by this option will contain a set call index that contains the names of GDX files with the individual solutions. For details see example model dumpsol in the GAMS Test Library. The option PoolSolutions, PoolSearchModel, and PoolGap control the search for alternative solutions. Please also refer to the secion Solution Pool.

solnpoolmerge (string): Controls export of alternate MIP solutions for merged GDX solution file ←

Similar to SolnPool this option stores multiple alternative solutions to a MIP problem, but in a single GDX file. The GDX file specified by this option will contain all variables with an additional first index (determined through SolnPoolPrefix) as parameters. The option PoolSolutions, PoolSearchModel, and PoolGap control the search for alternative solutions. Please also refer to the secion Solution Pool.

solnpoolnumsym (integer): Maximum number of variable symbols when writing merged GDX solution file ←

Default: 10

solnpoolprefix (string): First dimension of variables for merged GDX solution file or file name prefix for GDX solution files ←

Default: soln

solutionlimit (integer): MIP feasible solution limit ←

Default: maxint

solvefixed (boolean): Indicator for solving the fixed problem for a MIP to get a dual solution ←

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not solve the fixed problem</td>
</tr>
<tr>
<td>1</td>
<td>Solve the fixed problem</td>
</tr>
</tbody>
</table>

startnodelimit (integer): Node limit for MIP start sub-MIP ←

This parameter limits the number of branch-and-bound nodes explored when completing a partial MIP start. The default value of -1 uses the value of the SubMIPNodes parameter. A value of -2 means to only check full MIP starts for feasibility and to ignore partial MIP starts. A value of -3 shuts off MIP start processing entirely. Non-negative values are node limits.
Default: -1

**strongcgcuts (integer):** Strong-CG cut generation

Controls Strong Chvátal-Gomory (Strong-CG) cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the **Cuts** parameter.

Default: -1

**submipcuts (integer):** Sub-MIP cut generation

See the description of the global **Cuts** parameter for further information.

Default: -1

**submipnodes (integer):** Nodes explored by sub-MIP heuristics

Limits the number of nodes explored by the heuristics, like RINS. Exploring more nodes can produce better solutions, but it generally takes longer.

Default: 500

**symmetry (integer):** Symmetry detection

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>

<td>Conservative</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

**threads (integer):** Number of parallel threads to use

Default number of parallel threads allowed for any solution method. Non-positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks.

Default: **GAMS** threads

**timelimit (real):** Time limit

Default: **GAMS** reslim

**tunecleanup (real):** Enables a tuning cleanup phase

Enables a cleanup phase at the end of tuning. The parameter indicates the percentage of total tuning time to devote to this phase, with a goal of reducing the number of parameter changes required to achieve the best tuning result.

Default: 0

**tunecriterion (integer):** Specify tuning criterion
Modifies the tuning criterion for the tuning tool. The primary tuning criterion is always to minimize the runtime required to find a proven optimal solution. However, for MIP models that don't solve to optimality within the specified time limit, a secondary criterion is needed. Set this parameter to 1 to use the optimality gap as the secondary criterion. Choose a value of 2 to use the objective of the best feasible solution found. Choose a value of 3 to use the best objective bound. Choose 0 to ignore the secondary criterion and focus entirely on minimizing the time to find a proven optimal solution. The default value of -1 chooses automatically.

Default: -1

**tunejobs (integer):** Enables distributed tuning

Enables distributed parallel tuning, which can significantly increase the performance of the tuning tool. A value of \( n \) causes the tuning tool to distribute tuning work among \( n \) parallel jobs. These jobs are distributed among a set of workers. Use the **WorkerPool** parameter to provide a list of available workers.

Note that distributed tuning is most effective when the workers have similar performance. Distributed tuning doesn't attempt to normalize performance by worker, so it can incorrectly attribute a boost in performance to a parameter change when the associated setting is tried on a worker that is significantly faster than the others.

Default: 0

**tunemetric (integer):** Metric to aggregate results into a single measure

A single tuning run typically produces multiple timing results for each candidate parameter set, either as a result of performing multiple trials, or tuning multiple models, or both. This parameter controls how these results are aggregated into a single measure. The default setting (-1) chooses the aggregation automatically; setting 0 computes the average of all individual results; setting 1 takes the maximum.

Default: -1

**tuneoutput (integer):** Tuning output level

<table>

Default: 2

**tuneresults (integer):** Number of improved parameter sets returned

The tuning tool often finds multiple parameter sets that produce better results than the baseline settings. This parameter controls how many of these sets should be retained when tuning is complete. The default value retains the best results that were found for each count of changed parameters. In other words, it retains the best result for one changed parameter, for two changed parameter, etc. Results that aren't on the efficient frontier are discard.

Default: -1

**tunetargetmipgap (real):** A target gap to be reached

A target gap to be reached. As soon as the tuner has found parameter settings that allow Gurobi to reach the target gap for the given model(s), it stops trying to improve parameter settings further. Instead, the tuner switches into the cleanup phase (see TuneCleanup parameter).

Default: 0

**tunetargettime (real):** A target runtime in seconds to be reached

A target runtime in seconds to be reached. As soon as the tuner has found parameter settings that allow Gurobi to solve the model(s) within the target runtime, it stops trying to improve parameter settings further. Instead, the tuner switches into the cleanup phase (see TuneCleanup parameter).

Default: 0.005

**tunetimelimit (real):** Time limit for tuning

Limits total tuning runtime (in seconds). The default setting (-1) chooses a time limit automatically.

Default: -1

**tunetrials (integer):** Perform multiple runs on each parameter set to limit the effect of random noise

Performance on a MIP model can sometimes experience significant variations due to random effects. As a result, the tuning tool may return parameter sets that improve on the baseline only due to randomness. This parameter allows you to perform multiple solves for each parameter set, using different Seed values for each, in order to reduce the influence of randomness on the results. The default value of 0 indicates an automatic choice that depends on model characteristics.

Note: Only affects mixed integer programming (MIP) models

Default: 0

**Tuning (string):** Parameter Tuning

Invokes the Gurobi parameter tuning tool. The mandatory value following the keyword specifies a GAMS/Gurobi option file. All options found in this option file will be used but not modified during the tuning. A sequence of file names specifying existing problem files may follow the option file name. The files can be in MPS, REW, LP, RLP, and ILP format created by the WriteProb option. Gurobi will tune the parameters either for the problem provided by GAMS (no additional problem files specified) or for the suite of problems listed after the GAMS/Gurobi option file name without considering the problem provided by GAMS. The result of such a run is the updated GAMS/Gurobi option file with a tuned set of parameters. In case the option TuneResults is larger than 1, GAMS/Gurobi will create a sequence of GAMS/Gurobi option files. The solver and model status returned to GAMS will be NORMAL COMPLETION and NO SOLUTION. Tuning is incompatible with advanced features like FeasOpt of GAMS/Gurobi.

**usebasis (integer):** Use basis from GAMS

If UseBasis is not specified, GAMS (via option BRatio) decides if the starting basis or a primal/dual solution is given to Gurobi. If UseBasis is explicitly set in an option file then the basis or a primal/dual solution is passed to Gurobi independent of the GAMS option BRatio. Please note, if Gurobi uses a starting basis presolve will be skipped.

Default: GAMS bratio

</tbody>
</table>

`varhint (boolean)`: Guide heuristics and branching through variable hints

If you know that a variable is likely to take a particular value in high quality solutions of a MIP model, you can provide this information as a hint. If `VarHint` option is active, GAMS/Gurobi will pass variable levels rounded to the nearest integer as hints to Gurobi if their level is within `TryInt` of an integer. The closer the level is to the rounded integer the higher your level of confidence in this hint. Internally this is recalculated into a Gurobi variable hint priority: 

\[
\max\left(10^{-6}, \frac{1}{\left| x - \text{round}(x) \right|}\right)
\]

The Gurobi MIP solver will use these variable hints in a number of different ways. Hints will affect the heuristics that Gurobi uses to find feasible solutions, and the branching decisions that Gurobi makes to explore the MIP search tree. In general, high quality hints should produce high quality MIP solutions faster. In contrast, low quality hints will lead to some wasted effort, but shouldn't lead to dramatic performance degradations.

Variables hints and MIP starts are similar in concept, but they behave in very different ways. If you specify a MIP start, the Gurobi MIP solver will try to build a single feasible solution from the provided set of variable values. If you know a solution, you should use a MIP start to provide it to the solver. In contrast, variable hints provide guidance to the MIP solver that affects the entire solution process. If you have a general sense of the likely values for variables, you should provide them through variable hints.

Default: 0

`workerpassword (string)`: Password for distributed worker cluster

When using a distributed algorithm (the distributed concurrent MIP solver or distributed tuning), this parameter allows you to specify the password for the workers listed in the `WorkerPool` parameter.

`workerpool (string)`: Distributed worker cluster

When using a distributed algorithm (distributed MIP, distributed concurrent, or distributed tuning), this parameter allows you to specify a Remote Services cluster that will provide distributed workers. You should also specify the access password for that cluster, if there is one, in the `WorkerPassword` parameter.
You can provide a comma-separated list of machines for added robustness. If the first node in the list is unavailable, the client will attempt to contact the second node, etc.

To give an example, if you have a Remote Services cluster that uses port 61000 on a pair of machines named server1 and server2, you could set WorkerPool to `server1:61000,server2:61000`.

**worklimit**: Work limit

Limits the total work expended (in work units).

In contrast to the `TimeLimit`, work limits are deterministic. This means that on the same hardware and with the same parameter and attribute settings, a work limit will stop the optimization of a given model at the exact same point every time. One work unit corresponds very roughly to one second on a single thread, but this greatly depends on the hardware on which Gurobi is running and the model that is being solved.

Note that optimization may not stop immediately upon hitting the work limit. It will stop when the optimization is next in a deterministic state, and it will then perform the required additional computations of the attributes associated with the terminated optimization. As a result, the Work attribute may be larger than the specified WorkLimit upon completion, and repeating the optimization with a WorkLimit set to the Work attribute of the stopped optimization may result in additional computations and a larger attribute value.

Default: `maxdouble`

**writeparams**: Write Gurobi parameter file

**writeprob**: Save the problem instance

**zerohalfcuts**: Zero-half cut generation

See the description of the global `Cuts` parameter for further information.

Default: `-1`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Conservative</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

**zeroobjnodes**: Zero objective heuristic control

Note that this heuristic is only applied at the end of the MIP root, and only when no other root heuristic finds a feasible solution.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

Default: `-1`
5.17.8 Setting up a GAMS/Gurobi-Link license

The GAMS/Gurobi-Link requires two licenses:

- A GAMS license with components GAMS/GUROBI-Link and GAMS/BASE (to generate models beyond the demo limits)
- A Gurobi license which you need to get directly from Gurobi

An attempt to use the GAMS/Gurobi solver with a GAMS/Gurobi-Link license but without a properly set up Gurobi license will result in a licensing error with a message describing the problem. For example, the following message is sent to the log when attempting to solve a model with dimensions beyond the community limits:

```
--- Executing GUROBI (Solvelink=2): elapsed 0:00:00.047
Gurobi 32.2.0 rc62c018 Released Aug 26, 2020 WEI x86 64bit/MS Window
Gurobi link license.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)
```

Starting with GAMS distribution 24.7, even demo sized models require a license from Gurobi. An attempt to solve a demo sized model without a Gurobi license installed results in:

```
--- Executing GUROBI (Solvelink=2): elapsed 0:00:00.016
Gurobi 32.2.0 rc62c018 Released Aug 26, 2020 WEI x86 64bit/MS Window
*** This solver runs with a demo license. No commercial use. 
GAMS/Gurobi demo/community requires a Gurobi license from Gurobi Optimization.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)
```

To make the GAMS/Gurobi-Link work you do not need to download or install the Gurobi software but only your Gurobi license. GAMS will use its own Gurobi DLL/shared library, so the Gurobi license has to be valid for the Gurobi version GAMS uses. You can download your Gurobi license from [www.gurobi.com](http://www.gurobi.com). Log in to your Gurobi account and go to Download & Licenses -> Your Gurobi licenses.

Now click on the license you want to download and click on Get License Details. On the license detail page, copy the `grbgetkey` command on the bottom.

Paste the `grbgetkey` command to a command/terminal prompt. Your GAMS system directory contains the `grbgetkey` program, so to make sure it is found you should open the terminal via GAMS Studio or add your GAMS system directory to the path variable. After running the `grbgetkey` command, you will be asked where you would like to save your Gurobi license.

```
$ ./grbgetkey [...]
info : grbgetkey version 9.0.3, build v9.0.3rc0
info : Contacting Gurobi key server...
info : Key for license ID [...] was successfully retrieved
info : License expires at the end of the day on 2021-08-31
info : Saving license key...
```
In which directory would you like to store the Gurobi license key file?
[hit Enter to store it in /opt/gurobi]: /home/nb/gurobilic

info : License [...] written to file /home/nb/gurobilic/gurobi.lic
info : You may have saved the license key to a non-default location
info : You need to set the environment variable GRB_LICENSE_FILE before you can use this license key
info : GRB_LICENSE_FILE=/home/nb/gurobilic/gurobi.lic

Once you have saved your gurobi.lic file, you need to make GAMS/Gurobi aware of that license via environment variable GRB_LICENSE_FILE. The environmentVariables section in the GAMS configuration file (available as of GAMS version 31.1.0) is a convenient way to set the GRB_LICENSE_FILE environment variable. This can either be done by manually opening and editing the gamsconfig.yaml file which can be found in one of the standard locations or via the corresponding GAMS Configuration Editor in GAMS Studio. As a result, the configuration file should contain an entry for environment variable GRB_LICENSE_FILE that points to the Gurobi license, e.g.

[...]
environmentVariables:
[...]
  - GRB_LICENSE_FILE:
    value: /home/nb/gurobilic/gurobi.lic
[...]

As an alternative you could also set GRB_LICENSE_FILE via the usual OS-specific ways to set environment variables.

To test whether the license setup has been successful, you can solve a model from the GAMS Model library, e.g. [INDUS89], where you should get the following output.

$ gamslib indus89
Copy ASCII : indus89.gms
$ gams indus89 lp gurobi
--- Job indus89 Start 09/01/20 12:41:41 32.2.0 rc62c018 LEX-LEG x86 64bit/Linux
[...]
Gurobi 32.2.0 rc62c018 Released Aug 26, 2020 LEG x86 64bit/Linux

Gurobi link license.
Gurobi library version 9.0.3
[...]
Iteration    Objective     Primal Inf.  Dual Inf.   Time
0           7.1618935e+31 2.041808e+32  7.161894e+01   0s
2990         1.1487366e+05 0.000000e+00  0.000000e+00   0s

Solved in 2990 iterations and 0.32 seconds
Optimal objective 1.148736556e+05

User-callback calls 3040, time in user-callback 0.00 sec
LP status(2): Model was solved to optimality (subject to tolerances).
--- Reading solution for model wsisn
*** Status: Normal completion
--- Job indus89.gms Stop 09/01/20 12:29:49 elapsed 0:00:00.835

Note
To install a Gurobi license key as described above, the grbgetkey program needs to be able to communicate with the Gurobi website. If it fails to work, the grbprobe program which can also be found in your GAMS system directory may be used to retrieve the required hardware information which then needs to be manually submitted to the Gurobi Website (detailed instructions can be found here).
5.18 Gather-Update-Solve-Scatter (GUSS)

5.18.1 Introduction

The purpose of this chapter is to detail an extension of the GAMS modeling system that allows collections of models (parameterized exogenously by a set of samples or indices) to be described, instantiated, and solved efficiently.

As a specific example, we consider the parametric optimization problem \( P(s) \) defined by:

\[
\min_{x \in X(s)} f(x; s) \text{ s.t. } g(x; s) \leq 0
\]

where \( s \in S = \{1, \ldots, K\} \). Note that each scenario \( s \) represents a different problem for which the optimization variable is \( x \). The form of the constraint set as given above is simply for concreteness; equality constraints and range and bound constraints are trivial extensions of the above framework. Clearly the problems \( P(s) \) are interlinked. We intend to show how such problems can be easily specified within GAMS, and detail one type of algorithmic extension that can exploit the nature of the linkage.

Other extensions of GAMS allow solves to be executed in parallel or by using grid computing resources. Note that in our description we will use the terms indexed, parameterized, and scenario somewhat interchangeably. An extended version of this chapter containing several examples is available as a paper at http://www.gams.com/modlib/adddocs/gusspaper.pdf.

5.18.2 Design Methodology

One of the most important functions of GAMS is to build a model instance from the collection of equations (i.e. an optimization model defined by the GAMS keyword MODEL) and corresponding data (consisting of the content of GAMS (sub)sets and parameters). Such a model instance is constructed or generated when the GAMS execution system executes a SOLVE statement. The generated model instance is passed to a solver which searches for a solution of this model instance and returns status information, statistics, and a (primal and dual) solution of the model instance. After the solver terminates, GAMS brings the solution back into the GAMS database, i.e. it updates the level (.L) and marginal (.M) fields of variable and equation symbols used in the model instance. Hence, the SOLVE statement can be interpreted as a complex operator against the GAMS database. The model instance generated by a SOLVE statement only lives during the execution of this one statement, and hence has no representation within the GAMS language. Moreover, its structure does fit the relational data model of GAMS. A model instance consists of vectors of bounds and right hand sides, a sparse matrix representation of the Jacobian, a representation of the non-linear expressions that allow the efficient calculation of gradient vectors and Hessian matrices, and so on.

This chapter is concerned with solving collections of models that have similar structure but modified data. As an example, consider a linear program of the form:

\[
\min c^T x \text{ s.t. } Ax \geq b, \ell \leq x \leq u.
\]

The data in this problem is \((A, b, c, \ell, u)\). Omitting some details, the following code could be used within GAMS to solve a collection of such linear programs in which each member of the collection has a different \( A \) matrix and lower bound \( \ell \):

\begin{verbatim}
Set i / ... /, j / ... /;
Parameter A(i,j), b(i);
Variable x(j), z, ...;
Equation e(i), ...;
e(i).. sum(j, A(i,j)*x(j)) =g= b(i);
...
\end{verbatim}
model mymodel /all/;

Set s / s1*s10 /
Parameter
    A_s(s,i,j)  'Scenario data'
    xlo_s(s,j)  'Scenario lower bound for variable x'
    xl_s(s,j)   'Scenario solution for x.l'
    em_s(s,i)   'Scenario solution for e.m';
Loop(s,
    A(i,j) = A_s(s,i,j);
    x.lo(j)= xlo_s(s,j);
    solve mymodel min z using lp;
    xl_s(s,j) = x.l(j);
    em_s(s,i) = e.m(i);
);  

Summarizing, we solve one particular model (mymodel) in a loop over s with an unchanged model rim (i.e. the same individual variables and equations) but with different model data and different bounds for the variables. The change in model data for a subsequent solve statement does not depend on the previous model solutions in the loop.

The purpose of this new Gather-Update-Solve-Scatter (GUSS) manager is to provide syntax at the GAMS modeling level that makes an instance of a problem that provides limited access to treat that instance as an object, and allows the modeler to update portions of it iteratively. Specifically, we provide syntax that gives a list of data changes to an instance, and allows these changes to be applied sequentially to the instance (which is then solved without returning to GAMS). Thus, we can simulate a limited set of actions to be applied to the model instance object and retrieve portions of the solution of these changed instances back in the modeling environment. Such changes can be done to any model type in GAMS, including nonlinear problems and mixed integer models. However, the only changes we allow are to named parameters appearing in the equations and lower and upper bounds used in the model definition.

Thus, in the above example GUSS allows us to replace lines 15-21 by

Set dict / s. scenario. ''
    A. param.  A_s
    x. lower.  xlo_s
    x. level.  xl_s
    e. marginal. em_s /
; solve mymodel min z using lp scenario dict;

The three dimensional set dict (you can freely choose the name of this symbol) contains mapping information between symbols in the model (in the first position) and symbols that supply required update data or store solution information (in the third position), and the type of update/storing (in the second position). An exception to this rule is the tuple with label scenario in the second position. This tuple determines the symbol (in the first position) that is used as the scenario index. This scenario symbol can be a multidimensional set. A tuple in this set represents a single scenario. The remaining tuples in the set dict can be grouped into input and output tuples. Input tuples determine the modifications of the model instance prior to solving, while output tuples determine which part of the solution gets saved away. The following keywords can be used in the second position of the set dict:

<table>
<thead>
<tr>
<th>Type</th>
<th>Keywords</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input:</td>
<td>param</td>
<td>Supplies scenario data for a parameter used in the model</td>
</tr>
<tr>
<td></td>
<td>lower</td>
<td>Supplies scenario lower bounds for a variable</td>
</tr>
<tr>
<td></td>
<td>upper</td>
<td>Supplies scenario upper bounds for a variable</td>
</tr>
<tr>
<td></td>
<td>fixed</td>
<td>Supplies scenario fixed bounds for a variable</td>
</tr>
<tr>
<td>Output:</td>
<td>level</td>
<td>Stores the levels of a scenario solution of variable or equation</td>
</tr>
<tr>
<td></td>
<td>marginal</td>
<td>Stores the marginals of a scenario solution of variable or equation</td>
</tr>
</tbody>
</table>
Sets in the model cannot be updated. GUSS works as follows: GAMS generates the model instance for the original data. As with regular SOLVE statements, all the model data (e.g. parameter A) needs to be defined at this time. The model instance with the original data is also called the base case. The solution of the base case is reported back to GAMS in the regular way and is accessible via the regular .L and .M fields after the SOLVE statement. After solving the base case, the update data for the first scenario is applied to the model. The tuples with lower, upper, fixed update the bounds of the variables, whereas the tuples with param update the parameters in the model.

The scenario index s needs to be the first index in the parameters mapped in the set dict. The update of the model parameters goes far beyond updating the coefficients of the constraint matrix/objective function or the right hand side of an equation, as one can do with some other systems. GAMS stores all the necessary expressions of the constraints with the model instance, so the change in the constraint matrix coefficient is the result of an expression evaluation. For example, consider a term in the calculation of the cost for shipping a variable amount of goods \( x(i,j) \) between cities \( i \) and \( j \). The expression for shipping cost is \( d(i,j)*f*x(i,j) \), i.e. the distance between the cities times a freight rate \( f \) times the variable amount of goods. In order to find out the sensitivity of the solution with respect to the freight rate \( f \), one can solve the same model with different values for \( f \). In a matrix representation of the model one would need to calculate the coefficient of \( x(i,j) \) which is \( d(i,j)*f \), but with GUSS it is sufficient to supply different values for \( f \) that potentially result in many modified coefficients on the matrix level. GUSS evaluates the shipping cost term and communicates the resulting matrix coefficient to the solver reliably behind the scenes.

After the variable bound and the model parameter updates have been applied and the resulting updates to the model instance data structures (e.g. constraint matrix) has been determined, the modified model instance is passed to the solver. Some solvers (e.g. Cplex, Gurobi, SoPlex, and Xpress) allow modifying a model instance. In these cases GUSS only communicates the changes from the previous model instance to the solver. This reduces the amount of data communicated to the solver and also, in the case of an LP model, allows the solver to restart from an advanced basis and its factorization. In the case of an NLP model, this provides initial values. After the solver determines the solution of a model instance, GUSS stores the part of the solution requested by the output tuples of dict to some GAMS parameters and continues with the next scenario. GUSS emphasizes on speed and only works with solver that allow to communicate the model instance through memory. Hence, the following solvers cannot be used as subsolvers of GUSS: ALPHAECP, BARON, CONVERT, DECISC, DECISM, DICOPT, EXAMINER, GAMSCHK, JAMS, KESTREL, LOGMIP, MILES, MPSGE, NLPEC, PATHNLP, SBB.

### 5.18.3 GUSS Options

The execution of GUSS can be parameterized using some options. Options are not passed through a solver option file but via another tuple in the dict set. The keyword in the second position of this tuple is opt. A one dimensional parameter is expected in the first position (or the label &prime;&prime;). This parameter may contain some of the following labels with values:

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OptfileInit:</td>
<td>Option file number for the first solve (default from GAMS OptFile setting)</td>
</tr>
<tr>
<td>Optfile:</td>
<td>Option file number for subsequent solves (default 0)</td>
</tr>
<tr>
<td>LogOption:</td>
<td>Determines amount of log output:</td>
</tr>
<tr>
<td></td>
<td>0 - Moderate log (default)</td>
</tr>
<tr>
<td></td>
<td>1 - Minimal log</td>
</tr>
<tr>
<td></td>
<td>2 - Detailed log</td>
</tr>
<tr>
<td>NoHotStart:</td>
<td>Disable hot start capability in solver that supports hot starts (default 0)</td>
</tr>
<tr>
<td>NoMatchLimit:</td>
<td>Limit of unmatched scenario records (default 0)</td>
</tr>
<tr>
<td>RestartType:</td>
<td>Determines restart point for the scenarios</td>
</tr>
<tr>
<td></td>
<td>0 - Restart from last solution (default)</td>
</tr>
<tr>
<td></td>
<td>1 - Restart from solution of base case</td>
</tr>
<tr>
<td></td>
<td>2 - Restart from input point</td>
</tr>
<tr>
<td>Options</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SkipBaseCase</td>
<td>Switch for solving the base case (0 solves the base case)</td>
</tr>
<tr>
<td>ReportLastScen</td>
<td>Switch for reporting the solution of the last scenario rather than solution of the base case (default 0)</td>
</tr>
<tr>
<td>SolveEmpty</td>
<td>Limit of solved empty scenarios, afterwards empty scenarios will be skipped (default 0)</td>
</tr>
<tr>
<td>UpdateType</td>
<td>Scenario update mechanism: 0 - Set everything to zero and apply changes (default) 1 - Reestablish base case and apply changes 2 - Build on top of last scenario and apply changes</td>
</tr>
</tbody>
</table>

For the example model above the UpdateType setting would mean:

UpdateType=0:  loop(s, A(i,j) = A_s(s,i,j))
UpdateType=1:  loop(s, A(i,j) = A_base(i,j);
               A(i,j) $= A_s(s,i,j))
UpdateType=2:  loop(s, A(i,j) $= A_s(s,i,j))

The option SkipBaseCase=1 allows the user to skip the base case. This means only the scenarios are solved and there is no solution reported back to GAMS in the traditional way. The third position in the opt-tuple can contain a parameter for storing the scenario solution attribute information, e.g. model and solve status, or needs to have the label &prime;&prime;. The labels to store solution status information must be known to GAMS, so one needs to declare a set with such labels. A convenient way to enter these attributes is via System.GUSSModelAttributes:

Set ma 'GUSS Model Attributes' / System.GUSSModelAttributes /; display ma;

---- 1 SET ma GUSS Model Attributes

ModelStat, SolveStat, NumInfes, SumInfes, IterUsd
ResUsd, ObjVal, NodUsd, ObjEst, DomUsd
RObj, MaxInfes, MeanInfes

The following example shows how to use some of the GUSS options and the use of a parameter to store some solution status information:

Set h solution headers / System.GUSSModelAttributes /;
Parameter
  o / SkipBaseCase 1, UpdateType 1, Optfile 1 /
  r_s(s,h) Solution status report;
Set dict / s. scenario. ''
  o. opt. r_s
  a. param. a_s
  x. lower. xl_s
  x. level. xl_s
  e. marginal. em_s /;
solve mymodel min z using lp scenario dict;

Please note that the domain set of the solution status report attributes (here h) must only contain model attributes known to GUSS. If this domain (unless the domain in *) contains a label unknown to GUSS, a compilation error is triggered.
5.18.4 Implementation Details

This section describes some technical details that may provide useful insight in case of unexpected behavior.

Because GUSS changes all model parameters mentioned in the dict set to variables, a linear model can produce some non-linear instructions (e.g. \( d(i,j) = f \times x(i,j) \) becomes a non-linear expression since \( f \) becomes a variable in the model instance given to GUSS). This also explains why some models compile without complaint, but if the model is used in the context of GUSS, the compile time check of the model will fail because a parameter that is turned into a variable can no longer be used in that way. For example, suppose the model contains a constraint \( e(i) \cdot \sum(j A(i,j), ...) \). If \( A(i,j) \) is a parameter in the regular model, the compiler will not complain, but if \( A \) becomes a parameter that shows up in the first position of a param tuple in the dict set, the GAMS compiler will turn \( A \) into a variable and complain that an endogenous variable cannot be used in a $-condition.

The sparsity pattern of a model can be greatly affected by GUSS. In a regular model instance GAMS will only generate and pass on non-zero matrix elements of a constraint \( e(i) \cdot \sum(j, A(i,j) \times x(j)) \), so the sparsity of \( A \) determines the sparsity of the generated model instance. GUSS allows to use this constraint with different values for \( A \) hence GUSS cannot exclude any of the pairs \((i,j)\) and generate a dense matrix. The user can enforce some sparsity by explicitly restricting the \((i,j)\) pairs:

\[
e(i) \cdot \sum(ij(i,j), A(i,j) \times x(j))
\]

Attention

While GUSS is available for many model types quadratic models require special attention. Linear solvers that have been extended to cover (convex) quadratic models, e.g. Cplex, Gurobi, Mosek, Xpress, do not work properly if the modifying parameter affects the left hand side of linear equations or any modifications of quadratic equations. Bound updates as well as changes of the right hand side of linear constraints are okay (see the example of the quadratic support vector machine below).

Unfortunately, detecting if a quadratic model is okay or not for a given solver is at the moment difficult to detect, so use caution with quadratic models in combination with such (linear) solvers.

The actual change of the GAMS language required for the implementation of GUSS is minimal. The only true change is the extension of the SOLVE statement with the term SCENARIO dict. Existing language elements have been used to store symbol mapping information, options, and model result statistics. Some parts of the GUSS presentation look somewhat unnatural, e.g. since dict is a three dimensional set the specification the scenario set using keyword scenario requires a third dummy label &prime;&prime;.

However, this approach gives maximum flexibility for future extension, allows reliable consistency checks at compile and execution time, and allows the user to delay the commitment for significant and permanent syntax changes of a developing method to handle model instances at a GAMS language level.

5.18.5 Applications

5.18.5.1 Cross Validation in GAMS via GUSS

Cross validation is a statistical/machine learning technique that aims to evaluate the generalizability of a classifier (or other decision) process. It does this by setting aside a portion of the data for testing, and uses the remaining data entries to produce the classifier. The testing data is subsequently used to evaluate how well the classifier works. Cross validation performs this whole process a number of times in order to estimate the true power of the classifier.

Ten-fold cross validation is a special case, where the original data is split into ten pieces, and cross validation is performed using each of these ten pieces as the testing set. Thus, the training process is performed ten times, each of which uses the data obtained by deleting the testing set from the whole dataset. We show below how to carry this out using the Gather-Update-Solve-Scatter (GUSS) facility in GAMS.

A paper with the title "GUSS: Solving Collections of Data Related Models within GAMS" that contains two additional application examples for GUSS is available here.
5.18.5.1.1 GUSS formulation in GAMS  The following example compares the two formulations for a feature-selection model under cross-validation using data files  a_data.inc  and  b_data.inc . The actual source code for both of these GAMS formulations is available  here.

Original GAMS formulation (without the GAMS/DEA interface):

```gams
$title Ten-fold cross validation example $eolcom !
$setglobal num_folds 10

set a 'set for category 1' /1*1505/ 
b 'set for category 2' /1*957/ 
o 'observations' /1*14/ 
p 'folds to perform' /1*%num_folds%/ 
f 'maximum features to select' /1*10/

* Read in the data from the data files
parameter a_data(a, o) /
  $offlisting
  $include "a_data.inc"
  $onlisting
/;

parameter b_data(b, o) /
  $offlisting
  $include "b_data.inc"
  $onlisting
/;

set a_test(p,a), b_test(p,b) 'testing sets'
  a_trai(a), b_trai(b) 'training sets';

* Define problem
scalar w_tol /1/
  features /6/;

positive variables a_err(a), sla(a)
  b_err(b), slb(b);

variables c,
  weight(o),
  gamma;

binary variable y(o);

equations w_def1(o),
  w_def2(o),
  y_def,
  c_def,
  a_def(a),
  b_def(b);

w_def1(o).
  weight(o) =l= w_tol*y(o);

w_def2(o).
```

weight(o) =g= -w_tol*y(o);

y_def..
    sum(o, y(o)) =e= features;

c_def..
    c =e= sum(a, a_err(a)) + sum(b, b_err(b));

a_def(a)..
    -sum(o, a_data(a, o)*weight(o)) + gamma + 1 =l= a_err(a) + sla(a);

b_def(b)..
    sum(o, b_data(b, o)*weight(o)) - gamma + 1 =l= b_err(b) + slb(b);

model train /all/;

$batinclude gentestset.inc "p,a" "p,b"

set headers 'report' / modelstat, solvestat, objval /;
parameter rep(p,headers);
train.optfile = 0;
option limrow=0, limcol=0, solprint=silent, mip=xpress, solvelink=%solveLink.loadLibrary%, optcr=0, optca=0;
$echo loadmipsol=1 > xpress.opt

loop(p,
    a_err.up(a) = inf; a_err.up(a)$a_test(p,a) = 0);
    b_err.up(b) = inf; b_err.fx(b)$b_test(p,b) = 0;
    sla.fx(a) = 0; sla.up(a)$a_test(p,a) = inf;
    slb.fx(b) = 0; slb.up(b)$b_test(p,b) = inf;
    solve train using mip minimizing c;
    train.optfile = 1; ! use mipstart for the second run
    rep(p,'modelstat') = train.modelstat;
    rep(p,'solvestat') = train.solvestat;
    rep(p,'objval') = train.objval;
);
display rep;

Options file for the original formulation: xpress.opt

loadmipsol=1

The batinclude file gentestset.inc gives instructions for generating the testing sets. It produces
a_test and b_test that detail which equations are left out on solve p.

The actual model is set up to include all the data points in the equations a_def and b_def. To delete the
equations that correspond to the test set, we introduce nonnegative slack variables into all the equations.
We then set the upper bounds of the slack variables to zero in equations corresponding to the training set,
and to infinity in equations corresponding to the testing set. At the same time we fix the error measures
a_err and b_err belonging to the testing set by setting their upper bounds to zero. Thus the testing set
equations are always satisfiable by choice of the slack variables alone - essentially they are discarded from
the model as required. An alternative formulation could "include" the data equations that you need in
each scenario, but the update from one scenario to the next in the defining data is much larger.

Cross validation formulated using GUSS: This model essentially mimics what the standard model does,
but the implementation of the solver loop behind the scenes is much more efficient, and the consequences
are that are clear to see if you execute both model runs. The changes are in the last 40 lines of the GAMS
code.
$title Ten-fold cross validation example
$setglobal num_folds 10

set a 'set for category 1' /1*1505/
  b 'set for category 2' /1*957/
  o 'observations' /1*14/
  p 'folds to perform' /1*%num_folds%/ 
  f 'maximum features to select' /1*10/

* Read in the data from the data files
parameter a_data(a, o) /
  $offlisting
  $include "a_data.inc"
  $onlisting /

parameter b_data(b, o) /
  $offlisting

  a_def(a),
  b_def(b);

w_def1(o).
  weight(o) =l= w_tol*y(o);

w_def2(o).
  weight(o) =g= -w_tol*y(o);

y_def..
  sum(o, y(o)) =e= features;

c_def..
5.18 Gather-Update-Solve-Scatter (GUSS) 2061

\[ c = e = \sum(a, a_{err}(a)) + \sum(b, b_{err}(b)) \];

\[ a_{def}(a) .. -\sum(o, a_{data}(a, o) \times weight(o)) + \gamma + 1 = l = e = a_{err}(a) + sla(a) \];

\[ b_{def}(b) .. \sum(o, b_{data}(b, o) \times weight(o)) - \gamma + 1 = l = e = b_{err}(b) + slb(b) \];

model train /all/;
train.optfile = 1;

$batinclude gentestset.inc "p,a" "p,b"

parameter wval(p,o), gval(p);

set headers 'report' / modelstat, solvestat, objval /;
parameter

scenrep(p,headers)
scopt(*) / SkipBaseCase 1, Optfile 1, LogOption 2 /;

set dict / p. scenario.''
scopt. opt. scenrep
 a_err. upper. aupper
 b_err. upper. bupper
 sla. upper. afree
 slb. upper. bfree
 weight.level. wval
 gamma. level. gval /

$echo loadmipsol=1 > xpress.opt

Parameter aupper(p,a), bupper(p,b), afree(p,a), bfree(p,b);

aupper(p,a)$(not a_test(p,a)) = inf;
bupper(p,b)$(not b_test(p,b)) = inf;

afree(p,a)$a_test(p,a) = inf;
bfree(p,b)$b_test(p,b) = inf;

option mip=xpress, optcr=0, optca=0;
solve train using mip minimizing c scenario dict;
display scenrep, gval;

Firstly, parameters aupper, bupper, afree and bfree are used to set the bounds on the error and slack variables in the testing set equations respectively. The setting of the upper bounds are governed by the syntax shown in the controlling set dict. Furthermore, the output of the classifier (w, gamma) for each fold of the cross validation uses the dict set to place results into the parameters wval and gval respectively. Finally, the GUSS options are used to guarantee that the subsequent solves are instructed to process solver options (Optfile 1) which instruct the solver to use the previous solution to start the branch-and-cut process (loadmipsol=1).

The complete data and model files for this example are found in (galaxy zip archive). The data and model for a second instance based on the Wisconsin Diagnostic Breast Cancer Database is downloadable as (wdbc zip archive).

5.18.5.1.2 Quadratic Programs  GUSS is not limited to linear programs, but can be used more generally. Simple (indexed) quadratic models can be solved using GUSS. The following example illustrates
the use of GUSS for quadratic programs. In this example, a support vector machine is used to determine a linear classifier that separates data into two categories. We use the following model:

\[
\begin{align*}
\text{Min}_{w, g, z} & \quad \frac{1}{2}||w||^2 + C \rho^T z \\
\text{subject to} & \quad D(Aw - g) + z \geq 1 \\
& \quad z \geq 0 \tag{5.17}
\end{align*}
\]

Here, \( A \) is a matrix containing the training data (patients by features) and \( D \) is a diagonal matrix with values +1 or −1 (each denoting one of the two classes). \( C \) is a parameter weighting the importance of maximizing the margin between the classes (2/||w||^2) versus minimizing the misclassification error (z). The solution \( w \) and \( g \) are used to define a separating hyperplane \( \{x | w^T x = g\} \) to classify (unseen) data points.

As given, the standard linear support vector machine is not a slice model per se. It becomes a slice model under cross-validation training, where it is solved multiple times on different pieces of data. In this case, only the data \( A \) and \( D \) vary between solves, appropriately fitting the definition of a slice model.

The data for this example comes from the Wisconsin Diagnosis Breast Cancer Database, and is available here. The data was converted to the GAMS file \texttt{wdbc.gms} , which defines \( A \) and \( D \). The actual source code for the following GAMS formulation is available here.

The GUSS formulation for quadratic svm:

```gams
$title Ten-fold cross validation example using GUSS $eolcom !
$setglobal num_folds 10
set p /1*%num_folds%/; ! folds to perform
! Read in data
$include "wdbc.gms"
set test(p,i); ! testing set
! Define problem
parameter C /1/;
positive variables z(i);
variables obj, w(k), gamma, slack(i);
equations obj_def, sep_def(i);
obj_def.. obj =e= 1/2*sum(k, sqr(w(k))) + C*sum(i, z(i));
sep_def(i).. D(i)*(sum(k, A(i,k)*w(k)) - gamma) + z(i) + slack(i) =g= 1;
model train /all/;
! Generate testing sets (to be deleted in each problem)
loop(p, $batinclude gentestset2.inc "p,i"
);
set headers report / modelstat, solvestat, objval /;
parameter scenrep(p,headers)
scopt / SkipBaseCase 1, LogOption 2 /;
```
5.18 Gather-Update-Solve-Scatter (GUSS)

```gams
set dict / p. scenario.
    scopt.opt. scenrep
    z. upper. iupper
    slack.upper. ifree /;

Parameter iupper(p,i), ifree(p,i);
iupper(p,i)$(not test(p,i)) = inf;
ifree(p,i)$test(p,i) = inf;

option qcp=conopt, optcr=0, optca=0;
solve train using qcp minimizing obj scenario dict;
display scenrep;
```

Because the problem is quadratic, we must use a quadratic program solver. The variable values for weight
and gamma could be saved for later testing using the same method as detailed above for the linear case.

The batinclude file `gentestset2.inc` is very similar to `gentestset.inc` from the earlier cross-validation
examples. In `gentestset2.inc`, though, only one set is being dealt with rather than two. The complete
source GAMS code for this formulation is available in this zip archive.

5.18.5.2 DEA Modeling in GAMS via GUSS

Data Envelopment Analysis (DEA) models can be solved most efficiently in GAMS using the Gather-
Update-Solve-Scatter (GUSS) facility. This is the preferred method since release 23.7 of GAMS and hence
the GAMS/DEA solver is no longer available.

A paper with the title “GUSS: Solving Collections of Data Related Models within GAMS” that contains
two additional application examples for GUSS is available here.

5.18.5.2.1 Introduction The basic (CCR) DEA model is a collection of models indexed by $k$ and
defined by

\[
\begin{align*}
\max_{u,v} & \quad u^T Y_{*,k} & \text{(objective slice)} \\
\text{subject to} & \quad v^T X_{*,k} = 1 & \text{(slice constraint)} \\
& \quad u^T Y \leq v^T X & \text{(core constraint)} \\
& \quad u, v \geq 0 & \text{(core constraint)}
\end{align*}
\]

(5.18)

where $X, Y$ are data matrices.

Without using GUSS in GAMS, a model would be defined and solved in a loop over $k$, requiring the model
to be generated multiple times with different instances for each value of $k$. GUSS is an alternative (and
more efficient) way to define the individual programs and pass them to any underlying GAMS solver. In
this way, individual programs are not re-generated, but are instead defined as data modifications of each
other. This reduces overall model generation time. Further, previous solutions can be used as starting
points in later solves to speed up overall processing time.

Some DEA examples compare the two formulations. The actual source code for both of these formulations
is available here.
5.18.5.2.2 DEA Examples  Original GAMS formulation (without GUSS): In all these models the model setup and data are given at the top of the file and the code of interest is in the last 10 or so lines. In this setting we loop over the set k and change the data in the objective function and the first constraint of the model explicitly before each solve. We only output a minimal summary of the solution.

$title Data Envelopment Analysis - DEA

$ontext
Data Envelopment Analysis (DEA) is a technique for measuring the relative performance of organizational units where presence of multiple inputs and outputs makes comparison difficult.

\[ \text{efficiency} = \frac{\text{weighted sum of output}}{\text{weighted sum of input}} \]

Find weights that maximize the efficiency for one unit while ensuring that no other units has an efficiency < 1 using these weights. A primal and dual formulation is presented.

);
display rep;

The DEA problem formulated using GUSS: In this setting, the solve statement includes an extra keyword
scenario that points to a new set called dict. The contents of this set are directives to GUSS that state
the scenario index is k, the parameter slice is populated from the parameter data and the values of the
variable eff are stored into the parameter eff_k for each scenario solved. More details follow below.

    scopt / SkipBaseCase 1 /;
set dict / k .scenario.''
    slice .param. data
    eff .level. eff_k
    scopt .opt. scenrep /;
slice(j) = 0; option lp=cplex;
solve dea using lp max eff scenario dict;
display scenrep,eff_k;

In the GUSS version we indicate the collection of models to be solved using the set dict. The first element of dict determines the set to be used for the scenario (collection) index, in this case k. The second element of dict then details that in each scenario k, the parameter slice is instantiated using a slice of the parameter data. Essentially, this corresponds to the GAMS statement:

    slice(j) = data(k.j)

Note the scenario index k must appear as the first index of the parameter data. The third element of dict allows the modeler to collect information from each solve and store it into a GAMS parameter. Essentially, the third element of dict corresponds to the GAMS statement:

    eff_k(k) = eff.l
that gets executed immediately after the solve of scenario $k$.

More complex scenario models can also be formulated using GUSS, including multiple equations being updated. This is shown by the dual of the basic DEA model, given by

$$
\begin{align*}
\min_{z, \lambda} & \quad z \\
\text{subject to} & \quad X^* \lambda \leq z X_{+,k} \\
& \quad Y^* \lambda \geq Y_{+,k} \\
& \quad \lambda \geq 0
\end{align*}
\tag{5.19}
$$

The next example compares the two formulations for this model. The actual source code for both of these formulations is available here.

Extensions of these models to formulations with weighted outputs or variable returns to scale are easy to
formulate with the scenario solver within GAMS. This extended model can be downloaded here.

The DEA model in the model library is similar to the extended model, but does not make use of GUSS.

5.19 HiGHS

HiGHS is an optimization package for solving continuous and mixed-integer linear programming problems
(LPs and MIPs) using simplex, interior-point, and branch-and-cut algorithms. HiGHS is developed by the
Edinburgh Research Group in Optimization.

For more detailed information on the implemented simplex method, we refer to [98].

5.19.1 Usage

The following statement can be used inside your GAMS program to specify using HiGHS

Option MIP = HiGHS; { or LP or RMIP }

The above statement should appear before the Solve statement. If HiGHS was specified as the default
solver during GAMS installation, the above statement is not necessary.
5.19.1.1 Specification of HiGHS Options

GAMS/HiGHS supports the GAMS parameters reslim, iterlim, nodlim, optca, optcr, cutoff, and threads.

Options can be specified by a HiGHS options file. A HiGHS options file consists of one option or comment per line. A pound sign (#) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs).

A small example for a highs.opt file is:

```
solver = ipm
ipm_optimality_tolerance = 1e-6
run_crossover = false
```

It causes HiGHS to use an interior point solver for an LP solve, increases the optimality tolerance to $10^{-6}$, and turns off crossover to a basis solution.

5.19.2 List of HiGHS Options

In the following, we give a detailed list of all HiGHS options.

<table>

## 5.20 IPOPT and IPOPTH

**COIN-OR IPOPT** (Interior Point Optimizer) is an open-source solver for large-scale nonlinear programming (NLP). The code has been written primarily by Andreas Wächter.

IPOPT implements an interior point line search filter method for nonlinear programming models which functions can be nonconvex, but should be twice continuously differentiable. For more information on the algorithm we refer to [144] [196] [195] [197] [194] and the IPOPT documentation. Most of the IPOPT documentation in the section was taken from the IPOPT manual [104].

### 5.20.1 Available linear solvers

The performance and robustness of IPOPT on larger models heavily relies on the used solver for sparse symmetric indefinite linear systems.

GAMS/IPOPT includes the sparse solver MUMPS [8] [9] (currently the default), and MKL PARDISO [166] [167]. The latter is not available for systems on ARM64 CPUs. In the commercially licensed GAMS/IPOPTH version, also the Harwell Subroutine Library (HSL) solvers MA27, MA57, HSL_MA86, and HSL_MA97 are available and MA27 is used by default.

MUMPS, MA57, HSL_MA86, and HSL_MA97 use METIS for matrix ordering [103], see also the METIS manual. METIS is copyrighted by the regents of the University of Minnesota.
IPOPT and IPOPTH can exploit parallelization of the linear solvers MKL Pardiso, HSL MA86, and HSL MA97 and the linear algebra routines (see next section).

The linear solver is chosen by the `linear_solver` option. Benchmarks have shown that MA57 and HSL_MA97 are often able to outperform MA27 on larger instances. Further, PARDISO often allows for performance that is better than MUMPS and similar to the HSL solvers. If IPOPT fails to solve an instance with PARDISO, it’s worth to try changing the options `pardisomkl_order` and `pardisomkl_max_iterative_refinement_steps`.

It is also possible to use the linear solver PARDISO from the PARDISO Solver Project or the HSL routines with GAMS/IPOPT if a user provides libraries that can be loaded at runtime. PARDISO from the PARDISO Solver Project can provide performance that exceeds the one of PARDISO from Intel MKL. To build the HSL routines, COIN-OR project ThirdParty-HSL may be useful. See also options `linear_solver`, `linear_system_scaling`, `nlp_scaling_method`, `pardisolib`, and `hsllib`. Note that it is your responsibility to ensure that you are entitled to download and use these routines!

### 5.20.2 The linear algebra library

On systems for AMD and Intel CPUs, the IPOPT library distributed by GAMS and most of the linear solvers used by IPOPT use the Intel oneAPI Math Kernel Library (MKL), which provides a fast and parallel implementation of linear algebra routines (BLAS/LAPACK) and the linear solver PARDISO. MKL chooses an internal code path that provides the best possible performance for the used CPU type. As a consequence, results can be different when changing from one CPU to another. By setting an environment variable, the code path to use can be set by the user. See the Intel MKL documentation regarding Conditional Numerical Reproducibility for more details.

Intel MKL has been optimized for use with Intel CPUs. On CPUs from other vendors, MKL may not use an internal code path that could provide a better performance on that CPU. For example, it may not use AVX2 instructions on an AMD CPU that provides AVX2. However, Intel recently started to add optimized code for AMD’s Zen CPUs.

To gain more insight into the use of MKL in GAMS/IPOPT, one may set the environment variable `MKL_VERBOSE` to 1. This will print out information about the MKL library used, functions being called, time spend there, etc.

On the GAMS system for macOS on ARM64 CPUs, the Apple Accelerate framework is used as linear algebra library.

### 5.20.3 Usage

The following statement can be used inside your GAMS program to specify using IPOPT

```
Option NLP = IPOPT; { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```

The above statement should appear before the Solve statement. If IPOPT was specified as the default solver during GAMS installation, the above statement is not necessary.

To use IPOPTH, the statement should be

```
Option NLP = IPOPTH; { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```
5.20.3.1 Specification of Options

IPOPT has many options that can be adjusted for the algorithm (see Section List of IPOPT Options). Options are all identified by a string name, and their values can be of one of three types: Number (real), Integer, or String. Number options are used for things like tolerances, integer options are used for things like maximum number of iterations, and string options are used for setting algorithm details, like the NLP scaling method. Options can be set by creating a ipopt.opt file in the directory you are executing IPOPT.

The ipopt.opt file is read line by line and each line should contain the option name, followed by whitespace, and then the value. Comments can be included with the # symbol. For example, the following is a valid ipopt.opt file:

```
# This is a comment

# Turn off the NLP scaling
nlp_scaling_method none

# Change the initial barrier parameter
mu_init 1e-2

# Set the max number of iterations
max_iter 500
```

GAMS/IPOPT understands currently the following GAMS parameters: reslim (time limit), iterlim (iteration limit), domlim (domain violation limit). Further the option threads can be used to control the number of threads used in the linear algebra routines and the linear solver.

5.20.3.2 Warmstarting IPOPT

As an interior point solver, it is difficult to warm start IPOPT. By default, only the level values of the variables are passed as starting point to IPOPT. Setting the IPOPT option warm_start_init_point to yes enables that also dual values for variables and constraints are passed to IPOPT.

However, the expected behavior that IPOPT finishes within one iteration if optimal primal and dual values are passed is not reached this way, yet. This is, because IPOPT by default moves any initial value that is close to a bound into the interior. The amount on how much the initial point is moved can be controlled by various bound_push and bound_frac options. To make IPOPT accept an optimal primal/dual solution within one iteration, it should be sufficient to set the following options:

```
warm_start_init_point yes
warm_start_bound_push 1e-9
warm_start_bound_frac 1e-9
warm_start_slack_bound_frac 1e-9
warm_start_slack_bound_push 1e-9
warm_start_mult_bound_push 1e-9
```

Further, it can be useful to specify that IPOPT can use a less central path in its first iterations by reducing the value of option mu_init. This option is only used if option mu_strategy is set to "monotone", so the option file entries would be

```
mu_strategy monotone
mu_init 0.0001
```
Finally, IPOPT by default checks whether it should scale the problem. The computed scaling depends on the starting point, which can be undesired when warmstarting. Thus, it may be useful to turn off scaling via option `nlp_scaling_method`:

```
nlp_scaling_method none
```

If a modified but structurally equivalent problem instance is solved, e.g., via GUSS, option `warm_start_init_point` is automatically set to "yes" for every solve following the first one. If this is not desired, `warm_start_init_point` should explicitly be set to "no" in an IPOPT options file.

### 5.20.4 Output

This section describes the standard IPOPT console output. The output is designed to provide a quick summary of each iteration as IPOPT solves the problem.

Before IPOPT starts to solve the problem, it displays the problem statistics (number of nonzero-elements in the matrices, number of variables, etc.). Note that if you have fixed variables (both upper and lower bounds are equal), IPOPT may remove these variables from the problem internally and not include them in the problem statistics.

Following the problem statistics, IPOPT will begin to solve the problem and you will see output resembling the following,

```
iter    objective   inf_pr  inf_du  lg(mu)  ||d||  lg(rg) alpha_du alpha_pr  ls
   0  1.6109693e+01  1.12e+01  5.28e-01  0.00e+00 -0.00e+00  0.00e+00  0.00e+00  0  
   1  1.8029749e+01  9.90e-01  6.62e+01  0.10e+00  2.05e+00  2.14e-01  1.00e+00  1  
   2  1.8719906e+01  1.25e-02  9.04e+00 -2.20e+00  5.94e-02  8.04e-01  1.00e+00  1  
```

and the columns of output are defined as

- **iter**: The current iteration count. This includes regular iterations and iterations while in restoration phase. If the algorithm is in the restoration phase, the letter `r` will be appended to the iteration number.
- **objective**: The unscaled objective value at the current point. During the restoration phase, this value remains the unscaled objective value for the original problem.
- **inf_pr**: The unscaled constraint violation at the current point. This quantity is the infinity-norm (max) of the (unscaled) constraint violation. During the restoration phase, this value remains the constraint violation of the original problem at the current point. The option `inf_pr_output` can be used to switch to the printing of a different quantity. During the restoration phase, this value is the primal infeasibility of the original problem at the current point.
- **inf_du**: The scaled dual infeasibility at the current point. This quantity measure the infinity-norm (max) of the internal dual infeasibility (Eq. (4a) in [197]), including inequality constraints reformulated using slack variables and problem scaling. During the restoration phase, this value is the primal infeasibility for the restoration phase problem.
\[ \log_{10} \text{of the value of the barrier parameter } \mu. \]

\[ ||d|| \]

The infinity norm (max) of the primal step (for the original variables \( x \) and the internal slack variables \( s \)). During the restoration phase, this value includes the values of additional variables, \( p \) and \( n \) in Eq. (10) of [197].

\[ \log_{10} \text{of the value of the regularization term for the Hessian of the Lagrangian in the augmented system (} \delta_w \text{ in Eq. (26) of [197]). A dash (\(-\)) indicates that no regularization was done.} \]

\[ \alpha_{du} \]

The stepsize for the dual variables (\( \alpha_{\lambda} \) in Eq. (14c) of [197]).

\[ \alpha_{pr} \]

The stepsize for the primal variables (\( \alpha_k \) in Eq. (14a) of [197]). The number is usually followed by a character for additional diagnostic information regarding the step acceptance criterion:

- \( f \): f-type iteration in the filter method w/o second order correction
- \( F \): f-type iteration in the filter method w/ second order correction
- \( h \): h-type iteration in the filter method w/o second order correction
- \( H \): h-type iteration in the filter method w/ second order correction
- \( k \): penalty value unchanged in merit function method w/o second order correction
- \( K \): penalty value unchanged in merit function method w/ second order correction
- \( n \): penalty value updated in merit function method w/o second order correction
- \( N \): penalty value updated in merit function method w/ second order correction
- \( R \): Restoration phase just started
- \( w \): in watchdog procedure
- \( s \): step accepted in soft restoration phase
- \( t/T \): tiny step accepted without line search
- \( r \): some previous iterate restored

\[ \text{ls} \]

The number of backtracking line search steps (does not include second-order correction steps).

Note that the step acceptance mechanisms in IPOPT consider the barrier objective function (Eq. (3a) in [197]) which is usually different from the value reported in the objective column. Similarly, for the purposes of the step acceptance, the constraint violation is measured for the internal problem formulation, which includes slack variables for inequality constraints and potentially scaling of the constraint functions. This value, too, is usually different from the value reported in inf_pr. As a consequence, a new iterate might have worse values both for the objective function and the constraint violation as reported in the iteration output, seemingly contradicting globalization procedure.

When the algorithm terminates, IPOPT will output a message to the screen. The following is a list of the possible output messages and a brief description.

Optimal Solution Found.
This message indicates that IPOPT found a (locally) optimal point within the desired tolerances.

Solved To Acceptable Level.

This indicates that the algorithm did not converge to the "desired" tolerances, but that it was able to obtain a point satisfying the "acceptable" tolerance level as specified by acceptable-∗ options. This may happen if the desired tolerances are too small for the current problem.

Feasible point for square problem found.

This message is printed if the problem is "square" (i.e., it has as many equality constraints as free variables) and IPOPT found a point that is feasible w.r.t. constr_viol_tol. It may, however, not be feasible w.r.t. tol.

Converged to a point of local infeasibility. Problem may be infeasible.

The restoration phase converged to a point that is a minimizer for the constraint violation (in the ℓ₁-norm), but is not feasible for the original problem. This indicates that the problem may be infeasible (or at least that the algorithm is stuck at a locally infeasible point). The returned point (the minimizer of the constraint violation) might help you to find which constraint is causing the problem. If you believe that the NLP is feasible, it might help to start the optimization from a different point.

Search Direction is becoming Too Small.

This indicates that IPOPT is calculating very small step sizes and making very little progress. This could happen if the problem has been solved to the best numerical accuracy possible given the current scaling.

Iterates diverging; problem might be unbounded.

This message is printed if the max-norm of the iterates becomes larger than the value of the option diverging_iterates_tol. This can happen if the problem is unbounded below and the iterates are diverging.

Stopping optimization at current point as requested by user.

This message is printed if either an interrupt signal was received (e.g., Ctrl+C was pressed) or the domain violation limit is reached.

Maximum Number of Iterations Exceeded.

This indicates that IPOPT has exceeded the maximum number of iterations as specified by the IPOPT option max_iter or the GAMS option iterlim.

Maximum wallclock time exceeded.

This indicates that IPOPT has exceeded the maximum number of wallclock seconds as specified by the IPOPT option max_wall_time or the GAMS option reslim.

Maximum CPU time exceeded.

This indicates that IPOPT has exceeded the maximum number of CPU seconds as specified by the IPOPT option max_cpu_time.

Restoration Failed!
This indicates that the restoration phase failed to find a feasible point that was acceptable to the filter line search for the original problem. This could happen if the problem is highly degenerate, does not satisfy the constraint qualification, or if an external or extrinsic function in GAMS provides incorrect derivative information.

Error in step computation!

This messages is printed if IPOPT is unable to compute a step towards a new iterate and the current iterate is not acceptable for the specified tolerances.

A possible reason is that a search direction could not be computed despite several attempts to modify the iteration matrix. Usually, the value of the regularization parameter then becomes too large.

Another reason is that the feasibility restoration phase could not be activated because the current iterate is not infeasible. Reasons for this again include that the problem is highly degenerate, badly scaled, or does not satisfy the constraint qualification. Before IPOPT 3.14, this resulted in a Restoration Failed status code with message ”Restoration phase is called at almost feasible point...”.

Problem has too few degrees of freedom.

This indicates that your problem, as specified, has too few degrees of freedom. This can happen if you have too many equality constraints, or if you fix too many variables (IPOPT removes fixed variables by default, see also the option fixed_variable_treatment).

Not enough memory.

An error occurred while trying to allocate memory. The problem may be too large for your current memory and swap configuration. Sometimes it can help to choose a different linear solver.

INTERNAL ERROR: Unknown SolverReturn value - Notify IPOPT Authors.

An unknown internal error has occurred. Please notify the authors of the GAMS/IPOPT link or IPOPT (refer to support@gams.com).

5.20.4.1 Diagnostic Tags for IPOPT

To print additional diagnostic tags for each iteration of IPOPT, set the options print_info_string to yes. With this, a tag will appear at the end of an iteration line with the following diagnostic meaning that are useful to flag difficulties for a particular IPOPT run. The following is a list of possible strings:

- !: Tighten resto tolerance if only slightly infeasible, see Sec. 3.3 in [197]
- A: Current iteration is acceptable (alternate termination)
- a: Perturbation for PD Singularity can't be done, assume singular, see Sec. 3.1 in [197]
- C: Second Order Correction taken, see Sec. 2.4 in [197]
- Dh: Hessian degenerate based on multiple iterations, see Sec. 3.1 in [197]
- Dhj: Hessian/Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [197]
- Dj: Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [197]
- dx: δx perturbation too large, see Sec. 3.1 in [197]
• e: Cutting back $\alpha$ due to evaluation error (in backtracking line search)
• F-: Filter should be reset, but maximal resets exceeded, see Sec. 2.3 in [197]
• F+: Resetting filter due to last few rejections of filter, see Sec. 2.3 in [197]
• L: Degenerate Jacobian, $\delta_c$ already perturbed, see Sec. 3.1 in [197]
• l: Degenerate Jacobian, $\delta_c$ perturbed, see Sec. 3.1 in [197]
• M: Magic step taken for slack variables (in backtracking line search)
• Nh: Hessian not yet degenerate, see Sec. 3.1 in [197]
• Nhj: Hessian/Jacobian not yet degenerate, see Sec. 3.1 in [197]
• Nj: Jacobian not yet degenerate, see Sec. 3.1 in [197]
• Nh: Warm start initialization failed (in Warm Start Initialization)
• q: PD system possibly singular, attempt to improve solution quality, see Sec. 3.1 in [197]
• R: Solution of restoration phase, see Sec. 3.3 in [197]
• S: PD system possibly singular, accept current solution, see Sec. 3.1 in [197]
• s: PD system singular, see Sec. 3.1 in [197]
• s: Square Problem. Set multipliers to zero (default initialization routine)
• Tmax: Trial $\theta$ is larger than $\theta_{\text{max}}$ (filter parameter, Eq. (21) in [197])
• W: Watchdog line search procedure successful, see Sec. 3.2 in [197]
• w: Watchdog line search procedure unsuccessful, stopped, see Sec. 3.2 in [197]
• Wb: Undoing most recent SR1 update, see Sec. 5.4.1 in [23]
• We: Skip Limited-Memory Update in restoration phase, see Sec. 5.4.1 in [23]
• Wp: Safeguard $B^0 = \sigma I$ for Limited-Memory Update, see Sec. 5.4.1 in [23]
• Wr: Resetting Limited-Memory Update, see Sec. 5.4.1 in [23]
• Ws: Skip Limited-Memory Update since $s^T y$ is not positive, see Sec. 5.4.1 in [23]
• WS: Skip Limited-Memory Update since $\Delta x$ is too small, see Sec. 5.4.1 in [23]
• y: Dual infeasibility, use least square multiplier update (during IPOPT algorithm)
• z: Apply correction to bound multiplier if too large (during IPOPT algorithm)

5.20.5 List of IPOPT Options

5.20.5.1 Termination

<table>
<thead>
<tr>

<tr>
<td>filter_reset_trigger</td>
<td>Number of iterations that trigger the filter reset.</td>
<td>5</td>
</tr>
<tr>
<td>gamma_phi</td>
<td>Relaxation factor in the filter margin for the barrier function.</td>
<td>1e-08</td>
</tr>
<tr>
<td>gamma_theta</td>
<td>Relaxation factor in the filter margin for the constraint violation.</td>
<td>1e-05</td>
</tr>
<tr>
<td>kappa_sigma</td>
<td>Factor limiting the deviation of dual variables from primal estimates.</td>
<td>1e+10</td>
</tr>
<tr>
<td>kappa_soc</td>
<td>Factor in the sufficient reduction rule for second order correction.</td>
<td>0.99</td>
</tr>
<tr>
<td>line_search_method</td>
<td>Globalization method used in backtracking line search.</td>
<td>filter</td>
</tr>
<tr>
<td>max_filter_resets</td>
<td>Maximal allowed number of filter resets</td>
<td>5</td>
</tr>
<tr>
<td>nu_inc</td>
<td>Increment of the penalty parameter.</td>
<td>0.0001</td>
</tr>
<tr>
<td>nu_init</td>
<td>Initial value of the penalty parameter.</td>
<td>1e-06</td>
</tr>
<tr>
<td>obj_max_inc</td>
<td>Determines the upper bound on the acceptable increase of barrier objective function.</td>
<td>5</td>
</tr>
<tr>
<td>rho</td>
<td>Value in penalty parameter update formula.</td>
<td>0.1</td>
</tr>
<tr>
<td>s_phi</td>
<td>Exponent for linear barrier function model in the switching rule.</td>
<td>2.3</td>
</tr>
<tr>
<td>s_theta</td>
<td>Exponent for current constraint violation in the switching rule.</td>
<td>1.1</td>
</tr>
</tbody>
</table>
### 5.20 IPOPT and IPOPTH

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>skip_corr_if_neg_curv</code></td>
<td>Whether to skip the corrector step in negative curvature iteration.</td>
<td>yes</td>
</tr>
<tr>
<td><code>skip_corr_in_monotone_mode</code></td>
<td>Whether to skip the corrector step during monotone barrier parameter mode.</td>
<td>yes</td>
</tr>
<tr>
<td><code>slack_move</code></td>
<td>Correction size for very small slacks.</td>
<td>1.81899e-12</td>
</tr>
<tr>
<td><code>theta_max_fact</code></td>
<td>Determines upper bound for constraint violation in the filter.</td>
<td>10000</td>
</tr>
<tr>
<td><code>theta_min_fact</code></td>
<td>Determines constraint violation threshold in the switching rule.</td>
<td>0.0001</td>
</tr>
<tr>
<td><code>tiny_step_tol</code></td>
<td>Tolerance for detecting numerically insignificant steps.</td>
<td>2.22045e-15</td>
</tr>
<tr>
<td><code>tiny_step_y_tol</code></td>
<td>Tolerance for quitting because of numerically insignificant steps.</td>
<td>0.01</td>
</tr>
</tbody>
</table>

#### 5.20.5.10 Linear Solver

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hslib</code></td>
<td>Name of library containing HSL routines for load at runtime</td>
<td>libhsl.so (Linux), libhsl.dylib (macOS), libhsl.dll (Windows)</td>
</tr>
<tr>
<td><code>linear_scaling_on_demand</code></td>
<td>Flag indicating that linear scaling is only done if it seems required.</td>
<td>yes</td>
</tr>
<tr>
<td><code>linear_solver</code></td>
<td>Linear solver used for step computations.</td>
<td>ma27, if IpoptH, otherwise mumps</td>

<tr>
<td><code>pardisolib</code></td>
<td>Name of library containing Pardiso routines (from pardiso-project.org) for load at runtime</td>
<td>libpardiso.so (Linux), libpardiso.dylib (macOS), libpardiso.dll (Windows)</td>
</tr>
</tbody>
</table>

#### 5.20.5.11 Step Calculation

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fast_step_computation</code></td>
<td>Indicates if the linear system should be solved quickly.</td>
<td>no</td>
</tr>
<tr>
<td><code>first_hessian_perturbation</code></td>
<td>Size of first x-s perturbation tried.</td>
<td>0.0001</td>
</tr>
<tr>
<td><code>jacobian_regularization_value</code></td>
<td>Size of the regularization for rank-deficient constraint Jacobians.</td>
<td>1e-08</td>
</tr>
<tr>
<td><code>max_hessian_perturbation</code></td>
<td>Maximum value of regularization parameter for handling negative curvature.</td>
<td>1e+20</td>
</tr>
<tr>
<td><code>max_refinement_steps</code></td>
<td>Maximum number of iterative refinement steps per linear system solve.</td>
<td>10</td>
</tr>
<tr>
<td><code>mehrotra_algorithm</code></td>
<td>Indicates whether to do Mehrotra's predictor-corrector algorithm.</td>
<td>no</td>
</tr>
<tr>
<td><code>min_hessian_perturbation</code></td>
<td>Smallest perturbation of the Hessian block.</td>
<td>1e-20</td>
</tr>
<tr>
<td><code>min_refinement_steps</code></td>
<td>Minimum number of iterative refinement steps per linear system solve.</td>
<td>1</td>
</tr>
<tr>
<td><code>neg_curv_test_reg</code></td>
<td>Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).</td>
<td>yes</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>neg_curv_test_tol</td>
<td>Tolerance for heuristic to ignore wrong inertia.</td>
<td>0</td>
</tr>
<tr>
<td>perturb_decrefact</td>
<td>Decrease factor for x-s perturbation.</td>
<td>0.333333</td>
</tr>
<tr>
<td>perturb_incrfact</td>
<td>Increase factor for x-s perturbation.</td>
<td>8</td>
</tr>
<tr>
<td>perturb_incrfact_first</td>
<td>Increase factor for x-s perturbation for very first perturbation.</td>
<td>100</td>
</tr>
</tbody>
</table>

### Options for expert users

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>jacobian_regularization_exponent</td>
<td>Exponent for mu in the regularization for rank-deficient constraint Jacobians.</td>
<td>0.25</td>
</tr>
<tr>
<td>perturb_always_cd</td>
<td>Active permanent perturbation of constraint linearization.</td>
<td>no</td>
</tr>
<tr>
<td>residual_improvement_factor</td>
<td>Minimal required reduction of residual test ratio in iterative refinement.</td>
<td>1</td>
</tr>
<tr>
<td>residual_ratio_max</td>
<td>Iterative refinement tolerance</td>
<td>1e-10</td>
</tr>
<tr>
<td>residual_ratio_singular</td>
<td>Threshold for declaring linear system singular after failed iterative refinement.</td>
<td>1e-05</td>
</tr>
</tbody>
</table>

### 5.20.5.12 Restoration Phase

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>bound_mult_reset_threshold</td>
<td>Threshold for resetting bound multipliers after the restoration phase.</td>
<td>1000</td>
</tr>
<tr>
<td>constr_mult_reset_threshold</td>
<td>Threshold for resetting equality and inequality multipliers after restoration phase.</td>
<td>0</td>
</tr>
<tr>
<td>evaluate_orig_obj_at_resto_trial</td>
<td>Determines if the original objective function should be evaluated at restoration phase trial points.</td>
<td>yes</td>
</tr>
<tr>
<td>expect_infeasible_problem</td>
<td>Enable heuristics to quickly detect an infeasible problem.</td>
<td>no</td>
</tr>
<tr>
<td>expect_infeasible_problem_ctol</td>
<td>Threshold for disabling &quot;expect_infeasible_problem&quot; option.</td>
<td>0.001</td>
</tr>
<tr>
<td>expect_infeasible_problem_xtol</td>
<td>Multiplier threshold for activating &quot;expect_infeasible_problem&quot; option.</td>
<td>1e+08</td>
</tr>
<tr>
<td>required_infeasibility_reduction</td>
<td>Required reduction of infeasibility before leaving restoration phase.</td>
<td>0.9</td>
</tr>
<tr>
<td>soft_resto_perror_reduction_factor</td>
<td>Required reduction in primal-dual error in the soft restoration phase.</td>
<td>0.9999</td>
</tr>
<tr>
<td>start_with_resto</td>
<td>Whether to switch to restoration phase in first iteration.</td>
<td>no</td>
</tr>
</tbody>
</table>

### Options for expert users

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_resto_iter</td>
<td>Maximum number of successive iterations in restoration phase.</td>
<td>3000000</td>
</tr>
<tr>
<td>max_soft_resto_iter</td>
<td>Maximum number of iterations performed successively in soft restoration phase.</td>
<td>10</td>
</tr>
<tr>
<td>resto_failure_feasibility_threshold</td>
<td>Threshold for primal infeasibility to declare failure of restoration phase.</td>
<td>0</td>
</tr>
<tr>
<td>resto_penalty_parameter</td>
<td>Penalty parameter in the restoration phase objective function.</td>
<td>1000</td>
</tr>
<tr>
<td>resto_proximity_weight</td>
<td>Weighting factor for the proximity term in restoration phase objective.</td>
<td>1</td>
</tr>
</tbody>
</table>
5.20.5.13 Hessian Approximation

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>hessian_approximation</td>
<td>Indicates what Hessian information is to be used.</td>
<td>exact</td>

</tbody>
</table>

**Options for expert users**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>mumps_dep_tol</td>
<td>Threshold to consider a pivot at zero in detection of linearly dependent constraints with MUMPS.</td>
<td>0</td>
</tr>
</tbody>
</table>
5.20.6 Detailed Options Description

**accept_after_max_steps** *(advanced)*: Accept a trial point after maximal this number of steps even if it does not satisfy line search conditions. 

Setting this to -1 disables this option.

Range: {-1, ..., ∞}

Default: -1

**accept_every_trial_step**: Always accept the first trial step.

Setting this option to "yes" essentially disables the line search and makes the algorithm take aggressive steps, without global convergence guarantees.

Range: yes, no

Default: no

**acceptable_compl_inf_tol**: "Acceptance" threshold for the complementarity conditions.

Absolute tolerance on the complementarity. "Acceptable" termination requires that the max-norm of the (unscaled) complementarity is less than this threshold; see also acceptable_tol.

Range: (0, ∞]

Default: 0.01

**acceptable_constr_viol_tol**: "Acceptance" threshold for the constraint violation.

Absolute tolerance on the constraint violation. "Acceptable" termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold; see also acceptable_tol.

Range: (0, ∞]

Default: 0.01

**acceptable_dual_inf_tol**: "Acceptance" threshold for the dual infeasibility.

Absolute tolerance on the dual infeasibility. "Acceptable" termination requires that the (max-norm of the unscaled) dual infeasibility is less than this threshold; see also acceptable_tol.

Range: (0, ∞]

Default: 1e+10

**acceptable_iter**: Number of "acceptable" iterates before triggering termination.

If the algorithm encounters this many successive "acceptable" iterates (see "acceptable_tol"), it terminates, assuming that the problem has been solved to best possible accuracy given round-off. If it is set to zero, this heuristic is disabled.

Range: {0, ..., ∞}

Default: 0

**acceptable_obj_change_tol**: "Acceptance" stopping criterion based on objective function change.
If the relative change of the objective function (scaled by Max(1,|f(x)|)) is less than this value, this part of the acceptable tolerance termination is satisfied; see also acceptable_tol. This is useful for the quasi-Newton option, which has trouble to bring down the dual infeasibility.

Range: [0, ∞]
Default: 1e+20

acceptable_tol: "Acceptable" convergence tolerance (relative).

Determines which (scaled) overall optimality error is considered to be "acceptable". There are two levels of termination criteria. If the usual "desired" tolerances (see tol, dual_inf_tol etc) are satisfied at an iteration, the algorithm immediately terminates with a success message. On the other hand, if the algorithm encounters "acceptable_iter" many iterations in a row that are considered "acceptable", it will terminate before the desired convergence tolerance is met. This is useful in cases where the algorithm might not be able to achieve the "desired" level of accuracy.

Range: (0, ∞]
Default: 1e-06

adaptive_mu_globalization: Globalization strategy for the adaptive mu selection mode.

To achieve global convergence of the adaptive version, the algorithm has to switch to the monotone mode (Fiacco-McCormick approach) when convergence does not seem to appear. This option sets the criterion used to decide when to do this switch. (Only used if option "mu_strategy" is chosen as "adaptive").

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>kkt-error</td>
<td>nonmonotone decrease of kkt-error</td>
</tr>
<tr>
<td>obj-constr-filter</td>
<td>2-dim filter for objective and constraint violation</td>
</tr>
<tr>
<td>never-monotone-mode</td>
<td>disables globalization</td>
</tr>
</tbody>
</table>

Default: obj-constr-filter

adaptive_mu_kkterror_red_fact (advanced): Sufficient decrease factor for "kkt-error" globalization strategy.

When computing the KKT error for the globalization strategies, the norm to be used is specified with this option. Note, this option is also used in the QualityFunctionMuOracle.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-norm</td>
<td>use the 1-norm (abs sum)</td>
</tr>
<tr>
<td>2-norm-squared</td>
<td>use the 2-norm squared (sum of squares)</td>
</tr>
<tr>
<td>max-norm</td>
<td>use the infinity norm (max)</td>
</tr>
<tr>
<td>2-norm</td>
<td>use 2-norm</td>
</tr>
</tbody>
</table>

Default: 2-norm-squared
For the "kkt-error" based globalization strategy, the error must decrease by this factor to be deemed sufficient decrease.

Range: (0, 1)
Default: 0.9999

**adaptive_mu_kkt_error_red_iters (advanced):** Maximum number of iterations requiring sufficient progress.

For the "kkt-error" based globalization strategy, sufficient progress must be made for "adaptive_mu_kkt_error_red_iters" iterations. If this number of iterations is exceeded, the globalization strategy switches to the monotone mode.

Range: \{0, ..., \infty\}
Default: 4

**adaptive_mu_monotone_init_factor (advanced):** Determines the initial value of the barrier parameter when switching to the monotone mode.

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode and fixed_mu_oracle is chosen as "average_compl", the barrier parameter is set to the current average complementarity times the value of "adaptive_mu_monotone_init_factor".

Range: (0, \infty]
Default: 0.8

**adaptive_mu_restore_previous_iterate (advanced):** Indicates if the previous accepted iterate should be restored if the monotone mode is entered.

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode, it can either start from the most recent iterate (no), or from the last iterate that was accepted (yes).

Range: yes, no
Default: no

**alpha_for_y:** Method to determine the step size for constraint multipliers (alpha_y).

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>primal</td>
<td>use primal step size</td>
</tr>

<td>use the dual step size, and full step if \delta x \leq alpha_for_y_tol</td>
</tr>
<tr>
<td>acceptor</td>
<td>Call LSAcceptor to get step size for y</td>
</tr>
</tbody>
</table>
Default: primal

**alpha_for_y_tol**: Tolerance for switching to full equality multiplier steps.

This is only relevant if "alpha_for_y" is chosen "primal-and-full" or "dual-and-full". The step size for the equality constraint multipliers is taken to be one if the max-norm of the primal step is less than this tolerance.

Range: \([0, \infty]\]

Default: 10

**alpha_min_frac** *(advanced)*: Safety factor for the minimal step size (before switching to restoration phase).

This is gamma_alpha in Eqn. (23) in the implementation paper.

Range: \((0, 1)\)

Default: 0.05

**alpha_red_factor** *(advanced)*: Fractional reduction of the trial step size in the backtracking line search.

At every step of the backtracking line search, the trial step size is reduced by this factor.

Range: \((0, 1)\)

Default: 0.5

**barrier_tol_factor**: Factor for mu in barrier stop test.

The convergence tolerance for each barrier problem in the monotone mode is the value of the barrier parameter times "barrier_tol_factor". This option is also used in the adaptive mu strategy during the monotone mode. This is kappa_\epsilon in implementation paper.

Range: \((0, \infty]\)

Default: 10

**bound_frac**: Desired minimum relative distance from the initial point to bound.

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: \((0, 0.5]\)

Default: 0.01

**bound_mult_init_method**: Initialization method for bound multipliers

This option defines how the iterates for the bound multipliers are initialized. If "constant" is chosen, then all bound multipliers are initialized to the value of "bound_mult_init_val". If "mu-based" is chosen, then each value is initialized to the value of "mu_init" divided by the corresponding slack variable. This latter option might be useful if the starting point is close to the optimal solution.
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>constant</td>
<td>set all bound multipliers to the value of bound_mult_init_val</td>
</tr>
<tr>
<td>mu-based</td>
<td>initialize to mu_init/x_slack</td>
</tr>
</tbody>
</table>

Default: constant

**bound_mult_init_val**: Initial value for the bound multipliers.

All dual variables corresponding to bound constraints are initialized to this value.

Range: $\left(0, \infty\right]$  

Default: 1

**bound_mult_reset_threshold**: Threshold for resetting bound multipliers after the restoration phase.

After returning from the restoration phase, the bound multipliers are updated with a Newton step for complementarity. Here, the change in the primal variables during the entire restoration phase is taken to be the corresponding primal Newton step. However, if after the update the largest bound multiplier exceeds the threshold specified by this option, the multipliers are all reset to 1.

Range: $\left[0, \infty\right]$  

Default: 1000

**bound_push**: Desired minimum absolute distance from the initial point to bound.

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Range: $\left(0, \infty\right]$  

Default: 0.01

**bound_relax_factor**: Factor for initial relaxation of the bounds.

Before start of the optimization, the bounds given by the user are relaxed. This option sets the factor for this relaxation. Additional, the constraint violation tolerance constr_viol_tol is used to bound the relaxation by an absolute value. If it is set to zero, then then bounds relaxation is disabled. See Eqn.(35) in implementation paper. Note that the constraint violation reported by Ipopt at the end of the solution process does not include violations of the original (non-relaxed) variable bounds. See also option honor_original_bounds.

Range: $\left[0, \infty\right]$  

Default: $10^{-10}$

**check_derivatives_for_naninf**: Indicates whether it is desired to check for Nan/Inf in derivative matrices
Activating this option will cause an error if an invalid number is detected in the constraint Jacobians or the Lagrangian Hessian. If this is not activated, the test is skipped, and the algorithm might proceed with invalid numbers and fail. If test is activated and an invalid number is detected, the matrix is written to output with print_level corresponding to J_MOREDETAILED (7); so beware of large output!

Range: yes, no
Default: no

**compl_inf_tol**: Desired threshold for the complementarity conditions. ←

Absolute tolerance on the complementarity. Successful termination requires that the max-norm of the (unscaled) complementarity is less than this threshold.

Range: \((0, \infty]\)
Default: 0.0001

**constr_mult_init_max**: Maximum allowed least-square guess of constraint multipliers. ←

Determines how large the initial least-square guesses of the constraint multipliers are allowed to be (in max-norm). If the guess is larger than this value, it is discarded and all constraint multipliers are set to zero. This option is also used when initializing the restoration phase. By default, "resto.constr_mult_init_max" (the one used in RestoIterateInitializer) is set to zero.

Range: \([0, \infty]\)
Default: 1000

**constr_mult_reset_threshold**: Threshold for resetting equality and inequality multipliers after restoration phase. ←

After returning from the restoration phase, the constraint multipliers are recomputed by a least square estimate. This option triggers when those least-square estimates should be ignored.

Range: \([0, \infty]\)
Default: 0

**constr_viol_tol**: Desired threshold for the constraint and variable bound violation. ←

Absolute tolerance on the constraint and variable bound violation. Successful termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold. If option bound_relax_factor is not zero 0, then Ipopt relaxes given variable bounds. The value of constr_viol_tol is used to restrict the absolute amount of this bound relaxation.

Range: \((0, \infty]\)
Default: 1e-06

**constraint-violation-norm-type** *(advanced)*: Norm to be used for the constraint violation in the line search. ←

Determines which norm should be used when the algorithm computes the constraint violation in the line search.
### 5.20 IPOPT and IPOPTh

<table>

</tbody>
</table>

Default: 1-norm

**corrector_compl_avrg_red_fact** *(advanced)*: Complementarity tolerance factor for accepting corrector step.

This option determines the factor by which complementarity is allowed to increase for a corrector step to be accepted. Changing this option is experimental.

Range: \((0, \infty]\)

Default: 1

**corrector_type** *(advanced)*: The type of corrector steps that should be taken.

If "mu_strategy" is "adaptive", this option determines what kind of corrector steps should be tried. Changing this option is experimental.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>no corrector</td>
</tr>
<tr>

<td>corrector step towards current (\mu)</td>
</tr>
</tbody>
</table>

Default: none

**delta** *(advanced)*: Multiplier for constraint violation in the switching rule.

See Eqn. (19) in the implementation paper.

Range: \((0, \infty]\)

Default: 1

**dependency_detection_with_rhs** *(advanced)*: Indicates if the right hand sides of the constraints should be considered in addition to gradients during dependency detection

Range: yes, no

Default: no

**dependency_detector** *(advanced)*: Indicates which linear solver should be used to detect linearly dependent equality constraints.

This is experimental and does not work well.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>don't check; no extra work at beginning</td>
</tr>
<tr>
<td>mumps</td>
<td>use MUMPS</td>
</tr>
</tbody>
</table>
**diverging_iterates_tol**: Threshold for maximal value of primal iterates.  

If any component of the primal iterates exceeded this value (in absolute terms), the optimization is aborted with the exit message that the iterates seem to be diverging.

Range: $(0, \infty]$  
Default: $1e+20$

**dual_inf_tol**: Desired threshold for the dual infeasibility.  

Absolute tolerance on the dual infeasibility. Successful termination requires that the max-norm of the (unscaled) dual infeasibility is less than this threshold.

Range: $(0, \infty]$  
Default: 1

**eta_phi** *(advanced)*: Relaxation factor in the Armijo condition.  

See Eqn. (20) in the implementation paper.

Range: $(0, 0.5]$  
Default: $1e-08$

**evaluate_orig_obj_at_resto_trial**: Determines if the original objective function should be evaluated at restoration phase trial points.

Enabling this option makes the restoration phase algorithm evaluate the objective function of the original problem at every trial point encountered during the restoration phase, even if this value is not required. In this way, it is guaranteed that the original objective function can be evaluated without error at all accepted iterates; otherwise the algorithm might fail at a point where the restoration phase accepts an iterate that is good for the restoration phase problem, but not the original problem. On the other hand, if the evaluation of the original objective is expensive, this might be costly.

Range: yes, no  
Default: yes

**expect_infeasible_problem**: Enable heuristics to quickly detect an infeasible problem.

This option is meant to activate heuristics that may speed up the infeasibility determination if you expect that there is a good chance for the problem to be infeasible. In the filter line search procedure, the restoration phase is called more quickly than usually, and more reduction in the constraint violation is enforced before the restoration phase is left. If the problem is square, this option is enabled automatically.

Range: yes, no  
Default: no

**expect_infeasible_problem_ctol**: Threshold for disabling "expect_infeasible_problem" option.
If the constraint violation becomes smaller than this threshold, the "expect_infeasible_problem" heuristics in the filter line search are disabled. If the problem is square, this option is set to 0.

Range: \([0, \infty]\)
Default: 0.001

`expect_infeasible_problem_ytol`: Multiplier threshold for activating "expect_infeasible_problem" option.  

If the max norm of the constraint multipliers becomes larger than this value and "expect_infeasible_problem" is chosen, then the restoration phase is entered.

Range: \((0, \infty]\)
Default: 1e+08

`fast_step_computation`: Indicates if the linear system should be solved quickly.  

If enabled, the algorithm assumes that the linear system that is solved to obtain the search direction is solved sufficiently well. In that case, no residuals are computed to verify the solution and the computation of the search direction is a little faster.

Range: yes, no
Default: no

`filter_margin_fact` (advanced): Factor determining width of margin for obj-constr-filter adaptive globalization strategy.

When using the adaptive globalization strategy, ”obj-constr-filter”, sufficient progress for a filter entry is defined as follows:  
(new obj) < (filter obj) - filter_margin_fact*(new constr-viol)  
OR  
(new constr-viol) < (filter constr-viol) - filter_margin_fact*(new constr-viol).  
For the description of the ”kkt-error-filter" option see "filter_max_margin".

Range: \((0, 1]\)
Default: 1e-05

Range: \((0, \infty]\)
Default: 1

`filter_reset_trigger` (advanced): Number of iterations that trigger the filter reset.

If the filter reset heuristic is active and the number of successive iterations in which the last rejected trial step size was rejected because of the filter, the filter is reset.

Range: \(\{1, ..., \infty\}\)
Default: 5

`first_hessian_perturbation`: Size of first x-s perturbation tried.

The first value tried for the x-s perturbation in the inertia correction scheme. This is delta_0 in the implementation paper.

Range: \((0, \infty]\)
Default: 0.0001

`fixed_mu_oracle`: Oracle for the barrier parameter when switching to fixed mode.

Determines how the first value of the barrier parameter should be computed when switching to the "monotone mode" in the adaptive strategy. (Only considered if ”adaptive” is selected for option ”mu_strategy".)
The main difference between those options is that the starting point in the "make_constraint" case still has the fixed variables at their given values, whereas in the case "make_parameter(nodual)" the functions are always evaluated with the fixed values for those variables. Also, for "relax_bounds", the fixing bound constraints are relaxed (according to "bound_relax_factor"). For all but "make_parameter_nodual", bound multipliers are computed for the fixed variables.

<table>

<td>base on current average complementarity</td>
</tr>
</tbody>
</table>

Default: average_compl

**fixed_variable_treatment**: Determines how fixed variables should be handled. ←

The main difference between those options is that the starting point in the "make_constraint" case still has the fixed variables at their given values, whereas in the case "make_parameter(nodual)" the functions are always evaluated with the fixed values for those variables. Also, for "relax_bounds", the fixing bound constraints are relaxed (according to "bound_relax_factor"). For all but "make_parameter_nodual", bound multipliers are computed for the fixed variables.

<table>

<td>Relax fixing bound constraints</td>
</tr>
</tbody>
</table>

Default: make_parameter

**gamma_phi** *(advanced)*: Relaxation factor in the filter margin for the barrier function. ←

See Eqn. (18a) in the implementation paper.

Range: (0, 1)

Default: 1e-08

**gamma_theta** *(advanced)*: Relaxation factor in the filter margin for the constraint violation. ←

See Eqn. (18b) in the implementation paper.

Range: (0, 1)

Default: 1e-05

**hessian_approximation**: Indicates what Hessian information is to be used. ←

This determines which kind of information for the Hessian of the Lagrangian function is used by the algorithm.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>exact</td>
<td>Use second derivatives provided by the NLP.</td>
</tr>
<tr>
<td>limited-memory</td>
<td>Perform a limited-memory quasi-Newton approximation</td>
</tr>
</tbody>

**hessian_approximation_space** *(advanced)*: Indicates in which subspace the Hessian information is to be approximated.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>nonlinear-variables</td>
<td>only in space of nonlinear variables.</td>
</tr>
<tr>
<td>all-variables</td>
<td>in space of all variables (without slacks)</td>
</tr>
</tbody>
</table>

Default: nonlinear-variables

**honor_original_bounds**: Indicates whether final points should be projected into original bounds.

Ipopt might relax the bounds during the optimization (see, e.g., option "bound_relax_factor"). This option determines whether the final point should be projected back into the user-provided original bounds after the optimization. Note that violations of constraints and complementarity reported by Ipopt at the end of the solution process are for the non-projected point.

Range: yes, no

Default: no

**hslib**: Name of library containing HSL routines for load at runtime

Range: string

Default: libhsl.so (Linux), libhsl.dylib (macOS), libhsl.dll (Windows)

**inf_pr_output**: Determines what value is printed in the "inf_pr" output column.

Ipopt works with a reformulation of the original problem, where slacks are introduced and the problem might have been scaled. The choice "internal" prints out the constraint violation of this formulation. With "original" the true constraint violation in the original NLP is printed.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>internal</td>
<td>max-norm of violation of internal equality constraints</td>
</tr>
<tr>
<td>original</td>
<td>maximal constraint violation in original NLP</td>

</tbody>
</table>

Default: original

**jacobian_regularization_exponent** *(advanced)*: Exponent for mu in the regularization for rank-deficient constraint Jacobians.

This is kappa_c in the implementation paper.

Range: [0, ∞]

Default: 0.25

**jacobian_regularization_value**: Size of the regularization for rank-deficient constraint Jacobians.

This is bar delta_c in the implementation paper.

Range: [0, ∞]

Default: 1e-08
**kappa_d (advanced)**: Weight for linear damping term (to handle one-sided bounds).

See Section 3.7 in implementation paper.

Range: \([0, \infty]\)

Default: 1e-05

**kappa_sigma (advanced)**: Factor limiting the deviation of dual variables from primal estimates.

If the dual variables deviate from their primal estimates, a correction is performed. See Eqn. (16) in the implementation paper. Setting the value to less than 1 disables the correction.

Range: \((0, \infty]\)

Default: 1e+10

**kappa_soc (advanced)**: Factor in the sufficient reduction rule for second order correction.

This option determines how much a second order correction step must reduce the constraint violation so that further correction steps are attempted. See Step A-5.9 of Algorithm A in the implementation paper.

Range: \((0, \infty]\)

Default: 0.99

**least_square_init_duals**: Least square initialization of all dual variables

If set to yes, Ipopt tries to compute least-square multipliers (considering ALL dual variables). If successful, the bound multipliers are possibly corrected to be at least bound_mult_init_val. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP. This overwrites option "bound_mult_init_method".

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>use bound_mult_init_val and least-square equality constraint multipliers</td>
</tr>
<tr>
<td>yes</td>
<td>overwrite user-provided point with least-square estimates</td>
</tr>
</tbody>
</table>

Default: no

**least_square_init_primal**: Least square initialization of the primal variables

If set to yes, Ipopt ignores the user provided point and solves a least square problem for the primal variables (x and s) to fit the linearized equality and inequality constraints. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP.

<table>
<thead>
<tr>
<th>value</th>

</tbody>
</table>

Default: no

**limited_memory_aug_solver (advanced)**: Strategy for solving the augmented system for low-rank Hessian.
### Limited Memory initialization

The starting matrix in the low rank update, $B_0$, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

**value** | **meaning**
---|---
sherman-morrison | use Sherman-Morrison formula
extended | use an extended augmented system

**Default:** sherman-morrison

**limited_memory_init_val:** Value for $B_0$ in low-rank update.

The starting matrix in the low rank update, $B_0$, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

**Range:** $(0, \infty)$

**Default:** 1

**limited_memory_init_val_max:** Upper bound on value for $B_0$ in low-rank update.

The starting matrix in the low rank update, $B_0$, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

**Range:** $(0, \infty)$

**Default:** $1e+08$

**limited_memory_init_val_min:** Lower bound on value for $B_0$ in low-rank update.

The starting matrix in the low rank update, $B_0$, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

**Range:** $(0, \infty)$

**Default:** $1e-08$

**limited_memory_initialization:** Initialization strategy for the limited memory quasi-Newton approximation.

Determines how the diagonal Matrix $B_0$ as the first term in the limited memory approximation should be computed.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>scalar4</td>
<td>geometric average of scalar1 and scalar2</td>
</tr>
<tr>
<td>constant</td>
<td>$\sigma = \text{limited_memory_init_val}$</td>
</tr>
</tbody>
</table>

**Default:** scalar1

**limited_memory_max_history:** Maximum size of the history for the limited quasi-Newton Hessian approximation.

---
This option determines the number of most recent iterations that are taken into account for the limited-memory quasi-Newton approximation.

Range: \( \{0, ..., \infty\} \)

Default: 6

**limited_memory_max_skipping**: Threshold for successive iterations where update is skipped.

If the update is skipped more than this number of successive iterations, the quasi-Newton approximation is reset.

Range: \( \{1, ..., \infty\} \)

Default: 2

**limited_memory_special_for_resto**: Determines if the quasi-Newton updates should be special during the restoration phase.

Until Nov 2010, Ipopt used a special update during the restoration phase, but it turned out that this does not work well. The new default uses the regular update procedure and it improves results. If for some reason you want to get back to the original update, set this option to "yes".

Range: yes, no

Default: no

**limited_memory_update_type**: Quasi-Newton update formula for the limited memory quasi-Newton approximation.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bfgs</td>

Default: filter

**linear_scaling_on_demand**: Flag indicating that linear scaling is only done if it seems required.

This option is only important if a linear scaling method (e.g., mc19) is used. If you choose "no", then the scaling factors are computed for every linear system from the start. This can
be quite expensive. Choosing "yes" means that the algorithm will start the scaling method only when the solutions to the linear system seem not good, and then use it until the end.

Range: yes, no

Default: yes

**linear_solver**: Linear solver used for step computations. ↔

Determines which linear algebra package is to be used for the solution of the augmented linear system (for obtaining the search directions). Note, that MA27, MA57, MA86, and MA97 are included with a commercially supported GAMS/IpoptH license only. To use MA27, MA57, MA86, or MA97 with GAMS/Ipopt, or to use HSL_MA77, a HSL library needs to be provided by the user. To use Pardiso from pardiso-project.org, a Pardiso library needs to be provided by the user. **ATTENTION**: Before Ipopt 3.14 (GAMS 36), value **pardiso** specified to use Pardiso from Intel MKL. With GAMS 36, this value has been renamed to **pardisomkl**. On GAMS systems for ARM64 CPUs, option value **pardisomkl** is not available.

<table>
<thead>
<tr>
<th>value</th>

</tr>
<tr>
<td>pardisomkl</td>
<td>use the Pardiso package from Intel MKL</td>
</tr>
<tr>
<td>mumps</td>
<td>use the Mumps package</td>
</tr>
</tbody>
</table>

Default: ma27, if IpoptH, otherwise mumps

**linear_system_scaling**: Method for scaling the linear system. ↔

Determines the method used to compute symmetric scaling factors for the augmented system (see also the "linear_scaling_on_demand" option). This scaling is independent of the NLP problem scaling. Note, that MC19 is included with a commercially supported GAMS/IpoptH license only. To use MC19 with GAMS/Ipopt, a HSL library needs to be provided by the user.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

<tr>
<td>slack-based</td>
<td>use the slack values</td>
</tr>
</tbody>
</table>

Default: mc19, if IpoptH, otherwise none

**ma27_ignore_singularity** *(advanced)*: Whether to use MA27’s ability to solve a linear system even if the matrix is singular. ↔
Setting this option to "yes" means that Ipopt will call MA27 to compute solutions for right hand sides, even if MA27 has detected that the matrix is singular (but is still able to solve the linear system). In some cases this might be better than using Ipopt's heuristic of small perturbation of the lower diagonal of the KKT matrix.

Range: yes, no
Default: no

**ma27_la_init_factor**: Real workspace memory for MA27.

The initial real workspace memory = la_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by ma27_meminc_factor if required.

Range: [1, ∞]
Default: 5

**ma27_liw_init_factor**: Integer workspace memory for MA27.

The initial integer workspace memory = liw_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by ma27_meminc_factor if required.

Range: [1, ∞]
Default: 5

**ma27_meminc_factor**: Increment factor for workspace size for MA27.

If the integer or real workspace is not large enough, Ipopt will increase its size by this factor.

Range: [1, ∞]
Default: 2

**ma27_pivtol**: Pivot tolerance for the linear solver MA27.

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: (0, 1)
Default: 1e-08

**ma27_pivtolmax**: Maximum pivot tolerance for the linear solver MA27.

Ipopt may increase pivtol as high as ma27_pivtolmax to get a more accurate solution to the linear system.

Range: (0, 1)
Default: 0.0001

**ma27_print_level**: Debug printing level for the linear solver MA27.

0: no printing; 1: Error messages only; 2: Error and warning messages; 3: Error and warning messages and terse monitoring; 4: All information.

Range: {0, ..., 4}
Default: 0
**5.20 IPOPT and IPOPTH**

**ma27_skip_inertia_check (advanced):** Whether to always pretend that inertia is correct. ←

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no
Default: no

**ma57_automatic_scaling:** Controls whether to enable automatic scaling in MA57 ←

For higher reliability of the MA57 solver, you may want to set this option to yes. This is ICNTL(15) in MA57.

Range: yes, no
Default: no

**ma57_block_size:** Controls block size used by Level 3 BLAS in MA57BD ←

This is ICNTL(11) in MA57.

Range: \{1, ..., ∞\}
Default: 16

**ma57_node_amalgamation:** Node amalgamation parameter ←

This is ICNTL(12) in MA57.

Range: \{1, ..., ∞\}
Default: 16

**ma57_pivot_order:** Controls pivot order in MA57 ←

This is ICNTL(6) in MA57.

Range: \{0, ..., 5\}
Default: 5

**ma57_pivot:** Pivot tolerance for the linear solver MA57. ←

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: (0, 1)
Default: 1e-08

**ma57_pivotmax:** Maximum pivot tolerance for the linear solver MA57. ←

Ipopt may increase pivot as high as ma57_pivotmax to get a more accurate solution to the linear system.

Range: (0, 1)
Default: 0.0001

**ma57_pre_alloc:** Safety factor for work space memory allocation for the linear solver MA57. ←
If 1 is chosen, the suggested amount of work space is used. However, choosing a larger number might avoid reallocation if the suggest values do not suffice.

Range: \([1, \infty]\)
Default: 1.05

**ma57_print_level**: Debug printing level for the linear solver MA57

0: no printing; 1: Error messages only; 2: Error and warning messages; 3: Error and warning messages and terse monitoring; \(\geq 4\): All information.

Range: \(\{0, ..., \infty\}\)
Default: 0

**ma57_small_pivot_flag**: Handling of small pivots

If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient. This is ICNTL(16) in MA57.

Range: \(\{0, ..., 1\}\)
Default: 0

**ma77_buffer_lpage**: Number of scalars per MA77 in-core buffer page in the out-of-core solver MA77

Must be at most ma77_file_size.

Range: \(\{1, ..., \infty\}\)
Default: 4096

**ma77_buffer_npage**: Number of pages that make up MA77 buffer

Number of pages of size buffer_lpage that exist in-core for the out-of-core solver MA77.

Range: \(\{1, ..., \infty\}\)
Default: 1600

**ma77_file_size**: Target size of each temporary file for MA77, scalars per type

MA77 uses many temporary files, this option controls the size of each one. It is measured in the number of entries (int or double), NOT bytes.

Range: \(\{1, ..., \infty\}\)
Default: 2097152

**ma77_maxstore**: Maximum storage size for MA77 in-core mode

If greater than zero, the maximum size of factors stored in core before out-of-core mode is invoked.

Range: \(\{0, ..., \infty\}\)
Default: 0

**ma77_nemin**: Node Amalgamation parameter

Two nodes in elimination tree are merged if result has fewer than ma77_nemin variables.

Range: \(\{1, ..., \infty\}\)
Default: 8

**ma77_order**: Controls type of ordering used by MA77
<table>

Default: metis

**ma77_print_level:** Debug printing level for the linear solver MA77

\(<0: \text{no printing}; \hspace{1em} 0: \text{Error and warning messages only}; \hspace{1em} 1: \text{Limited diagnostic printing}; \hspace{1em} >1 \text{Additional diagnostic printing.} \)

Range: \(-\infty, ..., \infty\)

Default: -1

**ma77_small:** Zero Pivot Threshold

Any pivot less than ma77_small is treated as zero.

Range: \([0, \infty]\)

Default: 1e-20

**ma77_static:** Static Pivoting Threshold

See MA77 documentation. Either ma77_static=0.0 or ma77_static>ma77_small ma77_static=0.0 disables static pivoting.

Range: \([0, \infty]\)

Default: 0

**ma77_u:** Pivoting Threshold

See MA77 documentation.

Range: \([0, 0.5]\)

Default: 1e-08

**ma77_ymax:** Maximum Pivoting Threshold

Maximum value to which u will be increased to improve quality.

Range: \([0, 0.5]\)

Default: 0.0001

**ma86_nemin:** Node Amalgamation parameter

Two nodes in elimination tree are merged if result has fewer than ma86_nemin variables.

Range: \(\{1, ..., \infty\}\)

Default: 32

**ma86_order:** Controls type of ordering
<table>

<td>Scale linear system matrix using MC77 [1,3,0]</td>
</tr>
</tbody>
</table>

Default: mc64

### ma97_small

Zero Pivot Threshold

Any pivot less than `ma97_small` is treated as zero.

Range: `[0, \infty)`

Default: `1e-20`

### ma97_solve_blas3

(advanced): Controls if blas2 or blas3 routines are used for solve

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Use BLAS2 (faster, some implementations bit incompatible)</td>

<tr>
<td>od_hd</td>
<td>Combination of on_demand and high_delay</td>
</tr>
<tr>
<td>od_hd_reuse</td>
<td>Combination of on_demand_reuse and high_delay_reuse</td>
</tr>
</tbody>
</table>

Default: never

**ma97_u**: Pivoting Threshold ↔
See MA97 documentation.

Range: [0, 0.5]

Default: 1e-08

**ma97_uma**: Maximum Pivoting Threshold

See MA97 documentation.

Range: [0, 0.5]

Default: 0.0001

**max_cpu_time**: Maximum number of CPU seconds.

A limit on CPU seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding message.

Range: (0, ∞]

Default: 1e+20

**max_filter_resets (advanced)**: Maximal allowed number of filter resets

A positive number enables a heuristic that resets the filter, whenever in more than "filter_reset_trigger" successive iterations the last rejected trial steps size was rejected because of the filter. This option determine the maximal number of resets that are allowed to take place.

Range: {0, ..., ∞}

Default: 5

**max_hessian_perturbation**: Maximum value of regularization parameter for handling negative curvature.

In order to guarantee that the search directions are indeed proper descent directions, Ipopt requires that the inertia of the (augmented) linear system for the step computation has the correct number of negative and positive eigenvalues. The idea is that this guides the algorithm away from maximizers and makes Ipopt more likely converge to first order optimal points that are minimizers. If the inertia is not correct, a multiple of the identity matrix is added to the Hessian of the Lagrangian in the augmented system. This parameter gives the maximum value of the regularization parameter. If a regularization of that size is not enough, the algorithm skips this iteration and goes to the restoration phase. This is delta_w^max in the implementation paper.

Range: (0, ∞]

Default: 1e+20

**max_iter**: Maximum number of iterations.

The algorithm terminates with a message if the number of iterations exceeded this number.

Range: {0, ..., ∞}

Default: GAMS iterlim

**max_refinement_steps**: Maximum number of iterative refinement steps per linear system solve.
Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the maximum number of iterative refinement steps.

Range: \( \{0, \ldots, \infty\} \)
Default: 10

**max_resto_iter** *(advanced)*: Maximum number of successive iterations in restoration phase. ↔

The algorithm terminates with an error message if the number of iterations successively taken in the restoration phase exceeds this number.

Range: \( \{0, \ldots, \infty\} \)
Default: 3000000

**max_soc**: Maximum number of second order correction trial steps at each iteration. ↔

Choosing 0 disables the second order corrections. This is \( p^\text{max} \) of Step A-5.9 of Algorithm A in the implementation paper.

Range: \( \{0, \ldots, \infty\} \)
Default: 4

**max_soft_resto_iters** *(advanced)*: Maximum number of iterations performed successively in soft restoration phase. ↔

If the soft restoration phase is performed for more than so many iterations in a row, the regular restoration phase is called.

Range: \( \{0, \ldots, \infty\} \)
Default: 10

**max_wall_time**: Maximum number of walltime clock seconds. ↔

A limit on walltime clock seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding message.

Range: \((0, \infty]\)
Default: GAMS reslim

**mehrotra_algorithm**: Indicates whether to do Mehrotra's predictor-corrector algorithm. ↔

If enabled, line search is disabled and the (unglobalized) adaptive \( \mu \) strategy is chosen with the "probing" oracle, and "corrector_type=affine" is used without any safeguards; you should not set any of those options explicitly in addition. Also, unless otherwise specified, the values of "bound_push", "bound_frac", and "bound_mult_init_val" are set more aggressive, and sets "alpha_for_y=bound_mult". The Mehrotra's predictor-corrector algorithm works usually very well for LPs and convex QPs.

Range: yes, no
Default: no

**min_hessian_perturbation**: Smallest perturbation of the Hessian block. ↔
The size of the perturbation of the Hessian block is never selected smaller than this value, unless no perturbation is necessary. This is $\Delta w^\text{min}$ in implementation paper.

Range: $[0, \infty]$  
Default: $1e^{-20}$

`min_refinement_steps`: Minimum number of iterative refinement steps per linear system solve.  
Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the minimum number of iterative refinements (i.e. at least "min_refinement_steps" iterative refinement steps are enforced per right hand side.)

Range: $\{0, ..., \infty\}$  
Default: 1

`mu_allow_fast_monotone_decrease` *(advanced)*: Allow skipping of barrier problem if barrier test is already met.
5.20 IPOPT and IPOPTH

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Take at least one iteration per barrier problem even if the barrier test is already met for the updated barrier parameter</td>
</tr>
<tr>
<td>yes</td>
<td>Allow fast decrease of mu if barrier test it met</td>
</tr>
</tbody>
</table>

Default: yes

**mu_init**: Initial value for the barrier parameter. ⇐

This option determines the initial value for the barrier parameter (mu). It is only relevant in the monotone, Fiacco-McCormick version of the algorithm. (i.e., if "mu_strategy" is chosen as "monotone")

Range: (0, \(\infty\])

Default: 0.1

**mu_linear_decrease_factor**: Determines linear decrease rate of barrier parameter. ⇐

For the Fiacco-McCormick update procedure the new barrier parameter mu is obtained by taking the minimum of mu\(^*\)"mu_linear_decrease_factor" and mu\(^*\)"superlinear_decrease_power". This is kappa_munu in implementation paper. This option is also used in the adaptive mu strategy during the monotone mode.

Range: (0, 1)

Default: 0.2

**mu_max**: Maximum value for barrier parameter. ⇐

This option specifies an upper bound on the barrier parameter in the adaptive mu selection mode. If this option is set, it overwrites the effect of mu_max_fact. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: (0, \(\infty\])

Default: 100000

**mu_max_fact**: Factor for initialization of maximum value for barrier parameter. ⇐

This option determines the upper bound on the barrier parameter. This upper bound is computed as the average complementarity at the initial point times the value of this option. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: (0, \(\infty\])

Default: 1000

**mu_min**: Minimum value for barrier parameter. ⇐

This option specifies the lower bound on the barrier parameter in the adaptive mu selection mode. By default, it is set to the minimum of 1e-11 and min("tol","compl_inf_tol")/("barrier_tol_factor"+1), which should be a reasonable value. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: (0, \(\infty\])

Default: 1e-11

**mu_oracle**: Oracle for a new barrier parameter in the adaptive strategy. ⇐

Determines how a new barrier parameter is computed in each "free-mode" iteration of the adaptive barrier parameter strategy. (Only considered if "adaptive" is selected for option "mu_strategy").
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>probing</td>
<td>Mehrotra's probing heuristic</td>
</tr>
<tr>
<td>loqo</td>
<td>LOQO's centrality rule</td>
</tr>
<tr>
<td>quality-function</td>
<td>minimize a quality function</td>
</tr>
</tbody>
</table>

Default: quality-function

**mu_strategy**: Update strategy for barrier parameter. 

Determines which barrier parameter update strategy is to be used.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>monotone</td>
<td>use the monotone (Fiacco-McCormick) strategy</td>
</tr>
<tr>
<td>adaptive</td>
<td>use the adaptive update strategy</td>
</tr>
</tbody>
</table>

Default: adaptive

**mu_superlinear_decrease_power**: Determines superlinear decrease rate of barrier parameter. 

For the Fiacco-McCormick update procedure the new barrier parameter \( \mu \) is obtained by taking the minimum of \( \mu \cdot \text{"mu_linear_decrease_factor"} \) and \( \mu \cdot \text{"superlinear_decrease_power"} \). This is \( \theta_{\text{mu}} \) in implementation paper. This option is also used in the adaptive \( \mu \) strategy during the monotone mode.

Range: \((1, 2)\)

Default: 1.5

**mu_target**: Desired value of complementarity. 

Usually, the barrier parameter is driven to zero and the termination test for complementarity is measured with respect to zero complementarity. However, in some cases it might be desired to have Ipopt solve barrier problem for strictly positive value of the barrier parameter. In this case, the value of "mu_target" specifies the final value of the barrier parameter, and the termination tests are then defined with respect to the barrier problem for this value of the barrier parameter.

Range: \([0, \infty]\)

Default: 0

**mumps_dep_tol** *(advanced)*: Threshold to consider a pivot at zero in detection of linearly dependent constraints with MUMPS. 

This is CNTL(3) in MUMPS.

Range: real

Default: 0

**mumps_mem_percent**: Percentage increase in the estimated working space for MUMPS. 

When significant extra fill-in is caused by numerical pivoting, larger values of mumps_mem_percent may help use the workspace more efficiently. On the other hand, if memory requirements are too large at the very beginning of the optimization, choosing a much smaller value for this option, such as 5, might reduce memory requirements.

Range: \( \{0, ..., \infty\} \)

Default: 1000

**mumps_permuting_scaling**: Controls permuting and scaling in MUMPS

This is ICNTL(6) in MUMPS.

Range: \( \{0, ..., 7\} \)

Default: 7

**mumps_pivot_order**: Controls pivot order in MUMPS

This is ICNTL(7) in MUMPS.

Range: \( \{0, ..., 7\} \)

Default: 7

**mumps_pivtol**: Pivot tolerance for the linear solver MUMPS.

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: \([0, 1]\)

Default: 1\text{e}-06

**mumps_pivtolmax**: Maximum pivot tolerance for the linear solver MUMPS.

Ipopt may increase pivtol as high as pivtolmax to get a more accurate solution to the linear system.

Range: \([0, 1]\)

Default: 0.1

**mumps_print_level**: Debug printing level for the linear solver MUMPS

0: no printing; 1: Error messages only; 2: Error, warning, and main statistic messages; 3: Error and warning messages and terse diagnostics; \( \geq 4 \): All information.

Range: \( \{0, ..., \infty\} \)

Default: 0

**mumps_scaling**: Controls scaling in MUMPS

This is ICNTL(8) in MUMPS.

Range: \( \{-2, ..., 77\} \)

Default: 77

**neg_curv_test_reg**: Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>yes</td>
<td>use primal regularization with the inertia-free curvature test</td>
</tr>
<tr>
<td>no</td>
<td>use original IPOPT approach, in which the primal regularization is ignored</td>
</tr>
</tbody>
</table>

Default: yes

**neg_curv_test_tol**: Tolerance for heuristic to ignore wrong inertia. ←

If nonzero, incorrect inertia in the augmented system is ignored, and Ipopt tests if the direction is a direction of positive curvature. This tolerance is $\alpha_n$ in the paper by Zavala and Chiang (2014) and it determines when the direction is considered to be sufficiently positive. A value in the range of $[1e-12, 1e-11]$ is recommended.

Range: $[0, \infty]$  
Default: 0

**nlp_scaling_constr_target_gradient** *(advanced)*: Target value for constraint function gradient size. ←

If a positive number is chosen, the scaling factors for the constraint functions are computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max_gradient for the constraint functions.

Range: $[0, \infty]$  
Default: 0

**nlp_scaling_max_gradient**: Maximum gradient after NLP scaling. ←

This is the gradient scaling cut-off. If the maximum gradient is above this value, then gradient based scaling will be performed. Scaling parameters are calculated to scale the maximum gradient back to this value. (This is $g_{\text{max}}$ in Section 3.8 of the implementation paper.) Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Range: $(0, \infty]$  
Default: 100

**nlp_scaling_method**: Select the technique used for scaling the NLP. ←

Selects the technique used for scaling the problem internally before it is solved. For user-scaling, the parameters come from the NLP.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>no problem scaling will be performed</td>
</tr>
<tr>
<td>gradient-based</td>
<td>scale the problem so the maximum gradient at the starting point is nlp_scaling_max_gradient</td>
</tr>
<tr>
<td>equilibration-based</td>
<td>scale the problem so that first derivatives are of order 1 at random points (GAMS/Ipopt: requires user-provided library with HSL routine MC19)</td>
</tr>
</tbody>
</table>

Default: gradient-based if GAMS scaleopt is not set, otherwise none

**nlp_scaling_min_value**: Minimum value of gradient-based scaling values. ←
This is the lower bound for the scaling factors computed by gradient-based scaling method. If some derivatives of some functions are huge, the scaling factors will otherwise become very small, and the (unscaled) final constraint violation, for example, might then be significant. Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Range: \([0, \infty]\]
Default: 1e-08

**nlp_scaling_obj_target_gradient** *(advanced):* Target value for objective function gradient size. 

If a positive number is chosen, the scaling factor for the objective function is computed so that the gradient has the max norm of the given size at the starting point. This overrides **nlp_scaling_max_gradient** for the objective function.

Range: \([0, \infty]\]
Default: 0

**nu_inc** *(advanced):* Increment of the penalty parameter.

Range: \((0, \infty]\]
Default: 0.0001

**nu_init** *(advanced):* Initial value of the penalty parameter.

Range: \((0, \infty]\]
Default: 1e-06

**obj_max_inc** *(advanced):* Determines the upper bound on the acceptable increase of barrier objective function.

Trial points are rejected if they lead to an increase in the barrier objective function by more than obj_max_inc orders of magnitude.

Range: \((1, \infty]\]
Default: 5

**pardiso_iter_coarse_size** *(advanced):* Maximum Size of Coarse Grid Matrix

DPARM(3)
Range: \(\{1, \ldots, \infty\}\]
Default: 5000

**pardiso_iter_dropping_factor** *(advanced):* dropping value for incomplete factor

DPARM(5)
Range: \((0, 1]\)
Default: 0.5

**pardiso_iter_dropping_schur** *(advanced):* dropping value for sparsify schur complement factor
DPARM(6)
Range: (0, 1)
Default: 0.1

**pardiso_iter_inverse_norm_factor** *(advanced):* ←

DPARM(8)
Range: (1, \(\infty\])
Default: 5e+06

**pardiso_iter_max_levels** *(advanced):* Maximum Size of Grid Levels ←

DPARM(4)
Range: \(\{1, ..., \infty\}\}
Default: 10

**pardiso_iter_max_row_fill** *(advanced):* max fill for each row ←

DPARM(7)
Range: \(\{1, ..., \infty\}\}
Default: 10000000

**pardiso_iter_relative_tol** *(advanced):* Relative Residual Convergence ←

DPARM(2)
Range: (0, 1)
Default: 1e-06

**pardiso_iterative** *(advanced):* Switch for iterative solver in Pardiso library ←

Range: yes, no
Default: no

**pardiso_matching_strategy:** Matching strategy to be used by Pardiso ←

This is IPAR(13) in Pardiso manual.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>complete</td>
<td>Match complete (IPAR(13)=1)</td>

<td>constraints</td>
<td>Match constraints (IPAR(13)=3)</td>
</tr>
</tbody>
</table>

Default: complete+2x2
**pardiso_max_droptol_corrections** *(advanced)*: Maximal number of decreases of drop tolerance during one solve. ←

This is relevant only for iterative Pardiso options.

Range: \{1, ..., ∞\}

Default: 4

**pardiso_max_iter** *(advanced)*: Maximum number of Krylov-Subspace Iteration ←

DPARM(1)

Range: \{1, ..., ∞\}

Default: 500

**pardiso_max_iterative_refinement_steps**: Limit on number of iterative refinement steps. ←

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: \{-∞, ..., ∞\}

Default: 0

**pardiso_msglvl**: Pardiso message level ←

This is MSGLVL in the Pardiso manual.

Range: \{0, ..., ∞\}

Default: 0

**pardiso_order**: Controls the fill-in reduction ordering algorithm for the input matrix. ←

<table>
<thead>
<tr>

<td>Only redo symbolic factorization when elements were perturbed if also the inertia was wrong</td>
</tr>
</tbody>
</table>

Default: no

`pardiso_repeated_perturbation_means_singular` *(advanced)*: Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization. ←

Range: yes, no

Default: no

`pardiso_skip_inertia_check` *(advanced)*: Whether to pretend that inertia is correct. ←

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

`pardisolib`: Name of library containing Pardiso routines (from pardiso-project.org) for load at runtime ←

Range: string

Default: libpardiso.so (Linux), libpardiso.dylib (macOS), libpardiso.dll (Windows)

`pardisomkl_matching_strategy`: Matching strategy to be used by Pardiso ←

This is IPAR(13) in Pardiso manual.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>

<td>constraints</td>
<td>Match constraints (IPAR(13)=3)</td>
</tr>
</tbody>
</table>

Default: complete+2x2

`pardisomkl_max_iterative_refinement_steps`: Limit on number of iterative refinement steps. ←

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: {-∞, ..., ∞}

Default: 1

`pardisomkl_msglvl`: Pardiso message level ←
This is MSGLVL in the Pardiso manual.

Range: \( \{0, \ldots, \infty\} \)

Default: 0

**pardisomkl_order:** Controls the fill-in reduction ordering algorithm for the input matrix.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>amd</td>
<td>minimum degree algorithm</td>

Default:metis

**pardisomkl_redo_symbolic_fact_only_if_inertia_wrong (advanced):** Toggle for handling case when elements were perturbed by Pardiso.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Always redo symbolic factorization when elements were perturbed</td>
</tr>
<tr>
<td>yes</td>
<td>Only redo symbolic factorization when elements were perturbed if also the inertia was wrong</td>
</tr>
</tbody>
</table>

Default: no

**pardisomkl_repeated_perturbation_means_singular (advanced):** Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization.

Range: yes, no

Default: no

**pardisomkl_skip_inertia_check (advanced):** Whether to pretend that inertia is correct.

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

**perturb_always_cd (advanced):** Active permanent perturbation of constraint linearization.

Enabling this option leads to using the delta_c and delta_d perturbation for the computation of every search direction. Usually, it is only used when the iteration matrix is singular.

Range: yes, no

Default: no

**perturb_dec_fact:** Decrease factor for x-s perturbation.
The factor by which the perturbation is decreased when a trial value is deduced from the size of the most recent successful perturbation. This is kappa_w^- in the implementation paper.

Range: (0, 1)
Default: 0.333333

**perturb_inc_fact**: Increase factor for x-s perturbation.

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of all perturbations except for the first. This is kappa_w^+ in the implementation paper.

Range: (1, \infty]
Default: 8

**perturb_inc_fact_first**: Increase factor for x-s perturbation for very first perturbation.

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of the very first perturbation and allows a different value for the first perturbation than that used for the remaining perturbations. This is bar_kappa_w^+ in the implementation paper.

Range: (1, \infty]
Default: 100

**print_advanced_options** *(advanced)*: whether to print also advanced options

Range: yes, no
Default: no

**print_eval_error**: Switch to enable printing information about function evaluation errors into the GAMS listing file.

Range: no, yes
Default: yes

**print_frequency_iter**: Determines at which iteration frequency the summarizing iteration output line should be printed.

Summarizing iteration output is printed every print_frequency_iter iterations, if at least print_frequency_time seconds have passed since last output.

Range: \{1, ..., \infty\}
Default: 1

**print_frequency_time**: Determines at which time frequency the summarizing iteration output line should be printed.

Summarizing iteration output is printed if at least print_frequency_time seconds have passed since last output and the iteration number is a multiple of print_frequency_iter.

Range: [0, \infty]
Default: 0
**print_info_string**: Enables printing of additional info string at end of iteration output.

This string contains some insider information about the current iteration. For details, look for "Diagnostic Tags" in the Ipopt documentation.

Range: yes, no
Default: no

**print_level**: Output verbosity level.

Sets the default verbosity level for console output. The larger this value the more detailed is the output.

Range: \{0, ..., 12\}
Default: 5

**print_options_mode**: format in which to print options documentation

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>Ordinary text</td>
</tr>
<tr>
<td>latex</td>
<td>LaTeX formatted</td>
</tr>
<tr>
<td>doxygen</td>
<td>Doxygen (markdown) formatted</td>
</tr>
</tbody>
</table>

Default: text

**print_timing_statistics**: Switch to print timing statistics.

If selected, the program will print the time spend for selected tasks. This implies timing_statistics=yes.

Range: yes, no
Default: no

**quality_function_balancing_term** *(advanced)*: The balancing term included in the quality function for centrality.

This determines whether a term is added to the quality function that penalizes situations where the complementarity is much smaller than dual and primal infeasibilities. Only used if option "mu_oracle" is set to "quality-function".

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>no balancing term is added</td>
</tr>
<tr>
<td>cubic</td>
<td>(\text{Max}(0,\text{Max}(\text{dual}inf,\text{primal}inf)-\text{compl})^3)</td>
</tr>
</tbody>
</table>

Default: none

**quality_function_centrality** *(advanced)*: The penalty term for centrality that is included in quality function.

This determines whether a term is added to the quality function to penalize deviation from centrality with respect to complementarity. The complementarity measure here is the xi in the Loqo update rule. Only used if option "mu_oracle" is set to "quality-function".
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>no penalty term is added</td>
</tr>
<tr>
<td>log</td>
<td>complementarity * the log of the centrality measure</td>
</tr>
<tr>
<td>reciprocal</td>
<td>complementarity * the reciprocal of the centrality measure</td>
</tr>
<tr>
<td>cubed-reciprocal</td>
<td>complementarity * the reciprocal of the centrality measure cubed</td>
</tr>
</tbody>
</table>

Default: none

**quality_function_max_section_steps:** Maximum number of search steps during direct search procedure determining the optimal centering parameter.

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: \( \{0, ..., \infty\} \)

Default: 8

**quality_function_norm_type (advanced):** Norm used for components of the quality function.

Only used if option "mu_oracle" is set to "quality-function".

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-norm</td>
<td>use the 1-norm (abs sum)</td>
</tr>
<tr>
<td>2-norm-squared</td>
<td>use the 2-norm squared (sum of squares)</td>
</tr>
<tr>
<td>max-norm</td>
<td>use the infinity norm (max)</td>
</tr>
<tr>
<td>2-norm</td>
<td>use 2-norm</td>
</tr>
</tbody>
</table>

Default: 2-norm-squared

**quality_function_section_qf_tol (advanced):** Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space).

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: \([0, 1)\)

Default: 0

**quality_function_section_sigma_tol (advanced):** Tolerance for the section search procedure determining the optimal centering parameter (in sigma space).

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: \([0, 1)\)

Default: 0.01

**recale_y:** Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates.

This asks the algorithm to recompute the multipliers, whenever the current infeasibility is less than recalc_y_feas_tol. Choosing yes might be helpful in the quasi-Newton option. However, each recalculation requires an extra factorization of the linear system. If a limited memory quasi-Newton option is chosen, this is used by default.
### Recalculating Multipliers

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>use the Newton step to update the multipliers</td>
</tr>
<tr>
<td>yes</td>
<td>use least-square multiplier estimates</td>
</tr>
</tbody>
</table>

Default: no

**recalc_y_feas_tol**: Feasibility threshold for recomputation of multipliers. ←

If recalc_y is chosen and the current infeasibility is less than this value, then the multipliers are recomputed.

Range: \((0, \infty]\)

Default: 1e-06

**replace_bounds (advanced)**: Whether variable bounds should be replaced by inequality constraints ←

This option must be set for the inexact algorithm.

Range: yes, no

Default: no

**report_mininfeas_solution**: Switch to report intermediate solution with minimal constraint violation to GAMS if the final solution is not feasible. ←

This option allows to obtain the most feasible solution found by Ipopt during the iteration process, if it stops at a (locally) infeasible solution, due to a limit (time, iterations, ...), or with a failure in the restoration phase.

Range: no, yes

Default: no

**required_infeasibility_reduction**: Required reduction of infeasibility before leaving restoration phase. ←

The restoration phase algorithm is performed, until a point is found that is acceptable to the filter and the infeasibility has been reduced by at least the fraction given by this option.

Range: \([0, 1]\)

Default: 0.9

**residual_improvement_factor (advanced)**: Minimal required reduction of residual test ratio in iterative refinement. ←

If the improvement of the residual test ratio made by one iterative refinement step is not better than this factor, iterative refinement is aborted.

Range: \((0, \infty]\)

Default: 1

**residual_ratio_max (advanced)**: Iterative refinement tolerance ←
Iterative refinement is performed until the residual test ratio is less than this tolerance (or until "max_refinement_steps" refinement steps are performed).

Range: $[0, \infty)$

Default: $1e-10$

**residual_ratio_singular** *(advanced)*: Threshold for declaring linear system singular after failed iterative refinement. →

If the residual test ratio is larger than this value after failed iterative refinement, the algorithm pretends that the linear system is singular.

Range: $[0, \infty)$

Default: $1e-05$

**resto_failure_feasibility_threshold** *(advanced)*: Threshold for primal infeasibility to declare failure of restoration phase. →

If the restoration phase is terminated because of the "acceptable" termination criteria and the primal infeasibility is smaller than this value, the restoration phase is declared to have failed. The default value is actually $1e2*\text{tol}$, where $\text{tol}$ is the general termination tolerance.

Range: $[0, \infty)$

Default: 0

**resto_penalty_parameter** *(advanced)*: Penalty parameter in the restoration phase objective function. →

This is the parameter $\rho$ in equation (31a) in the Ipopt implementation paper.

Range: $[0, \infty)$

Default: 1000

**resto_proximity_weight** *(advanced)*: Weighting factor for the proximity term in restoration phase objective. →

This determines how the parameter $\zeta$ in equation (29a) in the implementation paper is computed. $\zeta$ here is $\text{resto_proximity_weight}\times\sqrt{\mu}$, where $\mu$ is the current barrier parameter.

Range: $[0, \infty)$

Default: 1

**rho** *(advanced)*: Value in penalty parameter update formula. →

Range: $(0, 1)$

Default: 0.1

**s_max** *(advanced)*: Scaling threshold for the NLP error. →
See paragraph after Eqn. (6) in the implementation paper.

Range: \((0, \infty]\)
Default: 100

**s Phi** *(advanced)*: Exponent for linear barrier function model in the switching rule.

See Eqn. (19) in the implementation paper.

Range: \((1, \infty]\)
Default: 2.3

**s Theta** *(advanced)*: Exponent for current constraint violation in the switching rule.

See Eqn. (19) in the implementation paper.

Range: \((1, \infty]\)
Default: 1.1

**Sigma Max** *(advanced)*: Maximum value of the centering parameter.

This is the upper bound for the centering parameter chosen by the quality function based barrier parameter update. Only used if option "mu_oracle" is set to "quality-function".

Range: \((0, \infty]\)
Default: 100

**Sigma Min** *(advanced)*: Minimum value of the centering parameter.

This is the lower bound for the centering parameter chosen by the quality function based barrier parameter update. Only used if option "mu_oracle" is set to "quality-function".

Range: \([0, \infty]\)
Default: 1e-06

**Skip Corr If Neg Curv** *(advanced)*: Whether to skip the corrector step in negative curvature iteration.

The corrector step is not tried if negative curvature has been encountered during the computation of the search direction in the current iteration. This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Range: yes, no
Default: yes

**Skip Corr In Monotone Mode** *(advanced)*: Whether to skip the corrector step during monotone barrier parameter mode.

The corrector step is not tried if the algorithm is currently in the monotone mode (see also option "barrier_strategy"). This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Range: yes, no
Default: yes
**slack_bound_frac**: Desired minimum relative distance from the initial slack to bound. 

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: (0, 0.5]

Default: 0.01

**slack_bound_push**: Desired minimum absolute distance from the initial slack to bound. 

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Range: (0, \(\infty\)]

Default: 0.01

**slack_move** *(advanced)*: Correction size for very small slacks. 

Due to numerical issues or the lack of an interior, the slack variables might become very small. If a slack becomes very small compared to machine precision, the corresponding bound is moved slightly. This parameter determines how large the move should be. Its default value is \(\text{mach}\_\text{eps}^{3/4}\). See also end of Section 3.5 in implementation paper - but actual implementation might be somewhat different.

Range: [0, \(\infty\)]

Default: 1.81899e-12

**soc_method**: Ways to apply second order correction

This option determines the way to apply second order correction, 0 is the method described in the implementation paper. 1 is the modified way which adds alpha on the rhs of x and s rows.

Range: \(\{0, ..., 1\}\)

Default: 0

**soft_resto_pderror_reduction_factor**: Required reduction in primal-dual error in the soft restoration phase.

The soft restoration phase attempts to reduce the primal-dual error with regular steps. If the damped primal-dual step (damped only to satisfy the fraction-to-the-boundary rule) is not decreasing the primal-dual error by at least this factor, then the regular restoration phase is called. Choosing "0" here disables the soft restoration phase.

Range: [0, \(\infty\)]

Default: 0.9999

**start_with_resto**: Whether to switch to restoration phase in first iteration.

Setting this option to "yes" forces the algorithm to switch to the feasibility restoration phase in the first iteration. If the initial point is feasible, the algorithm will abort with a failure.

Range: yes, no

Default: no
\textbf{tau\_min} \textit{(advanced)}: Lower bound on fraction-to-the-boundary parameter \(\tau\). \leftrightarrow

This is \(\text{tau}\_\text{min}\) in the implementation paper. This option is also used in the adaptive \(\mu\) strategy during the monotone mode.

Range: \((0, 1)\)
Default: 0.99

\textbf{theta\_max\_fact} \textit{(advanced)}: Determines upper bound for constraint violation in the filter. \leftrightarrow

The algorithmic parameter \(\theta_{\text{max}}\) is determined as \(\theta_{\text{max}}\)\_fact times the maximum of 1 and the constraint violation at initial point. Any point with a constraint violation larger than \(\theta_{\text{max}}\) is unacceptable to the filter (see Eqn. (21) in the implementation paper).

Range: \((0, \infty)\)
Default: 10000

\textbf{theta\_min\_fact} \textit{(advanced)}: Determines constraint violation threshold in the switching rule. \leftrightarrow

The algorithmic parameter \(\theta_{\text{min}}\) is determined as \(\theta_{\text{min}}\)\_fact times the maximum of 1 and the constraint violation at initial point. The switching rule treats an iteration as an h-type iteration whenever the current constraint violation is larger than \(\theta_{\text{min}}\) (see paragraph before Eqn. (19) in the implementation paper).

Range: \((0, \infty)\)
Default: 0.0001

\textbf{timing\_statistics} \textit{}: Indicates whether to measure time spend in components of Ipopt and NLP evaluation \leftrightarrow

The overall algorithm time is unaffected by this option.

Range: yes, no
Default: no

\textbf{tiny\_step\_tol} \textit{(advanced)}: Tolerance for detecting numerically insignificant steps. \leftrightarrow

If the search direction in the primal variables (\(x\) and \(s\)) is, in relative terms for each component, less than this value, the algorithm accepts the full step without line search. If this happens repeatedly, the algorithm will terminate with a corresponding exit message. The default value is 10 times machine precision.

Range: \([0, \infty]\)
Default: 2.22045e-15

\textbf{tiny\_step\_y\_tol} \textit{(advanced)}: Tolerance for quitting because of numerically insignificant steps. \leftrightarrow

If the search direction in the primal variables (\(x\) and \(s\)) is, in relative terms for each component, repeatedly less than \(\text{tiny\_step\_tol}\), and the step in the \(y\) variables is smaller than this threshold, the algorithm will terminate.

Range: \([0, \infty]\)
Default: 0.01
tol: Desired convergence tolerance (relative).

Determines the convergence tolerance for the algorithm. The algorithm terminates successfully, if the (scaled) NLP error becomes smaller than this value, and if the (absolute) criteria according to "dual_inf_tol", "constr_viol_tol", and "compl_inf_tol" are met. This is epsilon_tol in Eqn. (6) in implementation paper. See also "acceptable_tol" as a second termination criterion. Note, some other algorithmic features also use this quantity to determine thresholds etc.

Range: (0, ∞]
Default: 1e-08

warm_start_bound_frac: same as bound_frac for the regular initializer

Range: (0, 0.5]
Default: 0.001

warm_start_bound_push: same as bound_push for the regular initializer

Range: (0, ∞]
Default: 0.001

warm_start_init_point: Warm-start for initial point

Indicates whether this optimization should use a warm start initialization, where values of primal and dual variables are given (e.g., from a previous optimization of a related problem.)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>do not use the warm start initialization</td>
</tr>
<tr>
<td>yes</td>
<td>use the warm start initialization</td>
</tr>
</tbody>
</table>

Default: yes, if run on modified model instance (e.g., from GUSS), otherwise no

warm_start_mult_bound_push: same as mult_bound_push for the regular initializer

Range: (0, ∞]
Default: 0.001

warm_start_mult_init_max: Maximum initial value for the equality multipliers.

Range: real
Default: 1e+06

warm_start_slack_bound_frac: same as slack_bound_frac for the regular initializer

Range: (0, 0.5]
Default: 0.001

warm_start_slack_bound_push: same as slack_bound_push for the regular initializer
Range: \((0, \infty]\)

Default: 0.001

**warm_start_target_mu** (advanced): \(\leftarrow\)

Experimental!

Range: real

Default: 0

**watchdog_shortened_iter_trigger**: Number of shortened iterations that trigger the watchdog. \(\leftrightarrow\)

If the number of successive iterations in which the backtracking line search did not accept the first trial point exceeds this number, the watchdog procedure is activated. Choosing "0" here disables the watchdog procedure.

Range: \(\{0, ..., \infty\}\)

Default: 10

**watchdog_trial_iter_max**: Maximum number of watchdog iterations. \(\leftrightarrow\)

This option determines the number of trial iterations allowed before the watchdog procedure is aborted and the algorithm returns to the stored point.

Range: \(\{1, ..., \infty\}\)

Default: 3

### 5.21 JAMS and LogMIP

#### 5.21.1 Introduction

EMP (Extended Mathematical Programming) is not a solver but an (experimental) framework for automated mathematical programming reformulations. The idea behind EMP is that new upcoming types of models which currently cannot be solved reliably are reformulated into models of established math programming classes in order to use mature solver technology. At this stage, EMP supports the modeling of Bilevel Programs, Variational Inequalities, Disjunctive Programs, Extended Nonlinear Programs and Embedded Complementarity Systems.

Extended mathematical programs are collections of functions and variables joined together using specific optimization and complementarity primitives. EMP annotates the existing relationships within a model to facilitate higher level structure identification. A specific implementation of this framework is outlined that reformulates the original GAMS model automatically using directives contained in an "empinfo" file into an equivalent model that can be solved using existing GAMS solvers.

The reformulation is done by the solver JAMS which currently is the only solver that is capable of handling EMP models. Examples showing how to use the EMP framework and the solver JAMS are made available through the GAMS EMP Library which is included in the GAMS Distribution. In order to generate a copy of an EMPLIB model, one can use the library facility of the GAMS IDE, or execute the command line directive `emplib <modelname>`, where modelname is the (stem of the) file containing the model.

EMP has been developed jointly by Michael Ferris of UW-Madison, Ignacio Grossmann of Carnegie Mellon University, and GAMS Development Corporation. EMP and JAMS come free of charge with any licensed GAMS system but require a subsolver to solve the generated models.
5.21.2  JAMS: a reformulation tool

EMP models are currently processed by the JAMS solver. The solver JAMS creates a scalar version of the given GAMS model. This scalar version of the model is then solved by an appropriate subsolver. By default, there are no reformulations carried out, so the model generated is simply a GAMS scalar form of the model the actual subsolver will process. The subsolver used is by default the currently specified solver for the given model type.

5.21.2.1  The JAMS Option File

As with any GAMS solver, JAMS has an option file, typically called jams.opt. A JAMS option subsolver is available to change the subsolver used for the reformulated model, along with an option to utilize a subsolver option file (subsolveropt).

The actual scalar version of the model can also be seen by the modeler using the option filename. For example, the option file

```
subsolver path
subsolveropt 1
filename mcpmod.gms
```

when applied to an EMP model that is a complementarity problem will create a file called mcpmod.gms in the current directory and solve that model using the solver PATH utilizing any options for PATH that are specified in path.opt. The scalarized model is not particularly useful to look at since all of the original variables have been renamed into a scalar form. The mapping between original variables and the ones used in the scalar version of the model is given in a dictionary file that can also be seen by the modeler using the dict option. If a user simply wants to generate this scalar model, then the option terminate will not solve the generated model.

After the scalar version of the model is solved, the solution values are mapped back into the original namespace and returned to the modeler as usual in the listing file. The JAMS option margtol allows the modeler to suppress reporting marginals that have (absolute) values smaller than this tolerance.

Obviously, all of the above functionality is not of much value: the key part of JAMS is to interpret additional directives to take the original model and produce a reformulated scalar model. This is carried out using an "empinfo" file. The syntax and use of this file is the content of the remaining sections of this document.

The option EMPIInfoFile allows the user to specify the path and name of a file containing additional EMP information. The syntax of this file is described by examples elsewhere in this document and in section Empinfo file details . There is a subtlety that should be mentioned when a user writes this file in the default location in the GAMS scratch directory of the current run specified in the gams file using:

```
file empinfo / '%emp.info%' /;
```

wherein certain additional formatting instructions are given. If instead, the file handle is given by:

```
file empinfo / 'empinfo.txt' /;
```

for example, then to produce the same file the following lines must be added to the gams source file:

```
empinfo.pc = 8;
empinfo.pw = 255;
```

The following tables list all available options.

5.21.2.2  Reformulation Options
### 5.21 JAMS and LogMIP

<table>

5.21.3 Forming Optimality Conditions: NLP2MCP

The first nontrivial use of the JAMS solver is to automatically generate the first order conditions of a linear or nonlinear program; essentially we reformulate the optimization problem as a mixed complementarity problem (MCP). The "empinfo" file to do this simply contains the following line:

\texttt{modeltype mcp}

Behind the scenes, JAMS forms the Lagrangian of the nonlinear program and then forms its Karush-Kuhn-Tucker optimality conditions. To be clear, given the original nonlinear program

\[
\begin{align*}
\min_x f(x) \text{ s.t. } & g(x) \leq 0, \ h(x) = 0, \\
& (NLP)
\end{align*}
\]

the Lagrangian is:

\[
\mathcal{L}(x, \lambda, \mu) = f(x) - \langle \lambda, g(x) \rangle - \langle \mu, h(x) \rangle.
\]

The first order conditions are the following MCP:

\[
\begin{align*}
0 &= \nabla_x \mathcal{L}(x, \lambda, \mu) \perp x \text{ free} \\
0 &\geq -\nabla_\lambda \mathcal{L}(x, \lambda, \mu) \perp \lambda \leq 0 \\
0 &= -\nabla_\mu \mathcal{L}(x, \lambda, \mu) \perp \mu \text{ free}
\end{align*}
\]

A specific example is:

\[
\begin{align*}
\min_{x,y,z} & -3x + y \\
\text{s.t.} & x + y \leq 1, \ x + y - z = 2, \ x, y \geq 0
\end{align*}
\]

which is found in the EMPLIB model \texttt{nlp2mcp}:

```
Positive Variables x, y;
Variables f, z;
Equations g, b, defobj;
g.. x + y =e= 1;
b.. x + y - z =e= 2;
defobj.. f =e= -3*x + y;
model comp / defobj, g, b /;
file info / '%emp.info%' /;
putclose info / 'modeltype mcp';
solve comp using emp minimizing f;
```

The putclose line writes out the default "empinfo" file whose location is provided in the system string \texttt{%emp.info\%}. Armed with this additional information, the EMP tool automatically creates the following MCP:

\[
\begin{align*}
0 &\leq -3 - \lambda - \mu \perp x \geq 0 \\
0 &\leq 1 - \lambda - \mu \perp y \geq 0 \\
0 &= \mu \perp z \text{ free} \\
0 &\geq x + y - 1 \perp \lambda \leq 0 \\
0 &= x + y - z - 2 \perp \mu \text{ free}
\end{align*}
\]
5.21 JAMS and LogMIP

5.21.4 Soft Constraints

In many cases, we wish to relax certain constraints in a model during solution (to help identify feasibility issues for example). As an example, consider the problem

\[
\begin{align*}
\text{min} & \quad \exp(x_1) \\
\text{s.t.} & \quad \log(x_1) = 1, \\
& \quad x_2^2 \leq 2, \\
& \quad x_1/x_2 = \log(x_3), \\
& \quad 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0,
\end{align*}
\]

which can be formulated in GAMS as

```gams
$title simple example of ENLP
Variables obj, x1, x2, x3;
Equations f0, f1, f2, f3, f4;
f0.. obj =e= exp(x1);
f1.. log(x1) =e= 1;
f2.. x2.sqr =g= 2;
f3.. x1/x2 =e= log(x3);
f4.. 3*x1 + x2 =l= 5;
x1.lo = 0; x2.lo = 0;
model enlpemp /all/;
x1.l = 1; x2.l = 1; x3.l = 1;
solve enlpemp using nlp min obj;
```

5.21.4.1 Reformulation as a classical NLP

Soft constraints allow us to treat certain equations in the model as "soft" by removing the constraints and adding a penalty term to the objective function. Explicitly, we replace the above problem by:

\[
\begin{align*}
\text{min} & \quad \exp(x_1) + 5 \|\log(x_1) - 1\|^2 + 2 \max(x_2^2 - 2, 0) \\
\text{s.t.} & \quad x_1/x_2 = \log(x_3), \\
& \quad 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0.
\end{align*}
\]

In this problem, we still force \(x_1/x_2 = \log(x_3)\), but apply a least squares penalty to \(\log(x_1) - 1\) and a smaller one-sided penalization to \(x_2^2 - 2\).

The above formulation is nonsmooth due to the "max" term in the objective function; in practice we would replace this by:

\[
\begin{align*}
\text{min} & \quad \exp(x_1) + 5 (\log(x_1) - 1)^2 + 2w \\
\text{s.t.} & \quad x_1/x_2 = \log(x_3), \\
& \quad 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\
& \quad w \geq x_2^2 - 2, w \geq 0
\end{align*}
\]

and recover a standard form NLP.

The "empinfo" file:

```gams
modeltype NLP
adjustequ f1 sqr 5
f2 maxz 2
```

coupled with replacing the last line with

```gams
solve enlpemp using emp min obj;
```

achieves this goal. The parameter values provide the penalty coefficients above.
5.21.4.2 Reformulation as an MCP

As an alternative, we can rewrite the problem as an MCP, also dealing explicitly with the nonsmoothness. The “empinfo” file is given by:

modeltype NLP
adjustequ
f1 sqr 5
f2 maxz 2

and this generates the following MCP:

\[
\begin{align*}
0 &= \log(x_1) - 1 + y_1/10 & \perp & y_1 \text{ free,} \\
0 &\leq x_2^2 - 2 & \perp & y_2 \geq 0, \\
0 &= x_1/x_2 - \log(x_3) & \perp & y_3 \text{ free,} \\
0 &\geq 3x_1 + x_2 - 5 & \perp & y_4 \leq 0, \\
0 &\leq \exp(x_1) - y_1/x_1 - y_3/x_2 - 3y_4 & \perp & x_1 \geq 0, \\
0 &\leq -2y_2x_2 + x_1y_3/x_2^2 - y_4 & \perp & x_2 \geq 0, \\
0 &= y_3/x_3 & \perp & x_3 \text{ free,}
\end{align*}
\]

where \(y\) represent the multipliers.

A complete description of the process to derive this MCP will be given later in section Extended Nonlinear Programs.

5.21.5 Bilevel Programs

Mathematical programs with optimization problems in their constraints have a long history in operations research including \[15\] \[29\] \[71\]. New codes are being developed that exploit this structure, at least for simple hierarchies, and attempt to define and implement algorithms for their solution.

The simplest case is that of bilevel programming, where an upper level problem depends on the solution of a lower level optimization. For example:

\[
\begin{align*}
\min_{x,y} f(x,y) \\
\text{s.t. } g(x,y) &\leq 0, \\
y &\text{solves } \min_{y} v(x,y) \text{ s.t. } h(x,y) \geq 0.
\end{align*}
\]

Often, the upper level is referred to as the “leader”, while the lower level is the “follower”.

This problem can be reformulated as a Mathematical Program with Complementarity Constraints (MPCC) by replacing the lower level optimization problem by its first order optimality conditions:

\[
\begin{align*}
\min_{x,y} f(x,y) \\
\text{s.t. } g(x,y) &\leq 0, \\
0 &= \nabla_y v(x,y) - \lambda^T \nabla_y h(x,y) \perp x \text{ free} \\
0 &\leq h(x,y) \perp \lambda \geq 0.
\end{align*}
\]

We find a solution of the MPCC, not of the bilevel program. This approach allows the MPCC to be solved using the NLPEC code, for example. Note that this reformulation is potentially problematic. First order
conditions require theoretical assumptions to be necessary and sufficient for local optimality. There may be cases where the lower level problem has multiple local solutions, but the modeler really was interested in the global solution. The approach here may not produce this solution, even if a global solver is used within NLPEC.

The following example is Example 5.1.1, page 197 from [15]. Mathematically, the problem is

$$\begin{align*}
\min_{x,y} & \quad x - 4y \\
\text{s.t.} & \quad y \ \text{solves} \quad \min_y y \\
& \quad x + y \geq 3 \\
& \quad 2x - y \geq 0 \\
& \quad -2x - y \geq -12 \\
& \quad -3x + 2y \geq -4
\end{align*}$$

and the EMPLIB model bard511 contains the following code:

```plaintext
Positive variables x, y;
Variables objout, objin;
equations defout, defin, e1, e2, e3, e4;
defout.. objout =e= x - 4*y;
defin.. objin =e= y;
e1.. x + y =e= 3;
e2.. 2*x - y =e= 0;
e3.. -2*x - y =e= -12;
e4.. -3*x + 2*y =e= -4;
model bard / all /;
$echo bilevel x min objin y defin e1 e2 e3 e4 > "emp.info"
solve bard using emp minimizing objout;
```

Note that first the functions that form the objectives and constraints of the model are defined and the model is assembled. The $echo line writes the "empinfo" file and states that the lower level problem involves the objective objin which is to be minimized by choice of variables y subject to the constraints specified in (defin), e1, e2, e3, and e4.

Note that the variables x are declared to be variables of the upper level problem and this example has no upper level constraints g. Having written the problem in this way, the MPCC is generated automatically, and passed on to a solver. In the case where that solver is NLPEC, a further reformulation of the model is carried out to convert the MPCC into an equivalent NLP or a parametric sequence of NLP's.

Further examples of bilevel models in EMPLIB are named: bard*, ccmg74, ccmg153, flds*, jointc1, jointc2, mirrlees, transbp.

The EMP model type allows multiple lower level problems to be specified within the bilevel format. An example of this is given in EMPLIB as ccmg71. The equations and objectives are specified in the normal manner; the only change is the definition of the "empinfo" file, shown below:

```plaintext
... defh1.. h1 =e= sqr(u1-x1) + sqr(u2-x2) + sqr(u3-x3) + sqr(u4-x4);
e1.. 3*u1 + u2 + 2*u3 + u4 =e= 6;
...
$echo > "emp.info"
bilevel x1 x2 x3 x4
min h1 u1 u2 u3 u4 defh1 e1
min h2 v1 v2 v3 v4 defh2 e2
$echo
```

This corresponds to a bilevel program with two followers, both solving minimization problems. The first follower minimizes the objective function h1 (defined in defh1) over the variables u1, u2, u3, and u4 subject to the constraint given in e1. The second followers problem is defined analogously next. Note that h1 involves the variables x1, x2, x3, and x4 that are optimization variables of the leader. The constraint in e1 could also include these variables, and also the variables v1, v2, v3, or v4 of the second follower, but all of these would be treated as parameters by the first follower.

The actual model (ccmg71) in EMPLIB uses a shortcut notation:

```plaintext
... defh1.. h1 =e= sqr(u1-x1) + sqr(u2-x2) + sqr(u3-x3) + sqr(u4-x4);
```
In the followers problem, the 'w' notation indicates that this agent will optimize over all the variables used in defh1 and e1 that are not under the control of any other follower or the leader. In this case, this means u1, u2, u3, and u4. To avoid confusion, it is recommended that the modeler explicitly names all the variables in each followers problem as shown before.

5.21.6 Variational Inequalities

A variational inequality $VI(F,X)$ is to find $x \in X$:

$$ \langle F(x), (z - x) \rangle \geq 0, \text{ for all } z \in X. $$

Here $X$ is a closed (frequently assumed convex) set, defined for example as

$$ X = \{ x \mid x \geq 0, h(x) \geq 0 \}. $$

Note that the first-order (minimum principle) conditions of a nonlinear program

$$ \min_{x \in X} f(x) $$

are precisely of this form with $F(x) = \nabla f(x)$.

It is well known that such problems can be reformulated as complementarity problems when the set $X$ has the representation $\{ x \mid x \geq 0, h(x) \geq 0 \}$ by introducing multipliers $\lambda$ on the constraints $h(x) \geq 0$:

$$ 0 \leq F(x) - \langle \lambda, \nabla h(x) \rangle \perp x \geq 0 $$

$$ 0 \leq h(x) \perp \lambda \geq 0. $$

If $X$ has a different representation, this construction would be modified appropriately.

A simple two dimensional example may be useful to improve understanding. Let

$$ F(x) = \begin{bmatrix} x_1 + 2 \\ x_1 + x_2 - 3 \end{bmatrix}, \ X = \{ x \geq 0 \mid x_1 + x_2 \leq 1, $$

so that $F$ is an affine function, but $F$ is not the gradient of any function $f : \mathbb{R}^2 \rightarrow \mathbb{R}$. For this particular data, $VI(F,X)$ has a unique solution $x = (0,1)$.

Note that the first lines of this file define the $F$ and $h$ using standard GAMS syntax and include the defining equations in the model simpleVI. The extension is the annotation "empinfo" file that indicates certain equations are to be treated differently by the EMP tool. The annotation simply says that the model is a VI (vi) that pairs $F$ with $x$ and that the remaining (unpaired) equations form the constraint set $X$. (Alternative notation allows the keyword vi to be replaced by vifunc.) Thus, model equations $F$ define a function $F$ that is to be part of a variational inequality, while the equations $h$ define constraints of $X$. It is also acceptable in this setting to use the "empinfo" file defined by:
In this case, by default, any equations that are given in the model statement but not included as a pair in the \texttt{vi} statement are automatically used to form \( X \). An alternative way to write this model without using \texttt{sameas} is given in \texttt{EMPLIB} as \texttt{affinevi}.

Some subtleties related to VI's are demonstrated in the \texttt{EMPLIB} model \texttt{zerofunc}. In this model, the set \( X \) is defined using variables \( y \) and \( z \), for which \( z \) does not appear in the definition of \( F \equiv F_y \). In this case, the variable \( z \) is then matched with a "0" function. The "empinfo" file can be written in a number of different ways:

\begin{verbatim}
putclose fx 'vi F_y y';

or

putclose fx 'vi z F_y y';

or

putclose fx 'vi z F_y y gCons';

or

putclose fx 'vi F_z z F_y y gCons';
\end{verbatim}

where \( F_z \) simply defines the zero function. To some extent, our preferred notation is the one listed third: it explicitly includes all the variables and constraints that are present in the model and does not require the modeler to define \( F_z \) at all.

Further example models in \texttt{EMPLIB} are \texttt{simplevi}, \texttt{simplevi2}, \texttt{simplevi3}, \texttt{target}, \texttt{traffic}, \texttt{traffic2}, and \texttt{transvi}.

Note also that the lower level problems of a bilevel program could be VI's instead of optimization problems - these problems are called Mathematical Programs with Equilibrium Constraints (MPEC) in the literature. Note that since MPCC is a special case of MPEC, the GAMS model type MPEC covers both. An example demonstrating this setup is given in \texttt{EMPLIB} as \texttt{multmpec}. The actual model to solve is:

\begin{align*}
\min_{u,v,w,z} & \quad z \\
\text{s.t.} & \quad \exp(z) + w = 2, z \geq 1 \\
& \quad (u,v) \text{ solves } \text{VI}([v + w + z - 1; u - \log(v)], \{(u,v) \mid u \geq 0, v \geq 0\}) \\
& \quad w \text{ solves } \text{VI}(w + z + 3, \{w \mid w \text{ free}\})
\end{align*}

Note that the two VI's (due to the definitional sets) correspond respectively to a complementarity problem:

\begin{align*}
0 & \leq v + w + z - 1 \quad \perp \quad u \geq 0 \\
0 & \leq u - \log(v) \quad \perp \quad v \geq 0
\end{align*}

and a linear equation:

\begin{equation*}
w + z + 3 = 0
\end{equation*}
The actual GAMS code is as follows:

```gams
Positive Variable u;
Variables v, w, z;
Equations f1, f2, f3, h;
f1.. v + w + z =n= 1;
f2.. u =n= log(v);
f3.. w + z =n= -3;
h.. exp(z) + w =e= 2;

v.lo = 0; v.l = 1; z.lo = 1;
model mpecmod /all/;
file info / '%emp.info%' /;
put info / 'bilevel vi f1 u f2 v vi f3 w $offecho';
solve mpecmod using emp min z;
```

The initial level value for \( v \) \((v.l = 1)\) is needed to protect the evaluation of \( \log(v) \). The two complementarity problems are specified in the empinfo file (it is not really necessary to split these VI's apart, but it may give information to a solver that can be exploited). It is of course possible to write the MPCC directly in GAMS using the model type MPEC instead of EMP.

### 5.21.7 Embedded Complementarity Systems

A different type of embedded optimization model that arises frequently in applications is:

\[
\begin{align*}
\max_x & \quad f(x, y) \\
\text{s.t.} & \quad g(x, y) \leq 0 \quad (\perp p \geq 0) \\
& \quad H(x, y, p) = 0 \quad (\perp y \text{ free})
\end{align*}
\]

Note the difference here: the optimization problem is over the variable \( x \), and is parameterized by the variable \( y \). The choice of \( y \) is fixed by the (auxiliary) complementarity relationships depicted here by \( H \). Note that the \( H \) equations are not part of the optimization problem, but are essentially auxiliary constraints to tie down remaining variables in the model.

A specific example is:

\[
\begin{align*}
\max_x & \quad x \\
\text{s.t.} & \quad x + y \leq 1 \\
& \quad -3x + y = 0.5 \quad (\perp y \text{ free})
\end{align*}
\]

which is found in the EMPLIB model simpequil2:

```gams
Variables y;
Positive variables x;
Equations optcons, vicons;
optcons.. x + y =l= 1;
vicons.. -3*x + y =e= 0.5;
model comp / optcons, vicons /;
file info / 'emp.info' /;
put info / 'equilibrium';
put / 'max x optcons';
putclose / 'vi vicons y';
solve comp using emp;
```

In order that this model can be processed correctly as an EMP, the modeler provides additional annotations to the model defining equations in an "empinfo" file. Specifically, first it is indicated that the problem is an equilibrium problem involving one or more agent problems. Next, the first agent is defined as an optimizer (over \( x \)). Finally, the second agent is defined as solving a VI in \( y \). Armed with this additional information, the EMP tool automatically creates the following MCP:

\[
\begin{align*}
0 \leq -1 + p \quad & \perp x \geq 0 \\
0 \leq 1 - x - y \quad & \perp p \geq 0 \\
0 = -3x + y - 0.5 \quad & \perp y \text{ free},
\end{align*}
\]
(which is formed by the steps we outline below). EMP explicitly enforces the rule that every variable and constraint is under the control of exactly one agent. Thus a constraint or a variable cannot appear in both the max problem and the VI problem.

The above example is slightly simpler than the general form described above in which $H$ is a function of $x$, $y$, and $p$, the multiplier on the constraint of the optimization problem. The problem is that we do not have that variable around in the model code if we only specify the optimization problem there. This occurs for example in the classical PIES Model due to Hogan. In this setting, the problem is described by a linear program

$$
\begin{align*}
\min_x & \quad c^T x \\
\text{st.} & \quad Ax = q(p) \\
& \quad Bx = b \\
& \quad x \geq 0
\end{align*}
$$

in which the quantity $q$ is a function of $p$, which is a multiplier on one of the LP constraints. To do this in EMP, we simply add the annotation:

```plaintext
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'emp.info'/;
put myinfo 'equilibrium';
put 'min obj c o ct ot lt ht defobj dembal cmbal ombal lmbal hmbal ruse';
putclos myinfo 'dualvar p dembal';
solve piesemp using emp;
```

where `dembal` is the name of the constraint for which $p$ needs to be the multiplier. The full model is found in the EMPLIB model `pies`. Two final points: the `dualvar` directive identifies the variable $p$ with the multiplier on the `dembal` constraint, and all variables and constraints must be owned by a single agent. In this case, since there is only one agent (the minimizer), all constraints of the model are explicitly claimed, along with all variables except for $p$. However, next, $p$ is identified with the `dembal` constraint, which is owned by the min agent, and hence $p$ is also owned by that agent.

There are several shorthands possible here. The first is that the explicit statement of variables can be replaced by the `'*'` form:

```plaintext
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'emp.info'/;
put myinfo 'equilibrium';
put 'min obj * defobj dembal cmbal ombal lmbal hmbal ruse';
```

Alternatively, an even shorter version is possible since there is only one agent present in this model, namely:

```plaintext
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'emp.info'/;
putclos myinfo 'dualvar p dembal';
solve piesemp using emp minimizing obj;
```

Note that in this form, all the variables and constraints of the original model are included in the (single) agents problem, and the original variable $p$ is identified in the constructed MCP with the multiplier on the `dembal` constraint.

In the general case where the "empinfo" file contains all three lines:

```plaintext
min x optcons
vi vicons y
dualvar p optcons
```

namely that the function $H$ that is defined in `vicons` is complementary to the variable $y$ (and hence the variable $y$ is a parameter to the optimization problem), and furthermore that the dual variable associated with the equation `optcons` in the optimization problem is one and the same as the variable $p$ used to define $H$, the EMP tool automatically creates the following MCP:

$$
\begin{align*}
0 &= \nabla_x L(x, y, p) \quad \perp \quad x \text{ free} \\
0 &\geq -\nabla_p L(x, y, p) \quad \perp \quad p \leq 0 \\
0 &= H(x, y, p) \quad \perp \quad y \text{ free},
\end{align*}
$$

where the Lagrangian is defined as
\[ \mathcal{L}(x, y, p) = f(x, y) - (p, g(x, y)). \]

Essentially, this MCP consists of the first order optimality conditions of the optimization problem, coupled with the VI that is the second agents problem. An example that does both of these things together is provided in EMP LIB as `scarfemp-primal`.

Note that since the PIES model has no \( y \) variables, this is a special case of the general form in which the second agents (VI) problem is simply not present.

Example models are `ferris43`, `flipper pies`, `scarfemp-dual`, `simpequil`, `transecs`, and `transeql`.

### 5.21.8 MOPECs

MOPECs (Multiple Optimization Problems with Equilibrium Constraints) are a simple conceptual extension of the aforementioned embedded complementarity system. Instead of having a single optimizing agent and a variational inequality, one instead allows multiple optimizing agents coupled with an equilibrium constraint (the variational inequality).

Perhaps the most popular use of this formulation is where competition is allowed between agents. A standard method to deal with such cases is via the concept of Nash Games. In this setting \( x^* \) is a Nash Equilibrium if

\[ x_i^* \in \arg \min_{x_i \in X_i} \ell_i(x_i, x_{-i}^*, q), \forall i \in I, \]

where \( x_{-i} \) are other players decisions and the quantities \( q \) are given exogenously, or via complementarity:

\[ 0 \leq H(x, q) \perp q \geq 0. \]

This mechanism is extremely popular in economics, and Nash famously won the Nobel Prize for his contributions to this literature.

This format is again an EMP, more general than the example given above in two respects. Firstly, there is more than one optimization problem specified in the embedded complementarity system. Secondly, the parameters in each optimization problem consist of two types. Firstly, there are the variables \( q \) that are tied down by the auxiliary complementarity condition and hence are treated as parameters by the \( i \)th Nash player. Also there are the variables \( x_{-i} \) that are treated as parameters by the \( i \)th Nash player, but are treated as variables by a different player \( j \).

While we do not specify the syntax here for these issues, EMP LIB provides examples that outline how to carry out this matching within GAMS. Finally, two points of note: first it is clear that the resulting model is a complementarity problem and can be solved using PATH, for example. Secondly, performing the conversion from an embedded complementarity system or a Nash Game automatically is a critical step in making such models practically useful.

We note that there is a large literature on discrete-time finite-state stochastic games: this has become a central tool in analysis of strategic interactions among forward-looking players in dynamic environments. The model of dynamic competition in an oligopolistic industry given in [55] is exactly in the format described above, and has been used extensively in applications such as advertising, collusion, mergers, technology adoption, international trade and finance. Ongoing work aims to use the EMP format to model these problems.
5.21.9 Extended Nonlinear Programs

Optimization models have traditionally been of the form (NLP). Specialized codes have allowed certain problem structures to be exploited algorithmically, for example simple bounds on variables. However, for the most part, assumptions of smoothness of $f$, $g$ and $h$ are required for many solvers to process these problems effectively. In a series of papers, Rockafellar and colleagues [152] [153] [154] have introduced the notion of extended nonlinear programming, where the (primal) problem has the form:

$$\min_{x \in X} f(x) + \theta(g_1(x), \ldots, g_m(x)).$$

(ENLP)

In this setting, $X$ is assumed to be a nonempty polyhedral set, and the functions $f, g_1, \ldots, g_m$ are smooth. The function $\theta$ can be thought of as a generalized penalty function that may well be nonsmooth. However, when $\theta$ has the form

$$\theta(u) = \sup_{y \in Y} \{ \langle y, u \rangle - k(y) \},$$

($\theta$ conj)
a computationally exploitable and theoretically powerful framework can be developed based on conjugate duality. A key point for computation and modeling is that the function $\theta$ can be fully described by defining the set $Y$ and the function $k$. Furthermore, from a modeling perspective, an extended nonlinear program can be specified simply by defining the functions $f, g_1, \ldots, g_m$ in the manner already provided by the modeling system, with the additional issue of simply defining $Y$ and $k$. Conceptually, this is not much harder than what is carried out already, but leads to significant enhancements to the types of models that are available. Once a modeler determines which constraints are treated via which choice of $k$ and $Y$, the EMP model interface automatically forms an equivalent variational inequality or complementarity problem. As we show later, there may be alternative formulations that are computationally more appealing; such reformulations can be generated using different options to JAMS.

5.21.9.1 Forms of theta

The EMP model type makes the problem format (ENLP) available to users in GAMS. As special cases, we can model piecewise linear penalties, least squares, and $L_1$ approximation problems, as well as the notion of soft and hard constraints.

For ease of exposition, we now describe a subset of the types of functions $\theta$ that can be generated by particular choices of $Y$ and $k$. In many cases, the function $\theta$ is separable, that is

$$\theta(u) = \sum_{i=1}^{m} \theta_i(u_i),$$

so we can either specify $\theta_i$ or $\theta$ itself.

Extended nonlinear programs include the classical nonlinear programming form (NLP) as a special case. This follows from the observation that if $K$ is a closed convex cone, and we let $\psi_K$ denote the “indicator function” of $K$ defined by:

$$\psi_K(u) = \begin{cases} 0 & \text{if } u \in K, \\ \infty & \text{else,} \end{cases}$$

then (NLP) can be rewritten as:

$$\min_x f(x) + \psi_K((g(x), h(x)), \quad K = \mathbb{R}^m \times \{0\}^p,$$

where $m$ and $p$ are the dimensions of $g$ and $h$ respectively and $\mathbb{R}^m = \{u \in \mathbb{R}^m \mid u \leq 0\}$. An elementary calculation shows that

$$\psi_K(u) = \sup_{v \in \mathbb{R}^p} \langle u, v \rangle,$$
where $K^\circ = \{ u \mid \langle u, v \rangle \leq 0, \forall v \in K\}$ is the polar cone of the given cone $K$. Thus, when $\theta(u) = \psi_K(u)$ we simply take $k \equiv 0$ and $Y = K^\circ$. In our example, $K^\circ = \mathbb{R}_+^m \times \mathbb{R}^p$. To some extent, this is just a formalism that allows us to claim the classical case as a specialization; however when we take the cone $K$ to be more general than the polyhedral cone used above, we can generate conic programs for example.

The second example involves a piecewise linear function $\theta$: Formally, for $u \in \mathbb{R}$,

$$\theta(u) = \begin{cases} ho u & \text{if } u \geq 0, \\
\sigma u & \text{else}. \end{cases}$$

In this case, simple calculations prove that $\theta$ has the form $(\theta \text{ conj})$ for the choices $k \equiv 0$ and $Y = [\sigma, \rho]$.

The special case where $\sigma = -\rho$ results in

$$\theta(u) = \rho |u|.$$ 

This allows us to model nonsmooth $L_1$ approximation problems. Another special case results from the choice of $\sigma = -\gamma$, $\rho = 0$, whereby

$$\theta(u) = \gamma \max\{-u, 0\}.$$ 

This formulation corresponds to a soft penalization on an inequality constraint, namely if $\theta(-g_1(x))$ is used then nothing is added to the objective function if $g_1(x) \leq 0$, but $\gamma g_1(x)$ is added if the constraint $g_1(x) \leq 0$ is violated. Contrast this to the classical setting above, where $\infty$ is added to the objective if the inequality constraint is violated. It is interesting to see that truncating the set $Y$, which amounts to bounding the multipliers, results in replacing the classical constraint by a linearized penalty.

The third example involves a more interesting choice of $k$. If we wish to replace the "absolute value" penalization given above by a quadratic penalization (as in classical least squares analysis), that is

$$\theta(u) = \gamma u^2$$

then a simple calculation shows that we should take

$$k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = \mathbb{R}.$$ 

By simply specifying this different choice of $k$ and $Y$ we can generate such models easily and quickly within the modeling system. Note, however, that the reformulation we would use in $\theta(u) = \rho |u|$ and $\theta(u) = \gamma u^2$ are very different as we shall explain in the simple example below. Furthermore, in many applications it has become popular to penalize violations using a quadratic penalty only within a certain interval, afterwards switching to a linear penalty (chosen to make the penalty function $\theta$ continuously differentiable - see [99] ). That is:

$$\theta(u) = \begin{cases} \gamma u - \frac{1}{2}\gamma^2 & \text{if } u \geq \gamma \\
\frac{1}{2}u^2 - \frac{1}{2}\gamma^2 & \text{if } u \in [-\gamma, \gamma] \\
-\gamma u - \frac{1}{2}\gamma^2 & \text{else}. \end{cases}$$

Such functions arise from quadratic $k$ and simple bound sets $Y$. In particular, the somewhat more general function

$$\theta(u) = \begin{cases} \gamma\beta^2 + \rho(u - \beta) & \text{if } u \geq \beta \\
\gamma u^2 & \text{if } u \in [\alpha, \beta] \\
\gamma\alpha^2 + \sigma(u - \alpha) & \text{else} \end{cases}$$

arises from the choice of

$$k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = [\sigma, \rho],$$

with $\alpha = \frac{\sigma}{\gamma^2}$ and $\beta = \frac{\rho}{\gamma^2}$.

The final example that we give is that of $L_\infty$ penalization. This example is different to the examples given above in that $\theta$ is not separable. However, straightforward calculation can be used to show

$$\theta(u) = \max_{i=1,\ldots,m} u_i$$

results from the choice of

$$k \equiv 0 \text{ and } Y = \left\{ y \in \mathbb{R}^m \mid y \geq 0, \sum_{i=1}^m y_i = 1 \right\},$$

that is, $Y$ is the unit simplex.
5.21.9.2 Underlying theory

The underlying structure of $\theta$ leads to a set of extended optimality conditions and an elegant duality theory. This is based on an extended form of the Lagrangian:

$$
\mathcal{L}(x, y) = f(x) + \sum_{i=1}^{m} y_{i} g_{i}(x) - k(y)
$$

$$
x \in X, y \in Y
$$

Note that the Lagrangian $\mathcal{L}$ is smooth - all the nonsmoothness is captured in the $\theta$ function. The theory is an elegant combination of calculus arguments related to $g_i$ and its derivatives, and variational analysis for features related to $\theta$.

It is shown in [153] that under a standard constraint qualification, the first-order conditions of (ENLP) are precisely in the form of the following variational inequality:

$$
\text{VI} \left( \left[ \nabla_x \mathcal{L}(x, y) \right], X \times Y \right).
$$

When $X$ and $Y$ are simple bound sets, this is simply a complementarity problem.

Note that EMP exploits this result. In particular, if an extended nonlinear program of the form (ENLP) is given to EMP, then the optimality conditions (ENLP VI) are formed as a variational inequality problem and can be processed as outlined above. For a specific example, we cite the fact that if we use the (classical) choice $k \equiv 0$ and $Y = K^\circ$, then the optimality conditions of (ENLP) are precisely the standard complementarity problem given as (ENLP VI). While this is of interest, we believe that other choices of $k$ and $Y$ may be more useful and lead to models that have more practical significance.

Under appropriate convexity assumptions on this Lagrangian, it can be shown that a solution of the VI (ENLP VI) is a saddle point for the Lagrangian on $X \times Y$. Furthermore, in this setting, the saddle point generates solutions to the primal problem (ENLP) and its dual problem:

$$
\max_{y \in Y} d(y), \text{ where } d(y) = \inf_{x \in X} \mathcal{L}(x, y),
$$

with no duality gap.

Unfortunately, the perturbations $y$ in Rockafellar's theory are precisely the negative of those used throughout the GAMS system. Thus, we need to replace $y$ by $-y$ throughout in the above to recover the same multipliers as those GAMS uses.

5.21.9.3 A simple example

As an example, consider the problem

$$
\min_{x_1, x_2, x_3} \exp(x_1) + 5\| \log(x_1) - 1 \|^2 + 2 \max(x_3^2 - 2, 0)
$$

s.t. $x_1/x_2 = \log(x_3)$,

$$
3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0.
$$

In this problem, we would take

$$
X = \left\{ x \in \mathbb{R}^3 \mid 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \right\}.
$$
The function $\theta$ essentially treats 3 separable pieces:

$$
\begin{align*}
g_1(x) &= \log(x_1) - 1, \\
g_2(x) &= x_2^2 - 2, \\
g_3(x) &= \frac{x_1}{x_2} - \log(x_3).
\end{align*}
$$

A classical problem would force $g_1(x) = 0$, $g_2(x) \leq 0$, and $g_3(x) = 0$, while minimizing $f(x) = \exp(x_1)$. In our problem, we still force $g_3(x) = 0$, but apply a (soft) least squares penalty on $g_1(x)$ and a smaller one-sided penalization on $g_2(x)$. The above formulation is nonsmooth due to the "max" term in the objective function; in practice we could replace this by:

$$
\begin{align*}
&\min_{x_1, x_2, x_3, w} \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2w \\
\text{s.t.} \\
&x_1/x_2 = \log(x_3), \\
&3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\
&w \geq x_2^2 - 2, w \geq 0
\end{align*}
$$

and recover a standard form NLP. If the penalty on $g_1(x)$ would be replaced by a one-norm penalization (instead of least squares), we would have to play a similar game, moving the function $g_1(x)$ into the constraints and adding additional variable(s). To some extent, this seems unnatural - a modeler should be able to interchange the penalization without having to reformulate the problem from scratch. The proposed extended NLP would not be reformulated at all by the modeler, but allows all these "generalized constraints" to be treated in a similar manner within the modeling system. The actual formulation would take:

$$
\theta(u) = \theta_1(u_1) + \theta_2(u_2) + \theta_3(u_3)
$$

where

$$
\begin{align*}
\theta_1(u_1) &= 5u_1^2, \\
\theta_2(u_2) &= 2 \max(u_2, 0), \\
\theta_3(u_3) &= \psi_{[0]}(u_3).
\end{align*}
$$

The discussion above allows us to see that

$$
\begin{align*}
Y &= -(\mathbb{R} \times [0,2] \times \mathbb{R}), \\
k(y) &= \frac{1}{20}y_1^2 + 0 + 0 + 0
\end{align*}
$$

The corresponding Lagrangian is the smooth function:

$$
\mathcal{L}(x,y) = f(x) - \sum_{i=1}^{3} y_i g_i(x) - k(y).
$$

The corresponding VI (ENLP VI) can almost be formulated in GAMS (except that the linear constraint in $X$ cannot be handled currently except by introducing a $\theta_4(x)$). Thus

$$
g_4(x) = 3x_1 + x_2 - 5, \quad \theta_4(u) = \psi_{\mathbb{R}_-}
$$

resulting in the following choices for $Y$ and $k$:

$$
\begin{align*}
Y &= -(\mathbb{R} \times [0,2] \times \mathbb{R} \times \mathbb{R}_+), \\
k(y) &= \frac{1}{20}y_1^2 + 0 + 0 + 0
\end{align*}
$$

Since $X$ and $Y$ are now simple bound sets, (ENLP VI) is now a complementarity problem and can be solved for example using PATH. A simple "empinfo" file details the choices of $Y$ and $k$ from the implemented library:

Adjustequ
e1 sqr 5
e2 MaxZ 2
5.21.9.4 Reformulation as a classical NLP

Suppose

\[ \theta(u) = \sup_{y \in Y} \{ \langle u, y \rangle - \frac{1}{2} \langle y, Qy \rangle \} \]

for a polyhedral set \( Y \in \mathbb{R}^m \) and a symmetric positive semidefinite \( Q \in \mathbb{R}^{m \times m} \) (possibly \( Q = 0 \)).

Suppose further that

\[
X = \{ x | Rx \leq r \},
Y = \{ y | S^Ty \leq s \},
Q = DJ^{-1}D^T, \quad F(x) = (g_1(x), \ldots, g_m(x)),
\]

where \( J \) is symmetric and positive definite (for instance \( J = I \)). Then, as outlined by [154], the optimal solutions \( \bar{x} \) of (ENLP) are the \( \bar{x} \) components of the optimal solutions \((\bar{x}, \bar{z}, \bar{w})\) to

\[
\min f(x) + \langle s, z \rangle + \frac{1}{2} \langle w, Jw \rangle
\]

s.t. \( Rx \leq r, z \geq 0, F(x) - Sz - Dw = 0. \)

The multiplier on the equality constraint in the usual sense is the multiplier associated with \( \bar{x} \) in the extended Lagrangian for (ENLP). (Note that a Cholesky factorization may be needed to determine \( D \).)

It may be better to solve this reformulated NLP than to solve the VI (ENLP VI). However, it is important that we can convey all types of nonsmooth optimization problems to a solver as smooth optimization problems, and hence it is important to communicate the appropriate structure to the solver interface. We believe that specifying \( Y \) and \( k \) is a theoretically sound way to do this.

5.21.10 Disjunctive Programs (LogMIP)

There are many ways that the EMP model type can be used for further extensions to the modeling capabilities of a given system. In particular, the procedures outlined in [190] [73] for disjunctive programming extensions are also implemented within the EMP model type.

The disjunctive programming procedures are also known as the LogMIP 2.0 solver for solving linear and nonlinear disjunctive programming problems involving binary variables and disjunction definitions for modeling discrete choices. While the modeling and solution of these disjunctive optimization problems has not yet reached the stage of maturity and reliability as LP, MIP and NLP modeling, these problems have a rich area of applications.

LogMIP 2.0 has been developed by Dr. Aldo Vecchietti from INGAR (Santa Fe, Argentina) and Professor Ignacio E. Grossmann from Carnegie Mellon University (Pittsburgh, USA), and supersedes its previous version, LogMIP 1.0 (GAMS releases 22.6 (December 2007) to 23.6 (December 2010)). Changes in version 2.0 are at the level of language, where now the EMP syntax and mod-type is used, and at the level of solvers, where Big-M and convex-hull relaxations are combined. For more information see the website http://www.logmip.ceride.gov.ar/ and the documentation http://www.logmip.ceride.gov.ar/files/pdfs/newUserManual.pdf.

One simple example to highlight the disjunctive programming feature is the notion of an ordering of tasks, namely that either job \( i \) completes before job \( j \) starts or the converse, i.e., that the jobs cannot overlap. Such a disjunction can be specified using an empinfo file containing lines:

\[
\text{disjunction } \ast \text{ seq}(i,j) \text{ else seq}(j,i)
\]

In such an example, one can implement a Big-M method, employ indicator constraints, or utilize a convex hull reformulation. The convex hull reformulation is the default strategy; to utilize the Big-M formulation, the additional option
default bigm 1000

would add binary variables and constraints to impose the disjunction using a Big-M value of 1000. Alternatively, the option setting

default indic

writes out a model and an option file that implements a reformulation using indicator constraints, which can be handled by the solvers CPLEX, SCIP, and XPRESS. The EMPLIB model sequence is sequencing model that implements all of these options.

More complicated (nonlinear) examples make the utility of this approach clearer. The design of a multiproduct batch plan with intermediate storage described in [189] and a synthesis problem involving 8 processes from [186] are also included in the EMP model library. As a final example, the gasoline emission model outlined in [72] is precisely in the form that could exploit the features of EMP related to (nonlinear) disjunctive programming.

5.21.11 Empinfo file details

We have explained above many of the standard vectorized ways to write an "empinfo" file. The "empinfo" file has a vectorized format and a more powerful (but more complex) scalar version. We describe some of the features of the scalar version in this section.

An example of the use of the scalar syntax is given below

```plaintext
file info / '%emp.info%' /;
put info / 'equilibrium';
loop(h, 
   put / 'min' obj(h) /;
   loop(j, put x(h,j)); put /;
   loop(k, put z(h,k));
   put / costdef(h) /;
   loop(i, put nodebal(h,i)); put /;
);
loop(a, put 'vi',flowdef(a),f(a) /);
```

This is an example of a MOPEC in which the optimization agents are indexed by $h$ and each of these agents control variables $x_{hj}$ and $z_{hk}$. The objective function for each $h$ is defined in costdef, the constraints of each minimization problem are defined in nodebal, and the equilibrium constraints that link all the optimization problems are a VI defined by variables $f_a$ and functions within flowdef. Sometimes it is necessary to use syntax that generates the "tl" fields of sets, but this seems only necessary when abnormal side conditions are needed.

The format of the empinfo file is given below:

```
Disjunction [chull [big eps] | bigM [big eps threshold] | indic]
   [NOT] var|* [NOT] {equ} {ELSEIF [NOT] var|* [NOT] {equ}} [ELSE [NOT] {equ}]
Default [chull [big eps] | bigM [big eps threshold] | indic]
ParallelStep1 {equ|*}
AdjustEqu equ abs|sqr|maxz|... {weight}
```
5.22 KESTREL - Remote Solver Execution on NEOS Servers

5.22.1 Background

The Kestrel client/server is a way of sending your GAMS solve job to be solved via the NEOS Server from within your usual GAMS modeling environment and receiving results that can be processed as with any local solver. Starting with distribution 23.7 the Kestrel solver is part of the GAMS distribution. The solve statement using the GAMS/KESTREL solver invokes a client program that sends your problem to a solver running on one of the NEOS Server’s remote computers. The results from the NEOS Server are eventually returned through Kestrel to GAMS, where you can view and manipulate them locally in the usual way. The introduction below covers everything you need to know to start using GAMS/KESTREL. Further information about more advanced features and other uses of Kestrel can be found at the Kestrel page on the NEOS Server. Please also make you familiar with the NEOS optimization service terms of use before submitting jobs via GAMS/KESTREL.

5.22.2 Using GAMS/KESTREL

The Kestrel solver can be used to solve a GAMS model remotely. For example, consider the trnsport model. It can be solved locally in GAMS through the following statements,

```gams
model transport /all/;
solve transport using lp minimizing z;
```

which specify the trnsport model and solve it with the default linear programming solver. We can add an option statement to the code to explicitly specify the solver. For example, if we change the linear programming solver to GAMS/MINOS, the code becomes

```gams
model transport /all/;
option lp=minos;
solve transport using lp minimizing z;
```
To solve the same problem remotely through the NEOS Server, we simply change the linear programming solver to Kestrel. In addition we have to provide an email address. This can be specified either in an option file or by setting the environment variable NEOS_EMAIL. In order to set this permanently, it is recommended to add NEOS_EMAIL to your gamsconfig.yaml file.

Without an option file Kestrel will submit the model instance to the NEOS server and use the default LP solver on NEOS.

```gams
option lp=kestrel;
solve transport using lp minimizing z;
```

We can support a Kestrel option file and determine the solver on the NEOS server:

```gams
transport.optfile=1;
option lp=kestrel;
solve transport using lp minimizing z;
$echo email jdoe@jeangreyhigh.edu > kestrel.opt
$echo kestrel_solver minos >> kestrel.opt
```

The statement transport.optfile=1 specifies that an options file, called kestrel.opt, will be used. The options file contains the email address, the remote solver name as well as any options for the remote solver. We instruct the Kestrel solver to use GAMS/MINOS as the remote solver by writing the following kestrel.opt file:

```plaintext
email jdoe@jeangreyhigh.edu
kestrel_solver minos
```

If you do not know what solvers are available via GAMS/KESTREL on NEOS, submitting a job with a nonexistent solver set will return a list of enabled solvers. If you want to change the URL of the server, you can specify the option neos_server. The complete format of the parameter is protocol://host:port.

A subsequent run of the code through the GAMS interpreter results in the transport model being solved through the NEOS Server with the GAMS/MINOS solver. Once the job is submitted to the NEOS Server, a job number, password, and Web address are displayed to the screen, which provide information on accessing the job and viewing the intermediate output, for example,

--- Executing KESTREL
Job has been submitted to Kestrel
Kestrel/NEOS Job number : 93478
Kestrel/NEOS Job password : utiwtxTK
Check the following URL for progress report :
  https://neos-server.org/neos/cgi-bin/nph-neos-solver.cgi?admin=results&jobnumber=93478&pass=utiwtxTK

To look at the solver's output while it is running, point your browser at the URL given in the Kestrel output as shown above, and click on View Intermediate Results in the web page that appears. This will take you to another page that shows all of the output produced by the solver for your problem so far. To track the solver's progress, simply update this page periodically.

If the NEOS Server or the network becomes unavailable after the submission, a particular job can be retrieved by setting both the kestrel job and kestrel password in the options file.

```gams
kestrel_solver minos
kestrel_job 93478
kestrel_password utiwtxTK
```

Re-issuing the command gams transport with this options file will retrieve the results for the specified job number.

By specifying neos_username and neos_user_password in the option file, you can submit an authenticated job using your NEOS user account. Authenticated jobs will appear in your user account on the NEOS website.

```gams
neos_username username
neos_user_password password
```
Artelys Knitro is a software package for finding local solutions of both continuous (i.e. smooth) optimization problems, with or without constraints, and discrete optimization problems with integer or binary variables. Even though Knitro has been designed for solving large-scale general problems, it is efficient for solving all of the following classes of optimization problems:

- unconstrained,
- bound constrained,
- equality constrained,
- systems of nonlinear equations,
- least squares problems,
- linear programming problems (LPs),
- quadratic programming problems (QPs),
- general (inequality) constrained problems,
- (convex) mixed integer nonlinear programs (MINLP) of moderate size.

The Knitro package provides the following features:

- Efficient and robust solution of small or large problems,
- Solvers for both continuous and discrete problems,
- Derivative-free, 1st derivative and 2nd derivative options,
- Both interior-point (barrier) and active-set optimizers,
- Both feasible and infeasible versions,
- Both iterative and direct approaches for computing steps,

The problems solved by Knitro have the form

\[
\begin{align*}
\text{minimize} & \quad f(x) \\
\text{subject to} & \quad c^L \leq c(x) \leq c^U \\
& \quad b^L \leq x \leq b^U,
\end{align*}
\]

where the variables \(x\) can be continuous, binary, or integer. This allows many forms of constraints, including bounds on the variables. Knitro requires that the functions \(f(x)\) and \(c(x)\) be smooth functions.

Knitro implements both state-of-the-art interior-point and active-set methods for solving nonlinear optimization problems. In the interior method (also known as a barrier method), the nonlinear programming problem is replaced by a series of barrier sub-problems controlled by a barrier parameter \(\mu\). The algorithm uses trust regions and a merit function to promote convergence. The algorithm performs one or more minimization steps on each barrier problem, then decreases the barrier parameter, and repeats the process until the original problem (1) has been solved to the desired accuracy.
Knitro provides two procedures for computing the steps within the interior point approach. In the version known as Interior/CG each step is computed using a projected conjugate gradient iteration. This approach differs from most interior methods proposed in the literature in that it does not compute each step by solving a linear system involving the KKT (or primal-dual) matrix. Instead, it factors a projection matrix, and uses the conjugate gradient method, to approximately minimize a quadratic model of the barrier problem.

The second procedure for computing the steps, which we call Interior/Direct, always attempts to compute a new iterate by solving the primal-dual KKT matrix using direct linear algebra. In the case when this step cannot be guaranteed to be of good quality, or if negative curvature is detected, then the new iterate is computed by the Interior/CG procedure.

Knitro also implements an active-set sequential linear-quadratic programming (SLQP) algorithm which we call Active. This method is similar in nature to a sequential quadratic programming method but uses linear programming sub-problems to estimate the active-set at each iteration. This active-set code may be preferable when a good initial point can be provided, for example, when solving a sequence of related problems.

For problems with discrete variables, Knitro provides two variants of the branch and bound algorithm. The first is a standard implementation, while the second is specialized for convex, mixed-integer nonlinear problems.

We encourage the user to try all algorithmic options to determine which one is more suitable for the application at hand. For guidance on choosing the best algorithm see section Algorithm Options.

For a detailed description of the algorithm implemented in Interior/CG see [30] and for the global convergence theory see [31]. The method implemented in Interior/Direct is described in [198]. The Active algorithm is described in [33] and the global convergence theory for this algorithm is in [34]. An important component of Knitro is the HSL routine MA27 [92] which is used to solve the linear systems arising at every iteration of the algorithm. In addition, the Active Set algorithm in Knitro may make use of the COIN-OR Clp linear programming solver module. The version used in Knitro may be downloaded from http://www.artelys.com/tools/clp/.

5.23.2 Usage

Basic details of solver usage, including how to choose Knitro as the solver and how to use a solver-specific option file, are part of Chapter Solver Usage.

As an NLP solver, Knitro can also be used to solve linear programs (LP), and both convex and nonconvex quadratic programs (QCP).

5.23.3 GAMS Options

The following GAMS options are used by the GAMS/Knitro link:

- Option ResLim = x;
  Sets the time limit in seconds. If this limit is exceeded the solver will terminate and pass on the current solution to GAMS. See also reslim in section GAMS options.

- Option SysOut = On;
  This option sends additional Knitro messages to the GAMS listing file. It is useful in case of a solver failure or to get algorithmic details. See also sysout in section GAMS options.

- ModelName.optCA = x;
  Absolute gap stop criterion for a discrete problem. The Knitro option mip_opt_gap_abs takes its default from this value. See also optca in section GAMS options.

- ModelName.optCR = x;
  Relative gap stop criterion for a discrete problem. The Knitro option mip_opt_gap_rel takes its default from this value. See also optcr in section GAMS options.
5.23 KNITRO

5.23.4 Summary of Knitro Options

The Knitro options file `knitro.opt` allows the user to easily set options controlling Knitro’s behavior. Options are set by specifying a keyword and a corresponding value on a line in the `knitro.opt` file. Lines that begin with a `#` character are treated as comments and blank lines are ignored. For example, to set the maximum allowable number of iterations to 500, one could use the following options file:

```plaintext
maxit 500
```

5.23.4.1 General options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>algorithm</code></td>
<td>Indicates which algorithm to use to solve the problem</td>
<td>0</td>
</tr>
<tr>
<td><code>blasoption</code></td>
<td>Specifies the BLAS/LAPACK function library to use for basic vector and matrix computations</td>
<td>1 or 4 (platform dependent)</td>
</tr>
<tr>
<td><code>blasoptionlib</code></td>
<td>Specifies a dynamic library name that contains object code for BLAS/LAPACK functions</td>
<td></td>
</tr>
<tr>
<td><code>bndrange</code></td>
<td>Specifies max limits on the magnitude of constraint and variable bounds</td>
<td>1e+20</td>
</tr>
<tr>
<td><code>cg.maxit</code></td>
<td>Determines the maximum allowable number of inner conjugate gradient (CG) iterations per Knitro minor iteration</td>
<td>-1</td>
</tr>
<tr>
<td><code>cg.pmem</code></td>
<td>Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner</td>
<td>10</td>
</tr>
<tr>
<td><code>cg.precond</code></td>
<td>Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms</td>
<td>0</td>
</tr>
<tr>
<td><code>cg.stoptol</code></td>
<td>Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves</td>
<td>0.01</td>
</tr>
<tr>
<td><code>convex</code></td>
<td>Declare the problem as convex by setting to 1 or non-convex by setting to 0</td>
<td>-1</td>
</tr>
<tr>
<td><code>cpuplatform</code></td>
<td>This option can be used to specify the target instruction set architecture for the machine on which Knitro is running</td>
<td>-1</td>
</tr>
<tr>
<td><code>datacheck</code></td>
<td>Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure)</td>
<td>0</td>
</tr>
<tr>
<td><code>delta</code></td>
<td>Specifies the initial trust region radius scaling factor used to determine the initial trust region size</td>
<td>1</td>
</tr>
<tr>
<td><code>honorbnds</code></td>
<td>Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization</td>
<td>-1</td>
</tr>
<tr>
<td><code>initpenalty</code></td>
<td>Specifies the initial penalty parameter used in the Knitro merit functions</td>
<td>10</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>initvalues</td>
<td>Enable use of initial guess for levels and marginals (subsequent solves)</td>
<td>1</td>
</tr>
<tr>
<td>initvalues0</td>
<td>Enable use of initial guess for levels and marginals (first solve)</td>
<td>2</td>
</tr>
<tr>
<td>linesearch</td>
<td>Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate</td>
<td>0</td>
</tr>
<tr>
<td>linesearch_maxtrials</td>
<td>Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step</td>
<td>3</td>
</tr>
<tr>
<td>linsolver</td>
<td>Indicates which linear solver to use to solve linear systems arising in Knitro algorithms</td>
<td>0</td>
</tr>
<tr>
<td>linsolver_maxitref</td>
<td>Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro</td>
<td>2</td>
</tr>
<tr>
<td>linsolver_ooc</td>
<td>Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when linsolver = mklpardiso</td>
<td>0</td>
</tr>
<tr>
<td>linsolver_pivottol</td>
<td>Specifies the initial pivot threshold used in factorization routines</td>
<td>1e-08</td>
</tr>
<tr>
<td>names</td>
<td>Enable to pass variable and equation names to Knitro</td>
<td>0</td>
</tr>
<tr>
<td>ncvx_qcqp_init</td>
<td>Specifies the initialization strategy used for non-convex QPs and QCQPs</td>
<td>-1</td>
</tr>
<tr>
<td>newpoint</td>
<td>Specifies additional action to take after every iteration in a solve of a continuous problem</td>
<td>0</td>
</tr>
<tr>
<td>objrange</td>
<td>Specifies the extreme limits of the objective function for purposes of determining unboundedness</td>
<td>1e+20</td>
</tr>
<tr>
<td>option_file</td>
<td>additional option file name - read only by KNITRO solver lib</td>
<td></td>
</tr>
<tr>
<td>output_time</td>
<td>print output on where time is used</td>
<td>0</td>
</tr>
<tr>
<td>presolve</td>
<td>Determine whether or not to use the Knitro presolver to try to simplify the model by removing variables or constraints</td>
<td>1</td>
</tr>
<tr>
<td>presolveop_redundant</td>
<td>Determine whether or not to enable the Knitro presolve operation to detect and remove redundant constraints</td>
<td>1</td>
</tr>
<tr>
<td>presolveop_tighten</td>
<td>Determine whether or not to enable the Knitro presolve operation to tighten variable bounds or coefficients</td>
<td>-1</td>
</tr>
<tr>
<td>presolve_initpt</td>
<td>Control whether the Knitro presolver can shift a user-supplied initial point</td>
<td>-1</td>
</tr>
<tr>
<td>presolve_level</td>
<td>Set the level of presolve operations to enable through the Knitro presolver</td>
<td>-1</td>
</tr>
<tr>
<td>presolve_passes</td>
<td>Set a maximum limit on the number of passes through the Knitro presolve operations</td>
<td>10</td>
</tr>
</tbody>
</table>
5.23 KNITRO

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>presolve_tol</td>
<td>Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model</td>
<td>1e-06</td>
</tr>
<tr>
<td>qextractalg</td>
<td>quadratic extraction algorithm in GAMS interface</td>
<td>0</td>
</tr>
<tr>
<td>restarts</td>
<td>Specifies whether or not to enable automatic restarts in Knitro</td>
<td>-1</td>
</tr>
<tr>
<td>restarts_maxit</td>
<td>When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart</td>
<td>0</td>
</tr>
<tr>
<td>scale</td>
<td>Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables</td>
<td>1</td>
</tr>
<tr>
<td>soc</td>
<td>Specifies whether or not to try second order corrections (SOC)</td>
<td>1</td>
</tr>
<tr>
<td>strat_warm_start</td>
<td>Specifies whether or not to invoke a warm-start strategy</td>

5.23.4.2 Derivative options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>bfgs_scaling</td>
<td>Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation</td>
<td>0</td>
</tr>
<tr>
<td>findiff_estnoise</td>
<td>This option can be used to enable an estimate of the noise in the model when using finite-difference gradients</td>
<td>0</td>
</tr>
<tr>
<td>findiff_relstepsise</td>
<td>Specifies the relative stepsize used for finite-difference gradients during the optimization</td>
<td>0</td>
</tr>
<tr>
<td>findiff_terminate</td>
<td>This option specifies the termination criteria when using finite-difference gradients</td>
<td>1</td>
</tr>
<tr>
<td>gradopt</td>
<td>Specifies how to compute the gradients of the objective and constraint functions</td>
<td>1</td>
</tr>
<tr>
<td>hessopt</td>
<td>Specifies how to compute the (approximate) Hessian of the Lagrangian</td>
<td>0</td>
</tr>
<tr>
<td>lmsize</td>
<td>Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option</td>
<td>10</td>
</tr>
</tbody>
</table>

5.23.4.3 Termination options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>feastol</td>
<td>Specifies the final relative stopping tolerance for the feasibility error</td>
<td>1e-06</td>
</tr>
<tr>
<td>feastolabs</td>
<td>Specifies the final absolute stopping tolerance for the feasibility error</td>
<td>0.001</td>
</tr>
<tr>
<td>fstopval</td>
<td>Used to implement a custom stopping condition based on the objective function value</td>
<td>maxdouble</td>
</tr>
<tr>
<td>ftol</td>
<td>The optimization process will terminate if the relative change in the objective function is less than ftol for ftol_iters consecutive feasible iterations</td>
<td>1e-15</td>
</tr>
<tr>
<td>ftol_iters</td>
<td>The optimization process will terminate if the relative change in the objective function is less than ftol for ftol_iters consecutive feasible iterations</td>
<td>5</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>infeastol</td>
<td>Specifies the (relative) tolerance used for declaring infeasibility of a model</td>
<td>1e-08</td>
</tr>
<tr>
<td>infeastol_iters</td>
<td>The optimization process will terminate if the relative change in the feasibility error is less than infeastol for infeastol_iters consecutive infeasible iterations</td>
<td>50</td>
</tr>
<tr>
<td>maxfevals</td>
<td>Specifies the maximum number of function evaluations before termination</td>
<td>-1</td>
</tr>
<tr>
<td>maxit</td>
<td>Specifies the maximum number of iterations before termination</td>
<td>GAMS iterlim</td>
</tr>
<tr>
<td>maxtime_cpu</td>
<td>Specifies, in seconds, the maximum allowable CPU time before termination</td>
<td>10000000</td>
</tr>
<tr>
<td>maxtime_real</td>
<td>Specifies, in seconds, the maximum allowable real time before termination</td>
<td>GAMS reslim</td>
</tr>
<tr>
<td>opttol</td>
<td>Specifies the final relative stopping tolerance for the KKT (optimality) error</td>
<td>1e-06</td>
</tr>
<tr>
<td>opttolabs</td>
<td>Specifies the final absolute stopping tolerance for the KKT (optimality) error</td>
<td>0.001</td>
</tr>
<tr>
<td>xtol</td>
<td>The optimization process will terminate if the relative change in all components of the solution point estimate is less than xtol for xtol_iters</td>
<td>1e-12</td>
</tr>
<tr>
<td>xtol_iters</td>
<td>The optimization process will terminate if the relative change in the solution estimate is less than xtol for xtol_iters consecutive iterations</td>

</tbody>
</table>

5.23.4.4 Barrier options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar_conic_enable</td>
<td>Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm)</td>
<td>-1</td>
</tr>
<tr>
<td>bar_directinterval</td>
<td>Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra</td>
<td>-1</td>
</tr>
<tr>
<td>bar_feasible</td>
<td>Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms</td>
<td>0</td>
</tr>
<tr>
<td>bar_feasmodetol</td>
<td>Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible</td>
<td>0.0001</td>
</tr>
<tr>
<td>bar_initmu</td>
<td>Specifies the initial value for the barrier parameter $\mu$ used with the barrier algorithms</td>
<td>-1</td>
</tr>
<tr>
<td>bar_initpi_mpec</td>
<td>Specifies the initial value for the MPEC penalty parameter $\pi$ used when solving problems with complementarity constraints using the barrier algorithms</td>
<td>0</td>
</tr>
<tr>
<td>bar_initpt</td>
<td>Indicates initial point strategy for $x$, slacks and multipliers when using a barrier algorithm</td>
<td>0</td>
</tr>
<tr>
<td>bar_linsys</td>
<td>Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps</td>
<td>-1</td>
</tr>
<tr>
<td>bar_linsys_storage</td>
<td>Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps</td>
<td>-1</td>
</tr>
<tr>
<td>bar_maxcorrectors</td>
<td>Specifies the maximum number of corrector steps allowed for primal-dual steps</td>
<td>-1</td>
</tr>
<tr>
<td>bar_maxcrosst</td>
<td>Specifies the maximum number of crossover iterations before termination</td>
<td>0</td>
</tr>
<tr>
<td>bar_maxrefactor</td>
<td>Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step</td>
<td>-1</td>
</tr>
</tbody>
</table>
### 5.23.4.5 Active-set options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>act_lpfeastol</td>
<td>Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms</td>
<td>1e-08</td>
</tr>
<tr>
<td>act_lppenalty</td>
<td>Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms</td>
<td>1</td>
</tr>
<tr>
<td>act_lppresolve</td>
<td>Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms</td>
<td>0</td>
</tr>
<tr>
<td>act_parametric</td>
<td>Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms</td>
<td>1</td>
</tr>
<tr>
<td>act_qpalg</td>
<td>Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms</td>
<td>0</td>
</tr>
<tr>
<td>act_qppenalty</td>
<td>Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm</td>
<td>-1</td>
</tr>
</tbody>
</table>

### 5.23.4.6 MIP options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>mip_branchrule</td>
<td>Specifies which branching rule to use for MIP branch and bound procedure</td>
<td>0</td>
</tr>
<tr>
<td>mip_clique</td>
<td>Specifies rules for adding clique cuts</td>
<td>-1</td>
</tr>
<tr>
<td>mip_cutfactor</td>
<td>This value specifies a limit on the number of cuts added to a node subproblem</td>
<td>1</td>
</tr>
<tr>
<td>mip_cutoff</td>
<td>This value specifies the objective cutoff value for MIP</td>
<td>maxdouble</td>
</tr>
<tr>
<td>mip_cutting_plane</td>
<td>Specifies when to apply the cutting plane procedure</td>
<td>1</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td><code>mip_gomory</code></td>
<td>Specifies rules for adding Gomory mixed-integer cuts</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_gub_branch</code></td>
<td>Specifies whether or not to branch on generalized upper bounds (GUBs)</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_heuristic_diving</code></td>
<td>Specifies whether or not to enable the MIP diving heuristic</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_feaspump</code></td>
<td>Specifies whether or not to enable the MIP feasibility pump heuristic</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_lns</code></td>
<td>Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_maxit</code></td>
<td>Specifies the maximum number of iterations to allow for MIP heuristic, if one is enabled</td>
<td>100</td>
</tr>
<tr>
<td><code>mip_heuristic_misqp</code></td>
<td>Specifies whether or not to enable the MIP MISQP heuristic</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_mpec</code></td>
<td>Specifies whether or not to enable the MIP MPEC heuristic</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_strategy</code></td>
<td>Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_terminate</code></td>
<td>Specifies the condition for terminating the MIP heuristic</td>
<td>1</td>
</tr>
<tr>
<td><code>mip_implications</code></td>
<td>Specifies whether or not to add constraints to the MIP derived from logical implications</td>
<td>1</td>
</tr>
<tr>
<td><code>mip_integer_tol</code></td>
<td>This value specifies the threshold for deciding whether or not a variable is determined to be an integer</td>
<td>1e-08</td>
</tr>
<tr>
<td><code>mip_intvar_strategy</code></td>
<td>Specifies how to handle integer variables</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_knapsack</code></td>
<td>Specifies rules for adding MIP knapsack cuts</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_liftproject</code></td>
<td>Specifies rules for adding lift and project cuts</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_lalg</code></td>
<td>Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch-and-bound procedure</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_maxnodes</code></td>
<td>Specifies the maximum number of nodes explored (0 means no limit)</td>
<td>GAMS nodlim</td>
</tr>
<tr>
<td><code>mip_maxsolves</code></td>
<td>Specifies the maximum number of subproblem solves allowed (0 means no limit)</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_maxtime_cpu</code></td>
<td>Specifies the maximum allowable CPU time in seconds for the complete MIP solution</td>
<td>100000000</td>
</tr>
<tr>
<td><code>mip_maxtime_real</code></td>
<td>Specifies the maximum allowable real time in seconds for the complete MIP solution</td>
<td>GAMS reslim</td>
</tr>
<tr>
<td><code>mip_method</code></td>
<td>Specifies which MIP method to use</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_mir</code></td>
<td>Specifies rules for adding mixed-integer rounding cuts</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_multistart</code></td>
<td>Use to enable MIP multi-start at the branch-and-bound level</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_nodealg</code></td>
<td>Specifies which algorithm to use for standard node subproblem solves in MIP (same options as <code>algorithm</code> user option)</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_numthreads</code></td>
<td>Specify the number of threads to use for MIP branch-and-bound (when <code>mip_method</code> = 1)</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_opt_gap_abs</code></td>
<td>The absolute optimality gap stop tolerance for MIP</td>
<td>GAMS optca</td>
</tr>
<tr>
<td><code>mip_opt_gap_rel</code></td>
<td>The relative optimality gap stop tolerance for MIP</td>
<td>GAMS optcr</td>
</tr>
</tbody>
</table>
### 5.23 KNITRO

#### 5.23.4.7 Multi-algorithm options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ma_maxtime_cpu</td>
<td>Specifies, in seconds, the maximum allowable CPU time before termination for the multi-algorithm (&quot;MA&quot;) procedure (algorithm=5)</td>
<td>100000000</td>
</tr>
<tr>
<td>ma_maxtime_real</td>
<td>Specifies, in seconds, the maximum allowable real time before termination for the multi-algorithm (&quot;MA&quot;) procedure (algorithm=5)</td>
<td>100000000</td>
</tr>
<tr>
<td>ma_outsub</td>
<td>Enable writing algorithm output to files for the multi-algorithm (algorithm=5) procedure</td>
<td>0</td>
</tr>
<tr>
<td>ma_terminate</td>
<td>Define the termination condition for the multi-algorithm (algorithm=5) procedure</td>
<td>1</td>
</tr>
</tbody>
</table>

#### 5.23.4.8 Multi-start options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ms_deterministic</td>
<td>Indicates whether Knitro multi-start procedure will be deterministic (when ms_terminate = 0)</td>
<td>1</td>
</tr>
<tr>
<td>ms_enable</td>
<td>Indicates whether Knitro will solve from multiple start points to find a better local minimum</td>
<td>0</td>
</tr>
<tr>
<td>ms_maxbndrange</td>
<td>Specifies the maximum range that an unbounded variable can take when determining new start points</td>
<td>10000</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>ms_maxsolves</td>
<td>Specifies how many start points to try in multi-start</td>
<td>0</td>
</tr>
<tr>
<td>ms_maxtime_cpu</td>
<td>Specifies, in seconds, the maximum allowable CPU time before termination</td>
<td>100000000</td>
</tr>
<tr>
<td>ms_maxtime_real</td>
<td>Specifies, in seconds, the maximum allowable real time before termination</td>
<td>100000000</td>
</tr>
<tr>
<td>ms_numthreads</td>
<td>Specify the number of threads to use for multi-start (when ms_enable = 1)</td>
<td>0</td>
</tr>
<tr>
<td>ms_num_to_save</td>
<td>Specifies the number of distinct feasible points to save in a file named knitro_mspoints</td>
<td>0</td>
</tr>
<tr>
<td>ms_outsub</td>
<td>Enable writing algorithm output to files for the parallel multi-start procedure</td>
<td>0</td>
</tr>
<tr>
<td>ms_savetol</td>
<td>Specifies the tolerance for deciding if two feasible points are distinct</td>
<td>1e-06</td>
</tr>
<tr>
<td>ms_seed</td>
<td>Seed value used to generate random initial points in multi-start; should be a non-negative integer</td>
<td>0</td>
</tr>
<tr>
<td>ms_startprange</td>
<td>Specifies the maximum range that each variable can take when determining new start points</td>
<td>1e+20</td>
</tr>
<tr>
<td>ms_terminate</td>
<td>Specifies the condition for terminating multi-start</td>
<td>0</td>
</tr>
</tbody>
</table>

5.23.4.9 Parallelism options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>blas_numthreads</td>

5.23.5 Detailed Descriptions of Knitro Options

**act_lpfeasol** *(real)*: Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms

- **Range:** \([0, \infty]\)
- **Default:** \(1e^{-08}\)

**act_lppenalty** *(integer)*: Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms

- **Default:** 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(all) penalize all constraints.</td>
</tr>
<tr>
<td>2</td>
<td>(nonlinear) penalize only nonlinear constraints.</td>
</tr>
<tr>
<td>3</td>
<td>(dynamic) dynamically choose which constraints to penalize.</td>
</tr>
</tbody>
</table>

**act_lppresolve** *(boolean)*: Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms

- **Default:** 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(off) presolve turned off for LP subproblems.</td>
</tr>
<tr>
<td>1</td>
<td>(on) presolve turned on for LP subproblems.</td>
</tr>
</tbody>
</table>

**act_parametric** *(integer)*: Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms

Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms. A parametric approach will solve a sequence of closely related LPs instead of one LP. It may increase the cost of an active-set iteration, but perhaps lead to convergence in fewer iterations.
Default: 1
### act_qpalg (integer):
Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) do not use a parametric solve (i.e. solve a single LP).</td>
</tr>
<tr>
<td>1</td>
<td>(maybe) use a parametric solve sometimes.</td>
</tr>
<tr>
<td>2</td>
<td>(yes) always try a parametric solve.</td>
</tr>
</tbody>
</table>

Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms. This option has no effect on the Interior/Direct and Interior/CG algorithms.

Default: 0

### act_qppenalty (integer):
Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) let Knitro automatically decide.</td>
</tr>
<tr>
<td>0</td>
<td>(none) do not penalize constraints in QP subproblems.</td>
</tr>
<tr>
<td>1</td>
<td>(all) penalize all constraints in QP subproblems.</td>
</tr>
</tbody>
</table>

Default: -1

### algorithm (integer):
Indicates which algorithm to use to solve the problem

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) let Knitro automatically choose an algorithm, based on the problem characteristics.</td>
</tr>
<tr>
<td>1</td>
<td>(direct) use the Interior/Direct algorithm.</td>
</tr>
<tr>
<td>2</td>
<td>(cg) use the Interior/CG algorithm.</td>
</tr>
<tr>
<td>3</td>
<td>(active) use the Active Set algorithm.</td>
</tr>
<tr>
<td>4</td>
<td>(sqp) use the SQP algorithm.</td>
</tr>
<tr>
<td>5</td>
<td>(multi) run all algorithms, perhaps in parallel (see Algorithms).</td>
</tr>
</tbody>
</table>

Default: 0

### bar_conic_enable (integer):
Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm)

Default: -1
\begin{tabular}{|c|l|}
\hline
value & meaning \\
\hline
-1 & (auto) Let Knitro automatically choose the strategy. \\
0 & (none) Do not apply any special treatment for conic constraints. \\
1 & (soc) Apply special treatments for any Second Order Cone (SOC) constraints identified in the model. \\
\hline
\end{tabular}

bar\_directinterval (integer): Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra

Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra. This option is only valid for the Interior/Direct algorithm and may be useful on problems where Knitro appears to be taking lots of conjugate gradient steps. Setting bar\_directinterval to 0 will try to enforce that only direct steps are taken which may produce better results on some problems.

Range: \{−1, ..., ∞\}

Default: -1

bar\_feasible (integer): Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms

Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms. Note This option can only be used with the Interior/Direct and Interior/CG algorithms. If bar\_feasible = stay or bar\_feasible = get\_stay, this will activate the feasible version of Knitro. The feasible version of Knitro will force iterates to strictly satisfy inequalities, but does not require satisfaction of equality constraints at intermediate iterates. This option and the honorbnds option may be useful in applications where functions are undefined outside the region defined by inequalities. The initial point must satisfy inequalities to a sufficient degree; if not, Knitro may generate infeasible iterates and does not switch to the feasible version until a sufficiently feasible point is found. Sufficient satisfaction occurs at a point x if it is true for all inequalities that \( cl + tol \leq c(x) \leq cu - tol \) The constant tol is determined by the option bar\_feasmodetol. If bar\_feasible = get or bar\_feasible = get\_stay, Knitro will place special emphasis on first trying to get feasible before trying to optimize.

Default: 0

\begin{tabular}{|c|l|}
\hline
value & meaning \\
\hline
0 & (no) No special emphasis on feasibility. \\
1 & (stay) Iterates must satisfy inequality constraints once they become sufficiently feasible. \\
2 & (get) Special emphasis is placed on getting feasible before trying to optimize. \\
3 & (get\_stay) Implement both options 1 and 2 above. \\
\hline
\end{tabular}

bar\_feasmodetol (real): Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible

Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible. The tolerance applies to all inequality constraints in the problem. This option only has an effect if option bar\_feasible = stay or bar\_feasible = get\_stay.

Range: \([0, \infty]\)

Default: 0.0001
**bar_initmu** *(real)*: Specifies the initial value for the barrier parameter $\mu$ used with the barrier algorithms.

Specifies the initial value for the barrier parameter $\mu$ used with the barrier algorithms. This option has no effect on the Active Set algorithm.

Range: $[-\infty, \infty]$  
Default: $-1$

**bar_initpi_mpec** *(real)*: Specifies the initial value for the MPEC penalty parameter $\pi$ used when solving problems with complementarity constraints using the barrier algorithms.

Specifies the initial value for the MPEC penalty parameter $\pi$ used when solving problems with complementarity constraints using the barrier algorithms. If this value is non-positive, then Knitro uses an internal formula to initialize the MPEC penalty parameter.

Range: $[0, \infty]$  
Default: $0$

**bar_initpt** *(integer)*: Indicates initial point strategy for $x$, slacks and multipliers when using a barrier algorithm.

Indicates initial point strategy for $x$, slacks and multipliers when using a barrier algorithm. Note, this option only alters the initial $x$ values if the user does not specify an initial $x$. This option has no effect on the Active Set algorithm.

Default: $0$

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(convex) Initialization designed for convex models.</td>
</tr>
<tr>
<td>2</td>
<td>(nearbnd) Initialization strategy that stays closer to the bounds.</td>
</tr>
<tr>
<td>3</td>
<td>(central) Initialization strategy that is more central on double-bounded variables.</td>
</tr>
</tbody>
</table>

**bar_linsys** *(integer)*: Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps.

Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps. Eliminating more elements results in a smaller dimensional linear system (but also one that is, perhaps, less numerically stable). The bounds option may be preferable for very large problems with many bounded variables. The ineq option may generate significant speedups on models where the number of variables is small, but the number of inequality constraints is large.

Default: $-1$

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose the linear system form.</td>
</tr>
<tr>
<td>0</td>
<td>(full) Use the full linear system.</td>
</tr>
<tr>
<td>1</td>
<td>(slacks) Eliminate the slack variables.</td>
</tr>
<tr>
<td>2</td>
<td>(bounds) Eliminate the slack variables and bounds.</td>
</tr>
<tr>
<td>3</td>
<td>(ineqs) Eliminate the slack variables, bounds, and some inequalities.</td>
</tr>
</tbody>
</table>
**bar_linsys_storage** (*integer*): Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps

Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps. The lowmem option uses one storage location for multiple linear systems. As a result it may use much less memory, but also may be less efficient when the Interior/Direct algorithm takes a lot of CG steps. The normal option uses separate storage for different linear systems.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(lowmem) Use common storage for multiple linear systems.</td>
</tr>
<tr>
<td>2</td>
<td>(normal) Use separate storage for different linear systems.</td>
</tr>
</tbody>
</table>

**bar_maxcorrectors** (*integer*): Specifies the maximum number of corrector steps allowed for primal-dual steps

Specifies the maximum number of corrector steps allowed for primal-dual steps. If the value is positive and the algorithm used is Interior/Direct, then Knitro may add at most *bar_maxcorrectors* corrector steps to the primal-dual step to try to stay closer to the central path. This may speedup convergence on some models (although it may make the cost per iteration a little more expensive). If the value is negative, Knitro automatically determines the maximum number of corrector steps to apply.

Range: \([-\infty, ..., \infty]\)

Default: -1

**bar_maxcrossit** (*integer*): Specifies the maximum number of crossover iterations before termination

Specifies the maximum number of crossover iterations before termination. If the value is positive and the algorithm in operation is Interior/Direct or Interior/CG, then Knitro will crossover to the Active Set algorithm near the solution. The Active Set algorithm will then perform at most *bar_maxcrossit* iterations to get a more exact solution. If the value is 0, no Active Set crossover occurs and the interior-point solution is the final result. If Active Set crossover is unable to improve the approximate interior-point solution, then Knitro will restore the interior-point solution. In some cases (especially on large-scale problems or difficult degenerate problems) the cost of the crossover procedure may be significant – for this reason, crossover is disabled by default. Enabling crossover generally provides a more accurate solution than Interior/Direct or Interior/CG.

Range: \([0, ..., \infty]\)

Default: 0

**bar_maxrefactor** (*integer*): Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step

Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step. If this value is set to -1, it will use a dynamic strategy. These refactorizations are performed if negative curvature is detected in the model. Rather than reverting to a CG step, the Hessian matrix is modified in an attempt to make the subproblem convex and then the KKT system is refactored. Increasing this value will make the Interior/Direct algorithm less likely to take CG steps. If the Interior/Direct
algorithm is taking a large number of CG steps (as indicated by a positive value for “CGits” in the output), this may improve performance. This option has no effect on the Active Set algorithm.

Range: \{-1, ..., \infty\}

Default: \(-1\)

**bar_mpec_heuristic (boolean):** Specifies whether or not to use a heuristic approach when solving MPEC models with the barrier algorithm

Specifies whether or not to use a heuristic approach when solving MPEC models with the barrier algorithm. In some cases enabling this heuristic can speed up the convergence to the solution and provide a more precise solution on MPEC models (i.e., models with complementarity constraints).

Default: \(0\)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not enable the heuristic for MPEC models.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Enable the heuristic for MPEC models.</td>
</tr>
</tbody>
</table>

**bar_murule (integer):** Indicates which strategy to use for modifying the barrier parameter \(\mu\) in the barrier algorithms

Indicates which strategy to use for modifying the barrier parameter \(\mu\) in the barrier algorithms. Not all strategies are available for both barrier algorithms, as described below. This option has no effect on the Active Set algorithm.

Default: \(0\)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(monotone) Monotonically decrease the barrier parameter. Available only for both barrier algorithms.</td>
</tr>
<tr>
<td>2</td>
<td>(adaptive) Use an adaptive rule based on the complementarity gap to determine the value of the barrier parameter. Available only for both barrier algorithms.</td>
</tr>
<tr>
<td>3</td>
<td>(probing) Use a probing (affine-scaling) step to dynamically determine the barrier parameter. Available only for the Interior/Direct algorithm.</td>
</tr>
<tr>
<td>4</td>
<td>(dampmpc) Use a Mehrotra predictor-corrector type rule to determine the barrier parameter, with safeguards on the corrector step. Available only for the Interior/Direct algorithm.</td>
</tr>
<tr>
<td>5</td>
<td>(fullmpc) Use a Mehrotra predictor-corrector type rule to determine the barrier parameter, without safeguards on the corrector step. Available only for the Interior/Direct algorithm.</td>
</tr>
<tr>
<td>6</td>
<td>(quality) Minimize a quality function at each iteration to determine the barrier parameter. Available only for the Interior/Direct algorithm.</td>
</tr>
</tbody>
</table>

**bar_penaltycons (integer):** Indicates whether a penalty approach is applied to the constraints

Indicates whether a penalty approach is applied to the constraints. Using a penalty approach may be helpful when the problem has degenerate or difficult constraints. It may also help
to more quickly identify infeasible problems, or achieve feasibility in problems with difficult
constraints. This option has no effect on the Active Set algorithm.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>0</td>
<td>(none) No constraints are penalized.</td>
</tr>
<tr>
<td>2</td>
<td>(all) A penalty approach is applied to all general constraints.</td>
</tr>
<tr>
<td>3</td>
<td>(equalities) Apply a penalty approach to equality constraints only.</td>
</tr>
</tbody>
</table>

**bar_penaltyrule (integer):** Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate

Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate. This option has no effect on the Active Set algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(single) Use a single penalty parameter in the merit function to weight feasibility versus optimality.</td>
</tr>
<tr>
<td>2</td>
<td>(flex) Use a more tolerant and flexible step acceptance procedure based on a range of penalty parameter values.</td>
</tr>
</tbody>
</table>

**bar_refinement (boolean):** Specifies whether to try to refine the barrier solution for better precision

Specifies whether to try to refine the barrier solution for better precision. If enabled, once the optimality conditions are satisfied, Knitro will apply an additional refinement/postsolve phase to try to obtain more precision in the barrier solution. The effect is similar to the effect of enabling **bar_maxcrossit**, but it is usually much more efficient since it does not involve switching to the Active Set algorithm.

Default: 0

**bar_relaxcons (integer):** Indicates whether a relaxation approach is applied to the constraints

Indicates whether a relaxation approach is applied to the constraints. Using a relaxation approach may be helpful when the problem has degenerate or difficult constraints. This option has no effect on the Active Set algorithm.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) No constraints are relaxed.</td>
</tr>
<tr>
<td>1</td>
<td>(eqs) A relaxation approach is applied to general equality constraints.</td>
</tr>
<tr>
<td>2</td>
<td>(ineqs) A relaxation approach is applied to general inequality constraints.</td>
</tr>
<tr>
<td>3</td>
<td>(all) A relaxation approach is applied to all general constraints.</td>
</tr>
</tbody>
</table>

**bar_slackboundpush (real):** Specifies the amount by which the barrier slack variables are initially
pushed inside the bounds

Specifies the amount by which the barrier slack variables are initially pushed inside the bounds. A smaller value may be preferable when warm-starting from a point close to the solution.

Range: \([-\infty, \infty]\]

Default: \(-1\)

**bar switchobj** (integer): Indicates which objective function to use when the barrier algorithms switch to a pure feasibility phase

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) No (or zero) objective.</td>
</tr>
<tr>
<td>1</td>
<td>(scalarprox) Proximal point objective with scalar weighting.</td>
</tr>
<tr>
<td>2</td>
<td>(diagprox) Proximal point objective with diagonal weighting.</td>
</tr>
</tbody>
</table>

**bar switchrule** (integer): Indicates whether or not the barrier algorithms will allow switching from an optimality phase to a pure feasibility phase

Indicates whether or not the barrier algorithms will allow switching from an optimality phase to a pure feasibility phase. This option has no effect on the Active Set algorithm.

Default: \(-1\)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-1)</td>
<td>(auto) Let Knitro determine the switching procedure.</td>
</tr>
<tr>
<td>0</td>
<td>(never) Never switch to feasibility phase.</td>
</tr>
<tr>
<td>2</td>
<td>(moderate) Allow switches to feasibility phase.</td>
</tr>
<tr>
<td>3</td>
<td>(aggressive) Use a more aggressive switching rule.</td>
</tr>
</tbody>
</table>

**bar watchdog** (boolean): Specifies whether to enable watchdog heuristic for barrier algorithms

Specifies whether to enable watchdog heuristic for barrier algorithms. In general, enabling the watchdog heuristic makes the barrier algorithms more likely to accept trial points. Specifically, the watchdog heuristic may occasionally accept trial points that increase the merit function, provided that subsequent iterates decrease the merit function.

Default: 0

**bfgs scaling** (integer): Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(dynamic) Dynamically choose which scaling to use.</td>
</tr>
<tr>
<td>1</td>
<td>(invhess) The scaling approximates the scale of the inverse Hessian.</td>
</tr>
<tr>
<td>2</td>
<td>(hess) The scaling approximates the scale of the Hessian.</td>
</tr>
</tbody>
</table>
**blasoption** *(integer):* Specifies the BLAS/LAPACK function library to use for basic vector and matrix computations

Default: 1 or 4 (platform dependent)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(knitro) Use Knitro built-in functions.</td>
</tr>
<tr>
<td>1</td>
<td>(intel) Use Intel Math Kernel Library (MKL) functions on available platforms.</td>
</tr>
<tr>
<td>2</td>
<td>(dynamic) Use the dynamic library specified with option blasoptionlib.</td>
</tr>
<tr>
<td>3</td>
<td>(blis) Use BLIS functions on available platforms (currently not available on Windows OS).</td>
</tr>
<tr>
<td>4</td>
<td>(apple) Use Apple Accelerate (only available on Mac with M1 processor).</td>
</tr>
</tbody>
</table>

**blasoptionlib** *(string):* Specifies a dynamic library name that contains object code for BLAS/LAPACK functions

Specifies a dynamic library name that contains object code for BLAS/LAPACK functions. The library must implement all the functions declared in the file include/blas_lapack.h.

**blas_numthreads** *(integer):* Specify the number of threads to use for BLAS operations when blasoption = 1

Range: \( \{0, ..., \infty\} \)

Default: 0

**bndrange** *(real):* Specifies max limits on the magnitude of constraint and variable bounds

Specifies max limits on the magnitude of constraint and variable bounds. Any constraint or variable bounds whose magnitude is greater than or equal to bndrange will be treated as infinite by Knitro. Using very large, finite bounds is discouraged (and is generally an indication of a poorly scaled model).

Range: \([0, \infty]\)

Default: 1e+20

**cg_maxit** *(integer):* Determines the maximum allowable number of inner conjugate gradient (CG) iterations per Knitro minor iteration

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Let Knitro automatically determine a value.</td>
</tr>
<tr>
<td>0</td>
<td>Knitro will set a maximum value based on the problem size.</td>
</tr>
<tr>
<td>n</td>
<td>At most (n&gt;0) CG iterations may be performed during one minor iteration of Knitro.</td>
</tr>
</tbody>
</table>

**cg_pmem** *(integer):* Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner

Default: 10
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>At most $n &gt; 0$ nonzero elements per column.</td>
</tr>
</tbody>
</table>

**cg_precond** *(boolean)*: Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Not applied.</td>
</tr>
<tr>
<td>1</td>
<td>(chol) Preconditioner is applied.</td>
</tr>
</tbody>
</table>

**cg_stoptol** *(real)*: Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves

Range: $[0, \infty]$

Default: 0.01

**conic_numthreads** *(integer)*: Specify the number of threads to use for operations in the conic algorithm (when *bar_conic_enable* = 1)

Specify the number of threads to use for operations in the conic algorithm (when *bar_conic_enable* = 1). $0$ Let Knitro choose the number of threads (currently sets *conic_numthreads* based on numthreads). $n > 0$ Use $n$ threads for the conic solver.

Range: $\{0, ..., \infty\}$

Default: 0

**convex** *(integer)*: Declare the problem as convex by setting to 1 or non-convex by setting to 0

Declare the problem as convex by setting to 1 or non-convex by setting to 0. Otherwise, Knitro will try to determine this automatically, but may only be able to do so for simple model forms such as QPs or QCQPs. If your model is specified as (or automatically determined to be) convex, this will cause Knitro to apply specializations and tunings that are often beneficial for convex models to speed up the solution. Currently this option is only active for the Interior/Direct algorithm, but may be applied to other algorithms in the future.

Range: $\{-1, ..., 1\}$

Default: -1

**cpuplatform** *(integer)*: This option can be used to specify the target instruction set architecture for the machine on which Knitro is running

This option can be used to specify the target instruction set architecture for the machine on which Knitro is running. This can be used, for example, to try to produce more consistent Knitro performance across various architectures (at the expense of, perhaps, slower performance on some platforms). This option is currently only used for the Intel Math Kernel Library (MKL) functions used inside Knitro.

Range: $\{-1, ..., 5\}$

Default: -1
**datacheck** *(boolean)*: Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure).

Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure). The datacheck may have a non-trivial cost for large problems.

Default: 0

**delta** *(real)*: Specifies the initial trust region radius scaling factor used to determine the initial trust region size.

```
Range: [1e-14, \infty]
```

Default: 1

**feastol** *(real)*: Specifies the final relative stopping tolerance for the feasibility error.

Specifies the final relative stopping tolerance for the feasibility error. Smaller values of feastol result in a higher degree of accuracy in the solution with respect to feasibility.

```
Range: [0, \infty]
```

Default: 1e-06

**feastolabs** *(real)*: Specifies the final absolute stopping tolerance for the feasibility error.

Synonym: feastol_abs

Specifies the final absolute stopping tolerance for the feasibility error. Smaller values of feastol_abs result in a higher degree of accuracy in the solution with respect to feasibility.

```
Range: [0, \infty]
```

Default: 0.001

**findiff_estnoise** *(integer)*: This option can be used to enable an estimate of the noise in the model when using finite-difference gradients.

This option can be used to enable an estimate of the noise in the model when using finite-difference gradients. This noise estimate can then be used to set a finite-difference steplength appropriate for the estimated noise level. This can improve performance on models with noise (e.g., noisy black-box optimization models). The cost of the noise estimation procedure is usually a few extra function evaluations.

```
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not enable any noise estimation procedure for finite-difference gradients.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Enable noise estimation procedure for finite-difference gradients.</td>
</tr>
<tr>
<td>2</td>
<td>(withcurv) Enable noise estimation and curvature factor for finite-difference gradients.</td>
</tr>
</tbody>
</table>
```

Default: 0

**findiff_relstepsize** *(real)*: Specifies the relative stepsize used for finite-difference gradients during the optimization.
Specifies the relative stepsize used for finite-difference gradients during the optimization. This option sets the stepsize for all variables. Note that this option has no affect on the finite-difference derivatives computed for the derivative checker (default values are always used here). It is only used for the finite-difference derivatives computed during the optimization.

Range: \([-\infty, \infty]\)

Default: 0

**findiff terminate (boolean):** This option specifies the termination criteria when using finite-difference gradients

This option specifies the termination criteria when using finite-difference gradients. The optimality (or KKT) conditions for nonlinear optimization depend on gradient values of the nonlinear objective and constraint functions. When using finite-difference gradients (e.g. \(\text{gradopt} > 1\)), there will typically be small errors in the computed gradients that will limit the precision in the solution (and the ability to satisfy the optimality conditions). By default, Knitro will try to estimate these finite-difference gradient errors and terminate when it seems that no more accuracy in the solution is possible. The solution will be treated as optimal as long as it is feasible and the optimality conditions are satisfied either by the optimality tolerances (\(\text{opttol}\) and \(\text{opttol}_{\text{abs}}\)) or the error estimates. On some problems, the error estimates may result in extra function evaluations on some iterations, but will often prevent extra iterations that produce no significant improvement in the solution. This special termination can be disabled by setting \(\text{findiff terminate} = 0\) (none).

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) No special criteria; use the standard stopping conditions.</td>
</tr>
<tr>
<td>1</td>
<td>(errest) Allow termination based on estimates of the finite-difference error (when no more significant progress is likely).</td>
</tr>
</tbody>
</table>

**fstopval (real):** Used to implement a custom stopping condition based on the objective function value

Used to implement a custom stopping condition based on the objective function value. Knitro will stop and declare that a satisfactory solution was found if a feasible objective function value at least as good as the value specified by \(\text{fstopval}\) is achieved. This stopping condition is only active when the absolute value of \(\text{fstopval}\) is less than \(\text{objrange}\).

Range: \([-\infty, \infty]\)

Default: \(\text{maxdouble}\)

**ftol (real):** The optimization process will terminate if the relative change in the objective function is less than \(\text{ftol}\) for \(\text{ftol}_{\text{iters}}\) consecutive feasible iterations

Range: \([0, \infty]\)

Default: \(1e^{-15}\)

**ftol_iters (integer):** The optimization process will terminate if the relative change in the objective function is less than \(\text{ftol}\) for \(\text{ftol}_{\text{iters}}\) consecutive feasible iterations

Range: \([^1, \ldots, \infty]\)

Default: 5

**gradopt (integer):** Specifies how to compute the gradients of the objective and constraint functions

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(exact) User provides a routine for computing the exact gradients.</td>
</tr>
<tr>
<td>2</td>
<td>(forward) Knitro computes gradients by forward finite differences.</td>
</tr>
<tr>
<td>3</td>
<td>(central) Knitro computes gradients by central finite differences.</td>
</tr>
</tbody>
</table>

**hessopt (integer):** Specifies how to compute the (approximate) Hessian of the Lagrangian

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto)</td>
</tr>
<tr>
<td>1</td>
<td>(exact) User provides a routine for computing the exact Hessian.</td>

<tr>
<td>6</td>
<td>(bfgs) Knitro computes a limited-memory quasi-Newton BFGS Hessian (its size is determined by the option lmsize).</td>
</tr>
<tr>
<td>7</td>
<td>(gauss_newton) Knitro computes a Gauss-Newton approximation of the hessian (available for least-squares only, and default value for least-squares)</td>
</tr>
</tbody>
</table>

**honorbnds (integer):** Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization

Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization. This option and the `bar_feasible` option may be useful in applications where functions are undefined outside the region defined by inequalities.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Knitro automatically determine the best setting.</td>
</tr>
<tr>
<td>0</td>
<td>(no) Knitro does not require that the bounds on the variables be satisfied at intermediate iterates.</td>
</tr>
<tr>
<td>1</td>
<td>(always) Knitro enforces that the initial point and all subsequent solution estimates satisfy the bounds on the variables.</td>
</tr>
<tr>
<td>2</td>
<td>(initpt) Knitro enforces that the initial point satisfies the bounds on the variables.</td>
</tr>
</tbody>
</table>

**infeastol (real):** Specifies the (relative) tolerance used for declaring infeasibility of a model

Specifies the (relative) tolerance used for declaring infeasibility of a model. Smaller values of `infeastol` make it more difficult to satisfy the conditions Knitro uses for detecting infeasible models. If you believe Knitro incorrectly declares a model to be infeasible, then you should try a smaller value for `infeastol`.

Range: [0, ∞]

Default: 1e-08

**infeastol_iters (integer):** The optimization process will terminate if the relative change in the feasibility error is less than `infeastol` for `infeastol_iters` consecutive infeasible iterations
initpenalty (real): Specifies the initial penalty parameter used in the Knitro merit functions

Specifies the initial penalty parameter used in the Knitro merit functions. The Knitro merit functions are used to balance improvements in the objective function versus improvements in feasibility. A larger initial penalty value places more weight initially on feasibility in the merit function.

Range: $[1, \infty)$

Default: 50

initvalues (integer): Enable use of initial guess for levels and marginals (subsequent solves)

Default: 1

<table>
<thead>
<tr>
<th>value</th>

</tbody>
</table>

linesearch (integer): Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate

Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate. This option has no effect on the Interior/CG or Active Set algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(backtrack) Use a simple backtracking scheme.</td>
</tr>
<tr>
<td>2</td>
<td>(interpolate) Use a cubic interpolation scheme.</td>
</tr>
<tr>
<td>3</td>
<td>(weakwolfe) Use a linesearch that satisfies the weak Wolfe conditions (unconstrained only).</td>
</tr>
</tbody>
</table>

linesearch_maxtrials (integer): Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step
Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step. This option has no effect on the Interior/CG or Active Set algorithm.

| Range: \( \{0, \ldots, \infty\} \) |

| Default: 3 |

**linsolver** *(integer):* Indicates which linear solver to use to solve linear systems arising in Knitro algorithms

| Default: 0 |

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the linear solver.</td>
</tr>
<tr>
<td>1</td>
<td>(internal) Not currently used; reserved for future use. Same as auto for now.</td>
</tr>
<tr>
<td>2</td>
<td>(hybrid) Use a hybrid approach where the solver chosen depends on the particular linear system which needs to be solved.</td>
</tr>
<tr>
<td>3</td>
<td>(qr) Use a dense QR method. This approach uses LAPACK QR routines. Since it uses a dense method, it is only efficient for small problems. It may often be the most efficient method for small problems with dense Jacobians or Hessian matrices.</td>
</tr>
<tr>
<td>4</td>
<td>(ma27) Use the HSL MA27 sparse symmetric indefinite solver.</td>
</tr>
<tr>
<td>5</td>
<td>(ma57) Use the HSL MA57 sparse symmetric indefinite solver.</td>
</tr>
<tr>
<td>6</td>
<td>(mklpardiso) Use the Intel MKL PARDISO (parallel, deterministic) sparse symmetric indefinite solver.</td>
</tr>
<tr>
<td>7</td>
<td>(ma97) Use the HSL MA97 (parallel, deterministic) sparse symmetric indefinite solver.</td>
</tr>
<tr>
<td>8</td>
<td>(ma86) Use the HSL MA86 (parallel, non-deterministic) sparse symmetric indefinite solver.</td>
</tr>
</tbody>
</table>

**linsolver_maxitref** *(integer):* Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro

Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro. Iterative refinement steps may be applied when there are significant errors (e.g., large residuals) in the linear system solves. Applying more iterative refinement steps may improve the numerical accuracy of the linear solves at extra cost.

| Range: \( \{0, \ldots, \infty\} \) |

| Default: 2 |

**linsolver_numthreads** *(integer):* Specify the number of threads to use for linear system solve operations when **linsolver** = 6

| Range: \( \{0, \ldots, \infty\} \) |

| Default: 0 |

**linsolver_ooc** *(integer):* Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when **linsolver** = mklpardiso

Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when **linsolver** = mklpardiso. This option is only active when **linsolver** = mklpardiso.

<p>| Default: 0 |</p>
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not use Intel MKL PARDISO out-of-core option.</td>
</tr>
<tr>
<td>1</td>
<td>(maybe) Maybe solve out-of-core depending on how much space is needed.</td>
</tr>
<tr>
<td>2</td>
<td>(yes) Solve linear systems out-of-core when using Intel MKL PARDISO.</td>
</tr>
</tbody>
</table>

**linsolver pivottol (real):** Specifies the initial pivot threshold used in factorization routines

Specifies the initial pivot threshold used in factorization routines. The value should be in the range \([0, \ldots, 0.5]\) with higher values resulting in more pivoting (more stable factorizations). Values less than 0 will be set to 0 and values larger than 0.5 will be set to 0.5. If `linsolver pivottol` is non-positive, initially no pivoting will be performed. Smaller values may improve the speed of the code but higher values are recommended for more stability (for example, if the problem appears to be very ill-conditioned).

Range: \([0, 0.5]\]

Default: `1e-08`

**lmsize (integer):** Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option

Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option. The value must be between 1 and 100 and is only used with `hessopt = 6`. Larger values may give a more accurate, but more expensive, Hessian approximation. Smaller values may give a less accurate, but faster, Hessian approximation. When using the limited memory BFGS approach it is recommended to experiment with different values of this parameter.

Range: \(\{1, \ldots, 100\}\)

Default: 10

**maxfevals (integer):** Specifies the maximum number of function evaluations before termination

Specifies the maximum number of function evaluations before termination. Values less than zero imply no limit.

Range: \(\{-\infty, \ldots, \infty\}\)

Default: -1

**maxit (integer):** Specifies the maximum number of iterations before termination

Synonym: iterlim

Default: GAMS iterlim

<table>
<thead>

<tr>
<td>1</td>
<td>(root) Add clique cuts derived from the root node only.</td>
</tr>
<tr>
<td>2</td>
<td>(tree) Add clique cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.</td>
</tr>
</tbody>
</table>

**mip_cutfactor** *(real)*: This value specifies a limit on the number of cuts added to a node subproblem

This value specifies a limit on the number of cuts added to a node subproblem. If non-negative, a maximum of `mip_cutfactor` times the number of constraints is possibly appended.

Range: `[0, \infty]`

Default: 1

**mip_cutoff** *(real)*: This value specifies the objective cutoff value for MIP

Range: `[-\infty, \infty]`

Default: `maxdouble`

**mip_cutting_plane** *(boolean)*: Specifies when to apply the cutting plane procedure

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) No cutting plane procedure enabled.</td>
</tr>
<tr>
<td>1</td>
<td>(root) Perform cutting plane procedure at the root node only.</td>
</tr>
</tbody>
</table>

**mip_gomory** *(integer)*: Specifies rules for adding Gomory mixed-integer cuts

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>2</td>
<td>(tree) Add Gomory cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.</td>
</tr>
</tbody>
</table>
mip_gub_branch (boolean): Specifies whether or not to branch on generalized upper bounds (GUBs)

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not branch on GUBs.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Allow branching on GUBs.</td>
</tr>
</tbody>
</table>

mip_heuristic_diving (integer): Specifies whether or not to enable the MIP diving heuristic

Specifies whether or not to enable the MIP diving heuristic. This option is a bit-valued option where various diving heuristics can be enabled by activating the corresponding bit value as described below. Setting this option to -1 will use an automatic setting and setting the value to 0 will disable all diving heuristics. Otherwise, set this parameter value to the sum of the values for the individual diving heuristics you wish to enable. For example, to enable only the "fractional" and "linesearch" diving heuristics, you would set this option value to 9 (summing 1 for fractional and 8 for linesearch).

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro determine automatically from mip_heuristic_strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(bit 0) Enable fractional diving heuristic.</td>

</tr>
</tbody>
</table>

mip_heuristic_feaspump (integer): Specifies whether or not to enable the MIP feasibility pump heuristic

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro determine automatically from mip_heuristic_strategy.</td>
</tr>
<tr>
<td>0</td>
<td>(off) Feasibility pump heuristic is not applied.</td>
</tr>
<tr>
<td>1</td>
<td>(on) Feasibility pump heuristic is enabled.</td>
</tr>
</tbody>
</table>

mip_heuristic_lns (integer): Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics

Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics. This option is a bit-valued option where various LNS heuristics can be enabled by activating the corresponding bit value as described below. Setting this option to -1 will use an automatic setting and setting the value to 0 will disable all LNS heuristics. Otherwise, set this parameter value to the sum of the values for the individual LNS heuristics you wish to enable. For example, to enable both the "RENS" and "RINS" LNS heuristics, you would set this option value to 3 (summing 1 for RENS and 2 for RINS).

Default: -1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) let Knitro determine automatically from <code>mip_heuristic_strategy</code>.</td>

</table>

mip_maxnodes (integer): Specifies the maximum number of nodes explored (0 means no limit) ←

Synonym: nodlim

Range: \([0, \infty]\)

Default: GAMS nodlim

mip_maxsolves (integer): Specifies the maximum number of subproblem solves allowed (0 means no limit) ←

Range: \([0, \infty]\)

Default: 0

mip_maxtime_cpu (real): Specifies the maximum allowable CPU time in seconds for the complete MIP solution ←

Specifies the maximum allowable CPU time in seconds for the complete MIP solution. Use maxtime_cpu to additionally limit time spent per subproblem solve.

Range: \([0, \infty]\)

Default: 100000000

mip_maxtime_real (real): Specifies the maximum allowable real time in seconds for the complete MIP solution ←

Specifies the maximum allowable real time in seconds for the complete MIP solution. Use maxtime_real to additionally limit time spent per subproblem solve.

Range: \([0, \infty]\)

Default: GAMS reslim

mip_method (integer): Specifies which MIP method to use ←

Default: 0
### value | meaning
---|---
0 | (auto) Let Knitro automatically choose the method.  
1 | (BB) Use the standard branch-and-bound method.  
2 | (HQG) Use the hybrid Quesada-Grossman method (for convex, nonlinear problems only).  
3 | (MISQP) Use mixed-integer SQP method (allows for non-relaxable integer variables).

**mip_mir** *(integer)*: Specifies rules for adding mixed-integer rounding cuts

Default: -1

| value | meaning |
---|---|
-1 | (auto) Let Knitro decide whether to add mixed-integer rounding cuts.  
0 | (none) Do not add mixed-integer rounding cuts.  
1 | (root) Add mixed-integer rounding cuts derived from the root node only.  
2 | (tree) Add mixed-integer rounding cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.

**mip_multistart** *(boolean)*: Use to enable MIP multi-start at the branch-and-bound level

Default: 0

| value | meaning |
---|---|
0 | (off) Do not enable MIP multi-start for branch-and-bound.  
1 | (on) Enable MIP multi-start for branch-and-bound.

**mip_nodealg** *(integer)*: Specifies which algorithm to use for standard node subproblem solves in MIP (same options as algorithm user option)

Range: \{0, ..., 5\}

Default: 0

**mip_numthreads** *(integer)*: Specify the number of threads to use for MIP branch-and-bound (when mip_method = 1)

Specify the number of threads to use for MIP branch-and-bound (when **mip_method** = 1). 0 Let Knitro choose the number of threads.  

Range: \{0, ..., \infty\}

Default: 0

**mip_opt_gap_abs** *(real)*: The absolute optimality gap stop tolerance for MIP

Synonym: optca

Range: [-1, \infty]

Default: GAMS optca
**mip_opt_gap_rel** *(real)*: The relative optimality gap stop tolerance for MIP

   Synonym: optcr
   Range: \([-1, \infty]\]
   Default: GAMS optcr

**mip_outinterval** *(integer)*: Specifies node printing interval for mip_outlevel when mip_outlevel > 0

   Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Let Knitro decide.</td>
</tr>
<tr>
<td>1</td>
<td>Print output every node.</td>
</tr>
<tr>
<td>2</td>
<td>Print output every 2nd node.</td>
</tr>
<tr>
<td>n</td>
<td>Print output every Nth node.</td>
</tr>
</tbody>
</table>

**mip_outlevel** *(integer)*: Specifies how much MIP information to print

   Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Do not print any MIP node information.</td>
</tr>
<tr>
<td>1</td>
<td>(iters) Print one line of output for every node.</td>
</tr>
<tr>
<td>2</td>
<td>(iterstime) Also print accumulated time for every node.</td>
</tr>
<tr>
<td>3</td>
<td>(root) Also print detailed log from root node solve.</td>
</tr>
</tbody>
</table>

**mip_pseudoinit** *(integer)*: Specifies the method used to initialize pseudo-costs corresponding to variables that have not yet been branched on in the MIP method

   Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Let Knitro automatically choose the method.</td>
</tr>
<tr>
<td>1</td>
<td>Initialize using the average value of computed pseudo-costs.</td>
</tr>
<tr>
<td>2</td>
<td>Initialize using strong branching.</td>
</tr>
</tbody>
</table>

**mip_relaxable** *(boolean)*: Specifies whether integer variables are relaxable

   Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Integer variables are not relaxable.</td>
</tr>
<tr>
<td>1</td>
<td>(all) All integer variables are relaxable.</td>

</tbody>
</table>

**mip_restart** *(boolean)*: Specifies whether to enable the MIP restart procedure

   Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(off) Do not enable the MIP restart procedure.</td>
</tr>
<tr>
<td>1</td>
<td>(on) Enable the MIP restart procedure.</td>
</tr>
</tbody>
</table>

**mip_rootalg (integer)**: Specifies which algorithm to use for the root node solve in MIP (same options as `algorithm` user option) 

Range: \{0, ..., 5\}

Default: 0

**mip_rounding (integer)**: Specifies the MIP rounding rule to apply

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro choose the rounding rule.</td>
</tr>
<tr>
<td>0</td>
<td>(none) No rounding heuristic is used.</td>
</tr>
<tr>
<td>2</td>
<td>(heur_only) Round using a fast heuristic only.</td>
</tr>
<tr>
<td>3</td>
<td>(nlp_sometimes) Round and solve a subproblem if likely to succeed.</td>
</tr>
<tr>
<td>4</td>
<td>(nlp_always) Always round and solve a subproblem.</td>
</tr>
</tbody>
</table>

**mip_selectdir (boolean)**: Specifies the MIP node selection direction rule (for tiebreakers) for choosing the next node in the branch-and-bound tree

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(down) Choose the down (i.e. (\leq)) node first.</td>
</tr>
<tr>
<td>1</td>
<td>(up) Choose the up (i.e. (\geq)) node first.</td>
</tr>
</tbody>
</table>

**mip_selectrule (integer)**: Specifies the MIP select rule for choosing the next node in the branch-and-bound tree

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro choose the node selection rule.</td>
</tr>
<tr>
<td>1</td>
<td>(depth_first) Search the tree using a depth first procedure.</td>
</tr>
<tr>
<td>2</td>
<td>(best_bound) Select the node with the best relaxation bound.</td>
</tr>
<tr>
<td>3</td>
<td>(combo_1) Use depth first unless pruned, then best bound.</td>
</tr>
</tbody>
</table>

**mip_strong_candlim (integer)**: Specifies the maximum number of candidates to explore for MIP strong branching

Range: \(-\infty, ..., \infty\)

Default: 128
mip_strong_level \((integer)\): Specifies the maximum number of tree levels on which to perform MIP strong branching \(\leftarrow\)

Range: \([-\infty, \ldots, \infty]\)

Default: 10

mip_strong_maxit \((integer)\): Specifies the maximum number of iterations to allow for MIP strong branching solves \(\leftarrow\)

Range: \([-\infty, \ldots, \infty]\)

Default: 1000

mip_terminate \((integer)\): Specifies conditions for terminating the MIP algorithm \(\leftarrow\)

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(optimal) Terminate at optimum.</td>
</tr>
<tr>
<td>1</td>
<td>(feasible) Terminate at first integer feasible point.</td>
</tr>
</tbody>
</table>

mip_zerohalf \((integer)\): Specifies rules for adding zero-half cuts \(\leftarrow\)

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Automatically determine whether to add zero-half cuts.</td>
</tr>
<tr>
<td>0</td>
<td>(none) Do not add zero-half cuts.</td>
</tr>
<tr>
<td>1</td>
<td>(root) Add zero-half cuts derived from the root node only.</td>
</tr>
<tr>
<td>2</td>
<td>(tree) Add zero-half cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.</td>
</tr>
</tbody>
</table>

ms_deterministic \((boolean)\): Indicates whether Knitro multi-start procedure will be deterministic (when ms_terminate = 0) \(\leftarrow\)

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) multithreaded multi-start is non-deterministic.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) multithreaded multi-start is deterministic (when ms_terminate = 0).</td>
</tr>
</tbody>
</table>

ms_enable \((boolean)\): Indicates whether Knitro will solve from multiple start points to find a better local minimum \(\leftarrow\)

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Knitro solves from a single initial point.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Knitro solves using multiple start points.</td>
</tr>
</tbody>
</table>
**ms_maxbndrange** *(real)*: Specifies the maximum range that an unbounded variable can take when determining new start points

Specifies the maximum range that an unbounded variable can take when determining new start points. If a variable is unbounded in one or both directions, then new start point values are restricted by the option. If \( x_i \) is such a variable, then all initial values satisfy
\[
\max\{b_{L_i}, x_0^i - \text{ms_maxbndrange}/2\} \leq x_i \leq \min\{b_{U_i}, x_0^i + \text{ms_maxbndrange}/2\},
\]
where \( x_0^i \) is the initial value of \( x_i \) provided by the user, and \( b_{L_i} \) and \( b_{U_i} \) are the variable bounds (possibly infinite) on \( x_i \). This option has no effect unless \( \text{ms_enable} = \text{yes} \).

Range: \([-\infty, \infty]\)

Default: 1000

**ms_maxsolves** *(integer)*: Specifies how many start points to try in multi-start

Specifies how many start points to try in multi-start. This option has no effect unless \( \text{ms_enable} = \text{yes} \).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Let Knitro automatically choose a value based on the problem size and context.</td>
</tr>
<tr>
<td>n</td>
<td>Try ( n&gt;0 ) start points.</td>
</tr>
</tbody>
</table>

**ms_maxtime_cpu** *(real)*: Specifies, in seconds, the maximum allowable CPU time before termination

Specifies, in seconds, the maximum allowable CPU time before termination. The limit applies to the operation of Knitro since multi-start began; in contrast, the value of maxtime_cpu limits how long Knitro iterates from a single start point. Therefore, \( \text{ms_maxtime_cpu} \) should be greater than maxtime_cpu. This option has no effect unless \( \text{ms_enable} = \text{yes} \).

Range: \([-\infty, \infty]\)

Default: 100000000

**ms_maxtime_real** *(real)*: Specifies, in seconds, the maximum allowable real time before termination

Specifies, in seconds, the maximum allowable real time before termination. The limit applies to the operation of Knitro since multi-start began; in contrast, the value of maxtime_real limits how long Knitro iterates from a single start point. Therefore, \( \text{ms_maxtime_real} \) should be greater than maxtime_real. This option has no effect unless \( \text{ms_enable} = \text{yes} \).

Range: \([-\infty, \infty]\)

Default: 100000000

**ms_numthreads** *(integer)*: Specify the number of threads to use for multi-start (when \( \text{ms_enable} = 1 \))

Specify the number of threads to use for multi-start (when \( \text{ms_enable} = 1 \)). 0 Let Knitro choose the number of threads (currently sets \( \text{ms_numthreads} \) based on numthreads). \( n>0 \) Use \( n \) threads for the multi-start (solve \( n \) problems in parallel).

Range: \( \{0, ..., \infty\} \)

Default: 0
5.23 KNITRO

**ms_num_to_save** *(integer)*: Specifies the number of distinct feasible points to save in a file named `knitro_mspoints.log`.

Specifies the number of distinct feasible points to save in a file named `knitro_mspoints.log`. Each point results from a Knitro solve from a different starting point, and must satisfy the absolute and relative feasibility tolerances. The file stores points in order from best objective to worst. Points are distinct if they differ in objective value or some component by the value of `ms_savetol` using a relative tolerance test. This option has no effect unless `ms_enable = yes`.

Range: `{0, ..., ∞}`

Default: 0

**ms_outsub** *(boolean)*: Enable writing algorithm output to files for the parallel multi-start procedure

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not write detailed algorithm output to files.</td>
</tr>
<tr>
<td>1</td>
<td>Write detailed algorithm output to files named <code>knitro_ms_*</code>.log.</td>
</tr>
</tbody>
</table>

**ms_savetol** *(real)*: Specifies the tolerance for deciding if two feasible points are distinct

Specifies the tolerance for deciding if two feasible points are distinct. Points are distinct if they differ in objective value or some component by the value of `ms_savetol` using a relative tolerance test. A large value can cause the saved feasible points in the file `knitro_mspoints.log` to cluster around more widely separated points. This option has no effect unless `ms_enable = yes` and `ms_num_to_save` is positive.

Range: `[-∞, ∞]`

Default: `1e-06`

**ms_seed** *(integer)*: Seed value used to generate random initial points in multi-start; should be a non-negative integer

Default: 0

**ms_startptrange** *(real)*: Specifies the maximum range that each variable can take when determining new start points

Specifies the maximum range that each variable can take when determining new start points. If a variable has upper and lower bounds and the difference between them is less than or equal to `ms_startptrange`, then new start point values for the variable can be any number between its upper and lower bounds. If the variable is unbounded in one or both directions, or the difference between bounds is greater than `ms_startptrange`, then new start point values are restricted by the option. If $x_i$ is such a variable, then all initial values satisfy $\max\{b_i^U, x_i^0 - \tau\} \leq x_i \leq \min\{b_i^L, x_i^0 + \tau\}$, $\tau = \min\{ms_startptrange/2, ms_maxbndrange/2\}$, where $x_i^0$ is the initial value of $x_i$ provided by the user, and $b_i^L$ and $b_i^U$ are the variable bounds (possibly infinite) on $x_i$. This option has no effect unless `ms_enable = yes`.

Range: `[-∞, ∞]`

Default: `1e+20`

**ms_terminate** *(integer)*: Specifies the condition for terminating multi-start

Specifies the condition for terminating multi-start. This option has no effect unless `ms_enable = yes`.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Terminate after ms_maxsolves.</td>
</tr>
<tr>
<td>1</td>
<td>Terminate after the first local optimal solution is found or ms_maxsolves, whichever comes first.</td>
</tr>
<tr>
<td>2</td>
<td>Terminate after the first feasible solution estimate is found or ms_maxsolves, whichever comes first.</td>
</tr>
<tr>
<td>3</td>
<td>Terminate after the first solution estimate of any type is found or ms_maxsolves, whichever comes first.</td>
</tr>
</tbody>
</table>

**names (boolean):** Enable to pass variable and equation names to Knitro

Default: 0

**ncvx_qcqp_init (integer):** Specifies the initialization strategy used for non-convex QPs and QCQPs

Specifies the initialization strategy used for non-convex QPs and QCQPs. In particular, these strategies may be more likely to cause Knitro to find global or better local solutions on non-convex quadratic programs (QPs) or non-convex quadratically constrained quadratic programs (QCQPs).

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Knitro will automatically determine the strategy.</td>
</tr>
<tr>
<td>0</td>
<td>(none) No special initialization strategy is used.</td>
</tr>
<tr>
<td>1</td>
<td>(linear) Initialize by solving a linear relaxation.</td>
</tr>
<tr>
<td>2</td>
<td>(hybrid) Initialize by solving a hybrid formulation.</td>
</tr>
<tr>
<td>3</td>
<td>(penalty) Initialize by solving a penalty formulation.</td>
</tr>
<tr>
<td>4</td>
<td>(cvxquad) Initialize by solving a convex quadratic relaxation.</td>
</tr>
</tbody>
</table>

**newpoint (integer):** Specifies additional action to take after every iteration in a solve of a continuous problem

Specifies additional action to take after every iteration in a solve of a continuous problem. An iteration of Knitro results in a new point that is closer to a solution. The new point includes values of x and Lagrange multipliers lambda. The “newpoint” feature in Knitro is currently only available for continuous problems (solved via KN_solve()).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Knitro takes no additional action.</td>
</tr>
<tr>
<td>1</td>
<td>(saveone) Knitro writes x and lambda to the file knitro_newpoint.log. Previous contents of the file are overwritten.</td>
</tr>
<tr>
<td>2</td>
<td>(saveall) Knitro appends x and lambda to the file knitro_newpoint.log. Warning: this option can generate a very large file. All iterates, including the start point, crossover points, and the final solution are saved.</td>
</tr>
</tbody>
</table>

**objrange (real):** Specifies the extreme limits of the objective function for purposes of determining unboundedness
Specifies the extreme limits of the objective function for purposes of determining unboundedness. If the magnitude of the objective function becomes greater than objrange for a feasible iterate, then the problem is determined to be unbounded and Knitro proceeds no further.

Range: \([0, \infty]\)

Default: \(1e+20\)

**option_file (string):** additional option file name - read only by KNITRO solver lib

**opttol (real):** Specifies the final relative stopping tolerance for the KKT (optimality) error

Specifies the final relative stopping tolerance for the KKT (optimality) error. Smaller values of opttol result in a higher degree of accuracy in the solution with respect to optimality.

Range: \([0, \infty]\)

Default: \(1e-06\)

**opttolabs (real):** Specifies the final absolute stopping tolerance for the KKT (optimality) error

Synonym: opttol_abs

Specifies the final absolute stopping tolerance for the KKT (optimality) error. Smaller values of opttol_abs result in a higher degree of accuracy in the solution with respect to optimality.

Range: \([0, \infty]\)

Default: 0.001

**outappend (boolean):** Specifies whether output should be started in a new file, or appended to existing files

Specifies whether output should be started in a new file, or appended to existing files. The option affects knitro.log. It does not affect knitro_newpoint.log, which is controlled by option newpoint.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Erase any existing files when opening for output.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Append output to any existing files.</td>
</tr>
</tbody>
</table>

**outdir (string):** Specifies a single directory as the location to write all output files

Specifies a single directory as the location to write all output files. The option should be a full pathname to the directory, and the directory must already exist.

**outlev (integer):** Controls the level of output produced by Knitro

Default: 2
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Printing of all output is suppressed.</td>
</tr>
<tr>
<td>1</td>
<td>(summary) Print only summary information.</td>
</tr>
<tr>
<td>2</td>
<td>(iter,10) Print basic information every 10 iterations.</td>
</tr>
<tr>
<td>3</td>
<td>(iter) Print basic information at each iteration.</td>
</tr>
<tr>
<td>4</td>
<td>(iter,verbose) Print basic information and the function count at each iteration.</td>
</tr>
<tr>
<td>5</td>
<td>(iter,x) Print all the above, and the values of the solution vector x.</td>
</tr>
<tr>
<td>6</td>
<td>(all) Print all the above, and the values of the constraints c at x and the Lagrange multipliers lambda.</td>
</tr>
</tbody>
</table>

**outmode (integer):** Specifies where to direct the output from Knitro

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(screen) Output is directed to standard out (e.g., screen).</td>
</tr>
<tr>
<td>1</td>
<td>(file) Output is sent to a file named knitro.log.</td>
</tr>
<tr>
<td>2</td>
<td>(both) Output is directed to both the screen and file knitro.log.</td>
</tr>
</tbody>
</table>

**outname (string):** Use to specify a custom filename when output is written to a file using outmode

**output_time (boolean):** print output on where time is used

Default: 0

**out_csvinfo (boolean):** Controls whether or not to generates a file knitro_solve

Controls whether or not to generates a file knitro_solve.csv containing solve information in comma separated format.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) No solution information file is generated.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) The knitro_solve.csv solution file is generated.</td>
</tr>
</tbody>
</table>

**out_csvname (string):** Use to specify a custom csv filename when using out_csvinfo

**out_hints (boolean):** Specifies whether to print diagnostic hints (e.g. about user option settings) after solving

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not print any hints.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Print diagnostic hints on occasion.</td>
</tr>
</tbody>
</table>
**presolve** *(boolean)*: Determine whether or not to use the Knitro presolver to try to simplify the model by removing variables or constraints

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not use the Knitro presolver.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Enable the Knitro presolver.</td>
</tr>
</tbody>
</table>

**presolveop_redundant** *(integer)*: Determine whether or not to enable the Knitro presolve operation to detect and remove redundant constraints

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Do not remove redundant constraints.</td>
</tr>
<tr>
<td>1</td>
<td>(dupcon) Detect and remove duplicate constraints.</td>
</tr>
<tr>
<td>2</td>
<td>(depcon) Detect and remove linearly dependent constraints.</td>
</tr>
</tbody>
</table>

**presolveop_tighten** *(integer)*: Determine whether or not to enable the Knitro presolve operation to tighten variable bounds or coefficients

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Automatically determined (may depend on the algorithm).</td>
</tr>
<tr>
<td>0</td>
<td>(none) Do not tighten variable bounds (unless it removes a constraint).</td>
</tr>
<tr>
<td>1</td>
<td>(varbnd) Enable tightening variable bounds always.</td>
</tr>
<tr>
<td>2</td>
<td>(coef) Enable tightening coefficients in linear constraints.</td>
</tr>
<tr>
<td>3</td>
<td>(all) Enable tightening variable bounds and coefficients.</td>
</tr>
</tbody>
</table>

**presolve_initpt** *(integer)*: Control whether the Knitro presolver can shift a user-supplied initial point

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose whether to allow shifting.</td>
</tr>
<tr>
<td>0</td>
<td>(noshift) Do not allow presolver to shift user-supplied initial point.</td>
</tr>
<tr>
<td>1</td>
<td>(linshift) Allow presolver to shift user-supplied initial point if it only appears in linear constraints.</td>
</tr>
<tr>
<td>2</td>
<td>(anyshift) Allow presolver to shift any user-supplied initial point.</td>
</tr>
</tbody>
</table>

**presolve_level** *(integer)*: Set the level of presolve operations to enable through the Knitro presolver

Set the level of presolve operations to enable through the Knitro presolver. A higher presolve level enables more complex presolve operations.

Default: -1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose the presolve level.</td>
</tr>
<tr>
<td>1</td>
<td>(level1) Enable the most basic presolve operations.</td>
</tr>
<tr>
<td>2</td>
<td>(level2) Enable more advanced presolve operations.</td>
</tr>
</tbody>
</table>

**presolve.passes** *(integer)*: Set a maximum limit on the number of passes through the Knitro presolve operations

```
Range: \{0, \ldots, \infty\}
```

Default: 10

**presolve.tol** *(real)*: Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model

```
Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model. If you believe the Knitro presolver is incorrectly modifying the model, use a smaller value for this tolerance (or turn the presolver off).

Range: \([0, \infty]\)
```

Default: 1e-06

**qextractalg** *(integer)*: quadratic extraction algorithm in GAMS interface

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.</td>
</tr>
<tr>
<td>2</td>
<td>DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.</td>
</tr>
<tr>
<td>3</td>
<td>Concurrent: Uses ThreePass and DoubleForward in parallel. As soon as one finishes, the other one stops.</td>
</tr>
</tbody>
</table>

**restarts** *(integer)*: Specifies whether or not to enable automatic restarts in Knitro

```
Specifies whether or not to enable automatic restarts in Knitro. When enabled, if a Knitro algorithm seems to be converging slowly or not converging, the algorithm will automatically restart, which may help with convergence.
```

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No automatic restarts allowed.</td>
</tr>
<tr>
<td>n</td>
<td>At most n&gt;0 automatic restarts may be performed.</td>
</tr>
</tbody>
</table>

**restarts.maxit** *(integer)*: When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart
Default: 0
value | meaning
--- | ---
0 | No iteration limit on restarts enforced.
\(n\) | At most \(n > 0\) iterations are allowed without convergence before enforcing an automatic restart, if restarts are enabled.

**scale** *(integer)*: Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables.

Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables. If scaling is performed, internal computations, including some aspects of the optimality tests, are based on the scaled values, though the feasibility error is always computed in terms of the original, unscaled values.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) No scaling is performed.</td>
</tr>
<tr>
<td>1</td>
<td>(user_internal) User provided scaling is used if defined, otherwise Knitro internal scaling is applied.</td>
</tr>
<tr>
<td>2</td>
<td>(user_none) User provided scaling is used if defined, otherwise no scaling is applied.</td>
</tr>
<tr>
<td>3</td>
<td>(internal) Knitro internal scaling is applied.</td>
</tr>
</tbody>
</table>

**soc** *(integer)*: Specifies whether or not to try second order corrections (SOC).

Specifies whether or not to try second order corrections (SOC). A second order correction may be beneficial for problems with highly nonlinear constraints.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) No second order correction steps are attempted.</td>
</tr>
<tr>
<td>1</td>
<td>(maybe) Second order correction steps may be attempted on some iterations.</td>
</tr>
<tr>
<td>2</td>
<td>(yes) Second order correction steps are always attempted if the original step is rejected and there are nonlinear constraints.</td>
</tr>
</tbody>
</table>

**strat_warm_start** *(boolean)*: Specifies whether or not to invoke a warm-start strategy.

Specifies whether or not to invoke a warm-start strategy. A warm-start strategy may be beneficial when an initial point close to the solution can be provided. For example, this may occur when solving a sequence of closely related problems, and the solution from one problem can be used to initialize (or warm-start) the next problem in the sequence. The Knitro warm-start strategy will use this information to tune the algorithms to try to converge more quickly in this case. If the initial point is not sufficiently close to the solution, or is too infeasible, the warm-start strategy may not be helpful. This option is currently only used for the Knitro barrier/interior-point algorithms. In this case it may also be useful to experiment with different (smaller than default) values for the initial barrier parameter \(\text{bar}\_\text{initmu}\). In general, the closer the initial point is to the solution, the smaller this value should be (Knitro will try by default to initialize this to a good value when applying a warm-start strategy).

Default: 0
value | meaning
--- | ---
0 | (no) No warm-start strategy is applied.
1 | (yes) Knitro will apply a warm-start strategy with special tunings.

**threads (integer):** default thread count

Synonyms: gthreads numthreads

Controls the number of threads to use. Non-positive values are interpreted as the number of cores to leave free so setting `threads` to 0 uses all available cores while setting `threads` to -1 leaves one core free for other tasks.

By default, Knitro decides automatically how to use the threads specified. For example, if the multi-start method is enabled, it can run in parallel threads. If the multi-algorithm `algorithm=5` is selected, the different algorithms can be run in parallel threads if threads are allocated. In case only one algorithm is running, multiple threads can be allocated to the MKL BLAS library or to the PARDISO linear solver via the `threads` option: see the `blasoption`, `par_blasnumthreads`, and `par_lsnumpthreads` options for details.

Range: \([-\infty, \ldots, \infty]\)

Default: GAMS threads

**tuner (boolean):** Indicates whether to invoke the Knitro-Tuner

Default: 0

| value | meaning |
--- | --- |
0 | (off) Do not invoke the Knitro-Tuner. |
1 | (on) Invoke the Knitro-Tuner. |

**tuner_maxtime_cpu (real):** Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner

Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner. The limit applies to the operation of Knitro since the Knitro-Tuner began. In contrast, the value of `maxtime_cpu` places a time limit on each individual Knitro-Tuner solve for a particular option setting. Therefore, `tuner_maxtime_cpu` should be greater than `maxtime_cpu`. This option has no effect unless `tuner = on`.

Range: \([0, \infty]\)

Default: 100000000

**tuner_maxtime_real (real):** Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner

Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner. The limit applies to the operation of Knitro since the Knitro-Tuner began. In contrast, the value of `maxtime_real` places a time limit on each individual Knitro-Tuner solve for a particular option setting. Therefore, `tuner_maxtime_real` should be greater than `maxtime_real`. This option has no effect unless `tuner = on`.

Range: \([0, \infty]\)

Default: 100000000
**tuner_optionsfile** *(string)*: Can be used to specify the location of a Tuner options file

**tuner_outsub** *(integer)*: Enable writing additional Tuner subproblem solve output to files for the Knitro-Tuner procedure *(tuner=1)*

- **Default:** 0

<table>
<thead>
<tr>

**xtol** *(real)*: The optimization process will terminate if the relative change in all components of the solution point estimate is less than xtol for xtol\_iters

The optimization process will terminate if the relative change in all components of the solution point estimate is less than xtol for xtol\_iters consecutive iterations. If using the Interior/Direct or Interior/CG algorithm and the barrier parameter is still large, Knitro will first try decreasing the barrier parameter before terminating.

- **Range:** \([0, \infty]\)

- **Default:** 1e-12

**xtol\_iters** *(integer)*: The optimization process will terminate if the relative change in the solution estimate is less than xtol for xtol\_iters consecutive iterations

The optimization process will terminate if the relative change in the solution estimate is less than xtol for xtol\_iters consecutive iterations. If set to 0, Knitro chooses this value based on the solver and context. Currently Knitro sets this value to 3 unless the MISQP algorithm is being used, in which case the value is set to 1 by default.

- **Range:** \(\{0, \ldots, \infty\}\)

- **Default:** 0
5.23.6 Knitro Termination Test and Optimality

5.23.6.1 Continuous problems

The first-order conditions for identifying a locally optimal solution of the problem (1) are:

$$\nabla_x L(x, \lambda) = \nabla f(x) + \sum_{i=1}^{m} \lambda_i^c \nabla c_i(x) + \sum_{j=1}^{n} \lambda_j^b \nabla b_j(x) = 0$$

$$\lambda_i^c \min[(c_i(x) - c_i^L), (c_i^U - c_i(x))] = 0, \quad i = 1 \ldots m$$

$$\lambda_j^b \min[(x_j - b_j^L), (b_j^U - x_j)] = 0, \quad j = 1 \ldots n$$

$$c_i^L \leq c_i(x) \leq c_i^U, \quad i = 1 \ldots m$$

$$b_j^L \leq x_j \leq b_j^U, \quad j = 1 \ldots n$$

(3)

where $\mathcal{I}$ and $\mathcal{B}$ represent the sets of indices corresponding to the general inequality constraints and non-fixed variable bound constraints respectively, $\lambda_i^c$ is the Lagrange multiplier corresponding to constraint $c_i(x)$, and $\lambda_j^b$ is the Lagrange multiplier corresponding to the simple bounds on $x_j$. There is exactly one Lagrange multiplier for each constraint and variable. The Lagrange multiplier may be restricted to take on a particular sign depending on the corresponding constraint or variable bounds.

In Knitro we define the feasibility error ($\text{FeasErr}$) at a point $x^k$ to be the maximum violation of the constraints of (1), i.e.,

$$\text{FeasErr} = \max_{i=1 \ldots m, j=1 \ldots n} (0, (c_i^L - c_i(x^k)), (c_i^U - c_i(x^k)), (b_j^L - x_j^k), (x_j^k - b_j^U)).$$

while the optimality error ($\text{OptErr}$) is defined as the maximum violation of the first three conditions of (3)

$$\text{OptErr} = \max_{i=1 \ldots m, j=1 \ldots n} (\|\nabla_x L(x^k, \lambda^k)\|_\infty, \lambda_i^c \min[(c_i(x) - c_i^L), (c_i^U - c_i(x))], \lambda_j^b \min[(x_j - b_j^L), (b_j^U - x_j)]).$$

The remaining conditions on the sign of the multipliers are enforced explicitly throughout the optimization. In order to take into account problem scaling in the termination test, the following scaling factors are defined In order to take into account problem scaling in the termination test, the following scaling factors are defined

$$\tau_1 = \max(1, (c_i^L - c_i(x^0)), (c_i(x^0) - c_i^U), (b_j^L - x_j^0), (x_j^0 - b_j^U)))$$

$$\tau_2 = \left\{ \begin{array}{ll} \max(1, \|\nabla f(x^k)\|_\infty), & \text{for constrained problems,} \\ \max(1, \min(\|f(x^k)\|, \|\nabla f(x^0)\|_\infty)), & \text{for unconstrained problems,} \end{array} \right.$$  

where $x^0$ represents the initial point. The special treatment for unconstrained problems is necessary, as for these problems, $\|\nabla f(x^k)\|_\infty \to 0$ as a solution is approached, thus $\max(1, \|\nabla f(x^k)\|_\infty)$ would not be effective.

Knitro stops and declares Locally optimal solution found if the following stopping conditions are satisfied:

$$\text{FeasErr} \leq \max(\tau_1, \text{feastol, feastolabs})$$

(4)
\[ \text{OptErr} \leq \max(\tau_2 \ast \text{opttol}, \text{opttolabs}) \]  \hfill (5)

where \text{feastol}, \text{opttol}, \text{feastolabs} and \text{opttolabs} are user-defined options (see section Usage).

This stopping test is designed to give the user much flexibility in deciding when the solution returned by Knitro is accurate enough. One can use a purely scaled stopping test (which is the recommended and default option) by setting \text{feastolabs} and \text{opttolabs} equal to \(0.0e0\). Likewise, an absolute stopping test can be enforced by setting \text{feastol} and \text{opttol} equal to \(0.0e0\).

Unbounded problems

Since by default Knitro uses a relative/scaled stopping test it is possible for the optimality conditions to be satisfied for an unbounded problem. For example, if \(\tau_2 \to \infty\) while the optimality error \text{OptErr} stays bounded, condition \(5\) will eventually be satisfied for some \text{opttol}\(>0\). If you suspect that your problem may be unbounded, using an absolute stopping test will allow Knitro to detect this.

5.23.6.2 Discrete problems

Algorithms for solving versions of (1) where one or more of the variables are restricted to take on only discrete values, proceed by solving a sequence of continuous relaxations, where the discrete variables are relaxed such that they can take on any continuous value. The global solutions \(f(x_R)\) of these relaxed problems provide a lower bound on the optimal objective value for problem (1) (upper bound if maximizing). If a feasible point is found for problem (1) that satisfies the discrete restrictions on the variables, then this provides an upper bound on the optimal objective value of problem (1) (lower bound if maximizing). We will refer to these feasible points as incumbent points and denote the objective value at an incumbent point by \(f(x_I)\). Assuming all the continuous subproblems have been solved to global optimality (if the problem is convex, all local solutions are global solutions), an optimal solution of problem (1) is verified when the lower bound and upper bound are equal.

Knitro declares optimality for a discrete problem when the gap between the best (i.e., largest) lower bound \(f(x_R)\) and the best (i.e., smallest) upper bound \(f(x_I)\) is less than a threshold determined by the user options \text{mip\_opt\_gap\_abs} and \text{mip\_opt\_gap\_rel}. Specifically, Knitro declares optimality when either

\[ f(x_I) - f(x_R) \leq \text{mip\_integral\_gap\_abs} \]

or

\[ f(x_I) - f(x_R) \leq \text{mip\_integral\_gap\_rel} \cdot \max(1, |f(x_I)|), \]

where \text{mip\_opt\_gap\_abs} and \text{mip\_opt\_gap\_rel} are typically small positive numbers. Since these termination conditions assume that the continuous subproblems are solved to global optimality and Knitro only finds local solutions of nonconvex, continuous optimization problems, they are only reliable when solving convex, mixed integer problems. The integrality gap \(f(x_I) - f(x_R)\) should be non-negative although it may become slightly negative from roundoff error, or if the continuous subproblems are not solved to sufficient accuracy. If the integrality gap becomes largely negative, this may be an indication that the model is nonconvex, in which case Knitro may not converge to the optimal solution, and will be unable to verify optimality (even if it claims otherwise).

Note that the default values for \text{mip\_opt\_gap\_abs} and \text{mip\_opt\_gap\_rel} are taken from the GAMS options \text{optCA} and \text{optCR}, but an explicit setting of \text{mip\_opt\_gap\_abs} or \text{mip\_opt\_gap\_rel} will override those.
5.23.7 Knitro Output

If `outlev=0` then all printing of output is suppressed. The description below assumes the default output level (`outlev=2`) except where indicated:

Nondefault Options:

This output lists all user options (see section Usage) which are different from their default values. If nothing is listed in this section then all user options are set to their default values.

Problem Characteristics:

The output begins with a description of the problem characteristics.

Iteration Information - Continuous Problems:

An iteration, in the context of Knitro, is defined as a step which generates a new solution estimate (i.e., a successful step). The columns of the iteration log are as follows:

- **Iter** Iteration number.
- **fCount** The cumulative number of function evaluations, only included if (`outlev>3`)
- **Objective** Gives the value of the objective function at the current iterate.
- **FeasErr** Gives a measure of the feasibility violation at the current iterate.
- **OptErr** Gives a measure of the violation of the Karush-Kuhn-Tucker (KKT) (first-order) optimality conditions (not including feasibility) at the current iterate.
- **||Step||** The 2-norm length of the step (i.e., the distance between the new iterate and the previous iterate).
- **CG ita** The number of Projected Conjugate Gradient (CG) iterations required to compute the step.

If `outlev=2`, information is printed every 10 major iterations. If `outlev=3` information is printed at each major iteration. If `outlev>4` additional information is included in the log.

Iteration Information - Discrete Problems:

By default, the GAMS/Knitro link prints a log line at every 10'th node. This frequency can be changed via the `mip_outinterval` option. To turn off the node log completely, set the `mip_outlevel` option to 0. The columns of the iteration log for discrete models are as follows:

- **Node** The node number. If an integer feasible point was found at a given node, it is marked with a *
- **Left** The current number of active nodes left in the branch and bound tree.
- **Iinf** The current number of active nodes left in the branch and bound tree.
- **Objective** Gives the value of the objective function at the solution of the relaxed subproblem solved at the current node. If the subproblem was infeasible or failed, this is indicated. Additional symbols may be printed at some nodes if the node was pruned (`pr`), integer feasible (`f`), or an integer feasible point was found through rounding (`r`).
- **Best relaxatn** The value of the current best relaxation (lower bound on the solution if minimizing).
- **Best incumbent** The value of the current best integer feasible point (upper bound on the solution if minimizing).
**Termination Message:** At the end of the run a termination message is printed indicating whether or not the optimal solution was found and if not, why the solver terminated. Below is a list of some possible termination messages.

- **EXIT: Locally optimal solution found.**  
  Knitro found a locally optimal point which satisfies the stopping criterion (see section Knitro Termination Test and Optimality) for more detail on how this is defined. If the problem is convex (for example, a linear program), then this point corresponds to a globally optimal solution.

- **EXIT: Iteration limit reached.**  
  The iteration limit was reached before being able to satisfy the required stopping criteria.

- **EXIT: Convergence to an infeasible point. Problem appears to be locally infeasible.**  
  The algorithm has converged to an infeasible point from which it cannot further decrease the infeasibility measure. This happens when the problem is infeasible, but may also occur on occasion for feasible problems with nonlinear constraints or badly scaled problems. It is recommended to try various initial points. If this occurs for a variety of initial points, it is likely the problem is infeasible.

- **EXIT: Problem appears to be unbounded.**  
  The objective function appears to be decreasing without bound, while satisfying the constraints.

- **EXIT: Current point cannot be improved.**  
  No more progress can be made. If the current point is feasible it is likely it may be optimal, however the stopping tests cannot be satisfied perhaps because of degeneracy, ill-conditioning or bad scaling.

- **EXIT: Current point cannot be improved. Point appears to be optimal, but desired accuracy could not be achieved.**  
  No more progress can be made, but the stopping tests are close to being satisfied (within a factor of 100) and so the current approximate solution is believed to be optimal.

- **EXIT: Time limit reached.**  
  The time limit was reached before being able to satisfy the required stopping criteria.

- **EXIT: Evaluation error.**  
  This termination value indicates that an evaluation error occurred (e.g., divide by 0, taking the square root of a negative number), preventing the optimization from continuing.

- **EXIT: Not enough memory available to solve problem.**  
  This termination value indicates that there was not enough memory available to solve the problem.

**Final Statistics:**

Following the termination message some final statistics on the run are printed. Both relative and absolute error values are printed.

**Solution Vector/Constraints:**

If `outlev=5`, the values of the solution vector are printed after the final statistics. If `outlev=6`, the final constraint values are also printed before the solution vector and the values of the Lagrange multipliers (or dual variables) are printed next to their corresponding constraint or bound.
5.23.8 Algorithm Options

5.23.8.1 Automatic

By default, Knitro will automatically try to choose the best optimizer for the given problem based on the problem characteristics.

5.23.8.2 Interior/Direct

If the Hessian of the Lagrangian is ill-conditioned or the problem does not have a large-dense Hessian, it may be advisable to compute a step by directly factoring the KKT (primal-dual) matrix rather than using an iterative approach to solve this system. Knitro offers the Interior/Direct optimizer which allows the algorithm to take direct steps by setting \texttt{algorithm=1}. This option will try to take a direct step at each iteration and will only fall back on the iterative step if the direct step is suspected to be of poor quality, or if negative curvature is detected.

Using the Interior/Direct optimizer may result in substantial improvements over Interior/CG when the problem is ill-conditioned (as evidenced by Interior/CG taking a large number of Conjugate Gradient iterations). We encourage the user to try both options as it is difficult to predict in advance which one will be more effective on a given problem. In each case, also experiment with the \texttt{bar_murule} option, as it is difficult to predict which update rule will work best.

NOTE: Since the Interior/Direct algorithm in Knitro requires the explicit storage of a Hessian matrix, this version can only be used with Hessian options, \texttt{hessopt=1, 2, 3 or 6}. It may not be used with Hessian options, \texttt{hessopt=4 or 5}, which only provide Hessian-vector products. Both the Interior/Direct and Interior/CG methods can be used with the \texttt{bar_feasible} option.

5.23.8.3 Interior/CG

Since Knitro was designed with the idea of solving large problems, the Interior/CG optimizer in Knitro offers an iterative Conjugate Gradient approach to compute the step at each iteration. This approach has proven to be efficient in most cases and allows Knitro to handle problems with large, dense Hessians, since it does not require factorization of the Hessian matrix. The Interior/CG algorithm can be chosen by setting \texttt{algorithm=2}. It can use any of the Hessian options as well as the \texttt{bar_feasible} option.

5.23.8.4 Active Set

Knitro includes an active-set Sequential Linear-Quadratic Programing (SLQP) optimizer. This optimizer is particular advantageous when "warm starting" (i.e., when the user can provide a good initial solution estimate, for example, when solving a sequence of closely related problems). This algorithm is also the preferred algorithm for detecting infeasible problems quickly. The Active Set algorithm can be chosen by setting \texttt{algorithm=3}. It can use any of the Hessian options.

5.23.9 Other Knitro special features

This section describes in more detail some of the more important special features of Knitro and provides some guidance on how use them so that Knitro runs most efficiently for the problem at hand.
5.23.9.1 Second derivative options

The default version of Knitro assumes that exact second derivatives of the objective function and constraint functions can be computed. If this is possible and the cost of computing the second derivatives is not overly expensive, it is highly recommended to use exact second derivatives. However, Knitro also offers other options which are described in detail below.

(Dense) Quasi-Newton BFGS
The quasi-Newton BFGS option uses gradient information to compute a symmetric, positive-definite approximation to the Hessian matrix. Typically this method requires more iterations to converge than the exact Hessian version. However, since it is only computing gradients rather than Hessians, this approach may be more efficient in many cases. This option stores a dense quasi-Newton Hessian approximation so it is only recommended for small to medium problems ($n < 1000$). The quasi-Newton BFGS option can be chosen by setting options value $\text{hessopt}=2$.

(Dense) Quasi-Newton SR1
As with the BFGS approach, the quasi-Newton SR1 approach builds an approximate Hessian using gradient information. However, unlike the BFGS approximation, the SR1 Hessian approximation is not restricted to be positive-definite. Therefore the quasi-Newton SR1 approximation may be a better approach, compared to the BFGS method, if there is a lot of negative curvature in the problem since it may be able to maintain a better approximation to the true Hessian in this case. The quasi-Newton SR1 approximation maintains a dense Hessian approximation and so is only recommended for small to medium problems ($n < 1000$). The quasi-Newton SR1 option can be chosen by setting options value $\text{hessopt}=3$.

Finite-difference Hessian-vector product option
If the problem is large and gradient evaluations are not the dominate cost, then Knitro can internally compute Hessian-vector products using finite-differences. Each Hessian-vector product in this case requires one additional gradient evaluation. This option can be chosen by setting options value $\text{hessopt}=4$. This option is generally only recommended if the exact gradients are provided.

NOTE: This option may not be used when $\text{algorithm}=1$.

Exact Hessian-vector products
In some cases the problem which the user wishes to solve may have a large, dense Hessian which makes it impractical to store or work with the Hessian directly.

The performance of this option should be nearly identical to the exact Hessian option but requires much less storage. This option can be chosen by setting options value $\text{hessopt}=5$.

NOTE: This option may not be used when $\text{algorithm}=1$.

Limited-memory Quasi-Newton BFGS
The limited-memory quasi-Newton BFGS option is similar to the dense quasi-Newton BFGS option described above. However, it is better suited for large-scale problems since, instead of storing a dense Hessian approximation, it only stores a limited number of gradient vectors used to approximate the Hessian. In general it requires more iterations to converge than the dense quasi-Newton BFGS approach but will be much more efficient on large-scale problems. This option can be chosen by setting options value $\text{hessopt}=6$.

5.23.9.2 Feasible version

Knitro offers the user the option of forcing intermediate iterates to stay feasible with respect to the inequality constraints (it does not enforce feasibility with respect to the equality constraints however). Given an initial point which is sufficiently feasible with respect to all inequality constraints and selecting
bar_feasible = 1, forces all the iterates to strictly satisfy the inequality constraints throughout the solution process. For the feasible mode to become active the iterate $x$ must satisfy

$$cl + tol \leq c(x) \leq cu - tol$$

(21)

for all inequality constraints (i.e., for $cl \neq cu$). The tolerance $tol > 0$ by which an iterate must be strictly feasible for entering the feasible mode is determined by the parameter bar_feasmodetol which is $1.0e^{-4}$ by default. If the initial point does not satisfy (21) then the default infeasible version of Knitro will run until it obtains a point which is sufficiently feasible with respect to all the inequality constraints. At this point it will switch to the feasible version of Knitro and all subsequent iterates will be forced to satisfy the inequality constraints.

For a detailed description of the feasible version of Knitro see [32].

NOTE: This option may only be used when algorithm=2.

5.23.9.3 Honor Bounds

By default Knitro does not enforce that the simple bounds on the variables (1c) are satisfied throughout the optimization process. Rather, satisfaction of these bounds is only enforced at the solution. In some applications, however, the user may want to enforce that the initial point and all intermediate iterates satisfy the bounds $bl \leq x \leq bu$. This can be enforced by setting honorbnds=1.

5.23.9.4 Crossover

Interior-point (or barrier) methods are a powerful tool for solving large-scale optimization problems. However, one drawback of these methods is that they do not always provide a clear picture of which constraints are active at the solution. In general they return a less exact solution and less exact sensitivity information. For this reason, Knitro offers a crossover feature in which the interior-point method switches to the Active Set method at the interior-point solution estimate, in order to "clean up" the solution and provide more exact sensitivity and active set information. The crossover procedure is controlled by the bar_maxcrossit option. If this option is greater than 0, then Knitro will attempt to perform bar_maxcrossit Active Set crossover iterations after the interior-point method has finished, to see if it can provide a more exact solution. This can be viewed as a form of post-processing. If bar_maxcrossit is not positive, then no crossover iterations are attempted.

The crossover procedure will not always succeed in obtaining a more exact solution compared with the interior-point solution. If crossover is unable to improve the solution within bar_maxcrossit crossover iterations, then it will restore the interior-point solution estimate and terminate. By default, Knitro will then print a message indicating that it was unable to improve the solution within the iterations allowed. In this case, you may want to increase the value of bar_maxcrossit and try again. If Knitro determines that the crossover procedure will not succeed, no matter how many iterations are tried, then a message of the form Crossover mode unable to improve solution. will be printed.

The extra cost of performing crossover is problem dependent. In most small or medium scale problems, the crossover cost is a small fraction of the total solve cost. In these cases it may be worth using the crossover procedure to obtain a more exact solution. On some large scale or difficult degenerate problems, however, the cost of performing crossover may be significant. It is recommended to experiment with this option to see whether improvement in the exactness of the solution is worth the additional cost.
5.23.9.5 Tuner

The Knitro-Tuner can help you identify some non-default options settings that may improve performance on a particular model or set of models. The Knitro tuner is enabled with the tuner option and controlled via the tuner family of options. If you are unsure about what Knitro options should be tuned to try to improve performance, you can run the default Knitro-Tuner by simply setting the option tuner=1 when solving with Knitro. This will cause Knitro to run your model with a variety of automatically determined option settings, and report some statistics at the end. Any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.

If you have some ideas about which Knitro options you want to tune, you can tell Knitro which options you want it to tune, as well as specify the values for particular options that you want Knitro to explore. This can be done by specifying a Tuner options file. A Tuner options file is a simple text file that is similar to a standard Knitro options file, with some important differences:

- You can define multiple values (separated by spaces) for each option. This tells Knitro the values you want it to explore.
- You can specify an option name without any values. This will tell Knitro to explore all possible option values for that option. This only works for options that have a finite set of possible option value settings.
- A Tuner options file is loaded via the tuner_optionsfile option.

All possible combinations of options/values specified in a Tuner options file will be explored by Knitro, while any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.

5.23.9.6 Solving Systems of Nonlinear Equations

Knitro is quite effective at solving systems of nonlinear equations. To solve a square system of nonlinear equations using Knitro one should specify the nonlinear equations as equality constraints (i.e., constraints with \( cl = cu \)), and specify the objective function (1a) as zero (i.e., \( f(x) = 0 \)).

5.23.9.7 Solving Least Squares Problems

There are two ways of using Knitro for solving problems in which the objective function is a sum of squares of the form

\[
f(x) = \frac{1}{2} \sum_{j=1}^{q} r_j(x)^2.
\]

If the value of the objective function at the solution is not close to zero (the large residual case), the least squares structure of \( f \) can be ignored and the problem can be solved as any other optimization problem. Any of the Knitro options can be used.

On the other hand, if the optimal objective function value is expected to be small (small residual case) then Knitro can implement the Gauss-Newton or Levenberg-Marquardt methods which only require first derivatives of the residual functions, \( r_j(x) \), and yet converge rapidly. To do so, the user need only define the Hessian of \( f \) to be

\[
\nabla^2 f(x) = J(x)^T J(x),
\]

where

\[
J(x) = \left[ \frac{\partial r_j}{\partial x_i} \right]_{j=1,2,\ldots,q, i=1,2,\ldots,n}.
\]
The actual Hessian is given by
\[
\nabla^2 f(x) = J(x)^T J(x) + \sum_{j=1}^{q} r_j(x) \nabla^2 r_j(x);
\]
the Gauss-Newton and Levenberg-Marquardt approaches consist of ignoring the last term in the Hessian.

Knitro will behave like a Gauss-Newton method by setting `algorithm=1`, and will be very similar to the classical Levenberg-Marquardt method when `algorithm=2`. For a discussion of these methods see, for example, [143].

## 5.24 LINDO and LINDOGlobal

Lindo Systems, Inc.

### 5.24.1 Introduction

GAMS/LINDO finds guaranteed globally optimal solutions to general nonlinear problems with continuous and/or discrete variables. GAMS/LINDO supports most mathematical functions, including functions that are nonsmooth, such as \(\text{abs}(x)\) and or even discontinuous, such as \(\text{floor}(x)\). Nonlinear solvers employing methods like successive linear programming (SLP) or generalized reduced gradient (GRG) return a local optimal solution to an NLP problem. However, many practical nonlinear models are non-convex and have more than one local optimal solution. In some applications, the user may want to find a global optimal solution.

The LINDO global optimization procedure (GOP) employs branch-and-cut methods to break an NLP model down into a list of subproblems. Each subproblem is analyzed and either a) is shown to not have a feasible or optimal solution, or b) an optimal solution to the subproblem is found, e.g., because the subproblem is shown to be convex, or c) the subproblem is further split into two or more subproblems which are then placed on the list. Given appropriate tolerances, after a finite, though possibly large number of steps a solution provably global optimal to tolerances is returned. Traditional nonlinear solvers can get stuck at suboptimal, local solutions. This is no longer the case when using the global solver.

GAMS/LINDO can automatically linearize a number of nonlinear relationships, such as \(\max(x, y)\), through the addition of constraints and integer variables, so the transformed linearized model is mathematically equivalent to the original nonlinear model. Keep in mind, however, that each of these strategies will require additional computation time. Thus, formulating models, so they are convex and contain a single extremum, is desirable. In order to decrease required computing power and time it is also possible to disable the global solver and use GAMS/LINDO like a regular nonlinear solver.

GAMS/LINDO has a multistart feature that restarts the standard (non-global) nonlinear solver from a number of intelligently generated points. This allows the solver to find a number of locally optimal points and report the best one found. This alternative can be used when global optimization is costly. A user adjustable parameter controls the maximum number of multistarts to be performed.

LINDO automatically detects problem type and uses an appropriate solver, e.g., if you submit an LP model to LINDO, it will be solved as an LP at LP speed, regardless of what you said in the "solve using" statement. With the NLP parameter `NLP.QUADECHK` turned on, LINDO can detect hidden quadratic expressions and automatically recognize convex QCPs, as well as second-order cones (SOCP), like in Value-at-Risk models, allowing dramatically faster solution times via the barrier solver. When such models have integer variables, LINDO would use the barrier solver to solve all subproblems leading to significantly improved solution times when compared to the case with the standard NLP solver.
5.24.1.1 Licensing and software requirements

In order to use GAMS/LINDOGlobal, two licenses are required: a GAMS/LINDOGlobal license and a GAMS/CONOPT license. The additional CONOPT license requirement exists because LINDOGlobal uses CONOPT to solve the nonlinear subproblems. The GAMS/LINDOGlobal license places upper limits on the model size of 3,000 variables and 2,000 constraints.

To use GAMS/LINDO, only a GAMS/LINDO license is required. It imposes no upper limit on the model size and includes the capability to solve stochastic models (see section Stochastic Programming (SP) in GAMS/Lindo).

Neither the GAMS/LINDO nor the GAMS/LINDOGlobal license includes the Barrier solver option. The Barrier option is enabled via a separate license for the GAMS/MOSEK barrier solver.

5.24.1.2 Running GAMS/LINDO

GAMS/LINDO is capable of solving models of the following types: EMP (stochastic), LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP and MINLP. If GAMS/LINDO is not specified as the default solver for these models, it can be invoked by issuing one of the following command before the solve statement:

```gams
option xxx=lindo;
option xxx=lindoglobal;
```

where xxx is one of: EMP, LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP, or MINLP.

You can also find global optima to math programs with equilibrium or complementarity constraints, type MPEC, by using the GAMS/NLPEC translator in conjunction with LINDO. You use NLPEC to translate complementarities into standard mathematical statements, e.g. \( h^* y = 0 \), and then use LINDO as the DNLP (Discontinuous Nonlinear) solver to solve the translated model. The following little GAMS model illustrates:

```gams
$TITLE simple mpec example
variable f, x1, x2, y1, y2; positive
variable y1; y2.lo = -1; y2.up = 1;

equations cost, g, h1, h2;

cost..  f =E=  x1 + x2;
g..    sqr(x1) + sqr(x2) =L= 1;
h1..  x1 =G=  y1 - y2 + 1;
h2..  x2 + y2 =N= 0;

* declare h and y complementary
model example / cost, g, h1.y1, h2.y2 /;

option mpec=nlpec;
onption dnlp=lindo;
solve example using mpec min f;
```

5.24.2 Supported nonlinear functions

GAMS/LINDO supports most nonlinear functions in global mode, including +, -, *, /, floor, modulo, sign, min, max, sqr, exp, power, ln, log, sqrt, abs, cos, sin, tan, cosh, sinh, tanh, arccos, arcsin, arctan and logic expressions AND, OR, NOT, and IF. Be aware that using highly nonconvex functions may lead to long solve times.
5.24.3 Diagnosis of Infeasible or Unbounded Models

GAMS/LINDO offers two diagnostic tools, that can help users debug infeasible or unbounded optimization models. These tools can be called after the solver reports an infeasible or unbounded status for the model. When activating IIS Lindo finds an irreducible infeasible set (IIS) of constraints, whereas setting IUS, makes Lindo find an irreducible unbounded set (IUS) of variables. An IIS is a set of constraints that are infeasible taken together, but every strict subset is feasible. Similarly, an IUS is a set of unbounded variables such that fixing any one of them would make the model bounded. The IIS or IUS portion of the model will generally be much smaller than the original model. Thus, the user can track down formulation or data entry errors quickly. By isolating the source of infeasibility or unboundedness, the user can correct the model data such as right-hand side values, objective coefficients, senses of the constraints, and column bounds. Note that the IUS option is available for LPs only.

5.24.3.1 Infeasible Models

GAMS/Lindo’s IIS option activates the IIS finder, after a model was tried to be solved and the solver returned a ”no feasible solution” message. For an LP, if an infeasible basis is not resident in the solver, the IIS finder cannot initiate the process to isolate an IIS. This can occur if the infeasibility is detected in the pre-solver before a basis is created, or the barrier solver has terminated without performing a basis crossover. To obtain an IIS for such cases, the pre-solve option will be turned off automatically and the model gets optimized again.

The constraints and bounds in the IIS are further classified into two disjoint sets: a necessary set and a sufficient set. The sufficient set refers to a crucial subset of the IIS in the sense that removing any one of its members from the entire model renders the model feasible. Note that not all infeasible models have sufficient sets. The necessary set contains those constraints and bounds that are likely to contribute to the overall infeasibility of the entire model. Thus, the necessary set requires a correction in at least one member to make the original model feasible. A constraint that has been marked as sufficient has a high probability of containing an error. In fact, if the model contains only one bad coefficient, the constraint containing it will be marked as sufficient.

To control the level of analysis when locating an IIS, one can set the option IIS_ANALYZE_LEVEL.

5.24.3.2 Unbounded Linear Programs

GAMS/Lindo’s IUS option is similar to the IIS option, except that it is used to track down the source of an unbounded solution in a linear program. This tool analyzes the model and isolates an ”irreducibly unbounded set” (IUS) of variables. As in the infeasibility case, the IUS is partitioned into sufficient and necessary sets to indicate the role of the member variables for the unboundedness of the overall model.

The variables in the sufficient set are crucial in the sense that fixing any of these variables makes the overall model bounded. However, fixing the variables in the necessary set does not ensure that there are no other sets of unbounded variables that cause unboundedness for the overall model.

To control the level of analysis when locating an IUS, one can set the option IUS_ANALYZE_LEVEL.
5.24.4 GAMS/LINDO output

The log output below is obtained for the NLP model mhw4d.gms from the GAMS model library using LINDO's global solver.

After determining the different kinds of nonlinear operators LINDO tries to linearize these within the presolving. When a feasible starting point is found the optimization starts and the log provides information about the progress. At the end it is reported if an optimum could be found and then the results as well as the used resources are summarized.

The following flags can be seen in the progress log:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(+FP)</td>
<td>found a new MIP solution with feasibility pump</td>
</tr>
<tr>
<td>(+SBB)</td>
<td>found a new MIP solution in tree reorder</td>
</tr>
<tr>
<td>(+SE)</td>
<td>found a new MIP solution in simple enumeration</td>
</tr>
<tr>
<td>(+AB)</td>
<td>found a new MIP solution in advanced branching</td>
</tr>
<tr>
<td>(+AH)</td>
<td>found a new MIP solution with advanced heuristics</td>
</tr>
<tr>
<td>(+T)</td>
<td>found a new MIP solution on the top</td>
</tr>
<tr>
<td>(+SRH)</td>
<td>found a new MIP solution in simple rounding heuristics</td>
</tr>
<tr>
<td>(+SB)</td>
<td>found a new MIP solution in strong branching</td>
</tr>
<tr>
<td>(+K)</td>
<td>found a new MIP solution in knapsack enumerator</td>
</tr>
<tr>
<td>(+)</td>
<td>found a new MIP solution normal branching</td>
</tr>
<tr>
<td>(+?-)</td>
<td>found a new MIP solution with advanced heuristics (level$&gt;$10)</td>
</tr>
<tr>
<td>(+N)</td>
<td>found a new incumbent GOP solution</td>
</tr>
<tr>
<td>(+I)</td>
<td>stored a box with the incumbent solution into the GOP solution list</td>
</tr>
<tr>
<td>(+F)</td>
<td>determined the final GOP status</td>
</tr>

</table>

5.24.5 The GAMS/LINDO Options

GAMS/LINDO offers a diverse range of user-adjustable parameters to control the behavior of its solvers. While the default values of these parameters work best for most purposes, there may be cases the users prefer to work with different settings for a subset of the available parameters. This section gives a list of available GAMS/LINDO parameters, categorized by type, along with their brief descriptions. A more detailed description is given in the section that follows.
5.24.5.1 GAMS/LINDO Options File

In order to set GAMS/LINDO options, you need to set up an option file `lindo.opt` or `lindoglobal.opt` in your GAMS project directory. You must indicate in the model that you want to use the option file by inserting before the solve statement, the line:

```
<modelname>.optfile = 1;
```

where

```
<modelname>
```

is the name of the model referenced in the model statement. The option file is in plain text format containing a single GAMS/LINDO option per line. Each option identifier is followed by its target value with space or tab characters separating them. The lines starting with `*` character are treated as comments.

A sample option file `lindo.opt` looks like below

```
* Use(1) or Disable(0) global optimization for NLP/MINLP models
USEGOP 0

* Enable Multistart NLP solver
NLP_SOLVER 9

* Allow a maximum of 3 multistart attempts
NLP_MAXLOCALSEARCH 3

* Set an overall time limit of 200 secs.
SOLVER_TIMLMT 200
```

5.24.6 Summary of GAMS/Lindo Options

5.24.6.1 General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DECOMPOSITION_TYPE</code></td>
<td>decomposition to be performed on a linear or mixed integer model</td>
<td>1</td>
</tr>
<tr>
<td><code>FIND_BLOCK</code></td>
<td>graph partitioning method to find block structures</td>
<td>0</td>
</tr>
<tr>
<td><code>FIND_SYMMETRY_LEVEL</code></td>
<td>specifies the symmetry finding level.</td>
<td>-1</td>
</tr>
<tr>
<td><code>FIND_SYMMETRY_PRINT_LEVEL</code></td>
<td>specifies print level for symmetry finding</td>
<td>0</td>
</tr>
<tr>
<td><code>INSTRUCT_SUBOUT</code></td>
<td>flag to specify how to deal with fixed variables in the instruction list</td>
<td>-1</td>
</tr>
<tr>
<td><code>MULTITHREAD_MODE</code></td>
<td>threading mode</td>
<td>-1</td>
</tr>
<tr>
<td><code>NUM_THREADS</code></td>
<td>number of parallel threads to be used</td>
<td>GAMS Threads</td>
</tr>
<tr>
<td><code>PROFILER_LEVEL</code></td>
<td>specifies the profiler level to break down the total cpu time into.</td>
<td>0</td>
</tr>
<tr>
<td><code>SOLVER_CONCURRENT_OPTMODE</code></td>
<td>controls if simplex and interior-point optimizers will run concurrently</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>SOLVER_CUTOFFVAL</td>
<td>solver will exit if optimal solution is worse than this</td>
<td>0</td>
</tr>
<tr>
<td>SOLVER_FEASTOL</td>
<td>feasibility tolerance</td>
<td>1e-7</td>
</tr>
<tr>
<td>SOLVER_IPMSOL</td>
<td>basis crossover flag for barrier solver</td>
<td>0</td>
</tr>
<tr>
<td>SOLVER_IUSOL</td>
<td>flag for computing basic solution for infeasible model</td>
<td>0</td>
</tr>
<tr>
<td>SOLVER_METHOD</td>
<td>specifies the method to use when generic solver is invoked</td>
<td>0</td>
</tr>
<tr>
<td>SOLVER_MODE</td>
<td>controls some of the advanced strategies when solving LPs</td>
<td>1</td>
</tr>
<tr>
<td>SOLVER_OPTTOL</td>
<td>dual feasibility tolerance</td>
<td>1e-7</td>
</tr>
<tr>
<td>SOLVER_PRE_ELIM_FILL</td>
<td>fill-in introduced by the eliminations during pre-solve</td>
<td>1000</td>
</tr>
<tr>
<td>SOLVER_RESTART</td>
<td>starting basis flag</td>
<td>0</td>
</tr>
<tr>
<td>SOLVER_TIMLMT</td>
<td>time limit in seconds for continous solver</td>
<td>GAMS ResLim</td>
</tr>
<tr>
<td>SOLVER_USECUTOFFVAL</td>
<td>flag for using cutoff value</td>
<td>0</td>
</tr>
<tr>
<td>TUNER_PRINT_LEVEL</td>
<td>specifies the amount of print to do during parameter tuning</td>
<td>1</td>
</tr>
</tbody>
</table>

5.24.6.2 LP Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>LP_AIJ_ZEROTOL</td>
<td>coefficient matrix zero tolerance</td>
<td>2.22045e-16</td>
</tr>
<tr>
<td>LP_BIGM</td>
<td>big-M for phase-I</td>
<td>1e6</td>
</tr>
<tr>
<td>LP_BNDINF</td>
<td>big-M to truncate lower and upper bounds in single phase dual-simplex</td>
<td>1e15</td>
</tr>
<tr>
<td>LP_DPSWITCH</td>
<td>specifies whether LP primal-dual simplex switch is enabled or not</td>
<td>1</td>
</tr>
<tr>
<td>LP_DRATIO</td>
<td>controls the dual min-ratio strategy</td>
<td>1</td>
</tr>
<tr>
<td>LP_DYNOBJFACT</td>
<td>Dynamic obj factor</td>
<td>0.75</td>
</tr>
<tr>
<td>LP_DYNOBJMODE</td>
<td>Dynamic obj mode</td>
<td>0</td>
</tr>
<tr>
<td>LP_ITRLMT</td>
<td>simplex iteration limit</td>
<td>infinity</td>
</tr>
<tr>
<td>LP_PIV_BIGTOL</td>
<td>simplex maximum pivot tolerance</td>
<td>1e-5</td>
</tr>
<tr>
<td>LP_PIV_ZEROTOL</td>
<td>simplex pivot zero tolerance</td>
<td>1e-8</td>
</tr>
<tr>
<td>LP_PPARTIAL</td>
<td>primal simplex partial pricing method</td>
<td>0</td>
</tr>
<tr>
<td>LP_PRELEVEL</td>
<td>controls the amount and type of LP pre-solving</td>
<td>126</td>
</tr>
<tr>
<td>LP_RATRANGE</td>
<td>controls the number of pivot-candidates to consider when searching for a</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>stable pivot in LU decomposition</td>
<td></td>
</tr>
<tr>
<td>LP_SCALE</td>
<td>scaling flag</td>
<td>1</td>
</tr>
<tr>
<td>LP_SPRINT_COLFACT</td>
<td>maximum number of columns in Sprint as a factor of number of rows</td>
<td>10</td>
</tr>
<tr>
<td>LP_SPRINT_MAXPASS</td>
<td>maximum number of passes in Sprint method</td>
<td>100</td>
</tr>
<tr>
<td>LP_SPRINT_SUB</td>
<td>LP method for subproblem in Sprint method</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>PROB_TO_SOLVE</td>
<td>controls whether the explicit primal or dual form of the given LP problem will be solved</td>
<td>0</td>
</tr>
<tr>
<td>SPLEX_DPRICING</td>
<td>pricing option for dual simplex method</td>
<td>-1</td>
</tr>
<tr>
<td>SPLEX_DUAL_PHASE</td>
<td>controls the dual simplex strategy</td>
<td>0</td>
</tr>
<tr>
<td>SPLEX_PPRICING</td>
<td>pricing option for primal simplex method</td>
<td>-1</td>
</tr>
<tr>
<td>SPLEX_REFACFRQ</td>
<td>number of simplex iterations between two consecutive basis re-factorizations</td>
<td>100</td>
</tr>
</tbody>
</table>

### 5.24.6.3 IPM Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPM_BASIS_REL_TOL_S</td>
<td>maximum relative dual bound violation allowed in an optimal basic solution</td>
<td>1e-12</td>
</tr>
<tr>
<td>IPM_BASIS_TOL_S</td>
<td>maximum absolute dual bound violation in an optimal basic solution</td>
<td>1e-7</td>
</tr>
<tr>
<td>IPM_BASIS_TOL_X</td>
<td>maximum absolute primal bound violation allowed in an optimal basic solution</td>
<td>1e-7</td>
</tr>
<tr>
<td>IPM_BI_LU_TOL_REL_PIV</td>
<td>relative pivot tolerance used in the LU factorization in the basis identification procedure</td>
<td>1e-2</td>
</tr>
<tr>
<td>IPM_CHECK_CONVEXITY</td>
<td>flag to check convexity of a quadratic program using barrier solver</td>
<td>1</td>
</tr>
<tr>
<td>IPM_CO_TOL_DFEAS</td>
<td>dual feasibility tolerance for Conic solver</td>
<td>1e-8</td>
</tr>
<tr>
<td>IPM_CO_TOL_INFEAS</td>
<td>maximum bound infeasibility tolerance for Conic solver</td>
<td>1e-12</td>
</tr>
<tr>
<td>IPM_CO_TOL_MU_RED</td>
<td>optimality tolerance for Conic solver</td>
<td>1e-8</td>
</tr>
<tr>
<td>IPM_CO_TOL_PFEAS</td>
<td>primal feasibility tolerance for Conic solver</td>
<td>1e-8</td>
</tr>
<tr>
<td>IPM_MAX_ITERATIONS</td>
<td>ipm iteration limit</td>
<td>1000</td>
</tr>
<tr>
<td>IPM_NUM_THREADS</td>
<td>number of threads to run the interiorpoint optimizer on</td>
<td>1</td>
</tr>
<tr>
<td>IPM_OFF_COL_TRH</td>
<td>extent for detecting the offending columns in the Jacobian of the constraint matrix</td>
<td>40</td>
</tr>
<tr>
<td>IPM_TOL_DFEAS</td>
<td>dual feasibility</td>
<td>1e-8</td>
</tr>
<tr>
<td>IPM_TOL_DSAFE</td>
<td>controls the initial dual starting point</td>
<td>1</td>
</tr>
<tr>
<td>IPM_TOL_INFEAS</td>
<td>infeasibility tolerance</td>
<td>1e-10</td>
</tr>
<tr>
<td>IPM_TOL_MU_RED</td>
<td>relative complementarity gap tolerance</td>
<td>1e-16</td>
</tr>
<tr>
<td>IPM_TOL_PATH</td>
<td>how close to follow the central path</td>
<td>1e-8</td>
</tr>
<tr>
<td>IPM_TOL_PFEAS</td>
<td>primal feasibility</td>
<td>1e-8</td>
</tr>
<tr>
<td>IPM_TOL_PSAFE</td>
<td>controls the initial primal starting point</td>
<td>1</td>
</tr>
<tr>
<td>IPM_TOL_REL_STEP</td>
<td>relative step size to the boundary</td>
<td>0.9999</td>
</tr>
</tbody>
</table>

### 5.24.6.4 MIP Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIP_ABSCUTTOL</td>
<td>MIP absolute cut tolerance</td>
<td>-1.0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>MIP_ABSOPTTOL</td>
<td>MIP absolute optimality tolerance</td>
<td>GAMS OptCA</td>
</tr>
<tr>
<td>MIP_ADDCUTOBJTOL</td>
<td>required objective improvement to continue generating cuts</td>
<td>1.5625e-5</td>
</tr>
<tr>
<td>MIP_ADDCUTPER</td>
<td>percentage of constraint cuts that can be added</td>
<td>0.75</td>
</tr>
<tr>
<td>MIP_ADDCUTPER_TREE</td>
<td>percentage of constraint cuts that can be added at child nodes</td>
<td>0.5</td>
</tr>
<tr>
<td>MIP_AGGCUTLIM_TOP</td>
<td>max number of constraints involved in derivation of aggregation cut at root node</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_AGGCUTLIM_TREE</td>
<td>max number of constraints involved in derivation of aggregation cut at tree nodes</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_ANODES_SWITCH_DF</td>
<td>threshold on active nodes for switching to depth-first search</td>
<td>50000</td>
</tr>
<tr>
<td>MIP_AOPTTIMLIM</td>
<td>time in seconds beyond which the relative optimality tolerance will be applied</td>
<td>100</td>
</tr>
<tr>
<td>MIP_BIGM_FOR_INTTOL</td>
<td>threshold for which coefficient of a binary variable would be considered as big-M</td>
<td>1e8</td>
</tr>
<tr>
<td>MIP_BRANCHDIR</td>
<td>first branching direction</td>
<td>0</td>
</tr>
<tr>
<td>MIP_BRANCHRULE</td>
<td>rule for choosing the variable to branch</td>
<td>0</td>
</tr>
<tr>
<td>MIP_BRANCH_LIMIT</td>
<td>limit on the total number of branches to be created during branch and bound</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_BRANCH_Prio</td>
<td>controls how variable selection priorities are set and used</td>
<td>0</td>
</tr>
<tr>
<td>MIP.Concurrent.ReoptMode</td>
<td>specifies the concurrent optimization mode with warm start</td>
<td>0</td>
</tr>
<tr>
<td>MIP_Concurrent.Strategy</td>
<td>controls the concurrent MIP strategy</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_Concurrent.ToopMode</td>
<td>specifies the concurrent optimization mode with cold start</td>
<td>0</td>
</tr>
<tr>
<td>MIP_CUTDEPTH</td>
<td>threshold value for the depth of nodes in the branch and bound tree</td>
<td>8</td>
</tr>
<tr>
<td>MIP_CUTFREQ</td>
<td>frequency of invoking cut generation at child nodes</td>
<td>10</td>
</tr>
<tr>
<td>MIP_CUTLEVEL_Top</td>
<td>combination of cut types to try at the root node when solving a MIP</td>
<td>57342</td>
</tr>
<tr>
<td>MIP_CUTLEVEL_TreE</td>
<td>combination of cut types to try at child nodes in the branch and bound tree when solving a MIP</td>
<td>53246</td>
</tr>
<tr>
<td>MIP_CUTOFFOBJ</td>
<td>defines limit for branch and bound</td>
<td>1e30</td>
</tr>
<tr>
<td>MIP_CUTTIMLIM</td>
<td>time to be spent in cut generation</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_DELTA</td>
<td>near-zero value used in linearizing nonlinear expressions</td>
<td>1e-6</td>
</tr>
<tr>
<td>MIP_DUAL_SOLUITION</td>
<td>flag for computing dual solution of LP relaxation</td>
<td>0</td>
</tr>
<tr>
<td>MIP_FP_HEU_MODE</td>
<td>specifies the feasibility-pump (FP) heuristic mode</td>
<td>0</td>
</tr>
<tr>
<td>MIP_FP_ITRLIM</td>
<td>iteration limit for feasibility pump heuristic</td>
<td>500</td>
</tr>
<tr>
<td>MIP_FP_MODE</td>
<td>mode for the feasibility pump heuristic</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_FP_OPT_METHOD</td>
<td>optimization and reoptimization method for feasibility pump heuristic</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>MIP_FP_PROJECTION</td>
<td>type of objective function of LPs in projection step of the feasibility pump heuristic</td>
<td>0</td>
</tr>
<tr>
<td>MIP_FP_TIMLIM</td>
<td>time limit for feasibility pump heuristic</td>
<td>1800</td>
</tr>
<tr>
<td>MIP_FP_WEIGHT</td>
<td>weight of the objective function in the feasibility pump</td>
<td>1</td>
</tr>
<tr>
<td>MIP_GENERAL_MODE</td>
<td>general strategy in solving MIPs</td>
<td>0</td>
</tr>
<tr>
<td>MIP_HEULEVEL</td>
<td>specifies heuristic used to find integer solution</td>
<td>3</td>
</tr>
<tr>
<td>MIP_HEUMINTIMLIM</td>
<td>minimum time in seconds to be spent in finding heuristic solutions</td>
<td>0</td>
</tr>
<tr>
<td>MIP_HEU_DROP_OBJ</td>
<td>flag for whether to use without OBJ heuristic</td>
<td>0</td>
</tr>
<tr>
<td>MIP_HEU_MODE</td>
<td>heuristic used in MIP solver</td>
<td>0</td>
</tr>
<tr>
<td>MIP_INTTOL</td>
<td>absolute integer feasibility tolerance</td>
<td>1e-6</td>
</tr>
<tr>
<td>MIP_ITRLIM</td>
<td>iteration limit for branch and bound</td>
<td>infinity</td>
</tr>
<tr>
<td>MIP_KBEST_USE_GOP</td>
<td>specifies whether to use gop solver in MIP KBest</td>
<td>0</td>
</tr>
<tr>
<td>MIP_KEEPINMEM</td>
<td>flag for keeping LP bases in memory</td>
<td>1</td>
</tr>
<tr>
<td>MIP_LBIGM</td>
<td>Big-M value used in linearizing nonlinear expressions</td>
<td>10000</td>
</tr>
<tr>
<td>MIP_LSOLTIMLIM</td>
<td>time limit until finding a new integer solution</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_MAKECUT_INACTIVE_COUNT</td>
<td>threshold for times a cut could remain active after successive reoptimization</td>
<td>10</td>
</tr>

</tr>
</tbody>
</table>

### 5.24.7 Detailed Descriptions of GAMS/Lindo Options

**CHECKRANGE (string):** calculate feasible range for variables

If this option is set, Lindo calculates the feasible range (determined by an upper and lower bound) for every variable in each equation while all other variables are fixed to their level. If set, the value of this option defines the name of the GDX file where the results are written to. For every combination of equation- and variable block there will be one symbol in the format `EquBlock_VarBlock(equ_Ind_1, ..., equ_Ind_M, var_Ind_1, ..., var_Ind_N, directions)`.

Default: `range.gdx`

**CORE_ORDER_BY_STAGE (integer):** order nontemporal models or not

Order nontemporal models or not.

Default: 1

**DECOMPOSITION_TYPE (integer):** decomposition to be performed on a linear or mixed integer model

This refers to the type of decomposition to be performed on a linear or mixed integer model.

Default: 1
### EMPINFOFILE (string): Path and name of file containing additional EMP-SP information as randvar, jrandvar, stage etc.

Specifies the graph partitioning method to find block structures.

**Default:** 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use an edge-weight minimizing graph partitioning heuristic</td>

<tr>
<td>+16</td>
<td>Partition information</td>
<td></td>
</tr>
</tbody>
</table>

### GOP_ABSOPTTOL (real): absolute optimality tolerance
Synonym: ABSOPTTOL

This value is the GOP absolute optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: GAMS OptCA

**GOP_ALGREFORMMD** *(integer)*: algebraic reformulation rule for a GOP

Synonym: ALGREFORMMD

This controls the algebraic reformulation rule for a GOP. The algebraic reformulation and analysis is very crucial in building a tight convex envelope to enclose the nonlinear/nonconvex functions. A lower degree of overestimation on convex envelopes helps increase the convergence rate to the global optimum.

Default: 18

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Rearrange and collect terms</td>
</tr>
<tr>
<td>+4</td>
<td>Expand all parentheses</td>

<tr>
<td>+8</td>
<td>Retain nonlinear functions</td>
</tr>
<tr>
<td>+16</td>
<td>Selectively expand parentheses</td>
</tr>
</tbody>
</table>

**GOP_BBSRCHMD** *(integer)*: node selection rule in GOP branch-and-bound

Synonym: BBSRCHMD

This specifies the node selection rule for choosing between all active nodes in the GOP branch-and-bound tree when solving global optimization programs.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Depth first search</td>
</tr>
<tr>
<td>1</td>
<td>Choose node with worst bound</td>
</tr>
</tbody>
</table>

**GOP_BNDLIM** *(real)*: max magnitude of variable bounds used in GOP convexification

Synonym: BNDLIM

This value specifies the maximum magnitude of variable bounds used in the GOP convexification. Any lower bound smaller than the negative of this value will be treated as the negative of this value. Any upper bound greater than this value will be treated as this value. This helps the global solver focus on more productive domains.

Default: 1e10

**GOP_BOXTOL** *(real)*: minimal width of variable intervals

Synonym: BOXTOL

This value specifies the minimal width of variable intervals in a box allowed to branch.

Default: 1e-6
**GOP_BRANCHMD** (integer): direction to branch first when branching on a variable

Synonym: BRANCHMD

This specifies the direction to branch first when branching on a variable. The branch variable is selected as the one that holds the largest magnitude in the measure.

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Absolute width</td>
</tr>
<tr>
<td>1</td>
<td>Locally relative width</td>
</tr>
<tr>

</tr>
<tr>
<td>3</td>
<td>Globally relative distance from the convex minimum to the bounds</td>
</tr>
<tr>
<td>4</td>
<td>Absolute violation between the function and its convex envelope at the convex minimum</td>
</tr>
<tr>
<td>5</td>
<td>Relative violation between the function and its convex envelope at the convex minimum</td>
</tr>
</tbody>
</table>

**GOP_BRANCH_LIMIT** (integer): limit on the total number of branches to be created in GOP tree

Synonym: BRANCH_LIMIT

This is the limit on the total number of branches to be created during branch-and-bound in GOP tree. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible solution was found, it will be installed as the incumbent (best known) solution.

Range: \{-1, ..., \infty\}

Default: -1

**GOP_CMINLP** (integer): flag indicating if GOP exploits convex MINLP model

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

**GOP_CONIC_REFORM** (integer): flag indicating if GOP explore conic reformulation

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

**GOP_CORELEVEL** (integer): strategy of GOP branch-and-bound

Synonym: CORELEVEL

This controls the strategy of GOP branch-and-bound procedure.
Default: 14
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>LP convex relaxation</td>
</tr>
<tr>
<td>+4</td>
<td>NLP solving</td>
</tr>
<tr>
<td>+8</td>
<td>Box Branching</td>
</tr>
</tbody>
</table>

**GOP_DECOMPPTMD** *(integer)*: decomposition point selection rule in GOP branch-and-bound

Synonym: DECOMPPTMD

This specifies the decomposition point selection rule. In the branch step of GOP branch-and-bound, a branch point M is selected to decompose the selected variable interval \([Lb, Ub]\) into two subintervals, \([Lb, M]\) and \([M, Ub]\).

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Mid-point</td>
</tr>
<tr>
<td>1</td>
<td>Local minimum or convex minimum</td>
</tr>
</tbody>
</table>

**GOP_DELTATOL** *(real)*: delta tolerance in GOP convexification

Synonym: DELTATOL

This value is the delta tolerance in the GOP convexification. It is a measure of how closely the additional constraints added as part of convexification should be satisfied.

Default: 1e-7

**GOP_FLTTOL** *(real)*: floating-point tolerance

Synonym: FLTTOL

This value is the GOP floating-point tolerance. It specifies the maximum rounding errors in the floating-point computation.

Default: 1e-10

**GOP_HEU_MODE** *(integer)*: heuristic used in global solver

Synonym: HEU_MODE

This specifies the heuristic used in the global solver to find a good solution. Typically, if a heuristic is used, this will put more efforts in searching for good solutions, and less in bound tightening.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No heuristic is used</td>
</tr>
<tr>
<td>1</td>
<td>A simple heuristic is used</td>
</tr>
</tbody>
</table>

**GOP_ITRLIM** *(real)*: GOP iteration limit
Synonym: ITRLIM

This is the total iteration limit (including simplex, barrier and nonlinear iteration) summed over branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\)

Default: \(\text{infinity}\)

\textbf{GOP\_ITRLIM\_IPM} (\textit{real}): total barrier iteration limit summed over all branches in GOP

Synonym: ITRLIM\_IPM

This is the total barrier iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\)

Default: -1

\textbf{GOP\_ITRLIM\_NLP} (\textit{real}): total nonlinear iteration limit summed over all branches in GOP

Synonym: ITRLIM\_NLP

This is the total nonlinear iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\)

Default: -1

\textbf{GOP\_ITRLIM\_SIM} (\textit{real}): total simplex iteration limit summed over all branches in GOP

Synonym: ITRLIM\_SIM

This is the total simplex iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\)

Default: -1

\textbf{GOP\_LIM\_MODE} (\textit{integer}): flag indicating which heuristic limit on sub-solver in GOP is based

Synonym: LIM\_MODE

This is a flag indicating which heuristic limit on sub-solver in GOP is based.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No limit</td>
</tr>
<tr>
<td>1</td>
<td>Time based limit</td>
</tr>
<tr>
<td>2</td>
<td>Iteration based limit</td>
</tr>
<tr>
<td>3</td>
<td>Both time and iteration based limit</td>
</tr>
</tbody>
</table>
**GOP_LINEARZ** *(integer)*: flag indicating if GOP exploits linearizable model

This is a flag indicating if GOP exploits linearizable model.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exploit linearizable model</td>
</tr>
<tr>
<td>1</td>
<td>Do not exploit linearizable model</td>
</tr>
</tbody>
</table>

**GOP_LSOLBRANLIM** *(integer)*: branch limit until finding a new nonlinear solution

Synonym: LSOLBRANLIM

This value controls the branch limit until finding a new nonlinear solution since the last nonlinear solution is found. The default value is -1, which means no branch limit is imposed.

Range: \{-1, ..., ∞\}

Default: -1

**GOP_MAXWIDMD** *(integer)*: maximum width flag for the global solution

Synonym: MAXWIDMD

This is the maximum width flag for the global solution. The GOP branch-and-bound may continue contracting a box with an incumbent solution until its maximum width is smaller than **GOP_WIDTOL**.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The maximum width criterion is suppressed</td>
</tr>
<tr>
<td>1</td>
<td>The maximum width criterion is performed</td>
</tr>
</tbody>
</table>

**GOP_MULTILINEAR** *(integer)*: flag indicating if GOP exploits multi linear feature

This is a flag indicating if GOP exploits multi linear feature.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

**GOP_NUM_THREADS** *(integer)*: number of parallel threads to be used when solving a nonlinear model with the global optimization solver

This value specifies the number of parallel threads to be used when solving a nonlinear model with the global optimization solver.

Default: 1
GOP\_OBJ\_THRESHOLD \((\text{real})\): threshold of objective value in the GOP solver

This value specifies the threshold of objective value in the GOP solver. For min problem, if current incumbent solution is less than the threshold GOP solver will stop.

Range: \([-1e+30, \infty]\)

Default: \(-1e+30\)

GOP\_OPTCHKMD \((\text{integer})\): criterion used to certify the global optimality

This specifies the criterion used to certify the global optimality. When this value is 0, the absolute deviation of objective lower and upper bounds should be smaller than \(\text{GOP\_ABSOPTTOL}\) at the global optimum. When its value is 1, the relative deviation of objective lower and upper bounds should be smaller than \(\text{GOP\_RELOPTTOL}\) at the global optimum. 2 means either absolute or relative tolerance is satisfied at global optimum.

Default: 2

GOP\_OPT\_MODE \((\text{integer})\): mode for GOP optimization

This specifies the mode for GOP optimization.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Global search for a feasible solution (thus a feasibility certificate)</td>
</tr>
<tr>
<td>1</td>
<td>Global search for an optimal solution</td>
</tr>
<tr>
<td>2</td>
<td>Global search for an unboundedness certificate</td>
</tr>
</tbody>
</table>

GOP\_POSTLEVEL \((\text{integer})\): amount and type of GOP postsolving

This controls the amount and type of GOP post-solving. The default value is: \(6 = 2+4\) meaning to do both of the below options.

Default: 6

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Apply LSgetBestBound</td>
</tr>
<tr>
<td>+4</td>
<td>Reoptimize variable bounds</td>
</tr>
</tbody>
</table>

GOP\_PRELEVEL \((\text{integer})\): amount and type of GOP presolving

This controls the amount and type of GOP pre-solving. The default value is: \(30 = 2+4+8+16\) meaning to do all of the below options.

Default: 30
### GOP_QUADMD (integer): flag indicating if GOP exploits quadratic feature

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### GOP_QUAD_METHOD (integer): specifies if the GOP solver should solve the model as a QP when applicable

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>General GOP solver</td>
</tr>
<tr>
<td>1</td>
<td>Specified QP solver</td>
</tr>
</tbody>
</table>

### GOP_RELBRNDMD (integer): reliable rounding in the GOP branch-and-bound

Synonym: RELBRNDMD

This controls the reliable rounding rule in the GOP branch-and-bound. The global solver applies many suboptimizations to estimate the lower and upper bounds on the global optimum. A rounding error or numerical instability could unintentionally cut off a good solution. A variety of reliable approaches are available to improve the precision.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Use smaller optimality or feasibility tolerances and appropriate presolving options</td>
</tr>
<tr>
<td>+4</td>
<td>Apply interval arithmetic to reverify the solution feasibility</td>
</tr>
</tbody>
</table>

### GOP_RELOPTTOL (real): relative optimality tolerance

Synonyms: OPTTOL RELOPTTOL

This value is the GOP relative optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: GAMS OptCR

### GOP_SOLLIM (integer): integer solution limit for GOP branch-and-bound

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Range: \{-1, ..., \infty\}

Default: -1

**GOP_SUBOUT_MODE (integer):** substituting out fixed variables

Synonym: SUBOUT_MODE

This is a flag indicating whether fixed variables are substituted out of the instruction list used in the global solver.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not substitute out fixed variables</td>
</tr>
<tr>
<td>1</td>
<td>Substitute out fixed variables</td>
</tr>
</tbody>
</table>

**GOP_TIMLIM (integer):** time limit in seconds for GOP branch-and-bound

Synonym: TIMLIM

This is the time limit in seconds for GOP branch-and-bound.

Range: \{-1, ..., \infty\}

Default: GAMS ResLim

**GOP_USEBNDLIM (integer):** max magnitude of variable bounds flag for GOP convexification

Synonym: USEBNDLIM

This value is a flag for the parameter **GOP_BNDLIM**.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use the bound limit on the variables</td>
</tr>
<tr>
<td>1</td>
<td>Use the bound limit right at the beginning of global optimization</td>
</tr>
<tr>
<td>2</td>
<td>Use the bound limit after the initial local optimization if selected</td>
</tr>
</tbody>
</table>

**GOP_WIDTOL (real):** maximal width of variable intervals

Synonym: WIDTOL

This value specifies the maximal width of variable intervals for a box to be considered as an incumbent box containing an incumbent solution. It is used when **GOP_MAXWIDMD** is set at 1.

Default: 1e-4

**IIS (boolean):** run the IIS finder if the problem is infeasible

Default: 0

**IIS_ANALYZE_LEVEL (integer):** controls the level of analysis when locating an IIS

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+1</td>
<td>Search for necessary rows</td>
</tr>
<tr>
<td>+2</td>
<td>Search for necessary columns</td>
</tr>
<tr>
<td>+4</td>
<td>Search for sufficient rows</td>
</tr>
<tr>
<td>+8</td>
<td>Search for sufficient columns</td>
</tr>
<tr>
<td>+16</td>
<td>Consider integrality restrictions as the potential cause of infeasibilities and include it in the analysis</td>
</tr>
<tr>
<td>+32</td>
<td>Compute the underlying LTF matrix and use this as the basis of a ranking score to guide the IIS run</td>
</tr>
<tr>
<td>+64</td>
<td>If the underlying matrix is totally decomposable, rank blocks w.r.t their sizes and debug the smallest independent infeasible block</td>
</tr>
<tr>
<td>+128</td>
<td>Use the nonzero structure of the underlying matrix to compute a ranking score to guide the IIS run</td>
</tr>
<tr>
<td>+256</td>
<td>Treat iter/time limits as intractability</td>
</tr>
</tbody>
</table>

**IIS_GETMODE** *(integer)*: flag that controls whether variable bounds in the IIS should be retrieved or the integer restrictions ←

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Variable bound</td>
</tr>
<tr>
<td>1</td>
<td>Integer restrictions</td>
</tr>
</tbody>
</table>

**IIS_INFEAS_NORM** *(integer)*: specifies the norm to measure infeasibilities in IIS search ←

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use L-1 norm</td>
</tr>
<tr>
<td>2</td>
<td>L-infinity norm</td>
</tr>
</tbody>
</table>

**IIS_ITER_LIMIT** *(integer)*: the iteration limit for IIS search ←

Range: \{-1, ..., \infty\}

Default: -1

**IIS_METHOD** *(integer)*: specifies the method to use in analyzing infeasible models to locate an IIS ←

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Default filter</td>
</tr>
<tr>
<td>1</td>
<td>Standard deletion filter</td>
</tr>
<tr>
<td>2</td>
<td>Standard additive filter</td>

<tr>
<td>3</td>
<td>Generalized-binary-search filter</td>
</tr>
<tr>
<td>4</td>
<td>Depth-first-binary-search filter</td>
</tr>
<tr>
<td>5</td>
<td>Fast-scan filter</td>
</tr>
<tr>
<td>6</td>
<td>Standard elastic filter</td>
</tr>
</tbody>
</table>
**IIS_PRINT_LEVEL** (*integer*): specifies the amount of print to do during IIS search

Default: 2

**IIS_REOPT** (*integer*): specifies which optimization method to use when starting from a given basis

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Free</td>
</tr>
<tr>
<td>1</td>
<td>Primal Simplex</td>
</tr>
<tr>
<td>2</td>
<td>Dual Simplex</td>
</tr>
<tr>
<td>3</td>
<td>Barrier</td>
</tr>
<tr>
<td>4</td>
<td>NLP</td>
</tr>
</tbody>
</table>

**IIS_TIME_LIMIT** (*integer*): the time limit for IIS search

Range: \{-1, ..., \infty\}

Default: -1

**IIS_TOPOPT** (*integer*): specifies which optimization method to use when there is no previous basis

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Free</td>
</tr>
<tr>
<td>1</td>
<td>Primal Simplex</td>
</tr>
<tr>
<td>2</td>
<td>Dual Simplex</td>
</tr>
<tr>
<td>3</td>
<td>Barrier</td>
</tr>
<tr>
<td>4</td>
<td>NLP</td>
</tr>
</tbody>
</table>

**IIS_USE_EFILTER** (*integer*): flag that controls whether the Elastic Filter should be enabled as the supplementary filter in analyzing infeasible models

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Do not use elastic filter</td>
</tr>
<tr>
<td>1</td>
<td>Use elastic filter</td>
</tr>
</tbody>
</table>

**IIS_USE_GOP** (*integer*): flag that controls whether the global optimizer should be enabled in analyzing infeasible NLP models

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Do not use GOP</td>
</tr>
<tr>
<td>1</td>
<td>Use GOP</td>
</tr>
</tbody>
</table>
**IIS_USE_SFILTER** *(integer)*: flag indicating is sensitivity filter will be used during IIS search

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Do not use sensitivity filter</td>
</tr>
<tr>
<td>1</td>
<td>Use sensitivity filter</td>
</tr>
</tbody>
</table>

**INSTRUCT_SUBOUT** *(integer)*: flag to specify how to deal with fixed variables in the instruction list

This is a flag indicating whether 1) fixed variables are substituted out of the instruction list, 2) performing numerical calculation on constant numbers and replacing with the results.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Substitutions will not be performed</td>
</tr>
<tr>
<td>1</td>
<td>Substitutions will be performed</td>
</tr>
</tbody>
</table>

**IPM_BASIS_REL_TOL_S** *(real)*: maximum relative dual bound violation allowed in an optimal basic solution

Maximum relative dual bound violation allowed in an optimal basic solution.

Default: 1e-12

**IPM_BASIS_TOL_S** *(real)*: maximum absolute dual bound violation in an optimal basic solution

Maximum absolute dual bound violation in an optimal basic solution.

Default: 1e-7

**IPM_BASIS_TOL_X** *(real)*: maximum absolute primal bound violation allowed in an optimal basic solution

Maximum absolute primal bound violation allowed in an optimal basic solution.

Default: 1e-7

**IPM_BI_LU_TOL_REL_PIV** *(real)*: relative pivot tolerance used in the LU factorization in the basis identification procedure

Relative pivot tolerance used in the LU factorization in the basis identification procedure.

Range: [0, 0.999999]

Default: 1e-2

**IPM_CHECK_CONVEXITY** *(integer)*: flag to check convexity of a quadratic program using barrier solver

This is a flag to check convexity of a quadratic program using barrier solver.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Check convexity only without solving the model</td>
</tr>
<tr>
<td>0</td>
<td>Use barrier solver to check convexity</td>
</tr>
<tr>
<td>1</td>
<td>Do not use barrier solver to check convexity</td>
</tr>
</tbody>
</table>

**IPM_CO_TOL_DFEAS** *(real)*: dual feasibility tolerance for Conic solver

Default: 1e-8

**IPM_CO_TOL_INFEAS** *(real)*: maximum bound infeasibility tolerance for Conic solver

Maximum bound infeasibility tolerance for Conic solver.

Default: 1e-12

**IPM_CO_TOL_MU_RED** *(real)*: optimality tolerance for Conic solver

Default: 1e-8

**IPM_CO_TOL_PFEAS** *(real)*: primal feasibility tolerance for Conic solver

Default: 1e-8

**IPM_MAX_ITERATIONS** *(integer)*: ipm iteration limit

Controls the maximum number of iterations allowed in the interior-point optimizer.

Default: 1000

**IPM_NUM_THREADS** *(integer)*: number of threads to run the interiorpoint optimizer on

Number of threads to run the interiorpoint optimizer on. This value should be less than or equal to the actual number of processors or cores on a multi-core system.

Default: 1

**IPM_OFF_COL_TRH** *(integer)*: extent for detecting the offending columns in the Jacobian of the constraint matrix

Controls the extent for detecting the offending columns in the Jacobian of the constraint matrix. 0 means no offending columns will be detected. 1 means offending columns will be detected. In general, increasing the parameter value beyond the default value of 40 does not improve the result.

Default: 40

**IPM_TOL_DFEAS** *(real)*: dual feasibility tolerance

Dual feasibility tolerance used for linear and quadratic optimization problems.

Default: 1e-8

**IPM_TOL_DSAFE** *(real)*: controls the initial dual starting point
Controls the initial dual starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the dual variables associated with constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: \([1e^{-4}, \infty]\]

Default: 1

**IPM\_TOL\_INFEAS** *(real): infeasibility tolerance* ←

This is the tolerance to declare the model primal or dual infeasible using the interior-point optimizer. A smaller number means the optimizer gets more conservative about declaring the model infeasible.

Default: \(1e^{-10}\)

**IPM\_TOL\_MU\_RED** *(real): relative complementarity gap tolerance* ←

Relative complementarity gap tolerance.

Default: \(1e^{-16}\)

**IPM\_TOL\_PATH** *(real): how close to follow the central path* ←

Controls how close the interior-point optimizer follows the central path. A large value of this parameter means the central path is followed very closely. For numerically unstable problems it might help to increase this parameter.

Range: \([0, 0.5]\]

Default: \(1e^{-8}\)

**IPM\_TOL\_PFEAS** *(real): primal feasibility tolerance* ←

Primal feasibility tolerance used for linear and quadratic optimization problems.

Default: \(1e^{-8}\)

**IPM\_TOL\_PSAFE** *(real): controls the initial primal starting point* ←

Controls the initial primal starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: \([1e^{-2}, \infty]\]

Default: 1

**IPM\_TOL\_REL\_STEP** *(real): relative step size to the boundary* ←

Relative step size to the boundary for linear and quadratic optimization problems.

Range: \([0, 0.999999]\]

Default: 0.9999

**IUS** *(boolean): run the IUS finder if the problem is unbounded* ←

Default: 0

**IUS\_ANALYZE\_LEVEL** *(integer): controls the level of analysis when locating an IUS* ←

Default: 2
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Search for necessary columns</td>
</tr>
<tr>
<td>+8</td>
<td>Search for sufficient columns</td>
</tr>
</tbody>
</table>

**LP_AIJ_ZEROTOL (real):** coefficient matrix zero tolerance

Default: \(2.22045 \times 10^{-16}\)

**LP_BIGM (real):** big-M for phase-I

Default: \(1 \times 10^6\)

**LP_BNDINF (real):** big-M to truncate lower and upper bounds in single phase dual-simplex

Default: \(1 \times 10^{15}\)

**LP_DPSWITCH (integer):** specifies whether LP primal-dual simplex switch is enabled or not

Range: \(\{0, ..., 1\}\)

Default: 1

**LP_DRATIO (integer):** controls the dual min-ratio strategy

Range: \(\{0, ..., 2\}\)

Default: 1

**LP_DYNOBJFACT (real):** Dynamic obj factor

Range: \([0, 1]\)

Default: 0.75

**LP_DYNOBJMODE (integer):** Dynamic obj mode

Default: 0

**LP_ITRLMT (integer):** simplex iteration limit

Synonym: SPLEX_ITRLMT

Range: \(\{-1, ..., \infty\}\)

Default: infinity

**LP_PIV_BIGTOL (real):** simplex maximum pivot tolerance

Default: \(1 \times 10^{-5}\)

**LP_PIV_ZEROTOL (real):** simplex pivot zero tolerance

Default: \(1 \times 10^{-8}\)

**LP_PPARTIAL (integer):** primal simplex partial pricing method

Range: \(\{0, ..., 3\}\)

Default: 0

**LP_PRELEVEL (integer):** controls the amount and type of LP pre-solving

This controls the amount and type of LP pre-solving to be used.

Default: 126
5.24 LINDO and LINDOGlobal

</table>

**LP_RATRANGE** (*integer*): controls the number of pivot-candidates to consider when searching for a stable pivot in LU decomposition

Range: \{1, ..., ∞\}

Default: 4

**LP_SCALE** (*integer*): scaling flag

Synonym: SPLEX_SCALE

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Scaling is suppressed</td>

**LP_SPRINT_COLFACT** (*integer*): maximum number of columns in Sprint as a factor of number of rows

Range: \{1, ..., ∞\}

Default: 10

**LP_SPRINT_MAXPASS** (*integer*): maximum number of passes in Sprint method

Range: \{1, ..., ∞\}

Default: 100

**LP_SPRINT_SUB** (*integer*): LP method for subproblem in Sprint method

Default: 0

**MIP_ABSCUTTOL** (*real*): MIP absolute cut tolerance

This is the MIP absolute cut tolerance. If the value is less than or equal to zero, it will use the internal decided tolerace, otherwise it will use this value as the absolute tolerance for adding cuts.

Range: \([-1.0, ∞]\]

Default: -1.0

**MIP_ASOPTTOL** (*real*): MIP absolute optimality tolerance
This is the MIP absolute optimality tolerance. Solutions must beat the incumbent by at least this absolute amount to become the new, best solution.

Default: **GAMS OptCA**

**MIP_ADDCUTOBJTOL** **(real)**: required objective improvement to continue generating cuts

This specifies the minimum required improvement in the objective function for the cut generation phase to continue generating cuts.

Default: $1.5625 \times 10^{-5}$

**MIP_ADDCUTPER** **(real)**: percentage of constraint cuts that can be added

This determines how many constraint cuts can be added as a percentage of the number of original rows in an integer programming model.

Default: 0.75

**MIP_ADDCUTPER_TREE** **(real)**: percentage of constraint cuts that can be added at child nodes

This determines how many constraint cuts can be added at child nodes as a percentage of the number of original rows in an integer programming model.

Default: 0.5

**MIP_AGGCUTLIM_TOP** **(integer)**: max number of constraints involved in derivation of aggregation cut at root node

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the root node. The default is 0.1, which means that the solver will decide.

Range: $\{-1, ..., \infty\}$

Default: -1

**MIP_AGGCUTLIM_TREE** **(integer)**: max number of constraints involved in derivation of aggregation cut at tree nodes

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the tree nodes. The default is 0.1, which means that the solver will decide.

Range: $\{-1, ..., \infty\}$

Default: -1

**MIP_ANODES_SWITCH_DF** **(integer)**: threshold on active nodes for switching to depth-first search

This specifies the threshold on active nodes for switching to depth-first search rule.

Default: 50000

**MIP_AOPTTIMLIM** **(integer)**: time in seconds beyond which the relative optimality tolerance will be applied

This is the time in seconds beyond which the relative optimality tolerance, MIP_PEROPTTOL will be applied.

Default: 100

**MIP_BIGM_FOR_INTTOL** **(real)**: threshold for which coefficient of a binary variable would be considered as big-M

This value specifies the threshold for which the coefficient of a binary variable would be considered as big-M (when applicable).

Default: $1 \times 10^8$

**MIP_BRANCHDIR** **(integer)**: first branching direction

This specifies the direction to branch first when branching on a variable.

Default: 0
### MIP_BRANCHRULE (integer): rule for choosing the variable to branch

This specifies the rule for choosing the variable to branch on at the selected node.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Always branch up first</td>
</tr>
<tr>
<td>2</td>
<td>Always branch down first</td>
</tr>
</tbody>
</table>

### MIP_BRANCH_LIMIT (integer): limit on the total number of branches to be created during branch and bound

This is the limit on the total number of branches to be created during branch-and-bound. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: \{-1, ..., \infty\}

Default: -1

### MIP_BRANCH_Prio (integer): controls how variable selection priorities are set and used

This controls how variable selection priorities are set and used.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>If the user has specified priorities then use them Otherwise let LINDO API decide</td>
</tr>
<tr>
<td>1</td>

<td>If user has specified priorities then use them Otherwise do not use any priorities</td>
</tr>
<tr>
<td>3</td>
<td>Let LINDO API set the priorities and ignore any user specified priorities</td>
</tr>
<tr>
<td>4</td>
<td>Binaries always have higher priority over general integers</td>
</tr>
</tbody>
</table>

### MIP_CONCURRENT_REOPTMODE (integer): specifies the concurrent optimization mode with warm start

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no concurrent runs</td>
</tr>
<tr>
<td>1</td>
<td>run concurrently if at least 2 threads exist</td>
</tr>
<tr>
<td>2</td>
<td>run concurrently</td>
</tr>
</tbody>
</table>
MIP\_CONCURRENT\_STRATEGY \( (integer) \): controls the concurrent MIP strategy ↩

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Defines built-in priority lists for each thread</td>
</tr>
<tr>
<td>3</td>
<td>Defines heuristic based strategies for each thread</td>
</tr>
</tbody>
</table>

MIP\_CONCURRENT\_TOPOPTMODE \( (integer) \): specifies the concurrent optimization mode with cold start ↩

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no concurrent runs</td>
</tr>
<tr>
<td>1</td>
<td>run concurrently if at least 2 threads exist</td>
</tr>
<tr>
<td>2</td>
<td>run concurrently</td>
</tr>
</tbody>
</table>

MIP\_CUTDEPTH \( (integer) \): threshold value for the depth of nodes in the branch and bound tree ↩

This controls a threshold value for the depth of nodes in the B&B tree, so cut generation will be less likely at those nodes deeper than this threshold.

Default: 8

MIP\_CUTFREQ \( (integer) \): frequency of invoking cut generation at child nodes ↩

This controls the frequency of invoking cut generation at child nodes. The default value is 10, indicating that the MIP solver will try to generate cuts at every 10 nodes.

Default: 10

MIP\_CUTLEVEL\_TOP \( (integer) \): combination of cut types to try at the root node when solving a MIP ↩

This controls the combination of cut types to try at the root node when solving a MIP. Bit settings are used to enable the various cut types.

Default: 57342

<table>

MIP\_CUTLEVEL\_TREE \textit{(integer)}: combination of cut types to try at child nodes in the branch and bound tree when solving a MIP

This controls the combination of cut types to try at child nodes in the B&B tree when solving a MIP.

Default: 53246

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tbody>
</table>

MIP\_CUTOFFOBJ \textit{(real)}: defines limit for branch and bound

If this is specified, then any part of the branch-and-bound tree that has a bound worse than this value will not be considered. This can be used to reduce the running time if a good bound is known.

Default: 1e30

MIP\_CUTTIMLIM \textit{(integer)}: time to be spent in cut generation

This controls the total time to be spent in cut generation throughout the solution of a MIP. The default value is -1, indicating that no time limits will be imposed when generating cuts.

Range: \{-1, ..., \infty\}

Default: -1

MIP\_DELTA \textit{(real)}: near-zero value used in linearizing nonlinear expressions

This refers to a near-zero value used in linearizing nonlinear expressions.

Default: 1e-6

MIP\_DUAL\_SOLUTION \textit{(integer)}: flag for computing dual solution of LP relaxation

This flag controls whether the dual solution to the LP relaxation that yielded the optimal MIP solution will be computed or not.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not calculate dual solution for LP relaxation</td>
</tr>
<tr>
<td>1</td>
<td>Calculate dual solution for LP relaxation</td>
</tr>
</tbody>
</table>

**MIP_FP_HEU_MODE** *(integer)*: specifies the feasibility-pump (FP) heuristic mode

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FP is disabled</td>
</tr>
<tr>
<td>1</td>
<td>Solver decides</td>
</tr>

<tr>
<td>4</td>
<td>Same as 2 but also enable FP on child nodes in branch-bound tree</td>
</tr>
<tr>
<td>5</td>
<td>Same as 3 but also enable FP on child nodes in branch-bound tree</td>
</tr>
</tbody>
</table>

**MIP_FP_ITRLIM** *(integer)*: iteration limit for feasibility pump heuristic

This is the iteration limit in seconds for feasibility pump heuristic. A value of -1 means no iteration limit is imposed.

Default: 500

**MIP_FP_MODE** *(integer)*: mode for the feasibility pump heuristic

Controls the mode for the feasibility pump heuristic.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>

<td>On until the first solution</td>
</tr>
<tr>
<td>2</td>
<td>Try to get more than one solution</td>
</tr>
</tbody>
</table>

**MIP_FP_OPT_METHOD** *(integer)*: optimization and reoptimization method for feasibility pump heuristic

This specifies optimization and reoptimization method for feasibility pump heuristic.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Primal simplex</td>

<td>Dual simplex</td>
</tr>
<tr>
<td>3</td>
<td>Barrier</td>
</tr>
</tbody>
</table>

**MIP_FP_PROJECTION** *(integer)*: type of objective function of LPs in projection step of the feasibility pump heuristic
Range: \(\{0, ..., 1\}\)

Default: 0

**MIP\_FP\_TIMLIM** *(real)*: time limit for feasibility pump heuristic

This is the time limit in seconds for feasibility pump heuristic. A value of -1 implies no time limit is imposed.

Default: 1800

**MIP\_FP\_WEIGHT** *(real)*: weight of the objective function in the feasibility pump

Controls the weight of the objective function in the feasibility pump.

Range: \([0, 1]\)

Default: 1

**MIP\_GENERAL\_MODE** *(integer)*: general strategy in solving MIPs

This value specifies the general strategy in solving MIPs.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>+2</td>
<td>Disable all time-driven events for reproducibility of runs</td>
</tr>
<tr>
<td>+16</td>
<td>Disable cut generation before branching</td>
</tr>
</tbody>
</table>

**MIP\_HEULEVEL** *(integer)*: specifies heuristic used to find integer solution

This specifies the heuristic used to find the integer solution. Possible values are: 0: No heuristic is used. 1: A simple heuristic is used. Typically, this will find integer solutions only on problems with a certain structure. However, it tends to be fast. 2: This is an advanced heuristic that tries to find a "good" integer solution fast. In general, a value of 2 seems to not increase the total solution time and will find an integer solution fast on many problems. A higher value may find an integer solution faster, or an integer solution where none would have been found with a lower level. Try level 3 or 4 on "difficult" problems where 2 does not help. Higher values cause more time to be spent in the heuristic. The value may be set arbitrarily high. However, >20 is probably not worthwhile. **MIP\_HEUMINTIMLIM** controls the time to be spent in searching heuristic solutions.

Default: 3

**MIP\_HEUMINTIMLIM** *(integer)*: minimum time in seconds to be spent in finding heuristic solutions

This specifies the minimum time in seconds to be spent in finding heuristic solutions to the MIP model. **MIP\_HEULEVEL** controls the heuristic used to find the integer solution.

Default: 0

**MIP\_HEU\_DROP\_OBJ** *(integer)*: flag for whether to use without OBJ heuristic

This is a flag for whether to use without OBJ heuristic.

Default: 0
MIP_HEU_MODE (integer): heuristic used in MIP solver

This controls the MIP heuristic mode.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

MIP_INTTOL (real): absolute integer feasibility tolerance

An integer variable is considered integer feasible if the absolute difference from the nearest integer is smaller than this.

Default: 1e-6

MIP_ITRLIM (real): iteration limit for branch and bound

This is the total LP iteration limit summed over all branches for branch-and-bound. Range for The default value is -1, which means no iteration limit is imposed. If this iteration limit is reached, branch-and-bound will stop and the best feasible integer solution found will be installed as the incumbent (best known) solution.

Range: [-1, ∞]

Default: infinity

MIP_KBEST_USE_GOP (integer): specifies whether to use gop solver in MIP KBest

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

MIP_KEEPINMEM (integer): flag for keeping LP bases in memory

If this is set to 1, the integer pre-solver will try to keep LP bases in memory. This typically gives faster solution times, but uses more memory. Setting this parameter to 0 causes the pre-solver to erase bases from memory.

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not keep LP bases in memory</td>
</tr>
<tr>
<td>1</td>
<td>Keep LP bases in memory</td>
</tr>
</tbody>
</table>
MIP_LBIGM \textit{(real)}: Big-M value used in linearizing nonlinear expressions \red{←}

This refers to the Big-M value used in linearizing nonlinear expressions.
Default: 10000

MIP_LSOLTMLIM \textit{(integer)}: time limit until finding a new integer solution \red{←}

Range: \{−1, ..., ∞\}
Default: −1

MIP_MAKECUT_INACTIVE_COUNT \textit{(integer)}: threshold for times a cut could remain active after successive reoptimization \red{←}

This value specifies the threshold for the times a cut could remain active after successive reoptimization during branch-and-bound. If the count is larger than the specified level the solver will inactive the cut.
Default: 10

MIP_MAXCUTPASS_TOP \textit{(integer)}: number passes to generate cuts on the root node \red{←}

This controls the number passes to generate cuts on the root node. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.
Default: 200

MIP_MAXCUTPASS_TREE \textit{(integer)}: number passes to generate cuts on the child nodes \red{←}

This controls the number passes to generate cuts on the child nodes. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.
Default: 2

MIP_MAXNONIMP_CUTPASS \textit{(integer)}: number of passes allowed in cut-generation that does not improve current relaxation \red{←}

This controls the maximum number of passes allowed in cut-generation that does not improve the current relaxation.
Default: 3

MIP_MAXNUM_MIP_SOL_STORAGE \textit{(integer)}: maximum number of k-best solutions to store \red{←}

This specifies the maximum number of k-best solutions to store. Possible values are positive integers.
Default: 1

MIP_MINABSOBJSTEP \textit{(real)}: value to update cutoff value each time a mixed integer solution is found \red{←}

This specifies the value to update the cutoff value each time a mixed integer solution is found.
Default: 0

MIP_NODESELRULE \textit{(integer)}: specifies the node selection rule \red{←}

This specifies the node selection rule for choosing between all active nodes in the branch-and-bound tree when solving integer programs. Possible selections are: 0: Solver decides (default). 1: Depth first search. 2: Choose node with worst bound. 3: Choose node with best bound. 4: Start with best bound. If no improvement in the gap between best bound and best integer solution is obtained for some time, switch to: if (number of active nodes < 10000) Best estimate node selection (5). else Worst bound node selection (2). 5: Choose the node with the best estimate, where the new objective estimate is obtained using pseudo costs. 6: Same as (4), but start with the best estimate.
Default: 0
<table>

<td>Choose the node with the best estimate</td>
</tr>
<tr>
<td>6</td>
<td>Same as 4 but start with the best estimate</td>
</tr>
</tbody>
</table>

**MIP_NUM_THREADS** *(integer)*: number of parallel threads to use by the parallel MIP solver

This parameter specifies the number of parallel threads to use by the parallel MIP solver. Possible values are positive integers. The default is 1 implying that the parallel solver is disabled.

Range: \( \{1, \ldots, \infty\} \)

Default: 1

**MIP_PARA_FP** *(integer)*: flag for whether to use parallelization on the feasibility pump heuristic

This is a flag for whether to use parallelization on the feasibility pump heuristic.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>

</tbody>
</table>

**MIP_PARA_INIT_NODE** *(real)*: number of initial nodes for MIP parallelization

This value specifies the number of initial nodes for MIP parallelization.

Range: \([-1, \infty]\)

Default: -1

**MIP_PARA_ITR_MODE** *(integer)*: flag for iteration mode in MIP parallelization

This is a flag for iteration mode in MIP parallelization.

Default: 1
### MIP_PARA_RND_ITRLMT (real): iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations

This value specifies the iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations.

Default: 2.0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Each thread terminates as soon as arrives iteration limit</td>
</tr>
<tr>
<td>1</td>
<td>Each thread terminates until all threads get iteration limit</td>
</tr>
</tbody>
</table>

### MIP_PARA_SUB (integer): flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing

This is a flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

### MIP_PEROPTTOL (real): MIP relative optimality tolerance in effect after MIP_AOPTTIMLIM seconds

This is the MIP relative optimality tolerance that will be in effect after T seconds following the start. The value T should be specified using the MIP_AOPTTIMLIM parameter.

Default: 1e-5

### MIP_PERSPECTIVE_REFORM (integer): flag for whether to use Perspective Reformulation

This is the flag for whether to use Perspective Reformulation.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

### MIP_POLISH_ALPHA_TARGET (real): proportion solutions in the pool to initiate a polishing-task at the current node

This value specifies the proportion solutions in the pool to initiate a polishing-task at the current node.

Range: [0.01, 0.99]

Default: 0.6

### MIP_POLISH_MAX_BRANCH_COUNT (integer): maximum number of branches to polish

---
This value specifies the maximum number of branches to polish.

Default: 2000

**MIP POLISH_NUM_BRANCH_NEXT** *(integer)*: number of branches to polish in the next round

This value specifies the number of branches to polish in the next round.

Default: 4000

**MIP PREHEU_DFE_VSTLIM** *(integer)*: limit for the variable visit in depth first enumeration

Limit for the variable visit in depth first enumeration.

Default: 200

**MIP PREHEU_LEVEL** *(integer)*: heuristic level for the prerelax solver

The heuristic level for the prerelax solver.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Nothing</td>
</tr>
<tr>
<td>1</td>
<td>One-change</td>

<td>One-change and two-change</td>
</tr>
<tr>
<td>3</td>
<td>Depth first enumeration</td>
</tr>
</tbody>
</table>

**MIP PREHEU_TC_ITERLIM** *(integer)*: iteration limit for the two change heuristic

Iteration limit for the two change heuristic.

Default: 30000000

**MIP PREHEU_VAR_SEQ** *(integer)*: sequence of the variable considered by the prerelax heuristic

The sequence of the variable considered by the prerelax heuristic.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Backward</td>
</tr>
<tr>
<td>1</td>
<td>Forward</td>
</tr>
</tbody>
</table>

**MIP PRELEVEL** *(integer)*: controls the amount and type of MIP pre-solving at root node

This controls the amount and type of MIP pre-solving at root node.

Default: 3070

<table>
<thead>
<tr>

**MIP.PRE_ELIM_FILL (integer):** controls fill-in introduced by eliminations during pre-solve

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly more than the original model.

Default: 100

**MIP.PSEUDOCOST_RULE (integer):** specifies the rule in pseudocost computations for variable selection

This specifies the rule in pseudocost computations for variable selection.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Only use min pseudo cost</td>
</tr>
<tr>
<td>2</td>
<td>Only use max pseudo cost</td>
</tr>
<tr>
<td>3</td>
<td>Use quadratic score function and the pseudo cost weight</td>
</tr>
<tr>
<td>4</td>
<td>Same as 3 without quadratic score</td>
</tr>
</tbody>
</table>
MIP_PSEUDOCOST_WEIGHT (real): weight in pseudocost computations for variable selection

This specifies the weight in pseudocost computations for variable selection.

Default: 1.5625e-05

MIP_REDCOSTFIX_CUTOFF (real): cutoff value as a percentage of the reduced costs

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic.

Default: 0.9

MIP_REDCOSTFIX_CUTOFF_TREE (real): cutoff value as a percentage of the reduced costs at tree nodes

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic at tree nodes.

Default: 0.9

MIP_RELINTTOL (real): relative integer feasibility tolerance

An integer variable is considered integer feasible if the difference between its value and the nearest integer value divided by the value of the nearest integer is less than this.

Default: 8e-6

MIP_RELOPTTOL (real): MIP relative optimality tolerance

This is the MIP relative optimality tolerance. Solutions must beat the incumbent by at least this relative amount to become the new, best solution.

Default: GAMS OptCR

MIP_REEOPT (integer): optimization method to use when doing reoptimization

This specifies which optimization method to use when doing reoptimization from a given basis.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use primal method</td>
</tr>
<tr>
<td>2</td>
<td>Use dual simplex</td>
</tr>
<tr>
<td>3</td>
<td>Use barrier solver</td>
</tr>
</tbody>
</table>

MIP_SCALING_BOUND (integer): maximum difference between bounds of an integer variable for enabling scaling

This controls the maximum difference between the upper and lower bounds of an integer variable that will enable the scaling in the simplex solver when solving a subproblem in the branch-and-bound tree.

Default: 10000
MIP_SOLLIM (integer): integer solution limit for MIP solver

Range: \{-1, ..., \infty\}
Default: -1

MIP_SOLVERTYPE (integer): optimization method to use when solving mixed-integer models

This specifies the optimization method to use when solving mixed-integer models.
Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use Branch and Bound only</td>
</tr>
<tr>
<td>2</td>
<td>Use Enumeration and Knapsack solver only</td>
</tr>
</tbody>
</table>

MIP_STRONGBRANCHDONUM (integer): minimum number of variables to try the strong branching on

This value specifies the minimum number of variables, among all the candidates, to try the strong branching on.
Default: 3

MIP_STRONGBRANCHLEVEL (integer): depth from the root in which strong branching is used

This specifies the depth from the root in which strong branching is used. The default value of 10 means that strong branching is used on a level of 1 to 10 measured from the root. Strong branching finds the real bound for branching on a given variable, which, in most cases, requires a solution of a linear program and may therefore also be quite expensive in computing time. However, if used on nodes close to the root node of the tree, it also gives a much better bound for that part of the tree and can therefore reduce the size of the branch-and-bound tree.
Default: 10

MIP_SWITCHFAC_SIM_IPM_ITER (integer): specifies the (positive) factor that multiplies the number of constraints to impose an iteration limit to simplex method and trigger a switch over to the barrier method

Range: \{-1, ..., \infty\}
Default: -1

MIP_SWITCHFAC_SIM_IPM_TIME (real): factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method

This specifies the (positive) factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method. A value of -1.0 means that no time limit is imposed.
Range: \([-1, \infty]\)
Default: -1

MIP_SYMMETRY_MODE (integer): specifies mip symmetry handling methods

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use symmetries</td>
</tr>
<tr>
<td>1</td>
<td>Adding symmetry breaking cuts</td>
</tr>
<tr>
<td>2</td>
<td>Orbital fixing</td>
</tr>
</tbody>
</table>

**MIP_SYMMETRY_NONZ** *(integer)*: limit on number of nonzeros to look for symmetries

Range: \{0, \ldots, \infty\}

Default: 50000

**MIP_TIMLIM** *(integer)*: time limit in seconds for integer solver

This is the time limit in seconds for branch-and-bound. The default value is -1, which means no time limit is imposed. However, the value of **SOLVER_TIMLMT** will be applied to each continuous subproblem solve. If the value of this parameter is greater than 0, then the value of **SOLVER_TIMLMT** will be disregarded. If this time limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: \{-1, \ldots, \infty\}

Default: GAMS ResLim

**MIP_TOPOPT** *(integer)*: optimization method to use when there is no previous basis

This specifies which optimization method to use when there is no previous basis.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use primal method</td>
</tr>
<tr>
<td>2</td>
<td>Use dual simplex</td>
</tr>
<tr>
<td>3</td>
<td>Use barrier solver</td>
</tr>
</tbody>
</table>

**MIP_TREEREORDERLEVEL** *(integer)*: tree reordering level

This specifies the tree reordering level.

Default: 10

**MIP_TREEREORDERMODE** *(integer)*: tree reordering mode

This specifies the tree reordering mode.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Use tree reordering only for subproblems</td>
</tr>
<tr>
<td>2</td>
<td>Use tree reordering for subproblems and the main bub loop only when LP status is infeasible</td>
</tr>
<tr>
<td>3</td>
<td>Not use tree reordering</td>
</tr>
<tr>
<td>4</td>
<td>Use tree reordering based on MIP_TREEREORDERLEVEL</td>
</tr>
</tbody>
</table>
MIP_USECUTOFFOBJ (integer): flag for using branch and bound limit

This is a flag for the parameter MIP_CUTOFFOBJ. If you do not want to lose the value of the parameter MIP_CUTOFFOBJ, this provides an alternative to disabling the cutoff objective.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use current cutoff value</td>
</tr>
<tr>
<td>1</td>
<td>Use current cutoff value</td>
</tr>
</tbody>
</table>

MIP_USE_CUTS_HEU (integer): controls if cut generation is enabled during MIP heuristics

This flag controls if cut generation is enabled during MIP heuristics. The default is -1 (i.e. the solver decides).

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Do not use cut heuristic</td>
</tr>
<tr>
<td>1</td>
<td>Use cut heuristic</td>
</tr>
</tbody>
</table>

MIP_USE_ENUM_HEU (integer): frequency of enumeration heuristic

This specifies the frequency of enumeration heuristic.

Default: 4

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Only at top (root) node without cuts</td>
</tr>
<tr>
<td>2</td>
<td>Both at top (root) and tree nodes without cuts</td>
</tr>
<tr>
<td>3</td>
<td>Same as 1 with cuts</td>
</tr>
<tr>
<td>4</td>
<td>Same as 2 with cuts</td>
</tr>
</tbody>
</table>

MIP_USE_INT_ZERO_TOL (integer): controls if all MIP calculations would be based on absolute integer feasibility tolerance

This flag controls if all MIP calculations would be based on the integrality tolerance specified by MIP_INTTOL.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not base MIP calculations on MIP_INTTOL</td>
</tr>
<tr>
<td>1</td>
<td>Base MIP calculations on MIP_INTTOL</td>
</tr>
</tbody>
</table>

MULTITHREAD_MODE (integer): threading mode

This parameter controls the threading mode for solvers with multithreading support.
Default: -1
### NLP_AUTODERIV (integer): defining type of computing derivatives

This is a flag to indicate if automatic differentiation is the method of choice for computing derivatives and select the type of differentiation.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Finite Differences approach will be used</td>
</tr>
<tr>
<td>1</td>
<td>Forward type of Automatic Differentiation will be used</td>
</tr>
<tr>
<td>2</td>
<td>Backward type of Automatic Differentiation will be used</td>
</tr>
</tbody>
</table>

### NLP_AUTOHESS (integer): flag for using Second Order Automatic Differentiation for solving NLP

This is a flag to indicate if Second Order Automatic Differentiation will be performed in solving a nonlinear model. The second order derivatives provide an exact/precise Hessian matrix to the SQP algorithm, which may lead to less iterations and better solutions, but may also be quite expensive in computing time for some cases.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use Second Order Automatic Differentiation</td>
</tr>
<tr>
<td>1</td>
<td>Use Second Order Automatic Differentiation</td>
</tr>
</tbody>
</table>

### NLP_CONIC_REFORM (integer): determines if to explore conic reformulation

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### NLP_CONOPT_VER (integer): specifies the CONOPT version to be used in NLP optimizations

Range: \{3, ..., 4\}

Default: 3

### NLP_CUTOFFOBJ (real): as soon as any multi-start thread achieves this value all threads stop

If the current best objective of the NLP being solved in a multistart run is better than this value, the solver will terminate early without exhausting the maximum number of multistarts. This is a way of saving computer time if the current best solution is sufficiently attractive.
Range: \([-1e30, \infty]\)

Default: \(-1e30\)

\textbf{NLP\_DERIV\_DIFFTYPE} (integer): flag indicating the technique used in computing derivatives with finite differences

This is a flag indicating the technique used in computing derivatives with Finite Differences.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use forward differencing method</td>
</tr>
<tr>
<td>2</td>
<td>Use backward differencing method</td>
</tr>
<tr>
<td>3</td>
<td>Use center differencing method</td>
</tr>
</tbody>
</table>

\textbf{NLP\_FEASCHK} (integer): how to report results when solution satisfies tolerance of scaled but not original model

This input parameter specifies how the NLP solver reports the results when an optimal or local-optimal solution satisfies the feasibility tolerance (\texttt{NLP\_FEASTOL}) of the scaled model but not the original (descaled) one.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform no action accept the final solution</td>
</tr>
<tr>
<td>1</td>
<td>Declare the model status as FEASIBLE if maximum violation in the unscaled model is not higher than 10 times NLP_FEASTOL</td>
</tr>
<tr>
<td>2</td>
<td>Declare the model status as UNKNOWN if maximum violation in the unscaled model is higher than NLP_FEASTOL</td>
</tr>
</tbody>
</table>

\textbf{NLP\_FEASTOL} (real): feasibility tolerance for nonlinear constraints

This is the feasibility tolerance for nonlinear constraints. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: 1e-6

\textbf{NLP\_INF} (real): numeric infinity for nonlinear models

Specifies the numeric infinity for nonlinear models. Possible values are positive real numbers. Smaller values could cause numerical problems.

\texttt{nlp\_ipm2grg} This is a flag to switch from IPM solver to the standard NLP (GRG) solver when IPM fails due to numerical errors.

Default: 1e30

\textbf{NLP\_IPM2GRG} (integer): switch from IPM solver to GRG solver when IPM fails due to numerical errors

Default: 1
### NLP_ITERS_PER_LOGLINE (integer): number of nonlinear iterations to elapse before next progress message

Number of nonlinear iterations to elapse before next progress message.

Range: \( \{1, \ldots, \infty\} \)

Default: 10

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not switch</td>
</tr>
<tr>
<td>1</td>
<td>Switch</td>
</tr>
</tbody>
</table>

### NLP_ITRLMT (integer): nonlinear iteration limit

This controls the iteration limit on the number of nonlinear iterations performed.

Range: \( \{-1, \ldots, \infty\} \)

Default: `GAMS IterLim`

### NLP_LINEARZ (integer): extent to which the solver will attempt to linearize nonlinear models

This determines the extent to which the solver will attempt to linearize nonlinear models.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>No linearization occurs</td>
</tr>
<tr>
<td>2</td>
<td>Linearize ABS MAX and MIN functions</td>
</tr>
<tr>
<td>3</td>
<td>Same as option 2 plus IF AND OR NOT and all logical operators are linearized</td>
</tr>
</tbody>
</table>

### NLP_LINEARZ_WB_CONSISTENT (integer): determines if linearization process is consistent with WB/excel calculation

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### NLP_MAXLOCALSEARCH (integer): maximum number of local searches

This controls the maximum number of local searches (multistarts) when solving a NLP using the multistart solver.

Default: 5

### NLP_MAXLOCALSEARCH_TREE (integer): maximum number of multistarts

Maximum number of multistarts (at tree nodes)

Default: 1
**NLP_MAX_RETRY (integer):** maximum number refinement retries to purify the final NLP solution

> Maximum number refinement retries to purify the final NLP solution.
> Range: \{-1, ..., \infty\}
> Default: 5

**NLP_MSW_EUCDIST_THRES (real):** euclidean distance threshold in multistart search

> Euclidean distance threshold in multistart search
> Default: 0.001

**NLP_MSW_FILTMODE (integer):** filtering mode to exclude certain domains during sampling in multistart search

> Filtering mode to exclude certain domains during sampling in multistart search.
> Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>+1</td>
<td>Filter-out the points around known KKT or feasible points previously visited</td>
</tr>
<tr>
<td>+2</td>
<td>Filter-out the points whose p are in the vicinity of p(x)</td>
</tr>
<tr>
<td>+4</td>
<td>Filter-out the points in the vicinity of x where x are initial points of all previous local optimizations</td>
</tr>
<tr>
<td>+8</td>
<td>Filter-out the points whose p(.) values are below a dynamic threshold tolerance</td>
</tr>
</tbody>
</table>

**NLP_MSW_MAXNOIMP (integer):** maximum number of consecutive populations to generate without any improvements

> Maximum number of consecutive populations to generate without any improvements.
> Range: \{-1, ..., \infty\}
> Default: -1

**NLP_MSW_MAXPOP (integer):** maximum number of populations to generate in multistart search

> Maximum number of populations to generate in multistart search.
> Range: \{-1, ..., \infty\}
> Default: -1

**NLP_MSW_MAXREF (integer):** maximum number of reference points to generate trial points in multistart search

> Maximum number of reference points in the solution space to generate trial points in multistart search.
> Range: \{-1, ..., \infty\}
> Default: -1
**NLP_MSW_NORM** (integer): norm to measure the distance between two points in multistart search

Norm to measure the distance between two points in multistart search.

Range: \{-1, ..., \infty\}

Default: 2

**NLP_MSW_NUM_THREADS** (integer): number of parallel threads to be used when solving an NLP model with the multistart solver

This value specifies the number of parallel threads to be used when solving an NLP model with the multistart solver.

Default: 1

**NLP_MSW_OVERLAP_RATIO** (real): rate of replacement in successive populations

This value specifies the rate of replacement in successive populations. Higher values favors survival of points in the parent population.

Range: \[0.0, 1.0\]

Default: 0.1

**NLP_MSW_POXDIST_THRES** (real): penalty function neighborhood threshold in multistart search

Penalty function neighborhood threshold in multistart search

Default: 0.01

**NLP_MSW_PREPMODE** (integer): preprocessing strategies in multistart solver

This value specifies the preprocessing strategies in multistart solver.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>

<tr>
<td>+128</td>
<td>Collect sufficiently many trial points prior to local solves</td>
</tr>
<tr>
<td>+256</td>
<td>Enable power solver, trying several different local strategies</td>
</tr>
</tbody>
</table>

**NLP_MSW_RG_SEED** (integer): random number generator seed for the multistart solver

This value specifies the random number generator seed for the multistart solver.

Default: 1019
NLP_MSW_RMAPMODE (integer): specifies the mode to map reference points in the unit cube into the original space ←

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Use original variable bounds</td>
</tr>
<tr>
<td>1</td>
<td>Use min-max values over all sample points per each dimension</td>
</tr>
<tr>
<td>2</td>
<td>Use min-max values over all sample points over all dimensions</td>
</tr>
</tbody>
</table>

NLP_MSW_SOLIDX (integer): index of the multistart solution to be loaded ←

Index of the multistart solution to be loaded main solution structures.

Default: 0

NLP_MSW_XKKTRAD_FACTOR (real): KKT solution neighborhood factor in multistart search ←

KKT solution neighborhood factor in multistart search

Default: 0.85

NLP_MSW_XNULRAD_FACTOR (real): initial solution neighborhood factor in multistart search ←

Initial solution neighborhood factor in multistart search

Default: 0.5

NLP_PRELEVEL (integer): controls the amount and type of NLP pre-solving ←

This controls the amount and type of NLP pre-solving.

Default: 126

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Simple pre-solving</td>
</tr>
<tr>
<td>+4</td>
<td>Probing</td>

<td>Maximum pass</td>
</tr>
</tbody>
</table>

NLP_PSTEP_FINITEDIFF (real): value of the step length in computing the derivatives using finite differences ←

This controls the value of the step length in computing the derivatives using finite differences.

Default: 5e-7

NLP_QUADCHK (integer): flag for checking if NLP is quadratic ←
This is a flag indicating if the nonlinear model should be examined to check if it is a quadratic model.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not check if NLP is quadratic</td>
</tr>
<tr>
<td>1</td>
<td>Check if NLP is quadratic</td>
</tr>
</tbody>
</table>

**NLP_REDGTOL** *(real)*: tolerance for the gradients of nonlinear functions

This is the tolerance for the gradients of nonlinear functions. The (projected) gradient of a function is considered to be the zero-vector if its norm is below this tolerance.

Default: $1e^{-7}$

**NLP_SOLVER** *(integer)*: type of nonlinear solver

This value determines the type of nonlinear solver.

Default: 7

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Solver decides</td>
</tr>
<tr>
<td>5</td>
<td>Uses Levenberg-Marquardt method to solve nonlinear least-squares problem</td>
</tr>
<tr>
<td>6</td>
<td>Uses Barrier solver for convex QCP models</td>
</tr>
<tr>
<td>7</td>
<td>Uses CONOPTs reduced gradient solver</td>
</tr>
<tr>
<td>8</td>
<td>Uses SLP solver</td>
</tr>
<tr>
<td>9</td>
<td>Uses CONOPT with multistart feature enabled</td>
</tr>
</tbody>
</table>

**NLP_SOLVE_AS_LP** *(integer)*: flag indicating if the nonlinear model will be solved as an LP

This is a flag indicating if the nonlinear model will be solved as an LP. 1 means that an LP using first order approximations of the nonlinear terms in the model will be used when optimizing the model with the LSoptimize() function.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NLP will not be solved as LP</td>
</tr>
<tr>
<td>1</td>
<td>NLP will be solved as LP</td>
</tr>
</tbody>
</table>

**NLPSTALL_ITRLMT** *(integer)*: iteration limit before a sequence of non-improving NLP iterations is declared as stalling

This specifies the iteration limit before a sequence of non-improving NLP iterations is declared as stalling, thus causing the solver to terminate.

Default: 100

**NLP_STARTPOINT** *(integer)*: flag for using initial starting solution for NLP

This is a flag indicating if the nonlinear solver should accept initial starting solutions.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use initial starting solution for NLP</td>
</tr>
<tr>
<td>1</td>
<td>Use initial starting solution for NLP</td>
</tr>
</tbody>
</table>

**NLP_SUBSOLVER** *(integer): type of nonlinear subsolver*←

This controls the type of linear solver to be used for solving linear subproblems when solving nonlinear models.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Primal simplex method</td>
</tr>
<tr>
<td>2</td>
<td>Dual simplex method</td>
</tr>
<tr>
<td>3</td>
<td>Barrier solver with or without crossover</td>
</tr>
</tbody>
</table>

**NLP_USECUTOFFOBJ** *(integer): flag to use parameter NLP_CUTOFFOBJ*←

This is a flag for the parameter `NLP_CUTOFFOBJ`. The value of 0 means NLP_CUTOFFOBJ will be ignored, else it will be used as specified.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**NLP_USE_CRASH** *(integer): flag for using simple crash routines for initial solution*←

This is a flag indicating if an initial solution will be computed using simple crash routines.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use simple crash routines</td>
</tr>
<tr>
<td>1</td>
<td>Use simple crash routines</td>
</tr>
</tbody>
</table>

**NLP_USE_LINDO_CRASH** *(integer): flag for using advanced crash routines for initial solution*←

This is a flag indicating if an initial solution will be computed using advanced crash routines.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use advanced crash routines</td>
</tr>
<tr>
<td>1</td>
<td>Use advanced crash routines</td>
</tr>
</tbody>
</table>

**NLP_USE_SDP** *(integer): flag to use SDP solver for POSD constraint*←
Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**NLP_USE_SELCONEVAL** (integer): flag for using selective constraint evaluations for solving NLP

This is a flag indicating if selective constraint evaluations will be performed in solving a nonlinear model.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use selective constraint evaluations</td>
</tr>
<tr>
<td>1</td>
<td>Use selective constraint evaluations</td>
</tr>
</tbody>
</table>

**NLP_USE_SLP** (integer): flag for using sequential linear programming step directions for updating solution

This is a flag indicating if sequential linear programming step directions should be used in updating the solution.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Do not use sequential linear programming step directions</td>
</tr>
<tr>
<td>1</td>
<td>Use sequential linear programming step directions</td>
</tr>
</tbody>
</table>

**NLP_USE_STEEPEDGE** (integer): flag for using steepest edge directions for updating solution

This is a flag indicating if steepest edge directions should be used in updating the solution.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use steepest edge directions</td>
</tr>
<tr>
<td>1</td>
<td>Use steepest edge directions</td>
</tr>
</tbody>
</table>

**NUM_THREADS** (integer): number of parallel threads to be used

Synonym: gthreads

Number of threads to use in the solver routine to be called. It is a solver-independent parameter which internally sets solver-specific threading parameters automatically.

Range: \( \{1, \ldots, \infty\} \)

Default: GAMS Threads
**PROB_TO_SOLVE (integer):** controls whether the explicit primal or dual form of the given LP problem will be solved ↔

This flag controls whether the explicit primal or dual form of the given LP problem will be solved.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Explicit primal form</td>
</tr>
<tr>
<td>2</td>
<td>Explicit dual form</td>
</tr>
</tbody>
</table>

**PROFILER_LEVEL (integer):** specifies the profiler level to break down the total cpu time into. ↔

Specifies the profiler level to break down the total cpu time into.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Profiler is off</td>
</tr>
<tr>
<td>+1</td>
<td>Enable for simplex solver</td>
</tr>
<tr>
<td>+2</td>
<td>Enable for integer solver</td>
</tr>
<tr>
<td>+4</td>
<td>Enable for multistart solver</td>
</tr>
<tr>
<td>+8</td>
<td>Enable for global solver</td>
</tr>
</tbody>
</table>

**READPARAMS (string):** read Lindo parameter file ↔

**REPORTEVSSOL (no value):** solve and report the expected value solution ↔

Default: 0

**SAMP_CDSINC (real):** correlation matrix diagonal shift increment ↔

Correlation matrix diagonal shift increment.

Default: $1e^{-6}$

**SAMP_NCM_CUTOBJ (real):** objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem ↔

Objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem.

Default: $1e^{-30}$

**SAMP_NCM_DSTORAGE (integer):** flag to enable or disable sparse mode in NCM computations ↔

Flag to enable/disable sparse mode in NCM computations.

Range: $\{-1, ..., \infty\}$

Default: $-1$
**SAMP_NCM_ITERLIM** *(integer)*: iteration limit for NCM method

Iteration limit for NCM method.

Default: 100

**SAMP_NCM_METHOD** *(integer)*: bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem

Bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem.

Default: 5

**SAMP_NCM_OPTTOL** *(real)*: optimality tolerance for NCM method

Optimality tolerance for NCM method.

Default: 1e-7

**SAMP_NUM_THREADS** *(integer)*: specifies the number of parallel threads to be used when sampling

Default: 0

**SAMP_RG_BUFFER_SIZE** *(integer)*: specifies the buffer size for random number generators in running in parallel mode

Default: 0

**SAMP_SCALE** *(integer)*: flag to enable scaling of raw sample data

Flag to enable scaling of raw sample data.

Default: 0

**SOLVER_CONCURRENT_OPTMODE** *(integer)*: controls if simplex and interior-point optimizers will run concurrently

Controls if simplex and interior-point optimizers will run concurrently, 0 means no concurrent runs will be performed, 1 means both optimizers will run concurrently if at least two threads exist in system, 2 means both optimizers will run concurrently.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no concurrent runs</td>
</tr>
<tr>
<td>1</td>
<td>run concurrently if at least 2 threads exist</td>
</tr>
<tr>
<td>2</td>
<td>run concurrently</td>
</tr>
</tbody>
</table>

**SOLVER_CUTOFFVAL** *(real)*: solver will exit if optimal solution is worse than this

If the optimal objective value of the LP being solved is shown to be worse than this (e.g., if the dual simplex method is being used), then the solver will exit without finding a feasible solution. This is a way of saving computer time if there is no sufficiently attractive solution. **SOLVER_USECUTOFFVAL** needs to be set to 1 to activate this value.

Default: 0
**SOLVER_FEASTOL** *(real): feasibility tolerance* 

This is the feasibility tolerance. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: $1e^{-7}$

**SOLVER_IPMSOL** *(integer): basis crossover flag for barrier solver* 

This flag controls whether a basis crossover will be performed when solving LPs with the barrier solver. A value of 0 indicates that a crossover to a basic solution will be performed. If the value is 1, then the barrier solution will be left intact. For example, if alternate optima exist, the barrier method will return a solution that is, loosely speaking, the average of all alternate optima.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform crossover to basis solution</td>
</tr>
<tr>
<td>1</td>
<td>Leave barrier solution intact</td>
</tr>
</tbody>
</table>

**SOLVER_IUSOL** *(integer): flag for computing basic solution for infeasible model* 

This is a flag that, when set to 1, will force the solver to compute a basic solution to an infeasible model that minimizes the sum of infeasibilities and a basic feasible solution to an unbounded problem from which an extreme direction originates. When set to the default of 0, the solver will return with an appropriate status flag as soon as infeasibility or unboundedness is detected. If infeasibility or unboundedness is declared with presolver’s determination, no solution will be computed.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Return appropriate status if infeasibility is encountered</td>
</tr>
<tr>
<td>1</td>
<td>Force the solver to compute a basic solution to an infeasible model</td>
</tr>
</tbody>
</table>

**SOLVER_METHOD** *(integer): specifies the method to use when generic solver is invoked* 

Default: 0

</tr>
</tbody>
</table>

SOLVER_OPTTOL (real): dual feasibility tolerance

This is the optimality tolerance. It is also referred to as the dual feasibility tolerance. A dual slack (reduced cost) is considered violated if it violates its lower bound by the optimality tolerance.

Default: 1e-7

SOLVER_PRE_ELIM_FILL (integer): fill-in introduced by the eliminations during pre-solve

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly more than the original model.

Default: 1000

SOLVER_RESTART (integer): starting basis flag

This is the starting basis flag. 1 means LINDO API will perform warm starts using any basis currently in memory. 0 means LINDO API will perform cold starts discarding any basis in memory and starting from scratch.

Default: 0

<table>
<thead>
<tr>
<th>value</th>

SOLVER_TIMLMT (integer): time limit in seconds for continous solver

This is a time limit in seconds for the LP solver. The default value of -1 imposes no time limit.

Range: \{-1, ..., \infty\}

Default: GAMS ResLim

SOLVER_USECUTOFFVAL (integer): flag for using cutoff value

This is a flag for the parameter SOLVER_CUTOFFVAL

Default: 0

<table>
<thead>
<tr>
<th>value</th>

**SPLEX_REFACFRQ** *(integer)*: number of simplex iterations between two consecutive basis re-factorizations

This is a positive integer scalar referring to the simplex iterations between two consecutive basis re-factorizations. For numerically unstable models, setting this parameter to smaller values may help.

Default: 100

**STOC_ABSOPTTOL** *(real)*: absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver

Absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. Possible values are reals in (0,1) interval.

Default: GAMS OptCA

**STOC_ADD_MPI** *(integer)*: flag to use add-instructions mode when building deteq
Flag to use add-instructions mode when building deteq.
Default: 0

**STOC_ALD_DUAL_FEASTOL** *(real):* dual feasibility tolerance for ALD ←
Dual feasibility tolerance for ALD.
Default: 1e-4

**STOC_ALD_DUAL_STEPLEN** *(real):* dual step length for ALD ←
Dual step length for ALD.
Default: 0.9

**STOC_ALD_INNER_ITER_LIM** *(integer):* inner loop iteration limit for ALD ←
Inner loop iteration limit for ALD.
Default: 1000

**STOC_ALD_OUTER_ITER_LIM** *(integer):* outer loop iteration limit for ALD ←
Outer loop iteration limit for ALD.
Default: 200

**STOC_ALD_PRIMAL_FEASTOL** *(real):* primal feasibility tolerance for ALD ←
Primal feasibility tolerance for ALD.
Default: 1e-4

**STOC_ALD_PRIMAL_STEPLEN** *(real):* primal step length for ALD ←
Primal step length for ALD.
Default: 0.5

**STOC_AUTOAGGR** *(integer):* flag to enable or disable autoaggregation ←
Flag to enable or disable autoaggregation.
Default: 1

**STOC_BENCHMARK_SCEN** *(integer):* benchmark scenario to compare EVPI and EVMU against ←
Benchmark scenario to compare EVPI and EVMU against.
Range: {-2, ..., ∞}
Default: -2

**STOC_BIGM** *(real):* big-M value for linearization and penalty functions ←
Big-M value for linearization and penalty functions.
Default: 1e7

**STOC_BUCKET_SIZE** *(integer):* bucket size in Benders decomposition ←
Bucket size in Benders decomposition. Possible values are positive integers or (-1) for solver decides.
Range: {-1, ..., ∞}
Default: -1

**STOC_CALC_EVPI** *(integer):* flag to enable or disable calculation of EVPI ←
Flag to enable/disable calculation of lower bounds on EVPI.
Default: 1
<table>

**STOC_ELIM_FXVAR** *(integer)*: flag to enable elimination of fixed variables from deteq MPI

Flag to enable elimination of fixed variables from deteq MPI.

Default: 1

**STOC_INFBND** *(real)*: value to truncate infinite bounds at non-leaf nodes

Value to truncate infinite bounds at nonleaf nodes.

Default: 1e9

**STOC_ITER_LIM** *(integer)*: iteration limit for stochastic solver

Iteration limit for stochastic solver. Possible values are positive integers or (-1) no limit.

Range: \{-1, ..., \infty\}

Default: infinity

**STOC_MAP_MPI2LP** *(integer)*: flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements

Flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements.

Default: 0

**STOC_MAX_NUMSCENS** *(integer)*: maximum number of scenarios before forcing automatic sampling

Maximum number of scenarios before forcing automatic sampling. Possible values are positive integers.

Default: 40000

**STOC_METHOD** *(integer)*: stochastic optimization method to solve the model

Stochastic optimization method to solve the model.

Default: -1

<table>

**STOC_NSAMPLE_PER_STAGE** *(string)*: list of sample sizes per stage (starting at stage 2) ←

Comma separated list of sample sizes per stage. The sample size of stage 1 is assumed to be 1 so that this list starts with stage 2.

**STOC_NSAMPLE_SPAR** *(integer)*: common sample size per stochastic parameter ←

Common sample size per stochastic parameter. Possible values are positive integers.

Range: \([-1, \ldots, \infty]\)

Default: -1

**STOC_NSAMPLE_STAGE** *(integer)*: common sample size per stage ←

Common sample size per stage.

Range: \([-1, \ldots, \infty]\)

Default: -1

**STOC_NUM_THREADS** *(integer)*: number of parallel threads ←

This value specifies the number of parallel threads to be used when solving a stochastic programming model.

Default: 1

**STOC_RELOPTTOL** *(real)*: relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver ←

Relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. Possible values are reals in \((0,1)\) interval.

Default: GAMS OptCR

**STOC_REL_DSTEPTOL** *(real)*: dual-step tolerance ←

This value specifies the dual-step tolerance in decomposition based algorithms.

Default: 1e-7

**STOC_REL_PSTEPTOL** *(real)*: primal-step tolerance ←

This value specifies the primal-step tolerance in decomposition based algorithms.

Default: 1e-8

**STOC_REOPT** *(integer)*: reoptimization method to solve the node-models ←

Reoptimization method to solve the node-models.

Default: 0
<table>

**STOC_SBD_MAXCUTS** (*integer*): max cuts to generate for master problem

Max cuts to generate for master problem.

Range: \{-1, ..., \infty\}

Default: -1

**STOC_SBD_NUMCANDID** (*integer*): maximum number of candidate solutions to generate at SBD root

Maximum number of candidate solutions to generate at SBD root.

Range: \{-1, ..., \infty\}

Default: -1

**STOC_SBD_OBJCUTFLAG** (*integer*): flag to enable objective cut in SBD master problem

Flag to enable objective cut in SBD master problem.

Default: 1

**STOC_SBD_OBJCUTVAL** (*real*): RHS value of objective cut in SBD master problem

RHS value of objective cut in SBD master problem.

Default: 1e-30

**STOC_SHARE_BEGSTAGE** (*integer*): stage beyond which node-models are shared

Stage beyond which node-models are shared.
Stage beyond which node-models share the same model structure. Possible values are positive integers less than or equal to number of stages in the model or (-1) for solver decides.

Range: \{-1, ..., \infty\}

Default: -1

\textbf{STOC\_TIME\_LIM} (real): time limit for stochastic solver

Time limit for stochastic solver. Possible values are nonnegative real numbers or -1 for solver decides.

Range: [-1, \infty]

Default: GAMS ResLim

\textbf{STOC\_TOPOPT} (integer): optimization method to solve the root problem

Optimization method to solve the root problem.

Default: 0

WRITEDEMPI *(string)*: write deterministic equivalent in MPI format

WRITEDEMPES *(string)*: write deterministic equivalent in MPS format

WRITEMPI *(string)*: write (S)MPI file of processed model

If this option is set, Lindo write an MPI file of processed model. If set, the value of this option defines the name of the MPI file.

WRITEMPS *(string)*: write (S)MPS file of processed model

5.24.8 Stochastic Programming (SP) in GAMS/Lindo

GAMS/Lindo can also solve stochastic programming models. The syntax to set up an SP problem in GAMS is explained in the chapter Stochastic Programming (SP) with EMP. The options to control LINDO's stochastic solver are described in the subsection SP Options.
5.25 MILES

Thomas F. Rutherford, University of Colorado

5.25.1 Abstract

MILES is a solver for nonlinear complementarity problems and nonlinear systems of equations. The solver can be accessed through GAMS to solve MPSGE or MCP models. This paper documents the solution algorithm, user options, and solver output. The purpose of the paper is to provide users of MILES an overview of how the solver works so that they can use it effectively.

5.25.2 Introduction

MILES is a Fortran-based solver for nonlinear complementarity problems and nonlinear systems of equations. The solution procedure is a generalized Newton method with a backtracking line search. This code is based on an algorithm investigated by Mathiesen (1985) who proposed a modeling format and sequential method for solving economic equilibrium models. The method is closely related to algorithms proposed by Robinson (1975), Hogan (1977), Eaves (1978) and Josephy (1979). In this implementation, subproblems are solved as linear complementarity problems (LCPs), using an extension of Lemke’s almost-complementary pivoting scheme in which upper and lower bounds are represented implicitly. The linear solver employs the basis factorization package LUSOL, developed by Gill et al. (1991).

The class of problems for which MILES may be applied are referred to as ”generalized” or ”mixed” complementarity problems, which is defined as follows:

\[ F : \mathbb{R}^n \rightarrow \mathbb{R}^n, \quad \ell, u \in \mathbb{R}^n \]

Find: \[ z, w, v \in \mathbb{R}^n \]

such that \[ F(z) = w - v \]
\[ \ell \leq z \leq u, \quad w \geq 0, \quad v \geq 0 \]
\[ w^T(z - \ell) = 0, \quad v^T(u - z) = 0. \]

When \( \ell = -\infty \) and \( u = \infty \) MCP reduces to a nonlinear system of equations. When \( \ell = 0 \) and \( u = +\infty \), the MCP is a nonlinear complementarity problem. Finite dimensional variational inequalities are also MCP. MCP includes inequality-constrained linear, quadratic and nonlinear programs as special cases, although for these problems standard optimization methods may be preferred. MCP models which are not optimization problems encompass a large class of interesting mathematical programs. Specific examples of MCP formulations are not provided here. See Rutherford (1992a) for MCP formulations arising in economics. Other examples are provided by Harker and Pang (1990) and Dirkse (1993).

There are two types of GAMS models which can be presented to MILES:

1. MILES may be used to solve computable general equilibrium models generated by MPSGE as a GAMS subsystem. In the MPSGE language, a model-builder specifies classes of nonlinear functions using a specialized tabular input format embedded within a GAMS program. Using benchmark quantities and prices, MPSGE automatically calibrates function coefficients and generates nonlinear equations and Jacobian matrices. Large, complicated systems of nonlinear equations may be implemented and analyzed very easily using this interface to MILES. An introduction to general equilibrium modeling with GAMS/MPSGE is provided by Rutherford (1992a).
2. MILES may be accessed as a GAMS solver for mixed complementarity problems (MCP). If more than one MCP solver is available, the statement `OPTION MCP = MILES;` tells GAMS to use MILES as the MCP solution system. When problems are presented to MILES using the MCP format, the user specifies nonlinear functions using GAMS matrix algebra and the GAMS compiler automatically generates the Jacobian functions. An introduction to the GAMS/MCP modeling format is provided by Rutherford (1992b).

The purpose of this document is to provide users of MILES with an overview of how the solver works so that they can use the program more effectively. Section The Newton Algorithm introduces the Newton algorithm. Section Lemke’s Method with Implicit Bounds describes the implementation of Lemke’s algorithm which is used to solve linear subproblems. Section The Options File defines switches and tolerances which may be specified using the options file. Section Log File Output interprets the run-time log file which is normally directed to the screen. Section Status File Output interprets the status file and the detailed iteration reports which may be generated. Section Termination Messages lists and suggests remedies for abnormal termination conditions.

5.25.3 The Newton Algorithm

The iterative procedure applied within MILES to solve nonlinear complementarity problems is closely related to the classical Newton algorithm for nonlinear equations. This first part of this section reviews the classical procedure. A thorough introduction to these ideas is provided by Dennis and Schnabel (1983). For a practical perspective, see Press et al. (1986).

Newton algorithms for nonlinear equations begin with a local (Taylor series) approximation of the system of nonlinear equations. For a point $z$ in the neighborhood of $\bar{z}$, the system of nonlinear functions is linearized:

$$LF(z) = F(\bar{z}) + \nabla F(\bar{z})(z - \bar{z}).$$

Solving the linear system $LF(z) = 0$ provides the Newton direction from $\bar{z}$ which is given by $d = -\nabla F^{-1}F(\bar{z})$.

Newton iteration $k$ begins at point $z^k$. First, the linear model formed at $z^k$ is solved to determine the associated "Newton direction", $d^k$. Second, a line search in direction $d^k$ determines the scalar steplength and the subsequent iterate: $z^{k+1} = z^k + \lambda d^k$. An Armijo or "back-tracking" line search initially considers $\lambda = 1$. If $\|F(z^k + \lambda d^k)\| \leq \|F(z^k)\|$, the step size $\lambda$ is adopted, otherwise it is multiplied by a positive factor $\alpha$, $\alpha < 1$, and the convergence test is reapplied. This procedure is repeated until either an improvement results or $\lambda < \lambda_0$. When $\lambda_0 = 0$, a positive step is taken provided that

$$\frac{d}{d\lambda} \|F(z^k + \lambda d^k)\| < 0.$$

Convergence theory for this algorithm is quite well developed. See, for example, Ortega and Rheinbolt (1970) or Dennis and Schnabel (1983). The most attractive aspect of the Newton scheme with the backtracking line search is that in the neighborhood of a well-behaved fixed point, $\lambda = 1$ is the optimal step length and the rate of convergence can be quadratic. If this method finds a solution, it does so very quickly.

The application of Newton methods to nonlinear complementarity problems involves a modification of the search direction. Here, $d$ solves a linear complementarity problem (LCP) rather than a linear system of equations. For iteration $k$, $d$ solves:

3There is one other MCP solver available through GAMS: PATH (Ferris and Dirkse, 1992)

4$\alpha$ and $\lambda_0$ correspond to user-specified tolerances ‘DMPFAC’ and ‘MINSTP’, respectively
\[ F(z^k) + \nabla F(z^k)d - w + v = 0 \]

\[ \ell \leq d + z^k \leq u, \quad w \geq 0, \quad v \geq 0 \]

\[ w^T(d + z^k - \ell) = v^T(u - d - z^k) = 0. \]

Conceptually, we are solving for \(d\), but in practice MILES solves the linear problem in terms of the original variables \(z = z^k + d\):

\[ F(z^k) - \nabla F(z^k)z_k + \nabla F(z^k)z = w - v \]

\[ \ell \leq z \leq u, \quad w \geq 0, \quad v \geq 0 \]

\[ w^T(z - \ell) = 0, \quad v^T(u - z) = 0. \]

After computing the solution \(z\), MILES sets \(d^k = z - z^k\).

The linear subproblem incorporates upper and lower bounds on any or all of the variables, assuring that the iterative sequence always remains within the bounds: \((\ell \leq z^k \leq u)\). This can be helpful when, as is often the case, \(F()\) is undefined for some \(z \in \mathbb{R}^n\).

Convergence of the Newton algorithm applied to MCP hinges on three questions:

1. Does the linearized problem always have a solution?
2. If the linearized problem has a solution, does Lemke’s algorithm find it?
3. Is it possible to show that the computed direction \(d^k\) will provide an ”improvement” in the solution?

Only for a limited class of functions \(F()\) can all three questions be answered in the affirmative. For a much larger class of functions, the algorithm converges in practice but convergence is not ”provable” \(^5\).

The answer to question 3. depends on the choice of a norm by which an improvement is measured. The introduction of bounds and complementarity conditions makes the calculation of an error index more complicated. In MILES, the deviation associated with a candidate solution \(z, \epsilon(z)\), is based on a measure of the extent to which \(z, w\) and \(v\) violate applicable upper and lower bounds and complementarity conditions.

\(^5\)Kaneko (1978) provides some convergence theory for the linearized subproblem
5.25.3.1 Evaluating Convergence

Let $\delta^L_i$ and $\delta^U_i$ be indicator variables for whether $z_i$ is off its lower or upper bound. These are defined as

$$\delta^L_i = \min(1, (z_i - \ell_i)^+) \quad \text{and} \quad \delta^U_i = \min(1, (u_i - z_i)^+).$$

Given $z$, MILES uses the value of $F(z)$ to implicitly define the slack variables $w$ and $v$:

$$w_i = F_i(z)^+, \quad v_i = \left(-F_i(z)\right)^+.$$

There are two components to the error term associated with index $i$, one corresponding to $z_i$’s violation of upper and lower bounds:

$$\varepsilon^B_i = (z_i - u_i)^+ + (\ell_i - z_i)^+$$

and another corresponding to violations of complementarity conditions:

$$\varepsilon^C_i = \delta^L_i w_i + \delta^U_i v_i.$$

The error assigned to point $z$ is then taken:

$$\varepsilon(z) = \|\varepsilon^B(z) + \varepsilon^C(z)\|_p$$

for a pre-specified value of $p = 1, 2$ or $+\infty$.  

5.25.4 Lemke’s Method with Implicit Bounds

A mixed linear complementarity problem has the form:

Given: $M \in R^{n \times n}, \quad q, \ell, u \in R^n$

Find: $z, w, v \in R^n$

such that $Mz + q = w - v$,

$$\ell \leq z \leq u, \quad w \geq 0, \quad v \geq 0,$$

$$w^T(z - \ell) = 0, \quad v^T(u - z) = 0.$$

In the Newton subproblem at iteration $k$, the LCP data are given by $q = F(z^k) - \nabla F(z^k)z^k$ and $M = \nabla F(z^k)$.

---

6In the following $x^+ = \max(x, 0)$

7Parameter $p$ may be selected with input parameter ‘NORM’. The default value for $p$ is $+\infty$. 

5.25 MILES

5.25.4.1 The Working Tableau

In MILES, the pivoting scheme for solving the linear problem works with a re-labeled linear system of the form:

\[ \begin{bmatrix} B & x^B + N & x^N \end{bmatrix} = q \]

where \( x^B \in \mathbb{R}^n \), \( x^N \in \mathbb{R}^{2n} \), and the tableau \( [B|N] \) is a conformal "complementary permutation" of \( [-M|I| - I] \). That is, every column \( i \) in \( B \) must either be the \( i \)th column of \( M, I \) or \( -I \), while the corresponding columns \( i \) and \( i + n \) in \( N \) must be the two columns which were not selected for \( B \).

To move from the problem defined in terms of \( z, w \) and \( v \) to the problem defined in terms of \( x^B \) and \( x^N \), we assign upper and lower bounds for the \( x^B \) variables as follows:

\[
\begin{align*}
x^B_i &= \begin{cases} 
\ell_i, & \text{if } x^B_i = z_i \\
0, & \text{if } x^B_i = w_i \text{ or } v_i,
\end{cases} \\
x^B_i &= \begin{cases} u_i, & \text{if } x^B_i = z_i \\
\infty, & \text{if } x^B_i = w_i \text{ or } v_i
\end{cases}
\end{align*}
\]

The values of the non-basic variables \( x^N_i \) and \( x^N_{i+n} \) are determined by the assignment of \( x^B_i \):

\[
x^B_i = \begin{cases} 
z_i & \Rightarrow \begin{cases} x^N_i = w_i = 0 \\
x^N_{i+n} = v_i = 0
\end{cases} \\
w_i & \Rightarrow \begin{cases} x^N_i = z_i = \ell_i \\
x^N_{i+n} = v_i = 0
\end{cases} \\
v_i & \Rightarrow \begin{cases} x^N_i = w_i = 0 \\
x^N_{i+n} = z_i = u_i
\end{cases}
\end{cases}
\]

In words: if \( z_i \) is basic then both \( w_i \) and \( v_i \) equal zero. If \( z_i \) is non-basic at its lower bound, then \( w_i \) is possibly non-zero and \( v_i \) is non-basic at zero. If \( z_i \) is non-basic at its upper bound, then \( v_i \) is possibly non-zero and \( w_i \) is non-basic at zero.

Conceptually, we could solve the LCP by evaluating \( 3^n \) linear systems of the form:

\[ x^B = B^{-1} \left( q - N x^N \right) \]

Lemke's pivoting algorithm provides a procedure for finding a solution by sequentially evaluating some (hopefully small) subset of these \( 3^n \) alternative linear systems.
5.25.4.2 Initialization

Let $B^0$ denote the initial basis matrix. The initial values for basic variables are then:

$$\bar{x}^B = (B^0)^{-1}(q - N \bar{x}^N).$$

If $\bar{x}^B \leq \bar{x}^B \leq \bar{x}^B$, then the initial basis is feasible and the complementarity problem is solved. Otherwise, MILES introduces an artificial variable $z_0$ and an artificial column $h$. Basic variables are then expressed as follows:

$$x^B = \bar{x}^B - \hat{h}z_0,$$

where $\hat{h}$ is the "transformed artificial column" (the untransformed column is $h = B^0\hat{h}$). The coefficients of $\hat{h}$ are selected so that:

1. The values of "feasible" basis variables are unaffected by $z_0$: ($x^B_i \leq x^B_i \leq \bar{x}^B_i \Rightarrow \bar{h}_i = 0$).
2. The "most infeasible" basic variable ($i = p$) is driven to its upper or lower bound when $z_0 = 1$:

$$\bar{h}_p = \begin{cases} \bar{x}_p - x^B_p, & \text{if } \bar{x}_p > x^B_p \\ \bar{x}_p - x^B_p, & \text{if } \bar{x}_p < x^B_p. \end{cases}$$

3. All other infeasible basic variables assume values between their upper and lower bounds when $z_0$ increases to 1:

$$x_i^B = \begin{cases} 1 + x_i^B, & \text{if } x_i^B > -\infty, \quad \bar{x}_i^B = +\infty \\ \frac{x_i^B + x_i^B}{2}, & \text{if } x_i^B > -\infty, \quad \bar{x}_i^B < +\infty \\ \bar{x}_i^B - 1, & \text{if } x_i^B = -\infty, \quad \bar{x}_i^B < +\infty. \end{cases}$$

5.25.4.3 Pivoting Rules

When $z_0$ enters the basis, it assumes a value of unity, and at this point (barring degeneracy), the subsequent pivot sequence is entirely determined. The entering variable in one iteration is determined by the exiting basic variable in the previous iteration. For example, if $z_i$ were in $B^0$ and introducing $z_0$ caused $z_i$ to move onto its lower bound, then the subsequent iteration introduces $w_i$. Conversely, if $w_i$ were in $B^0$ and $z_0$ caused $w_i$ to fall to zero, the subsequent iteration increases $z_i$ from $\ell_i$. Finally, if $v_i$ were in $B^0$ and $z_0$’s introduction caused $v_i$ to fall to zero, the subsequent iteration decreases $z_i$ from $u_i$.

Table 1 Pivot Sequence Rules for Lemke’s Algorithm with Implicit Bounds

<table>
<thead>
<tr>
<th>N</th>
<th>Exiting Variable</th>
<th>Entering Variable</th>
<th>Change in Non-basic Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>$z_i$ at lower bound</td>
<td>$w_i$ increases from 0</td>
<td>$x_i^N = z_i = \ell_i$</td>
</tr>
<tr>
<td>II</td>
<td>$z_i$ at upper bound</td>
<td>$v_i$ increases from 0</td>
<td>$x_i^N = z_i = u_i$</td>
</tr>
<tr>
<td>III</td>
<td>$w_i$ at 0</td>
<td>$z_i$ increases from $\ell_i$</td>
<td>$x_i^N = x_i^N + 0$</td>
</tr>
<tr>
<td>IV</td>
<td>$v_i$ at 0</td>
<td>$z_i$ decreases from $u_i$</td>
<td>$x_i^N = x_i^N + 0$</td>
</tr>
</tbody>
</table>

\(^8\)In Miles, $B^0$ is chosen using the initially assigned values for $z$. When $z_i \leq \ell_i$, then $x_i^B = w_i$; when $z_i \geq u_i$, then $x_i^B = v_i$; otherwise $x_i^B = z_i$.

\(^9\)The present version of the code simply sets $B^0 = -I$ and $x^B = 0$ when the user-specified basis is singular. A subsequent version of the code will incorporate the algorithm described by Austreicher, Lee, and Rutherford [1992] for coping with singularity.
The full set of pivoting rules is displayed in Table 1. One difference between this algorithm and the original Lemke (type III) pivoting scheme (see Lemke (1965), Garcia and Zangwill (1981), or Cottle and Pang (1992)) is that structural variables \( z_i \)'s may enter or exit the basis at their upper bound values. The algorithm, therefore, must distinguish between pivots in which the entering variable increases from a lower bound and those in which the entering variable decreases from an upper bound.

Another difference with the "usual" Lemke pivot procedure is that an entering structural variable may move from one bound to another. When this occurs, the subsequent pivot introduces the corresponding slack variable. For example, if \( z_i \) is increased from \( \ell_i \) to \( u_i \) without driving a basic variable infeasible, then \( z_i \) becomes non-basic at \( u_i \), and the subsequent pivot introduces \( v_i \). This type of pivot may be interpreted as \( z_i \) entering and exiting the basis in a single step.

In theory it is convenient to ignore degeneracy, while in practice degeneracy is unavoidable. The present algorithm does not incorporate a lexicographic scheme to avoid cycling, but it does implement a ratio test procedure which assures that when there is more than one candidate, priority is given to the most stable pivot. The admissible set of pivots is determined on both an absolute pivot tolerance (\( Z_{TOLPV} \)) and a relative pivot tolerance (\( Z_{TOLRP} \)). No pivot with absolute value smaller than \( \min (Z_{TOLPV}, Z_{TOLRP} \|V\|) \) is considered, where \( \|V\| \) is the norm of the incoming column.

### 5.25.4.4 Termination on a Secondary Ray

Lemke's algorithm terminates normally when the introduction of a new variable drives \( z_0 \) to zero. This is the desired outcome, but it does not always happen. The algorithm may be interrupted prematurely when no basic variable "blocks" an incoming variable, a condition known as "termination on a secondary ray". In anticipation of such outcomes, MILES maintains a record of the value of \( z_0 \) for successive iterations, and it saves basis information associated with the smallest observed value, \( z_0^* \). (In Lemke's algorithm, the pivot sequence is determined without regard for the effect on \( z_0 \), and the value of the artificial variable may follow an erratic (non-monotone) path from its initial value of one to the final value of zero.)

When MILES encounters a secondary ray, a restart procedure is invoked in which the set of basic variables associated with \( z_0^* \) are reinstalled. This basis (augmented with one column from the non-basic triplet to replace \( z_0 \)) serves as \( B_0 \), and the algorithm is restarted. In some cases this procedure permits the pivot sequence to continue smoothly to a solution, while in other cases may only lead to another secondary ray.

### 5.25.5 The Options File

The standard GAMS options (e.g. iterlim, reslim) can be used to control MILES. For more details, see section Controlling a Solver via GAMS Options.

In addition, MILES-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

The following is a typical MILES options file:

```
ITLIMT = 50
CONTOL = 1.0E-8
LUSIZE = 16
```

In the remainder of this section we describe the MILES options and give their default values.

---

\(^{10}\) If all structural variables are subject to finite upper and lower bounds, then no \( z_i \) variables may be part of a homogeneous solution adjacent to a secondary ray. This does not imply, however, that secondary rays are impossible when all \( z_i \) variables are bounded, as a ray may then be comprised of \( w_i \) and \( v_i \) variables.

### 5.25.6 Log File Output

The log file is intended for display on the screen in order to permit monitoring progress. Relatively little output is generated.

A sample iteration log is displayed in Table 2. This output is from two cases solved in succession. This and subsequent output comes from program TRNSP.FOR which calls the MILES library directly. (When MILES is invoked from within GAMS, at most one case is processed at a time.)

The first line of the log output gives the MILES program date and version information. This information is important for bug reports.

The line beginning "Work space..." reports the amount of memory which has been allocated to solve the model - 10K for this example. Thereafter is reported the initial deviation together with the name of the variable associated with the largest imbalance ($\epsilon^B_i + \epsilon^C_i$). The next line reports the convergence tolerance.

The lines beginning 0 and 1 are the major iteration reports for those iterations. the number following the iteration number is the current deviation, and the third number is the Armijo step length. The name of the variable complementary to the equation with the largest associated deviation is reported in parenthesis at the end of the line.

Following the final iteration is a summary of iterations, refactorizations, and final deviation. The final message reports the solution status. In this case, the model has been successfully processed ("Solved.").

### 5.25.7 Status File Output

The status file reports more details regarding the solution process than are provided in the log file. Typically, this file is written to disk and examined only if a problem arises. Within GAMS, the status file appears in the listing only following the GAMS statement `OPTION SYSOUT=ON;`.

The level of output to the status file is determined by the options passed to the solver. In the default configuration, the status file receives all information written to the log file together with a detailed listing of all switches and tolerances and a report of basis factorization statistics.

When output levels are increased from their default values using the options file, the status file can receive considerably more output to assist in debugging. Table 3 - Table 6 present a status file generated with `LEVOUT=3` (maximum), `PIVLOG=T`, and `LCPECH=T`.

The status file begins with the same header as the log file. Thereafter is a complete echo-print of the user-supplied option file when one is provided. Following the core allocation report is a full echo-print of control parameters, switches and tolerance as specified for the current run.

Table 4 continues the status file. The iteration-by-iteration report of variable and function values is produced whenever `LEVOUT >= 2`. Table 4 also contains an LCP echo-print. This report has two sections: `$ROWS` and `$COLUMNS`. The four columns of numbers in the `$ROWS` section are the constant vector \( q \), the current estimate of level values for the associated variables \( z \), and the lower and upper bounds vectors \( \ell \) and \( u \). The letters \( L \) and \( U \) which appear between the ROW and Z columns are used to identify variables which are non-basic at their lower and upper bounds, respectively. In this example, all upper bounds equal \( +\infty \), so no variables are non-basic at their upper bound.

By convention, only variable (and not equation names) appear in the status file. An equation is identified by the corresponding variable. We therefore see in the `$COLUMNS` section of the matrix echo-print, the row names correspond to the names of \( z \) variables. The names assigned to variables \( z_i \), \( w_i \) and \( v_i \) are
The status file output continues on Table 5 where the first half of the table reports output from the matrix scaling procedure, and the second half reports the messages associated with initiation of Lemke's procedure.

The "lu6chk warning" is a LUSOL report. Thereafter are two factorization reports. Two factorizations are undertaken here because the first basis was singular, so the program installs all the lower bound slacks in place of the matrix defined by the initial values, $z$.

Following the second factorization report, at the bottom of Table 5 is a summary of the initial pivot. "Infeasible in 3 rows." indicates that $\tilde{h}$ contains 3 nonzero elements. "Maximum infeasibility" reports the largest amount by which a structural variable violates an upper or lower bound. "Artificial column with 3 elements." indicates that the vector $h = B^0\tilde{h}$ contains 3 elements (note that in this case $B^0 = -I$ because the initial basis was singular, hence the equivalence between the number of nonzeros in $\tilde{h}$ and $h$).

Table 6 displays the final section of the status file. At the top of the table is the Lemke iteration log. The columns are interpreted as follows:

- **ITER** is the iteration index beginning with 0.
- **STATUS** is a statistic representing the efficiency of the Lemke path. Formally, status is the ratio of the minimum number of pivots from $B_0$ to the current basis divided by the actual number of pivots. When the status is 1, Lemke's algorithm is performing virtually as efficiently as a direct factorization (apart from the overhead of basis factor updates.)
- **Z%** indicates the percentage of columns in the basis are "structural" ($z$’s).
- **Z0** indicates the value of the artificial variable. Notice that in this example, the artificial variable declines monotonically from its initial value of unity.
- **ERROR** is a column in which the factorization error is reported, when it is computed. For this run, ITCH=30 and hence no factorization errors are computed.
- **INFEAS** is a column in which the magnitude of the infeasibility introduced by the artificial column (defined using the box-norm) is reported. (In MILES the cover vector $h$ contains many different nonzero values, not just 1’s; so there may be a large difference between the magnitude of the artificial variable and the magnitude of the induced infeasibility.
- **PIVOTS** reports the pivot magnitude in both absolute terms (the first number) and relative terms (the second number). The relative pivot size is the ratio of the pivot element to the norm of the incoming column.
- **IN/OUT** report the indices (not names) of the incoming and outgoing columns for every iteration. Notice that Lemke's iteration log concludes with variable $z_0$ exiting the basis.

The convergence report for iteration 1 is no different from the report written to the log file, and following this is a second report of variable and function values. We see here that a solution has been obtained following a single subproblem. This is because the underlying problem is, in fact, linear.

The status file (for this case) concludes with an iteration summary identical to the log file report and a summary of how much CPU time was employed overall and within various subtasks. (Don’t be alarmed if the sum of the last five numbers does not add up to the first number - some cycles are not monitored precisely.)

5.25.8 Termination Messages

Basis factorization error in INVERT. An unexpected error code returned by LUSOL. This should normally not occur. Examine the status file for a message from LUSOL.\footnote{Within GAMS, insert the line "OPTION SYSOUT=ON;" prior to the solve statement and resubmit the program in order to pass the MILES solver status file through to the listing.}
Failure to converge. Two successive iterates are identical - the Newton search direction is not defined. This should normally not occur.

Inconsistent parameters ZTOLZ0, ZTOLZE. ZTOLZ0 determines the smallest value loaded into the cover vector $h$, whereas ZTOLZE is the feasibility tolerance employed in the Harris pivot selection procedure. If $ZTOLZ0 < -ZTOLZE$, Lemke's algorithm cannot be executed because the initial basis is infeasible.

Insufficient space for linearization. Available memory is inadequate for holding the nonzeros in the Jacobian. More memory needs to be allocated. If there is insufficient space for the (Jacobi) matrix, there is far too little memory for holding the LU factors of the same matrix.

Insufficient space to invert. More memory needs to be allocated for basis factors. Increase the value of LUSIZE in the options file, or assign a larger value to `<model>.workspace`.

Iteration limit exceeded. This can result from either exceeding the major (Newton) or minor (Lemke) iterations limit. When MILES is invoked from GAMS, the cumulative Lemke iteration limit can be set with the statement `<model>.iterlim = xx`; The Newton iteration limit is 100 by default, and it can be modified only through the ITLIMT option.

Resource interrupt. Elapsed CPU time exceeds options parameter RESLIM. To increase this limit, either add RESLIM = xxx in the options file or add a GAMS statement `<model>.RESLIM = xxx`.

Singular matrix encountered. Lemke's algorithm has been interrupted due to a singularity arising in the basis factorization, either during a column replacement or during a refactorization. For some reason, a restart is not possible.

Termination on a secondary ray. Lemke's algorithm terminated on a secondary ray. For some reason, a restart is not possible.

Unknown termination status. The termination status flag has not been set, but the code has interrupted. Look in the status file for a previous message. This termination code should not happen often.

5.26 MINOS and QUADMINOS

Bruce A. Murtagh; Graduate School of Management, Macquarie University, Sydney, Australia

Michael A. Saunders, Walter Murray; Department of EESOR, Stanford University, CA

Philip E. Gill; Department of Mathematics, University of California, San Diego, La Jolla, CA

5.26.1 Introduction

This document describes the GAMS interface to MINOS which is a general purpose nonlinear programming solver. For a quad-precision MINOS, see quadMINOS.

GAMS/MINOS is a specially adapted version of the solver that is used for solving linear and nonlinear programming problems in a GAMS environment.

GAMS/MINOS is designed to find solutions that are locally optimal. The nonlinear functions in a problem must be smooth (i.e., their first derivatives must exist). The functions need not be separable. Integer restrictions cannot be imposed directly.

A certain region is defined by the linear constraints in a problem and by the bounds on the variables. If the nonlinear objective and constraint functions are convex within this region, any optimal solution obtained will be a global optimum. Otherwise there may be several local optima, and some of these may not be global. In such cases the chances of finding a global optimum are usually increased by choosing a staring point that is sufficiently close, but there is no general procedure for determining what "close" means, or for verifying that a given local optimum is indeed global.

Linearly constrained models are solved with a very efficient and reliable reduced gradient technique that takes advantage of the sparsity of the model. Models with nonlinear constraints are solved with a method that iteratively solves subproblems with linearized constraints and an augmented Lagrangian objective function. This iterative scheme implies that only the final, optimal solution is sure to be feasible w.r.t. the nonlinear constraints. This is in contrast to the feasible path method used by some other NLP solvers, e.g., CONOPT. MINOS and CONOPT are very complementary to each other as they employ very different algorithms. See MINOS vs CONOPT for a comparison of the two solvers.

GAMS allows you to specify values for many parameters that control GAMS/MINOS, and with careful experimentation you may be able to influence the solution process in a helpful way. All MINOS options available through GAMS/MINOS are summarized at the end of this document.
5.26.2 How to Run a Model with GAMS/MINOS

MINOS is capable of solving many types of models, including LP, NLP, DNLP and QCP. If MINOS is not specified as the default solver for the desired model type (e.g. NLP), then the following statement can be used in your GAMS model to select MINOS:

```gams
option nlp=minos;
```

The option statement should appear before the `solve` statement.

To be complete, we mention that the solver can be also specified on the command line, as in:

```
> gams camcge nlp=minos
```

This will override the global default, but if an algorithm option has been specified inside the model, then that specification takes precedence.

5.26.3 Overview of GAMS/MINOS

GAMS/MINOS is a system designed to solve large-scale optimization problems expressed in the following form:

\[
\begin{align*}
\text{NLP :} & \quad \text{minimize} \quad F(x) + c^T x + d^T y \\
& \quad \text{subject to} \quad f(x) + A_1 y \sim b_1 \\
& \quad \quad \quad A_2 x + A_3 y \sim b_2 \\
& \quad \quad \quad \ell \leq \begin{pmatrix} x \\ y \end{pmatrix} \leq u
\end{align*}
\]

where the vectors \( c, d, b_1, b_2, \ell, u \) and the matrices \( A_1, A_2, A_3 \) are constant, \( F(x) \) is a smooth scalar function, and \( f(x) \) is a vector of smooth functions. The \( \sim \) signs mean that individual constraints may be defined using \( \leq, = \text{ or } \geq \) corresponding to the GAMS constructs \( \ast\text{L}=, \ast\text{E}= \) and \( \ast\text{G}=. \)

The components of \( x \) are called the nonlinear variables, and the components of \( y \) are the linear variables. Similarly, the equations in (2) are called the nonlinear constraints, and the equations in (3) are the linear constraints. Equations (2) and (3) together are called the general constraints.

Let \( m_1 \) and \( n_1 \) denote the number of nonlinear constraints and variables, and let \( m \) and \( n \) denote the total number of (general) constraints and variables. Thus, \( A_3 \) has \( m - m_1 \) rows and \( n - n_1 \) columns. The constraints (4) specify upper and lower bounds on all variables. These are fundamental to many problem formulations and are treated specially by the solution algorithms in GAMS/MINOS. Some of the components of \( \ell \) and \( u \) may be \( -\infty \) or \( +\infty \) respectively, in accordance with the GAMS use of \( -\text{INF} \) and \( +\text{INF} \).

The vectors \( b_1 \) and \( b_2 \) are called the right-hand side, and together are denoted by \( b \).
5.26.3.1 Linear Programming

If the functions $F(x)$ and $f(x)$ are absent, the problem becomes a linear program. Since there is no need to distinguish between linear and nonlinear variables, we use $x$ rather than $y$. GAMS/MINOS converts all general constraints into equalities, and the only remaining inequalities are simple bounds on the variables. Thus, we write linear programs in the form

$$
\text{LP : minimize } c^T x \\
\text{subject to } Ax + Is = 0 \\
\ell \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u
$$

where the elements of $x$ are your own GAMS variables, and $s$ is a set of slack variables: one for each general constraint. For computational reasons, the right-hand side $b$ is incorporated into the bounds on $s$.

In the expression $Ax + Is = 0$ we write the identity matrix explicitly if we are concerned with columns of the associated matrix $(A \ I)$. Otherwise we will use the equivalent notation $Ax + s = 0$.

GAMS/MINOS solves linear programs using a reliable implementation of the primal simplex method \cite{41} , in which the constraints $Ax + Is = 0$ are partitioned into the form

$$
Bx_B + Nx_N = 0,
$$

where the basis matrix is square and nonsingular. The elements of $x_B$ and $x_N$ are called the basic or nonbasic variables respectively. Together they are a permutation of the vector $\begin{pmatrix} x \\ s \end{pmatrix}$.

Normally, each nonbasic variable is equal to one of its bounds, and the basic variables take on whatever values are needed to satisfy the general constraints. (The basic variables may be computed by solving the linear equations $Bx_B = Nx_N$.) It can be shown that if an optimal solution to a linear program exists, then it has this form.

The simplex method reaches such a solution by performing a sequence of iterations, in which one column of $B$ is replaced by one column of $N$ (and vice versa), until no such interchange can be found that will reduce the value of $c^T x$.

As indicated nonbasic variables usually satisfy their upper and lower bounds. If any components of $x_B$ lie significantly outside their bounds, we say that the current point is infeasible. In this case, the simplex method uses a Phase 1 procedure to reduce the sum of infeasibilities to zero. This is similar to the subsequent Phase 2 procedure that optimizes the true objective function $c^T x$.

If the solution procedures are interrupted, some of the nonbasic variables may lie strictly between their bounds $\ell_j < x_j < u_j$. In addition, at a "feasible" or "optimal" solution, some of the basic variables may lie slightly outside their bounds: $\ell_j - \delta < x_j < \ell_j$ or $u_j < x_j < u_j + \delta$ where $\delta$ is a feasibility tolerance (typically $10^{-6}$). In rare cases, even nonbasic variables might lie outside their bounds by as much as $\delta$.

GAMS/MINOS maintains a sparse $LU$ factorization of the basis matrix $B$, using a Markowitz ordering scheme and Bartels-Golub updates, as implemented in the Fortran package LUSOL \cite{82} (see \cite{16} \cite{17} \cite{147} \cite{148} ). The basis factorization is central to the efficient handling of sparse linear and nonlinear constraints.
5.26.3.2 Problems with a Nonlinear Objective

When nonlinearities are confined to the term \( F(x) \) in the objective function, the problem is a linearly constrained nonlinear program. GAMS/MINOS solves such problems using a reduced-gradient algorithm [203] combined with a quasi-Newton algorithm that is described in [139]. In the reduced-gradient method, the constraints \( Ax + Is = 0 \) are partitioned into the form

\[
Bx_B + Sx_S + Nx_N = 0
\]

where \( x_s \) is a set of superbasic variables. At a solution, the basic and superbasic variables will lie somewhere between their bounds (to within the feasibility tolerance \( \delta \)), while nonbasic variables will normally be equal to one of their bounds, as before. Let the number of superbasic variables be \( s \), the number of columns in \( S \). (The context will always distinguish \( s \) from the vector of slack variables.) At a solution, \( s \) will be no more than \( n_1 \), the number of nonlinear variables. In many practical cases we have found that \( s \) remains reasonably small, say 200 or less, even if \( n_1 \) is large.

In the reduced-gradient algorithm, \( x_s \) is regarded as a set of "independent variables" or "free variables" that are allowed to move in any desirable direction, namely one that will improve the value of the objective function (or reduce the sum of infeasibilities). The basic variables can then be adjusted in order to continue satisfying the linear constraints.

If it appears that no improvement can be made with the current definition of \( B, S \) and \( N \), some of the nonbasic variables are selected to be added to \( S \), and the process is repeated with an increased value of \( s \). At all stages, if a basic or superbasic variable encounters one of its bounds, the variable is made nonbasic and the value of \( s \) is reduced by one.

A step of the reduced-gradient method is called a minor iteration. For linear problems, we may interpret the simplex method as being the same as the reduced-gradient method, with the number of superbasic variable oscillating between 0 and 1.

A certain matrix \( Z \) is needed now for descriptive purposes. It takes the form

\[
\begin{pmatrix}
-B^{-1}S \\
I \\
0
\end{pmatrix}
\]

though it is never computed explicitly. Given an \( LU \) factorization of the basis matrix \( B \), it is possible to compute products of the form \( Zq \) and \( Z^Tg \) by solving linear equations involving \( B \) or \( B^T \). This in turn allows optimization to be performed on the superbasic variables, while the basic variables are adjusted to satisfy the general linear constraints.

An important feature of GAMS/MINOS is a stable implementation of a quasi-Newton algorithm for optimizing the superbasic variables. This can achieve superlinear convergence during any sequence of iterations for which the \( B, S, N \) partition remains constant. A search direction \( q \) for the superbasic variables is obtained by solving a system of the form

\[
R^T R q = -Z^T g
\]

where \( g \) is a gradient of \( F(x) \), \( Z^T g \) is the reduced gradient, and \( R \) is a dense upper triangular matrix. GAMS computes the gradient vector \( g \) analytically, using automatic differentiation. The matrix \( R \) is updated in various ways in order to approximate the reduced Hessian according to \( R^T R \approx Z^T H Z \) where \( H \) is the matrix of second derivatives of \( F(x) \) (the Hessian).

Once \( q \) is available, the search direction for all variables is defined by \( p = Zq \). A line search is then performed to find an approximate solution to the one-dimensional (w.r.t. \( \alpha \)) problem

\[
\text{minimize } F(x + \alpha p) \\
\text{subject to } 0 < \alpha < \beta
\]
where $\beta$ is determined by the bounds on the variables. Another important piece in GAMS/MINOS is a step-length procedure used in the linesearch to determine the step-length $\alpha$ (see [80]). The number of nonlinear function evaluations required may be influenced by setting the Line-search tolerance, as discussed in Section Detailed Description of MINOS Options.

As in a linear programming solver, an equation $B^T \pi = gB$ is solved to obtain the dual variables or shadow prices $\pi$ where $gB$ is the gradient of the objective function associated with basic variables. It follows that $gB - B^T \pi = 0$. The analogous quantity for superbasic variables is the reduced-gradient vector $Z^T g = gs - s^T \pi$; this should also be zero at an optimal solution. (In practice its components will be of order $r||\pi||$ where $r$ is the optimality tolerance, typically $10^{-6}$, and $||\pi||$ is a measure of the size of the elements of $\pi$.)

### 5.26.3.3 Problems with Nonlinear Constraints

If any of the constraints are nonlinear, GAMS/MINOS employs a project Lagrangian algorithm, based on a method due to [150], see [140]. This involves a sequence of major iterations, each of which requires the solution of a linearly constrained subproblem. Each subproblem contains linearized versions of the nonlinear constraints, as well as the original linear constraints and bounds.

At the start of the $k$-th major iteration, let $x_k$ be an estimate of the nonlinear variables, and let $\lambda_k$ be an estimate of the Lagrange multipliers (or dual variables) associated with the nonlinear constraints. The constraints are linearized by changing $f(x)$ in equation (2) to its linear approximation:

$$f'(x, x_k) = f(x_k) + J(x_k)(x - x_k)$$

or more briefly

$$f' = f_k + J_k(x - x_k)$$

where $J(x_k)$ is the Jacobian matrix evaluated at $x_k$. (The $i$-th row of the Jacobian is the gradient vector of the $i$-th nonlinear constraint function. As with the objective gradient, GAMS calculates the Jacobian using automatic differentiation).

The subproblem to be solved during the $k$-th major iteration is then

\[
\begin{align*}
\text{minimize} & \quad F(x) + c^T x + d^T y - \lambda_k^T (f - f') + 0.5\rho(f - f')^T (f - f') \\
\text{subject to} & \quad f' + A_1 y \sim b_1 \\
& \quad A_2 x + A_3 y \sim b_2 \\
& \quad \ell \leq \begin{pmatrix} x \\ y \end{pmatrix} \leq u
\end{align*}
\]  

The objective function (5) is called an augmented Lagrangian. The scalar $\rho$ is a penalty parameter, and the term involving $\rho$ is a modified quadratic penalty function.

GAMS/MINOS uses the reduced-gradient algorithm to minimize (5) subject to (6) – (8). As before, slack variables are introduced and $b_1$ and $b_2$ are incorporated into the bounds on the slacks. The linearized constraints take the form

\[
\begin{pmatrix} J_k & A_1 \\ A_2 & A_3 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \begin{pmatrix} s_1 \\ s_2 \end{pmatrix} = \begin{pmatrix} J_k x_k - f_k \\ 0 \end{pmatrix}
\]

This system will be referred to as $Ax + Is = 0$ as in the linear case. The Jacobian $J_k$ is treated as a sparse matrix, the same as the matrices $A_1$, $A_2$, and $A_3$.

In the output from GAMS/MINOS, the term Feasible subproblem indicates that the linearized constraints have been satisfied. In general, the nonlinear constraints are satisfied only in the limit, so that feasibility and optimality occur at essentially the same time. The nonlinear constraint violation is printed every major iteration. Even if it is zero early on (say at the initial point), it may increase and perhaps fluctuate before tending to zero. On "well behaved problems", the constraint violation will decrease quadratically (i.e., very quickly) during the final few major iterations.
5.26.4 Modeling Issues

Formulating nonlinear models requires that the modeler pays attention to some details that play no role when dealing with linear models.

5.26.4.1 Starting Points

The first issue is specifying a starting point. It is advised to specify a good starting point for as many nonlinear variables as possible. The GAMS default of zero is often a very poor choice, making this even more important.

As an (artificial) example consider the problem where we want to find the smallest circle that contains a number of points \((x_i, y_i)\):

\[
\begin{align*}
\text{Example:} & \quad \text{minimize} \quad & r \\
\text{subject to} & \quad (x_i - a)^2 + (y_i - b)^2 \leq r^2, \quad r \geq 0.
\end{align*}
\]

This problem can be modeled in GAMS as follows.

```plaintext
set i 'points' /p1*p10/;
parameters
  x(i) 'x coordinates',
  y(i) 'y coordinates';
* fill with random data
  x(i) = uniform(1,10);
  y(i) = uniform(1,10);
variables
  a 'x coordinate of center of circle'
  b 'y coordinate of center of circle'
  r 'radius';
equations
  e(i) 'points must be inside circle';
e(i).. sqr(x(i)-a) + sqr(y(i)-b) =l= sqr(r);
  r.lo = 0;
model m /all/;
option nlp=minos;
solve m using nlp minimizing r;
```

Without help, MINOS will not be able to find an optimal solution. The problem will be declared infeasible. In this case, providing a good starting point is very easy. If we define

\[
\begin{align*}
x_{\min} &= \min_i x_i, \\
y_{\min} &= \min_i y_i, \\
x_{\max} &= \max_i x_i, \\
y_{\max} &= \max_i y_i,
\end{align*}
\]
then good estimates are

\[ a = \frac{x_{\text{min}} + x_{\text{max}}}{2}, \]
\[ b = \frac{y_{\text{min}} + y_{\text{max}}}{2}, \]
\[ r = \sqrt{(a - x_{\text{min}})^2 + (b - y_{\text{min}})^2}. \]

Thus we include in our model:

```gams
parameters xmin,ymin,xmax,ymax;
xmin = smin(i, x(i));
ymin = smin(i, y(i));
xmax = smax(i, x(i));
ymax = smax(i, y(i));

* set starting point
a.l = (xmin+xmax)/2;
b.l = (ymin+ymax)/2;
r.l = sqrt( sqr(a.l-xmin) + sqr(b.l-ymin) );
```

and now the model solves very easily.

Level values can also be set away from zero implicitly as a result of assigning bounds. When a variable is bounded away from zero, for instance by the statement `Y.LO = 1;`, the implicit projection of variable levels onto their bounds that occurs when a model is solved will initialize Y away from zero.

5.26.4.2 Bounds

Setting appropriate bounds can be very important to steer the algorithm away from uninteresting areas, and to prevent function evaluation errors from happening.

If your model contains a real power of the form \( x^n \) it is important to add a bound \( x > 0.001 \), as real exponentiation is evaluated in GAMS as \( \exp(y \log(x)) \). In some cases one cannot write a bound directly, e.g. if the equation is \( z = x^f(y) \). In that case it is advised to introduce an extra variable and equation:

\[ z = x^\vartheta \]
\[ \vartheta = f(y) \]
\[ \vartheta \geq \varepsilon \]

(Note that the functions `SQR(x)` and `POWER(x,k)` are integer powers and do not require \( x \) to be positive).

If the model produces function evaluation errors adding bounds is preferred to raising the `DOMLIM` limit.

Bounds in GAMS are specified using `X.LO(i)=0.001` and `X.UP(i) = 1000.`

5.26.4.3 Scaling

Although MINOS has some facilities to scale the problem before starting to optimize it, it remains an important task for the modeler to provide a well-scaled model. This is especially the case for nonlinear models. GAMS has special syntax features to specify row and column scales that allow the modeler to keep the equations in a most natural form. For more information consult the GAMS User's Guide.
5.26.4.4 The Objective Function

The first step GAMS/MINOS performs is to try to reconstruct the objective function. In GAMS, optimization models minimize or maximize an objective variable. MINOS however works with an objective function. One way of dealing with this is to add a dummy linear function with just the objective variable. Consider the following GAMS fragment:

```
obj.. z =e= sum(i, sqr(resid(i)));
model m /all/
solve m using nlp minimizing z;
```

This can be cast in form NLP (equations (1) – (4)) by saying minimize \( z \) subject to \( z = \sum res i d_i^2 \) and the other constraints in the model. Although simple, this approach is not always preferable. Especially when all constraints are linear it is important to minimize \( \sum res i d_i^2 \) directly. This can be achieved by a simple reformulation: \( z \) can be substituted out. The substitution mechanism carries out the formulation if all of the following conditions hold:

- the objective variable \( z \) is a free continuous variable (no bounds are defined on \( z \)),
- \( z \) appears linearly in the objective function,
- the objective function is formulated as an equality constraint,
- \( z \) is only present in the objective function and not in other constraints.

For many models it is very important that the nonlinear objective function be used by MINOS. For instance the model [CHEM] from the model library solves in 21 iterations. When we add the bound

```
energy.lo = 0;
```

to the objective variable \texttt{energy} and thus prevent it from being substituted out, MINOS will not be able to find a feasible point for the given starting point.

This reformulation mechanism has been extended for substitutions along the diagonal. For example, the GAMS model

```
Variables x,y,z;
Equations e1,e2;
e1..z =e= y;
e2..y =e= sqr(1+x);
model m /all/;
option nlp=minos;
solve m using nlp minimizing z;
```

will be reformulated as an \textit{unconstrained} optimization problem

\[
\text{minimize } f(x) = (1 + x)^2.
\]

These additional reformulations can be turned off by using the statement \texttt{option reform = 0}; (see Section GAMS Options).
5.26 MINOS and QUADMINOS

5.26.5 GAMS Options

The standard GAMS options (e.g. iterlim, domlim) can be used to control GAMS/MINOS. For more details, see section Controlling a Solver via GAMS Options. We highlight some of the details of this usage below for cases of special interest.

iterlim

Sets the minor iteration limit. MINOS will stop as soon as the number of minor iterations exceeds the iteration limit and report the current solution.

domlim

Sets the domain error limit. Domain errors are evaluation errors in the nonlinear functions. An example of a domain error is trying to evaluate $\sqrt{x}$ for $x < 0$. Other examples include taking logs of negative numbers, and evaluating the real power $x^y$ for $x < \varepsilon$ ($x^y$ is evaluated as $\exp(y \log x)$). When such an error occurs the count of domain errors is incremented: MINOS will stop if this count exceeds the limit. If the limit has not been reached, reasonable estimates for the function (and derivatives, if requested) are returned and MINOS continues. For example, in the case of $\sqrt{x}, x < 0$ a zero is passed back for the function value and a large value for the derivative. In many cases MINOS will be able to recover from these domain errors, especially when they happen at some intermediate point. Nevertheless it is best to add appropriate bounds or linear constraints to ensure that these domain errors don't occur. For example, when an expression $\log(x)$ is present in the model, add a statement like $x.lo = 0.001$.

bratio

Ratio used in basis acceptance test. When a previous solution or solution estimate exists, GAMS automatically passes this solution to MINOS so that it can reconstruct an advanced basis. When too many new (i.e. uninitialized with level and/or marginal values) variables or constraints enter the model, it may be better not to use existing basis information, but to instead crash a new basis. The bratio determines how quickly an existing basis is discarded. A value of 1.0 will discard any basis, while a value of 0.0 will retain any basis.

workfactor

By default, GAMS/MINOS computes an estimate of the amount of workspace needed by MINOS, and passes this workspace on to MINOS for use in solving the model. This estimate is based on the model statistics: number of (nonlinear) equations, number of (nonlinear) variables, number of (nonlinear) nonzeroes, etc. In most cases this is sufficient to solve the model. In some rare cases MINOS may need more memory, and the user can provide this by specifying a value of workfactor greater than 1. The computed memory estimate is multiplied by the workfactor to determine the amount of workspace made available to MINOS for the solve.

workspace

The workspace option is deprecated: use the workfactor option instead. The workspace option specifies the amount of memory, in MB, that MINOS will use.

reform

This option controls the objective reformulation mechanism described in Section The Objective Function. The default value of 100 will cause GAMS/MINOS to try further substitutions along the diagonal after the objective variable has been removed. Any other value will disable this diagonal procedure.
5.26.6 Summary of MINOS Options

The performance of GAMS/MINOS is controlled by a number of parameters or "options." Each option has a default value that should be appropriate for most problems. For special situations it is possible to specify non-standard values for some or all of the options through the MINOS option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

Note that the option file is not case sensitive. Examples for using the option file can be found at the end of this section. The tables below contain summary information about the MINOS options, default values, and links to more detailed explanations.

### 5.26.6.5 Examples of GAMS/MINOS Option File

The following example illustrates the use of certain options that might be helpful for “difficult” models involving nonlinear constraints. Experimentation may be necessary with the values specified, particularly if the sequence of major iterations does not converge using default values.

* These options might be relevant for very nonlinear models.

- Major damping parameter 0.2 * may prevent divergence.
- Minor damping parameter 0.2 * if there are singularities
  * in the nonlinear functions.
- Penalty parameter 10.0 * or 100.0 perhaps—a value
  * higher than the default.
- Scale linear variables * (This is the default.)

Conversely, nonlinearly constrained models that are very nearly linear may optimize more efficiently if some of the cautious defaults are relaxed:

* Suggestions for models with MILDLY nonlinear constraints

- Completion Full
- Penalty parameter 0.0 * or 0.1 perhaps—a value
  * smaller than the default.
  * Scale one of the following
- Scale all variables * if starting point is VERY GOOD.
- Scale linear variables * if they need it.
- Scale No * otherwise.

Most of the options should be left at their default values for any given model. If experimentation is necessary, we recommend changing just one option at a time.

### 5.26.7 Special Notes

#### 5.26.7.1 Modeling Hints

Unfortunately, there is no guarantee that the algorithm just described will converge from an arbitrary starting point. The concerned modeler can influence the likelihood of convergence as follows:
• Specify initial activity levels for the nonlinear variables as carefully as possible (using the GAMS suffix .L).
• Include sensible upper and lower bounds on all variables.
• Specify a Major damping parameter that is lower than the default value, if the problem is suspected of being highly nonlinear.
• Specify a Penalty parameter \( \rho \) that is higher than the default value, again if the problem is highly nonlinear.

In rare cases it may be safe to request the values \( \lambda_k = 0 \) and \( \rho = 0 \) for all subproblems, by specifying Lagrangian=No. However, convergence is much more likely with the default setting, Lagrangian=Yes. The initial estimate of the Lagrange multipliers is then \( \lambda_0 = 0 \), but for later subproblems \( \lambda_k \) is taken to be the Lagrange multipliers associated with the (linearized) nonlinear constraints at the end of the previous major iteration.

For the first subproblem, the default value for the penalty parameter is \( \rho = 100.0/m_1 \) where \( m_1 \) is the number of nonlinear constraints. For later subproblems, \( \rho \) is reduced in stages when it appears that the sequence \( \{x_k, \lambda_k\} \) is converging. In many cases it is safe to specify \( \lambda = 0 \), particularly if the problem is only mildly nonlinear. This may improve the overall efficiency.

5.26.7.2 Storage

GAMS/MINOS uses one large array of memory for most of its workspace. The implementation places no fixed limit on the size of a problem or on its shape (many constraints and relatively few variables, or vice versa). In general, the limiting factor will be the amount of physical memory available on a particular machine, and the amount of computation time one is willing to spend.

Some detailed knowledge of a particular model will usually indicate whether the solution procedure is likely to be efficient. An important quantity is \( m \), the total number of general constraints in (2) and (3). The amount of workspace required by GAMS/MINOS is roughly \( 100m \) doubles, or \( 800m \) bytes for workspace. A further \( 300K \) bytes, approximately, are needed for the program itself, along with buffer space for several files. Very roughly, then, a model with \( m \) general constraints requires about \( (m + 300) \) K bytes of memory.

Another important quantity is \( n \), the total number of variables in \( x \) and \( y \). The above comments assume that \( n \) is not much larger than \( m \), the number of constraints. A typical ratio for \( n/m \) is 2 or 3.

If there are many nonlinear variables (i.e., if \( n_1 \) is large), much depends on whether the objective function or the constraints are highly nonlinear or not. The degree of nonlinearity affects \( s \), the number of superbasic variables. Recall that \( s \) is zero for purely linear problems. We know that \( s \) need never be larger than \( n_1 + 1 \). In practice, \( s \) is often very much less than this upper limit.

In the quasi-Newton algorithm, the dense triangular matrix \( R \) has dimension \( s \) and requires about \( s^2/2 \) words of storage. If it seems likely that \( s \) will be very large, some aggregation or reformulation of the problem should be considered.

5.26.8 The GAMS/MINOS Log File

MINOS writes different logs for LPs, NLPs with linear constraints, and NLPs with non-linear constraints. In this section, a sample log file is shown for each case, and the messages that appear are explained.
MINOS uses a standard two-phase simplex method for LPs. In the first phase, the sum of the infeasibilities at each iteration is minimized. Once feasibility is attained, MINOS switches to phase 2 where it minimizes (or maximizes) the original objective function. The different objective functions are called the phase 1 and phase 2 objectives. Notice that the marginals in phase 1 are with respect to the phase 1 objective. This means that if MINOS interrupts in phase 1, the marginals are "wrong" in the sense that they do not reflect the original objective.

The log for the problem TURKPOW is as follows:

*** Status: Normal completion

The first line that is written by MINOS is the version string: GAMS/MINOS Aug 18, 2010 23.5.2 WIN 19143.19383 VS8 x86/MS Windows This line identifies which version of the MINOS libraries and links you are using, and is only to be deciphered by GAMS support personnel.

After some advertisement text we see the amount of work space (i.e. memory) that is allocated: 1.60 Mb. When MINOS is loaded, the amount of memory needed is first estimated. This estimate is based on
statistics like the number of rows, columns and non-zeros. This amount of memory is then allocated and the problem loaded into MINOS.

The columns have the following meaning:

\textbf{Itn}

Iteration number.

\textbf{ninf}

Number of infeasibilities. If nonzero the current iterate is still infeasible.

\textbf{sinf}

The sum of the infeasibilities. This number is minimized during Phase I. Once the model is feasible this number is zero.

\textbf{objective}

The value of the objective function: \( z = \sum c_i x_i \). In phase II this number is maximized or minimized. In phase I it may move in the wrong direction.

The final line indicates the exit status of MINOS.

\subsection*{5.26.8.2 Linearly Constrained NLP's}

The log is basically the same as for linear models. The only difference is that not only matrix rows and columns need to be loaded, but also instructions for evaluating functions and gradients.

The log for the problem \textbf{WEAPONS} is as follows:

--- Restarting execution
Two sets of iterations, major and minor, are now reported. A description of the various columns present in this log file follows:

**Major**

A major iteration involves linearizing the nonlinear constraints and performing a number of minor iterations on the resulting subproblem. The objective for the subproblem is an augmented Lagrangian, not the true objective function.

**minor**

The number of minor iterations performed on the linearized subproblem. If it is a simple number like 90, then the subproblem was solved to optimality. Here, 2T means that the subproblem was terminated. In general the T is not something to worry about. Other possible flags are I and U, which mean that the subproblem was infeasible or unbounded. MINOS may have difficulty if these keep occurring.

**step**

The step size taken towards the solution suggested by the last major iteration. Ideally this should be 1.0, especially near an optimum. If the subproblem solutions are widely different, MINOS may reduce the step size under control of the Major Damping parameter.

**objective**

The objective function for the original nonlinear program.

**Feasible**

Primal infeasibility, indicating the maximum non-linear constraint violation.

**Optimal**

The maximum dual infeasibility, measured as the maximum departure from complementarity. If we call $d_j$ the reduced cost of variable $x_j$, then the dual infeasibility of $x_j$ is $d_j \times \min\{x_j - \ell_j, 1\}$ or $-d_j \times \min\{u_j - x_j, 1\}$ depending on the sign of $d_j$.

**nsb**

Number of superbasics. If the model is feasible this number cannot exceed the superbasic limit, which may need to be reset to a larger number if the numbers in this column become larger.

**ncon**

The number of times MINOS has evaluated the nonlinear constraints and their derivatives.

**penalty**

The current value of the penalty parameter in the augmented Lagrangian (the objective for the subproblems). If the major iterations appear to be converging, MINOS will decrease the penalty parameter. If there appears to be difficulty, such as unbounded subproblems, the penalty parameter will be increased.

**BSswp**

Number of basis swaps: the number of $(B \rightarrow S)$ (i.e. basic vs. superbasic) changes.

Note: The CAMCGE model (like many CGE models or other almost square systems) can better be solved with the MINOS option Start Assigned Nonlinesars Basic.
5.26.9 Detailed Description of MINOS Options

The following is an alphabetical list of the keywords that may appear in the GAMS/MINOS options file, and a description of their effect. Options not specified will take the default values shown.

**check frequency (integer):** Controls frequency of linear constraint satisfaction test

Every $i$th iteration after the most recent basis factorization, a numerical test is made to see if the current solution $x$ satisfies the general linear constraints (including linearized nonlinear constraints, if any). The constraints are of the form $Ax+s=0$ where $s$ is the set of slack variables. To perform the numerical test, the residual vector $r = Ax+s$ is computed. If the largest component of $r$ is judged to be too large, the current basis is refactorized and the basic variables are recomputed to satisfy the general constraints more accurately.

Range: $\{1, ..., \infty\}$

Default: 60

**completion (string):** Completion level for subproblems (full/partial)

When there are nonlinear constraints, this determines whether subproblems should be solved to moderate accuracy (partial completion) or to full accuracy (full completion). GAMS/MINOS implements the option by using two sets of convergence tolerances for the subproblems. Use of partial completion may reduce the work during early major iterations, unless the Minor iterations limit is active. The optimal set of basic and superbasic variables will probably be determined for any given subproblem, but the reduced gradient may be larger than it would have been with full completion. An automatic switch to full completion occurs when it appears that the sequence of major iterations is converging. The switch is made when the nonlinear constraint error is reduced below $100 \times $ (Row tolerance), the relative change in $\Lambda_k$ is 0.1 or less, and the previous subproblem was solved to optimality. Full completion tends to give better Lagrange-multiplier estimates. It may lead to fewer major iterations, but may result in more minor iterations.

Default: FULL

<table>
<thead>
<tr>

<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FULL</td>
<td>Solve subproblems to full accuracy</td>
</tr>
<tr>
<td>PARTIAL</td>
<td>Solve subproblems to moderate accuracy</td>
</tr>
</tbody>
</table>

**crash option (integer):** Controls the basis crash algorithm

If a restart is not being performed, an initial basis will be selected from certain columns of the constraint matrix ($A$ $I$). The value of the parameter $i$ determines which columns of $A$ are eligible. Columns of $I$ are used to fill gaps where necessary. If $i > 0$, three passes are made through the relevant columns of $A$, searching for a basis matrix that is essentially triangular. A column is assigned to pivot on a particular row if the column contains a suitably large element in a row that has not yet been assigned. (The pivot elements ultimately form the diagonals of the triangular basis). Pass 1 selects pivots from free columns (corresponding to variables with no upper and lower bounds). Pass 2 requires pivots to be in rows associated with equality (=E=) constraints. Pass 3 allows the pivots to be in inequality rows. For remaining (unassigned) rows, the associated slack variables are inserted to complete the basis.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial basis will be a slack basis</td>
</tr>
</tbody>
</table>
### crash tolerance (real): Allow crash procedure to ignore small elements in eligible columns

The "Crash tolerance r" allows the starting procedure CRASH to ignore certain small nonzeros in each column of $A$. If $a_{max}$ is the largest element in column $j$, other nonzeros $a_{ij}$ in the column are ignored if $|a_{ij}| < a_{max} \times r$. To be meaningful, the parameter $r$ should be in the range $0 <= r < 1$. When $r > 0.0$ the basis obtained by CRASH may not be strictly triangular, but it is likely to be nonsingular and almost triangular. The intention is to obtain a starting basis containing more columns of $A$ and fewer (arbitrary) slacks. A feasible solution may be reached sooner on some problems. For example, suppose the first $m$ columns of $A$ are the matrix shown under LU factor tolerance; i.e., a tridiagonal matrix with entries -1, 4, -1. To help CRASH choose all $m$ columns for the initial basis, we could specify Crash tolerance $r$ for some value of $r > 0.25$.

**Range:** [0, 1.0]

**Default:** 0.1

### debug level (integer): Controls amount of debug information written

This causes various amounts of information to be output. Most debug levels will not be helpful to GAMS users, but they are listed here for completeness. Note that you will need to use the GAMS statement \texttt{OPTION SYSOUT=on;} to echo the MINOS listing to the GAMS listing file.

- **debug level 0**
  No debug output.
- **debug level 2** (or more)
  Output from \texttt{M5SETX} showing the maximum residual after a row check.
- **debug level 40**
  Output from \texttt{LU8RPC} (which updates the LU factors of the basis matrix), showing the position of the last nonzero in the transformed incoming column.
- **debug level 50**
  Output from \texttt{LU1MAR} (which updates the LU factors each refactorization), showing each pivot row and column and the dimensions of the dense matrix involved in the associated elimination.
- **debug level 100**
  Output from \texttt{M2BFAC} and \texttt{M5LOG} listing the basic and superbasic variables and their values at every iteration.

**Default:** 0

### expand frequency (integer): Setting for anti-cycling mechanism

This option is part of an anti-cycling procedure designed to guarantee progress even on highly degenerate problems. For linear models, the strategy is to force a positive step at every iteration, at the expense of violating the bounds on the variables by a small amount. Suppose the specified feasibility tolerance is $\delta$ and the expand frequency is $k$. Over a period of $k$ iterations, the tolerance actually used by GAMS/MINOS increases from $0.5 \times \delta$ to $\delta$ (in steps $0.5 \times \delta / k$). For nonlinear models, the same procedure is used for iterations in which there is only one superbasic variable. (Cycling can occur only when the current solution is
at a vertex of the feasible region.) Thus, zero steps are allowed if there is more than one superbasic variable, but otherwise positive steps are enforced. At least every $k$ iterations, a resetting procedure eliminates any infeasible nonbasic variables. Increasing $k$ helps to reduce the number of these slightly infeasible nonbasic variables. However, it also diminishes the freedom to choose a large pivot element (see Pivot tolerance).

Range: \{1, ..., \infty\}
Default: 10000

**factorization frequency** (integer): Number of iterations between basis factorizations

At most $i$ basis updates will occur between factorizations of the basis matrix. With linear programs, basis updates usually occur at every iteration. The default $i$ is reasonable for typical problems. Higher values up to $i = 200$ (say) may be more efficient on problems that are extremely sparse and well scaled. When the objective function is nonlinear, fewer basis updates will occur as an optimum is approached. The number of iterations between basis factorizations will therefore increase. During these iterations a test is made regularly (according to the Check frequency) to ensure that the general constraints are satisfied. If necessary the basis will be re-factorized before the limit of $i$ updates is reached. When the constraints are nonlinear, the Minor iterations limit will probably preempt $i$.

Range: \{1, ..., \infty\}
Default: 100

**feasibility tolerance** (real): Feasibility tolerance for linear constraints

When the constraints are linear, a feasible solution is one in which all variables, including slacks, satisfy their upper and lower bounds to within the absolute tolerance $r$. (Since slacks are included, this means that the general linear constraints are also satisfied within $r$.) GAMS/MINOS attempts to find a feasible solution before optimizing the objective function. If the sum of infeasibilities cannot be reduced to zero, the problem is declared infeasible. Let $SINF$ be the corresponding sum of infeasibilities. If $SINF$ is quite small, it may be appropriate to raise $r$ by a factor of 10 or 100. Otherwise, some error in the data should be suspected. If $SINF$ is not small, there may be other points that have a significantly smaller sum of infeasibilities. GAMS/MINOS does not attempt to find a solution that minimizes the sum. If Scale option = 1 or 2, feasibility is defined in terms of the scaled problem (since it is then more likely to be meaningful). A nonlinear objective function $F(x)$ will be evaluated only at feasible points. If there are regions where $F(x)$ is undefined, every attempt should be made to eliminate these regions from the problem. For example, for a function $F(x) = \sqrt{x_1} + \log(x_2)$, it should be essential to place lower bounds on both variables. If Feasibility tolerance = $10^{-6}$, the bounds $x_1 > 10^{-5}$ and $x_2 > 10^{-4}$ might be appropriate. (The log singularity is more serious; in general, keep variables as far away from singularities as possible.) If the constraints are nonlinear, the above comments apply to each major iteration. A feasible solution satisfies the current linearization of the constraints to within the tolerance $r$. The associated subproblem is said to be feasible. As for the objective function, bounds should be used to keep $x$ more than $r$ away from singularities in the constraint functions $f(x)$. At the start of major iteration $k$, the constraint functions $f(x_k)$ are evaluated at a certain point $x_k$. This point always satisfies the relevant bounds ($l < x_k < u$), but may not satisfy the general linear constraints. During the associated minor iterations, $F(x)$ and $f(x)$ will be evaluated only at points $x$ that satisfy the bound and the general linear constraints (as well as the linearized nonlinear constraints). If a subproblem is infeasible, the bounds on the linearized constraints are relaxed temporarily, in several stages. Feasibility with respect to the nonlinear constraints themselves is measured against the Row tolerance (not against $r$). The relevant test is made at the start of a major iteration.

Default: $1.0e-6$
**hessian dimension (integer):** Size of Hessian matrix

This specifies that an \( r \times r \) triangular matrix \( R \) is to be available for use by the quasi-Newton algorithm. The matrix \( R \) approximates the reduced Hessian in that \( R^T R \) approximates \( Z^T H Z \). Suppose there are \( s \) superbasic variables at a particular iteration. Whenever possible, \( r \) should be greater than \( s \). If \( r > s \), the first \( s \) columns of \( R \) will be used to approximate the reduced Hessian in the normal manner. If there are no further changes to the set of superbasic variables, the rate of convergence will ultimately be superlinear. If \( r < s \), a matrix of the form

\[
R = \text{diag}(R_r, D)
\]

will be used to approximate the reduced Hessian, where \( R_r \) is an \( r \) \( \times \) \( r \) upper triangular matrix and \( D \) is a diagonal matrix of order \( s - r \). The rate of convergence will no longer be superlinear (and may be arbitrarily slow). The storage required is of the order \( \text{sqrt}(r)/2 \), i.e., quadratic in \( r \). In general, \( r \) should be a slight over-estimate of the final number of superbasic variables, whenever storage permits. It need never be larger than \( n_1 + 1 \), where \( n_1 \) is the number of nonlinear variables. For many problems it can be much smaller than \( n_1 \). If Superbasics limit \( s \) is specified, the default value of \( r \) is the same number, \( s \) (and conversely). This is a safeguard to ensure super-linear convergence wherever possible. If neither \( r \) nor \( s \) is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: \( \{1, \ldots, \infty\} \)

Default: 1

**iterations limit (integer):** Minor iteration limit

The maximum number of minor iterations allowed (i.e., iterations of the simplex method or the reduced-gradient method). This option, if set, overrides the GAMS ITERLIM specification. If \( i = 0 \), no minor iterations are performed, but the starting point is tested for both feasibility and optimality.

Default: GAMS iterlim

**lagrangian (string):** Determines form of objection function in the linearized subproblems

This determines the form of the objective function used for the linearized subproblems. The default value yes is highly recommended. The Penalty parameter value is then also relevant. If No is specified, the nonlinear constraint functions will be evaluated only twice per major iteration. Hence this option may be useful if the nonlinear constraints are very expensive to evaluate. However, in general there is a great risk that convergence may not occur.

Default: YES

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>Nondefault value (not recommended)</td>
</tr>
<tr>
<td>YES</td>
<td>Default value (recommended)</td>
</tr>
</tbody>
</table>

**linesearch tolerance (real):** Controls accuracy of steplength selected

For nonlinear problems, this controls the accuracy with which a steplength \( \alpha \) is located in the one-dimensional problem

\[
\begin{align*}
\text{minimize} & \quad F(x + \alpha p) \\
\text{subject to} & \quad 0 < \alpha \leq \beta
\end{align*}
\]
A linesearch occurs on most minor iterations for which $x$ is feasible. (If the constraints are nonlinear, the function being minimized is the augmented Lagrangian.) $r$ must be a real value in the range $0.0 < r < 1.0$. The default value $r = 0.1$ requests a moderately accurate search. It should be satisfactory in most cases. If the nonlinear functions are cheap to evaluate, a more accurate search may be appropriate: try $r = 0.01$ or $r = 0.001$. The number of iterations should decrease, and this will reduce total run time if there are many linear or nonlinear constraints. If the nonlinear function are expensive to evaluate, a less accurate search may be appropriate; try $r = 0.5$ or perhaps $r = 0.9$. (The number of iterations will probably increase but the total number of function evaluations may decrease enough to compensate.)

Range: $[0, 1.0]$

Default: 0.1

**log frequency (integer):** Controls iteration logging to listing file

In general, one line of the iteration log is printed every $i$th minor iteration. A heading labels the printed items, which include the current iteration number, the number and sum of feasibilities (if any), the subproblem objective value (if feasible), and the number of evaluations of the nonlinear functions. A value such as $i = 10, 100$ or larger is suggested for those interested only in the final solution. Log frequency 0 may be used as shorthand for Log frequency 99999. If Print level > 0, the default value of $i$ is 1. If Print level = 0, the default value of $i$ is 100. If Print level = 0 and the constraints are nonlinear, the minor iteration log is not printed (and the Log frequency is ignored). Instead, one line is printed at the beginning of each major iteration.

Range: \{1, ..., \infty\}

Default: 100

**LU complete pivoting (no value):** LUSOL pivoting strategy

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The rook and complete pivoting options are more expensive than partial pivoting but are more stable and better at revealing rank, as long as the LU factor tolerance is not too large (say < 2.0).

**LU density tolerance (real):** When to use dense factorization

The density tolerance is used during LUSOL's basis factorization $B=LU$. Columns of $L$ and rows of $U$ are formed one at a time, and the remaining rows and columns of the basis are altered appropriately. At any stage, if the density of the remaining matrix exceeds this tolerance, the Markowitz strategy for choosing pivots is terminated and the remaining matrix is factored by a dense $LU$ procedure. Raising the tolerance towards 1.0 may give slightly sparser factors, with a slight increase in factorization time.

Range: $[0, 1.0]$

Default: 0.5

**LU factor tolerance (real):** Trade-off between stability and sparsity in basis factorization

This tolerance affects the stability and sparsity of the basis factorization $B = LU$ during factorization. The value $r$ specified must satisfy $r >= 1.0$.

- The default value $r = 100.0$ usually strikes a good compromise between stability and sparsity.
• For large and relatively dense problems, a larger value may give a useful improvement in sparsity without impairing stability to a serious degree.

• For certain very regular structures (e.g., band matrices) it may be necessary to set \( r \) to a value smaller than the default in order to achieve stability.

Range: \([1.0, \infty]\)

Default: 100.0

**LU partial pivoting (no value):** LUSOL pivoting strategy

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say < 2.0).

**LU rook pivoting (no value):** LUSOL pivoting strategy

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say < 2.0).

**LU singularity tolerance (real):** Protection against ill-conditioned basis matrices

When the basis is refactorized, the diagonal elements of \( U \) are tested as follows: if \(|U_{jj}| < r \) or \(|U_{pj}| < r \cdot \max_i |U_{ii}|\), the \( j \)th column of the basis is replaced by the corresponding slack variable. (This is most likely to occur after a restart, or at the start of a major iteration.) In some cases, the Jacobian matrix may converge to values that make the basis very ill-conditioned, causing the optimization to progress very slowly (if at all). Setting \( r = 1.0 \times 10^{-4} \), say, may help cause a judicious change of basis.

Default: 1.0e-11

**LU update tolerance (real):** Trade-off between stability and sparsity in basis updating

This tolerance affects the stability and sparsity of the basis factorization \( B = LU \) during updates. The value \( r \) specified must satisfy \( r \geq 1.0 \).

• The default value \( r = 10.0 \) usually strikes a good compromise between stability and sparsity.

• For large and relatively dense problems, \( r = 25.0 \) (say) may give a useful improvement in sparsity without impairing stability to a serious degree.

• For certain very regular structures (e.g., band matrices) it may be necessary to set \( r \) to a value smaller than the default in order to achieve stability.

Range: \([1.0, \infty]\)

Default: 10.0

**major damping parameter (real):** Prevents large relative changes between subproblem solutions
The parameter may assist convergence on problems that have highly nonlinear constraints. It is intended to prevent large relative changes between subproblem solutions \((x_k, \lambda_k)\) and \((x_{k+1}, \lambda_{k+1})\). For example, the default value 2.0 prevents the relative change in either \(x_k\) or \(\lambda_k\) from exceeding 200 percent. It will not be active on well behaved problems. The parameter is used to interpolate between the solutions at the beginning and end of each major iteration. Thus \(x_{k+1}\) and \(\lambda_{k+1}\) are changed to \(x_k + \sigma \cdot (x_{k+1} - x_k)\) and \(\lambda_k + \sigma \cdot (\lambda_{k+1} - \lambda_k)\) for some step-length \(\sigma < 1\). In the case of nonlinear equations (where the number of constraints is the same as the number of variables) this gives a damped Newton method. This is a very crude control. If the sequence of major iterations does not appear to be converging, one should first re-run the problem with a higher Penalty parameter (say 10 or 100 times the default \(\rho\)). (Skip this re-run in the case of nonlinear equations: there are no degrees of freedom and the value of \(\rho\) is irrelevant.) If the subproblem solutions continue to change violently, try reducing \(\rho\) to 0.2 or 0.1 (say). For implementation reasons, the shortened step to \(\sigma\) applies to the nonlinear variables \(x\), but not to the linear variables \(y\) or the slack variables \(s\). This may reduce the efficiency of the control.

Default: 2.0

**major iterations (integer):** Max number of major iterations

The maximum number of major iterations allowed. It is intended to guard against an excessive number of linearizations of the nonlinear constraints, since in some cases the sequence of major iterations may not converge. The progress of the major iterations can be best monitored using Print level 0 (the default).

Default: 50

**minor damping parameter (real):** Limit change in \(x\) during linesearch

This parameter limits the change in \(x\) during a linesearch. It applies to all nonlinear problems, once a feasible solution or feasible subproblem has been found. A linesearch of the form

\[
\text{minimize}_\alpha F(x + \alpha \cdot p)
\]

is performed over the range \(0 < \alpha <= \beta\), where \(\beta\) is the step to the nearest upper or lower bound on \(x\). Normally, the first step length tried is \(\alpha_1 = \min(1, \beta)\). In some cases, such as \(F(x) = ae^{bx}\) or \(F(x) = ax^b\), even a moderate change in the components of \(x\) can lead to floating-point overflow. The parameter \(\rho\) is therefore used to define a limit

\[
\beta_2 = \rho (1 + ||x||/||p||)
\]

and the first evaluation of \(F(x)\) is at the potentially smaller steplength \(\alpha_1 = \min(1, \beta, \beta_2)\). Wherever possible, upper and lower bounds on \(x\) should be used to prevent evaluation of nonlinear functions at meaningless points. The Minor damping parameter provides an additional safeguard. The default value \(\rho = 2.0\) should not affect progress on well behaved problems, but setting \(\rho = 0.1\) or 0.01 may be helpful when rapidly varying functions are present. A good starting point may be required. An important application is to the class of nonlinear least squares problems. In cases where several local optima exist, specifying a small value for \(\rho\) may help locate an optimum near the starting point.

Default: 2.0

**minor iterations (integer):** Max number of minor iterations between linearizations of nonlinear constraints
The maximum number of feasible minor iterations allowed between successive linearizations of the nonlinear constraints. A moderate value (e.g., $20 \leq i \leq 50$) prevents excessive efforts being expended on early major iterations, but allows later subproblems to be solved to completion. The limit applies to both infeasible and feasible iterations. In some cases, a large number of iterations (say $K$) might be required to obtain a feasible subproblem. If good starting values are supplied for variables appearing nonlinearly in the constraints, it may be sensible to specify a limit $> K$, to allow the first major iteration to terminate at a feasible (and perhaps optimal) subproblem solution. If a good initial subproblem is arbitrarily interrupted by a small limit, the subsequent linearization may be less favorable than the first. In general it is unsafe to specify a value as small as $i = 1$ or $2$. Even when an optimal solution has been reached, a few minor iterations may be needed for the corresponding subproblem to be recognized as optimal. The *Iteration limit* provides an independent limit on the total minor iterations (across all subproblems). If the constraints are linear, only the *Iteration limit* applies: the minor iterations value is ignored.

Default: 40

**multiple price (integer):** Multiple pricing

Pricing refers to a scan of the current non-basic variables to determine which, if any, are eligible to become (super)basic. The multiple pricing parameter $k$ controls the number of entering variables to choose: the $k$ best non-basic variables are selected for admission to the set of (super)basic variables. The default $k = 1$ is best for linear programs, since an optimal solution will have zero superbasic variables. **Warning:** If $k > 1$, GAMS/MINOS will use the reduced-gradient method rather than the simplex method, even on purely linear problems. The subsequent iterations do not correspond to the efficient minor iterations carried out by commercial linear programming systems using multiple pricing. (In the latter systems, the classical simplex method is applied to a tableau involving $k$ dense columns of dimension $m$, and $k$ is therefore limited for storage reasons typically to the range $2 \leq k \leq 7$.) GAMS/MINOS varies all superbasic variables simultaneously. For linear problems its storage requirements are essentially independent of $k$. Larger values of $k$ are therefore practical, but in general the iterations and time required when $k > 1$ are greater than when the simplex method is used ($k = 1$). On large nonlinear problems it may be important to set $k > 1$ if the starting point does not contain many superbasic variables. For example, if a problem has 3000 variables and 500 of them are nonlinear, the optimal solution may well have 200 variables superbasic. If the problem is solved in several runs, it may be beneficial to use $k = 10$ (say) for early runs, until it seems that the number of superbasics has leveled off. If *Multiple price k* is specified, it is also necessary to specify *Superbasic limit s* for some $s > k$.

Range: $\{1, \ldots, \infty\}$

Default: 1

**optimality tolerance (real):** Reduced gradient optimality check

This is used to judge the size of the reduced gradients $d_j = g_j - p^T a_j$, where $g_j$ is the gradient of the objective function corresponding to the $j^{th}$ variable, $a_j$ is the associated column of the constraint matrix (or Jacobian), and $p$ is the set of dual variables. By construction, the reduced gradients for basic variables are always zero. Optimality will be declared if the reduced gradients for nonbasic variables at their lower or upper bounds satisfy $d_j / ||p|| > = -r$ or $d_j / ||p|| < = r$ respectively, and if $d_j / ||p|| < = r$ for superbasic variables. The $||p||$ is a measure of the size of the dual variables. It is included to make the tests independent of a scale factor on the objective function. The quantity actually used is defined by

$$
\sigma = \sum(i, \text{abs}(pi(i))), \quad ||p|| = \max\{\sigma/\sqrt{m}, 1\}
$$

so that only large scale factors are compensated for. As the objective scale decreases, the optimality test tends to become an absolute (instead of a relative) test.

Default: $1.0e^{-6}$
**partial price (integer):** Number of segments in partial pricing strategy

This parameter is recommended for large problems that have significantly more variables than constraints. It reduces the work required for each pricing operation (when a nonbasic variable is selected to become basic or superbasic). When \( i = 1 \), all columns of the constraints matrix \((A I)\) are searched. Otherwise, \( A_j \) and \( I \) are partitioned to give \( i \) roughly equal segments \( A_j, I_j \) (\( j = 1 \) to \( i \)). If the previous search was successful on \( A_{j-1}, I_{j-1} \), the next search begins on the segments \( A_j, I_j \). (All subscripts here are modulo \( i \).) If a reduced gradient is found that is larger than some dynamic tolerance, the variable with the largest such reduced gradient (of appropriate sign) is selected to become superbasic. (Several may be selected if multiple pricing has been specified.) If nothing is found, the search continues on the next segments \( A_{j+1}, I_{j+1} \) and so on. **Partial price t (or t/2 or t/3)** may be appropriate for time-stage models having \( t \) time periods.

Range: \( \{1, ..., \infty\} \)

Default: 10

**penalty parameter (real):** Used in modified augmented Lagrangian

This specifies the value of \( \rho \) in the modified augmented Lagrangian. It is used only when \( \text{Lagrangian} = \text{yes} \) (the default setting). For early runs on a problem with unknown characteristics, the default value should be acceptable. If the problem is known to be highly nonlinear, specify a large value, such as 10 times the default. In general, a positive value of \( \rho \) may be necessary to ensure convergence, even for convex programs. On the other hand, if \( \rho \) is too large, the rate of convergence may be unnecessarily slow. If the functions are not highly nonlinear or a good starting point is known, it will often be safe to specify **penalty parameter 0.0**. When solving a sequence of related problems, initially, use a moderate value for \( \rho \) (such as the default) and a reasonably low **Iterations** and/or **major iterations limit**. If successive major iterations appear to be terminating with radically different solutions, the **penalty parameter** should be increased. (See also the **Major damping parameter**.) If there appears to be little progress between major iterations, it may help to reduce the **penalty parameter**.

Default: automatic

**print level (integer):** Controls amount of information printed during optimization

This varies the amount of information that will be output during optimization. **Print level 0** sets the default log and summary frequencies to 100. It is then easy to monitor the progress of the run. **Print level 1** (or more) sets the default log and summary frequencies to 1, giving a line of output for every minor iteration. **Print level 1** also produces basis statistics, i.e., information relating to LU factors of the basis matrix whenever the basis is re-factorized. For problems with nonlinear constraints, certain quantities are printed at the start of each major iteration. The option value is best thought of as a binary number of the form

\[ \text{Print level} \ JFLXB \]

where each letter stands for a digit that is either 0 or 1. The quantities referred to are:

- **B** Basis statistics, as mentioned above
- **X** \( x_k \), the nonlinear variables involved in the objective function or the constraints.
- **L** \( \lambda_k \), the Lagrange-multiplier estimates for the nonlinear constraints. (Suppressed if \( \text{Lagrangian}=\text{No} \), since then \( \lambda_k = 0 \).)
- **F** \( f(x_k) \), the values of the nonlinear constraint functions.
- **J** \( J(x_k) \), the Jacobian matrix.
To obtain output of any item, set the corresponding digit to 1, otherwise to 0. For example, *Print level 10* sets \( X = 1 \) and the other digits equal to zero; the nonlinear variables will be printed each major iteration. If \( J = 1 \), the Jacobian matrix will be output column-wise at the start of each major iteration. Column \( j \) will be preceded by the value of the corresponding variable \( x_j \) and a key to indicate whether the variable is basic, superbasic or nonbasic. (Hence if \( J = 1 \), there is no reason to specify \( X = 1 \) unless the objective contains more nonlinear variables than the Jacobian.) A typical line of output is

\[
3 \ 1.250000D+01 \ BS \ 1 \ 1.00000D+00 \ 4 \ 2.00000D+00
\]

which would mean that \( x_3 \) is basic at value 12.5, and the third column of the Jacobian has elements of 1.0 and 2.0 in rows 1 and 4. (Note: the GAMS/MINOS row numbers are usually different from the GAMS row numbers; see the Solution option.)

Default: 0

**radius of convergence** *(real)*: controls final reduction of penalty parameter

This determines when the penalty parameter \( \rho \) will be reduced, assuming \( \rho \) was initially positive. Both the nonlinear constraint violation (see *ROWERR* below) and the relative change in consecutive Lagrange multiplier estimates must be less than \( r \) at the start of a major iteration before \( \rho \) is reduced or set to zero. A few major iterations later, full completion will be requested if not already set, and the remaining sequence of major iterations should converge quadratically to an optimum.

Default: 0.01

**row tolerance** *(real)*: Accuracy requirement for nonlinear rows

This specifies how accurately the nonlinear constraints should be satisfied at a solution. The default value is usually small enough, since model data is often specified to about this accuracy. Let \( \text{ROWERR} \) be the maximum component of the residual vector \( f(x) + A_1 y - b_1 \), normalized by the size of the solution. Thus

\[
\text{ROWERR} = \| f(x) + A_1 y - b_1 \|_{\infty} / (1 + XNORM)
\]

where \( XNORM \) is a measure of the size of the current solution \((x, y)\). The solution is considered to be feasible if \( \text{ROWERR} \leq r \). If the problem functions involve data that is known to be of low accuracy, a larger Row tolerance may be appropriate.

Default: 1.0e-6

**scale all variables** *(no value)*: Synonym to scale option 2

**scale linear variables** *(no value)*: Synonym to scale option 1

**scale no** *(no value)*: Synonym to scale option 0

**scale nonlinear variables** *(no value)*: Synonym to scale option 2

**scale option** *(integer)*: Scaling

*Scale Yes* sets the default. (Caution: If all variables are nonlinear, *Scale Yes* unexpectedly does nothing, because there are no linear variables to scale). *Scale No* suppresses scaling (equivalent to Scale Option 0). If nonlinear constraints are present, Scale option 1 or 0 should generally be tried first. Scale option 2 gives scales that depend on the initial Jacobian, and should therefore be used only if (a) a good starting point is provided, and (b) the problem is not highly nonlinear.

Default: 1
### Scale Options

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | No scaling  
If storage is at a premium, this option should be used. |
| 1     | Scale linear variables  
Linear constraints and variables are scaled by an iterative procedure that attempts to make the matrix coefficients as close as possible to 1.0 (see [5]). This will sometimes improve the performance of the solution procedures. Scale linear variables is an equivalent option. |
| 2     | Scale linear + nonlinear variables  
All constraints and variables are scaled by the iterative procedure. Also, a certain additional scaling is performed that may be helpful if the right-hand side b or the solution x is large. This takes into account columns of (A I) that are fixed or have positive lower bounds or negative upper bounds. Scale nonlinear variables or Scale all variables are equivalent options. |

#### scale print (no value): Print scaling factors ←

This causes the row-scales $r(i)$ and column-scales $c(j)$ to be printed. The scaled matrix coefficients are $\hat{a}_{ij} = a_{ij}c(j)/r(i)$. The scaled bounds on the variables and slacks are $\hat{b}_j = b_j/c(j)$ and $\hat{u}_j = u_j/c(j)$, where $c(j) = r(j - n)$ if $j > n$. If a Scale option has not already been specified, Scale print sets the default scaling.

#### scale print tolerance (real): Scale print flag and set tolerance ←

See Scale Tolerance. This option also turns on printing of the scale factors.

Range: $[0, 1.0]$  
Default: $0.9$

#### scale tolerance (real): Scale tolerance ←

All forms except Scale option may specify a tolerance $r$ where $0 < r < 1$ (for example: Scale Print Tolerance = 0.99). This affects how many passes might be needed through the constraint matrix. On each pass, the scaling procedure computes the ratio of the largest and smallest nonzero coefficients in each column:

$$
\rho_{ij} = \max_i |a_{ij}|/\min_j |a_{ij}| \quad (a_{ij} \neq 0)
$$

If $\max_j \rho_{ij}$ is less than $r$ times its previous value, another scaling pass is performed to adjust the row and column scales. Raising $r$ from 0.9 to 0.99 (say) usually increases the number of scaling passes through $A$. At most 10 passes are made. If a Scale option has not already been specified, Scale tolerance sets the default scaling.

Range: $[0, 1.0]$  
Default: $0.9$

#### scale yes (no value): Synonym to scale option 1 ←

#### solution (string): Prints MINOS solution ←

This controls whether or not GAMS/MINOS prints the final solution obtained. There is one line of output for each constraint and variable. The lines are in the same order as in the GAMS solution, but the constraints and variables labeled with internal GAMS/MINOS numbers rather than GAMS names. (The numbers at the left of each line are GAMS/MINOS column numbers, and those at the right of each line in the rows section are GAMS/MINOS slacks.) The GAMS/MINOS solution may be useful occasionally to interpret certain messages that occur during the optimization, and to determine the final status of certain variables (basic, superbasic or nonbasic).

Default: NO
5.26 MINOS and QUADMINOS

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>Turn off printing of solution</td>
</tr>
<tr>
<td>YES</td>
<td>Turn on printing of solution</td>
</tr>
</tbody>
</table>

**start assigned nonlinear** *(string)*: Starting strategy when there is no basis

This option affects the starting strategy when there is no basis (i.e., for the first solve or when the GAMS statement *option bratio = 1* is used to reject an existing basis.) This option applies to all nonlinear variables that have been assigned nondefault initial values and are strictly between their bounds. Free variables at their default value of zero are excluded. Let $K$ denote the number of such assigned nonlinear variables.

Default: **SUPERBASIC**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUPERBASIC</td>
<td>Default Specify <em>superbasic</em> for highly nonlinear models, as long as $K$ is not too large (say $K &lt; 100$) and the initial values are good.</td>
</tr>
<tr>
<td>BASIC</td>
<td>Good for square systems Specify <em>basic</em> for models that are essentially square (i.e., if there are about as many general constraints as variables).</td>
</tr>
<tr>
<td>NONBASIC</td>
<td>Specify <em>nonbasic</em> if $K$ is large.</td>
</tr>
<tr>
<td>ELIGIBLE FOR CRASH</td>
<td>Specify <em>Eligible for Crash</em> for linear or nearly linear models. The nonlinear variables will be treated in the manner described under <em>Crash</em> option.</td>
</tr>
</tbody>
</table>

**subspace tolerance** *(real)*: Determines when nonbasics becomes superbasic

This controls the extent to which optimization is confined to the current set of basic and superbasic variables (Phase 4 iterations), before one or more nonbasic variables are added to the superbasic set (Phase 3). The parameter $r$ must be a real number in the range $0 < r \leq 1$. When a nonbasic variable $x_j$ is made superbasic, the resulting norm of the reduced-gradient vector (for all superbasics) is recorded. Let this be $\|Z^T g_0\|$. (In fact, the norm will be $|d_j|$ , the size of the reduced gradient for the new superbasic variable $x_j$. Subsequent Phase 4 iterations will continue at least until the norm of the reduced-gradient vector satisfies $\|Z^T g_0\| < = r \|Z^T g_0\|$ is the size of the largest reduced-gradient component among the superbasic variables.) A smaller value of $r$ is likely to increase the total number of iterations, but may reduce the number of basic changes. A larger value such as $r = 0.9$ may sometimes lead to improved overall efficiency, if the number of superbasic variables has to increase substantially between the starting point and an optimal solution. Other convergence tests on the change in the function being minimized and the change in the variables may prolong Phase 4 iterations. This helps to make the overall performance insensitive to larger values of $r$.

Range: $[0, 1.0]$  

Default: $0.5$

**summary frequency** *(integer)*: Controls iteration logging to summary (log file)

A brief form of the iteration log is output to the MINOS summary file (i.e. the GAMS log file). In general, one line is output every $i^{th}$ minor iteration. In an interactive environment, the output normally appears at the terminal and allows a run to be monitored. If something looks wrong, the run can be manually terminated. The summary frequency controls summary output in the same way as the log frequency controls output to the print file. A value such as
Summary Frequency = 10 or 100 is often adequate to determine if the solve is making progress. If Print level = 0, the default value of Summary Frequency is 100. If Print level > 0, the default value of Summary Frequency is 1. If Print level = 0 and the constraints are nonlinear, the Summary Frequency is ignored. Instead, one line is printed at the beginning of each major iteration.

Range: \{1, ..., \infty\}

Default: 100

**superbasics limit** \((\text{integer})\): Maximum number of superbasics

This places a limit on the storage allocated for superbasic variables. Ideally, the parameter \(i\) should be set slightly larger than the number of degrees of freedom expected at an optimal solution. For linear problems, an optimum is normally a basic solution with no degrees of freedom. (The number of variables lying strictly between their bounds is not more than \(m\), the number of general constraints.) The default value of \(i\) is therefore 1. For nonlinear problems, the number of degrees of freedom is often called the number of independent variables. Normally, \(i\) need not be greater than \(n_1 + 1\), where \(n_1\) is the number of nonlinear variables. For many problems, \(i\) may be considerably smaller than \(n_1\). This will save storage if \(n_1\) is very large. This parameter also sets the Hessian dimension, unless the latter is specified explicitly (and conversely). If neither parameter is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: \{1, ..., \infty\}

Default: 1

**unbounded objective value** \((\text{real})\): Determines when a problem is called unbounded

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

\[
\text{minimize}_{\alpha} F(x + \alpha p)
\]

If \(|F|\) exceeds the parameter \(r\) or if \(\alpha\) exceeds the unbounded stepsize, iterations are terminated with the exit message **PROBLEM IS UNBOUNDED (OR BADLY SCALED)**. If singularities are present, unboundedness in \(F(x)\) may be manifested by a floating-point overflow (during the evaluation of \(F(x + \alpha p)\), before the test against \(r\) can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the **Minor damping parameter**.

Default: 1.0e20

**unbounded step size** \((\text{real})\): Determines when a problem is called unbounded

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

\[
\text{minimize}_{\alpha} F(x + \alpha p)
\]

If \(\alpha\) exceeds the parameter \(r\) or if \(|F|\) exceeds the unbounded objective value, iterations are terminated with the exit message **PROBLEM IS UNBOUNDED (OR BADLY SCALED)**. If singularities are present, unboundedness in \(F(x)\) may be manifested by a floating-point overflow (during the evaluation of \(F(x + \alpha p)\), before the test against \(r\) can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the **Minor damping parameter**.

Default: 1.0e10
verify constraint gradients (no value): Synonym to verify level 2

verify gradients (no value): Synonym to verify level 3

verify level (integer): Controls verification of gradients

This option controls the finite-difference check performed by MINOS on the gradients (first derivatives) computed by GAMS for each nonlinear function. GAMS computes gradients analytically, and the values obtained should normally be taken as correct.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | Cheap test  
Only a cheap test is performed, requiring three evaluations of the nonlinear objective and two evaluations of the nonlinear constraints. Verify No is an equivalent option. |
| 1     | Check objective  
A more reliable check is made on each component of the objective gradient. Verify objective gradients is an equivalent option. |
| 2     | Check Jacobian  
A check is made on each column of the Jacobian matrix associated with the nonlinear constraints. Verify constraint gradients is an equivalent option. |
| 3     | Check objective and Jacobian  
A detailed check is made on both the objective and the Jacobian. Verify, Verify gradients, and Verify Yes are equivalent options. |
| -1    | No check |

verify no (no value): Synonym to verify level 0

verify objective gradients (no value): Synonym to verify level 1

verify yes (no value): Synonym to verify level 3

weight on linear objective (real): Composite objective weight

This option controls the so-called composite objective technique. If the first solution obtained is infeasible, and if the objective function contains linear terms, and the objective weight \( w \) is positive, this technique is used. While trying to reduce the sum of infeasibilities, the method also attempts to optimize the linear portion of the objective. At each infeasible iteration, the objective function is defined to be

\[
\text{minimize}_x \quad \sigma \cdot w(c^T x) + \text{(sum of infeasibilities)}
\]

where \( \sigma = 1 \) for minimization and \( \sigma = -1 \) for maximization and \( c \) is the linear portion of the objective. If an optimal solution is reached while still infeasible, \( w \) is reduced by a factor of 10. This helps to allow for the possibility that the initial \( w \) is too large. It also provides dynamic allowance for the fact the sum of infeasibilities is tending towards zero. The effect of \( w \) is disabled after five such reductions, or if a feasible solution is obtained. This option is intended mainly for linear programs. It is unlikely to be helpful if the objective function is nonlinear.

Default: 0.0
5.26.10 Exit Conditions

This section discusses the exit codes printed by MINOS at the end of the optimization run.

EXIT – Optimal solution found

This is the message we all hope to see! It is certainly preferable to every other message. Of course it is quite possible that there are model formulation errors, which will (hopefully) lead to unexpected objective values and solutions. The reported optimum may be a local, and other much better optima may exist.

EXIT – The problem is infeasible

When the constraints are linear, this message can probably be trusted. Feasibility is measured with respect to the upper and lower bounds on the variables (the bounds on the slack variables correspond to the GAMS constraints). The message tells us that among all the points satisfying the general constraints $Ax + s = 0$, there is apparently no point that satisfies the bounds on $x$ and $s$. Violations as small as the FEASIBILITY TOLERANCE are ignored, but at least one component of $x$ or $s$ violates a bound by more than the tolerance.

Note: Although the objective function is the sum of the infeasibilities, this sum will usually not have been minimized when MINOS recognizes the situation and exits. There may exist other points that have significantly lower sum of infeasibilities.

When nonlinear constraints are present, infeasibility is much harder to recognize correctly. Even if a feasible solution exists, the current linearization of the constraints may not contain a feasible point. In an attempt to deal with this situation MINOS may relax the bounds on the slacks associated with nonlinear rows. This perturbation is allowed a fixed number of times. Normally a feasible point will be obtained relative to the perturbed constraints, and optimization can continue on the subproblem. However, if several consecutive subproblems require such perturbation, the problem is terminated and declared INFEASIBLE. Clearly this is an ad-hoc procedure. Wherever possible, nonlinear constraints should be defined in such a way that feasible points are known to exist when the constraints are linearized.

EXIT – The problem is unbounded (or badly scaled)

For linear problems, unboundedness is detected by the simplex method when a nonbasic variable can apparently be increased by an arbitrary amount without causing a basic variable to violate a bound. A simple way to diagnose such a model is to add an appropriate bound on the objective variable.

Very rarely, the scaling of the problem could be so poor that numerical error will give an erroneous indication of unboundedness. Consider using the SCALE option.

For nonlinear problems, MINOS monitors both the size of the current objective function and the size of the change in the variables at each step. If either of these is very large (as judged by the UNBOUNDED parameter), the problem is terminated and declared UNBOUNDED. To avoid large function values, it may be necessary to impose bounds on some of the variables in order to keep them away from singularities in the nonlinear functions.

EXIT – User Interrupt

This exit code is a result of interrupting the optimization process by hitting Ctrl-C. Inside the IDE this is accomplished by hitting the Interrupt button. The solver will finish its current iteration, and return the current solution. This solution can be still intermediate infeasible or intermediate non-optimal.

EXIT – Too many iterations
The iteration limit was hit. Either the \texttt{ITERLIM}, or in some cases the \texttt{ITERATIONS LIMIT} or \texttt{MAJOR ITERATION LIMIT} was too small to solve the problem. In most cases increasing the GAMS \texttt{ITERLIM} option will resolve the problem. In other cases you will need to create a MINOS option file and set a \texttt{MAJOR ITERATION LIMIT}. The listing file will give more information regarding what limit was hit.

The GAMS iteration limit is displayed in the listing file under the section \texttt{SOLVE SUMMARY}. If the \texttt{ITERLIM} was hit, the message will look like:

\begin{verbatim}
ITERATION COUNT, LIMIT  10001  10000
\end{verbatim}

\textbf{EXIT – Resource Interrupt}

The solver hit the \texttt{RESLIM} resource limit, which is a time limit. It returned the solution at that time, which may be still intermediate infeasible or intermediate non-optimal.

The GAMS resource limit is displayed in the listing file under the section \texttt{SOLVE SUMMARY}. If the GAMS \texttt{RESLIM} was hit, the message will look like:

\begin{verbatim}
RESOURCE USAGE, LIMIT  1001.570  1000.000
\end{verbatim}

\textbf{EXIT – The objective has not changed for many iterations}

This is an emergency measure for the rare occasions when the solution procedure appears to be \textit{cycling}. Suppose that a zero step is taken for several consecutive iterations, with a basis change occurring each time. It is theoretically possible for the set of basic variables to become the same as they were one or more iterations earlier. The same sequence of iterations would then occur \textit{ad infinitum}.

\textbf{EXIT – The Superbasics Limit is too small}

The problem appears to be more non-linear than anticipated. The current set of basic and superbasic variables have been optimized as much as possible and an increase in the number of superbasics is needed. You can use the option \texttt{SUPERBASICS LIMIT} to increase the limit. See also option \texttt{HESSIAN DIMENSION}.

\textbf{EXIT – Constraint and objective function could not be calculated}

The function or gradient could not be evaluated. For example, this can occur when MINOS attempts to take a log or a square root of a negative number, when evaluating the expression $x^y$ with $x \leq 0$, or when evaluating $exp(x)$ for large $x$ and the result is too large to store. The listing file will contain details about where and why evaluation errors occur. To fix this problem, add bounds so that all functions can be properly evaluated. E.g. if you have an expression $x^y$, add a lower bound \texttt{X.LO=0.001} to your model.

In many cases the algorithm can recover from function evaluation errors, for instance if they happen in the line search while evaluating trial points. The message above appears in cases where the algorithm can not recover, and requires a reliable function or gradient evaluation.

\textbf{EXIT – Function evaluation error limit}
The limit of allowed function evaluation errors DOMLIM has been exceeded.

Function evaluation errors occur when MINOS attempts to evaluate the objective and/or constraints at points where these functions or their derivatives are not defined or where overflows occur. Some examples are given above. The listing file contains details about these errors.

The quick and dirty way to solve this is to increase the GAMS DOMLIM setting, but in general it is better to add bounds. E.g. if you have an expression $x^y$, then add a bound $x.LO=0.001$ to your model.

EXIT – The current point can not be improved

The line search failed. This can happen if the model is very nonlinear or if the functions are nonsmooth (using a DNLP model type).

If the model is non-smooth, consider a smooth approximation. It may be useful to check the scaling of the model and think more carefully about choosing a good starting point. Sometimes it can help to restart the model with full scaling turned on:

```gams
option nlp=minos;
solve m minimizing z using nlp; // this one gives "current point cannot be improved"
file fopt /minos.opt/; // write option file
putclose fopt "scale all variables";/
m.optfile=1;
solve m minimizing z using nlp; // solve with "scale all variables"
```

EXIT – Numerical error in trying to satisfy the linear constraints (or the linearized constraints)

The basis is very ill-conditioned.

This is often a scaling problem. Try the full scaling option scale all variables or, better yet, rescale the model in GAMS via the .scale suffix or by choosing more appropriate units for variables and RHS values.

EXIT – Not enough storage to solve the model

The amount of workspace allocated for MINOS to solve the model is insufficient. Consider increasing the GAMS option workfactor to increase the workspace allocated for MINOS to use. The listing file and log file (screen) will contain information about the current workspace allocation. Increasing the workfactor by 50% is a reasonable strategy.

EXIT– Systems error

This is a catch all return for other serious problems. Check the listing file for more messages. If needed rerun the model with OPTION SYSOUT=ON;.

5.27 MOSEK

MOSEK ApS, C/O Symbion Science Park, Fruebjergvej 3, Box 16, 2100 Copenhagen Ø, Denmark
5.27 MOSEK

5.27.1 Introduction

MOSEK is a software package for the solution of linear, mixed-integer linear, quadratic, mixed-integer quadratic, quadratically constrained, conic, and semidefinite mathematical optimization problems. MOSEK is particularly well suited for solving large-scale linear, convex quadratically constraint, and conic programs using an extremely efficient interior point algorithm.

These problem classes can be solved using an appropriate optimizer built into MOSEK. All the optimizers available in MOSEK are built for the solution of large-scale sparse problems. Current optimizers include:

- Interior-point optimizers for continuous and conic problems
- Simplex optimizer for linear problems
- Branch-and-cut optimizer for mixed-integer linear, quadratic, and conic problems

5.27.1.1 Licensing

Licensing of GAMS/MOSEK is similar to other GAMS solvers. MOSEK is licensed in two different ways:

- **GAMS/MOSEK**: All model types.
- **GAMS/MOSEK Solver Link**: Users must have a separate, licensed MOSEK system. For users who wish to use MOSEK within GAMS and also in other environments.

Attention

The free bare-bone link mode (previously GAMS/OSIMOSEK) that allowed to solve LP and MIP when the user had a separate MOSEK license installed has been removed. If you relied on using this bare-bone link option, then do not hesitate to contact sales@mosek.com to arrange for a GAMS/MOSEK Solver Link license.

For information regarding MOSEK standalone or interfacing MOSEK with other applications contact sales@mosek.com.

5.27.1.2 Solving Problems in Parallel

MOSEK can exploit multiple CPUs (or a CPU with multiple cores) to solve an optimization problem when using the interior-point or the mixed-integer optimizers.

This implies that whenever the MOSEK interior-point optimizer should solve an optimization problem, then it will try to divide the work so each CPU gets a share of the work. The user decides how many CPUs MOSEK should exploit. Unfortunately, it is not always easy to divide the work. Also some of the coordination work must occur in sequential. Therefore, the speed-up obtained when using multiple CPUs is highly problem dependent. However, as a rule of thumb, if the problem solves very quickly, i.e., in less than 60 seconds, then there is no advantage in using the parallel option.

The parameter `MSK_IPAR_NUM_THREADS` sets the number of threads (and therefore the number of CPU's) that the optimizer will use.
5.27.1.3 Infeasible/Unbounded Models

5.27.1.3.1 Farkas Certificates MOSEK determines if either the primal or the dual problem is infeasible by means of a Farkas certificate. In such a case MOSEK returns a certificate indicating primal or dual infeasibility.

The primal infeasibility certificate indicates a primal infeasible model. For a minimization problem

\[
\text{minimize} \quad \langle c, x \rangle \\
\text{subject to} \quad Ax = b, \\
x \geq 0,
\]

the primal infeasibility certificate is the solution \( y \) satisfying \( A' y \leq 0 \) and \( \langle b, y \rangle > 0 \).

A primal infeasibility certificate is reported in the marginal records of the variables and equations. As no primal solution is available in this case, the level values for variables and equations and the objective function value are set to 0 (setting them to NA would be more appropriate, but GAMS does not support this well). At the moment, primal infeasibility certificate are not available for conic programs.

Since GAMS reports all model statuses in the primal space, the notion of dual infeasibility does not exist and GAMS reports a status of unboundedness, which assumes that the primal problem is feasible. Although GAMS reports the primal as unbounded, there is the possibility that both the primal and dual problem are infeasible. To check if this is the case, the user can set appropriate lower and upper bounds on the objective variable, using the \((\text{variable}).\text{LO}\) and \((\text{variable}).\text{UP}\) suffixes and resolve.

The dual infeasibility certificate is reported in the level values for the variables. As no dual solution exists, the marginal values for both variables and equations are set to NA.

For more details on primal and dual infeasibility certificates see the MOSEK Modeling Cookbook.

5.27.1.3.2 Infeasibility Report MOSEK has some facilities for diagnosing the cause of a primal or dual infeasibility. They can be turned on using the parameter setting \texttt{MSK_IPAR_INFEAS_REPORT.AUTO}. This causes MOSEK to print a report about an infeasible subset of the constraints, when an infeasibility is encountered. Moreover, the parameter \texttt{MSK_IPAR_INFEAS_REPORT_LEVEL} controls the amount of information presented in the infeasibility report. We will use the TRNSPORT example from the GAMS Model Library with increased demand \((b(j) \leftarrow 1.6 b(j))\) to make the model infeasible. MOSEK produces the following infeasibility report:

MOSEK PRIMAL INFEASIBILITY REPORT.

Problem status: The problem is primal infeasible

The following constraints are involved in the primal infeasibility.

<table>
<thead>
<tr>
<th>Index</th>
<th>Name</th>
<th>Lower bound</th>
<th>Upper bound</th>
<th>Dual lower</th>
<th>Dual upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>supply(seattle)</td>
<td>none</td>
<td>3.500000e+002</td>
<td>0.000000e+000</td>
<td>1.000000e+000</td>
</tr>
<tr>
<td>2</td>
<td>supply(san-diego)</td>
<td>none</td>
<td>6.000000e+002</td>
<td>0.000000e+000</td>
<td>1.000000e+000</td>
</tr>
<tr>
<td>3</td>
<td>demand(new-york)</td>
<td>5.200000e+002</td>
<td>none</td>
<td>1.000000e+000</td>
<td>0.000000e+000</td>
</tr>
<tr>
<td>4</td>
<td>demand(chicago)</td>
<td>4.800000e+002</td>
<td>none</td>
<td>1.000000e+000</td>
<td>0.000000e+000</td>
</tr>
<tr>
<td>5</td>
<td>demand(topeka)</td>
<td>4.400000e+002</td>
<td>none</td>
<td>1.000000e+000</td>
<td>0.000000e+000</td>
</tr>
</tbody>
</table>

The following bound constraints are involved in the infeasibility.

<table>
<thead>
<tr>
<th>Index</th>
<th>Name</th>
<th>Lower bound</th>
<th>Upper bound</th>
<th>Dual lower</th>
<th>Dual upper</th>
</tr>
</thead>
</table>

The report indicates which constraints and bounds are causing the infeasibility. In this case, the constraints causing infeasibility are \texttt{supply} and \texttt{demand}. The values in the columns \texttt{Dual lower} and \texttt{Dual upper} are also useful, because if the dual lower value is different from zero for a constraint, then it implies that the lower bound on the constraint is important for the infeasibility. Similarly, if the dual upper value is different from zero on a constraint, then this implies the upper bound on the constraint is important for infeasibility.
5.27 MOSEK

5.27.1.4 Conic Programming

MOSEK is well suited for solving generalized linear programs involving certain conic constraints.

For an overview of quadratic conic programming and how these conic constraints are implemented in GAMS, see the Section Conic Programming in the GAMS User’s Guide. Note, that for Mosek no variable can appear in more than one conic constraint.

Additionally, the primal power cone, defined as

\[ x_0^\alpha x_1^{1-\alpha} \geq \sqrt{\sum_{i=2}^{n} x_i^2}, \quad x_0, x_1 \geq 0, \]

with \( \alpha \in (0, 1) \), and the primal exponential cone, defined as

\[ x_0 \geq x_1 \exp(x_2/x_1), \quad x_0, x_1 \geq 0, \]

are available.

Since GAMS does not offer capabilities to directly restrict a variable to one of these cones, the GAMS/MOSEK link tries to detect the above algebra from a general nonlinear equation. For example, the following GAMS code should work with MOSEK:

```
Set i / 0*10 /
Variable x(i);
Equations e1, e2;
Scalar alpha;
e1.. x('0')^alpha * x('1')^(1-alpha) =G= sqrt(sum(i$(ord(i)>2), sqr(x(i))));
e2.. x('0') =G= x('1') * exp(x('2') / x('1'));
x.lo('0') = 0;
x.lo('1') = 0;
```

See also testlib models powercone1, powercone2, and expcone1.

5.27.2 Solver Options

MOSEK works like other GAMS solvers, and many options can be set in the GAMS model (see GAMS Options). The most relevant GAMS options are reslim, nodlim, iterlim (iteration limit for simplex and interior point algorithms), optca, optcr, and optfile. A description of all available GAMS options can be found in GAMS Options and Solver related options.

We remark that MOSEK contains many complex solver options, many of which require a deep understanding of the algorithms used. For information on how to use a GAMS/Mosek options file, see The Solver Option File. For example, an option file

```
MSK_IPAR_INTPNT_MAX_ITERATIONS 20
MSK_IPAR_INTPNT_SCALING MSK_SCALING_NONE
```

limits the number of interior-point iterations to 20 and disables scaling.

In the following, we summarize the MOSEK options that are available through the GAMS/MOSEK interface. For details, see Detailed Descriptions of MOSEK Options.

5.27.2.1 General
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_DPAR_OPTIMIZER_MAX_TIME</td>
<td>Maximum amount of time the optimizer is allowed to spend on the optimization.</td>
<td>GAMS ResLim</td>
</tr>
<tr>
<td>MSK_DPAR_SEMIDEFINITE_TOL_APPROX</td>
<td>Tolerance to define a matrix to be positive semidefinite.</td>
<td>1e-10</td>
</tr>
<tr>
<td>MSK_IPAR_AUTO_SORT_A_BEFORE_OPT</td>
<td>Controls whether the elements in each column of the coefficient matrix are sorted before an optimization is performed.</td>

5.27.3 The MOSEK Log File

The MOSEK log output gives much useful information about the current solver progress and individual phases.

5.27.3.1 Log Using the Interior Point Optimizer

The following is a MOSEK log output from running the TRNSPORT model from the GAMS Model Library:

Optimizer started.
Interior-point optimizer started.
Presolve started.
Linear dependency checker started.
Linear dependency checker terminated.
Eliminator - tries : 0 time : 0.00
Lin. dep. - tries : 1 time : 0.00
Lin. dep. - number : 0
Presolve terminated. Time: 0.00
Optimizer - threads : 1
Optimizer - solved problem : the primal
Optimizer - Constraints : 5
Optimizer - Cones : 0
Optimizer - Scalar variables : 11 conic : 0
Optimizer - Semi-definite variables: 0 scalarized : 0
Factor - setup time : 0.00 dense det. time : 0.00
Factor - ML order time : 0.00 GP order time : 0.00
Factor - nonzeros before factor : 11 after factor : 12
Factor - dense dim. : 0 flops : 1.80e+02

The first part gives information about the presolve (if used). The main log follows:

Return code - 0 [MSK_RES_OK]: No error occurred.

The last section gives details about the model and solver status, primal and dual feasibilities, as well as solver resource times. Furthermore, the log gives information about the basis identification phase. Some of this information is listed in the GAMS solve summary in the model listing (.LST) file as well.

Relative gap: 0.916667

5.27.4 Semidefinite Programming with GAMS/MOSEK (experimental)

With Version 7, MOSEK introduced a semidefinite programming (SDP) solver into their portfolio. The following introduction is taken from the MOSEK Documentation.

Semidefinite programming is a generalization of quadratic conic programming, allowing the use of matrix variables belonging to the convex cone of positive semidefinite matrices

\[ S_r^+ = \{ X \in S_r : z^T X z \geq 0, \forall z \in \mathbb{R}^r \} , \]

where \( S_r \) is the set of \( r \times r \) real-valued symmetric matrices. MOSEK can solve semidefinite optimization problems of the form

\[
\begin{align*}
\text{minimize} & \quad \sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \langle C_j, X_j \rangle + c^f \\
\text{subject to} & \quad l_i^c \leq \sum_{j=0}^{n-1} a_{ij} x_j + \sum_{j=0}^{p-1} \langle A_{ij}, X_j \rangle \leq u_i^c, \quad i = 0, \ldots, m-1, \\
& \quad l_j^f \leq x_j \leq u_j^f, \quad j = 0, \ldots, n-1, \quad j = 0, \ldots, p-1,
\end{align*}
\]

(SDP)

where the problem has \( p \) symmetric positive semidefinite (PSD) variables \( X_j \in S_{r_j}^+ \) of dimension \( r_j \) with symmetric coefficient matrices \( C_j \in S_{r_j} \) and \( A_{ij} \in S_{r_j} \). We use the standard notation for the matrix inner product, i.e., for \( A, B \in \mathbb{R}^{m \times n} \) we have

\[ \langle A, B \rangle := \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} A_{ij} B_{ij} . \]
5.27.4.1 Example

An example for a mixed semidefinite and conic quadratic programming problem with a 3-dimensional PSD matrix variable is the following:

\[
\begin{align*}
& \text{minimize} & & \langle \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix}, X \rangle + x_0 \\
& \text{subject to} & & \langle \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, X \rangle + x_0 = 1 \\
& & & \langle \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, X \rangle + x_1 + x_2 = \frac{1}{2} \\
& & & x_0 \geq \sqrt{x_1^2 + x_2^2} \\
& & & \bar{X} \succeq 0
\end{align*}
\]

The GAMS/MOSEK interface offers an experimental interface to MOSEK's SDP solver. It allows to state SDP's of the form (SDP) in GAMS language. For instance, the example problem from above can be formulated as follows (sdp01 in the GAMS Test Library):

Set i / 0 * 2 /;
alias(i, ip);
Variables barX(i,i) PSDMATRIX
x(i) simple vars
z objective var;
x.lo('0') = 0;
Parameters barAobj(i,i) coefficients of barX in objective
barAe1(i,i) coefficients of barX in e1
barAe2(i,i) coefficients of barX in e2;
Table barAobj(i,i)
0 1 2
0 2.0 1.0 0.0
1 1.0 2.0 1.0
2 0.0 1.0 2.0
All-one matrix
barAe1(i,i) = 1.0;
barAe2(i,ip) = 1.0;
Equations obj, e1, e2, e3;
obj.. z =e= sum((i,ip), barAobj(i,ip) * barX(i,ip)) + x('0');
e1.. 1 =e= sum((i,ip), barAe1(i,ip) * barX(i,ip)) + x('0');
e2.. 0.5 =e= sum((i,ip), barAe2(i,ip) * barX(i,ip)) + x('1') + x('2');
e3.. -sqr(x('0')) + sqr(x('1')) + sqr(x('2')) =l= 0;
Model m / all /

We see that the matrix $\bar{X}$ is defined via the 2-dimensional GAMS variable barX. Additionally, the keyword PSDMATRIX at the beginning of the descriptive text (!) of the variable is used to indicate that the variables belonging to symbol barX are to be interpreted as a matrix variable with PSD constraint.

The Model shown above can be solved with MOSEK via the statements

```
option qcp = mosek;
Solve m minimizing z using QCP;
```

As GAMS has no native support for conic programming, the modeltype is specified as QCP.

The solve statement produces the following log output (see also Log Using the Interior Point Optimizer):
Recognizing SDP variables for symbols barX (1)
Recognized 1 quadratic equation as conic constraint.

Finally, the optimal value for the matrix $\bar{X}$ and the dual values associated with bound constraints on entries of the matrix $\bar{X}$ can be displayed in GAMS as usual: display $X.l$, $X.m$;
5.27.4.2 Usage

The general syntax for defining a symmetric matrix or an (indexed) set of symmetric matrices with PSD constraints in GAMS is

Variable \( X(a,b,c,\ldots,i_1,\ldots,i_k,i_1,\ldots,i_k) \) "PSDMATRIX_k <explanatory text>";

The number \( k > 0 \) specifies the number of indices that define the row/column dimension of the matrix. Specifying only the term PSDMATRIX is equivalent to PSDMATRIX_1. For a given \( k \), the \( 2k \)-last indices are used to index the rows and columns of the matrix. The dimensions \( a, b, c, \ldots \) are optional and can be used to index a set of matrices. In the GAMS/MOSEK output, a number in parenthesis is used to indicate the number of PSD matrices that have been found for one symbol. For example, the code

\[
\begin{align*}
\text{Set } i &/ a,b /; \\
\text{Set } j &/ s01 \ldots s42 /; \\
\text{Variables } z, X(j,i,i) \text{ PSDMATRIX};
\end{align*}
\]

generates the output

Recognizing SDP variables for symbols \( X \) (42)

if all matrices \( X(j,\ldots) \) also occur in a model instantiation.

Note

The current syntax for declaring PSD matrix variables via the explanatory text a variable is a temporary solution that will hopefully be replaced by a GAMS language feature in the future.

Variables that were tagged as belonging to a PSD matrix can only occur in linear constraints. Within these constraints, the coefficient matrix for a PSD matrix needs to be specified in symmetric form. That is, if the parameter matrix \( \text{bar\_obj} \) in the example above is equivalently specified as

\[
\begin{array}{c|ccc}
 & 0 & 1 & 2 \\
\hline
0 & 2.0 & 0.0 & 0.0 \\
1 & 2.0 & 2.0 & 0.0 \\
2 & 0.0 & 2.0 & 2.0 \\
\end{array}
\]

the GAMS/MOSEK interface will quit with the error message

SDP coefficient matrix not symmetric: defObj_z: 2*barX(1,0) != 0*barX(0,1)

Bounds on entries in a PSD matrix variable can be specified as usual with .lo and .up attributes. These bound constraints are translated into linear constraints by the interface. If different bounds are given to symmetric entries of a PSD matrix variable (\( X_{i,j} \) vs. \( X_{j,i} \)), the stronger bounds are used, which is equivalent to adding constraints for each of the matrix entries. For nonpositive lower bounds on diagonal entries, no extra constraints are added, as they are implied by the PSD constraint.
5.27 MOSEK

5.27.4.3 GAMS variables vs. PSD matrix entries

As GAMS is not aware that a indexed variable will be interpreted as PSD matrix variable, it may not generate variables for all matrix entries when instantiating a model. This is especially critical if the modeler specified bounds on matrix entries that do not appear in any of the model equations, as these bounds would not be visible to the GAMS/MOSEK interface.

As an example, consider the SDP relaxation \(\max\{-\langle W, \bar{X} \rangle : X_{ii} = 1 \forall i, X \succeq 0\}\) corresponding to the Goemans-Williamson Randomized Approximation Algorithm for MaxCut:

Parameter \(W(i,i)\) edge weights;
Variable \(X(i,j)\) PSDMATRIX
sdobjvar objective var;
Equation sdprob objective function;
\[\text{sdprob}.. \sum((i,j), -W(i,j)*(X(i,j) + X(j,i))) =e= \text{sdobjvar};\]
\[X.fx(i,i) = 1.0;\]
model maxcutsdp / all /;

As \(W(i,i)=0\), GAMS will not create any variables for \(X(i,i)\) when instantiating the model in a solve statement. As a consequence, the constraints \(X(i,i)=1\) will not be visible to GAMS/MOSEK. However, as MOSEK will compute values for the full matrix \(X\), it will also compute values for the diagonal entries of \(X\).

Further, the GAMS/MOSEK interface can pass primal solution values only for those entries of a PSD matrix variable that have a corresponding GAMS variable. This may make a solution matrix appear not to be PSD in GAMS, because not all entries have been passed back.

To be aware of such problems, the GAMS/MOSEK interface checks that it has a GAMS variable available for every entry of a PSD matrix variable. If not, it will report an error like

\texttt{ERROR: Have 1600 GAMS variables for entries of 400 x 400 PSD Variable X(,), expected 160000 many.}

This check can be disabled by setting the option \texttt{SDPCHECKVARS} to 0. Note, that the check is not able to alarm the user in situations where no GAMS variables were created for all entries of a row and corresponding column.

A simple workaround for this issue is to force all variables to be generated when a model is instantiated. This can be done by adding something like \texttt{eps*sum((i,j),X(i,j))} to one of the equations. Note, that \texttt{eps} is numerically equal to a 0.0 in GAMS, but has the effect that the term \texttt{sum((i,j),X(i,j))} is passed to the solver with 0.0-coefficient.

5.27.4.4 Dual Values for PSD constraints

The PSD constraint on a matrix variable \(\bar{X}\) is associated with a dual PSD matrix variable \(\bar{Y}\). As GAMS is not aware of the PSD constraints, it is also not aware of the corresponding dual variables. Thus, there is no native way to pass the duals for the PSD constraints back to GAMS. (Recall, that the marginals for a PSDMATRIX variable \(X\) are used to store the dual values associated with the bound constraints on matrix entries.)

To work around this issue, the GAMS/MOSEK interface offers the option \texttt{SDPSOLUFILE}. This option allows to specify the name of a GDX file that stores primal values for all entries of a matrix variable and dual values of the corresponding PSD constraint. For a variable \(X(i,j)\), the GDX file stores the primal matrix value for all entries \((i,j)\) (i.e., not just the ones for which GAMS variables were created, therefore offering another workaround for the issue discussed in the previous section) as level values of variable \(X\) and the dual matrix for the PSD constraint as marginal values.
5.27.4.5 Infeasible and Unbounded SDPs

The GAMS/Mosek link currently does not pass on certificates for primal or dual infeasibility from Mosek to GAMS if PSD variables are present.

5.27.5 Detailed Descriptions of MOSEK Options

**FIXOPTFILE (string):** Name of option file which is read just before solving the fixed problem. ←

**MSK_DPAR_ANA_SOL_INFEAS_TOL (real):** If a constraint violates its bound with an amount larger than this value, the constraint name, index and violation will be printed by the solution analyzer. ←

Default: 1e-06

**MSK_DPAR_BASIS_REL_TOL_S (real):** Maximum relative dual bound violation allowed in an optimal basic solution. ←

Default: 1e-12

**MSK_DPAR_BASIS_TOL_S (real):** Maximum absolute dual bound violation in an optimal basic solution. ←

Range: [1e-09, ∞]

Default: 1e-06

**MSK_DPAR_BASIS_TOL_X (real):** Maximum absolute primal bound violation allowed in an optimal basic solution. ←

Range: [1e-09, ∞]

Default: 1e-06

**MSK_DPAR_CHECK_CONVEXITY_REL_TOL (real):** Not in use. ←

Default: 1e-10

**MSK_DPAR_DATA_SYM_MAT_TOL (real):** Absolute zero tolerance for elements in in symmetric matrices. ←

If any value in a symmetric matrix is smaller than this parameter in absolute terms MOSEK will treat the values as zero and generate a warning.

Range: [1e-16, 1e-06]

Default: 1e-12

**MSK_DPAR_DATA_SYM_MAT_TOL_HUGE (real):** An element in a symmetric matrix which is larger than this value in absolute size causes an error. ←

Default: 1e+20

**MSK_DPAR_DATA_SYM_MAT_TOL_LARGE (real):** An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed. ←
Default: $1e+10$

**MSK_DPAR_DATA_TOL_AIJ_HUGE** *(real)*: An element in the constraint matrix which is larger than this value in absolute size causes an error.

Default: $1e+20$

**MSK_DPAR_DATA_TOL_AIJ_LARGE** *(real)*: An element in the constraint matrix which is larger than this value in absolute size causes a warning message.

Default: $1e+10$

**MSK_DPAR_DATA_TOL_BOUND_INF** *(real)*: Any bound which in absolute value is greater than this parameter is considered infinite.

Default: $1e+16$

**MSK_DPAR_DATA_TOL_BOUND_WRN** *(real)*: If a bound value is larger than this value in absolute size, then a warning message is issued.

Default: $1e+08$

**MSK_DPAR_DATA_TOL_CJ_LARGE** *(real)*: A coefficient in the objective function which is larger than this value in absolute terms causes a warning message.

Default: $1e+08$

**MSK_DPAR_DATA_TOL_C_HUGE** *(real)*: A coefficient in the objective function which is larger than the value in absolute terms is considered to be huge and generates an error.

Default: $1e+16$

**MSK_DPAR_DATA_TOL_QIJ** *(real)*: Absolute zero tolerance for coefficients of quadratic terms.

Default: $1e-16$

**MSK_DPAR_DATA_TOL_X** *(real)*: Zero tolerance for constraints and variables i.e. if the distance between the lower and upper bound is less than this value, then the lower and upper bound is considered identical.

Default: $1e-08$

**MSK_DPAR_INTPNT_CO_TOL_DFEAS** *(real)*: Dual feasibility tolerance used by the interior-point optimizer for conic problems.

Range: $[0, 1]$

Default: $1e-08$

See also: **MSK_DPAR_INTPNT_CO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_CO_TOL_INFEAS** *(real)*: Infeasibility tolerance used by the interior-point optimizer for conic problems.

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: $[0, 1]$

Default: $1e-12$
**MSK_DPAR_INTPNT_CO_TOL_MU_RED (real):** Relative complementarity gap tolerance used by the interior-point optimizer for conic problems.  

- Range: $[0, 1]$
- Default: $1e^{-08}$

**MSK_DPAR_INTPNT_CO_TOL_NEAR_REL (real):** Termination tolerance multiplier that is used if no accurate solution can be found.  

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

- Range: $[1, \infty]$  
- Default: 1

**MSK_DPAR_INTPNT_CO_TOL_PFEAS (real):** Primal feasibility tolerance used by the interior-point optimizer for conic problems.  

- Range: $[0, 1]$
- Default: $1e^{-08}$

See also: **MSK_DPAR_INTPNT_CO_TOL_NEAR_REL.**

**MSK_DPAR_INTPNT_CO_TOL_REL_GAP (real):** Relative gap termination tolerance used by the interior-point optimizer for conic problems.  

- Range: $[0, 1]$
- Default: $1e^{-08}$

See also: **MSK_DPAR_INTPNT_CO_TOL_NEAR_REL.**

**MSK_DPAR_INTPNT_QO_TOL_DFEAS (real):** Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.  

- Range: $[0, 1]$
- Default: $1e^{-08}$

See also: **MSK_DPAR_INTPNT_QO_TOL_NEAR_REL.**

**MSK_DPAR_INTPNT_QO_TOL_INFEAS (real):** Infeasibility tolerance used by the interior-point optimizer for quadratic problems.  

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

- Range: $[0, 1]$
- Default: $1e^{-12}$

**MSK_DPAR_INTPNT_QO_TOL_MU_RED (real):** Relative complementarity gap tolerance used by the interior-point optimizer for quadratic problems.  

- Range: $[0, 1]$
- Default: $1e^{-08}$
**MSK_DPAR_INTPNT_QO_TOL_NEAR_REL** (real): Termination tolerance multiplier that is used if no accurate solution can be found.

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: \([0, 1]\)

Default: \(1e^{-08}\)

**MSK_DPAR_INTPNT_QO_TOL_PFEAS** (real): Primal feasibility tolerance used by the interior-point optimizer for quadratic problems.

Range: \([0, 1]\)

Default: \(1e^{-08}\)

See also: **MSK_DPAR_INTPNT_QO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_QO_TOL_REL_GAP** (real): Relative gap termination tolerance used by the interior-point optimizer for quadratic problems.

Range: \([0, 1]\)

Default: \(1e^{-08}\)

See also: **MSK_DPAR_INTPNT_QO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_TOL_DFEAS** (real): Dual feasibility tolerance used by the interior-point optimizer for linear problems.

Range: \([0, 1]\)

Default: \(1e^{-08}\)

**MSK_DPAR_INTPNT_TOL_DSAFE** (real): Controls the initial dual starting point used by the interior-point optimizer.

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: \([0.0001, \infty]\)

Default: 1

**MSK_DPAR_INTPNT_TOL_INFEAS** (real): Infeasibility tolerance used by the interior-point optimizer for linear problems.

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: \([0, 1]\)

Default: \(1e^{-10}\)
**MSK_DPAR_INTPNT_TOL_MU_RED (real):** Relative complementarity gap tolerance used by the interior-point optimizer for linear problems.

Range: [0, 1]
Default: 1e-16

**MSK_DPAR_INTPNT_TOL_PATH (real):** Controls how close the interior-point optimizer follows the central path.

A large value of this parameter means the central path is followed very closely. On numerically unstable problems it may be worthwhile to increase this parameter.

Range: [0, 0.9999]
Default: 1e-08

**MSK_DPAR_INTPNT_TOL_PFEAS (real):** Primal feasibility tolerance used by the interior-point optimizer for linear problems.

Range: [0, 1]
Default: 1e-08

**MSK_DPAR_INTPNT_TOL_PSAFE (real):** Controls the initial primal starting point used by the interior-point optimizer.

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it may be worthwhile to increase this value.

Range: [0.0001, \( \infty \)]
Default: 1

**MSK_DPAR_INTPNT_TOL_REL_GAP (real):** Relative gap termination tolerance used by the interior-point optimizer for linear problems.

Range: [1e-14, \( \infty \)]
Default: 1e-08

**MSK_DPAR_INTPNT_TOL_REL_STEP (real):** Relative step size to the boundary for linear and quadratic optimization problems.

Range: [0.0001, 0.999999]
Default: 0.9999

**MSK_DPAR_INTPNT_TOL_STEP_SIZE (real):** Step size tolerance.

If the step size falls below the value of this parameter, then the interior-point optimizer assumes it is stalled. In other words the interior-point optimizer does not make any progress and therefore it is better stop.

Range: [0, 1]
Default: 1e-06

**MSK_DPAR_LOWER_OBJ_CUT (real):** Lower objective limit.
If either a primal or dual feasible solution is found proving that the optimal objective value is outside the interval (MSK_DPAR_LOWER_OBJ_CUT, MSK_DPAR_UPPER_OBJ_CUT), then MOSEK is terminated.

Range: \([-\infty, \infty]\)

Default: \(-1e+30\)

See also: MSK_DPAR_LOWER_OBJ_CUTFINITE_TRH.

**MSK_DPAR_LOWER_OBJ_CUTFINITE_TRH** (*real*): Lower objective limit threshold.

If the lower objective cut (MSK_DPAR_LOWER_OBJ_CUT) is less than this value, then it is treated as infinity.

Range: \([-\infty, \infty]\)

Default: \(-5e+29\)

**MSK_DPAR_MIO_MAX_TIME** (*real*): This parameter limits the maximum time spent by the mixed-integer optimizer.

A negative number means infinity.

Range: \([-\infty, \infty]\)

Default: \(-1\)

**MSK_DPAR_MIO_REL_GAP_CONST** (*real*): This value is used to compute the relative gap for the solution to an integer optimization problem.

Range: \([1e-15, \infty]\)

Default: \(1e-10\)

**MSK_DPAR_MIO_TOL_ABS_GAP** (*real*): Absolute optimality tolerance employed by the mixed-integer optimizer.

Default: GAMS OptCA

**MSK_DPAR_MIO_TOL_ABS_RELAX_INT** (*real*): Absolute relaxation tolerance of the integer constraints.

That means if the fractional part of a discrete variable (\(\min(|x| - \lfloor |x| \rfloor, \lceil |x| \rceil - |x|)\)) is less than the tolerance, then the integer restriction is assumed to be satisfied.

Range: \([1e-09, \infty]\)

Default: \(1e-05\)

**MSK_DPAR_MIO_TOL_FEAS** (*real*): Feasibility tolerance for mixed integer solver.

Range: \([1e-09, 0.001]\)

Default: \(1e-06\)

**MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT** (*real*): If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation.
A value of 0.0 means that the value is selected automatically.

Range: \([0, 1]\)

Default: 0

**MSK_DPAR_MIO_TOL_REL_GAP** *(real)*: Relative optimality tolerance employed by the mixed-integer optimizer.  

Default: GAMS OptCR

**MSK_DPAR_OPTIMIZER_MAX_TIME** *(real)*: Maximum amount of time the optimizer is allowed to spent on the optimization.  

A negative number means infinity.

Range: \([-\infty, \infty]\)

Default: GAMS ResLim

**MSK_DPAR_PRESOLVE_TOL_ABS_LINDEP** *(real)*: Absolute tolerance employed by the linear dependency checker.  

Default: 1e-06

**MSK_DPAR_PRESOLVE_TOL_AIJ** *(real)*: Absolute zero tolerance employed for constraint coefficients in presolve.  

Range: \([1e-15, \infty]\)

Default: 1e-12

**MSK_DPAR_PRESOLVE_TOL_PRIMAL_INFEAS_PERTURBATION** *(real)*: The presolve is allowed to perturb a bound on a constraint or variable by this amount if it removes an infeasibility.  

Default: 1e-06

**MSK_DPAR_PRESOLVE_TOL_REL_LINDEP** *(real)*: Relative tolerance employed by the linear dependency checker.  

Default: 1e-10

**MSK_DPAR_PRESOLVE_TOL_S** *(real)*: Absolute zero tolerance employed for dual variables in presolve.  

Default: 1e-08

**MSK_DPAR_PRESOLVE_TOL_X** *(real)*: Absolute zero tolerance employed for primal variables in presolve.  

Default: 1e-08

**MSK_DPAR_QCQO_REFORMULATE_REL_DROP_TOL** *(real)*: This parameter determines when columns are dropped in incomplete Cholesky factorization during reformulation of quadratic problems.  

Default: 1e-15

**MSK_DPAR_SEMIDEFINITE_TOL_APPROX** *(real)*: Tolerance to define a matrix to be positive semidefinite.  

Default: 1e-08
Range: \([1e-15, \infty]\)
Default: 1e-10

**MSK_DPAR_SIMPLEX_ABS_TOL_PIV** *(real)*: Absolute pivot tolerance employed by the simplex optimizers. ⇐

Range: \([1e-12, \infty]\)
Default: 1e-07

**MSK_DPAR_SIM_LU_TOL_REL_PIV** *(real)*: Relative pivot tolerance for LU factorization in simplex optimizers and basis identification. ⇐

A value closer to 1.0 generally improves numerical stability but typically also implies an increase in the computational work.

Range: \([1e-06, 0.999999]\)
Default: 0.01

**MSK_DPAR_UPPER_OBJ_CUT** *(real)*: Upper objective limit. ⇐

If either a primal or dual feasible solution is found proving that the optimal objective value is outside the interval \(\text{MSK_DPAR_LOWER_OBJ_CUT, MSK_DPAR_UPPER_OBJ_CUT}\), then MOSEK is terminated.

Range: \([-\infty, \infty]\)
Default: 1e+30

See also: **MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH**.

**MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH** *(real)*: Upper objective limit threshold. ⇐

If the upper objective cut \text{MSK_DPAR_UPPER_OBJ_CUT} is greater than this value, then it is treated as infinity.

Range: \([-\infty, \infty]\)
Default: 5e+29

**MSK_IPAR_AUTO_SORT_A_BEFORE_OPT** *(string)*: Controls whether the elements in each column of the coefficient matrix are sorted before an optimization is performed. ⇐

This is not required but makes the optimization insusceptible to reorderings of variables.

Default: **MSK_OFF**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_BICLEAN_OPTIMIZER** *(string)*: Controls which simplex optimizer is used in the clean-up phase. ⇐
Anything else than primal or dual simplex is equivalent to free simplex.

Default: MSK_OPTIMIZER_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_OPTIMIZER_FREE</td>
<td>The optimizer is chosen automatically.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_PRIMAL_SIMPLEX</td>
<td>The primal simplex optimizer is used.</td>

<tr>
<td>MSK_OPTIMIZER_DUAL_SIMPLEX</td>
<td>The dual simplex optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_FREE_SIMPLEX</td>
<td>One of the simplex optimizers is used.</td>
</tr>
</tbody>
</table>

MSK_IPAR_BI_IGNORE_MAX_ITER (string): Controls if basis identification is performed under certain conditions.

If the parameter MSK_IPAR_INTPNT_BASIS has the value MSK_BI_NO_ERROR and the interior-point optimizer has terminated due to maximum number of iterations, then basis identification is performed if this parameter has the value MSK_ON.

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

MSK_IPAR_BI_IGNORE_NUM_ERROR (string): Turns on basis identification if interior-point optimizer is terminated due to a numerical problem.

If the parameter MSK_IPAR_INTPNT_BASIS has the value MSK_BI_NO_ERROR and the interior-point optimizer has terminated due to a numerical problem, then basis identification is performed if this parameter has the value MSK_ON.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

MSK_IPAR_BI_MAX_ITERATIONS (integer): Controls the maximum number of simplex iterations allowed to optimize a basis after the basis identification.

Default: 1000000

MSK_IPAR_INFEAS_PREFER_PRIMAL (string): If both certificates of primal and dual infeasibility are supplied then only the primal is used when this option is turned on.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

MSK_IPAR_INFEAS_REPORT_AUTO (string): Controls whether an infeasibility report is auto-
matically produced after the optimization if the problem is primal or dual infeasible.

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INFEAS_REPORT_LEVEL** (*integer*): Controls the amount of information presented in an infeasibility report.

Higher values imply more information.

Default: 1

**MSK_IPAR_INTPNT_BASIS** (*string*): Controls whether the interior-point optimizer also computes an optimal basis.

Default: MSK_BI_ALWAYS

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_BI_NEVER</td>
<td>Never do basis identification.</td>
</tr>
<tr>
<td>MSK_BI_ALWAYS</td>
<td>Basis identification is always performed even if the interior-point optimizer terminates abnormally.</td>
</tr>
<tr>
<td>MSK_BI_NO_ERROR</td>
<td>Basis identification is performed if the interior-point optimizer terminates without an error.</td>
</tr>
<tr>
<td>MSK_BI_IF_FEASIBLE</td>
<td>Basis identification is not performed if the interior-point optimizer terminates with a problem status saying that the problem is primal or dual infeasible.</td>
</tr>
</tbody>
</table>

See also: **MSK_IPAR_BI_CLEAN_OPTIMIZER**, **MSK_IPAR_BI_IGNORE_MAX_ITER**, **MSK_IPAR_BI_IGNORE_NUM_ERROR**, **MSK_IPAR_BI_MAX_ITERATIONS**.

**MSK_IPAR_INTPNT_DIFF_STEP** (*string*): Controls whether different step sizes are allowed in the primal and dual space.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_MAX_ITERATIONS** (*integer*): Controls the maximum number of iterations allowed in the interior-point optimizer.

Default: GAMS IterLim

**MSK_IPAR_INTPNT_MAX_NUM_COR** (*integer*): Controls the maximum number of correctors allowed by the multiple corrector procedure.

A negative value means that MOSEK is making the choice.

Range: \{-1, ..., ∞\}

Default: -1
**MSK_IPAR_INTPNT_MAX_NUM_REFINEMENT_STEPS** *(integer)*: Maximum number of steps to be used by the iterative refinement of the search direction.  

A negative value implies that the optimizer chooses the maximum number of iterative refinement steps.

Range: \(\{-\infty, \ldots, \infty\}\)

Default: -1

**MSK_IPAR_INTPNT_OFF_COL_TRH** *(integer)*: Controls how aggressively offending columns are detected in the Jacobian of the constraint matrix.  

0 means no detection, 1 means aggressive detection, and higher values mean less aggressive detection.

Default: 40

**MSK_IPAR_INTPNT_ORDER_GP_NUM_SEEDS** *(integer)*: The GP ordering is dependent on a random seed.

Therefore, trying several random seeds may lead to a better ordering. This parameter controls the number of random seeds tried. A value of 0 means that MOSEK makes the choice.

Default: 0

**MSK_IPAR_INTPNT_ORDER_METHOD** *(string)*: Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system.

Default: **MSK_ORDER_METHOD_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ORDER_METHOD_FREE</td>
<td>The ordering method is chosen automatically.</td>
</tr>
<tr>
<td>MSK_ORDER_METHOD_APPMINLOC</td>
<td>Approximate minimum local fill-in ordering is employed.</td>
</tr>
<tr>
<td>MSK_ORDER_METHOD_TRY_GRAPHPAR</td>
<td>Always try the graph partitioning based ordering.</td>
</tr>
<tr>
<td>MSK_ORDER_METHOD_FORCE_GRAPHPAR</td>
<td>Always use the graph partitioning based ordering even if it is worse than the approximate minimum local fill ordering.</td>
</tr>
<tr>
<td>MSK_ORDER_METHOD_NONE</td>
<td>No ordering is used. Note using this value almost always leads to a significantly slow down.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_REGULARIZATION_USE** *(string)*: Controls whether regularization is allowed.

Default: **MSK_ON**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_SCALING** *(string)*: Controls how the problem is scaled before the interior-point optimizer is used.  

Default: MSK_SCALING_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SCALING_FREE</td>
<td>The optimizer chooses the scaling heuristic.</td>
</tr>
<tr>
<td>MSK_SCALING_NONE</td>
<td>No scaling is performed.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_SOLVE_FORM (string)**: Controls whether the primal or the dual problem is solved. 

Default: MSK_SOLVE_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SOLVE_FREE</td>
<td>The optimizer is free to solve either the primal or the dual problem.</td>
</tr>
<tr>
<td>MSK_SOLVE_PRIMAL</td>
<td>The optimizer should solve the primal problem.</td>
</tr>
<tr>
<td>MSK_SOLVE_DUAL</td>
<td>The optimizer should solve the dual problem.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_STARTING_POINT (string)**: Starting point used by the interior-point optimizer.

Default: MSK_STARTING_POINT_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_STARTING_POINT_FREE</td>
<td>The starting point is chosen automatically.</td>
</tr>
<tr>
<td>MSK_STARTING_POINT_GUESS</td>
<td>The optimizer guesses a starting point.</td>
</tr>
<tr>
<td>MSK_STARTING_POINT_CONSTANT</td>
<td>The optimizer constructs a starting point by assigning a constant value to all primal and dual variables. This starting point is normally robust.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_LOG (integer)**: Controls the amount of log information.

The value 0 implies that all log information is suppressed. A higher level implies that more information is logged.

Default: 10

**MSK_IPAR_LOG_BI (integer)**: Controls the amount of output printed by the basis identification procedure.

A higher level implies that more information is logged.

Default: 1

**MSK_IPAR_LOG_BI_FREQ (integer)**: Controls logging frequency of the basis identification

Default: 2500

**MSK_IPAR_LOG_FEAS_REPAIR (integer)**: Controls the amount of output printed when performing feasibility repair.

Default: 1

**MSK_IPAR_LOG_INFEAS_ANA (integer)**: Controls amount of output printed by the infeasibility analyzer procedures.
A higher level implies that more information is logged.

Default: 1

**MSK_IPAR_LOG_INTPNT (integer):** Controls amount of output printed by the interior-point optimizer. ←

A higher level implies that more information is logged.

Default: 1

**MSK_IPAR_LOG_MIO (integer):** Controls the log level for the mixed-integer optimizer. ←

A higher level implies that more information is logged.

Default: 4

**MSK_IPAR_LOG_MIO_FREQ (integer):** Controls how frequent the mixed-integer optimizer prints the log line. ←

It will print a line every time **MSK_INTPAR_LOG_MIO_FREQ** relaxations have been solved.

Range: \{-∞, ..., ∞\}

Default: 10

**MSK_IPAR_LOG_ORDER (integer):** If turned on, then factor lines are added to the log. ←

Default: 1

**MSK_IPAR_LOG_PRESOLVE (integer):** Controls amount of output printed by the presolve procedure. ←

A higher level implies that more information is logged.

Default: 1

**MSK_IPAR_LOG_RESPONSE (integer):** Controls amount of output printed when response codes are reported. ←

A higher level implies that more information is logged.

Default: 0

**MSK_IPAR_LOG_SIM (integer):** Controls amount of output printed by the simplex optimizer. ←

A higher level implies that more information is logged.

Default: 4

**MSK_IPAR_LOG_SIM_FREQ (integer):** Controls simplex optimizer logging frequency. ←

Default: 1000

**MSK_IPAR_LOG_STORAGE (integer):** When turned on, MOSEK prints messages regarding the storage usage and allocation. ←

Default: 0

**MSK_IPAR_MIO_BRANCH_DIR (string):** Controls whether the mixed-integer optimizer is branching up or down by default. ←

Default: **MSK_BRANCH_DIR_FREE**
The mixed-integer optimizer decides which branch to choose.

The mixed-integer optimizer always chooses the up branch first.

The mixed-integer optimizer always chooses the down branch first.

Branch in direction nearest to selected fractional variable.

Branch in direction farthest from selected fractional variable.

Chose direction based on root lp value of selected variable.

Branch in direction of current incumbent.

Branch based on the pseudocost of the variable.

**MSK_IPAR_MIO_CONIC_OUTER_APPROXIMATION (string):** If this option is turned on outer approximation is used when solving relaxations of conic problems; otherwise interior point is used.

Default: **MSK_OFF**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tbody>
</table>

MSK_IPAR_MIO_DUALRAY_ANALYSIS_LEVEL (string): Controls the amount of symmetry detection and handling employed by the mixed-integer optimizer in presolve. 

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses the level of dual ray analysis employed.</td>
</tr>
<tr>
<td>0</td>
<td>Dual ray analysis is disabled.</td>
</tr>
<tr>
<td>1</td>
<td>A lower amount of dual ray analysis is employed.</td>
</tr>
<tr>
<td>2</td>
<td>A higher amount of dual ray analysis is employed.</td>
</tr>
</tbody>
</table>

MSK_IPAR_MIO_FEASPUMP_LEVEL (string): Controls the way the Feasibility Pump heuristic is employed by the mixed-integer optimizer. 

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses how the Feasibility Pump is used.</td>
</tr>
<tr>
<td>0</td>
<td>The Feasibility Pump is disabled.</td>
</tr>
<tr>
<td>1</td>
<td>The Feasibility Pump is enabled with an effort to improve solution quality.</td>
</tr>
<tr>
<td>2</td>
<td>The Feasibility Pump is enabled with an effort to reach feasibility early.</td>
</tr>
</tbody>
</table>

MSK_IPAR_MIO_HEURISTIC_LEVEL (integer): Controls the heuristic employed by the mixed-integer optimizer to locate an initial good integer feasible solution. 

A value of zero means the heuristic is not used at all. A larger value than 0 means that a gradually more sophisticated heuristic is used which is computationally more expensive. A negative value implies that the optimizer chooses the heuristic. Normally a value around 3 to 5 should be optimal.

Range: \(-\infty, \ldots, \infty\)

Default: -1

MSK_IPAR_MIO_MAX_NUM_BRANCHES (integer): Maximum number of branches allowed during the branch and bound search. 

A negative value means infinite.

Range: \(-\infty, \ldots, \infty\)

Default: -1
**MSK_IPAR_MIO_MAX_NUM_RELAXS** (*integer*): Maximum number of relaxations allowed during the branch and bound search. 

A negative value means infinite.

Range: \{-\infty, ..., \infty\}

Default: `GAMS NodLim`

**MSK_IPAR_MIO_MAX_NUM_RESTARTS** (*integer*): Maximum number of restarts allowed during the branch and bound search.

Default: 0

**MSK_IPAR_MIO_MAX_NUM_ROOT_CUT_ROUNDS** (*integer*): Maximum number of cut separation rounds at the root node.

Default: 100

**MSK_IPAR_MIO_MAX_NUM_SOLUTIONS** (*integer*): The mixed-integer optimizer can be terminated after a certain number of different feasible solutions has been located.

If this parameter has the value \( n > 0 \), then the mixed-integer optimizer will be terminated when \( n \) feasible solutions have been located.

Range: \{-\infty, ..., \infty\}

Default: -1

**MSK_IPAR_MIO_MEMORY_EMPHASIS_LEVEL** (*string*): Controls how much emphasis is put on reducing memory usage.

Being more conservative about memory usage may come at the cost of decreased solution speed.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The optimizer chooses.</td>
</tr>
<tr>
<td>1</td>
<td>More emphasis is put on reducing memory usage and less on speed.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_MIN_REL** (*integer*): Number of times a variable must have been branched on for its pseudocost to be considered reliable.

Default: 5

**MSK_IPAR_MIO_NODE_OPTIMIZER** (*string*): Controls which optimizer is employed at the non-root nodes in the mixed-integer optimizer.

Default: `MSK_OPTIMIZER_FREE`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_OPTIMIZER_FREE</code></td>
<td>The optimizer is chosen automatically.</td>
</tr>
<tr>
<td><code>MSK_OPTIMIZER_INTPNT</code></td>
<td>The interior-point optimizer is used.</td>
</tr>
<tr>
<td><code>MSK_OPTIMIZER_CONIC</code></td>
<td>The optimizer for problems having conic constraints.</td>
</tr>
</tbody>
</table>
**value** | **meaning**  
---|---  
MSK_OPTIMIZER_PRIMAL_SIMPLEX | The primal simplex optimizer is used.  
MSK_OPTIMIZER_DUAL_SIMPLEX | The dual simplex optimizer is used.  
MSK_OPTIMIZER_FREE_SIMPLEX | One of the simplex optimizers is used.  
MSK_OPTIMIZER_MIXED_INT | The mixed-integer optimizer.

**MSK_IPAR_MIO_NODE_SELECTION** *(string)*: Controls the node selection strategy employed by the mixed-integer optimizer.  

Default: MSK_MIO_NODE_SELECTION_FREE

**value** | **meaning**  
---|---  
MSK_MIO_NODE_SELECTION_FREE | The optimizer decides the node selection strategy.  
MSK_MIO_NODE_SELECTION_FIRST | The optimizer employs a depth first node selection strategy.  
MSK_MIO_NODE_SELECTION_BEST | The optimizer employs a best bound node selection strategy.  
MSK_MIO_NODE_SELECTION_PSEUDO | The optimizer employs selects the node based on a pseudo cost estimate.

**MSK_IPAR_MIO_NUMERICAL_EMPHASIS_LEVEL** *(string)*: Controls how much emphasis is put on reducing numerical problems possibly at the expense of solution speed.  

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The optimizer chooses.</td>
</tr>
<tr>
<td>1</td>
<td>More emphasis is put on reducing numerical problems.</td>
</tr>
<tr>
<td>2</td>
<td>Even more emphasis.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE** *(string)*: Enables or disables perspective reformulation in presolve.  

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_PRESOLVE_AGGREGATOR_USE** *(string)*: Controls if the aggregator should be used.  

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_PROBING_LEVEL** *(integer)*: Controls the amount of probing employed by the
mixed-integer optimizer in presolve. 

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses the level of probing employed</td>
</tr>
<tr>
<td>0</td>
<td>Probing is disabled</td>
</tr>
<tr>
<td>1</td>
<td>A low amount of probing is employed</td>
</tr>
<tr>
<td>2</td>
<td>A medium amount of probing is employed</td>
</tr>
<tr>
<td>3</td>
<td>A high amount of probing is employed</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_PROPAGATE_OBJECTIVE_CONSTRAINT** (string): Use objective domain propagation. 

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_QCQO_REFORMULATION_METHOD** (string): Controls what reformulation method is applied to mixed-integer quadratic problems. 

Default: MSK_MIO_QCQO_REFORMULATION_METHOD_FREE

<table>
<thead>
<tr>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_MIO_QCQO_REFORMULATION_METHOD_FREE</td>
</tr>
<tr>
<td>MSK_MIO_QCQO_REFORMULATION_METHOD_NONE</td>
</tr>
<tr>
<td>MSK_MIO_QCQO_REFORMULATION_METHOD_LINEARIZATION</td>
</tr>
<tr>
<td>MSK_MIO_QCQO_REFORMULATION_METHOD_EIGEN_METHOD</td>
</tr>
<tr>
<td>MSK_MIO_QCQO_REFORMULATION_METHOD_DIAG_PERT</td>
</tr>
<tr>
<td>MSK_MIO_QCQO_REFORMULATION_METHOD_RELAX</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_RINS_MAX_NODES** (integer): Controls the maximum number of nodes allowed in each call to the RINS heuristic. 

The default value of -1 means that the value is determined automatically. A value of zero turns off the heuristic.

Range: \{-1, ..., \infty\}

Default: -1

**MSK_IPAR_MIO_ROOT_OPTIMIZER** (string): Controls which optimizer is employed at the root node in the mixed-integer optimizer. 

Default: MSK_OPTIMIZER_FREE
The optimizer is chosen automatically.

The interior-point optimizer is used.

The optimizer for problems having conic constraints.

The primal simplex optimizer is used.

The dual simplex optimizer is used.

One of the simplex optimizers is used.

Default: -1

-1 The optimizer chooses whether presolve is repeated.
0 Never repeat presolve.
1 Always repeat presolve.

Selecting a different seed can change the path the optimizer takes to the optimal solution.

Default: 42

Controls the amount of symmetry detection and handling employed by the mixed-integer optimizer.

Default: -1

-1 The optimizer chooses the level of symmetry detection and handling employed.
0 Symmetry detection and handling is disabled.
1 A low amount of symmetry detection and handling is employed.
2 A medium amount of symmetry detection and handling is employed.
3 A high amount of symmetry detection and handling is employed.
4 An extremely high amount of symmetry detection and handling is employed.

Controls the variable selection strategy employed by the mixed-integer optimizer.

Default: MSK_MIO_VAR_SELECTION_FREE

The optimizer decides the variable selection strategy.

The optimizer employs pseudocost variable selection.

The optimizer employs strong branching variable selection.
**MSK_IPAR_MIO_VB_DETECTION_LEVEL** (integer): Controls how much effort is put into detecting variable bounds. 

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses.</td>
</tr>
<tr>
<td>0</td>
<td>No variable bounds are detected.</td>
</tr>
<tr>
<td>1</td>
<td>Only detect variable bounds that are directly represented in the problem.</td>
</tr>
<tr>
<td>2</td>
<td>Detect variable bounds in probing.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_NUM_THREADS** (integer): Controls the number of threads employed by the optimizer.

If set to 0 the number of threads used will be equal to the number of cores detected on the machine.

Default: GAMS Threads

**MSK_IPAR_OPF_WRITE_HEADER** (string): Write a text header with date and MOSEK version in an OPF file.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_HINTS** (string): Write a hint section with problem dimensions in the beginning of an OPF file.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_LINE_LENGTH** (integer): Aim to keep lines in OPF files not much longer than this.

Default: 80

**MSK_IPAR_OPF_WRITE_PARAMETERS** (string): Write a parameter section in an OPF file.

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_PROBLEM** (string): Write objective, constraints, bounds etc.
to an OPF file.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>

<td>MSK_OPTIMIZER_MIXED_INT</td>
<td>The mixed-integer optimizer.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL** (integer): Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve. ←

A negative value means the parameter value is selected automatically.

Range: \{-\infty, ..., \infty\}

Default: -1

**MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_NUMTRIES** (integer): Control the maximum number of times the eliminator is tried. ←

A negative value implies MOSEK decides.

Range: \{-\infty, ..., \infty\}

Default: -1

**MSK_IPAR_PRESOLVE_LINDEP_ABS_WORK_TRH** (integer): Controls the linear dependency check, which is potentially computationally expensive. ←

Range: \{-\infty, ..., \infty\}

Default: 100

**MSK_IPAR_PRESOLVE_LINDEP_NEW** (string): Controls whether a new experimental linear dependency checker is employed. ←

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PRESOLVE_LINDEP_REL_WORK_TRH** (integer): Controls the linear dependency check, which is potentially computationally expensive. ←

Range: \{-\infty, ..., \infty\}

Default: 100
**MSK_IPAR_PRESOLVE_LINDEP_USE** *(string)*: Controls whether the linear constraints are checked for linear dependencies.  

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PRESOLVE_MAX_NUM_PASS** *(integer)*: Controls the maximum number of times presolve passes over the problem.  

A negative value implies MOSEK decides.

Range: \(-\infty, ..., \infty\)

Default: -1

**MSK_IPAR_PRESOLVE_MAX_NUM_REDUCTIONS** *(integer)*: Controls the maximum number of reductions performed by the presolve.  

The value of the parameter is normally only changed in connection with debugging. A negative value implies that an infinite number of reductions are allowed.

Range: \(-\infty, ..., \infty\)

Default: -1

**MSK_IPAR_PRESOLVE_USE** *(string)*: Controls whether the presolve is applied to a problem before it is optimized.  

Default: MSK_PRESOLVE_MODE_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_PRESOLVE_MODE_OFF</td>
<td>The problem is not presolved before it is optimized.</td>
</tr>
<tr>
<td>MSK_PRESOLVE_MODE_ON</td>
<td>The problem is presolved before it is optimized.</td>
</tr>
<tr>
<td>MSK_PRESOLVE_MODE_FREE</td>
<td>It is decided automatically whether to presolve before the problem is optimized.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PTF_WRITE_PARAMETERS** *(string)*: If enabled, then the parameters section is written.  

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PTF_WRITE_SOLUTIONS** *(string)*: If enabled, then the solution section is written if any solutions are available, otherwise solution section is not written even if solutions are available.  

Default: MSK_OFF
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PTF_WRITE_TRANSFORM** *(string)*: If enabled, then constraint blocks with identifiable conic slacks are transformed into conic constraints and the slacks are eliminated. 

Default: **MSK_ON**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_SIM_BASIS_FACTOR_USE** *(string)*: Controls whether an LU factorization of the basis is used in a hot-start. 

Forcing a refactorization sometimes improves the stability of the simplex optimizers, but in most cases there is a performance penalty.

Default: **MSK_ON**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_SIM_DEGEN** *(string)*: Controls how aggressively degeneration is handled.

Default: **MSK_SIM_DEGEN_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SIM_DEGEN_NONE</td>
<td>The simplex optimizer should use no degeneration strategy.</td>
</tr>
<tr>
<td>MSK_SIM_DEGEN_FREE</td>
<td>The simplex optimizer chooses the degeneration strategy.</td>
</tr>
<tr>
<td>MSK_SIM_DEGEN_AGGRESSIVE</td>
<td>The simplex optimizer should use an aggressive degeneration strategy.</td>
</tr>
<tr>
<td>MSK_SIM_DEGEN_MODERATE</td>
<td>The simplex optimizer should use a moderate degeneration strategy.</td>
</tr>
<tr>
<td>MSK_SIM_DEGEN_MINIMUM</td>
<td>The simplex optimizer should use a minimum degeneration strategy.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_SIM_DUAL_CRASH** *(integer)*: Controls whether crashing is performed in the dual simplex optimizer. 

In general if a basis consists of more than \((100 + \text{MSK_IPAR_SIM_DUAL_CRASH})\) percent fixed variables, then a crash will be performed.

Default: **90**

**MSK_IPAR_SIM_DUAL_RESTRICT_SELECTION** *(integer)*: Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the dual simplex. 

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
The dual simplex optimizer can use a so-called restricted selection/pricing strategy to chooses the outgoing variable. Hence, if restricted selection is applied, then the dual simplex optimizer first choose a subset of all the potential outgoing variables. Next, for some time it will choose the outgoing variable only among the subset. From time to time the subset is redefined. A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Range: \( \{0, ..., 100\} \)

Default: 50

**MSK_IPAR_SIM_DUAL_SELECTION** (*string*): Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer.

Default: **MSK_SIM_SELECTION_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SIM_SELECTION_FREE</td>
<td>The optimizer chooses the pricing strategy.</td>
</tr>
<tr>
<td>MSK_SIM_SELECTION_FULL</td>
<td>The optimizer uses full pricing.</td>
</tr>
<tr>
<td>MSK_SIM_SELECTION_ASE</td>
<td>The optimizer uses approximate steepest-edge pricing.</td>
</tr>
<tr>
<td>MSK_SIM_SELECTION_DEVEX</td>
<td>The optimizer uses devex steepest-edge pricing. If it is not available an approximate steep-edge selection is chosen.</td>
</tr>
<tr>
<td>MSK_SIM_SELECTION_SE</td>
<td>The optimizer uses steepest-edge selection.</td>
</tr>
<tr>
<td>MSK_SIM_SELECTION_PARTIAL</td>
<td>The optimizer uses a partial selection approach. The approach is usually beneficial if the number of variables is much larger than the number of constraints.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_SIM_EXPLOIT_DUPVEC** (*string*): Controls if the simplex optimizers are allowed to exploit duplicated columns.

Default: **MSK_SIM_EXPLOIT_DUPVEC_OFF**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SIM_EXPLOIT_DUPVEC_ON</td>
<td>Allow the simplex optimizer to exploit duplicated columns.</td>
</tr>
<tr>
<td>MSK_SIM_EXPLOIT_DUPVEC_OFF</td>
<td>Disallow the simplex optimizer to exploit duplicated columns.</td>
</tr>
<tr>
<td>MSK_SIM_EXPLOIT_DUPVEC_FREE</td>
<td>The simplex optimizer can choose freely.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_SIM_HOTSTART** (*string*): Controls the type of hot-start that the simplex optimizer perform.

Default: **MSK_SIM_HOTSTART_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SIM_HOTSTART_NONE</td>
<td>The simplex optimizer performs a coldstart.</td>
</tr>
<tr>
<td>MSK_SIM_HOTSTART_FREE</td>
<td>The simplex optimizer chooses the hot-start type.</td>
</tr>
<tr>
<td>MSK_SIM_HOTSTART_STATUS_KEYS</td>
<td>Only the status keys of the constraints and variables are used to choose the type of hot-start.</td>
</tr>
</tbody>
</table>
**MSK_IPAR_SIM_HOTSTART_LU** *(string):* Determines if the simplex optimizer should exploit the initial factorization.  

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**Default:** MSK_ON

**MSK_IPAR_SIM_MAX_ITERATIONS** *(integer):* Maximum number of iterations that can be used by a simplex optimizer.  

Default: GAMS IterLim

**MSK_IPAR_SIM_MAX_NUM_SETBACKS** *(integer):* Controls how many set-backs are allowed within a simplex optimizer.  

A set-back is an event where the optimizer moves in the wrong direction. This is impossible in theory but may happen due to numerical problems.

Default: 250

**MSK_IPAR_SIM_NON_SINGULAR** *(string):* Controls if the simplex optimizer ensures a non-singular basis, if possible.  

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>

**Default:** MSK_ON

**MSK_IPAR_SIM_PRIMAL_CRASH** *(integer):* Controls whether crashing is performed in the primal simplex optimizer.  

In general if a basis consists of more than \((100 \times \text{MSK_IPAR_SIM_PRIMAL_CRASH})\) percent fixed variables, then a crash will be performed.

Default: 90

**MSK_IPAR_SIM_PRIMAL_RESTRICT_SELECTION** *(integer):* Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the primal simplex.  

The primal simplex optimizer can use a so-called restricted selection/pricing strategy to choose the outgoing variable. Hence, if restricted selection is applied, then the primal simplex optimizer first choose a subset of all the potential incoming variables. Next, for some time it will choose the incoming variable only among the subset. From time to time the subset is redefined. A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Range: \{0, ..., 100\}

Default: 50

**MSK_IPAR_SIM_PRIMAL_SELECTION** *(string):* Controls the choice of the incoming variable, known as the selection strategy, in the primal simplex optimizer.  

Default: MSK_SIM_SELECTION_FREE
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>

<tr>
<td>MSK_SOLVE_PRIMAL</td>
<td>The optimizer should solve the primal problem.</td>
</tr>
<tr>
<td>MSK_SOLVE_DUAL</td>
<td>The optimizer should solve the dual problem.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_SIM_STABILITY_PRIORITY** *(integer)*: Controls how high priority the numerical stability should be given.

- Range: \{0, ..., 100\}
- Default: 50

**MSK_IPAR_SIM_SWITCH_OPTIMIZER** *(string)*: Controls the simplex behavior.

The simplex optimizer sometimes chooses to solve the dual problem instead of the primal problem. This implies that if you have chosen to use the dual simplex optimizer and the problem is dualized, then it actually makes sense to use the primal simplex optimizer instead. If this parameter is on and the problem is dualized and furthermore the simplex optimizer is chosen to be the primal (dual) one, then it is switched to the dual (primal).

- Default: MSK_OFF

<table>

<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_WRITE_LP_LINE_WIDTH** *(integer)*: Maximum width of line in an LP file written by MOSEK.  

Range: \{40, ..., \infty\}

Default: 80
**MSK_IPAR_WRITE_MPS_FORMAT** *(string)*: Controls in which format the MPS is written. 

Default: **MSK_MPS_FORMAT_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_MPS_FORMAT_STRICT</td>
<td>It is assumed that the input file satisfies the MPS format strictly.</td>
</tr>
<tr>
<td>MSK_MPS_FORMAT_RELAXED</td>
<td>It is assumed that the input file satisfies a slightly relaxed version of the MPS format.</td>
</tr>
<tr>
<td>MSK_MPS_FORMAT_FREE</td>
<td>It is assumed that the input file satisfies the free MPS format. This implies that spaces are not allowed in names. Otherwise the format is free.</td>
</tr>
<tr>
<td>MSK_MPS_FORMAT_CPLEX</td>
<td>The CPLEX compatible version of the MPS format is employed.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_WRITE_MPS_INT** *(string)*: Controls if marker records are written to the MPS file to indicate whether variables are integer restricted.

Default: **MSK_ON**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>

2398 Solver Manuals
5.28 NLPEC

5.28.1 Introduction

The GAMS/NLPEC solver, developed jointly by Michael Ferris of UW-Madison and GAMS Development, solves MPEC and MCP models via reformulation of the complementarity constraints. The resulting sequence of NLP models are parameterized by a scalar $\mu$ and solved by existing NLP solvers. The resulting solutions are used to recover an MPEC or MCP solution.

GAMS/NLPEC serves a number of purposes. In many cases, it is an effective tool for solving MPEC models, the first such tool available within GAMS. It also serves as a way to experiment with the many reformulation strategies proposed for solving MPEC and MCP models. Without something like NLPEC (and a library of models to test with) a comprehensive and thorough test and comparison of the various reformulation strategies would not be possible. To better serve these purposes, NLPEC has an open architecture. The model reformulations are written out as GAMS source for solution via an NLP solver, so it is possible to view this source and modify it if desired.

A brief note about notation is in order. The GAMS keyword positive is used to indicate nonnegative variables. The same holds for nonpositive variables and the GAMS keyword negative.

5.28.2 Usage

GAMS/NLPEC can solve models of two types: MPEC and MCP. If you did not specify NLPEC as the default MPEC or MCP solver, use the following statement in your GAMS model before the solve statement:

```gams
option MPEC=nlpec; { or MCP }
```

You can also make NLPEC the default solver via the command line:

```gams
gams nash MPEC=nlpec MCP=nlpec
```

You can use NLPEC with its default strategy and formulation, but most users will want to use an options file (Section Options) after reading about the different types of reformulations possible (Section Reformulation). In addition, an understanding of the architecture of NLPEC (Section Open Architecture) will be helpful in understanding how GAMS options are treated. Although NLPEC doesn't use the GAMS options workspace, workfactor, optcr, optca, reslim, iterlim, and domlim directly, it passes these options on in the reformulated model so they are available to the NLP subsolver.

5.28.3 Reformulation

In this section we describe the different ways that the NLPEC solver can reformulate an MPEC as an NLP. The description also applies to MCP models: just consider MCP to be an MPEC with a constant objective. The choice of reformulation, and the subsidiary choices each reformulation entails, are controlled by the options described in the section on Setting the Reformulation Options and referenced throughout this section.

The original MPEC model is given as:

$$\min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m} f(x, y)$$

(1)
subject to the constraints
\[ g(x, y) \leq 0 \]  
and
\[ y \text{ solves } \text{MCP}(h(x, \cdot), B). \]

In most of the reformulations, the objective function (1) is included in the reformulated model without change. In some cases, it may be augmented with a penalty function. The variables \( x \) are typically called upper level variables (because they are associated with the upper level optimization problem) whereas the variables \( y \) are sometimes termed lower level variables.

The constraints (2) are standard nonlinear programming constraints specified in GAMS in the standard fashion. In particular, these constraints may be less than inequalities as shown above, or equalities or greater than inequalities. The constraints will be unaltered by all our reformulations. These constraints may involve both \( x \) and \( y \), or just \( x \) or just \( y \), or may not be present at all in the problem.

The constraints of interest are the equilibrium constraints (3), where (3) signifies that \( y \in \mathbb{R}^m \) is a solution to the mixed complementarity problem (MCP) defined by the function \( h(x, \cdot) \) and the box \( B \) containing (possibly infinite) simple bounds on the variables \( y \). A point \( y \) with \( a_i \leq y_i \leq b_i \) solves (3) if for each \( i \) at least one of the following holds:

\[ h_i(x, y) = 0 \]
\[ h_i(x, y) \geq 0, \quad y_i = a_i; \]
\[ h_i(x, y) \leq 0, \quad y_i = b_i. \]

As a special case of (4), consider the case where \( a = 0 \) and \( b = +\infty \). Since \( y_i \) can never be \( +\infty \) at a solution, (4) simplifies to the nonlinear complementarity problem (NCP):

\[ 0 \leq h_i(x, y), 0 \leq y_i \text{ and } y_i h_i(x, y) = 0, \quad i = 1, \ldots, m \]

namely that \( h \) and \( y \) are nonnegative vectors with \( h \) perpendicular to \( y \). This motivates our shorthand for (4), the "perp to" symbol \( \perp \):

\[ h_i(x, y) \perp y_i \in [a_i, b_i] \]

The different ways to force (6) to hold using (smooth) NLP constraints are the basis of the NLPEC solver.

We introduce a simple example now that we will use throughout this document for expositional purposes:

\[ \min_{x_1, x_2, y_1, y_2} x_1 + x_2 \]
subject to
\[ x_1^2 + x_2^2 \leq 1 \]
\[ y_1 - y_2 + 1 \leq x_1 \perp y_1 \geq 0 \]
\[ x_2 + y_2 \perp y_2 \in [-1, 1] \]

This problem has the unique solution \( x_1 = 0, x_2 = -1, y_1 = 0, y_2 = 1 \). Note that \( f(x, y) = x_1 + x_2 \) and \( g(x, y) = x_1^2 + x_2^2 - 1 \) are the objective function and the standard nonlinear programming constraints for this problem. The function \( h(x, y) \) is given by:

\[ h(x, y) = \begin{bmatrix} x_1 - y_1 + y_2 - 1 \\ x_2 + y_2 \end{bmatrix} \]

and
\[ a = \begin{bmatrix} 0 \\ -1 \end{bmatrix}, \quad b = \begin{bmatrix} \infty \\ 1 \end{bmatrix} \].

This example is written very succinctly in GAMS notation as:
$TITLE simple mpec example

variable f, x1, x2, y1, y2;
positive variable y1;
y2.lo = -1;
y2.up = 1;

equations cost, g, h1, h2;

cost.. f =E= x1 + x2;
g.. sqr(x1) + sqr(x2) =L= 1;
h1.. x1 =G= y1 - y2 + 1;
h2.. x2 + y2 =N= 0;

model example / cost, g, h1.y1, h2.y2 /;
solve example using mpec min f;

Note that the equation cost is used to define f, the constraint g defines the function g, and h is defined by h1 and h2. The complementarity constraints utilize the standard GAMS convention of specifying the orthogonality relationship between h and y in the model statement. The interpretation of the "." relies on the bounds a and b that are specified using positive, negative, or lo and up keywords in GAMS.

Note that since h2 really specifies a function h and not a constraint h2(x,y) = 0, we use the GAMS syntax =N= to ensure this is clear here. Since the relationships satisfied by h1 and h2 are determined by the bounds, =G= could also be replaced by =N= in h1.

In describing the various reformulations for (6), it is convenient to partition the y variables into free F, lower bounded L, upper bounded U and doubly bounded B variables respectively, that is:

\[ B := \{ y = (y_F, y_L, y_U, y_B) : a_L \leq y_L \leq b_L, a_U \leq y_U \leq b_U, a_B \leq y_B \leq b_B \} \]

We will assume (without loss of generality) that \( a_B < b_B \). If \( a_i = b_i \) then (6) holds trivially for the index i and we can remove the constraint \( h_i \) and its corresponding (fixed) variable \( y_i \) from the model. The complementarity condition for variables in \( y_i \in F \) is simply the equality \( h_i(x,y) = 0 \) so these equality constraints are moved directly into the NLP constraints of the original model as equalities. Thus, NLPEC needs only to treat the singly-bounded variables in \( L \) and \( U \) and the doubly-bounded variables in \( B \). In the above example, \( L = \{ 1 \}, U = \emptyset \) and \( B = \{ 2 \} \).

5.28.3.1 Product reformulations

Product reformulations all involve products of \( y_i \) with \( h_i \), or products of \( y_i \) with some auxiliary or slack variables that are set equal to \( h_i \). The underlying point is that the constraints (3) are entirely equivalent to the following system of equalities and inequalities:

\[
\begin{align*}
    w_L &= h_L(x,y), \quad a_L \leq y_L \leq b_L, \quad w_L \geq 0 \quad \text{and} \quad (y_L - a_L)^T w_L = 0 \\
    v_U &= -h_U(x,y), \quad a_U \leq y_U \leq b_U, \quad v_U \geq 0 \quad \text{and} \quad (b_U - y_U)^T v_U = 0 \\
    w_B - v_B &= h_B(x,y), \quad a_B \leq y_B \leq b_B, \quad w_B \geq 0, \quad v_B \geq 0 \\
    (y_B - a_B)^T w_B &= 0, \quad (b_B - y_B)^T v_B &= 0.
\end{align*}
\]  

Note that each inner product is a summation of products of nonnegative terms: a slack variable and the difference between a variable and its bound. In each of these products, either the slack variable or its complement must be zero in order to have a solution. Complementarity is forced by the multiplication of these two terms. The above reformulation is specified using option reftype mult.

There are a number of variations on this theme, all of which can be specified via an options file. All of the inner products could be put into the same equation, left as in (7) above, or broken out into individual products (one for each \( i \in L \cup U \), two for each \( i \in B \)). For example, the complementarity constraints

\[
\begin{align*}
    w_L &= h_L(x,y), \quad a_L \leq y_L \leq b_L, \quad w_L \geq 0 \quad \text{and} \quad (y_L - a_L)^T w_L = 0 \\
    v_U &= -h_U(x,y), \quad a_U \leq y_U \leq b_U, \quad v_U \geq 0 \quad \text{and} \quad (b_U - y_U)^T v_U = 0 \\
    w_B - v_B &= h_B(x,y), \quad a_B \leq y_B \leq b_B, \quad w_B \geq 0, \quad v_B \geq 0 \\
    (y_B - a_B)^T w_B &= 0, \quad (b_B - y_B)^T v_B &= 0.
\end{align*}
\]
associated with lower bounded variables involve nonnegativity of \( w_L, y_L \geq a_L \) and either of the following alternatives:

\[
(y_L - a_L)^T w_L = \sum (i \in L (y_i - a_i)) w_i = 0
\]

or

\[(y_i - a_i)w_i = 0, i = 1, \ldots, m\]

These different levels of aggregation are chosen using option `aggregate none|partial|full`.

Since all of the inner products in (7) involve nonnegative terms, we can set the inner products equal to zero or set them \( \leq 0 \) without changing the feasible set. To choose one or the other, use the option `constraint equality|inequality`.

As a concrete example, consider the option file

```
reftype mult
aggregate none
constraint inequality
```

applied to the simple example given above. Such an option file generates the nonlinear programming model:

\[
\begin{align*}
\text{min} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\
& \quad w_1 y_1 \leq \mu \\
& \quad w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1, 1] \\
& \quad (y_2 + 1)w_2 \leq \mu, (1 - y_2)v_2 \leq \mu
\end{align*}
\]

(8)

By default, a single model is generated with the value \( \mu \) set to 0. There are many examples (e.g. interior point codes, many LP and NLP packages, published results on reformulation approaches to MPEC) that illustrate the value of starting with a “nearly-complementary” solution and pushing the complementarity gap down to zero. For this reason, the inner products in (7) above are always set equal to (or \( \leq \)) a scalar \( \mu \) instead of zero. By default \( \mu \) is zero, but options exist to start \( \mu \) at a positive value (e.g. \texttt{InitMu 1e-2}), to decrease it by a constant factor in a series of looped solves (e.g. \texttt{NumSolves 4, UpdateFac 0.1}), and to solve one last time with a final value for \( \mu \) (e.g. \texttt{FinalMu 0}). If the following lines are added to the option file

```
initmu 1.0 
num solves 4
```

then five consecutive solves of the nonlinear program (8) are performed, the first one using \( \mu = 1 \) and each subsequent solve dividing \( \mu \) by 10 (and starting the NLP solver at the solution of the previous model in this sequence).

As a final example, we use a combination of these options to generate a sequence of nonlinear programs whose solutions attempt to trace out the “central path” favored by interior point and barrier algorithms:

```
reftype mult 
constraint equality
initmu 1.0
num solves 4
updatefac 0.1
finalmu 1e-6
```

produces 6 nonlinear programs of the form

\[
\begin{align*}
\text{min} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\
& \quad w_1 y_1 = \mu \\
& \quad w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1, 1] \\
& \quad (y_2 + 1)w_2 = \mu, (y_2 - 1)v_2 = \mu
\end{align*}
\]

for values of \( \mu = 1, 0.1, 0.01, 0.001, 0.0001 \) and 1e-6.
Slacks and doubly bounded variables

Slack variables can be used to reduce the number of times a complex nonlinear expression appears in the nonlinear programming model, as was carried out in (7). For a simpler illustrative example the NCP constraints (5) are equivalent to the constraints:

\[ w_i = h_i(x, y), \quad 0 \leq w_i, \quad 0 \leq y_i, \quad y_i w_i = 0, \quad i = 1, \ldots, m \]

This reformulation has an additional equality constraint, and additional variables \( w \), but the expression \( h_i \) only appears once. There are cases when this formulation will be preferable, and the simple option \texttt{slack none|positive} controls the use of the \( w \) variables.

When there are doubly bounded variables present, these two slack options work slightly differently. For the \texttt{positive} case, the reformulation introduces two nonnegative variables \( w_i \) and \( v_i \) that take on the positive and negative parts of \( h_i \) at the solution as shown in (7). Since this is the default value of the option \texttt{slack}, the example (8) shows what ensues to both singly and doubly bounded variables under this setting.

For the case \texttt{slack none}, Scholtes proposed a way to use a multiplication to force complementarity that requires no slack variables:

\[
\begin{align*}
\begin{array}{c}
\mathbf{h}_i \perp \\
\mathbf{a}_i \leq \mathbf{y}_i \leq \mathbf{b}_i \iff \mathbf{a}_i \leq \mathbf{y}_i \leq \mathbf{b}_i, \quad (\mathbf{y}_i - \mathbf{a}_i)\mathbf{h}_i \leq \mu, \quad (\mathbf{y}_i - \mathbf{b}_i)\mathbf{h}_i \leq \mu
\end{array}
\end{align*}
\]

Note that unlike the inner products in Section Reformulation, we can expect that one of the inequalities in (9) is unlikely to be binding at a solution (i.e. when \( h_i \) is nonzero). Therefore, we cannot use an equality in this reformulation, and furthermore the products must not be aggregated. Thus, if you use this option, the reformulation automatically enforces the additional options \texttt{constraint inequality} and \texttt{aggregate none} on the doubly bounded variables, even if the user specifies a conflicting option. Thus the option file

\texttt{reftype mult}
\texttt{slack none}

results in the model

\[
\begin{align*}
\min_{x_1,x_2,y_1,y_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad x_1 - y_1 + y_2 - 1 \geq 0, \quad y_1 \geq 0 \\
& \quad (x_1 - y_1 + y_2 - 1)y_1 = \mu \\
& \quad y_2 \in [-1,1], \quad (y_2 + 1)(x_2 + y_2) \leq \mu, \quad (y_2 - 1)(x_2 + y_2) \leq \mu
\end{align*}
\]

Note that the complementarity constraint associated with \( y_1 \) is an equality (the default) while the constraints associated with \( y_2 \) are inequalities for the reasons outlined above.

In the case of doubly bounded variables, a third option is available for the slack variables, namely \texttt{slack one}. In this case, only one slack is introduced, and this slack removes the need to write the function \( h_i \) twice in the reformulated model as follows:

\[
\begin{align*}
\mathbf{h}_i(x, y) \perp \mathbf{a}_i \leq \mathbf{y}_i \leq \mathbf{b}_i \iff \mathbf{a}_i \leq \mathbf{y}_i \leq \mathbf{b}_i, \quad w_i = h_i(x, y), \quad (y_i - a_i)w_i \leq \mu, \quad (y_i - b_i)w_i \leq \mu
\end{align*}
\]

Note that the slack variable \( w \) that is introduced is a free variable. It is not known before solving the problem whether \( w_i \) will be positive or negative at the solution.

We take this opportunity to introduce a simple extension to our option mechanism, namely the ability to set the options for singly and doubly bounded variables differently. For example, the option file

\[
\begin{align*}
\texttt{reftype mult} \\
\texttt{slack positive one}
\end{align*}
\]
sets the option slack positive for the singly bounded variables and the option slack one for the doubly bounded variables resulting in the model

\[
\begin{align*}
\min_{x_1, x_2, y_1, y_2, w_1, w_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\
& \quad w_1 y_1 = \mu_1 \\
& \quad w_2 = x_2 + y_2, y_2 \in [-1, 1], (y_2 + 1) w_2 \leq \mu_2, (y_2 - 1) w_2 \leq \mu_2
\end{align*}
\]

Additional options such as

\begin{verbatim}
initmu 1.0 3.0
num solves 2
updat fac 0.1 0.2
\end{verbatim}

allow the values of \( \mu \) for the singly and doubly bounded variables to be controlled separately. In this case \( \mu_1 \) takes on values of 1, 0.1 and 0.01, while \( \mu_2 \) takes on values 3.0, 0.6 and 0.12 in each of the three nonlinear programming models generated.

### 5.28.3.2 NCP functions

An NCP-function is a function \( \phi(r, s) \) with the following property:

\[
\phi(r, s) = 0 \iff r \geq 0, s \geq 0, rs = 0
\]

Clearly, finding a zero of an NCP-function solves a complementarity problem in \( (r, s) \). We can replace the inner products of nonnegative vectors in (7) with a vector of NCP functions whose arguments are complementary pairs, e.g. \((y_L - a_L)^T w_L = 0\) becomes \(\phi(y_i - a_i, w_i) = 0, i \in L\) and arrive at another way to treat the complementarity conditions. Note that an NCP function forces both nonnegativity and complementarity, so constraints to explicitly force nonnegativity are not required, though they can be included.

Examples of NCP functions include the min function, \( \min(r, s) \), and the Fischer-Burmeister function

\[
\phi(r, s) = \sqrt{r^2 + s^2} - r - s
\]

There is no requirement that an NCP function be nonnegative everywhere (it may be strictly negative at some points), so there is little point in setting the option constraint; it will automatically take on the value constraint equality. NCP functions cannot be aggregated, so the aggregate option will always be set to none.

Since the arguments to the NCP functions are going to be nonnegative at solution, we cannot use the functions \( h_i \) directly in the case of doubly-bounded variables. We must use slacks \( w - v = h_i \) to separate \( h_i \) into its positive and negative parts (but see Section Doubly bounded variables below). The slacks can be positive or free, since the NCP function will force positivity at solution. For the singly-bounded variables, slacks are optional, and can also be positive or free.

Both of the NCP functions mentioned above suffer from being non-differentiable at the origin (and at points where \( r = s \) for the min function). Various smoothed NCP-functions have been proposed that are differentiable. These smooth functions are parameterized by \( \mu \), and approach the true NCP-function as the smoothing parameter approaches zero. For example, the Fischer-Burmeister function includes a perturbation \( \mu \) that guarantees differentiability:

\[
\phi_{FB}(r, s) := \sqrt{r^2 + s^2 + 2\mu} - (r + s).
\]

You can choose these particular NCP functions using option RefType min|FB|fFB. The difference between the last two is that RefType FB writes out GAMS code to compute the function \( \phi_{FB} \), while RefType fFB makes use of the GAMS intrinsic function NCPFB(r,s,\mu) that computes \( \phi_{FB} \) internally. In general, using the GAMS intrinsic function should work better since the intrinsic can guard against overflow, scale the arguments before computing the function, and use alternative formulas that give more accurate results for certain input ranges.

As an example, the option file
generates the reformulation
\[
\begin{align*}
\min_{x_1,x_2,y_1,y_2,w_1,w_2,v_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1 \\
& \quad \phi_{FB}(w_1,y_1,\mu) = 0 \\
& \quad w_2 - v_2 = x_2 + y_2 \\
& \quad \phi_{FB}(y_2 + 1, w_2, \mu) = 0, \; \phi_{FB}(1 - y_2, v_2, \mu) = 0
\end{align*}
\]
with a value of \( \mu = 0.01 \). Following a path of solutions for decreasing values of \( \mu \) is possible using the options discussed above.

Each of the two arguments to the NCP function will be nonnegative at solution, but for each argument we have the option of including a nonnegativity constraint explicitly as well. This results in the 4 values for the option NCPBounds none|all|function|variable. When no slacks are present, this option controls whether to bound the function \( h_i \) as well as including it in the NCP function, e.g. \( h_i \geq 0, \phi(h_i, y_i - a_i) = 0 \).

When slacks are present, we require that the slack setting be consistent with the bound setting for the function argument to the NCP function, where NCPBounds none|variable is consistent with free slack variables and NCPBounds all|function is consistent with positive slack variables.

Thus, the option file

\begin{verbatim}
reftype min
slack positive
NCPBounds function
\end{verbatim}

generates the reformulation
\[
\begin{align*}
\min_{x_1,x_2,y_1,y_2,w_1,w_2,v_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, \; w_1 \geq 0 \\
& \quad \min(w_1, y_1) = \mu \\
& \quad w_2 - v_2 = x_2 + y_2, \; w_2, v_2 \geq 0 \\
& \quad \min(y_2 + 1, w_2) = \mu, \; \min(1 - y_2, v_2) = \mu
\end{align*}
\]

The NCPBounds function option means that the variable argument to the NCP function (in this case \( y \)) does not have its bounds explicitly enforced. It should be noted that this nonlinear program has nondifferentiable constraints for every value of \( \mu \). For this reason, the model is constructed as a dnlp model (instead of an nlp model) in GAMS.

A smoothed version of the min function was proposed by Chen & Mangasarian:
\[
\phi_{CM}(r,s) := r - \mu \log(1 + \exp((r - s)/\mu)). \tag{11}
\]
This function is not symmetric in its two arguments, so \( \phi_{CM}(r,s) \neq \phi_{CM}(s,r) \). For this reason, we distinguish between the two cases. Unlike the Fischer-Burmeister function \( \phi_{FB} \), \( \phi_{CM} \) is not defined in the limit (i.e. for \( \mu = 0 \)) if you use GAMS code to compute it. However, the GAMS intrinsic NCPCM(r,s,mu) handles this limit case internally. The option RefType CMxf|CMfx|fCMxf|fCMfx chooses a reformulation based on the function \( \phi_{CM} \). Again, the last two choices use the GAMS intrinsic function.
5.28.3.2.1 Doubly bounded variables  Like the mult reformulation (7), reformulations using NCP functions are appropriate as long as we split the function $h_i$ matching a doubly-bounded variable into its positive and negative parts $w_i - v_i = h_i$. To avoid this, Billups has proposed using a composition of NCP functions to treat the doubly-bounded case:

$$h_i \perp a_i \leq y_i \leq b_i \iff \phi_{FB}(y_i - a_i, \phi_{FB}(b_i - y_i, -h_i)) = 0$$  \hspace{1cm} (12)

Use option RefType Bill|fBill to choose such a reformulation for the doubly-bounded variables. The first option value writes out the function in explicit GAMS code, while the second writes it out using the GAMS intrinsic function NCPFB.

5.28.3.3 Penalty functions

All of the reformulations discussed so far have reformulated the complementarity conditions as constraints. It is also possible to treat these by moving them into the objective function with a penalty parameter $1/\mu$: as $\mu$ goes to zero, the relative weight placed on complementarity increases. Ignoring the NLP constraints, we can rewrite the original MPEC problem as

$$\min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m} f(x, y) + \frac{1}{\mu}((y_L - a_L)^T w_L + (b_L - y_L)^T v_L + (y_B - a_B)^T w_B + (b_B - y_B)^T v_B)$$  \hspace{1cm} (13)

subject to the constraints

$$w_L = h_L(x, y), \quad a_L \leq y_L, \quad w_L \geq 0$$

$$v_L = -h_L(x, y), \quad y_L \leq b_L, \quad v_L \geq 0$$

$$w_B - v_B = h_B(x, y), \quad a_B \leq y_B, \quad w_B \geq 0, \quad v_B \geq 0$$  \hspace{1cm} (14)

Choose this treatment using option refType penalty. The options aggregate and constraint are ignored, since the inner products here are all aggregated and there are no relevant constraints. It is possible to do a similar reformulation without using slacks, so the options slack none|positive can be used in conjunction with this reformulation type.

The following option file shows the use of the penalty reformulation, but also indicates how to use a different reformulation for the singly and doubly bounded variables:

```
reftype penalty mult
slack none *
initmu 1.0
numsolves 2
updatefac 0.1 0.2
```

The "*" value allows the slack option to take on its existing value, in this case positive. Applied to our simple example given above, such an option file generates the nonlinear programming model:

$$\min_{x_1, x_2, y_1, y_2, w_2, v_2} x_1 + x_2 + \frac{1}{\mu_1} y_1(x_1 - y_1 + y_2 - 1)$$

subject to

$$x_1^2 + x_2^2 \leq 1$$

$$x_1 - y_1 + y_2 - 1 \geq 0, \quad y_1 \geq 0$$

$$w_2 - v_2 = x_2 + y_2, \quad w_2, v_2 \geq 0, \quad y_2 \in [-1, 1]$$

$$(y_2 + 1)w_2 \leq \mu_2, \quad (1 - y_2)v_2 \leq \mu_2$$

The penalty parameter $\mu_1$ is controlled separately from the doubly bounded constraint parameter $\mu_2$. For consistency with other options, the penalty parameter in the objective is $1/\mu$ meaning that as $\mu_1$ tends to zero, the penalty increases. The option initmu has only one value, so both the singly and doubly bounded $\mu$ values are initialized to 1. In the above example, three solves are performed with $\mu_1 = 1, 0.1$ and 0.01 and $\mu_2 = 1, 0.2$ and 0.04.
5.28.3.4 Testing for complementarity

In some cases a solution to the reformulated model may not satisfy the complementarity constraints of the original MPEC, e.g. if a large penalty parameter is used in the reformulation. It can also happen that the solution tolerances used in the NLP solver allow solutions with small error in the NLP model but large error in the original MPEC. For example if \( x = f(x) = .001 \) then the NLP constraint \( x f(x) = 0 \) may satisfy the NLP feasibility tolerance but it's not so easy to claim that either \( x \) or \( f(x) \) is zero. The NLPEC solver includes a check that the proposed solution does in fact satisfy the complementarity constraints. The complementarity gap is computed using the definition common to all GAMS MCP solvers in computing the \( objval \) model attribute for an MCP model. The tolerance used for this complementarity gap can be adjusted using the \texttt{testtol} option.

5.28.4 Options

For details on how to create and use an option file, see the introductory chapter on \texttt{solver usage}.

For most GAMS solvers, the use of an options file is discouraged, at least for those unfamiliar with the solver. For NLPEC, however, we expect that most users will want to use an options file from the very beginning. NLPEC is as much a tool for experimentation as it is a solver, and as such use of the options file is encouraged.

Option values can take many different types (e.g. strings, integers, or reals). Perhaps the most important option to remember is one with no value at all: the \texttt{help} option. \texttt{Help} prints a list of the available options, along with their possible values and some helpful text. The options file is read sequentially, so in case an option value is set twice, the latter value takes precedence. However, any consistency checks performed on the options values (e.g. \texttt{RefType fBill} cannot be used with \texttt{aggregate full}) are made after the entire options file is read in, so the order in which different options appear is not important, provided the options are not specified twice.

5.28.4.1 Setting the Reformulation Options

While NLPEC has many options, there is a small set of five options that, taken together, serve to define the type of reformulation used. Listed in order of importance (highest priority items first), these \textit{reformulation options} are the \texttt{RefType}, \texttt{slack}, \texttt{constraint}, \texttt{aggregate} and \texttt{NCPBounds} options. In some cases, setting the highest-priority option \texttt{RefType} is enough to completely define a reformulation (e.g. \texttt{RefType penalty} in the case of doubly-bounded variables). In most cases though, the lower-priority options play a role in defining or modifying a reformulation. It's useful to consider the reformulation options in priority order when creating option files to define reformulations.

Some of the combinations of the reformulation options don't make sense. For example, the use of an NCP function to force complementarity between its two input arguments requires a separate function for each complementary pair, so setting both \texttt{RefType min} and \texttt{aggregate full} is inconsistent. NLPEC implements consistency checks on the reformulation options using the priority order: Given a consistent setting of the higher priority options, the next-highest priority option is checked and, if necessary, reset to be consistent with the items of higher priority. The end result is a set of consistent options that will result in a working reformulation. NLPEC prints out the pre- and post-checked sets of reformulation options, as well as warning messages about changes made. In case you want to use an option that NLPEC doesn't think is consistent, you can use the \texttt{NoCheck} option: this supresses the consistency checks.

Each of the reformulation options in the table below takes two values - one for the singly-bounded variables in \( \mathcal{L} \cup \mathcal{U} \) and another for the doubly-bounded variables in \( \mathcal{B} \). If one option value appears, it sets both option values. When setting both option values, use an asterisk \( "*" \) to indicate no change. So for example, an option file

\begin{verbatim}
RefType  fCMxf
RefType  * fBill
\end{verbatim}

first sets the \texttt{RefType} to \texttt{fCMxf} for all variable types, and then resets the \texttt{RefType} to \texttt{fBill} for doubly-bounded variables.
### 5.28.4.2 Reformulation Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
</table>
| aggregate  | controls constraint aggregation  
Determine if certain constraints are aggregated or not. E.g. to force \( w \geq 0 \) and \( y \geq 0 \) to be complementary we can write either \( w^T y \leq 0 \) or \( w_i^T y_i \leq 0 \), for all \( i \).  
none: use no aggregation  
partial: aggregate doubly-bounded variables separately from others  
full: use maximum aggregation possible | none |
| constraint | controls use of equality/inequality  
Determine if certain constraints are written down using equalities or inequalities. E.g. to force \( w \geq 0 \) and \( y \geq 0 \) to be complementary we can write either \( w^T y \leq 0 \) or \( w^T y = 0 \). This option only plays a role when bounding a quantity whose sign cannot be both positive and negative and which must be 0 at a solution.  
equality: use \( =E= \) constraints  
inequality: use \( =L= \) constraints | equality |
| NCPBounds  | sets explicit bounds on arguments of NCP functions  
Determine which of the two arguments to an NCP function \( \Phi(r,s) \) are explicitly constrained to be nonnegative. The explicit constraints are in addition to those imposed by the constraint \( \Phi(r,s) = 0 \), which implies nonnegativity of \( r \) and \( s \).  
none: no explicit bounds  
function: explicit bound on function/slack argument  
variable: explicit bound on variable argument  
all: explicit bound on both function and variable arguments | none |
| refType    | reformulation type  
Determine the type of reformulation used. Our notation and descriptions are taken from a special case of the MPEC, the NCP: find \( x \geq 0 \), \( f(x) \geq 0 \), \( x^T f(x) = 0 \).  
mult: inner product \( <x,f> = 0 \)  
min: NCP function \( \min(x,f) \)  
CMxf: Chen-Mangasarian NCP function, explicit  
CMfx: Chen-Mangasarian NCP function, explicit  
fCMxf: Chen-Mangasarian NCP function, intrinsic  
fCMfx: Chen-Mangasarian NCP function, intrinsic  
FB: Fischer-Burmeister NCP function, explicit  
fFB: Fischer-Burmeister NCP function, intrinsic  
FB_neg: Fischer-Burmeister NCP function negated, explicit  
fFB_neg: Fischer-Burmeister NCP function negated, intrinsic  
Bill: Billups function for doubly-bounded variables, explicit  
fBill: Billups function for doubly-bounded variables, intrinsic  
penalty: weighted penalization of non-complementarity in objective  
median: median function for doubly-bounded variables, explicit  
fvUmin: Veelken-Ulbrich NCP function (smoothed min), intrinsic  
fvUpow: Veelken-Ulbrich NCP function (smoothed min), intrinsic | mult |
| slack      | control use of slacks for function values  
Determine if slacks are used to treat the functions \( h_i \). For single-bounded variables, we use at most one slack (either free or positive) for each \( h_i \).  
For doubly-bounded variables, we can have no slacks, one slack (necessarily free), or two slacks (either free or positive) for each \( h_i \).  
none: no slacks will be used  
free: free slacks will be used  
positive: non-negative slacks will be used  
one: one free slack will be used for each \( h_i \) in the doubly bounded case | positive |
5.28.4.3 General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>

</thead>
<tbody>
<tr>
<td>allSolves</td>
<td>do all solves in a loop regardless of previous failure</td>
<td>0</td>
</tr>
</tbody>
</table>
|                | In case multiple (looped) solves are specified, the default is to skip sub-
|                | sequent solves when any solve terminates without getting a solution. Setting |         |
|                | this flag removes the check and all solves are done, regardless of previous |         |
|                | failures.                                                                   |         |
| dotGams        | name of gams source file for scalar model                                   | auto    |
| dumpValid      | dump valid reformulation options to a GDX file and exit                     | 0       |
| equReform      | final value of parameter mu                                                 | 0       |
|                | If specified, an extra solve is carried out with mu set to this value. Can be |         |
|                | set independently for singly and doubly bounded variables.                  |         |
| finalMu        | initial value of parameter mu                                               | 0       |
|                | A single solve of the nonlinear program is carried out for this value. Note |         |
|                | that mu must be positive for some settings of reftype, e.g. penalty. Can be |         |
|                | be set independently for singly and doubly bounded variables.               |         |
| initSLo        | lower bound for artificials added to the problem                           | 0       |
|                | Range: [-∞, ∞]                                                              |         |
| initSUP        | upper bound for artificials added to the problem                            | +inf    |
|                | Range: [-∞, ∞]                                                              |         |
| noCheck        | do not check consistency of reformulation options                           | 0       |
| numSolves      | number of looped solves                                                     | 0       |
|                | This should be set in conjunction with the updateFac option, so that the mu |         |
|                | values are lowered successively.                                            |         |
| parmFile       | extra GAMS options for running scalar model                                 |         |
| subSolver      | controls what subsolver to run                                              | auto    |
|                | If this option is not specified, the usual GAMS rules for selecting the solver |         |
|                | to run are used.                                                            |         |
| subSolverOpt   | optional value to pass to the subsolver                                     | 0       |
| terminate      | terminate after generating scalar GAMS source code                          | 0       |
| testTol        | tolerance for complementarity check in MPEC/MCP                             | 1e-005  |
| updateFac      | update factor for mu                                                        | 1e-1    |
|                | The factor that multiplies mu before each of the extra solves triggered by |         |
|                | the numSolves option.                                                       |         |
|                | Can be set independently for singly and doubly bounded variables.          |         |
|                | Range: [1e-280, 1.0]                                                        |         |

5.28.4.4 The Outdated equReform Option

In the early versions of NLPEC the only way to set the reform type was via the equReform option. Each valid equReform value represented a preselected combination of the options from Section Setting the Reformulation Options. This made it difficult to experiment with combinations not preselected, so the options in Section Setting the Reformulation Options were added. Be default, the equReform option has value 0 and is not used. To get the old behavior, set equReform to a positive value - this will force the options in Section Setting the Reformulation Options to be ignored. The general options in Section General Options are used no matter how the reformulation type is selected - via RefType or equReform.
<table>

Table 1: Values for `equreform` option.

### 5.28.5 Open Architecture

In this section we describe the architecture of the NLPEC solver, i.e. the way the solver is put together. This should be useful to anybody using NLPEC for experiments or to those wanting to know the details of how NLPEC works.

The foundation for the NLPEC solver is the software library (also used in the GAMS/CONVERT solver) that allows us to write out a scalar GAMS model that is mathematically equivalent to the original, or
to write out selected pieces of such a model. Using this software, NLPEC creates a GAMS NLP model using one of the reformulation strategies from Section Reformulation. This model may contain many new variables and/or equations, but it will surely contain the (non)linear expressions defining the original model as well. Once the scalar model has been created, NLPEC calls GAMS to solve this model, using the current NLP solver. The option parmFile can be used to pass on additional options to this GAMS job. After the model has solved, NLPEC reads the NLP solution, extracts the MPEC solution from it, and passes this MPEC solution back to GAMS as it terminates.

There are a number of advantages to this architecture. First, its openness makes it easy to see exactly what reformulation is being done. The intermediate scalar GAMS NLP model can be made available after the run by either saving the scratch directory (i.e. run with keep=1) or using the dotGams option to select an alternate file name. This intermediate model contains all the details of the reformulation. It can be used for debugging in case things didn’t work out as expected. It is also possible to modify this file to do some quick and dirty experiments with similar reformulation strategies. Another advantage is the variety of NLP solvers that can be plugged in to solve the reformulated model. There is no need to program (and debug) an interface to an NLP package to run experiments with an NLP solver - the existing GAMS link is all that is needed. It is also easy to experiment with non-default solver options that may be more appropriate for reformulated MPEC models or for a particular choice of reformulation.

5.29 Octeract Engine

Octeract Engine is a deterministic solver to find globally optimal solutions for mixed-integer nonlinear programs (MINLPs). Distinguishing highlights of Octeract are its powerful and flexible symbolic reformulation engine and its parallelism capabilities. For more detailed information, we refer to the Octeract Math Blog.

5.29.1 Usage

The following statement can be used inside your GAMS program to specify that Octeract should be used:

```
Option SOLVER = OCTERACT;
```

The above statement should appear before the Solve statement. If Octeract was specified as the default solver during GAMS installation, the above statement is not necessary.

GAMS/Octeract by default uses CPLEX to solve LP/MIP/QP/QCQP problems, if licensed, and CLP/CBC (for LP/MIP) or Ipopt (for QP/QCQP) otherwise. By setting options MIP_SOLVER, LP_SOLVER, MILP_SOLVER, QP_SOLVER, or QCQP_SOLVER, the automatic solver selection can be overwritten.

5.29.1.1 Specification of Octeract Options

GAMS/OCTERACT supports the GAMS parameters reslim, iterlim, nodlim, workspace, optcr, optca, and threads. The interpretation of threads differs from its original meaning in the sense that also on systems with hyperthreading enabled only the number of actual processor cores is taken into account. Further, GAMS/OCTERACT is limited to the use of at most 16 cores and distributed parallelization is not available.

Options can be specified by a solver options file. A small example for an octeract.opt file is:

```
LP_SOLVER    HiGHS
MILP_SOLVER  HiGHS
STARTING_POINT_IPOPT VARIABLE_MID_POINT
```

It causes Octeract to use HiGHS to solve LP or MIP problems and to use a different starting point strategy for calls of Ipopt.
5.29.2 List of Octeract Options

In the following, we give a detailed list of all Octeract options.

5.29.2.1 Octeract Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPLY_CB</td>
<td>This enables or disables constraint probing for domain reduction.</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>BIG_COEFF_TOLERANCE</td>
<td>Sets the maximum acceptable absolute value of a coefficient in the lower bounding problem.</td>
<td>1e+09</td>
</tr>
<tr>
<td></td>
<td>If a coefficient is greater than this number, the solver will use other, less effective methods instead of solving the lower bounding linear problem (LP). Coefficients are naturally improved through branching. However, if the problem is not numerically well-behaved, increasing this tolerance will force the solver to solve the ill-posed lower bounding problems. This is small-ish by default because the global solution guarantee can be compromised otherwise, but in practice it’s perfectly fine to increase this most of the time. Your clue that there might be a problem relating to this is that an (MI)LP relaxation was generated and you get a gap that never improves.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: [0, ∞]</td>
<td></td>
</tr>
<tr>
<td>BIG_GAP_TOLERANCE</td>
<td>If the difference between a node’s upper bound and the parent’s lower bound is smaller than BIG_GAP_TOLERANCE, then solve the relaxation, otherwise skip.</td>
<td>1e+60</td>
</tr>
<tr>
<td></td>
<td>Range: [0, ∞]</td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------</td>
</tr>
<tr>
<td>BINARY_REFORMULATION_PROCEDURE</td>
<td>If REFORMULATE_BINARIES is enabled, this option determines which method to use in the reformulation of binary variables. All of these methods transform the binary variables to continuous, either by adding constraints, or simply by dropping integrality (Continuous Relaxation). The constraint adding methods tend to suck, and obviously dropping integrality means you’re now solving a different problem, so you should only really fiddle with this if you’re reaaaally desperate or you really know what you’re doing. Range: Quadratic Concave Constraint, Quadratic Equality Constraint, Exponential Reformulation, Continuous Relaxation.</td>
<td>Quadratic Concave Constraint</td>
</tr>
<tr>
<td>BOUND_VIOLATION_TOLERANCE</td>
<td>Bound violation tolerance is used to confirm whether solutions returned by third-party solvers (IPOPT, CPLEX, Gurobi, CBC, etc) are indeed feasible within that tolerance. Relaxing this tolerance can help in problems where finding a feasible solution is difficult, or where the global solution is eliminated due to slight constraint violations. Range: [1e-12, 1]</td>
<td>1e-06</td>
</tr>
<tr>
<td>BQCQP_REFORMULATION_METHOD</td>
<td>Type of reformulation used for BQCQPs. The default option is SSLINEARBQCQP, which linearises the BQCQP following Sherali and Smith, “An improved linearization strategy for zero-one quadratic programming problems”, 2007. The CONVEXIFY option tries to convexify the problem in a similar way as the convexification for BQPs. See also the Octeract docu. Range: SSLINEARBQCQP, CONVEXIFY</td>
<td>SSLINEARBQCQP</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>BQP_REFORMULATION_METHOD</td>
<td>This option forces the reformulation method applied to Binary Quadratic Problems. SSSLINEAR linearises the BQP using a modified version of Sherali and Smith, “An improved linearization strategy for zero-one quadratic programming problems”, 2007. Note that this applies to the preprocessing state machine, i.e., if your problem is reformulated to a BQP by the preprocessor, you can use this option to force how that BQP will be reformulated. See also the Octeract docu. Range: AUTOMATIC, LINEAR, QUADRATIC, SSSLINEAR</td>
<td>AUTOMATIC</td>
</tr>
<tr>
<td>BQP_SPARSITY_TOLERANCE</td>
<td>The maximal sparsity for a BQP to be reformulated as a linear problem. Range: [0, 1]</td>
<td>0.8</td>
</tr>
<tr>
<td>BRANCHING_STRATEGY</td>
<td>The heuristic for selecting the variable to branch in the branch and bound method when solving a problem. See also the Octeract docu. Range: AUTOMATIC, MOST_VIOLATED_TERM, HYBRID_INTEGER_LEAST_REduced_AXIS, MAX_SEPARATION_DISTANCE, STRONG_BRANCHING, MOST_FRACTIONAL_VARIABLE, MODIFIED_MOST_NONCONVEX_VARIABLE</td>
<td>AUTOMATIC</td>
</tr>
<tr>
<td>CALCULATE_LB_LARGE_COEFFS</td>
<td>If this option is enabled the Engine will treat constraints with large coefficients as every other constraint. This check happens when solving a relaxation to find the lower bound at every node, and by default the engine will modify the pathological constraints to a safer form. However, this safety-first approach enlarges the feasible region, which means that your LLB may get stuck or improve much more slowly than it otherwise could. If you observe this behaviour, try setting this to true. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>CONSTRAINT_VIOLATION_TOLERANCE</td>
<td>This is the acceptable constraint violation when qualifying a solution as feasible. Relaxing this tolerance can help in problems where finding a feasible solution is difficult, or where the global solution is eliminated due to slight constraint violations. Range: [0, 1]</td>
<td>1e-06</td>
</tr>
<tr>
<td>CONVERGENCE_TOLERANCE</td>
<td>This sets a tolerance to determine whether the algorithm has converged to global optimality. Note that this is used as both absolute and a relative gap tolerance. See also the Octeract docu. Range: [0, ∞]</td>
<td>min(GAMS optcr, GAMS optca)</td>
</tr>
<tr>
<td>CP_MAX_ITERATIONS</td>
<td>This option sets the limit for the number of passes performed by Constraint Propagation (CP) per node. More of this means potentially better domain reduction per node, at the expense of speed and numerical correctness. See also the Octeract docu. Range: {0, ..., ∞}</td>
<td>5</td>
</tr>
<tr>
<td>CP_NUMBER_COMPARISON_TOLERANCE</td>
<td>This is the tolerance for comparison of two values within the Constraint Propagation (CP) algorithm. CP is numerically unsafe by nature, so we have a metric ton of fail-safes and tolerances built into the implementation to make sure it doesn’t eliminate the global solution. This tolerance specifies when CP can safely consider whether a number is definitely larger/smaller/equal than another very similar one. Decreasing this can improve the stability of the algorithm, and increasing it can improve the quality of domain reduction by allowing more numerically unsafe operations. See also the Octeract docu. Range: [0, 1]</td>
<td>1e-06</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>CP_SCALING</td>
<td>Enabling this option may help avoid numerical issues for extremely badly scaled problems, i.e., constraints containing coefficients of widely different scales, wide range of scales for variable bounds, etc. For MINLPs this can also be the case when you have fractions in your formulation without having properly contained the denominator range. This option sucks for regular problems, but it might help you in cases where the global solution is getting incorrectly fathomed. See also the Octeract docu. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>CP_VOLUME_IMPROVEMENT_FACTOR</td>
<td>This sets the required volume improvement factor for iterations of constraint propagation. More of this gives you more aggressive (and expensive) CP. See also the Octeract docu. Range: [0, 1]</td>
<td>0.999</td>
</tr>
<tr>
<td>CUT_POOL_MAX_SIZE</td>
<td>This sets the maximum number of cuts to be kept in the cut pool. Range: {0, ..., ∞}</td>
<td>10000</td>
</tr>
<tr>
<td>FBBT_MAX_ITERATIONS</td>
<td>This option sets the maximum number of variable bisections when performing Feasibility Based Bounds Tightening (FBBT). More of this means more more domain reduction, but this can be really expensive, especially if you have dense nonlinear functions in your model. As with all domain reduction-related settings, doing more of it increases the odds of numerics going wrong, so use with caution. See also the Octeract docu. Range: {0, ..., ∞}</td>
<td>5</td>
</tr>
<tr>
<td>FBBT_TIMEOUT</td>
<td>Sets a working limit, in seconds, for Feasibility Based Bounds Tightening (FBBT). This is typically applied per node of the branch-and-bound tree. See also the Octeract docu. Range: [0, ∞]</td>
<td>0.3</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>FBBT_TOLERANCE</td>
<td>This is the epsilon-termination condition for the width of a variable box when performing Feasibility Based Bounds Tightening (FBBT). See also the <a href="#">Octeract docu.</a> Range: [0, 1]</td>
<td>0.0001</td>
</tr>
<tr>
<td>FIRST_FEASIBLE_SOLUTION</td>
<td>Setting this to true will force the engine to exit the moment a feasible solution is found, even if it’s a very bad one. See also the <a href="#">Octeract docu.</a> Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>FORCE_EXPANSION</td>
<td>If USE_AUTOMATIC_EXPANSION is disabled, this setting gives you control over symbolic expansion. Setting this to true will force the engine to symbolically expand all formulas in your problem, and setting this to false will force the engine to process the formulas exactly as you input them. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>HEUR_CONSTRAINT_PENALTY</td>
<td>Controls the constraint penalty heuristic. See also the <a href="#">Octeract docu.</a> Range: OFF, NONLINEAR_CONSTRAINTS, ALL_CONSTRAINTS</td>
<td>OFF</td>
</tr>
<tr>
<td>HEUR_CONSTRAINT_PENALTY_COEFF</td>
<td>This sets the penalty coefficient for the Constraint Penalty primal heuristic. Higher values will make the solver prioritise feasibility over optimality, but will also increase the likelihood of numerical instability. Range: [0, (\infty)]</td>
<td>1000</td>
</tr>
<tr>
<td>HEUR_CS</td>
<td>Enables or disables the Constraint Satisfaction (CS) heuristic. This can be quite expensive, so try turning this off if the solver is spending too much time trying to find a feasible solution. Range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>HEUR_FIXING</td>
<td>Enables or disables a basic fixing heuristic. Range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>HEUR_GUIDED_DIVING</td>
<td>Enables or disables the Guided Diving heuristic. Can be quite expensive, so it’s off by default. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>HEUR_INEQUALITY</td>
<td>Enables or disables the Inequality heuristic.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>HEUR_LB</td>
<td>Enables or disables a simple Lower Bound (LB) heuristic.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>HEUR_MINLP_DIVING</td>
<td>Enables or disables all Diving heuristics.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>HEUR_NL_FEASIBILITY_PUMP</td>
<td>Enables or disables the Non-linear (NL) Feasibility Pump heuristic.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>HEUR_PENALTY</td>
<td>Enables or disables a simple penalty heuristic.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>HEUR_QPDIVING</td>
<td>Enables or disables the QP Diving heuristic.</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>This can be very good for convex MI problems, but it’s pretty expensive so</td>
<td></td>
</tr>
<tr>
<td></td>
<td>it’s off by default.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>HEUR_SAP</td>
<td>Enables or disables the Shift and Propagate (SAP) heuristic.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>HEUR_SUPREME</td>
<td>Primal heuristic that can be useful for some unbounded problems.</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>HEUR_ZERO</td>
<td>Enables or disables the Zero heuristic.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>INFINITY</td>
<td>Default bound for unbounded variables.</td>
<td>$1e+07$</td>
</tr>
<tr>
<td></td>
<td>Note that if unbounded variables are bounded this way, optimal solutions</td>
<td></td>
</tr>
<tr>
<td></td>
<td>may be cutoff, thus global optimality is no longer guaranteed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The returned model status and dual bound may NOT be valid in this case.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: $[0, \infty]$</td>
<td></td>
</tr>
<tr>
<td>INTEGER_REFORMULATION_VAR_RANGE_LIMIT</td>
<td>This option sets the max integer variable range up to which which integers will be reformulated to binaries.</td>
<td>5000</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>INTEGRALITY_VIOLATION_TOLERANCE</td>
<td>Integrality violation tolerance is the acceptable violation before the solver determines that a variable is no longer an integer. Relaxing this tolerance can make it much easier for the solver to find feasible solutions for discrete problems, especially problems with many integers or highly non-linear discrete functional forms. Range: [0, 1]</td>
<td>0.001</td>
</tr>
<tr>
<td>IPOPT_INITIAL_VALUE</td>
<td>When STARTING_POINT_IPOPT is set to CUSTOM_CONSTANT_VALUE, this option determines the value of the initialisation of the primal variables given to IPOPT. See also the Octeract docum. Range: real</td>
<td>1</td>
</tr>
<tr>
<td>LLB_TOLERANCE</td>
<td>Tolerance used to decide whether solutions from lower and upper problems are the &quot;same&quot;. See also the Octeract docum. Range: [0, \infty]</td>
<td>0.001</td>
</tr>
<tr>
<td>LOCAL_SEARCH</td>
<td>If enabled, the engine will run in local optimisation mode. This mode skips all expensive preprocessing, and uses specialised local search algorithms to return a good feasible solution as quickly as possible. Highly recommended for folks who dislike waiting. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>LP_SOLVER</td>
<td>This sets the solver which will be used to solve Linear Programming (LP) problems. Range: IPOPT, OSICLP, OSICBC, CPLEX, HIGHS</td>
<td>OSICLP</td>
</tr>
<tr>
<td>MAX_CBDEPTH</td>
<td>This sets the maximum depth in the branching tree at which constraint probing should be adding additional constraints. If this is set to 0, depth is unlimited. Range: {0, \ldots, \infty}</td>
<td>1</td>
</tr>
<tr>
<td>MAX_SOLVER_ITERATIONS</td>
<td>This sets the maximum number of solver iterations in serial mode. This option is ignored in parallel mode. Range: {1, \ldots, \infty}</td>
<td>GAMS iterlim</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>MAX_SOLVER_MEMORY</td>
<td>This option sets the memory limit allowed during the solving process in MB. If the memory used exceeds this limit the solving process is terminated. Note that when running MPI this is the memory consumed by the main process. Before you ask, yes, we could make this include the workers too but (i) getting precise memory consumption for the OS is iffy at best, and (ii) these system calls are actually quite expensive. Range: ( {0, \ldots, \infty} )</td>
<td>GAMS workspace</td>
</tr>
<tr>
<td>MAX_SOLVER_TIME</td>
<td>Sets the timeout for the solver in real time seconds. Range: ([1, \infty])</td>
<td>GAMS reslim</td>
</tr>
<tr>
<td>MILP_LB_MAX_NODES</td>
<td>This sets the maximum number of nodes that the MILP solver will be allowed to explore when solving a lower bounding problem. By default it’s infinite (-1), but setting this to a finite number can improve the performance of MILP relaxations per node, at the expense of the quality of the lower bound per said node. Range: ([-1, \ldots, 200000000])</td>
<td>-1</td>
</tr>
<tr>
<td>MILP_LB_TIMEOUT</td>
<td>This option sets the timeout (in real-time seconds) for the MIP solver that it is used to solve MILP lower bounding problems at every node of the branch-and-bound tree. Giving the MIP solver more time means that the lower bound per node can be superior, at the expense of computing time. Increase the timeout if: Your MIP relaxation starts clustering when it gets close to the global solution. Decrease the timeout if: A lot of time is spent solving MIP problems but you don’t see the bounds improving even after a lot of nodes have been explored. Range: ([1, \infty])</td>
<td>5</td>
</tr>
<tr>
<td>MILP_SOLVER</td>
<td>Sets the solver which will be used to solve MILP problems. Range: OSICBC, CPLEX, HIGHS</td>
<td>OSICBC</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>MIP_SOLVER</td>
<td>Umbrella option to use the specified MIP solver to solve all types of sub-problems it supports. If set, it will overwrite LP_SOLVER and MILP_SOLVER. If set to CPLEX, it will also override QP_SOLVER and QCQP_SOLVER. Range: CPLEX, OSICBC, HIGHS</td>
<td>CPLEX if licensed, otherwise OSICBC.</td>
</tr>
<tr>
<td>NUM_CORES</td>
<td>Number of MPI processes to spawn. If the problem is reformulated to a MIP, the MPI workers go to sleep and this setting determines the number of threads for the MIP solver. Range: {-∞, ..., 16}</td>
<td>GAMS threads</td>
</tr>
<tr>
<td>NUMBER_COMPARISON_TOLERANCE</td>
<td>This tolerance is used to determine whether two floating point numbers are the same. Its use in the engine is context sensitive, therefore changing this can have unforeseen consequences, for the better or worse. Reducing this tolerance smaller can accelerate convergence, as the solver becomes more aggressive in domain reduction, at the risk of eliminating otherwise acceptable solutions. Increasing this tolerance can slows down convergence, as the solver adopts a more conservative approach, but may help in cases where the global solution is being incorrectly fathomed. Range: [0, 1]</td>
<td>1e-06</td>
</tr>
<tr>
<td>OBBT_MAX_DEPTH</td>
<td>This sets the maximum depth in the branch-and-bound tree at which Optimality Based Bounds Tightening (OBBT) should be applied. See also the Octeract docu. Range: {1, ..., ∞}</td>
<td>∞</td>
</tr>
<tr>
<td>OBBT_MAX_ITERATIONS</td>
<td>This sets the maximum number of passes for OBBT. See also the Octeract docu. Range: {1, ..., ∞}</td>
<td>1</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>OUTPUT_FREQUENCY</td>
<td>The solver will print output every OUTPUT_FREQUENCY iterations. This only has meaning in serial mode, as there are no iterations in MPI mode. Range: ([1, \ldots, \infty])</td>
<td>1</td>
</tr>
<tr>
<td>OUTPUT_TIME_FREQUENCY</td>
<td>The solver will print output every OUTPUT_TIME_FREQUENCY seconds. Range: ([1, \ldots, \infty])</td>
<td>1</td>
</tr>
<tr>
<td>PRESOLVE</td>
<td>Enables or disables the presolver. Range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>PURGE_CUTS</td>
<td>Disable this if you want the solver to save all cuts since the beginning of time in its cut pool. This will override all other cut management options, including the limit for max cuts. Is it not recommended to change this option. Range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>QCQP_SOLVER</td>
<td>Sets the solver that will be used to solve QCQP sub-problems. Setting the MIP_SOLVER option overrides this option. Range: CPLEX, IPOPT</td>
<td>IPOPT</td>
</tr>
<tr>
<td>QP_SOLVER</td>
<td>Sets the solver that will be used to solve QP sub-problems. Setting the MIP_SOLVER option overrides this option. Range: CPLEX, IPOPT</td>
<td>IPOPT</td>
</tr>
<tr>
<td>REDUCE_LINEAR_CONSTRAINTS</td>
<td>Enables or disables the reduction of the linear constraints by eliminating a variable in the constraint if its coefficient is close to zero. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>REFORMULATE_BINARIES</td>
<td>Enables or disables the reformulation of binary variables into continuous nonlinear constraints according to the BINARY_REFORMULATION_PROCEDURE option. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>REFORMULATE_INTEGERS</td>
<td>Enables or disables the reformulation of integer variables as binary. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>REFORMULATE_INTEGERS_IN_MIQCQP</td>
<td>Enables or disables the reformulation of integer variables as binary in MIQCQCP problems. Range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>SOLVE_CONTINUOUS_RELAXATION</td>
<td>Setting this option to true will relax all discrete variables to continuous. This can be useful if you want to investigate the lower bound of large problems with a lot of integer or binary variables. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>STARTING_POINT_IPOPT</td>
<td>Set the strategy that the engine will use to generate starting points for IPOPT. Change this if you are having trouble getting IPOPT to converge, or if it’s being too slow. See also the Octeract docu. Range: CONSTANT_VALUE_ONE</td>
<td></td>
</tr>
<tr>
<td>STRENGTHEN_LINEAR_CONSTRAINTS</td>
<td>If enabled, for each linear constraint that contains binary or integer variables, the engine will try to find a tighter constraint by changing the coefficients of said variables. Range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>STRONG_BRANCHING_DEPTH</td>
<td>When BRANCHING_STRATEGY = STRONG_BRANCHING, this option sets the maximum tree depth up to which to apply strong branching. The solver will then revert back to AUTOMATIC. Range: ([0, \infty])</td>
<td>0</td>
</tr>
<tr>
<td>STRONG_BRANCHING_VARIABLE_COUNT</td>
<td>When BRANCHING_STRATEGY = STRONG_BRANCHING, this option sets the (maximum) number of variables to “test” while strong branching. See also the Octeract docu. Range: ([0, \infty])</td>
<td>100</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>UB_FREQUENCY</td>
<td>This option sets how often the solver should solve local optimisation problems to find upper bounds. Small values for this option can be helpful in problems where finding feasible upper bounds is challenging. For instance, UB_FREQUENCY = 1 will instruct the solver to calculate an upper bound on every node processed in the branch and bound algorithm, increasing the probability that a feasible solution is going to be located. This, of course, comes with a trade-off of increased solution time, i.e. the smaller the UB_FREQUENCY, the more time is spent every iteration solving the upper bounding problem. The value of this option highly affects solver performance, especially in problems where a lot of time is spent solving primal heuristics. Note that the value of this option is more of a hint for the solver of how much to focus on solving UB problems rather than a hard-coded value, as it will load balance automatically when/which primal heuristics are solved. Range: {1, ..., \infty}</td>
<td>4</td>
</tr>
<tr>
<td>USE_AUTOMATIC_EXPANSION</td>
<td>This option enables or disables the dual expansion algorithm for mathematical expressions. If enabled, the engine will create an alternative expanded version of the problem where functions like ((x-2)^2) will be replaced by (x^2-4x+4). The engine will then use a heuristic to select the most promising model to solve between the original (un-expanded) and alternative (expanded) version. Range: boolean</td>

### 5.30 ODHCPLEX

#### 5.30.1 Introduction

GAMS/ODHCPLEX is a solver from Optimization Direct Inc. that implements a set of heuristic methods (named ODHeuristics) for finding feasible solutions to Mixed Integer Programming (MIP and MIQCP) models that uses IBM CPLEX as its underlying solver engine. It is designed for large-scale models which a MIP solver would find intractable: either by it being unable to find feasible solutions at all or; more usually, by being unable to find feasible solutions of adequate quality in the time available to its user.

It is intended for users who are familiar with MIP modelling and have some knowledge of using the GAMS/CPLEX solver. GAMS/ODHCPLEX does not demand expert specialism in this field.

ODHCLEX can be used in two ways: it is implemented as a stand-alone ODHeuristic engine, which can be used on its own (ODHeuristicMethod=STANDALONE); and also within the CPLEX optimizer, within which it can supply and receive solutions from the main CPLEX caller (ODHeuristicMethod=ODH-CPLEX (default)) thereby accelerating optimization compared with GAMS/CPLEX run on its own.

The ODHeuristic engine has a heuristic method for finding an initial feasible solution that it designed to complement, those of CPLEX. Since its main algorithmic procedure works by improving an incumbent feasible solution, getting an initial one is important and may consume a significant part of its total runtime. When used on its own (i.e. ODHeuristicMethod=STANDALONE), users should experiment to discover whether ODHeuristics' or CPLEX's initial feasible solution methods work best, but within ODH-CPLEX (i.e. ODHeuristicMethod=ODH-CPLEX) both methods are run in parallel and the winner is chosen automatically.

ODHeuristics' principal algorithm works by solving a sequence of sub-models. An innovative aspect of this process is its ability to use the model's symbolic structure to achieve the sub-model decomposition. It does this by analyzing the symbolic names that the user gives to the decision variables and careful specification of how this should be done this is worthwhile. ODHCLEX can work without this analysis, but it usually takes about twice as much runtime.

#### 5.30.2 Specifying Model Structure

The ODHeuristic method needs to break the model down into sub-models. It can do this in one of three ways:

1. Automatically using its decomposition heuristic;
2. Using information specified by the user in the IndexKey parameter;
3. By simply assigning each variable to a different block (or key); or
4. By using the dot option notation with the option .key.
By default, the program will use information specified by the IndexKey parameter if it is set and its automatic decomposition heuristic otherwise. This may be overridden by the Decomposition parameter. If it is set to 0 (zero), option 3 above is selected. If it is set to 1, its automatic decomposition method is used, and if it is set to 2, option 4 above is selected.

Whilst the automatic decomposition method often works well, there may be an advantage to specifying decomposition through the IndexKey parameter. After performing the decomposition in whatever way, the program analyses the decomposition and displays statistics showing the maximum and minimum number of variables in each key or block and showing a percentage score to the decomposition as a whole. A typical display is of the form:

Variables/key 205.58 (+/-304.79), max/min variables/key 933(32) / 60(113).
There are 227 keys (4149 keys were dropped) with 46872 values.
Decomposition score 13.66%, graph score 2074/3135232.

Other things (such as the distribution of variables in keys and the number of keys) being equal, the smaller the percentage decomposition score, the better the decomposition is and the more effective the program will be.

5.30.2.1 Using the IndexKey parameter

The program needs to associate sets of variables with distinct values of a single index. The user can specify this association with a pattern to which some or all of the variables conform. The pattern is in standard C scanf format (see, for example, Kernighan and Ritchie’s 2nd edition of The C Programming Language, section B1.3 Formatted Input). Currently allowable index values must be non-negative integers, so the pattern must include \( d \). For example, if we have variables \( x \) whose first index names start with a number of letters then an underscore followed by a numeric index value (like \( x(firstone_1) \), \( x(another_1) \), \( x(firstone_2) \), \( x(another_2) \), ..) the pattern

\[
x(%*[a-z]_\%d)
\]

associates those variables whose name ends in \_1 with index value 1, those whose name ends in \_2 with index value 2 and so on. The pattern is called an index key referred to by the program as the option parameter IndexKey, for example

\[\text{IndexKey}=%*[xy](t_\%d)\]

It may, however, be desirable to consider variables whose names are, say, \( x(t_2) \) and \( y(t_2) \), to belong to different index values, i.e. to belong to different groups. One way of doing this is to identify them with separate index keys. These can be supplied to IndexKey as two fields separated by a semi-colon, for example

\[\text{IndexKey}=x(t_\%d);y(t_\%d)\]

Up to 10 fields can be specified in this way.

On the other hand, it may be desirable to consider such variables as having the same index key and their nomenclature may not permit their identification by a single key field. For example, suppose there are variables \( john(t_1) \), \( john(t_2) \), .., \( jane(t_1) \), \( jane(t_2) \) .. and \( johnny(t_1) \), \( johnny(t_2) \) .. and we want to associate \( john(t_x) \) and \( jane(t_x) \) as belonging to key value \( x \), but want to ignore \( johnny(t_x) \).

Two key fields can be used to do this by
INDEXKEY=\text{john}(t\_d);\text{jane}(t\_d)

By default $\text{john}(t_2)$ and $\text{jane}(t_2)$ would not share the same index value, but if the option parameter KeyType, is set to 1, the heuristic will group them together so as to share the same index.

If IndexKey is not specified, the program uses a default decomposition.

The program divides the model up into parts associated with different values of the IndexKey (if specified), using an integer interval divisor. Initially this is a number not less than 2 and it is increased as the search progresses. When no improved solution is found after a number, MaxRepeat, of attempts with the maximum interval divisor, MaxInterDiv, the program terminates. Default values are provided for MaxRepeat and MaxInterDiv, so these do not have to be specified by the user.

### 5.30.3 Heuristic Parameters

There are a number of other parameters which control the behaviour of the heuristic program. These may be left at their default values or specified on the GAMS/ODHCPLEX option file. In addition, many GAMS/CPLEX options can be supplied in the GAMS/ODHCPLEX option file to tweak the CPLEX behavior, see tables below. Note however that - although they can be technically set - these GAMS/CPLEX options may not have any influence on a GAMS/ODHCPLEX solve. For detailed descriptions of the GAMS/CPLEX options, see Detailed Descriptions of CPLEX Options.

Parameter names and their meanings are summarized in the table below.

#### 5.30.3.1 GAMS/ODHCPLEX: General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>addcuts</td>
<td>Indicator for adding cuts from CPLEX master solve</td>
<td>2</td>
</tr>
<tr>
<td>cpxpresolve</td>
<td>Applies CPLEX presolve to full model</td>
<td>0</td>
</tr>
<tr>
<td>decompdensity</td>
<td>Matrix density above which automatic decomposition assigns each variable to a separate key</td>
<td>0.3</td>
</tr>
<tr>
<td>decomposition</td>
<td>Model decomposition method.</td>
<td>-1</td>
</tr>
<tr>
<td>deterministic</td>
<td>Specifies whether the solution improvement heuristic is run in deterministic or opportunistic (i.e. non-deterministic) mode</td>
<td>1</td>
</tr>
<tr>
<td>divisor</td>
<td>Initial divisor for sub models</td>
<td>automatic</td>
</tr>
<tr>
<td>dynamicsearch</td>
<td>Search strategy for CPLEX caller and sub-model solves</td>

5.30.4 Parallel execution using multiple threads

Both ODHheuristicMethods STANDALONE and ODH-CPLEX can use multiple simultaneous threads. ODH-CPLEX must use separate threads for the main CPLEX solve and for the ODHheuristics engine. The STANDALONE just uses the ODHheuristics engine which may use multiple simultaneous threads. Thus the processing capability of multi-core hardware can be exploited effectively.

GAMS/ODHCPLEX will ignore the GAMS threads parameter and use its own default. The default ODHheuristic method (i.e. ODH-CPLEX) requires multiple threads to works and with the GAMS threads default of 1 this will not work.

Whilst there are good defaults for allocating available threads, it may be worthwhile to give some attention to the allocation of threads between the main CPLEX solver and the ODHheuristics engine for ODH-CPLEX and STANDALONE.

If the option ODHThreads is set to $n$, $n$ threads are allocated in total, otherwise the total number of threads allocated for both ODH-CPLEX and STANDALONE is set to the number of physical processors.
available on the computer. If the `ODHThreads` option is set to a number greater than the number of available processors, multiple threads will have to share the same processor, which may severely degrade performance.

In general, the more threads allocated to the main CPLEX solver, the faster it will run, and similarly, the more allocated to the ODHeuristics engine, the faster it will run. The best balance depends on the model being solved and whether it is intended to run to optimality or to an optimality gap of (say) 0.05 or 0.1. If the GAMS/Cplex `Threads` is not set, ODH-CPLEX defaults to allocating a quarter of the threads to the ODHeuristics engine and the remainder to the main CPLEX solve. Otherwise it allocates the specified number of threads to the main CPLEX solver and the remainder to the ODHeuristics engine.

Within the ODHeuristics engine, the principal heuristic algorithm can run in parallel on multiple threads. Each algorithmic thread uses CPLEX to solve sub-models and each such instance of CPLEX can itself run on multiple threads. So some attention needs to be given to the allocation of threads between them. If `SUB_CPX_THREADS` is not set, the CPLEX solver will use one thread for each available logical processor to solve the sub-models. This means that only one thread will be available for the solution improvement heuristic. If the option `SUB_CPX_THREADS` is set, then by default the heuristic engine sets its number of algorithmic threads to

\[
\text{number_of_available_processors} / \text{SUB_CPX_THREADS}
\]

where `number_of_available_processors` is: the number of logical processors for STANDALONE; and for ODH-CPLEX it is this number less those allocated to the main CPLEX solver.

Many Intel and compatible processors support hyperthreading (where this is enabled on the computer and operating system) and if so there will be two logical processors for every physical core. Using them can severely degrade performance, so if they are enabled it is often a good idea to set `ODHThreads` to the number of physical processors. Note that on machines with a large number of processors (cores), the principal bottleneck for large scale optimization is usually memory access. In practice it is often better to use only about half of the available cores on (say) a 24 core Intel Xeon system. This is model dependent and some experimentation is worthwhile.

Although the operating system's scheduler usually allocates threads to logical processors so that they run on separate physical cores where possible, it will have more threads to manage than those of the heuristic or CPLEX and so will change this allocation as the heuristic and CPLEX run so as to balance its workload effectively. There is a performance penalty to doing this from the perspective of the heuristic run time. For the ODHeuristics STANDALONE, this can be avoided by locking the heuristic threads to specific processors by setting the heuristic option parameter `ProcessorLock` to 1. It is not supported for ODH-CPLEX. Under Windows, beware that the threads need to be locked at an above normal priority so this may have a negative impact on other programs concurrently running on the machine.

### 5.30.5 Determinism

Many users require that repeated runs of their applications under the same conditions give the same results, albeit in slightly variable times. The heuristic runs in this way by default. However, there is a performance penalty that has to be paid for synchronizing the threads. On average, performance can be considerably improved performance at the expense of non-repeatable execution by setting the heuristic option parameter `Deterministic` to 0. This is often preferred by users with particularly large and difficult models.

### 5.30.6 Detailed Descriptions of ODHCLPEX Options

**addcuts (integer):** Indicator for adding cuts from CPLEX master solve

- Default: 2
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not add cuts</td>
</tr>
<tr>
<td>1</td>
<td>Add cuts from CPLEX master solve at root</td>
</tr>
<tr>
<td>2</td>
<td>Add cuts from CPLEX master solve at root and in tree</td>
</tr>
</tbody>
</table>

**advind** *(integer)*: advanced basis use

Default: 1

**aggcutlim** *(integer)*: aggregation limit for cut generation

Default: 3

**aggfill** *(integer)*: aggregator fill parameter

Default: 10

**aggind** *(integer)*: aggregator on/off

Default: -1

**auxrootthreads** *(integer)*: number of threads for auxiliary tasks at the root node

Default: 0

**baralg** *(integer)*: algorithm selection

Default: 0

**barcolnz** *(integer)*: dense column handling

Default: 0

**barcrossalg** *(integer)*: barrier crossover method

Default: 0

**bardisplay** *(integer)*: progress display level

Default: 1

**barepcomp** *(real)*: convergence tolerance

Default: 1.0e−08

**bargrowth** *(real)*: unbounded face detection

Default: 1.0e+12

**baritlim** *(integer)*: iteration limit

Default: 2147483647

**barmaxcor** *(integer)*: maximum correction limit

Default: -1

**barobjrng** *(real)*: maximum objective function
barorder (integer): row ordering algorithm selection
Default: 0

barqcppepcomp (real): convergence tolerance for the barrier optimizer for QCPs
Default: 1.0e-07

barstartalg (integer): barrier starting point algorithm
Default: 1

bbinterval (integer): best bound interval
Default: 7

bendersfeascuttol (real): Tolerance for whether a feasibility cut has been violated in Benders decomposition
Default: 1.0e-06

bendersoptcuttol (real): Tolerance for optimality cuts in Benders decomposition
Default: 1.0e-06

bendersstrategy (integer): Benders decomposition algorithm as a strategy
Default: 0

bndstrenind (integer): bound strengthening
Default: -1

bqpcuts (integer): boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality
Default: 0

brdir (integer): set branching direction
Default: 0

bttol (real): backtracking limit
Default: 1.0

calcqcpduals (integer): calculate the dual values of a quadratically constrained problem
Default: 1

cliques (integer): clique cut generation
Default: 0

clocktype (integer): clock type for computation time
Default: 2
**clonelog (integer):** enable clone logs

Default: 0

**coeredind (integer):** coefficient reduction on/off

Default: -1

**conflictalg (integer):** algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model

Default: 0

**conflictdisplay (integer):** decides how much information CPLEX reports when the conflict refiner is working

Default: 1

**covers (integer):** cover cut generation

Default: 0

**cpumask (string):** switch and mask to bind threads to processors (Linux only)

Default: auto

**cpxpresolve (integer):** Applies CPLEX presolve to full model

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Apply only for first feasible heuristic</td>
</tr>
<tr>
<td>-2</td>
<td>Do not apply at all</td>
</tr>
<tr>
<td>0</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>1</td>
<td>Always applied</td>
</tr>
</tbody>
</table>

**craind (integer):** crash strategy (used to obtain starting basis)

Default: 1

**cutlo (real):** lower cutoff for tree search

Default: -1.0e+75

**cutoff (real):** GMO cutoff

Default: 0.0

**cutpass (integer):** maximum number of cutting plane passes

Default: 0

**cuts (string):** default cut generation

Default: 0
**cutsfactor (real):** cut limit ↦

Default: -1.0

**cutup (real):** upper cutoff for tree search ↦

Default: 1.0e+75

**datacheck (integer):** controls data consistency checking and modeling assistance ↦

Default: 0

**decompdensity (real):** Matrix density above which automatic decomposition assigns each variable to a separate key ↦

Default: 0.3

**decomposition (integer):** Model decomposition method. ↦

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>0</td>
<td>Assign each variable to a separate key</td>
</tr>
<tr>
<td>1</td>
<td>Use automatic decomposition method</td>
</tr>
<tr>
<td>2</td>
<td>Use decomposition based on dot option .key</td>
</tr>
</tbody>
</table>

**depind (integer):** dependency checker on/off ↦

Default: -1

**deterministic (boolean):** Specifies whether the solution improvement heuristic is run in deterministic or opportunistic (i.e. non-deterministic) mode ↦

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Opportunistic</td>
</tr>
<tr>
<td>1</td>
<td>Deterministic</td>
</tr>
</tbody>
</table>

**dettilim (real):** deterministic time limit ↦

Default: 1.0e+75

**disjcuts (integer):** disjunctive cuts generation ↦

Default: 0

**divetype (integer):** MIP dive strategy ↦

Default: 0

**.divflt (real):** solution pool range filter coefficients ↦
Default: 0

divfltlo (real): lower bound on diversity ←
Default: mindouble

divfltup (real): upper bound on diversity ←
Default: maxdouble

divisor (integer): Initial divisor for sub models ←
Initial sub model size is model_size times 1 over Divisor. Ignored if InterDiv is set.
Default: automatic

domlim (integer): domain violation number ←
Default: 0

dpriind (integer): dual simplex pricing ←
Default: 0

dynamicrows (integer): switch for dynamic management of rows ←
Default: -1

dynamicsearch (integer): Search strategy for CPLEX caller and sub-model solves ←
Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>0</td>
<td>Use traditional branch &amp; cut</td>
</tr>
<tr>
<td>1</td>
<td>Use dynamic search</td>
</tr>
</tbody>
</table>

eachcutlim (integer): sets a limit for each type of cut ←
Default: 2100000000

epagap (real): absolute stopping tolerance ←
Synonym: optca
Default: 1.0e-06

epgap (real): relative stopping tolerance ←
Synonym: optcr
Default: 1.0e-04

epint (real): integrality tolerance ←
Default: 1.0e-05
eplin (real): degree of tolerance used in linearization

Default: 0.001

epmrk (real): Markowitz pivot tolerance

Default: 0.01

epopt (real): optimality tolerance

Default: 1.0e-06

epper (real): perturbation constant

Default: 1.0e-06

eprelax (real): relaxation for feasOpt

Default: 1.0e-06

eprhs (real): feasibility tolerance

Default: 1.0e-06

extracplexlog (boolean): Write addition CPLEX output to log

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not write extra CPLEX information</td>

<tr>
<td>1</td>
<td>Write extra CPLEX information</td>
</tr>
</tbody>
</table>

feasoptmode (integer): mode of FeasOpt

Default: 0

feastol (real): Feasibility tolerance

Range: [0, 1.0]

Default: 1e-6

firstfeas (integer): Use first feasible heuristic for finding an initial feasible solution

The default for ODH-CPLEX is 1 while for the heuristic engine the default is -1.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tbody>
</table>

**firstfeaseffort (integer):** Effort limit on first feasible heuristic $\leftarrow$

If the option value is positive the exact value is used as the level of effort. If the value is negative no more than the absolute value of the option is used as the level of effort. The larger the effort level, the more effort is expended before giving up.

Default: -500

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;0</td>
<td>Use this level of effort</td>
</tr>
<tr>
<td>&lt;0</td>
<td>Use no more than -firstfeaseffort effort</td>
</tr>
</tbody>
</table>

**firstfeaslpitlim (integer):** Limit on number of relaxed re-solves in first feasible heuristic $\leftarrow$

Default: 10

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>No limit</td>
</tr>
<tr>
<td>0</td>
<td>No relaxed re-solves</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Limit</td>
</tr>
</tbody>
</table>

**firstfeasrelaxcrit (real):** Smallest sum of infeasibilites/row where relaxed solution used $\leftarrow$

Default: 0.01

**firstfeasshift (integer):** First feasible heuristic variable shifting in found solutions $\leftarrow$

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not shift</td>
</tr>
<tr>
<td>1</td>
<td>Moderate shifting</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive shifting</td>
</tr>
</tbody>
</table>

**fixoptfile (string):** name of option file which is read just before solving the fixed problem $\leftarrow$

**flowcovers (integer):** flow cover cut generation $\leftarrow$

Default: 0

**flowpaths (integer):** flow path cut generation $\leftarrow$

Default: 0
folding (integer): LP folding will be attempted during the preprocessing phase ←
  Default: -1

fpheur (integer): feasibility pump heuristic ←
  Default: 0

fraccand (integer): candidate limit for generating Gomory fractional cuts ←
  Default: 200

fraccuts (integer): Gomory fractional cut generation ←
  Default: 0

fracpass (integer): maximum number of passes for generating Gomory fractional cuts ←
  Default: 0

freegamsmodel (boolean): preserves memory by dumping the GAMS model instance representation temporarily to disk ←
  Default: 0

globalbounds (integer): Use of global bounds from CPLEX caller ←
  Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Never use</td>
</tr>
<tr>
<td>5</td>
<td>Always use</td>
</tr>
<tr>
<td>1-4</td>
<td>Intensity of use</td>
</tr>
</tbody>
</table>

gubcovers (integer): GUB cover cut generation ←
  Default: 0

heurfreq (integer): heuristic frequency ←
  Default: 0

heuristic effort (real): the effort that CPLEX spends on heuristics during a MIP solve ←
  Default: 1.0

ignoresetslvrparams (boolean): Flag to control whether solver parameters can be dynamically altered by ODH ←
  Default: 0

implbd (integer): implied bound cut generation ←
  Default: 0
indexkey (string): Pattern used to match variable names for grouping into sub-models discussed above

indicoptstrict (boolean): abort in case of an error in indicator constraint in solver option file

    Default: 1

integeronly (integer): Variables to include in INDEXKEY

    Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>0</td>
<td>All variables</td>
</tr>
<tr>
<td>1</td>
<td>Only non-continuous variables</td>
</tr>
</tbody>
</table>

integertol (real): Integrality tolerance for variable values

    Default: 1e-5

interdiv (integer): Initial divisor value

    Default: 4

intsollim (integer): maximum number of integer solutions

    Default: 2147483647

itlim (integer): iteration limit

    Synonym: iterlim

    Default: 2147483647

.key (integer): Variable block or key number

    Default: 0

keypartition (integer): Use of solver partition information

    Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use</td>
</tr>
<tr>
<td>1</td>
<td>Use solver partition information to generate keys</td>
</tr>
<tr>
<td>2</td>
<td>Use keys to generate sub-solver partition information</td>
</tr>
</tbody>
</table>

keysminimum (integer): Minimum number of keys that the automatic decomposition method attempts to find

    Default: 512
keytype (boolean): Treatment of multiple INDEXKEYs

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Considered separately e.g. INDEXKEY=x_2; y_2 means x_2 and y_2 belong to separate groups</td>
</tr>
<tr>
<td>1</td>
<td>Considered together e.g. INDEXKEY=x_2; y_2 means x_2 and y_2 belong to the same group</td>
</tr>
</tbody>
</table>

.lazy (boolean): Lazy constraints activation

Default: 0

lazyconstraints (boolean): Indicator to use lazy constraints

Default: 0

lbheur (boolean): local branching heuristic

Default: 0

liftprojcuts (integer): lift-and-project cuts

Default: 0

localimplied (integer): generation of locally valid implied bound cuts

Default: 0

localsearch (boolean): Indicator for local search heuristic

Default: 1

loosefeastol (real): Loose feasibility tolerance

Default: 1e-5

lpmethod (integer): algorithm to be used for LP problems

Default: 0

maxbacktrack (integer): The maximum number of backtracks permitted in sub-model solves

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>0</td>
<td>Infinite</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Use this value if a better solution is available</td>
</tr>
</tbody>
</table>

maxbound (real): The largest(smallest) non infinite bound value ODH will accept for upper(lower) bounds

Default: -1
If this value is positive, bounds exceeding MAXBOUND are reduced to MAXBOUND; if this value is negative, bounds exceeding -MAXBOUND are ignored.

Default: $1 \times 10^9$

**maxinfrepeat (integer)**: Maximum divisor value when solution is infeasible

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Use this value</td>
</tr>
</tbody>
</table>

**maxinterdiv (integer)**: Maximum divisor value

Default: 0

**maxrepeat (integer)**: Maximum number of sub-model repeat solves for each divisor value

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Use this value</td>
</tr>
</tbody>
</table>

**mcfcuts (integer)**: multi-commodity flow cut generation

Default: 0

**memoryemphasis (boolean)**: reduces use of memory

Default: 0

**mipdisplay (integer)**: progress display level

Default: 2

**mipemphasis (integer)**: MIP solution tactics

Default: 0

**mipinterval (integer)**: progress display interval

Default: 0

**mipkappastats (integer)**: MIP kappa computation

Default: 0

**mipordind (boolean)**: priority list on/off

Synonym: prioropt

Default: 1
mipordtype (integer): priority order generation ←

Default: 0

mipsearch (integer): search strategy for mixed integer programs ←

Default: 0

mipstart (integer): use mip starting values ←

Default: 0

miqcpstrat (integer): MIQCP relaxation choice ←

Default: 0

mircuts (integer): mixed integer rounding cut generation ←

Default: 0

mpslongnum (boolean): MPS file format precision of numeric output ←

Default: 1

multimipstart (string): use multiple mipstarts provided via gdx files ←

multobjdisplay (integer): level of display during multiobjective optimization ←

Default: 1

names (boolean): load GAMS names into Cplex ←

Default: 1

netdisplay (integer): network display level ←

Default: 2

netepopt (real): optimality tolerance for the network simplex method ←

Default: 1.0e−06

neteprhs (real): feasibility tolerance for the network simplex method ←

Default: 1.0e−06

netfind (integer): attempt network extraction ←

Default: 2

netitlim (integer): iteration limit for network simplex ←

Default: 2147483647

netppriind (integer): network simplex pricing ←

Default: 0
**nodecuts** (integer): decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree

Default: 0

**nodefileind** (integer): node storage file indicator

Default: 1

**nodelim** (integer): maximum number of nodes to solve

Synonym: nodlim

Default: 2147483647

**nodesel** (integer): node selection strategy

Default: 1

**numericalemphasis** (boolean): emphasizes precision in numerically unstable or difficult problems

Default: 0

**objdif** (real): overrides GAMS Cheat parameter

Synonym: cheat

Default: 0.0

**objllim** (real): objective function lower limit

Default: -1.0e+75

**objcutoff** (real): Target objective value

ODHeuristics terminates when this value is reached. Defaults to -infinity for minimization or +infinity for maximization models.

Default: 0

**objthreshold** (real): Threshold for absolute value of objective coefficients

Variables with coefficients greater than this value are always considered for optimization.

Default: 1e99

**objulim** (real): objective function upper limit

Default: 1.0e+75

**odheuristicmethod** (string): ODHeuristic method section

Default: ODH-CPLEX

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ODH-CPLEX</td>
<td>ODHeuristic within the CPLEX optimizer</td>
</tr>
<tr>
<td>STANDALONE</td>
<td>Stand-alone ODHeuristic engine</td>
</tr>
</tbody>
</table>
**odhfeasopt** (boolean): Optimization method for sub-models in phaseI

Default: 0

**odhtthreads** (integer): The number of heuristic threads used by ODH-CPLEX or STANDALONE

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>0</td>
<td>Run in serial mode</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Use the specified number of threads</td>
</tr>
</tbody>
</table>

**odhtimelimit** (real): Elapsed time limit in seconds

Synonym: reslim

Default: GAMS ResLim

**optimalitytarget** (integer): type of optimality that Cplex targets

Default: 0

**parallelmode** (integer): parallel optimization mode

Default: 0

**paramdisplay** (boolean): display the nondefault parameters before optimization

Default: 1

**penalty** (real): The objective function coefficient value for penalties

The objective function coefficient value for the penalties introduced to deal with infeasibilities in the solution improvement heuristic. It is set by default when required and if not specified.

Default: -1

**penperturb** (real): Perturbation tolerance for penalties coefficients

Default: 0

**perind** (boolean): force initial perturbation

Default: 0

**perlim** (integer): number of stalled iterations before perturbation

Default: 0

**phase12** (boolean): Specifies whether to use a phaseI/phaseII method to remove infeasibilities

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use composite objective method</td>
</tr>
<tr>
<td>1</td>
<td>Use phaseI/phaseII method</td>
</tr>
</tbody>
</table>

**polishafterdettime** *(real)*: deterministic time before starting to polish a feasible solution

Default: 1.0e+75

**polishafterepagap** *(real)*: absolute MIP gap before starting to polish a feasible solution

Default: 0.0

**polishafterepgap** *(real)*: relative MIP gap before starting to polish a solution

Default: 0.0

**polishafterintsol** *(integer)*: MIP integer solutions to find before starting to polish a feasible solution

Default: 2147483647

**polishafternode** *(integer)*: nodes to process before starting to polish a feasible solution

Default: 2147483647

**polishaftertime** *(real)*: time before starting to polish a feasible solution

Default: 1.0e+75

**populatelim** *(integer)*: limit of solutions generated for the solution pool by populate method

Default: 20

**ppriind** *(integer)*: primal simplex pricing

Default: 0

**predual** *(integer)*: give dual problem to the optimizer

Default: 0

**preind** *(boolean)*: turn presolver on/off

Default: 1

**prelinear** *(boolean)*: linear reduction indicator

Default: 1

**prepass** *(integer)*: number of presolve applications to perform

Default: -1

**prereform** *(integer)*: set presolve reformulations

Default: 3

**preslvnd** *(integer)*: node presolve selector
pricelim (integer): pricing candidate list

Default: 0

printoptions (boolean): list values of all options to GAMS listing file

Default: 0

probe (integer): perform probing before solving a MIP

Default: 0

probedettime (real): deterministic time spent probing

Default: 1.0e+75

probetime (real): time spent probing

Default: 1.0e+75

processorlock (boolean): Thread allocation

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not lock threads to processors</td>
</tr>
<tr>
<td>1</td>
<td>Lock threads to processors</td>
</tr>
</tbody>
</table>

qextractalg (integer): quadratic extraction algorithm in GAMS interface

Default: 0

qpmakepsdind (boolean): adjust MIQP formulation to make the quadratic matrix positive-semi-definite

Default: 1

qpmethod (integer): algorithm to be used for QP problems

Default: 0

qtolin (integer): linearization of the quadratic terms in the objective function of a QP or MIQP model

Default: -1

quality (boolean): write solution quality statistics

Default: 0

quickfirstsolve (boolean): Accelerate initial CPLEX solve

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not unless presolve applied to full model</td>
</tr>
<tr>
<td>1</td>
<td>Use existing presolved model</td>
</tr>
</tbody>
</table>

**randomseed** *(integer)*: sets the random seed differently for diversity of solutions

Default: 202009243

**readflt** *(string)*: reads Cplex solution pool filter file

**record** *(boolean)*: Records invocations of Callable Library routines

Default: 0

**recurse** *(integer)*: Recurse using heuristic to solve sub-models when a feasible solution has been obtained

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not recurse</td>
</tr>
<tr>
<td>1</td>
<td>Recurse thread 0 only</td>
</tr>
<tr>
<td>2</td>
<td>Recurse odd numbered threads</td>
</tr>
<tr>
<td>3</td>
<td>Recurse all threads</td>
</tr>
<tr>
<td>&lt;0</td>
<td>Recurse when working with an infeasible solution. values are negated (e.g. -3 = recursion of all threads)</td>
</tr>
</tbody>
</table>

**recursedecomp** *(integer)*: Recursed model decomposition method

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Use initial model decomposition</td>
</tr>
<tr>
<td>0</td>
<td>Assign each variable to a separate key</td>
</tr>
<tr>
<td>1</td>
<td>Use automatic decomposition method</td>
</tr>
</tbody>
</table>

**recurseiterlim** *(integer)*: Recursed heuristic iteration limit for sub-solves

Default: 40

**recurselog** *(boolean)*: Write thread log files for recursed sub-solves

Default: 0

**recurseminiterlim** *(integer)*: Recursed heuristic minimum iterations before a solution is found in sub-solves

Default: 10

**recursesoliterlim** *(integer)*: Recursed heuristic sub-solves quit after these iterations if a solution is found

Default: maxint

**reduce (integer):** primal and dual reduction type

Default: 3

**reinv (integer):** refactorization frequency

Default: 0

**rejectinfsol (integer):** Reject infeasible solutions to sub-models

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not check feasibility or reject</td>
</tr>
<tr>
<td>1</td>
<td>Check feasibility and warn if infeasible, but accept</td>
</tr>
<tr>
<td>2</td>
<td>Check feasibility and reject if infeasible</td>
</tr>
</tbody>
</table>

**relaxfixedinfeas (boolean):** accept small infeasibilities in the solve of the fixed problem

Default: 0

**relaxpreind (integer):** presolve for initial relaxation on/off

Default: -1

**relaxsos2 (integer):** Treatment of SOS2 members

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Aggressive use in reducing sub-model size</td>
</tr>
<tr>
<td>1</td>
<td>Moderate use in reducing sub-model size</td>
</tr>
<tr>
<td>2</td>
<td>Ignored in sub-model creation</td>
</tr>
</tbody>
</table>

**relobjidif (real):** relative cheat parameter

Default: 0.0

**repairtries (integer):** try to repair infeasible MIP start

Default: 0

**repeatpresolve (integer):** reapply presolve at root after preprocessing

Default: -1

**rerun (string):** rerun problem if presolve infeasible or unbounded

Default: nono

**rinsheur (integer):** relaxation induced neighborhood search frequency
Default: 0

**rltcuts** *(integer)*: Reformulation Linearization Technique (RLT) cuts

Default: 0

**scaind** *(integer)*: matrix scaling on/off

Default: 0

**seed** *(integer)*: Initial random number seed

Default: 12345

**siftalg** *(integer)*: sifting subproblem algorithm

Default: 0

**siftdisplay** *(integer)*: sifting display level

Default: 1

**sifting** *(boolean)*: switch for sifting from simplex optimization

Default: 1

**siftitlim** *(integer)*: limit on sifting iterations

Default: 2147483647

**simdisplay** *(integer)*: simplex display level

Default: 1

**singlim** *(integer)*: limit on singularity repairs

Default: 10

**solnpool** *(string)*: solution pool file name

**solnpoolagap** *(real)*: absolute tolerance for the solutions in the solution pool

Default: 1.0e+75

**solnpoolcapacity** *(integer)*: limits of solutions kept in the solution pool

Default: 2100000000

**solnpoolgap** *(real)*: relative tolerance for the solutions in the solution pool

Default: 1.0e+75

**solnpoolintensity** *(integer)*: solution pool intensity for ability to produce multiple solutions

Default: 0

**solnpoolmerge** *(string)*: solution pool file name for merged solutions
solnpoolnumsym (integer): maximum number of variable symbols when writing merged solutions

    Default: 10

solnpoolprefix (string): file name prefix for GDX solution files

    Default: soln

solnpoolreplace (integer): strategy for replacing a solution in the solution pool

    Default: 0

solutiontype (integer): type of solution (basic or non basic) for an LP or QP

    Default: 0

solvefinal (boolean): switch to solve the problem with fixed discrete variables

    Default: 1

sos1reform (integer): automatic logarithmic reformulation of special ordered sets of type 1 (SOS1)

    Default: 0

sos2reform (integer): automatic logarithmic reformulation of special ordered sets of type 2 (SOS2)

    Default: 0

sosfind (boolean): Automatic detection of Special Ordered Sets (SOSs)

    Default: 0

sosinkey (integer): Assign each SOS to its own sub-model component (key)

    Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Treat SOS members as normal i.e. in keys iff declared non-continuous or integeronly =0;</td>
</tr>
<tr>
<td>1</td>
<td>SOS members always in keys</td>
</tr>
<tr>
<td>2</td>
<td>SOS members always in keys and members of each SOS to their own key</td>
</tr>
</tbody>
</table>

sosmember (string): Automatically detect SOSs whose variable member names match this pattern

sosovar (string): Automatically detect SOSs whose output variable name matches this pattern

sosselect (string): Select sub-set of SOS members
sosselect16 (string): Select sub-set of SOS members for sets with 16 or fewer members only →

soswvar (string): Automatically detect SOSs whose input(weight) variable name matches this pattern →

startalg (integer): MIP starting algorithm →

   Default: 0

strategy (integer): ODH-Cplex Strategy →

   The aggressive setting attempt to make more progress with each sub-model solve at the cost of more expensive sub solves. Amongst other changes, it sets InterDiv, MaxInterDiv and MaxRepeat if they are not explicitly set by the user.

   Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Conservative</td>
</tr>
<tr>
<td>1</td>
<td>Normal</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

strictdeterministic (integer): Terminate ODH deterministically when improvement heuristic finishes →

   Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Terminate ODH as soon as possible which can violate determinism</td>
</tr>
<tr>
<td>1</td>
<td>Terminate ODH deterministically</td>
</tr>
</tbody>
</table>

strongcandlim (integer): size of the candidates list for strong branching →

   Default: 10

strongitlim (integer): limit on iterations per branch for strong branching →

   Default: 0

subalg (integer): algorithm for subproblems →

   Default: 0

subcheckfreq (integer): Frequency with which sub-model LPs are interrupted for mutual communication →

   Default: 10

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not interrupt sub-model LPs</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Interrupt sub-model LPs. The smaller this value then more often they are interrupted.</td>
</tr>
</tbody>
</table>
submipnodelim (integer): limit on number of nodes in an RINS subMIP

Default: 500

submipscale (integer): scale the problem matrix when CPLEX solves a subMIP during MIP optimization

Default: 0

submipstartalg (integer): starting algorithm for a subMIP of a MIP

Default: 0

submipsubalg (integer): algorithm for subproblems of a subMIP of a MIP

Default: 0

subnodelimit (integer): Node limit for submodel searches

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Set node limit to this value</td>
</tr>
</tbody>
</table>

suborder (integer): Use of priority order in sub-solves

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use any supplied priority order information in sub-solves</td>
</tr>
<tr>
<td>1</td>
<td>Use any supplied priority order information in sub-solves</td>
</tr>
</tbody>
</table>

sub_cpx_threads (integer): Threads available for the solves within ODHeuristic

Default: 1

symmetry (integer): symmetry breaking cuts

Default: -1

syncfreq (integer): Thread synchronization frequency in deterministic parallel mode

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Low frequency</td>
</tr>
<tr>
<td>1</td>
<td>High frequency</td>
</tr>
</tbody>
</table>

threadlog (boolean): Write thread log files

Default: 0
threads (integer): global default thread count

Synonym: gthreads

Default: 0

threadzerosync (integer): Which CPLEX threads to use for synchronization

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Synchronize with multiple CPLEX threads</td>
</tr>
<tr>
<td>1</td>
<td>Only synchronize with CPLEX thread 0</td>
</tr>
</tbody>
</table>

tightenprebounds (integer): Level of bound tightening in ODH presolved model

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not tighten bounds</td>
</tr>
<tr>
<td>1</td>
<td>Least aggressive</td>
</tr>
<tr>
<td>2</td>
<td>Moderate aggressive</td>
</tr>
<tr>
<td>3</td>
<td>Most aggressive</td>
</tr>
</tbody>
</table>

tilim (real): overrides the GAMS ResLim option

Default: 1.0e+75
trelim (real): maximum space in memory for tree

Default: 1.0e+75

trialbound (integer): Trial bound heuristic

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>As option 1 plus retain trial bounds for whole optimization</td>
</tr>
<tr>
<td>-2</td>
<td>As option 2 plus retain trial bounds for whole optimization</td>
</tr>
<tr>
<td>0</td>
<td>Read trial bounds from trialboundfile if it is specified</td>
</tr>
<tr>
<td>1</td>
<td>Read trial bounds from trialboundfile</td>
</tr>
<tr>
<td>2</td>
<td>Auto generate trial bounds and write them to trialboundfile if it is specified</td>
</tr>
</tbody>
</table>

trialboundfile (string): The trial bound file

Bounds are used to attempt finding an initial feasible solution

trialboundsetsize (integer): Size adjustment to automatically generated trial bound sets

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not adjust set size</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Use no more than this number of set members</td>
</tr>
<tr>
<td>&lt;0</td>
<td>Decrease set size by this value</td>
</tr>
</tbody>
</table>

**tryint (real):** GMO tryint

Default: 0.0

**tuningdettilim (real):** tuning deterministic time limit per model or suite

Default: 1.0e+75

**tuningdisplay (integer):** level of information reported by the tuning tool

Default: 1

**tuningmeasure (integer):** measure for evaluating progress for a suite of models

Default: 1

**tuningrepeat (integer):** number of times tuning is to be repeated on perturbed versions

Default: 1

**tuningtilim (real):** tuning time limit per model or suite

Default: 1.0e+75

**usebasis (boolean):** GMO usebasis

Default: 0

**usehistory (integer):** Use of past sub-model selections in current selection

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>0</td>
<td>Never use historical information</td>

<tr>
<td>2</td>
<td>Barrier</td>
</tr>
</tbody>
</table>
variableclean (integer): Clean variable values from sub-models

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No cleaning</td>
</tr>
<tr>
<td>1</td>
<td>Quick cleaning and allow feasible uncleaned solutions if unable to clean</td>
</tr>
<tr>
<td>2</td>
<td>Quick cleaning and disallow uncleaned solutions</td>
</tr>
<tr>
<td>3</td>
<td>Thorough cleaning</td>
</tr>
</tbody>
</table>

varsel (integer): variable selection strategy at each node

Default: 0

warninglimit (integer): determines how many times warnings of a specific type (datacheck=2) will be displayed

Default: 10

workdir (string): directory for working files

Default: .

workeralgorithm (integer): set method for optimizing benders subproblems

Default: 0

workmem (real): memory available for working storage

Default: 2048.0

writeannotation (string): produce a Cplex annotation file

writebas (string): produce a Cplex basis file

writeflt (string): produce a Cplex solution pool filter file

writelp (string): produce a Cplex LP file

writemps (string): produce a Cplex MPS file

writemst (string): produce a Cplex mst file

writeord (string): produce a Cplex ord file
5.31 PATHNLP

5.31.1 Introduction

This document describes the GAMS/PATHNLP solver for non-linear programs and the options unique to this solver.

PATHNLP solves an NLP by internally constructing the Karush-Kuhn-Tucker (KKT) system of first-order optimality conditions associated with the NLP and solving this system using the PATH solver for complementarity problems. The solution to the original NLP is extracted from the KKT solution and returned to GAMS. All of this takes place automatically - no special syntax or user reformulation is required.

Typically, PATHNLP works very well for convex models. It also has a comparative advantage on models whose solution via reduced gradient methods results in a large number of superbasic variables, since the PATH solver won’t construct a dense reduced Hessian in the space of the superbasic variables as reduced gradient solvers do. For nonconvex models, however, PATHNLP is not as robust as the reduced gradient methods.

The theory relating NLP to their KKT systems is well-known: assuming differentiability without convexity, and assuming a constraint qualification holds, then a solution to the NLP must also be a solution to the KKT system. If we also assume convexity, then a solution to the KKT system is also a solution to the NLP - no further constraint qualification is required.

In case PATH fails to find a solution to the KKT system for the NLP, a phase I / phase II method is used in which the phase I objective is simply the feasibility error and the original objective is ignored. If a feasible point is found in phase I then phase II, an attempt to solve the KKT system for the NLP using the current feasible point, is entered.

PATHNLP is installed automatically with your GAMS system. With a demo or community license, it will solve small models only. If your GAMS license includes PATH, this size restriction is removed.

**writeparam** *(string)*: produce a Cplex parameter file with all active options

**writepre** *(string)*: produce a Cplex LP/MPS/SAV file of the presolved problem

**writeprob** *(string)*: produce a Cplex problem file and infers the type from the extension

**writesav** *(string)*: produce a Cplex binary problem file

**zerohalfcuts** *(integer)*: zero-half cuts

Default: 0

**zerotol** *(real)*: Zero tolerance for variable values

Default: $1e^{-9}$
5.31.2 Usage

If you have installed the system and configured PATHNLP as the default NLP solver, all NLP models without a specific solver option will be solved with PATHNLP. If you installed another solver as the default, you can explicitly request that a particular model be solved using PATHNLP by inserting the statement

```
option NLP = pathnlp;
```

somewhere before the `solve` statement. Similar comments hold for the other model types (LP, RMINLP, QCP, etc.) PATHNLP can handle.

The standard GAMS model options `iterlim` and `reslim` can be used to control PATHNLP. A description of these options can be found in the GAMS Options section of the chapter on basic solver usage. In general this is enough to use PATHNLP effectively. In some cases, however, you may want to use some of the PATH or PATHNLP options to gain further performance improvements or for other reasons. The rules for using an option file are described in the chapter on basic solver usage. The options used to control PATH can also be used to control PATHNLP. There are also some options unique to PATHNLP.

5.31.3 Options

The tables that follow describe the options unique to PATHNLP as well as the options shared with the PATH solver for MCP models.

5.31.3.1 General options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

#### 5.32.1 Complementarity

A fundamental problem of mathematics is to find a solution to a square system of nonlinear equations. Two generalizations of nonlinear equations have been developed, a constrained nonlinear system which incorporates bounds on the variables, and the complementarity problem (MCP). This document is primarily concerned with the complementarity problem.

The PATH solver for MCP models is a Newton-based solver that combines a number of the most effective variations, extensions, and enhancements of this powerful technique. See PATH vs MILES for a comparison with MILES. Algorithmic details can also be found in papers and technical reports by Dirkse, Ferris, and Munson on Ferris’ Home Page.

The complementarity problem adds a combinatorial twist to the classic square system of nonlinear equations, thus enabling a broader range of situations to be modeled. In its simplest form, the combinatorial problem is to choose from $2^n$ inequalities a subset of $n$ that will be satisfied as equations. These problems arise in a variety of disciplines including engineering and economics [60] where we might want to compute Wardropian and Walrasian equilibria, and optimization where we can model the first order optimality conditions for nonlinear programs [102] [114]. Other examples, such as bimatrix games [117] and options pricing [97], abound.

Our development of complementarity is done by example. We begin by looking at the optimality conditions for a transportation problem and some extensions leading to the nonlinear complementarity problem. We then discuss a Walrasian equilibrium model and use it to motivate the more general mixed complementarity problem. We conclude this chapter with information on solving the models using the PATH solver and interpreting the results.

#### 5.32.1.1 Transportation Problem

The transportation model is a linear program where demand for a single commodity must be satisfied by suppliers at minimal transportation cost. The underlying transportation network is given as a set $\mathcal{A}$ of arcs, where $(i, j) \in \mathcal{A}$ means that there is a route from supplier $i$ to demand center $j$. The problem variables are the quantities $x_{i,j}$ shipped over each arc $(i, j) \in \mathcal{A}$. The linear program can be written mathematically as

\[
\begin{align*}
\min_{x \geq 0} & \quad \sum_{(i, j) \in \mathcal{A}} c_{i,j} x_{i,j} \\
\text{subject to} & \quad \sum_{j \in (i, j) \in \mathcal{A}} x_{i,j} \leq s_i, \ \forall i \\
& \quad \sum_{i \in (i, j) \in \mathcal{A}} x_{i,j} \geq d_j, \ \forall j.
\end{align*}
\]

where $c_{i,j}$ is the unit shipment cost on the arc $(i, j)$, $s_i$ is the available supply at $i$, and $d_j$ is the demand at $j$.

#### 5.32.1 Complementarity

A fundamental problem of mathematics is to find a solution to a square system of nonlinear equations. Two generalizations of nonlinear equations have been developed, a constrained nonlinear system which incorporates bounds on the variables, and the complementarity problem (MCP). This document is primarily concerned with the complementarity problem.

The PATH solver for MCP models is a Newton-based solver that combines a number of the most effective variations, extensions, and enhancements of this powerful technique. See PATH vs MILES for a comparison with MILES. Algorithmic details can also be found in papers and technical reports by Dirkse, Ferris, and Munson on Ferris’ Home Page.

The complementarity problem adds a combinatorial twist to the classic square system of nonlinear equations, thus enabling a broader range of situations to be modeled. In its simplest form, the combinatorial problem is to choose from $2^n$ inequalities a subset of $n$ that will be satisfied as equations. These problems arise in a variety of disciplines including engineering and economics [60] where we might want to compute Wardropian and Walrasian equilibria, and optimization where we can model the first order optimality conditions for nonlinear programs [102] [114]. Other examples, such as bimatrix games [117] and options pricing [97], abound.

Our development of complementarity is done by example. We begin by looking at the optimality conditions for a transportation problem and some extensions leading to the nonlinear complementarity problem. We then discuss a Walrasian equilibrium model and use it to motivate the more general mixed complementarity problem. We conclude this chapter with information on solving the models using the PATH solver and interpreting the results.

#### 5.32.1.1 Transportation Problem

The transportation model is a linear program where demand for a single commodity must be satisfied by suppliers at minimal transportation cost. The underlying transportation network is given as a set $\mathcal{A}$ of arcs, where $(i, j) \in \mathcal{A}$ means that there is a route from supplier $i$ to demand center $j$. The problem variables are the quantities $x_{i,j}$ shipped over each arc $(i, j) \in \mathcal{A}$. The linear program can be written mathematically as

\[
\begin{align*}
\min_{x \geq 0} & \quad \sum_{(i, j) \in \mathcal{A}} c_{i,j} x_{i,j} \\
\text{subject to} & \quad \sum_{j \in (i, j) \in \mathcal{A}} x_{i,j} \leq s_i, \ \forall i \\
& \quad \sum_{i \in (i, j) \in \mathcal{A}} x_{i,j} \geq d_j, \ \forall j.
\end{align*}
\]

where $c_{i,j}$ is the unit shipment cost on the arc $(i, j)$, $s_i$ is the available supply at $i$, and $d_j$ is the demand at $j$.
The derivation of the optimality conditions for this linear program begins by associating with each constraint a multiplier, alternatively termed a dual variable or shadow price. These multipliers represent the marginal price on changes to the corresponding constraint. We label the prices on the supply constraint \( p^s \) and those on the demand constraint \( p^d \). Intuitively, for each supply node \( i \)

\[
0 \leq p^s_i, \quad s_i \geq \sum_{j:(i,j) \in A} x_{i,j}.
\]

Consider the case when \( s_i > \sum_{j:(i,j) \in A} x_{i,j} \), that is there is excess supply at \( i \). Then, in a competitive marketplace, no rational person is willing to pay for more supply at node \( i \); it is already over-supplied. Therefore, \( p^s_i = 0 \). Alternatively, when \( s_i = \sum_{j:(i,j) \in A} x_{i,j} \), that is node \( i \) is clear, we might be willing to pay for additional supply of the good. Therefore, \( p^s_i \geq 0 \). We write these two conditions succinctly as:

\[
0 \leq p^s_i \perp s_i \geq \sum_{j:(i,j) \in A} x_{i,j}, \quad \forall i
\]

where the \( \perp \) notation is understood to mean that at least one of the adjacent inequalities must be satisfied as an equality. For example, either \( 0 = p^s_i \), the first case, or \( s_i = \sum_{j:(i,j) \in A} x_{i,j} \), the second case.

Similarly, at each node \( j \), the demand must be satisfied in any feasible solution, that is

\[
\sum_{i:(i,j) \in A} x_{i,j} \geq d_j.
\]

Furthermore, the model assumes all prices are nonnegative, \( 0 \leq p^d_j \). If there is too much of the commodity supplied, \( \sum_{i:(i,j) \in A} x_{i,j} > d_j \), then, in a competitive marketplace, the price \( p^d_j \) will be driven down to 0. Summing these relationships gives the following complementarity condition:

\[
0 \leq p^d_j \perp \sum_{i:(i,j) \in A} x_{i,j} \geq d_j, \quad \forall j.
\]

The supply price at \( i \) plus the transportation cost \( c_{i,j} \) from \( i \) to \( j \) must exceed the market price at \( j \). That is, \( p^s_i + c_{i,j} \geq p^d_j \). Otherwise, in a competitive marketplace, another producer will replicate supplier \( i \) increasing the supply of the good in question which drives down the market price. This chain would repeat until the inequality is satisfied. Furthermore, if the cost of delivery strictly exceeds the market price, that is \( p^s_i + c_{i,j} > p^d_j \), then nothing is shipped from \( i \) to \( j \) because doing so would incur a loss and \( x_{i,j} = 0 \). Therefore,

\[
0 \leq x_{i,j} \perp p^s_i + c_{i,j} \geq p^d_j, \quad \forall (i,j) \in A.
\]

We combine the three conditions into a single problem,

\[
\begin{align*}
0 & \leq p^s_i \perp s_i \geq \sum_{j:(i,j) \in A} x_{i,j}, \quad \forall i \\
0 & \leq p^d_j \perp \sum_{i:(i,j) \in A} x_{i,j} \geq d_j, \quad \forall j \\
0 & \leq x_{i,j} \perp p^s_i + c_{i,j} \geq p^d_j, \quad \forall (i,j) \in A.
\end{align*}
\]

This model defines a linear complementarity problem that is easily recognized as the complementary slackness conditions [37] of the linear program (1). For linear programs the complementary slackness conditions are both necessary and sufficient for \( x \) to be an optimal solution of the problem (1). Furthermore, the conditions (2) are also the necessary and sufficient optimality conditions for a related problem in the variables \((p^s, p^d)\)

\[
\max_{p^s, p^d \geq 0} \sum_{j} d_j p^d_j - \sum_{i} s_i p^s_i
\]

subject to \( c_{i,j} \geq p^d_j - p^s_i, \quad \forall (i,j) \in A \)

termed the dual linear program (hence the nomenclature "dual variables").

Looking at (2) a bit more closely we can gain further insight into complementarity problems. A solution of (2) tells us the arcs used to transport goods. A priori we do not need to specify which arcs to use, the solution itself indicates them. This property represents the key contribution of a complementarity problem over a system of equations. If we know what arcs to send flow down, we can just solve a simple system of linear equations. However, the key to the modeling power of complementarity is that it chooses which of the inequalities in (2) to satisfy as equations. In economics we can use this property to generate a model with different regimes and let the solution determine which ones are active. A regime shift could, for example, be a back stop technology like windmills that become profitable if a \( CO_2 \) tax is increased.
5.32.1.1.1 GAMS Code  The GAMS code for the complementarity version of the transportation problem is given in Figure 1; the actual data for the model is assumed to be given in the file transmcp.dat. Note that the model written corresponds very closely to (2). In GAMS, the $\bot$ sign is replaced in the model statement with a ".". It is precisely at this point that the pairing of variables and equations shown in (2) occurs in the GAMS code. For example, the function defined by rational is complementary to the variable x. To inform a solver of the bounds, the standard GAMS statements on the variables can be used, namely (for a declared variable z(i)):

```
z.lo(i) = 0;
```

or alternatively

```
positive variable z;
```

Further information on the GAMS syntax can be found in [155]. Note that GAMS requires the modeler to write $F(z) \leq 0$ whenever the complementary variable is lower bounded, and does not allow the alternative form $0 \leq F(z)$.

**Figure 1**: A simple MCP model in GAMS, transmcp.gms

```gams
sets i canning plants, j markets ;
parameter s(i) capacity of plant i in cases, d(j) demand at market j in cases, c(i,j) transport cost in thousands of dollars per case ;
$include transmcp.dat
positive variables x(i,j) shipment quantities in cases p_demand(j) price at market j p_supply(i) price at plant i;

equations
supply(i) observe supply limit at plant i
demand(j) satisfy demand at market j rational(i,j);
supply(i) .. s(i) =g= sum(j, x(i,j)) ;
demand(j) .. sum(i, x(i,j)) =g= d(j) ;
rational(i,j) .. p_supply(i) + c(i,j) =g= p_demand(j) ;

model transport / rational.x, demand.p_demand, supply.p_supply /;

solve transport using mcp;
```
5.32.1.1.2 Extension: Model Generalization While many interior point methods for linear programming exploit this complementarity framework (so-called primal-dual methods [205]), the real power of this modeling format is the new problem instances it enables a modeler to create. We now show some examples of how to extend the simple model (2) to investigate other issues and facets of the problem at hand.

Demand in the model of Figure 1 is independent of the prices $p$. Since the prices $p$ are variables in the complementarity problem (2), we can easily replace the constant demand $d$ with a function $d(p)$ in the complementarity setting. Clearly, any algebraic function of $p$ that can be expressed in GAMS can now be added to the model given in Figure 1. For example, a linear demand function could be expressed using

$$
\sum_{i:(i,j) \in A} x_{i,j} \geq d_j(1 - p d_j), \ \forall j.
$$

Note that the demand is rather strange if $p d_j$ exceeds 1. Other more reasonable examples for $d(p)$ are easily derived from Cobb-Douglas or CES utilities. For those examples, the resulting complementarity problem becomes nonlinear in the variables $p$. Details of complementarity for more general transportation models can be found in [48], [62].

Another feature that can be added to this model are tariffs or taxes. In the case where a tax is applied at the supply point, the third general inequality in (2) is replaced by

$$
p_s i (1 + t_i) + c_{i,j} \geq p d_j, \ \forall (i,j) \in A.
$$

The taxes can be made endogenous to the model, details are found in [155].

The key point is that with either of the above modifications, the complementarity problem is not just the optimality conditions of a linear program. In many cases, there is no optimization problem corresponding to the complementarity conditions.

5.32.1.1.3 Nonlinear Complementarity Problem We now abstract from the particular example to describe more carefully the complementarity problem in its mathematical form. All the above examples can be cast as nonlinear complementarity problems (NCPs) defined as follows:

\[ (NCP) \text{ Given a function } F : \mathbb{R}^n \to \mathbb{R}^n, \text{ find } z \in \mathbb{R}^n \text{ such that } \]

\[
0 \leq z \perp F(z) \geq 0.
\]

Recall that the $\perp$ sign signifies that one of the inequalities is satisfied as an equality, so that componentwise, $z_i F_i(z) = 0$. We frequently refer to this property as $z_i$ is complementary to $F_i$. A special case of the NCP that has received much attention is when $F$ is a linear function, the linear complementarity problem [40].

5.32.1.2 Walrasian Equilibrium

A Walrasian equilibrium can also be formulated as a complementarity problem (see [132]). In this case, we want to find a price $p \in \mathbb{R}^m$ and an activity level $y \in \mathbb{R}^n$ such that

\[
\begin{align*}
0 \leq y & \perp L(p) := -A^T p \geq 0 \\
0 \leq p & \perp S(p,y) := b + Ay - d(p) \geq 0
\end{align*}
\]

where $S(p,y)$ represents the excess supply function and $L(p)$ represents the loss function. Complementarity allows us to choose the activities $y_j$ to run (i.e. only those that do not make a loss). The second set of inequalities state that the price of a commodity can only be positive if there is no excess supply. These conditions indeed correspond to the standard exposition of Walras' law which states that supply equals demand if we assume all prices $p$ will be positive at a solution. Formulations of equilibria as systems of equations do not allow the model to choose the activities present, but typically make an a priori assumption on this matter.
5.32.1.2.1 GAMS Code  A GAMS implementation of (3) is given in Figure 2. Many large scale models of this nature have been developed. An interested modeler could, for example, see how a large scale complementarity problem was used to quantify the effects of the Uruguay round of talks [95].

Figure 2: Walrasian equilibrium as an NCP, walras1.gms

$include walras.dat

positive variables p(i), y(j);
equations S(i), L(j);
S(i).. b(i) + sum(j, A(i,j)*y(j)) - c(i)*sum(k, g(k)*p(k)) / p(i)
   =g= 0;
L(j).. -sum(i, p(i)*A(i,j)) =g= 0;
model walras / S.p, L.y /;
solve walras using mcp;

5.32.1.2.2 Extension: Intermediate Variables  In many modeling situations, a key tool for clarification is the use of intermediate variables. As an example, the modeler may wish to define a variable corresponding to the demand function $d(p)$ in the Walrasian equilibrium (3). The syntax for carrying this out is shown in Figure 3 where we use the variables $d$ to store the demand function referred to in the excess supply equation. The model walras now contains a mixture of equations and complementarity constraints. Since constructs of this type are prevalent in many practical models, the GAMS syntax allows such formulations.

Figure 3: Walrasian equilibrium as an MCP, walras2.gms

$include walras.dat

positive variables p(i), y(j);
variables d(i);
equations S(i), L(j), demand(i);
demand(i)..
   d(i) =e= c(i)*sum(k, g(k)*p(k)) / p(i) ;
S(i).. b(i) + sum(j, A(i,j)*y(j)) - d(i) =g= 0 ;
L(j).. -sum(i, p(i)*A(i,j)) =g= 0 ;
model walras / demand.d, S.p, L.y /;
solve walras using mcp;

Note that positive variables are paired with inequalities, while free variables are paired with equations. A crucial point misunderstood by many modelers (new and experienced alike) is that the bounds on the variable determine the relationships satisfied by the function $F$. Thus in Figure 3, $d$ is a free variable and therefore its paired equation demand is an equality. Similarly, since $p$ is nonnegative, its paired relationship $S$ is a (greater-than) inequality. See the MCP definition below for details.

A simplification is allowed to the model statement in Figure 3. It is not required to match free variables explicitly to equations; we only require that there are the same number of free columns (i.e. single variables) as unmatched rows (i.e. single equations). Thus, in the example of Figure 3, the model statement could be replaced by...
model walras / demand, S.p, L.y /

This extension allows existing GAMS models consisting of a square system of nonlinear equations to be easily recast as a complementarity problem - the model statement is unchanged. GAMS generates a list of all variables appearing in the equations found in the model statement, performs explicitly defined pairings and then checks that the number of remaining equality rows equals the number of remaining free columns. However, if an explicit match is given, the PATH solver can frequently exploit the information for better solution. Note that all variables that are not free and all inequalities must be explicitly matched.

5.32.1.2.3 Mixed Complementarity Problem A mixed complementarity problem (MCP) is specified by three pieces of data, namely the lower bounds \( \ell \), the upper bounds \( u \) and the function \( F \).

\[(\text{MCP}) \quad \text{Given lower bounds } \ell \in \{R \cup \{-\infty\}\}^n, \text{ upper bounds } u \in \{R \cup \{\infty\}\}^n \text{ and a function } F : R^n \rightarrow R^n, \text{ find } z \in R^n \text{ such that precisely one of the following holds for each } i \in \{1, \ldots, n\}:\]

\[
    F_i(z) = 0 \quad \text{and} \quad \ell_i \leq z_i \leq u_i
\]

\[
    F_i(z) > 0 \quad \text{and} \quad z_i = \ell_i
\]

\[
    F_i(z) < 0 \quad \text{and} \quad z_i = u_i.
\]

These relationships define a general MCP (sometimes termed a rectangular variational inequality [94]). We will write these conditions compactly as

\[
\ell \leq x \leq u \perp F(x).
\]

As the MCP model type as defined above is the one used in GAMS, there are some consequences of the definition worth emphasizing here. Firstly, the bounds on the variable determine the relationships satisfied by the function \( F \): the constraint type (e.g. \( =G=, =L= \)) chosen plays no role in defining the problem. This being the case, it is acceptable (and perhaps advisable!) to use an \( =N= \) in the definition of all equations used in complementarity models to highlight the dependence on the variable bounds in defining the MCP. This is not required, however. The constraint types \( =G=, =L= \) and \( =E= \) are also allowed. If the variable bounds are inconsistent with the constraint type chosen, GAMS will either reject the model (e.g. an \( =L= \) row matched with a lower-bounded variable) or silently and temporarily ignore the issue (e.g. an \( =E= \) row matched with a lower-bounded variable). In the latter case, if equality does not hold at solution (allowable if the variable is at lower bound) the is marked in the listing file with a redef.

Secondly, note the contrast between complementarity conditions like \( g(z) \leq 0, z \geq 0 \) and a complementarity problem like \( F(x) \perp 0 \leq x \leq \infty \). The former requires a trivial transformation in order to fit into the MCP framework: \(-g(z) \perp 0 \leq z \leq \infty \). This simple issue is a frequent source of problems and worth looking out for.

The nonlinear complementarity problem of Nonlinear Complementarity Problem is a special case of the MCP. For example, to formulate an NCP in the GAMS/MCP format we set

\[
z.\text{lo}(I) = 0;
\]

or declare

\[
\text{positive variable } z;
\]

Another special case is a square system of nonlinear equations

\[(\text{NE}) \quad \text{Given a function } F : R^n \rightarrow R^n \text{ find } z \in R^n \text{ such that } F(z) = 0.\]

In order to formulate this in the GAMS/MCP format we just declare
5.32 PATH

free variable z;

In both the above cases, we must not modify the lower and upper bounds on the variables later (unless we wish to drastically change the problem under consideration).

An advantage of the extended formulation described above is the pairing between "fixed" variables (ones with equal upper and lower bounds) and a component of $F$. If a variable $z_i$ is fixed, then $F_i(z)$ is unrestricted since precisely one of the three conditions in the MCP definition automatically holds when $z_i = \ell_i = u_i$. Thus if a variable is fixed in a GAMS model, the paired equation is completely dropped from the model. This convenient modeling trick can be used to remove particular constraints from a model at generation time. As an example, in economics, fixing a level of production will remove the zero-profit condition for that activity.

Simple bounds on the variables are a convenient modeling tool that translates into efficient mathematical programming tools. For example, specialized codes exist for the bound constrained optimization problem

$$\min f(x) \text{ subject to } \ell \leq x \leq u.$$ 

The first order optimality conditions for this problem class are precisely MCP($\nabla f(x), [\ell, u]$). We can easily see this condition in a one dimensional setting. If we are at an unconstrained stationary point, then $\nabla f(x) = 0$. Otherwise, if $x$ is at its lower bound, then the function must be increasing as $x$ increases, so $\nabla f(x) \geq 0$. Conversely, if $x$ is at its upper bound, then the function must be increasing as $x$ decreases, so that $\nabla f(x) \leq 0$. The MCP allows such problems to be easily and efficiently processed.

Upper bounds can be used to extend the utility of existing models. For example, in Figure 3 it may be necessary to have an upper bound on the activity level $y$. In this case, we simply add an upper bound to $y$ in the model statement, and we can replace the loss equation with the following definition:

```gams
y.up(j) = 10;
L(j).. -sum(i, p(i)*A(i,j)) =e= 0 ;
```

Here, for bounded variables, we do not know beforehand if the constraint will be satisfied as an equation, less-than inequality or greater-than inequality, since this determination depends on the values of the solution variables. However, let us interpret the relationships that the above change generates. If $y_j = 0$, the loss function can be positive since we are not producing in the $j$th sector. If $y_j$ is strictly between its bounds, then the loss function must be zero by the definition of complementarity; this is the competitive assumption. Finally, if $y_j$ is at its upper bound, then the loss function can be negative. Of course, if the market does not allow free entry, some firms may operate at a profit (negative loss). For more examples of problems, the interested reader is referred to [45], [59], [60].

5.32.1.3 Solution

We will assume that a file named transmcp.gms has been created using the GAMS syntax which defines an MCP model transport as developed in Transportation Problem. The modeler has a choice of the complementarity solver to use. We are going to further assume that the modeler wants to use PATH.

There are two ways to ensure that PATH is used as opposed to any other GAMS/MCP solver. These are as follows:

1. Add the following line to the transmcp.gms file prior to the solve statement

   ```gams
   option mcp = path;
   ```

   PATH will then be used instead of the default solver provided.
2. Choose PATH as the default solver for MCP (via the IDE on Windows or elsewhere by rerunning `gamsinst` from the GAMS system directory).

To solve the problem, the modeler executes the command:

```
gams transmcp
```

where `transmcp` can be replaced by any filename containing a GAMS model. Many other command line options for GAMS exist; the reader is referred to List of Command Line Parameters for further details.

At this stage, control is handed over to the solver which creates a log providing information on what the solver is doing as time elapses. See Section PATH for details about the log file. After the solver terminates, a listing file is generated containing the solution to the problem. We now describe the listing file output specifically related to complementarity problems.

### 5.32.1.3.1 Listing File

The listing file is the standard GAMS mechanism for reporting model results. This file contains information regarding the compilation process, the form of the generated equations in the model, and a report from the solver regarding the solution process.

We now detail the last part of this output, an example of which is given in Figure 4. We use "..." to indicate where we have omitted continuing similar output.

**Figure 4:** Listing File for solving `transmcp.gms`

```
S O L V E    S U M M A R Y

---- VAR X  shipment quantities in cases

      LOWER    LEVEL    UPPER   MARGINAL
    seattle .new-york  .  50.000  +INF   
```
After a summary line indicating the model name and type and the solver name, the listing file shows a solver status and a model status. Table 1 and Table 2 display the relevant codes that are returned under different circumstances. A modeler can access these codes within the transmcp.gms file using transport.solveStat and transport.modelStat respectively.

Table 1: Solver Status Codes

<table>

<tr>
<td>1</td>
<td>Optimal</td>
<td>Solver found a solution of the problem</td>
</tr>
<tr>
<td>6</td>
<td>Intermediate infeasible</td>
<td>Solver failed to solve the problem</td>
</tr>
</tbody>
</table>

After this, a listing of the time and iterations used is given, along with a count on the number of evaluation errors encountered. If the number of evaluation errors is greater than zero, further information can typically be found later in the listing file, prefaced by "****". Information provided by the solver is then displayed.

Next comes the solution listing, starting with each of the equations in the model. For each equation passed to the solver, four columns are reported, namely the lower bound, level, upper bound and marginal. GAMS moves all parts of a constraint involving variables to the left hand side, and accumulates the constants on the right hand side. The lower and upper bounds correspond to the constants that GAMS generates. For equations, these should be equal, whereas for inequalities one of them should be infinite. The level value of the equation (an evaluation of the left hand side of the constraint at the current point) should be between these bounds, otherwise the solution is infeasible and the equation is marked as follows:

```
seattle .chicago -0.153 -2.000 +INF 300.000 INFES
```

The marginal column in the equation contains the value of the variable that was matched with this equation.

For the variable listing, the lower, level and upper columns indicate the lower and upper bounds on the variables and the solution value. The level value returned by PATH will always be between these bounds. The marginal column contains the value of the slack on the equation that was paired with this variable. If a variable appears in one of the constraints in the model statement but is not explicitly paired to a
constraint, the slack reported here contains the internally matched constraint slack. The definition of this slack is the minimum of equ.l - equ.lower and equ.l - equ.upper, where equ is the paired equation.

Finally, a summary report is given that indicates how many errors were found. Figure 4 is nicely-solved case; when the model has infeasibilities, these can be found by searching for the string "INFES" as described above.

5.32.1.3.2 Redefined Equations

Unfortunately, this is not the end of the story. Some equations may have the following form:

<table>
<thead>
<tr>
<th>LOWER</th>
<th>LEVEL</th>
<th>UPPER</th>
<th>MARGINAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>new-york</td>
<td>325.000</td>
<td>350.000</td>
<td>325.000</td>
</tr>
</tbody>
</table>

This should be construed as a warning from GAMS, as opposed to an error. In principle, the REDEF should only occur if the paired variable to the constraint has a finite lower and/or upper bound and the variable is at one of these bounds. In this case, at the solution of the complementarity problem the sense of the constraint (e.g. =E=) may not be satisfied. This occurs when GAMS constraints are used to define the function $F$. The bounds on each component of the function $F$ are derived from the bounds on the matching variable component, and these bounds may be inconsistent with those implied by the constraint type used. GAMS warns the user via the REDEF label when the solution found leads to a violated "constraint". To avoid REDEF warnings the =N= can be used to define all complementarity functions.

Note that a REDEF is not an error; just a warning. The solver has solved the complementarity problem specified. GAMS gives this report to ensure that the modeler understands that the complementarity problem derives the relationships on the equations from the variable bounds, not from the equation definition.

5.32.1.4 Pitfalls

As indicated above, the ordering of an equation is important in the specification of an MCP. Since the data of the MCP is the function $F$ and the bounds $\ell$ and $u$, it is important for the modeler to pass the solver the function $F$ and not $-F$.

For example, if we have the optimization problem,

$$\min_{x \in [0, 2]} (x - 1)^2$$

then the first order optimality conditions are

$$0 \leq x \leq 2 \perp 2(x - 1)$$

which has a unique solution, $x = 1$. Figure 5 provides correct GAMS code for this problem.

Figure 5: First order conditions as an MCP, first.gms

variables x;
equations d_f;
x.lo = 0;
x.up = 2;
d_f.. 2*(x - 1) =e= 0;
model first / d_f.x /;
solve first using mcp;
However, if we accidentally write the valid equation

\[ d_f .. 0 =e= 2*(x - 1); \]

the problem given to the solver is

\[ 0 \leq x \leq 2 \perp -2(x - 1) \]

which has three solutions, \( x = 0, x = 1, \) and \( x = 2. \) This problem is in fact the stationary conditions for the nonconvex quadratic problem,

\[ \max_{x \in [0,2]} (x - 1)^2, \]

not the problem we intended to solve.

Continuing with the example, when \( x \) is a free variable, we might conclude that the ordering of the equation is irrelevant because we always have the equation, \( 2(x - 1) = 0, \) which does not change under multiplication by \(-1.\) In most cases, the ordering of equations (which are complementary to free variables) does not make a difference since the equation is internally "substituted out" of the model. In particular, for defining equations, such as that presented in Figure 3, the choice appears to be arbitrary.

However, in difficult (singular or near singular) cases, the substitution cannot be performed, and instead a perturbation is applied to \( F, \) in the hope of "(strongly) convexifying" the problem. If the perturbation happens to be in the wrong direction because \( F \) was specified incorrectly, the perturbation actually makes the problem less convex, and hence less likely to solve. Note that determining which of the above orderings of the equations makes most sense is typically tricky. One rule of thumb is to check whether if you replace the \( "=e=" \) by \( "=g=" \), and then increase \( "x" \), is the inequality intuitively more likely to be satisfied. If so, you probably have it the right way round, if not, reorder.

Furthermore, underlying model convexity is important. For example, if we have the linear program

\[
\begin{align*}
\min_x & \quad c^T x \\
\text{subject to} & \quad Ax = b, \ x \geq 0
\end{align*}
\]

we can write the first order optimality conditions as either

\[
0 \leq x \perp -A^T \mu + c
\]

\[
\mu \text{ free} \perp Ax - b
\]

or, equivalently,

\[
0 \leq x \perp -A^T \mu + c
\]

\[
\mu \text{ free} \perp b - Ax
\]

because we have an equation. The former is a linear complementarity problem with a positive semidefinite matrix, while the latter is almost certainly indefinite. Also, if we need to perturb the problem because of numerical problems, the former system will become positive definite, while the later becomes highly nonconvex and unlikely to solve. The rule of thumb here is to consider what happens when the dual multiplier \( \mu \) is made non-negative in the KKT system. In the former system, the constraint becomes \( Ax \geq b, \) which is consistent with a minimization and a positive multiplier. In the latter system, we get \( Ax \leq b, \) which is backwards.

Finally, users are strongly encouraged to match equations and free variables when the matching makes sense for their application. Structure and convexity can be destroyed if it is left to the solver to perform the matching. For example, in the above example, we could lose the positive semidefinite matrix with an arbitrary matching of the free variables.
Newton’s method, perhaps the most famous solution technique, has been extensively used in practice to solve square systems of nonlinear equations. The basic idea is to construct a local approximation of the nonlinear equations around a given point, \( x^k \), solve the approximation to find the Newton point, \( x^N \), update the iterate, \( x^{k+1} = x^N \), and repeat until we find a solution to the nonlinear system. This method works extremely well close to a solution, but can fail to make progress when started far from a solution. To guarantee progress is made, a line search between \( x^k \) and \( x^N \) is used to enforce sufficient decrease on an appropriately defined merit function. Typically, \( \frac{1}{2} \| F(x) \|^2 \) is used.

PATH uses a generalization of this method on a nonsmooth reformulation of the complementarity problem. To construct the Newton direction, we use the normal map \([151]\) representation

\[
F(\pi(x)) + x - \pi(x)
\]

associated with the MCP, where \( \pi(x) \) represents the projection of \( x \) onto [\( \ell, u \)] in the Euclidean norm. We note that if \( x \) is a zero of the normal map, then \( \pi(x) \) solves the MCP. At each iteration, a linearization of the normal map, a linear complementarity problem, is solved using a pivotal code related to Lemke’s method.

Versions of PATH prior to 4.x are based entirely on this formulation using the residual of the normal map

\[
\| F(\pi(x)) + x - \pi(x) \|
\]

as a merit function. However, the residual of the normal map is not differentiable, meaning that if a subproblem is not solvable then a ”steepest descent” step on this function cannot be taken. PATH 4.x considers an alternative nonsmooth system \([63]\), \( \Phi(x) = 0 \), where \( \Phi_i(x) = \phi(x_i, F_i(x)) \) and \( \phi(a, b) := \sqrt{a^2 + b^2} - a - b \). The merit function, \( \| \Phi(x) \|^2 \), in this case is differentiable, and is used for globalization purposes. When the subproblem solver fails, a projected gradient direction for this merit function is searched. It is shown in [61] that this provides descent and a new feasible point to continue PATH, and convergence to stationary points and/or solutions of the MCP is provided under appropriate conditions.

The remainder of this chapter details the interpretation of output from PATH and ways to modify the behavior of the code. To this end, we will assume that the modeler has created a file named \texttt{transmcp.gms} which defines an MCP model \texttt{transport} as described in Section Transportation Problem and is using PATH 4.x to solve it. See Section Solution for information on changing the solver.

5.32.2.1 Log File

We will now describe the behavior of the PATH algorithm in terms of the output typically produced. An example of the log for a particular run is given in Figure 6 and Figure 7.

The first few lines on this log file are printed by GAMS during its compilation and generation phases. The model is then passed off to PATH at the stage where the "Executing PATH" line is written out. After some basic memory allocation and problem checking, the PATH solver checks if the modeler required an option file to be read. In the example this is not the case. If PATH is directed to read an option file (see PATH Options below), then the following output is generated after the PATH banner.

```
Reading options file PATH.OPT
  > output_linear_model yes;
  Options: Read: Line 2 invalid: hi_there;
  Read of options file complete.
```

If the option reader encounters an invalid option (as above), it reports this but carries on executing the algorithm. Following this, the algorithm starts working on the problem.

5.32.2.1.1 Diagnostic Information Some diagnostic information is initially generated by the solver at the starting point. Included is information about the initial point and function evaluation. The log file here tells the value of the largest element of the starting point and the variable where it occurs. Similarly, the maximum function value is displayed along with the row producing it. The maximum element in the gradient is also presented with the equation and variable where it is located.

The second block provides more information about the Jacobian at the starting point. This information can be used to help scale the model. See Section Advanced Topics for complete details.

5.32.2.1.2 Crash Log The first phase of the code is a crash procedure attempting to quickly determine which of the inequalities should be active. This procedure is documented fully in [47], and an example of the Crash Log can be seen in Figure 6. The first column of the crash log is just a label indicating the current iteration number, the second gives an indication of how many function evaluations have been performed so far. Note that precisely one Jacobian (gradient) evaluation is performed per crash iteration. The number of changes to the active set between iterations of the crash procedure is shown under the "diff" column. The crash procedure terminates if this becomes small. Each iteration of this procedure involves a factorization of a matrix whose size is shown in the next column. The residual is a measure of how far the current iterate is from satisfying the complementarity conditions (MCP); it is zero at a solution. See Merit Functions for further information. The column "step" corresponds to the steplength taken in this iteration - ideally this should be 1. If the factorization fails, then the matrix is perturbed by an identity matrix scaled by the value indicated in the "prox" column. The "label" column indicates which row in the model is furthest away from satisfying the conditions (MCP). Typically, relatively few crash iterations are performed. Section PATH Options gives mechanisms to affect the behavior of these steps.

5.32.2.1.3 Major Iteration Log After the crash is completed, the main algorithm starts as indicated by the "Major Iteration Log" flag (see Figure 7). The columns that have the same labels as in the crash log have precisely the same meaning described above. However, there are some new columns that we now explain. Each major iteration attempts to solve a linear mixed complementarity problem using a pivotal method that is a generalization of Lemke's method [117]. The number of pivots performed per major iteration is given in the "minor" column.

The "grad" column gives the cumulative number of Jacobian evaluations used; typically one evaluation is performed per iteration. The "inorm" column gives the value of the error in satisfying the equation indicated in the "label" column.

At each iteration of the algorithm, several different step types can be taken, due to the use of nonmonotone searches [46] , [56] which are used to improve robustness. In order to help the PATH user, we have added two code letters indicating the return code from the linear solver and the step type to the log file. Table 3 explains the return codes for the linear solver and Table 4 explains the meaning of each step type. The ideal output in this column is "SO"; "SD" and "SB" also indicate reasonable progress. Codes different from these are not catastrophic, but typically indicate the solver is having difficulties due to numerical issues or nonconvexities in the model.

### 5.32.2.1.4 Minor Iteration Log

If more than 500 pivots are performed, a minor log is output that gives more details of the status of these pivots. A listing from transmcp model follows, where we have set the output minor iteration frequency option to 1.

<table>
<thead>
<tr>
<th>Minor Iteration Log</th>
<th>minor</th>
<th>t</th>
<th>z</th>
<th>w</th>
<th>v</th>
<th>art</th>
<th>ckpts</th>
<th>enter</th>
<th>leave</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1</td>
<td>4.2538e-01</td>
<td>8</td>
<td>2</td>
<td>0</td>
<td>0</td>
<td>t[0]</td>
<td>z[11]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>1.0000e+00</td>
<td>9</td>
<td>2</td>
<td>0</td>
<td>0</td>
<td>z[10]</td>
<td>t[0]</td>
<td></td>
</tr>
</tbody>
</table>

\( t \) is a parameter that goes from zero to 1 for normal starts in the pivotal code. When the parameter reaches 1, we are at a solution to the subproblem. The \( t \) column gives the current value for this parameter. The next columns report the current number of problem variables \( z \) and slacks corresponding to variables at lower bound \( w \) and at upper bound \( v \). Artificial variables are also noted in the minor log, see [57] for further details. Checkpoints are times where the basis matrix is refactorized. The number of checkpoints is indicated in the \( \text{ckpts} \) column. Finally, the minor iteration log displays the entering and leaving variables during the pivot sequence.

### 5.32.2.1.5 Restart Log

The PATH code attempts to fully utilize the resources provided by the modeler to solve the problem. Versions of PATH after 3.0 have been much more aggressive in determining that a stationary point of the residual function has been encountered. When it is determined that no progress is being made, the problem is restarted from the initial point supplied in the GAMS file with a different set of options. These restarts give the flexibility to change the algorithm in the hopes that the modified algorithm leads to a solution. The ordering and nature of the restarts were determined by empirical evidence based upon tests performed on real-world problems.

The exact options set during the restart are given in the restart log, part of which is reproduced below.
If a particular problem solves under a restart, a modeler can circumvent the wasted computation by setting the appropriate options as shown in the log. Note that sometimes an option is repeated in this log. In this case, it is the last option that is used.

### 5.32.2.1.6 Solution Log
A solution report is now given by the algorithm for the point returned. The first component is an evaluation of several different merit functions. Next, a display of some statistics concerning the final point is given. This report can be used detect problems with the model and solution as detailed in Section Advanced Topics.

At the end of the log file, summary information regarding the algorithm's performance is given. The string ”**EXIT - solution found”. is an indication that PATH solved the problem. Any other EXIT string indicates a termination at a point that may not be a solution. These strings give an indication of what modelStat and solveStat will be returned to GAMS. After this, the ”Restarting execution” flag indicates that GAMS has been restarted and is processing the results passed back by PATH.

### 5.32.2.2 Status File
If for some reason the PATH solver exits without writing a solution, or the sysout flag is turned on, the status file generated by the PATH solver will be reported in the listing file. The status file is similar to the log file, but provides more detailed information. The modeler is typically not interested in this output.

### 5.32.2.3 User Interrupts
A user interrupt can be effected by typing Ctrl-C. We only check for interrupts every major iteration. If a more immediate response is wanted, repeatedly typing Ctrl-C will eventually kill the job. The number needed is controlled by the interrupt limit option. In this latter case, when a kill is performed, no solution is written and an execution error will be generated in GAMS.

### 5.32.2.4 Preprocessing
The purpose of a preprocessor is to reduce the size and complexity of a model to achieve improved performance by the main algorithm. Another benefit of the analysis performed is the detection of some provably unsolvable problems. A comprehensive preprocessor has been incorporated into PATH as developed in [58].

The preprocessor reports its finding with some additional output to the log file. This output occurs before the initial point statistics. An example of the preprocessing on the forcebsm model is presented below.

```plaintext
Zero:  0 Single: 112 Double: 0 Forced: 0
Preprocessed size: 72
```

The preprocessor looks for special polyhedral structure and eliminates variables using this structure. These are indicated with the above line of text. Other special structure is also detected and reported.

On exit from the algorithm, we must generate a solution for the original problem. This is done during the postsolve. Following the postsolve, the residual using the original model is reported.

```plaintext
Postsolved residual: 1.0518e-10
```

This number should be approximately the same as the final residual reported on the presolved model.
5.32.2.4.1 **Constrained Nonlinear System** Modelers typically add bounds to their variables when attempting to solve nonlinear problems in order to restrict the domain of interest. For example, many square nonlinear systems are formulated as

\[ F(z) = 0, \ell \leq z \leq u, \]

where typically, the bounds on \( z \) are inactive at the solution. This is not an MCP, but is an example of a "constrained nonlinear system" (CNS). It is important to note the distinction between MCP and CNS. The MCP uses the bounds to infer relationships on the function \( F \). If a finite bound is active at a solution, the corresponding component of \( F \) is only constrained to be nonnegative or nonpositive in the MCP, whereas in CNS it must be zero. Thus there may be many solutions of MCP that do not satisfy \( F(z) = 0 \). Only if \( z^* \) is a solution of MCP with \( \ell < z^* < u \) is it guaranteed that \( F(z^*) = 0 \).

Internally, PATH reformulates a constrained nonlinear system of equations to an equivalent complementarity problem. The reformulation adds variables, \( y \), with the resulting problem written as:

\[ \ell \leq x \leq u \quad \perp -y \quad \perp F(x). \]

This is the MCP model passed on to the PATH solver.

### 5.32.3 PATH Options

The default options of PATH should be sufficient for most models. If desired, PATH-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

We give a list of the available PATH options along with their defaults and meaning below. Note that only the first three characters of every word are significant.

#### 5.32.3.1 General options

GAMS controls the total number of pivots allowed via the `iterlim` option. If more pivots are needed for a particular model then either of the following lines should be added to the `transmcp.gms` file before the solve statement:

```plaintext
option iterlim = 2000;
transport.iterlim = 2000;
```

Problems with a singular basis matrix can be overcome by using the `proximal_perturbation` option [26], and linearly dependent columns can be output with the `output_factorization_singularities` option. For more information on singularities, we refer the reader to Section Advanced Topics.

As a special case, PATH can emulate Lemke's method [39], [117] for LCP with the following options:

```plaintext
crash_method none
crash_perturb no
major_iteration_limit 1
lemke_start first
nms no
```

If instead, PATH is to imitate the Successive Linear Complementarity method (SLCP, often called the Josephy Newton method) [101], [132], [131] for MCP with an Armijo style linesearch on the normal map residual, then the options to use are:

```plaintext
crash_method none
crash_perturb no
lemke_start always
nms_initial_reference_factor 1
nms_memory size 1
nms_mstep_frequency 1
nms_searchtype line
merit_function normal
```

Note that `nms_memory_size 1` and `nms_initial_reference_factor 1` turn off the nonmonotone linesearch, while `nms_mstep_frequency 1` turns off watchdogging [35]. `nms_searchtype line` forces PATH to search the line segment between the initial point and the solution to the linear model, while `merit_function normal` tell PATH to use the normal map for calculating the residual.

### 5.32.4 Advanced Topics

This chapter discusses some of the difficulties encountered when dealing with complementarity problems. We start off with a very formal definition of a complementarity problem (similar to the one given previously) which is used in later sections on merit functions and ill-defined, poorly-scaled, and singular models.

#### 5.32.4.1 Formal Definition of MCP

The mixed complementarity problem is defined by a function, $F : D \to \mathbb{R}^n$ where $D \subseteq \mathbb{R}^n$ is the domain of $F$, and possibly infinite lower and upper bounds, $\ell$ and $u$. Let $C := \{x \in \mathbb{R}^n \mid \ell \leq x \leq u\}$, a Cartesian product of closed (possibly infinite) intervals. The problem is given as

$$MCP : \text{find } x \in C \cap D \text{ s.t. } (F(x), y - x) \geq 0, \forall y \in C.$$  

This formulation is a special case of the variational inequality problem defined by $F$ and a (nonempty, closed, convex) set $C$. Special choices of $\ell$ and $u$ lead to the familiar cases of a system of nonlinear equations

$$F(x) = 0$$

(generated by $\ell \equiv -\infty$, $u \equiv +\infty$) and the nonlinear complementarity problem

$$0 \leq x \perp F(x) \geq 0$$

(generated using $\ell \equiv 0$, $u \equiv +\infty$).
5.32.4.2 Algorithmic Features

We now describe some of the features of the PATH algorithm and the options affecting each.

5.32.4.2.1 Merit Functions

A solver for complementarity problems typically employs a merit function to indicate the closeness of the current iterate to the solution set. The merit function is zero at a solution to the original problem and strictly positive otherwise. Numerically, an algorithm terminates when the merit function is approximately equal to zero, thus possibly introducing spurious "solutions".

The modeler needs to be able to determine with some reasonable degree of accuracy whether the algorithm terminated at solution or if it simply obtained a point satisfying the desired tolerances that is not close to the solution set. For complementarity problems, we can provide several indicators with different characteristics to help make such a determination. If one of the indicators is not close to zero, then there is some evidence that the algorithm has not found a solution. We note that if all of the indicators are close to zero, we are reasonably sure we have found a solution. However, the modeler has the final responsibility to evaluate the "solution" and check that it makes sense for their application.

For the NCP, a standard merit function is

$$
\|(-x^+,-F(x)^+,[x_i^+,(F_i(x))^+]\|
$$

with the first two terms measuring the infeasibility of the current point and the last term indicating the complementarity error. In this expression, we use $(-)_{+}$ to represent the Euclidean projection of $x$ onto the nonnegative orthant, that is $(x)_{+} = \max(x, 0)$. For the more general MCP, we can define a similar function:

$$
\|x - \pi(x), \left[ \left( \frac{x_i - \ell_i}{\|u_i\| + 1} \right)_{+} (F_i(x))^+ \right], \left[ \left( \frac{u_i - x_i}{\|u_i\| + 1} \right)_{+} (-F_i(x))^+ \right] \|
$$

where $\pi(x)$ represents the Euclidean projection of $x$ onto $C$. We can see that if we have an NCP, the function is exactly the one previously given and for nonlinear systems of equations, this becomes $\|F(x)\|$.

There are several reformulations of the MCP as a system of nonlinear (nonsmooth) equations for which the corresponding residual is a natural merit function. Some of these are as follows:

- Generalized Minimum Map: $x - \pi(x - F(x))$
- Normal Map: $F(\pi(y)) + y - \pi(y)$
- Fischer Function: $\Phi(x)$, where $\Phi_i(x) := \phi(x_i, F_i(x))$ with

$$
\phi(a, b) := \sqrt{a^2 + b^2} - a - b.
$$

Note that $\phi(a, b) = 0$ if and only if $0 \leq a \perp b \geq 0$. A straightforward extension of $\Phi$ to the MCP format is given for example in [61].

In the context of nonlinear complementarity problems the generalized minimum map corresponds to the classic minimum map $\min(x, F(x))$. Furthermore, for NCPs the minimum map and the Fischer function are both local error bounds and were shown to be equivalent in [185]. Figure 10 in the subsequent section plots all of these merit functions for the ill-defined example discussed therein and highlights the differences between them.

The squared norm of $\Phi$, namely $\Psi(x) := \frac{1}{2} \sum \phi(x_i, F_i)^2$, is continuously differentiable on $\mathbb{R}^n$ provided $F$ itself is. Therefore, the first order optimality conditions for the unconstrained minimization of $\Psi(x)$, namely $\nabla \Psi(x) = 0$ give another indication as to whether the point under consideration is a solution of MCP.

The merit functions and the information PATH provides at the solution can be useful for diagnostic purposes. By default, PATH 4.x returns the best point with respect to the merit function because this iterate likely provides better information to the modeler. As detailed in Section PATH Options, the default merit function in PATH 4.x is the Fischer function. To change this behavior the merit_function option can be used.
5.32.4.2.2 Crashing Method  The crashing technique [47] is used to quickly identify an active set from the user-supplied starting point. At this time, a proximal perturbation scheme [24], [25] is used to overcome problems with a singular basis matrix. The proximal perturbation is introduced in the crash method, when the matrix factored is determined to be singular. The value of the perturbation is based on the current merit function value.

Even if the crash method is turned off, for example via the option crash_method none, perturbation can be added. This is determined by factoring the matrix that crash would have initially formed. This behavior is extremely useful for introducing a perturbation for singular models. It can be turned off by issuing the option crash_perturb no.

5.32.4.2.3 Nonmonotone Searches  The first line of defense against convergence to stationary points is the use of a nonmonotone linesearch [90], [91], [56]. In this case we define a reference value, $R^k$, and we use this value to test for sufficient decrease:

$$\Psi(x^k + t_k d^k) \leq R^k + t_k \nabla \Psi(x^k)^T d^k.$$  

Depending upon the choice of the reference value, this allows the merit function to increase from one iteration to the next. This strategy can not only improve convergence, but can also avoid local minimizers by allowing such increases.

We now need to detail our choice of the reference value. We begin by letting $\{M_1, \ldots, M_m\}$ be a finite set of values initialized to $\kappa \Psi(x^0)$, where $\kappa$ is used to determine the initial set of acceptable merit function values. The value of $\kappa$ defaults to 1 in the code and can be modified with the nms_initial_reference_factor option; $\kappa = 1$ indicates that we are not going to allow the merit function to increase beyond its initial value.

Having defined the values of $\{M_1, \ldots, M_m\}$ (where the code by default uses $m = 10$), we can now calculate a reference value. We must be careful when we allow gradient steps in the code. Assuming that $d^k$ is the Newton direction, we define $i_0 = \text{argmax} M_i$ and $R^k = M_{i_0}$. After the nonmonotone linesearch rule above finds $t_k$, we update the memory so that $M_{i_0} = \Psi(x^k + t_k d^k)$, i.e. we remove an element from the memory having the largest merit function value.

When we decide to use a gradient step, it is beneficial to let $x^k = x_{\text{best}}$ where $x_{\text{best}}$ is the point with the absolute best merit function value encountered so far. We then recalculate $d^k = -\nabla \Psi(x^k)$ using the best point and let $R^k = \Psi(x^k)$. That is to say that we force decrease from the best iterate found whenever a gradient step is performed. After a successful step we set $M_i = \Psi(x^k + t_k d^k)$ for all $i \in [1, \ldots, m]$. This prevents future iterates from returning to the same problem area.

A watchdog strategy [35] is also available for use in the code. The method employed allows steps to be accepted when they are "close" to the current iterate. Nonmonotonic decrease is enforced every $m$ iterations, where $m$ is set by the nms_mstep_frequency option.

5.32.4.2.4 Linear Complementarity Problems  PATH solves a linear complementarity problem at each major iteration. Let $M \in \mathbb{R}^{n \times n}$, $q \in \mathbb{R}^n$, and $B = [l, u]$ be given. $(z, w, v)$ solves the linear mixed complementarity problem defined by $M$, $q$, and $B$ if and only if it satisfies the following constrained system of equations:

\begin{align*}
Mz - w + v + q &= 0 \quad (4) \\
w^T(z - l) &= 0 \quad (5) \\
v^T(u - z) &= 0 \quad (6)
\end{align*}
where \( x + \infty = \infty \) for all \( x \in \mathbb{R} \) and \( 0 \cdot \infty = 0 \) by convention. A triple, \((\hat{z}, \hat{w}, \hat{v})\), satisfying equations (4) - (6) is called a complementary triple.

The objective of the linear model solver is to construct a path from a given complementary triple \((\hat{z}, \hat{w}, \hat{v})\) to a solution \((\bar{z}, \bar{w}, \bar{v})\). The algorithm used to solve the linear problem is identical to that given in [44]; however, artificial variables are incorporated into the model. The augmented system is then:

\[
Mz - w + v + Da + (1 - t) s (sr) + q = 0 \tag{8}
\]

\[
w^T (z - l) = 0 \tag{9}
\]

\[
v^T (u - z) = 0 \tag{10}
\]

\[
z \in B, w \in \mathbb{R}_+^n, v \in \mathbb{R}_+^n, a \equiv 0, t \in [0, 1] \tag{11}
\]

where \( r \) is the residual, \( t \) is the path parameter, and \( a \) is a vector of artificial variables. The residual is scaled by \( s \) to improve numerical stability.

The addition of artificial variables enables us to construct an initial invertible basis consistent with the given starting point even under rank deficiency. The procedure consists of two parts: constructing an initial guess as to the basis and then recovering from rank deficiency to obtain an invertible basis. The crash technique gives a good approximation to the active set. The first phase of the algorithm uses this information to construct a basis by partitioning the variables into three sets:

1. \( W = \{ i \in \{1, \ldots, n\} \mid \hat{z}_i = l_i \text{ and } \hat{w}_i > 0 \} \)
2. \( V = \{ i \in \{1, \ldots, n\} \mid \hat{z}_i = u_i \text{ and } \hat{v}_i > 0 \} \)
3. \( Z = \{1, \ldots, n\} \setminus W \cup V \)

Since \((\hat{z}, \hat{w}, \hat{v})\) is a complementary triple, \( Z \cap W \cap V = \emptyset \) and \( Z \cup W \cup V = \{1, \ldots, n\} \). Using the above guess, we can recover an invertible basis consistent with the starting point by defining \( D \) appropriately. The technique relies upon the factorization to indicate the linearly dependent rows and columns of the basis matrix. Some of the variables may be nonbasic, but not at their bounds. For such variables, the corresponding artificial will be basic.

We use a modified version of EXPAND [83] to perform the ratio test. Variables are prioritized as follows:

1. \( t \) leaving at its upper bound.
2. Any artificial variable.
3. Any \( z, w, \) or \( v \) variable.

If a choice as to the leaving variable can be made while maintaining numerical stability and sparsity, we choose the variable with the highest priority (lowest number above).

When an artificial variable leaves the basis and a \( z \)-type variable enters, we have the choice of either increasing or decreasing that entering variable because it is nonbasic but not at a bound. The determination is made such that \( t \) increases and stability is preserved.

If the code is forced to use a ray start at each iteration (\texttt{lemke\_start always}), then the code carries out Lemke’s method, which is known [39] not to cycle. However, by default, we use a regular start to
guarantee that the generated path emanates from the current iterate. Under appropriate conditions, this guarantees a decrease in the nonlinear residual. However, it is then possible for the pivot sequence in the linear model to cycle. To prevent this undesirable outcome, we attempt to detect the formation of a cycle with the heuristic that if a variable enters the basis more than a given number of times, we are cycling. The number of times the variable has entered is reset whenever $t$ increases beyond its previous maximum or an artificial variable leaves the basis. If cycling is detected, we terminate the linear solver at the largest value of $t$ and return this point.

Another heuristic is added when the linear code terminates on a ray. The returned point in this case is not the base of the ray. We move a slight distance up the ray and return this new point. If we fail to solve the linear subproblem five times in a row, a Lemke ray start will be performed in an attempt to solve the linear subproblem. Computational experience has shown this to be an effective heuristic and generally results in solving the linear model. Using a Lemke ray start is not the default mode, since typically many more pivots are required.

For times when a Lemke start is actually used in the code, an advanced ray can be used. We basically choose the "closest" extreme point of the polytope and choose a ray in the interior of the normal cone at this point. This helps to reduce the number of pivots required. However, this can fail when the basis corresponding to the cell is not invertible. We then revert to the Lemke start.

Since the EXPAND pivot rules are used, some of the variables may be nonbasic, but slightly infeasible, as the solution. Whenever the linear code finishes, the nonbasic variables are put at their bounds and the basic variables are recomputed using the current factorization. This procedure helps to find the best possible solution to the linear system.

The resulting linear solver as modified above is robust and has the desired property that we start from $(\hat{z}, \hat{w}, \hat{v})$ and construct a path to a solution.

5.32.4.2.5 Other Features Some other heuristics are incorporated into the code. During the first iteration, if the linear solver fails to find a Newton point, a Lemke start is used. Furthermore, under repeated failures during the linear solve, a Lemke start will be attempted. A gradient step can also be used when we fail repeatedly.

The proximal perturbation is reduced at each major iteration. However, when numerical difficulties are encountered, it will be increased to a fraction of the current merit function value. These are determined when the linear solver returns a Reset or Singular status.

Spacer steps are taken every major iteration, in which the iterate is chosen to be the best point for the normal map. The corresponding basis passed into the Lemke code is also updated.

Scaling is done based on the diagonal of the matrix passed into the linear solver.

We finally note, that if the merit function fails to show sufficient decrease over the last 100 iterates, a restart will be performed, as this indicates we are close to a stationary point.

5.32.4.3 Difficult Models

5.32.4.3.1 Ill-Defined Models A problem can be ill-defined for several different reasons. We concentrate on the following particular cases. We will call $F$ well-defined at $\bar{x} \in C$ if $\bar{x} \in D$ and ill-defined at $\bar{x}$ otherwise. Furthermore, we define $F$ to be well-defined near $\bar{x} \in C$ if there exists an open neighborhood of $\bar{x}, N(\bar{x})$, such that $C \cap N(\bar{x}) \subseteq D$. By saying the function is well-defined near $\bar{x}$, we are simply stating that $F$ is defined for all $x \in C$ sufficiently close to $\bar{x}$. A function not well-defined near $\bar{x}$ is termed ill-defined near $\bar{x}$.

We will say that $F$ has a well-defined Jacobian at $\bar{x} \in C$ if there exists an open neighborhood of $\bar{x}, N(\bar{x})$, such that $N(\bar{x}) \subseteq D$ and $F$ is continuously differentiable on $N(\bar{x})$. Otherwise the function has
an ill-defined Jacobian at \( \bar{x} \). We note that a well-defined Jacobian at \( \bar{x} \) implies that the MCP has a well-defined function near \( \bar{x} \), but the converse is not true.

PATH uses both function and Jacobian information in its attempt to solve the MCP. Therefore, both of these definitions are relevant. We discuss cases where the function and Jacobian are ill-defined in the next two subsections. We illustrate uses for the merit function information and final point statistics within the context of these problems.

**Function Undefined** We begin with a one-dimensional problem for which \( F \) is ill-defined at \( x = 0 \) as follows:

\[
0 \leq x - 1/2 \geq 0.
\]

Here \( x \) must be strictly positive because \( 1/x \) is undefined at \( x = 0 \). This condition implies that \( F(x) \) must be equal to zero. Since \( F(x) \) is strictly positive for all \( x \) strictly positive, this problem has no solution.

We are able to perform this analysis because the dimension of the problem is small. Preprocessing linear problems can be done by the solver in an attempt to detect obviously inconsistent problems, reduce problem size, and identify active components at the solution. Similar processing can be done for nonlinear models, but the analysis becomes more difficult to perform. Currently, PATH only checks the consistency of the bounds and removes fixed variables and the corresponding complementary equations from the model.

A modeler would likely not know a priori that a problem has no solution and would thus attempt to formulate and solve it. GAMS code for the model above is provided in **Figure 8**. We must specify an initial value for \( x \) in the code. If we were to not provide one, GAMS would use \( x = 0 \) as the default value, notice that \( F \) is undefined at the initial point, and terminate before giving the problem to PATH. The error message indicates that the function \( 1/x \) is ill-defined at \( x = 0 \), but does not imply that the corresponding MCP problem has no solution.

**Figure 8: GAMS Code for Ill-Defined Function**

```gams
positive variable x;

equations F;

F.. 1 / x =g= 0;

model simple / F.x /;

x.l = 1e-6;

solve simple using mcp;
```

After setting the starting point, GAMS generates the model, and PATH proceeds to "solve" it. A portion of the output relating statistics about the solution is given in **Figure 9**. PATH uses the Fischer Function indicator as its termination criteria by default, but evaluates all of the merit functions given in Section Merit Functions at the final point. The Normal Map merit function, and to a lesser extent, the complementarity error, indicate that the "solution" found does not necessarily solve the MCP.

**Figure 9: PATH Output for Ill-Defined Function**

**FINAL STATISTICS**

- Inf-Norm of Complementarity . 1.0000e+00 eqn: (F)
- Inf-Norm of Normal Map . . . . . . 1.1181e+16 eqn: (F)
- Inf-Norm of Minimum Map . . . . . 8.9441e-17 eqn: (F)
- Inf-Norm of Fischer Function . . . . 8.9441e-17 eqn: (F)
- Inf-Norm of Grad Fischer Fcn . . . 8.9441e-17 eqn: (F)

**FINAL POINT STATISTICS**

- Maximum of X . . . . . . . . . . . 8.9441e-17 var: (X)
- Maximum of F . . . . . . . . . . . . . 1.1181e+16 eqn: (F)
- Maximum of Grad F . . . . . . . . 1.2501e+32 eqn: (F) var: (X)
To indicate the difference between the merit functions, Figure 10 plots them all for this simple example. We note that as $x$ approaches positive infinity, numerically, we are at a solution to the problem with respect to all of the merit functions except for the complementarity error, which remains equal to one. As $x$ approaches zero, the merit functions diverge, also indicating that $x = 0$ is not a solution.

The natural residual and Fischer function tend toward 0 as $x \downarrow 0$. From these measures, we might think $x = 0$ is the solution. However, as previously remarked $F$ is ill-defined at $x = 0$. $F$ and $\nabla F$ become very large, indicating that the function (and Jacobian) might not be well-defined. We might be tempted to conclude that if one of the merit function indicators is not close to zero, then we have not found a solution. This conclusion is not always warranted. When one of the indicators is non-zero, we have reservations about the solution, but we cannot eliminate the possibility that we are actually close to a solution. If we slightly perturb the original problem to

$$0 \leq x \perp \frac{1}{x + \epsilon} \geq 0$$

for a fixed $\epsilon > 0$, the function is well-defined over $C = \mathbb{R}_{+}^{n}$ and has a unique solution at $x = 0$. In this case, by starting at $x > 0$ and sufficiently small, all of the merit functions, with the exception of the Normal Map, indicate that we have solved the problem as is shown by the output in Figure 11 for $\epsilon = 1 \times 10^{-6}$ and $x = 1 \times 10^{-20}$.

Figure 11: PATH Output for Well-Defined Function

FINAL STATISTICS
Inf-Norm of Complementarity . . 1.0000e-14 eqn: (G)
Inf-Norm of Normal Map . . . . 1.0000e+06 eqn: (G)
Inf-Norm of Minimum Map . . . . 1.0000e-20 eqn: (G)
Inf-Norm of Fischer Function . . 1.0000e-20 eqn: (G)
Inf-Norm of Grad Fischer Fcn. . . 1.0000e-20 eqn: (G)
In this case, the Normal Map is quite large and we might think that the function and Jacobian are undefined. When only the normal map is non-zero, we may have just mis-identified the optimal basis. By setting the merit_function normal option, we can resolve the problem, identify the correct basis, and solve the problem with all indicators being close to zero. This example illustrates the point that all of these tests are not infallible. The modeler still needs to do some detective work to determine if they have found a solution or if the algorithm is converging to a point where the function is ill-defined.

**Jacobian Undefined** Since PATH uses a Newton-like method to solve the problem, it also needs the Jacobian of $F$ to be well-defined. One model for which the function is well-defined over $C$, but for which the Jacobian is undefined at the solution is: $0 \leq x \perp -\sqrt{x} \geq 0$. This model has a unique solution at $x = 0$.

Using PATH and starting from the point $x = 1 \times 10^{-14}$, PATH generates the output given in Figure 12.

**Figure 12:** PATH Output for Ill-Defined Jacobian

We can see that the gradient of the Fischer Function is nonzero and the Jacobian is beginning to become large. These conditions indicate that the Jacobian is undefined at the solution. It is therefore important for a modeler to inspect the given output to guard against such problems.

If we start from $x = 0$, PATH correctly informs us that we are at the solution. The large value reported for the Jacobian is an indication that the Jacobian is undefined.

### 5.32.4.3.2 Poorly Scaled Models

Well-defined problems can still have various numerical problems that impede the algorithm's convergence. One particular problem is a badly scaled Jacobian. In such cases, we can obtain a poor "Newton" direction because of numerical problems introduced in the linear algebra performed. This problem can also lead the code to a point from which it cannot recover.

The final model given to the solver should be scaled such that we avoid numerical difficulties in the linear algebra. The output provided by PATH can be used to iteratively refine the model so that we eventually end up with a well-scaled problem. We note that we only calculate our scaling statistics at the starting point provided. For nonlinear problems these statistics may not be indicative of the overall scaling of the model. Model specific knowledge is very important when we have a nonlinear problem because it can be used to appropriately scale the model to achieve a desired result.

We look at the `titan.gms` model in MCPLIB, that has some scaling problems. The relevant output from PATH for the original code is given in Figure 13.

**Figure 13:** PATH Output - Poorly Scaled Model
INITIAL POINT STATISTICS
Maximum of X . . . . . . . . . . 4.1279e+06 var: (w.29)
Maximum of F . . . . . . . . . . 2.2516e+00 eqn: (a1.33)
Maximum of Grad F . . . . . . . 6.7753e+06 eqn: (a1.29) var: (x1.29)

INITIAL JACOBIAN NORM STATISTICS
Maximum Row Norm . . . . . . . 9.4504e+06 eqn: (a2.29)
Minimum Row Norm . . . . . . . 2.7680e-03 eqn: (g.10)
Maximum Column Norm . . . . . 9.4504e+06 var: (x2.29)
Minimum Column Norm . . . . . 1.3840e-03 var: (w.10)

The maximum row norm is defined as
\[ \max_{1 \leq i \leq n} \sum_{1 \leq j \leq n} |(\nabla F(x))_{ij}| \]
and the minimum row norm is
\[ \min_{1 \leq i \leq n} \sum_{1 \leq j \leq n} |(\nabla F(x))_{ij}|. \]

Similar definitions are used for the column norm. The norm numbers for this particular example are not extremely large, but we can nevertheless improve the scaling. We first decided to reduce the magnitude of the a1 block of equations as indicated by PATH. Using the GAMS modeling language, we can scale particular equations and variables using the .scale attribute. To turn the scaling on for the model we use the .scaleopt model attribute. After scaling the a1 block, we re-ran PATH and found an additional block of equations that also needed scaling, a2. We also scaled some of the variables, g and w. The code added to the model follows:

```
titan.scaleopt = 1;
a1.scale(i) = 1000;
a2.scale(i) = 1000;
g.scale(i) = 1/1000;
w.scale(i) = 10000;
```

By scaling these equation and variable blocks, we have improved the model scaling. The statistics for the manually scaled model are given in Figure 14.

**Figure 14:** PATH Output - Well-Scaled Model

INITIAL POINT STATISTICS
Maximum of X . . . . . . . . . . 1.0750e+03 var: (x1.49)
Maximum of F . . . . . . . . . . 3.9829e-01 eqn: (g.10)
Maximum of Grad F . . . . . . . 6.7753e+06 eqn: (a1.29) var: (x1.29)

INITIAL JACOBIAN NORM STATISTICS
Maximum Row Norm. . . . . . . . 9.4524e+06 eqn: (a2.29)
Minimum Row Norm. . . . . . . . 2.7680e-03 eqn: (g.10)
Maximum Column Norm . . . . . 9.4904e+03 var: (x2.29)
Minimum Column Norm . . . . . 1.3840e-01 var: (w.10)

For this particular problem PATH cannot solve the unscaled model, while it can find a solution to the scaled model. Using the scaling features of the GAMS language and the information provided by PATH we are able to remove some of the problem’s difficulty and obtain better performance from PATH.

It is possible to get even more information on initial point scaling by inspecting the GAMS listing file. The equation row listing gives the values of all the entries of the Jacobian at the starting point. The row norms generated by PATH give good pointers for starting to use the row listing.

Not all of the numerical problems are directly attributable to poorly scaled models. Problems for which the Jacobian of the active constraints is singular or nearly singular can also cause numerical difficulty as illustrated next.
5.32.4.3.3 Singular Models Assuming that the problem is well-defined and properly scaled, we can still have a Jacobian for which the active constraints are singular or nearly singular (i.e. it is ill-conditioned). When problems are singular or nearly singular, we are also likely to have numerical problems. As a result the "Newton" direction obtained from the linear problem solver can be very bad. In PATH, we can use proximal perturbation or add artificial variables to attempt to remove the singularity problems from the model. However, it is most often beneficial for solver robustness to remove singularities if possible.

The easiest problems to detect are those for which the Jacobian has zero rows and columns. A simple problem for which we have zero rows and columns is:

\[-2 \leq x \leq 2 \perp -x^2 + 1.\]

Note that the Jacobian, $-2x$, is non-singular at all three solutions, but singular at the point $x = 0$. Output from PATH on this model starting at $x = 0$ is given in Figure 15.

**Figure 15:** PATH Output - Zero Rows and Columns

</tbody>
</table>

We display in the code the variables and equations for which the row/column in the Jacobian is close to zero. These situations are problematic and for nonlinear problems likely stem from the modeler providing an inappropriate starting point or fixing some variables resulting in some equations becoming constant. We note that the solver may perform well in the presence of zero rows and/or columns, but the modeler should make sure that these are what was intended.

Singularities in the model can also be detected by the linear solver. This in itself is a hard problem and prone to error. For matrices which are poorly scaled, we can incorrectly identify "linearly dependent" rows because of numerical problems. Setting `output_factorization_singularities yes` in an options file will inform the user which equations the linear solver thinks are linearly dependent. Typically, singularity does not cause a lot of problems and the algorithm can handle the situation appropriately. However, an excessive number of singularities are cause for concern. A further indication of possible singularities at the solution is a lack of quadratic convergence to the solution.

5.32.5 Case Study: Von Thunen Land Model

We now turn our attention towards using the diagnostic information provided by PATH to improve an actual model. The Von Thunen land model is a problem recognized in the mathematical programming literature for its computational difficulty. We attempt to understand more carefully the facets of the problem that make it difficult to solve. This will enable us to outline and identify these problems and furthermore to extend the model to a more realistic and computationally more tractable form.
5.32.5.1 Classical Model

The problem is cast in the Arrow-Debreu framework as an equilibrium problem. The basic model is a closed economy consisting of three economic agents, a landowner, a worker and a porter. There is a central market, around which concentric regions of land are located. Since the produced goods have to be delivered to the market, this is an example of a spatial price equilibrium. The key variables of the model are the prices of commodities, land, labour and transport. Given these prices, it is assumed that the agents demand certain amounts of the commodities, which are supplied so as to maximize profit in each sector. Walras’ law is then a consequence of the assumed competitive paradigm, namely that supply will equal demand in the equilibrium state.

We now describe the problems that the consumers and the producers face. We first look at consumption and derive a demand function for each of the consumer agents in the economy. Each of these agents has a utility function, that they wish to maximize subject to their budgetary constraints. As is typical in such problems, the utility function is assumed to be Cobb-Douglas:

\[ u_a(d) = \prod_c d_c^{\alpha_{c,a}}, \quad \alpha_{c,a} \geq 0, \sum_c \alpha_{c,a} = 1, \]

where the \( \alpha_{c,a} \) are given parameters dependent only on the agent. For each agent \( a \), the variables \( d_c \) represent quantities of the desired commodities \( c \). In the Von Thunen model, the goods are wheat, rice, corn and barley. The agent’s endowments determine their budgetary constraint as follows. Given current market prices, an agent’s wealth is the value of the initial endowment of goods at those prices. The agent’s problem is therefore

\[ \max u_a(d) \text{ subject to } \langle p, d \rangle \leq \langle p, e_a \rangle, d \geq 0, \]

where \( e_a \) is the endowment bundle for agent \( a \). A closed form solution, corresponding to demand from agent \( a \) for commodity \( c \) is thus

\[ d_{c,a}(p) := \frac{\alpha_{c,a}[p, e_a]}{p_c}. \]

Note that this assumes the prices of the commodities \( p_c \) are positive.

The supply side of the economy is similar. The worker earns a wage \( w_L \) for his labour input. The land is distributed around the market in rings with a rental rate \( w_r \) associated with each ring \( r \) of land. The area of land \( a_r \) in each ring is an increasing function of \( r \). The model assumes that labour and land are substitutable via a constant elasticities of substitution (CES) function.

Consider the production \( x_{c,r} \) of commodity \( c \) in region \( r \). In order to maximize profit (or minimize costs), the labour \( y_L \) and land use \( y_r \) solve

\[ \min w_L y_L + w_r y_r \text{ subject to } \phi_c y_L^\beta_c y_r^{1-\beta_c} \geq x_{c,r}, \ y_L, y_r \geq 0, \]  

where \( \phi_c \) is a given cost function scale parameter, and \( \beta_c \in [0, 1] \) is the share parameter. The technology constraint is precisely the CES function allowing a suitable mix of labour and land use. Again, a closed form solution can be calculated. For example, the demand for labour in order to produce \( x_{c,r} \) is given by

\[ x_{c,r} \frac{\beta_c \left( \frac{w_r}{w_c} \right)^{\beta_c} \left( \frac{w_r}{1-\beta_c} \right)^{1-\beta_c}}{\phi_c w_L}. \]

Considering all such demands, this clearly assumes the prices of inputs \( w_L, w_r \) are positive. A key point to note is that input commodity (factor) demands to produce \( x_{c,r} \) can be determined by first solving (12) for unit demand \( x_{c,r} \equiv 1 \) and then multiplying these factor demands by the actual amount desired. Let \( \bar{y}_L \) and \( \bar{y}_r \) denote the optimal solutions of (12) with \( x_{c,r} \equiv 1 \). Using this fact, the unit production cost \( \gamma_{c,r} \) for commodity \( c \) in region \( r \) can be calculated as follows:
\[
\gamma_{c,r} = w_L y_L + w_r y_r = w_L \left( \frac{w_L}{\phi_c w_L} \right)^{\beta_c} \left( \frac{w_r}{1-\beta_c} \right) + w_r \left( \frac{w_r}{\phi_c w_r} \right)^{\beta_c} \left( \frac{w_r}{w_r} \right)^{1-\beta_c} \left( \frac{w_r}{1-\beta_c} \right) = \frac{1}{\phi_c} \left( \frac{w_L}{\beta_c} \right)^{\beta_c} \left( \frac{w_r}{1-\beta_c} \right)^{1-\beta_c} \left( \frac{w_r}{1-\beta_c} \right).
\]

Transportation is provided by a porter, earning a wage \(w_p\). If we denote the unit cost for transportation of commodity \(c\) by \(t_c\), then unit transportation cost to market is
\[
T_{c,r}(w_p) := t_c d_r w_p,
\]
where \(d_r\) is the distance of region \(r\) to the market. Spatial price equilibrium arises from the consideration:
\[
0 \leq x_{c,r} \perp \gamma_{c,r}(w_L, w_r) + T_{c,r}(w_p) \geq p_c.
\]
This is intuitively clear; it states that commodity \(c\) will be produced in region \(r\) only if the combined cost of production and transportation equals the market price.

The above derivations assumed that the producers and consumers acted as price takers. Walras’ law is now invoked to determine the prices so that markets clear. The resulting complementarity problem is:

\[
\gamma_{c,r} = \frac{1}{\phi_c} \left( \frac{w_L}{\beta_c} \right)^{\beta_c} \left( \frac{w_r}{1-\beta_c} \right)^{1-\beta_c} \left( \frac{w_r}{1-\beta_c} \right).
\]

\[
0 \leq x_{c,r} \perp \gamma_{c,r}(w_L, w_r) + T_{c,r}(w_p) \geq p_c
\]

\[
0 \leq w_L \perp \epsilon_L \geq \sum_{r,c} \frac{\beta_c \gamma_{c,r}}{w_L}
\]

\[
0 \leq w_r \perp \epsilon_r \geq \sum_{c} \frac{x_{c,r}(1-\beta_c)\gamma_{c,r}}{w_r}
\]

\[
0 \leq w_p \perp \epsilon_p \geq \sum_{r,c} t_c d_r x_{c,r}
\]

\[
0 \leq p_c \perp \sum_{r} x_{c,r} \geq \frac{\alpha_c p e p w_p + \alpha_c L \epsilon_l w_l + \alpha_c O \sum_r w_r a_r}{p_c}
\]

Note that in (15), (16) and (17), the amounts of labour, land and transport are bounded from above, and hence the prices on these inputs are determined as multipliers (or shadow prices) on the corresponding constraints. The final relationship (18) in the above complementarity problem corresponds to market clearance; prices are nonnegative and can only be positive if supply equals demand. (Some modelers multiply the last inequality throughout by \(p_c\). This removes problems where \(p_c\) becomes zero, but can also introduce spurious solutions.)

The Arrow-Debreu theory guarantees that the problem is homogeneous in prices; \((x, \lambda w, \lambda p)\) is also a solution whenever \((x, w, p)\) solves the above. Typically this singularity in the model is removed by fixing a numeraire, that is fixing a price (for example \(w_L = 1\)) and dropping the corresponding complementary relationship.
Unfortunately, in this formulation even after fixing a numéraire, some of the variables \( p \) and \( w \) may go to zero, resulting in an ill-defined problem. In the case of the Von Thunen land model, the rental price of land \( w_r \) decreases as the distance to market increases, and for remote rings of land, it becomes zero. A standard modeling fix is to put artificial lower bounds on these variables. Even with this fix, the problem typically remains very hard to solve. More importantly, the homogeneity property of the prices used above to fix a numéraire no longer holds, and the corresponding complementary relationship (which was dropped from the problem) may fail to be satisfied. It therefore matters which numéraire is fixed, and many modelers run into difficulty since in many cases the solution found by a solver is invalid for the originally posed model.

In order to test our diagnostic information, we implemented a version of the above model in GAMS. The model corresponds closely to the MCPLIB model pgvon105.gms except we added more regions to make the problem even more difficult. The model file has been documented more fully, and the data rounded to improve clarity.

Our first trial was to solve the model without fixing a numéraire. In this case, PATH 4.x failed to find a solution. At the starting point, the indicators described in Section Ill-Defined Models are reasonable, and there are no zero rows/columns in the Jacobian. At the best point found, all indicators are still reasonable. However, the listing file indicates a large number of division by zero problems occurring in Equations (16). We also note that a nonzero proximal perturbation is used in the first iteration of the crash method. This is an indication of singularities. We therefore added an option to output factorization singularities, and singularities appeared in the first iteration. At this point, we decided to fix a numéraire to see if this alleviated the problem.

We chose to fix the labour wage rate to 1. After increasing the iterations allowed to 100,000, PATH 4.x solved the problem. The statistics at the solution are cause for concern. In particular, the gradient of the Fischer function is 7 orders of magnitude larger than all the other residuals. Furthermore, the Jacobian is very large at the solution point. Looking further in the listing file, a large number of division by zero problems occur in (16).

To track down the problem further, we added an artificial lower bound on the variables \( w_r \) of \( 10^{-5} \), that would not be active at the aforementioned solution. Resolving gave the same "solution", but resulted in the domain errors disappearing.

Although the problem is solved, there is concern on two fronts. Firstly, the gradient of the Fischer function should go to zero at the solution. Secondly, if a modeler happens to make the artificial lower bounds on the variables a bit larger, then they become active at the solution, and hence the constraint that has been dropped by fixing the price of labour at 1 is violated at this point. Of course, the algorithm is unable to detect this problem, since it is not part of the model that is passed to it, and the corresponding output looks satisfactory.

We are therefore led to the conclusion that the model as postulated is ill-defined. The remainder of this section outlines two possible modeling techniques to overcome the difficulties with ill-defined problems of this type.

### 5.32.5.2 Intervention Pricing

The principal difficulty is the fact that the rental prices on land go to zero as proximity to the market decreases, and become zero for sufficiently remote rings. Such a property is unlikely to hold in a practical setting. Typically, a landowner has a minimum rental price (for example, land in fallow increases in value). As outlined above, a fixed lower bound on the rental price violates the well-established homogeneity property. A suggestion postulated by Professor Thomas Rutherford is to allow the landowner to intervene and "purchase-back" his land whenever the rental cost gets smaller than a certain fraction of the labour wage.

The new model adds a (homogeneous in price) constraint

\[
0 \leq i_r, \quad w_r \geq 0.0001 \cdot w_L
\]
and modifies (16) and (18) as follows:

\[ 0 \leq w_r \perp a_r - i_r \geq \sum_c x_{c,r}(1 - \beta_c)\gamma_{c,r} \]

\[ 0 \leq p_c \perp \sum_r x_{c,r} \geq \frac{\alpha_c,PEPw_p + \alpha_c,LELWL + \alpha_c,O \sum_r w_r(a_r - i_r)}{p_c}. \]

(19)

Given the intervention purchase, we can now add a lower bound on \(w_r\) to avoid division by zero errors. In our model we chose \(10^{-5}\) since this will never be active at the solution and therefore will not affect the positive homogeneity. After this reformulation, PATH 4.x solves the problem. Furthermore, the gradient of the Fischer function, although slightly larger than the other residuals, is quite small, and can be made even smaller by reducing the convergence tolerance of PATH. Inspecting the listing file, the only difficulties mentioned are division by zero errors in the market clearance condition (19), that can be avoided a posteori by imposing an artificial (inactive) lower bound on these prices. We chose not to do this however.

### 5.32.5.3 Nested Production and Maintenance

Another observation that can be used to overcome the land price going to zero is the fact that land typically requires some maintenance labour input to keep it usable for crop growth. Traditionally, in economics, this is carried out by providing a nested CES function as technology input to the model. The idea is that commodity \(c\) in region \(r\) is made from labour and an intermediate good, which is "maintained land". Essentially, the following production problem replaces (12):

\[
\begin{align*}
\min_{y_M, y_L, y_r, g} & \quad w_L(y_M + y_L) + w_r y_r \\
\text{subject to} & \quad y_r \geq (1 - \beta_c - \epsilon) g \\
& \quad y_M \geq \epsilon g \\
& \quad \phi_c y_L^{\beta_c} g^{-\beta_c} \geq 1, \\
& \quad y_M, y_L, y_r, g \geq 0.
\end{align*}
\]

Note that the variable \(y_M\) represents "maintenance labour" and \(g\) represents the amount of "maintained land" produced, an intermediate good. The process of generating maintained land uses a Leontieff production function, namely

\[
\min(\lambda_r y_r, \lambda_M y_M) \geq g.
\]

Here \(\lambda_M = \frac{1}{2}, \epsilon\) small, corresponds to small amounts of maintenance labour, while \(\lambda_r = \frac{1}{1 - \beta_c - \epsilon}\) is chosen to calibrate the model correctly. A simple calculus exercise then generates appropriate demand and cost expressions. The resulting complementarity problem comprises (14), (17), (18) and

\[
\begin{align*}
\gamma_{c,r} &= \frac{w_L^{\mu_c}}{\phi_c} \left( \frac{w_L \epsilon + w_r(1 - \beta_c - \epsilon)}{1 - \beta_c} \right)^{1 - \beta_c} \\
0 &\leq w_L \perp e_L \geq \sum_{r,c} x_{c,r} \gamma_{c,r} \left( \frac{\beta_c}{w_L} + \epsilon(1 - \beta_c) \frac{(1 - \beta_c - \epsilon)}{w_L \epsilon + w_r(1 - \beta_c - \epsilon)} \right) \\
0 &\leq w_r \perp a_r \geq \sum_c x_{c,r} \gamma_{c,r} (1 - \beta_c)(1 - \beta_c - \epsilon) \frac{1}{w_L \epsilon + w_r(1 - \beta_c - \epsilon)}.
\end{align*}
\]

After making the appropriate modifications to the model file, PATH 4.x solved the problem on defaults without any difficulties. All indicators showed the problem and solution found to be well-posed.
5.33 quadMINOS

For LP (and RMIP) models that cause difficulty for the standard solvers, quadMINOS provides considerably greater reliability and accuracy than MINOS by using quadruple-precision floating-point arithmetic. Although it is slower by a factor of 20 or 30 for cold-start runs, you can use standard MINOS or another LP solver first and let them do their best. Warm-starts with quadMINOS may give greatly improved solutions at moderate cost.

To take advantage of quadMINOS, the main requirement is to set a few runtime options to non-default values in order to request higher accuracy. For example, it is reasonable to set

\begin{verbatim}
Feasibility tolerance 1e-15
Optimality tolerance 1e-15
\end{verbatim}

because IEEE Quad floating-point has nearly 34 digits of precision. For an example of using Double and Quad MINOS together, see [DQQ] in the GAMS model library.

Note

GAMS/quadMINOS can only solve LPs and RMIPs at the moment because GAMS does not provide function evaluations in quad-precision.

The documentation of MINOS also refers to quadMINOS.

5.34 SBB

5.34.1 Introduction

SBB is a GAMS solver for Mixed Integer Nonlinear Programming (MINLP) models. It is based on a combination of the standard Branch and Bound (B&B) method known from Mixed Integer Linear Programming and some of the standard NLP solvers already supported by GAMS. SBB can use all GAMS NLP solvers as subsolvers but it works best with NLP solvers that can utilize a near optimal point as a starting point like Conopt, Minos, and Snopt.

SBB supports all types of discrete variables supported by GAMS, including Binary, Integer, SemiCont, SemiInt, Sos1, and Sos2.

5.34.2 The Branch and Bound Algorithm

The Relaxed Mixed Integer Nonlinear Programming (RMINLP) model is initially solved using the starting point provided by the modeler. SBB will stop immediately if the RMINLP model is unbounded or infeasible, or if it fails (see option infeasseq and failseq below for an exception). If all discrete variables in the RMINLP model are integer, SBB will return this solution as the optimal integer solution. Otherwise, the current solution is stored and the Branch and Bound procedure will start.

During the Branch and Bound process, the feasible region for the discrete variables is subdivided, and bounds on discrete variables are tightened to new integer values to cut off the current non-integer solutions. Each time a bound is tightened, a new, tighter NLP submodel is solved starting from the optimal solution to the previous looser submodel. The objective function values from the NLP submodel is assumed to be lower bounds on the objective in the restricted feasible space (assuming minimization), even though the local optimum found by the NLP solver may not be a global optimum. If the NLP solver returns a Locally Infeasible status for a submodel, it is usually assumed that there is no feasible solution to the submodel, even though the infeasibility only has been determined locally (see option infeasseq below for an exception). If the model is convex, these assumptions will be satisfied and SBB will provide correct bounds. If the model is not convex, the objective bounds may not be correct and better solutions may exist in other, unexplored parts of the search space.
5.34.3 SBB with Pseudo Costs

Over the last decades quite a number of search strategies have been successfully introduced for mixed integer linear programming (for details see e.g. J.T. Linderoth and M.W.P. Savelsbergh, A Computational Study of Search Strategies for Mixed Integer Programming, INFORMS Journal on Computing, 11(2), 1999). Pseudo costs are key elements of sophisticated search strategies. Using pseudo costs, we can estimate the degradation of the objective function if we move a fractional variable to a close integer value. Naturally, the variable selection can be based on pseudo costs (see SBB option varsel). Node selection can also make use of pseudo cost: If we can estimate the change of the objective for moving one fractional variable to the closed integer value, we can then aggregate this change for all fractional variables, to estimate the objective of the best integer solution reachable from a particular node (see SBB option nodesel).

Unfortunately, the computation of pseudo cost can be a substantial part of the overall computation. Models with a large number of fractional variables in the root node are not good candidates for search strategies which require pseudo costs (varsel 3, nodesel 3,5,6). The impact (positive or negative) of using pseudo cost depends significantly on the particular model. At this stage, general statements are difficult to make.

Selecting pseudo cost related search strategies (varsel 3, nodesel 3,5,6) may use computation time which sometimes does not pay off. However, we encourage the user to try these options for difficult models which require a large number of branch-and-bound nodes to solve.

5.34.4 The SBB Options

SBB works like other GAMS solvers, and many options can be set in the GAMS model. The most relevant GAMS options are IterLim, ResLim, NodLim, OptCA, OptCR, OptfFile, Cheat, and CutOff. A description of all available GAMS options can be found in the GAMS User's Guide Solver related options. GAMS options PriorOpt and TryInt are also accepted by SBB.

SBB uses the var.prior information to select the fractional variable with the smallest priority during the variable selection process. SBB uses the TryInt information to set the branching direction in the B&B algorithm. At the beginning, SBB looks at the levels of the discrete variables provided by the user and if Abs(Round(x.l)-x.l) < m.TryInt, SBB will branch on that variable in the direction of Round(x.l). For example, x.l=0.9 and m.TryInt=0.2. We have Abs(Round(0.9)-0.9)=0.1 < 0.2, so when SBB decides to branch on this variable (because it is fractional, lets say with value 0.5), the node explored next will have the additional constraint x ≥ 1 (the node with x ≤ 0 will be explored later). If everything goes well (there is the chance that we end up in a different local optima in the subsolves for non-convex problems), SBB should reproduce a preset incumbent solution in a couple of nodes.

If you specify <modelname>.Optfile = 1; before the Solve statement in your GAMS model, SBB will then look for and read an option file with the name sbb.opt (see The Solver Option File for general use of solver option files). Unless explicitly specified in the SBB option file, the NLP subsolvers will not read an option file. The syntax for the SBB option file is

    optname value

with one option on each line.

For example,

    rootsolver conopt.1
    subsolver snopt
    loginterval 10

The first two lines determine the NLP subsolvers for the Branch and Bound procedure. CONOPT with the option file conopt.opt will be used for solving the root node. SNOPT with no option file will be used for the remaining nodes. The last option determines the frequency for log line printing. Every 10th node, and each node with a new integer solution, causes a log line to be printed. The following options are implemented:
<table>

</tbody>
</table>
acceptnonopt (boolean): accepts feasible solution from subsolver →

If this option is set to 1 and the subsolver terminates with solver status *Terminated by Solver* and model status *Intermediate Nonoptimal* SBB takes this as a good solution and keeps on going. In default mode such a return is treated as a subsolver failure and the `failseq` is consulted.

Default: 0

avgresmult (integer): average resource multiplicator →

Similar to `subres`, this option allows the user to control the time limit spend in a node. SBB keeps track of how much time is spent in the nodes, and builds an average over time. This average multiplied by the factor `avgresmult` is set as a time limit for solving a node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure: the node is ignored or the solvers in the `failseq` are called. The default multiplier `avgresmult` is 5. Setting `avgresmult` to 0 will disable the automatic time limit feature. A multiplier is not very useful for very small node solution times; therefore, independent of each node, SBB grants the solver at least 5 seconds to solve the node. The competing option `subres` overwrites the automatically generated resource limit.

Default: 5

dfsstay (integer): keeps DFS node selection after solution has been found →

If the node selection is a B*/DFS mix, SBB switches frequently to DFS node selection mode. It switches back into B* node selection mode, if no subnodes were created (new int, pruned, infeasible, fail). It can be advantageous to search the neighborhood of the last node also in a DFS manner. Setting `dfsstay` to `n` instructs SBB to stay in DFS mode for another `n` nodes.

Default: 0

epint (real): integer feasibility tolerance →

The integer infeasibility tolerance.

Range: \([1e-9, 1]\]

Default: 1.0e-5

failseq (string): solver sequence for failed nodes →

`solver1[.n1] solver2[.n2] ...` where `solver1` is the name of a GAMS NLP solver to be used if the default solver fails, i.e., if it was not stopped by an iteration, resource, or domain limit and does not return a locally optimal or locally infeasible solution. `n1` is the value of optfile passed to the alternative NLP solver. If `.n1` is left blank it is interpreted as zero. Similarly, `solver2` is the name of a GAMS NLP solver that is used if `solver1` fails, and `n2` is the value of optfile passed to the second NLP solver. If you have a difficult model where solver failures are not unlikely, you may add more `solver.n` pairs. You can use the same solver several times with different options files. `failseq conopt conopt.2 conopt.3` means to try CONOPT with no options file. If this approach also fails, try CONOPT with options file `conopt.op2`, and if it again fails, try CONOPT with options file `conopt.op3`. If all solver and options file combinations fail the node will be labeled `ignored` and the node will not be explored further. The default is to try only one solver (the `rootsolver` or `subsolver`) and to ignore nodes with a solver failure.

infeasseq (string): solver sequence for infeasible nodes →
level solver1[.n1] solver2[.n2] ... The purpose of infeasseq is to avoid cutting parts of the search tree that appear to be infeasible but really are feasible. If the NLP solver labels a node *Locally Infeasible* and the model is not convex a feasible solution may actually exist. If SBB is high in the search tree it can be very drastic to prune the node immediately. SBB is therefore directed to try the solver/option combinations in the list as long as the depth in the search tree is less than the integer value level. If the list is exhausted without finding a feasible solution, the node is assumed to be infeasible. The default is to trust that *Locally Infeasible* nodes are indeed infeasible and to remove them from further consideration.

**intsollim (integer):** maximum number of integer solutions

Maximum number of integer solutions. If this number is exceeded, SBB will terminate and return the best solution found so far.

Default: 2100000000

**loginterval (integer):** progress display interval

The interval (number of nodes) for which log lines are written.

Default: 1

**loglevel (integer):** level of solver display

The level of log output.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>only SBB log lines with one line every loginterval nodes</td>
</tr>
<tr>

<td>NLP solver log for the root node plus SBB log lines as 0</td>
</tr>
<tr>
<td>2</td>
<td>NLP solver log for all nodes plus SBB log lines as 0</td>
</tr>
</tbody>
</table>

**memnodes (integer):** maximum number of nodes in memory

The maximum number of nodes SBB can have in memory. If this number is exceeded, SBB will terminate and return the best solution found so far.

Default: 10000

**miptrace (string):** filename of MIP trace file

More info is available in chapter Solve trace

**miptracenode (integer):** node interval when a trace record is written

More info is available in chapter Solve trace

Default: 100

**miptracetime (real):** time interval when a trace record is written

More info is available in chapter Solve trace

Default: 5.0

**nodesel (integer):** node selection strategy

Node selection scheme.

Default: 0
**printbbinfo (integer):** prints additional node info

Additional info of log output.

Default: 0

<table>
<thead>
<tr>

<td>print variable selection letter</td>
</tr>
<tr>
<td></td>
<td>The node and variable selection for the current node are indicated by a two letter code at the end of the log line. The first letter represents the node selection: D for DFS, B for Best Bound, and E for Best Estimate. The second letter represents the variable selection: X for maximum infeasibility, N for minimum infeasibility, and P for pseudo cost.</td>
</tr>
<tr>
<td>2</td>
<td>print best estimate</td>
</tr>
</tbody>
</table>

**rootsolver (string):** solver for the root node

solver[.n] Solver is the name of the GAMS NLP solver that should be used in the root node, and n is the integer corresponding to optfile for the root node. If .n is missing, the optfile treated as zero i.e. the NLP solver will not look for an options file. This SBB option can be used to overwrite the default that uses the NLP solver specified with an Option NLP = solver; statement or the default GAMS solver for NLP.

Default: GAMS NLP solver

**solvelink (integer):** Solvelink for GAMS NLP solver

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

</tr>
<tr>
<td>2</td>
<td>Call GAMS NLP solver via module</td>
</tr>
<tr>
<td>5</td>
<td>Call GAMS NLP solver in memory</td>
</tr>
</tbody>
</table>

**subiter (integer):** iteration limit for the subsolve

The default for subiter passed on through iterlim. Similar to subres but sets the iteration limit for solving a node in the B&B tree.

Default: GAMS iterlim
subres (real): resource limit for the subsolve

The default for subres passed on through reslim. Sets the time limit in seconds for solving a node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure and the node is ignored, or the solvers in the failseq are called.
Default: GAMS reslim

subsolver (string): solver for the subproblems

 solver[n] Similar to rootsolver but applied to the subnodes.
Default: GAMS NLP solver

usercallparmfile (string): Command-line parameter include file used in GAMS command-line calls triggered by BCH

usergdxname (string): the name of the GDX file exported from the solver with the solution at the node

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.
Default: bchout.gdx

usergdxnameinc (string): the name of the GDX file exported from the solver with the incumbent solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.
Default: bchout_i.gdx

userheurcall (string): the GAMS command line to call the heuristic

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userheurfirst (integer): calls the cut generator for the first n nodes

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.
Default: 10

userheurfreq (integer): determines the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.
Default: 10

userheurinterval (integer): determines the interval when to apply the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.
Default: 100

userheurmult (integer): determines the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.
Default: 2

userheurnewint (boolean): calls the heuristic if the solver found a new integer feasible solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.
Default: 0

userheurobjfirst (integer): Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.
Default: 50

varsel (integer): variable selection strategy at each node

Variable selection scheme.
Default: 0
5.34.5 The SBB Log File

The SBB Log file (usually directed to the screen) can be controlled with the loginterval and loglevel options in SBB. It will by default first show the iteration output from the NLP solver that solves the root node. This is followed by output from SBB describing the search tree. An example of this search tree output follows:

```
Root node solved locally optimal.

| Node | Act. Lev. | Objective | IInf | Best Int. | Best Bound | Gap (2 secs)
|------|-----------|-----------|------|-----------|------------|-------------
| 0    | 0         | 8457.6878 | 3    | -         | 8457.6878 | -           |
| 1    | 1         | 8491.2869 | 2    | -         | 8457.6878 | -           |
| 2    | 2         | 8518.1779 | 1    | -         | 8457.6878 | -           |
| *    | 3         | 9338.1020 | 0    | 9338.1020 | 8457.6878 | 0.1041      |
| 4    | 2         | pruned    | -    | 9338.1020 | 8491.2869 | 0.0997      |

Solution satisfies optcr

</tr>
<tr>
<td>IInf</td>
<td>The number of integer infeasibilities, i.e. the number of variables that are supposed to be binary or integer that do not satisfy the integrality requirement. Semi continuous variables and SOS variables may also contribute to IInf.</td>
</tr>
<tr>
<td>Best Int</td>
<td>The value of the best integer solution found so far. A dash (-) indicates that an integer solution has not yet been found. A star (*) in column one indicates that the node is integer and that the solution is better than the best yet found.</td>
</tr>
<tr>
<td>Best Bound</td>
<td>The minimum value of &quot;Objective&quot; for the subnodes that have not been solved yet (maximum for maximization models). For convex models, Best Bound will increase monotonically. For nonconvex models, Best Bound may decrease, indicating that the Objective value for a node was not a valid lower bound for that node.</td>
</tr>
<tr>
<td>Gap</td>
<td>The relative gap between the Best Integer solution and the Best Bound.</td>
</tr>
</tbody>
</table>

The remaining part of the Log file displays various solution statistics similar to those provided by the MIP solvers. This information can also be found in the Solver Status area of the GAMS listing file.

The following Log file shows cases where the NLP solver fails to solve a subnode. The text "ignored" in the Objective field shows the failure, and the values in parenthesis following the Gap field are the Solve and Model status returned by the NLP solver:

```
Root node solved locally optimal.
Node Act. Lev. Objective IInf Best Int. Best Bound Gap (2 secs)
0 0 0 6046.0186 12             -  6046.0186  -
1 1 1 infeasible -              -  6046.0186  -
2 0 1 6042.0995 10             -  6042.0995  -
3 1 2 ignored -                -  6042.0995  - (4,6)
4 0 2 5804.5856 8              -  5804.5856  -
5 1 3 ignored -                -  5804.5856  - (4,7)
```

The next Log file shows the effect of the `infeasseq` and `failseq` options on the model above. CONOPT with options file `conopt.opt` (the default solver and options file pair for this model) considers the first subnode to be locally infeasible. CONOPT, MINOS, and SNOPT, all with no options file, are therefore tried in sequence. In this case, they all declare the node infeasible and it is considered to be infeasible.

In node 3, CONOPT with option file fails but CONOPT without option file finds a Locally Optimal solution, and this solution is then used for further search. The SBB option file for the following run would be:

```
rootsolver conopt.1
subsolver conopt.1
failseq conopt
infeasseq 100 conopt minos snopt
```

The log looks as follows:

```
Root node solved locally optimal.
conopt.1 reports locally infeasible
Executing conopt
conopt reports locally infeasible
Executing minos
minos reports locally infeasible
```
Executing snopt
1 1 1 infeasible - - 6046.0186 -
2 0 1 6042.0995 10 - 6042.0995 -

conopt.1 failed. 4 TERMINATED BY SOLVER, 7 FEASIBLE SOLUTION

Executing conopt
3 1 2 4790.2373 8 - 6042.0995 -
4 2 3 4481.4156 6 - 6042.0995 -

conopt.1 reports locally infeasible

Executing conopt
conopt reports locally infeasible

Executing minos
minos failed. 4 TERMINATED BY SOLVER, 6 INTERMEDIATE INFEASIBLE

Executing snopt
5 3 4 infeasible - - 6042.0995 -
6 2 4 4480.3778 4 - 6042.0995 -

The Log file shows a solver statistic at the end, summarizing how many times an NLP was executed and how often it failed:

NLP Solver Statistics
Total Number of NLP solves : 45
Total Number of NLP failures: 13
Details: conopt minos snopt
# execs 34 3 8
# failures 4 3 6

The solutions found by the NLP solver to the subproblems in the Branch and Bound may not be the global optima. Therefore, the objective can improve even though we restrict the problem by tightening some bounds. These jumps of the objective in the wrong direction which might also have an impact on the best bound/possible are reported in a separate statistic:

Non convex model!
# jumps in best bound : 2
Maximum jump in best bound : 20.626587 in node 13
# jumps to better objective : 2
Maximum jump in objective : 20.626587 in node 13

5.34.6 Comparison of SBB and other MINLP Solvers

GAMS offers a variety of MINLP solvers including local and global MINLP solver. They implement different algorithms and it is usually unclear which solver performs best. Here we give a brief comparison between SBB and the well known solver DICOPT.

DICOPT is based on the outer approximation method. Initially, the RMINLP model is solved just as in SBB. The model is then linearized around this point and a linear MIP model is solved. The discrete variables are then fixed at the optimal values from the MIP model, and the resulting NLP model is solved. If the NLP model is feasible, we have an integer feasible solution.

The model is linearized again and a new MIP model with both the old and new linearized constraints is solved. The discrete variables are again fixed at the optimal values, and a new NLP model is solved.

The process stops when the MIP model becomes infeasible, when the NLP solution becomes worse, or, in some cases, when bounds derived from the MIP model indicate that it is safe to stop.
DICOPT is based on the assumption that MIP models can be solved efficiently while NLP models can be expensive and difficult to solve. The MIP models try to approximate the NLP model over a large area and solve it using much cheaper linear technology. Ideally, only a few NLPs must be solved.

DICOPT can experience difficulties solving models, if many or all the NLP submodels are infeasible. DICOPT can also have problems if the linearizations used for the MIP model create ill-conditioned models. The MIP models may become very difficult to solve, and the results from the MIP models may be poor as initial values for the NLP models. The linearized constraint used by DICOPT may also exclude certain areas of the feasible space from consideration.

SBB uses different assumptions and works very differently. Most of the work in SBB involves solving NLP models. Since the NLP submodels differ only in one or a few bounds, the assumption is that the NLP models can be solved quickly using a good restart procedure. Since the NLP models differ very little and good initial values are available, the solution process will be fairly reliable compared to the solution process in DICOPT, where initial values of good quality seldom are available. Because search space is reduced based on very different grounds than in DICOPT, other solutions may therefore be explored.

Overall, DICOPT should perform better on models that have a significant and difficult combinatorial part, while SBB may perform better on models that have fewer discrete variables but more difficult nonlinearities (and possibly also on models that are fairly non convex).

### 5.35 SCIP

**SCIP** (Solving Constraint Integer Programs) is a framework for Constraint Integer Programming oriented towards the needs of Mathematical Programming experts who want to have total control of the solution process and access detailed information down to the guts of the solver. SCIP can also be used as a pure MIP or MINLP solver or as a framework for branch-cut-and-price. Within GAMS, the MIP and MINLP solving facilities of SCIP are available.

For more detailed information, we refer to [4] [1] [2] [21] [20] [74] [127] [88] [89] [75] [22] [192] [191] [204] and the [SCIP web site](http://scip.zib.de). GAMS/SCIP uses CPLEX, if licensed, and otherwise Sopalx [206] as LP solver, the COIN-OR Interior Point Optimizer IPOPT [197] as nonlinear solver, and CppAD to compute derivatives of nonlinear functions.

SCIP supports continuous, binary, integer, semi-continuous, semi-integer variables, indicator constraints, special ordered sets, and branching priorities for discrete variables.

#### 5.35.1 Usage

The following statement can be used inside your GAMS program to specify using SCIP

```
Option MIP = SCIP;  { or QCP or NLP or MIQCP or MINLP or ... }
```

The above statement should appear before the Solve statement. If SCIP was specified as the default solver during GAMS installation, the above statement is not necessary.
5.35 SCIP

5.35.1.1 Specification of SCIP Options

GAMS/SCIP supports the GAMS parameters reslim, iterlim, nodlim, optca, optcr, and workspace. Further, the option threads can be used to control the number of threads used in the MILP presolver, the linear algebra routines of IPOPT, and for solving LPs if CPLEX’ barrier solver is used.

Options can be specified by a SCIP options file. A SCIP options file consists of one option or comment per line. A pound sign (#) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs). Further, string values have to be enclosed in quotation marks.

A small example for a scip.opt file is:

```
propagating/probing/maxprerounds = 0
separating/maxrounds = 0
separating/maxroundsroot = 0
```

It causes GAMS/SCIP to disable probing during presolve and to turn off all cut generators.

5.35.1.2 Specification of Indicators

Indicators are a modeling tool to specify that certain equations in a model must only be satisfied if certain binary variables take a specified value. Indicators are not supported by the GAMS language, but can be passed to SCIP via a separate file, see Indicator Constraints for more details on its syntax. The name of that file is specified via the option gams/indicatorfile in a SCIP option file. Currently, indicators can only be used for linear equations.

5.35.2 Special Features

5.35.2.1 SCIP interactive shell

The interactive shell in SCIP is a powerful tool that allows the user to display various information (e.g., branching statistics, presolved model), load emphasis settings, interrupt a solve to change parameters or trigger a restart, write the model in various file formats, start SCIPs solution counter, and many more things.

When setting the option gams/interactive to a nonempty string, the GAMS/SCIP interface opens the interactive shell of SCIP after having load the GAMS problem and parameters and passes the value of the gams/interactive parameter to the SCIP interactive shell.

By default, SCIP behaves as if gams/interactive has been set to "optimize write gamssol quit", that is, SCIP is requested to solve the problem, then to pass the solution back to GAMS, and to quit.

An example use of the SCIP interactive shell feature via GAMS is to add the following line to your SCIP options file:

```
gams/interactive = "write prob orig.lp presolve write transprob presol.mps opt write gamssol quit"
```

This instructs SCIP to write the original problem to the file orig.lp in LP format, to presolve the instance, to write the presolved problem to the file presolved.mps in MPS format, to solve the instance, to write the solution out to GAMS, and to finish.

By omitting the quit command, SCIPs interactive shell remains open and awaits user input. The command help prints a list of available commands. Note, that on Windows, GAMS need to be called with the option interactivesolver enabled to allow user input for the solver process.

A tutorial on using the SCIP shell is available at https://www.scipopt.org/doc/html/SHELL.php.
5.35.2.2 Emphasis Settings

SCIP includes various emphasis settings, which are predefined values for a set of SCIP parameters. Such predefined settings are available for setting the effort that SCIP should spend for, e.g., presolving, separation, or heuristics.

The emphasis settings are not available as single parameters, but can be set via SCIPs interactive shell. E.g., writing `set heuristics emphasis` in the shell displays the available emphasis settings for heuristics (aggressive, fast, off) and expects the user to input which setting to use. Further, general emphasis settings are available in the `set emphasis` menu, some of them giving predefined settings similar to the CPLEX option mipemphasis.

Via the `gams/interactive` option, c.f. Section SCIP interactive shell, emphasis settings can be activated via a SCIP options file. For example, adding the option

```
gams/interactive = "set emphasis feasibility set loadgams optimize write gamssol quit"
```

instructs SCIP to load the emphasis setting `feasibility` prior to optimizing the model and passing the solution back to GAMS. Note, that setting one of the emphasis settings `feasibility`, `hardlp`, and `optimality` resets all previously set parameters to their default values, which includes the ones that are set by the GAMS/SCIP interface or which were loaded from a SCIP options file. Therefore, the command `set loadgams` has been used above to restore these parameter settings.

The following emphasis settings are available in SCIP:

<table>
<thead>
<tr>
<th>shell command</th>
<th>purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>set emphasis easycip</td>
<td>use for easy problems</td>
</tr>
<tr>
<td>set emphasis feasibility</td>
<td>emphasize finding a feasible solution</td>
</tr>
<tr>
<td>set emphasis hardlp</td>
<td>use for problems with a hard LP</td>
</tr>
<tr>
<td>set emphasis optimality</td>
<td>emphasize proving optimality</td>
</tr>
<tr>
<td>set emphasis numerics</td>
<td>increase numerical stability</td>
</tr>
<tr>
<td>set emphasis cpsolver</td>
<td>setup a constraint programming like search</td>
</tr>
<tr>
<td>set heuristic emphasis aggressive</td>
<td>use primal heuristics aggressively</td>
</tr>
<tr>
<td>set heuristic emphasis fast</td>
<td>use only fast primal heuristics</td>
</tr>
<tr>
<td>set heuristic emphasis off</td>
<td>disable all primal heuristics</td>
</tr>
<tr>
<td>set presolving emphasis aggressive</td>
<td>do aggressive presolving</td>
</tr>
<tr>
<td>set presolving emphasis fast</td>
<td>use only fast presolving steps</td>
</tr>
<tr>
<td>set presolving emphasis off</td>
<td>disable presolving</td>
</tr>
<tr>
<td>set separating emphasis aggressive</td>
<td>use cutting plane separators aggressively</td>
</tr>
<tr>
<td>set separating emphasis fast</td>
<td>use only fast cutting plane separators</td>
</tr>
<tr>
<td>set separating emphasis off</td>
<td>disable all cutting plane separators</td>
</tr>
</tbody>
</table>

5.35.2.3 Starting point

Using the completesol heuristic, SCIP can try to find a feasible solution based on values given by the user for all or some of the variables. The values need to be specified as variable levels in the GAMS model. The heuristic solves a copy of the problem where variables for which values have been provided are restricted to be close to that value. When an integral value is specified for a binary or integer variable, the variable is fixed to that value. See also Section 2.3.2 in [127] for a more detailed description of the heuristic.

For which variables the level values are passed from GAMS to SCIP is controlled by the parameter `gams/mipstart`. The parameter values have the following meaning:
- 0: do not pass any variable values to SCIP, the heuristic will not run
- 1: pass values for all binary and integer variables to SCIP and let SCIP try to find a feasible solution in its neighborhood by using the completesol heuristic
- 2 (default): pass values for all variables to SCIP and let SCIP check feasibility of the given solution, the heuristic will not run
- 3: pass values for all variables to SCIP and let SCIP try to find a feasible solution in the neighborhood by using the completesol heuristic
- 4: pass values for all binary and integer variables to SCIP which fractionality is at most the value of GAMS option `tryint` (thus, with default `tryint=0`, only for variables with integral values, the value is passed to SCIP) and let SCIP try to find a feasible solution in the neighborhood by using the completesol heuristic

Note, that the completesol heuristic will not run if there are too many variables with unknown values. This behavior can be adjusted by setting parameter `heuristics/completesol/maxunknownrate`.

5.35.2.4 Decomposition Information

SCIP potentially can make use of a user-provided problem decomposition, e.g., in primal heuristics PADM or GINS. Note, that SCIP's Benders Decomposition is not available with GAMS at the moment. A GAMS user can inform SCIP about such a decomposition by using the `.stage` variable suffix.

In an attempt to following the same convention on interpreting the `.stage` variable suffix as the GAMS/CPLEX link, variables which `.stage` suffix is set to an integral value greater than 0 are assigned to a block with this number. Variables which `.stage` suffix is set to a fractional value or a value smaller than 1 are assigned to no block.

Note, that the default value for the `.stage` suffix is 1. Therefore, GAMS/SCIP only passes decomposition information to SCIP if at least one variable has its `.stage` suffix set to a value different than 1. Moreover, in order to receive the `.stage` values, `scaleOpt` and `priorOpt` must be left at their default of 0.

5.35.2.5 Solution Pool

When SCIP solves a problem, it may find several solutions, whereof only the best one is available to the GAMS user via the variable level values in the GAMS model. If the option `gams/dumpsolutions` is specified, then all alternative solutions found by SCIP are written into GDX files and an index file with the name given by the this option is written. If the option `gams/dumpsolutionsmerged` is specified, then all alternative solutions found by SCIP are written into a single GDX file, which name is given by the this option.

The GAMS testlib model `dumpsol` shows an example use for this option.

5.35.2.6 Solving process tracing

The option `gams/solvetrace/file` can be used to specify the name of a file where information about the progress of the branch-and-bound tree search in SCIP is stored. The file is created and updated during the solution process, so it may also be used to monitor the progress of SCIP while it still solves the model.

New entries are written periodically, depending on how many nodes have been processed or how much time has been elapsed since the last entry was written. Each entry contains information on the current primal and dual bound.
5.35.2.7 Notes on solving MINLPs

SCIP includes capabilities to handle nonlinear functions that are specified via algebraic expressions. Therefore, neither external/extrinsic functions nor all GAMS mathematical functions are supported.

Nonconvex MINLPs are solved via a spatial branch-and-bound algorithm using linear relaxations. The tightness of this relaxation depends heavily on the variable bounds, thus tight bounds for the nonlinear variables are crucial for SCIP.

Convex MINLPs are much easier to solve for SCIP, provided it recognizes the convexity of the model. The convexity check implemented in SCIP may not give a conclusive answer in all cases. However, setting the option constraints/nonlinear/assumeconvex to TRUE can be used to tell SCIP that it should assume all nonlinear constraints to be of convex type. This may help to improve solving times for convex MINLPs considerably in some cases. However, it can also deteriorate performance as it prevents the use of certain extended formulations.

Another feature that can be especially useful for convex MINLPs is to enable the generation of cuts in feasible solutions, since these supporting hyperplanes can be strong. At the moment, this is only enabled for purely continuous nonlinear programs (QCPs and NLPs), but can be adjusted by parameter constraints/nonlinear/linearizeheursol. In this connection, it may also be beneficial to set separating/poolfreq to 1.

5.35.3 Components

In the following, we list components that are available in SCIP together with some common properties. Many of these properties can be modified with corresponding parameters.

5.35.3.1 Branching Rules

<table>

5.35.4 List of SCIP Options

SCIP supports a large set of options. In the following, we give a detailed list of all SCIP options.

5.35.4.1 gams

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>gams/dumpsolutions</td>
<td>name of solutions index gdx file for writing all alternate solutions</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/dumpsolutionsmerged</td>
<td>name of gdx file for writing all alternate solutions into a single file</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/indicatorfile</td>
<td>name of GAMS options file that contains definitions on indicators</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/infbound</td>
<td>value to use for variable bounds that are missing or exceed numerics/infinity</td>
<td>(\infty)</td>
</tr>
<tr>
<td></td>
<td>Range: ([0, \infty])</td>
<td></td>
</tr>
<tr>
<td>gams/interactive</td>
<td>command to be issued to the SCIP shell instead of issuing a solve command</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/mipstart</td>
<td>how to handle initial variable levels, see also section Starting point</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>Range: ({0, ..., 4})</td>
<td></td>
</tr>
</tbody>
</table>

5.35.4.2 gams/solvtrace

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>gams/solvtrace/file</td>
<td>name of file where to write branch-and-bound trace information too</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/solvtrace/nodefreq</td>
<td>frequency in number of nodes when to write branch-and-bound trace information, 0 to disable</td>
<td>100</td>
</tr>
<tr>
<td></td>
<td>Range: ({0, ..., \infty})</td>
<td></td>
</tr>
<tr>
<td>gams/solvtrace/timefreq</td>
<td>frequency in seconds when to write branch-and-bound trace information, 0.0 to disable</td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>Range: ([0, \infty])</td>
<td></td>
</tr>
</tbody>
</table>

5.35.4.3 branching

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/clamp</td>
<td>minimal relative distance of branching point to bounds when branching on a continuous variable</td>
<td>0.2</td>
</tr>
<tr>
<td></td>
<td>Range: ([0, 0.5])</td>
<td></td>
</tr>
<tr>
<td>branching/delaypscostupdate</td>
<td>should updating pseudo costs for continuous variables be delayed to the time after separation?</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>branching/divingpscost</td>
<td>should pseudo costs be updated also in diving and probing mode?</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lpgainnormalize</td>
<td>strategy for normalization of LP gain when updating pseudo-costs of continuous variables (divide by movement of 'l'p value, reduction in 'd'omain width, or reduction in domain width of 's'ibling)</td>
<td>s</td>
</tr>
<tr>
<td></td>
<td>Range: d, l, s</td>
<td></td>
</tr>
<tr>
<td>branching/midpull</td>
<td>fraction by which to move branching point of a continuous variable towards the middle of the domain; a value of 1.0 leads to branching always in the middle of the domain</td>
<td>0.75</td>
</tr>
<tr>
<td></td>
<td>Range: [0, 1]</td>
<td></td>
</tr>
<tr>
<td>branching/midpullreldomtrig</td>
<td>multiply midpull by relative domain width if the latter is below this value</td>
<td>0.5</td>
</tr>
<tr>
<td></td>
<td>Range: [0, 1]</td>
<td></td>
</tr>
<tr>
<td>branching/preferbinary</td>
<td>should branching on binary variables be preferred?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>Options for expert users</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/checksol</td>
<td>should LP solutions during strong branching with propagation be checked for feasibility?</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/firstsbchild</td>
<td>child node to be regarded first during strong branching</td>
<td>a</td>
</tr>
<tr>
<td></td>
<td>(only with propagation): 'u'p child, 'd'own child, 'h'istory-based, or 'a'utomatic</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: a, d, u, h</td>
<td></td>
</tr>
<tr>
<td>branching/forceallchildren</td>
<td>should all strong branching children be regarded even if one is detected to be infeasible? (only with propagation)</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/roundsbsol</td>
<td>should LP solutions during strong branching with propagation be rounded?</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>(only when checksbsol=TRUE)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/scorefac</td>
<td>branching score factor to weigh downward and upward gain prediction in sum score function</td>
<td>0.167</td>
</tr>
<tr>
<td></td>
<td>Range: [0, 1]</td>
<td></td>
</tr>
<tr>
<td>branching/scorefunc</td>
<td>branching score function ('s'um, 'p'roduct, 'q'uotient)</td>
<td>p</td>
</tr>
<tr>
<td></td>
<td>Range: s, p, q</td>
<td></td>
</tr>
<tr>
<td>branching/sumadjustscore</td>
<td>score adjustment near zero by adding epsilon (TRUE) or using maximum (FALSE)</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
</tbody>
</table>

### 5.35.4.4 branching/allfullstrong

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/allfullstrong/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: [0, 1]</td>
<td></td>
</tr>
<tr>
<td>branching/allfullstrong/maxdepth</td>
<td>maximal depth level, up to which branching rule &lt;allfullstrong&gt; should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td></td>
<td>Range: {-1, ..., 65534}</td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>branching/allfullstrong/priority</td>
<td>priority of branching rule &lt;allfullstrong&gt;</td>
<td>-1000</td>
</tr>
<tr>
<td>Range: {-536870912, ..., 536870911}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 5.35.4.5 branching/cloud

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/cloud/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>Range: ([0, 1])</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/cloud/maxdepth</td>
<td>maximal depth level, up to which branching rule &lt;cloud&gt; should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>Range: ([-1, ..., 65534]}</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/cloud/maxdepthunion</td>
<td>maximum depth for the union</td>
<td>65000</td>
</tr>
<tr>
<td>Range: ([0, 65000])</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/cloud/maxpoints</td>
<td>maximum number of points for the cloud (-1 means no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>Range: ([-1, ..., \infty])</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/cloud/minsuccessrate</td>
<td>minimum success rate for the cloud</td>
<td>0</td>
</tr>
<tr>
<td>Range: ([0, 1])</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/cloud/minsuccessunion</td>
<td>minimum success rate for the union</td>
<td>0</td>
</tr>
<tr>
<td>Range: ([0, 1])</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/cloud/onlyF2</td>
<td>should only F2 be used?</td>
<td>0</td>
</tr>
<tr>
<td>Range: boolean</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/cloud/priority</td>
<td>priority of branching rule &lt;cloud&gt;</td>
<td>0</td>
</tr>
<tr>
<td>Range: {-536870912, ..., 536870911}</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/cloud/usecloud</td>
<td>should a cloud of points be used?</td>
<td>1</td>
</tr>
<tr>
<td>Range: boolean</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/cloud/useunion</td>
<td>should the union of candidates be used?</td>
<td>0</td>
</tr>
<tr>
<td>Range: boolean</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 5.35.4.6 branching/distribution

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/distribution/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>Range: ([0, 1])</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/distribution/maxdepth</td>
<td>maximal depth level, up to which branching rule &lt;distribution&gt; should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>Range: ([-1, ..., 65534]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/distribution/priority</td>
<td>priority of branching rule &lt;distribution&gt;</td>
<td>0</td>
</tr>
<tr>
<td>Range: {-536870912, ..., 536870911}</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Options for expert users</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/distribution/onlyactivecols</td>
<td>should only active rows which are active at the current node be considered?</td>
<td>0</td>
</tr>
<tr>
<td>Range: boolean</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>branching/distribution/scoreparam</td>
<td>the score; largest 'd'ifference, 'l'owest cumulative probability, 'h'ighest c.p., 'v'otes lowest c.p., votes highest c.p.('w')</td>
<td>v</td>
</tr>
<tr>
<td>branching/distribution/weightedscore</td>
<td>should the branching score weigh up- and down-scores of a variable</td>
<td>0</td>
</tr>
</tbody>
</table>

### 5.35.4.7 branching/fullstrong

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/fullstrong/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>branching/fullstrong/maxdepth</td>
<td>maximal depth level, up to which branching rule &lt;fullstrong&gt; should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>branching/fullstrong/priority</td>
<td>priority of branching rule &lt;fullstrong&gt;</td>
<td>0</td>
</tr>
</tbody>
</table>

**Options for expert users**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/fullstrong/forcestrongbranch</td>
<td>should strong branching be applied even if there is just a single candidate?</td>
<td>0</td>
</tr>
<tr>
<td>branching/fullstrong/maxproprounds</td>
<td>maximum number of propagation rounds to be performed during strong branching before solving the LP (-1: no limit, -2: parameter settings)</td>
<td>-2</td>
</tr>
<tr>
<td>branching/fullstrong/probingbounds</td>
<td>should valid bounds be identified in a probing-like fashion during strong branching (only with propagation)?</td>
<td>1</td>
</tr>
<tr>
<td>branching/fullstrong/reevalage</td>
<td>number of intermediate LPs solved to trigger reevaluation of strong branching value for a variable that was already evaluated at the current node</td>
<td>10</td>
</tr>
</tbody>
</table>

### 5.35.4.8 branching/inference

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/inference/conflictprio</td>
<td>priority value for using conflict weights in lex. order</td>
<td>1</td>
</tr>
<tr>
<td>branching/inference/cutoffprio</td>
<td>priority value for using cutoff weights in lex. order</td>
<td>1</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>branching/inference/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>branching/inference/maxdepth</td>
<td>maximal depth level, up to which branching rule <code>&lt;inference&gt;</code> should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>branching/inference/priority</td>
<td>priority of branching rule <code>&lt;inference&gt;</code></td>
<td>1000</td>
</tr>
<tr>
<td>branching/inference/useweightedsum</td>
<td>should a weighted sum of inference, conflict and cutoff weights be used?</td>
<td>1</td>
</tr>
</tbody>
</table>

**Options for expert users**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/inference/conflictweight</td>
<td>weight in score calculations for conflict score</td>
<td>1000</td>
</tr>
<tr>
<td>branching/inference/cutoffweight</td>
<td>weight in score calculations for cutoff score</td>
<td>1</td>
</tr>
<tr>
<td>branching/inference/fractionals</td>
<td>should branching on LP solution be restricted to the fractional variables?</td>
<td>1</td>
</tr>
<tr>
<td>branching/inference/inferenceweight</td>
<td>weight in score calculations for inference score</td>
<td>1</td>
</tr>
<tr>
<td>branching/inference/reliablescore</td>
<td>weight in score calculations for conflict score</td>
<td>0.001</td>
</tr>
</tbody>
</table>

### 5.35.4.9 branching/leastinf

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/leastinf/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>branching/leastinf/maxdepth</td>
<td>maximal depth level, up to which branching rule <code>&lt;leastinf&gt;</code> should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>branching/leastinf/priority</td>
<td>priority of branching rule <code>&lt;leastinf&gt;</code></td>
<td>50</td>
</tr>
</tbody>
</table>

### 5.35.4.10 branching/lookahead

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/lookahead/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>branching/lookahead/maxdepth</td>
<td>maximal depth level, up to which branching rule (&lt;\text{lookahead}&gt;) should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td></td>
<td>Range: {-1,...,65534}</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/priority</td>
<td>priority of branching rule (&lt;\text{lookahead}&gt;)</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: {-536870912,...,536870911}</td>
<td></td>
</tr>
<tr>
<td>Options for expert users</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/abbreviated</td>
<td>toggles the abbreviated LAB.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/abbrevpseudo</td>
<td>if abbreviated: Use pseudo costs to estimate the score of a candidate.</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/addbinconsrow</td>
<td>should binary constraints be added as rows to the base LP? (0: no, 1: separate, 2: as initial rows)</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: {0,...,2}</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/addclique</td>
<td>add binary constraints with two variables found at the root node also as a clique</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/addnonviocons</td>
<td>should binary constraints, that are not violated by the base LP, be collected and added?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/applychildbounds</td>
<td>should bounds known for child nodes be applied?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/deeperscoringfunction</td>
<td>scoring function to be used at deeper levels</td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>Range: {d,f,s,w,l,c,r,x}</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/enforcemaxdomreds</td>
<td>should the maximum number of domain reductions (\text{maxviolateddomreds}) be enforced?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/filterbymaxgain</td>
<td>should lookahead branching only be applied if the max gain in level 1 is not uniquely that of the best candidate?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/level2avgscore</td>
<td>should the average score be used for uninitialized scores in level 2?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/level2zeroscore</td>
<td>should uninitialized scores in level 2 be set to 0?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/maxncands</td>
<td>if abbreviated: (\text{The max number of candidates to consider at the node}.</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>Range: {1,...,\infty}</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/maxndeepercands</td>
<td>if abbreviated: (\text{The max number of candidates to consider per deeper node}.</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>Range: {0,...,\infty}</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/maxviolatedbincons</td>
<td>how many binary constraints that are violated by the base lp solution should be gathered until the rule is stopped and they are added? [0 \text{ for unrestricted}]</td>
<td>0</td>
