The actual change of the GAMS language required for the implementation of GUSS is minimal. The only true change is the extension of the SOLVE statement with the term SCENARIO dict. Existing language elements have been used to store symbol mapping information, options, and model result statistics. Some parts of the GUSS presentation look somewhat unnatural, e.g. since dict is a three dimensional set the specification the scenario set using keyword scenario requires a third dummy label ' '. However, this approach gives maximum flexibility for future extension, allows reliable consistency checks at compile and execution time, and allows the user to delay the commitment for significant and permanent syntax changes of a developing method to handle model instances at a GAMS language level.

4.23.5 Applications

4.23.5.1 Cross Validation in GAMS via GUSS

Cross validation is a statistical/machine learning technique that aims to evaluate the generalizability of a classifier (or other decision) process. It does this by setting aside a portion of the data for testing, and uses the remaining data entries to produce the classifier. The testing data is subsequently used to evaluate how well the classifier works. Cross validation performs this whole process a number of times in order to estimate the true power of the classifier.

Ten-fold cross validation is a special case, where the original data is split into ten pieces, and cross validation is performed using each of these ten pieces as the testing set. Thus, the training process is performed ten times, each of which uses the data obtained by deleting the testing set from the whole dataset. We show below how to carry this out using the Gather-Update-Solve-Scatter (GUSS) facility in GAMS.

A paper with the title "GUSS: Solving Collections of Data Related Models within GAMS" that contains two additional application examples for GUSS is available [here](link).

4.23.5.1.1 GUSS formulation in GAMS The following example compares the two formulations for a feature-selection model under cross-validation using data files a.data.inc and b.data.inc. The actual source code for both of these GAMS formulations is available [here](link).

Original GAMS formulation (without the GAMS/DEA interface):

```gams
$title Ten-fold cross validation example $setcom !

$setglobal num_folds 10

set a 'set for category 1' /1*1505/
b 'set for category 2' /1*957/
o 'observations' /1*14/
p 'folds to perform' /1*%num_folds%/
f 'maximum features to select' /1*10/
```
4.23 Gather-Update-Solve-Scatter (GUSS) 1651

* Read in the data from the data files
parameter a_data(a, o) /$
$offlisting
$include "a_data.inc"
$onlisting
/
;

parameter b_data(b, o) /$
$offlisting
$include "b_data.inc"
$onlisting
/
;

set a_test(p,a), b_test(p,b) 'testing sets'
   a_trai(a), b_trai(b) 'training sets';

* Define problem
scalar w_tol /1/
   features /6/;

positive variables a_err(a), sla(a)
   b_err(b), slb(b);

variables c,
   weight(o),
   gamma;

binary variable y(o);

equations w_def1(o),
   w_def2(o),
   y_def,
   c_def,
   a_def(a),
   b_def(b);

w_def1(o)..
   weight(o) =l= w_tol*y(o);

w_def2(o)..
   weight(o) =g= -w_tol*y(o);

y_def..
   sum(o, y(o)) =e= features;

c_def..
   c =e= sum(a, a_err(a)) + sum(b, b_err(b));

a_def(a)..
   -sum(o, a_data(a, o)*weight(o)) + gamma + 1 =l= a_err(a) + sla(a);

b_def(b)..
   sum(o, b_data(b, o)*weight(o)) - gamma + 1 =l= b_err(b) + slb(b);

model train /all/;

$batinclude  gentestset.inc  "p,a"  "p,b"

set headers 'report' / modelstat, solvestat, objval /
parameter rep(p,headers);
train.optfile = 0;
option limrow=0, limcol=0, solprint=silent, mip=xpress,
      solvelink=%Solvelink.LoadLibrary%, optcr=0, optca=0;
$echo loadmipsol=1 > xpress.opt

loop(p,
a_err.up(a) = inf; a_err.up(a)$a_test(p,a) = 0;
b_err.up(b) = inf; b_err.fx(b)$b_test(p,b) = 0;
sla.fx(a) = 0; sla.up(a)$a_test(p,a) = inf;
slb.fx(b) = 0; slb.up(b)$b_test(p,b) = inf;
solve train using mip minimizing c;
train.optfile = 1; ! use mipstart for the second run
rep(p,'modelstat') = train.modelstat;
rep(p,'solvestat') = train.solvestat;
rep(p,'objval') = train.objval;
);
display rep;

Options file for the original formulation: xpress.opt
loadmipsol=1

The batinclude file gentestset.inc gives instructions for generating the testing sets. It produces a_test and b_test that detail which equations are left out on solve p.

The actual model is set up to include all the data points in the equations a_def and b_def. To delete the equations that correspond to the test set, we introduce nonnegative slack variables into all the equations. We then set the upper bounds of the slack variables to zero in equations corresponding to the training set, and to infinity in equations corresponding to the testing set. At the same time we fix the error measures a_err and b_err belonging to the testing set by setting their upper bounds to zero. Thus the testing set equations are always satisfiable by choice of the slack variables alone - essentially they are discarded from the model as required. An alternative formulation could "include" the data equations that you need in each scenario, but the update from one scenario to the next in the defining data is much larger.

Cross validation formulated using GUSS: This model essentially mimics what the standard model does, but the implementation of the solver loop behind the scenes is much more efficient, and the consequences are that are clear to see if you execute both model runs. The changes are in the last 40 lines of the GAMS code.

$title Ten-fold cross validation example
$eolcom !
$setglobal  num_folds  10

set a 'set for category 1' /1*1505/
b 'set for category 2' /1*957/
o 'observations' /1*14/
p 'folds to perform' /1*%num_folds%/f 'maximum features to select' /1*10/
4.23 Gather-Update-Solve-Scatter (GUSS)

* Read in the data from the data files
  parameter a_data(a, o) /
  $offlisting
  $include "a_data.inc"
  $onlisting
  /;

  parameter b_data(b, o) /
  $offlisting
  $include "b_data.inc"
  $onlisting
  /;

  set a_test(p,a), b_test(p,b) 'testing sets'
    a_trai(a), b_trai(b) 'training sets';

* Define problem
  scalar w_tol /1/
      features /6/;

  positive variables a_err(a), sla(a)
    b_err(b), slb(b);

  variables c,
      weight(o),
      gamma;

  binary variable y(o);

  equations w_def1(o),
        w_def2(o),
        y_def,
        c_def,
        a_def(a),
        b_def(b);

  w_def1(o)..   weight(o) =l= w_tol*y(o);

  w_def2(o)..   weight(o) =g= -w_tol*y(o);

  y_def..
      sum(o, y(o)) =e= features;

  c_def..
      c =e= sum(a, a_err(a)) + sum(b, b_err(b));

  a_def(a)..
      -sum(o, a_data(a, o)*weight(o)) + gamma + 1 =l= a_err(a) + sla(a);

  b_def(b)..
      sum(o, b_data(b, o)*weight(o)) - gamma + 1 =l= b_err(b) + slb(b);

  model train /all/;
  train.optfile = 1;
Parameter wval(p,o), gval(p);

set headers 'report' / modelstat, solvestat, objval /;

parameter scenrep(p,headers)
scenrep.$(not a_test(p,a)) = inf;

bupper(p,b)$b_test(p,b) = inf;

afree(p,a)$a_test(p,a) = inf;

bfree(p,b)$b_test(p,b) = inf;

option mip=xpress, optcr=0, optca=0;
solve train using mip minimizing c scenario dict;
display scenrep, gval;

Firstly, parameters upper, bupper, afree and bfree are used to set the bounds on the error and slack variables in the testing set equations respectively. The setting of the upper bounds are governed by the syntax shown in the controlling set dict. Furthermore, the output of the classifier $(w, gamma)$ for each fold of the cross validation uses the dict set to place results into the parameters wval and gval respectively. Finally, the GUSS options are used to guarantee that the subsequent solves are instructed to process solver options (Optfile 1) which instruct the solver to use the previous solution to start the branch-and-cut process (loadmipsol=1).

The complete data and model files for this example are found in galaxy zip archive. The data and model for a second instance based on the Wisconsin Diagnostic Breast Cancer Database is downloadable as wdbc zip archive.

4.23.5.1.2 Quadratic Programs GUSS is not limited to linear programs, but can be used more generally. Simple (indexed) quadratic models can be solved using GUSS. The following example illustrates the use of GUSS for quadratic programs. In this example, a support vector machine is used to determine a linear classifier that separates data into two categories. We use the following model:

\[
\begin{align*}
\text{Min} & \quad (1/2)\|w\|^2 + Ce^Tz \\
\text{subject to} & \quad D(Aw - g) + z \geq 1 \\
& \quad z \geq 0
\end{align*}
\] (4.12)

Here, $A$ is a matrix containing the training data (patients by features) and $D$ is a diagonal matrix with values +1 or -1 (each denoting one of the two classes). $C$ is a parameter weighting the importance of
maximizing the margin between the classes \( \frac{2}{\|w\|_2} \) versus minimizing the misclassification error \( z \). The solution \( w \) and \( g \) are used to define a separating hyperplane \( \{x | w^T x = g\} \) to classify (unseen) data points.

As given, the standard linear support vector machine is not a slice model per se. It becomes a slice model under cross-validation training, where it is solved multiple times on different pieces of data. In this case, only the data \( A \) and \( D \) vary between solves, appropriately fitting the definition of a slice model.

The data for this example comes from the Wisconsin Diagnosis Breast Cancer Database, and is available here. The data was converted to the GAMS file \texttt{wdbc.gms} , which defines \( A \) and \( D \). The actual source code for the following GAMS formulation is available here.

The GUSS formulation for quadratic svm:

```gams
$title Ten-fold cross validation example using GUSS
$setglobal num_folds 10

set p /1*%num_folds%/;  ! folds to perform

! Read in data
$include "wdbc.gms"

set test(p,i);  ! testing set

! Define problem
parameter C /1/;
positive variables z(i);
variables obj, w(k), gamma, slack(i);
equations obj_def, sep_def(i);

obj_def.. obj =e= 1/2*sum(k, sqr(w(k))) + C*sum(i, z(i));
sep_def(i).. D(i)*(sum(k, A(i,k)*w(k)) - gamma) + z(i) + slack(i) =g= 1;

model train /all/;

! Generate testing sets (to be deleted in each problem)
loop(p,
 $batinclude gentestset2.inc "p,i"
);

set headers report / modelstat, solvestat, objval /;
parameter scenrep(p,headers)
  scopt / SkipBaseCase 1, LogOption 2 /;
set dict / p. scenario."
    scopt.opt. scenrep
    z. upper. ipper
    slack.upper. ifree /;

Parameter ipper(p,i), ifree(p,i);
ipper(p,i)$not test(p,i) = inf;
ifree(p,i)$test(p,i) = inf;
```
option qcp=conopt, optcr=0, optca=0;
solve train using qcp minimizing obj scenario dict;
display scenrep;

Because the problem is quadratic, we must use a quadratic program solver. The variable values for weight and gamma could be saved for later testing using the same method as detailed above for the linear case.

The batinclude file gentestset2.inc is very similar to gentestset.inc from the earlier cross-validation examples. In gentestset2.inc, though, only one set is being dealt with rather than two. The complete source GAMS code for this formulation is available in this zip archive.

4.23.5.2 DEA Modeling in GAMS via GUSS

Data Envelopment Analysis (DEA) models can be solved most efficiently in GAMS using the Gather-Update-Solve-Scatter (GUSS) facility. This is the preferred method since release 23.7 of GAMS and hence the GAMS/DEA solver is no longer available.

A paper with the title “GUSS: Solving Collections of Data Related Models within GAMS” that contains two additional application examples for GUSS is available here.

4.23.5.2.1 Introduction The basic (CCR) DEA model is a collection of models indexed by \( k \) and defined by

\[
\begin{align*}
\text{max}_{u,v} & \quad u^T Y_{*,k} & \text{(objective slice)} \\
\text{subject to} & \quad v^T X_{*,k} = 1 & \text{(slice constraint)} \\
& \quad u^T Y \leq v^T X & \text{(core constraint)} \\
& \quad u,v \geq 0 & \text{(core constraint)}
\end{align*}
\]

(4.13)

where \( X, Y \) are data matrices.

Without using GUSS in GAMS, a model would be defined and solved in a loop over \( k \), requiring the model to be generated multiple times with different instances for each value of \( k \). GUSS is an alternative (and more efficient) way to define the individual programs and pass them to any underlying GAMS solver. In this way, individual programs are not re-generated, but are instead defined as data modifications of each other. This reduces overall model generation time. Further, previous solutions can be used as starting points in later solves to speed up overall processing time.

Some DEA examples compare the two formulations. The actual source code for both of these formulations is available here.

4.23.5.2.2 DEA Examples Original GAMS formulation (without GUSS): In all these models the model setup and data are given at the top of the file and the code of interest is in the last 10 or so lines. In this setting we loop over the set \( k \) and change the data in the objective function and the first constraint of the model explicitly before each solve. We only output a minimal summary of the solution.

$title Data Envelopment Analysis - DEA
$ontext
Data Envelopment Analysis (DEA) is a technique for measuring the relative performance of organizational units where presence of multiple inputs and outputs makes comparison difficult.

\text{efficiency} = \text{weighted sum of output} / \text{weighted sum of input}
Find weights that maximize the efficiency for one unit while ensuring that no other units has an efficiency < 1 using these weights. A primal and dual formulation is presented.

);
display rep;

The DEA problem formulated using GUSS: In this setting, the solve statement includes an extra keyword scenario that points to a new set called dict. The contents of this set are directives to GUSS that state the scenario index is k, the parameter slice is populated from the parameter data and the values of the variable eff are stored into the parameter eff.k for each scenario solved. More details follow below.

    scopt / SkipBaseCase 1 /

set dict / k .scenario.''
    slice .param. data
    eff .level. eff_k
    scopt .opt. scenrep /;

slice(j) = 0; option lp=cplexd;
solve dea using lp max eff scenario dict;
display scenrep,eff_k;

In the GUSS version we indicate the collection of models to be solved using the set dict. The first element
of dict determines the set to be used for the scenario (collection) index, in this case k. The second
element of dict then details that in each scenario k, the parameter slice is instantiated using a slice of the
parameter data. Essentially, this corresponds to the GAMS statement:
\[
\text{slice}(j) = \text{data}(k,j)
\]

Note the scenario index \(k\) must appear as the first index of the parameter data. The third element of dict
allows the modeler to collect information from each solve and store it into a GAMS parameter. Essentially,
the third element of dict corresponds to the GAMS statement:
\[
\text{eff}_k(k) = \text{eff}.l
\]

that gets executed immediately after the solve of scenario \(k\).

More complex scenario models can also be formulated using GUSS, including multiple equations being
updated. This is shown by the dual of the basic DEA model, given by

\[
\begin{align*}
\min_{z,\lambda} \quad & z \\
\text{subject to} \quad & X^*\lambda \leq zX_{*,k} & \text{(objective)} \\
& Y^*\lambda \geq Y_{*,k} & \text{(slice constraint)} \\
& \lambda \geq 0 & \text{(core constraint)}
\end{align*}
\]

The next example compares the two formulations for this model. The actual source code for both of these
formulations is available here.

Original GAMS formulation (without GUSS):

Extensions of these models to formulations with weighted outputs or variable returns to scale are easy to formulate with the scenario solver within GAMS. This extended model can be downloaded here.

The DEA model in the model library is similar to the extended model, but does not make use of GUSS.

### 4.24 IPOPT and IPOPTH

COIN-OR IPOPT (Interior Point Optimizer) is an open-source solver for large-scale nonlinear programming (NLP). The code has been written primarily by Andreas Wächter.

IPOPT implements an interior point line search filter method for nonlinear programming models which functions can be nonconvex, but should be twice continuously differentiable. For more information on the algorithm we refer to [188] [248] [247] [249] [246] and the IPOPT web site. Most of the IPOPT documentation in the section was taken from the IPOPT manual [137].

#### 4.24.1 The linear solver in IPOPT

The performance and robustness of IPOPT on larger models heavily relies on the used solver for sparse symmetric indefinite linear systems.

GAMS/IPOPT includes the sparse solver MUMPS [14] [15] (currently the default), and MKL PARDISO [217] [218] (only Linux, Mac OS X, and Windows). In the commerically licensed GAMS/IPOPTH version, also the Harwell Subroutine Library (HSL) solvers MA27, MA57, HSL_MA86, and HSL_MA97 are available and MA27 is used by default.

MUMPS, MA57, HSL_MA86, and HSL_MA97 use METIS for matrix ordering [136], see also the METIS manual. METIS is copyrighted by the regents of the University of Minnesota.

IPOPT and IPOPTH can exploit parallelization of the linear solvers MKL Pardiso, HSL MA86, and HSL MA97 and the linear algebra routines (MKL Blas and Lapack).

The linear solver is chosen by the linear_solver option. Benchmarks have shown that MA57 and HSL_MA97 are often able to outperform MA27 on larger instances. Further, PARDISO often allows for performance that is better than MUMPS and similar to the HSL solvers. If IPOPT fails to solve an instance with PARDISO, it’s worth to try changing the options pardiso_order and pardiso_max_iterative_refinement_steps.
4.24 IPOPT and IPOPTH

4.24.2 Usage

The following statement can be used inside your GAMS program to specify using IPOPT

Option NLP = IPOPT; { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }

The above statement should appear before the Solve statement. If IPOPT was specified as the default solver during GAMS installation, the above statement is not necessary.

To use IPOPTH, the statement should be

Option NLP = IPOPTH; { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }

4.24.2.1 Using Harwell Subroutine Library routines with GAMS/IPOPT.

GAMS/IPOPT can use the HSL routines MA27, MA28, MA57, HSL_MA77, HSL_MA86, HSL_MA97, MC19, and HSL_MC68 when provided as shared library. By telling IPOPT to use one of these routines (see options linear_solver, linear_system_scaling, nlp_scaling_method, dependency_detector), GAMS/IPOPT attempts to load the required routines from the library libhsl.so (Unix-Systems), libhsl.dylib (MacOS X), or libhsl.dll (Windows), respectively.

The HSL routines are available at http://www.hsl.rl.ac.uk/ipopt. Note that it is your responsibility to ensure that you are entitled to download and use these routines!

4.24.2.2 Specification of Options

IPOPT has many options that can be adjusted for the algorithm (see Section List of IPOPT Options). Options are all identified by a string name, and their values can be of one of three types: Number (real), Integer, or String. Number options are used for things like tolerances, integer options are used for things like maximum number of iterations, and string options are used for setting algorithm details, like the NLP scaling method. Options can be set by creating a ipopt.opt file in the directory you are executing IPOPT.

The ipopt.opt file is read line by line and each line should contain the option name, followed by whitespace, and then the value. Comments can be included with the # symbol. For example, the following is a valid ipopt.opt file:

# This is a comment

# Turn off the NLP scaling
nlp_scaling_method none

# Change the initial barrier parameter
mu_init 1e-2

# Set the max number of iterations
max_iter 500

GAMS/IPOPT understands currently the following GAMS parameters: reslim (time limit), iterlim (iteration limit), domlim (domain violation limit). Further the option threads can be used to control the number of threads used in the linear algebra routines and the linear solver.
4.24.2.3 Warmstarting Ipopt

As an interior point solver, it is difficult to warm start IPOPT. By default, only the level values of the variables are passed as starting point to IPOPT. Setting the IPOPT option `warm_start_init_point` to `yes` enables that also dual values for variables and constraints are passed to IPOPT.

However, the expected behavior that IPOPT finishes within one iteration if optimal primal and dual values are passed is not reached this way, yet. This is, because IPOPT by default moves any initial value that is close to a bound into the interior. The amount on how much the initial point is moved can be controlled by various `bound_push` and `bound_frac` options. To make IPOPT accept an optimal primal/dual solution within one iteration, it should be sufficient to set the following options:

- `warm_start_init_point yes`
- `warm_start_bound_push 1e-9`
- `warm_start_bound_frac 1e-9`
- `warm_start_slack_bound_frac 1e-9`
- `warm_start_slack_bound_push 1e-9`
- `warm_start_mult_bound_push 1e-9`

4.24.3 Output

This section describes the standard IPOPT console output. The output is designed to provide a quick summary of each iteration as IPOPT solves the problem.

Before IPOPT starts to solve the problem, it displays the problem statistics (number of nonzero-elements in the matrices, number of variables, etc.). Note that if you have fixed variables (both upper and lower bounds are equal), IPOPT may remove these variables from the problem internally and not include them in the problem statistics.

Following the problem statistics, IPOPT will begin to solve the problem and you will see output resembling the following:

| iter | objective | inf_pr | inf_du | lg(mu) | ||d|| | lg(rg) | alpha_du | alpha_pr | ls |
|------|-----------|--------|--------|--------|-------|--------|----------|----------|----|
| 0    | 1.6109693e+01 | 1.12e+01 | 5.28e-01 | 0.0    | 0.00e+00 | 0.00e+00 | 0        |
| 1    | 1.8029749e+01 | 9.90e-01 | 6.62e+01 | 0.1    | 2.05e+00 | 2.14e-01 | 1.00e+00 |
| 2    | 1.8719906e+01 | 1.25e-02 | 9.04e+00 | -2.2   | 5.94e-02 | 2.0     | 8.04e-01 |

and the columns of output are defined as

- **iter**
  - The current iteration count. This includes regular iterations and iterations while in restoration phase. If the algorithm is in the restoration phase, the letter *r* will be appended to the iteration number.

- **objective**
  - The unscaled objective value at the current point. During the restoration phase, this value remains the unscaled objective value for the original problem.

- **inf_pr**
  - The unscaled objective value at the current point. During the restoration phase, this value remains the unscaled objective value for the original problem.
The unscaled constraint violation at the current point. This quantity is the infinity-norm (max) of the (unscaled) constraint violation. During the restoration phase, this value remains the constraint violation of the original problem at the current point. The option inf.pr.output can be used to switch to the printing of a different quantity. During the restoration phase, this value is the primal infeasibility of the original problem at the current point.

inf_du

The scaled dual infeasibility at the current point. This quantity measure the infinity-norm (max) of the internal dual infeasibility (Eq. (4a) in [249]), including inequality constraints reformulated using slack variables and problem scaling. During the restoration phase, this is the value of the dual infeasibility for the restoration phase problem.

lg(mu)

\( \log_{10} \) of the value of the barrier parameter \( \mu \).

\[ \|d\| \]

The infinity norm (max) of the primal step (for the original variables \( x \) and the internal slack variables \( a \)). During the restoration phase, this value includes the values of additional variables, \( p \) and \( n \) in Eq. (10) of [249] .

lg(rg)

\( \log_{10} \) of the value of the regularization term for the Hessian of the Lagrangian in the augmented system ( \( \delta_w \) in Eq. (26) of [249]). A dash (\( - \)) indicates that no regularization was done.

alpha_du

The stepsize for the dual variables ( \( \alpha^z_k \) in Eq. (14c) of [249]).

alpha_pr

The stepsize for the primal variables ( \( \alpha_k \) in Eq. (14a) of [249]). The number is usually followed by a character for additional diagnostic information regarding the step acceptance criterion:

- \( f \): f-type iteration in the filter method w/o second order correction
- \( F \): f-type iteration in the filter method w/ second order correction
- \( h \): h-type iteration in the filter method w/o second order correction
- \( H \): h-type iteration in the filter method w/ second order correction
- \( k \): penalty value unchanged in merit function method w/o second order correction
- \( K \): penalty value unchanged in merit function method w/ second order correction
- \( n \): penalty value updated in merit function method w/o second order correction
- \( N \): penalty value updated in merit function method w/ second order correction
- \( R \): Restoration phase just started
- \( w \): in watchdog procedure
- \( s \): step accepted in soft restoration phase
- \( t/T \): tiny step accepted without line search
- \( r \): some previous iterate restored

ls

The number of backtracking line search steps (does not include second-order correction steps).
Note that the step acceptance mechanisms in IPOPT consider the barrier objective function (Eq. (3a) in [249]) which is usually different from the value reported in the objective column. Similarly, for the purposes of the step acceptance, the constraint violation is measured for the internal problem formulation, which includes slack variables for inequality constraints and potentially scaling of the constraint functions. This value, too, is usually different from the value reported in $\text{inf}_\text{pr}$. As a consequence, a new iterate might have worse values both for the objective function and the constraint violation as reported in the iteration output, seemingly contradicting globalization procedure.

When the algorithm terminates, IPOPT will output a message to the screen. The following is a list of the possible output messages and a brief description.

Optimal Solution Found.

This message indicates that IPOPT found a (locally) optimal point within the desired tolerances.

Solved To Acceptable Level.

This indicates that the algorithm did not converge to the "desired" tolerances, but that it was able to obtain a point satisfying the "acceptable" tolerance level as specified by acceptable-\* options. This may happen if the desired tolerances are too small for the current problem.

Feasible point for square problem found.

This message is printed if the problem is "square" (i.e., it has as many equality constraints as free variables) and IPOPT found a feasible point.

Converged to a point of local infeasibility. Problem may be infeasible.

The restoration phase converged to a point that is a minimizer for the constraint violation (in the $\ell_1$-norm), but is not feasible for the original problem. This indicates that the problem may be infeasible (or at least that the algorithm is stuck at a locally infeasible point). The returned point (the minimizer of the constraint violation) might help you to find which constraint is causing the problem. If you believe that the NLP is feasible, it might help to start the optimization from a different point.

Search Direction is becoming Too Small.

This indicates that IPOPT is calculating very small step sizes and making very little progress. This could happen if the problem has been solved to the best numerical accuracy possible given the current scaling.

Iterates diverging; problem might be unbounded.

This message is printed if the max-norm of the iterates becomes larger than the value of the option diverging_iterates_tol. This can happen if the problem is unbounded below and the iterates are diverging.

Stopping optimization at current point as requested by user.

This message is printed if either the Ctrl+C was pressed or the domain violation limit is reached.

Maximum Number of Iterations Exceeded.

This indicates that IPOPT has exceeded the maximum number of iterations as specified by the IPOPT option max_iter or the GAMS option iterlim.

Maximum CPU time exceeded.
This indicates that IPOPT has exceeded the maximum number of seconds as specified by the IPOPT option `max_cpu_time` or the GAMS option `reslim`.

Restoration Failed!

This indicates that the restoration phase failed to find a feasible point that was acceptable to the filter line search for the original problem. This could happen if the problem is highly degenerate or does not satisfy the constraint qualification, or if an external function in GAMS provides incorrect derivative information.

Error in step computation (regularization becomes too large?)!

This messages is printed if IPOPT is unable to compute a search direction, despite several attempts to modify the iteration matrix. Usually, the value of the regularization parameter then becomes too large.

Problem has too few degrees of freedom.

This indicates that your problem, as specified, has too few degrees of freedom. This can happen if you have too many equality constraints, or if you fix too many variables (IPOPT removes fixed variables).

Not enough memory.

An error occurred while trying to allocate memory. The problem may be too large for your current memory and swap configuration.

INTERNAL ERROR: Unknown SolverReturn value - Notify IPOPT Authors.

An unknown internal error has occurred. Please notify the authors of the GAMS/IPOPT link or IPOPT (refer to support@gams.com).

### 4.24.3.1 Diagnostic Tags for IPOPT

To print additional diagnostic tags for each iteration of IPOPT, set the options `print_info_string` to `yes`. With this, a tag will appear at the end of an iteration line with the following diagnostic meaning that are useful to flag difficulties for a particular IPOPT run. The following is a list of possible strings:

- !: Tighten resto tolerance if only slightly infeasible, see Sec. 3.3 in [249]
- A: Current iteration is acceptable (alternate termination)
- a: Perturbation for PD Singularity can't be done, assume singular, see Sec. 3.1 in [249]
- C: Second Order Correction taken, see Sec. 2.4 in [249]
- Dh: Hessian degenerate based on multiple iterations, see Sec. 3.1 in [249]
- Dhj: Hessian/Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [249]
- Dj: Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [249]
- dx: $\delta_x$ perturbation too large, see Sec. 3.1 in [249]
- e: Cutting back $\alpha$ due to evaluation error (in backtracking line search)
- F-: Filter should be reset, but maximal resets exceeded, see Sec. 2.3 in [249]
- F+: Resetting filter due to last few rejections of filter, see Sec. 2.3 in [249]
- L: Degenerate Jacobian, $\delta_c$ already perturbed, see Sec. 3.1 in [249]
• 1: Degenerate Jacobian, $\delta_c$ perturbed, see Sec. 3.1 in [249]
• M: Magic step taken for slack variables (in backtracking line search)
• Nh: Hessian not yet degenerate, see Sec. 3.1 in [249]
• Nhj: Hessian/Jacobian not yet degenerate, see Sec. 3.1 in [249]
• Nj: Jacobian not yet degenerate, see Sec. 3.1 in [249]
• NW: Warm start initialization failed (in Warm Start Initialization)
• q: PD system possibly singular, attempt to improve solution quality, see Sec. 3.1 in [249]
• R: Solution of restoration phase, see Sec. 3.3 in [249]
• S: PD system possibly singular, accept current solution, see Sec. 3.1 in [249]
• s: PD system singular, see Sec. 3.1 in [249]
• t: Square Problem. Set multipliers to zero (default initialization routine)
• Tmax: Trial $\theta$ is larger than $\theta_{\text{max}}$ (filter parameter, Eq. (21) in [249])
• W: Watchdog line search procedure successful, see Sec. 3.2 in [249]
• w: Watchdog line search procedure unsuccessful, stopped, see Sec. 3.2 in [249]
• Wb: Undoing most recent SR1 update, see Sec. 5.4.1 in [39]
• We: Skip Limited-Memory Update in restoration phase, see Sec. 5.4.1 in [39]
• Wp: Safeguard $B^0 = \sigma I$ for Limited-Memory Update, see Sec. 5.4.1 in [39]
• Wr: Resetting Limited-Memory Update, see Sec. 5.4.1 in [39]
• Ws: Skip Limited-Memory Update since $s^Ty$ is not positive, see Sec. 5.4.1 in [39]
• WS: Skip Limited-Memory Update since $\Delta x$ is too small, see Sec. 5.4.1 in [39]
• y: Dual infeasibility, use least square multiplier update (during IPOPT algorithm)
• z: Apply correction to bound multiplier if too large (during IPOPT algorithm)

### 4.24.4 List of IPOPT Options

#### 4.24.4.1 Barrier Parameter Update

<table>
<thead>
<tr>

<tr>
<td><code>jacobian_regularization_value</code></td>
<td>Size of the regularization for rank-deficient constraint Jacobians.</td>
<td><code>1e-08</code></td>
</tr>
<tr>
<td><code>max_hessian_perturbation</code></td>
<td>Maximum value of regularization parameter for handling negative curvature.</td>
<td><code>1e+20</code></td>
</tr>
<tr>
<td><code>max_refinement_steps</code></td>
<td>Maximum number of iterative refinement steps per linear system solve.</td>
<td><code>10</code></td>
</tr>
<tr>
<td><code>mehrotra_algorithm</code></td>
<td>Indicates if we want to do Mehrotra's algorithm.</td>
<td><code>no</code></td>
</tr>
<tr>
<td><code>min_hessian_perturbation</code></td>
<td>Smallest perturbation of the Hessian block.</td>
<td><code>1e-20</code></td>
</tr>
<tr>
<td><code>min_refinement_steps</code></td>
<td>Minimum number of iterative refinement steps per linear system solve.</td>
<td><code>1</code></td>
</tr>
<tr>
<td><code>neg_curv_test_reg</code></td>
<td>Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).</td>
<td><code>yes</code></td>
</tr>
<tr>
<td><code>neg_curv_test_tol</code></td>
<td>Tolerance for heuristic to ignore wrong inertia.</td>
<td><code>0</code></td>
</tr>
<tr>
<td><code>perturb_always_cd</code></td>
<td>Active permanent perturbation of constraint linearization.</td>
<td><code>no</code></td>
</tr>
<tr>
<td><code>perturb_dec_fact</code></td>
<td>Decrease factor for x-s perturbation.</td>
<td><code>0.333333</code></td>
</tr>
<tr>
<td><code>perturb_inc_fact</code></td>
<td>Increase factor for x-s perturbation.</td>
<td><code>8</code></td>
</tr>
<tr>
<td><code>perturb_inc_fact_first</code></td>
<td>Increase factor for x-s perturbation for very first perturbation.</td>
<td><code>100</code></td>
</tr>
<tr>
<td><code>residual_improvement_factor</code></td>
<td>Minimal required reduction of residual test ratio in iterative refinement.</td>
<td><code>1</code></td>
</tr>
</tbody>
</table>
### 4.24.4.20 Warm Start

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>warm_start_bound_frac</code></td>
<td>same as <code>bound_frac</code> for the regular initializer.</td>

<tr>
<td><code>warm_start_slack_bound_push</code></td>
<td>same as <code>slack_bound_push</code> for the regular initializer.</td>
<td>0.001</td>
</tr>
</tbody>
</table>

### 4.24.5 Detailed Options Description

**acceptable_compl_inf_tol** *(real)*: 'Acceptance' threshold for the complementarity conditions. →

Absolute tolerance on the complementarity. "Acceptable" termination requires that the max-norm of the (unscaled) complementarity is less than this threshold; see also `acceptable_tol`.

Default: 0.01

**acceptable_constr_viol_tol** *(real)*: 'Acceptance' threshold for the constraint violation. ↔

Absolute tolerance on the constraint violation. "Acceptable" termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold; see also `acceptable_tol`.

Default: 0.01

**acceptable_dual_inf_tol** *(real)*: 'Acceptance' threshold for the dual infeasibility. ↔

Absolute tolerance on the dual infeasibility. "Acceptable" termination requires that the (max-norm of the unscaled) dual infeasibility is less than this threshold; see also `acceptable_tol`.

Default: 1e+10

**acceptable_iter** *(integer)*: Number of 'acceptable' iterates before triggering termination. ↔

If the algorithm encounters this many successive "acceptable" iterates (see "acceptable_tol"), it terminates, assuming that the problem has been solved to best possible accuracy given round-off. If it is set to zero, this heuristic is disabled.

Default: 15

**acceptable_obj_change_tol** *(real)*: 'Acceptance' stopping criterion based on objective function change. ↔
If the relative change of the objective function (scaled by Max(1,|f(x)|)) is less than this value, this part of the acceptable tolerance termination is satisfied; see also acceptable_tol. This is useful for the quasi-Newton option, which has trouble to bring down the dual infeasibility.

Default: 1e+20

**acceptable_tol** (real): 'Acceptable' convergence tolerance (relative).

Determines which (scaled) overall optimality error is considered to be "acceptable." There are two levels of termination criteria. If the usual "desired" tolerances (see tol, dual_inf_tol etc) are satisfied at an iteration, the algorithm immediately terminates with a success message. On the other hand, if the algorithm encounters "acceptable_iter" many iterations in a row that are considered "acceptable", it will terminate before the desired convergence tolerance is met. This is useful in cases where the algorithm might not be able to achieve the "desired" level of accuracy.

Default: 1e-06

**accept_after_max_steps** (integer): Accept a trial point after maximal this number of steps.

Even if it does not satisfy line search conditions.

Range: [-1, \infty]

Default: -1

**accept_every_trial_step** (string): Always accept the first trial step.

Setting this option to "yes" essentially disables the line search and makes the algorithm take aggressive steps, without global convergence guarantees.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>don't arbitrarily accept the full step</td>
</tr>
<tr>
<td>yes</td>
<td>always accept the full step</td>
</tr>
</tbody>
</table>

**adaptive_mu_globalization** (string): Globalization strategy for the adaptive mu selection mode.

To achieve global convergence of the adaptive version, the algorithm has to switch to the monotone mode (Fiacco-McCormick approach) when convergence does not seem to appear. This option sets the criterion used to decide when to do this switch. (Only used if option "mu_strategy" is chosen as "adaptive").

Default: obj-constr-filter

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>kkt-error</td>
<td>nonmonotone decrease of kkt-error</td>
</tr>
<tr>
<td>never-monotone-mode</td>
<td>disables globalization</td>
</tr>
<tr>
<td>obj-constr-filter</td>
<td>2-dim filter for objective and constraint violation</td>
</tr>
</tbody>
</table>

**adaptive_mu_kkt_error_red_fact** (real): Sufficient decrease factor for 'kkt-error' globalization strategy.
For the "kkt-error" based globalization strategy, the error must decrease by this factor to be deemed sufficient decrease.

Range: \([0, 1]\)

Default: 0.9999

**adaptive_mu_kkt_error_red_iters** *(integer)*: Maximum number of iterations requiring sufficient progress. 

For the "kkt-error" based globalization strategy, sufficient progress must be made for "adaptive_mu_kkt_error_red_iters" iterations. If this number of iterations is exceeded, the globalization strategy switches to the monotone mode.

Default: 4

**adaptive_mu_kkt_norm_type** *(string)*: Norm used for the KKT error in the adaptive mu globalization strategies.

When computing the KKT error for the globalization strategies, the norm to be used is specified with this option. Note, this option is also used in the QualityFunctionMuOracle.

Default: 2-norm-squared

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-norm</td>
<td>use the 1-norm (abs sum)</td>
</tr>
<tr>
<td>2-norm</td>
<td>use 2-norm</td>
</tr>
<tr>
<td>2-norm-squared</td>
<td>use the 2-norm squared (sum of squares)</td>
</tr>
<tr>
<td>max-norm</td>
<td>use the infinity norm (max)</td>
</tr>
</tbody>
</table>

**adaptive_mu_monotone_init_factor** *(real)*: Determines the initial value of the barrier parameter when switching to the monotone mode.

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode and fixed_mu_oracle is chosen as "average_compl", the barrier parameter is set to the current average complementarity times the value of "adaptive_mu_monotone_init_factor".

Default: 0.8

**adaptive_mu_restore_previous_iterate** *(string)*: Indicates if the previous iterate should be restored if the monotone mode is entered.

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode, it can either start from the most recent iterate (no), or from the last iterate that was accepted (yes).

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>don’t restore accepted iterate</td>
</tr>
<tr>
<td>yes</td>
<td>restore accepted iterate</td>
</tr>
</tbody>
</table>

**alpha_for_y** *(string)*: Method to determine the step size for constraint multipliers.
This option determines how the step size (\(\alpha_y\)) will be calculated when updating the constraint multipliers.

Default: **primal**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>acceptor</td>
<td>Call LSAccept to get step size for (y)</td>
</tr>
<tr>
<td>bound-mult</td>

</tr>
<tr>
<td>primal-and-full</td>
<td>use the primal step size, and full step if (\delta x \leq \alpha_{\text{for }y\text{_tol}})</td>
</tr>
<tr>
<td>safer-min-dual-infeas</td>
<td>like 'min-dual-infeas', but safeguarded by 'min' and 'max'</td>
</tr>
</tbody>
</table>

\(\alpha_{\text{for }y\text{_tol}}\) **(real)**: Tolerance for switching to full equality multiplier steps. ←

This is only relevant if "\(\alpha_{\text{for }y\text{}}\)" is chosen "primal-and-full" or "dual-and-full". The step size for the equality constraint multipliers is taken to be one if the max-norm of the primal step is less than this tolerance.

Default: 10

\(\alpha_{\text{min frac}}\) **(real)**: Safety factor for the minimal step size (before switching to restoration phase). ←

(This is gamma_\(\alpha\) in Eqn. (20) in the implementation paper.)

Range: \([0, 1]\)

Default: 0.05

\(\alpha_{\text{red factor}}\) **(real)**: Fractional reduction of the trial step size in the backtracking line search. ←

At every step of the backtracking line search, the trial step size is reduced by this factor.

Range: \([0, 1]\)

Default: 0.5

\(\text{barrier\_tol\_factor}\) **(real)**: Factor for \(\mu\) in barrier stop test. ←

The convergence tolerance for each barrier problem in the monotone mode is the value of the barrier parameter times "\(\text{barrier\_tol\_factor}\)". This option is also used in the adaptive \(\mu\) strategy during the monotone mode. (This is kappa_\(\epsilon\) in implementation paper).

Default: 10

\(\text{bound\_frac}\) **(real)**: Desired minimum relative distance from the initial point to bound. ←

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "\(\text{bound\_push}\)"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: \([0, 0.5]\)

Default: 0.01

\(\text{bound\_mult\_init\_method}\) **(string)**: Initialization method for bound multipliers ←

This option defines how the iterates for the bound multipliers are initialized. If "constant" is chosen, then all bound multipliers are initialized to the value of "\(\text{bound\_mult\_init\_val}\)". If "\(\mu\)-based" is chosen, the each value is initialized to the the value of "\(\mu\_init\)" divided by the corresponding slack variable. This latter option might be useful if the starting point is close to the optimal solution.

Default: **constant**
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>constant</td>
<td>set all bound multipliers to the value of bound_mult_init_val</td>
</tr>
<tr>
<td>mu-based</td>
<td>initialize to mu_init/x_slack</td>
</tr>
</tbody>
</table>

**bound_mult_init_val (real):** Initial value for the bound multipliers.  

All dual variables corresponding to bound constraints are initialized to this value.

Default: 1

**bound_mult_reset_threshold (real):** Threshold for resetting bound multipliers after the restoration phase.

After returning from the restoration phase, the bound multipliers are updated with a Newton step for complementarity. Here, the change in the primal variables during the entire restoration phase is taken to be the corresponding primal Newton step. However, if after the update the largest bound multiplier exceeds the threshold specified by this option, the multipliers are all reset to 1.

Default: 1000

**bound_push (real):** Desired minimum absolute distance from the initial point to bound.

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Default: 0.01

**bound_relax_factor (real):** Factor for initial relaxation of the bounds.

Before start of the optimization, the bounds given by the user are relaxed. This option sets the factor for this relaxation. If it is set to zero, then the bounds relaxation is disabled. (See Eqn.(35) in implementation paper.)

Default: 1e-10

**check_derivatives_for_naninf (string):** Indicates whether it is desired to check for Nan/Inf in derivative matrices.

Activating this option will cause an error if an invalid number is detected in the constraint Jacobians or the Lagrangian Hessian. If this is not activated, the test is skipped, and the algorithm might proceed with invalid numbers and fail. If test is activated and an invalid number is detected, the matrix is written to output with print_level corresponding to J_MORE_DETAILED; so beware of large output!

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Don't check (faster).</td>
</tr>
<tr>
<td>yes</td>
<td>Check Jacobians and Hessian for Nan and Inf.</td>
</tr>
</tbody>
</table>

**compl_inf_tol (real):** Desired threshold for the complementarity conditions.
Absolute tolerance on the complementarity. Successful termination requires that the max-norm of the (unscaled) complementarity is less than this threshold.

Default: 0.0001

**constraint violation norm type** *(string)*: Norm to be used for the constraint violation in the line search.

Determines which norm should be used when the algorithm computes the constraint violation in the line search.

Default: 1-norm

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-norm</td>
<td>use the 1-norm</td>
</tr>
<tr>
<td>2-norm</td>
<td>use the 2-norm</td>
</tr>
<tr>
<td>max-norm</td>
<td>use the infinity norm</td>
</tr>
</tbody>
</table>

**constr mult init max** *(real)*: Maximum allowed least-square guess of constraint multipliers.

Determines how large the initial least-square guesses of the constraint multipliers are allowed to be (in max-norm). If the guess is larger than this value, it is discarded and all constraint multipliers are set to zero. This option is also used when initializing the restoration phase. By default, "resto.constr mult init max" (the one used in RestoIterateInitializer) is set to zero.

Default: 1000

**constr mult reset threshold** *(real)*: Threshold for resetting equality and inequality multipliers after restoration phase.

After returning from the restoration phase, the constraint multipliers are recomputed by a least square estimate. This option triggers when those least-square estimates should be ignored.

Default: 0

**constr viol tol** *(real)*: Desired threshold for the constraint violation.

Absolute tolerance on the constraint violation. Successful termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold.

Default: 0.0001

**corrector compl avrg red fact** *(real)*: Complementarity tolerance factor for accepting corrector step.

This option determines the factor by which complementarity is allowed to increase for a corrector step to be accepted. Changing this option is experimental.

Default: 1

**corrector type** *(string)*: The type of corrector steps that should be taken.

If "mu strategy" is "adaptive", this option determines what kind of corrector steps should be tried. Changing this option is experimental.

Default: none
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>affine</td>
<td>corrector step towards $\mu=0$</td>
</tr>
<tr>
<td>none</td>
<td>no corrector</td>
</tr>
<tr>
<td>primal-dual</td>
<td>corrector step towards current $\mu$</td>
</tr>
</tbody>
</table>

**delta** (*real*): Multiplier for constraint violation in the switching rule.  

(See Eqn. (19) in the implementation paper.)

Default: 1

**dependency_detection_with_rhs** (*string*): Indicates if the right hand sides of the constraints should be considered during dependency detection.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>only look at gradients</td>
</tr>
<tr>
<td>yes</td>
<td>also consider right hand side</td>
</tr>
</tbody>
</table>

**dependency_detector** (*string*): Indicates which linear solver should be used to detect linearly dependent equality constraints.

The default and available choices depend on how Ipopt has been compiled. This is experimental and does not work well.

Default: none

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ma28</td>
<td>use MA28</td>
</tr>
<tr>
<td>mumps</td>
<td>use MUMPS</td>
</tr>
<tr>
<td>none</td>
<td>don’t check; no extra work at beginning</td>
</tr>
</tbody>
</table>

**diverging_iterates_tol** (*real*): Threshold for maximal value of primal iterates.

If any component of the primal iterates exceeded this value (in absolute terms), the optimization is aborted with the exit message that the iterates seem to be diverging.

Default: $1e+20$

**dual_inf_tol** (*real*): Desired threshold for the dual infeasibility.

Absolute tolerance on the dual infeasibility. Successful termination requires that the max-norm of the (unscaled) dual infeasibility is less than this threshold.

Default: 1

**eta_phi** (*real*): Relaxation factor in the Armijo condition.

(See Eqn. (20) in the implementation paper)

Range: $[0, 0.5]$  

Default: $1e-08$
evaluate_orig_obj_at_resto_trial (string): Determines if the original objective function should be evaluated at restoration phase trial points.

Setting this option to "yes" makes the restoration phase algorithm evaluate the objective function of the original problem at every trial point encountered during the restoration phase, even if this value is not required. In this way, it is guaranteed that the original objective function can be evaluated without error at all accepted iterates; otherwise the algorithm might fail at a point where the restoration phase accepts an iterate that is good for the restoration phase problem, but not for the original problem. On the other hand, if the evaluation of the original objective is expensive, this might be costly.

Default: yes

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>skip evaluation</td>
</tr>
<tr>
<td>yes</td>
<td>evaluate at every trial point</td>
</tr>
</tbody>
</table>

expect_infeasible_problem (string): Enable heuristics to quickly detect an infeasible problem.

This option is meant to activate heuristics that may speed up the infeasibility determination if you expect that there is a good chance for the problem to be infeasible. In the filter line search procedure, the restoration phase is called more quickly than usually, and more reduction in the constraint violation is enforced before the restoration phase is left. If the problem is square, this option is enabled automatically.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>the problem probably be feasible</td>
</tr>
<tr>
<td>yes</td>
<td>the problem has a good chance to be infeasible</td>
</tr>
</tbody>
</table>

expect_infeasible_problem_ctol (real): Threshold for disabling 'expect_infeasible_problem' option.

If the constraint violation becomes smaller than this threshold, the "expect_infeasible_problem" heuristics in the filter line search are disabled. If the problem is square, this option is set to 0.

Default: 0.001

expect_infeasible_problem_ytol (real): Multiplier threshold for activating 'expect_infeasible_problem' option.

If the max norm of the constraint multipliers becomes larger than this value and "expect_infeasible_problem" is chosen, then the restoration phase is entered.

Default: 1e+08

fast_step_computation (string): Indicates if the linear system should be solved quickly.

If set to yes, the algorithm assumes that the linear system that is solved to obtain the search direction, is solved sufficiently well. In that case, no residuals are computed, and the computation of the search direction is a little faster.

Default: no
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Verify solution of linear system by computing residuals.</td>
</tr>
<tr>
<td>yes</td>
<td>Trust that linear systems are solved well.</td>
</tr>
</tbody>
</table>

**filter_margin_fact** *(real)*: Factor determining width of margin for obj-constr-filter adaptive globalization strategy. ←

When using the adaptive globalization strategy, "obj-constr-filter", sufficient progress for a filter entry is defined as follows: (new obj) < (filter obj) - filter_margin_fact*(new constr-viol) OR (new constr-viol) < (filter constr-viol) - filter_margin_fact*(new constr-viol). For the description of the "kkt-error-filter" option see "filter_max_margin".

Range: [0, 1]

Default: 1e-05

**filter_max_margin** *(real)*: Maximum width of margin in obj-constr-filter adaptive globalization strategy. ←

Default: 1

**filter_reset_trigger** *(integer)*: Number of iterations that trigger the filter reset. ←

If the filter reset heuristic is active and the number of successive iterations in which the last rejected trial step size was rejected because of the filter, the filter is reset.

Range: [1, ∞]

Default: 5

**first_hessian_perturbation** *(real)*: Size of first x-s perturbation tried. ←

The first value tried for the x-s perturbation in the inertia correction scheme.(This is delta_0 in the implementation paper.)

Default: 0.0001

**fixed_mu_oracle** *(string)*: Oracle for the barrier parameter when switching to fixed mode. ←

Determines how the first value of the barrier parameter should be computed when switching to the "monotone mode" in the adaptive strategy. (Only considered if "adaptive" is selected for option "mu_strategy".)

Default: average_compl

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>average_compl</td>
<td>base on current average complementarity</td>
</tr>
<tr>
<td>loqo</td>
<td>LOQO's centrality rule</td>
</tr>
<tr>
<td>probing</td>
<td>Mehrotra's probing heuristic</td>
</tr>
<tr>
<td>quality-function</td>
<td>minimize a quality function</td>
</tr>
</tbody>
</table>

**fixed_variable_treatment** *(string)*: Determines how fixed variables should be handled. ←
The main difference between those options is that the starting point in the "make_constraint" case still has the fixed variables at their given values, whereas in the case "make_parameter" the functions are always evaluated with the fixed values for those variables. Also, for "relax_bounds", the fixing bound constraints are relaxed (according to" bound_relax_factor"). For both "make_constraints" and "relax_bounds", bound multipliers are computed for the fixed variables.

**Value** | **Meaning**
---|---
make_constraint | Add equality constraints fixing variables
make_parameter | Remove fixed variable from optimization variables
relax_bounds | Relax fixing bound constraints

**gamma_phi** *(real)*: Relaxation factor in the filter margin for the barrier function. ↓

(See Eqn. (18a) in the implementation paper.)

Range: [0, 1]
Default: 1e-08

**gamma_theta** *(real)*: Relaxation factor in the filter margin for the constraint violation. ↓

(See Eqn. (18b) in the implementation paper.)

Range: [0, 1]
Default: 1e-05

**hessian_approximation** *(string)*: Indicates what Hessian information is to be used. ↓

This determines which kind of information for the Hessian of the Lagrangian function is used by the algorithm.

Default: exact

**Value** | **Meaning**
---|---
exact | Use second derivatives provided by the NLP.
limited-memory | Perform a limited-memory quasi-Newton approximation

**hessian_approximation_space** *(string)*: Indicates in which subspace the Hessian information is to be approximated. ↓

Default: nonlinear-variables

**Value** | **Meaning**
---|---
all-variables | in space of all variables (without slacks)
nonlinear-variables | only in space of nonlinear variables.

**honor_original_bounds** *(string)*: Indicates whether final points should be projected into original bounds. ↓
Ipopt might relax the bounds during the optimization (see, e.g., option "bound_relax_factor"). This option determines whether the final point should be projected back into the user-provide original bounds after the optimization.

Default: yes

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Leave final point unchanged</td>
</tr>
<tr>
<td>yes</td>
<td>Project final point back into original bounds</td>
</tr>
</tbody>
</table>

**inf_pr_output (string):** Determines what value is printed in the 'inf_pr' output column.

Ipopt works with a reformulation of the original problem, where slacks are introduced and the problem might have been scaled. The choice "internal" prints out the constraint violation of this formulation. With "original" the true constraint violation in the original NLP is printed.

Default: original

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>internal</td>
<td>max-norm of violation of internal equality constraints</td>
</tr>
<tr>
<td>original</td>
<td>maximal constraint violation in original NLP</td>
</tr>
</tbody>
</table>

**jacobian_regularization_exponent (real):** Exponent for mu in the regularization for rank-deficient constraint Jacobians.

(This is kappa\(_c\) in the implementation paper.)

Default: 0.25

**jacobian_regularization_value (real):** Size of the regularization for rank-deficient constraint Jacobians.

(This is bar delta\(_c\) in the implementation paper.)

Default: 1e-08

**jac_e_constant (string):** Indicates whether all equality constraints are linear

Activating this option will cause Ipopt to ask for the Jacobian of the equality constraints only once from the NLP and reuse this information later.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Don't assume that all equality constraints are linear</td>
</tr>
<tr>
<td>yes</td>
<td>Assume that equality constraints Jacobian are constant</td>
</tr>
</tbody>
</table>

**jac_d_constant (string):** Indicates whether all inequality constraints are linear

Activating this option will cause Ipopt to ask for the Jacobian of the inequality constraints only once from the NLP and reuse this information later.

Default: no
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Don’t assume that all inequality constraints are linear</td>
</tr>
<tr>
<td>yes</td>
<td>Assume that equality constraints Jacobian are constant</td>
</tr>
</tbody>
</table>

**kappa_d** *(real):* Weight for linear damping term (to handle one-sided bounds). 

(see Section 3.7 in implementation paper.)

Default: 1e-05

**kappa_sigma** *(real):* Factor limiting the deviation of dual variables from primal estimates.

If the dual variables deviate from their primal estimates, a correction is performed. (See Eqn. (16) in the implementation paper.) Setting the value to less than 1 disables the correction.

Default: 1e+10

**kappa_soc** *(real):* Factor in the sufficient reduction rule for second order correction.

This option determines how much a second order correction step must reduce the constraint violation so that further correction steps are attempted. (See Step A-5.9 of Algorithm A in the implementation paper.)

Default: 0.99

**least_square_init_duals** *(string):* Least square initialization of all dual variables

If set to yes, Ipopt tries to compute least-square multipliers (considering ALL dual variables). If successful, the bound multipliers are possibly corrected to be at least bound_mult_init_val. This might be useful if the user doesn’t know anything about the starting point, or for solving an LP or QP. This overwrites option "bound_mult_init_method".

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>use bound_mult_init_val and least-square equality constraint multipliers</td>
</tr>
<tr>
<td>yes</td>
<td>overwrite user-provided point with least-square estimates</td>
</tr>
</tbody>
</table>

**least_square_init_primal** *(string):* Least square initialization of the primal variables

If set to yes, Ipopt ignores the user provided point and solves a least square problem for the primal variables (x and s), to fit the linearized equality and inequality constraints. This might be useful if the user doesn’t know anything about the starting point, or for solving an LP or QP.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>take user-provided point</td>
</tr>
<tr>
<td>yes</td>
<td>overwrite user-provided point with least-square estimates</td>
</tr>
</tbody>
</table>

**limited_memory_aug_solver** *(string):* Strategy for solving the augmented system for low-rank Hessian.
Default: sherman-morrison

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>extended</td>
<td>use an extended augmented system</td>
</tr>
<tr>
<td>sherman-morrison</td>
<td>use Sherman-Morrison formula</td>
</tr>
</tbody>
</table>

**limited_memory_initialization** *(string)*: Initialization strategy for the limited memory quasi-Newton approximation. 

Determines how the diagonal Matrix $B_0$ as the first term in the limited memory approximation should be computed.

Default: scalar1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>constant</td>
<td>$\sigma = \text{limited_memory_init_val}$</td>
</tr>
<tr>
<td>scalar1</td>
<td>$\sigma = s^{\lambda}y/s^{\lambda}T$s</td>
</tr>
<tr>
<td>scalar2</td>
<td>$\sigma = y^{\lambda}y/s^{\lambda}T$s</td>
</tr>
<tr>
<td>scalar3</td>
<td>arithmetic average of scalar1 and scalar2</td>
</tr>
<tr>
<td>scalar4</td>
<td>geometric average of scalar1 and scalar2</td>
</tr>
</tbody>
</table>

**limited_memory_init_val** *(real)*: Value for $B_0$ in low-rank update.

The starting matrix in the low rank update, $B_0$, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if ”limited_memory_initialization” is ”constant”.

Default: 1

**limited_memory_init_val_max** *(real)*: Upper bound on value for $B_0$ in low-rank update.

The starting matrix in the low rank update, $B_0$, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if ”limited_memory_initialization” is ”constant”.

Default: $1e+08$

**limited_memory_init_val_min** *(real)*: Lower bound on value for $B_0$ in low-rank update.

The starting matrix in the low rank update, $B_0$, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if ”limited_memory_initialization” is ”constant”.

Default: $1e-08$

**limited_memory_max_history** *(integer)*: Maximum size of the history for the limited quasi-Newton Hessian approximation.

This option determines the number of most recent iterations that are taken into account for the limited-memory quasi-Newton approximation.

Default: 6

**limited_memory_max_skipping** *(integer)*: Threshold for successive iterations where update is skipped.
If the update is skipped more than this number of successive iterations, we quasi-Newton approximation is reset.

Range: \([1, \infty]\)

Default: 2

**limited_memory_special_for_resto (string)**: Determines if the quasi-Newton updates should be special during the restoration phase.

Until Nov 2010, Ipopt used a special update during the restoration phase, but it turned out that this does not work well. The new default uses the regular update procedure and it improves results. If for some reason you want to get back to the original update, set this option to "yes".

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>use the same update as in regular iterations</td>
</tr>
<tr>
<td>yes</td>
<td>use the a special update during restoration phase</td>
</tr>
</tbody>
</table>

**limited_memory_update_type (string)**: Quasi-Newton update formula for the limited memory approximation.

Determines which update formula is to be used for the limited-memory quasi-Newton approximation.

Default: bfgs

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bfgs</td>
<td>BFGS update (with skipping)</td>
</tr>
<tr>
<td>sr1</td>
<td>SR1 (not working well)</td>
</tr>
</tbody>
</table>

**linear_scaling_on_demand (string)**: Flag indicating that linear scaling is only done if it seems required.

This option is only important if a linear scaling method (e.g., mc19) is used. If you choose "no", then the scaling factors are computed for every linear system from the start. This can be quite expensive. Choosing "yes" means that the algorithm will start the scaling method only when the solutions to the linear system seem not good, and then use it until the end.

Default: yes

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Always scale the linear system.</td>
</tr>
<tr>
<td>yes</td>
<td>Start using linear system scaling if solutions seem not good.</td>
</tr>
</tbody>
</table>

**linear_solver (string)**: Linear solver used for step computations.

Determines which linear algebra package is to be used for the solution of the augmented linear system (for obtaining the search directions). Note, that MA27, MA57, MA86, and MA97 are only available with a commercially supported GAMS/IpoptH license, or when the user
provides a library with HSL code separately. If no GAMS/IpoptH license is available, the default linear solver is MUMPS. Pardiso is only available on Linux and Windows systems. For using Pardiso on non-Linux/Windows systems or MA77, a Pardiso or HSL library need to be provided.

Default: **ma27**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ma27</td>
<td>use the Harwell routine MA27</td>
</tr>
<tr>
<td>ma57</td>
<td>use the Harwell routine MA57</td>
</tr>
<tr>
<td>ma77</td>
<td>use the Harwell routine HSL_MA77</td>
</tr>
<tr>
<td>ma86</td>
<td>use the Harwell routine HSL_MA86</td>
</tr>
<tr>
<td>ma97</td>
<td>use the Harwell routine HSL_MA97</td>
</tr>
<tr>
<td>mumps</td>
<td>use MUMPS package</td>
</tr>
<tr>
<td>pardiso</td>
<td>use the Pardiso package</td>
</tr>
</tbody>
</table>

**linear_system_scaling** *(string)*: Method for scaling the linear system. ➡️

Determines the method used to compute symmetric scaling factors for the augmented system (see also the "linear_scaling_on_demand" option). This scaling is independent of the NLP problem scaling. By default, MC19 is only used if MA27 or MA57 are selected as linear solvers. Note, that MC19 is only available with a commercially supported GAMS/IpoptH license, or when the user provides a library with HSL code separately. If no commercial GAMS/IpoptH license is available, the default scaling method is slack-based.

Default: **mc19**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>mc19</td>
<td>use the Harwell routine MC19</td>
</tr>
<tr>
<td>none</td>
<td>no scaling will be performed</td>
</tr>
<tr>
<td>slack-based</td>
<td>use the slack values</td>
</tr>
</tbody>
</table>

**line_search_method** *(string)*: Globalization method used in backtracking line search ➡️

Only the "filter" choice is officially supported. But sometimes, good results might be obtained with the other choices.

Default: **filter**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>cg-penalty</td>
<td>Chen-Goldfarb penalty function</td>
</tr>
<tr>
<td>filter</td>
<td>Filter method</td>
</tr>
<tr>
<td>penalty</td>
<td>Standard penalty function</td>
</tr>
</tbody>
</table>

**ma27_ignore_singularity** *(string)*: Enables MA27's ability to solve a linear system even if the matrix is singular. ➡️

Setting this option to "yes" means that Ipopt will call MA27 to compute solutions for right hand sides, even if MA27 has detected that the matrix is singular (but is still able to solve the linear system). In some cases this might be better than using Ipopt's heuristic of small perturbation of the lower diagonal of the KKT matrix.

Default: **no**
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Don't have MA27 solve singular systems</td>
</tr>
<tr>
<td>yes</td>
<td>Have MA27 solve singular systems</td>
</tr>
</tbody>
</table>

**ma27_la_init_factor** *(real):* Real workspace memory for MA27. 

The initial real workspace memory = la_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by meminc_factor if required. This option is only available if Ipopt has been compiled with MA27.

Range: $[1, \infty]$  
Default: 5

**ma27_liw_init_factor** *(real):* Integer workspace memory for MA27. 

The initial integer workspace memory = liw_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by meminc_factor if required. This option is only available if Ipopt has been compiled with MA27.

Range: $[1, \infty]$  
Default: 5

**ma27_meminc_factor** *(real):* Increment factor for workspace size for MA27. 

If the integer or real workspace is not large enough, Ipopt will increase its size by this factor. This option is only available if Ipopt has been compiled with MA27.

Range: $[1, \infty]$  
Default: 2

**ma27_pivtol** *(real):* Pivot tolerance for the linear solver MA27. 

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MA27.

Range: $[0, 1]$  
Default: $1e-08$

**ma27_pivtoltmax** *(real):* Maximum pivot tolerance for the linear solver MA27. 

Ipopt may increase pivtol as high as pivtoltmax to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MA27.

Range: $[0, 1]$  
Default: 0.0001

**ma27_skip_inertia_check** *(string):* Always pretend inertia is correct. 

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.  
Default: no
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>check inertia</td>
</tr>
<tr>
<td>yes</td>
<td>skip inertia check</td>
</tr>
</tbody>
</table>

**ma28_pivtol** *(real)*: Pivot tolerance for linear solver MA28.

This is used when MA28 tries to find the dependent constraints.

Range: \([0, 1]\)

Default: 0.01

**ma57_automatic_scaling** *(string)*: Controls MA57 automatic scaling

This option controls the internal scaling option of MA57. For higher reliability of the MA57 solver, you may want to set this option to yes. This is ICNTL(15) in MA57.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Do not scale the linear system matrix</td>
</tr>
<tr>
<td>yes</td>
<td>Scale the linear system matrix</td>
</tr>
</tbody>
</table>

**ma57_block_size** *(integer)*: Controls block size used by Level 3 BLAS in MA57BD

This is ICNTL(11) in MA57.

Range: \([1, \infty]\)

Default: 16

**ma57_node_amalgamation** *(integer)*: Node amalgamation parameter

This is ICNTL(12) in MA57.

Range: \([1, \infty]\)

Default: 16

**ma57_pivot_order** *(integer)*: Controls pivot order in MA57

This is ICNTL(6) in MA57.

Range: \([0, 5]\)

Default: 5

**ma57_pivtol** *(real)*: Pivot tolerance for the linear solver MA57.

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MA57.

Range: \([0, 1]\)

Default: 1e-08
**ma57_pivtolmax** (real): Maximum pivot tolerance for the linear solver MA57.

IPOPT may increase pivot as high as ma57_pivtolmax to get a more accurate solution to the linear system. This option is only available if IPOPT has been compiled with MA57.

- Range: $[0, 1]$
- Default: 0.0001

**ma57_pre_alloc** (real): Safety factor for work space memory allocation for the linear solver MA57.

- If 1 is chosen, the suggested amount of work space is used. However, choosing a larger number might avoid reallocation if the suggest values do not suffice. This option is only available if IPOPT has been compiled with MA57.
- Range: $[1, \infty]$
- Default: 1.05

**ma57_small_pivot_flag** (integer): If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient.

- This is ICNTL(16) in MA57.
- Range: $[0, 1]$
- Default: 0

**ma77_buffer_lpage** (integer): Number of scalars per MA77 buffer page

- Number of scalars per an in-core buffer in the out-of-core solver MA77. Must be at most ma77_file_size.
- Range: $[1, \infty]$
- Default: 4096

**ma77_buffer_npage** (integer): Number of pages that make up MA77 buffer

- Number of pages of size buffer_lpage that exist in-core for the out-of-core solver MA77.
- Range: $[1, \infty]$
- Default: 1600

**ma77_file_size** (integer): Target size of each temporary file for MA77, scalars per type

- MA77 uses many temporary files, this option controls the size of each one. It is measured in the number of entries (int or double), NOT bytes.
- Range: $[1, \infty]$
- Default: 2097152

**ma77_maxstore** (integer): Maximum storage size for MA77 in-core mode

- If greater than zero, the maximum size of factors stored in core before out-of-core mode is invoked.
- Default: 0

**ma77_nemin** (integer): Node Amalgamation parameter

- Two nodes in elimination tree are merged if result has fewer than ma77_nemin variables.
- Range: $[1, \infty]$
- Default: 8

**ma77_order** (string): Controls type of ordering used by HSL_MA77

- This option controls ordering for the solver HSL_MA77.
- Default: metis
### ma77_print_level (integer): Debug printing level for the linear solver MA77

Range: \([-\infty, \infty]\)

Default: -1

### ma77_small (real): Zero Pivot Threshold

Any pivot less than \(\text{ma77\_small}\) is treated as zero.

Default: \(1e-20\)

### ma77_static (real): Static Pivoting Threshold

See MA77 documentation. Either \(\text{ma77\_static}=0.0\) or \(\text{ma77\_static}>\text{ma77\_small}\).

Default: 0

### ma77_u (real): Pivoting Threshold

See MA77 documentation.

Range: \([0, 0.5]\)

Default: \(1e-08\)

### ma77_umax (real): Maximum Pivoting Threshold

Maximum value to which \(u\) will be increased to improve quality.

Range: \([0, 0.5]\)

Default: 0.0001

### ma86_nemin (integer): Node Amalgamation parameter

Two nodes in elimination tree are merged if result has fewer than \(\text{ma86\_nemin}\) variables.

Range: \([1, \infty]\)

Default: 32

### ma86_order (string): Controls type of ordering used by HSL\_MA86

This option controls ordering for the solver HSL\_MA86.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

**ma86_small (real):** Zero Pivot Threshold

- **Any pivot less than ma86_small is treated as zero.**
- **Default:** 1e-20

**ma86_static (real):** Static Pivoting Threshold

- **See MA86 documentation.** Either ma86_static=0.0 or ma86_static>ma86_small. ma86 statically=0.0 disables static pivoting.
- **Default:** 0

**ma86_u (real):** Pivoting Threshold

- **See MA86 documentation.**
- **Range:** \([0, 0.5]\)
- **Default:** 1e-08

**ma86_umax (real):** Maximum Pivoting Threshold

- **Maximum value to which u will be increased to improve quality.**
- **Range:** \([0, 0.5]\)
- **Default:** 0.0001

**ma97_nemin (integer):** Node Amalgamation parameter

- **Two nodes in elimination tree are merged if result has fewer than ma97_nemin variables.**
- **Range:** \([1, \infty]\)
- **Default:** 8

**ma97_order (string):** Controls type of ordering used by HSL_MA97

- **Default:** auto
<table>

</tbody>
</table>

**ma97_u (real):** Pivoting Threshold  🔄

See MA97 documentation.

Range: [0, 0.5]

Default: 1e-08

**ma97_umax (real):** Maximum Pivoting Threshold  🔄

See MA97 documentation.

Range: [0, 0.5]

Default: 0.0001
max_cpu_time (real): Maximum number of CPU seconds.

A limit on CPU seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding error message.

Default: 1000

max_filter_resets (integer): Maximal allowed number of filter resets

A positive number enables a heuristic that resets the filter, whenever in more than "filter_reset_trigger" successive iterations the last rejected trial steps size was rejected because of the filter. This option determines the maximal number of resets that are allowed to take place.

Default: 5

max_hessian_perturbation (real): Maximum value of regularization parameter for handling negative curvature.

In order to guarantee that the search directions are indeed proper descent directions, Ipopt requires that the inertia of the (augmented) linear system for the step computation has the correct number of negative and positive eigenvalues. The idea is that this guides the algorithm away from maximizers and makes Ipopt more likely converge to first order optimal points that are minimizers. If the inertia is not correct, a multiple of the identity matrix is added to the Hessian of the Lagrangian in the augmented system. This parameter gives the maximum value of the regularization parameter. If a regularization of that size is not enough, the algorithm skips this iteration and goes to the restoration phase. (This is delta_w^\max in the implementation paper.)

Default: 1e+20

max_iter (integer): Maximum number of iterations.

The algorithm terminates with an error message if the number of iterations exceeded this number.

Default: maxint

max_refinement_steps (integer): Maximum number of iterative refinement steps per linear system solve.

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the maximum number of iterative refinement steps.

Default: 10

max_resto_iter (integer): Maximum number of successive iterations in restoration phase.

The algorithm terminates with an error message if the number of iterations successively taken in the restoration phase exceeds this number.

Default: 3000000

max_soc (integer): Maximum number of second order correction trial steps at each iteration.

Choosing 0 disables the second order corrections. (This is p^\{max\} of Step A-5.9 of Algorithm A in the implementation paper.)

Default: 4
**max_soft_resto_ iters (integer):** Maximum number of iterations performed successively in soft restoration phase.

If the soft restoration phase is performed for more than so many iterations in a row, the regular restoration phase is called.

Default: 10

**mehrotra_algorithm (string):** Indicates if we want to do Mehrotra's algorithm.

If set to yes, Ipopt runs as Mehrotra's predictor-corrector algorithm. This works usually very well for LPs and convex QPs. This automatically disables the line search, and chooses the (unglobalized) adaptive mu strategy with the "probing" oracle, and uses "corrector_type=affine" without any safeguards; you should not set any of those options explicitly in addition. Also, unless otherwise specified, the values of "bound_push", "bound_frac", and "bound_mult_init_val" are set more aggressive, and sets "alpha_for_y=bound_mult".

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Do the usual Ipopt algorithm.</td>
</tr>
<tr>
<td>yes</td>
<td>Do Mehrotra's predictor-corrector algorithm.</td>
</tr>
</tbody>
</table>

**min_hessian_perturbation (real):** Smallest perturbation of the Hessian block.

The size of the perturbation of the Hessian block is never selected smaller than this value, unless no perturbation is necessary. (This is delta_w^min in implementation paper.)

Default: 1e-20

**min_refinement_steps (integer):** Minimum number of iterative refinement steps per linear system solve.

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the minimum number of iterative refinements (i.e. at least "min_refinement_steps" iterative refinement steps are enforced per right hand side.)

Default: 1

**mumps_dep_tol (real):** Pivot threshold for detection of linearly dependent constraints in MUMPS.

When MUMPS is used to determine linearly dependent constraints, this determines the threshold for a pivot to be considered zero. This is CNTL(3) in MUMPS.

Range: \([-\infty, \infty]\]

Default: 0

**mumps_mem_percent (integer):** Percentage increase in the estimated working space for MUMPS.

In MUMPS when significant extra fill-in is caused by numerical pivoting, larger values of mumps_mem_percent may help use the workspace more efficiently. On the other hand, if memory requirement are too large at the very beginning of the optimization, choosing a much smaller value for this option, such as 5, might reduce memory requirements.

Default: 1000
**mumps_permuting_scaling** *(integer)*: Controls permuting and scaling in MUMPS

This is ICNTL(6) in MUMPS.

Range: [0, 7]

Default: 7

**mumps_pivot_order** *(integer)*: Controls pivot order in MUMPS

This is ICNTL(7) in MUMPS.

Range: [0, 7]

Default: 7

**mumps_pivtol** *(real)*: Pivot tolerance for the linear solver MUMPS.

A smaller number pivots for sparsity, a larger number pivots for stability. This option is only available if Ipopt has been compiled with MUMPS.

Range: [0, 1]

Default: 1e-06

**mumps_pivtolmax** *(real)*: Maximum pivot tolerance for the linear solver MUMPS.

Ipopt may increase pivtol as high as pivtolmax to get a more accurate solution to the linear system. This option is only available if Ipopt has been compiled with MUMPS.

Range: [0, 1]

Default: 0.1

**mumps_scaling** *(integer)*: Controls scaling in MUMPS

This is ICNTL(8) in MUMPS.

Range: [-2, 77]

Default: 77

**mu_allow_fast_monotone_decrease** *(string)*: Allow skipping of barrier problem if barrier test it already met.

If set to "no", the algorithm enforces at least one iteration per barrier problem, even if the barrier test is already met for the updated barrier parameter.

Default: yes

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Take at least one iteration per barrier problem</td>
</tr>
<tr>
<td>yes</td>
<td>Allow fast decrease of mu if barrier test it met</td>
</tr>
</tbody>
</table>

**mu_init** *(real)*: Initial value for the barrier parameter.
This option determines the initial value for the barrier parameter (mu). It is only relevant in
the monotone, Fiacco-McCormick version of the algorithm. (i.e., if "mu_strategy" is chosen as
"monotone")

Default: 0.1

**mu_linear_decrease_factor (real):** Determines linear decrease rate of barrier parameter.

For the Fiacco-McCormick update procedure the new barrier parameter mu is obtained by
taking the minimum of mu^"mu_linear_decrease_factor" and mu^"superlinear_decrease_power".
(This is kappa_mu in implementation paper.) This option is also used in the adaptive mu
strategy during the monotone mode.

Range: \([0, 1]\)

Default: 0.2

**mu_max (real):** Maximum value for barrier parameter.

This option specifies an upper bound on the barrier parameter in the adaptive mu selection
mode. If this option is set, it overwrites the effect of mu_max_fact. (Only used if option
"mu_strategy" is chosen as "adaptive".)

Default: 100000

**mu_max_fact (real):** Factor for initialization of maximum value for barrier parameter.

This option determines the upper bound on the barrier parameter. This upper bound is
computed as the average complementarity at the initial point times the value of this option.
(Only used if option "mu_strategy" is chosen as "adaptive".)

Default: 1000

**mu_min (real):** Minimum value for barrier parameter.

This option specifies the lower bound on the barrier parameter in the adaptive mu selection
mode. By default, it is set to the minimum of 1e-11 and min("tol","compl_inf_tol")/("barrier_tol_factor"+1),
which should be a reasonable value. (Only used if option "mu_strategy" is chosen as "adaptive".)

Default: 1e-11

**mu_oracle (string):** Oracle for a new barrier parameter in the adaptive strategy.

Determines how a new barrier parameter is computed in each "free-mode" iteration of the
adaptive barrier parameter strategy. (Only considered if "adaptive" is selected for option
"mu_strategy").

Default: quality-function

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>loqo</td>
<td>LOQO’s centrality rule</td>
</tr>
<tr>
<td>probing</td>
<td>Mehrotra’s probing heuristic</td>
</tr>
<tr>
<td>quality-function</td>
<td>minimize a quality function</td>
</tr>
</tbody>
</table>

**mu_strategy (string):** Update strategy for barrier parameter.
Determines which barrier parameter update strategy is to be used.

Default: adaptive

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>adaptive</td>
<td>use the adaptive update strategy</td>
</tr>
<tr>
<td>monotone</td>
<td>use the monotone (Fiacco-McCormick) strategy</td>
</tr>
</tbody>
</table>

**mu_superlinear_decrease_power** *(real):* Determines superlinear decrease rate of barrier parameter.

For the Fiacco-McCormick update procedure the new barrier parameter \( \mu \) is obtained by taking the minimum of \( \mu \times \text{mu\_linear\_decrease\_factor} \) and \( \mu^\text{superlinear\_decrease\_power} \). (This is \( \theta_{\mu} \) in implementation paper.) This option is also used in the adaptive \( \mu \) strategy during the monotone mode.

Range: \([1, 2]\)

Default: 1.5

**mu_target** *(real):* Desired value of complementarity.

Usually, the barrier parameter is driven to zero and the termination test for complementarity is measured with respect to zero complementarity. However, in some cases it might be desired to have Ipopt solve barrier problem for strictly positive value of the barrier parameter. In this case, the value of "mu_target" specifies the final value of the barrier parameter, and the termination tests are then defined with respect to the barrier problem for this value of the barrier parameter.

Default: 0

**neg_curv_test_reg** *(string):* Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).

Default: yes

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>use original IPOPT approach, in which the primal regularization is ignored</td>
</tr>
<tr>
<td>yes</td>
<td>use primal regularization with the inertia-free curvature test</td>
</tr>
</tbody>
</table>

**neg_curv_test_tol** *(real):* Tolerance for heuristic to ignore wrong inertia.

If nonzero, incorrect inertia in the augmented system is ignored, and Ipopt tests if the direction is a direction of positive curvature. This tolerance is \( \alpha_n \) in the paper by Zavala and Chiang (2014) and it determines when the direction is considered to be sufficiently positive. A value in the range of \([1e-12, 1e-11]\) is recommended.

Default: 0

**nlp_scaling_constr_target_gradient** *(real):* Target value for constraint function gradient size.

If a positive number is chosen, the scaling factor the constraint functions is computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max-gradient for the constraint functions.

Default: 0
**nlp_scaling_max_gradient** (real): Maximum gradient after NLP scaling. →

This is the gradient scaling cut-off. If the maximum gradient is above this value, then gradient based scaling will be performed. Scaling parameters are calculated to scale the maximum gradient back to this value. (This is \( g_{\text{max}} \) in Section 3.8 of the implementation paper.) Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Default: 100

**nlp_scaling_method** (string): Select the technique used for scaling the NLP. →

Selects the technique used for scaling the problem internally before it is solved. For user-scaling, the parameters come from the NLP. If you are using AMPL, they can be specified through suffixes ("scaling_factor")

Default: gradient-based

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>equilibration-based</td>
<td>scale the problem so that first derivatives are of order 1 at random points (only available with MC19)</td>
</tr>
<tr>
<td>gradient-based</td>
<td>scale the problem so the maximum gradient at the starting point is scaling_max_gradient</td>
</tr>
<tr>
<td>none</td>
<td>no problem scaling will be performed</td>
</tr>
</tbody>
</table>

**nlp_scaling_min_value** (real): Minimum value of gradient-based scaling values. →

This is the lower bound for the scaling factors computed by gradient-based scaling method. If some derivatives of some functions are huge, the scaling factors will otherwise become very small, and the (unscaled) final constraint violation, for example, might then be significant. Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Default: 1e-08

**nlp_scaling_obj_target_gradient** (real): Target value for objective function gradient size. →

If a positive number is chosen, the scaling factor the objective function is computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max_gradient for the objective function.

Default: 0

**nu_inc** (real): Increment of the penalty parameter. →

Default: 0.0001

**nu_init** (real): Initial value of the penalty parameter. →

Default: 1e-06

**obj_max_inc** (real): Determines the upper bound on the acceptable increase of barrier objective function. →

Trial points are rejected if they lead to an increase in the barrier objective function by more than obj_max_inc orders of magnitude.

Range: [1, \( \infty \)]

Default: 5

**pardiso_matching_strategy** (string): Matching strategy to be used by Pardiso →

This is IPAR(13) in Pardiso manual.

Default: complete+2x2
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>complete</td>
<td>Match complete (IPAR(13)=1)</td>
</tr>
<tr>

<td>Match complete+2x2 (IPAR(13)=2)</td>
</tr>
<tr>
<td>constraints</td>
<td>Match constraints (IPAR(13)=3)</td>
</tr>
</tbody>
</table>

**pardiso_max_iterative_refinement_steps** *(integer)*: Limit on number of iterative refinement steps. ↔

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: \([-\infty, \infty]\]

Default: 1

**pardiso_msglvl** *(integer)*: Pardiso message level ↔

This determines the amount of analysis output from the Pardiso solver. This is MSGlvl in the Pardiso manual.

Default: 0

**pardiso_order** *(string)*: Controls the fill-in reduction ordering algorithm for the input matrix. ↔

Default: metis

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>amd</td>
<td>minimum degree algorithm</td>

</tbody>
</table>

**pardiso_redo_symbolic_fact_only_if_inertia_wrong** *(string)*: Toggle for handling case when elements were perturbed by Pardiso. ↔

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Always redo symbolic factorization when elements were perturbed</td>
</tr>
<tr>
<td>yes</td>
<td>Only redo symbolic factorization when elements were perturbed if also the inertia was wrong</td>
</tr>
</tbody>
</table>

**pardiso_repeated_perturbation_means_singular** *(string)*: Interpretation of perturbed elements. ↔

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Don't assume that matrix is singular if elements were perturbed after recent symbolic factorization</td>
</tr>
<tr>
<td>value</td>
<td>meaning</td>
</tr>
<tr>
<td>-------</td>
<td>---------</td>
</tr>
<tr>
<td>yes</td>
<td>Assume that matrix is singular if elements were perturbed after recent symbolic factorization</td>
</tr>
</tbody>
</table>

**pardiso_skip_inertia_check** *(string)*: Always pretend inertia is correct. ←

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>check inertia</td>
</tr>
<tr>
<td>yes</td>
<td>skip inertia check</td>
</tr>
</tbody>
</table>

**perturb_always_cd** *(string)*: Active permanent perturbation of constraint linearization. ←

This option makes the delta_c and delta_d perturbation be used for the computation of every search direction. Usually, it is only used when the iteration matrix is singular.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>perturbation only used when required</td>
</tr>
<tr>
<td>yes</td>
<td>always use perturbation</td>
</tr>
</tbody>
</table>

**perturb_dec_fact** *(real)*: Decrease factor for x-s perturbation. ←

The factor by which the perturbation is decreased when a trial value is deduced from the size of the most recent successful perturbation. (This is kappa_w^- in the implementation paper.)

Range: [0, 1]
Default: 0.333333

**perturb_inc_fact** *(real)*: Increase factor for x-s perturbation. ←

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of all perturbations except for the first. (This is kappa_w^+ in the implementation paper.)

Range: [1, ∞]
Default: 8

**perturb_inc_fact_first** *(real)*: Increase factor for x-s perturbation for very first perturbation. ←

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of the very first perturbation and allows a different value for for the first perturbation than that used for the remaining perturbations. (This is bar_kappa_w^+ in the implementation paper.)

Range: [1, ∞]
Default: 100

**print_eval_error** *(string)*: Switch to enable printing information about function evaluation errors into the GAMS listing file. ←

Default: yes
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>don’t print string</td>
</tr>
<tr>
<td>yes</td>
<td>print string at end of each iteration output</td>
</tr>
</tbody>
</table>

**print_frequency_iter (integer):** Determines at which iteration frequency the summarizing iteration output line should be printed. ←

Summarizing iteration output is printed every print_frequency_iter iterations, if at least print_frequency_time seconds have passed since last output.

Range: \([1, \infty]\)

Default: 1

**print_frequency_time (real):** Determines at which time frequency the summarizing iteration output line should be printed. ←

Summarizing iteration output is printed if at least print_frequency_time seconds have passed since last output and the iteration number is a multiple of print_frequency_iter.

Default: 0

**print_info_string (string):** Enables printing of additional info string at end of iteration output. ←

This string contains some insider information about the current iteration. For details, look for “Diagnostic Tags” in the Ipopt documentation.

Default: no

**print_level (integer):** Output verbosity level. ←

Sets the default verbosity level for console output. The larger this value the more detailed is the output.

Range: \([0, 12]\)

Default: 5

**print_timing_statistics (string):** Switch to print timing statistics. ←

If selected, the program will print the CPU usage (user time) for selected tasks.

Default: no

**quality_function_balancing_term (string):** The balancing term included in the quality function for
This determines whether a term is added to the quality function that penalizes situations where the complementarity is much smaller than dual and primal infeasibilities. (Only used if option "mu_oracle" is set to "quality-function").

Default: none

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>cubic</td>
<td>Max(0,Max(dual_inf,primal_inf)-compl)^3</td>
</tr>
<tr>
<td>none</td>
<td>no balancing term is added</td>
</tr>
</tbody>
</table>

**quality_function_centrality** *(string)*: The penalty term for centrality that is included in quality function.

This determines whether a term is added to the quality function to penalize deviation from centrality with respect to complementarity. The complementarity measure here is the $x_i$ in the Loqo update rule. (Only used if option "mu_oracle" is set to "quality-function").

Default: none

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>cubed-reciprocal</td>
<td>complementarity * the reciprocal of the centrality measure cubed</td>
</tr>
<tr>
<td>log</td>
<td>complementarity * the log of the centrality measure</td>
</tr>
<tr>
<td>none</td>
<td>no penalty term is added</td>
</tr>
<tr>
<td>reciprocal</td>
<td>complementarity * the reciprocal of the centrality measure</td>
</tr>
</tbody>
</table>

**quality_function_max_section_steps** *(integer)*: Maximum number of search steps during direct search procedure determining the optimal centering parameter.

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function").

Default: 8

**quality_function_norm_type** *(string)*: Norm used for components of the quality function.

(Only used if option "mu_oracle" is set to "quality-function").

Default: 2-norm-squared

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-norm</td>
<td>use the 1-norm (abs sum)</td>
</tr>
<tr>
<td>2-norm</td>
<td>use 2-norm</td>
</tr>
<tr>
<td>2-norm-squared</td>
<td>use the 2-norm squared (sum of squares)</td>
</tr>
<tr>
<td>max-norm</td>
<td>use the infinity norm (max)</td>
</tr>
</tbody>
</table>

**quality_function_section_qf_tol** *(real)*: Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space).

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function").
4.24 IPOPT and IPOPTH

Range: [0, 1]
Default: 0

**quality_function_section_sigma_tol** *(real)*: Tolerance for the section search procedure determining the optimal centering parameter (in sigma space).

The golden section search is performed for the quality function based mu oracle. (Only used if option "mu_oracle" is set to "quality-function".)

Range: [0, 1]
Default: 0.01

**recale_y** *(string)*: Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates.

This asks the algorithm to recompute the multipliers, whenever the current infeasibility is less than recalc_y_feas_tol. Choosing yes might be helpful in the quasi-Newton option. However, each recalculation requires an extra factorization of the linear system. If a limited memory quasi-Newton option is chosen, this is used by default.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>use the Newton step to update the multipliers</td>
</tr>
<tr>
<td>yes</td>
<td>use least-square multiplier estimates</td>
</tr>
</tbody>
</table>

**recale_y_feas_tol** *(real)*: Feasibility threshold for recomputation of multipliers.

If recalc_y is chosen and the current infeasibility is less than this value, then the multipliers are recomputed.

Default: 1e-06

**replace_bounds** *(string)*: Indicates if all variable bounds should be replaced by inequality constraints

This option must be set for the inexact algorithm

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>leave bounds on variables</td>
</tr>
<tr>
<td>yes</td>
<td>replace variable bounds by inequality constraints</td>
</tr>
</tbody>
</table>

**report_mininfeas_solution** *(string)*: Switch to report intermediate solution with minimal constraint violation to GAMS if the final solution is not feasible.

This option allows to obtain the most feasible solution found by Ipopt during the iteration process, if it stops at a (locally) infeasible solution, due to a limit (time, iterations, ...), or with a failure in the restoration phase.

Default: no
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td></td>
</tr>
<tr>
<td>yes</td>
<td></td>
</tr>
</tbody>
</table>

**required_infeasibility_reduction** *(real)*: Required reduction of infeasibility before leaving restoration phase. ←

The restoration phase algorithm is performed, until a point is found that is acceptable to the filter and the infeasibility has been reduced by at least the fraction given by this option.

Range: 
Default: 0.9

**residual_improvement_factor** *(real)*: Minimal required reduction of residual test ratio in iterative refinement. ←

If the improvement of the residual test ratio made by one iterative refinement step is not better than this factor, iterative refinement is aborted.

Default: 1

**residual_ratio_max** *(real)*: Iterative refinement tolerance ←

Iterative refinement is performed until the residual test ratio is less than this tolerance (or until “max_refinement_steps” refinement steps are performed).

Default: 1e-10

**residual_ratio_singular** *(real)*: Threshold for declaring linear system singular after failed iterative refinement. ←

If the residual test ratio is larger than this value after failed iterative refinement, the algorithm pretends that the linear system is singular.

Default: 1e-05

**resto_failure_feasibility_threshold** *(real)*: Threshold for primal infeasibility to declare failure of restoration phase. ←

If the restoration phase is terminated because of the "acceptable" termination criteria and the primal infeasibility is smaller than this value, the restoration phase is declared to have failed. The default value is 1e2*tol, where tol is the general termination tolerance.

Default: 0

**resto_penalty_parameter** *(real)*: Penalty parameter in the restoration phase objective function. ←

This is the parameter rho in equation (31a) in the Ipopt implementation paper.

Default: 1000

**resto_proximity_weight** *(real)*: Weighting factor for the proximity term in restoration phase objective. ←
This determines how the parameter zera in equation (29a) in the implementation paper is computed. zeta here is resto_proximity_weight*sqrt(mu), where mu is the current barrier parameter.

Default: 1

\textbf{rho (real):} Value in penalty parameter update formula. \leftarrow

Range: [0, 1]

Default: 0.1

\textbf{sigma\_max (real):} Maximum value of the centering parameter. \leftarrow

This is the upper bound for the centering parameter chosen by the quality function based barrier parameter update. (Only used if option "mu\_oracle" is set to "quality-function".)

Default: 100

\textbf{sigma\_min (real):} Minimum value of the centering parameter. \leftarrow

This is the lower bound for the centering parameter chosen by the quality function based barrier parameter update. (Only used if option "mu\_oracle" is set to "quality-function".)

Default: 1e-06

\textbf{skip\_corr\_if\_neg\_curv (string):} Skip the corrector step in negative curvature iteration. \leftarrow

The corrector step is not tried if negative curvature has been encountered during the computation of the search direction in the current iteration. This option is only used if "mu\_strategy" is "adaptive". Changing this option is experimental.

Default: yes

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>don't skip</td>
</tr>
<tr>
<td>yes</td>
<td>skip</td>
</tr>
</tbody>
</table>

\textbf{skip\_corr\_in\_monotone\_mode (string):} Skip the corrector step during monotone barrier parameter mode. \leftarrow

The corrector step is not tried if the algorithm is currently in the monotone mode (see also option "barrier\_strategy"). This option is only used if "mu\_strategy" is "adaptive". Changing this option is experimental.

Default: yes

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>don't skip</td>
</tr>
<tr>
<td>yes</td>
<td>skip</td>
</tr>
</tbody>
</table>

\textbf{slack\_bound\_frac (real):} Desired minimum relative distance from the initial slack to bound. \leftarrow

Determines how much the initial slack variables might have to be modified in order to be
sufficiently inside the inequality bounds (together with "slack_bound_push"). (This is \( \kappa_2 \) in Section 3.6 of implementation paper.)

Range: \([0, 0.5]\)

Default: 0.01

**slack_bound_push (real):** Desired minimum absolute distance from the initial slack to bound. ←

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_frac"). (This is \( \kappa_1 \) in Section 3.6 of implementation paper.)

Default: 0.01

**slack_move (real):** Correction size for very small slacks. ←

Due to numerical issues or the lack of an interior, the slack variables might become very small. If a slack becomes very small compared to machine precision, the corresponding bound is moved slightly. This parameter determines how large the move should be. Its default value is \( \text{mach}_\text{eps}^{\frac{3}{4}} \). (See also end of Section 3.5 in implementation paper - but actual implementation might be somewhat different.)

Default: 1.81899e-12

**soc_method (integer):** Ways to apply second order correction ←

This option determines the way to apply second order correction, 0 is the method described in the implementation paper. 1 is the modified way which adds alpha on the rhs of \( x \) and \( s \) rows.

Range: \([0, 1]\)

Default: 0

**soft_resto_pderror_reduction_factor (real):** Required reduction in primal-dual error in the soft restoration phase. ←

The soft restoration phase attempts to reduce the primal-dual error with regular steps. If the damped primal-dual step (damped only to satisfy the fraction-to-the-boundary rule) is not decreasing the primal-dual error by at least this factor, then the regular restoration phase is called. Choosing "0" here disables the soft restoration phase.

Default: 0.9999

**start_with_resto (string):** Tells algorithm to switch to restoration phase in first iteration. ←

Setting this option to "yes" forces the algorithm to switch to the feasibility restoration phase in the first iteration. If the initial point is feasible, the algorithm will abort with a failure.

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>don't force start in restoration phase</td>
</tr>
<tr>
<td>yes</td>
<td>force start in restoration phase</td>
</tr>
</tbody>
</table>

**s_max (real):** Scaling threshold for the NLP error. ←
(See paragraph after Eqn. (6) in the implementation paper.)

Default: 100

\texttt{s.phi} (real): Exponent for linear barrier function model in the switching rule. ↔

(See Eqn. (19) in the implementation paper.)

Range: \([1, \infty]\)

Default: 2.3

\texttt{s.theta} (real): Exponent for current constraint violation in the switching rule. ↔

(See Eqn. (19) in the implementation paper.)

Range: \([1, \infty]\)

Default: 1.1

\texttt{tau_min} (real): Lower bound on fraction-to-the-boundary parameter \(\tau\). ↔

(This is \(\texttt{tau.min}\) in the implementation paper.) This option is also used in the adaptive \(\mu\) strategy during the monotone mode.

Range: \([0, 1]\)

Default: 0.99

\texttt{theta_max_fact} (real): Determines upper bound for constraint violation in the filter. ↔

The algorithmic parameter \(\theta_{\text{max}}\) is determined as \(\theta_{\text{max}}\times\text{fact}\) times the maximum of 1 and the constraint violation at initial point. Any point with a constraint violation larger than \(\theta_{\text{max}}\) is unacceptable to the filter (see Eqn. (21) in the implementation paper).

Default: 10000

\texttt{theta_min_fact} (real): Determines constraint violation threshold in the switching rule. ↔

The algorithmic parameter \(\theta_{\text{min}}\) is determined as \(\theta_{\text{min}}\times\text{fact}\) times the maximum of 1 and the constraint violation at initial point. The switching rules treats an iteration as an h-type iteration whenever the current constraint violation is larger than \(\theta_{\text{min}}\) (see paragraph before Eqn. (19) in the implementation paper).

Default: 0.0001

\texttt{tiny_step_tol} (real): Tolerance for detecting numerically insignificant steps. ↔

If the search direction in the primal variables (\(x\) and \(s\)) is, in relative terms for each component, less than this value, the algorithm accepts the full step without line search. If this happens repeatedly, the algorithm will terminate with a corresponding exit message. The default value is 10 times machine precision.

Default: 2.22045e-15

\texttt{tiny_step_y_tol} (real): Tolerance for quitting because of numerically insignificant steps. ↔
If the search direction in the primal variables (x and s) is, in relative terms for each component, repeatedly less than tiny_step_tol, and the step in the y variables is smaller than this threshold, the algorithm will terminate.

Default: 0.01

tol (real): Desired convergence tolerance (relative).

Determines the convergence tolerance for the algorithm. The algorithm terminates successfully, if the (scaled) NLP error becomes smaller than this value, and if the (absolute) criteria according to "dual_inf_tol", "constr_viol_tol", and "compl_inf_tol" are met. (This is epsilon_tol in Eqn. (6) in implementation paper). See also "acceptable_tol" as a second termination criterion. Note, some other algorithmic features also use this quantity to determine thresholds etc.

Default: 1e-08

warm_start_bound_frac (real): same as bound_frac for the regular initializer.

Range: [0, 0.5]

Default: 0.001

warm_start_bound_push (real): same as bound_push for the regular initializer.

Default: 0.001

warm_start_init_point (string): Warm-start for initial point

Indicates whether this optimization should use a warm start initialization, where values of primal and dual variables are given (e.g., from a previous optimization of a related problem.)

Default: no

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>do not use the warm start initialization</td>
</tr>
<tr>
<td>yes</td>
<td>use the warm start initialization</td>
</tr>
</tbody>
</table>

warm_start_mult_bound_push (real): same as mult_bound_push for the regular initializer.

Default: 0.001

warm_start_mult_init_max (real): Maximum initial value for the equality multipliers.

Range: [-∞, ∞]

Default: 1e+06

warm_start_slack_bound_frac (real): same as slack_bound_frac for the regular initializer.

Range: [0, 0.5]

Default: 0.001

warm_start_slack_bound_push (real): same as slack_bound_push for the regular initializer.
4.25 JAMS and LogMIP

4.25.1 Introduction

EMP (Extended Mathematical Programming) is not a solver but an (experimental) framework for automated mathematical programming reformulations. The idea behind EMP is that new upcoming types of models which currently cannot be solved reliably are reformulated into models of established math programming classes in order to use mature solver technology. At this stage, EMP supports the modeling of Bilevel Programs, Variational Inequalities, Disjunctive Programs, Extended Nonlinear Programs and Embedded Complementarity Systems.

Extended mathematical programs are collections of functions and variables joined together using specific optimization and complementarity primitives. EMP annotates the existing relationships within a model to facilitate higher level structure identification. A specific implementation of this framework is outlined that reformulates the original GAMS model automatically using directives contained in an "empinfo" file into an equivalent model that can be solved using existing GAMS solvers.

The reformulation is done by the solver JAMS which currently is the only solver that is capable of handling EMP models. Examples showing how to use the EMP framework and the solver JAMS are made available through the GAMS EMP Library which is included in the GAMS Distribution. In order to generate a copy of an EMPLIB model, one can use the library facility of the GAMS IDE, or execute the command line directive `emplib <modelname>`, where modelname is the (stem of the) file containing the model.

EMP has been developed jointly by Michael Ferris of UW-Madison, Ignacio Grossmann of Carnegie Mellon University, and GAMS Development Corporation. EMP and JAMS come free of charge with any licensed GAMS system but require a subsolver to solve the generated models.

4.25.2 JAMS: a reformulation tool

EMP models are currently processed by the JAMS solver. The solver JAMS creates a scalar version of the given GAMS model. This scalar version of the model is then solved by an appropriate subsolver. By default, there are no reformulations carried out, so the model generated is simply a GAMS scalar form of the model the actual subsolver will process. The subsolver used is by default the currently specified solver for the given model type.
4.25.2.1 The JAMS Option File

As with any GAMS solver, JAMS has an option file, typically called jams.opt. A JAMS option subsolver is available to change the subsolver used for the reformulated model, along with an option to utilize a subsolver option file (subsolveropt).

The actual scalar version of the model can also be seen by the modeler using the option filename. For example, the option file

```
subsolver path
subsolveropt 1
filename mcpmod.gms
```

when applied to an EMP model that is a complementarity problem will create a file called mcpmod.gms in the current directory and solve that model using the solver PATH utilizing any options for PATH that are specified in path.opt. The scalarized model is not particularly useful to look at since all of the original variables have been renamed into a scalar form. The mapping between original variables and the ones used in the scalar version of the model is given in a dictionary file that can also be seen by the modeler using the dict option. If a user simply wants to generate this scalar model, then the option terminate will not solve the generated model.

After the scalar version of the model is solved, the solution values are mapped back into the original namespace and returned to the modeler as usual in the listing file. The JAMS option margtol allows the modeler to suppress reporting marginals that have (absolute) values smaller than this tolerance.

Obviously, all of the above functionality is not of much value: the key part of JAMS is to interpret additional directives to take the original model and produce a reformulated scalar model. This is carried out using an "empinfo" file. The syntax and use of this file is the content of the remaining sections of this document.

The option EMPInfoFile allows the user to specify the path and name of a file containing additional EMP information. The syntax of this file is described by examples elsewhere in this document and in section Empinfo file details. There is a subtlety that should be mentioned when a user writes this file in the default location in the GAMS scratch directory of the current run specified in the gams file using:

```
file empinfo / '%emp.info%' /;
```

wherein certain additional formatting instructions are given. If instead, the file handle is given by:

```
file empinfo / 'empinfo.txt' /;
```

for example, then to produce the same file the following lines must be added to the gams source file:

```
empinfo.pc = 8;
empinfo.pw = 255;
```

The following tables list all available options.

4.25.2.2 Reformulation Options
### 4.25.2.3 General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompModel</td>
<td>Complementarity model (MCP or VI) to generate for equilibrium problems.</td>
<td>mcp</td>
</tr>
<tr>
<td>Dict</td>
<td>Generate a dictionary file that maps original variable and equation names to the ones of the scalar JAMS model.</td>
<td>dict.txt</td>
</tr>
<tr>
<td>DisjBinRelax</td>
<td>Relax requirement that disjunction variables are binary.</td>
<td>0</td>
</tr>
<tr>
<td>EMPInfoFile</td>
<td>Path and name of file containing additional EMP information as disjunctions, perpendiculars, bilevel characterization etc. By default, the file is expected to exist in the GAMS scratch directory of the current run (gams.scrdir). If this option is used, EMP searches for the file based on the provided relative or absolute path. In case of a given relative path, it is assumed to be relative to the working directory.</td>
<td></td>
</tr>
<tr>
<td>FileName</td>
<td>Filename of generated scalar reformulated GAMS model.</td>
<td>emp.gms</td>
</tr>
<tr>
<td>ImplVarModel</td>
<td>Reformulation model to generate for implicit variables.</td>
<td>switching</td>
</tr>
<tr>
<td>SubSolvePar</td>
<td>User defined GAMS parameters for subsolve</td>
<td></td>
</tr>
<tr>
<td>SubSolver</td>
<td>Subsolver used to solve the reformulated model.</td>
<td></td>
</tr>
<tr>
<td>SubSolverOpt</td>
<td>Optfile value to pass to the subsolver</td>
<td>1</td>
</tr>
<tr>
<td>Terminate</td>
<td>Generate the GAMS source code of the reformulated model in a file and terminate without solving the model.</td>
<td>0</td>
</tr>
<tr>
<td>ZipDebug</td>
<td>Zip-file name to create if the internal GAMS model fails</td>
<td>none</td>
</tr>
</tbody>
</table>

### 4.25.3 Forming Optimality Conditions: NLP2MCP

The first nontrivial use of the JAMS solver is to automatically generate the first order conditions of a linear or nonlinear program; essentially we reformulate the optimization problem as a mixed complementarity.
modeltype mcp

Behind the scenes, JAMS forms the Lagrangian of the nonlinear program and then forms its Karush-Kuhn-Tucker optimality conditions. To be clear, given the original nonlinear program

\[
\min_x f(x) \text{ s.t. } g(x) \leq 0, \ h(x) = 0, \quad \text{(NLP)}
\]

the Lagrangian is:

\[
\mathcal{L}(x, \lambda, \mu) = f(x) - \langle \lambda, g(x) \rangle - \langle \mu, h(x) \rangle.
\]

The first order conditions are the following MCP:

\[
\begin{align*}
0 &= \nabla_x \mathcal{L}(x, \lambda, \mu) \perp x \text{ free} \\
0 &\geq -\nabla_\lambda \mathcal{L}(x, \lambda, \mu) \perp \lambda \leq 0 \\
0 &= -\nabla_\mu \mathcal{L}(x, \lambda, \mu) \perp \mu \text{ free}
\end{align*}
\]

A specific example is:

\[
\min_{x, y, z} -3x + y \\
\text{s.t. } x + y \leq 1, \ x + y - z = 2, \ x, y \geq 0
\]

which is found in the EMPLIB model \texttt{nlp2mcp}:

```
Positive Variables x, y;
Variables f, z;
Equations g, h, defobj;
  g.. x + y =l= 1;
  h.. x + y - z =e= 2;
  defobj.. f =e= -3*x + y;
model comp / defobj, g, h /;
file info / '%emp.info%' /;
putclose info / 'modeltype mcp';
solve comp using emp minimizing f;
```

The putclose line writes out the default "empinfo" file whose location is provided in the system string \texttt{%emp.info\%}. Armed with this additional information, the EMP tool automatically creates the following MCP:

\[
\begin{align*}
0 \leq -3 - \lambda - \mu & \perp x \geq 0 \\
0 \leq 1 - \lambda - \mu & \perp y \geq 0 \\
0 = \mu & \perp z \text{ free} \\
0 \geq x + y - 1 & \perp \lambda \leq 0 \\
0 = x + y - z - 2 & \perp \mu \text{ free}.
\end{align*}
\]
4.25.4 Soft Constraints

In many cases, we wish to relax certain constraints in a model during solution (to help identify feasibility issues for example). As an example, consider the problem

$$\begin{align*}
\min_{x_1, x_2, x_3} & \quad \exp(x_1) \\
\text{s.t.} & \quad \log(x_1) = 1, \\
& \quad x_2^2 \leq 2, \\
& \quad x_1/x_2 = \log(x_3), \\
& \quad 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0,
\end{align*}$$

which can be formulated in GAMS as

```gams
$title simple example of ENLP
Variables obj, x1, x2, x3;
Equations f0, f1, f2, f3, f4;
f0.. obj =e= exp(x1);
f1.. log(x1) =e= 1;
f2.. sqr(x2) =g= 2;
f3.. x1/x2 =e= log(x3);
f4.. 3*x1 + x2 =l= 5;
x1.lo = 0; x2.lo = 0;
model enlpemp /all/;
x1.l = 1; x2.l = 1; x3.l = 1;
solve enlpemp using nlp min obj;
```

4.25.4.1 Reformulation as a classical NLP

Soft constraints allow us to treat certain equations in the model as "soft" by removing the constraints and adding a penalty term to the objective function. Explicitly, we replace the above problem by:

$$\begin{align*}
\min_{x_1, x_2, x_3} & \quad \exp(x_1) + 5 \|\log(x_1) - 1\|^2 + 2 \max(x_2^2 - 2, 0) \\
\text{s.t.} & \quad x_1/x_2 = \log(x_3), \\
& \quad 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0.
\end{align*}$$

In this problem, we still force $x_1/x_2 = \log(x_3)$, but apply a least squares penalty to $\log(x_1) - 1$ and a smaller one-sided penalization to $x_2^2 - 2$.

The above formulation is nonsmooth due to the "max" term in the objective function; in practice we would replace this by:

$$\begin{align*}
\min_{x_1, x_2, x_3, w} & \quad \exp(x_1) + 5 (\log(x_1) - 1)^2 + 2w \\
\text{s.t.} & \quad x_1/x_2 = \log(x_3), \\
& \quad 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\
& \quad w \geq x_2^2 - 2, w \geq 0
\end{align*}$$

and recover a standard form NLP.

The "empinfo" file:

```gams
modeltype NLP
adjustequ f1 sqr 5
f2 maxz 2
model enlpemp /all/;
solve enlpemp using nlp min obj;
```

achieves this goal. The parameter values provide the penalty coefficients above.
4.25.4.2 Reformulation as an MCP

As an alternative, we can rewrite the problem as an MCP, also dealing explicitly with the nonsmoothness. The "empinfo" file is given by:

```
modeltype NLP
adjustequ
f1 sqr 5
f2 max 2
```

and this generates the following MCP:

\[
\begin{align*}
0 &= \log(x_1) - 1 + y_1/10 & \perp & y_1 \text{ free}, \\
0 &\leq x_2^2 - 2 & \perp & y_2 \geq 0, \\
0 &= x_1/x_2 - \log(x_3) & \perp & y_3 \text{ free}, \\
0 &\geq 3x_1 + x_2 - 5 & \perp & y_4 \leq 0, \\
0 &\leq \exp(x_1) - y_1/x_1 - y_3/x_2 - 3y_4 & \perp & x_1 \geq 0, \\
0 &\leq -2y_2x_2 + x_1y_3/x_2^2 - y_4 & \perp & x_2 \geq 0, \\
0 &= y_3/x_3 & \perp & x_3 \text{ free},
\end{align*}
\]

where \( y \) represent the multipliers.

A complete description of the process to derive this MCP will be given later in section Extended Nonlinear Programs.

4.25.5 Bilevel Programs

Mathematical programs with optimization problems in their constraints have a long history in operations research including [28] [49] [99]. New codes are being developed that exploit this structure, at least for simple hierarchies, and attempt to define and implement algorithms for their solution.

The simplest case is that of bilevel programming, where an upper level problem depends on the solution of a lower level optimization. For example:

\[
\begin{align*}
\min_{x,y} f(x,y) \\
\text{s.t. } g(x,y) &\leq 0, \\
&\text{ } y \text{ solves } \min_{y} v(x,y) \text{ s.t. } h(x,y) \geq 0.
\end{align*}
\]

Often, the upper level is referred to as the “leader”, while the lower level is the “follower”.

This problem can be reformulated as a Mathematical Program with Complementarity Constraints (MPCC) by replacing the lower level optimization problem by its first order optimality conditions:

\[
\begin{align*}
\min_{x,y} f(x,y) \\
\text{s.t. } g(x,y) &\leq 0, \\
0 &= \nabla_y v(x,y) - \lambda^T \nabla_y h(x,y) & \perp & x \text{ free} \\
0 &\leq h(x,y) & \perp & \lambda \geq 0.
\end{align*}
\]

We find a solution of the MPCC, not of the bilevel program. This approach allows the MPCC to be solved using the NLPEC code, for example. Note that this reformulation is potentially problematic. First order
conditions require theoretical assumptions to be necessary and sufficient for local optimality. There may be cases where the lower level problem has multiple local solutions, but the modeler really was interested in the global solution. The approach here may not produce this solution, even if a global solver is used within NLPEC.

The following example is Example 5.1.1, page 197 from [28]. Mathematically, the problem is

\[
\begin{align*}
\min_{x,y} & \quad x - 4y \\
\text{s.t.} & \quad y \text{ solves } \min_{y} \quad y \\
& \quad x + y \geq 3 \\
& \quad 2x - y \geq 0 \\
& \quad -2x - y \geq -12 \\
& \quad -3x + 2y \geq -4
\end{align*}
\]

and the EMPLIB model bard511 contains the following code:

```plaintext
Positive variables x, y;
Variables objout, objin;
equations defout, defin, e1, e2, e3, e4;

defout.. objout =e= x - 4*y;
defin.. objin =e= y;
e1.. x + y =g= 3;
e2.. 2*x - y =g= 0;
e3.. -2*x - y =g= -12;
e4.. -3*x + 2*y =g= -4;

model bard / all /;
$echo bilevel x min objin y defin e1 e2 e3 e4 > "%emp.info%"
solve bard using emp minimizing objout;
```

Note that first the functions that form the objectives and constraints of the model are defined and the model is assembled. The $echo line writes the "empinfo" file and states that the lower level problem involves the objective objin which is to be minimized by choice of variables y subject to the constraints specified in (defin), e1, e2, e3, and e4.

Note that the variables x are declared to be variables of the upper level problem and this example has no upper level constraints g. Having written the problem in this way, the MPCC is generated automatically, and passed on to a solver. In the case where that solver is NLPEC, a further reformulation of the model is carried out to convert the MPCC into an equivalent NLP or a parametric sequence of NLP's.

Further examples of bilevel models in EMPLIB are named: bard*, ccmg74, ccmg153, flds*, jointc1, jointc2, mirrlees, transbp.

The EMP model type allows multiple lower level problems to be specified within the bilevel format. An example of this is given in EMPLIB as ccmg71. The equations and objectives are specified in the normal manner; the only change is the definition of the "empinfo" file, shown below:

```plaintext
... defh1.. h1 =e= sqr(u1-x1) + sqr(u2-x2) + sqr(u3-x3) + sqr(u4-x4);
e1.. 3*u1 + u2 + 2*u3 + u4 =e= 6;
...
$onecho > "%emp.info%"
  bilevel x1 x2 x3 x4
  min h1 u1 u2 u3 u4 defh1 e1
  min h2 v1 v2 v3 v4 defh2 e2
$offecho
```
This corresponds to a bilevel program with two followers, both solving minimization problems. The first follower minimizes the objective function \( h_1 \) (defined in \( \text{defh1} \)) over the variables \( u_1, u_2, u_3, \) and \( u_4 \) subject to the constraint given in \( e_1 \). The second followers problem is defined analogously next. Note that \( h_1 \) involves the variables \( x_1, x_2, x_3, \) and \( x_4 \) that are optimization variables of the leader. The constraint in \( e_1 \) could also include these variables, and also the variables \( v_1, v_2, v_3, \) or \( v_4 \) of the second follower, but all of these would be treated as parameters by the first follower.

The actual model (\( \text{ccmg71} \)) in EMPLIB uses a shortcut notation:

```
...
\text{defh1}.. h_1 =e= \text{sqr}(u_1-x_1) + \text{sqr}(u_2-x_2) + \text{sqr}(u_3-x_3) + \text{sqr}(u_4-x_4);
\text{e1}.. 3*u_1 + u_2 + 2*u_3 + u_4 =e= 6;
...
```

In the followers problem, the '∗' notation indicates that this agent will optimize over all the variables used in \( \text{defh1} \) and \( e_1 \) that are not under the control of any other follower or the leader. In this case, this means \( u_1, u_2, u_3, \) and \( u_4 \). To avoid confusion, it is recommended that the modeler explicitly names all the variables in each followers problem as shown before.

### 4.25.6 Variational Inequalities

A variational inequality \( \text{VI}(F,X) \) is to find \( x \in X \):

\[
\langle F(x), (z - x) \rangle \geq 0, \text{ for all } z \in X.
\]

Here \( X \) is a closed (frequently assumed convex) set, defined for example as

\[
X = \{ x \mid x \geq 0, h(x) \geq 0 \}.
\]

Note that the first-order (minimum principle) conditions of a nonlinear program

\[
\min_{z \in X} f(z)
\]

are precisely of this form with \( F(x) = \nabla f(x) \).

It is well known that such problems can be reformulated as complementarity problems when the set \( X \) has the representation \( \{ x \mid x \geq 0, h(x) \geq 0 \} \) by introducing multipliers \( \lambda \) on the constraints \( h(x) \geq 0 \):

\[
0 \leq F(x) - \langle \lambda, \nabla h(x) \rangle \perp x \geq 0
\]

\[
0 \leq h(x) \perp \lambda \geq 0.
\]

If \( X \) has a different representation, this construction would be modified appropriately.

A simple two dimensional example may be useful to improve understanding. Let

\[
F(x) = \begin{bmatrix} x_1 + 2 \\ x_1 + x_2 - 3 \end{bmatrix}, \quad X = \{ x \geq 0 \mid x_1 + x_2 \leq 1, \}
\]

so that \( F \) is an affine function, but \( F \) is not the gradient of any function \( f : \mathbb{R}^2 \to \mathbb{R} \). For this particular data, \( \text{VI}(F,X) \) has a unique solution \( x = (0,1) \).
4.25 JAMS and LogMIP

Set J / 1, 2 /;
Positive Variable x(J)

1725

’vars, perp to f(J)’;

Equations F(J), h;
F(J)..
h..

(x(’1’) + 2)$sameas(J,’1’) + (x(’1’) + x(’2’) - 3)$sameas(J,’2’) =n= 0 ;
x(’1’) + x(’2’) =l= 1;

model simpleVI / F, h/;
file fx /"%emp.info%"/;
putclose fx ’vi F x h’;
solve simpleVI using emp;

Note that the first lines of this file define the F and h using standard GAMS syntax and include the
defining equations in the model simpleVI. The extension is the annotation ”empinfo” file that indicates
certain equations are to be treated differently by the EMP tool. The annotation simply says that the
model is a VI (vi) that pairs F with x and that the remaining (unpaired) equations form the constraint
set X. (Alternative notation allows the keyword vi to be replaced by vifunc.) Thus, model equations F
define a function F that is to be part of a variational inequality, while the equations h define constraints
of X. It is also acceptable in this setting to use the ”empinfo” file defined by:

putclose fx ’vi F x’;
In this case, by default, any equations that are given in the model statement but not included as a pair in
the vi statement are automatically used to form X. An alternative way to write this model without using
sameas is given in EMPLIB as affinevi.
Some subtleties related to VI's are demonstrated in the EMPLIB model zerofunc. In this model, the
set X is defined using variables y and z, for which z does not appear in the definition of F ≡ Fy . In this
case, the variable z is then matched with a ”0” function. The ”empinfo” file can be written in a number
of different ways:

putclose fx ’vi F_y y’;
or

putclose fx ’vi z F_y y’;
or

putclose fx ’vi z F_y y gCons’;
or

putclose fx ’vi F_z z F_y y gCons’;
where F z simply defines the zero function. To some extent, our preferred notation is the one listed third:
it explicitly includes all the variables and constraints that are present in the model and does not require
the modeler to define F z at all.
Further example models in EMPLIB are simplevi, simplevi2, simplevi3, target, traffic, traffic2,
and transvi.


Note also that the lower level problems of a bilevel program could be VI's instead of optimization problems - these problems are called Mathematical Programs with Equilibrium Constraints (MPEC) in the literature. Note that since MPCC is a special case of MPEC, the GAMS model type MPEC covers both. An example demonstrating this setup is given in EMPLIB as multmpec. The actual model to solve is:

\[
\begin{align*}
\min_{u,v,w,z} & \quad z \\
\text{s.t.} & \quad \exp(z) + w = 2, z \geq 1 \\
& \quad (u,v) \text{ solves } \text{VI}([v + w + z - 1; u - \log(v)]), \{(u,v) \mid u \geq 0, v \geq 0\} \\
& \quad w \text{ solves } \text{VI}(w + z + 3, \{w \mid w \text{ free}\})
\end{align*}
\]

Note that the two VI's (due to the definitional sets) correspond respectively to a complementarity problem:

\[
\begin{align*}
0 & \leq v + w + z - 1 \quad \perp u \geq 0 \\
0 & \leq u - \log(v) \quad \perp v \geq 0
\end{align*}
\]

and a linear equation:

\[
w + z + 3 = 0
\]

The actual GAMS code is as follows:

```gams
Positive Variable u;
Variables v, w, z;
Equations f1, f2, f3, h;
f1.. v + w + z =:= 1;
f2.. u =:= \log(v);
f3.. w + z =:= -3;
h.. \exp(z) + w =e= 2;
v.lo = 0; v.l = 1; z.lo = 1;
model mpecmod /all/;
$onecho > %emp.info%
bilevel
vi f1 u
vi f2 v
vi f3 w
$offecho
solve mpecmod using emp min z;
$offecho
```

The initial level value for \(v\) \((v.l = 1)\) is needed to protect the evaluation of \(\log(v)\). The two complementarity problems are specified in the empinfo file (it is not really necessary to split these VI's apart, but it may give information to a solver that can be exploited). It is of course possible to write the MPCC directly in GAMS using the model type MPEC instead of EMP.

### 4.25.7 Embedded Complementarity Systems

A different type of embedded optimization model that arises frequently in applications is:

\[
\begin{align*}
\max_x & \quad f(x, y) \\
\text{s.t.} & \quad g(x, y) \leq 0 \quad (\perp p \geq 0) \\
& \quad H(x, y, p) = 0 \quad (\perp y \text{ free})
\end{align*}
\]
Note the difference here: the optimization problem is over the variable $x$, and is parameterized by the variable $y$. The choice of $y$ is fixed by the (auxiliary) complementarity relationships depicted here by $H$. Note that the $H$ equations are not part of the optimization problem, but are essentially auxiliary constraints to tie down remaining variables in the model.

A specific example is:

\[
\begin{align*}
\text{max} & \quad x \\
\text{s.t.} & \quad x + y \leq 1 \\
& \quad -3x + y = 0.5 \quad (\perp \text{y free})
\end{align*}
\]

which is found in the EMPLIB model `simpequil2`:

Variables y;
Positive variables x;
Equations optcons, vicons;

\[
\begin{align*}
\text{optcons..} & \quad x + y = \leq 1; \\
\text{vicons..} & \quad -3x + y = \equiv 0.5;
\end{align*}
\]

model comp / optcons, vicons /;

file info / '%emp.info%' /;
put info / 'equilibrium';
put / 'max x optcons';
putclose / 'vi vicons y';
solve comp using emp;

In order that this model can be processed correctly as an EMP, the modeler provides additional annotations to the model defining equations in an "empinfo" file. Specifically, first it is indicated that the problem is an equilibrium problem involving one or more agent problems. Next, the first agent is defined as an optimizer (over $x$). Finally, the second agent is defined as solving a VI in $y$. Armed with this additional information, the EMP tool automatically creates the following MCP:

\[
\begin{align*}
0 & \leq -1 + p & \perp x \geq 0 \\
0 & \leq 1 - x - y & \perp p \geq 0 \\
0 & = -3x + y - 0.5 & \perp y \text{ free}
\end{align*}
\]

(which is formed by the steps we outline below). EMP explicitly enforces the rule that every variable and constraint is under the control of exactly one agent. Thus a constraint or a variable cannot appear in both the max problem and the VI problem.

The above example is slightly simpler than the general form described above in which $H$ is a function of $x$, $y$, and $p$, the multiplier on the constraint of the optimization problem. The problem is that we do not have that variable around in the model code if we only specify the optimization problem there. This occurs for example in the classical PIES Model due to Hogan. In this setting, the problem is described by a linear program

\[
\begin{align*}
\text{min}_x & \quad c^T x \\
\text{s.t.} & \quad Ax = q(p) \\
& \quad Bx = b \\
& \quad x \geq 0
\end{align*}
\]

in which the quantity $q$ is a function of $p$, which is a multiplier on one of the LP constraints. To do this in EMP, we simply add the annotation:

model piesemp / defobj, dembal, cnbal, cnbal, lnbal, lnbal, hmbal, hnbal, ruse /;

file myinfo / '%emp.info%'/;
put myinfo 'equilibrium';
put 'min obj c o ct ot at ht defobj dembal cnbal cnbal lnbal lnbal hmbal hnbal ruse';
putclose 'dualvar p dembal';
solve piesemp using emp;
where **dembal** is the name of the constraint for which \( p \) needs to be the multiplier. The full model is found in the EMPLIB model **pies**. Two final points: the **dualvar** directive identifies the variable \( p \) with the multiplier on the **dembal** constraint, and all variables and constraints must be owned by a single agent. In this case, since there is only one agent (the minimizer), all constraints of the model are explicitly claimed, along with all variables except for \( p \). However, next, \( p \) is identified with the **dembal** constraint, which is owned by the min agent, and hence \( p \) is also owned by that agent.

There are several shorthands possible here. The first is that the explicit statement of variables can be replaced by the '∗' form:

```plaintext
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'%emp.info%'/;
put myinfo 'equilibrium ';
put 'min obj * defobj dembal cmbal ombal lmbal hmbal ruse ';
```

Alternatively, an even shorter version is possible since there is only one agent present in this model, namely:

```plaintext
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'%emp.info%'/;
putclose myinfo 'dualvar p dembal';
solve piesemp using emp minimizing obj;
```

Note that in this form, all the variables and constraints of the original model are included in the (single) agents problem, and the original variable \( p \) is identified in the constructed MCP with the multiplier on the **dembal** constraint.

In the general case where the "empinfo" file contains all three lines:

```plaintext
min x optcons
vi vicons y
dualvar p optcons
```

namely that the function \( H \) that is defined in **vicons** is complementary to the variable \( y \) (and hence the variable \( y \) is a parameter to the optimization problem), and furthermore that the dual variable associated with the equation **optcons** in the optimization problem is one and the same as the variable \( p \) used to define \( H \), the EMP tool automatically creates the following MCP:

\[
\begin{align*}
0 &= \nabla_x \mathcal{L}(x, y, p) \perp x \text{ free} \\
0 &\geq -\nabla_p \mathcal{L}(x, y, p) \perp p \leq 0 \\
0 &= H(x, y, p) \perp y \text{ free},
\end{align*}
\]

where the Lagrangian is defined as

\[
\mathcal{L}(x, y, p) = f(x, y) - \langle p, g(x, y) \rangle.
\]

Essentially, this MCP consists of the first order optimality conditions of the optimization problem, coupled with the VI that is the second agents problem. An example that does both of these things together is provided in EMPLIB as **scarfemp-primal**.

Note that since the PIES model has no \( y \) variables, this is a special case of the general form in which the second agents (VI) problem is simply not present.

Example models are **ferris43**, **flipper pies**, **scarfemp-dual**, **simpequil**, **transecs**, and **transeql**.
4.25.8 MOPECs

MOPECs (Multiple Optimization Problems with Equilibrium Constraints) are a simple conceptual extension of the aforementioned embedded complementarity system. Instead of having a single optimizing agent and a variational inequality, one instead allows multiple optimizing agents coupled with an equilibrium constraint (the variational inequality).

Perhaps the most popular use of this formulation is where competition is allowed between agents. A standard method to deal with such cases is via the concept of Nash Games. In this setting $x^\ast$ is a Nash Equilibrium if

$$
x^\ast_i \in \arg \min_{x_i \in X_i} f_i(x_i, x^\ast_{-i}, q), \forall i \in I,
$$

where $x_{-i}$ are other players decisions and the quantities $q$ are given exogenously, or via complementarity:

$$
0 \leq H(x, q) \perp q \geq 0.
$$

This mechanism is extremely popular in economics, and Nash famously won the Nobel Prize for his contributions to this literature.

This format is again an EMP, more general than the example given above in two respects. Firstly, there is more than one optimization problem specified in the embedded complementarity system. Secondly, the parameters in each optimization problem consist of two types. Firstly, there are the variables $q$ that are tied down by the auxiliary complementarity condition and hence are treated as parameters by the $i$th Nash player. Also there are the variables $x_{-i}$ that are treated as parameters by the $i$th Nash player, but are treated as variables by a different player $j$.

While we do not specify the syntax here for these issues, EMPLIB provides examples that outline how to carry out this matching within GAMS. Finally, two points of note: first it is clear that the resulting model is a complementarity problem and can be solved using PATH, for example. Secondly, performing the conversion from an embedded complementarity system or a Nash Game automatically is a critical step in making such models practically useful.

We note that there is a large literature on discrete-time finite-state stochastic games: this has become a central tool in analysis of strategic interactions among forward-looking players in dynamic environments. The model of dynamic competition in an oligopolistic industry given in [78] is exactly in the format described above, and has been used extensively in applications such as advertising, collusion, mergers, technology adoption, international trade and finance. Ongoing work aims to use the EMP format to model these problems.

4.25.9 Extended Nonlinear Programs

Optimization models have traditionally been of the form (NLP). Specialized codes have allowed certain problem structures to be exploited algorithmically, for example simple bounds on variables. However, for the most part, assumptions of smoothness of $f$, $g$ and $h$ are required for many solvers to process these problems effectively. In a series of papers, Rockafellar and colleagues [201] [202] [203] have introduced the notion of extended nonlinear programming, where the (primal) problem has the form:

$$
\min_{x \in X} f(x) + \theta(g_1(x), \ldots, g_m(x)). \quad (\text{ENLP})
$$

In this setting, $X$ is assumed to be a nonempty polyhedral set, and the functions $f, g_1, \ldots, g_m$ are smooth. The function $\theta$ can be thought of as a generalized penalty function that may well be nonsmooth. However, when $\theta$ has the form

$$
\theta(u) = \sup_{y \in Y} \{ (y, u) - k(y) \}, \quad (\theta \text{ conj})
$$

a computationally exploitable and theoretically powerful framework can be developed based on conjugate
duality. A key point for computation and modeling is that the function $\theta$ can be fully described by defining
the set $Y$ and the function $k$. Furthermore, from a modeling perspective, an extended nonlinear program
can be specified simply by defining the functions $f, g_1, \ldots, g_m$ in the manner already provided by the
modeling system, with the additional issue of simply defining $Y$ and $k$. Conceptually, this is not much
harder than what is carried out already, but leads to significant enhancements to the types of models that
are available. Once a modeler determines which constraints are treated via which choice of $k$ and $Y$, the
EMP model interface automatically forms an equivalent variational inequality or complementarity problem.
As we show later, there may be alternative formulations that are computationally more appealing; such
reformulations can be generated using different options to JAMS.

4.25.9.1 Forms of theta

The EMP model type makes the problem format (ENLP) available to users in GAMS. As special cases,
we can model piecewise linear penalties, least squares, and $L_1$ approximation problems, as well as the
notion of soft and hard constraints.

For ease of exposition, we now describe a subset of the types of functions $\theta$ that can be generated by
particular choices of $Y$ and $k$. In many cases, the function $\theta$ is separable, that is

$$\theta(u) = \sum_{i=1}^{m} \theta_i(u_i),$$

so we can either specify $\theta_i$ or $\theta$ itself.

Extended nonlinear programs include the classical nonlinear programming form (NLP) as a special case.
This follows from the observation that if $K$ is a closed convex cone, and we let $\psi_K$ denote the “indicator
function” of $K$ defined by:

$$\psi_K(u) = \begin{cases} 0 & \text{if } u \in K, \\ \infty & \text{else}, \end{cases}$$

then (NLP) can be rewritten as:

$$\min_x f(x) + \psi_K((g(x), h(x))), \quad K = \mathbb{R}_m^m \times \{0\}^p,$$

where $m$ and $p$ are the dimensions of $g$ and $h$ respectively and $\mathbb{R}_m^m = \{u \in \mathbb{R}^m | u \leq 0\}$. An elementary
calculation shows that

$$\psi_K(u) = \sup_{v \in K^\circ} \langle u, v \rangle,$$

where $K^\circ = \{u \mid \langle u, v \rangle \leq 0, \forall v \in K\}$ is the polar cone of the given cone $K$. Thus, when $\theta(u) = \psi_K(u)$ we
simply take $k \equiv 0$ and $Y = K^\circ$. In our example, $K^\circ = \mathbb{R}_m^m \times \mathbb{R}^p$. To some extent, this is just a formalism
that allows us to claim the classical case as a specialization; however when we take the cone $K$ to be more
general than the polyhedral cone used above, we can generate conic programs for example.

The second example involves a piecewise linear function $\theta$: Formally, for $u \in \mathbb{R}$,

$$\theta(u) = \begin{cases} \rho u & \text{if } u \geq 0, \\ \sigma u & \text{else}. \end{cases}$$

In this case, simple calculations prove that $\theta$ has the form $(\theta \text{ conj})$ for the choices

$$k \equiv 0 \text{ and } Y = [\sigma, \rho].$$

The special case where $\sigma = -\rho$ results in

$$\theta(u) = \rho |u| .$$

This allows us to model nonsmooth $L_1$ approximation problems. Another special case results from the
choice of $\sigma = -\gamma$, $\rho = 0$, whereby

$$\theta(u) = \gamma \max\{-u, 0\} .$$
This formulation corresponds to a soft penalization on an inequality constraint, namely if \( \theta(-g_1(x)) \) is used then nothing is added to the objective function if \( g_1(x) \leq 0 \), but \( \gamma g_1(x) \) is added if the constraint \( g_1(x) \leq 0 \) is violated. Contrast this to the classical setting above, where \( \infty \) is added to the objective if the inequality constraint is violated. It is interesting to see that truncating the set \( Y \), which amounts to bounding the multipliers, results in replacing the classical constraint by a linearized penalty.

The third example involves a more interesting choice of \( k \). If we wish to replace the "absolute value" penalization given above by a quadratic penalization (as in classical least squares analysis), that is
\[
\theta(u) = \gamma u^2
\]
then a simple calculation shows that we should take
\[
k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = \mathbb{R}.
\]
By simply specifying this different choice of \( k \) and \( Y \) we can generate such models easily and quickly within the modeling system. Note, however, that the reformulation we would use in \( \theta(u) = \rho |u| \) and \( \theta(u) = \gamma u^2 \) are very different as we shall explain in the simple example below. Furthermore, in many applications it has become popular to penalize violations using a quadratic penalty only within a certain interval, afterwards switching to a linear penalty (chosen to make the penalty function \( \theta \) continuously differentiable - see [129] ). That is:
\[
\theta(u) = \begin{cases} 
\gamma u - \frac{1}{2} \gamma^2 & \text{if } u \geq \gamma \\
\frac{1}{2} u^2 & \text{if } u \in [-\gamma, \gamma] \\
-\gamma u - \frac{1}{2} \gamma^2 & \text{else.}
\end{cases}
\]
Such functions arise from quadratic \( k \) and simple bound sets \( Y \). In particular, the somewhat more general function
\[
\theta(u) = \begin{cases} 
\gamma \beta^2 + \rho(u - \beta) & \text{if } u \geq \beta \\
\gamma u^2 & \text{if } u \in [\alpha, \beta] \\
\gamma \alpha^2 + \sigma(u - \alpha) & \text{else}
\end{cases}
\]
arises from the choice of
\[
k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = [\sigma, \rho],
\]
with \( \alpha = \frac{\sigma}{2\gamma} \) and \( \beta = \frac{\rho}{2\gamma} \).

The final example that we give is that of \( L_\infty \) penalization. This example is different to the examples given above in that \( \theta \) is not separable. However, straightforward calculation can be used to show
\[
\theta(u) = \max_{i=1,\ldots,m} u_i
\]
results from the choice of
\[
k \equiv 0 \text{ and } Y = \left\{ y \in \mathbb{R}^m \mid y \geq 0, \sum_{i=1}^m y_i = 1 \right\},
\]
that is, \( Y \) is the unit simplex.

### 4.25.9.2 Underlying theory

The underlying structure of \( \theta \) leads to a set of extended optimality conditions and an elegant duality theory. This is based on an extended form of the Lagrangian:
\[
\mathcal{L}(x, y) = f(x) + \sum_{i=1}^m y_i g_i(x) - k(y)
\]
\[
x \in X, y \in Y
\]
Note that the Lagrangian $\mathcal{L}$ is smooth - all the nonsmoothness is captured in the $\theta$ function. The theory is an elegant combination of calculus arguments related to $g_i$ and its derivatives, and variational analysis for features related to $\theta$.

It is shown in [202] that under a standard constraint qualification, the first-order conditions of (ENLP) are precisely in the form of the following variational inequality:

$$\text{VI} \left( \begin{bmatrix} \nabla_x \mathcal{L}(x,y) \\ -\nabla_y \mathcal{L}(x,y) \end{bmatrix}, X \times Y \right). \quad \text{(ENLP VI)}$$

When $X$ and $Y$ are simple bound sets, this is simply a complementarity problem.

Note that EMP exploits this result. In particular, if an extended nonlinear program of the form (ENLP) is given to EMP, then the optimality conditions (ENLP VI) are formed as a variational inequality problem and can be processed as outlined above. For a specific example, we cite the fact that if we use the (classical) choice $k \equiv 0$ and $Y = K$, then the optimality conditions of (ENLP) are precisely the standard complementarity problem given as (ENLP VI). While this is of interest, we believe that other choices of $k$ and $Y$ may be more useful and lead to models that have more practical significance.

Under appropriate convexity assumptions on this Lagrangian, it can be shown that a solution of the VI (ENLP VI) is a saddle point for the Lagrangian on $X \times Y$. Furthermore, in this setting, the saddle point generates solutions to the primal problem (ENLP) and its dual problem:

$$\max_{y \in Y} d(y), \text{ where } d(y) = \inf_{x \in X} \mathcal{L}(x,y),$$

with no duality gap.

Unfortunately, the perturbations $y$ in Rockafellar's theory are precisely the negative of those used throughout the GAMS system. Thus, we need to replace $y$ by $-y$ throughout in the above to recover the same multipliers as those GAMS uses.

### 4.25.9.3 A simple example

As an example, consider the problem

$$\min_{x_1,x_2,x_3} \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2\max(x_2^2 - 2, 0)$$

s.t. $x_1/x_2 = \log(x_3)$,

$$3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0.$$  

In this problem, we would take

$$X = \{x \in \mathbf{R}^3 \mid 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0\}.$$  

The function $\theta$ essentially treats 3 separable pieces:

$$g_1(x) = \log(x_1) - 1,$$

$$g_2(x) = x_2^2 - 2,$$

$$g_3(x) = x_1/x_2 - \log(x_3).$$  

A classical problem would force $g_1(x) = 0$, $g_2(x) \leq 0$, and $g_3(x) = 0$, while minimizing $f(x) = \exp(x_1)$. In our problem, we still force $g_1(x) = 0$, but apply a (soft) least squares penalty on $g_1(x)$ and a smaller one-sided penalization on $g_2(x)$. The above formulation is nonsmooth due to the "max" term in the objective function; in practice we could replace this by:

$$\min_{x_1,x_2,x_3,w} \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2w$$

s.t. $x_1/x_2 = \log(x_3)$,

$$3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0$$

$$w \geq x_2^2 - 2, w \geq 0.$$
and recover a standard form NLP. If the penalty on \( g_1(x) \) would be replaced by a one-norm penalization (instead of least squares), we would have to play a similar game, moving the function \( g_1(x) \) into the constraints and adding additional variable(s). To some extent, this seems unnatural - a modeler should be able to interchange the penalization without having to reformulate the problem from scratch. The proposed extended NLP would not be reformulated at all by the modeler, but allows all these "generalized constraints" to be treated in a similar manner within the modeling system. The actual formulation would take:

\[
\theta(u) = \theta_1(u_1) + \theta_2(u_2) + \theta_3(u_3)
\]

where

\[
\begin{align*}
\theta_1(u_1) &= 5u_1^2, \\
\theta_2(u_2) &= 2 \max(u_2, 0), \\
\theta_3(u_3) &= \psi(0)(u_3).
\end{align*}
\]

The discussion above allows us to see that

\[
Y = -(\mathbb{R} \times [0,2] \times \mathbb{R}),
\]

\[
k(y) = \frac{1}{20} y_1^2 + 0 + 0.
\]

The corresponding Lagrangian is the smooth function:

\[
\mathcal{L}(x, y) = f(x) - \sum_{i=1}^{3} y_i g_i(x) - k(y).
\]

The corresponding VI (ENLP VI) can almost be formulated in GAMS (except that the linear constraint in \( X \) cannot be handled currently except by introducing a \( \theta_4(x) \)). Thus

\[
g_4(x) = 3x_1 + x_2 - 5, \ \theta_4(u) = \psi_{\mathbb{R}}
\]

resulting in the following choices for \( Y \) and \( k \):

\[
Y = -(\mathbb{R} \times [0,2] \times \mathbb{R} \times \mathbb{R}_+),
\]

\[
k(y) = \frac{1}{20} y_1^2 + 0 + 0 + 0.
\]

Since \( X \) and \( Y \) are now simple bound sets, (ENLP VI) is now a complementarity problem and can be solved for example using PATH. A simple "empinfo" file details the choices of \( Y \) and \( k \) from the implemented library:

```
Adjustequ
e1 sqr 5
  e2 MaxZ 2
```

### 4.25.9.4 Reformulation as a classical NLP

Suppose

\[
\theta(u) = \sup_{y \in Y} \{ (u, y) - \frac{1}{2} (y, Qy) \}
\]

for a polyhedral set \( Y \in \mathbb{R}^m \) and a symmetric positive semidefinite \( Q \in \mathbb{R}^{m \times m} \) (possibly \( Q = 0 \)).

Suppose further that

\[
X = \{ x \mid Rx \leq r \}, Y = \{ y \mid S^T y \leq s \},
\]

\[
Q = DJ^{-1}D^T, \ F(x) = (g_1(x), \ldots, g_m(x)),
\]
where \( J \) is symmetric and positive definite (for instance \( J = I \)). Then, as outlined by [203], the optimal solutions \( \mathbf{x} \) of (ENLP) are the \( \bar{x} \) components of the optimal solutions \( (\bar{x}, \bar{z}, \bar{w}) \) to

\[
\begin{align*}
\min & \quad f(x) + \langle s, z \rangle + \frac{1}{2} \langle w, Jw \rangle \\
\text{s.t.} & \quad Rx \leq r, z \geq 0, F(x) - Sz - Dw = 0.
\end{align*}
\]

The multiplier on the equality constraint in the usual sense is the multiplier associated with \( \bar{x} \) in the extended Lagrangian for (ENLP). (Note that a Cholesky factorization may be needed to determine \( D \).)

It may be better to solve this reformulated NLP than to solve the VI (ENLP VI). However, it is important that we can convey all types of nonsmooth optimization problems to a solver as smooth optimization problems, and hence it is important to communicate the appropriate structure to the solver interface. We believe that specifying \( Y \) and \( k \) is a theoretically sound way to do this.

### 4.25.10 Disjunctive Programs (LogMIP)

There are many ways that the EMP model type can be used for further extensions to the modeling capabilities of a given system. In particular, the procedures outlined in [241] for disjunctive programming extensions are also implemented within the EMP model type.

The disjunctive programming procedures are also known as the LogMIP 2.0 solver for solving linear and nonlinear disjunctive programming problems involving binary variables and disjunction definitions for modeling discrete choices. While the modeling and solution of these disjunctive optimization problems has not yet reached the stage of maturity and reliability as LP, MIP and NLP modeling, these problems have a rich area of applications.

LogMIP 2.0 has been developed by Dr. Aldo Vecchietti from INGAR (Santa Fe, Argentina) and Professor Ignacio E. Grossmann from Carnegie Mellon University (Pittsburgh, USA), and supersedes its previous version, LogMIP 1.0 (GAMS releases 22.6 (December 2007) to 23.6 (December 2010)). Changes in version 2.0 are at the level of language, where now the EMP syntax and modeltype is used, and at the level of solvers, where Big-M and convex-hull relaxations are combined. For more information see the website [http://www.logmip.ceride.gov.ar/](http://www.logmip.ceride.gov.ar/) and the documentation [http://www.logmip.ceride.gov.ar/files/pdfs/newUserManual.pdf](http://www.logmip.ceride.gov.ar/files/pdfs/newUserManual.pdf).

One simple example to highlight the disjunctive programming feature is the notion of an ordering of tasks, namely that either job \( i \) completes before job \( j \) starts or the converse, i.e., that the jobs cannot overlap. Such a disjunction can be specified using an empinfo file containing lines:

```plaintext
disjunction * seq(i,j) else seq(j,i)
```

In such an example, one can implement a Big-M method, employ indicator constraints, or utilize a convex hull reformulation. The convex hull reformulation is the default strategy; to utilize the Big-M formulation, the additional option

```
default bigm 1000
```

would add binary variables and constraints to impose the disjunction using a Big-M value of 1000. Alternatively, the option setting

```
default indic
```

writes out a model and an option file that implements a reformulation using indicator constraints, which can be handled by the solvers CPLEX, SCIP, and XPRESS. The EMPLIB model `sequence` is sequencing model that implements all of these options.

More complicated (nonlinear) examples make the utility of this approach clearer. The design of a multiproduct batch plan with intermediate storage described in [240] and a synthesis problem involving 8 processes from [237] are also included in the EMP model library. As a final example, the gasoline emission model outlined in [100] is precisely in the form that could exploit the features of EMP related to (nonlinear) disjunctive programming.
4.25.11 Empinfo file details

We have explained above many of the standard vectorized ways to write an "empinfo" file. The "empinfo" file has a vectorized format and a more powerful (but more complex) scalar version. We describe some of the features of the scalar version in this section.

An example of the use of the scalar syntax is given below:

```plaintext
file info / '%emp.info%' /;
put info / 'equilibrium';
loop(h,
   put / 'min' obj(h) /;
   loop(j, put x(h,j)); put /;
   loop(k, put z(h,k));
   put / costdef(h) /;
   loop(i, put nodebal(h,i)); put /;
);
loop(a, put 'vi',flowdef(a),f(a) /);
```

This is an example of a MOPEC in which the optimization agents are indexed by \( h \) and each of these agents control variables \( x_{hj} \) and \( z_{hk} \). The objective function for each \( h \) is defined in `costdef`, the constraints of each minimization problem are defined in `nodebal`, and the equilibrium constraints that link all the optimization problems are a VI defined by variables \( f_a \) and functions within `flowdef`. Sometimes it is necessary to use syntax that generates the "tl" fields of sets, but this seems only necessary when abnormal side conditions are needed.

The format of the empinfo file is given below:

```
Disjunction [chull [big eps] | bigM [big eps threshold] | indic]
   [NOT] var|* [NOT] {equ} {ELSEIF [NOT] var|* [NOT] {equ}} [ELSE [NOT] {equ}]
Default [chull [big eps] | bigM [big eps threshold] | indic]
ParallelStep1 {equ}*;
AdjustEqu equ abs|sqr|maxz|... {weight}
ModelType MCP|NLP|MIP|...
BiLevel {var} {MAX|MIN obj {var}*} {[-] equ} {VI {var}*} {[-] equ var} {[-] equ}
   {DualVar {var [-] equ}}
Equilibrium {Implicit {var equ}} {VIsol {equ}}
   {MAX|MIN obj {var}*} {[-] equ} {VI {var}*} {[-] equ var} {[-] equ}
   {DualVar {var [-] equ}}
VI {var}*} {[-] equ var} {[-] equ}
DualEqu {[ -] equ var}
DualVar {var [-] equ}
```

4.26 KESTREL - Remote Solver Execution on NEOS Servers

4.26.1 Background

The Kestrel client/server is a way of sending your GAMS solve job to be solved via the NEOS Server from within your usual GAMS modeling environment and receiving results that can be processed as with any local solver. Starting with distribution 23.7 the Kestrel solver is part of the GAMS distribution. The solve statement using the GAMS/KESTREL solver invokes a client program that sends your problem to a solver running on one of the NEOS Server's remote computers. The results from the NEOS Server are eventually returned through Kestrel to GAMS, where you can view and manipulate them locally in the usual way. The introduction below covers everything you need to know to start using GAMS/KESTREL. Further information about more advanced features and other uses of Kestrel can be found at the Kestrel page on the NEOS Server. Note that GAMS/Kestrel requires a Python 2 installation on platforms other than Windows. The interpreter executable (python2) needs to be found in the PATH environment variable.

4.26.1.1 Kestrel and IBM DOcloud

With GAMS 24.6 the GAMS/Kestrel client has been adjusted to work with IBM's cloud service Decision Optimization on Cloud (DOcloud). When the Kestrel option doclouduri is set, the generated model instance will be automatically translated into an MPS format and send to DOcloud and solved by Cplex in IBM's cloud. So no GAMS/Cplex license is required on your local machine. You as a user need to register with IBM on the web page mentioned about and pay IBM for the solution time spend in IBM's cloud. IBM provides details how to get started with DOcloud.

4.26.2 Using GAMS/KESTREL

The Kestrel solver can be used to solve a GAMS model remotely. For example, consider the trnsport model. It can be solved locally in GAMS through the following statements,

```
model transport /all/;
solve transport using lp minimizing z;
```

which specify the trnsport model and solve it with the default linear programming solver. We can add an option statement to the code to explicitly specify the solver. For example, if we change the linear programming solver to GAMS/MINOS, the code becomes

```
model transport /all/;
option lp=minos;
solve transport using lp minimizing z;
```

To solve the same problem remotely through the NEOS Server, we simply change the linear programming solver to Kestrel. Without an option file Kestrel will submit the model instance to the NEOS server and use the default LP solver on NEOS.

```
option lp=kestrel;
solve transport using lp minimizing z;
```

We can support a Kestrel option file and determine the solver on the NEOS server:
transport.optfile=1;
option lp=kestrel;
solve transport using lp minimizing z;
$echo kestrel_solver minos > kestrel.opt

The statement transport.optfile=1 specifies that an options file, called kestrel.opt, will be used. The options file contains the remote solver name as well as any options for the remote solver. We instruct the Kestrel solver to use GAMS/MINOS as the remote solver by writing the following kestrel.opt file:

kestrel_solver minos

If you do not know what solvers are available via GAMS/KESTREL on NEOS, submitting a job with a nonexistent solver set will return a list of enabled solvers. If you want to change the URL of the server, you can specify the option neos_server. The complete format of the parameter is protocol://host:port.

A subsequent run of the code through the GAMS interpreter results in the transport model being solved through the NEOS Server with the GAMS/MINOS solver. Once the job is submitted to the NEOS Server, a job number, password, and Web address are displayed to the screen, which provide information on accessing the job and viewing the intermediate output, for example,

--- Executing KESTREL
Job has been submitted to Kestrel
Kestrel/NEOS Job number : 93478
Kestrel/NEOS Job password : utiwtxTK
Check the following URL for progress report :
https://neos-server.org/neos/cgi-bin/nph-neos-solver.cgi?admin=results&jobnumber=93478&pass=utiwtxTK

To look at the solver's output while it is running, point your browser at the URL given in the Kestrel output as shown above, and click on View Intermediate Results in the web page that appears. This will take you to another page that shows all of the output produced by the solver for your problem so far. To track the solver's progress, simply update this page periodically.

If the NEOS Server or the network becomes unavailable after the submission, a particular job can be retrieved by setting both the kestrel job and kestrel password in the options file.

kestrel_solver minos
kestrel_job 93478
kestrel_password utiwtxTK

Re-issuing the command gams transport with this options file will retrieve the results for the specified job number.

By specifying neos_username and neos_user_password in the option file, you can submit an authenticated job using your NEOS user account. Authenticated jobs will appear in your user account on the NEOS website.

neos_username username
neos_user_password password
4.26.2.1 Using GAMS/Kestrel with IBM DOcloud

In order to use GAMS/Kestrel to solve model instances with Cplex on IBM's DOcloud, the only thing that needs to be done is to provide a different option file. The option `docloud_url` triggers the submission to IBM's DOcloud rather than NEOS. You need an account on DOcloud (and pay IBM for the Cplex solution time in their cloud). Some additional account information needs to be specified in the Kestrel option `docloud_key`. The use of Cplex in DOcloud is limited to solve a model instance, special options that are available in the GAMS/Cplex system, like IIS or FeasOpt cannot be used (yet) through Kestrel/DOcloud. Moreover, for problems with discrete variables, only the primal solution is returned. If you want to specify Cplex options this needs to be done with a Cplex parameter file which is quite different from the GAMS/Cplex option file. You can use a GAMS/Cplex option file and have the additional option `WriteParam` to produce such a Cplex parameter file. The Cplex parameter file might have a few more options compared to the GAMS/Cplex option file because some GAMS options set Cplex parameters. Please note that you can produce the Cplex parameter file with GAMS/Cplex even if you do not have a license for GAMS/Cplex as long as you run a demo sized model (e.g. from the GAMS Model Library) to produce the Cplex parameter file. The following GAMS/Cplex optfile

```gams
lpmethod 4
advind 0
eprhs 1e-4
scaind 1
writeparam cplex.prm
```

produces the Cplex parameter file `cplex.prm` which can be submitted to Kestrel/DOcloud via the option `docloud_prmfile`:

```plaintext
CPLEX Parameter File Version 12.6.3.0
CPX_PARAM_ADVIND 0
CPX_PARAM_EPRHS 1.00000000000000e-04
CPX_PARAM_SINDDISPLAY 2
CPX_PARAM_SCAIND 1
CPX_PARAM_TILIM 1.00000000000000e+03
CPX_PARAM_LPMETHOD 4
CPX_PARAM_THREADS 1
CPX_PARAM_PARALLELMODE 1
```

Users of GAMS/Kestrel on platforms other than Windows will need to install the GAMS Python API and the IBM DOcloud Python package.

4.27 KNITRO

4.27.1 Introduction

Artelys Knitro is a software package for finding local solutions of both continuous (i.e. smooth) optimization problems, with or without constraints, and discrete optimization problems with integer or binary variables. Even though Knitro has been designed for solving large-scale general problems, it is efficient for solving all of the following classes of optimization problems:

- unconstrained,
- bound constrained,
equal constrained,
- systems of nonlinear equations,
- least squares problems,
- linear programming problems (LPs),
- quadratic programming problems (QPs),
- general (inequality) constrained problems,
- (convex) mixed integer nonlinear programs (MINLP) of moderate size.

The Knitro package provides the following features:

- Efficient and robust solution of small or large problems,
- Solvers for both continuous and discrete problems,
- Derivative-free, 1st derivative and 2nd derivative options,
- Both interior-point (barrier) and active-set optimizers,
- Both feasible and infeasible versions,
- Both iterative and direct approaches for computing steps,

The problems solved by Knitro have the form

\[
\begin{align*}
\text{minimize} & \quad f(x) \\
\text{subject to} & \quad c^L \leq c(x) \leq c^U \quad (1a) \\
& \quad b^L \leq x \leq b^U \quad (1b)
\end{align*}
\]

where the variables \( x \) can be continuous, binary, or integer. This allows many forms of constraints, including bounds on the variables. Knitro requires that the functions \( f(x) \) and \( c(x) \) be smooth functions.

Knitro implements both state-of-the-art interior-point and active-set methods for solving nonlinear optimization problems. In the interior method (also known as a barrier method), the nonlinear programming problem is replaced by a series of barrier sub-problems controlled by a barrier parameter \( \mu \). The algorithm uses trust regions and a merit function to promote convergence. The algorithm performs one or more minimization steps on each barrier problem, then decreases the barrier parameter, and repeats the process until the original problem (1) has been solved to the desired accuracy.

Knitro provides two procedures for computing the steps within the interior point approach. In the version known as \texttt{Interior/CG} each step is computed using a projected conjugate gradient iteration. This approach differs from most interior methods proposed in the literature in that it does not compute each step by solving a linear system involving the KKT (or primal-dual) matrix. Instead, it factors a projection matrix, and uses the conjugate gradient method, to approximately minimize a quadratic model of the barrier problem.

The second procedure for computing the steps, which we call \texttt{Interior/Direct}, always attempts to compute a new iterate by solving the primal-dual KKT matrix using direct linear algebra. In the case when this step cannot be guaranteed to be of good quality, or if negative curvature is detected, then the new iterate is computed by the \texttt{Interior/CG} procedure.

Knitro also implements an active-set sequential linear-quadratic programming (SLQP) algorithm which we call \texttt{Active}. This method is similar in nature to a sequential quadratic programming method but uses linear programming sub-problems to estimate the active-set at each iteration. This active-set code may
be preferable when a good initial point can be provided, for example, when solving a sequence of related problems.

For problems with discrete variables, Knitro provides two variants of the branch and bound algorithm. The first is a standard implementation, while the second is specialized for convex, mixed-integer nonlinear problems.

We encourage the user to try all algorithmic options to determine which one is more suitable for the application at hand. For guidance on choosing the best algorithm see section Algorithm Options.

For a detailed description of the algorithm implemented in Interior/CG see [50] and for the global convergence theory see [51]. The method implemented in Interior/Direct is described in [250]. The Active algorithm is described in [53] and the global convergence theory for this algorithm is in [54]. An important component of Knitro is the HSL routine MA27 [120] which is used to solve the linear systems arising at every iteration of the algorithm. In addition, the Active Set algorithm in Knitro may make use of the COIN-OR Clp linear programming solver module. The version used in Knitro may be downloaded from http://www.artelys.com/tools/clp/.

4.27.2 Usage

Basic details of solver usage, including how to choose Knitro as the solver and how to use a solver-specific option file, are part of Chapter Solver Usage.

As an NLP solver, Knitro can also be used to solve linear programs (LP), and both convex and nonconvex quadratic programs (QCP).

4.27.3 GAMS Options

The following GAMS options are used by the GAMS/Knitro link:

- Option ResLim = x;
  Sets the time limit in seconds. If this limit is exceeded the solver will terminate and pass on the current solution to GAMS. See also reslim in section GAMS options.

- Option SysOut = On;
  This option sends additional Knitro messages to the GAMS listing file. It is useful in case of a solver failure or to get algorithmic details. See also sysout in section GAMS options.

- ModelName.optCA = x;
  Absolute gap stop criterion for a discrete problem. The Knitro option mip.integral_gap_abs takes its default from this value. See also optca in section GAMS options.

- ModelName.optCR = x;
  Relative gap stop criterion for a discrete problem. The Knitro option mip.integral_gap_rel takes its default from this value. See also optcr in section GAMS options.

4.27.4 Summary of Knitro Options

The Knitro options file knitro.opt allows the user to easily set options controlling Knitro’s behavior. Options are set by specifying a keyword and a corresponding value on a line in the knitro.opt file. Lines that begin with a # character are treated as comments and blank lines are ignored. For example, to set the maximum allowable number of iterations to 500, one could use the following options file:

4.27.4.1 Barrier options
### 4.27 KNITRO

<table>
<thead>
<tr>
<th>Option</th>

<td>active-set CG method</td>
</tr>
<tr>
<td>4</td>
<td>active-set SQP method</td>
</tr>
<tr>
<td>5</td>
<td>multi-method, perhaps in parallel</td>
</tr>
</tbody>
</table>
**bar_directinterval** (integer): limit on consecutive CG steps before Knitro will try to force a direct linear algebra step

- **Range:** $[0, \infty)$
- **Default:** 10

**bar_feasible** (integer): specifies whether special emphasis is placed on getting and staying feasible

Indicates whether or not to use the feasible version of Knitro.

**NOTE:** This option can be used only with the Interior/CG and Interior/Direct algorithms, i.e. when `algorithm=2` or `algorithm=3`. See section Feasible version for more details.

Options 1 and 3 above activate the feasible version of KNITRO. Given an initial point which sufficiently satisfies all inequality constraints as defined by,

$$cl + tol \leq c(x) \leq cu - tol$$  \hspace{1cm} (4.15)

(for $cl \neq cu$), the feasible version of Knitro ensures that all subsequent solution estimates strictly satisfy the *inequality* constraints. However, the iterates may not be feasible with respect to the *equality* constraints. The tolerance $tol > 0$ in (2) for determining when the feasible mode is active is determined by the double precision parameter `bar_feasmodetol` described below. This tolerance (i.e. `bar_feasmodetol`) must be strictly positive. That is, in order to enter feasible mode, the point given to Knitro must be strictly feasible with respect to the inequality constraints.

If the initial point is infeasible (or not sufficiently feasible according to (2)) with respect to the *inequality* constraints, then Knitro will run the infeasible version until a point is obtained which sufficiently satisfies all the *inequality* constraints. At this point it will switch to feasible mode.

**Default:** 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No special emphasis on feasibility</td>
</tr>
<tr>
<td>1</td>
<td>Iterates must satisfy inequality cons once they become sufficiently feasible</td>
</tr>
<tr>
<td>2</td>
<td>Special emphasis is placed on getting feasible before trying to optimize</td>
</tr>
<tr>
<td>3</td>
<td>Implement both options 1 and 2 above</td>
</tr>
</tbody>
</table>

**bar_feasmodetol** (real): tolerance for activation of `bar_feasible` mode

Specifies the tolerance in (2) by which the iterate must be feasible with respect to the inequality constraints before the feasible mode becomes active. This option is only relevant when `feasible=1`.

- **Default:** $1e^{-4}$

**bar_initmu** (real): initial barrier parameter value

Specifies the initial value for the barrier parameter $\mu$.

- **Default:** $1e^{-1}$

**bar_initpt** (integer): initial point strategy for barrier algorithms

Indicates whether an initial point strategy is used.

- **Default:** 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>let KNITRO choose the initial point strategy</td>
</tr>
<tr>
<td>1</td>
<td>initialization strategy 1</td>
</tr>
<tr>
<td>2</td>
<td>initialization strategy 2</td>
</tr>
<tr>
<td>3</td>
<td>initialization strategy 3</td>
</tr>
</tbody>
</table>

**bar_maxbacktrack** *(integer)*: limit on backtracks during the linesearch of the Interior/Direct algorithm

Indicates the maximum allowable number of backtracks during the linesearch of the Interior/Direct algorithm before reverting to a CG step.

Increasing this value will make the Interior/Direct algorithm less likely to take CG steps. If the Interior/Direct algorithm is taking a large number of CG steps (as indicated by a positive value for “CGits” in the output), this may improve performance. This option has no effect on the Active Set algorithm.

Default: 3

**bar_maxcrossit** *(integer)*: limit on crossover iterations

Specifies the maximum number of crossover iterations before termination. If the value is positive, then KNITRO will crossover from the barrier to the Active Set algorithm near the solution. The Active Set algorithm will then perform at most n iterations to get a more exact solution. If the value is 0, no Active Set crossover occurs and the interior-point solution is the final result.

If Active Set crossover is unable to improve the approximate interior-point solution, then KNITRO will restore the interior-point solution. In some cases (especially on large-scale problems or difficult degenerate problems) the cost of the crossover procedure may be significant - for this reason, crossover is disabled by default. Enabling crossover generally provides a more accurate solution than Interior/Direct or Interior/CG.

Default: 0

**bar_maxrefactor** *(integer)*: limit on KKT refactorizations per iteration of the Interior/Direct algorithm

Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step. If this value is set to -1, it will use a dynamic strategy.

These refactorizations are performed if negative curvature is detected in the model. Rather than reverting to a CG step, the Hessian matrix is modified in an attempt to make the subproblem convex and then the KKT system is refactorized. Increasing this value will make the Interior/Direct algorithm less likely to take CG steps. If the Interior/Direct algorithm is taking a large number of CG steps (as indicated by a positive value for “CGits” in the output), this may improve performance. This option has no effect on the Active Set algorithm.

Range: \([-1, \infty]\)

Default: *auto*

**bar_murule** *(integer)*: controls the barrier parameter update strategy

**NOTE**: Only strategies 0-2 are available for the Interior/CG algorithm. All strategies are available for the Interior/Direct algorithm. Strategies 4 and 5 are typically recommended for linear programs or convex quadratic programs.

Default: 0
bar_pencons (integer): controls whether a penalty approach is applied to the constraints

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>automatic</td>
</tr>
<tr>
<td>1</td>
<td>no constraints are penalized</td>
</tr>
<tr>
<td>2</td>
<td>a penalty approach is applied to all general constraints</td>
</tr>
</tbody>
</table>

bar_penrule (integer): controls penalty parameter strategy used to accept a trial iterate

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

</tr>
<tr>
<td>2</td>
<td>use a more tolerant and flexible step acceptance procedure</td>
</tr>
</tbody>
</table>

bar_refinement (boolean): toggles barrier solution refinement method

Default: 0

bar_relaxcons (integer): controls application of a relaxation approach to the constraints

Using a relaxation approach may be helpful when the problem has degenerate or difficult constraints. This option has no effect on the Active Set algorithm.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no constraints are relaxed</td>
</tr>
<tr>
<td>1</td>
<td>general equality constraints are relaxed</td>
</tr>
<tr>

<tr>
<td>3</td>
<td>all general constraints are relaxed</td>
</tr>
</tbody>
</table>

bar_switchrule (integer): controls switch to new feasibility-only phase

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**NOTE:** The feasibility-only phase is new in Knitro 8.0. To get the behavior of older Knitro versions, choose strategy 1 (never switch).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>automatic</td>
</tr>
<tr>
<td>1</td>
<td>never switch to feasibility phase</td>

</tr>
<tr>
<td>3</td>
<td>more aggressive switches to feasibility phase</td>
</tr>
</tbody>
</table>

**bar_watchdog (boolean):** toggles watchdog heuristic for barrier algorithms

In general, enabling the watchdog heuristic makes the barrier algorithms more likely to accept trial points. Specifically, the watchdog heuristic may occasionally accept trial points that increase the merit function, provided that subsequent iterates decrease the merit function.

Default: 0

**blasoption (integer):** specifies the BLAS/LAPACK function library to use for basic vector and matrix computations

BLAS and LAPACK functions from the Intel Math Kernel Library (MKL) are provided with the Knitro solver. The MKL is available for Windows, Linux, and Mac OS X; it is not available for Solaris. The number of threads to use for the MKL BLAS are specified via the `par_blasnumthreads` option.

BLAS (Basic Linear Algebra Subroutines) and LAPACK (Linear Algebra PACKage) functions are used throughout Knitro for fundamental vector and matrix calculations. Some optimization problems are observed to spend very little CPU time in BLAS/LAPACK operations, while others spend more than 50% there. Be aware that the different implementations can return slightly different results. Thus, changing the value of `blasoption` can alter the iterates generated by Knitro, or even the final solution point.

Setting `blasoption=0` (the Knitro option) uses built-in BLAS/LAPACK functions based on standard netlib routines (www.netlib.org). The Intel option `blasoption=1` uses MKL functions written especially for x86 and x86_64 processor architectures. On a machine running an Intel processor (e.g., Pentium 4), testing indicates that the MKL functions can significantly reduce the CPU time in BLAS/LAPACK operations.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>use Knitro built-in functions</td>
</tr>
<tr>
<td>1</td>
<td>use Intel MKL functions on supported platforms</td>

</tbody>
</table>

**datacheck (boolean):** toggles KNITRO check for structural errors in problem input

Default: 0

**delta (real):** initial trust region radius scaling factor

Specifies the initial trust region radius scaling factor used to determine the initial trust region size.

Default: 1e-0
**feastol** *(real)*: relative feasibility error tolerance

Specifies the final relative stopping tolerance for the feasibility error. Smaller values of *feastol* result in a higher degree of accuracy in the solution with respect to feasibility.

Default: 1e-6

**feastolabs** *(real)*: absolute feasibility error tolerance

Synonym: *feastol_abs*

Specifies the final absolute stopping tolerance for the feasibility error. Smaller values of *feastolabs* result in a higher degree of accuracy in the solution with respect to feasibility.

Default: 1.0e-3

**fstopval** *(real)*: custom stopping condition on objective value

Knitro will stop and declare that a satisfactory solution was found if a feasible objective function value at least as good as *fstopval* is achieved.

Default: none

**ftol** *(real)*: control termination based on successive small objective changes

The optimization process will terminate if the relative change in the objective function is less than *ftol* for *ftol_iters* consecutive iterations.

Range: [0, ∞]

Default: 1e-15

**ftol_iters** *(integer)*: control termination based on successive small objective changes

The optimization process will terminate if the relative change in the objective function is less than *ftol* for *ftol_iters* consecutive iterations.

Range: [1, ∞]

Default: 5

**gradopt** *(integer)*: controls gradient computation

Specifies how to compute the gradients of the objective and constraint functions.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>use exact gradients computed by GAMS</td>
</tr>
<tr>
<td>2</td>
<td>KNITRO computes gradients by forward finite differences</td>
</tr>
<tr>
<td>3</td>
<td>KNITRO computes gradients by central finite differences</td>
</tr>
</tbody>
</table>

**hessopt** *(integer)*: controls Hessian computation

Specifies how to compute the (approximate) Hessian of the Lagrangian.
NOTE: In nearly all cases it is strongly recommended to use the exact Hessian option (option 1) or the exact Hessian-vector product option (option 5).

If exact Hessians (or exact Hessian-vector products) are not efficient to compute but exact gradients are provided and are not too expensive to compute, option 4 above is typically recommended. The finite-difference Hessian-vector option is comparable in terms of robustness to the exact Hessian option (assuming exact gradients are provided) and typically not too much slower in terms of time if gradient evaluations are not the dominant cost.

In the event that the exact Hessian (or Hessian-vector products) are too expensive to compute, multiple quasi-Newton options which internally approximate the Hessian matrix using first derivative information are provided. Options 2 and 3 are only recommended for small problems (n < 1000) since they require working with a dense Hessian approximation. Option 6 should be used in the large-scale case.

NOTE: Options hessopt= and hessopt=5 are not available when algorithm=1. See section "Second derivative options" for more detail on second derivative options.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>use exact Hessians computed by GAMS</td>
</tr>
<tr>

<td>use a limited-memory quasi-Newton BFGS Hessian</td>
</tr>
</tbody>
</table>

honorbnds (integer): maintain feasibility of intermediate iterates w.r.t. variable bounds ←

Indicates whether or not to enforce satisfaction of the simple bounds (1c) throughout the optimization (see section Honor Bounds).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>does not enforce that the bounds on the variables are satisfied at intermediate iterates</td>
</tr>
<tr>

</tr>
<tr>
<td>2</td>
<td>enforces that the initial point satisfies the bounds on the variables</td>
</tr>
</tbody>
</table>

infeastol (real): controls relative tolerance for declaring a model infeasible ←

Smaller values make it more difficult to satisfy the conditions Knitro uses for detecting infeasible models. If you believe Knitro incorrectly declares a model to be infeasible, you should try a smaller value for infeastol.

Default: 1e-8

lin solver (integer): controls which linear system solver to use ←

Indicates which linear solver to use to solve linear systems arising in KNITRO algorithms.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>automatic: based on problem characteristics</td>

</tr>
<tr>
<td>8</td>
<td>MA86: use the HSL MA86 (parallel, non-deterministic) sparse symmetric indefinite solver</td>
</tr>
</tbody>
</table>

**linsolver_ooc** *(integer)*: controls out-of-core behavior for MKL PARDISO

Indicates whether to use out-of-core solve of linear systems when using Intel MKL PARDISO as the linear solver. N.B.: this option is only active when linsolver=6.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no: do not use MKL PARDISO out-of-core option</td>
</tr>
<tr>

<td>automatic: MKL PARDISO decides whether to use out-of-core option</td>
</tr>
<tr>
<td>2</td>
<td>yes: do use MKL PARDISO out-of-core option</td>
</tr>
</tbody>
</table>

**lmsize** *(integer)*: controls number of limited-memory pairs stored for quasi-Newton BFGS

Specifies the number of limited-memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option *(hessopt=6)*. Larger values may give a more accurate, but more expensive, Hessian approximation. Smaller values may give a less accurate, but faster, Hessian approximation. When using the limited memory BFGS approach it is recommended to experiment with different values of this parameter.

Range: \([1, 100]\]

Default: 10

**maxcgit** *(integer)*: limit on inner CG iterations per minor iteration

Specifies the maximum allowable number of inner conjugate gradient (CG) iterations per KNITRO minor iteration.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>upper bound determined automatically</td>

</tr>
</tbody>
</table>

**maxtime_cpu** (real): CPU time limit \( \leftarrow \)

Specifies the CPU time limit, in seconds.

Default: \( 1e8 \)

**maxtime_real** (real): real or wall-clock time limit \( \leftarrow \)

Specifies the real or wall-clock time limit, in seconds.

Default: \( 1e8 \)

**ma_maxtime_cpu** (real): cumulative CPU time limit for multi-algorithm method \( \leftarrow \)

Default: \( 1e8 \)

**ma_maxtime_real** (real): cumulative real or wall-clock time limit for multi-algorithm method \( \leftarrow \)

Default: \( 1e8 \)

**maTerminate** (integer): condition for terminating the multi-algorithm method \( \leftarrow \)

Default: 1

<table>
<thead>
<tr>
<th>value</th>

<td>use strong branching</td>
</tr>
</tbody>
</table>

**mip_gub_branch** *(boolean)*: toggles branching on generalized upper bounds

Toggles branching on generalized upper bounds.

Default: 0

**mip_heuristic** *(integer)*: MIP heuristic to use in searching for an initial integer feasible point

Heuristic to use in searching for an initial integer feasible point.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>automatic</td>
</tr>
<tr>

<td>heuristic based on MPEC formulation</td>
</tr>
</tbody>
</table>

**mip_heuristic_maxit** *(integer)*: maximum iterations to allow the MIP heuristic

Specifies the maximum number of iterations to allow for MIP heuristic, if one is enabled.

Default: 100

**mip_implications** *(boolean)*: toggles addition of constraints derived from logical implications

Toggles addition of constraints derived from logical implications

Default: 1

**mip_integer_tol** *(real)*: integrality tolerance

Specifies the integrality tolerance for discrete variables.

Default: 1e-8

**mip_integral_gap_abs** *(real)*: absolute stopping tolerance for MIP

The absolute integrality gap stop tolerance. If not set by the user, the GAMS optCA value is used.

Default: 1e-6

**mip_integral_gap_rel** *(real)*: relative stopping tolerance for MIP

The relative integrality gap stop tolerance. If not set by the user, the GAMS optCA value is used.

Default: 1e-6

**mip_knapsack** *(integer)*: knapsack cut generation control

Default: 1
### mip_lpalg (integer): algorithm to use for LP subproblems

Specifies which algorithm to use for any LP subproblem solves that may occur in the B&B procedure. LP subproblems may arise if the problem has no nonlinear parts or if using `mip_method=2`.

- Default: 0

<table>
<thead>
<tr>
<th>Value</th>

<td>use the Active Set (simplex) algorithm</td>
</tr>
</tbody>
</table>

### mip_maxnodes (integer): maximum number of nodes to explore: 0=no limit

Specifies the maximum number of nodes explored (0 means no limit).

- Default: 100000

### mip_maxsolves (integer): maximum number of subproblem solves: 0=no limit

Specifies the maximum number of subproblem solves allowed (0 means no limit).

- Default: 200000

### mip_maxtime_cpu (real): cumulative CPU time limit for MIP

Specifies the cumulative CPU time limit, in seconds.

- Default: 1e8

### mip_maxtime_real (real): cumulative real or wall-clock time limit for MIP

Specifies the cumulative real or wall-clock time limit, in seconds.

- Default: 1e8

### mip_method (integer): specify MIP method to use

Specifies which method to use.

- Default: 0

<table>

<tr>
<td>3</td>
<td>use depth first unless pruned, then best bound</td>
</tr>
</tbody>
</table>

**mip_strong_candlim** (*integer*): max candidates to explore in strong branching

Specifies the maximum number of candidates to explore for strong branching.

Default: 10

**mip_strong_level** (*integer*): max levels on which to perform strong branching

Specifies the maximum number of tree levels on which to perform strong branching.

Default: 10

**mip_strong_maxit** (*integer*): max iterations to allow for strong branching

Specifies the maximum number of iterations to allow for strong branching.

Default: 1000

**mip_terminate** (*integer*): condition for terminating the MIP algorithm

Specifies conditions for terminating the MIP algorithm.

Default: 0
<table>
<thead>
<tr>
<th>value</th>

**ms_deterministic** *(boolean)*: allow for deterministic parallel MS if ms_terminate=0

Default: 1

**ms_enable** *(boolean)*: toggles multi-start method

Toggles multi-start method.

Default: 0

**ms_maxbndrange** *(real)*: maximum range to vary unbounded x when generating start points

Maximum range to vary unbounded x when generating start points.

Default: $1e3$

**ms_maxsolves** *(integer)*: maximum number of start points to try during multi-start

Specifies the maximum number of start points to try during multi-start.

Default: auto

<table>
<thead>
<tr>

<tr>
<td>n</td>
<td>try exactly $n &gt; 0$ start points</td>
</tr>
</tbody>
</table>

**ms_maxtime_cpu** *(real)*: cumulative CPU time limit for multi-start

Specifies the cumulative CPU time limit, in seconds.

Default: $1e8$

**ms_maxtime_real** *(real)*: cumulative real or wall-clock time limit for multi-start

Specifies the cumulative real or wall-clock time limit, in seconds.

Default: $1e8$

**ms_seed** *(integer)*: random seed for generating start points

Default: 0

**ms_startprrange** *(real)*: maximum range to vary all x when generating start points

Maximum range to vary all x when generating start points.

Default: $1e20$

**ms_terminate** *(integer)*: termination condition for multi-start

Specifies conditions for terminating the multi-start algorithm.

Default: 0
<table>
<thead>
<tr>

<tr>
<td>3</td>
<td>terminate at first solver completion</td>
</tr>
</tbody>
</table>

**objrange** *(real)*: parameter used in unboundedness check

Specifies the extreme limits of the objective function for purposes of determining unboundedness. If the magnitude of the objective function is greater than `objrange` and the iterate is feasible, then the problem is determined to be unbounded and Knitro proceeds no further.

Default: `1e20`

**option_file** *(string)*: additional option file name - read only by KNITRO solver lib

**opttol** *(real)*: relative optimality error tolerance

Specifies the final relative stopping tolerance for the KKT (optimality) error. Smaller values of `opttol` result in a higher degree of accuracy in the solution with respect to optimality.

Default: `1e-6`

**opttolabs** *(real)*: absolute optimality error tolerance

Synonym: `opttol_abs`

Specifies the final absolute stopping tolerance for the KKT (optimality) error. Smaller values of `opttolabs` result in a higher degree of accuracy in the solution with respect to optimality.

Default: `1.0e-3`

**outlev** *(integer)*: controls the level of output

controls the level of output.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>printing of all output is suppressed</td>
</tr>
<tr>
<td>1</td>

<tr>
<td>5</td>
<td>print all of the above, and the values of the solution vector (x)</td>
</tr>
<tr>
<td>6</td>
<td>print all of the above, and the values of the constraints (c) and the Lagrange multipliers (\lambda)</td>
</tr>
</tbody>
</table>

**output_time** *(boolean)*: print output on where time is used

Default: 0
par_blasnumthreads (integer): number of threads to use for BLAS operations

This value is used when blasoption=1 (the default). Avoid setting both par_blasnumthreads and par_lnumthreads to values greater than one.

Range: [1, \(\infty\)]

Default: 1

par_lnumthreads (integer): number of threads to use for PARDISO linear system solver

This value is used when the PARDISO linear system solver is used, i.e. when linsolver=6. Avoid setting both par_blasnumthreads and par_lnumthreads to values greater than one.

Range: [1, \(\infty\)]

Default: 1

pivot (real): initial pivot threshold used in the factorization routine

Specifies the initial pivot threshold used in the factorization routine. The value should be in the range \([0 \ldots 0.5]\) with higher values resulting in more pivoting (more stable factorizations). Values less than 0 will be set to 0 and values larger than 0.5 will be set to 0.5. If pivot is non-positive initially no pivoting will be performed. Smaller values may improve the speed of the code but higher values are recommended for more stability (for example, if the problem appears to be very ill-conditioned).

Range: \([0, 0.5]\)

Default: 1e-8

presolve (integer): controls presolve level

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no presolve</td>
</tr>
<tr>
<td>1</td>
<td>basic presolve</td>
</tr>
</tbody>
</table>

presolve_tol (real): controls presolver tolerance

Controls the presolver tolerance for removing variables and constraints. If you believe the Knitro presolver is incorrectly modifying the model, or you want to limit the changes made by the presolver, use a tighter tolerance or set presolve=0.

Default: 1e-6

reform (boolean): allow objective reformulation

Default: 1

scale (integer): toggles problem scaling

Performs a scaling of the objective and constraint functions based on their values at the initial point. If scaling is performed, all internal computations, including the stopping tests, are based on the scaled values.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No scaling is performed.</td>
</tr>
<tr>
<td>1</td>
<td>The objective function and constraints may be scaled.</td>
</tr>
</tbody>
</table>

**soc** *(integer)*: toggles the second order correction option ➔

Specifies whether or not to try second order corrections (SOC). A second order correction may be beneficial for problems with highly nonlinear constraints.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No second-order correction steps are attempted.</td>
</tr>
<tr>
<td>1</td>
<td>Second-order correction steps may be attempted.</td>
</tr>
<tr>
<td>2</td>
<td>Second-order correction steps are always attempted if the original step is rejected and there are nonlinear constraints.</td>
</tr>
</tbody>
</table>

**threads** *(integer)*: default thread count ➔

Synonym: par_numthreads

Controls the number of threads to use. Non-positive values are interpreted as the number of cores to leave free so setting `threads` to 0 uses all available cores while setting `threads` to -1 leaves one core free for other tasks.

By default, Knitro decides automatically how to use the threads specified. For example, if the multi-start method is enabled, it can run in parallel threads. If the multi-algorithm `algorithm=5` is selected, the different algorithms can be run in parallel threads if threads are allocated. In case only one algorithm is running, multiple threads can be allocated to the MKL BLAS library or to the PARDISO linear solver via the `threads` option: see the `blasoption`, `par_blasnumthreads`, and `par_lsnnumthreads` options for details.

**xtol (real):** tolerance for termination on a small stepsize ←

Specifies when to terminate the optimization based on stepsize. The optimization will terminate when the relative change in the solution estimate is less than $\text{xtol}$. If using an interior-point algorithm and the barrier parameter is still large, Knitro will first try decreasing the barrier parameter before terminating.

Default: $1e^{-15}$

### 4.27.6 Knitro Termination Test and Optimality

#### 4.27.6.1 Continuous problems

The first-order conditions for identifying a locally optimal solution of the problem (1) are:

$$
\nabla_x \mathcal{L}(x, \lambda) = \nabla f(x) + \sum_{i=1}^{m} \lambda^c_i \nabla c_i(x) + \sum_{j=1}^{n} \lambda^b_j \nabla b_j(x) = 0
$$

$$
\lambda^c_i \min[(c_i(x) - c^L_i), (c^U_i - c_i(x))] = 0, \quad i = 1 \ldots m
$$

$$
\lambda^b_j \min[(x_j - b^L_j), (b^U_j - x_j)] = 0, \quad j = 1 \ldots n
$$

$$
c^L_i \leq c_i(x) \leq c^U_i, \quad i = 1 \ldots m
$$

$$
b^L_j \leq x_j \leq b^U_j, \quad j = 1 \ldots n
$$

where $\mathcal{I}$ and $\mathcal{B}$ represent the sets of indices corresponding to the general inequality constraints and non-fixed variable bound constraints respectively, $\lambda^c_i$ is the Lagrange multiplier corresponding to constraint $c_i(x)$, and $\lambda^b_j$ is the Lagrange multiplier corresponding to the simple bounds on $x_j$. There is exactly one Lagrange multiplier for each constraint and variable. The Lagrange multiplier may be restricted to take on a particular sign depending on the corresponding constraint or variable bounds.

In Knitro we define the feasibility error ($\text{FeasErr}$) at a point $x^k$ to be the maximum violation of the constraints of (1), i.e.,

$$
\text{FeasErr} = \max_{i=1 \ldots m, j=1 \ldots n} (0, (c^L_i - c_i(x^k)), (c_i(x^k) - c^U_i), (b^L_j - x^k_j), (x^k_j - b^U_j)),
$$
while the optimality error ($\text{OptErr}$) is defined as the maximum violation of the first three conditions of (3)

$$\text{OptErr} = \max_{i=1...m, j=1...n} (\|
abla_x L(x^k, \lambda^k)\|_{\infty}, \lambda_i^k \min[(c_i(x) - c^L_i), (c^U_i - c_i(x))], \lambda_j^k \min[(x_j - b^L_j), (b^U_j - x_j)])$$.

The remaining conditions on the sign of the multipliers are enforced explicitly throughout the optimization.

In order to take into account problem scaling in the termination test, the following scaling factors are defined

$$\tau_1 = \max(1, (c^L_i - c_i(x^0)), (c_i(x^0) - c^U_i), (b^L_j - x^0_j), (x^0_j - b^U_j)))$$,

$$\tau_2 = \begin{cases} 
\max(1, \|\nabla f(x^k)\|_{\infty}), & \text{for constrained problems,} \\
\max(1, \min(|f(x^k)|, \|\nabla f(x^0)\|_{\infty})), & \text{for unconstrained problems,}
\end{cases}$$

where $x^0$ represents the initial point. The special treatment for unconstrained problems is necessary, as for these problems, $\|\nabla f(x^k)\|_{\infty} \to 0$ as a solution is approached, thus $\max(1, \|\nabla f(x^k)\|_{\infty})$ would not be effective.

Knitro stops and declares **Locally optimal solution found** if the following stopping conditions are satisfied:

$$\text{FeasErr} \leq \max(\tau_1 \ast \text{feastol, feastolabs})$$ (4)

$$\text{OptErr} \leq \max(\tau_2 \ast \text{opttol, opttolabs})$$ (5)

where feastol, opttol, feastolabs and opttolabs are user-defined options (see section Usage).

This stopping test is designed to give the user much flexibility in deciding when the solution returned by Knitro is accurate enough. One can use a purely scaled stopping test (which is the recommended and default option) by setting feastolabs and opttolabs equal to $0.0e0$. Likewise, an absolute stopping test can be enforced by setting feastol and opttol equal to $0.0e0$.

**Unbounded problems**

Since by default Knitro uses a relative/scaled stopping test it is possible for the optimality conditions to be satisfied for an unbounded problem. For example, if $\tau_2 \to \infty$ while the optimality error $\text{OptErr}$ stays bounded, condition (5) will eventually be satisfied for some $\text{opttol} > 0$. If you suspect that your problem may be unbounded, using an absolute stopping test will allow Knitro to detect this.

4.27.6.2 **Discrete problems**

Algorithms for solving versions of (1) where one or more of the variables are restricted to take on only discrete values, proceed by solving a sequence of continuous relaxations, where the discrete variables are relaxed such that they can take on any continuous value. The **global solutions** $f(x_R)$ of these relaxed problems provide a lower bound on the optimal objective value for problem (1) (upper bound if maximizing). If a feasible point is found for problem (1) that satisfies the discrete restrictions on the variables, then this provides an upper bound on the optimal objective value of problem (1) (lower bound if maximizing). We will refer to these feasible points as **incumbent** points and denote the objective value at an incumbent point by $f(x_I)$. Assuming all the continuous subproblems have been solved to global optimality (if the problem is convex, all local solutions are global solutions), an optimal solution of problem (1) is verified when the lower bound and upper bound are equal.
Knitro declares optimality for a discrete problem when the gap between the best (i.e., largest) lower bound $f(x_R)$ and the best (i.e., smallest) upper bound $f(x_I)$ is less than a threshold determined by the user options `mip_integral_gap_abs` and `mip_integral_gap_rel`. Specifically, Knitro declares optimality when either

$$f(x_I) - f(x_R) \leq \text{mip\_integral\_gap\_abs}$$

or

$$f(x_I) - f(x_R) \leq \text{mip\_integral\_gap\_rel} \cdot \max(1, |f(x_I)|),$$

where `mip_integral_gap_abs` and `mip_integral_gap_rel` are typically small positive numbers. Since these termination conditions assume that the continuous subproblems are solved to global optimality and Knitro only finds local solutions of nonconvex, continuous optimization problems, they are only reliable when solving convex, mixed integer problems. The integrality gap $f(x_I) - f(x_R)$ should be non-negative although it may become slightly negative from roundoff error, or if the continuous subproblems are not solved to sufficient accuracy. If the integrality gap becomes largely negative, this may be an indication that the model is nonconvex, in which case Knitro may not converge to the optimal solution, and will be unable to verify optimality (even if it claims otherwise).

Note that the default values for `mip_integral_gap_abs` and `mip_integral_gap_rel` are taken from the GAMS options `optCA` and `optCR`, but an explicit setting of `mip_integral_gap_abs` or `mip_integral_gap_rel` will override those.

### 4.27.7 Knitro Output

If `outlev=0` then all printing of output is suppressed. The description below assumes the default output level (`outlev=2`) except where indicated:

**Nondefault Options:**

This output lists all user options (see section Usage) which are different from their default values. If nothing is listed in this section then all user options are set to their default values.

**Problem Characteristics:**

The output begins with a description of the problem characteristics.

**Iteration Information - Continuous Problems:**

An iteration, in the context of Knitro, is defined as a step which generates a new solution estimate (i.e., a successful step). The columns of the iteration log are as follows:

- **Iter** Iteration number.
- **fCount** The cumulative number of function evaluations, only included if (`outlev>3`)
- **Objective** Gives the value of the objective function at the current iterate.
- **FeasErr** Gives a measure of the feasibility violation at the current iterate.
- **OptErr** Gives a measure of the violation of the Karush-Kuhn-Tucker (KKT) (first-order) optimality conditions (not including feasibility) at the current iterate.
- **||Step||** The 2-norm length of the step (i.e., the distance between the new iterate and the previous iterate).
- **CG its** The number of Projected Conjugate Gradient (CG) iterations required to compute the step.
If `outlev=2`, information is printed every 10 major iterations. If `outlev=3` information is printed at each major iteration. If `outlev>4` addition information is included in the log.

**Iteration Information - Discrete Problems:**

By default, the GAMS/Knitro link prints a log line at every 10'th node. This frequency can be changed via the `mip_outinterval` option. To turn off the node log completely, set the `mip_outlevel` option to 0. The columns of the iteration log for discrete models are as follows:

- **Node** The node number. If an integer feasible point was found at a given node, it is marked with a *
- **Left** The current number of active nodes left in the branch and bound tree.
- **Iinf** The current number of active nodes left in the branch and bound tree.
- **Objective** Gives the value of the objective function at the solution of the relaxed subproblem solved at the current node. If the subproblem was infeasible or failed, this is indicated. Additional symbols may be printed at some nodes if the node was pruned (pr), integer feasible (f), or an integer feasible point was found through rounding (r).
- **Best relaxatn** The value of the current best relaxation (lower bound on the solution if minimizing).
- **Best incumbent** The value of the current best integer feasible point (upper bound on the solution if minimizing).

**Termination Message:** At the end of the run a termination message is printed indicating whether or not the optimal solution was found and if not, why the solver terminated. Below is a list of some possible termination messages.

- **EXIT: Locally optimal solution found.**
  Knitro found a locally optimal point which satisfies the stopping criterion (see section Knitro Termination Test and Optimality) for more detail on how this is defined). If the problem is convex (for example, a linear program), then this point corresponds to a globally optimal solution.

- **EXIT: Iteration limit reached.**
  The iteration limit was reached before being able to satisfy the required stopping criteria.

- **EXIT: Convergence to an infeasible point. Problem appears to be locally infeasible.**
  The algorithm has converged to an infeasible point from which it cannot further decrease the infeasibility measure. This happens when the problem is infeasible, but may also occur on occasion for feasible problems with nonlinear constraints or badly scaled problems. It is recommended to try various initial points. If this occurs for a variety of initial points, it is likely the problem is infeasible.

- **EXIT: Problem appears to be unbounded.**
  The objective function appears to be decreasing without bound, while satisfying the constraints.

- **EXIT: Current point cannot be improved.**
  No more progress can be made. If the current point is feasible it is likely it may be optimal, however the stopping tests cannot be satisfied perhaps because of degeneracy, ill-conditioning or bad scaling).

- **EXIT: Current point cannot be improved. Point appears to be optimal, but desired accuracy could not be achieved.**
No more progress can be made, but the stopping tests are close to being satisfied (within a factor of 100) and so the current approximate solution is believed to be optimal.

- **EXIT: Time limit reached.**
  The time limit was reached before being able to satisfy the required stopping criteria.

- **EXIT: Evaluation error.**
  This termination value indicates that an evaluation error occurred (e.g., divide by 0, taking the square root of a negative number), preventing the optimization from continuing.

- **EXIT: Not enough memory available to solve problem.**
  This termination value indicates that there was not enough memory available to solve the problem.

### Final Statistics:

Following the termination message some final statistics on the run are printed. Both relative and absolute error values are printed.

### Solution Vector/Constraints:

If `outlev=5`, the values of the solution vector are printed after the final statistics. If `outlev=6`, the final constraint values are also printed before the solution vector and the values of the Lagrange multipliers (or dual variables) are printed next to their corresponding constraint or bound.

#### 4.27.8 Algorithm Options

##### 4.27.8.1 Automatic

By default, Knitro will automatically try to choose the best optimizer for the given problem based on the problem characteristics.

##### 4.27.8.2 Interior/Direct

If the Hessian of the Lagrangian is ill-conditioned or the problem does not have a large-dense Hessian, it may be advisable to compute a step by directly factoring the KKT (primal-dual) matrix rather than using an iterative approach to solve this system. Knitro offers the Interior/Direct optimizer which allows the algorithm to take direct steps by setting `algorithm=1`. This option will try to take a direct step at each iteration and will only fall back on the iterative step if the direct step is suspected to be of poor quality, or if negative curvature is detected.

Using the Interior/Direct optimizer may result in substantial improvements over Interior/CG when the problem is ill-conditioned (as evidenced by Interior/CG taking a large number of Conjugate Gradient iterations). We encourage the user to try both options as it is difficult to predict in advance which one will be more effective on a given problem. In each case, also experiment with the `bar_murule` option, as it is difficult to predict which update rule will work best.

**NOTE:** Since the Interior/Direct algorithm in Knitro requires the explicit storage of a Hessian matrix, this version can only be used with Hessian options, `hessopt=1, 2, 3` or `6`. It may not be used with Hessian options, `hessopt=4` or `5`, which only provide Hessian-vector products. Both the Interior/Direct and Interior/CG methods can be used with the `bar_feasible` option.
4.27.8.3 Interior/CG

Since Knitro was designed with the idea of solving large problems, the Interior/CG optimizer in Knitro offers an iterative Conjugate Gradient approach to compute the step at each iteration. This approach has proven to be efficient in most cases and allows Knitro to handle problems with large, dense Hessians, since it does not require factorization of the Hessian matrix. The Interior/CG algorithm can be chosen by setting `algorithm=2`. It can use any of the Hessian options as well as the `bar_feasible` option.

4.27.8.4 Active Set

Knitro includes an active-set Sequential Linear-Quadratic Programing (SLQP) optimizer. This optimizer is particularly advantageous when "warm starting" (i.e., when the user can provide a good initial solution estimate, for example, when solving a sequence of closely related problems). This algorithm is also the preferred algorithm for detecting infeasible problems quickly. The Active Set algorithm can be chosen by setting `algorithm=3`. It can use any of the Hessian options.

4.27.9 Other Knitro special features

This section describes in more detail some of the more important special features of Knitro and provides some guidance on how to use them so that Knitro runs most efficiently for the problem at hand.

4.27.9.1 Second derivative options

The default version of Knitro assumes that exact second derivatives of the objective function and constraint functions can be computed. If this is possible and the cost of computing the second derivatives is not overly expensive, it is highly recommended to use exact second derivatives. However, Knitro also offers other options which are described in detail below.

(Dense) Quasi-Newton BFGS

The quasi-Newton BFGS option uses gradient information to compute a symmetric, *positive-definite* approximation to the Hessian matrix. Typically this method requires more iterations to converge than the exact Hessian version. However, since it is only computing gradients rather than Hessians, this approach may be more efficient in many cases. This option stores a *dense* quasi-Newton Hessian approximation so it is only recommended for small to medium problems (\( n < 1000 \)). The quasi-Newton BFGS option can be chosen by setting options value `hessopt=2`.

(Dense) Quasi-Newton SR1

As with the BFGS approach, the quasi-Newton SR1 approach builds an approximate Hessian using gradient information. However, unlike the BFGS approximation, the SR1 Hessian approximation is not restricted to be positive-definite. Therefore the quasi-Newton SR1 approximation may be a better approach, compared to the BFGS method, if there is a lot of negative curvature in the problem since it may be able to maintain a better approximation to the true Hessian in this case. The quasi-Newton SR1 approximation maintains a *dense* Hessian approximation and so is only recommended for small to medium problems (\( n < 1000 \)). The quasi-Newton SR1 option can be chosen by setting options value `hessopt=3`.

Finite-difference Hessian-vector product option

If the problem is large and gradient evaluations are not the dominate cost, then Knitro can internally compute Hessian-vector products using finite-differences. Each Hessian-vector product in this case requires one additional gradient evaluation. This option can be chosen by setting options value `hessopt=4`. This option is generally only recommended if the exact gradients are provided.

NOTE: This option may not be used when `algorithm=1`. 
Exact Hessian-vector products
In some cases the problem which the user wishes to solve may have a large, dense Hessian which makes it impractical to store or work with the Hessian directly. The performance of this option should be nearly identical to the exact Hessian option but requires much less storage. This option can be chosen by setting options value `hessopt=5`.

**NOTE:** This option may not be used when `algorithm=1`.

Limited-memory Quasi-Newton BFGS
The limited-memory quasi-Newton BFGS option is similar to the dense quasi-Newton BFGS option described above. However, it is better suited for large-scale problems since, instead of storing a dense Hessian approximation, it only stores a limited number of gradient vectors used to approximate the Hessian. In general it requires more iterations to converge than the dense quasi-Newton BFGS approach but will be much more efficient on large-scale problems. This option can be chosen by setting options value `hessopt=6`.

### 4.27.9.2 Feasible version

Knitro offers the user the option of forcing intermediate iterates to stay feasible with respect to the inequality constraints (it does not enforce feasibility with respect to the equality constraints however). Given an initial point which is sufficiently feasible with respect to all inequality constraints and selecting `bar_feasible = 1`, forces all the iterates to strictly satisfy the inequality constraints throughout the solution process. For the feasible mode to become active the iterate $x$ must satisfy

$$cl + tol \leq c(x) \leq cu - tol$$

(21)

for all inequality constraints (i.e., for $cl \neq cu$). The tolerance $tol > 0$ by which an iterate must be strictly feasible for entering the feasible mode is determined by the parameter `bar_feasmodetol` which is $1.0e-4$ by default. If the initial point does not satisfy (21) then the default infeasible version of Knitro will run until it obtains a point which is sufficiently feasible with respect to all the inequality constraints. At this point it will switch to the feasible version of Knitro and all subsequent iterates will be forced to satisfy the inequality constraints.

For a detailed description of the feasible version of Knitro see [52].

**NOTE:** This option may only be used when `algorithm=2`.

### 4.27.9.3 Honor Bounds

By default Knitro does not enforce that the simple bounds on the variables (1c) are satisfied throughout the optimization process. Rather, satisfaction of these bounds is only enforced at the solution. In some applications, however, the user may want to enforce that the initial point and all intermediate iterates satisfy the bounds $bl \leq x \leq bu$. This can be enforced by setting `honorbnds=1`. 
4.27.9.4  Crossover

Interior-point (or barrier) methods are a powerful tool for solving large-scale optimization problems. However, one drawback of these methods is that they do not always provide a clear picture of which constraints are active at the solution. In general, they return a less exact solution and less exact sensitivity information. For this reason, Knitro offers a crossover feature in which the interior-point method switches to the Active Set method at the interior-point solution estimate, in order to "clean up" the solution and provide more exact sensitivity and active set information. The crossover procedure is controlled by the \texttt{bar_maxcrossit} option. If this option is greater than 0, then Knitro will attempt to perform \texttt{bar_maxcrossit} Active Set crossover iterations after the interior-point method has finished, to see if it can provide a more exact solution. This can be viewed as a form of post-processing. If \texttt{bar_maxcrossit} is not positive, then no crossover iterations are attempted.

The crossover procedure will not always succeed in obtaining a more exact solution compared with the interior-point solution. If crossover is unable to improve the solution within \texttt{bar_maxcrossit} crossover iterations, then it will restore the interior-point solution estimate and terminate. By default, Knitro will then print a message indicating that it was unable to improve the solution within the iterations allowed. In this case, you may want to increase the value of \texttt{bar_maxcrossit} and try again. If Knitro determines that the crossover procedure will not succeed, no matter how many iterations are tried, then a message of the form \texttt{Crossover mode unable to improve solution.} will be printed.

The extra cost of performing crossover is problem dependent. In most small or medium scale problems, the crossover cost is a small fraction of the total solve cost. In these cases, it may be worth using the crossover procedure to obtain a more exact solution. On some large scale or difficult degenerate problems, however, the cost of performing crossover may be significant. It is recommended to experiment with this option to see whether improvement in the exactness of the solution is worth the additional cost.

4.27.9.5  Tuner

The Knitro-Tuner can help you identify some non-default options settings that may improve performance on a particular model or set of models. The Knitro tuner is enabled with the \texttt{tuner} option and controlled via the \texttt{tuner} family of options. If you are unsure about what Knitro options should be tuned to try to improve performance, you can run the default Knitro-Tuner by simply setting the option \texttt{tuner=1} when solving with Knitro. This will cause Knitro to run your model with a variety of automatically determined option settings, and report some statistics at the end. Any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.

If you have some ideas about which Knitro options you want to tune, you can tell Knitro which options you want it to tune, as well as specify the values for particular options that you want Knitro to explore. This can be done by specifying a Tuner options file. A Tuner options file is a simple text file that is similar to a standard Knitro options file, with some important differences:

- You can define multiple values (separated by spaces) for each option. This tells Knitro the values you want it to explore.

- You can specify an option name without any values. This will tell Knitro to explore all possible option values for that option. This only works for options that have a finite set of possible option value settings.

- A Tuner options file is loaded via the \texttt{tuner_optionsfile} option.

All possible combinations of options/values specified in a Tuner options file will be explored by Knitro, while any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.
4.27.9.6 Solving Systems of Nonlinear Equations

Knitro is quite effective at solving systems of nonlinear equations. To solve a square system of nonlinear equations using Knitro one should specify the nonlinear equations as equality constraints (i.e., constraints with cl = cu), and specify the objective function (1a) as zero (i.e., f(x) = 0).

4.27.9.7 Solving Least Squares Problems

There are two ways of using Knitro for solving problems in which the objective function is a sum of squares of the form

\[ f(x) = \frac{1}{2} \sum_{j=1}^{q} r_j(x)^2. \]

If the value of the objective function at the solution is not close to zero (the large residual case), the least squares structure of f can be ignored and the problem can be solved as any other optimization problem. Any of the Knitro options can be used.

On the other hand, if the optimal objective function value is expected to be small (small residual case) then Knitro can implement the Gauss-Newton or Levenberg-Marquardt methods which only require first derivatives of the residual functions, r_j(x), and yet converge rapidly. To do so, the user need only define the Hessian of f to be

\[ \nabla^2 f(x) = J(x)^T J(x), \]

where

\[ J(x) = \left[ \frac{\partial r_j}{\partial x_i} \right]_{j=1, \ldots, q, \ i=1, \ldots, n}. \]

The actual Hessian is given by

\[ \nabla^2 f(x) = J(x)^T J(x) + \sum_{j=1}^{q} r_j(x) \nabla^2 r_j(x); \]

the Gauss-Newton and Levenberg-Marquardt approaches consist of ignoring the last term in the Hessian.

Knitro will behave like a Gauss-Newton method by setting algorithm=1, and will be very similar to the classical Levenberg-Marquardt method when algorithm=2. For a discussion of these methods see, for example, [187].

4.28 LGO

János D. Pintér, Pintér Consulting Services, Inc. Halifax, NS, Canada, B3M 1J2
jdtpinter@hfx.eastlink.ca, http://www.pinterconsulting.com

4.28.1 Introduction

4.28.1.1 The LGO Solver Suite

The Lipschitz-Continuous Global Optimizer \(^3\) (LGO) serves for the analysis and global solution of general nonlinear programming (NLP) models. The LGO solver system has been developed and gradually extended for more than a decade and it now incorporates a suite of robust and efficient global and local nonlinear solvers. It can also handle small LP models.

GAMS/LGO can be used in several search modes, providing a robust, effective, and flexible solver suite approach to a broad range of nonlinear models. The solver suite approach increases the reliability of the overall solution process. GAMS/LGO integrates the following global scope algorithms:

\(^3\)Also see http://www.springer.com/us/book/9780792337577
- Branch-and-bound (adaptive partition and sampling) based global search (BB)
- Adaptive global random search (GARS)
- Adaptive multistart global random search (MS)

LGO also includes the following local solver strategies:

- Heuristic global scope scatter search method (HSS)
- Bound-constrained local search, based on the use of an exact penalty function (EPM)
- Constrained local search, based on sequential model linearization (SLP)
- Constrained local search, based on a generalized reduced gradient approach (GRG).

The overall solution approach followed by GAMS/LGO is based on the seamless combination of the global and local search strategies. This allows for a broad range of operations. In particular, a solver suite approach supports the flexible usage of the component solvers: one can execute fully automatic (global and/or local search based) optimization, and can design customized interactive runs.

GAMS/LGO does not rely on any sub-solvers, and it does not require any structural information about the model. It is particularly suited to solve even 'black box' (closed, confidential), or other complex models, in which the available analytical information may be limited. GAMS/LGO needs only computable function values (without a need for higher order analytical information). GAMS/LGO can even solve models having constraints involving continuous, but non-differentiable functions. Thus, within GAMS, LGO is well suited to solve DNLP models.

GAMS/LGO can also be used in conjunction with other GAMS solvers. For instance, the local solver CONOPT can be used after LGO is finished to verify the solution and/or to provide additional information such as marginal values. To call CONOPT, the user can specify the LGO solver option 'callConopt'. See the LGO Options section for details.

The LGO solver suite has been successfully applied to complex, large-scale models both in educational/research and commercial contexts for over a decade. Possible application areas include advanced engineering design, econometrics and finance, medical research and biotechnology, chemical and process industries, and scientific modeling. Tractable model sizes depend only on the available hardware, although LGO has a 3000 variable, 2000 constraint size limit.

For more information, we refer to

- GAMS/LGO Nonlinear Solver Suite: Key Features, Usage, and Numerical Performance
- Nonlinear Optimization with GAMS/LGO (2006)

### 4.28.1.2 Running GAMS/LGO

GAMS/LGO is capable of solving the following model types: LP, RMIP, NLP, and DNLP. If LGO is not specified as the default solver for these models, it can be invoked by issuing the following command before the solve statement:

```plaintext
option (modeltype) = lgo;
```

where (modeltype) stands for LP, RMIP, NLP, or DNLP.
4.28 LGO

4.28.2 LGO Options

GAMS/LGO works like other GAMS solvers, and many options can be set directly within the GAMS model. The most relevant GAMS options are reslim, iterlim, and optfile. For details on these and other options, see the section on GAMS Options.

In addition, LGO-specific options can be specified by using a solver option file. For details on creating and using solver options files, see the section basic option file usage. The options supported by the GAMS/LGO solver are detailed below.

</tbody>
</table>

Note that the local search operational mode (opmode 0) is the fastest, and that it will work for convex, as well as for some non-convex models. If the model has a highly non-convex (multiextremal) structure, then at least one of the global search modes should be used. It may be a good idea to apply all three global search modes, to verify the global solution, or perhaps to find alternative good solutions. Usually, opmode 3 is the safest (and slowest), since it applies several local searches; opmodes 1 and 2 launch only a single local search from the best point found in the global search phase.

Note that if model-specific information is known (more sensible target objective/merit function value, tolerances, tighter variable bounds), then such information should always be used, since it may help to solve the model far more efficiently than would be the case using the defaults.

### 4.28.3 The GAMS/LGO Log File

The GAMS/LGO log file gives much useful information about the current solver progress and its individual phases. To illustrate, we use the nonconvex model `mhw4d.gms` from the GAMS model library:

```plaintext
$Title Nonlinear Test Problem (MHW4D,SEQ=84)

$Ontext
Another popular testproblem for NLP codes.

Wright, M H, Numerical Methods for Nonlinearly Constrained Optimization.
$Offtext

Variables m, x1, x2, x3, x4, x5;
Equations funct, eq1, eq2, eq3;

funct.. m =e= sqr(x1-1) + sqr(x1-x2) + power(x2-x3,3)
```
\[
+ \text{power}(x3-x4,4) + \text{power}(x4-x5,4) ;
\]
\[
eq 1: x1 + \text{sqr}(x2) + \text{power}(x3,3) = 3*\sqrt{2} + 2 ;
\]
\[
eq 2: x2 - \text{sqr}(x3) + x4 = 2*\sqrt{2} - 2 ;
\]
\[
eq 3: x1*x5 = 2 ;
\]

Model wright / all / ;

\[
x1.l = -1; x2.l = 2; x3.l = 1; x4.l = -2; x5.l = -2;
\]
Solve wright using nlp minimizing m;

Note that the solution given by LGO (shown on the next page) corresponds to the global minimum. For comparison, note that local scope nonlinear solvers will not find the global solution, unless started from a suitable neighbourhood (i.e., the model- and solver-specific region of attraction) of that solution.

In this example we use an option file to print out log information every 500 iterations, regardless of the elapsed time. Note that we set the \text{log.time} option to 0 to ignore the \text{log.time} interval.

LGO 1.0 May 15, 2003 LNX.LG.NA 21.0 001.000.000.LXI Lib001-030502

--- Using option file C:/GAMSPROJECTS/LGODOC/LGO.OPT

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iter</td>
<td>Current iteration.</td>
</tr>
<tr>
<td>Objective</td>
<td>Current objective function value.</td>
</tr>
<tr>

<td>Maximum constraint infeasibility.</td>
</tr>
<tr>
<td>Seconds</td>
<td>Current elapsed time in seconds.</td>
</tr>
<tr>
<td>Errors</td>
<td>Number of errors and type. Type can either be D/E: Evaluation error B: Bound violation.</td>
</tr>
</tbody>
</table>

The first part prints out information about the model size after presolve. In this particular problem, the original model had 4 rows, 6 columns, and 14 non-zeroes, of which 3 were defined constraints, meaning that they could be eliminated via GAMS/LGO presolve techniques. Note that none of these were fixed or free constraints. Furthermore, LGO presolve reduced the model size further to 1 row (LGO equations) and 3 columns (LGO variables).

The main log gives information for every \( n \) iterations about current progress. The main fields are given in the table below:

<table>
<thead>
<tr>
<th>Iter</th>
<th>Objective</th>
<th>SumInf</th>
<th>MaxInf</th>
<th>Seconds</th>
<th>Errors</th>
</tr>
</thead>
<tbody>
<tr>
<td>500</td>
<td>4.515428E-01</td>
<td>5.76E-02</td>
<td>5.8E-02</td>
<td>0.007</td>
<td></td>
</tr>
</tbody>
</table>
LGO then reports the termination status, in this case globally optimal, together with the solver resource time. The resource time is also disaggregated by the total time spent performing function evaluations and the number of milliseconds (ms) spent for each function evaluation.

--- LGO Exit: Terminated by solver - Global solution
0.047 LGO Secs (0.015 Eval Secs, 0.001 ms/eval)

A local solver such as CONOPT can be called to compute marginal values. To invoke a postsolve using CONOPT, the user specifies the callConopt option with a positive value, indicating the number of seconds CONOPT is given to solve. See the LGO Options section for details.

4.28.4 Illustrative References

4.29 LINDO and LINDOGlobal

Lindo Systems, Inc.
4.29.1 Introduction

GAMS/LINDO finds guaranteed globally optimal solutions to general nonlinear problems with continuous and/or discrete variables. GAMS/LINDO supports most mathematical functions, including functions that are nonsmooth, such as abs(x) and or even discontinuous, such as floor(x). Nonlinear solvers employing methods like successive linear programming (SLP) or generalized reduced gradient (GRG) return a local optimal solution to an NLP problem. However, many practical nonlinear models are non-convex and have more than one local optimal solution. In some applications, the user may want to find a global optimal solution.

The LINDO global optimization procedure (GOP) employs branch-and-cut methods to break an NLP model down into a list of subproblems. Each subproblem is analyzed and either a) is shown to not have a feasible or optimal solution, or b) an optimal solution to the subproblem is found, e.g., because the subproblem is shown to be convex, or c) the subproblem is further split into two or more subproblems which are then placed on the list. Given appropriate tolerances, after a finite, though possibly large number of steps a solution provably global optimal to tolerances is returned. Traditional nonlinear solvers can get stuck at suboptimal, local solutions. This is no longer the case when using the global solver.

GAMS/LINDO can automatically linearize a number of nonlinear relationships, such as max(x,y), through the addition of constraints and integer variables, so the transformed linearized model is mathematically equivalent to the original nonlinear model. Keep in mind, however, that each of these strategies will require additional computation time. Thus, formulating models, so they are convex and contain a single extremum, is desirable. In order to decrease required computing power and time it is also possible to disable the global solver and use GAMS/LINDO like a regular nonlinear solver.

GAMS/LINDO has a multistart feature that restarts the standard (non-global) nonlinear solver from a number of intelligently generated points. This allows the solver to find a number of locally optimal points and report the best one found. This alternative can be used when global optimization is costly. A user adjustable parameter controls the maximum number of multistarts to be performed.

LINDO automatically detects problem type and uses an appropriate solver, e.g., if you submit an LP model to LINDO, it will be solved as an LP at LP speed, regardless of what you said in the “solve using” statement. With the NLP parameter NLPQUADCHK turned on, LINDO can detect hidden quadratic expressions and automatically recognize convex QCPs, as well as second-order cones (SOCP), like in Value-at-Risk models, allowing dramatically faster solution times via the barrier solver. When such models have integer variables, LINDO would use the barrier solver to solve all subproblems leading to significantly improved solution times when compared to the case with the standard NLP solver.

4.29.1.1 Licensing and software requirements

In order to use GAMS/LINDOGlobal, two licenses are required: a GAMS/LINDOGlobal license and a GAMS/CONOPT license. The additional CONOPT license requirement exists because LINDOGlobal uses CONOPT to solve the nonlinear subproblems. The GAMS/LINDOGlobal license places upper limits on the model size of 3,000 variables and 2,000 constraints.

To use GAMS/LINDO, only a GAMS/LINDO license is required. It imposes no upper limit on the model size and includes the capability to solve stochastic models (see section Stochastic Programming (SP) in GAMS/Lindo).

Neither the GAMS/LINDO nor the GAMS/LINDOGlobal license includes the Barrier solver option. The Barrier option is enabled via a separate license for the GAMS/MOSEK barrier solver.
4.29.1.2 Running GAMS/LINDO

GAMS/LINDO is capable of solving models of the following types: EMP (stochastic), LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP and MINLP. If GAMS/LINDO is not specified as the default solver for these models, it can be invoked by issuing one of the following command before the solve statement:

```plaintext
option xxx=lindo;
option xxx=lindoglobal;
```

where xxx is one of: EMP, LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP, or MINLP.

You can also find global optima to math programs with equilibrium or complementarity constraints, type MPEC, by using the GAMS/NLPEC translator in conjunction with LINDO. You use NLPEC to translate complementarities into standard mathematical statements, e.g. \( h^*y = 0 \), and then use LINDO as the DNLP (Discontinuous Nonlinear) solver to solve the translated model. The following little GAMS model illustrates:

```plaintext
$title simple mpec example
variable f, x1, x2, y1, y2; positive
variable y1; y2.lo = -1; y2.up = 1;

equations cost, g, h1, h2;

cost.. f =e= x1 + x2;
g.. sqr(x1) + sqr(x2) =l= 1;
h1.. x1 =g= y1 - y2 + 1;
h2.. x2 + y2 =n= 0;

* declare h and y complementary
model example / cost, g, h1.y1, h2.y2 /;

option mpec=nlpec;
option dnlp=lindo;
solve example using mpec min f;
```

4.29.2 Supported nonlinear functions

GAMS/LINDO supports most nonlinear functions in global mode, including +, -, *, /, floor, modulo, sign, min, max, sgn, exp, power, ln, log, sqrt, abs, cos, sin, tan, cosh, sinh, tanh, arccos, arcsin, arctan and logic expressions AND, OR, NOT, and IF. Be aware that using highly nonconvex functions may lead to long solve times.

4.29.3 GAMS/LINDO output

The log output below is obtained for the NLP model mhw4d.gms from the GAMS model library using LINDO's global solver.

After determining the different kinds of nonlinear operators LINDO tries to linearize these within the presolving. When a feasible starting point is found the optimization starts and the log provides information about the progress. At the end it is reported if an optimum could be found and then the results as well as the used resources are summarized.

The following flags can be seen in the progress log:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(+FP)</td>
<td>found a new MIP solution with feasibility pump</td>
</tr>
<tr>
<td>(+SBB)</td>
<td>found a new MIP solution in tree reorder</td>
</tr>
<tr>
<td>(+SE)</td>
<td>found a new MIP solution in simple enumeration</td>
</tr>
<tr>
<td>(+AB)</td>
<td>found a new MIP solution in advanced branching</td>
</tr>
<tr>

<tr>
<td>(+F)</td>
<td>determined the final GOP status</td>
</tr>
</tbody>
</table>

4.29.4 The GAMS/LINDO Options

GAMS/LINDO offers a diverse range of user-adjustable parameters to control the behavior of its solvers. While the default values of these parameters work best for most purposes, there may be cases the users prefer to work with different settings for a subset of the available parameters. This section gives a list of available GAMS/LINDO parameters, categorized by type, along with their brief descriptions. A more detailed description is given in the section that follows.

4.29.4.1 GAMS/LINDO Options File

In order to set GAMS/LINDO options, you need to set up an option file lindo.opt or lindoglobal.opt in your GAMS project directory. You must indicate in the model that you want to use the option file by inserting before the solve statement, the line:
<modelname>.optfile = 1;

where

<modelname>

is the name of the model referenced in the model statement. The option file is in plain text format containing a single GAMS/LINDO option per line. Each option identifier is followed by its target value with space or tab characters separating them. The lines starting with * character are treated as comments.

A sample option file *lindo.opt* looks like below

* Use(1) or Disable(0) global optimization for NLP/MINLP models
USEGOP 0

* Enable Multistart NLP solver
NLP_SOLVER 9

* Allow a maximum of 3 multistart attempts
NLP_MAXLOCALSEARCH 3

* Set an overall time limit of 200 secs.
SOLVER_TIMLMT 200

## 4.29.5 Summary of GAMS/Lindo Options

### 4.29.5.1 General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

### 4.29.6 Detailed Descriptions of GAMS/Lindo Options

**CHECKRANGE (string):** calculate feasible range for variables

If this option is set, Lindo calculates the feasible range (determined by an upper and lower bound) for every variable in each equation while all other variables are fixed to their level. If set, the value of this option defines the name of the GDX file where the results are written to. For every combination of equation- and variable block there will be one symbol in the format `EquBlock_VarBlock(equInd_1, ..., equInd_M, varInd_1, ..., varInd_N, directions)`.

Default: `range.gdx`

**CORE_ORDER_BY_STAGE (integer):** order nontemporal models or not

Order nontemporal models or not.

Default: 1

**DECOMPOSITION_TYPE (integer):** decomposition to be performed on a linear or mixed integer model

This refers to the type of decomposition to be performed on a linear or mixed integer model.

Default: 1

</tbody>
</table>

GOP\_ABSOPTTOL \texttt{(real): absolute optimality tolerance} \leftrightarrow

Synonym: ABSOPTTOL

This value is the GOP absolute optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: GAMS OptCA

GOP\_ALGREFORMMD \texttt{(integer): algebraic reformulation rule for a GOP} \leftrightarrow

Synonym: ALGREFORMMD

This controls the algebraic reformulation rule for a GOP. The algebraic reformulation and analysis is very crucial in building a tight convex envelope to enclose the nonlinear/nonconvex functions. A lower degree of overestimation on convex envelopes helps increase the convergence rate to the global optimum.

Default: 18
### GOP_BBSRCHMD (integer): node selection rule in GOP branch-and-bound

**Synonym:** BBSRCHMD

This specifies the node selection rule for choosing between all active nodes in the GOP branch-and-bound tree when solving global optimization programs.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Depth first search</td>
</tr>
<tr>
<td>1</td>
<td>Choose node with worst bound</td>
</tr>
</tbody>
</table>

### GOP_BNDLIM (real): max magnitude of variable bounds used in GOP convexification

**Synonym:** BNDLIM

This value specifies the maximum magnitude of variable bounds used in the GOP convexification. Any lower bound smaller than the negative of this value will be treated as the negative of this value. Any upper bound greater than this value will be treated as this value. This helps the global solver focus on more productive domains.

Default: 1e10

### GOP_BOXTOL (real): minimal width of variable intervals

**Synonym:** BOXTOL

This value specifies the minimal width of variable intervals in a box allowed to branch.

Default: 1e-6

### GOP_BRANCHMD (integer): direction to branch first when branching on a variable

**Synonym:** BRANCHMD

This specifies the direction to branch first when branching on a variable. The branch variable is selected as the one that holds the largest magnitude in the measure.

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Absolute width</td>
</tr>
<tr>
<td>1</td>
<td>Locally relative width</td>

</tr>
<tr>
<td>5</td>
<td>Relative violation between the function and its convex envelope at the convex minimum</td>
</tr>
</tbody>
</table>
**GOP_BRANCH_LIMIT** *(integer)*: limit on the total number of branches to be created in GOP tree

Synonym: BRANCH_LIMIT

This is the limit on the total number of branches to be created during branch-and-bound in GOP tree. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible solution was found, it will be installed as the incumbent (best known) solution.

Range: \([-1, \infty]\)

Default: -1

**GOP_CORELEVEL** *(integer)*: strategy of GOP branch-and-bound

Synonym: CORELEVEL

This controls the strategy of GOP branch-and-bound procedure.

Default: 14

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>LP convex relaxation</td>

</tr>
</tbody>
</table>

**GOP_DECOMPPTMD** *(integer)*: decomposition point selection rule in GOP branch-and-bound

Synonym: DECOMPPTMD

This specifies the decomposition point selection rule. In the branch step of GOP branch-and-bound, a branch point M is selected to decompose the selected variable interval \([Lb, Ub]\) into two subintervals, \([Lb, M]\) and \([M, Ub]\).

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Mid-point</td>
</tr>
<tr>
<td>1</td>
<td>Local minimum or convex minimum</td>
</tr>
</tbody>
</table>

**GOP_DELTA_TOL** *(real)*: delta tolerance in GOP convexification

Synonym: DELTATOL

This value is the delta tolerance in the GOP convexification. It is a measure of how closely the additional constraints added as part of convexification should be satisfied.

Default: \(1 \times 10^{-7}\)

**GOP_FLT_TOL** *(real)*: floating-point tolerance

Synonym: FLTTOL

This value is the GOP floating-point tolerance. It specifies the maximum rounding errors in the floating-point computation.

Default: \(1 \times 10^{-10}\)
**GOP_HEU_MODE** (*integer*): heuristic used in global solver ↔

Synonym: HEU_MODE

This specifies the heuristic used in the global solver to find a good solution. Typically, if a heuristic is used, this will put more efforts in searching for good solutions, and less in bound tightening.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No heuristic is used</td>
</tr>
<tr>
<td>1</td>
<td>A simple heuristic is used</td>
</tr>
</tbody>
</table>

**GOP_ITRLIM** (*real*): GOP iteration limit ↔

Synonym: ITRLIM

This is the total iteration limit (including simplex, barrier and nonlinear iteration) summed over branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\)

Default: infinity

**GOP_ITRLIM_IPM** (*real*): total barrier iteration limit summed over all branches in GOP ↔

Synonym: ITRLIM_IPM

This is the total barrier iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\)

Default: -1

**GOP_ITRLIM_NLP** (*real*): total nonlinear iteration limit summed over all branches in GOP ↔

Synonym: ITRLIM_NLP

This is the total nonlinear iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\)

Default: -1

**GOP_ITRLIM_SIM** (*real*): total simplex iteration limit summed over all branches in GOP ↔

Synonym: ITRLIM_SIM

This is the total simplex iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\)

Default: -1

**GOP_LIM_MODE** (*integer*): flag indicating which heuristic limit on sub-solver in GOP is based ↔

Synonym: LIM_MODE

This is a flag indicating which heuristic limit on sub-solver in GOP is based.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No limit</td>
</tr>
<tr>
<td>1</td>
<td>Time based limit</td>
</tr>
<tr>
<td>2</td>
<td>Iteration based limit</td>
</tr>
<tr>
<td>3</td>
<td>Both time and iteration based limit</td>
</tr>
</tbody>
</table>

**GOP_LINEARZ (integer)**: flag indicating if GOP exploits linearizable model

This is a flag indicating if GOP exploits linearizable model.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exploit linearizable model</td>
</tr>
<tr>
<td>1</td>
<td>Do not exploit linearizable model</td>
</tr>
</tbody>
</table>

**GOP_LSOLBRANLIM (integer)**: branch limit until finding a new nonlinear solution

Synonym: LSOLBRANLIM

This value controls the branch limit until finding a new nonlinear solution since the last nonlinear solution is found. The default value is -1, which means no branch limit is imposed.

Range: \([-1, \infty]\)

Default: -1

**GOP_MAXWIDMD (integer)**: maximum width flag for the global solution

Synonym: MAXWIDMD

This is the maximum width flag for the global solution. The GOP branch-and-bound may continue contracting a box with an incumbent solution until its maximum width is smaller than **GOP_WIDTOL**.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The maximum width criterion is suppressed</td>
</tr>
<tr>
<td>1</td>
<td>The maximum width criterion is performed</td>
</tr>
</tbody>
</table>

**GOP_MULTILINEAR (integer)**: flag indicating if GOP exploits multi linear feature

This is a flag indicating if GOP exploits multi linear feature.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>
GOP_NUM_THREADS (integer): number of parallel threads to be used when solving a nonlinear model with the global optimization solver

This value specifies the number of parallel threads to be used when solving a nonlinear model with the global optimization solver.

Default: 1

GOP_OBJ_THRESHOLD (real): threshold of objective value in the GOP solver

This value specifies the threshold of objective value in the GOP solver. For min problem, if current incumbent solution is less than the threshold GOP solver will stop.

Range: \([-1e+30, \infty]\]

Default: \(-1e+30\)

GOP_OPTCHKMD (integer): criterion used to certify the global optimality

Synonym: OPTCHKMD

This specifies the criterion used to certify the global optimality. When this value is 0, the absolute deviation of objective lower and upper bounds should be smaller than \(GOP_{\text{ABSOPTTOL}}\) at the global optimum. When its value is 1, the relative deviation of objective lower and upper bounds should be smaller than \(GOP_{\text{RELOPTTOL}}\) at the global optimum. 2 means either absolute or relative tolerance is satisfied at global optimum.

Default: 2

GOP_OPT_MODE (integer): mode for GOP optimization

Synonym: OPT_MODE

This specifies the mode for GOP optimization.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Global search for a feasible solution (thus a feasibility certificate)</td>
</tr>
<tr>
<td>1</td>
<td>Global search for an optimal solution</td>
</tr>
<tr>
<td>2</td>
<td>Global search for an unboundedness certificate</td>
</tr>
</tbody>
</table>

GOP_POSTLEVEL (integer): amount and type of GOP postsolving

Synonym: POSTLEVEL

This controls the amount and type of GOP post-solving. The default value is: 6 = 2+4 meaning to do both of the below options.

Default: 6

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Apply LSgetBestBound</td>
</tr>
<tr>
<td>+4</td>
<td>Reoptimize variable bounds</td>
</tr>
</tbody>
</table>
GOP_PRELEVEL (integer): amount and type of GOP presolving

Synonym: PRELEVEL

This controls the amount and type of GOP pre-solving. The default value is: \(30 = 2+4+8+16\) meaning to do all of the below options.

Default: 30

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Initial local optimization</td>
</tr>
<tr>
<td>+4</td>
<td>Initial linear constraint propagation</td>
</tr>
<tr>
<td>+8</td>
<td>Recursive linear constraint propagation</td>
</tr>
<tr>
<td>+16</td>
<td>Recursive nonlinear constraint propagation</td>
</tr>
</tbody>
</table>

GOP_QUAD_METHOD (integer): specifies if the GOP solver should solve the model as a QP when applicable

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>General GOP solver</td>
</tr>
<tr>
<td>1</td>
<td>Specified QP solver</td>
</tr>
</tbody>
</table>

GOP_RELBRNDMD (integer): reliable rounding in the GOP branch-and-bound

Synonym: RELBRNDMD

This controls the reliable rounding rule in the GOP branch-and-bound. The global solver applies many suboptimizations to estimate the lower and upper bounds on the global optimum. A rounding error or numerical instability could unintentionally cut off a good solution. A variety of reliable approaches are available to improve the precision.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Use smaller optimality or feasibility tolerances and appropriate presolving options</td>
</tr>
<tr>
<td>+4</td>
<td>Apply interval arithmetic to reverify the solution feasibility</td>
</tr>
</tbody>
</table>

GOP_RELOPTTOL (real): relative optimality tolerance

Synonyms: OPTTOL RELOPTTOL

This value is the GOP relative optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: GAMS OptCR

GOP_SUBOUT_MODE (integer): substituting out fixed variables

Synonym: SUBOUT_MODE

This is a flag indicating whether fixed variables are substituted out of the instruction list used in the global solver.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not substitute out fixed variables</td>
</tr>
<tr>
<td>1</td>
<td>Substitute out fixed variables</td>
</tr>
</tbody>
</table>

**GOP_TIMLIM** *(integer)*: time limit in seconds for GOP branch-and-bound

Synonym: TIMLIM

This is the time limit in seconds for GOP branch-and-bound.

Range: \([-1, \infty]\)

Default: GAMS ResLim

**GOP_USEBNDLIM** *(integer)*: max magnitude of variable bounds flag for GOP convexification

Synonym: USEBNDLIM

This value is a flag for the parameter **GOP_BNDLIM**.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use the bound limit on the variables</td>
</tr>
<tr>
<td>1</td>
<td>Use the bound limit right at the beginning of global optimization</td>
</tr>
<tr>
<td>2</td>
<td>Use the bound limit after the initial local optimization if selected</td>
</tr>
</tbody>
</table>

**GOP_WIDTOL** *(real)*: maximal width of variable intervals

Synonym: WIDTOL

This value specifies the maximal width of variable intervals for a box to be considered as an incumbent box containing an incumbent solution. It is used when **GOP_MAXWIDMD** is set at 1.

Default: \(1e^{-4}\)

**INSTRUCT_SUBOUT** *(integer)*: flag to specify how to deal with fixed variables in the instruction list

This is a flag indicating whether 1) fixed variables are substituted out of the instruction list, 2) performing numerical calculation on constant numbers and replacing with the results.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Substitutions will not be performed</td>
</tr>
<tr>
<td>1</td>
<td>Substitutions will be performed</td>
</tr>
</tbody>
</table>

**IPM_BASIS_REL_TOL_S** *(real)*: maximum relative dual bound violation allowed in an optimal basic solution

Maximum relative dual bound violation allowed in an optimal basic solution.
Default: $1e^{-12}$

**IPM\_BASIS\_TOL\_S** *(real)*: maximum absolute dual bound violation in an optimal basic solution

Maximum absolute dual bound violation in an optimal basic solution.

Default: $1e^{-7}$

**IPM\_BASIS\_TOL\_X** *(real)*: maximum absolute primal bound violation allowed in an optimal basic solution

Maximum absolute primal bound violation allowed in an optimal basic solution.

Default: $1e^{-7}$

**IPM\_BI\_LU\_TOL\_REL\_PIV** *(real)*: relative pivot tolerance used in the LU factorization in the basis identification procedure

Relative pivot tolerance used in the LU factorization in the basis identification procedure.

Range: $[0, 0.999999]$  

Default: $1e^{-2}$

**IPM\_CHECK\_CONVEXITY** *(integer)*: flag to check convexity of a quadratic program using barrier solver

This is a flag to check convexity of a quadratic program using barrier solver.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Check convexity only without solving the model</td>
</tr>
<tr>
<td>0</td>
<td>Use barrier solver to check convexity</td>
</tr>
<tr>
<td>1</td>
<td>Do not use barrier solver to check convexity</td>
</tr>
</tbody>
</table>

**IPM\_CO\_TOL\_INFEAS** *(real)*: maximum bound infeasibility tolerance for Conic solver

Maximum bound infeasibility tolerance for Conic solver.

Default: $1e^{-10}$

**IPM\_MAX\_ITERATIONS** *(integer)*: ipm iteration limit

Controls the maximum number of iterations allowed in the interior-point optimizer.

Default: 1000

**IPM\_NUM\_THREADS** *(integer)*: number of threads to run the interiorpoint optimizer on

Number of threads to run the interiorpoint optimizer on. This value should be less than or equal to the actual number of processors or cores on a multi-core system.

Default: 1
**IPM_OFF_COL_TRH** (integer): extent for detecting the offending columns in the Jacobian of the constraint matrix

Controls the extent for detecting the offending columns in the Jacobian of the constraint matrix. 0 means no offending columns will be detected. 1 means offending columns will be detected. In general, increasing the parameter value beyond the default value of 40 does not improve the result.

Default: 40

**IPM_TOL_DFEAS** (real): dual feasibility tolerance

Dual feasibility tolerance used for linear and quadratic optimization problems.

Default: 1e-8

**IPM_TOL_DSAFE** (real): controls the initial dual starting point

Controls the initial dual starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the dual variables associated with constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: [1e-4, $\infty$]

Default: 1

**IPM_TOL_INFEAS** (real): infeasibility tolerance

This is the tolerance to declare the model primal or dual infeasible using the interior-point optimizer. A smaller number means the optimizer gets more conservative about declaring the model infeasible.

Default: 1e-10

**IPM_TOL_MU_RED** (real): relative complementarity gap tolerance

Relative complementarity gap tolerance.

Default: 1e-16

**IPM_TOL_PATH** (real): how close to follow the central path

Controls how close the interior-point optimizer follows the central path. A large value of this parameter means the central path is followed very closely. For numerically unstable problems it might help to increase this parameter.

Range: [0, 0.5]

Default: 1e-8

**IPM_TOL_PFEAS** (real): primal feasibility tolerance

Primal feasibility tolerance used for linear and quadratic optimization problems.

Default: 1e-8

**IPM_TOL_PSAFE** (real): controls the initial primal starting point

Controls the initial primal starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: [1e-2, $\infty$]

Default: 1

**IPM_TOL_REL_STEP** (real): relative step size to the boundary

Relative step size to the boundary for linear and quadratic optimization problems.

Range: [0, 0.999999]

Default: 0.9999

**LP_PRELEVEL** (integer): controls the amount and type of LP pre-solving

This controls the amount and type of LP pre-solving to be used.

Default: 126
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Simple pre-solving</td>
</tr>
<tr>
<td>+4</td>
<td>Probing</td>

<tr>
<td>+64</td>
<td>Use dual information</td>
</tr>
<tr>
<td>+512</td>
<td>Maximum pass</td>
</tr>
</tbody>
</table>

**MIP_ABSCUTTOL** *(real):* MIP absolute cut tolerance

This is the MIP absolute cut tolerance. If the value is less than or equal to zero, it will use the internal decided tolerance, otherwise it will use this value as the absolute tolerance for adding cuts.

Range: \([-1.0, \infty]\)

Default: \(-1.0\)

**MIP_ABSOPTTOL** *(real):* MIP absolute optimality tolerance

This is the MIP absolute optimality tolerance. Solutions must beat the incumbent by at least this absolute amount to become the new, best solution.

Default: \(\text{GAMS OptCA}\)

**MIP_ADDCUTOBJTOL** *(real):* required objective improvement to continue generating cuts

This specifies the minimum required improvement in the objective function for the cut generation phase to continue generating cuts.

Default: \(1.5625e-5\)

**MIP_ADDCUTPER** *(real):* percentage of constraint cuts that can be added

This determines how many constraint cuts can be added as a percentage of the number of original rows in an integer programming model.

Default: \(0.75\)

**MIP_ADDCUTPER_TREE** *(real):* percentage of constraint cuts that can be added at child nodes

This determines how many constraint cuts can be added at child nodes as a percentage of the number of original rows in an integer programming model.

Default: \(0.5\)

**MIP_AGGCUTLIM_TOP** *(integer):* max number of constraints involved in derivation of aggregation cut at root node

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the root node. The default is \(0.1\), which means that the solver will decide.

Range: \([-1, \infty]\)

Default: \(-1\)
MIP\_AGGCUTLIM\_TREE \textit{(integer)}: max number of constraints involved in derivation of aggregation cut at tree nodes -

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the tree nodes. The default is .1, which means that the solver will decide.

Range: \([-1, \infty]\)

Default: -1

MIP\_ANODES\_SWITCH\_DF \textit{(integer)}: threshold on active nodes for switching to depth-first search -

This specifies the threshold on active nodes for switching to depth-first search rule.

Default: 50000

MIP\_AOPTTIMLIM \textit{(integer)}: time in seconds beyond which the relative optimality tolerance will be applied -

This is the time in seconds beyond which the relative optimality tolerance, MIP\_PEROPTTOL will be applied.

Default: 100

MIP\_BIGM\_FOR\_INTTOL \textit{(real)}: threshold for which coefficient of a binary variable would be considered as big-M -

This value specifies the threshold for which the coefficient of a binary variable would be considered as big-M (when applicable).

Default: 1e8

MIP\_BRANCHDIR \textit{(integer)}: first branching direction -

This specifies the direction to branch first when branching on a variable.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Always branch up first</td>
</tr>
<tr>
<td>2</td>
<td>Always branch down first</td>
</tr>
</tbody>
</table>

MIP\_BRANCHRULE \textit{(integer)}: rule for choosing the variable to branch -

This specifies the rule for choosing the variable to branch on at the selected node.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Basis rounding with pseudo reduced costs</td>

<tr>
<td>2</td>
<td>Maximum infeasibility</td>
</tr>
</tbody>
</table>
MIP_BRANCH_LIMIT (integer): limit on the total number of branches to be created during branch and bound

This is the limit on the total number of branches to be created during branch-and-bound. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: \([-1, \infty]\]

Default: -1

MIP_BRANCH_Prio (integer): controls how variable selection priorities are set and used

This controls how variable selection priorities are set and used.

Default: 0

MIP_CUTDEPTH (integer): threshold value for the depth of nodes in the branch and bound tree

This controls a threshold value for the depth of nodes in the B&B tree, so cut generation will be less likely at those nodes deeper than this threshold.

Default: 8

MIP_CUTFREQ (integer): frequency of invoking cut generation at child nodes

This controls the frequency of invoking cut generation at child nodes. The default value is 10, indicating that the MIP solver will try to generate cuts at every 10 nodes.

Default: 10

MIP_CUTLEVEL_TOP (integer): combination of cut types to try at the root node when solving a MIP

This controls the combination of cut types to try at the root node when solving a MIP. Bit settings are used to enable the various cut types.

Default: 57342

<table>
<thead>
<tr>

### MIP\_CUTOFFOBJ (real): defines limit for branch and bound

If this is specified, then any part of the branch-and-bound tree that has a bound worse than this value will not be considered. This can be used to reduce the running time if a good bound is known.

Default: 1e30

### MIP\_CUTTIMLIM (integer): time to be spent in cut generation
This controls the total time to be spent in cut generation throughout the solution of a MIP. The default value is -1, indicating that no time limits will be imposed when generating cuts.

Range: [-1, ∞]
Default: -1

MIP_DELTA (real): near-zero value used in linearizing nonlinear expressions

This refers to a near-zero value used in linearizing nonlinear expressions.

Default: 1e-6

MIP_DUAL_SOLUTION (integer): flag for computing dual solution of LP relaxation

This flag controls whether the dual solution to the LP relaxation that yielded the optimal MIP solution will be computed or not.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not calculate dual solution for LP relaxation</td>
</tr>
<tr>
<td>1</td>
<td>Calculate dual solution for LP relaxation</td>
</tr>
</tbody>
</table>

MIP_FP_ITRLIM (integer): iteration limit for feasibility pump heuristic

This is the iteration limit in seconds for feasibility pump heuristic. A value of -1 means no iteration limit is imposed.

Default: 500

MIP_FP_MODE (integer): mode for the feasibility pump heuristic

Controls the mode for the feasibility pump heuristic.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>

</table>
**MIP_FP_TIMLIM** *(real)*: time limit for feasibility pump heuristic

This is the time limit in seconds for feasibility pump heuristic. A value of -1 implies no time limit is imposed.

Default: 1800

**MIP_FP_WEIGHT** *(real)*: weight of the objective function in the feasibility pump

Controls the weight of the objective function in the feasibility pump.

Range: [0, 1]

Default: 1

**MIP_GENERAL_MODE** *(integer)*: general strategy in solving MIPs

This value specifies the general strategy in solving MIPs.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>+2</td>
<td>Disable all time-driven events for reproducibility of runs</td>
</tr>
<tr>
<td>+16</td>
<td>Disable cut generation before branching</td>
</tr>
</tbody>
</table>

**MIP_HEULEVEL** *(integer)*: specifies heuristic used to find integer solution

This specifies the heuristic used to find the integer solution. Possible values are: 0: No heuristic is used. 1: A simple heuristic is used. Typically, this will find integer solutions only on problems with a certain structure. However, it tends to be fast. 2: This is an advanced heuristic that tries to find a “good” integer solution fast. In general, a value of 2 seems to not increase the total solution time and will find an integer solution fast on many problems. A higher value may find an integer solution faster, or an integer solution where none would have been found with a lower level. Try level 3 or 4 on ”difficult” problems where 2 does not help. Higher values cause more time to be spent in the heuristic. The value may be set arbitrarily high. However, >20 is probably not worthwhile. **MIP_HEUMINTIMLIM** controls the time to be spent in searching heuristic solutions.

Default: 3

**MIP_HEUMINTIMLIM** *(integer)*: minimum time in seconds to be spent in finding heuristic solutions

This specifies the minimum time in seconds to be spent in finding heuristic solutions to the MIP model. **MIP_HEULEVEL** controls the heuristic used to find the integer solution.

Default: 0

**MIP_HEU_DROP_OBJ** *(integer)*: flag for whether to use without OBJ heuristic

This is a flag for whether to use without OBJ heuristic.

Default: 0
MIP_HEU_MODE (integer): heuristic used in MIP solver

This controls the MIP heuristic mode.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

MIP_INTTOL (real): absolute integer feasibility tolerance

An integer variable is considered integer feasible if the absolute difference from the nearest integer is smaller than this.

Default: 1e-6

MIP_ITRLIM (real): iteration limit for branch and bound

This is the total LP iteration limit summed over all branches for branch-and-bound. Range for The default value is -1, which means no iteration limit is imposed. If this iteration limit is reached, branch-and-bound will stop and the best feasible integer solution found will be installed as the incumbent (best known) solution.

Range: [-1, ∞]

Default: infinity

MIP_KBEST_USE_GOP (integer): specifies whether to use gop solver in MIP KBest

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

MIP_KEEPINMEM (integer): flag for keeping LP bases in memory

If this is set to 1, the integer pre-solver will try to keep LP bases in memory. This typically gives faster solution times, but uses more memory. Setting this parameter to 0 causes the pre-solver to erase bases from memory.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not keep LP bases in memory</td>
</tr>
<tr>
<td>1</td>
<td>Keep LP bases in memory</td>
</tr>
</tbody>
</table>
MIP_LBIGM \( (\text{real}) \): Big-M value used in linearizing nonlinear expressions

This refers to the Big-M value used in linearizing nonlinear expressions.

Default: 10000

MIP_LSOLTLIMLIM \( (\text{integer}) \): time limit until finding a new integer solution

Range: \([-1, \infty]\]

Default: -1

MIP_MAKECUT_INACTIVE_COUNT \( (\text{integer}) \): threshold for times a cut could remain active after successive reoptimization

This value specifies the threshold for the times a cut could remain active after successive reoptimization during branch-and-bound. If the count is larger than the specified level the solver will inactive the cut.

Default: 10

MIP_MAXCUTPASS_TOP \( (\text{integer}) \): number passes to generate cuts on the root node

This controls the number passes to generate cuts on the root node. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.

Default: 200

MIP_MAXCUTPASS_TREE \( (\text{integer}) \): number passes to generate cuts on the child nodes

This controls the number passes to generate cuts on the child nodes. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.

Default: 2

MIP_MAXNONIMP_CUTPASS \( (\text{integer}) \): number of passes allowed in cut-generation that does not improve current relaxation

This controls the maximum number of passes allowed in cut-generation that does not improve the current relaxation.

Default: 3

MIP_MAXNUM_MIP_SOL_STORAGE \( (\text{integer}) \): maximum number of k-best solutions to store

This specifies the maximum number of k-best solutions to store. Possible values are positive integers.

Default: 1

MIP_MINABSOBJSTEP \( (\text{real}) \): value to update cutoff value each time a mixed integer solution is found

This specifies the value to update the cutoff value each time a mixed integer solution is found.

Default: 0

MIP_NODESELRULE \( (\text{integer}) \): specifies the node selection rule

This specifies the node selection rule for choosing between all active nodes in the branch-and-bound tree when solving integer programs. Possible selections are: 0: Solver decides (default). 1: Depth first search. 2: Choose node with worst bound. 3: Choose node with best bound. 4: Start with best bound. If no improvement in the gap between best bound and best integer solution is obtained for some time, switch to: if (number of active nodes < 10000) Best estimate node selection (5), else Worst bound node selection (2). 5: Choose the node with the best estimate, where the new objective estimate is obtained using pseudo costs. 6: Same as (4), but start with the best estimate.

Default: 0
<table>

</tbody>
</table>

**MIP_NUM_THREADS** (*integer*): number of parallel threads to use by the parallel MIP solver

This parameter specifies the number of parallel threads to use by the parallel MIP solver. Possible values are positive integers. The default is 1 implying that the parallel solver is disabled.

Range: \([1, \infty]\)

Default: 1

**MIP_PARA_FP** (*integer*): flag for whether to use parallelization on the feasibility pump heuristic

This is a flag for whether to use parallelization on the feasibility pump heuristic.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</table>

**MIP_PARA_RND_ITRLMT** *(real)*: iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations

This value specifies the iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations.

Default: 2.0

**MIP_PARA_SUB** *(integer)*: flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing

This is a flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>

</table>

**MIP_PEROPTTOL** *(real)*: MIP relative optimality tolerance in effect after MIP_AOPTTIMLIM seconds

This is the MIP relative optimality tolerance that will be in effect after T seconds following the start. The value T should be specified using the **MIP_AOPTTIMLIM** parameter.

Default: 1e-5

**MIP_PERSPECTIVE_REFORM** *(integer)*: flag for whether to use Perspective Reformulation

This is the flag for wether to use Persective Reformulation.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>

</table>

**MIP_POLISH_ALPHA_TARGET** *(real)*: proportion solutions in the pool to initiate a polishing-task at the current node

This value specifies the proportion solutions in the pool to initiate a polishing-task at the current node.

Range: [0.01, 0.99]

Default: 0.6

**MIP_POLISH_MAX_BRANCH_COUNT** *(integer)*: maximum number of branches to polish
This value specifies the maximum number of branches to polish.

Default: 2000

**MIP_POLISH_NUM_BRANCH_NEXT** *(integer)*: number of branches to polish in the next round

This value specifies the number of branches to polish in the next round.

Default: 4000

**MIP_PREHEU_DFE_VSTLIM** *(integer)*: limit for the variable visit in depth first enumeration

Limit for the variable visit in depth first enumeration.

Default: 200

**MIP_PREHEU_LEVEL** *(integer)*: heuristic level for the prerelax solver

The heuristic level for the prerelax solver.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Nothing</td>
</tr>
<tr>

<tr>
<td>3</td>
<td>Depth first enumeration</td>
</tr>
</tbody>
</table>

**MIP_PREHEU_TC_ITERLIM** *(integer)*: iteration limit for the two change heuristic

Iteration limit for the two change heuristic.

Default: 30000000

**MIP_PREHEU_VAR_SEQ** *(integer)*: sequence of the variable considered by the prerelax heuristic

The sequence of the variable considered by the prerelax heuristic.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Backward</td>
</tr>
<tr>
<td>1</td>
<td>Forward</td>

</table>

MIP_PRE_ELIM_FILL (integer): controls fill-in introduced by eliminations during pre-solve

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly more than the original model.

Default: 100

MIP_PSEUDOCOST_RULE (integer): specifies the rule in pseudocost computations for variable selection

This specifies the rule in pseudocost computations for variable selection.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Only use min pseudo cost</td>

<tr>
<td>3</td>
<td>Use quadratic score function and the pseudo cost weight</td>
</tr>
<tr>
<td>4</td>
<td>Same as 3 without quadratic score</td>
</tr>
</tbody>
</table>
**MIP_PSEUDOCOST_WEIGHT** *(real)*: weight in pseudocost computations for variable selection

This specifies the weight in pseudocost computations for variable selection.

Default: $1.5625 \times 10^{-5}$

**MIP_REDCOSTFIX_CUTOFF** *(real)*: cutoff value as a percentage of the reduced costs

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic.

Default: 0.9

**MIP_REDCOSTFIX_CUTOFF_TREE** *(real)*: cutoff value as a percentage of the reduced costs at tree nodes

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic at tree nodes.

Default: 0.9

**MIP_RELINTTOL** *(real)*: relative integer feasibility tolerance

An integer variable is considered integer feasible if the difference between its value and the nearest integer value divided by the value of the nearest integer is less than this.

Default: $8 \times 10^{-6}$

**MIP_RELOPTTOL** *(real)*: MIP relative optimality tolerance

This is the MIP relative optimality tolerance. Solutions must beat the incumbent by at least this relative amount to become the new, best solution.

Default: GAMS OptCR

**MIP_REEOPT** *(integer)*: optimization method to use when doing reoptimization

This specifies which optimization method to use when doing reoptimization from a given basis.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use primal method</td>
</tr>
<tr>
<td>2</td>
<td>Use dual simplex</td>
</tr>
<tr>
<td>3</td>
<td>Use barrier solver</td>
</tr>
</tbody>
</table>

**MIP_SCALING_BOUND** *(integer)*: maximum difference between bounds of an integer variable for enabling scaling

This controls the maximum difference between the upper and lower bounds of an integer variable that will enable the scaling in the simplex solver when solving a subproblem in the branch-and-bound tree.

Default: 10000
MIP_SOLLIM (integer): integer solution limit for MIP solver

Range: [-1, ∞]
Default: -1

MIP_SOLVERTYPE (integer): optimization method to use when solving mixed-integer models

This specifies the optimization method to use when solving mixed-integer models.
Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use Branch and Bound only</td>
</tr>
<tr>
<td>2</td>
<td>Use Enumeration and Knapsack solver only</td>
</tr>
</tbody>
</table>

MIP_STRONGBRANCHDONUM (integer): minimum number of variables to try the strong branching on

This value specifies the minimum number of variables, among all the candidates, to try the strong branching on.
Default: 3

MIP_STRONGBRANCHLEVEL (integer): depth from the root in which strong branching is used

This specifies the depth from the root in which strong branching is used. The default value of 10 means that strong branching is used on a level of 1 to 10 measured from the root. Strong branching finds the real bound for branching on a given variable, which, in most cases, requires a solution of a linear program and may therefore also be quite expensive in computing time. However, if used on nodes close to the root node of the tree, it also gives a much better bound for that part of the tree and can therefore reduce the size of the branch-and-bound tree.
Default: 10

MIP_SWITCHFAC_SIM_IPM_TIME (real): factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method

This specifies the (positive) factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method. A value of -1.0 means that no time limit is imposed.

Range: [-1, ∞]
Default: -1

MIP_SYMMETRY_MODE (integer): specifies mlp symmetry handling methods

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use symmetries</td>
</tr>
<tr>
<td>1</td>
<td>Adding symmetry breaking cuts</td>
</tr>
<tr>
<td>2</td>
<td>Orbital fixing</td>
</tr>
</tbody>
</table>
**MIP.TIMLIM (integer)**: time limit in seconds for integer solver  

This is the time limit in seconds for branch-and-bound. The default value is -1, which means no time limit is imposed. However, the value of SOLVER_TIMLMT will be applied to each continuous subproblem solve. If the value of this parameter is greater than 0, then the value of SOLVER_TIMLMT will be disregarded. If this time limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: [-1, ∞]  

Default: GAMS ResLim

**MIP.TOPOPT (integer)**: optimization method to use when there is no previous basis  

This specifies which optimization method to use when there is no previous basis.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use primal method</td>

<tr>
<td>3</td>
<td>Use barrier solver</td>
</tr>
</tbody>
</table>

**MIP.TREEREORDERLEVEL (integer)**: tree reordering level  

This specifies the tree reordering level.

Default: 10

**MIP.TREEREORDERMODE (integer)**: tree reordering mode  

This specifies the tree reordering mode.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Use tree reordering only for subproblems</td>
</tr>
<tr>
<td>2</td>

</tr>
<tr>
<td>4</td>
<td>Try concurrent mode only</td>
</tr>
</tbody>
</table>

NLP_AUTODERIV (integer): defining type of computing derivatives

---

4.29 LINDO and LINDOGlobal 1815
This is a flag to indicate if automatic differentiation is the method of choice for computing derivatives and select the type of differentiation.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Finite Differences approach will be used</td>
</tr>
<tr>
<td>1</td>
<td>Forward type of Automatic Differentiation will be used</td>
</tr>
<tr>

<td>Backward type of Automatic Differentiation will be used</td>
</tr>
</tbody>
</table>

**NLP_AUTOHESS** *(integer)*: flag for using Second Order Automatic Differentiation for solving NLP

This is a flag to indicate if Second Order Automatic Differentiation will be performed in solving a nonlinear model. The second order derivatives provide an exact/precise Hessian matrix to the SQP algorithm, which may lead to less iterations and better solutions, but may also be quite expensive in computing time for some cases.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use Second Order Automatic Differentiation</td>
</tr>
<tr>
<td>1</td>
<td>Use Second Order Automatic Differentiation</td>
</tr>
</tbody>
</table>

**NLP_CUTOFFOBJ** *(real)*: as soon as any multi-start thread achieves this value all threads stop

If the current best objective of the NLP being solved in a multistart run is better than this value, the solver will terminate early without exhausting the maximum number of multistarts. This is a way of saving computer time if the current best solution is sufficiently attractive.

Range: \([-1e30, \infty]\]

Default: \(-1e30\)

**NLP_DERIV_DIFFTYPE** *(integer)*: flag indicating the technique used in computing derivatives with finite differences

This is a flag indicating the technique used in computing derivatives with Finite Differences.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use forward differencing method</td>
</tr>
<tr>

<td>Use backward differencing method</td>
</tr>
<tr>
<td>3</td>
<td>Use center differencing method</td>
</tr>
</tbody>
</table>

**NLP_FEASCHK** *(integer)*: how to report results when solution satisfies tolerance of scaled but not original model

This input parameter specifies how the NLP solver reports the results when an optimal or local-optimal solution satisfies the feasibility tolerance *(NLP_FEASTOL)* of the scaled model but not the original (descaled) one.
Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform no action accept the final solution</td>
</tr>
<tr>
<td>1</td>
<td>Declare the model status as FEASIBLE if maximum violation in the unscaled model is not higher than 10 times NLP_FEASTOL</td>
</tr>
<tr>
<td>2</td>
<td>Declare the model status as UNKNOWN if maximum violation in the unscaled model is higher than NLP_FEASTOL</td>
</tr>
</tbody>
</table>

**NLP_FEASTOL** (*real*): feasibility tolerance for nonlinear constraints

This is the feasibility tolerance for nonlinear constraints. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: $1e^{-6}$

**NLP_INF** (*real*): numeric infinity for nonlinear models

Specifies the numeric infinity for nonlinear models. Possible values are positive real numbers. Smaller values could cause numerical problems.

nlp_ipm2grg This is a flag to switch from IPM solver to the standard NLP (GRG) solver when IPM fails due to numerical errors.

Default: $1e30$

**NLP_IPM2GRG** (*integer*): switch from IPM solver to GRG solver when IPM fails due to numerical errors

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not switch</td>
</tr>
<tr>
<td>1</td>
<td>Switch</td>
</tr>
</tbody>
</table>

**NLP_ITERS_PER_LOGLINE** (*integer*): number of nonlinear iterations to elapse before next progress message

Number of nonlinear iterations to elapse before next progress message.

Range: $[1, \infty]$  
Default: 10

**NLP_ITRLMT** (*integer*): nonlinear iteration limit

This controls the iteration limit on the number of nonlinear iterations performed.

Range: $[-1, \infty]$  
Default: GAMS IterLim

**NLP_LINEARZ** (*integer*): extent to which the solver will attempt to linearize nonlinear models

This determines the extent to which the solver will attempt to linearize nonlinear models.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>

**NLP_MAXLOCALSEARCH (integer):** maximum number of local searches ⬤

This controls the maximum number of local searches (multistarts) when solving a NLP using the multistart solver.

Default: 5

**NLP_MAXLOCALSEARCH_TREE (integer):** maximum number of multistarts ⬤

Maximum number of multistarts (at tree nodes)

Default: 1

**NLP_MAX_RETRY (integer):** maximum number refinement retries to purify the final NLP solution ⬤

Maximum number refinement retries to purify the final NLP solution.

Range: $[-1, \infty]$

Default: 5

**NLP_MSW_EUCDIST_THRES (real):** euclidean distance threshold in multistart search ⬤

Euclidean distance threshold in multistart search

Default: 0.001

**NLP_MSW_FILTMODE (integer):** filtering mode to exclude certain domains during sampling in multistart search ⬤

Filtering mode to exclude certain domains during sampling in multistart search.

Default: −1

<table>

</tbody>
</table>
NLP_MSW_MAXNOIMP (integer): maximum number of consecutive populations to generate without any improvements

Maximum number of consecutive populations to generate without any improvements.

Range: $[-1, \infty]$  
Default: $-1$

NLP_MSW_MAXPOP (integer): maximum number of populations to generate in multistart search

Maximum number of populations to generate in multistart search.

Range: $[-1, \infty]$  
Default: $-1$

NLP_MSW_MAXREF (integer): maximum number of reference points to generate trial points in multistart search

Maximum number of reference points in the solution space to generate trial points in multistart search.

Range: $[-1, \infty]$  
Default: $-1$

NLP_MSW_NORM (integer): norm to measure the distance between two points in multistart search

Norm to measure the distance between two points in multistart search.

Range: $[-1, \infty]$  
Default: 2

NLP_MSW_NUM_THREADS (integer): number of parallel threads to be used when solving an NLP model with the multistart solver

This value specifies the number of parallel threads to be used when solving an NLP model with the multistart solver.

Default: 1

NLP_MSW_OVERLAP_RATIO (real): rate of replacement in successive populations

This value specifies the rate of replacement in successive populations. Higher values favors survival of points in the parent population.

Range: $[0.0, 1.0]$  
Default: 0.1

NLP_MSW_POXDIST_THRES (real): penalty function neighborhood threshold in multistart search

Penalty function neighborhood threshold in multistart search

Default: 0.01

NLP_MSW_PREPMODE (integer): preprocessing strategies in multistart solver

This value specifies the preprocessing strategies in multistart solver.

Default: $-1$
### NLP\_MSW\_RG\_SEED (integer): random number generator seed for the multistart solver

This value specified the random number generator seed for the multistart solver.

Default: 1019

### NLP\_MSW\_SOLIDX (integer): index of the multistart solution to be loaded

Index of the multistart solution to be loaded main solution structures.

Default: 0

### NLP\_MSW\_XKKTRAD\_FACTOR (real): KKT solution neighborhood factor in multistart search

KKT solution neighborhood factor in multistart search

Default: 0.85

### NLP\_MSW\_XNULRAD\_FACTOR (real): initial solution neighborhood factor in multistart search

Initial solution neighborhood factor in multistart search

Default: 0.5

### NLP\_PRELEVEL (integer): controls the amount and type of NLP pre-solving

This controls the amount and type of NLP pre-solving.

Default: 126

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tr>
</tbody>
</table>
**NLP_PSTEP_FINITEDIFF** (*real*): value of the step length in computing the derivatives using finite differences

This controls the value of the step length in computing the derivatives using finite differences.

Default: $5e^{-7}$

**NLP_QUADCHK** (*integer*): flag for checking if NLP is quadratic

This is a flag indicating if the nonlinear model should be examined to check if it is a quadratic model.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not check if NLP is quadratic</td>
</tr>
<tr>
<td>1</td>
<td>Check if NLP is quadratic</td>
</tr>
</tbody>
</table>

**NLP_REDGTL0** (*real*): tolerance for the gradients of nonlinear functions

This is the tolerance for the gradients of nonlinear functions. The (projected) gradient of a function is considered to be the zero-vector if its norm is below this tolerance.

Default: $1e^{-7}$

**NLP_SOLVER** (*integer*): type of nonlinear solver

This value determines the type of nonlinear solver.

Default: 7

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Solver decides</td>
</tr>
<tr>
<td>5</td>
<td>Uses Levenberg-Marquardt method to solve nonlinear least-squares problem</td>

</tr>
<tr>
<td>9</td>
<td>Uses CONOPT with multistart feature enabled</td>
</tr>
</tbody>
</table>

**NLP_SOLVE_AS_LP** (*integer*): flag indicating if the nonlinear model will be solved as an LP

This is a flag indicating if the nonlinear model will be solved as an LP. 1 means that an LP using first order approximations of the nonlinear terms in the model will be used when optimizing the model with the LSoptimize() function.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NLP will not be solved as LP</td>
</tr>
<tr>
<td>1</td>
<td>NLP will be solved as LP</td>
</tr>
</tbody>
</table>

**NLP_STALL_ITRLMT** (*integer*): iteration limit before a sequence of non-improving NLP iterations is
declared as stalling

This specifies the iteration limit before a sequence of non-improving NLP iterations is declared as stalling, thus causing the solver to terminate.

Default: 100

**NLP_STARTPOINT (integer):** flag for using initial starting solution for NLP

This is a flag indicating if the nonlinear solver should accept initial starting solutions.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use initial starting solution for NLP</td>
</tr>
<tr>
<td>1</td>
<td>Use initial starting solution for NLP</td>
</tr>
</tbody>

<td>Barrier solver with or without crossover</td>
</tr>
</tbody>
</table>

**NLP_USECUTOFFOBJ (integer):** flag to use parameter NLP_CUTOFFOBJ

This is a flag for the parameter NLP_CUTOFFOBJ. The value of 0 means NLP_CUTOFFOBJ will be ignored, else it will be used as specified.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>

<td>Yes</td>
</tr>
</tbody>
</table>

**NLP_USE_CRASH (integer):** flag for using simple crash routines for initial solution

This is a flag indicating if an initial solution will be computed using simple crash routines.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use simple crash routines</td>
</tr>
<tr>
<td>1</td>
<td>Use simple crash routines</td>
</tr>
</tbody>
</table>
NLP_USE_LINDO_CRASH (integer): flag for using advanced crash routines for initial solution

This is a flag indicating if an initial solution will be computed using advanced crash routines.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use advanced crash routines</td>
</tr>
<tr>
<td>1</td>
<td>Use advanced crash routines</td>
</tr>
</tbody>
</table>

NLP_USE_SDP (integer): flag to use SDP solver for POSD constraint

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

NLP_USE_SELCONEVAL (integer): flag for using selective constraint evaluations for solving NLP

This is a flag indicating if selective constraint evaluations will be performed in solving a nonlinear model.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use selective constraint evaluations</td>
</tr>
<tr>
<td>1</td>
<td>Use selective constraint evaluations</td>

</tbody>
</table>

NLP_USE_SLP (integer): flag for using sequential linear programming step directions for updating solution

This is a flag indicating if sequential linear programming step directions should be used in updating the solution.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Do not use sequential linear programming step directions</td>
</tr>
<tr>
<td>1</td>
<td>Use sequential linear programming step directions</td>
</tr>
</tbody>
</table>

NLP_USE_STEEPEDGE (integer): flag for using steepest edge directions for updating solution

This is a flag indicating if steepest edge directions should be used in updating the solution.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use steepest edge directions</td>
</tr>
<tr>
<td>1</td>
<td>Use steepest edge directions</td>
</tr>
</tbody>
</table>
**NUM_THREADS** *(integer)*: number of parallel threads to be used

Synonym: gthreads

Number of threads to use in the solver routine to be called. It is a solver-independent parameter which internally sets solver-specific threading parameters automatically.

Range: $[1, \infty]$  

Default: GAMS Threads

**PROB_TO_SOLVE** *(integer)*: controls whether the explicit primal or dual form of the given LP problem will be solved

This flag controls whether the explicit primal or dual form of the given LP problem will be solved.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Explicit primal form</td>
</tr>
<tr>
<td>2</td>
<td>Explicit dual form</td>
</tr>
</tbody>
</table>

**PROFILER_LEVEL** *(integer)*: specifies the profiler level to break down the total cpu time into.

Specifies the profiler level to break down the total cpu time into.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Profiler is off</td>
</tr>
<tr>
<td>+1</td>
<td>Enable for simplex solver</td>
</tr>
<tr>
<td>+2</td>
<td>Enable for integer solver</td>
</tr>
<tr>
<td>+4</td>
<td>Enable for multistart solver</td>
</tr>
<tr>
<td>+8</td>
<td>Enable for global solver</td>
</tr>
</tbody>
</table>

**READPARAMS** *(string)*: read Lindo parameter file

**REPORTEVSOL** *(no value)*: solve and report the expected value solution

Default: 0

**SAMP_CDSINC** *(real)*: correlation matrix diagonal shift increment

Correlation matrix diagonal shift increment.

Default: $1e^{-6}$

**SAMP_NCM_CUTOBJ** *(real)*: objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem
Objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem.

Default: $1e^{-30}$

**SAMP_NCM_DSTORAGE (integer):** flag to enable or disable sparse mode in NCM computations

Flag to enable/disable sparse mode in NCM computations.

Range: $[-1, \infty]$  
Default: $-1$

**SAMP_NCM_ITERLIM (integer):** iteration limit for NCM method

Iteration limit for NCM method.

Default: 100

**SAMP_NCM_METHOD (integer):** bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem

Bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem.

Default: 5

**SAMP_NCM_OPTTOL (real):** optimality tolerance for NCM method

Optimality tolerance for NCM method.

Default: $1e^{-7}$

**SAMP_SCALE (integer):** flag to enable scaling of raw sample data

Flag to enable scaling of raw sample data.

Default: 0

**SOLVER_CONCURRENT_OPTMODE (integer):** controls if simplex and interior-point optimizers will run concurrently

Controls if simplex and interior-point optimizers will run concurrently, 0 means no concurrent runs will be performed, 1 means both optimizers will run concurrently if at least two threads exist in system, 2 means both optimizers will run concurrently.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no concurrent runs</td>
</tr>
<tr>
<td>1</td>
<td>run concurrently if at least 2 threads exist</td>
</tr>
<tr>
<td>2</td>
<td>run concurrently</td>
</tr>
</tbody>
</table>

**SOLVER_CUTOFFVAL (real):** solver will exit if optimal solution is worse than this

If the optimal objective value of the LP being solved is shown to be worse than this (e.g., if the dual simplex method is being used), then the solver will exit without finding a feasible
solution. This is a way of saving computer time if there is no sufficiently attractive solution. `SOLVER_USECUTOFFVAL` needs to be set to 1 to activate this value.

Default: 0

**SOLVER_FEASTOL** *(real)*: feasibility tolerance ←

This is the feasibility tolerance. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: $1e^{-7}$

**SOLVER_IPMSOL** *(integer)*: basis crossover flag for barrier solver ←

This flag controls whether a basis crossover will be performed when solving LPs with the barrier solver. A value of 0 indicates that a crossover to a basic solution will be performed. If the value is 1, then the barrier solution will be left intact. For example, if alternate optima exist, the barrier method will return a solution that is, loosely speaking, the average of all alternate optima.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform crossover to basis solution</td>
</tr>
<tr>
<td>1</td>
<td>Leave barrier solution intact</td>
</tr>
</tbody>
</table>

**SOLVER_IUSOL** *(integer)*: flag for computing basic solution for infeasible model ←

This is a flag that, when set to 1, will force the solver to compute a basic solution to an infeasible model that minimizes the sum of infeasibilities and a basic feasible solution to an unbounded problem from which an extreme direction originates. When set to the default of 0, the solver will return with an appropriate status flag as soon as infeasibility or unboundedness is detected. If infeasibility or unboundedness is declared with presolver's determination, no solution will be computed.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Return appropriate status if infeasibility is encountered</td>
</tr>
<tr>
<td>1</td>
<td>Force the solver to compute a basic solution to an infeasible model</td>
</tr>
</tbody>
</table>

**SOLVER_OPTTOL** *(real)*: dual feasibility tolerance ←

This is the optimality tolerance. It is also referred to as the dual feasibility tolerance. A dual slack (reduced cost) is considered violated if it violates its lower bound by the optimality tolerance.

Default: $1e^{-7}$

**SOLVER_PRE_ELIM_FILL** *(integer)*: fill-in introduced by the eliminations during pre-solve ←

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly more than the original model.

Default: 1000
**SOLVER_RESTART** *(integer)*: starting basis flag

This is the starting basis flag. 1 means LINDO API will perform warm starts using any basis currently in memory. 0 means LINDO API will perform cold starts discarding any basis in memory and starting from scratch.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform cold start</td>
</tr>
<tr>
<td>1</td>
<td>Perform warm start</td>
</tr>
</tbody>
</table>

**SOLVER_TIMLMT** *(integer)*: time limit in seconds for continous solver

This is a time limit in seconds for the LP solver. The default value of -1 imposes no time limit.

Range: \([-1, \infty]\]

Default: GAMS ResLim

**SOLVER_USECUTOFFVAL** *(integer)*: flag for using cutoff value

This is a flag for the parameter **SOLVER_CUTOFFVAL**

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use cutoff value</td>
</tr>
<tr>
<td>1</td>
<td>Use cutoff value</td>
</tr>
</tbody>
</table>

**SPLEX_DPRICING** *(integer)*: pricing option for dual simplex method

This is the pricing option to be used by the dual simplex method.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides the dual pricing method</td>
</tr>
<tr>
<td>0</td>
<td>Partial pricing</td>
</tr>
<tr>
<td>1</td>
<td>Steepest edge</td>
</tr>
</tbody>
</table>

**SPLEX_DUAL_PHASE** *(integer)*: controls the dual simplex strategy

This controls the dual simplex strategy, single-phase versus two-phase.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Single-phase</td>
</tr>
<tr>
<td>2</td>
<td>Two-phase</td>
</tr>
</tbody>
</table>
**SPLEX_ITRLMT** (integer): simplex iteration limit ←

This is a limit on the number of iterations the solver will perform before terminating. If this value is a nonnegative integer, then it will be used as an upper bound on the number of iterations the solver will perform. If this value is -1, then no iteration limit will be used. The solution may be infeasible.

Range: \([-1, \infty]\)

Default: infinity

**SPLEX_PPRICING** (integer): pricing option for primal simplex method ←

This is the pricing option to be used by the primal simplex method.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides the primal pricing method</td>
</tr>
<tr>
<td>0</td>
<td>Partial pricing</td>
</tr>
<tr>
<td>1</td>
<td>Devex</td>
</tr>
</tbody>
</table>

**SPLEX_REFACFRQ** (integer): number of simplex iterations between two consecutive basis refactorizations ←

This is a positive integer scalar referring to the simplex iterations between two consecutive basis re-factorizations. For numerically unstable models, setting this parameter to smaller values may help.

Default: 100

**SPLEX_SCALE** (integer): scaling flag ←

This is the scaling flag. Scaling multiplies the rows and columns of the model by appropriate factors in an attempt to avoid numerical difficulties by reducing the range of coefficient values.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Scaling is suppressed</td>
</tr>
<tr>
<td>1</td>
<td>Scaling is performed</td>
</tr>
</tbody>
</table>

**STOC_ABSOPTTOL** (real): absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver ←

Absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. Possible values are reals in \((0,1)\) interval.

Default: GAMS OptCA

**STOC_ADD_MPI** (integer): flag to use add-instructions mode when building deteq ←

Flag to use add-instructions mode when building deteq.

Default: 0
STOC_ALD_DUAL_FEASTOL (real): dual feasibility tolerance for ALD

   Dual feasibility tolerance for ALD.
   Default: 1e-4

STOC_ALD_DUAL_STEplen (real): dual step length for ALD

   Dual step length for ALD.
   Default: 0.9

STOC_ALD_INNER_ITER_LIM (integer): inner loop iteration limit for ALD

   Inner loop iteration limit for ALD.
   Default: 1000

STOC_ALD_OUTER_ITER_LIM (integer): outer loop iteration limit for ALD

   Outer loop iteration limit for ALD.
   Default: 200

STOC_ALD_PRIMAL_FEASTOL (real): primal feasibility tolerance for ALD

   Primal feasibility tolerance for ALD.
   Default: 1e-4

STOC_ALD_PRIMAL_STEplen (real): primal step length for ALD

   Primal step length for ALD.
   Default: 0.5

STOC_AUTOAGGR (integer): flag to enable or disable autoaggregation

   Flag to enable or disable autoaggregation.
   Default: 1

STOC_BENCHMARK_SCEN (integer): benchmark scenario to compare EVPI and EVMU against

   Benchmark scenario to compare EVPI and EVMU against.
   Range: [-2, ∞]
   Default: -2

STOC_BIGM (real): big-M value for linearization and penalty functions

   Big-M value for linearization and penalty functions.
   Default: 1e7

STOC_BUCKET_SIZE (integer): bucket size in Benders decomposition

   Bucket size in Benders decomposition. Possible values are positive integers or (-1) for solver
   decides.
   Range: [-1, ∞]
   Default: -1

STOC_CALC_EVPI (integer): flag to enable or disable calculation of EVPI

   Flag to enable/disable calculation of lower bounds on EVPI.
   Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>disable</td>
</tr>
<tr>
<td>1</td>
<td>enable</td>
</tr>
</tbody>
</table>

**STOC.CORRELATION_TYPE** (*integer*): correlation type associated with correlation matrix  

Correlation type associated with the correlation matrix.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Target correlation</td>
</tr>
<tr>
<td>0</td>
<td>Pearson correlation</td>

<tr>
<td>1</td>
<td>Kendall correlation</td>
</tr>
<tr>
<td>2</td>
<td>Spearman correlation</td>
</tr>
</tbody>
</table>

**STOC.DEQOPT** (*integer*): method to solve the DETEQ problem  

This specifies the method to use when solving the deterministic equivalent.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>10</td>
<td>Use simple Benders Decomposition</td>
</tr>
</tbody>
</table>

**STOC.DETEQ.TYPE** (*integer*): type of deterministic equivalent  

Type of deterministic equivalent to be used by the solver. Implicit deterministic equivalent is valid for linear and integer models only.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Implicit deterministic equivalent</td>
</tr>
<tr>
<td>1</td>
<td>Explicit deterministic equivalent</td>
</tr>
</tbody>
</table>

**STOC.DS_SUBFORM** (*integer*): subproblem formulation to use in DirectSearch  

This parameter specifies the type of subproblem formulation to be used in heuristic search.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Perform heuristic search in the original solution space</td>
</tr>
<tr>
<td>1</td>
<td>Perform heuristic search in the space of discrete variables coupled with optimizations in the linear space</td>
</tr>
</tbody>
</table>
**STOC_ELIM_FXVAR** *(integer)*: flag to enable elimination of fixed variables from deteq MPI

Flag to enable elimination of fixed variables from deteq MPI.

Default: 1

**STOC_INFBND** *(real)*: value to truncate infinite bounds at non-leaf nodes

Value to truncate infinite bounds at nonleaf nodes.

Default: $1e9$

**STOC_ITER_LIM** *(integer)*: iteration limit for stochastic solver

Iteration limit for stochastic solver. Possible values are positive integers or (-1) no limit.

Range: $[-1, \infty]$

Default: infinity

**STOC_MAP_MPI2LP** *(integer)*: flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements

Flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements.

Default: 0

**STOC_MAX_NUMSCENS** *(integer)*: maximum number of scenarios before forcing automatic sampling

Maximum number of scenarios before forcing automatic sampling. Possible values are positive integers.

Default: 40000

**STOC_METHOD** *(integer)*: stochastic optimization method to solve the model

Stochastic optimization method to solve the model.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solve with the method chosen by the solver</td>
</tr>
<tr>
<td>0</td>
<td>Solve the deterministic equivalent (DETEQ)</td>
</tr>
<tr>
<td>1</td>
<td>Solve with the Nested Benders Decomposition (NBD) method</td>
</tr>
</tbody>
</table>

**STOC_NAMERDATA_LEVEL** *(integer)*: name data level

Name data level.

Default: 1

**STOC_NODELP_PRELEVEL** *(integer)*: presolve level solving node-models

Presolve level solving node-models.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Simple pre-solving</td>
</tr>

</table>

**STOC_NSAMPLE_PER_STAGE** *(string):* list of sample sizes per stage (starting at stage 2) ←
Comma separated list of sample sizes per stage. The sample size of stage 1 is assumed to be 1 so that this list starts with stage 2.

**STOC_NSAMPLE_SPAR** *(integer):* common sample size per stochastic parameter ←
Common sample size per stochastic parameter. Possible values are positive integers.
Range: $[-1, \infty]$  
Default: $-1$

**STOC_NSAMPLE_STAGE** *(integer):* common sample size per stage ←
Common sample size per stage.
Range: $[-1, \infty]$  
Default: $-1$

**STOC_NUM_THREADS** *(integer):* number of parallel threads ←
This value specifies the number of parallel threads to be used when solving a stochastic programming model.
Default: 1

**STOC_RELOPTTOL** *(real):* relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver ←
Relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. Possible values are reals in (0,1) interval.
Default: GAMS OptCR

**STOC_REL_DSTEPTOL** *(real):* dual-step tolerance ←
This value specifies the dual-step tolerance in decomposition based algorithms.
Default: $1e-7$

**STOC_REL_PSTEPTOL** *(real):* primal-step tolerance ←
This value specifies the primal-step tolerance in decomposition based algorithms.
Default: $1e-8$

**STOC_REOPT** *(integer):* reoptimization method to solve the node-models ←
Reoptimization method to solve the node-models.
Default: 0

**WRITEMPS** *(string)*: write (S)MPS file of processed model

### 4.29.7 Stochastic Programming (SP) in GAMS/Lindo

GAMS/Lindo can also solve stochastic programming models. The syntax to set up an SP problem in GAMS is explained in the chapter Stochastic Programming (SP) with EMP. The options to control LINDO’s stochastic solver are described in the subsection SP Options.

### 4.30 LINGO

#### 4.30.1 Introduction

GAMS/LINGO allows users to solve GAMS models using solvers within the LINDO modeling system. The GAMS/LINGO link comes free with any GAMS system. Users must have a licensed LINGO system installed and have the LINGO executable in their path.

To run GAMS/LINGO, just specify the solver as `lingo`. For example, if we wish to solve the `trnsport.gms` model, we would run

```
>> gams trnsport.gms lp=lingo;
```

As for other GAMS solvers, options can be passed on via solver option files. GAMS/LINGO specific options are described in the section GAMS/LINGO Options.

By default, GAMS/LINGO returns a model status of 14 (no solution) and a solver return status of 1 (normal completion), provided the link is executed normally. This includes the case where the LINGO executable is not found.
4.30.2 Lingo Path

GAMS searches for a LINGO executable using the following hierarchy:

- Via the options LingoPath and RunLingo within a GAMS/LINGO solver option file.
- A lingopath.txt file located in the GAMS system directory specifying the path of the LINGO executable.
- The system path.

For example, GAMS will first search for the LINGO executable within the lingo.opt file, if specified. If not found, it will search within the GAMS system directory for a file called lingopath.txt specifying the LINGO directory. Finally if lingopath.txt is not found, GAMS will try the system path.

If no LINGO executable is found, the user will see a message similar to

LINGO Link 0. Jan 26, 2005 LNX.00.NA 21.6 002.000.000.LXI P3PC
--- No LingoPath option or "lingopath.txt" file found
--- System PATH will be used

sh: line 1: runlingo: command not found

The last line is platform dependent but indicates that LINGO was not found, either because it is not installed or because it is not found in the system path.

4.30.3 GAMS/LINGO Options

GAMS/LINGO solver options are passed on through solver option files. If you specify

<modelname>.optfile = 1;

before the SOLVE statement in your GAMS model, GAMS/LINGO will then look for and read an option file with the name lingo.opt (see also The Solver Options File).

LocalSolver

LocalSolver www.localsolver.com is an innovative mathematical programming solver developed and maintained by the company Innovation 24. LocalSolver finds high-quality solutions for large-scale mixed-variable non-convex optimization problems. Based on a unique hybrid neighborhood search approach, it combines local search techniques, constraint propagation and inference techniques, linear and mixed-integer programming techniques, as well as nonlinear programming techniques.

LocalSolver works on the algebraic representation of the model. As such, most common GAMS functions are supported, including logical operators. However, GAMS extrinsic functions cannot be used together with LocalSolver. Also special-ordered-set variables are currently not supported.

LocalSolver requires all variables to have finite bounds. Currently, the GAMS/LocalSolver link sets missing variable bounds to ±1e10, but the user is invited to provide proper bounds. However, no bounds should be set for variables that can be aggregate out by the solver link (aggrvars option).

LocalSolver might not able to prove infeasibility of the problem or global optimality of a solution and thus continues the search until interrupted by a limit (iterlim, reslim) or the user (Ctrl+C) or when found a solution with value equal or better of the dualbound option. It is thus important to set an iteration limit or a time limit that is appropriate to the model.

The search in LocalSolver is not deterministic due to hybridizing various optimization techniques in a concurrent way. That is, obtaining the same results cannot be ensured when repeatedly running the same model with the same data and parameters on the same machine.

4.31.1 The License

Starting with LocalSolver 7.5, Innovation 24 requires the user to install a machine-specific LocalSolver license on their machine. Having LocalSolver as part of the GAMS license is not sufficient anymore. Further, users that have a GAMS/LocalSolver link license need to provide a separate LocalSolver license.

Users that bought a GAMS/LocalSolver license can obtain a machine-specific LocalSolver license by, first, executing the tool lskeygen that is part of the GAMS distribution. This will give an output like the following:

LocalSolver 7.5 (MacOS64, build 20171117)
Copyright (C) 2017 Innovation 24, Aix-Marseille University, CNRS.
All rights reserved. See LocalSolver Terms and Conditions for details.
Hardware signature : 170EEAC5C295E6A2

Please send this output and your GAMS license to the GAMS sales & marketing department (sales@gams.com). They will contact Innovation 24 to get a hardware-specific LocalSolver license for you and send this license back to you. Please do so with any machine on which you expect to run GAMS/LocalSolver.

Users with a GAMS/LocalSolver link license should contact Innovation 24 directly to obtain a LocalSolver license.

Next, the LocalSolver license file (license.dat) needs to be places on the machine so that it can be found by LocalSolver. By default, LocalSolver looks for its license file in 3 different locations in the following order:

1. In the file specified by the environment variable LS_LICENSE_PATH.
2. In the current directory, that is the directory from where GAMS is spawned. If a file license.dat exists in this directory, it is used as default license.
3. In /opt/localsolver_X.Y/license.dat on Linux and Mac OS X and C:\localsolver_X.Y\license.dat on Windows.

Alternatively, it is currently still possible to use LocalSolver 7.0 with GAMS. To do so, change the solver to LOCALSOLVER70. For this use case, a GAMS/LocalSolver license is sufficient.
4.31.2 Using GAMS/LocalSolver

The following statement can be used inside your GAMS program to specify using LocalSolver:

```gams
Option MIP = LocalSolver; { or MIQCP or MINLP or ... }
```

The above statement should appear before the `solve` statement. If LocalSolver was specified as the default solver during GAMS installation, the above statement is not necessary.

Alternatively, LocalSolver 7.0 can be used by specifying

```gams
Option MIP = LocalSolver70; { or MIQCP or MINLP or ... }
```

The following GAMS options are used by GAMS/LocalSolver: `iterlim`, `reslim`, and `threads`.

Additionally, a GAMS/LocalSolver run can be customized by a using a solver options file. With the following example, one disables the automated aggregation of variables in the GAMS/LocalSolver link and sets the seed for the random number generator in LocalSolver to 42:

```gams
aggrvars 0
seed 42
```

The following options can be set:

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>
4.31.2.1 Hierarchical Optimization of Multiple Objective Functions

If the option `hierarchicalobj` is enabled, then the objective function in the GAMS model is interpreted as a specification of the priorities for an hierarchical optimization.

That is, assume the GAMS objective function is

\[ \sum_{i=1}^{p} c_i x_i \]

If `hierarchicalobj` is enabled, the GAMS/LocalSolver link will request LocalSolver to optimize each of the \( x_i \) variables in a hierarchical way. The highest priority will be given to a variable with largest value for \(|c_i|\), the 2nd highest priority to a variable with 2nd largest absolute coefficient value, etc. Further, if \( c_i \) is negative, then the optimization direction for \( x_i \) will be flipped (w.r.t. the objective sense specified in the GAMS solve statement).

Note, that GAMS will still report the value of the objective function \( \sum_{i=1}^{p} c_i x_i \) in the GAMS listing file and model attribute.

4.31.2.1.1 Example  Let's assume we have 3 hierarchical objective functions,

\[ o_1 = e= \ldots \]
\[ o_2 = e= \ldots \]
\[ o_3 = e= \ldots \]

Assume we want to first minimize \( o_1 \), secondly maximize \( o_2 \), and thirdly minimize \( o_3 \). To do this with GAMS/LocalSolver, you have to build a "weighted" combined objective and using the weights and the sign of the weight to determine the order and the direction:

\[ o = e= 1000*o_1 - 200*o_2 + 50*o_1; \]
\[ \text{solve m minimizing o using mip;} \]

or

\[ o = e= -1000*o_1 + 200*o_2 - 50*o_3; \]
\[ \text{solve m maximizing o using mip;} \]

4.31.3 Output

When LocalSolver tries to find good solutions, it prints a number of statistics to the log. Next to the number of infeasible expressions or the objective value, these are

- \textbf{mov}: the number of moves performed,
- \textbf{inf}: the percentage of infeasible moves,
- \textbf{acc}: the percentage of accepted moves,
- \textbf{imp}: the number of improving moves.
4.32 Least Squares (LS)

4.32.1 Introduction

There can be difficulties working with linear regression models in GAMS. An explicit minimization problem will be non-linear, as it needs to express a sum of squares. This model may be difficult to solve. Alternatively, it is well known that a linear formulation using the normal equations ($X'X)b=X'y$ will introduce numerical instability.

We have therefore introduced a compact notation where the objective is replaced by a dummy equation: the solver will implicitly understand that we need to minimize the sum of squared residuals. The LS solver will understand this notation and can apply a stable QR decomposition to solve the model quickly and accurately.

4.32.2 Basic Usage

A least squares model contains a dummy objective and a set of linear equations:

```
sumsq..  sse =n= 0;
fit(i)..  data(i,'y') =e=  b0 + b1*data(i,'x');

option lp = ls;
model leastsq /fit,sumsq/;
solve leastsq using lp minimizing sse;
```

Here $sse$ is a free variable that will hold the sum of squared residuals after solving the model. The variables $b0$ and $b1$ are the statistical coefficients to be estimated. On return the levels are the estimates and the marginals are the standard errors. The fit equations describe the equation to be fitted.

The constant term or intercept is included in the above example. If you don't specify it explicitly, and the solver detects the absence of a column of ones in the data matrix $X$, then a constant term will be added automatically. When you need to do a regression without intercept you will need to use an option `add_constant_term 0`.

It is not needed or beneficial to specify initial values (levels) or an advanced basis (marginals), as they are ignored by the solver.

The estimates are returned as the levels of the variables. The marginals will contain the standard errors. The row levels reported are the residuals errors. In addition a GDX file is written which will contain all regression statistics.

Several complete examples of LS solver usage are available in `testlib` starting with GAMS Distribution 22.8. For example, model `ls01` takes the data from the Norris dataset found in the NIST collection of statistical reference datasets and reproduces the results and regression statistics found there.

Erwin Kalvelagen is the original author. Further information can be found at Amsterdam Optimization Modeling Group's web site.

4.32.3 Options

The following options are recognized:
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxn</td>
<td>Maximum number of cases or observations. This is the number of rows (not counting the dummy objective). When the number of rows is very large, this is probably not a regression problem but a generic LP model. To protect against these cases GAMS does not accept models with an enormous number of rows.</td>
<td>1000</td>
</tr>
<tr>
<td>maxp</td>
<td>Maximum number of coefficients to estimate. This is the number of columns or variables (not counting the dummy objective variable). When the number of variables is very large, this is probably not a regression problem but a generic LP model. To protect against these cases GAMS does not accept models with an enormous number of columns.</td>
<td>25</td>
</tr>
<tr>
<td>add_constant_term</td>
<td>Must be 0, 1, or 2. If the number is zero no constant term or intercept will be added to the problem. If the number is one a constant term will always be added. If the number is two the algorithm will add a constant term only if there is no data column with all ones in the matrix. In this automatic mode, if the user already specified an explicit intercept in the problem, no additional constant term will be added. As the default is two, you will need to add add_constant_term 0 in case you want to solve a regression problem without an intercept.</td>

### 4.33 MILES

**Thomas F. Rutherford, University of Colorado**

#### 4.33.1 Abstract

MILES is a solver for nonlinear complementarity problems and nonlinear systems of equations. The solver can be accessed through GAMS to solve MPSGE or MCP models. This paper documents the solution algorithm, user options, and solver output. The purpose of the paper is to provide users of MILES an overview of how the solver works so that they can use it effectively.

#### 4.33.2 Introduction

MILES is a Fortran-based solver for nonlinear complementarity problems and nonlinear systems of equations. The solution procedure is a generalized Newton method with a backtracking line search. This code is based on an algorithm investigated by Mathiesen (1985) who proposed a modeling format and sequential method for solving economic equilibrium models. The method is closely related to algorithms proposed by Robinson (1975), Hogan (1977), Eaves (1978) and Josephy (1979). In this implementation, subproblems are solved as linear complementarity problems (LCPs), using an extension of Lemke's almost-complementary pivoting scheme in which upper and lower bounds are represented implicitly. The linear solver employs the basis factorization package LUSOL, developed by Gill et al. (1991).

The class of problems for which MILES may be applied are referred to as "generalized" or "mixed" complementarity problems, which is defined as follows:
Given: $F : \mathbb{R}^n \rightarrow \mathbb{R}^n$, $\ell, u \in \mathbb{R}^n$

Find: $z, w, v \in \mathbb{R}^n$

such that

$F(z) = w - v$

$\ell \leq z \leq u$, $w \geq 0$, $v \geq 0$

$w^T(z - \ell) = 0$, $v^T(u - z) = 0$.

When $\ell = -\infty$ and $u = \infty$ MCP reduces to a nonlinear system of equations. When $\ell = 0$ and $u = +\infty$, the MCP is a nonlinear complementarity problem. Finite dimensional variational inequalities are also MCP. MCP includes inequality-constrained linear, quadratic and nonlinear programs as special cases, although for these problems standard optimization methods may be preferred. MCP models which are not optimization problems encompass a large class of interesting mathematical programs. Specific examples of MCP formulations are not provided here. See Rutherford (1992a) for MCP formulations arising in economics. Other examples are provided by Harker and Pang (1990) and Dirkse (1993).

There are two types of GAMS models which can be presented to MILES:

1. MILES may be used to solve computable general equilibrium models generated by MPSGE as a GAMS subsystem. In the MPSGE language, a model-builder specifies classes of nonlinear functions using a specialized tabular input format embedded within a GAMS program. Using benchmark quantities and prices, MPSGE automatically calibrates function coefficients and generates nonlinear equations and Jacobian matrices. Large, complicated systems of nonlinear equations may be implemented and analyzed very easily using this interface to MILES. An introduction to general equilibrium modeling with GAMS/MPSGE is provided by Rutherford (1992a).

2. MILES may be accessed as a GAMS solver for mixed complementarity problems (MCP). If more than one MCP solver is available, the statement `OPTION MCP = MILES;` tells GAMS to use MILES as the MCP solution system. When problems are presented to MILES using the MCP format, the user specifies nonlinear functions using GAMS matrix algebra and the GAMS compiler automatically generates the Jacobian functions. An introduction to the GAMS/MCP modeling format is provided by Rutherford (1992b).

The purpose of this document is to provide users of MILES with an overview of how the solver works so that they can use the program more effectively. Section The Newton Algorithm introduces the Newton algorithm. Section Lemke’s Method with Implicit Bounds describes the implementation of Lemke’s algorithm which is used to solve linear subproblems. Section The Options File defines switches and tolerances which may be specified using the options file. Section Log File Output interprets the run-time log file which is normally directed to the screen. Section Status File Output interprets the status file and the detailed iteration reports which may be generated. Section Termination Messages lists and suggests remedies for abnormal termination conditions.

### 4.33.3 The Newton Algorithm

The iterative procedure applied within MILES to solve nonlinear complementarity problems is closely related to the classical Newton algorithm for nonlinear equations. This first part of this section reviews the classical procedure. A thorough introduction to these ideas is provided by Dennis and Schnabel (1983). For a practical perspective, see Press et al. (1986).

Newton algorithms for nonlinear equations begin with a local (Taylor series) approximation of the system of nonlinear equations. For a point $z$ in the neighborhood of $\hat{z}$, the system of nonlinear functions is linearized:

\[ F(z) = w - v \]

\[ \ell \leq z \leq u, \quad w \geq 0, \quad v \geq 0 \]

\[ w^T(z - \ell) = 0, \quad v^T(u - z) = 0. \]
\[ LF(z) = F(\bar{z}) + \nabla F(\bar{z})(z - \bar{z}) \].

Solving the linear system \( LF(z) = 0 \) provides the Newton direction from \( \bar{z} \) which is given by \( d = -\nabla F^{-1}(\bar{z}) \).

Newton iteration \( k \) begins at point \( z^k \). First, the linear model formed at \( z^k \) is solved to determine the associated "Newton direction", \( d^k \). Second, a line search in direction \( d^k \) determines the scalar steplength and the subsequent iterate:

\[ z^{k+1} = z^k + \lambda d^k. \]

An Armijo or "back-tracking" line search initially considers \( \lambda = 1 \). If \( \|F(z^k + \lambda d^k)\| \leq \|F(z^k)\| \), the step size \( \lambda \) is adopted, otherwise it is multiplied by a positive factor \( \alpha \), \( \alpha < 1 \), and the convergence test is reapplied. This procedure is repeated until either an improvement results or \( \lambda < \lambda^* \). When \( \lambda = 0 \), a positive step is taken provided that \( 5\alpha \) and \( \lambda^* \) correspond to user-specified tolerances 'DMPFAC' and 'MINSTP', respectively.

Convergence theory for this algorithm is quite well developed. See, for example, Ortega and Rheinboldt (1970) or Dennis and Schnabel (1983). The most attractive aspect of the Newton scheme with the backtracking line search is that in the neighborhood of a well-behaved fixed point, \( \lambda = 1 \) is the optimal step length and the rate of convergence can be quadratic. If this method finds a solution, it does so very quickly.

The application of Newton methods to nonlinear complementarity problems involves a modification of the search direction. Here, \( d \) solves a linear complementarity problem (LCP) rather than a linear system of equations. For iteration \( k \), \( d \) solves:

\[ F(z^k) + \nabla F(z^k)d - w + v = 0 \]

\[ \ell \leq d + z^k \leq u, \quad w \geq 0, \quad v \geq 0 \]

\[ w^T(d + z^k - \ell) = v^T(u - d - z^k) = 0. \]

Conceptually, we are solving for \( d \), but in practice MILES solves the linear problem in terms of the original variables \( z = z^k + d \):

\[ F(z^k) - \nabla F(z^k)z_k + \nabla F(z^k)z = w - v \]

\[ \ell \leq z \leq u, \quad w \geq 0, \quad v \geq 0 \]

\[ w^T(z - \ell) = 0, \quad v^T(u - z) = 0. \]

After computing the solution \( z \), MILES sets \( d^k = z - z^k \).

The linear subproblem incorporates upper and lower bounds on any or all of the variables, assuring that the iterative sequence always remains within the bounds: \( \ell \leq z^k \leq u \). This can be helpful when, as is often the case, \( F() \) is undefined for some \( z \in \mathbb{R}^n \).

Convergence of the Newton algorithm applied to MCP hinges on three questions:
1. Does the linearized problem always have a solution?
2. If the linearized problem has a solution, does Lemke’s algorithm find it?
3. Is it possible to show that the computed direction \( d^k \) will provide an “improvement” in the solution?

Only for a limited class of functions \( F() \) can all three questions be answered in the affirmative. For a much larger class of functions, the algorithm converges in practice but convergence is not “provable”\(^6\).

The answer to question 3. depends on the choice of a norm by which an improvement is measured. The introduction of bounds and complementarity conditions makes the calculation of an error index more complicated. In MILES, the deviation associated with a candidate solution \( z, \epsilon(z) \), is based on a measure of the extent to which \( z, w \) and \( v \) violate applicable upper and lower bounds and complementarity conditions.

### 4.33.3.1 Evaluating Convergence

Let \( \delta^L_i \) and \( \delta^U_i \) be indicator variables for whether \( z_i \) is off its lower or upper bound. These are defined as \(^7\)

\[
\delta^L_i = \min(1, (z_i - \ell_i)^+) \quad \text{and} \quad \delta^U_i = \min(1, (u_i - z_i)^+).
\]

Given \( z \), MILES uses the value of \( F(z) \) to implicitly define the slack variables \( w \) and \( v \):

\[
w_i = F_i(z)^+, \quad v_i = (-F_i(z))^+.
\]

There are two components to the error term associated with index \( i \), one corresponding to \( z_i \)’s violation of upper and lower bounds:

\[
\epsilon^B_i = (z_i - u_i)^+ + (\ell_i - z_i)^+
\]

and another corresponding to violations of complementarity conditions:

\[
\epsilon^C_i = \delta^L_i w_i + \delta^U_i v_i.
\]

The error assigned to point \( z \) is then taken:

\[
\epsilon(z) = \| \epsilon^B(z) + \epsilon^C(z) \|_p
\]

for a pre-specified value of \( p = 1, 2 \) or \(+\infty\). \(^8\)

---

\(^6\)Kaneko (1978) provides some convergence theory for the linearized subproblem

\(^7\)In the following \( x^+ = \max(x, 0) \)

\(^8\)Parameter \( p \) may be selected with input parameter ‘NORM’. The default value for \( p \) is \(+\infty\).
4.33.4 Lemke’s Method with Implicit Bounds

A mixed linear complementarity problem has the form:

Given: \( M \in \mathbb{R}^{n \times n}, \ q, \ell, u \in \mathbb{R}^n \)

Find: \( z, w, v \in \mathbb{R}^n \)

such that \( Mz + q = w - v, \ \ell \leq z \leq u, \ w \geq 0, \ v \geq 0, \ w^T(z - \ell) = 0, \ v^T(u - z) = 0. \)

In the Newton subproblem at iteration \( k \), the LCP data are given by \( q = F(z^k) - \nabla F(z^k)z^k \) and \( M = \nabla F(z^k) \).

4.33.4.1 The Working Tableau

In MILES, the pivoting scheme for solving the linear problem works with a re-labeled linear system of the form:

\[ Bx^B + Nx^N = q, \]

where \( x^B \in \mathbb{R}^n, \ x^N \in \mathbb{R}^{2n} \), and the tableau \([B|N]\) is a conformal “complementary permutation” of \([-M | I | -I]\). That is, every column \( i \) in \( B \) must either be the \( i \)th column of \( M, I \) or \(-I\), while the corresponding columns \( i \) and \( i + n \) in \( N \) must be the two columns which were not selected for \( B \).

To move from the problem defined in terms of \( z, w \), and \( v \) to the problem defined in terms of \( x^B \) and \( x^N \), we assign upper and lower bounds for the \( x^B \) variables as follows:

\[
x^B_i = \begin{cases} 
\ell_i, & \text{if } x^B_i = z_i \\
0, & \text{if } x^B_i = w_i \text{ or } v_i,
\end{cases}
\]

\[
x^B_i = \begin{cases} 
u_i, & \text{if } x^B_i = z_i \\
\infty, & \text{if } x^B_i = w_i \text{ or } v_i
\end{cases}
\]

The values of the non-basic variables \( x^N_i \) and \( x^N_{i+n} \) are determined by the assignment of \( x^B_i \):

\[
x^B_i = \begin{cases} 
z_i \Rightarrow \begin{cases} x^N_i = w_i = 0 \\
x^N_{i+n} = v_i = 0\end{cases} \\
w_i \Rightarrow \begin{cases} x^N_i = z_i = \ell_i \\
x^N_{i+n} = v_i = 0\end{cases} \\
v_i \Rightarrow \begin{cases} x^N_i = w_i = 0 \\
x^N_{i+n} = z_i = u_i.
\end{cases}
\end{cases}
\]

In words: if \( z_i \) is basic then both \( w_i \) and \( v_i \) equal zero. If \( z_i \) is non-basic at its lower bound, then \( w_i \) is possibly non-zero and \( v_i \) is non-basic at zero. If \( z_i \) is non-basic at its upper bound, then \( v_i \) is possibly non-zero and \( w_i \) is non-basic at zero.

Conceptually, we could solve the LCP by evaluating \( 3^n \) linear systems of the form:

\[ x^B = B^{-1}(q - Nx^N). \]

Lemke’s pivoting algorithm provides a procedure for finding a solution by sequentially evaluating some (hopefully small) subset of these \( 3^n \) alternative linear systems.
4.33.4.2 Initialization

Let \( B^0 \) denote the initial basis matrix. The initial values for basic variables are then:

\[
\dot{x}^B = (B^0)^{-1}(q - N \cdot \dot{x}^N).
\]

If \( \dot{x}^B \leq \dot{x}^B \leq \dot{x}^B \), then the initial basis is feasible and the complementarity problem is solved. Otherwise, MILES introduces an artificial variable \( z_0 \) and an artificial column \( h \). Basic variables are then expressed as follows:

\[
x^B = \dot{x}^B - \tilde{h}z_0,
\]

where \( \tilde{h} \) is the “transformed artificial column” (the untransformed column is \( h = B^0\tilde{h} \)). The coefficients of \( \tilde{h} \) are selected so that:

1. The values of “feasible” basis variables are unaffected by \( z_0 \): \( x^B_0 \leq x^B_1 \leq \dot{x}^B \Rightarrow \tilde{h}_i = 0 \).
2. The “most infeasible” basic variable \( (i = p) \) is driven to its upper or lower bound when \( z_0 = 1 \):

\[
\tilde{h}_p = \begin{cases} 
\dot{x}^B_p - \dot{x}^B, & \text{if } \dot{x}^B_p > \dot{x}^B_p \\
\dot{x}^B_p - \dot{x}^B, & \text{if } \dot{x}^B_p < \dot{x}^B_p .
\end{cases}
\]

3. All other infeasible basic variables assume values between their upper and lower bounds when \( z_0 \) increases to 1:

\[
x^B_i = \begin{cases} 
1 + \frac{x^B_i}{B^0}, & \text{if } \dot{x}^B_i > -\infty, \dot{x}^B_i = +\infty \\
\frac{x^B_i + B^0}{B^0}, & \text{if } \dot{x}^B_i > -\infty, \dot{x}^B_i < +\infty \\
\dot{x}^B_i - 1, & \text{if } \dot{x}^B_i = -\infty, \dot{x}^B_i < +\infty .
\end{cases}
\]

4.33.4.3 Pivoting Rules

When \( z_0 \) enters the basis, it assumes a value of unity, and at this point (barring degeneracy), the subsequent pivot sequence is entirely determined. The entering variable in one iteration is determined by the exiting basic variable in the previous iteration. For example, if \( z_i \) were in \( B^0 \) and introducing \( z_0 \) caused \( z_i \) to move onto its lower bound, then the subsequent iteration introduces \( w_i \). Conversely, if \( w_i \) were in \( B^0 \) and \( z_0 \) caused \( w_i \) to fall to zero, the subsequent iteration increases \( z_i \) from \( \ell_i \). Finally, if \( v_i \) were in \( B^0 \) and \( z_0 \)’s introduction caused \( v_i \) to fall to zero, the subsequent iteration decreases \( z_i \) from \( u_i \).

| Table 1 Pivot Sequence Rules for Lemke’s Algorithm with Implicit Bounds |
|------------------|------------------|------------------|
| N    | Exiting Variable | Entering Variable | Change in Non-basic Values |
| I    | \( z_i \) at lower bound | \( w_i \) increases from 0 | \( x_i^N = z_i = \ell_i \) |
| II   | \( z_i \) at upper bound | \( v_i \) increases from 0 | \( x_i^{N+1} = z_i = u_i \) |
| III  | \( w_i \) at 0 | \( z_i \) increases from \( \ell_i \) | \( x_i^N = x_{i+1}^{N+1} = 0 \) |
| IV   | \( v_i \) at 0 | \( z_i \) decreases from \( u_i \) | \( x_i^N = x_i^{N+1} = 0 \) |

\(^9\)In MILES, \( B^0 \) is chosen using the initially assigned values for \( z \). When \( z_i \leq \ell_i \), then \( x^B_i = w_i \); when \( z_i \geq u_i \), then \( x^B_i = v_i \); otherwise \( x^B_i = z_i \).  
\(^10\)The present version of the code simply sets \( B^0 = -I \) and \( x^B = w \) when the user-specified basis is singular. A subsequent version of the code will incorporate the algorithm described by Aanstreicher, Lee, and Rutherford [1992] for coping with singularity.
The full set of pivoting rules is displayed in Table 1. One difference between this algorithm and the original Lemke (type III) pivoting scheme (see Lemke (1965), Garcia and Zangwill (1981), or Cottle and Pang (1992)) is that structural variables (\( z_i \)'s) may enter or exit the basis at their upper bound values. The algorithm, therefore, must distinguish between pivots in which the entering variable increases from a lower bound and those in which the entering variable decreases from an upper bound.

Another difference with the "usual" Lemke pivot procedure is that an entering structural variable may move from one bound to another. When this occurs, the subsequent pivot introduces the corresponding slack variable. For example, if \( z_i \) is increased from \( \ell_i \) to \( u_i \) without driving a basic variable infeasible, then \( z_i \) becomes non-basic at \( u_i \), and the subsequent pivot introduces \( v_i \). This type of pivot may be interpreted as \( z_i \) entering and exiting the basis in a single step.\(^{11}\)

In theory it is convenient to ignore degeneracy, while in practice degeneracy is unavoidable. The present algorithm does not incorporate a lexicographic scheme to avoid cycling, but it does implement a ratio test procedure which assures that when there is more than one candidate, priority is given to the most stable pivot. The admissible set of pivots is determined on both an absolute pivot tolerance (\( ZTOLPV \)) and a relative pivot tolerance (\( ZTOLRP \)). No pivot with absolute value smaller than \( \min(ZTOLPV, ZTOLRP \|V\|) \) is considered, where \( \|V\| \) is the norm of the incoming column.

### 4.33.4.4 Termination on a Secondary Ray

Lemke's algorithm terminates normally when the introduction of a new variable drives \( z_0 \) to zero. This is the desired outcome, but it does not always happen. The algorithm may be interrupted prematurely when no basic variable "blocks" an incoming variable, a condition known as "termination on a secondary ray". In anticipation of such outcomes, MILES maintains a record of the value of \( z_0 \) for successive iterations, and it saves basis information associated with the smallest observed value, \( z_0^* \). (In Lemke's algorithm, the pivot sequence is determined without regard for the effect on \( z_0 \), and the value of the artificial variable may follow an erratic (non-monotone) path from its initial value of one to the final value of zero.)

When MILES encounters a secondary ray, a restart procedure is invoked in which the set of basic variables associated with \( z_0^* \) are reinstalled. This basis (augmented with one column from the non-basic triplet to replace \( z_0 \)) serves as \( B^0 \), and the algorithm is restarted. In some cases this procedure permits the pivot sequence to continue smoothly to a solution, while in other cases may only lead to another secondary ray.

### 4.33.5 The Options File

The standard GAMS options (e.g. iterlim, reslim) can be used to control MILES. For more details, see section Controlling a Solver via GAMS Options.

In addition, MILES-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

The following is a typical MILES options file:

```
ITLIMT  = 50
CONTOL  = 1.0E-8
LUSIZE  = 16
```

In the remainder of this section we describe the MILES options and give their default values.

---

\(^{11}\)If all structural variables are subject to finite upper and lower bounds, then no \( z_i \) variables may be part of a homogeneous solution adjacent to a secondary ray. This does not imply, however, that secondary rays are impossible when all \( z_i \) variables are bounded, as a ray may then be comprised of \( w_i \) and \( v_i \) variables.

### 4.33.6 Log File Output

The log file is intended for display on the screen in order to permit monitoring progress. Relatively little output is generated.

A sample iteration log is displayed in Table 2. This output is from two cases solved in succession. This and subsequent output comes from program TRNSP.FOR which calls the MILES library directly. (When MILES is invoked from within GAMS, at most one case is processed at a time.)

The first line of the log output gives the MILES program date and version information. This information is important for bug reports.

The line beginning "Work space..." reports the amount of memory which has been allocated to solve the model - 10K for this example. Thereafter is reported the initial deviation together with the name of the variable associated with the largest imbalance (\( \epsilon_B^i + \epsilon_C^i \)). The next line reports the convergence tolerance.

The lines beginning 0 and 1 are the major iteration reports for those iterations. the number following the iteration number is the current deviation, and the third number is the Armijo step length. The name of the variable complementary to the equation with the largest associated deviation is reported in parenthesis at the end of the line.

Following the final iteration is a summary of iterations, refactorizations, and final deviation. The final message reports the solution status. In this case, the model has been successfully processed ("Solved.").

4.33.7 Status File Output

The status file reports more details regarding the solution process than are provided in the log file. Typically, this file is written to disk and examined only if a problem arises. Within GAMS, the status file appears in the listing only following the GAMS statement `OPTION SYSOUT=ON;`.

The level of output to the status file is determined by the options passed to the solver. In the default configuration, the status file receives all information written to the log file together with a detailed listing of all switches and tolerances and a report of basis factorization statistics.

When output levels are increased from their default values using the options file, the status file can receive considerably more output to assist in debugging. Table 3 - Table 6 present a status file generated with LEVOUT=3 (maximum), PIVLOG=T, and LCPECH=T.

The status file begins with the same header as the log file. Thereafter is a complete echo-print of the user-supplied option file when one is provided. Following the core allocation report is a full echo-print of control parameters, switches and tolerance as specified for the current run.

Table 4 continues the status file. The iteration-by-iteration report of variable and function values is produced whenever LEVOUT >= 2. Table 4 also contains an LCP echo-print. This report has two sections: $ROWS and $GLOBALS. The four columns of numbers in the $ROWS section are the constant vector (q), the current estimate of level values for the associated variables (z), and the lower and upper bounds vectors (ℓ and u). The letters L and U which appear between the ROW and Z columns are used to identify variables which are non-basic at their lower and upper bounds, respectively. In this example, all upper bounds equal +∞, so no variables are non-basic at their upper bound.

By convention, only variable (and not equation names) appear in the status file. An equation is identified by the corresponding variable. We therefore see in the $GLOBALS: section of the matrix echo-print, the row names correspond to the names of z variables. The names assigned to variables $z_i$, $w_i$ and $v_i$ are...
$z \leftarrow \text{<name i>}, w \leftarrow \text{<name i>},$ and $v \leftarrow \text{<name i>}$, as shown in the `$\text{COLUMNS}$ section. The nonzeros for $w \leftarrow <$ and $v \leftarrow <$ variables are not shown because they are assumed to be $-/ + I$.

The status file output continues on Table 5 where the first half of the table reports output from the matrix scaling procedure, and the second half reports the messages associated with initiation of Lemke's procedure.

The "lu6chk warning" is a LUSOL report. Thereafter are two factorization reports. Two factorizations are undertaken here because the first basis was singular, so the program installs all the lower bound slacks in place of the matrix defined by the initial values, $z$.

Following the second factorization report, at the bottom of Table 5 is a summary of the initial pivot. "Infeasible in 3 rows." indicates that $\tilde{h}$ contains 3 nonzero elements. "Maximum infeasibility" reports the largest amount by which a structural variable violates an upper or lower bound. "Artificial column with 3 elements." indicates that the vector $h = B^0\tilde{h}$ contains 3 elements (note that in this case $B^0 = -I$ because the initial basis was singular, hence the equivalence between the number of nonzeros in $\tilde{h}$ and $h$).

Table 6 displays the final section of the status file. At the top of the table is the Lemke iteration log. The columns are interpreted as follows:

- **ITER** is the iteration index beginning with 0.
- **STATUS** is a statistic representing the efficiency of the Lemke path. Formally, status is the ratio of the minimum number of pivots from $B_0$ to the current basis divided by the actual number of pivots. When the status is 1, Lemke's algorithm is performing virtually as efficiently as a direct factorization (apart from the overhead of basis factor updates.)
- **$Z\%$** indicates the percentage of columns in the basis are "structural" (z's).
- **$Z_0$** indicates the value of the artificial variable. Notice that in this example, the artificial variable declines monotonically from its initial value of unity.
- **ERROR** is a column in which the factorization error is reported, when it is computed. For this run, ITCH=30 and hence no factorization errors are computed.
- **INFEAS** is a column in which the magnitude of the infeasibility introduced by the artificial column (defined using the box-norm) is reported. (In MILES the cover vector $h$ contains many different nonzero values, not just 1's; so there may be a large difference between the magnitude of the artificial variable and the magnitude of the induced infeasibility.
- **PIVOTS** reports the pivot magnitude in both absolute terms (the first number) and relative terms (the second number). The relative pivot size is the ratio of the pivot element to the norm of the incoming column.
- **IN/OUT** report the indices (not names) of the incoming and outgoing columns for every iteration. Notice that Lemke's iteration log concludes with variable $z_0$ exiting the basis.

The convergence report for iteration 1 is no different from the report written to the log file, and following this is a second report of variable and function values. We see here that a solution has been obtained following a single subproblem. This is because the underlying problem is, in fact, linear.

The status file (for this case) concludes with an iteration summary identical to the log file report and a summary of how much CPU time was employed overall and within various subtasks. (Don't be alarmed if the sum of the last five numbers does not add up to the first number - some cycles are not monitored precisely.)

4.33.8 Termination Messages

Basis factorization error in INVERT. An unexpected error code returned by LUSOL. This should normally not occur. Examine the status file for a message from LUSOL.\(^\text{12}\).

\(^\text{12}\)Within GAMS, insert the line "OPTION SYSOUT=ON;" prior to the solve statement and resubmit the program in order to pass the MILES solver status file through to the listing.
**Failure to converge.** Two successive iterates are identical - the Newton search direction is not defined. This should normally not occur.

**Inconsistent parameters** $\text{ZTOLZ0}$, $\text{ZTOLZE}$. $\text{ZTOLZ0}$ determines the smallest value loaded into the cover vector $h$, whereas $\text{ZTOLZE}$ is the feasibility tolerance employed in the Harris pivot selection procedure. If $\text{ZTOLZ0} < -\text{ZTOLZE}$, Lemke's algorithm cannot be executed because the initial basis is infeasible.

**Insufficient space for linearization.** Available memory is inadequate for holding the nonzeros in the Jacobian. More memory needs to be allocated. If there is insufficient space for the Jacobian matrix, there is far too little memory for holding the LU factors of the same matrix.

**Insufficient space to invert.** More memory needs to be allocated for basis factors. Increase the value of $\text{LUSIZE}$ in the options file, or assign a larger value to `<model>.workspace`.

**Iteration limit exceeded.** This can result from either exceeding the major (Newton) or minor (Lemke) iterations limit. When MILES is invoked from GAMS, the cumulative Lemke iteration limit can be set with the statement `<model>.iterlim = xx` . The Newton iteration limit is 100 by default, and it can be modified only through the `ITLIMT` option.

**Resource interrupt.** Elapsed CPU time exceeds options parameter `RESLIM`. To increase this limit, either add `RESLIM = xxx` in the options file or add a GAMS statement `<model>.RESLIM = xxx`.

**Singular matrix encountered.** Lemke's algorithm has been interrupted due to a singularity arising in the basis factorization, either during a column replacement or during a refactorization. For some reason, a restart is not possible.

**Termination on a secondary ray.** Lemke's algorithm terminated on a secondary ray. For some reason, a restart is not possible.

**Unknown termination status.** The termination status flag has not been set, but the code has interrupted. Look in the status file for a previous message. This termination code should not happen often.

$TITLE LP TRANSPORTATION PROBLEM FORMULATED AS A ECONOMIC EQUILIBRIUM
*============================================================================
* In this file, Dantzig's original transportation model is
* reformulated as a linear complementarity problem. We first
* solve the model with fixed demand and supply quantities, and
* then we incorporate price-responsiveness on both sides of the
* market.
* T.Rutherford 3/91 (revised 5/91)
*============================================================================
* This problem finds a least cost shipping schedule that meets
* requirements at markets and supplies at factories
*

4.34.1  Introduction

This document describes the GAMS interface to MINOS which is a general purpose nonlinear programming solver.

GAMS/MINOS is a specially adapted version of the solver that is used for solving linear and nonlinear programming problems in a GAMS environment.

GAMS/MINOS is designed to find solutions that are locally optimal. The nonlinear functions in a problem must be smooth (i.e., their first derivatives must exist). The functions need not be separable. Integer restrictions cannot be imposed directly.

A certain region is defined by the linear constraints in a problem and by the bounds on the variables. If the nonlinear objective and constraint functions are convex within this region, any optimal solution obtained will be a global optimum. Otherwise there may be several local optima, and some of these may not be global. In such cases the chances of finding a global optimum are usually increased by choosing a staring point that is "sufficiently close", but there is no general procedure for determining what "close" means, or for verifying that a given local optimum is indeed global.

Linearly constrained models are solved with a very efficient and reliable reduced gradient technique that takes advantage of the sparsity of the model. Models with nonlinear constraints are solved with a method that iteratively solves subproblems with linearized constraints and an augmented Lagrangian objective function. This iterative scheme implies that only the final, optimal solution is sure to be feasible w.r.t the nonlinear constraints. This is in contrast to the feasible path method used by some other NLP solvers, e.g., CONOPT. MINOS and CONOPT are very complementary to each other as they employ very different algorithms. See MINOS vs CONOPT for a comparison of the two solvers.

GAMS allows you to specify values for many parameters that control GAMS/MINOS, and with careful experimentation you may be able to influence the solution process in a helpful way. All MINOS options available through GAMS/MINOS are summarized at the end of this document.
4.34 MINOS and QUADMINOS

4.34.2 GAMS/QUADMINOS

For LP (and RMIP) models that cause difficulty for the standard solvers, QUADMINOS provides considerably greater reliability and accuracy by using quadruple-precision floating-point arithmetic. Although it is slower by a factor of 20 or 30 for cold-start runs, you can use standard MINOS or another LP solver first and let them do their best. Warm-starts with QUADMINOS may give greatly improved solutions at moderate cost.

The documentation below refers to both MINOS and QUADMINOS. To take advantage of QUADMINOS, the main requirement is to set a few runtime options to non-default values in order to request higher accuracy. For example, it is reasonable to set

- Feasibility tolerance 1e-15
- Optimality tolerance 1e-15

because IEEE Quad floating-point has nearly 34 digits of precision. For an example of using Double and Quad MINOS together, see [DQQ] in the GAMS model library.

4.34.3 How to Run a Model with GAMS/MINOS

MINOS is capable of solving many types of models, including LP, NLP, DNLP and QCP. If MINOS is not specified as the default solver for the desired model type (e.g. NLP), then the following statement can be used in your GAMS model to select MINOS:

```
option nlp=minos;
```

The option statement should appear before the `solve` statement.

To be complete, we mention that the solver can be also specified on the command line, as in:

```
> gams camcge nlp=minos
```

This will override the global default, but if an algorithm option has been specified inside the model, then that specification takes precedence.

4.34.4 Overview of GAMS/MINOS

GAMS/MINOS is a system designed to solve large-scale optimization problems expressed in the following form:

\[
\begin{align*}
\text{NLP :} & \quad \text{minimize} & & F(x) + c^T x + d^T y \\
& \text{subject to} & & f(x) + A_1 y \sim b_1 \\
& & & A_2 x + A_3 y \sim b_2 \\
& & & \ell \leq \begin{pmatrix} x \\ y \end{pmatrix} \leq u
\end{align*}
\]

(1) \hspace{2cm} (2) \hspace{2cm} (3) \hspace{2cm} (4)

where the vectors \(c, d, b_1, b_2, \ell, u\) and the matrices \(A_1, A_2, A_3\) are constant, \(F(x)\) is a smooth scalar function, and \(f(x)\) is a vector of smooth functions. The \(\sim\) signs mean that individual constraints may be defined using \(\leq, =\) or \(\geq\) corresponding to the GAMS constructs \(=L=, =E=\) and \(=G=\).

The components of \(x\) are called the nonlinear variables, and the components of \(y\) are the linear variables. Similarly, the equations in (2) are called the nonlinear constraints, and the equations in (3) are the linear constraints. Equations (2) and (3) together are called the general constraints.

Let \(m_1\) and \(n_1\) denote the number of nonlinear constraints and variables, and let \(m\) and \(n\) denote the total number of (general) constraints and variables. Thus, \(A_3\) has \(m - m_1\) rows and \(n - n_1\) columns. The constraints (4) specify upper and lower bounds on all variables. These are fundamental to many problem formulations and are treated specially by the solution algorithms in GAMS/MINOS. Some of the components of \(\ell\) and \(u\) may be \(-\infty\) or \(+\infty\) respectively, in accordance with the GAMS use of \(-\text{INF}\) and \(+\text{INF}\).

The vectors \(b_1\) and \(b_2\) are called the right-hand side, and together are denoted by \(b\).
4.34.4.1 Linear Programming

If the functions \( F(x) \) and \( f(x) \) are absent, the problem becomes a linear program. Since there is no need to distinguish between linear and nonlinear variables, we use \( x \) rather than \( y \). GAMS/MINOS converts all general constraints into equalities, and the only remaining inequalities are simple bounds on the variables. Thus, we write linear programs in the form

\[
\text{LP : } \text{minimize } c^T x \\
\text{subject to } Ax + Is = 0 \\
\ell \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u
\]

where the elements of \( x \) are your own GAMS variables, and \( s \) is a set of slack variables: one for each general constraint. For computational reasons, the right-hand side \( b \) is incorporated into the bounds on \( s \).

In the expression \( Ax + Is = 0 \) we write the identity matrix explicitly if we are concerned with columns of the associated matrix \( (A \ I) \). Otherwise we will use the equivalent notation \( Ax + s = 0 \).

GAMS/MINOS solves linear programs using a reliable implementation of the primal simplex method \([63]\) , in which the constraints \( Ax + Is = 0 \) are partitioned into the form

\[
Bx_B + Nx_N = 0,
\]

where the basis matrix is square and nonsingular. The elements of \( x_B \) and \( x_N \) are called the basic or nonbasic variables respectively. Together they are a permutation of the vector

\[
\begin{pmatrix} x \\ s \end{pmatrix}.
\]

Normally, each nonbasic variable is equal to one of its bounds, and the basic variables take on whatever values are needed to satisfy the general constraints. (The basic variables may be computed by solving the linear equations \( Bx_B = Nx_N \).) It can be shown that if an optimal solution to a linear program exists, then it has this form.

The simplex method reaches such a solution by performing a sequence of iterations, in which one column of \( B \) is replaced by one column of \( N \) (and vice versa), until no such interchange can be found that will reduce the value of \( c^T x \).

As indicated nonbasic variables usually satisfy their upper and lower bounds. If any components of \( x_B \) lie significantly outside their bounds, we say that the current point is infeasible. In this case, the simplex method uses a Phase 1 procedure to reduce the sum of infeasibilities to zero. This is similar to the subsequent Phase 2 procedure that optimizes the true objective function \( c^T x \).

If the solution procedures are interrupted, some of the nonbasic variables may lie strictly between their bounds \( \ell_j < x_j < u_j \). In addition, at a "feasible" or "optimal" solution, some of the basic variables may lie slightly outside their bounds: \( \ell_j - \delta < x_j < \ell_j \) or \( u_j < x_j < u_j + \delta \) where \( \delta \) is a feasibility tolerance (typically \( 10^{-6} \)). In rare cases, even nonbasic variables might lie outside their bounds by as much as \( \delta \).

GAMS/MINOS maintains a sparse \( LU \) factorization of the basis matrix \( B \), using a Markowitz ordering scheme and Bartels-Golub updates, as implemented in the Fortran package LUSOL \([110]\) (see \([29]\) \([30]\) \([196]\) \([197]\) ). The basis factorization is central to the efficient handling of sparse linear and nonlinear constraints.
4.34 MINOS and QUADMINOS

4.34.4.2 Problems with a Nonlinear Objective

When nonlinearities are confined to the term $F(x)$ in the objective function, the problem is a linearly constrained nonlinear program. GAMS/MINOS solves such problems using a reduced-gradient algorithm [256] combined with a quasi-Newton algorithm that is described in [183]. In the reduced-gradient method, the constraints $Ax+Is=0$ are partitioned into the form

$$Bx_B + Sx_S + Nx_N = 0$$

where $x_s$ is a set of superbasic variables. At a solution, the basic and superbasic variables will lie somewhere between their bounds (to within the feasibility tolerance $\delta$, while nonbasic variables will normally be equal to one of their bounds, as before. Let the number of superbasic variables be $s$, the number of columns in $S$. (The context will always distinguish $s$ from the vector of slack variables.) At a solution, $s$ will be no more than $n_1$, the number of nonlinear variables. In many practical cases we have found that $s$ remains reasonably small, say 200 or less, even if $n_1$ is large.

In the reduced-gradient algorithm, $x_s$ is regarded as a set of ”independent variables” or ”free variables” that are allowed to move in any desirable direction, namely one that will improve the value of the objective function (or reduce the sum of infeasibilities). The basic variables can then be adjusted in order to continue satisfying the linear constraints.

If it appears that no improvement can be made with the current definition of $B$, $S$ and $N$, some of the nonbasic variables are selected to be added to $S$, and the process is repeated with an increased value of $s$. At all stages, if a basic or superbasic variable encounters one of its bounds, the variable is made nonbasic and the value of $s$ is reduced by one.

A step of the reduced-gradient method is called a minor iteration. For linear problems, we may interpret the simplex method as being the same as the reduced-gradient method, with the number of superbasic variable oscillating between 0 and 1.

A certain matrix $Z$ is needed now for descriptive purposes. It takes the form

$$
\begin{pmatrix}
-B^{-1}S \\
I \\
0
\end{pmatrix}
$$

though it is never computed explicitly. Given an $LU$ factorization of the basis matrix $B$, it is possible to compute products of the form $Zq$ and $Z^Tg$ by solving linear equations involving $B$ or $B^T$. This in turn allows optimization to be performed on the superbasic variables, while the basic variables are adjusted to satisfy the general linear constraints.

An important feature of GAMS/MINOS is a stable implementation of a quasi-Newton algorithm for optimizing the superbasic variables. This can achieve superlinear convergence during any sequence of iterations for which the $B$, $S$, $N$ partition remains constant. A search direction $q$ for the superbasic variables is obtained by solving a system of the form

$$R^T R q = -Z^T g$$

where $g$ is a gradient of $F(x)$, $Z^T g$ is the reduced gradient, and $R$ is a dense upper triangular matrix. GAMS computes the gradient vector $g$ analytically, using automatic differentiation. The matrix $R$ is updated in various ways in order to approximate the reduced Hessian according to $R^T R \approx Z^T H Z$ where $H$ is the matrix of second derivatives of $F(x)$ (the Hessian).

Once $q$ is available, the search direction for all variables is defined by $p = Zq$. A ine search is then performed to find an approximate solution to the one-dimensional (w.r.t. $\alpha$) problem

$$\begin{align*}
\text{minimize} & \quad F(x + \alpha p) \\
\text{subject to} & \quad 0 < \alpha < \beta
\end{align*}$$
where $\beta$ is determined by the bounds on the variables. Another important piece in GAMS/MINOS is a step-length procedure used in the linesearch to determine the step-length $\alpha$ (see [108]). The number of nonlinear function evaluations required may be influenced by setting the Linesearch tolerance, as discussed in Section Detailed Description of MINOS Options.

As in a linear programming solver, an equation $B^T \pi = gB$ is solved to obtain the dual variables or shadow prices $\pi$ where $gB$ is the gradient of the objective function associated with basic variables. It follows that $gB - B^T \pi = 0$. The analogous quantity for superbasic variables is the reduced-gradient vector $Z^T g = gs - s^T \pi$; this should also be zero at an optimal solution. (In practice its components will be of order $r||\pi||$ where $r$ is the optimality tolerance, typically $10^{-6}$, and $||\pi||$ is a measure of the size of the elements of $\pi$.)

### 4.34.4.3 Problems with Nonlinear Constraints

If any of the constraints are nonlinear, GAMS/MINOS employs a project Lagrangian algorithm, based on a method due to [199], see [184]. This involves a sequence of major iterations, each of which requires the solution of a linearly constrained subproblem. Each subproblem contains linearized versions of the nonlinear constraints, as well as the original linear constraints and bounds.

At the start of the $k$-th major iteration, let $x_k$ be an estimate of the nonlinear variables, and let $\lambda_k$ be an estimate of the Lagrange multipliers (or dual variables) associated with the nonlinear constraints. The constraints are linearized by changing $f(x)$ in equation (2) to its linear approximation:

$$f'(x, x_k) = f(x_k) + J(x_k)(x - x_k)$$

or more briefly

$$f' = f_k + J_k(x - x_k)$$

where $J(x_k)$ is the Jacobian matrix evaluated at $x_k$. (The $i$-th row of the Jacobian is the gradient vector of the $i$-th nonlinear constraint function. As with the objective gradient, GAMS calculates the Jacobian using automatic differentiation).

The subproblem to be solved during the $k$-th major iteration is then

\[
\begin{align*}
\text{minimize} & \quad F(x) + c^T x + d^T y - \lambda_k^T (f - f') + 0.5 \rho (f - f')^T (f - f') \\
\text{subject to} & \quad f' + A_1 y \sim b_1 \\
& \quad A_2 x + A_3 y \sim b_2 \\
& \quad \ell \leq \begin{pmatrix} x \\ y \end{pmatrix} \leq u
\end{align*}
\]  
(5) (6) (7) (8)

The objective function (5) is called an augmented Lagrangian. The scalar $\rho$ is a penalty parameter, and the term involving $\rho$ is a modified quadratic penalty function.

GAMS/MINOS uses the reduced-gradient algorithm to minimize (5) subject to (6) – (8). As before, slack variables are introduced and $b_1$ and $b_2$ are incorporated into the bounds on the slacks. The linearized constraints take the form

$$\begin{pmatrix} J_k & A_1 \\ A_2 & A_3 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \begin{pmatrix} s_1 \\ s_2 \end{pmatrix} = \begin{pmatrix} J_k x_k - f_k \\ 0 \end{pmatrix}$$

This system will be referred to as $Ax + Is = 0$ as in the linear case. The Jacobian $J_k$ is treated as a sparse matrix, the same as the matrices $A_1$, $A_2$, and $A_3$.

In the output from GAMS/MINOS, the term Feasible subproblem indicates that the linearized constraints have been satisfied. In general, the nonlinear constraints are satisfied only in the limit, so that feasibility and optimality occur at essentially the same time. The nonlinear constraint violation is printed every major iteration. Even if it is zero early on (say at the initial point), it may increase and perhaps fluctuate before tending to zero. On "well behaved problems", the constraint violation will decrease quadratically (i.e., very quickly) during the final few major iterations.
4.34.5 Modeling Issues

Formulating nonlinear models requires that the modeler pays attention to some details that play no role when dealing with linear models.

4.34.5.1 Starting Points

The first issue is specifying a starting point. It is advised to specify a good starting point for as many nonlinear variables as possible. The GAMS default of zero is often a very poor choice, making this even more important.

As an (artificial) example consider the problem where we want to find the smallest circle that contains a number of points \((x_i, y_i)\):

Example:

\[
\begin{align*}
\text{minimize} & \quad r \\
\text{subject to} & \quad (x_i - a)^2 + (y_i - b)^2 \leq r^2, \quad r \geq 0.
\end{align*}
\]

This problem can be modeled in GAMS as follows.

```gams
set i 'points' /p1*p10/;
parameters
  x(i)  'x coordinates',
  y(i)  'y coordinates';
* fill with random data
x(i) = uniform(1,10);
y(i) = uniform(1,10);
variables
  a      'x coordinate of center of circle'
  b      'y coordinate of center of circle'
  r      'radius';
equations
  e(i)   'points must be inside circle';
e(i)..  sqr(x(i)-a) + sqr(y(i)-b) =l=  sqr(r);
r.lo = 0;
model m /all/;
option nlp=minos;
solve m using nlp minimizing r;
```

Without help, MINOS will not be able to find an optimal solution. The problem will be declared infeasible. In this case, providing a good starting point is very easy. If we define

\[
\begin{align*}
  x_{\min} &= \min_i x_i, \\
  y_{\min} &= \min_i y_i, \\
  x_{\max} &= \max_i x_i, \\
  y_{\max} &= \max_i y_i,
\end{align*}
\]
then good estimates are

\[ a = \frac{(x_{\text{min}} + x_{\text{max}})}{2}, \]

\[ b = \frac{(y_{\text{min}} + y_{\text{max}})}{2}, \]

\[ r = \sqrt{(a - x_{\text{min}})^2 + (b - y_{\text{min}})^2}. \]

Thus we include in our model:

```plaintext
parameters xmin, ymin, xmax, ymax;
xmin = smin(i, x(i));
ymin = smin(i, y(i));
xmax = smax(i, x(i));
ymax = smax(i, y(i));

* set starting point
a.l = (xmin + xmax)/2;
b.l = (ymin + ymax)/2;
r.l = sqrt(sqr(a.l-xmin) + sqr(b.l-ymin));
```

and now the model solves very easily.

Level values can also be set away from zero implicitly as a result of assigning bounds. When a variable is bounded away from zero, for instance by the statement `Y.LO = 1;`, the implicit projection of variable levels onto their bounds that occurs when a model is solved will initialize `Y` away from zero.

### 4.3.4.5.2 Bounds

Setting appropriate bounds can be very important to steer the algorithm away from uninteresting areas, and to prevent function evaluation errors from happening.

If your model contains a real power of the form `x**y` it is important to add a bound `x > 0.001`, as real exponentation is evaluated in GAMS as `exp(y log(x))`. In some cases one cannot write a bound directly, e.g. if the equation is `z = x^f(y)`. In that case it is advised to introduce an extra variable and equation:

\[ z = x^\vartheta \]

\[ \vartheta = f(y) \]

\[ \vartheta \geq \varepsilon \]

(Note that the functions `SQR(x)` and `POWER(x,k)` are integer powers and do not require `x` to be positive).

If the model produces function evaluation errors adding bounds is prefered to raising the `DOMLIM` limit.

Bounds in GAMS are specified using `X.LO(i)=0.001` and `X.UP(i) = 1000`.

### 4.3.4.5.3 Scaling

Although MINOS has some facilities to scale the problem before starting to optimize it, it remains an important task for the modeler to provide a well-scaled model. This is especially the case for nonlinear models. GAMS has special syntax features to specify row and column scales that allow the modeler to keep the equations in a most natural form. For more information consult the GAMS User's Guide.
4.34.5.4 The Objective Function

The first step GAMS/MINOS performs is to try to reconstruct the objective function. In GAMS, optimization models minimize or maximize an objective variable. MINOS however works with an objective function. One way of dealing with this is to add a dummy linear function with just the objective variable. Consider the following GAMS fragment:

```
obj.. z =e= sum(i, sqr(resid(i)));
model m /all/;
solve m using nlp minimizing z;
```

This can be cast in form NLP (equations (1) – (4)) by saying minimize $z$ subject to $z = \sum_i resid_i^2$ and the other constraints in the model. Although simple, this approach is not always preferable. Especially when all constraints are linear it is important to minimize $\sum_i resid_i^2$ directly. This can be achieved by a simple reformulation: $z$ can be substituted out. The substitution mechanism carries out the formulation if all of the following conditions hold:

- the objective variable $z$ is a free continuous variable (no bounds are defined on $z$),
- $z$ appears linearly in the objective function,
- the objective function is formulated as an equality constraint,
- $z$ is only present in the objective function and not in other constraints.

For many models it is very important that the nonlinear objective function be used by MINOS. For instance the model [CHEM] from the model library solves in 21 iterations. When we add the bound

```
energy.lo = 0;
```

to the objective variable energy and thus prevent it from being substituted out, MINOS will not be able to find a feasible point for the given starting point.

This reformulation mechanism has been extended for substitutions along the diagonal. For example, the GAMS model

```
Variables x,y,z;
Equations e1,e2;
e1..z =e= y;
e2..y =e= sqr(1+x);
model m /all/;
option nlp=minos;
solve m using nlp minimizing z;
```

will be reformulated as an unconstrained optimization problem

$$\text{minimize } f(x) = (1 + x)^2.$$  

These additional reformulations can be turned off by using the statement `option reform = 0;` (see Section GAMS Options).
4.34.6 GAMS Options

The standard GAMS options (e.g. iterlim, domlim) can be used to control GAMS/MINOS. For more details, see section Controlling a Solver via GAMS Options. We highlight some of the details of this usage below for cases of special interest.

iterlim

Sets the minor iteration limit. MINOS will stop as soon as the number of minor iterations exceeds the iteration limit and report the current solution.

domlim

Sets the domain error limit. Domain errors are evaluation errors in the nonlinear functions. An example of a domain error is trying to evaluate $\sqrt{x}$ for $x < 0$. Other examples include taking logs of negative numbers, and evaluating the real power $x^y$ for $x < \varepsilon$ ($x^y$ is evaluated as $\exp(y \log x)$). When such an error occurs the count of domain errors is incremented: MINOS will stop if this count exceeds the limit. If the limit has not been reached, reasonable estimates for the function (and derivatives, if requested) are returned and MINOS continues. For example, in the case of $\sqrt{x}, x < 0$ a zero is passed back for the function value and a large value for the derivative. In many cases MINOS will be able to recover from these domain errors, especially when they happen at some intermediate point. Nevertheless it is best to add appropriate bounds or linear constraints to ensure that these domain errors don’t occur. For example, when an expression $\log(x)$ is present in the model, add a statement like $x.lo = 0.001$.

bratio

Ratio used in basis acceptance test. When a previous solution or solution estimate exists, GAMS automatically passes this solution to MINOS so that it can reconstruct an advanced basis. When too many new (i.e. uninitialized with level and/or marginal values) variables or constraints enter the model, it may be better not to use existing basis information, but to instead crash a new basis. The bratio determines how quickly an existing basis is discarded. A value of 1.0 will discard any basis, while a value of 0.0 will retain any basis.

workfactor

By default, GAMS/MINOS computes an estimate of the amount of workspace needed by MINOS, and passes this workspace on to MINOS for use in solving the model. This estimate is based on the model statistics: number of (nonlinear) equations, number of (nonlinear) variables, number of (nonlinear) nonzeroes, etc. In most cases this is sufficient to solve the model. In some rare cases MINOS may need more memory, and the user can provide this by specifying a value of workfactor greater than 1. The computed memory estimate is multiplied by the workfactor to determine the amount of workspace made available to MINOS for the solve.

workspace

The workspace option is deprecated: use the workfactor option instead. The workspace option specifies the amount of memory, in MB, that MINOS will use.

reform

This option controls the objective reformulation mechanism described in Section The Objective Function. The default value of 100 will cause GAMS/MINOS to try further substitutions along the diagonal after the objective variable has been removed. Any other value will disable this diagonal procedure.
4.34.7 Summary of MINOS Options

The performance of GAMS/MINOS is controlled by a number of parameters or "options." Each option has a default value that should be appropriate for most problems. For special situations it is possible to specify non-standard values for some or all of the options through the MINOS option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

Note that the option file is not case sensitive. Examples for using the option file can be found at the end of this section. The tables below contain summary information about the MINOS options, default values, and links to more detailed explanations.

### 4.34.7.1 Output related options

### 4.34.7.5 Examples of GAMS/MINOS Option File

The following example illustrates the use of certain options that might be helpful for “difficult” models involving nonlinear constraints. Experimentation may be necessary with the values specified, particularly if the sequence of major iterations does not converge using default values.

* These options might be relevant for very nonlinear models.

- **Major damping parameter** 0.2 * may prevent divergence.
- **Minor damping parameter** 0.2 * if there are singularities
  * in the nonlinear functions.
- **Penalty parameter** 10.0 * or 100.0 perhaps—a value
  * higher than the default.
- **Scale linear variables** * (This is the default.)

Conversely, nonlinearly constrained models that are very nearly linear may optimize more efficiently if some of the cautious defaults are relaxed:

* Suggestions for models with MILDLY nonlinear constraints

- **Completion Full**
- **Penalty parameter** 0.0 * or 0.1 perhaps—a value
  * smaller than the default.
  * Scale one of the following
- **Scale all variables** * if starting point is VERY GOOD.
- **Scale linear variables** * if they need it.
- **Scale No** * otherwise.

Most of the options should be left at their default values for any given model. If experimentation is necessary, we recommend changing just one option at a time.

### 4.34.8 Special Notes

#### 4.34.8.1 Modeling Hints

Unfortunately, there is no guarantee that the algorithm just described will converge from an arbitrary starting point. The concerned modeler can influence the likelihood of convergence as follows:
- Specify initial activity levels for the nonlinear variables as carefully as possible (using the GAMS suffix .L).

- Include sensible upper and lower bounds on all variables.

- Specify a Major damping parameter that is lower than the default value, if the problem is suspected of being highly nonlinear.

- Specify a Penalty parameter $\rho$ that is higher than the default value, again if the problem is highly nonlinear.

In rare cases it may be safe to request the values $\lambda_k = 0$ and $\rho = 0$ for all subproblems, by specifying Lagrangian=No. However, convergence is much more likely with the default setting, Lagrangian=Yes. The initial estimate of the Lagrange multipliers is then $\lambda_0 = 0$, but for later subproblems $\lambda_k$ is taken to be the Lagrange multipliers associated with the (linearized) nonlinear constraints at the end of the previous major iteration.

For the first subproblem, the default value for the penalty parameter is $\rho = 100.0/m_1$ where $m_1$ is the number of nonlinear constraints. For later subproblems, $\rho$ is reduced in stages when it appears that the sequence $\{x_k, \lambda_k\}$ is converging. In many cases it is safe to specify $\lambda = 0$, particularly if the problem is only mildly nonlinear. This may improve the overall efficiency.

### 4.34.8.2 Storage

GAMS/MINOS uses one large array of memory for most of its workspace. The implementation places no fixed limit on the size of a problem or on its shape (many constraints and relatively few variables, or vice versa). In general, the limiting factor will be the amount of physical memory available on a particular machine, and the amount of computation time one is willing to spend.

Some detailed knowledge of a particular model will usually indicate whether the solution procedure is likely to be efficient. An important quantity is $m$, the total number of general constraints in (2) and (3). The amount of workspace required by GAMS/MINOS is roughly $100m$ doubles, or $800m$ bytes for workspace. A further $300K$ bytes, approximately, are needed for the program itself, along with buffer space for several files. Very roughly, then, a model with $m$ general constraints requires about $(m + 300) K$ bytes of memory.

Another important quantity is $n$, the total number of variables in $x$ and $y$. The above comments assume that $n$ is not much larger than $m$, the number of constraints. A typical ratio for $n/m$ is 2 or 3.

If there are many nonlinear variables (i.e., if $n_1$ is large), much depends on whether the objective function or the constraints are highly nonlinear or not. The degree of nonlinearity affects $s$, the number of superbasic variables. Recall that $s$ is zero for purely linear problems. We know that $s$ need never be larger than $n_1 + 1$. In practice, $s$ is often very much less than this upper limit.

In the quasi-Newton algorithm, the dense triangular matrix $R$ has dimension $s$ and requires about $s^2/2$ words of storage. If it seems likely that $s$ will be very large, some aggregation or reformulation of the problem should be considered.

### 4.34.9 The GAMS/MINOS Log File

MINOS writes different logs for LPs, NLPs with linear constraints, and NLPs with non-linear constraints. In this section, a sample log file is shown for each case, and the messages that appear are explained.
4.34.9.1 Linear Programs

MINOS uses a standard two-phase simplex method for LPs. In the first phase, the sum of the infeasibilities at each iteration is minimized. Once feasibility is attained, MINOS switches to phase 2 where it minimizes (or maximizes) the original objective function. The different objective functions are called the phase 1 and phase 2 objectives. Notice that the marginals in phase 1 are with respect to the phase 1 objective. This means that if MINOS interrupts in phase 1, the marginals are "wrong" in the sense that they do not reflect the original objective.

The log for the problem TURKPOW is as follows:

--- Starting compilation
--- Generating LP model turkey
--- Executing MINOS: elapsed 0:00:00.025

GAMS/MINOS 5.51 (Jun 2004)

Work space allocated -- 1.60 Mb

EXIT - Optimal Solution found, objective: 12657.77

--- Restarting execution
--- Reading solution for model turkey

The first line that is written by MINOS is the version string: GAMS/MINOS Aug 18, 2010 23.5.2 WIN 19143.19383 V8 x86/MS Windows This line identifies which version of the MINOS libraries and links you are using, and is only to be deciphered by GAMS support personnel.

After some advertisement text we see the amount of work space (i.e. memory) that is allocated: 1.60 Mb. When MINOS is loaded, the amount of memory needed is first estimated. This estimate is based on
statistics like the number of rows, columns and non-zeros. This amount of memory is then allocated and
the problem loaded into MINOS.

The columns have the following meaning:

**Itn**

Iteration number.

**ninf**

Number of infeasibilities. If nonzero the current iterate is still infeasible.

**sinf**

The sum of the infeasibilities. This number is minimized during Phase I. Once the model is
feasible this number is zero.

**objective**

The value of the objective function: \[ z = \sum c_i x_i \]. In phase II this number is maximized or
minimized. In phase I it may move in the wrong direction.

The final line indicates the exit status of MINOS.

### 4.34.9.2 Linearly Constrained NLP's

The log is basically the same as for linear models. The only difference is that not only matrix rows and
columns need to be loaded, but also instructions for evaluating functions and gradients.

The log for the problem **WEAPONS** is as follows:

EXIT - Optimal Solution found, objective: 191.7346

--- Restarting execution
Two sets of iterations, major and minor, are now reported. A description of the various columns present in this log file follows:

**Major**

A major iteration involves linearizing the nonlinear constraints and performing a number of minor iterations on the resulting subproblem. The objective for the subproblem is an augmented Lagrangian, not the true objective function.

**minor**

The number of minor iterations performed on the linearized subproblem. If it is a simple number like 90, then the subproblem was solved to optimality. Here, 2T means that the subproblem was terminated. In general the T is not something to worry about. Other possible flags are I and U, which mean that the subproblem was infeasible or unbounded. MINOS may have difficulty if these keep occurring.

**step**

The step size taken towards the solution suggested by the last major iteration. Ideally this should be 1.0, especially near an optimum. If the subproblem solutions are widely different, MINOS may reduce the step size under control of the Major Damping parameter.

**objective**

The objective function for the original nonlinear program.

**Feasible**

Primal infeasibility, indicating the maximum non-linear constraint violation.

**Optimal**

The maximum dual infeasibility, measured as the maximum departure from complementarity. If we call $d_j$ the reduced cost of variable $x_j$, then the dual infeasibility of $x_j$ is $d_j \times \min\{x_j - \ell_j, 1\}$ or $-d_j \times \min\{u_j - x_j, 1\}$ depending on the sign of $d_j$.

**nsb**

Number of superbasics. If the model is feasible this number cannot exceed the superbasic limit, which may need to be reset to a larger number if the numbers in this column become larger.

**ncon**

The number of times MINOS has evaluated the nonlinear constraints and their derivatives.

**penalty**

The current value of the penalty parameter in the augmented Lagrangian (the objective for the subproblems). If the major iterations appear to be converging, MINOS will decrease the penalty parameter. If there appears to be difficulty, such as unbounded subproblems, the penalty parameter will be increased.

**BSswp**

Number of basis swaps: the number of $B \rightarrow S$ (i.e. basic vs. superbasic) changes.

Note: The CAMCGE model (like many CGE models or other almost square systems) can better be solved with the MINOS option Start Assigned Nonlinear Basic.
4.34.10 Detailed Description of MINOS Options

The following is an alphabetical list of the keywords that may appear in the GAMS/MINOS options file, and a description of their effect. Options not specified will take the default values shown.

**check frequency (integer)**: Controls frequency of linear constraint satisfaction test

Every $i$th iteration after the most recent basis factorization, a numerical test is made to see if the current solution $x$ satisfies the general linear constraints (including linearized nonlinear constraints, if any). The constraints are of the form $Ax+s=0$ where $s$ is the set of slack variables. To perform the numerical test, the residual vector $r = Ax + s$ is computed. If the largest component of $r$ is judged to be too large, the current basis is refactorized and the basic variables are recomputed to satisfy the general constraints more accurately.

Range: $[1, \infty)$

Default: 60

**completion (string)**: Completion level for subproblems (full/partial)

When there are nonlinear constraints, this determines whether subproblems should be solved to moderate accuracy (partial completion) or to full accuracy (full completion). GAMS/MINOS implements the option by using two sets of convergence tolerances for the subproblems. Use of partial completion may reduce the work during early major iterations, unless the Minor iterations limit is active. The optimal set of basic and superbasic variables will probably be determined for any given subproblem, but the reduced gradient may be larger than it would have been with full completion. An automatic switch to full completion occurs when it appears that the sequence of major iterations is converging. The switch is made when the nonlinear constraint error is reduced below $100 \times \text{(Row tolerance)}$, the relative change in $\Lambda_k$ is 0.1 or less, and the previous subproblem was solved to optimality. Full completion tends to give better Lagrange-multiplier estimates. It may lead to fewer major iterations, but may result in more minor iterations.

Default: FULL

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FULL</td>
<td>Solve subproblems to full accuracy</td>
</tr>
<tr>
<td>PARTIAL</td>
<td>Solve subproblems to moderate accuracy</td>
</tr>
</tbody>
</table>

**crash option (integer)**: Controls the basis crash algorithm

If a restart is not being performed, an initial basis will be selected from certain columns of the constraint matrix $A(I)$. The value of the parameter $i$ determines which columns of $A$ are eligible. Columns of $I$ are used to fill gaps where necessary. If $i > 0$, three passes are made through the relevant columns of $A$, searching for a basis matrix that is essentially triangular. A column is assigned to pivot on a particular row if the column contains a suitably large element in a row that has not yet been assigned. (The pivot elements ultimately form the diagonals of the triangular basis). Pass 1 selects pivots from free columns (corresponding to variables with no upper and lower bounds). Pass 2 requires pivots to be in rows associated with equality ($=E=$) constraints. Pass 3 allows the pivots to be in inequality rows. For remaining (unassigned) rows, the associated slack variables are inserted to complete the basis.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial basis will be a slack basis</td>
</tr>
</tbody>
</table>
### crash tolerance (real): Allow crash procedure to ignore small elements in eligible columns

The *Crash tolerance* $r$ allows the starting procedure *CRASH* to ignore certain small nonzeros in each column of $A$. If $a_{\text{max}}$ is the largest element in column $j$, other nonzeros $a_{ij}$ in the column are ignored if $|a_{ij}| < a_{\text{max}} \times r$. To be meaningful, the parameter $r$ should be in the range $0 < r < 1$. When $r > 0.0$ the basis obtained by *CRASH* may not be strictly triangular, but it is likely to be nonsingular and almost triangular. The intention is to obtain a starting basis containing more columns of $A$ and fewer (arbitrary) slacks. A feasible solution may be reached sooner on some problems. For example, suppose the first $m$ columns of $A$ are the matrix shown under LU factor tolerance; i.e., a tridiagonal matrix with entries -1, 4, -1. To help *CRASH* choose all $m$ columns for the initial basis, we could specify *Crash tolerance* $r$ for some value of $r > 0.25$.

Range: $[0, 1.0]$

Default: 0.1

### debug level (integer): Controls amount of debug information written

This causes various amounts of information to be output. Most debug levels will not be helpful to GAMS users, but they are listed here for completeness. Note that you will need to use the GAMS statement `OPTION SYSOUT=on;` to echo the MINOS listing to the GAMS listing file.

- **debug level 0**
  No debug output.

- **debug level 2** (or more)
  Output from *M5SETX* showing the maximum residual after a row check.

- **debug level 40**
  Output from *LU8RPC* (which updates the LU factors of the basis matrix), showing the position of the last nonzero in the transformed incoming column.

- **debug level 50**
  Output from *LU1MAR* (which updates the LU factors each refactorization), showing each pivot row and column and the dimensions of the dense matrix involved in the associated elimination.

- **debug level 100**
  Output from *M2BFAC* and *M5LOG* listing the basic and superbasic variables and their values at every iteration.

Default: 0

### expand frequency (integer): Setting for anti-cycling mechanism

This option is part of an anti-cycling procedure designed to guarantee progress even on highly degenerate problems. For linear models, the strategy is to force a positive step at every iteration, at the expense of violating the bounds on the variables by a small amount. Suppose the specified feasibility tolerance is $\delta$ and the expand frequency is $k$. Over a period of $k$ iterations, the tolerance actually used by GAMS/MINOS increases from $0.5 \times \delta$ to $\delta$ (in steps $0.5 \times \delta / k$). For nonlinear models, the same procedure is used for iterations in which there is only one superbasic variable. (Cycling can occur only when the current solution is
at a vertex of the feasible region.) Thus, zero steps are allowed if there is more than one superbasic variable, but otherwise positive steps are enforced. At least every $k$ iterations, a resetting procedure eliminates any infeasible nonbasic variables. Increasing $k$ helps to reduce the number of these slightly infeasible nonbasic variables. However, it also diminishes the freedom to choose a large pivot element (see Pivot tolerance).

Range: $[1, \infty]$  
Default: 10000

**factorization frequency** (integer): Number of iterations between basis factorizations

At most $i$ basis updates will occur between factorizations of the basis matrix. With linear programs, basis updates usually occur at every iteration. The default $i$ is reasonable for typical problems. Higher values up to $i = 200$ (say) may be more efficient on problems that are extremely sparse and well scaled. When the objective function is nonlinear, fewer basis updates will occur as an optimum is approached. The number of iterations between basis factorizations will therefore increase. During these iterations a test is made regularly (according to the Check frequency) to ensure that the general constraints are satisfied. If necessary the basis will be re-factorized before the limit of $i$ updates is reached. When the constraints are nonlinear, the Minor iterations limit will probably preempt $i$.

Range: $[1, \infty]$  
Default: 100

**feasibility tolerance** (real): Feasibility tolerance for linear constraints

When the constraints are linear, a feasible solution is one in which all variables, including slacks, satisfy their upper and lower bounds to within the absolute tolerance $r$. (Since slacks are included, this means that the general linear constraints are also satisfied within $r$.) GAMS/MINOS attempts to find a feasible solution before optimizing the objective function. If the sum of infeasibilities cannot be reduced to zero, the problem is declared infeasible. Let $SINF$ be the corresponding sum of infeasibilities. If $SINF$ is quite small, it may be appropriate to raise $r$ by a factor of 10 or 100. Otherwise, some error in the data should be suspected. If $SINF$ is not small, there may be other points that have a significantly smaller sum of infeasibilities. GAMS/MINOS does not attempt to find a solution that minimizes the sum. If Scale option = 1 or 2, feasibility is defined in terms of the scaled problem (since it is then more likely to be meaningful). A nonlinear objective function $F(x)$ will be evaluated only at feasible points. If there are regions where $F(x)$ is undefined, every attempt should be made to eliminate these regions from the problem. For example, for a function $F(x) = \sqrt{x1} + \log(x2)$, it should be essential to place lower bounds on both variables. If Feasibility tolerance = $10^{-6}$, the bounds $x_1 > 10^{-5}$ and $x_2 > 10^{-4}$ might be appropriate. (The log singularity is more serious; in general, keep variables as far away from singularities as possible.) If the constraints are nonlinear, the above comments apply to each major iteration. A feasible solution satisfies the current linearization of the constraints to within the tolerance $r$. The associated subproblem is said to be feasible. As for the objective function, bounds should be used to keep $x$ more than $r$ away from singularities in the constraint functions $f(x)$. At the start of major iteration $k$, the constraint functions $f(x_k)$ are evaluated at a certain point $x_k$. This point always satisfies the relevant bounds ($l < x_k < u$), but may not satisfy the general linear constraints. During the associated minor iterations, $F(x)$ and $f(x)$ will be evaluated only at points $x$ that satisfy the bound and the general linear constraints (as well as the linearized nonlinear constraints). If a subproblem is infeasible, the bounds on the linearized constraints are relaxed temporarily, in several stages. Feasibility with respect to the nonlinear constraints themselves is measured against the Row tolerance (not against $r$). The relevant test is made at the start of a major iteration.

Default: $1.0e^{-6}$
**hessian dimension** *(integer): Size of Hessian matrix* ←

This specifies that an \( r \times r \) triangular matrix \( R \) is to be available for use by the quasi-Newton algorithm. The matrix \( R \) approximates the reduced Hessian in that \( R^T R \approx Z^T H Z \). Suppose there are \( s \) superbasic variables at a particular iteration. Whenever possible, \( r \) should be greater than \( s \). If \( r > s \), the first \( s \) columns of \( R \) will be used to approximate the reduced Hessian in the normal manner. If there are no further changes to the set of superbasic variables, the rate of convergence will ultimately be superlinear. If \( r < s \), a matrix of the form

\[
R = \text{diag}(R_r, D)
\]

will be used to approximate the reduced Hessian, where \( R_r \) is an \( r \times r \) upper triangular matrix and \( D \) is a diagonal matrix of order \( s - r \). The rate of convergence will no longer be superlinear (and may be arbitrarily slow). The storage required is of the order \( \text{sq}(r)/2 \), i.e. quadratic in \( r \). In general, \( r \) should be a slight over-estimate of the final number of superbasic variables, whenever storage permits. It need never be larger than \( n_1 + 1 \), where \( n_1 \) is the number of nonlinear variables. For many problems it can be much smaller than \( n_1 \). If *Superbasics limit* \( s \) is specified, the default value of \( r \) is the same number, \( s \) (and conversely). This is a safeguard to ensure super-linear convergence wherever possible. If neither \( r \) nor \( s \) is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: \([1, \infty)\]

Default: 1

**iterations limit** *(integer): Minor iteration limit* ←

The maximum number of minor iterations allowed (i.e., iterations of the simplex method or the reduced-gradient method). This option, if set, overrides the GAMS *ITERLIM* specification. If \( i = 0 \), no minor iterations are performed, but the starting point is tested for both feasibility and optimality.

Default: GAMS *iterlim*

**lagrangian** *(string): Determines form of objection function in the linearized subproblems* ←

This determines the form of the objective function used for the linearized subproblems. The default value *yes* is highly recommended. The *Penalty parameter* value is then also relevant. If *No* is specified, the nonlinear constraint functions will be evaluated only twice per major iteration. Hence this option may be useful if the nonlinear constraints are very expensive to evaluate. However, in general there is a great risk that convergence may not occur.

Default: *YES*

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>Nondefault value (not recommended)</td>
</tr>
<tr>
<td>YES</td>
<td>Default value (recommended)</td>
</tr>
</tbody>
</table>

**linesearch tolerance** *(real): Controls accuracy of steplength selected* ←

For nonlinear problems, this controls the accuracy with which a steplength \( \alpha \) is located in the one-dimensional problem

\[
\begin{align*}
\text{minimize} & \quad F(x + \alpha p) \\
\text{subject to} & \quad 0 < \alpha \leq \beta
\end{align*}
\]
A linesearch occurs on most minor iterations for which \( x \) is feasible. (If the constraints are nonlinear, the function being minimized is the augmented Lagrangian.) \( r \) must be a real value in the range \( 0.0 < r < 1.0 \). The default value \( r = 0.1 \) requests a moderately accurate search. It should be satisfactory in most cases. If the nonlinear functions are cheap to evaluate, a more accurate search may be appropriate; try \( r = 0.01 \) or \( r = 0.001 \). The number of iterations should decrease, and this will reduce total run time if there are many linear or nonlinear constraints. If the nonlinear function are expensive to evaluate, a less accurate search may be appropriate; try \( r = 0.5 \) or perhaps \( r = 0.9 \). (The number of iterations will probably increase but the total number of function evaluations may decrease enough to compensate.)

Range: \([0.0, 1.0]\)

Default: 0.1

log frequency (integer): Controls iteration logging to listing file $\leftrightarrow$

In general, one line of the iteration log is printed every \( i \)th minor iteration. A heading labels the printed items, which include the current iteration number, the number and sum of feasibilities (if any), the subproblem objective value (if feasible), and the number of evaluations of the nonlinear functions. A value such as \( i = 10, 100 \) or larger is suggested for those interested only in the final solution. Log frequency 0 may be used as shorthand for Log frequency 99999.

If Print level > 0, the default value of \( i \) is 1. If Print level = 0, the default value of \( i \) is 100. If Print level = 0 and the constraints are nonlinear, the minor iteration log is not printed (and the Log frequency is ignored). Instead, one line is printed at the beginning of each major iteration.

Range: \([1, \infty]\)

Default: 100

LU complete pivoting (no value): LUSOL pivoting strategy $\leftrightarrow$

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The rook and complete pivoting options are more expensive than partial pivoting but are more stable and better at revealing rank, as long as the LU factor tolerance is not too large (say < 2.0).

LU density tolerance (real): When to use dense factorization $\leftrightarrow$

The density tolerance is used during LUSOL's basis factorization \( B=LU \). Columns of \( L \) and rows of \( U \) are formed one at a time, and the remaining rows and columns of the basis are altered appropriately. At any stage, if the density of the remaining matrix exceeds this tolerance, the Markowitz strategy for choosing pivots is terminated and the remaining matrix is factored by a dense \( LU \) procedure. Raising the tolerance towards 1.0 may give slightly sparser factors, with a slight increase in factorization time.

Range: \([0.0, 1.0]\)

Default: 0.5

LU factor tolerance (real): Trade-off between stability and sparsity in basis factorization $\leftrightarrow$

This tolerance affects the stability and sparsity of the basis factorization \( B = LU \) during factorization. The value \( r \) specified must satisfy \( r > 1.0 \).

- The default value \( r = 100.0 \) usually strikes a good compromise between stability and sparsity.
• For large and relatively dense problems, a larger value may give a useful improvement in sparsity without impairing stability to a serious degree.
• For certain very regular structures (e.g., band matrices) it may be necessary to set \( r \) to a value smaller than the default in order to achieve stability.

Range: \([1.0, \infty]\)

Default: 100.0

**LU partial pivoting (no value): LUSOL pivoting strategy**

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say < 2.0).

**LU rook pivoting (no value): LUSOL pivoting strategy**

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say < 2.0).

**LU singularity tolerance (real): Protection against ill-conditioned basis matrices**

When the basis is refactorized, the diagonal elements of \( U \) are tested as follows: if \(|U_{jj}| < r\) or \(|U_{jj}^p| < r \cdot \max_i |U_{ii}|\), the \( j \)th column of the basis is replaced by the corresponding slack variable. (This is most likely to occur after a restart, or at the start of a major iteration.) In some cases, the Jacobian matrix may converge to values that make the basis very ill-conditioned, causing the optimization to progress very slowly (if at all). Setting \( r = 1.0^{-4} \), say, may help cause a judicious change of basis.

Default: \(1.0e^{-11}\)

**LU update tolerance (real): Trade-off between stability and sparsity in basis updating**

This tolerance affects the stability and sparsity of the basis factorization \( B = LU \) during updates. The value \( r \) specified must satisfy \( r > 1.0 \).

• The default value \( r = 10.0 \) usually strikes a good compromise between stability and sparsity.
• For large and relatively dense problems, \( r = 25.0 \) (say) may give a useful improvement in sparsity without impairing stability to a serious degree.
• For certain very regular structures (e.g., band matrices) it may be necessary to set \( r \) to a value smaller than the default in order to achieve stability.

Range: \([1.0, \infty]\)

Default: 10.0

**major damping parameter (real): Prevents large relative changes between subproblem solutions**
The parameter may assist convergence on problems that have highly nonlinear constraints. It is intended to prevent large relative changes between subproblem solutions \((x_k, \lambda_k)\) and \((x_{k+1}, \lambda_{k+1})\). For example, the default value 2.0 prevents the relative change in either \(x_k\) or \(\lambda_k\) from exceeding 200 percent. It will not be active on well behaved problems. The parameter is used to interpolate between the solutions at the beginning and end of each major iteration. Thus \(x_{k+1}\) and \(\lambda_{k+1}\) are changed to \(x_k + \sigma(x_{k+1} - x_k)\) and \(\lambda_k + \sigma(\lambda_{k+1} - \lambda_k)\) for some step-length \(\sigma < 1\). In the case of nonlinear equations (where the number of constraints is the same as the number of variables) this gives a damped Newton method. This is a very crude control. If the sequence of major iterations does not appear to be converging, one should first re-run the problem with a higher Penalty parameter (say 10 or 100 times the default \(\rho\)). (Skip this re-run in the case of nonlinear equations: there are no degrees of freedom and the value of \(\rho\) is irrelevant.) If the subproblem solutions continue to change violently, try reducing \(r\) to 0.2 or 0.1 (say). For implementation reasons, the shortened step to \(\sigma\) applies to the nonlinear variables \(x\), but not to the linear variables \(y\) or the slack variables \(s\). This may reduce the efficiency of the control.

Default: 2.0

**major iterations (integer):** Max number of major iterations

The maximum number of major iterations allowed. It is intended to guard against an excessive number of linearizations of the nonlinear constraints, since in some cases the sequence of major iterations may not converge. The progress of the major iterations can be best monitored using Print level 0 (the default).

Default: 50

**minor damping parameter (real):** Limit change in \(x\) during linesearch

This parameter limits the change in \(x\) during a linesearch. It applies to all nonlinear problems, once a feasible solution or feasible subproblem has been found. A linesearch of the form

\[
\text{minimize}_{\alpha} F(x + \alpha p)
\]

is performed over the range \(0 < \alpha <= \beta\), where \(\beta\) is the step to the nearest upper or lower bound on \(x\). Normally, the first step length tried is \(\alpha_1 = \min(1, \beta)\). In some cases, such as \(F(x) = a e^{bx}\) or \(F(x) = ax^b\), even a moderate change in the components of \(x\) can lead to floating-point overflow. The parameter \(r\) is therefore used to define a limit

\[
\beta_2 = r(1 + ||x||)/||p||
\]

and the first evaluation of \(F(x)\) is at the potentially smaller steplength \(\alpha_1 = \min(1, \beta, \beta_2)\). Wherever possible, upper and lower bounds on \(x\) should be used to prevent evaluation of nonlinear functions at meaningless points. The **Minor damping parameter** provides an additional safeguard. The default value \(r = 2.0\) should not affect progress on well behaved problems, but setting \(r = 0.1\) or \(0.01\) may be helpful when rapidly varying functions are present. A good starting point may be required. An important application is to the class of nonlinear least squares problems. In cases where several local optima exist, specifying a small value for \(r\) may help locate an optimum near the starting point.

Default: 2.0

**minor iterations (integer):** Max number of minor iterations between linearizations of nonlinear constraints

---

4.34 MINOS and QUADMINOS

---

1885
The maximum number of feasible minor iterations allowed between successive linearizations of the nonlinear constraints. A moderate value (e.g., $20 \leq i \leq 50$) prevents excessive efforts being expended on early major iterations, but allows later subproblems to be solved to completion. The limit applies to both infeasible and feasible iterations. In some cases, a large number of iterations (say $K$) might be required to obtain a feasible subproblem. If good starting values are supplied for variables appearing nonlinearly in the constraints, it may be sensible to specify a limit $> K$, to allow the first major iteration to terminate at a feasible (and perhaps optimal) subproblem solution. If a good initial subproblem is arbitrarily interrupted by a small limit, the subsequent linearization may be less favorable than the first. In general it is unsafe to specify a value as small as $i = 1$ or 2. Even when an optimal solution has been reached, a few minor iterations may be needed for the corresponding subproblem to be recognized as optimal. The *Iteration limit* provides an independent limit on the total minor iterations (across all subproblems). If the constraints are linear, only the *Iteration limit* applies: the minor iterations value is ignored.

Default: 40

**multiple price** *(integer):* Multiple pricing

Pricing refers to a scan of the current non-basic variables to determine which, if any, are eligible to become (super)basic. The multiple pricing parameter $k$ controls the number of entering variables to choose: the $k$ best non-basic variables are selected for admission to the set of (super)basic variables. The default $k = 1$ is best for linear programs, since an optimal solution will have zero superbasic variables. *Warning:* If $k > 1$, GAMS/MINOS will use the reduced-gradient method rather than the simplex method, even on purely linear problems. The subsequent iterations do not correspond to the efficient minor iterations carried out by commercial linear programming systems using multiple pricing. (In the latter systems, the classical simplex method is applied to a tableau involving $k$ dense columns of dimension $m$, and $k$ is therefore limited for storage reasons typically to the range $2 < k < 7$.) GAMS/MINOS varies all superbasic variables simultaneously. For linear problems its storage requirements are essentially independent of $k$. Larger values of $k$ are therefore practical, but in general the iterations and time required when $k > 1$ are greater than when the simplex method is used ($k = 1$). On large nonlinear problems it may be important to set $k > 1$ if the starting point does not contain many superbasic variables. For example, if a problem has 3000 variables and 500 of them are nonlinear, the optimal solution may well have 200 variables superbasic. If the problem is solved in several runs, it may be beneficial to use $k = 10$ (say) for early runs, until it seems that the number of superbasics has leveled off. If *Multiple price* $k$ is specified, it is also necessary to specify *Superbasic limit* $s$ for some $s > k$.

Range: $[1, \infty]$  

Default: 1

**optimality tolerance** *(real):* Reduced gradient optimality check

This is used to judge the size of the reduced gradients $d_j = g_j - p_i^T a_j$, where $g_j$ is the gradient of the objective function corresponding to the $j^{th}$ variable, $a_j$ is the associated column of the constraint matrix (or Jacobian), and $pi$ is the set of dual variables. By construction, the reduced gradients for basic variables are always zero. Optimality will be declared if the reduced gradients for nonbasic variables at their lower or upper bounds satisfy $d_j/||p_i|| > -r$ or $d_j/||p_i|| < = r$ respectively, and if $d_j/||p_i|| < = r$ for superbasic variables. The $||p_i||$ is a measure of the size of the dual variables. It is included to make the tests independent of a scale factor on the objective function. The quantity actually used is defined by

$$\sigma = \sum(i, \text{abs}(p_i(i))), ||p_i|| = \max\{\sigma/\sqrt{m},1\}$$

so that only large scale factors are compensated for. As the objective scale decreases, the optimality test tends to become an absolute (instead of a relative) test.

Default: $1.0e-6$
**partial price** (integer): Number of segments in partial pricing strategy

This parameter is recommended for large problems that have significantly more variables than constraints. It reduces the work required for each pricing operation (when a nonbasic variable is selected to become basic or superbasic). When \( i = 1 \), all columns of the constraints matrix \((A \ I)\) are searched. Otherwise, \( A_j \) and \( I \) are partitioned to give \( i \) roughly equal segments \( A_{j}, I_{j} \) \((j = 1 \text{ to } i)\). If the previous search was successful on \( A_{j-1}, I_{j-1} \), the next search begins on the segments \( A_{j}, I_{j} \). (All subscripts here are modulo \( i \).) If a reduced gradient is found that is larger than some dynamic tolerance, the variable with the largest such reduced gradient (of appropriate sign) is selected to become superbasic. (Several may be selected if multiple pricing has been specified.) If nothing is found, the search continues on the next segments \( A_{j+1}, I_{j+1} \) and so on. Partial price \( t \) (or \( t/2 \) or \( t/3 \)) may be appropriate for time-stage models having \( t \) time periods.

Range: \([1, \infty]\)

Default: 10

**penalty parameter** (real): Used in modified augmented Lagrangian

This specifies the value of \( \rho \) in the modified augmented Lagrangian. It is used only when \( \text{Lagrangian} = \text{yes} \) (the default setting). For early runs on a problem with unknown characteristics, the default value should be acceptable. If the problem is known to be highly nonlinear, specify a large value, such as 10 times the default. In general, a positive value of \( \rho \) may be necessary to ensure convergence, even for convex programs. On the other hand, if \( \rho \) is too large, the rate of convergence may be unnecessarily slow. If the functions are not highly nonlinear or a good starting point is known, it will often be safe to specify \( \text{penalty parameter} 0.0 \). When solving a sequence of related problems, initially, use a moderate value for \( \rho \) (such as the default) and a reasonably low \( \text{Iterations} \) and/or \( \text{major iterations limit} \). If successive major iterations appear to be terminating with radically different solutions, the \( \text{penalty parameter} \) should be increased. (See also the \( \text{Major damping parameter} \).) If there appears to be little progress between major iterations, it may help to reduce the \( \text{penalty parameter} \).

Default: automatic

**print level** (integer): Controls amount of information printed during optimization

This varies the amount of information that will be output during optimization. \( \text{Print level} 0 \) sets the default log and summary frequencies to 100. It is then easy to monitor the progress of the run. \( \text{Print level} 1 \) (or more) sets the default log and summary frequencies to 1, giving a line of output for every minor iteration. \( \text{Print level} 1 \) also produces basis statistics, i.e., information relating to LU factors of the basis matrix whenever the basis is re-factorized. For problems with nonlinear constraints, certain quantities are printed at the start of each major iteration. The option value is best thought of as a binary number of the form

\[ \text{Print level} \ JFLXB \]

where each letter stands for a digit that is either 0 or 1. The quantities referred to are:

- **B** Basis statistics, as mentioned above
- **X** \( x_k \), the nonlinear variables involved in the objective function or the constraints.
- **L** \( \lambda_{dk} \), the Lagrange-multiplier estimates for the nonlinear constraints. (Suppressed if \( \text{Lagrangian}=\text{No} \), since then \( \lambda_{dk} = 0 \).)
- **F** \( f(x_k) \), the values of the nonlinear constraint functions.
- **J** \( J(x_k) \), the Jacobian matrix.
To obtain output of any item, set the corresponding digit to 1, otherwise to 0. For example, 
*Print level 10* sets \( X = 1 \) and the other digits equal to zero; the nonlinear variables will be 
printed each major iteration. If \( J = 1 \), the Jacobian matrix will be output column-wise at the 
start of each major iteration. Column \( j \) will be preceded by the value of the corresponding 
variable \( x_j \) and a key to indicate whether the variable is basic, superbasic or nonbasic. (Hence 
if \( J = 1 \), there is no reason to specify \( X = 1 \) unless the objective contains more nonlinear 
variables than the Jacobian.) A typical line of output is

\[
3 \quad 1.2500000D+01 \quad BS \quad 1 \quad 1.00000D+00 \quad 4 \quad 2.00000D+00
\]

which would mean that \( x_3 \) is basic at value 12.5, and the third column of the Jacobian has 
elements of 1.0 and 2.0 in rows 1 and 4. (Note: the GAMS/MINOS row numbers are usually 
different from the GAMS row numbers; see the Solution option.)

Default: 0

**radius of convergence** *(real):* controls final reduction of penalty parameter \( \rho \)

This determines when the penalty parameter \( \rho \) will be reduced, assuming \( \rho \) was initially 
positive. Both the nonlinear constraint violation (see *ROWERR* below) and the relative 
change in consecutive Lagrange multiplier estimates must be less than \( r \) at the start of a major 
itration before \( \rho \) is reduced or set to zero. A few major iterations later, full completion 
will be requested if not already set, and the remaining sequence of major iterations should 
converge quadratically to an optimum.

Default: 0.01

**row tolerance** *(real):* Accuracy requirement for nonlinear rows \( \rightarrow \)

This specifies how accurately the nonlinear constraints should be satisfied at a solution. The 
default value is usually small enough, since model data is often specified to about this accuracy. 
Let *ROWERR* be the maximum component of the residual vector \( f(x) + A_1 y - b_1 \), normalized 
by the size of the solution. Thus 

\[
\text{ROWERR} = \| f(x) + A_1 y - b_1 \|_{\text{inf}}/(1 + \text{XNORM})
\]

where \( \text{XNORM} \) is a measure of the size of the current solution \((x, y)\). The solution is considered 
to be feasible if \( \text{ROWERR} \leq r \). If the problem functions involve data that is known to be of 
low accuracy, a larger *Row tolerance* may be appropriate.

Default: 1.0e-6

**scale all variables** *(no value):* Synonym to scale option 2 \( \rightarrow \)

**scale linear variables** *(no value):* Synonym to scale option 1 \( \rightarrow \)

**scale no** *(no value):* Synonym to scale option 0 \( \rightarrow \)

**scale nonlinear variables** *(no value):* Synonym to scale option 2 \( \rightarrow \)

**scale option** *(integer):* Scaling \( \rightarrow \)

*Scale Yes* sets the default. (*Caution: If all variables are nonlinear, Scale Yes unexpectedly does 
nothing, because there are no linear variables to scale). *Scale No* suppresses scaling (equivalent 
to *Scale Option 0*). If nonlinear constraints are present, *Scale option 1* or *0* should generally 
be tried at first. *Scale option 2* gives scales that depend on the initial Jacobian, and should 
therefore be used only if (a) a good starting point is provided, and (b) the problem is not 
highly nonlinear.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | No scaling  
If storage is at a premium, this option should be used. |
| 1     | Scale linear variables  
Linear constraints and variables are scaled by an iterative procedure that attempts  
to make the matrix coefficients as close as possible to 1.0 (see [5]). This will  
sometimes improve the performance of the solution procedures. Scale linear  
variables is an equivalent option. |
| 2     | Scale linear + nonlinear variables  
All constraints and variables are scaled by the iterative procedure. Also, a certain  
additional scaling is performed that may be helpful if the right-hand side \( b \) or the  
solution \( x \) is large. This takes into account columns of \( (A \ I) \) that are fixed or  
have positive lower bounds or negative upper bounds. Scale nonlinear variables  
or Scale all variables are equivalent options. |

scale print (no value): Print scaling factors ←

This causes the row-scales \( r(i) \) and column-scales \( c(j) \) to be printed. The scaled matrix  
coefficients are \( \hat{a}_{ij} = a_{ij} c(j)/r(i) \). The scaled bounds on the variables and slacks are \( \hat{b}_j = l_j/c(j) \) and \( \hat{u}_j = u_j/c(j) \), where \( c(j) = r(j - n) \) if \( j > n \). If a Scale option has not already been  
specified, Scale print sets the default scaling.

scale print tolerance (real): Scale print flag and set tolerance ←

See Scale Tolerance. This option also turns on printing of the scale factors.  
Range: [0, 1.0]  
Default: 0.9

scale tolerance (real): Scale tolerance ←

All forms except Scale option may specify a tolerance \( r \) where \( 0 < r < 1 \) (for example: Scale  
Print Tolerance = 0.99). This affects how many passes might be needed through the constraint  
matrix. On each pass, the scaling procedure computes the ratio of the largest and smallest  
nonzero coefficients in each column:  
\[
\rho_{o,j} = \max_i |a_{ij}|/\min_i |a_{ij}| \quad (a_{ij} \neq 0)
\]

If \( \max_j \rho_{o,j} \) is less than \( r \) times its previous value, another scaling pass is performed to adjust  
the row and column scales. Raising \( r \) from 0.9 to 0.99 (say) usually increases the number of  
scaling passes through \( A \). At most 10 passes are made. If a Scale option has not already been  
specified, Scale tolerance sets the default scaling.  
Range: [0, 1.0]  
Default: 0.9

scale yes (no value): Synonym to scale option 1 ←

solution (string): Prints MINOS solution ←

This controls whether or not GAMS/MINOS prints the final solution obtained. There is one  
line of output for each constraint and variable. The lines are in the same order as in the GAMS  
solution, but the constraints and variables labeled with internal GAMS/MINOS numbers  
rather than GAMS names. (The numbers at the left of each line are GAMS/MINOS column  
numbers, and those at the right of each line in the rows section are GAMS/MINOS slacks.)  
The GAMS/MINOS solution may be useful occasionally to interpret certain messages that  
occur during the optimization, and to determine the final status of certain variables (basic,  
superbasic or nonbasic).  
Default: NO
### start assigned nonlines (string): Starting strategy when there is no basis

This option affects the starting strategy when there is no basis (i.e., for the first solve or when the GAMS statement `option bratio = 1` is used to reject an existing basis.) This option applies to all nonlinear variables that have been assigned nondefault initial values and are strictly between their bounds. Free variables at their default value of zero are excluded. Let \( K \) denote the number of such assigned nonlinear variables.

Default: **SUPERBASIC**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUPERBASIC</td>
<td>Default Specify <code>superbasic</code> for highly nonlinear models, as long as ( K ) is not too large (say ( K &lt; 100 )) and the initial values are good.</td>
</tr>
<tr>
<td>BASIC</td>
<td>Good for square systems Specify <code>basic</code> for models that are essentially square (i.e., if there are about as many general constraints as variables).</td>
</tr>
<tr>
<td>NONBASIC</td>
<td>Specify <code>nonbasic</code> if ( K ) is large.</td>
</tr>
<tr>
<td>ELIGIBLE FOR CRASH</td>
<td>Specify <code>Eligible for Crash</code> for linear or nearly linear models. The nonlinear variables will be treated in the manner described under <code>Crash</code> option.</td>
</tr>
</tbody>
</table>

### subspace tolerance (real): Determines when nonbasics becomes superbasic

This controls the extent to which optimization is confined to the current set of basic and superbasic variables (Phase 4 iterations), before one or more nonbasic variables are added to the superbasic set (Phase 3). The parameter \( r \) must be a real number in the range \( 0 < r \leq 1 \). When a nonbasic variable \( x_j \) is made superbasic, the resulting norm of the reduced-gradient vector (for all superbasics) is recorded. Let this be \( ||Z^T g_0|| \). (In fact, the norm will be \( |d_j| \), the size of the reduced gradient for the new superbasic variable \( x_j \). Subsequent Phase 4 iterations will continue at least until the norm of the reduced-gradient vector satisfies \( ||Z^T g_0|| < r ||Z^T g_0|| \) is the size of the largest reduced-gradient component among the superbasic variables.) A smaller value of \( r \) is likely to increase the total number of iterations, but may reduce the number of basic changes. A larger value such as \( r = 0.9 \) may sometimes lead to improved overall efficiency, if the number of superbasic variables has to increase substantially between the starting point and an optimal solution. Other convergence tests on the change in the function being minimized and the change in the variables may prolong Phase 4 iterations. This helps to make the overall performance insensitive to larger values of \( r \).

Range: \([0, 1.0]\]

Default: \( 0.5 \)

### summary frequency (integer): Controls iteration logging to summary (log file)

A brief form of the iteration log is output to the MINOS summary file (i.e. the GAMS log file). In general, one line is output every \( i \)th minor iteration. In an interactive environment, the output normally appears at the terminal and allows a run to be monitored. If something looks wrong, the run can be manually terminated. The summary frequency controls summary output in the same way as the log frequency controls output to the print file. A value such as
Summary Frequency = 10 or 100 is often adequate to determine if the solve is making progress. If Print level = 0, the default value of Summary Frequency is 100. If Print level > 0, the default value of Summary Frequency is 1. If Print level = 0 and the constraints are nonlinear, the Summary Frequency is ignored. Instead, one line is printed at the beginning of each major iteration.

Range: [1, ∞]
Default: 100

superbasics limit (integer): Maximum number of superbasics

This places a limit on the storage allocated for superbasic variables. Ideally, the parameter i should be set slightly larger than the number of degrees of freedom expected at an optimal solution. For linear problems, an optimum is normally a basic solution with no degrees of freedom. (The number of variables lying strictly between their bounds is not more than m, the number of general constraints.) The default value of i is therefore 1. For nonlinear problems, the number of degrees of freedom is often called the number of independent variables. Normally, i need not be greater than $n_1 + 1$, where $n_1$ is the number of nonlinear variables. For many problems, i may be considerably smaller than $n_1$. This will save storage if $n_1$ is very large. This parameter also sets the Hessian dimension, unless the latter is specified explicitly (and conversely). If neither parameter is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: [1, ∞]
Default: 1

unbounded objective value (real): Determines when a problem is called unbounded

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

$$\text{minimize}_{\alpha} F(x + \alpha p)$$

If $|F|$ exceeds the parameter r or if $\alpha$ exceeds the unbounded stepsize, iterations are terminated with the exit message PROBLEM IS UNBOUNDED (OR BADLY SCALED). If singularities are present, unboundedness in $F(x)$ may be manifested by a floating-point overflow (during the evaluation of $F(x + \alpha p)$, before the test against r can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the Minor damping parameter.

Default: 1.0e20

unbounded step size (real): Determines when a problem is called unbounded

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

$$\text{minimize}_{\alpha} F(x + \alpha p)$$

If $\alpha$ exceeds the parameter r or if $|F|$ exceeds the unbounded objective value, iterations are terminated with the exit message PROBLEM IS UNBOUNDED (OR BADLY SCALED). If singularities are present, unboundedness in $F(x)$ may be manifested by a floating-point overflow (during the evaluation of $F(x + \alpha p)$, before the test against r can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the Minor damping parameter.

Default: 1.0e10
verify constraint gradients (no value): Synonym to verify level 2

verify gradients (no value): Synonym to verify level 3

verify level (integer): Controls verification of gradients

This option controls the finite-difference check performed by MINOS on the gradients (first derivatives) computed by GAMS for each nonlinear function. GAMS computes gradients analytically, and the values obtained should normally be taken as correct.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | Cheap test  
Only a cheap test is performed, requiring three evaluations of the nonlinear objective and two evaluations of the nonlinear constraints. Verify No is an equivalent option. |
| 1     | Check objective  
A more reliable check is made on each component of the objective gradient. Verify objective gradients is an equivalent option. |
| 2     | Check Jacobian  
A check is made on each column of the Jacobian matrix associated with the nonlinear constraints. Verify constraint gradients is an equivalent option. |
| 3     | Check objective and Jacobian  
A detailed check is made on both the objective and the Jacobian. Verify, Verify gradients, and Verify Yes are equivalent options. |
| -1    | No check |

verify no (no value): Synonym to verify level 0

verify objective gradients (no value): Synonym to verify level 1

verify yes (no value): Synonym to verify level 3

weight on linear objective (real): Composite objective weight

This option controls the so-called composite objective technique. If the first solution obtained is infeasible, and if the objective function contains linear terms, and the objective weight \( w \) is positive, this technique is used. While trying to reduce the sum of infeasibilities, the method also attempts to optimize the linear portion of the objective. At each infeasible iteration, the objective function is defined to be

\[
\min_{x} \sigma w(c^T x) + \text{(sum of infeasibilities)}
\]

where \( \sigma = 1 \) for minimization and \( \sigma = -1 \) for maximization and \( c \) is the linear portion of the objective. If an optimal solution is reached while still infeasible, \( w \) is reduced by a factor of 10. This helps to allow for the possibility that the initial \( w \) is too large. It also provides dynamic allowance for the fact the sum of infeasibilities is tending towards zero. The effect of \( w \) is disabled after five such reductions, or if a feasible solution is obtained. This option is intended mainly for linear programs. It is unlikely to be helpful if the objective function is nonlinear.

Default: 0.0
4.34.11 Exit Conditions

This section discusses the exit codes printed by MINOS at the end of the optimization run.

EXIT – Optimal solution found

This is the message we all hope to see! It is certainly preferable to every other message. Of course it is quite possible that there are model formulation errors, which will (hopefully) lead to unexpected objective values and solutions. The reported optimum may be a local, and other much better optima may exist.

EXIT – The problem is infeasible

When the constraints are linear, this message can probably be trusted. Feasibility is measured with respect to the upper and lower bounds on the variables (the bounds on the slack variables correspond to the GAMS constraints). The message tells us that among all the points satisfying the general constraints $Ax + s = 0$, there is apparently no point that satisfies the bounds on $x$ and $s$. Violations as small as the FEASIBILITY TOLERANCE are ignored, but at least one component of $x$ or $s$ violates a bound by more than the tolerance.

Note: Although the objective function is the sum of the infeasibilities, this sum will usually not have been minimized when MINOS recognizes the situation and exits. There may exist other points that have significantly lower sum of infeasibilities.

When nonlinear constraints are present, infeasibility is much harder to recognize correctly. Even if a feasible solution exists, the current linearization of the constraints may not contain a feasible point. In an attempt to deal with this situation MINOS may relax the bounds on the slacks associated with nonlinear rows. This perturbation is allowed a fixed number of times. Normally a feasible point will be obtained relative to the perturbed constraints, and optimization can continue on the subproblem. However, if several consecutive subproblems require such perturbation, the problem is terminated and declared INFEASIBLE. Clearly this is an ad-hoc procedure. Wherever possible, nonlinear constraints should be defined in such a way that feasible points are known to exist when the constraints are linearized.

EXIT – The problem is unbounded (or badly scaled)

For linear problems, unboundedness is detected by the simplex method when a nonbasic variable can apparently be increased by an arbitrary amount without causing a basic variable to violate a bound. A simple way to diagnose such a model is to add an appropriate bound on the objective variable.

Very rarely, the scaling of the problem could be so poor that numerical error will give an erroneous indication of unboundedness. Consider using the SCALE option.

For nonlinear problems, MINOS monitors both the size of the current objective function and the size of the change in the variables at each step. If either of these is very large (as judged by the UNBOUNDED parameter), the problem is terminated and declared UNBOUNDED. To avoid large function values, it may be necessary to impose bounds on some of the variables in order to keep them away from singularities in the nonlinear functions.

EXIT – User Interrupt

This exit code is a result of interrupting the optimization process by hitting Ctrl-C. Inside the IDE this is accomplished by hitting the Interrupt button. The solver will finish its current iteration, and return the current solution. This solution can be still intermediate infeasible or intermediate non-optimal.

EXIT – Too many iterations
The iteration limit was hit. Either the *ITERLIM*, or in some cases the *ITERATIONS LIMIT* or *MAJOR ITERATION LIMIT* was too small to solve the problem. In most cases increasing the GAMS *ITERLIM* option will resolve the problem. In other cases you will need to create a MINOS option file and set a *MAJOR ITERATION LIMIT*. The listing file will give more information regarding what limit was hit.

The GAMS iteration limit is displayed in the listing file under the section *SOLVE SUMMARY*. If the *ITERLIM* was hit, the message will look like:

**ITERATION COUNT, LIMIT**

<table>
<thead>
<tr>
<th>Limit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>10001</td>
<td>10000</td>
</tr>
</tbody>
</table>

**EXIT – Resource Interrupt**

The solver hit the *RESLIM* resource limit, which is a time limit. It returned the solution at that time, which may be still intermediate infeasible or intermediate non-optimal.

The GAMS resource limit is displayed in the listing file under the section *SOLVE SUMMARY*. If the GAMS *RESLIM* was hit, the message will look like:

**RESOURCE USAGE, LIMIT**

<table>
<thead>
<tr>
<th>Limit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001.570</td>
<td>1000.000</td>
</tr>
</tbody>
</table>

**EXIT – The objective has not changed for many iterations**

This is an emergency measure for the rare occasions when the solution procedure appears to be *cycling*. Suppose that a zero step is taken for several consecutive iterations, with a basis change occurring each time. It is theoretically possible for the set of basic variables to become the same as they were one or more iterations earlier. The same sequence of iterations would then occur *ad infinitum*.

**EXIT – The Superbasics Limit is too small**

The problem appears to be more non-linear than anticipated. The current set of basic and superbasic variables have been optimized as much as possible and an increase in the number of superbasics is needed. You can use the option *SUPERBASICS LIMIT* to increase the limit. See also option *HESSIAN DIMENSION*.

**EXIT – Constraint and objective function could not be calculated**

The function or gradient could not be evaluated. For example, this can occur when MINOS attempts to take a log or a square root of a negative number, when evaluating the expression $x^y$ with $x \leq 0$, or when evaluating $exp(x)$ for large $x$ and the result is too large to store. The listing file will contain details about where and why evaluation errors occur. To fix this problem, add bounds so that all functions can be properly evaluated. E.g. if you have an expression $x^y$, add a lower bound $X.LO=0.001$ to your model.

In many cases the algorithm can recover from function evaluation errors, for instance if they happen in the line search while evaluating trial points. The message above appears in cases where the algorithm can not recover, and requires a reliable function or gradient evaluation.

**EXIT – Function evaluation error limit**
The limit of allowed function evaluation errors DOMLIM has been exceeded.

Function evaluation errors occur when MINOS attempts to evaluate the objective and/or constraints at points where these functions or their derivatives are not defined or where overflows occur. Some examples are given above. The listing file contains details about these errors.

The quick and dirty way to solve this is to increase the GAMS DOMLIM setting, but in general it is better to add bounds. E.g. if you have an expression \( x^y \), then add a bound \( x.LO=0.001 \) to your model.

EXIT – The current point can not be improved

The line search failed. This can happen if the model is very nonlinear or if the functions are nonsmooth (using a DNLP model type).

If the model is non-smooth, consider a smooth approximation. It may be useful to check the scaling of the model and think more carefully about choosing a good starting point. Sometimes it can help to restart the model with full scaling turned on:

```gams
option nlp=minos;
solve m minimizing z using nlp; // this one gives "current point cannot be improved"
file fopt /minos.opt/;        // write option file
putclose fopt "scale all variables"/
M.optfile=1;
solve m minimizing z using nlp; // solve with "scale all variables"
```

EXIT – Numerical error in trying to satisfy the linear constraints (or the linearized constraints)
The basis is very ill-conditioned.

This is often a scaling problem. Try the full scaling option scale all variables or, better yet, rescale the model in GAMS via the .scale suffix or by choosing more appropriate units for variables and RHS values.

EXIT – Not enough storage to solve the model

The amount of workspace allocated for MINOS to solve the model is insufficient. Consider increasing the GAMS option workfactor to increase the workspace allocated for MINOS to use. The listing file and log file (screen) will contain information about the current workspace allocation. Increasing the workfactor by 50% is a reasonable strategy.

EXIT – Systems error

This is a catch all return for other serious problems. Check the listing file for more messages. If needed rerun the model with OPTION SYSOUT=ON;.
4.35.1 Introduction

MOSEK is a software package for the solution of linear, mixed-integer linear, quadratic, mixed-integer quadratic, quadratically constraint, convex nonlinear, and semidefinite mathematical optimization problems. MOSEK is particularly well suited for solving large-scale linear, convex quadratically constraint, and conic programs using an extremely efficient interior point algorithm.

These problem classes can be solved using an appropriate optimizer built into MOSEK. All the optimizers available in MOSEK are built for the solution of large-scale sparse problems. Current optimizers include:

- Interior-point optimizers for continuous and conic problems
- Simplex optimizer for linear problems
- Branch-and-cut optimizer for mixed-integer linear, quadratic, and conic problems

4.35.1.1 Licensing

Licensing of GAMS/MOSEK is similar to other GAMS solvers. MOSEK is licensed in four different ways:

- **GAMS/MOSEK Base:**
  All model types.

- **GAMS/MOSEK Extended:**
  Same as GAMS/MOSEK Base.

- **GAMS/MOSEK Solver Link:**
  Users must have a separate, licensed MOSEK system. For users who wish to use MOSEK within GAMS and also in other environments.

- **GAMS/OsiMosek:**
  Finally, a bare-bone interface to the LP and MIP solver of Mosek is available under the name OSIMOSEK. It comes free of charge with any GAMS system.

For information regarding MOSEK standalone or interfacing MOSEK with other applications contact sales@mosek.com.

4.35.1.2 Solving Problems in Parallel

MOSEK can exploit multiple CPUs (or a CPU with multiple cores) to solve an optimization problem when using the interior-point or the mixed-integer optimizers.

This implies that whenever the MOSEK interior-point optimizer should solve an optimization problem, then it will try to divide the work so each CPU gets a share of the work. The user decides how many CPUs MOSEK should exploit. Unfortunately, it is not always easy to divide the work. Also some of the coordination work must occur in sequential. Therefore, the speed-up obtained when using multiple CPUs is highly problem dependent. However, as a rule of thumb, if the problem solves very quickly, i.e., in less than 60 seconds, then there is no advantage in using the parallel option.

The parameter `MSK_IPAR_NUM_THREADS` sets the number of threads (and therefore the number of CPU's) that the optimizer will use.
4.35.1.3 Infeasible/Unbounded Models

4.35.1.3.1 Farkas Certificates  MOSEK determines if either the primal or the dual problem is infeasible by means of a Farkas certificate. In such a case MOSEK returns a certificate indicating primal or dual infeasibility. A primal infeasibility certificate indicates a primal infeasible model and the certificate is reported in the marginals of the equations in the listing file. The primal infeasibility certificate for a minimization problem

\[
\begin{align*}
\text{minimize} & \quad \langle c, x \rangle \\
\text{subject to} & \quad Ax = b, \\
& \quad x \geq 0
\end{align*}
\]

is the solution \( y \) satisfying \( A'y \leq 0 \) and \( \langle b, y \rangle > 0 \).

Since GAMS reports all model statuses in the primal space, the notion of dual infeasibility does not exist and GAMS reports a status of unbounded, which assumes the primal problem is feasible. Although GAMS reports the primal as unbounded, there is the possibility that both the primal and dual problem are infeasible. To check if this is the case, the user can set appropriate upper and lower bounds on the objective variable, using the (variable).LO and (variable).UP suffixes and resolve.

For more details on primal and dual infeasibility certificates see the MOSEK Modeling Cookbook.

4.35.1.3.2 Infeasibility Report  MOSEK has some facilities for diagnosing the cause of a primal or dual infeasibility. They can be turned on using the parameter setting MSK_IPAR_INFEAS_REPORT_AUTO. This causes MOSEK to print a report about an infeasible subset of the constraints, when an infeasibility is encountered. Moreover, the parameter MSK_IPAR_INFEAS_REPORT_LEVEL controls the amount of information presented in the infeasibility report. We will use the TRNSPORT example from the GAMS Model Library with increased demand \( (b(j) \leftarrow 1.6b(j)) \) to make the model infeasible. MOSEK produces the following infeasibility report:

MOSEK PRIMAL INFEASIBILITY REPORT.

Problem status: The problem is primal infeasible

The following constraints are involved in the primal infeasibility.

<table>
<thead>
<tr>
<th>Index</th>
<th>Name</th>
<th>Lower bound</th>
<th>Upper bound</th>
<th>Dual lower</th>
<th>Dual upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>supply(seattle)</td>
<td>none</td>
<td>3.500000e+02</td>
<td>0.000000e+00</td>
<td>1.000000e+00</td>
</tr>
<tr>
<td>2</td>
<td>supply(san-diego)</td>
<td>none</td>
<td>6.000000e+02</td>
<td>0.000000e+00</td>
<td>1.000000e+00</td>
</tr>
<tr>
<td>3</td>
<td>demand(new-york)</td>
<td>5.200000e+02</td>
<td>none</td>
<td>1.000000e+00</td>
<td>0.000000e+00</td>
</tr>
<tr>
<td>4</td>
<td>demand(chicago)</td>
<td>4.800000e+02</td>
<td>none</td>
<td>1.000000e+00</td>
<td>0.000000e+00</td>
</tr>
<tr>
<td>5</td>
<td>demand(topeka)</td>
<td>4.400000e+02</td>
<td>none</td>
<td>1.000000e+00</td>
<td>0.000000e+00</td>
</tr>
</tbody>
</table>

The following bound constraints are involved in the infeasibility.

<table>
<thead>
<tr>
<th>Index</th>
<th>Name</th>
<th>Lower bound</th>
<th>Upper bound</th>
<th>Dual lower</th>
<th>Dual upper</th>
</tr>
</thead>
</table>

The report indicates which constraints and bounds are causing the infeasibility. In this case, the constraints causing infeasibility are supply and demand. The values in the columns Dual lower and Dual upper are also useful, because if the dual lower value is different from zero for a constraint, then it implies that the lower bound on the constraint is important for the infeasibility. Similarly, if the dual upper value is different from zero on a constraint, then this implies the upper bound on the constraint is important for infeasibility.
4.35.1.4 Quadratic Conic Programming

MOSEK is well suited for solving generalized linear programs involving nonlinear conic constraints. For an overview of quadratic conic programming and how these conic constraints are implemented in GAMS, see the Section Conic Programming in the GAMS User’s Guide. Note, that for Mosek no variable can appear in more than one conic constraint.

4.35.1.5 Nonlinear Programs

MOSEK can efficiently solve convex programs, but is not intended for nonconvex optimization. MOSEK can detect some nonconvexities and will print out a warning message and terminate. If MOSEK does not detect nonconvexities for a nonconvex model, the optimizer may continue but stagnate. Hence care must be taken when solving nonlinear programs if convexity is not immediately known.

4.35.1.6 Modeling Issues Involving Convex Programs

It is often preferable to model convex programs in separable form, if possible. Consider the following example of minimizing an objective function \( f(x) \):

\[
    f(x) = \log(\langle a, x \rangle)
\]

where \( a \in \mathbb{R}^n \) is a parameter and \( x \in \mathbb{R}^n \) the decision variable. The equation implies an implicit constraint of \( \langle a, x \rangle > 0 \). Unfortunately, domain violations can still occur because no restrictions are set on \( \langle a, x \rangle \). A better approach is to introduce an intermediate variable \( y \):

\[
    f(x) = \log(y) \\
    y = \langle a, x \rangle \\
    y \geq 0
\]

This accomplishes two things. It implies an explicit bound on \( \langle a, x \rangle \), thereby reducing the risk of domain violations. Secondly, it speeds up computation since computations of gradients and Hessians in the first (non-separable) form are more expensive. Finally, it reduces the amount of memory needed.

4.35.2 Solver Options

MOSEK works like other GAMS solvers, and many options can be set in the GAMS model (see GAMS Options). The most relevant GAMS options are reslim, nodlim, iterlim (iteration limit for simplex and interior point algorithms), optca, optcr, and optfile. A description of all available GAMS options can be found in GAMS Options and Solver related options.

We remark that MOSEK contains many complex solver options, many of which require a deep understanding of the algorithms used. For information on how to use a GAMS/Mosek options file, see The Solver Option File. For example, an option file

```
MSK_IPAR_INTPNT_MAX_ITERATIONS 20
MSK_IPAR_INTPNT_SCALING MSK_SCALING_NONE
```

limits the number of interior-point iterations to 20 and disables scaling.

In the following, we summarize the MOSEK options that are available through the GAMS/MOSEK interface. For details, see Detailed Descriptions of MOSEK Options.

4.35.2.1 General
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_DPAR_OPTIMIZER_MAX_TIME</td>
<td>Maximum amount of time the optimizer is allowed to spent on the optimization.</td>
<td>GAMS ResLim</td>

### Option Description Default

**MSK_IPAR_INTPNT_ORDER_METHOD**
Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system. **MSK_ORDER_METHOD_FREE**

**MSK_IPAR_INTPNT_REGULARIZATION_USE**
Controls whether regularization is allowed. **MSK_ON**

**MSK_IPAR_INTPNT_SCALING**
Controls how the problem is scaled before the interior-point optimizer is used. **MSK_SCALING_FREE**

**MSK_IPAR_INTPNT_SOLVE_FORM**
Controls whether the primal or the dual problem is solved. **MSK_SOLVE_FREE**

**MSK_IPAR_INTPNT_STARTING_POINT**
Starting point used by the interior-point optimizer. **MSK_STARTING_POINT_FREE**

### 4.35.3 The MOSEK Log File

The MOSEK log output gives much useful information about the current solver progress and individual phases.

#### 4.35.3.1 Log Using the Interior Point Optimizer

The following is a MOSEK log output from running the TRNSPORT model from the GAMS Model Library:

```
Optimizer started.
Interior-point optimizer started.
Presolve started.
Linear dependency checker started.
Linear dependency checker terminated.
Eliminator - tries = 0  time = 0.00
Lin. dep. - tries = 1  time = 0.00
Lin. dep. - number = 0
Presolve terminated. Time: 0.00
Optimizer - threads = 1
Optimizer - solved problem = the primal
```
The first part gives information about the presolve (if used). The main log follows:

<table>

</tbody>
</table>

Return code = 0 [MSK_RES_OK]: No error occurred.

The last section gives details about the model and solver status, primal and dual feasibilities, as well as solver resource times. Furthermore, the log gives information about the basis identification phase. Some of this information is listed in the GAMS solve summary in the model listing (.LST) file as well.

The fields in the main MOSEK log output are:

The log then gives information about solving the model with discrete variables fixed in order to determine marginals. Option SOLVEFINAL can be used to disable this step. The fixed problem is solved as a regular LP with warm start information. So the log looks identical to the MOSEK simplex optimizer for linear programs:

MIP Solution: 4.000000 (3466 iterations, 347 nodes)
Final Solve: 4.000000 (0 iterations)
4.35.4 Semidefinite Programming with GAMS/MOSEK (experimental)

With Version 7, MOSEK introduced a semidefinite programming (SDP) solver into their portfolio. The following introduction is taken from the Mosek Documentation.

Semidefinite programming is a generalization of quadratic conic programming, allowing the use of matrix variables belonging to the convex cone of positive semidefinite matrices

$$S^+_r = \{ X \in S_r : z^T X z \geq 0, \forall z \in \mathbb{R}^r \},$$

where $S_r$ is the set of $r \times r$ real-valued symmetric matrices. MOSEK can solve semidefinite optimization problems of the form

$$\begin{align*}
\text{minimize} & \quad \sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \langle C_j, X_j \rangle + c_f \\
\text{subject to} & \quad l_i^x \leq \sum_{j=0}^{n-1} a_{ij} x_j + \sum_{j=0}^{p-1} \langle A_{ij}, X_j \rangle \leq u_i^x, \quad i = 0, \ldots, m - 1, \\
& \quad l_j^x \leq x_j, \quad x_j \in C, \quad X_j \in S^+_r, \quad j = 0, \ldots, n - 1, \\
& \quad x_j \in C, \quad X_j \in S^+_r, \quad j = 0, \ldots, p - 1,
\end{align*}$$

where the problem has $p$ symmetric positive semidefinite (PSD) variables $X_j \in S^+_r$ of dimension $r_j$ with symmetric coefficient matrices $C_j \in S_{r_j}$ and $A_{ij} \in S_{r_j}$. We use the standard notation for the matrix inner product, i.e., for $A, B \in \mathbb{R}^{m \times n}$ we have

$$\langle A, B \rangle := \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} A_{ij} B_{ij}.$$

### 4.35.4.1 Example

An example for a mixed semidefinite and conic quadratic programming problem with a 3-dimensional PSD matrix variable is the following:

$$\begin{align*}
\text{minimize} & \quad \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix} \begin{bmatrix} x_0 \\ x_1 \\ x_2 \end{bmatrix} + x_0 \\
\text{subject to} & \quad \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_0 \\ x_1 \\ x_2 \end{bmatrix} + x_0 = 1 \\
& \quad \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} x_0 \\ x_1 \\ x_2 \end{bmatrix} + x_1 + x_2 = \frac{1}{2} \\
& \quad x_0 \geq \sqrt{x_1^2 + x_2^2} \\
& \quad X \succeq 0
\end{align*}$$

The GAMS/MOSEK interface offers an experimental interface to MOSEK’s SDP solver. It allows to state SDP’s of the form (SDP) in GAMS language. For instance, the example problem from above can be formulated as follows (sdp01 in the GAMS Test Library):
Set i / 0 * 2 /;
alias(i, ip);

Variables barX(i,i) PSDMATRIX
    x(i) simple vars
    z objective var

    x.lo('0') = 0;

Parameters barAobj(i,i) coefficients of barX in objective
    barAe1(i,i) coefficients of barX in e1
    barAe2(i,i) coefficients of barX in e2

Table barAobj(i,i)
    0   1   2
    0 2.0 1.0 0.0
    1 1.0 2.0 1.0
    2 0.0 1.0 2.0

    identity matrix
    barAe1(i,i) = 1.0;

    all-one matrix
    barAe2(i,ip) = 1.0;

Equations obj, e1, e2, e3;

obj.. z =e= sum((i,ip), barAobj(i,ip) * barX(i,ip)) + x('0');
e1.. 1 =e= sum((i,ip), barAe1(i,ip) * barX(i,ip)) + x('0');
e2.. 0.5 =e= sum((i,ip), barAe2(i,ip) * barX(i,ip)) + x('1') + x('2');
e3.. - sqr(x('0')) + sqr(x('1')) + sqr(x('2')) =l= 0;

Model m / all /;

We see that the matrix $\bar{X}$ is defined via the 2-dimensional GAMS variable barX. Additionally, the keyword PSDMATRIX at the beginning of the descriptive text (!) of the variable is used to indicate that the variables belonging to symbol barX are to be interpreted as a matrix variable with PSD constraint.

The Model shown above can be solved with MOSEK via the statements

```plaintext
option qcp = mosek;
Solve m minimizing z using QCP;
```

As GAMS has no native support for conic programming, the modeltype is specified as QCP.

The solve statement produces the following log output (see also Log Using the Interior Point Optimizer):

```

Return code - 0 [MSK_RES_OK]: No error occurred.

Finally, the optimal value for the matrix $\bar{X}$ and the dual values associated with bound constraints on entries of the matrix $\bar{X}$ can be displayed in GAMS as usual: display X.l, X.m;

4.35.4.2 Usage

The general syntax for defining a symmetric matrix or an (indexed) set of symmetric matrices with PSD constraints in GAMS is

Variable X(a,b,c,...,i1,...,ik,i1,...,ik) "PSDMATRIX_k <explanatory text>";

The number $k>0$ specifies the number of indices that define the row/column dimension of the matrix. Specifying only the term `PSDMATRIX` is equivalent to `PSDMATRIX_1`. For a given $k$, the $2k$-last indices are used to index the rows and columns of the matrix. The dimensions $a$, $b$, $c$, ... are optional and can be used to index a set of matrices. In the GAMS/MOSEK output, a number in parenthesis is used to indicate the number of PSD matrices that have been found for one symbol. For example, the code
Set i / a,b /;
Set j / s01*s42 /;
Variables z, X(j,i,i) PSDMATRIX;

generates the output

Recognizing SDP variables for symbols X (42)

if all matrices X(j,...) also occur in a model instantiation.

Note

The current syntax for declaring PSD matrix variables via the explanatory text a variable is a temporary solution that will hopefully be replaced by a GAMS language feature in the future.

Variables that were tagged as belonging to a PSD matrix can only occur in linear constraints. Within these constraints, the coefficient matrix for a PSD matrix needs to be specified in symmetric form. That is, if the parameter matrix $\mathbf{barA}_{obj}$ in the example above is equivalently specified as

<table>
<thead>
<tr>
<th>Table $\mathbf{barA}_{obj}(i,i)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1 2</td>
</tr>
<tr>
<td>0 2.0 0.0 0.0</td>
</tr>
<tr>
<td>1 2.0 2.0 0.0</td>
</tr>
<tr>
<td>2 0.0 2.0 2.0</td>
</tr>
</tbody>
</table>

the GAMS/MOSEK interface will quit with the error message

SDP coefficient matrix not symmetric: defObj_z: 2*barX(1,0) != 0*barX(0,1)

 Bounds on entries in a PSD matrix variable can be specified as usual with .lo and .up attributes. These bound constraints are translated into linear constraints by the interface. If different bounds are given to symmetric entries of a PSD matrix variable (X_{i,j} vs. X_{j,i}), the stronger bounds are used, which is equivalent to adding constraints for each of the matrix entries. For nonpositive lower bounds on diagonal entries, no extra constraints are added, as they are implied by the PSD constraint.

4.35.4.3 GAMS variables vs. PSD matrix entries

As GAMS is not aware that a indexed variable will be interpreted as PSD matrix variable, it may not generate variables for all matrix entries when instantiating a model. This is especially critical if the modeler specified bounds on matrix entries that do not appear in any of the model equations, as these bounds would not be visible to the GAMS/MOSEK interface.

As an example, consider the SDP relaxation $\max \{ -\langle W,\bar{X} \rangle : X_{i,i} = 1 \ \forall i, X \succeq 0 \}$ corresponding to the Goemans-Williamson Randomized Approximation Algorithm for MaxCut:

<table>
<thead>
<tr>
<th>Parameter W(i,i) edge weights;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable X(i,j) PSDMATRIX</td>
</tr>
<tr>
<td>Equation sdobj objective function;</td>
</tr>
<tr>
<td>sdobj.. sum((i,j), W(i,j)*X(i,j) + X(j,i)) =e= sdobjvar;</td>
</tr>
<tr>
<td>X.fx(i,i) = 1.0;</td>
</tr>
<tr>
<td>model maxcutsdp / all /;</td>
</tr>
</tbody>
</table>
As $W(i,i)=0$, GAMS will not create any variables for $X(i,i)$ when instantiating the model in a solve statement. As a consequence, the constraints $X(i,i)=1$ will not be visible to GAMS/MOSEK. However, as MOSEK will compute values for the full matrix $X$, it will also compute values for the diagonal entries of $X$.

Further, the GAMS/MOSEK interface can pass primal solution values only for those entries of a PSD matrix variable that have a corresponding GAMS variable. This may make a solution matrix appear not to be PSD in GAMS, because not all entries have been passed back.

To be aware of such problems, the GAMS/MOSEK interface checks that it has a GAMS variable available for every entry of a PSD matrix variable. If not, it will report an error like

```
ERROR: Have 1600 GAMS variables for entries of 400 x 400 PSD Variable X(,), expected 160000 many.
```

This check can be disabled by setting the option SDPCHECKVARS to 0. Note, that the check is not able to alarm the user in situations where no GAMS variables were created for all entries of a row and corresponding column.

A simple workaround for this issue is to force all variables to be generated when a model is instantiated. This can be done by adding something like \( \text{eps} \times \sum((i,j), X(i,j)) \) to one of the equations. Note, that \( \text{eps} \) is numerically equal to a 0.0 in GAMS, but has the effect that the term \( \sum((i,j), X(i,j)) \) is passed to the solver with 0.0-coefficient.

### 4.35.4.4 Dual Values for PSD constraints

The PSD constraint on a matrix variable $\bar{X}$ is associated with a dual PSD matrix variable $\bar{Y}$. As GAMS is not aware of the PSD constraints, it is also not aware of the corresponding dual variables. Thus, there is no native way to pass the duals for the PSD constraints back to GAMS. (Recall, that the marginals for a PSDMATRIX variable $X$ are used to store the dual values associated with the bound constraints on matrix entries.)

To work around this issue, the GAMS/MOSEK interface offers the option `SDPSOLUFILE`. This option allows to specify the name of a GDX file that stores primal values for all entries of a matrix variable and dual values of the corresponding PSD constraint. For a variable $X(i,j)$, the GDX file stores the primal matrix value for all entries $(i,j)$ (i.e., not just the ones for which GAMS variables were created, therefore offering another workaround for the issue discussed in the previous section) as level values of variable $X$ and the dual matrix for the PSD constraint as marginal values.

### 4.35.5 Detailed Descriptions of MOSEK Options

**FIXOPTFILE** *(string)*: Name of option file which is read just before solving the fixed problem.

**MSK_DPAR_ANA_SOL_INFEAS_TOL** *(real)*: If a constraint violates its bound with an amount larger than this value, the constraint name, index and violation will be printed by the solution analyzer.

Default: \(1\times 10^{-6}\)

**MSK_DPAR_BASIS_REL_TOL_S** *(real)*: Maximum relative dual bound violation allowed in an optimal basic solution.

Default: \(1\times 10^{-12}\)
**MSK_DPAR_BASIS_TOL_S** *(real):* Maximum absolute dual bound violation in an optimal basic solution.

- **Range:** [1e-09, ∞]
- **Default:** 1e-06

**MSK_DPAR_BASIS_TOL_X** *(real):* Maximum absolute primal bound violation allowed in an optimal basic solution.

- **Range:** [1e-09, ∞]
- **Default:** 1e-06

**MSK_DPAR_CHECK_CONVEXITY_REL_TOL** *(real):* This parameter controls when the full convexity check declares a problem to be non-convex.

Increasing this tolerance relaxes the criteria for declaring the problem non-convex. A problem is declared non-convex if negative (positive) pivot elements are detected in the Cholesky factor of a matrix which is required to be PSD (NSD). This parameter controls how much this non-negativity requirement may be violated. The matrix $Q$ is considered to not be PSD if the pivot element for column $i$ is less or equal $-|Q_{ii}| \times$ **MSK_DPAR_CHECK_CONVEXITY_REL_TOL**.

- **Default:** 1e-10

**MSK_DPAR_DATA_SYM_MAT_TOL** *(real):* Absolute zero tolerance for elements in symmetric matrices.

- **Range:** [1e-16, 1e-06]
- **Default:** 1e-12

**MSK_DPAR_DATA_SYM_MAT_TOL_HUGE** *(real):* An element in a symmetric matrix which is larger than this value in absolute size causes an error.

- **Default:** 1e+20

**MSK_DPAR_DATA_SYM_MAT_TOL_LARGE** *(real):* An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed.

- **Default:** 1e+10

**MSK_DPAR_DATA_TOL_AIJ** *(real):* Absolute zero tolerance for elements in the constraint matrix.

If any value in the constraint matrix is smaller than this parameter in absolute terms MOSEK will treat the values as zero and generate a warning.

- **Range:** [1e-16, 1e-06]
- **Default:** 1e-12

**MSK_DPAR_DATA_TOL_AIJ_HUGE** *(real):* An element in the constraint matrix which is larger than this value in absolute size causes an error.

- **Default:** 1e+20
**MSK_DPAR_DATA_TOL_AIJ_LARGE (real)**: An element in the constraint matrix which is larger than this value in absolute size causes a warning message.

Default: $1e+10$

**MSK_DPAR_DATA_TOL_BOUND_INF (real)**: Any bound which in absolute value is greater than this parameter is considered infinite.

Default: $1e+16$

**MSK_DPAR_DATA_TOL_BOUND_WRN (real)**: If a bound value is larger than this value in absolute size, then a warning message is issued.

Default: $1e+08$

**MSK_DPAR_DATA_TOL_CJ_LARGE (real)**: A coefficient in the objective function which is larger than this value in absolute terms causes a warning message.

Default: $1e+08$

**MSK_DPAR_DATA_TOL_C_HUGE (real)**: A coefficient in the objective function which is larger than the value in absolute terms is considered to be huge and generates an error.

Default: $1e+16$

**MSK_DPAR_DATA_TOL_QIJ (real)**: Absolute zero tolerance for coefficients of quadratic terms.

Default: $1e-16$

**MSK_DPAR_DATA_TOL_X (real)**: Zero tolerance for constraints and variables i.e. if the distance between the lower and upper bound is less than this value, then the lower and upper bound is considered identical.

Default: $1e-08$

**MSK_DPAR_INTPNT_CO_TOL_DFEAS (real)**: Dual feasibility tolerance used by the conic interior-point optimizer.

Range: $[0, 1]$

Default: $1e-08$

See also: **MSK_DPAR_INTPNT_CO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_CO_TOL_INFEAS (real)**: Controls when the conic interior-point optimizer declares the model primal or dual infeasible.

A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: $[0, 1]$

Default: $1e-10$

**MSK_DPAR_INTPNT_CO_TOL_MU_RED (real)**: Relative complementarity gap feasibility tolerance used by the conic interior-point optimizer.
MSK_DPAR_INTPNT_CO_TOL_NEAR_REL (real): Termination tolerance multiplier that is used if no accurate solution can be found.

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: [1, ∞]
Default: 1000

MSK_DPAR_INTPNT_CO_TOL_PFEAS (real): Primal feasibility tolerance used by the conic interior-point optimizer.

Range: [0, 1]
Default: 1e-08

See also: MSK_DPAR_INTPNT_CO_TOL_NEAR_REL.

MSK_DPAR_INTPNT_CO_TOL_REL_GAP (real): Relative gap termination tolerance used by the conic interior-point optimizer.

Range: [0, 1]
Default: 1e-07

See also: MSK_DPAR_INTPNT_CO_TOL_NEAR_REL.

MSK_DPAR_INTPNT_NL_MERIT_BAL (real): Controls if the complementarity and infeasibility is converging to zero at about equal rates.

Range: [0, 0.99]
Default: 0.0001

MSK_DPAR_INTPNT_NL_TOL_DFEAS (real): Dual feasibility tolerance used when a nonlinear model is solved.

Range: [0, 1]
Default: 1e-08

MSK_DPAR_INTPNT_NL_TOL_MU_RED (real): Relative complementarity gap tolerance for the nonlinear solver.

Range: [0, 1]
Default: 1e-12

MSK_DPAR_INTPNT_NL_TOL_NEAR_REL (real): Termination tolerance multiplier that is used if no accurate solution can be found.
If the MOSEK nonlinear interior-point optimizer cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: $[1, \infty]$

Default: 1000

**MSK_DPAR_INTPNT_NL_TOL_PFEAS** (*real*): Primal feasibility tolerance used when a nonlinear model is solved. →

Range: $[0, 1]$

Default: $1e-08$

**MSK_DPAR_INTPNT_NL_TOL_REL_GAP** (*real*): Relative gap termination tolerance for nonlinear problems. →

Range: $[1e-14, \infty]$

Default: $1e-06$

**MSK_DPAR_INTPNT_NL_TOL_REL_STEP** (*real*): Relative step size to the boundary for general nonlinear optimization problems. →

Range: $[0.0001, 1]$

Default: 0.995

**MSK_DPAR_INTPNT_QO_TOL_DFEAS** (*real*): Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem. →

Range: $[0, 1]$

Default: $1e-08$

See also: **MSK_DPAR_INTPNT_QO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_QO_TOL_INFEAS** (*real*): Controls when the conic interior-point optimizer declares the model primal or dual infeasible. →

A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: $[0, 1]$

Default: $1e-10$

**MSK_DPAR_INTPNT_QO_TOL_MU_RED** (*real*): Relative complementarity gap feasibility tolerance used when interior-point optimizer is applied to a quadratic optimization problem. →

Range: $[0, 1]$

Default: $1e-08$

**MSK_DPAR_INTPNT_QO_TOL_NEAR_REL** (*real*): Termination tolerance multiplier that is used if no accurate solution can be found. →
If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: \([1, \infty]\]
Default: 1000

**MSK_DPAR_INTPNT_QO_TOL_PFEAS** *(real)*: Primal feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem. ←

Range: \([0, 1]\]
Default: \(1e^{-08}\)

See also: **MSK_DPAR_INTPNT_QO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_QO_TOL_REL_GAP** *(real)*: Relative gap termination tolerance used when the interior-point optimizer is applied to a quadratic optimization problem. ←

Range: \([0, 1]\]
Default: \(1e^{-08}\)

See also: **MSK_DPAR_INTPNT_QO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_TOL_DFEAS** *(real)*: Dual feasibility tolerance used for linear optimization problems. ←

Range: \([0, 1]\]
Default: \(1e^{-08}\)

**MSK_DPAR_INTPNT_TOL_DSAFE** *(real)*: Controls the initial dual starting point used by the interior-point optimizer. ←

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: \([0.0001, \infty]\]
Default: 1

**MSK_DPAR_INTPNT_TOL_INFEAS** *(real)*: Controls when the optimizer declares the model primal or dual infeasible. ←

A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: \([0, 1]\]
Default: \(1e^{-10}\)

**MSK_DPAR_INTPNT_TOL_MU_RED** *(real)*: Relative complementarity gap tolerance for linear problems. ←

Range: \([0, 1]\]
Default: \(1e^{-16}\)
**MSK_DPAR_INTPNT_TOL_PATH** *(real)*: Controls how close the interior-point optimizer follows the central path. 

A large value of this parameter means the central is followed very closely. On numerical unstable problems it may be worthwhile to increase this parameter.

Range: \([0, 0.9999]\]

Default: \(1e-08\)

**MSK_DPAR_INTPNT_TOL_PFEAS** *(real)*: Primal feasibility tolerance used for linear optimization problems.

Range: \([0, 1]\]

Default: \(1e-08\)

**MSK_DPAR_INTPNT_TOL_PSAFE** *(real)*: Controls the initial primal starting point used by the interior-point optimizer.

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it may be worthwhile to increase this value.

Range: \([0.0001, \infty]\]

Default: 1

**MSK_DPAR_INTPNT_TOL_REL_GAP** *(real)*: Relative gap termination tolerance for linear problems.

Range: \([1e-14, \infty]\]

Default: \(1e-08\)

**MSK_DPAR_INTPNT_TOL_REL_STEP** *(real)*: Relative step size to the boundary for linear and quadratic optimization problems.

Range: \([0.0001, 0.999999]\]

Default: 0.9999

**MSK_DPAR_INTPNT_TOL_STEP_SIZE** *(real)*: Step size tolerance.

If the step size falls below the value of this parameter, then the interior-point optimizer assumes it is stalled. In other words the interior-point optimizer does not make any progress and therefore it is better stop.

Range: \([0, 1]\]

Default: \(1e-06\)

**MSK_DPAR_LOWER_OBJ_CUT** *(real)*: Lower objective limit.

If either a primal or dual feasible solution is found proving that the optimal objective value is outside, the interval *(MSK_DPAR_LOWER_OBJ_CUT, MSK_DPAR_UPPER_OBJ_CUT)*, then MOSEK is terminated.

Range: \([-\infty, \infty]\]

Default: \(-1e+30\)

See also: **MSK_DPAR_LOWER_OBJ_CUT_FINITE_TRH**.
MSK_DPAR_LOWER_OBJ_CUT_FINITE_TRH (real): Lower objective limit threshold. 

If the lower objective cut (MSK_DPAR_LOWER_OBJ_CUT) is less than this value, then it is treated as infinity.

Range: $[-\infty, \infty]$ 
Default: $-5e+29$

MSK_DPAR_MIO_DISABLE_TERM_TIME (real): Disables termination criteria for a certain time.

This parameter specifies the number of seconds during which the termination criteria governed by

- MSK_IPAR_MIO_MAX_NUM_RELAXS
- MSK_IPAR_MIO_MAX_NUM_BRANCHES
- MSK_DPAR_MIO_NEAR_TOL_ABS_GAP
- MSK_DPAR_MIO_NEAR_TOL_REL_GAP

are disabled since the beginning of the optimization. A negative value is identical to infinity i.e. the termination criteria are never checked.

Range: $[-\infty, \infty]$ 
Default: 0

See also: MSK_DPAR_MIO_NEAR_TOL_ABS_GAP, MSK_DPAR_MIO_NEAR_TOL_REL_GAP, MSK_IPAR_MIO_MAX_NUM_BRANCHES, MSK_IPAR_MIO_MAX_NUM_RELAXS.

MSK_DPAR_MIO_MAX_TIME (real): This parameter limits the maximum time spent by the mixed-integer optimizer.

A negative number means infinity.

Range: $[-\infty, \infty]$ 
Default: -1

MSK_DPAR_MIO_NEAR_TOL_ABS_GAP (real): Relaxed absolute optimality tolerance employed by the mixed-integer optimizer.

This termination criteria is delayed.

Default: GAMS OptCA

See also: MSK_DPAR_MIO_DISABLE_TERM_TIME.

MSK_DPAR_MIO_NEAR_TOL_REL_GAP (real): Relaxed relative optimality tolerance employed by the mixed integer optimizer.

The mixed integer optimizer is terminated when this tolerance is satisfied. This termination criteria is delayed.

Default: GAMS OptCR

See also: MSK_DPAR_MIO_DISABLE_TERM_TIME.
**MSK_DPAR_MIO_REL_GAP_CONST** *(real):* This value is used to compute the relative gap for the solution to an integer optimization problem.

- **Range:** \([1e^{-15}, \infty]\)
- **Default:** 1e-10

**MSK_DPAR_MIO_TOL_ABS_GAP** *(real):* Absolute optimality tolerance employed by the mixed-integer optimizer.

- **Default:** 0

**MSK_DPAR_MIO_TOL_ABS_RELAX_INT** *(real):* Absolute relaxation tolerance of the integer constraints.

That means if the fractional part of a discrete variable \(\min(|x| - \lfloor x \rfloor, \lceil x \rceil - |x|)\) is less than the tolerance, then the integer restriction is assumed to be satisfied.

- **Range:** \([1e^{-09}, \infty]\)
- **Default:** 1e-05

**MSK_DPAR_MIO_TOL_FEAS** *(real):* Feasibility tolerance for mixed integer solver.

- **Range:** \([1e^{-09}, 0.001]\)
- **Default:** 1e-06

**MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT** *(real):* If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation.

- A value of 0.0 means that the value is selected automatically.
- **Range:** \([0, 1]\)
- **Default:** 0

**MSK_DPAR_MIO_TOL_REL_GAP** *(real):* Relative optimality tolerance employed by the mixed-integer optimizer.

- **Default:** 0

**MSK_DPAR_OPTIMIZER_MAX_TIME** *(real):* Maximum amount of time the optimizer is allowed to spent on the optimization.

- A negative number means infinity.
- **Range:** \([-\infty, \infty]\)
- **Default:** GAMS ResLim

**MSK_DPAR_PRESOLVE_TOL_ABS_LINDEP** *(real):* Absolute tolerance employed by the linear dependency checker.

- **Default:** 1e-06

**MSK_DPAR_PRESOLVE_TOL_AIJ** *(real):* Absolute zero tolerance employed for constraint coefficients in presolve.
Range: $[1e^{-15}, \infty)$
Default: $1e^{-12}$

**MSK_DPAR_PRESOLVE_TOL_REL_LINDEP** *(real):* Relative tolerance employed by the linear dependency checker. ←
Default: $1e^{-10}$

**MSK_DPAR_PRESOLVE_TOL_S** *(real):* Absolute zero tolerance employed for dual variables in presolve. ←
Default: $1e^{-08}$

**MSK_DPAR_PRESOLVE_TOL_X** *(real):* Absolute zero tolerance employed for primal variables in presolve. ←
Default: $1e^{-08}$

**MSK_DPAR_QCQO_REFORMULATE_REL_DROP_TOL** *(real):* This parameter determines when columns are dropped in incomplete Cholesky factorization during reformulation of quadratic problems. ←
Default: $1e^{-15}$

**MSK_DPAR_SEMIDEFINITE_TOL_APPROX** *(real):* Tolerance to define a matrix to be positive semidefinite. ←
Range: $[1e^{-15}, \infty)$
Default: $1e^{-10}$

**MSK_DPAR_SIMPLEX_ABS_TOL_PIV** *(real):* Absolute pivot tolerance employed by the simplex optimizers. ←
Range: $[1e^{-12}, \infty)$
Default: $1e^{-07}$

**MSK_DPAR_SIM_LU_TOL_REL_PIV** *(real):* Relative pivot tolerance for LU factorization in simplex optimizers and basis identification. ←
A value closer to 1.0 generally improves numerical stability but typically also implies an increase in the computational work.
Range: $[1e^{-06}, 0.999999]$  
Default: 0.01

**MSK_DPAR_UPPER_OBJ_CUT** *(real):* Upper objective limit. ←
If either a primal or dual feasible solution is found proving that the optimal objective value is outside the interval **MSK_DPAR_LOWER_OBJ_CUT, MSK_DPAR_UPPER_OBJ_CUT**, then MOSEK is terminated.
Range: $[-\infty, \infty)$
Default: $1e+30$
See also: **MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH**.

**MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH** *(real):* Upper objective limit threshold. ←
If the upper objective cut **MSK_DPAR_UPPER_OBJ_CUT** is greater than this value, then it is treated as infinity.
Range: $[-\infty, \infty)$
Default: $5e+29$

**MSK_IPAR_AUTO_SORT_A_BEFORE_OPT** *(string):* Controls whether the elements in each column of the coefficient matrix are sorted before an optimization is performed. ←
This is not required but makes the optimization insusceptible to reorderings of variables.
Default: MSK_OFF
MSK_IPAR_BI_CLEAN_OPTIMIZER (string): Controls which simplex optimizer is used in the clean-up phase.

Default: MSK_OPTIMIZER_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_OPTIMIZER_FREE</td>
<td>The optimizer is chosen automatically.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_PRIMAL_SIMPLEX</td>
<td>The primal simplex optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_DUAL_SIMPLEX</td>
<td>The dual simplex optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_FREE_SIMPLEX</td>
<td>One of the simplex optimizers is used.</td>
</tr>
</tbody>
</table>

MSK_IPAR_BI_IGNORE_MAX_ITER (string): Controls if basis identification is performed under certain conditions.

If the parameter MSK_IPAR_INTPNT_BASIS has the value MSK_BI_NO_ERROR and the interior-point optimizer has terminated due to maximum number of iterations, then basis identification is performed if this parameter has the value MSK_ON.

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

MSK_IPAR_BI_IGNORE_NUM_ERROR (string): Turns on basis identification if interior-point optimizer is terminated due to a numerical problem.

If the parameter MSK_IPAR_INTPNT_BASIS has the value MSK_BI_NO_ERROR and the interior-point optimizer has terminated due to a numerical problem, then basis identification is performed if this parameter has the value MSK_ON.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

MSK_IPAR_BI_MAX_ITERATIONS (integer): Controls the maximum number of simplex iterations allowed to optimize a basis after the basis identification.

Default: 1000000

MSK_IPAR_CHECK_CONVEXITY (string): Specify the level of convexity check on quadratic problems.

Default: MSK_CHECK_CONVEXITY_FULL
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_CHECK_CONVEXITY_NONE</td>
<td>No convexity check.</td>
</tr>
<tr>
<td>MSK_CHECK_CONVEXITY_SIMPLE</td>
<td>Perform simple and fast convexity check.</td>
</tr>
<tr>
<td>MSK_CHECK_CONVEXITY_FULL</td>
<td>Perform a full convexity check.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INFEAS_PREFER_PRIMAL** *(string)*: If both certificates of primal and dual infeasibility are supplied then only the primal is used when this option is turned on.  

Default: **MSK.ON**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK.ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK.OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INFEAS_REPORT_AUTO** *(string)*: Controls whether an infeasibility report is automatically produced after the optimization if the problem is primal or dual infeasible.  

Default: **MSK.OFF**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK.ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK.OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INFEAS_REPORT_LEVEL** *(integer)*: Controls the amount of information presented in an infeasibility report.  

Higher values imply more information.

Default: 1

**MSK_IPAR_INTPNT_BASIS** *(string)*: Controls whether the interior-point optimizer also computes an optimal basis.  

Default: **MSK.BI_ALWAYS**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK.BI_NEVER</td>
<td>Never do basis identification.</td>
</tr>
<tr>
<td>MSK.BI_ALWAYS</td>
<td>Basis identification is always performed even if the interior-point optimizer terminates abnormally.</td>
</tr>
<tr>
<td>MSK.BI_NO_ERROR</td>
<td>Basis identification is performed if the interior-point optimizer terminates without an error.</td>
</tr>
<tr>
<td>MSK.BI_IF_FEASIBLE</td>
<td>Basis identification is not performed if the interior-point optimizer terminates with a problem status saying that the problem is primal or dual infeasible.</td>
</tr>
</tbody>
</table>

See also:  **MSK_IPAR_BI_CLEAN_OPTIMIZER, MSK_IPAR_BI_IGNORE_MAX_ITER, MSK_IPAR_BI_IGNORE_NUM_ERROR, MSK_IPAR_BI_MAX_ITERATIONS**.

**MSK_IPAR_INTPNT_DIFF_STEP** *(string)*: Controls whether different step sizes are allowed in the primal and dual space.  

Default: **MSK.ON**
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>

<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_MAX_ITERATIONS** *(integer)*: Controls the maximum number of iterations allowed in the interior-point optimizer.

Default: GAMS IterLim

**MSK_IPAR_INTPNT_MAX_NUM_COR** *(integer)*: Controls the maximum number of correctors allowed by the multiple corrector procedure.

A negative value means that MOSEK is making the choice.

Range: \([-1, \infty]\]

Default: -1

**MSK_IPAR_INTPNT_MAX_NUM_REFINEMENT_STEPS** *(integer)*: Maximum number of steps to be used by the iterative refinement of the search direction.

A negative value implies that the optimizer chooses the maximum number of iterative refinement steps.

Range: \([-\infty, \infty]\]

Default: -1

**MSK_IPAR_INTPNT_MULTI_THREAD** *(string)*: Controls whether the interior-point optimizers can employ multiple threads if available.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_OFF_COL_TRH** *(integer)*: Controls how aggressively offending columns are detected in the Jacobian of the constraint matrix.

0 means no detection, 1 means aggressive detection, and higher values mean less aggressive detection.

Default: 40

**MSK_IPAR_INTPNT_ORDER_METHOD** *(string)*: Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system.

Default: MSK_ORDER_METHOD_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ORDER_METHOD_FREE</td>
<td>The ordering method is chosen automatically.</td>

<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_SCALING** *(string)*: Controls how the problem is scaled before the interior-point optimizer is used. ←

Default: **MSK_SCALING_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SCALING_FREE</td>
<td>The optimizer chooses the scaling heuristic.</td>
</tr>
<tr>
<td>MSK_SCALING_NONE</td>
<td>No scaling is performed.</td>
</tr>
<tr>
<td>MSK_SCALING_MODERATE</td>
<td>A conservative scaling is performed.</td>
</tr>
<tr>
<td>MSK_SCALING_AGGRESSIVE</td>
<td>A very aggressive scaling is performed.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_SOLVE_FORM** *(string)*: Controls whether the primal or the dual problem is solved. ←

Default: **MSK_SOLVE_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SOLVE_FREE</td>
<td>The optimizer is free to solve either the primal or the dual problem.</td>
</tr>
<tr>
<td>MSK_SOLVE_PRIMAL</td>

**MSK_IPAR_INTPNT_STARTING_POINT** *(string)*: Starting point used by the interior-point optimizer. ←

Default: **MSK_STARTING_POINT_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_STARTING_POINT_FREE</td>
<td>The starting point is chosen automatically.</td>
</tr>
<tr>
<td>MSK_STARTING_POINT_GUESS</td>
<td>The optimizer guesses a starting point.</td>
</tr>
<tr>
<td>MSK_STARTING_POINT_CONSTANT</td>
<td>The optimizer constructs a starting point by assigning a constant value to all primal and dual variables. This starting point is normally robust.</td>
</tr>
</tbody>
</table>
The starting point is chosen to satisfy all the simple bounds on nonlinear variables. If this starting point is employed, then more care than usual should employed when choosing the bounds on the nonlinear variables. In particular very tight bounds should be avoided.

**MSK_IPAR_LOG** *(integer)*: Controls the amount of log information.

The value 0 implies that all log information is suppressed. A higher level implies that more information is logged.

Default: 10

**MSK_IPAR_LOG_BI** *(integer)*: Controls the amount of output printed by the basis identification procedure.

A higher level implies that more information is logged.

Default: 1

**MSK_IPAR_LOG_BI_FREQ** *(integer)*: Controls logging frequency of the basis identification

Default: 2500

**MSK_IPAR_LOG_CHECK_CONVEXITY** *(integer)*: Controls logging in convexity check on quadratic problems.

Set to a positive value to turn logging on. If a quadratic coefficient matrix is found to violate the requirement of PSD (NSD) then a list of negative (positive) pivot elements is printed. The absolute value of the pivot elements is also shown.

Default: 0

**MSK_IPAR_LOG_FEAS_REPAIR** *(integer)*: Controls the amount of output printed when performing feasibility repair.

Default: 1

**MSK_IPAR_LOG_INFEAS_ANA** *(integer)*: Controls amount of output printed by the infeasibility analyzer procedures.

A higher level implies that more information is logged.

Default: 1

**MSK_IPAR_LOG_INTPNT** *(integer)*: Controls amount of output printed by the interior-point optimizer.

A higher level implies that more information is logged.

Default: 1

**MSK_IPAR_LOG_MIO** *(integer)*: Controls the log level for the mixed-integer optimizer.
A higher level implies that more information is logged.

Default: 4

**MSK_IPAR_LOG_MIO_FREQ** *(integer)*: Controls how frequent the mixed-integer optimizer prints the log line. ←

It will print a line every time **MSK_INTPAR_LOG_MIO_FREQ** relaxations have been solved.

Range: \([-\infty, \infty]\)

Default: 10

**MSK_IPAR_LOG_ORDER** *(integer)*: If turned on, then factor lines are added to the log. ←

Default: 1

**MSK_IPAR_LOG_PRESOLVE** *(integer)*: Controls amount of output printed by the presolve procedure. ←

A higher level implies that more information is logged.

Default: 1

**MSK_IPAR_LOG_RESPONSE** *(integer)*: Controls amount of output printed when response codes are reported. ←

A higher level implies that more information is logged.

Default: 0

**MSK_IPAR_LOG_SIM** *(integer)*: Controls amount of output printed by the simplex optimizer. ←

A higher level implies that more information is logged.

Default: 4

**MSK_IPAR_LOG_SIM_FREQ** *(integer)*: Controls simplex optimizer logging frequency. ←

Default: 1000

**MSK_IPAR_LOG_STORAGE** *(integer)*: When turned on, MOSEK prints messages regarding the storage usage and allocation. ←

Default: 0

**MSK_IPAR_MIO_BRANCH_DIR** *(string)*: Controls whether the mixed-integer optimizer is branching up or down by default. ←

Default: **MSK_BRANCH_DIR_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>MSK_BRANCH_DIR_FREE</strong></td>
<td>The mixed-integer optimizer decides which branch to choose.</td>
</tr>
<tr>
<td><strong>MSK_BRANCH_DIR_UP</strong></td>
<td>The mixed-integer optimizer always chooses the up branch first.</td>
</tr>
<tr>
<td><strong>MSK_BRANCH_DIR_DOWN</strong></td>
<td>The mixed-integer optimizer always chooses the down branch first.</td>
</tr>
<tr>
<td><strong>MSK_BRANCH_DIR_NEAR</strong></td>
<td>Branch in direction nearest to selected fractional variable.</td>
</tr>
<tr>
<td><strong>MSK_BRANCH_DIR_FAR</strong></td>
<td>Branch in direction farthest from selected fractional variable.</td>
</tr>
<tr>
<td><strong>MSK_BRANCH_DIR_ROOT_LP</strong></td>
<td>Chose direction based on root lp value of selected variable.</td>
</tr>
</tbody>
</table>
**MSK_IPAR_MIO_CONSTRUCT_SOL (string):** Controls construction of an initial mixed integer solution from the values of the integer variables →

Synonym: mipstart

If set to MSK_ON and all integer variables have been given a value for which a feasible mixed integer solution exists, then MOSEK generates an initial solution to the mixed integer problem by fixing all integer values and solving the remaining problem.

Default: MSK_OFF

<table>
<thead>

</tbody>
</table>

**MSK_IPAR_MIO_CUT_GMI (string):** Controls whether GMI cuts should be generated. ↔

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_CUT IMPLIED_BOUND (string):** Controls whether implied bound cuts should be generated. ↔

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_CUT_KNAPSACK_COVER (string):** Controls whether knapsack cover cuts
should be generated.

Default: \texttt{MSK\_OFF}

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{MSK_ON}</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>\texttt{MSK_OFF}</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

\textbf{MSK\_IPAR\_MIO\_CUT\_SELECTION\_LEVEL} \textit{(integer)}: Controls how aggressively generated cuts are selected to be included in the relaxation.

Default: \(-1\)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-1)</td>
<td>The optimizer chooses the level of cut selection.</td>
</tr>
<tr>
<td>0</td>
<td>Generated cuts less likely to be added to the relaxation.</td>
</tr>
<tr>
<td>1</td>
<td>Cuts are more aggressively selected to be included in the relaxation.</td>
</tr>
</tbody>
</table>

\textbf{MSK\_IPAR\_MIO\_HEURISTIC\_LEVEL} \textit{(integer)}: Controls the heuristic employed by the mixed-integer optimizer to locate an initial good integer feasible solution.

A value of zero means the heuristic is not used at all. A larger value than 0 means that a gradually more sophisticated heuristic is used which is computationally more expensive. A negative value implies that the optimizer chooses the heuristic. Normally a value around 3 to 5 should be optimal.

Range: \([-\infty, \infty]\)

Default: \(-1\)

\textbf{MSK\_IPAR\_MIO\_MAX\_NUM\_BRANCHES} \textit{(integer)}: Maximum number of branches allowed during the branch and bound search.

A negative value means infinite.

Range: \([-\infty, \infty]\)

Default: \(-1\)

See also: \texttt{MSK\_DPAR\_MIO\_DISABLE\_TERM\_TIME}.

\textbf{MSK\_IPAR\_MIO\_MAX\_NUM\_RELAXS} \textit{(integer)}: Maximum number of relaxations allowed during the branch and bound search.

A negative value means infinite.

Range: \([-\infty, \infty]\)

Default: \texttt{GAMS NodLim}

See also: \texttt{MSK\_DPAR\_MIO\_DISABLE\_TERM\_TIME}.

\textbf{MSK\_IPAR\_MIO\_MAX\_NUM\_SOLUTIONS} \textit{(integer)}: The mixed-integer optimizer can be terminated after a certain number of different feasible solutions has been located.
If this parameter has the value $n > 0$, then the mixed-integer optimizer will be terminated when $n$ feasible solutions have been located.

Range: $[-\infty, \infty]$

Default: -1

See also: MSK_DPAR_MIO_DISABLE_TERM_TIME.

**MSK_IPAR_MIO_NODE_OPTIMIZER** *(string)*: Controls which optimizer is employed at the non-root nodes in the mixed-integer optimizer.

Default: MSK_OPTIMIZER_FREE
### MSK\_OPTIMIZER

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_OPTIMIZER_FREE</td>
<td>The optimizer is chosen automatically.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_INTPNT</td>
<td>The interior-point optimizer is used.</td>

<tr>
<td>MSK_OPTIMIZER_MIXED_INT</td>
<td>The mixed-integer optimizer.</td>
</tr>
</tbody>
</table>

### MSK\_IPAR\_MIO\_NODE\_SELECTION

(string): Controls the node selection strategy employed by the mixed-integer optimizer.

Default: MSK\_MIO\_NODE\_SELECTION\_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_MIO_NODE_SELECTION_FREE</td>
<td>The optimizer decides the node selection strategy.</td>
</tr>
<tr>
<td>MSK_MIO_NODE_SELECTION_FIRST</td>
<td>The optimizer employs a depth first node selection strategy.</td>
</tr>
<tr>
<td>MSK_MIO_NODE_SELECTION_BEST</td>
<td>The optimizer employs a best bound node selection strategy.</td>
</tr>
<tr>
<td>MSK_MIO_NODE_SELECTION_WORST</td>
<td>The optimizer employs a worst bound node selection strategy.</td>
</tr>
<tr>
<td>MSK_MIO_NODE_SELECTION_HYBRID</td>
<td>The optimizer employs a hybrid strategy.</td>
</tr>
<tr>
<td>MSK_MIO_NODE_SELECTION_PSEUDO</td>
<td>The optimizer employs selects the node based on a pseudo cost estimate.</td>
</tr>
</tbody>
</table>

### MSK\_IPAR\_MIO\_PERSPECTIVE\_REFORMULATE

(string): Enables or disables perspective reformulation in presolve.

Default: MSK\_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

### MSK\_IPAR\_MIO\_PROBING\_LEVEL

(integer): Controls the amount of probing employed by the mixed-integer optimizer in presolve.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses the level of probing employed</td>
</tr>
<tr>
<td>0</td>
<td>Probing is disabled</td>
</tr>
<tr>
<td>1</td>
<td>A low amount of probing is employed</td>
</tr>
<tr>
<td>2</td>
<td>A medium amount of probing is employed</td>
</tr>
<tr>
<td>3</td>
<td>A high amount of probing is employed</td>
</tr>
</tbody>
</table>

### MSK\_IPAR\_MIO\_RINS\_MAX\_NODES

(integer): Controls the maximum number of nodes allowed in each call to the RINS heuristic.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---
The default value of -1 means that the value is determined automatically. A value of zero turns off the heuristic.

Range: [-1, ∞]

Default: -1

**MSK_IPAR_MIO_ROOT_OPTIMIZER** *(string):* Controls which optimizer is employed at the root node in the mixed-integer optimizer. ←

Default: MSK_OPTIMIZER_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_OPTIMIZER_FREE</td>
<td>The optimizer is chosen automatically.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_INTPNT</td>
<td>The interior-point optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_CONIC</td>
<td>The optimizer for problems having conic constraints.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_PRIMAL_SIMPLEX</td>
<td>The primal simplex optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_DUAL_SIMPLEX</td>
<td>The dual simplex optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_FREE_SIMPLEX</td>
<td>One of the simplex optimizers is used.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL** *(integer):* Controls whether presolve can be repeated at root node. ←

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses whether presolve is repeated.</td>
</tr>
<tr>
<td>0</td>
<td>Never repeat presolve.</td>
</tr>
<tr>
<td>1</td>
<td>Always repeat presolve.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_VB_DETECTION_LEVEL** *(integer):* Controls how much effort is put into detecting variable bounds. ←

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses.</td>
</tr>
<tr>
<td>0</td>
<td>No variable bounds are detected.</td>
</tr>
<tr>
<td>1</td>
<td>Only detect variable bounds that are directly represented in the problem.</td>
</tr>
<tr>
<td>2</td>
<td>Detect variable bounds in probing.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_NUM_THREADS** *(integer):* Controls the number of threads employed by the optimizer. ←

If set to 0 the number of threads used will be equal to the number of cores detected on the machine.

Default: GAMS Threads

**MSK_IPAR_OPF_MAX_TERMS_PER_LINE** *(integer):* The maximum number of terms (linear and quadratic) per line when an OPF file is written. ←
Default: 5

**MSK_IPAR_OPF_WRITE_HEADER** *(string)*: Write a text header with date and MOSEK version in an OPF file. 

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_HINTS** *(string)*: Write a hint section with problem dimensions in the beginning of an OPF file.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_PARAMETERS** *(string)*: Write a parameter section in an OPF file.

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_PROBLEM** *(string)*: Write objective, constraints, bounds etc. to an OPF file.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_SOLUTIONS** *(string)*: Enable inclusion of solutions in the OPF files.

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_SOL_BAS** *(string)*: Whether to include basic solution in OPF files.

If **MSK_IPAR_OPF_WRITE_SOLUTIONS** is MSK_ON and a basic solution is defined, include the basic solution in OPF files.
Default: \texttt{MSK\_ON} \\

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{MSK_ON}</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>\texttt{MSK_OFF}</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

\textbf{MSK\_IPAR\_OPF\_WRITE\_SOL\_ITG} \textit{(string)}: Whether to include integer solution in OPF files. \leftrightarrow \\

If \texttt{MSK\_IPAR\_OPF\_WRITE\_SOLUTIONS} is \texttt{MSK\_ON} and an integer solution is defined, write the integer solution to OPF files.

Default: \texttt{MSK\_ON} \\

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{MSK_ON}</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>\texttt{MSK_OFF}</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

\textbf{MSK\_IPAR\_OPF\_WRITE\_SOL\_ITR} \textit{(string)}: Whether to include interior solution in OPF files. \leftrightarrow \\

If \texttt{MSK\_IPAR\_OPF\_WRITE\_SOLUTIONS} is \texttt{MSK\_ON} and an interior solution is defined, write the interior solution to OPF files.

Default: \texttt{MSK\_ON} \\

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{MSK_ON}</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>\texttt{MSK_OFF}</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

\textbf{MSK\_IPAR\_OPTIMIZER} \textit{(string)}: The parameter controls which optimizer is used to optimize the task. \leftrightarrow \\

Default: \texttt{MSK\_OPTIMIZER\_FREE} \\

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{MSK_OPTIMIZER_FREE}</td>
<td>The optimizer is chosen automatically.</td>
</tr>
<tr>
<td>\texttt{MSK_OPTIMIZER_INTPNT}</td>
<td>The interior-point optimizer is used.</td>
</tr>
<tr>
<td>\texttt{MSK_OPTIMIZER_CONIC}</td>
<td>The optimizer for problems having conic constraints.</td>
</tr>
<tr>
<td>\texttt{MSK_OPTIMIZER_PRIMAL_SIMPLEX}</td>
<td>The primal simplex optimizer is used.</td>
</tr>
<tr>
<td>\texttt{MSK_OPTIMIZER_DUAL_SIMPLEX}</td>
<td>The dual simplex optimizer is used.</td>
</tr>
<tr>
<td>\texttt{MSK_OPTIMIZER_FREE_SIMPLEX}</td>
<td>One of the simplex optimizers is used.</td>
</tr>
<tr>
<td>\texttt{MSK_OPTIMIZER_MIXED_INT}</td>
<td>The mixed-integer optimizer.</td>
</tr>
</tbody>
</table>

\textbf{MSK\_IPAR\_PRESOLVE\_ELIMINATOR\_MAX\_FILL} \textit{(integer)}: Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve. \leftrightarrow \\

A negative value means the parameter value is selected automatically.

Range: \([-\infty, \infty]\) \\

Default: \texttt{-1}
**MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_NUM_TRIES** *(integer)*: Control the maximum number of times the eliminator is tried. 🔄

A negative value implies MOSEK decides.

Range: \([-\infty, \infty]\)

Default: \(-1\)

**MSK_IPAR_PRESOLVE_LINDEP_ABS_WORK_TRH** *(integer)*: Controls the linear dependency check, which is potentially computationally expensive. 🔄

Range: \([-\infty, \infty]\)

Default: 100

**MSK_IPAR_PRESOLVE_LINDEP_REL_WORK_TRH** *(integer)*: Controls the linear dependency check, which is potentially computationally expensive. 🔄

Range: \([-\infty, \infty]\)

Default: 100

**MSK_IPAR_PRESOLVE_LINDEP_USE** *(string)*: Controls whether the linear constraints are checked for linear dependencies. 🔄

Default: `MSK_ON`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_ON</code></td>
<td>Switch the option on.</td>
</tr>
<tr>
<td><code>MSK_OFF</code></td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PRESOLVE_MAX_NUM_REDUCTIONS** *(integer)*: Controls the maximum number of reductions performed by the presolve. 🔄

The value of the parameter is normally only changed in connection with debugging. A negative value implies that an infinite number of reductions are allowed.

Range: \([-\infty, \infty]\)

Default: \(-1\)

**MSK_IPAR_PRESOLVE_USE** *(string)*: Controls whether the presolve is applied to a problem before it is optimized. 🔄

Default: `MSK_PRESOLVE_MODE_FREE`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_PRESOLVE_MODE_OFF</code></td>
<td>The problem is not presolved before it is optimized.</td>
</tr>
<tr>
<td><code>MSK_PRESOLVE_MODE_ON</code></td>
<td>The problem is presolved before it is optimized.</td>
</tr>
<tr>
<td><code>MSK_PRESOLVE_MODE_FREE</code></td>
<td>It is decided automatically whether to presolve before the problem is optimized.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_SIM_BASIS_FACTOR_USE** *(string)*: Controls whether an LU factorization of the basis
is used in a hot-start. ←

Forcing a refactorization sometimes improves the stability of the simplex optimizers, but in most cases there is a performance penalty.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

MSK_IPAR_SIM_DEGEN (string): Controls how aggressively degeneration is handled. ←

Default: MSK_SIM_DEGEN_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SIM_DEGEN_NONE</td>
<td>The simplex optimizer should use no degeneration strategy.</td>
</tr>
<tr>
<td>MSK_SIM_DEGEN_FREE</td>
<td>The simplex optimizer chooses the degeneration strategy.</td>
</tr>
<tr>
<td>MSK_SIM_DEGEN_AGGRESSIVE</td>
<td>The simplex optimizer should use an aggressive degeneration strategy.</td>
</tr>
<tr>
<td>MSK_SIM_DEGEN_MODERATE</td>
<td>The simplex optimizer should use a moderate degeneration strategy.</td>
</tr>
<tr>
<td>MSK_SIM_DEGEN_MINIMUM</td>
<td>The simplex optimizer should use a minimum degeneration strategy.</td>
</tr>
</tbody>
</table>

MSK_IPAR_SIM_DUAL_CRASH (integer): Controls whether crashing is performed in the dual simplex optimizer. ←

In general if a basis consists of more than \((100+\text{MSK\_IPAR\_SIM\_DUAL\_CRASH})\) percent fixed variables, then a crash will be performed.

Default: 90

MSK_IPAR_SIM_DUAL_RESTRICT_SELECTION (integer): Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the dual simplex. ←

The dual simplex optimizer can use a so-called restricted selection/pricing strategy to chooses the outgoing variable. Hence, if restricted selection is applied, then the dual simplex optimizer first choose a subset of all the potential outgoing variables. Next, for some time it will choose the outgoing variable only among the subset. From time to time the subset is redefined. A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Range: \([0, 100]\]

Default: 50

MSK_IPAR_SIM_DUAL_SELECTION (string): Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer. ←
**MSK_SIM_SELECTION**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SIM_SELECTION_FREE</td>
<td>The optimizer chooses the pricing strategy.</td>
</tr>
<tr>
<td>MSK_SIM_SELECTION_FULL</td>
<td>The optimizer uses full pricing.</td>

</tr>
</tbody>
</table>

**MSK_IPAR_SIM_MAX_ITERATIONS** *(integer)*: Maximum number of iterations that can be used
by a simplex optimizer.  

Default: GAMS IterLim

**MSK_IPAR_SIM_MAX_NUM_SETBACKS** *(integer)*: Controls how many set-backs are allowed within a simplex optimizer.  

A set-back is an event where the optimizer moves in the wrong direction. This is impossible in theory but may happen due to numerical problems.

Default: 250

**MSK_IPAR_SIM_NON_SINGULAR** *(string)*: Controls if the simplex optimizer ensures a non-singular basis, if possible.  

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>

</tbody>
</table>

**MSK_IPAR_SIM_STABILITY_PRIORITY** *(integer)*: Controls how high priority the numerical stability should be given. ⬤

Range: `[0, 100]`

Default: 50

**MSK_IPAR_SIM_SWITCH_OPTIMIZER** *(string)*: Controls the simplex behavior. ⬤

The simplex optimizer sometimes chooses to solve the dual problem instead of the primal problem. This implies that if you have chosen to use the dual simplex optimizer and the problem is dualized, then it actually makes sense to use the primal simplex optimizer instead. If this parameter is on and the problem is dualized and furthermore the simplex optimizer is chosen to be the primal (dual) one, then it is switched to the dual (primal).

Default: `MSK_OFF`

4.36 OQNLP and MSNLP

Optimal Methods Inc, 7134 Valburn Dr., Austin, TX 78731 www.optimalmeth.com, 512-346-7837

4.36.1 Introduction

OQNLP and MSNLP are multistart heuristic algorithms designed to find global optima of smooth constrained nonlinear programs (NLPs). By "multistart" we mean that the algorithm calls an NLP solver from multiple starting points, keeps track of all feasible solutions found by that solver, and reports back the best of these as its final solution. The starting points are computed by a scatter search implementation called OptQuest (see www.opttek.com and [Laguna and Marti, 2003]) or by a randomized driver, which generates starting points using probability distributions. There are currently two randomized drivers, Pure Random and Smart Random - see the description of the POINT_GENERATION parameter. The Smart Random generator uses an initial coarse search to define a promising region within which random starting points are concentrated. With OQNLP, all three drivers are provided, while OptQuest is not present in MSNLP. When interfaced with the GAMS modeling language, any GAMS NLP solver can be called. When used as a callable system, MSNLP/OQNLP uses the LSGRG2 or any GAMS NLP solver (see www.optimalmeth.com and (Smith and Lasdon, 1992)), and this is also provided (optionally) in the GAMS version.

Only the OptQuest driver can handle discrete variables, so OQNLP can attack problems with some or all discrete variables, but MSNLP cannot solve problems with discrete variables. If all variables in a problem are discrete, OQNLP can be applied, but the NLP solver calls play no role, since such solvers vary only the continuous variables, and there aren't any. Thus the OPTQUEST_ONLY option should be used. If a problem is nonsmooth (discontinuous functions and/or derivatives, GAMS problem type DNLP), the NLP solver calls may be less reliable than if the problem was smooth. The OPTQUEST_ONLY option may also be useful in this case.

There is no guarantee that the final solution is a global optimum, and no bound is provided on how far that solution is from the global optimum. However, the algorithm has been tested extensively on 135 problems from the set gathered by Chris Floudas [Floudas, et al., 1999], and it found the best known solution on all but three of them to within a percentage gap of 1%, using default parameters and options (which specify 1000 iterations). It solved two of those three to within 1% given 2000 iterations. It also solved 332 of 339 problems from the GAMS Globallib library to within 1% of the best known solution using default parameters, and solved most of the seven remaining ones by increasing the iteration limit or using another NLP solver. These results are described in [Lasdon et al., 2004]. For more information on OQNLP, see [Ugray, et. al., 2003].

A multistart algorithm can improve the reliability of any NLP solver, by calling it with many starting points. If you have a problem where you think the current NLP solver is failing to find even a local solution, choose an NLP solver and a limit on the number of solver calls, and try OQNLP or MSNLP. Even if a single call to the solver fails, multiple calls from the widely spaced starting points provided by this algorithm have a much better chance of success.

Often an NLP solver fails when it terminates at an infeasible solution. In this situation, the user is not sure if the problem is really infeasible or if the solver is at fault (if all constraints are linear or convex the problem is most likely infeasible). A multistart algorithm can help in such cases. To use it, the problem can be solved in its original form, and some solver calls may terminate with feasible solutions. The algorithm will return the best of these. If all solver calls terminate infeasible, the problem can be reformulated as a feasibility problem. That is, introduce "deviation" or "elastic" variables into each constraint, which measure the amount by which it is violated, and minimize the sum of these violations, ignoring the true objective. OQNLP or MSNLP can be applied to this problem, and either has a much
better chance of finding a feasible solution (if one exists) than does a single call to an NLP solver. If no feasible solution is found, you have much more confidence that the problem is truly infeasible.

The OptQuest and randomized drivers generate trial points which are candidate starting points for the NLP solver. These are filtered to provide a smaller subset from which the solver attempts to find a local optimum. In the discussion which follows, we refer to this NLP solver as \textit{L}, for Local solver.

The most general problem OQNLP and MSNLP can solve has the form

$$\begin{align}
\text{minimize } & f(x, y) \\
\text{subject to the nonlinear constraints } & g_l \leq G(x, y) \leq g_u \\
\text{and the linear constraints } & l \leq A_1 x + A_2 y \leq u
\end{align}$$

where \( x \) is an \( n \)-dimensional vector of continuous decision variables, \( y \) is a \( p \)-dimensional vector of discrete decision variables, and the vectors \( g_l, g_u, l, \) and \( u \) contain upper and lower bounds for the nonlinear and linear constraints respectively. The matrices \( A_1 \) and \( A_2 \) are \( m_2 \) by \( n \) and \( m_2 \) by \( p \) respectively, and contain the coefficients of any linear constraints. The set \( S \) is defined by simple bounds on \( x \), and we assume that it is closed and bounded, i.e., that each component of \( x \) has a finite upper and lower bound. This is required by all drivers (see parameter \textbf{ARTIFICIAL\_BOUND} which provides bounds when none are specified in the model). The set \( Y \) is assumed to be finite, and is often the set of all \( p \)-dimensional binary or integer vectors \( y \). The objective function \( f \) and the \( m_1 \)-dimensional vector of constraint functions \( G \) are assumed to have continuous first partial derivatives at all points in \( S \times Y \). This is necessary so that \textit{L} can be applied to the relaxed NLP sub-problems formed from (4.16) - (4.19) by allowing the \( y \) variables to be continuous. The MSNLP system does not allow any discrete variables.

An important function used in this multistart algorithm is the \( L_1 \) exact penalty function, defined as

$$P_1(x, w) = f(x) + \sum_{i=1}^{m} W_i \text{viol}(g_i(x))$$

where the \( w_i \) are nonnegative penalty weights, \( m = m_1 + m_2 \), and the vector \( g \) has been extended to include the linear constraints (4.19). For simplicity, we assume there are no \( y \) variables: these would be fixed when this function is used. The function \( \text{viol}(g_i(x)) \) is equal to the absolute amount by which the \( i \)th constraint is violated at the point \( x \). It is well known (see [Nash and Sofer, 1996]) that if \( x^* \) is a local optimum of (4.16) - (4.19), \( u^* \) is a corresponding optimal multiplier vector, the second order sufficiency conditions are satisfied at \( (x^*, u^*) \), and

$$w_i > \text{abs}(u^*_i)$$

then \( x^* \) is a local unconstrained minimum of \( P_1 \). If (4.16) - (4.19) has several local minima, and each \( w_i \) is larger than the maximum of all absolute multipliers for constraint \( i \) over all these optima, then \( P_1 \) has a local minimum at each of these local constrained minima. We will use \( P_1 \) to set thresholds in the merit filter.
4.36.2 Combining Search Methods and Gradient-Based NLP Solvers

For smooth problems, the relative advantages of a search method over a gradient-based NLP solver are its ability to locate an approximation to a good local solution (often the global optimum), and the fact that it can handle discrete variables. Gradient-based NLP solvers converge to the "nearest" local solution, and have no facilities for discrete variables, unless they are embedded in a rounding heuristic or branch-and-bound method. Relative disadvantages of search methods are their limited accuracy, and their weak abilities to deal with equality constraints (more generally, narrow feasible regions). They find it difficult to satisfy many nonlinear constraints to high accuracy, but this is a strength of gradient-based NLP solvers. Search methods also require an excessive number of iterations to find approximations to local or global optima accurate to more than two or three significant figures, while gradient-based solvers usually achieve four to eight-digit accuracy rapidly. The motivation for combining search and gradient-based solvers in a multi-start procedure is to achieve the advantages of both while avoiding the disadvantages of either.

4.36.3 Output

4.36.3.1 Log File

When it operates as a GAMS solver, OQNLP and MSNLP will by default write information on their progress to the GAMS log file. When used as a callable system, this information, if requested, will be written to a file opened in the users calling program. The information written consists of:

1. Echos of important configuration and setup values
2. Echo (optionally) of options file settings processed
3. Echos of important algorithm settings, parameters, and termination criteria
4. The iteration log
5. Final results, termination messages, and status report

A segment of that iteration log from stages 1 and 2 of the algorithm is shown below for the problem ex8.6.2.30.gms, which is one of a large set of problems described in [Floudas, et al., 1999]. This is a 91 variable unconstrained minimization problem, available from GLOBALLib. There are 200 iterations in stage one and 1000 total iterations (see Appendix A for an algorithm description), with output every 20 iterations and every solver call.

The headings below have the following meanings:

<table>
<thead>
<tr>
<th>Heading</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Itn</td>
<td>iteration number</td>
</tr>
<tr>
<td>Penval</td>
<td>Penalty function value</td>
</tr>
<tr>
<td>Merit Filter</td>
<td>ACC if the merit filter accepts the point, REJ if it rejects</td>
</tr>
<tr>
<td>Merit Threshold</td>
<td>threshold value for merit filter: accepts if Penval &lt; Threshold</td>
</tr>
<tr>
<td>Dist Filter</td>
<td>ACC if the distance filter accepts the point, REJ if it rejects</td>
</tr>
<tr>
<td>Best Obj</td>
<td>Best feasible objective value found thus far</td>
</tr>
<tr>
<td>Solver Obj</td>
<td>Objective value found by NLP solver at this iteration</td>
</tr>
</tbody>
</table>
Iterations 0 through 200 below show the initial NLP solver call (at the user-specified initial point, which finds a local minimum with objective value -161.8), and every 20th iteration of stage 1, which has no other solver calls. At iteration 200 stage 1 ends, and the solver is started at the best of the 200 stage 1 points, finding a local min with objective -176.0. The next solver call at iteration 207 finds a better objective of -176.4. Note that, at iteration 207, the OptQuest trial solution has a Penval of -23.18, and this is less than the merit threshold of -20.75, so the merit filter ACCepts the trial solution, as does the distance filter. The next 9 solver calls do not find an improved solution and are not shown. The solution with value -177.5 is the best known solution, but MSNLP/OQNLP cannot guarantee this.
4.36.3.2 The LOCALS File

The LOCALS file is a text file containing objective and variable values for all local solutions found by MSNLP/OQNLP. It is controlled by the LOCALS_FILE and LOCALS_FILE_FORMAT keywords in the MSNLP/OQNLP options file. An example for the problem EX_8_1_5 from the Floudas problem set (available on GLOBALLib) is shown below. The headings, included for explanatory purposes and not part of the file, have the following meaning:

<table>
<thead>
<tr>
<th>Heading</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>No.</td>
<td>index of local solution</td>
</tr>
<tr>
<td>Obj</td>
<td>objective value of local solution</td>
</tr>
<tr>
<td>Var</td>
<td>variable index</td>
</tr>
<tr>
<td>Value</td>
<td>variable value</td>
</tr>
</tbody>
</table>

Thus local solutions 1 and 2 both have objective values of -1.03163. The first solution has variable values $x = -8.98448e-002$, $y = 7.12656e-001$, where these are in the same order as they are defined in the gams model. The second local solution has $x = 8.98418e-002$, $y = -7.12656e-001$. Seven local solutions are found. This output is produced with all default parameter values for MSNLP/OQNLP options and tolerances, except the distance and merit filters were turned off, i.e. the keywords USE_DISTANCE_FILTER and USE_MERIT_FILTER were set to 0 in the MSNLP/OQNLP options file. This causes the NLP solver to be called at every stage 2 trial point, and is recommended if you wish to obtain as many local solutions as possible.

4.36.4 The Options File

The options file is a text file containing a set of records, one per line. Each record has the form `<keyword> <value>`, where the keyword and value are separated by one or more spaces. All relevant options are listed in this guide. You can also get a sample option file with all options and their default values by specifying the single option help in an option file. The list of all options appears in the log file. The options are described below.

</tbody>
</table>

**artificial_bound** *(real):* default upper/lower bound ←

This value (its negative) is given to the driver as the upper (lower) bound for any variable with no upper or lower bound. However, the original bounds are given to the local solver, so it can produce solutions not limited by this artificial bound. All drivers must have finite upper and lower bounds for each variable. If artificial_bound (or any of the user-supplied bounds) is much larger than any component of the optimal solution, the driver will be less efficient because it is searching over a region that is much larger than needed. Hence the user is advised to try to provide realistic values for all upper and lower bounds. It is even more dangerous to make artificial_bound smaller than some component of a globally optimal solution, since the driver can never generate a trial point near that solution. It is possible, however, for the local solver to reach a global solution in this case, since the artificial bounds are not imposed on it.

Default: 10000

**basin_decrease_factor** *(real):* reduction of MAXDIST ←

This value must be between 0 and 1. If dynamic_distance_filter is set to 1, the MAXDIST value associated with any local solution is reduced by \((1 - \text{basin_decrease_factor})\) if distance_waitcycle consecutive trial points have distance from that solution less than MAXDIST.

Range: \([0, 1]\)

Default: 0.2

**basin_overlap_fix** *(boolean):* switch for MAXDIST logic ←

A value of 1 turns on logic which checks the MAXDIST values of all pairs of local solutions, and reduces any pair of MAXDIST values if their sum is greater than the distance between the 2 solutions. This ensures that the spherical models of their basins of attracting do not overlap. A value of 0 turns off this logic. Turning it off can reduce the number of NLP solver calls, but can also cause the algorithm to miss the global solution.

Default: 1

**distance_factor** *(real):* distance activation factor ←

If the distance between a trial point and any local solution found previously is less than \(\text{distance_factor} \times \text{MAXDIST}\), the NLP solver is not started from that trial point. MAXDIST is the largest distance ever traveled to get to that local solution. Increasing distance_factor leads to fewer solver calls and risks finding a worse solution. Decreasing it leads to more solver calls and possibly a better solution.

Default: 1

**distance_waitcycle** *(integer):* iterations before distance filter threshold is increased ←

This value must be a positive integer. If the distance filter is used, and there are distance_waitcycle consecutive iterations where the distance filter logic causes the NLP solver not to be started, the distance filter threshold is increased by the factor threshold_increase_factor. Increasing distance_waitcycle usually leads to fewer solver calls, but risks finding a worse solution. Decreasing it leads to more solver calls, but may find a better solution.

Default: 20
**dynamic_distance_filter** *(boolean): switch for MAXDIST reduction logic*  

A value of 1 turns on logic which reduces the value of MAXDIST (described under the use_distance_filter keyword) for a local solution if use_distance_filter consecutive trial points have a their distances from that solution less than MAXDIST. MAXDIST is multiplied by (1-basin_decrease_factor). A value of 0 turns off this logic. Turning it off can decrease the number of NLP solver calls, but can also lead to a worse final solution.

Default: 1

**dynamic_merit_filter** *(integer): switch for merit threshold increase logic*  

A value of 1 turns on logic which dynamically varies the parameter which increases the merit filter threshold, threshold_increase_factor. If merit_waitcycle consecutive trial points have been rejected by the merit filter, this value is replaced by max(threshold_increase_factor, val), where val is the value of threshold_increase_factor which causes the merit filter to just accept the best of the previous merit_waitcycle trial points. A value of 0 turns off this logic. Turning it off can reduce NLP solver calls, but may lead to a worse final solution.

Default: 1

**enable_screen_output** *(boolean): switch for log output*  

A value of 0 turns off the writing of the iteration log and termination messages to the GAMS log file that appears on the screen, while 1 enables it.

Default: 0

**enable_statistics_log** *(boolean): switch for statistics file stats.log*  

Using a value of 1 creates a text file called stats.log in the project directory containing one line of problem (name, variables, constraints) and performance information (best objective value, total solver time, iterations, iterations to best solution, etc) for each problem solved.

Default: 0

**feasibility_tolerance** *(real): feasibility check for point returned by NLP solver*  

This tolerance is used to check each point returned by an NLP solver for feasibility. If the largest absolute infeasibility at the point is larger than this tolerance, the point is classified infeasible. This test is made because points returned by NLP solvers may occasionally be infeasible despite feasible status codes. Some NLP solvers use internal scaling before testing for feasibility. The unscaled problem may be infeasible, while the scaled one is feasible. If this occurs, increasing this tolerance (to 1.e-2 or larger) often eliminates the problem.

Default: 0.0001

**iteration_limit** *(integer): total number of MSNLP/OQNLP iterations*  

Increasing this limit can allow MSNLP/OQNLP to find a better solution. Try it if your run using 1000 iterations does not take too long. Surprisingly, the best solution using, say 2000 iterations, may be found in the first 1000 iterations, and that solution may be better than the one found with an iteration limit of 1000. This is because OptQuest changes its search strategy depending on the iteration limit. Because of this, it is also possible that increasing the iteration limit will yield a worse solution, but this is rare. Decreasing this iteration limit usually leads to a worse solution, but also reduces run time. MSNLP/OQNLP iterations can not be set using GAMS IterLim. The GAMS IterLim is used as the iteration limit for the NLP subsolves in a MSNLP/OQNLP run.

Default: 1000
iteration_print_frequency (integer): frequency of iteration print

   Synonym: gams_itn_print_frequency

   If the MSNLP/OQNLP iteration log is written to the GAMS log file, one line of output is
   written every kth iteration, where k is the value given here.

   Default: 20

locals_file (string): filename for local file

   Specify a complete path and name for a file to which the objective value and values of all vari-
   ables for all local solutions found will be written. For example, C:\mydirectory\locals.out.
   There are 2 possible formats for this file, specified by the locals_file_format option below. If
   there is no locals_file record in the options file, the locals file will not be created.

locals_file_format (string): file format for local file

   There are 2 possible values for this option. The report entry creates the locals file in a format
   designed to be examined easily by eye, but processed less easily by a computer program or
   spreadsheet. The data1 entry creates a file with many records, each on a single line, each line
   having the following format: [index of local optimum] [objval] [var index] [var value]

   Default: report

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>report</td>
<td>Report file format</td>
</tr>
<tr>
<td>data1</td>
<td>Data1 file format</td>
</tr>
</tbody>
</table>

maxtime (integer): maximum runtime in seconds

   Synonym: reslim

   When the execution time exceeds this value, the system will stop, returning the best solution
   found.

   Default: GAMS ResLim

max_locals (integer): maximum number of local optima found

   When the number of distinct local solutions found exceeds the value specified here, the system
   will stop, returning the best solution found.

   Default: 1000

max_solver_calls (integer): maximum number of NLP solver calls

   When the number of calls to the NLP solver exceeds the value specified here, the system will
   stop, returning the best solution found.

   Default: 1000

max_solver_calls_noimprovement (integer): maximum number non-improving solver calls

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>report</td>
<td>Report file format</td>
</tr>
<tr>
<td>data1</td>
<td>Data1 file format</td>
</tr>
</tbody>
</table>
The positive integer specified here will cause the system to stop whenever the number of consecutive solver calls with a fractional improvement in the best objective value found less than 1.e-4 exceeds that value. In other words, if the value specified is 50, and there are more than 50 consecutive solver calls where the relative change in the best objective was less than 1.e-4 in all iterations, the system will stop.

Default: 0

**merit_waitcycle** *(integer):* iterations before merit filter threshold is increased

This value must be a positive integer. If the merit filter is used, and there are **merit_waitcycle** consecutive iterations where the merit filter logic causes the NLP solver not to be started, the merit filter threshold is increased by the factor **threshold_increase_factor**. Increasing **merit_waitcycle** usually leads to fewer solver calls, but risks finding a worse solution. Decreasing it leads to more solver calls, but may find a better solution.

Default: 20

**nlpsolver** *(string):* NLP solver to be used

This option is available only within GAMS. It specifies the NLP solver to be called. Any GAMS NLP solver for which the user has a license can be used. Further, one can specify an option file for the GAMS NLP solver by appending a `.n` with `n=1..999` to the solver name. For example, `NLPSOLVER conopt.1` will instruct the NLP solver CONOPT to use option file `conopt.opt`, `NLPSOLVER conopt.2` will make CONOPT read option file `conopt.op2` and so on.

Default: Conopt if licensed otherwise lsgrg

**optquest_only** *(boolean):* switch for using local solvers

This option applies only to the OptQuest driver only available in OQNLP. If you think the NLP solver is taking too long and/or not working well, choosing 1 will stop it from being called. This may occur if the problem is of type DNLP, where one or more problem functions are discontinuous or have discontinuous derivatives. If the problem has only discrete (integer) variables, choose 1, as there is nothing for the NLP solver to do (since it optimizes over the continuous variables when the integers are fixed, and there none).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>use local solver</td>
</tr>
<tr>
<td>1</td>
<td>no local solver calls</td>
</tr>
</tbody>
</table>

**oqnlp_debug** *(integer):* enable debug info

Synonym: `msnlp_debug`

Values of 1 or 2 cause more information to be written to the iteration log. The default value of 0 suppresses all this output.

Range: `[0, 2]`

Default: 0

**point_generation** *(string):* starting point generator

Selection of point generation algorithm. The optquest generator is available in OQNLP only and is the default. For MSNLP the default is smartrandom.

Default: auto
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>random</td>
<td>random point generation Causes trial points to be generated by sampling each variable from a uniform distribution defined within its bounds</td>
</tr>
<tr>
<td>hitandrun</td>
<td>hit and run point generation</td>
</tr>
<tr>
<td>smartrandom1</td>
<td>smart random point generation Generates trial points by sampling each variable independently from either normal or triangular distributions, whose parameters are determined as described in Appendix A of the MSNLP/OQNLP User Guide.</td>
</tr>
<tr>

<td>test2 point generation</td>
</tr>
<tr>
<td>test3</td>
<td>test3 point generation</td>
</tr>
<tr>
<td>optquest</td>
<td>OptQuest generates starting point Causes trial points to be generated by the OptQuest driver</td>
</tr>
</tbody>
</table>

**sampling_distribution** *(integer):* distribution for smartrandom1

This keyword is relevant only when **point_generation** is set to **smartrandom1**. Then a value of 0 causes normal distributions to be used to generate trial points, while a value of 1 causes triangular distributions to be used.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>normal</td>
</tr>
<tr>
<td>1</td>
<td>triangular</td>
</tr>
</tbody>
</table>

**search_type** *(string):* search strategy

This option applies only to the OptQuest driver, and controls the search strategy used by OptQuest. There are three choices that are relevant for use within OQNLP.

Default: boundary

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggressive</td>
<td>aggressive search</td>
</tr>
<tr>
<td>boundary</td>
<td>boundary search</td>
</tr>
<tr>
<td>crossover</td>
<td>crossover search</td>
</tr>
</tbody>
</table>

**solvelink** *(integer):* solvelink for GAMS NLP solver
Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Call GAMS NLP solver via script</td>
</tr>
<tr>
<td>2</td>
<td>Call GAMS NLP solver via module</td>
</tr>
<tr>
<td>5</td>
<td>Call GAMS NLP solver in memory</td>
</tr>
</tbody>
</table>

**solver_log_to_gams_log** *(boolean):* switch to copy the NLP solver log to the normal log file

Setting the parameter to 1 instructs MSNLP/OQNLP to copy the log from the NLP subsolver to the MSNLP/OQNLP log. It can be very helpful to inspect the NLP subsolver log especially if the solver termination code is ???.

Default: 0

**stage1_iterations** *(integer):* number of iterations in stage 1

Specifies the total number of iterations in stage 1 of the algorithm, where no NLP solver calls are made. Increasing this sometimes leads to a better starting point for the first local solver call in stage 2, at the cost of delaying that call. Decreasing it can lead to more solver calls, but the first call occurs sooner.

Default: 200

**threshold_increase_factor** *(real):* factor to increase merit filter threshold

This value must be nonnegative. If there are `merit_waitcycle` consecutive MSNLP/OQNLP iterations where the merit filter logic causes the NLP solver not to be called, the merit threshold is increased by multiplying it by $(1+\text{threshold\_increase\_factor})$. The same applies to the `distance_waitcycle`.

Default: 0.2

**use_distance_filter** *(boolean):* distance filter

Use 0 to turn off the distance filter, the logic which starts the NLP solver at a trial point only if the (Euclidean) distance from that point to any local solution found thus far is greater than the distance threshold. Turning off the distance filter leads to more solver calls and more run time, and increases the chances of finding a global solution. Turn off both distance and merit filters to find (almost) all local solutions.

Default: 1

**use_linear_constraints** *(boolean):* satisfy linear constraints

This option applies only to the OptQuest driver, and to problems that have linear constraints other than simple bounds on the variables. Using 1 (all OptQuest trial points satisfy the linear constraints) often leads to fewer iterations and solver calls, but OptQuest has to solve an LP to project each trial point onto the linear constraints. For large problems (more than 100 variables), this can greatly increase run time, so the default value is off (0).

Default: 0

**use_merit_filter** *(boolean):* merit filter

Use 0 to turn off the merit filter, the logic which starts the NLP solver at a trial point only if the penalty function value at that point is below the merit threshold. This will lead to more solver calls, but increases the chances of finding a global solution. Turn off both filters if you want to find (almost) all local solutions. This will cause the solver to be called at each stage 2 iteration.

Default: 1
4.36.5 Use as a Callable System

MSNLP and OQNLP is also available as a callable system. It currently uses the LSGRG2 or any GAMS NLP solver as its local solver. A sample calling program is available from Optimal Methods which a user can easily adapt. The user must provide a C function which computes values of the objective and all constraint functions, given current values of all variables. First partial derivatives of these functions can be approximated by forward or central differences, or may be computed in a user-provided function.

4.36.6 Appendix

4.36.6.1 Appendix A: Description of the Algorithm

A pseudo-code description of the MSNLP/OQNLP algorithm follows, in which SP $x_t$ denotes the starting point generator and $x_t$ is the candidate starting point produced. We refer to the local NLP solver as $L(x_s,x_f)$, where $x_s$ is the starting point and $x_f$ the final point. The function UPDATE LOCALS $(x_s,x_f,w)$ processes and stores solver output $x_f$, using the starting point $x_s$ to compute the distance from $x_s$ to $x_f$, and produces updated penalty weights, $w$. For more details, see [Lasdon, Plummer et al., 2004].

MSNLP/OQNLP Algorithm

STAGE 1

$x_0 =$ user initial point

Call $L(x_0,x_f)$

Call UPDATE LOCALS $(x_0,x_f,w)$

FOR $i = 1, n_1$ DO

Call SP $(x_t(i))$

Evaluate $P(x_t(i),w)$

ENDDO

$x_t^* =$ point yielding best value of $P(x_t(i),w)$ over all stage one points, $(i = 1, 2, ..., n_1)$.

call $L(x_t^*,x_f)$

Call UPDATE LOCALS $(x_t^*,x_f,w)$

threshold = $P(x_t^*,w)$

STAGE 2

FOR $i = 1, n_2$ DO

Call SP $(x_t(i))$

Evaluate $P(x_t(i),w)$

Perform merit and distance filter tests:

Call distance filter( $x_t(i)$, dstatus )
Call merit filter( xt(i), threshold, mstatus )

IF (dstatus and mstatus = "accept") THEN
    Call L(xt(i), xf)
    Call UPDATE LOCALS (xt(i), xf, w)
ENDIF
ENDDO

After an initial call to L at the user-provided initial point, x₀, stage 1 of the algorithm performs n₁ iterations in which SP (xt) is called, and the L₁ exact penalty value P (xt, w) is calculated. The user can set n₁ through the MSNLPOQNL options file using the STAGE1_ITERATIONS keyword. The point with the smallest of these P values is chosen as the starting point for the next call to L, which begins stage 2. In this stage, n₂ iterations are performed in which candidate starting points are generated and L is started at any one which passes the distance and merit filter tests.

The distance filter helps ensure that the starting points for L are diverse, in the sense that they are not too close to any previously found local solution. Its goal is to prevent L from starting more than once within the basin of attraction of any local optimum. When a local solution is found, it is stored in a linked list, ordered by its objective value, as is the Euclidean distance between it and the starting point that led to it. If a local solution is located more than once, the maximum of these distances, maxdist, is updated and stored. For each trial point, t, if the distance between t and any local solution already found is less than DISTANCE_FACTOR * maxdist, L is not started from the point, and we obtain the next trial solution from the generator.

This distance filter implicitly assumes that the attraction basins are spherical, with radii at least maxdist. The default value of DISTANCE_FACTOR is 1.0, and it can be set to any positive value in the MSNLPOQNL options file-see Section Output. As DISTANCE_FACTOR approaches zero, the filtering effect vanishes, as would be appropriate if there were many closely spaced local solutions. As it becomes larger than 1, the filtering effect increases until eventually L is never started.

The merit filter helps ensure that the starting points for L have high quality, by not starting from candidate points whose exact penalty function value P₁ (see equation (5), Section Introduction) is greater than a threshold. This threshold is set initially to the P₁ value of the best candidate point found in the first stage of the algorithm. If trial points are rejected by this test for more than WAITCYCLE consecutive iterations, the threshold is increased by the updating rule:

\[
\text{threshold} \leftarrow \text{threshold} + \text{THRESHOLD_INCREASE_FACTOR} \times (1.0 + \text{abs(threshold)})
\]

where the default value of THRESHOLD_INCREASE_FACTOR is 0.2 and that for WAITCYCLE is 20. The additive 1.0 term is included so that threshold increases by at least THRESHOLD_INCREASE_FACTOR when its current value is near zero. When a trial point is accepted by the merit filter, threshold is decreased by setting it to the P₁ value of that point.

The combined effect of these 2 filters is that L is started at only a few percent of the trial points, yet global optimal solutions are found for a very high percentage of the test problems. However, the chances of finding a global optimum are increased by increasing ITERATION_LIMIT (which we recommend trying first) or by "loosening" either or both filters, although this is rarely necessary in our tests if the dynamic filters and basin overlap fix are used, as they are by default. If the ratio of stage 2 iterations to solver calls is more than 20 using the current filter parameters, and computation times with the default filter parameters are reasonable, you can try loosening the filters. This is achieved for the merit filter either by decreasing WAITCYCLE or by increasing THRESHOLD_INCREASE_FACTOR (or doing both), and for the distance filter by decreasing DISTANCE_FACTOR. Either or both filters may be turned off, by setting USE_DISTANCE_FILTER and/or USE_MERIT_FILTER to 0. Turning off both causes an NLP solver call at every stage 2 trial point. This is the best way to insure that all local optima are found, but it can take a long time.
4.36.6.2 Appendix B: Pure and 'Smart' Random Drivers

The "pure" random (PR) driver generates uniformly distributed points within the hyper-rectangle $S$ defined by the variable bounds. However, this rectangle is often very large, because users often set bounds to $(-\infty, +\infty), (0, +\infty)$, or to large positive and/or negative numbers, particularly in problems with many variables. This usually has little adverse impact on a good local solver, as long as the starting point is chosen well inside the bounds. But the PR generator will often generate starting points with very large absolute component values when some bounds are very large, and this sharply degrades solver performance. Thus we were motivated to develop random generators which control the likelihood of generating candidate points with large components, and intensify the search by focusing points into promising regions. We present two variants, one using normal, the other triangular distributions. Pseudo-code for this "smart random" generator using normal distributions follows, where w is the set of penalty weights determined by the "update locals" logic discussed above, after the first solver call at the user-specified initial point.

Smart Random Generator with Normal Distributions, SRN ($xt$)

**IF** (first call) **THEN**

Generate $k_1$ (default 400) diverse points in $S$ and evaluate the exact penalty function $P (x, w)$ at each point.

$B=\text{subset of } S \text{ with } k_2 \text{ (default 10) best } P \text{ values}$

**FOR** $i = 1, \text{nvars} \ **DO**

$x_{\text{max}}(i) = \text{max of component } i \text{ of points in } B$

$x_{\text{min}}(i) = \text{min of component } i \text{ of points in } B$

$\mu(i) = (x_{\text{max}}(i) + x_{\text{min}}(i))/2$

$\text{ratio}(i) = (x_{\text{max}}(i) - x_{\text{min}}(i))/(1+\text{buvar}(i)-\text{blvar}(i))$

$\text{sigfactor} = 2.0$

**IF** (ratio $> 0.7$) $\text{sigfactor} = f(\text{ratio})$

$\sigma(i) = (x_{\text{max}}(i) - x_{\text{min}}(i))/\text{sigfactor}$

**ENDDO**

**ENDIF**

**FOR** $i = 1, \text{nvars} \ **DO**

Generate a normally distributed random variable $rv(i)$ with mean $\mu(i)$ and standard deviation $\sigma(i)$

If $rv(i)$ is between $\text{blvar}(i)$ and $\text{buvar}(i)$, $xt(i) = rv(i)$

If $rv(i) < \text{blvar}(i)$, generate $xt(i)$ uniformly between $\text{blvar}(i)$ and $x_{\text{min}}(i)$

If $rv(i) < \text{buvar}(i)$, generate $xt(i)$ uniformly between $x_{\text{max}}(i)$ and $\text{buvar}(i)$
Return \( x_t \)

This SRN generator attempts to find a subset, \( B \), of \( k_2 \) “good” points, and generates most of its trial points \( x_t \), within the smallest rectangle containing \( B \). It first generates a set of \( k_1 \) diverse points within the bounds using a stratified random sampling procedure with frequency-based memory. For each variable \( x(i) \), this divides the interval \([blvar(i), buvar(i)]\) into 4 equal segments, chooses a segment with probability inversely proportional to the frequency with which it has been chosen thus far, then generates a random point in this segment. We choose \( k_2 \) of these points having the best \( P(x, w) \) penalty values, and use the smallest rectangle containing these, intersecting the \( i \)th axis at points \([xmin(i), xmax(i)]\), to define \( n \) univariate normal distributions (driver SRN) or \( n \) univariate triangular distributions (driver SRT). The mean of the \( i \)th normal distribution, \( mu(i) \), is the midpoint of the interval \([xmin(i), xmax(i)]\), and this point is also the mode of the \( i \)th triangular distribution, whose lower and upper limits are \( blvar(i) \) and \( buvar(i) \). The standard deviation of the \( i \)th normal distribution is selected as described below. The trial point \( x_t \) is generated by sampling \( n \) times independently from these distributions. For the driver using normals, if the generated point lies within the bounds, it is accepted. Otherwise, we generate a uniformly distributed point between the violated bound and the start of the interval.

To determine the standard deviation of the normal distributions, we compute \( ratio \), roughly the ratio of interval width to distance between bounds, where the factor 1.0 is included to avoid division by zero when the bounds are equal (fixed variables). If the interval width is small relative to the distance between bounds for variable \( i \) (\( ratio \leq 0.7 \)), then the standard deviation \( \sigma(i) \) is half the interval width, so about 1/3 of the \( x_t(i) \) values fall outside the interval, providing diversity when the interval does not contain an optimal value for \( x(i) \). If the bounds are large, then \( ratio \) should be small, say less than 0.1, so \( x_t(i) \) values near the bounds are very unlikely. If \( ratio > 0.7 \), the function \( f \) sets \( sigfactor \) equal to 2.56 if \( ratio \) is between 0.7 and 0.8, increasing in steps to 6.2 if \( ratio > 0.999 \). Thus if \( ratio \) is near 1.0, more than 99% of the values fall within the interval, and few have to be projected back within the bounds. The projecting back process avoids undesirable clustering of trial points at a bound, by generating points uniformly between the violated bound and the nearest edge of the interval \([xmin(i), xmax(i)]\). When the interval \([xmin(i), xmax(i)]\) is sharply skewed toward one of the variable bounds and is much narrower than the distance between the bounds, a symmetric distribution like the normal, combined with our projection procedure, generates too many points between the interval and its nearest bound. A quick scan of the test results indicates that this happens rarely, but an asymmetric distribution like the triangular overcomes this difficulty, and needs no projection.

### 4.36.7 References

4.37 NLPEC

4.37.1 Introduction

The GAMS/NLPEC solver, developed jointly by Michael Ferris of UW-Madison and GAMS Development, solves MPEC and MCP models via reformulation of the complementarity constraints. The resulting sequence of NLP models are parameterized by a scalar $\mu$ and solved by existing NLP solvers. The resulting solutions are used to recover an MPEC or MCP solution.

GAMS/NLPEC serves a number of purposes. In many cases, it is an effective tool for solving MPEC models, the first such tool available within GAMS. It also serves as a way to experiment with the many reformulation strategies proposed for solving MPEC and MCP models. Without something like NLPEC (and a library of models to test with) a comprehensive and thorough test and comparison of the various reformulation strategies would not be possible. To better serve these purposes, NLPEC has an open architecture. The model reformulations are written out as GAMS source for solution via an NLP solver, so it is possible to view this source and modify it if desired.

A brief note about notation is in order. The GAMS keyword \texttt{positive} is used to indicate nonnegative variables. The same holds for nonpositive variables and the GAMS keyword \texttt{negative}.

4.37.2 Usage

GAMS/NLPEC can solve models of two types: MPEC and MCP. If you did not specify NLPEC as the default MPEC or MCP solver, use the following statement in your GAMS model before the solve statement:

```
option MPEC=nlpec; { or MCP }
```

You can also make NLPEC the default solver via the command line:

```
gams nash MPEC=nlpec MCP=nlpec
```

You can use NLPEC with its default strategy and formulation, but most users will want to use an options file (Section \texttt{Options}) after reading about the different types of reformulations possible (Section \texttt{Reformulation}). In addition, an understanding of the architecture of NLPEC (Section \texttt{Open Architecture}) will be helpful in understanding how GAMS options are treated. Although NLPEC doesn't use the GAMS options \texttt{workspace}, \texttt{workfactor}, \texttt{optcr}, \texttt{optca}, \texttt{reslim}, \texttt{iterlim}, and \texttt{domlim} directly, it passes these options on in the reformulated model so they are available to the NLP subsolver.

4.37.3 Reformulation

In this section we describe the different ways that the NLPEC solver can reformulate an MPEC as an NLP. The description also applies to MCP models: just consider MCP to be an MPEC with a constant objective. The choice of reformulation, and the subsidiary choices each reformulation entails, are controlled by the options described in the section on Setting the Reformulation Options and referenced throughout this section.

The original MPEC model is given as:

$$
\min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m} f(x, y)
$$

(1)
subject to the constraints
\[ g(x, y) \leq 0 \] (2)
and
\[ y \text{ solves } \text{MCP}(h(x, \cdot), B). \] (3)
In most of the reformulations, the objective function (1) is included in the reformulated model without change. In some cases, it may be augmented with a penalty function. The variables \( x \) are typically called upper level variables (because they are associated with the upper level optimization problem) whereas the variables \( y \) are sometimes termed lower level variables.

The constraints (2) are standard nonlinear programming constraints specified in GAMS in the standard fashion. In particular, these constraints may be less than inequalities as shown above, or equalities or greater than inequalities. The constraints will be unaltered by all our reformulations. These constraints may involve both \( x \) and \( y \), or just \( x \) or just \( y \), or may not be present at all in the problem.

The constraints of interest are the equilibrium constraints (3), where (3) signifies that \( y \in \mathbb{R}^m \) is a solution to the mixed complementarity problem (MCP) defined by the function \( h(x, \cdot) \) and the box \( B \) containing (possibly infinite) simple bounds on the variables \( y \). A point \( y \) with \( a_i \leq y_i \leq b_i \) solves (3) if for each \( i \) at least one of the following holds:
\[ h_i(x, y) = 0 \]
\[ h_i(x, y) \geq 0, \ y_i = a_i; \]
\[ h_i(x, y) \leq 0, \ y_i = b_i. \] (4)

As a special case of (4), consider the case where \( a = 0 \) and \( b = +\infty \). Since \( y_i \) can never be \( +\infty \) at a solution, (4) simplifies to the nonlinear complementarity problem (NCP):
\[ 0 \leq h_i(x, y), 0 \leq y_i \text{ and } y_i h_i(x, y) = 0, i = 1, \ldots, m \] (5)

namely that \( h \) and \( y \) are nonnegative vectors with \( h \) perpendicular to \( y \). This motivates our shorthand for (4), the "perp to" symbol \( \perp \):
\[ h_i(x, y) \perp y_i \in [a_i, b_i] \] (6)

The different ways to force (6) to hold using (smooth) NLP constraints are the basis of the NLPEC solver.

We introduce a simple example now that we will use throughout this document for expositional purposes:

\[ \min_{x_1, x_2, y_1, y_2} \]
\[ \text{subject to} \]
\[ x_1 + x_2 \]
\[ x_1^2 + x_2^2 \leq 1 \]
\[ y_1 - y_2 + 1 \leq x_1 \perp y_1 \geq 0 \]
\[ x_2 + y_2 \perp y_2 \in [-1, 1] \]

This problem has the unique solution \( x_1 = 0, x_2 = -1, y_1 = 0, y_2 = 1 \). Note that \( f(x, y) = x_1 + x_2 \) and \( g(x, y) = x_1^2 + x_2^2 - 1 \) are the objective function and the standard nonlinear programming constraints for this problem. The function \( h(x, y) \) is given by:
\[ h(x, y) = \begin{bmatrix} x_1 - y_1 + y_2 - 1 \\ x_2 + y_2 \end{bmatrix} \]

and
\[ a = \begin{bmatrix} 0 \\ -1 \end{bmatrix}, \ b = \begin{bmatrix} \infty \\ 1 \end{bmatrix}. \]

This example is written very succinctly in GAMS notation as:
$TITLE simple mpec example

variable f, x1, x2, y1, y2;
positive variable y1;
y2.lo = -1;
y2.up = 1;

equations cost, g, h1, h2;
cost.. f =E= x1 + x2;
g.. sqr(x1) + sqr(x2) =L= 1;
h1.. x1 =G= y1 - y2 + 1;
h2.. x2 + y2 =N= 0;

model example / cost, g, h1.y1, h2.y2 /;
solve example using mpec min f;

Note that the equation cost is used to define f, the constraint g defines the function g, and h is defined by h1 and h2. The complementarity constraints utilize the standard GAMS convention of specifying the orthogonality relationship between h and y in the model statement. The interpretation of the "." relies on the bounds a and b that are specified using positive, negative, or lo and up keywords in GAMS.

In describing the various reformulations for (6), it is convenient to partition the y variables into free F, lower bounded L, upper bounded U and doubly bounded B variables respectively, that is:

\[ B := \{ y = (y_F, y_L, y_U, y_B) : a_L \leq y_L, y_U \leq b_U, a_B \leq y_B \leq b_B \}. \]

We will assume (without loss of generality) that \( a_B < b_B \). If \( a_i = b_i \) then (6) holds trivially for the index i and we can remove the constraint \( h_i \) and its corresponding (fixed) variable \( y_i \) from the model. The complementarity condition for variables in \( y_i \in F \) is simply the equality \( h_i(x, y) = 0 \) so these equality constraints are moved directly into the NLP constraints of the original model as equalities. Thus, NLPEC needs only to treat the singly-bounded variables in \( L \) and \( U \) and the doubly-bounded variables in \( B \). In the above example, \( L = \{1\}, U = \emptyset \) and \( B = \{2\} \).

4.37.3.1 Product reformulations

Product reformulations all involve products of \( y_i \) with \( h_i \), or products of \( y_i \) with some auxiliary or slack variables that are set equal to \( h_i \). The underlying point is that the constraints (3) are entirely equivalent to the following system of equalities and inequalities:

\[
\begin{align*}
w_L &= h_L(x, y), & a_L &\leq y_L, & w_L &\geq 0 \quad \text{and} \quad (y_L - a_L)^T w_L = 0 \\
v_U &= -h_U(x, y), & y_U &\leq b_U, & v_U &\geq 0 \quad \text{and} \quad (b_U - y_U)^T v_U = 0 \\
w_B - v_B &= h_B(x, y), & a_B &\leq y_B \leq b_B, & w_B &\geq 0, & v_B &\geq 0 \\
(y_B - a_B)^T w_B = 0, & (b_B - y_B)^T v_B = 0.
\end{align*}
\]

Note that each inner product is a summation of products of nonnegative terms: a slack variable and the difference between a variable and its bound. In each of these products, either the slack variable or its complement must be zero in order to have a solution. Complementarity is forced by the multiplication of these two terms. The above reformulation is specified using option reftype mult.

There are a number of variations on this theme, all of which can be specified via an options file. All of the inner products could be put into the same equation, left as in (7) above, or broken out into individual products (one for each \( i \in L \cup U \), two for each \( i \in B \)). For example, the complementarity constraints
associated with lower bounded variables involve nonnegativity of \( w_L, y_L \geq a_L \) and either of the following alternatives:

\[
(y_L - a_L)^T w_L = \sum_{i \in L} (y_i - a_i) w_i = 0
\]

or

\[
(y_i - a_i) w_i = 0, \ i = 1, \ldots, m
\]

These different levels of aggregation are chosen using option aggregate none|partial|full.

Since all of the inner products in (7) involve nonnegative terms, we can set the inner products equal to zero or set them \( \leq 0 \) without changing the feasible set. To choose one or the other, use the option constraint equality|inequality.

As a concrete example, consider the option file

reftype mult
aggregate none
constraint inequality

applied to the simple example given above. Such an option file generates the nonlinear programming model:

\[
\begin{align*}
\text{min} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\
& \quad w_1 y_1 \leq \mu \\
& \quad w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1, 1] \\
& \quad (y_2 + 1) w_2 \leq \mu, (1 - y_2) v_2 \leq \mu
\end{align*}
\]

By default, a single model is generated with the value \( \mu \) set to 0. There are many examples (e.g. interior point codes, many LP and NLP packages, published results on reformulation approaches to MPEC) that illustrate the value of starting with a "nearly-complementary" solution and pushing the complementarity gap down to zero. For this reason, the inner products in (7) above are always set equal to (or \( \leq \)) a scalar \( \mu \) instead of zero. By default \( \mu \) is zero, but options exist to start \( \mu \) at a positive value (e.g. InitMu 1e-2), to decrease it by a constant factor in a series of looped solves (e.g. NumSolves 4, UpdateFac 0.1), and to solve one last time with a final value for \( \mu \) (e.g. FinalMu 0). If the following lines are added to the option file

initmu 1.0
num solves 4

then five consecutive solves of the nonlinear program (8) are performed, the first one using \( \mu = 1 \) and each subsequent solve dividing \( \mu \) by 10 (and starting the NLP solver at the solution of the previous model in this sequence).

As a final example, we use a combination of these options to generate a sequence of nonlinear programs whose solutions attempt to trace out the "central path" favored by interior point and barrier algorithms:

reftype mult
constraint equality
initmu 1.0
num solves 4
updatefac 0.1
finalmu 1e-6

produces 6 nonlinear programs of the form

\[
\begin{align*}
\text{min} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\
& \quad w_1 y_1 = \mu \\
& \quad w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1, 1], (y_2 + 1) w_2 = \mu, (y_2 - 1) v_2 = \mu
\end{align*}
\]

for values of \( \mu = 1, 0.1, 0.01, 0.001, 0.0001 \) and 1e-6.
### 4.37.3.1.1 Slacks and doubly bounded variables

Slack variables can be used to reduce the number of times a complex nonlinear expression appears in the nonlinear programming model, as was carried out in (7). For a simpler illustrative example the NCP constraints (5) are equivalent to the constraints:

\[ w_i = h_i(x, y), 0 \leq w_i, 0 \leq y_i \text{ and } y_iw_i = 0, i = 1, \ldots, m \]

This reformulation has an additional equality constraint, and additional variables \( w_i \), but the expression \( h_i \) only appears once. There are cases when this formulation will be preferable, and the simple option `slack none` controls the use of the \( w \) variables.

When there are doubly bounded variables present, these two slack options work slightly differently. For the positive case, the reformulation introduces two nonnegative variables \( w_i \) and \( v_i \) that take on the positive and negative parts of \( h_i \) at the solution as shown in (7). Since this is the default value of the option `slack`, the example (8) shows what ensues to both singly and doubly bounded variables under this setting.

For the case `slack none`, Scholtes proposed a way to use a multiplication to force complementarity that requires no slack variables:

\[ h_i \perp a_i \leq y_i \leq b_i \iff a_i \leq y_i \leq b_i, (y_i - a_i)h_i \leq \mu, (y_i - b_i)h_i \leq \mu \] \hspace{1cm} (9)

Note that unlike the inner products in Section Reformulation, we can expect that one of the inequalities in (9) is unlikely to be binding at a solution (i.e. when \( h_i \) is nonzero). Therefore, we cannot use an equality in this reformulation, and furthermore the products must not be aggregated. Thus, if you use this option, the reformulation automatically enforces the additional options `constraint inequality` and `aggregate none` on the doubly bounded variables, even if the user specifies a conflicting option. Thus the option file

```
reftype mult
slack none
```

results in the model

\[
\begin{align*}
\min_{x_1, x_2, y_1, y_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad x_1 - y_1 + y_2 - 1 \geq 0, y_1 \geq 0 \\
& \quad (x_1 - y_1 + y_2 - 1)y_1 = \mu \\
& \quad y_2 \in [-1, 1], (y_2 + 1)(x_2 + y_2) \leq \mu, (y_2 - 1)(x_2 + y_2) \leq \mu
\end{align*}
\]

Note that the complementarity constraint associated with \( y_1 \) is an equality (the default) while the constraints associated with \( y_2 \) are inequalities for the reasons outlined above.

In the case of doubly bounded variables, a third option is available for the slack variables, namely `slack one`. In this case, only one slack is introduced, and this slack removes the need to write the function \( h_i \) twice in the reformulated model as follows:

\[ h_i(x, y) \perp a_i \leq y_i \leq b_i \iff a_i \leq y_i \leq b_i, w_i = h_i(x, y), (y_i - a_i)w_i \leq \mu, (y_i - b_i)w_i \leq \mu \]

Note that the slack variable \( w \) that is introduced is a free variable. It is not known before solving the problem whether \( w \) will be positive or negative at the solution.

We take this opportunity to introduce a simple extension to our option mechanism, namely the ability to set the options for singly and doubly bounded variables differently. For example, the option file

```
reftype mult
slack positive one
```
sets the option `slack positive` for the singly bounded variables and the option `slack one` for the doubly bounded variables resulting in the model

\[
\begin{align*}
\min & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\
& \quad w_1 y_1 = \mu_1 \\
& \quad w_2 = x_2 + y_2, y_2 \in [-1, 1], (y_2 + 1)w_2 \leq \mu_2, (y_2 - 1)w_2 \leq \mu_2
\end{align*}
\]

Additional options such as

- `initmu 1.0 3.0`
- `num solves 2`
- `updatefac 0.1 0.2`

allow the values of \( \mu \) for the singly and doubly bounded variables to be controlled separately. In this case \( \mu_1 \) takes on values of 1, 0.1 and 0.01, while \( \mu_2 \) takes on values 3.0, 0.6 and 0.12 in each of the three nonlinear programming models generated.

### 4.3.7.3.2 NCP functions

An NCP-function is a function \( \phi(r, s) \) with the following property:

\[
\phi(r, s) = 0 \iff r \geq 0, s \geq 0, rs = 0
\]

Clearly, finding a zero of an NCP-function solves a complementarity problem in \((r, s)\). We can replace the inner products of nonnegative vectors in (7) with a vector of NCP functions whose arguments are complementary pairs, e.g. \((y_i - a_i, w_i)^T w_L = 0\) becomes \(\phi(y_i - a_i, w_i) = 0\), \(i \in L\) and arrive at another way to treat the complementarity conditions. Note that an NCP function forces both nonnegativity and complementarity, so constraints to explicitly force nonnegativity are not required, though they can be included.

Examples of NCP functions include the min function, \(\min(r, s)\), and the Fischer-Burmeister function

\[
\phi(r, s) = \sqrt{r^2 + s^2} - r - s
\]

There is no requirement that an NCP function be nonnegative everywhere (it may be strictly negative at some points), so there is little point in setting the option `constraint`; it will automatically take on the value `constraint equality`. NCP functions cannot be aggregated, so the `aggregate` option will always be set to `none`.

Since the arguments to the NCP functions are going to be nonnegative at solution, we cannot use the functions \(h_i\) directly in the case of doubly-bounded variables. We must use slacks \(w - v = h_i\) to separate \(h_i\) into its positive and negative parts (but see Section Doubly bounded variables below). The slacks can be positive or free, since the NCP function will force positivity at solution. For the singly-bounded variables, slacks are optional, and can also be positive or free.

Both of the NCP functions mentioned above suffer from being non-differentiable at the origin (and at points where \(r = s\) for the min function). Various smoothed NCP-functions have been proposed that are differentiable. These smooth functions are parameterized by \(\mu\), and approach the true NCP-function as the smoothing parameter approaches zero. For example, the Fischer-Burmeister function includes a perturbation \(\mu\) that guarantees differentiability:

\[
\phi_{FB}(r, s) := \sqrt{r^2 + s^2 + 2\mu} - (r + s).
\]

You can choose these particular NCP functions using option `RefType min|FB|fFB`. The difference between the last two is that `RefType FB` writes out GAMS code to compute the function \(\phi_{FB}\), while `RefType fFB` makes use of the GAMS intrinsic function `NCPFB(r,s,\mu)` that computes \(\phi_{FB}\) internally. In general, using the GAMS intrinsic function should work better since the intrinsic can guard against overflow, scale the arguments before computing the function, and use alternative formulas that give more accurate results for certain input ranges.

As an example, the option file
generates the reformulation

\[
\begin{align*}
\min_{x_1,x_2,y_1,y_2,w_1,v_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1 \\
& \quad \phi_{FB}(w_1, y_1, \mu) = 0 \\
& \quad w_2 - v_2 = x_2 + y_2 \\
& \quad \phi_{FB}(y_2 + 1, w_2, \mu) = 0, \ \phi_{FB}(1 - y_2, v_2, \mu) = 0
\end{align*}
\]

with a value of \( \mu = 0.01 \). Following a path of solutions for decreasing values of \( \mu \) is possible using the options discussed above.

Each of the two arguments to the NCP function will be nonnegative at solution, but for each argument we have the option of including a nonnegativity constraint explicitly as well. This results in the 4 values for the option NCPBounds none|all|function|variable. When no slacks are present, this option controls whether to bound the function \( h_i \) as well as including it in the NCP function, e.g. \( h_i \geq 0, \phi(h_i, y_i - a_i) = 0 \).

When slacks are present, we require that the slack setting be consistent with the bound setting for the function argument to the NCP function, where NCPBounds none|variable is consistent with free slack variables and NCPBounds all|function is consistent with positive slack variables.

Thus, the option file

reftype min
slack positive
NCPBounds function

generates the reformulation

\[
\begin{align*}
\min_{x_1,x_2,y_1,y_2,w_1,v_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0 \\
& \quad \min(w_1, y_1) = \mu \\
& \quad w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0 \\
& \quad \min(y_2 + 1, w_2) = \mu, \ \min(1 - y_2, v_2) = \mu
\end{align*}
\]

The NCPBounds function option means that the variable argument to the NCP function (in this case \( y \)) does not have its bounds explicitly enforced. It should be noted that this nonlinear program has nondifferentiable constraints for every value of \( \mu \). For this reason, the model is constructed as a dnlp model (instead of an nlp model) in GAMS.

A smoothed version of the min function was proposed by Chen & Mangasarian:

\[
\phi_{CM}(r, s) := r - \mu \log(1 + \exp((r - s)/\mu)).
\]  \hspace{1cm} (11)

This function is not symmetric in its two arguments, so \( \phi_{CM}(r, s) \neq \phi_{CM}(s, r) \). For this reason, we distinguish between the two cases. Unlike the Fischer-Burmeister function \( \phi_{FB} \), \( \phi_{CM} \) is not defined in the limit (i.e. for \( \mu = 0 \)) if you use GAMS code to compute it. However, the GAMS intrinsic NCPCM(r,s,mu) handles this limit case internally. The option RefType CMxf|CMfx|fCMxf|fCMfx chooses a reformulation based on the function \( \phi_{CM} \). Again, the last two choices use the GAMS intrinsic function.
4.37.3.2.1 Doubly bounded variables  Like the mult reformulation (7), reformulations using NCP functions are appropriate as long as we split the function $h_i$ matching a doubly-bounded variable into its positive and negative parts $w_i - v_i = h_i$. To avoid this, Billups has proposed using a composition of NCP functions to treat the doubly-bounded case:

$$h_i \perp a_i \leq y_i \leq b_i \iff \phi_{FB}(y_i - a_i, \phi_{FB}(b_i - y_i, -h_i)) = 0$$  

Use option RefType Bill|fBill to choose such a reformulation for the doubly-bounded variables. The first option value writes out the function in explicit GAMS code, while the second writes it out using the GAMS intrinsic function NCPFB.

4.37.3.3 Penalty functions

All of the reformulations discussed so far have reformulated the complementarity conditions as constraints. It is also possible to treat these by moving them into the objective function with a penalty parameter $1/\mu$: as $\mu$ goes to zero, the relative weight placed on complementarity increases. Ignoring the NLP constraints, we can rewrite the original MPEC problem as

$$\min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m} f(x, y) + \frac{1}{\mu} ((y_L - a_L)^T w_L + (b_L - y_L)^T v_L + (y_B - a_B)^T w_B + (b_B - y_B)^T v_B)$$

subject to the constraints

$$w_L = h_L(x, y), \ a_L \leq y_L, \ w_L \geq 0$$
$$v_L = -h_L(x, y), \ y_L \leq b_L, \ v_L \geq 0$$
$$w_B - v_B = h_B(x, y) \ a_B \leq y_B \leq b_B, \ w_B \geq 0, \ v_B \geq 0$$

Choose this treatment using option refType penalty. The options aggregate and constraint are ignored, since the inner products here are all aggregated and there are no relevant constraints. It is possible to do a similar reformulation without using slacks, so the options slack none|positive can be used in conjunction with this reformulation type.

The following option file shows the use of the penalty reformulation, but also indicates how to use a different reformulation for the singly and doubly bounded variables:

```
refType penalty mult
slack none *
initmu 1.0
numsolves 2
updatefac 0.1 0.2
```

The "*" value allows the slack option to take on its existing value, in this case positive. Applied to our simple example given above, such an option file generates the nonlinear programming model:

$$\min_{x_1, x_2, y_1, y_2, w_2, v_2} x_1 + x_2 + \frac{1}{\mu_1} y_1 (x_1 - y_1 + y_2 - 1)$$
subject to

$$x_1^2 + x_2^2 \leq 1$$
$$x_1 - y_1 + y_2 - 1 \geq 0, \ y_1 \geq 0$$
$$w_2 - v_2 = x_2 + y_2, \ w_2, v_2 \geq 0, \ y_2 \in [-1, 1]$$
$$(y_2 + 1)w_2 \leq \mu_2, \ (1 - y_2)v_2 \leq \mu_2$$

The penalty parameter $\mu_1$ is controlled separately from the doubly bounded constraint parameter $\mu_2$. For consistency with other options, the penalty parameter in the objective is $1/\mu$ meaning that as $\mu_1$ tends to zero, the penalty increases. The option initmu has only one value, so both the singly and doubly bounded $\mu$ values are initialized to 1. In the above example, three solves are performed with $\mu_1 = 1, 0.1$ and 0.01 and $\mu_2 = 1, 0.2$ and 0.04.
4.37.3.4 Testing for complementarity

In some cases a solution to the reformulated model may not satisfy the complementarity constraints of the original MPEC, e.g. if a large penalty parameter is used in the reformulation. It can also happen that the solution tolerances used in the NLP solver allow solutions with small error in the NLP model but large error in the original MPEC. For example if \( x = f(x) = .001 \) then the NLP constraint \( xf(x) = 0 \) may satisfy the NLP feasibility tolerance but it's not so easy to claim that either \( x \) or \( f(x) \) is zero. The NLPEC solver includes a check that the proposed solution does in fact satisfy the complementarity constraints. The complementarity gap is computed using the definition common to all GAMS MCP solvers in computing the \textit{objval} model attribute for an MCP model. The tolerance used for this complementarity gap can be adjusted using the testtol option.

4.37.4 Options

For details on how to create and use an option file, see the introductory chapter on solver usage.

For most GAMS solvers, the use of an options file is discouraged, at least for those unfamiliar with the solver. For NLPEC, however, we expect that most users will want to use an options file from the very beginning. NLPEC is as much a tool for experimentation as it is a solver, and as such use of the options file is encouraged.

Option values can take many different types (e.g. strings, integers, or reals). Perhaps the most important option to remember is one with no value at all: the \textit{help} option. \textit{Help} prints a list of the available options, along with their possible values and some helpful text. The options file is read sequentially, so in case an option value is set twice, the latter value takes precedence. However, any consistency checks performed on the options values (e.g. \textit{RefType fBill} cannot be used with \textit{aggregate full}) are made after the entire options file is read in, so the order in which different options appear is not important, provided the options are not specified twice.

4.37.4.1 Setting the Reformulation Options

While NLPEC has many options, there is a small set of five options that, taken together, serve to define the type of reformulation used. Listed in order of importance (highest priority items first), these reformulation options are the \textit{RefType}, \textit{slack}, \textit{constraint}, \textit{aggregate} and \textit{NCPBounds} options. In some cases, setting the highest-priority option \textit{RefType} is enough to completely define a reformulation (e.g. \textit{RefType penalty} in the case of doubly-bounded variables). In most cases though, the lower-priority options play a role in defining or modifying a reformulation. It's useful to consider the reformulation options in priority order when creating option files to define reformulations.

Some of the combinations of the reformulation options don't make sense. For example, the use of an NCP function to force complementarity between its two input arguments requires a separate function for each complementary pair, so setting both \textit{RefType min} and \textit{aggregate full} is inconsistent. NLPEC implements consistency checks on the reformulation options using the priority order: Given a consistent setting of the higher priority options, the next-highest priority option is checked and, if necessary, reset to be consistent with the items of higher priority. The end result is a set of consistent options that will result in a working reformulation. NLPEC prints out the pre- and post-checked sets of reformulation options, as well as warning messages about changes made. In case you want to use an option that NLPEC doesn't think is consistent, you can use the \textit{NoCheck} option: this supresses the consistency checks.

Each of the reformulation options in the table below takes two values - one for the singly-bounded variables in \( L \cup U \) and another for the doubly-bounded variables in \( B \). If one option value appears, it sets both option values. When setting both option values, use an asterisk \( "*" \) to indicate no change. So for example, an option file

\[
\begin{align*}
\text{RefType} & \quad fCMxf \\
\text{RefType} & \quad * \ fBill
\end{align*}
\]

first sets the \textit{RefType} to \textit{fCMxf} for all variable types, and then resets the \textit{RefType} to \textit{fBill} for doubly-bounded variables.
## 4.37.4.2 Reformulation Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>

<td>update factor for mu. The factor that multiplies mu before each of the extra solves triggered by the numsolves option. Can be set independently for singly and doubly bounded variables.</td>
<td>1e-1</td>
</tr>
</tbody>
</table>

### 4.37.4.4 The Outdated equreform Option

In the early versions of NLPEC the only way to set the reform type was via the equreform option. Each valid equreform value represented a preselected combination of the options from Section Setting the Reformulation Options. This made it difficult to experiment with combinations not preselected, so the options in Section Setting the Reformulation Options were added. Be default, the equreform option has value 0 and is not used. To get the old behavior, set equreform to a positive value - this will force the options in Section Setting the Reformulation Options to be ignored. The general options in Section General Options are used no matter how the reformulation type is selected - via RefType or equreform.
The values allowed for `equreform` and their implications are given by the following table.

<table>

Table 1: Values for `equreform` option.

### 4.37.5 Open Architecture

In this section we describe the architecture of the NLPEC solver, i.e. the way the solver is put together. This should be useful to anybody using NLPEC for experiments or to those wanting to know the details of how NLPEC works.

The foundation for the NLPEC solver is the software library (also used in the GAMS/CONVERT solver) that allows us to write out a scalar GAMS model that is mathematically equivalent to the original, or
to write out selected pieces of such a model. Using this software, NLPEC creates a GAMS NLP model using one of the reformulation strategies from Section Reformulation. This model may contain many new variables and/or equations, but it will surely contain the (non)linear expressions defining the original model as well. Once the scalar model has been created, NLPEC calls GAMS to solve this model, using the current NLP solver. The option parmFile can be used to pass on additional options to this GAMS job. After the model has solved, NLPEC reads the NLP solution, extracts the MPEC solution from it, and passes this MPEC solution back to GAMS as it terminates.

There are a number of advantages to this architecture. First, its openness makes it easy to see exactly what reformulation is being done. The intermediate scalar GAMS NLP model can be made available after the run by either saving the scratch directory (i.e. run with keep=1) or using the dotGams option to select an alternate file name. This intermediate model contains all the details of the reformulation. It can be used for debugging in case things didn’t work out as expected. It is also possible to modify this file to do some quick and dirty experiments with similar reformulation strategies. Another advantage is the variety of NLP solvers that can be plugged in to solve the reformulated model. There is no need to program (and debug) an interface to an NLP package to run experiments with an NLP solver - the existing GAMS link is all that is needed. It is also easy to experiment with non-default solver options that may be more appropriate for reformulated MPEC models or for a particular choice of reformulation.

4.38 ODHCPLEX

4.38.1 Introduction

GAMS/ODHCPLEX is a solver from Optimization Direct Inc. that implements a set of heuristic methods (named ODHeuristics) for finding feasible solutions to Mixed Integer Programming (MIP and MIQCP) models that uses IBM CPLEX as its underlying solver engine. It is designed for large-scale models which a MIP solver would find intractable: either by it being unable to find feasible solutions at all or; more usually, by being unable to find feasible solutions of adequate quality in the time available to its user.

It is intended for users who are familiar with MIP modelling and have some knowledge of using the GAMS/CPLEX solver. GAMS/ODHCPLEX does not demand expert specialism in this field.

ODHCPLEX can be used in two ways: it is implemented as a stand-alone ODHeuristic engine, which can be used on its own (ODHeuristicMethod=STANDALONE); and also within the CPLEX optimizer, within which it can supply and receive solutions from the main CPLEX caller (ODHeuristicMethod=ODH-CPLEX (default)) thereby accelerating optimization compared with GAMS/CPLEX run on its own.

The ODHeuristic engine has a heuristic method for finding an initial feasible solution that it designed to complement, those of CPLEX. Since its main algorithmic procedure works by improving an incumbent feasible solution, getting an initial one is important and may consume a significant part of its total runtime. When used on its own (i.e. ODHeuristicMethod=STANDALONE), users should experiment to discover whether ODHeuristics’ or CPLEX’s initial feasible solution methods work best, but within ODH-CPLEX (i.e. ODHeuristicMethod=ODH-CPLEX) both methods are run in parallel and the winner is chosen automatically.

ODHeuristics’ principal algorithm works by solving a sequence of sub-models. An innovative aspect of this process is its ability to use the model's symbolic structure to achieve the sub-model decomposition. It does this by analyzing the symbolic names that the user gives to the decision variables and careful specification of how this should be done this is worthwhile. ODHCPLEX can work without this analysis, but it usually takes about twice as much runtime.
4.38.2 Specifying Model Structure

The ODHeuristic method needs to break the model down into sub-models. It can do this in one of three ways:

1. Automatically using its decomposition heuristic;
2. Using information specified by the user in the IndexKey parameter;
3. By simply assigning each variable to a different block (or key); or
4. By using the dot option notation with the option .key.

By default, the program will use information specified by the IndexKey parameter if it is set and its automatic decomposition heuristic otherwise. This may be overridden by the Decomposition parameter. If it is set to 0 (zero), option 3 above is selected. If it is set to 1, its automatic decomposition method is used, and if it is set to 2, option 4 above is selected.

Whilst the automatic decomposition method often works well, there may be an advantage to specifying decomposition through the IndexKey parameter. After performing the decomposition in whatever way, the program analyses the decomposition and displays statistics showing the maximum and minimum number of variables in each key or block and showing a percentage score to the decomposition as a whole. A typical display is of the form:

Variables/key 205.58 (+/-304.79), max/min variables/key 933(32) / 60(113).
There are 227 keys (4149 keys were dropped) with 46872 values.
Decomposition score 13.66%, graph score 2074/3135232.

Other things (such as the distribution of variables in keys and the number of keys) being equal, the smaller the percentage decomposition score, the better the decomposition is and the more effective the program will be.

4.38.2.1 Using the IndexKey parameter

The program needs to associate sets of variables with distinct values of a single index. The user can specify this association with a pattern to which some or all of the variables conform. The pattern is in standard C scanf format (see, for example, Kernighan and Ritchie's 2nd edition of The C Programming Language, section B1.3 Formatted Input). Currently allowable index values must be non-negative integers, so the pattern must include d. For example, if we have variables x whose first index names starts with a number of letters then an underscore followed by a numeric index value (like x(firstone_1), x(another_1), x(firstone_2), x(another_2), ...) the pattern

\[x(%*[a-z]_d)\]

associates those variables whose name ends in _1 with index value 1, those whose name ends in _2 with index value 2 and so on. The pattern is called an index key referred to by the program as the option parameter IndexKey, for example

\[\text{IndexKey}=%*[xyl](t_\_d)\]
It may, however, be desirable to consider variables whose names are, say, \( x(t_{2}) \) and \( y(t_{2}) \), to belong to different index values, i.e. to belong to different groups. One way of doing this is to identify them with separate index keys. These can be supplied to \texttt{IndexKey} as two fields separated by a semi-colon, for example

\[
\text{IndexKey}=x(t_{\%d});y(t_{\%d})
\]

Up to 10 fields can be specified in this way.

On the other hand, it may be desirable to consider such variables as having the same index key and their nomenclature may not permit their identification by a single key field. For example, suppose there are variables \( \text{john}(t_{1}), \text{john}(t_{2}),..., \text{jane}(t_{1}), \text{jane}(t_{2}),... \) and \( \text{johnny}(t_{1}), \text{johnny}(t_{2}),... \) and we want to associate \( \text{john}(t_{x}) \) and \( \text{jane}(t_{x}) \) as belonging to key value \( x \), but want to ignore \( \text{johnny}(t_{x}) \).

Two key fields can be used to do this by

\[
\text{INDEXKEY}=\text{john}(t_{\%d});\text{jane}(t_{\%d})
\]

By default \( \text{john}(t_{2}) \) and \( \text{jane}(t_{2}) \) would not share the same index value, but if the option parameter \texttt{KeyType}, is set to 1, the heuristic will group them together so as to share the same index.

If \texttt{IndexKey} is not specified, the program uses a default decomposition.

The program divides the model up into parts associated with different values of the \texttt{IndexKey} (if specified), using an integer interval divisor. Initially this is a number not less than 2 and it is increased as the search progresses. When no improved solution is found after a number, \texttt{MaxRepeat}, of attempts with the maximum interval divisor, \texttt{MaxInterDiv}, the program terminates. Default values are provided for \texttt{MaxRepeat} and \texttt{MaxInterDiv}, so these do not have to be specified by the user.

### 4.38.3 Heuristic Parameters

There are a number of other parameters which control the behaviour of the heuristic program. These may be left at their default values or specified on the GAMS/ODHCPLEX option file. In addition, all GAMS/CPLEX options can be supplied in the GAMS/ODHCPLEX option file to tweak the CPLEX behavior.

Parameter names and their meanings are summarized in the table below.

<table>

4.38.4 Parallel execution using multiple threads

Both ODHheuristicMethods STANDALONE and ODH-CPLEX can use multiple simultaneous threads. ODH-CPLEX must use separate threads for the main CPLEX solve and for the ODHeuristics engine. The STANDALONE just uses the ODHeuristics engine which may use multiple simultaneous threads. Thus the processing capability of multi-core hardware can be exploited effectively.

GAMS/ODHCPLEX will ignore the GAMS threads parameter and use its own default. The default ODHeuristic method (i.e. ODH-CPLEX) requires multiple threads to work and with the GAMS threads default of 1 this will not work.

Whilst there are good defaults for allocating available threads, it may be worthwhile to give some attention to the allocation of threads between the main CPLEX solver and the ODHeuristics engine for ODH-CPLEX and STANDALONE.

If the option ODHThreads is set to $n$, $n$ threads are allocated in total, otherwise the total number of threads allocated for both ODH-CPLEX and STANDALONE is set to the number of physical processors available on the computer. If the ODHThreads option is set to a number greater than the number of available processors, multiple threads will have to share the same processor, which may severely degrade performance.

In general, the more threads allocated to the main CPLEX solver, the faster it will run, and similarly, the more allocated to the ODHeuristics engine, the faster it will run. The best balance depends on the model being solved and whether it is intended to run to optimality or to an optimality gap of (say) 0.05 or 0.1. If the GAMS/Cplex Threads is not set, ODH-CPLEX defaults to allocating a quarter of the threads to the ODHeuristics engine and the remainder to the main CPLEX solve. Otherwise it allocates the specified number of threads to the main CPLEX solver and the remainder to the ODHeuristics engine.

Within the ODHeuristics engine, the principal heuristic algorithm can run in parallel on multiple threads. Each algorithmic thread uses CPLEX to solve sub-models and each such instance of CPLEX can itself run on multiple threads. So some attention needs to be given to the allocation of threads between them. If SUB_CPX_THREADS is not set, the CPLEX solver will use one thread for each available logical processor to solve the sub-models. This means that only one thread will be available for the solution improvement heuristic. If the option SUB_CPX_THREADS is set, then by default the heuristic engine sets its number of algorithmic threads to

$$\text{number_of_available_processors / SUB_CPX_THREADS}$$

where number_of_available_processors is: the number of logical processors for STANDALONE; and for ODH-CPLEX it is this number less those allocated to the main CPLEX solver.

Many Intel and compatible processors support hyperthreading (where this is enabled on the computer and operating system) and if so there will be two logical processors for every physical core. Using them can severely degrade performance, so if they are enabled it is often a good idea to set ODHThreads to the number of physical processors. Note that on machines with a large number of processors (cores), the principal bottleneck for large scale optimization is usually memory access. In practice it is often better to use only about half of the available cores on (say) a 24 core Intel Xeon system. This is model dependent and some experimentation is worthwhile.

Although the operating system’s scheduler usually allocates threads to logical processors so that they run on separate physical cores where possible, it will have more threads to manage than those of the heuristic or CPLEX and so will change this allocation as the heuristic and CPLEX run so as to balance its workload effectively. There is a performance penalty to doing this from the perspective of the heuristic run time. For the ODHeuristics STANDALONE, this can be avoided by locking the heuristic threads to specific processors by setting the heuristic option parameter ProcessorLock to 1. It is not supported for ODH-CPLEX. Under Windows, beware that the threads need to be locked at an above normal priority so this may have a negative impact on other programs concurrently running on the machine.
4.38.5 Determinism

Many users require that repeated runs of their applications under the same conditions give the same results, albeit in slightly variable times. The heuristic runs in this way by default. However, there is a performance penalty that has to be paid for synchronizing the threads. On average, performance can be considerably improved by setting the heuristic option parameter Deterministic to 0. This is often preferred by users with particularly large and difficult models.

4.39 OSICPLEX, OSIGUROBI, OSIMOSEK, OSIXPRESS

The "bare bone" solver links GAMS/OSICPLEX, GAMS/OSIGUROBI, GAMS/OSIMOSEK, and GAMS/OSIXPRESS allow users to solve their GAMS models with a standalone license of CPLEX, GUROBI, MOSEK, or XPRESS. The links use the COIN-OR Open Solver Interface (OSI) to communicate with these solvers. The OSICPLEX link has been written primarily by Tobias Achterberg, the OSIGUROBI link has been written primarily by Stefan Vigerske, the OSIMOSEK link has been written primarily by Bo Jensen, and the OSIXPRESS link has been written primarily by John Doe. Matthew Saltzman is the COIN-OR project leader for OSI.

For more information we refer to the OSI web site.

The OSI links support linear equations and continuous, binary, and integer variables. Semicontinuous and Semiinteger variables, special ordered sets, branching priorities, and indicator constraints are not supported by OSI.

4.39.1 Usage

The following statement can be used inside your GAMS program to specify using OSIGUROBI

Option LP = OSIGUROBI; { or MIP or RMIP }

Similar statements apply to OSICPLEX, OSIMOSEK, and OSIXPRESS.

The above statement should appear before the Solve statement.

The links support the general GAMS options reslim (time limit), iterlim (iteration limit), nodlim (node limit), optca (absolute gap tolerance), optcr (relative gap tolerance), cheat (cutoff decrement, only Xpress), and threads. An option file in the format required by the solver can be provided via the GAMS optfile option. See Section Option files for details.

If a MIP is solved via one of the OSI links, only primal solution values are reported by default. To receive also the dual values for the LP that is obtained from the MIP by fixing all discrete variables, the GAMS option integer1 must be set to a nonzero value. Note that this may lead to solving another LP after the MIP solve has finished.

Setting the GAMS option integer2 to a nonzero value makes variable and equation names available to the solver. This option may be useful for debugging purposes.

Setting the GAMS option integer3 to a nonzero value leads to writing the model instance to a file in LP or MPS format before starting the solution process. integer3=1 writes an MPS file, integer3=2 writes an LP files, integer3=4 writes a native MPS file; sum these values to write several files). The name of the MPS file is chosen to be the name of the GAMS model file with the extension .gms replaced by .mps. This option may be useful for debugging purposes.

For OSICPLEX, OSIGUROBI, and OSIXPRESS, setting the GAMS option integer4 to a nonzero value leads to passing the variable level values (.l suffix) to the MIP solver as initial solution. This is analog to mipstart option of the full CPLEX and GUROBI links and the loadmipsol option of the full XPRESS link.
4.39.1.1 Option files

4.39.1.1.1 OSICPLEX Options In an OSICPLEX option file, each line lists one option setting, where the option name and value are separated by space.

Example:

CPX_PARAM_MIPEMPHASIS 2
CPX_PARAM_HEURFREQ 42
CPX_PARAM_MIPDISPLAY 4

4.39.1.1.2 OSIGUROBI Options In an OSIGUROBI option file, each line lists one option setting, where the option name and value are separated by space.

Example:

Cuts 2
Heuristics 0.1

4.39.1.1.3 OSIMOSEK Options An OSIMOSEK option file begins with the line BEGIN MOSEK and terminates with END MOSEK. Comments are introduced with an '%' empty lines are ignored. Each other line starts with a MOSEK parameter value, followed by space, and a value for that parameter.

Example:

BEGIN MOSEK
% disable probing and solve the root node by the interior point solver
MSK_IPAR_MIO_PRESOLVE_PROBING MSK_OFF
MSK_IPAR_MIO_ROOT_OPTIMIZER MSK_OPTIMIZER_INTPNT
END MOSEK

4.39.1.1.4 OSIXPRESS Options In an OSIXPRESS option file, each line lists one option setting, where the option name and value are separated by an equal sign.

Example:

MIPLOG = 3
HEURFREQ = 2
4.40 PATHNLP

4.40.1 Introduction

This document describes the GAMS/PATHNLP solver for non-linear programs and the options unique to this solver.

PATHNLP solves an NLP by internally constructing the Karush-Kuhn-Tucker (KKT) system of first-order optimality conditions associated with the NLP and solving this system using the PATH solver for complementarity problems. The solution to the original NLP is extracted from the KKT solution and returned to GAMS. All of this takes place automatically - no special syntax or user reformulation is required.

Typically, PATHNLP works very well for convex models. It also has a comparative advantage on models whose solution via reduced gradient methods results in a large number of superbasic variables, since the PATH solver won’t construct a dense reduced Hessian in the space of the superbasic variables as reduced gradient solvers do. For nonconvex models, however, PATHNLP is not as robust as the reduced gradient methods.

The theory relating NLP to their KKT systems is well-known: assuming differentiability without convexity, and assuming a constraint qualification holds, then a solution to the NLP must also be a solution to the KKT system. If we also assume convexity, then a solution to the KKT system is also a solution to the NLP - no further constraint qualification is required.

In case PATH fails to find a solution to the KKT system for the NLP, a phase I / phase II method is used in which the phase I objective is simply the feasibility error and the original objective is ignored. If a feasible point is found in phase I then phase II, an attempt to solve the KKT system for the NLP using the current feasible point, is entered.

PATHNLP is installed automatically with your GAMS system. Without a license, it will run in student or demonstration mode (i.e. it will solve small models only). If your GAMS license includes PATH, this size restriction is removed.

4.40.2 Usage

If you have installed the system and configured PATHNLP as the default NLP solver, all NLP models without a specific solver option will be solved with PATHNLP. If you installed another solver as the default, you can explicitly request that a particular model be solved using PATHNLP by inserting the statement

```
option NLP = pathnlp;
```

somewhere before the `solve` statement. Similar comments hold for the other model types (LP, RMINLP, QCP, etc.) PATHNLP can handle.

The standard GAMS model options `iterlim` and `reslim` can be used to control PATHNLP. A description of these options can be found in the GAMS Options section of the chapter on basic solver usage. In general this is enough to use PATHNLP effectively. In some cases, however, you may want to use some of the PATH or PATHNLP options to gain further performance improvements or for other reasons. The rules for using an option file are described in the chapter on basic solver usage. The options used to control PATH can also be used to control PATHNLP. There are also some options unique to PATHNLP.

4.40.3 Options

The tables that follow describe the options unique to PATHNLP as well as the options shared with the PATH solver for MCP models.

4.40.3.1 General options

## 4.41 PATH 4.7

Michael C. Ferris

Todd S. Munson

### 4.41.1 Complementarity

A fundamental problem of mathematics is to find a solution to a square system of nonlinear equations. Two generalizations of nonlinear equations have been developed, a constrained nonlinear system which incorporates bounds on the variables, and the complementarity problem (MCP). This document is primarily concerned with the complementarity problem.

The PATH solver for MCP models is a Newton-based solver that combines a number of the most effective variations, extensions, and enhancements of this powerful technique. See [PATH vs MILES](#) for a comparison with MILES. Algorithmic details can also be found in papers and technical reports by Dirkse, Ferris, and Munson on [Ferris' Home Page](#).

The complementarity problem adds a combinatorial twist to the classic square system of nonlinear equations, thus enabling a broader range of situations to be modeled. In its simplest form, the combinatorial problem...
is to choose from $2n$ inequalities a subset of $n$ that will be satisfied as equations. These problems arise in a variety of disciplines including engineering and economics [84] where we might want to compute Wardropian and Walrasian equilibria, and optimization where we can model the first order optimality conditions for nonlinear programs [135] [147]. Other examples, such as bimatrix games [153] and options pricing [128], abound.

Our development of complementarity is done by example. We begin by looking at the optimality conditions for a transportation problem and some extensions leading to the nonlinear complementarity problem. We then discuss a Walrasian equilibrium model and use it to motivate the more general mixed complementarity problem. We conclude this chapter with information on solving the models using the PATH solver and interpreting the results.

### 4.41.1.1 Transportation Problem

The transportation model is a linear program where demand for a single commodity must be satisfied by suppliers at minimal transportation cost. The underlying transportation network is given as a set $A$ of arcs, where $(i, j) \in A$ means that there is a route from supplier $i$ to demand center $j$. The problem variables are the quantities $x_{i,j}$ shipped over each arc $(i, j) \in A$. The linear program can be written mathematically as

$$
\min_{x \geq 0} \quad \sum_{(i,j) \in A} c_{i,j} x_{i,j}
\text{subject to} \quad \sum_{j \in (i,j) \in A} x_{i,j} \leq s_i, \quad \forall i;
\sum_{i \in (i,j) \in A} x_{i,j} \geq d_j, \quad \forall j.
$$

(1)

where $c_{i,j}$ is the unit shipment cost on the arc $(i, j)$, $s_i$ is the available supply at $i$, and $d_j$ is the demand at $j$.

The derivation of the optimality conditions for this linear program begins by associating with each constraint a multiplier, alternatively termed a dual variable or shadow price. These multipliers represent the marginal price on changes to the corresponding constraint. We label the prices on the supply constraint $p^s$ and those on the demand constraint $p^d$. Intuitively, for each supply node $i$

$$
0 \leq p^s_i, \quad s_i \geq \sum_{j : (i,j) \in A} x_{i,j}.
$$

Consider the case when $s_i > \sum_{j : (i,j) \in A} x_{i,j}$, that is there is excess supply at $i$. Then, in a competitive marketplace, no rational person is willing to pay for more supply at node $i$; it is already over-supplied. Therefore, $p^s_i = 0$. Alternatively, when $s_i = \sum_{j : (i,j) \in A} x_{i,j}$, that is node $i$ clears, we might be willing to pay for additional supply of the good. Therefore, $p^s_i \geq 0$. We write these two conditions succinctly as:

$$
0 \leq p^s_i \quad \perp \quad s_i \geq \sum_{j : (i,j) \in A} x_{i,j}, \quad \forall i
$$

where the $\perp$ notation is understood to mean that at least one of the adjacent inequalities must be satisfied as an equality. For example, either $0 = p^s_i$, the first case, or $s_i = \sum_{j : (i,j) \in A} x_{i,j}$, the second case.

Similarly, at each node $j$, the demand must be satisfied in any feasible solution, that is

$$
\sum_{i : (i,j) \in A} x_{i,j} \geq d_j.
$$

Furthermore, the model assumes all prices are nonnegative, $0 \leq p^d_j$. If there is too much of the commodity supplied, $\sum_{i : (i,j) \in A} x_{i,j} > d_j$, then, in a competitive marketplace, the price $p^d_j$ will be driven down to 0. Summing these relationships gives the following complementarity condition:

$$
0 \leq p^d_j \quad \perp \quad \sum_{i : (i,j) \in A} x_{i,j} \geq d_j, \quad \forall j.
$$

The supply price at $i$ plus the transportation cost $c_{i,j}$ from $i$ to $j$ must exceed the market price at $j$. That is, $p^s_i + c_{i,j} \geq p^d_j$. Otherwise, in a competitive marketplace, another producer will replicate supplier $i$ increasing the supply of the good in question which drives down the market price. This chain would
repeat until the inequality is satisfied. Furthermore, if the cost of delivery strictly exceeds the market price, that is $p^s_i + c_{i,j} > p^d_j$, then nothing is shipped from $i$ to $j$ because doing so would incur a loss and $x_{i,j} = 0$. Therefore,

$$0 \leq x_{i,j} \perp p^s_i + c_{i,j} \geq p^d_j, \forall (i,j) \in A.$$ 

We combine the three conditions into a single problem,

$$0 \leq p^s_i \perp s_i \geq \sum_{j \in A} x_{i,j}, \forall i$$

$$0 \leq p^d_j \perp \sum_{i \in A} x_{i,j} \geq d_j, \forall j$$

$$0 \leq x_{i,j} \perp p^s_i + c_{i,j} \geq p^d_j, \forall (i,j) \in A.$$ 

This model defines a linear complementarity problem that is easily recognized as the complementary slackness conditions [57] of the linear program (1). For linear programs the complementary slackness conditions are both necessary and sufficient for $x$ to be an optimal solution of the problem (1). Furthermore, the conditions (2) are also the necessary and sufficient optimality conditions for a related problem in the variables $(p^s, p^d)$

$$\max_{p^s, p^d \geq 0} \sum_j d_j p^d_j - \sum_i s_i p^s_i$$

subject to $c_{i,j} \geq p^d_j - p^s_i, \forall (i,j) \in A$

termed the dual linear program (hence the nomenclature "dual variables").

Looking at (2) a bit more closely we can gain further insight into complementarity problems. A solution of (2) tells us the arcs used to transport goods. A priori we do not need to specify which arcs to use, the solution itself indicates them. This property represents the key contribution of a complementarity problem over a system of equations. If we know what arcs to send flow down, we can just solve a simple system of linear equations. However, the key to the modeling power of complementarity is that it chooses which of the inequalities in (2) to satisfy as equations. In economics we can use this property to generate a model with different regimes and let the solution determine which ones are active. A regime shift could, for example, be a back stop technology like windmills that become profitable if a CO$_2$ tax is increased.

4.41.1.1 GAMS Code The GAMS code for the complementarity version of the transportation problem is given in Figure 1; the actual data for the model is assumed to be given in the file transmcp.dat. Note that the model written corresponds very closely to (2). In GAMS, the $\perp$ sign is replaced in the model statement with a ".". It is precisely at this point that the pairing of variables and equations shown in (2) occurs in the GAMS code. For example, the function defined by rational is complementary to the variable $x$. To inform a solver of the bounds, the standard GAMS statements on the variables can be used, namely (for a declared variable $z(i)$):

$$z.lo(i) = 0;$$

or alternatively

$$\text{positive variable } z;$$

Further information on the GAMS syntax can be found in [205]. Note that GAMS requires the modeler to write $F(z) \geq 0$ whenever the complementary variable is lower bounded, and does not allow the alternative form $0 \leq F(z)$.

Figure 1: A simple MCP model in GAMS, transmcp.gms

model transport / rational.x, demand.p_demand, supply.p_supply /;

solve transport using mcp;

4.41.1.2 Extension: Model Generalization

While many interior point methods for linear programming exploit this complementarity
framework (so-called primal-dual methods [258] ), the real power
of this modeling format is the new problem instances it enables a modeler to create. We now show some
examples of how to extend the simple model (2) to investigate other issues and facets of the problem at
hand.

Demand in the model of Figure 1 is independent of the prices $p$. Since the prices $p$ are variables in
the complementarity problem (2), we can easily replace the constant demand $d$ with a function $d(p)$ in
the complementarity setting. Clearly, any algebraic function of $p$ that can be expressed in GAMS can now
be added to the model given in Figure 1. For example, a linear demand function could be expressed using

$$
\sum_{i : (i,j) \in A} x_{i,j} \geq d_j (1 - p^d_j), \forall j.
$$

Note that the demand is rather strange if $p^d_j$ exceeds 1. Other more reasonable examples for $d(p)$ are
easily derived from Cobb-Douglas or CES utilities. For those examples, the resulting complementarity
problem becomes nonlinear in the variables $p$. Details of complementarity for more general transportation
models can be found in [70], [86].

Another feature that can be added to this model are tariffs or taxes. In the case where a tax is applied at
the supply point, the third general inequality in (2) is replaced by

$$
p^s_i (1 + t_i) + c_{i,j} \geq p^d_j, \forall (i,j) \in A.
$$

The taxes can be made endogenous to the model, details are found in [205].

The key point is that with either of the above modifications, the complementarity problem is not just the
optimality conditions of a linear program. In many cases, there is no optimization problem corresponding
to the complementarity conditions.
4.41 PATH 4.7

4.41.1.1.3 Nonlinear Complementarity Problem  We now abstract from the particular example to describe more carefully the complementarity problem in its mathematical form. All the above examples can be cast as nonlinear complementarity problems (NCPs) defined as follows:

\[(NCP) \text{ Given a function } F: \mathbb{R}^n \to \mathbb{R}^n, \text{ find } z \in \mathbb{R}^n \text{ such that } 0 \leq z \perp F(z) \geq 0.\]

Recall that the \( \perp \) sign signifies that one of the inequalities is satisfied as an equality, so that componentwise, \( z_i F_i(z) = 0 \). We frequently refer to this property as \( z_i \) is complementary to \( F_i \). A special case of the NCP that has received much attention is when \( F \) is a linear function, the linear complementarity problem [62].

4.41.1.2 Walrasian Equilibrium

A Walrasian equilibrium can also be formulated as a complementarity problem (see [169]). In this case, we want to find a price \( p \in \mathbb{R}^m \) and an activity level \( y \in \mathbb{R}^n \) such that

\[
0 \leq y \perp L(p) := -A^T p \geq 0 \\
0 \leq p \perp S(p,y) := b + Ay - d(p) \geq 0
\]

where \( S(p,y) \) represents the excess supply function and \( L(p) \) represents the loss function. Complementarity allows us to choose the activities \( y_j \) to run (i.e. only those that do not make a loss). The second set of inequalities state that the price of a commodity can only be positive if there is no excess supply. These conditions indeed correspond to the standard exposition of Walras' law which states that supply equals demand if we assume all prices \( p \) will be positive at a solution. Formulations of equilibria as systems of equations do not allow the model to choose the activities present, but typically make an a priori assumption on this matter.

4.41.1.2.1 GAMS Code  A GAMS implementation of (3) is given in Figure 2. Many large scale models of this nature have been developed. An interested modeler could, for example, see how a large scale complementarity problem was used to quantify the effects of the Uruguay round of talks [124].

Figure 2: Walrasian equilibrium as an NCP, walras1.gms

$include walras.dat

positive variables p(i), y(j);
equations S(i), L(j);
S(i).. b(i) + sum(j, A(i,j)*y(j)) - c(i)*sum(k, g(k)*p(k)) / p(i) =g= 0;
L(j).. -sum(i, p(i)*A(i,j)) =g= 0;
model walras / S.p, L.y /;
solve walras using mcp;
4.41.1.2.2 Extension: Intermediate Variables  In many modeling situations, a key tool for clarification is the use of intermediate variables. As an example, the modeler may wish to define a variable corresponding to the demand function \( d(p) \) in the Walrasian equilibrium (3). The syntax for carrying this out is shown in Figure 3 where we use the variables \( d \) to store the demand function referred to in the excess supply equation. The model \texttt{walras} now contains a mixture of equations and complementarity constraints. Since constructs of this type are prevalent in many practical models, the GAMS syntax allows such formulations.

Figure 3: Walrasian equilibrium as an MCP, \texttt{walras2.gms}

$include walras.dat

positive variables \( p(i), y(j) \);
variables \( d(i) \);
equations \( S(i), L(j), demand(i) \);

\[
demand(i)
\begin{align*}
d(i) &= c(i) \cdot \sum(k) g(k) \cdot p(k) / p(i) ;
\end{align*}
\]

\[
S(i)
\begin{align*}
b(i) + \sum(j) A(i,j) \cdot y(j) - d(i) & \geq 0 ;
\end{align*}
\]

\[
L(j)
\begin{align*}
- \sum(i) p(i) \cdot A(i,j) & \geq 0 ;
\end{align*}
\]

model walras / demand.d, S.p, L.y /;
solve walras using mcp;

Note that positive variables are paired with inequalities, while free variables are paired with equations. A crucial point misunderstood by many modelers (new and experienced alike) is that the bounds on the variable determine the relationships satisfied by the function \( F \). Thus in Figure 3, \( d \) is a free variable and therefore its paired equation \( \text{demand} \) is an equality. Similarly, since \( p \) is nonnegative, its paired relationship \( S \) is a (greater-than) inequality. See the MCP definition below for details.

A simplification is allowed to the model statement in Figure 3. It is not required to match free variables explicitly to equations; we only require that there are the same number of free columns (i.e. single variables) as unmatched rows (i.e. single equations). Thus, in the example of Figure 3, the model statement could be replaced by

\[
\text{model walras} / \text{demand, S.p, L.y} /;
\]

This extension allows existing GAMS models consisting of a square system of nonlinear equations to be easily recast as a complementarity problem - the model statement is unchanged. GAMS generates a list of all variables appearing in the equations found in the model statement, performs explicitly defined pairings and then checks that the number of remaining equality rows equals the number of remaining free columns. However, if an explicit match is given, the PATH solver can frequently exploit the information for better solution. Note that all variables that are not free and all inequalities must be explicitly matched.

4.41.1.2.3 Mixed Complementarity Problem  A mixed complementarity problem (MCP) is specified by three pieces of data, namely the lower bounds \( \ell \), the upper bounds \( u \) and the function \( F \).

(MCP) Given lower bounds \( \ell \in \{ \mathbb{R} \cup \{-\infty\}\}^n \), upper bounds \( u \in \{ \mathbb{R} \cup \{\infty\}\}^n \) and a function \( F : \mathbb{R}^n \rightarrow \mathbb{R}^n \), find \( z \in \mathbb{R}^n \) such that precisely one of the following holds for each \( i \in \{1, \ldots, n\} \):

\[
\begin{align*}
F_i(z) &= 0 \quad \text{and} \quad \ell_i \leq z_i \leq u_i \\
F_i(z) &= 0 \quad \text{and} \quad z_i = \ell_i \\
F_i(z) &= 0 \quad \text{and} \quad z_i = u_i.
\end{align*}
\]
These relationships define a general MCP (sometimes termed a rectangular variational inequality \[123\]). We will write these conditions compactly as

\[ \ell \leq x \leq u \perp F(x). \]

As the MCP model type as defined above is the one used in GAMS, there are some consequences of the definition worth emphasizing here. Firstly, the bounds on the variable determine the relationships satisfied by the function \(F\): the constraint type (e.g. \(=G\), \(=L\)) chosen plays no role in defining the problem. This being the case, it is acceptable (and perhaps advisable!) to use an \(=N\) in the definition of all equations used in complementarity models to highlight the dependence on the variable bounds in defining the MCP. This is not required, however. The constraint types \(=G\), \(=L\) and \(=E\) are also allowed. If the variable bounds are inconsistent with the constraint type chosen, GAMS will either reject the model (e.g. an \(=L\) row matched with a lower-bounded variable) or silently and temporarily ignore the issue (e.g. an \(=E\) row matched with a lower-bounded variable). In the latter case, if equality does not hold at solution (allowable if the variable is at lower bound) the is marked in the listing file with a redef.

Secondly, note the contrast between complementarity conditions like \(g(z) \leq 0, z \geq 0\) and a complementarity problem like \(F(x) \perp 0 \leq x \leq \infty\). The former requires a trivial transformation in order to fit into the MCP framework: \(-g(z) \perp 0 \leq z \leq \infty\). This simple issue is a frequent source of problems and worth looking out for.

The nonlinear complementarity problem of Nonlinear Complementarity Problem is a special case of the MCP. For example, to formulate an NCP in the GAMS/MCP format we set

\[
z\lo(I) = 0;
\]

or declare

\[
\text{positive variable } z;
\]

Another special case is a square system of nonlinear equations

(NE) Given a function \(F : \mathbb{R}^n \to \mathbb{R}^n\) find \(z \in \mathbb{R}^n\) such that

\[
F(z) = 0.
\]

In order to formulate this in the GAMS/MCP format we just declare

\[
\text{free variable } z;
\]

In both the above cases, we must not modify the lower and upper bounds on the variables later (unless we wish to drastically change the problem under consideration).

An advantage of the extended formulation described above is the pairing between "fixed" variables (ones with equal upper and lower bounds) and a component of \(F\). If a variable \(z_i\) is fixed, then \(F_i(z)\) is unrestricted since precisely one of the three conditions in the MCP definition automatically holds when \(z_i = \ell_i = u_i\). Thus if a variable is fixed in a GAMS model, the paired equation is completely dropped from the model. This convenient modeling trick can be used to remove particular constraints from a model at generation time. As an example, in economics, fixing a level of production will remove the zero-profit condition for that activity.

Simple bounds on the variables are a convenient modeling tool that translates into efficient mathematical programming tools. For example, specialized codes exist for the bound constrained optimization problem

\[
\min f(x) \text{ subject to } \ell \leq x \leq u.
\]
The first order optimality conditions for this problem class are precisely MCP($\nabla f(x), [\ell, u]$). We can easily see this condition in a one dimensional setting. If we are at an unconstrained stationary point, then $\nabla f(x) = 0$. Otherwise, if $x$ is at its lower bound, then the function must be increasing as $x$ increases, so $\nabla f(x) \geq 0$. Conversely, if $x$ is at its upper bound, then the function must be increasing as $x$ decreases, so that $\nabla f(x) \leq 0$. The MCP allows such problems to be easily and efficiently processed.

Upper bounds can be used to extend the utility of existing models. For example, in Figure 3 it may be necessary to have an upper bound on the activity level $y$. In this case, we simply add an upper bound to $y$ in the model statement, and we can replace the loss equation with the following definition:

\[
y_{up}(j) = 10;
L(j).. -\sum(i, p(i)*A(i,j)) =e= 0
\]

Here, for bounded variables, we do not know beforehand if the constraint will be satisfied as an equation, less-than inequality or greater-than inequality, since this determination depends on the values of the solution variables. However, let us interpret the relationships that the above change generates. If $y_j = 0$, the loss function can be positive since we are not producing in the $j$th sector. If $y_j$ is strictly between its bounds, then the loss function must be zero by the definition of complementarity; this is the competitive assumption. Finally, if $y_j$ is at its upper bound, then the loss function can be negative. Of course, if the market does not allow free entry, some firms may operate at a profit (negative loss). For more examples of problems, the interested reader is referred to [67], [83], [84].

4.41.1.3 Solution

We will assume that a file named transmcp.gms has been created using the GAMS syntax which defines an MCP model transport as developed in Transportation Problem. The modeler has a choice of the complementarity solver to use. We are going to further assume that the modeler wants to use PATH.

There are two ways to ensure that PATH is used as opposed to any other GAMS/MCP solver. These are as follows:

1. Add the following line to the transmcp.gms file prior to the solve statement

   \[
   \text{option mcp = path;}
   \]

   PATH will then be used instead of the default solver provided.

2. Choose PATH as the default solver for MCP (via the IDE on Windows or elsewhere by rerunning gamsinst from the GAMS system directory).

To solve the problem, the modeler executes the command:

\[
gams transmcp
\]

where transmcp can be replaced by any filename containing a GAMS model. Many other command line options for GAMS exist; the reader is referred to List of Command Line Parameters for further details.

At this stage, control is handed over to the solver which creates a log providing information on what the solver is doing as time elapses. See Section PATH for details about the log file. After the solver terminates, a listing file is generated containing the solution to the problem. We now describe the listing file output specifically related to complementarity problems.
4.41.1.3.1 Listing File  The listing file is the standard GAMS mechanism for reporting model results. This file contains information regarding the compilation process, the form of the generated equations in the model, and a report from the solver regarding the solution process.

We now detail the last part of this output, an example of which is given in Figure 4. We use "..." to indicate where we have omitted continuing similar output.

After a summary line indicating the model name and type and the solver name, the listing file shows a solver status and a model status. Table 1 and Table 2 display the relevant codes that are returned under different circumstances. A modeler can access these codes within the transmcp.gms file using transport.solvestat and transport.modelstat respectively.

**Table 1: Solver Status Codes**
Table 2: Model Status Codes

<table>
<thead>
<tr>
<th>Code</th>
<th>String</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Normal completion</td>
<td>Solver finished normally</td>

<td>Solver reached the time limit</td>
</tr>
<tr>
<td>4</td>
<td>Terminated by solver</td>
<td>Solver reached an unspecified limit</td>
</tr>
<tr>
<td>8</td>
<td>User interrupt</td>
<td>The user interrupted the solution process</td>
</tr>
</tbody>
</table>

After this, a listing of the time and iterations used is given, along with a count on the number of evaluation errors encountered. If the number of evaluation errors is greater than zero, further information can typically be found later in the listing file, prefaced by "****". Information provided by the solver is then displayed.

Next comes the solution listing, starting with each of the equations in the model. For each equation passed to the solver, four columns are reported, namely the lower bound, level, upper bound and marginal. GAMS moves all parts of a constraint involving variables to the left hand side, and accumulates the constants on the right hand side. The lower and upper bounds correspond to the constants that GAMS generates. For equations, these should be equal, whereas for inequalities one of them should be infinite. The level value of the equation (an evaluation of the left hand side of the constraint at the current point) should be between these bounds, otherwise the solution is infeasible and the equation is marked as follows:

```
seattle .chicago -0.153 -2.000 +INF 300.000 INFES
```

The marginal column in the equation contains the value of the variable that was matched with this equation.

For the variable listing, the lower, level and upper columns indicate the lower and upper bounds on the variables and the solution value. The level value returned by PATH will always be between these bounds. The marginal column contains the value of the slack on the equation that was paired with this variable. If a variable appears in one of the constraints in the model statement but is not explicitly paired to a constraint, the slack reported here contains the internally matched constraint slack. The definition of this slack is the minimum of equ.l - equ.lower and equ.l - equ.upper, where equ is the paired equation.

Finally, a summary report is given that indicates how many errors were found. Figure 4 is nicely-solved case; when the model has infeasibilities, these can be found by searching for the string "INFES" as described above.

### 4.41.1.3.2 Redefined Equations

Unfortunately, this is not the end of the story. Some equations may have the following form:

```
LOWER       LEVEL       UPPER       MARGINAL
new-york   325.000  350.000   325.000    0.225 REDEF
```
This should be construed as a warning from GAMS, as opposed to an error. In principle, the REDEF should only occur if the paired variable to the constraint has a finite lower and/or upper bound and the variable is at one of those bounds. In this case, at the solution of the complementarity problem the sense of the constraint (e.g. \(\neq\)) may not be satisfied. This occurs when GAMS constraints are used to define the function \(F\). The bounds on each component of the function \(F\) are derived from the bounds on the matching variable component, and these bounds may be inconsistent with those implied by the constraint type used. GAMS warns the user via the REDEF label when the solution found leads to a violated "constraint". To avoid REDEF warnings the \(\neq\) can be used to define all complementarity functions.

*Note that a REDEF is not an error, just a warning. The solver has solved the complementarity problem specified.* GAMS gives this report to ensure that the modeler understands that the complementarity problem derives the relationships on the equations from the variable bounds, not from the equation definition.

### 4.41.1.4 Pitfalls

As indicated above, the ordering of an equation is important in the specification of an MCP. Since the data of the MCP is the function \(F\) and the bounds \(\ell\) and \(u\), it is important for the modeler to pass the solver the function \(F\) and not \(-F\).

For example, if we have the optimization problem,

\[
\min_{x \in [0, 2]} (x - 1)^2
\]

then the first order optimality conditions are

\[
0 \leq x \leq 2 \perp 2(x - 1)
\]

which has a unique solution, \(x = 1\). Figure 5 provides correct GAMS code for this problem.

**Figure 5:** First order conditions as an MCP, `first.gms`

```gams
variables x;
equations d_f;
x.lo = 0;
x.up = 2;
d_f.. 2*(x - 1) =e= 0;
model first / d_f.x /;
solve first using mcp;
```

However, if we accidentally write the valid equation

\[
d_f.. 0 =e= 2*(x - 1);
\]

the problem given to the solver is

\[
0 \leq x \leq 2 \perp -2(x - 1)
\]

which has three solutions, \(x = 0\), \(x = 1\), and \(x = 2\). This problem is in fact the stationary conditions for the nonconvex quadratic problem,

\[
\max_{x \in [0, 2]} (x - 1)^2,
\]
Continuing with the example, when $x$ is a free variable, we might conclude that the ordering of the equation is irrelevant because we always have the equation, $2(x - 1) = 0$, which does not change under multiplication by $-1$. In most cases, the ordering of equations (which are complementary to free variables) does not make a difference since the equation is internally "substituted out" of the model. In particular, for defining equations, such as that presented in Figure 3, the choice appears to be arbitrary.

However, in difficult (singular or near singular) cases, the substitution cannot be performed, and instead a perturbation is applied to $F$, in the hope of "(strongly) convexifying" the problem. If the perturbation happens to be in the wrong direction because $F$ was specified incorrectly, the perturbation actually makes the problem less convex, and hence less likely to solve. Note that determining which of the above orderings of the equations makes most sense is typically tricky. One rule of thumb is to check whether if you replace the "=$e=$" by "=$g=$", and then increase "$x$", is the inequality intuitively more likely to be satisfied. If so, you probably have it the right way round, if not, reorder.

Furthermore, underlying model convexity is important. For example, if we have the linear program

$$
\min_x \quad c^T x \\
\text{subject to} \quad Ax = b, \ x \geq 0
$$

we can write the first order optimality conditions as either

$$
0 \leq x \perp -A^T \mu + c \\
\mu \text{ free} \perp Ax - b
$$

or, equivalently,

$$
0 \leq x \perp -A^T \mu + c \\
\mu \text{ free} \perp b - Ax
$$

because we have an equation. The former is a linear complementarity problem with a positive semidefinite matrix, while the latter is almost certainly indefinite. Also, if we need to perturb the problem because of numerical problems, the former system will become positive definite, while the later becomes highly nonconvex and unlikely to solve. The rule of thumb here is to consider what happens when the dual multiplier $\mu$ is made non-negative in the KKT system. In the former system, the constraint becomes $Ax \geq b$, which is consistent with a minimization and a positive multiplier. In the latter system, we get $Ax \leq b$, which is backwards.

Finally, users are strongly encouraged to match equations and free variables when the matching makes sense for their application. Structure and convexity can be destroyed if it is left to the solver to perform the matching. For example, in the above example, we could lose the positive semidefinite matrix with an arbitrary matching of the free variables.

4.41.2 PATH

Newton’s method, perhaps the most famous solution technique, has been extensively used in practice to solve square systems of nonlinear equations. The basic idea is to construct a local approximation of the nonlinear equations around a given point, $x^k$, solve the approximation to find the Newton point, $x^N$, update the iterate, $x^{k+1} = x^N$, and repeat until we find a solution to the nonlinear system. This method works extremely well close to a solution, but can fail to make progress when started far from a solution. To guarantee progress is made, a line search between $x^k$ and $x^N$ is used to enforce sufficient decrease on an appropriately defined merit function. Typically, $\frac{1}{2}\|F(x)\|^2$ is used.

PATH uses a generalization of this method on a nonsmooth reformulation of the complementarity problem. To construct the Newton direction, we use the normal map [200] representation

$$
F(\pi(x)) + x - \pi(x)
$$
associated with the MCP, where \( \pi(x) \) represents the projection of \( x \) onto \([\ell, u] \) in the Euclidean norm. We note that if \( x \) is a zero of the normal map, then \( \pi(x) \) solves the MCP. At each iteration, a linearization of the normal map, a linear complementarity problem, is solved using a pivotal code related to Lemke’s method.

Versions of PATH prior to 4.x are based entirely on this formulation using the residual of the normal map
\[
\|F(\pi(x)) + x - \pi(x)\|
\]
as a merit function. However, the residual of the normal map is not differentiable, meaning that if a subproblem is not solvable then a “steepest descent” step on this function cannot be taken. PATH 4.x considers an alternative nonsmooth system \([87]\), \( \Phi(x) = 0 \), where \( \Phi_i(x) = \phi(F_i(x)) \) and \( \phi(a,b) := \sqrt{a^2 + b^2} - a - b \). The merit function, \( \|\Phi(x)\|^2 \), in this case is differentiable, and is used for globalization purposes. When the subproblem solver fails, a projected gradient direction for this merit function is searched. It is shown in \([85]\) that this provides descent and a new feasible point to continue PATH, and convergence to stationary points and/or solutions of the MCP is provided under appropriate conditions.

The remainder of this chapter details the interpretation of output from PATH and ways to modify the behavior of the code. To this end, we will assume that the modeler has created a file named transmcp.gms which defines an MCP model transport as described in Section Transportation Problem and is using PATH 4.x to solve it. See Section Solution for information on changing the solver.

### 4.41.2.1 Log File

We will now describe the behavior of the PATH algorithm in terms of the output typically produced. An example of the log for a particular run is given in Figure 6 and Figure 7.

--- Restarting execution

The first few lines on this log file are printed by GAMS during its compilation and generation phases. The model is then passed off to PATH at the stage where the "Executing PATH" line is written out. After some basic memory allocation and problem checking, the PATH solver checks if the modeler required an option file to be read. In the example this is not the case. If PATH is directed to read an option file (see PATH Options below), then the following output is generated after the PATH banner.

Reading options file PATH.OPT
> output_linear_model yes;
Options: Read: Line 2 invalid: hi_there;
Read of options file complete.

If the option reader encounters an invalid option (as above), it reports this but carries on executing the algorithm. Following this, the algorithm starts working on the problem.
4.41.2.1.1 Diagnostic Information  Some diagnostic information is initially generated by the solver at the starting point. Included is information about the initial point and function evaluation. The log file here tells the value of the largest element of the starting point and the variable where it occurs. Similarly, the maximum function value is displayed along with the row producing it. The maximum element in the gradient is also presented with the equation and variable where it is located.

The second block provides more information about the Jacobian at the starting point. This information can be used to help scale the model. See Section Advanced Topics for complete details.

4.41.2.1.2 Crash Log  The first phase of the code is a crash procedure attempting to quickly determine which of the inequalities should be active. This procedure is documented fully in [69], and an example of the Crash Log can be seen in Figure 6. The first column of the crash log is just a label indicating the current iteration number, the second gives an indication of how many function evaluations have been performed so far. Note that precisely one Jacobian (gradient) evaluation is performed per crash iteration. The number of changes to the active set between iterations of the crash procedure is shown under the "diff" column. The crash procedure terminates if this becomes small. Each iteration of this procedure involves a factorization of a matrix whose size is shown in the next column. The residual is a measure of how far the current iterate is from satisfying the complementarity conditions (MCP); it is zero at a solution. See Merit Functions for further information. The column "step" corresponds to the steplength taken in this iteration - ideally this should be 1. If the factorization fails, then the matrix is perturbed by an identity matrix scaled by the value indicated in the "prox" column. The "label" column indicates which row in the model is furthest away from satisfying the conditions (MCP). Typically, relatively few crash iterations are performed. Section PATH Options gives mechanisms to affect the behavior of these steps.

4.41.2.1.3 Major Iteration Log  After the crash is completed, the main algorithm starts as indicated by the "Major Iteration Log" flag (see Figure 7). The columns that have the same labels as in the crash log have precisely the same meaning described above. However, there are some new columns that we now explain. Each major iteration attempts to solve a linear mixed complementarity problem using a pivotal method that is a generalization of Lemke’s method [153]. The number of pivots performed per major iteration is given in the "minor" column.

The "grad" column gives the cumulative number of Jacobian evaluations used; typically one evaluation is performed per iteration. The "inorm" column gives the value of the error in satisfying the equation indicated in the "label" column.

At each iteration of the algorithm, several different step types can be taken, due to the use of nonmonotone searches [68], [80] which are used to improve robustness. In order to help the PATH user, we have added two code letters indicating the return code from the linear solver and the step type to the log file. Table 3 explains the return codes for the linear solver and Table 4 explains the meaning of each step type. The ideal output in this column is "SO"; "SD" and "SB" also indicate reasonable progress. Codes different from these are not catastrophic, but typically indicate the solver is having difficulties due to numerical issues or nonconvexities in the model.

<td>A Watchdog step was performed in which we returned to the last point encountered with a better merit function value than the nonmonotone reference value (M, O, or B step), regenerated the Newton point, and performed a backtracking search.</td>
</tr>
</tbody>
</table>

4.41.2.1.4 Minor Iteration Log If more than 500 pivots are performed, a minor log is output that gives more details of the status of these pivots. A listing from transmp model follows, where we have set the output_minor_iteration_frequency option to 1.

```
Minor Iteration Log
minor t z w v art ckpts enter leave
1 4.2538e-01 8 2 0 0 0 t[ 0] z[ 11] w[ 0]
2 9.0823e-01 8 2 0 0 0 w[ 11] w[ 10] z[ 0]
3 1.0000e+00 9 2 0 0 0 z[ 10] t[ 0]
```

\(t\) is a parameter that goes from zero to 1 for normal starts in the pivotal code. When the parameter reaches 1, we are at a solution to the subproblem. The \(t\) column gives the current value for this parameter. The next columns report the current number of problem variables \(z\) and slacks corresponding to variables at lower bound \(w\) and at upper bound \(v\). Artificial variables are also noted in the minor log, see [81] for further details. Checkpoints are times where the basis matrix is refactorized. The number of checkpoints is indicated in the \(ckpts\) column. Finally, the minor iteration log displays the entering and leaving variables during the pivot sequence.

4.41.2.1.5 Restart Log The PATH code attempts to fully utilize the resources provided by the modeler to solve the problem. Versions of PATH after 3.0 have been much more aggressive in determining that a stationary point of the residual function has been encountered. When it is determined that no progress is being made, the problem is restarted from the initial point supplied in the GAMS file with a different set of options. These restarts give the flexibility to change the algorithm in the hopes that the modified algorithm leads to a solution. The ordering and nature of the restarts were determined by empirical evidence based upon tests performed on real-world problems.

The exact options set during the restart are given in the restart log, part of which is reproduced below.

```
Restart Log
proximal_perturbation 0
crash_method none
crash_perturb yes
nms_initial_reference_factor 2
proximal_perturbation 1.0000e-01
```

If a particular problem solves under a restart, a modeler can circumvent the wasted computation by setting the appropriate options as shown in the log. Note that sometimes an option is repeated in this log. In this case, it is the last option that is used.
4.41.2.1.6 Solution Log  A solution report is now given by the algorithm for the point returned. The first component is an evaluation of several different merit functions. Next, a display of some statistics concerning the final point is given. This report can be used to detect problems with the model and solution as detailed in Section Advanced Topics.

At the end of the log file, summary information regarding the algorithm's performance is given. The string "** EXIT - solution found" is an indication that PATH solved the problem. Any other EXIT string indicates a termination at a point that may not be a solution. These strings give an indication of what modelstat and solvestat will be returned to GAMS. After this, the "Restarting execution" flag indicates that GAMS has been restarted and is processing the results passed back by PATH.

4.41.2.2 Status File

If for some reason the PATH solver exits without writing a solution, or the sysout flag is turned on, the status file generated by the PATH solver will be reported in the listing file. The status file is similar to the log file, but provides more detailed information. The modeler is typically not interested in this output.

4.41.2.3 User Interrupts

A user interrupt can be effected by typing Ctrl-C. We only check for interrupts every major iteration. If a more immediate response is wanted, repeatedly typing Ctrl-C will eventually kill the job. The number needed is controlled by the interrupt_limit option. In this latter case, when a kill is performed, no solution is written and an execution error will be generated in GAMS.

4.41.2.4 Preprocessing

The purpose of a preprocessor is to reduce the size and complexity of a model to achieve improved performance by the main algorithm. Another benefit of the analysis performed is the detection of some provably unsolvable problems. A comprehensive preprocessor has been incorporated into PATHC as developed in [82].

The preprocessor reports its finding with some additional output to the log file. This output occurs before the initial point statistics. An example of the preprocessing on the forcebsm model is presented below.

Zero: 0 Single: 112 Double: 0 Forced: 0
Preprocessed size: 72

The preprocessor looks for special polyhedral structure and eliminates variables using this structure. These are indicated with the above line of text. Other special structure is also detected and reported.

On exit from the algorithm, we must generate a solution for the original problem. This is done during the postsolve. Following the postsolve, the residual using the original model is reported.

Postsolved residual: 1.0518e-10

This number should be approximately the same as the final residual reported on the presolved model.
4.41.2.4.1 Constrained Nonlinear System  Modelers typically add bounds to their variables when attempting to solve nonlinear problems in order to restrict the domain of interest. For example, many square nonlinear systems are formulated as

\[ F(z) = 0, \ell \leq z \leq u, \]

where typically, the bounds on z are inactive at the solution. This is not an MCP, but is an example of a "constrained nonlinear system" (CNS). It is important to note the distinction between MCP and CNS. The MCP uses the bounds to infer relationships on the function \( F \). If a finite bound is active at a solution, the corresponding component of \( F \) is only constrained to be nonnegative or nonpositive in the MCP, whereas in CNS it must be zero. Thus there may be many solutions of MCP that do not satisfy \( F(z) = 0 \). Only if \( z^* \) is a solution of MCP with \( \ell < z^* < u \) is it guaranteed that \( F(z^*) = 0 \).

Internally, PATHC reformulates a constrained nonlinear system of equations to an equivalent complementarity problem. The reformulation adds variables, \( y \), with the resulting problem written as:

\[ \ell \leq x \leq u \quad \perp -y \\
y \text{ free} \quad \perp F(x). \]

This is the MCP model passed on to the PATH solver.

4.41.3 PATH Options

The default options of PATH should be sufficient for most models. If desired, PATH-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

We give a list of the available PATH options along with their defaults and meaning below. Note that only the first three characters of every word are significant.

GAMS controls the total number of pivots allowed via the `iterlim` option. If more pivots are needed for a particular model then either of the following lines should be added to the `transmcp.gms` file before the solve statement

```gams
option iterlim = 2000;
transport.iterlim = 2000;
```

Problems with a singular basis matrix can be overcome by using the `proximal_perturbation` option [42], and linearly dependent columns can be output with the `output_factorization_singularities` option. For more information on singularities, we refer the reader to Section Advanced Topics.

As a special case, PATH can emulate Lemke’s method [61], [153] for LCP with the following options:

```gams
crash_method none
crash_perturb no
major_iteration_limit 1
lemke_start first
nms no
```

If instead, PATH is to imitate the Successive Linear Complementarity method (SLCP, often called the Josephy Newton method) [132], [169], [168] for MCP with an Armijo style linesearch on the normal map residual, then the options to use are:

```gams
crash_method none
crash_perturb no
lemke_start always
nms_initial_reference_factor 1
nms_memory size 1
nms_mstep_frequency 1
nms_searchtype line
merit_function normal
```

Note that `nms_memory size 1` and `nms_initial_reference_factor 1` turn off the nonmonotone linesearch, while `nms_mstep_frequency 1` turns off watchdogging [55]. `nms_searchtype line` forces PATH to search the line segment between the initial point and the solution to the linear model, while `merit_function normal` tell PATH to use the normal map for calculating the residual.

### 4.41.4 Advanced Topics

This chapter discusses some of the difficulties encountered when dealing with complementarity problems. We start off with a very formal definition of a complementarity problem (similar to the one given previously) which is used in later sections on merit functions and ill-defined, poorly-scaled, and singular models.

#### 4.41.4.1 Formal Definition of MCP

The mixed complementarity problem is defined by a function, $F : D \to \mathbb{R}^n$ where $D \subseteq \mathbb{R}^n$ is the domain of $F$, and possibly infinite lower and upper bounds, $\ell$ and $u$. Let $C := \{ x \in \mathbb{R}^n \mid \ell \leq x \leq u \}$, a Cartesian product of closed (possibly infinite) intervals. The problem is given as

$$
\text{MCP : find } x \in C \cap D \text{ s.t. } \langle F(x), y - x \rangle \geq 0, \forall y \in C.
$$

This formulation is a special case of the variational inequality problem defined by $F$ and a (nonempty, closed, convex) set $C$. Special choices of $\ell$ and $u$ lead to the familiar cases of a system of nonlinear equations

$$
F(x) = 0
$$

(generated by $\ell \equiv -\infty$, $u \equiv +\infty$) and the nonlinear complementarity problem

$$
0 \leq x \perp F(x) \geq 0
$$

(generated using $\ell \equiv 0$, $u \equiv +\infty$).
4.41.4.2 Algorithmic Features

We now describe some of the features of the PATH algorithm and the options affecting each.

4.41.4.2.1 Merit Functions

A solver for complementarity problems typically employs a merit function to indicate the closeness of the current iterate to the solution set. The merit function is zero at a solution to the original problem and strictly positive otherwise. Numerically, an algorithm terminates when the merit function is approximately equal to zero, thus possibly introducing spurious “solutions”.

The modeler needs to be able to determine with some reasonable degree of accuracy whether the algorithm terminated at solution or if it simply obtained a point satisfying the desired tolerances that is not close to the solution set. For complementarity problems, we can provide several indicators with different characteristics to help make such a determination. If one of the indicators is not close to zero, then there is some evidence that the algorithm has not found a solution. We note that if all of the indicators are close to zero, we are reasonably sure we have found a solution. However, the modeler has the final responsibility to evaluate the ”solution” and check that it makes sense for their application.

For the NCP, a standard merit function is

\[ \|(-x)_+, (-F(x))_+, [(x_i)_{+}(F_i(x))_{+}]\| \]

with the first two terms measuring the infeasibility of the current point and the last term indicating the complementarity error. In this expression, we use \((x)_+\) to represent the Euclidean projection of \(x\) onto the nonnegative orthant, that is \((x)_+ = \max(x, 0)\). For the more general MCP, we can define a similar function:

\[ \|x - \pi(x), \left( \frac{x_i - \ell_i}{\|x_i\| + 1} \right)_+, (F_i(x))_+, \left( \frac{u_i - x_i}{\|u_i\| + 1} \right)_+, (-F_i(x))_+ \| \]

where \(\pi(x)\) represents the Euclidean projection of \(x\) onto \(C\). We can see that if we have an NCP, the function is exactly the one previously given and for nonlinear systems of equations, this becomes \(\|F(x)\|\).

There are several reformulations of the MCP as a system of nonlinear (nonsmooth) equations for which the corresponding residual is a natural merit function. Some of these are as follows:

- Generalized Minimum Map: \(x - \pi(x - F(x))\)
- Normal Map: \(F(\pi(y)) + y - \pi(y)\)
- Fischer Function: \(\Phi(x)\), where \(\Phi_i(x) := \phi(x_i, F_i(x))\) with
  \[ \phi(a, b) := \sqrt{a^2 + b^2} - a - b. \]
  Note that \(\phi(a, b) = 0\) if and only if \(0 \leq a \bot b \geq 0\). A straightforward extension of \(\Phi\) to the MCP format is given for example in [85].

In the context of nonlinear complementarity problems the generalized minimum map corresponds to the classic minimum map \(\min(x, F(x))\). Furthermore, for NCPs the minimum map and the Fischer function are both local error bounds and were shown to be equivalent in [236]. Figure 10 in the subsequent section plots all of these merit functions for the ill-defined example discussed therein and highlights the differences between them.

The squared norm of \(\Phi\), namely \(\Psi(x) := \frac{1}{2} \sum \phi(x_i, F_i)^2\), is continuously differentiable on \(\mathbb{R}^n\) provided \(F\) itself is. Therefore, the first order optimality conditions for the unconstrained minimization of \(\Psi(x)\), namely \(\nabla \Psi(x) = 0\) give another indication as to whether the point under consideration is a solution of MCP.

The merit functions and the information PATH provides at the solution can be useful for diagnostic purposes. By default, PATH 4.x returns the best point with respect to the merit function because this iterate likely provides better information to the modeler. As detailed in Section PATH Options, the default merit function in PATH 4.x is the Fischer function. To change this behavior the merit_function option can be used.
4.41.4.2.2 Crashing Method  The crashing technique [69] is used to quickly identify an active set from the user-supplied starting point. At this time, a proximal perturbation scheme [40], [41] is used to overcome problems with a singular basis matrix. The proximal perturbation is introduced in the crash method, when the matrix factored is determined to be singular. The value of the perturbation is based on the current merit function value.

Even if the crash method is turned off, for example via the option crash_method none, perturbation can be added. This is determined by factoring the matrix that crash would have initially formed. This behavior is extremely useful for introducing a perturbation for singular models. It can be turned off by issuing the option crash_perturb no.

4.41.4.2.3 Nonmonotone Searches  The first line of defense against convergence to stationary points is the use of a nonmonotone linesearch [118], [119], [80]. In this case we define a reference value, \( R^k \), and we use this value to test for sufficient decrease:

\[
\Psi(x^k + t_k d^k) \leq R^k + t_k \nabla \Psi(x^k)^T d^k.
\]

Depending upon the choice of the reference value, this allows the merit function to increase from one iteration to the next. This strategy can not only improve convergence, but can also avoid local minimizers by allowing such increases.

We now need to detail our choice of the reference value. We begin by letting \( \{ M_1, \ldots, M_m \} \) be a finite set of values initialized to \( \kappa \Psi(x^0) \), where \( \kappa \) is used to determine the initial set of acceptable merit function values. The value of \( \kappa \) defaults to 1 in the code and can be modified with the nms_initial_reference_factor option; \( \kappa = 1 \) indicates that we are not going to allow the merit function to increase beyond its initial value.

Having defined the values of \( \{ M_1, \ldots, M_m \} \) (where the code by default uses \( m = 10 \)), we can now calculate a reference value. We must be careful when we allow gradient steps in the code. Assuming that \( d^k \) is the Newton direction, we define \( i_0 = \text{argmax} M_i \) and \( R^k = M_{i_0} \). After the nonmonotone linesearch rule above finds \( t_k \), we update the memory so that \( M_{i_0} = \Psi(x^k + t_k d^k) \), i.e. we remove an element from the memory having the largest merit function value.

When we decide to use a gradient step, it is beneficial to let \( x^k = x^{\text{best}} \) where \( x^{\text{best}} \) is the point with the absolute best merit function value encountered so far. We then recalculate \( d^k = -\nabla \Psi(x^k) \) using the best point and let \( R^k = \Psi(x^k) \). That is to say that we force decrease from the best iterate found whenever a gradient step is performed. After a successful step we set \( M_i = \Psi(x^k + t_k d^k) \) for all \( i \in [1, \ldots, m] \). This prevents future iterates from returning to the same problem area.

A watchdog strategy [55] is also available for use in the code. The method employed allows steps to be accepted when they are "close" to the current iterate. Nonmonotonic decrease is enforced every \( m \) iterations, where \( m \) is set by the nms_mstep_frequency option.

4.41.4.2.4 Linear Complementarity Problems  PATH solves a linear complementarity problem at each major iteration. Let \( M \in \mathbb{R}^{n \times n} \), \( q \in \mathbb{R}^n \), and \( B = [l, u] \) be given. \((z, w, v)\) solves the linear mixed complementarity problem defined by \( M \), \( q \), and \( B \) if and only if it satisfies the following constrained system of equations:

\[
Mz - w + v + q = 0 \quad (4)
\]
\[
w^T(z - l) = 0 \quad (5)
\]
\[
v^T(u - z) = 0 \quad (6)
\]
$z \in B, w \in \mathbb{R}_+^n, v \in \mathbb{R}_+^n$ (7)

where $x + \infty = \infty$ for all $x \in \mathbb{R}$ and $0 \cdot \infty = 0$ by convention. A triple, $(\hat{z}, \hat{w}, \hat{v})$, satisfying equations (4) - (6) is called a complementary triple.

The objective of the linear model solver is to construct a path from a given complementary triple $(\hat{z}, \hat{w}, \hat{v})$ to a solution $(\bar{z}, \bar{w}, \bar{v})$. The algorithm used to solve the linear problem is identical to that given in [66]; however, artificial variables are incorporated into the model. The augmented system is then:

\[
Mz - w + v + Da + \frac{(1 - t)}{s}(sr) + q = 0 \quad (8)
\]

\[
w^T(z - l) = 0 \quad (9)
\]

\[
v^T(u - z) = 0 \quad (10)
\]

\[
z \in B, w \in \mathbb{R}_+^n, v \in \mathbb{R}_+^n, a \equiv 0, t \in [0, 1] \quad (11)
\]

where $r$ is the residual, $t$ is the path parameter, and $a$ is a vector of artificial variables. The residual is scaled by $s$ to improve numerical stability.

The addition of artificial variables enables us to construct an initial invertible basis consistent with the given starting point even under rank deficiency. The procedure consists of two parts: constructing an initial guess as to the basis and then recovering from rank deficiency to obtain an invertible basis. The crash technique gives a good approximation to the active set. The first phase of the algorithm uses this information to construct a basis by partitioning the variables into three sets:

1. $W = \{ i \in \{1, \ldots, n\} \mid \hat{z}_i = l_i \text{ and } \hat{w}_i > 0 \}$
2. $V = \{ i \in \{1, \ldots, n\} \mid \hat{z}_i = u_i \text{ and } \hat{v}_i > 0 \}$
3. $Z = \{1, \ldots, n\} \setminus W \cup V$

Since $(\hat{z}, \hat{w}, \hat{v})$ is a complementary triple, $Z \cap W \cap V = \emptyset$ and $Z \cup W \cup V = \{1, \ldots, n\}$. Using the above guess, we can recover an invertible basis consistent with the starting point by defining $D$ appropriately. The technique relies upon the factorization to indicate the linearly dependent rows and columns of the basis matrix. Some of the variables may be nonbasic, but not at their bounds. For such variables, the corresponding artificial will be basic.

We use a modified version of EXPAND [111] to perform the ratio test. Variables are prioritized as follows:

1. $t$ leaving at its upper bound.
2. Any artificial variable.
3. Any $z$, $w$, or $v$ variable.

If a choice as to the leaving variable can be made while maintaining numerical stability and sparsity, we choose the variable with the highest priority (lowest number above).

When an artificial variable leaves the basis and a $z$-type variable enters, we have the choice of either increasing or decreasing that entering variable because it is nonbasic but not at a bound. The determination is made such that $t$ increases and stability is preserved.

If the code is forced to use a ray start at each iteration (lemke_start always), then the code carries out Lemke’s method, which is known [61] not to cycle. However, by default, we use a regular start to
guarantee that the generated path emanates from the current iterate. Under appropriate conditions, this
guarantees a decrease in the nonlinear residual. However, it is then possible for the pivot sequence in the
linear model to cycle. To prevent this undesirable outcome, we attempt to detect the formation of a cycle
with the heuristic that if a variable enters the basis more that a given number of times, we are cycling.
The number of times the variable has entered is reset whenever \( t \) increases beyond its previous maximum
or an artificial variable leaves the basis. If cycling is detected, we terminate the linear solver at the largest
value of \( t \) and return this point.

Another heuristic is added when the linear code terminates on a ray. The returned point in this case is
not the base of the ray. We move a slight distance up the ray and return this new point. If we fail to solve
the linear subproblem five times in a row, a Lemke ray start will be performed in an attempt to solve the
linear subproblem. Computational experience has shown this to be an effective heuristic and generally
results in solving the linear model. Using a Lemke ray start is not the default mode, since typically many
more pivots are required.

For times when a Lemke start is actually used in the code, an advanced ray can be used. We basically
choose the ”closest” extreme point of the polytope and choose a ray in the interior of the normal cone at
this point. This helps to reduce the number of pivots required. However, this can fail when the basis
responding to the cell is not invertible. We then revert to the Lemke start.

Since the EXPAND pivot rules are used, some of the variables may be nonbasic, but slightly infeasible,
as the solution. Whenever the linear code finishes, the nonbasic variables are put at their bounds and
the basic variables are recomputed using the current factorization. This procedure helps to find the best
possible solution to the linear system.

The resulting linear solver as modified above is robust and has the desired property that we start from
\((\hat{z}, \hat{w}, \hat{v})\) and construct a path to a solution.

4.41.4.2.5 Other Features Some other heuristics are incorporated into the code. During the first
iteration, if the linear solver fails to find a Newton point, a Lemke start is used. Furthermore, under
repeated failures during the linear solve, a Lemke start will be attempted. A gradient step can also be
used when we fail repeatedly.

The proximal perturbation is reduced at each major iteration. However, when numerical difficulties are
encountered, it will be increased to a fraction of the current merit function value. These are determined
when the linear solver returns a Reset or Singular status.

Spacer steps are taken every major iteration, in which the iterate is chosen to be the best point for the
normal map. The corresponding basis passed into the Lemke code is also updated.

Scaling is done based on the diagonal of the matrix passed into the linear solver.

We finally note, that if the merit function fails to show sufficient decrease over the last 100 iterates, a
restart will be performed, as this indicates we are close to a stationary point.

4.41.4.3 Difficult Models

4.41.4.3.1 Ill-Defined Models A problem can be ill-defined for several different reasons. We con-
centrate on the following particular cases. We will call \( F \) well-defined at \( \bar{x} \in C \) if \( \bar{x} \in D \) and ill-defined at
\( \bar{x} \) otherwise. Furthermore, we define \( F \) to be well-defined near \( \bar{x} \in C \) if there exists an open neighborhood
of \( \bar{x}, N(\bar{x}) \), such that \( C \cap N(\bar{x}) \subseteq D \). By saying the function is well-defined near \( \bar{x} \), we are simply stating
that \( F \) is defined for all \( x \in C \) sufficiently close to \( \bar{x} \). A function not well-defined near \( \bar{x} \) is termed
ill-defined near \( \bar{x} \).

We will say that \( F \) has a well-defined Jacobian at \( \bar{x} \in C \) if there exists an open neighborhood of \( \bar{x},
N(\bar{x}) \), such that \( N(\bar{x}) \subseteq D \) and \( F \) is continuously differentiable on \( N(\bar{x}) \). Otherwise the function has
an ill-defined Jacobian at $\bar{x}$. We note that a well-defined Jacobian at $\bar{x}$ implies that the MCP has a well-defined function near $\bar{x}$, but the converse is not true.

PATH uses both function and Jacobian information in its attempt to solve the MCP. Therefore, both of these definitions are relevant. We discuss cases where the function and Jacobian are ill-defined in the next two subsections. We illustrate uses for the merit function information and final point statistics within the context of these problems.

**Function Undefined** We begin with a one-dimensional problem for which $F$ is ill-defined at $x = 0$ as follows:

$$0 \leq x \perp \frac{1}{x} \geq 0.$$

Here $x$ must be strictly positive because $\frac{1}{x}$ is undefined at $x = 0$. This condition implies that $F(x)$ must be equal to zero. Since $F(x)$ is strictly positive for all $x$ strictly positive, this problem has no solution.

We are able to perform this analysis because the dimension of the problem is small. Preprocessing linear problems can be done by the solver in an attempt to detect obviously inconsistent problems, reduce problem size, and identify active components at the solution. Similar processing can be done for nonlinear models, but the analysis becomes more difficult to perform. Currently, PATH only checks the consistency of the bounds and removes fixed variables and the corresponding complementary equations from the model.

A modeler would likely not know a priori that a problem has no solution and would thus attempt to formulate and solve it. GAMS code for the model above is provided in Figure 8. We must specify an initial value for $x$ in the code. If we were to not provide one, GAMS would use $x = 0$ as the default value, notice that $F$ is undefined at the initial point, and terminate before giving the problem to PATH. The error message indicates that the function $\frac{1}{x}$ is ill-defined at $x = 0$, but does not imply that the corresponding MCP problem has no solution.

**Figure 8: GAMS Code for Ill-Defined Function**

```gams
positive variable x;
equations F;
F.. 1 / x =g= 0;
model simple / F.x /;
x.l = 1e-6;
solve simple using mcp;
```

After setting the starting point, GAMS generates the model, and PATH proceeds to "solve" it. A portion of the output relating statistics about the solution is given in Figure 9. PATH uses the Fischer Function indicator as its termination criteria by default, but evaluates all of the merit functions given in Section Merit Functions at the final point. The Normal Map merit function, and to a lesser extent, the complementarity error, indicate that the "solution" found does not necessarily solve the MCP.

**Figure 9: PATH Output for Ill-Defined Function**

To indicate the difference between the merit functions, Figure 10 plots them all for this simple example. We note that as $x$ approaches positive infinity, numerically, we are at a solution to the problem with respect to all of the merit functions except for the complementarity error, which remains equal to one. As $x$ approaches zero, the merit functions diverge, also indicating that $x = 0$ is not a solution.

The natural residual and Fischer function tend toward 0 as $x \downarrow 0$. From these measures, we might think $x = 0$ is the solution. However, as previously remarked $F$ is ill-defined at $x = 0$. $F$ and $\nabla F$ become very large, indicating that the function (and Jacobian) might not be well-defined. We might be tempted to conclude that if one of the merit function indicators is not close to zero, then we have not found a solution. This conclusion is not always warranted. When one of the indicators is non-zero, we have reservations about the solution, but we cannot eliminate the possibility that we are actually close to a solution. If we slightly perturb the original problem to

$$0 \leq x \perp \frac{1}{x+\epsilon} \geq 0$$

for a fixed $\epsilon > 0$, the function is well-defined over $C = \mathbb{R}_+^n$ and has a unique solution at $x = 0$. In this case, by starting at $x > 0$ and sufficiently small, all of the merit functions, with the exception of the Normal Map, indicate that we have solved the problem as is shown by the output in Figure 11 for $\epsilon = 1 \times 10^{-6}$ and $x = 1 \times 10^{-20}$.

In this case, the Normal Map is quite large and we might think that the function and Jacobian are undefined. When only the normal map is non-zero, we may have just mis-identified the optimal basis. By setting the merit_function normal option, we can resolve the problem, identify the correct basis, and solve the problem with all indicators being close to zero. This example illustrates the point that all of these tests are not infallible. The modeler still needs to do some detective work to determine if they have found a solution or if the algorithm is converging to a point where the function is ill-defined.

**Jacobian Undefined** Since PATH uses a Newton-like method to solve the problem, it also needs the Jacobian of $F$ to be well-defined. One model for which the function is well-defined over $C$, but for which the Jacobian is undefined at the solution is: $0 \leq x_{\bot} - \sqrt{x} \geq 0$. This model has a unique solution at $x = 0$.

Using PATH and starting from the point $x = 1 \times 10^{-14}$, PATH generates the output given in Figure 12.

**Figure 12:** PATH Output for Ill-Defined Jacobian

We can see that the gradient of the Fischer Function is nonzero and the Jacobian is beginning to become large. These conditions indicate that the Jacobian is undefined at the solution. It is therefore important for a modeler to inspect the given output to guard against such problems.

If we start from $x = 0$, PATH correctly informs us that we are at the solution. The large value reported for the Jacobian is an indication that the Jacobian is undefined.

### 4.41.4.3.2 Poorly Scaled Models

Well-defined problems can still have various numerical problems that impede the algorithm's convergence. One particular problem is a badly scaled Jacobian. In such cases, we can obtain a poor "Newton" direction because of numerical problems introduced in the linear algebra performed. This problem can also lead the code to a point from which it cannot recover.

The final model given to the solver should be scaled such that we avoid numerical difficulties in the linear algebra. The output provided by PATH can be used to iteratively refine the model so that we eventually end up with a well-scaled problem. We note that we only calculate our scaling statistics at the starting point provided. For nonlinear problems these statistics may not be indicative of the overall scaling of the model. Model specific knowledge is very important when we have a nonlinear problem because it can be used to appropriately scale the model to achieve a desired result.

We look at the titan.gms model in MCPLIB, that has some scaling problems. The relevant output from PATH for the original code is given in Figure 13.

**Figure 13:** PATH Output - Poorly Scaled Model
INITIAL POINT STATISTICS
Maximum of X. . . . . . . . . . 4.1279e+06 var: (w.29)
Maximum of F. . . . . . . . . . 2.2516e+00 eqn: (a1.33)
Maximum of Grad F . . . . . . 6.7753e+06 eqn: (a1.29) var: (x1.29)

INITIAL JACOBIAN NORM STATISTICS
Maximum Row Norm. . . . . . . 9.4504e+06 eqn: (a2.29)
Minimum Row Norm. . . . . . . 2.7680e-03 eqn: (g.10)
Maximum Column Norm . . . . . 9.4504e+06 var: (x2.29)
Minimum Column Norm . . . . . 1.3840e-03 var: (w.10)

The maximum row norm is defined as
\[
\max_{1 \leq i \leq n} \sum_{1 \leq j \leq n} |(\nabla F(x))_{ij}|
\]
and the minimum row norm is
\[
\min_{1 \leq i \leq n} \sum_{1 \leq j \leq n} |(\nabla F(x))_{ij}| .
\]
Similar definitions are used for the column norm. The norm numbers for this particular example are not extremely large, but we can nevertheless improve the scaling. We first decided to reduce the magnitude of the a1 block of equations as indicated by PATH. Using the GAMS modeling language, we can scale particular equations and variables using the .scale attribute. To turn the scaling on for the model we use the .scaleopt model attribute. After scaling the a1 block, we re-ran PATH and found an additional block of equations that also needed scaling, a2. We also scaled some of the variables, g and w. The code added to the model follows:

```gams
  titan.scaleopt = 1;
a1.scale(i) = 1000;
a2.scale(i) = 1000;
g.scale(i) = 1/1000;
w.scale(i) = 100000;
```

By scaling these equation and variable blocks, we have improved the model scaling. The statistics for the manually scaled model are given in Figure 14.

**Figure 14:** PATH Output - Well-Scaled Model

INITIAL POINT STATISTICS
Maximum of X. . . . . . . . . . 1.0750e+03 var: (x1.49)
Maximum of F. . . . . . . . . . 3.9829e-01 eqn: (g.10)
Maximum of Grad F . . . . . . 6.7753e+02 eqn: (a1.29) var: (x1.29)

INITIAL JACOBIAN NORM STATISTICS
Maximum Row Norm. . . . . . . . 9.4504e+06 eqn: (a2.29)
Minimum Row Norm. . . . . . . . 2.7680e-03 eqn: (g.10)
Maximum Column Norm . . . . . . 9.4904e+03 var: (x2.29)
Minimum Column Norm . . . . . . 1.3840e-01 var: (w.10)

For this particular problem PATH cannot solve the unscaled model, while it can find a solution to the scaled model. Using the scaling features of the GAMS language and the information provided by PATH we are able to remove some of the problem's difficulty and obtain better performance from PATH.

It is possible to get even more information on initial point scaling by inspecting the GAMS listing file. The equation row listing gives the values of all the entries of the Jacobian at the starting point. The row norms generated by PATH give good pointers for starting to use the row listing.

Not all of the numerical problems are directly attributable to poorly scaled models. Problems for which the Jacobian of the active constraints is singular or nearly singular can also cause numerical difficulty as illustrated next.
4.41.4.3.3 Singular Models  
Assuming that the problem is well-defined and properly scaled, we can still have a Jacobian for which the active constraints are singular or nearly singular (i.e. it is ill-conditioned). When problems are singular or nearly singular, we are also likely to have numerical problems. As a result the "Newton" direction obtained from the linear problem solver can be very bad. In PATH, we can use proximal perturbation or add artificial variables to attempt to remove the singularity problems from the model. However, it is most often beneficial for solver robustness to remove singularities if possible.

The easiest problems to detect are those for which the Jacobian has zero rows and columns. A simple problem for which we have zero rows and columns is:

\[-2 \leq x \leq 2 \perp -x^2 + 1.\]

Note that the Jacobian, \(-2x\), is non-singular at all three solutions, but singular at the point \(x = 0\). Output from PATH on this model starting at \(x = 0\) is given in Figure 15.

**Figure 15: PATH Output - Zero Rows and Columns**

We display in the code the variables and equations for which the row/column in the Jacobian is close to zero. These situations are problematic and for nonlinear problems likely stem from the modeler providing an inappropriate starting point or fixing some variables resulting in some equations becoming constant. We note that the solver may perform well in the presence of zero rows and/or columns, but the modeler should make sure that these are what was intended.

Singularities in the model can also be detected by the linear solver. This in itself is a hard problem and prone to error. For matrices which are poorly scaled, we can incorrectly identify "linearly dependent" rows because of numerical problems. Setting `output_factorization_singularities yes` in an options file will inform the user which equations the linear solver thinks are linearly dependent. Typically, singularity does not cause a lot of problems and the algorithm can handle the situation appropriately. However, an excessive number of singularities are cause for concern. A further indication of possible singularities at the solution is a lack of quadratic convergence to the solution.

4.41.5 Case Study: Von Thunen Land Model

We now turn our attention towards using the diagnostic information provided by PATH to improve an actual model. The Von Thunen land model is a problem recognized in the mathematical programming literature for its computational difficulty. We attempt to understand more carefully the facets of the problem that make it difficult to solve. This will enable us to outline and identify these problems and furthermore to extend the model to a more realistic and computationally more tractable form.
4.41.5.1 Classical Model

The problem is cast in the Arrow-Debreu framework as an equilibrium problem. The basic model is a closed economy consisting of three economic agents, a landowner, a worker, and a porter. There is a central market, around which concentric regions of land are located. Since the produced goods have to be delivered to the market, this is an example of a spatial price equilibrium. The key variables of the model are the prices of commodities, land, labour and transport. Given these prices, it is assumed that the agents demand certain amounts of the commodities, which are supplied so as to maximize profit in each sector. Walras’ law is then a consequence of the assumed competitive paradigm, namely that supply will equal demand in the equilibrium state.

We now describe the problems that the consumers and the producers face. We first look at consumption and derive a demand function for each of the consumer agents in the economy. Each of these agents has a utility function, that they wish to maximize subject to their budgetary constraints. As is typical in such problems, the utility function is assumed to be Cobb-Douglas:

\[ u_a(d) = \prod_c d_c^{\alpha_{c,a}}, \quad \alpha_{c,a} \geq 0, \sum_c \alpha_{c,a} = 1, \]

where the \( \alpha_{c,a} \) are given parameters dependent only on the agent. For each agent \( a \), the variables \( d_c \) represent quantities of the desired commodities \( c \). In the Von Thunen model, the goods are wheat, rice, corn and barley. The agent’s endowments determine their budgetary constraint as follows. Given current market prices, an agent’s wealth is the value of the initial endowment of goods at those prices. The agent’s problem is therefore

\[ \max d u_a(d) \text{ subject to } \langle p, d \rangle \leq \langle p, e_a \rangle, d \geq 0, \]

where \( e_a \) is the endowment bundle for agent \( a \). A closed form solution, corresponding to demand from agent \( a \) for commodity \( c \) is thus

\[ d_{c,a}(p) := \frac{\alpha_{c,a} \langle p, e_a \rangle}{p_c}. \]

Note that this assumes the prices of the commodities \( p_c \) are positive.

The supply side of the economy is similar. The worker earns a wage \( w_L \) for his labour input. The land is distributed around the market in rings with a rental rate \( w_r \) associated with each ring \( r \) of land. The area of land \( a_r \) in each ring is an increasing function of \( r \). The model assumes that labour and land are substitutable via a constant elasticities of substitution (CES) function.

Consider the production \( x_{c,r} \) of commodity \( c \) in region \( r \). In order to maximize profit (or minimize costs), the labour \( y_L \) and land use \( y_r \) solve

\[ \min w_L y_L + w_r y_r \text{ subject to } \phi_c y_L^\beta_c y_r^{1-\beta_c} \geq x_{c,r}, y_L, y_r \geq 0, \]

where \( \phi_c \) is a given cost function scale parameter, and \( \beta_c \in [0, 1] \) is the share parameter. The technology constraint is precisely the CES function allowing a suitable mix of labour and land use. Again, a closed form solution can be calculated. For example, the demand for labour in order to produce \( x_{c,r} \) of commodity \( c \) in region \( r \) is given by

\[ x_{c,r} \left( \frac{w_r}{\phi_c w_L} \right)^{\beta_c} \left( \frac{w_L}{w_r} \right)^{1-\beta_c}. \]

Considering all such demands, this clearly assumes the prices of inputs \( w_L, w_r \) are positive. A key point to note is that input commodity (factor) demands to produce \( x_{c,r} \) can be determined by first solving (12) for unit demand \( x_{c,r} \equiv 1 \) and then multiplying these factor demands by the actual amount desired. Let \( \bar{y}_L \) and \( \bar{y}_r \) denote the optimal solutions of (12) with \( x_{c,r} \equiv 1 \). Using this fact, the unit production cost \( \gamma_{c,r} \) for commodity \( c \) in region \( r \) can be calculated as follows:
Transportation is provided by a porter, earning a wage \( w_p \). If we denote the unit cost for transportation of commodity \( c \) by \( t_c \), then unit transportation cost to market is

\[
T_{c,r}(w_p) := t_c d_r w_p,
\]

where \( d_r \) is the distance of region \( r \) to the market. Spatial price equilibrium arises from the consideration:

\[
0 \leq x_{c,r} \perp \gamma_{c,r}(w_L, w_r) + T_{c,r}(w_p) \geq p_c.
\]

This is intuitively clear; it states that commodity \( c \) will be produced in region \( r \) only if the combined cost of production and transportation equals the market price.

The above derivations assumed that the producers and consumers acted as price takers. Walras’ law is now invoked to determine the prices so that markets clear. The resulting complementarity problem is:

\[
\gamma_{c,r} = \frac{1}{\phi_c} \left( \frac{w_L}{\beta_c} \right)^{\beta_c} \left( \frac{w_r}{1 - \beta_c} \right)^{1 - \beta_c}
\]

\[
0 \leq x_{c,r} \perp \gamma_{c,r} + T_{c,r}(w_p) \geq p_c
\]

\[
0 \leq w_L \perp e_L \geq \sum_{r,c} x_{c,r} \frac{\beta_c \gamma_{c,r}}{w_L}
\]

\[
0 \leq w_r \perp a_r \geq \sum_{c} x_{c,r} (1 - \beta_c) \gamma_{c,r} \frac{1}{w_r}
\]

\[
0 \leq w_p \perp e_P \geq \sum_{r,c} t_c d_r x_{c,r}
\]

\[
0 \leq p_c \perp \sum_{r} x_{c,r} \geq \frac{\alpha_c, p e_p w_p + \alpha_c, L e_l w_L + \alpha_c, O \sum_r w_r a_r}{p_c}
\]

Note that in (15), (16) and (17), the amounts of labour, land and transport are bounded from above, and hence the prices on these inputs are determined as multipliers (or shadow prices) on the corresponding constraints. The final relationship (18) in the above complementarity problem corresponds to market clearance; prices are nonnegative and can only be positive if supply equals demand. (Some modelers multiply the last inequality throughout by \( p_c \). This removes problems where \( p_c \) becomes zero, but can also introduce spurious solutions.)

The Arrow-Debreu theory guarantees that the problem is homogeneous in prices; \((x, \lambda w, \lambda p)\) is also a solution whenever \((x, w, p)\) solves the above. Typically this singularity in the model is removed by fixing a numeraire, that is fixing a price (for example \( w_L = 1 \)) and dropping the corresponding complementary relationship.
Unfortunately, in this formulation even after fixing a numeraire, some of the variables \( p \) and \( w \) may go to zero, resulting in an ill-defined problem. In the case of the Von Thunen land model, the rental price of land \( w_r \) decreases as the distance to market increases, and for remote rings of land, it becomes zero. A standard modeling fix is to put artificial lower bounds on these variables. Even with this fix, the problem typically remains very hard to solve. More importantly, the homogeneity property of the prices used above to fix a numeraire no longer holds, and the corresponding complementary relationship (which was dropped from the problem) may fail to be satisfied. It therefore matters which numeraire is fixed, and many modelers run into difficulty since in many cases the solution found by a solver is invalid for the originally posed model.

In order to test our diagnostic information, we implemented a version of the above model in GAMS. The model corresponds closely to the MCPLIB model pgvon105.gms except we added more regions to make the problem even more difficult. The model file has been documented more fully, and the data rounded to improve clarity.

Our first trial was to solve the model without fixing a numeraire. In this case, PATH 4.x failed to find a solution. At the starting point, the indicators described in Section Ill-Defined Models are reasonable, and there are no zero rows/columns in the Jacobian. At the best point found, all indicators are still reasonable. However, the listing file indicates a large number of division by zero problems occurring in (16). We also note that a nonzero proximal perturbation is used in the first iteration of the crash method. This is an indication of singularities. We therefore added an option to output factorization singularities, and singularities appeared in the first iteration. At this point, we decided to fix a numeraire to see if this alleviated the problem.

We chose to fix the labour wage rate to 1. After increasing the iterations allowed to 100,000, PATH 4.x solved the problem. The statistics at the solution are cause for concern. In particular, the gradient of the Fischer function is 7 orders of magnitude larger than all the other residuals. Furthermore, the Jacobian is very large at the solution point. Looking further in the listing file, a large number of division by zero problems occur in (16).

To track down the problem further, we added an artificial lower bound on the variables \( w_r \) of \( 10^{-5} \), that would not be active at the aforementioned solution. Resolving gave the same “solution”, but resulted in the domain errors disappearing.

Although the problem is solved, there is concern on two fronts. Firstly, the gradient of the Fischer function should go to zero at the solution. Secondly, if a modeler happens to make the artificial lower bounds on the variables a bit larger, then they become active at the solution, and hence the constraint that has been dropped by fixing the price of labour at 1 is violated at this point. Of course, the algorithm is unable to detect this problem, since it is not part of the model that is passed to it, and the corresponding output looks satisfactory.

We are therefore led to the conclusion that the model as postulated is ill-defined. The remainder of this section outlines two possible modeling techniques to overcome the difficulties with ill-defined problems of this type.

### 4.41.5.2 Intervention Pricing

The principal difficulty is the fact that the rental prices on land go to zero as proximity to the market decreases, and become zero for sufficiently remote rings. Such a property is unlikely to hold in a practical setting. Typically, a landowner has a minimum rental price (for example, land in fallow increases in value). As outlined above, a fixed lower bound on the rental price violates the well-established homogeneity property. A suggestion postulated by Professor Thomas Rutherford is to allow the landowner to intervene and “purchase-back” his land whenever the rental cost gets smaller than a certain fraction of the labour wage.

The new model adds a (homogeneous in price) constraint

\[
0 \leq i_r \quad \perp \quad w_r \geq 0.0001 \times w_L
\]
and modifies (16) and (18) as follows:

\[
0 \leq w_r \perp a_r - i_r \geq \sum_c x_{c,r} \frac{(1 - \beta_c) \gamma_{c,r}}{w_r}
\]

\[
0 \leq p_c \perp \sum_r x_{c,r} \frac{\alpha_{c,p} p w_p + \alpha_{c,L} w_L + \alpha_{c,O} \sum_r w_r (a_r - i_r)}{p_c}
\]

Given the intervention purchase, we can now add a lower bound on \( w_r \) to avoid division by zero errors. In our model we chose \( 10^{-5} \) since this will never be active at the solution and therefore will not affect the positive homogeneity. After this reformulation, PATH 4.x solves the problem. Furthermore, the gradient of the Fischer function, although slightly larger than the other residuals, is quite small, and can be made even smaller by reducing the convergence tolerance of PATH. Inspecting the listing file, the only difficulties mentioned are division by zero errors in the market clearance condition (19), that can be avoided a posteriori by imposing an artificial (inactive) lower bound on these prices. We chose not to do this however.

4.41.5.3 Nested Production and Maintenance

Another observation that can be used to overcome the land price going to zero is the fact that land typically requires some maintenance labour input to keep it usable for crop growth. Traditionally, in economics, this is carried out by providing a nested CES function as technology input to the model. The idea is that commodity \( c \) in region \( r \) is made from labour and an intermediate good, which is "maintained land". Essentially, the following production problem replaces (12):

\[
\begin{align*}
\min_{y_M, y_L, y_r, g} & \quad w_L (y_M + y_L) + w_r y_r \\
\text{subject to} & \quad y_r \geq (1 - \beta_c - \epsilon) g \\
& \quad y_M \geq \epsilon g \\
& \quad \phi_c y_L^{\beta_c} g^{-\beta_c} \geq 1, \\
& \quad y_M, y_L, y_r, g \geq 0.
\end{align*}
\]

Note that the variable \( y_M \) represents "maintenance labour" and \( g \) represents the amount of "maintained land" produced, an intermediate good. The process of generating maintained land uses a Leontieff production function, namely

\[
\min (\lambda_r y_r, \lambda_M y_M) \geq g.
\]

Here \( \lambda_M = \frac{1}{\lambda_r} \), \( \epsilon \) small, corresponds to small amounts of maintenance labour, while \( \lambda_r = \frac{1}{1 - \beta_c - \epsilon} \) is chosen to calibrate the model correctly. A simple calculus exercise then generates appropriate demand and cost expressions. The resulting complementarity problem comprises (14), (17), (18) and

\[
\gamma_{c,r} = \frac{w_r^{\beta_c}}{\phi_c} \left( \frac{w_L \epsilon + w_r (1 - \beta_c - \epsilon)}{1 - \beta_c} \right)^{1-\beta_c}
\]

\[
0 \leq w_L \perp e_L \geq \sum_{r,c} x_{c,r} \gamma_{c,r} \frac{\beta_c}{w_L} + \frac{\epsilon (1 - \beta_c)}{w_L \epsilon + w_r (1 - \beta_c - \epsilon)}
\]

\[
0 \leq w_r \perp a_r \geq \sum_c x_{c,r} \gamma_{c,r} \frac{(1 - \beta_c)}{w_L \epsilon + w_r (1 - \beta_c - \epsilon)}
\]

After making the appropriate modifications to the model file, PATH 4.x solved the problem on defaults without any difficulties. All indicators showed the problem and solution found to be well-posed.
4.42 PYOMO

4.42.1 Introduction

GAMS/PYOMO allows users to solve GAMS models using solvers within the PYOMO modeling system. The GAMS/PYOMO link comes free with any GAMS system. Users must have a licensed PYOMO system installed and have the PYOMO executable in their path.

To run GAMS/PYOMO, just specify the solver as pyomo. For example, if we wish to solve the transport.gms model, we would run

```bash
>> gams transport.gms lp=pyomo
```

For other GAMS solvers, options can be passed on via solver option files. GAMS/PYOMO specific options are described in the section GAMS/PYOMO Options.

By default, GAMS/PYOMO tries to map the status from the Pyomo run into the GAMS solve- and model status.

GAMS external equations and extrinsic functions cannot be used with GAMS/PYOMO.

4.42.2 PYOMO Path

GAMS searches for an PYOMO executable using the following hierarchy:

- Via the options PyomoPath and RunPyomo within a GAMS/PYOMO solver option file.
- An pyomopath.txt file located in the GAMS system directory specifying the path of the PYOMO executable.
- The system path.

For example, GAMS will first search for the PYOMO executable within the pyomo.opt file, if specified. If not found, it will search within the GAMS system directory for a file called pyomopath.txt specifying the PYOMO directory. If pyomopath.txt is still not found GAMS will try the system path.

If no PYOMO executable is found, the user will see a message similar to

```
PYOMO Link 24.5.1 r50798 Released Jun 23, 2015 VS8 x86 32bit/MS Windows
--- Using Pyomo solver bonmin
--- No PyomoPath option or "pyomopath.txt" file found
--- System PATH will be used
```

There may also be an output indicating that PYOMO was not found, either because it was not installed or because it was not found in the system path.

4.42.3 GAMS/PYOMO Options

4.42.3.1 General options
### 4.42.3.2 Other options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>DotMod</td>
<td>Pyomo input file name</td>
<td>model.py</td>
</tr>
</tbody>
</table>

The **Option** specifier is used to specify desired PYOMO options within the PYOMO modeling system. For example, if a user wishes to run PYOMO/CBC with the options `threads=4 scaling=off` then the user creates a file called `pyomo.opt` with the entry

```plaintext
option "thread=4 scaling=off";
```

### 4.43 SBB

#### 4.43.1 Introduction

SBB is a GAMS solver for Mixed Integer Nonlinear Programming (MINLP) models. It is based on a combination of the standard Branch and Bound (B&B) method known from Mixed Integer Linear Programming and some of the standard NLP solvers already supported by GAMS. SBB can use all GAMS NLP solvers as subsolvers but it works best with NLP solvers that can utilize a near optimal point as a starting point like Conopt, Minos, and Snopt.

SBB supports all types of discrete variables supported by GAMS, including Binary, Integer, Semiint, Sos1, and Sos2.

#### 4.43.2 The Branch and Bound Algorithm

The Relaxed Mixed Integer Nonlinear Programming (RMINLP) model is initially solved using the starting point provided by the modeler. SBB will stop immediately if the RMINLP model is unbounded or infeasible, or if it fails (see option `infeasseq` and `failseq` below for an exception). If all discrete variables in the RMINLP model are integer, SBB will return this solution as the optimal integer solution. Otherwise, the current solution is stored and the Branch and Bound procedure will start.

During the Branch and Bound process, the feasible region for the discrete variables is subdivided, and bounds on discrete variables are tightened to new integer values to cut off the current non-integer solutions. Each time a bound is tightened, a new, tighter NLP submodel is solved starting from the optimal solution to the previous looser submodel. The objective function values from the NLP submodel is assumed to
be lower bounds on the objective in the restricted feasible space (assuming minimization), even though
the local optimum found by the NLP solver may not be a global optimum. If the NLP solver returns a
Locally Infeasible status for a submodel, it is usually assumed that there is no feasible solution to the
submodel, even though the infeasibility only has been determined locally (see option infeasseq below for
an exception). If the model is convex, these assumptions will be satisfied and SBB will provide correct
bounds. If the model is not convex, the objective bounds may not be correct and better solutions may
exist in other, unexplored parts of the search space.

4.43.3 SBB with Pseudo Costs

Over the last decades quite a number of search strategies have been successfully introduced for mixed
integer linear programming (for details see e.g. J.T. Linderoth and M.W.P. Savelsbergh, A Computational
Study of Search Strategies for Mixed Integer Programming, INFORMS Journal on Computing, 11(2),
1999). Pseudo costs are key elements of sophisticated search strategies. Using pseudo costs, we can
estimate the degradation of the objective function if we move a fractional variable to a close integer
value. Naturally, the variable selection can be based on pseudo costs (see SBB option varsel). Node
selection can also make use of pseudo cost: If we can estimate the change of the objective for moving
one fractional variable to the closed integer value, we can then aggregate this change for all fractional
variables, to estimate the objective of the best integer solution reachable from a particular node (see SBB
option nodesel).

Unfortunately, the computation of pseudo cost can be a substantial part of the overall computation.
Models with a large number of fractional variables in the root node are not good candidates for search
strategies which require pseudo costs (varsel 3, nodesel 3,5,6). The impact (positive or negative) of
using pseudo cost depends significantly on the particular model. At this stage, general statements are
difficult to make.

Selecting pseudo cost related search strategies (varsel 3, nodesel 3,5,6) may use computation time
which sometimes does not pay off. However, we encourage the user to try these options for difficult models
which require a large number of branch-and-bound nodes to solve.

4.43.4 The SBB Options

SBB works like other GAMS solvers, and many options can be set in the GAMS model. The most
relevant GAMS options are IterLim, ResLim, NodLim, OptCA, OptCR, OptfFile, Cheat, and CutOff. A
description of all available GAMS options can be found in the GAMS User's Guide Solver related options.
GAMS options PriorOpt and TryInt are also accepted by SBB.

SBB uses the var.prior information to select the fractional variable with the smallest priority during
the variable selection process. SBB uses the TryInt information to set the branching direction in the B&B
algorithm. At the beginning, SBB looks at the levels of the discrete variables provided by the user and if
Abs(Round(x.l)-x.l) < m.TryInt, SBB will branch on that variable in the direction of Round(x.l). For
example, x.l=0.9 and m.TryInt=0.2. We have Abs(Round(0.9)-0.9)=0.1 < 0.2, so when SBB decides to
branch on this variable (because it is fractional, lets say with value 0.5), the node explored next will have
the additional constraint x ≥ 1 (the node with x ≤ 0 will be explored later). If everything goes well (there
is the chance that we end up in a different local optima in the subsolves for non-convex problems), SBB
should reproduce a preset incumbent solution in a couple of nodes.

If you specify <modelname>.OptFile = 1; before the Solve statement in your GAMS model, SBB will
then look for and read an option file with the name sbb.opt (see The Solver Option File for general use
of solver option files). Unless explicitly specified in the SBB option file, the NLP subsolvers will not read
an option file. The syntax for the SBB option file is

    optname value
with one option on each line.

For example,

```
rootsolver conopt.1
subsolver snopt
loginterval 10
```

The first two lines determine the NLP subsolvers for the Branch and Bound procedure. CONOPT with the option file `conopt.opt` will be used for solving the root node. SNOPT with no option file will be used for the remaining nodes. The last option determines the frequency for log line printing. Every 10th node, and each node with a new integer solution, causes a log line to be printed. The following options are implemented:

<table>

</tbody>
</table>

**acceptnonopt (boolean):** accepts feasible solution from subsolver

If this option is set to 1 and the subsolver terminates with solver status *Terminated by Solver* and model status *Intermediate Nonoptimal* SBB takes this as a good solution and keeps on going. In default mode such a return is treated as a subsolver failure and the failseq is consulted.

Default: 0

**avgresmult (integer):** average resource multiplicator

Similar to subres, this option allows the user to control the time limit spend in a node. SBB keeps track of how much time is spent in the nodes, and builds an average over time. This average multiplied by the factor `avgresmult` is set as a time limit for solving a node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure: the node is ignored or the solvers in the failseq are called. The default multiplier `avgresmult` is 5. Setting `avgresmult` to 0 will disable the automatic time limit feature. A multiplier is not very useful for very small node solution times; therefore, independent of each node, SBB grants the solver at least 5 seconds to solve the node. The competing option `subres` overwrites the automatically generated resource limit.

Default: 5

**dfsstay (integer):** keeps DFS node selection after solution has been found

If the node selection is a B*/DFS mix, SBB switches frequently to DFS node selection mode. It switches back into B* node selection mode, if no subnodes were created (new int, pruned, infeasible, fail). It can be advantageous to search the neighborhood of the last node also in a DFS manner. Setting `dfsstay` to `n` instructs SBB to stay in DFS mode for another `n` nodes.

Default: 0

**epint (real):** integer feasibility tolerance

The integer infeasibility tolerance.

Range: $[1e-9, 1]$

Default: 1.0e-5

**failseq (string):** solver sequence for failed nodes
where \texttt{solver1} is the name of a GAMS NLP solver to be used if the default solver fails, i.e., if it was not stopped by an iteration, resource, or domain limit and does not return a locally optimal or locally infeasible solution. \texttt{n1} is the value of optfile passed to the alternative NLP solver. If \texttt{.n1} is left blank it is interpreted as zero. Similarly, \texttt{solver2} is the name of a GAMS NLP solver that is used if \texttt{solver1} fails, and \texttt{n2} is the value of optfile passed to the second NLP solver. If you have a difficult model where solver failures are not unlikely, you may add more \texttt{solver.n} pairs. You can use the same solver several times with different options files. \texttt{failseq conopt conopt.2 conopt.3} means to try CONOPT with no options file. If this approach also fails, try CONOPT with options file \texttt{conopt.op2}, and if it again fails, try CONOPT with options file \texttt{conopt.op3}. If all solver and options file combinations fail the node will be labeled \textit{ignored} and the node will not be explored further. The default is to try only one solver (the \texttt{rootsolver} or \texttt{subsolver}) and to ignore nodes with a solver failure.

\textbf{infeasseq} (string): solver sequence for infeasible nodes

\texttt{level solver1[.n1] solver2[.n2] ...} The purpose of \texttt{infeasseq} is to avoid cutting parts of the search tree that appear to be infeasible but really are feasible. If the NLP solver labels a node \textit{Locally Infeasible} and the model is not convex a feasible solution may actually exist. If SBB is high in the search tree it can be very drastic to prune the node immediately. SBB is therefore directed to try the solver/option combinations in the list as long as the depth in the search tree is less than the integer value \texttt{level}. If the list is exhausted without finding a feasible solution, the node is assumed to be infeasible. The default is to trust that \textit{Locally Infeasible} nodes are indeed infeasible and to remove them from further consideration.

\textbf{intsollim} (integer): maximum number of integer solutions

Maximum number of integer solutions. If this number is exceeded, SBB will terminate and return the best solution found so far.

Default: 2100000000

\textbf{loginterval} (integer): progress display interval

The interval (number of nodes) for which log lines are written.

Default: 1

\textbf{loglevel} (integer): level of solver display

The level of log output.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>only SBB log lines with one line every loginterval nodes</td>
</tr>
<tr>
<td>1</td>
<td>NLP solver log for the root node plus SBB log lines as 0</td>
</tr>
<tr>
<td>2</td>
<td>NLP solver log for all nodes plus SBB log lines as 0</td>
</tr>
</tbody>
</table>

\textbf{memnodes} (integer): maximum number of nodes in memory

The maximum number of nodes SBB can have in memory. If this number is exceeded, SBB will terminate and return the best solution found so far.

Default: 10000
**miptrace (string):** filename of MIP trace file

More info is available in chapter Solve trace

**miptracenode (integer):** node interval when a trace record is written

More info is available in chapter Solve trace

Default: 100

**miptracetime (real):** time interval when a trace record is written

More info is available in chapter Solve trace

Default: 5.0

**nodesel (integer):** node selection strategy

Node selection scheme.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>automatic</td>
</tr>
<tr>
<td>1</td>
<td>Depth First Search (DFS)</td>
</tr>

**printbbinfo (integer):** prints additional node info

Additional info of log output.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>print no additional info</td>
</tr>
</tbody>
</table>
| 1     | print variable selection letter  
  The node and variable selection for the current node are indicated by a two letter code at the end of the log line. The first letter represents the node selection: D for DFS, B for Best Bound, and E for Best Estimate. The second letter represents the variable selection: X for maximum infeasibility, N for minimum infeasibility, and P for pseudo cost. |
| 2     | print best estimate          |

**rootsolver (string):** solver for the root node

`solver[,n]` Solver is the name of the GAMS NLP solver that should be used in the root node, and `n` is the integer corresponding to optfile for the root node. If `.n` is missing, the optfile treated as zero i.e. the NLP solver will not look for an options file. This SBB option can
be used to overwrite the default that uses the NLP solver specified with an Option NLP = 
solver; statement or the default GAMS solver for NLP.

Default: GAMS NLP solver

solvelink (integer): Solvelink for GAMS NLP solver

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Call GAMS NLP solver via script</td>
</tr>
<tr>
<td>2</td>
<td>Call GAMS NLP solver via module</td>
</tr>
<tr>
<td>5</td>
<td>Call GAMS NLP solver in memory</td>
</tr>
</tbody>
</table>

subiter (integer): iteration limit for the subsolve

The default for subiter passed on through iterlim. Similar to subres but sets the iteration
limit for solving a node in the B&B tree.

Default: GAMS iterlim

subres (real): resource limit for the subsolve

The default for subres passed on through reslim. Sets the time limit in seconds for solving a
node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure and the
node is ignored, or the solvers in the failseq are called.

Default: GAMS reslim

subsolver (string): solver for the subproblems

solver[n]. Similar to rootsolver but applied to the subnodes.

Default: GAMS NLP solver

usergdxname (string): the name of the GDX file exported from the solver with the solution at the node

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchout.gdx

usergdxnameinc (string): the name of the GDX file exported from the solver with the incumbent
solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchout.i.gdx

userheurcall (string): the GAMS command line to call the heuristic

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userheurfirst (integer): calls the cut generator for the first n nodes
More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

**userheurfreq (integer):** determines the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

**userheurinterval (integer):** determines the interval when to apply the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 100

**userheurmult (integer):** determines the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 2

**userheurnewint (boolean):** calls the heuristic if the solver found a new integer feasible solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 0

**userheurobjfirst (integer):** Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 50

**varsel (integer):** variable selection strategy at each node

Variable selection scheme.

Default: 0

### 4.43.5 The SBB Log File

The SBB Log file (usually directed to the screen) can be controlled with the **loginterval** and **loglevel** options in SBB. It will by default first show the iteration output from the NLP solver that solves the root node. This is followed by output from SBB describing the search tree. An example of this search tree output follows:
Root node solved locally optimal.

<table>
<thead>
<tr>
<th>Node</th>

- B&B nodes: 3
- MIP solution: 9338.101979 found in node 3
- Best possible: 8491.286941
- Absolute gap: 846.815039
- Relative gap: 0.099728
- Model Status: 8
- Solver Status: 1

NLP Solver Statistics

- Total Number of NLP solves: 7
- Total Number of NLP failures: 0
- Details: conopt
  - # execs: 7
  - # failures: 0

Terminating.

The fields in the log are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node</td>
<td>The number of the current node. The root node is node 0.</td>
</tr>
<tr>
<td>Act</td>
<td>The number of active nodes defined as the number of subnodes that have not yet been solved.</td>
</tr>
<tr>
<td>Lev</td>
<td>The level in the search tree, i.e., the number of branches needed to reach this node.</td>
</tr>
<tr>
<td>Objective</td>
<td>The objective function value for the node. A numerical value indicates that the node was solved and the objective was good enough for the node to not be ignored. &quot;pruned&quot; indicates that the objective value was worse than the Best Integer value, &quot;infeasible&quot; indicates that the node was Infeasible or Locally Infeasible, and &quot;ignored&quot; indicates that the node could not be solved (see under failseq above).</td>
</tr>
<tr>
<td>IInf</td>
<td>The number of integer infeasibilities, i.e. the number of variables that are supposed to be binary or integer that do not satisfy the integrality requirement. Semi continuous variables and SOS variables may also contribute to IInf.</td>
</tr>
<tr>
<td>Best Int</td>
<td>The value of the best integer solution found so far. A dash (-) indicates that an integer solution has not yet been found. A star (*) in column one indicates that the node is integer and that the solution is better than the best yet found.</td>
</tr>
<tr>
<td>Best Bound</td>
<td>The minimum value of &quot;Objective&quot; for the subnodes that have not been solved yet (maximum for maximization models). For convex models, Best Bound will increase monotonically. For nonconvex models, Best Bound may decrease, indicating that the Objective value for a node was not a valid lower bound for that node.</td>
</tr>
<tr>
<td>Gap</td>
<td>The relative gap between the Best Integer solution and the Best Bound.</td>
</tr>
</tbody>
</table>

The remaining part of the Log file displays various solution statistics similar to those provided by the MIP solvers. This information can also be found in the Solver Status area of the GAMS listing file.

The following Log file shows cases where the NLP solver fails to solve a subnode. The text "ignored" in
the Objective field shows the failure, and the values in parenthesis following the Gap field are the Solve and Model status returned by the NLP solver:

<table>
<thead>
<tr>
<th>Node</th>
<th>Act. Lev</th>
<th>Objective</th>
<th>IInf</th>
<th>Best Int</th>
<th>Best Bound</th>
<th>Gap (2 secs)</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>5</td>
<td>1 3</td>
<td>ignored</td>
<td>-</td>
<td>-</td>
<td>5804.5856</td>
<td><em>4,7</em></td>
</tr>
</tbody>
</table>

The next Log file shows the effect of the `infeasseq` and `failseq` options on the model above. CONOPT with options file `conopt.opt` (the default solver and options file pair for this model) considers the first subnode to be locally infeasible. CONOPT, MINOS, and SNOPT, all with no options file, are therefore tried in sequence. In this case, they all declare the node infeasible and it is considered to be infeasible.

In node 3, CONOPT with option file fails but CONOPT without option file finds a Locally Optimal solution, and this solution is then used for further search. The SBB option file for the following run would be:

```
rootsolver conopt.1
subsolver conopt.1
failseq conopt
infeasseq 100 conopt minos snopt
```

The log looks as follows:

```
Root node solved locally optimal.
Node Act. Lev. Objective IInf Best Int. Best Bound Gap (2 secs)
0 0 0 6046.0186 12 - 6046.0186 -
conopt.1 reports locally infeasible
Executing conopt
conopt reports locally infeasible
Executing minos
minos reports locally infeasible
Executing snopt
1 1 1 infeasible - - 6046.0186 -
2 0 1 6042.0995 10 - 6042.0995 -
conopt.1 failed. 4 TERMINATED BY SOLVER, 7 FEASIBLE SOLUTION
Executing conopt
3 1 2 4790.2373 8 - 6042.0995 -
4 2 3 4481.4156 6 - 6042.0995 -
conopt.1 reports locally infeasible
Executing conopt
conopt reports locally infeasible
Executing minos
minos failed. 4 TERMINATED BY SOLVER, 6 INTERMEDIATE INFEASIBLE
Executing snopt
5 3 4 infeasible - - 6042.0995 -
6 2 4 4480.3778 4 - 6042.0995 -
```

The Log file shows a solver statistic at the end, summarizing how many times an NLP was executed and how often it failed:
The solutions found by the NLP solver to the subproblems in the Branch and Bound may not be the global optima. Therefore, the objective can improve even though we restrict the problem by tightening some bounds. These jumps of the objective in the wrong direction which might also have an impact on the best bound/possible are reported in a separate statistic:

Non convex model!
# jumps in best bound : 2
Maximum jump in best bound : 20.626587 in node 13
# jumps to better objective : 2
Maximum jump in objective : 20.626587 in node 13

4.43.6 Comparison of SBB and other MINLP Solvers

GAMS offers a variety of MINLP solvers including local and global MINLP solver. They implement different algorithms and it is usually unclear which solver performs best. Here we give a brief comparison between SBB and the well known solver DICOPT.

DICOPT is based on the outer approximation method. Initially, the RMINLP model is solved just as in SBB. The model is then linearized around this point and a linear MIP model is solved. The discrete variables are then fixed at the optimal values from the MIP model, and the resulting NLP model is solved. If the NLP model is feasible, we have an integer feasible solution.

The model is linearized again and a new MIP model with both the old and new linearized constraints is solved. The discrete variables are again fixed at the optimal values, and a new NLP model is solved.

The process stops when the MIP model becomes infeasible, when the NLP solution becomes worse, or, in some cases, when bounds derived from the MIP model indicate that it is safe to stop.

DICOPT is based on the assumption that MIP models can be solved efficiently while NLP models can be expensive and difficult to solve. The MIP models try to approximate the NLP model over a large area and solve it using much cheaper linear technology. Ideally, only a few NLPs must be solved.

DICOPT can experience difficulties solving models, if many or all the NLP submodels are infeasible. DICOPT can also have problems if the linearizations used for the MIP model create ill-conditioned models. The MIP models may become very difficult to solve, and the results from the MIP models may be poor as initial values for the NLP models. The linearized constraint used by DICOPT may also exclude certain areas of the feasible space from consideration.

SBB uses different assumptions and works very differently. Most of the work in SBB involves solving NLP models. Since the NLP submodels differ only in one or a few bounds, the assumption is that the NLP models can be solved quickly using a good restart procedure. Since the NLP models differ very little and good initial values are available, the solution process will be fairly reliable compared to the solution process in DICOPT, where initial values of good quality seldom are available. Because search space is reduced based on very different grounds than in DICOPT, other solutions may therefore be explored.

Overall, DICOPT should perform better on models that have a significant and difficult combinatorial part, while SBB may perform better on models that have fewer discrete variables but more difficult nonlinearities (and possibly also on models that are fairly non convex).
4.44 SCIP

SCIP (Solving Constraint Integer Programs) is developed at the Zuse Institute Berlin (ZIB) in cooperation with TU Darmstadt, RWTH Aachen, and University of Erlangen-Nürnberg, see the SCIP webpage for the current list of developers.

SCIP is a framework for Constraint Integer Programming oriented towards the needs of Mathematical Programming experts who want to have total control of the solution process and access detailed information down to the guts of the solver. SCIP can also be used as a pure MIP or MINLP solver or as a framework for branch-cut-and-price. Within GAMS, the MIP and MINLP solving facilities of SCIP are available.

For more detailed information, we refer to [5] [2] [3] [38] [37] [103] [163] [116] [243] [242] [257] and the SCIP web site.

GAMS/SCIP uses CPLEX, if licensed, and otherwise SOPLEX [259] as LP solver, the COIN-OR Interior Point Optimizer IPOPT [249] as nonlinear solver, and CppAD to compute derivatives of nonlinear functions.

SCIP supports continuous, binary, integer, semi-continuous, semi-integer variables, indicator constraints, special ordered sets, and branching priorities for discrete variables.

4.44.1 Usage

The following statement can be used inside your GAMS program to specify using SCIP

\[
\text{Option MIP = SCIP; \{ or QCP or NLP or MIQCP or MINLP or ... \}}
\]

The above statement should appear before the Solve statement. If SCIP was specified as the default solver during GAMS installation, the above statement is not necessary.

GAMS/SCIP currently does not support the GAMS Branch-and-Cut-and-Heuristic (BCH) Facility. If you need to use GAMS/SCIP with BCH, please consider to use a GAMS system of version \( \leq 23.3 \).

4.44.1.1 Specification of SCIP Options

GAMS/SCIP supports the GAMS parameters reslim, iterlim, nodlim, optca, optcr, and workspace. Further, the option threads can be used to control the number of threads used in the linear algebra routines of IPOPT and for solving LPs (if CPLEX' barrier solver is used).

Options can be specified by a SCIP options file. A SCIP options file consists of one option or comment per line. A pound sign (\#) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs). Further, string values have to be enclosed in quotation marks.

A small example for a scip.opt file is:

\[
\begin{align*}
\text{propagating/probing/maxprerounds} & = 0 \\
\text{separating/maxrounds} & = 0 \\
\text{separating/maxroundsroot} & = 0
\end{align*}
\]

It causes GAMS/SCIP to disable probing during presolve and to turn off all cut generators.
4.44.1.2 Specification of Indicators

Indicators are a modeling tool to specify that certain equations in a model must only be satisfied if certain binary variables take a specified value. Indicators are not supported by the GAMS language, but can be passed to SCIP via a separate file, see Indicator Constraints for more details on its syntax. The name of that file is specified via the option gams/indicatorfile in a SCIP option file. Currently, indicators can only be used for linear equations.

4.44.2 Special Features

4.44.2.1 SCIP interactive shell

The interactive shell in SCIP is a powerful tool that allows the user to display various information (e.g., branching statistics, presolved model), load emphasis settings, interrupt a solve to change parameters or trigger a restart, write the model in various file formats, start SCIP's solution counter, and many more things.

When setting the option gams/interactive to a nonempty string, the GAMS/SCIP interface opens the interactive shell of SCIP after having load the GAMS problem and parameters and passes the value of the gams/interactive parameter to the SCIP interactive shell.

By default, SCIP behaves as if gams/interactive has been set to "optimize write gamssol quit", that is, SCIP is requested to solve the problem, then to pass the solution back to GAMS, and to quit.

An example use of the SCIP interactive shell feature via GAMS is to add the following line to your SCIP options file:

gams/interactive = "write prob orig.lp presolve write transprob presol.mps opt write gamssol quit"

This instructs SCIP to write the original problem to the file orig.lp in LP format, to presolve the instance, to write the presolved problem to the file presolved.mps in MPS format, to solve the instance, to write the solution out to GAMS, and to finish.

By omitting the quit command, SCIPs interactive shell remains open and awaits user input. The command help prints a list of available commands. Note, that on Windows, GAMS need to be called with the option interactivesolver enabled to allow user input for the solver process.

4.44.2.2 Emphasis Settings

SCIP includes various emphasis settings, which are predefined values for a set of SCIP parameters. Such predefined settings are available for setting the effort that SCIP should spend for, e.g., presolving, separation, or heuristics.

The emphasis settings are not available as single parameters, but can be set via SCIPs interactive shell. E.g., writing set heuristics emphasis in the shell displays the available emphasis settings for heuristics (aggressive, fast, off) and expects the user to input which setting to use. Further, general emphasis settings are available in the set emphasis menu, some of them giving predefined settings similar to the CPLEX option mipemphasis.

Via the gams/interactive option, c.f. Section SCIP interactive shell, emphasis settings can be activated via a SCIP options file. For example, adding the option

gams/interactive = "set emphasis feasibility set loadgams optimize write gamssol quit"

instructs SCIP to load the emphasis setting feasibility prior to optimizing the model and passing the solution back to GAMS. Note, that setting one of the emphasis settings feasibility, hardlp, and optimality resets all previously set parameters to their default values, which includes the ones that are set by the GAMS/SCIP interface or which were loaded from a SCIP options file. Therefore, the command set loadgams has been used above to restore these parameter settings.

The following emphasis settings are available in SCIP:
<table>
<thead>
<tr>
<th>shell command</th>
<th>purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>set emphasis easycip</td>
<td>use for easy problems</td>
</tr>
<tr>
<td>set emphasis feasibility</td>
<td>emphasize finding a feasible solution</td>
</tr>
<tr>
<td>set emphasis hardlp</td>
<td>use for problems with a hard LP</td>
</tr>
<tr>
<td>set emphasis optimality</td>
<td>emphasize proving optimality</td>
</tr>
<tr>
<td>set heuristic emphasis aggressive</td>
<td>use primal heuristics aggressively</td>
</tr>
<tr>
<td>set heuristic emphasis fast</td>
<td>use only fast primal heuristics</td>
</tr>
<tr>
<td>set heuristic emphasis off</td>
<td>disable all primal heuristics</td>
</tr>
<tr>
<td>set presolving emphasis aggressive</td>
<td>do aggressive presolving</td>
</tr>
<tr>
<td>set presolving emphasis fast</td>
<td>use only fast presolving steps</td>
</tr>
<tr>
<td>set presolving emphasis off</td>
<td>disable presolving</td>
</tr>
<tr>
<td>set separating emphasis aggressive</td>
<td>use cutting plane separators aggressively</td>
</tr>
<tr>
<td>set separating emphasis fast</td>
<td>use only fast cutting plane separators</td>
</tr>
<tr>
<td>set separating emphasis off</td>
<td>disable all cutting plane separators</td>
</tr>
</tbody>
</table>

### 4.44.2.3 Starting point

Using the `completesol` heuristic, SCIP can try to find a feasible solution based on values given by the user for all or some of the variables. The values need to be specified as variable levels in the GAMS model. The heuristic solves a copy of the problem where variables for which values have been provided are restricted to be close to that value. When an integral value is specified for a binary or integer variable, the variable is fixed to that value. See also Section 2.3.2 in [163] for a more detailed description of the heuristic.

For which variables the level values are passed from GAMS to SCIP is controlled by the parameter `gams/mipstart`. The parameter values have the following meaning:

- 0: do not pass any variable values to SCIP, the heuristic will not run
- 1: pass values for all binary and integer variables to SCIP and let SCIP try to find a feasible solution in its neighborhood by using the `completesol` heuristic
- 2 (default): pass values for all variables to SCIP and let SCIP check feasibility of the given solution, the heuristic will not run
- 3: pass values for all variables to SCIP and let SCIP try to find a feasible solution in the neighborhood by using the `completesol` heuristic
- 4: pass values for all binary and integer variables to SCIP which fractionality is at most the value of GAMS option `tryint` (thus, with default `tryint=0`, only for variables with integral values, the value is passed to SCIP) and let SCIP try to find a feasible solution in the neighborhood by using the `completesol` heuristic

Note, that the `completesol` heuristic will not run if there are too many variables with unknown values. This behavior can be adjusted by setting parameter `heuristics/completesol/maxunknownrate`.

### 4.44.2.4 Solution Pool

When SCIP solves a problem, it may find several solutions, whereof only the best one is available to the GAMS user via the variable level values in the GAMS model. If the option `gams/dumpsolutions` is specified, then all alternative solutions found by SCIP are written into GDX files and an index file with the name given by the this option is written. If the option `gams/dumpsolutionsmerged` is specified, then all alternative solutions found by SCIP are written into a single GDX file, which name is given by the this option.

The GAMS testlib model `dumpsol` shows an example use for this option via GUROBI. It can easily be adapted to be used with SCIP.
4.44.2.5 Solving process tracing

The option gams/solvetrace/file can be used to specify the name of a file where information about the progress of the branch-and-bound tree search in SCIP is stored. The file is created and updated during the solution process, so it may also be used to monitor the progress of SCIP while it still solves the model.

New entries are written periodically, depending on how many nodes have been processed or how much time has been elapsed since the last entry was written. Each entry contains information on the current primal and dual bound.

4.44.2.6 Notes on solving MINLPs with SCIP

SCIP includes capabilities to handle nonlinear functions that are specified via algebraic expressions. Therefore, neither external/extrinsic functions nor all GAMS operands (e.g., trigonometric ones) are supported yet.

Nonconvex MINLPs are solved via a spatial branch-and-bound algorithm using linear relaxations. The tightness of this relaxation depends heavily on the variable bounds, thus tight bounds for the nonlinear variables are crucial for SCIP.

4.44.2.6.1 Special options for convex MINLPs  Convex MINLPs are much easier to solve for SCIP, provided it recognizes the convexity of the model. So far, only a simple convexity check is implemented in SCIP, which may not give a conclusive answer in all cases. However, setting the option constraints/nonlinear/assumeconvex to TRUE can be used to tell SCIP that it should assume all nonlinear constraints to be of convex type. This may help to improve solving times for convex MINLPs considerably.

Another feature that can be especially useful for convex MINLPs is to enable the generation of cuts in the solution of the NLP relaxation in the root node and to consider using these cuts during the whole solution process. This is achieved by the parameters

constraints/quadratic/sepanlpmincont = 0
constraints/soc/sepanlpmincont = 0
constraints/nonlinear/sepanlpmincont = 0
constraints/abspower/sepanlpmincont = 0
separating/poolfreq = 1

However, it has been shown that these settings can also deteriorate performance.

4.44.3 Components

In the following, we list components that are available in SCIP together with some common properties. Some of these properties can be modified with corresponding parameters.
### 4.44.3.1 Branching Rules

<table>

gauge | 0 | -1 | 1 | gauge separator |
impliedbounds | -50 | 10 | 1 | implied bounds separator |
intobj | -100 | -1 | 0 | integer objective value separator |
cgmip | -1000 | -1 | 0 | Chvatal-Gomory cuts via MIPs separator |
gomory | -1000 | 10 | 1 | Gomory MIR cuts separator |
strongcg | -2000 | 10 | 1 | Strong CG cuts separator (Letchford and Lodi) |
aggregation | -3000 | 10 | 1 | aggregation heuristic for complemented mixed integer rounding cuts and flowcover cuts |
clique | -5000 | 0 | 0 | clique separator of stable set relaxation |
zerohalf | -6000 | 10 | 1 | \(\{0,1/2\}\)-cuts separator |
mcf | -10000 | 0 | 0 | multi-commodity-flow network cut separator |
ceccts | -13000 | -1 | 1 | separator for edge-concave functions |
oddcycle | -15000 | -1 | 1 | odd cycle separator |
flowcover | -100000 | 10 | 0 | separator for flowcover cuts |
cmir | -100000 | 10 | 0 | separator for cmir cuts |
rapidlearning | -1200000 | -1 | 1 | rapid learning heuristic and separator |

4.44.4 List of SCIP Options

SCIP supports a large set of options. In the following, we give a detailed list of all SCIP options.

4.44.4.1 gams

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>gams/dumpsolutions</td>
<td>name of solutions index gdx file for writing all alternate solutions</td>
<td></td>
</tr>
<tr>
<td>gams/dumpsolutionsmerged</td>
<td>name of gdx file for writing all alternate solutions into a single file</td>
<td></td>
</tr>
<tr>
<td>gams/indicatorfile</td>
<td>name of GAMS options file that contains definitions on indicators</td>
<td></td>
</tr>
<tr>
<td>gams/interactive</td>
<td>command to be issued to the SCIP shell instead of issuing a solve command</td>
<td></td>
</tr>
<tr>
<td>gams/mipstart</td>
<td>how to handle initial variable levels, see also section Starting point</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>Range: [0, 4]</td>
<td></td>
</tr>
<tr>
<td>gams/resolvenlp</td>
<td>whether to resolve MINLP with fixed discrete variables if best solution violates some constraints</td>
<td>1</td>
</tr>
</tbody>
</table>

4.44.4.2 gams/solvtrace

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>gams/solvtrace/file</td>
<td>name of file where to write branch-and-bound trace information too</td>
<td></td>
</tr>
<tr>
<td>gams/solvtrace/nodefreq</td>
<td>frequency in number of nodes when to write branch-and-bound trace information, 0 to disable</td>
<td>100</td>
</tr>
<tr>
<td>gams/solvtrace/timefreq</td>
<td>frequency in seconds when to write branch-and-bound trace information, 0.0 to disable</td>
<td>5</td>
</tr>
</tbody>
</table>

4.44.4.3 branching

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/checksol</td>
<td>should LP solutions during strong branching with propagation be checked for feasibility?</td>
<td>1</td>
</tr>
<tr>
<td>branching/clamp</td>
<td>minimal relative distance of branching point to bounds when branching on a continuous variable</td>
<td>0.2</td>
</tr>
<tr>
<td></td>
<td>Range: [0, 0.5]</td>
<td></td>
</tr>
<tr>
<td>branching/delaypscostupdate</td>
<td>should updating pseudo costs for continuous variables be delayed to the time after separation?</td>
<td>1</td>
</tr>
<tr>
<td>branching/divingpscost</td>
<td>should pseudo costs be updated also in diving and probing mode?</td>
<td>1</td>
</tr>
<tr>
<td>branching/firstsbchild</td>
<td>child node to be regarded first during strong branching (only with propagation): 'u'p child, 'd'own child, 'h'istory-based, or 'a'utomatic</td>
<td>a</td>
</tr>
</tbody>
</table>
### 4.44 SCIP

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/forceallchildren</td>
<td>should all strong branching children be regarded even if one is detected to be infeasible? (only with propagation)</td>
<td>0</td>
</tr>
<tr>
<td>branching/lpgainnormalize</td>
<td>strategy for normalization of LP gain when updating pseudocosts of continuous variables (divide by movement of ( l'p ) value, reduction in ( d'omain ) width, or reduction in domain width of ( s'ibling ))</td>
<td>s</td>
</tr>
<tr>
<td>branching/preferbinary</td>
<td>should branching on binary variables be preferred?</td>
<td>0</td>
</tr>
<tr>
<td>branching/roundsbsol</td>
<td>should LP solutions during strong branching with propagation be rounded? (only when checksbsol=TRUE)</td>
<td>1</td>
</tr>
<tr>
<td>branching/scorefac</td>
<td>branching score factor to weigh downward and upward gain prediction in sum score function Range: ([0, 1])</td>
<td>0.167</td>
</tr>
<tr>
<td>branching/scorefunc</td>
<td>branching score function (('s'um, 'p'roduct, 'q'uotient))</td>
<td>p</td>
</tr>
<tr>
<td>branching/sumadjustscore</td>
<td>score adjustment near zero by adding epsilon (TRUE) or using maximum (FALSE)</td>
<td>0</td>
</tr>
</tbody>
</table>

#### 4.44.4.4 branching/allfullstrong

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/allfullstrong/maxbounndist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: ([0, 1])</td>
<td>1</td>
</tr>
<tr>
<td>branching/allfullstrong/maxdepth</td>
<td>maximal depth level, up to which branching rule (&lt;allfullstrong&gt;) should be used (-1 for no limit) Range: ([-1, 65534])</td>
<td>-1</td>
</tr>
<tr>
<td>branching/allfullstrong/priority</td>
<td>priority of branching rule (&lt;allfullstrong&gt;) Range: ([-536870912, 536870911])</td>
<td>-1000</td>
</tr>
</tbody>
</table>

#### 4.44.4.5 branching/cloud

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/cloud/maxbounndist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: ([0, 1])</td>
<td>1</td>
</tr>
<tr>
<td>branching/cloud/maxdepth</td>
<td>maximal depth level, up to which branching rule (&lt;cloud&gt;) should be used (-1 for no limit) Range: ([-1, 65534])</td>
<td>-1</td>
</tr>
<tr>
<td>branching/cloud/maxdepthunion</td>
<td>maximum depth for the union Range: ([0, 65000])</td>
<td>65000</td>
</tr>
<tr>
<td>branching/cloud/maxpoints</td>
<td>maximum number of points for the cloud (-1 means no limit) Range: ([-1, \infty])</td>
<td>-1</td>
</tr>
<tr>
<td>branching/cloud/minsuccessrate</td>
<td>minimum success rate for the cloud Range: ([0, 1])</td>
<td>0</td>
</tr>
</tbody>
</table>
### 4.44.4.6 branching/distribution

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/distribution/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>branching/distribution/maxdepth</td>
<td>maximal depth level, up to which branching rule &lt;distribution&gt; should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>branching/distribution/onlyactive rows</td>
<td>should only rows which are active at the current node be considered?</td>
<td>0</td>
</tr>
<tr>
<td>branching/distribution/priority</td>
<td>priority of branching rule &lt;distribution&gt;</td>
<td>0</td>
</tr>
<tr>
<td>branching/distribution/scoreparam</td>
<td>the score:largest 'd'ifference, 'l'owest cumulative probability,'h'ighest c.p., 'v'otes lowest c.p., votes highest c.p.('w')</td>
<td>v</td>
</tr>
<tr>
<td>branching/distribution/weightscore</td>
<td>should the branching score weigh up- and down-scores of a variable</td>
<td>0</td>
</tr>
</tbody>
</table>

### 4.44.4.7 branching/fullstrong

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/fullstrong/forcestrongbranch</td>
<td>should strong branching be applied even if there is just a single candidate?</td>
<td>0</td>
</tr>
<tr>
<td>branching/fullstrong/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>branching/fullstrong/maxdepth</td>

### 4.45 SELKIE

Youngdae Kim, youngdae@anl.gov; Mathematics and Computer Science Division; Argonne National Laboratory

Michael C. Ferris; Computer Science Department; UW-Madison

23 Jan 2019 :

#### 4.45.1 Introduction

This document describes the GAMS/SELKIE solver for equilibrium models. This is a research code, so you should set your expectations accordingly. It doesn’t come with extensive documentation or a history of continuous development and improvement. To learn more about the algorithms SELKIE implements and related topics, see Y. Kim’s Ph.D. thesis or home page.

#### 4.45.2 Usage

To explicitly request that a model be solved with SELKIE, insert the statement

```plaintext
option EMP = selkie;
```

somewhere before the solve statement in the GAMS source. If SELKIE has been selected as the default EMP solver (e.g. by including EMP=selkie in the command line arguments of the GAMS run) the above statement is not necessary.

SELKIE-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

An example of a valid SELKIE option file is:

```plaintext
* lines starting with a star are comments
diagonalization_method jacobi
parallel_jacobi yes
output_group_log yes
```

4.46.1 Introduction

This section describes the GAMS interface to the general-purpose NLP solver SNOPT, (Sparse Nonlinear Optimizer) which implements a sequential quadratic programming (SQP) method for solving constrained optimization problems with smooth nonlinear functions in the objective and constraints. The optimization problem is assumed to be stated in the form

\[
\text{NP : minimize or maximize } f_0(x) \\
\text{s.t. } f(x) \sim b_1 \\
A_L x \sim b_2 \\
l \leq x \leq u,
\]

where \( x \in \mathbb{R}^n \), \( f_0(x) \) is a linear or nonlinear smooth objective function, \( l \) and \( u \) are constant lower and upper bounds, \( f(x) \) is a set of nonlinear constraint functions, \( A_L \) is a sparse matrix, \( \sim \) is a vector of relational operators (\( \leq, \geq \) or \( = \)), and \( b_1 \) and \( b_2 \) are right-hand side constants. \( f(x) \sim b_1 \)s are the nonlinear constraints of the model and \( A_L x \sim b_2 \) form the linear constraints.

The gradients of \( f_0 \) and \( f_i \) are automatically provided by GAMS, using its automatic differentiation engine.

The bounds may include special values \(-\infty\) or \(+\infty\) to indicate \( l_j = -\infty \) or \( u_j = +\infty \) for appropriate \( j \). Free variables have both bounds infinite and fixed variables have \( l_j = u_j \).

SNOPT uses a sequential quadratic programming (SQP) algorithm that obtains search directions from a sequence of quadratic programming subproblems. Each QP subproblem minimizes a quadratic model of a certain Lagrangian function subject to a linearization of the constraints. An augmented Lagrangian merit function is reduced along each search direction to ensure convergence from any starting point.

SNOPT is most efficient if only some of the variables enter nonlinearly, or if the number of active constraints (including simple bounds) is nearly as large as the number of variables. SNOPT requires relatively few evaluations of the problem functions.

4.46 SNOPT

4.46.1.1 Problem Types

If the nonlinear functions are absent, the problem is a linear program (LP) and SNOPT applies the primal simplex method [63]. Sparse basis factors are maintained by LUSOL [110] as in MINOS [185].

If only the objective is nonlinear, the problem is linearly constrained (LC) and tends to solve more easily than the general case with nonlinear constraints (NC). Note that GAMS models have an objective variable instead of an objective function. The GAMS/SNOPT link will try to substitute out the objective variable and reformulate the model such that SNOPT will see a true objective function.

For both linearly and nonlinearly constrained problems SNOPT applies a sparse sequential quadratic programming (SQP) method [113] using limited-memory quasi-Newton approximations to the Hessian of the Lagrangian. The merit function for steplength control is an augmented Lagrangian, as in the dense SQP solver NPSOL [109] [112].

In general, SNOPT requires less matrix computation than NPSOL and fewer evaluations of the functions than the nonlinear algorithms in MINOS [183] [184]. It is suitable for nonlinear problems with thousands of constraints and variables, and is most efficient if only some of the variables enter nonlinearly, or there are relatively few degrees of freedom at a solution (i.e., many constraints are active). However, unlike previous versions of SNOPT, there is no limit on the number of degrees of freedom.

4.46.1.2 Selecting the SNOPT Solver

If SNOPT is not specified as the default solver for the desired model type (e.g. NLP), then the following statement can be used in your GAMS model to select SNOPT:

```gams
option nlp=SNOPT;
```

The option statement should appear before the `solve` statement. To be complete, we mention that the solver can be also specified on the command line, as in:

```bash
> gams camcge nlp=snopt
```

This will override the global default, but if an algorithm option has been specified inside the model, then that specification takes precedence.

If the model contains non-smooth functions like abs (x), or max(x, y) you can try to get it solved by SNOPT using

```gams
option dnlp=SNOPT;
```

These models have discontinuous derivatives however, and SNOPT was not designed for solving such models. Discontinuities in the gradients can sometimes be tolerated if they appear away from an optimum.

4.46.2 Description of the method

Here we briefly describe the main features of the SQP algorithm used in SNOPT and introduce some terminology. The SQP algorithm is fully described by by Gill, Murray and Saunders [114].
4.46.2.1 Objective function reconstruction

The first step GAMS/SNOPT performs is to try to reconstruct the objective function. In GAMS, optimization models minimize or maximize an objective variable. SNOPT however works with an objective function. One way of dealing with this is to add a dummy linear function with just the objective variable. Consider the following GAMS fragment:

```gams
obj.. z =e= sum(i, sqr(r(i)));
model m /all/;
solve m using nlp minimizing z;
```

This can be cast in form (1) by saying minimize $z$ subject to $z = \sum_i r_i^2$ and the other constraints in the model. Although simple, this approach is not always preferable. Especially when all constraints are linear it is important to minimize the nonlinear expression $\sum_i r_i^2$ directly. This can be achieved by a simple reformulation: $z$ can be substituted out. The substitution mechanism carries out the formulation if all of the following conditions hold:

- the objective variable $z$ is a free continuous variable (no bounds are defined on $z$),
- $z$ appears linearly in the objective function,
- the objective function is formulated as an equality constraint,
- $z$ is only present in the objective function and not in other constraints.

For many models it is very important that the nonlinear objective function be used by SNOPT. For instance the model `chem.gms` from the model library solves in 16 iterations. When we add the bound

```gams
energy.lo = 0;
```

on the objective variable `energy` and thus preventing it from being substituted out, SNOPT will not be able to find a feasible point for the given starting point.

This reformulation mechanism has been extended for substitutions along the diagonal. For example, the GAMS model

```gams
variables x,y,z;
equations e1,e2;
e1..z =e= y;
e2..y =e= sqr(1+x);
model m /all/;
option nlp=snopt;
solve m using nlp minimizing z;
```

will be reformulated as an *unconstrained* optimization problem

$$
\min f(x) = (1 + x)^2.
$$

These additional reformulations can be turned off by using the statement `option reform = 0;` (see *GAMS Options*).
4.46 SNOPT

4.46.2.2 Constraints and slack variables

Problem (1) contains \( n \) variables in \( x \). Let \( m \) be the number of components of \( f(x) \) and \( A_Lx \) combined. The upper and lower bounds on those terms define the general constraints of the problem. SNOPT converts the general constraints to equalities by introducing a set of slack variables \( s = (s_1, s_2, \ldots, s_m)^T \). For example, the linear constraint \( 5 \leq 2x_1 + 3x_2 \leq +\infty \) is replaced by \( 2x_1 + 3x_2 - s_1 = 0 \) together with the bounded slack \( 5 \leq s_1 \leq +\infty \). Problem (1) can be written in the equivalent form

\[
\begin{align*}
\text{minimize} & \quad f_0(x) \\
\text{subject to} & \quad f(x) - s = 0, \quad l \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u.
\end{align*}
\]

where a maximization problem is cast into a minimization by multiplying the objective function by \(-1\).

The linear and nonlinear general constraints become equalities of the form \( f(x) - s_N = 0 \) and \( A_Lx - s_L = 0 \), where \( s_L \) and \( s_N \) are known as the linear and nonlinear slack.

4.46.2.3 Major iterations

The basic structure of SNOPT's solution algorithm involves major and minor iterations. The major iterations generate a sequence of iterates \( (x_k) \) that satisfy the linear constraints and converge to a point that satisfies the first-order conditions for optimality. At each iterate \( x_k \) a QP subproblem is used to generate a search direction towards the next iterate \( x_{k+1} \). The constraints of the subproblem are formed from the linear constraints \( A_Lx - s_L = 0 \) and the nonlinear constraint linearization

\[
f(x_k) + f'(x_k)(x - x_k) - s_N = 0,
\]

where \( f'(x_k) \) denotes the Jacobian: a matrix whose rows are the first derivatives of \( f(x) \) evaluated at \( x_k \). The QP constraints therefore comprise the \( m \) linear constraints

\[
f'(x_k)x - s_N = -f(x_k) + f'(x_k)x_k, \quad A_Lx - s_L = 0,
\]

where \( x \) and \( s \) are bounded by \( l \) and \( u \) as before. If the \( m \times n \) matrix \( A \) and \( m \)-vector \( b \) are defined as

\[
A = \begin{pmatrix} f'(x_k) \\ A_L \end{pmatrix} \quad \text{and} \quad b = \begin{pmatrix} -f(x_k) + f'(x_k)x_k \\ 0 \end{pmatrix},
\]

then the QP subproblem can be written as

\[
\begin{align*}
\text{QP}_k: \quad \min_{x,s} & \quad q(x, x_k) = g_k^T(x - x_k) + \frac{1}{2}(x - x_k)^T H_k(x - x_k) \\
\text{subject to} & \quad Ax - s = b, \quad l \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u.
\end{align*}
\]

where \( q(x, x_k) \) is a quadratic approximation to a modified Lagrangian function \[113\]. The matrix \( H_k \) is a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration. If some of the variables enter the Lagrangian linearly the Hessian will have some zero rows and columns. If the nonlinear variables appear first, then only the leading \( n_1 \) rows and columns of the Hessian need be approximated, where \( n_1 \) is the number of nonlinear variables.
4.46.2.4 Minor iterations

Solving the QP subproblem is itself an iterative procedure. Here, the iterations of the QP solver SQOPT [115] form the minor iterations of the SQP method.

SQOPT uses a reduced-Hessian active-set method implemented as a reduced-gradient method similar to that in MINOS [183].

At each minor iteration, the constraints $Ax - s = b$ are partitioned into the form

$$Bx_B + Sx_S + Nx_N = b,$$

where the basis matrix $B$ is square and nonsingular and the matrices $S$, $N$ are the remaining columns of $(A - I)$. The vectors $x_B$, $x_S$, $x_N$ are the associated basic, superbasic, and nonbasic components of the variables $(x, s)$.

The term active-set method arises because the nonbasic variables $x_N$ are temporarily frozen at their upper or lower bounds, and their bounds are considered to be active. Since the general constraints are satisfied also, the set of active constraints takes the form

$$
\begin{bmatrix}
B & S & N \\
I
\end{bmatrix}
\begin{bmatrix}
x_B \\
x_S \\
x_N
\end{bmatrix}
= 
\begin{bmatrix}
b \\
x_N
\end{bmatrix},
$$

where $x_N$ represents the current values of the nonbasic variables. (In practice, nonbasic variables are sometimes frozen at values strictly between their bounds.) The reduced-gradient method chooses to move the superbasic variables in a direction that will improve the objective function. The basic variables "tag along" to keep $Ax - s = b$ satisfied, and the nonbasic variables remain unaltered until one of them is chosen to become superbasic.

At a nonoptimal feasible point $(x, s)$ we seek a search direction $p$ such that $(x, s) + p$ remains on the set of active constraints yet improves the QP objective. If the new point is to be feasible, we must have $Bp_B + Sp_S + Np_N = 0$ and $p_N = 0$. Once $p_S$ is specified, $p_B$ is uniquely determined from the system $Bp_B = -Sp_S$. It follows that the superbasic variables may be regarded as independent variables that are free to move in any desired direction. The number of superbasic variables ( $n_S$ say) therefore indicates the number of degrees of freedom remaining after the constraints have been satisfied. In broad terms, $n_S$ is a measure of how nonlinear the problem is. In particular, $n_S$ need not be more than one for linear problems.

4.46.2.5 The reduced Hessian and reduced gradient

The dependence of $p$ on $p_S$ may be expressed compactly as $p = Zp_S$, where $Z$ is a matrix that spans the null space of the active constraints:

$$Z = P
\begin{pmatrix}
-B^{-1}S \\
I \\
0
\end{pmatrix}
$$

where $P$ permutes the columns of $(A - I)$ into the order $(B S N)$. Minimizing $q(x, x_k)$ with respect to $p_S$ now involves a quadratic function of $p_S$:

$$g^T Zp_S + \frac{1}{2}p_S^T H Z p_S,$$

where $g$ and $H$ are expanded forms of $g_k$ and $H_k$ defined for all variables $(x, s)$. This is a quadratic with Hessian $Z^T H Z$ (the reduced Hessian) and constant vector $Z^T g$ (the reduced gradient). If the reduced Hessian is nonsingular, $p_S$ is computed from the system

$$Z^T H Z p_S = -Z^T g.$$
The matrix $Z$ is used only as an operator, i.e., it is not stored explicitly. Products of the form $Zv$ or $Z^T g$ are obtained by solving with $B$ or $B^T$. The package LUSOL [110] is used to maintain sparse LU factors of $B$ as the $BSN$ partition changes. From the definition of $Z$, we see that the reduced gradient can be computed from
\[
B^T \pi = g_B, \quad Z^T g = g_s - S^T \pi,
\]
where $\pi$ is an estimate of the dual variables associated with the $m$ equality constraints $Ax - s = b$, and $g_B$ is the basic part of $g$.

By analogy with the elements of $Z^T g$, we define a vector of reduced gradients (or reduced costs) for all variables in $(x, s)$:
\[
d = g - (A^T \pi), \quad \text{so that } d_s = Z^T g.
\]
At a feasible point, the reduced gradients for the slacks $s$ are the dual variables $\pi$.

The optimality conditions for subproblem QP $k$ \((2)\) may be written in terms of $d$. The current point is optimal if $d_j \geq 0$ for all nonbasic variables at their lower bounds, $d_j \leq 0$ for all nonbasic variables at their upper bounds, and $d_j = 0$ for all superbasic variables ($d_s = 0$). In practice, SNOPT requests an approximate QP solution \((\hat{x}_k, \hat{s}_k, \hat{\pi}_k)\) with slightly relaxed conditions on $d_j$.

If $d_s = 0$, no improvement can be made with the current $BSN$ partition, and a nonbasic variable with non-optimal reduced gradient is selected to be added to $S$. The iteration is then repeated with $n_S$ increased by one. At all stages, if the step $(x, s) + p$ would cause a basic or superbasic variable to violate one of its bounds, a shorter step $(x, s) + \alpha p$ is taken, one of the variables is made nonbasic, and $n_S$ is decreased by one.

The process of computing and testing reduced gradients $d_N$ is known as pricing (a term introduced in the context of the simplex method for linear programming). Pricing the $j$th variable means computing $d_j = g_j - a_j^T \pi$, where $a_j$ is the $j$th column of $(A - I)$. If there are significantly more variables than general constraints (i.e., $n \gg m$), pricing can be computationally expensive. In this case, a strategy known as partial pricing can be used to compute and test only a subset of $d_N$.

Solving the reduced Hessian system \((5)\) is sometimes expensive. With the option QPSolver Cholesky, an upper-triangular matrix $R$ is maintained satisfying $R^T R = Z^T H Z$. Normally, $R$ is computed from $Z^T H Z$ at the start of phase 2 and is then updated as the $BSN$ sets change. For efficiency the dimension of $R$ should not be excessive (say, $n_S \leq 1000$). This is guaranteed if the number of nonlinear variables is "moderate". Other QPSolver options are available for problems with many degrees of freedom.

### 4.46.2.6 The merit function

After a QP subproblem has been solved, new estimates of the NLP solution are computed using a linesearch on the augmented Lagrangian merit function
\[
\mathcal{M}(x, s, \pi) = f(x) - \pi^T (F(x) - s_N) + \frac{1}{2} (F(x) - s_N)^T D (F(x) - s_N), \tag{6}
\]
where $D$ is a diagonal matrix of penalty parameters. If $(x_k, s_k, \pi_k)$ denotes the current solution estimate and $(\hat{x}_k, \hat{s}_k, \hat{\pi}_k)$ denotes the optimal QP solution, the linesearch determines a step $\alpha_k$ ($0 < \alpha_k \leq 1$) such that the new point
\[
\begin{pmatrix}
    x_{k+1} \\
    s_{k+1} \\
    \pi_{k+1}
\end{pmatrix} =
\begin{pmatrix}
    x_k \\
    s_k \\
    \pi_k
\end{pmatrix} + \alpha_k \begin{pmatrix}
    \hat{x}_k - x_k \\
    \hat{s}_k - s_k \\
    \hat{\pi}_k - \pi_k
\end{pmatrix} \tag{7}
\]
gives a sufficient decrease in the merit function. When necessary, the penalties in $D$ are increased by the minimum-norm perturbation that ensures descent for $\mathcal{M}$ [112]. As in NPSOL, $s_N$ is adjusted to minimize the merit function as a function of $s$ prior to the solution of the QP subproblem. For more details, see [109] [76].
4.46.2.7 Treatment of constraint infeasibilities

SNOPT makes explicit allowance for infeasible constraints. Infeasible linear constraints are detected first by solving a problem of the form

$$\text{FLP : minimize } e^T(v + w)$$

subject to

$$\ell \leq \left( \frac{x}{A_L x - v + w} \right) \leq u, \, v \geq 0, \, w \geq 0,$$

where $e$ is a vector of ones. This is equivalent to minimizing the sum of the general linear constraint violations subject to the simple bounds. (In the linear programming literature, the approach is often called elastic programming. We also describe it as minimizing the $\ell_1$ norm of the infeasibilities.)

If the linear constraints are infeasible ( $v \neq 0$ or $w \neq 0$), SNOPT terminates without computing the nonlinear functions.

If the linear constraints are feasible, all subsequent iterates satisfy the linear constraints. (Such a strategy allows linear constraints to be used to define a region in which the functions can be safely evaluated.) SNOPT proceeds to solve NP (1) as given, using search directions obtained from a sequence of quadratic programming subproblems (2).

If a QP subproblem proves to be infeasible or unbounded (or if the dual variables $\pi$ for the nonlinear constraints become large), SNOPT enters "elastic" mode and solves the problem

$$\text{NP}(\gamma) : \quad \text{minimize } f_0(x) + \gamma e^T(v + w)$$

subject to

$$\ell \leq \left( \frac{x}{f(x) - v + w} \right) \leq u, \, v \geq 0, \, w \geq 0,$$

where $\gamma$ is a nonnegative parameter (the elastic weight), and $f(x) + \gamma e^T(v + w)$ is called a composite objective. If $\gamma$ is sufficiently large, this is equivalent to minimizing the sum of the nonlinear constraint violations subject to the linear constraints and bounds. A similar $\ell_1$ formulation of NP is fundamental to the $S \ell_1$QP algorithm of Fletcher [88]. See also Conn [59].

The initial value of $\gamma$ is controlled by the optional parameter elastic weight.

4.46.3 Starting points and advanced bases

A good starting point may be essential for solving nonlinear models. We show how such a starting point can be specified in a GAMS environment, and how SNOPT will use this information.

A related issue is the use of "restart" information in case a number of related models are solved in a row. Starting from an optimal point of a previous solve statement is in such situations often beneficial. In a GAMS environment this means reusing primal and dual information, which is stored in the .L and .M fields of variables and equations.
4.46 SNOPT

4.46.3.1 Starting points

To specify a starting point for SNOPT use the .L level values in GAMS. For example, to set all variables \( x_{i,j} := 1 \) use \( x.l(i,j)=1; \). The default values for level values are zero.

Setting a good starting point can be crucial for getting good results. As an (artificial) example consider the problem where we want to find the smallest circle that contains a number of points \((x_i, y_i)\):

Example:

\[
\begin{align*}
\text{minimize} & \quad r \\
\text{subject to} & \quad (x_i - a)^2 + (y_i - b)^2 \leq r^2, \quad r \geq 0.
\end{align*}
\]

This problem can be modeled in GAMS as follows.

```gams
set i points /p1*p10/;

parameters
   x(i) x coordinates,
   y(i) y coordinates;

* fill with random data
x(i) = uniform(1,10);
y(i) = uniform(1,10);

variables
   a x coordinate of center of circle
   b y coordinate of center of circle
   r radius;

equations
   e(i) points must be inside circle;

   e(i).. sqr(x(i)-a) + sqr(y(i)-b) =l= sqr(r);
   r.lo = 0;

model m /all/;
option nlp=snopt;
solve m using nlp minimizing r;
```

Without help, SNOPT will not be able to find an optimal solution. The problem will be declared infeasible. In this case, providing a good starting point is very easy. If we define

\[
\begin{align*}
x_{\text{min}} &= \min_i x_i, \\
y_{\text{min}} &= \min_i y_i, \\
x_{\text{max}} &= \max_i x_i, \\
y_{\text{max}} &= \max_i y_i,
\end{align*}
\]

then good estimates are

\[
\begin{align*}
a &= (x_{\text{min}} + x_{\text{max}})/2, \\
b &= (y_{\text{min}} + y_{\text{max}})/2, \\
r &= \sqrt{(a - x_{\text{min}})^2 + (b - y_{\text{min}})^2}.
\end{align*}
\]

Thus we include in our model:
parameters xmin, ymin, xmax, ymax;
xmin = smin(i, x(i));
ymin = smin(i, x(i));
xmax = smax(i, x(i));
ymax = smax(i, y(i));

* set starting point
a.l = (xmin+xmax)/2;
b.l = (ymin+ymax)/2;
r.l = sqrt( sqr(a.l-xmin) + sqr(b.l-ymin) );

and now the model solves very easily.

Level values can also be set implicitly as a result of assigning bounds, since GAMS will project variable levels onto their bounds as part of executing a solve statement. For example, when a variable is bounded away from zero by a statement like Y.LO = 1; and Y is at its default level of zero, the SOLVE statement will set the level Y.L to 1.

Note: another way to formulate the model would be to minimize $r^2$ instead of $r$. This allows SNOPT to solve the problem even with the default starting point.

4.46.3.2 Advanced basis

GAMS automatically passes on level values and basis information from one solve to the next. Thus, when we have two solve statements in a row, with just a few changes in between SNOPT will typically need very few iterations to find an optimal solution in the second solve. For instance, when we add a second solve to the fawley.gms model from the model library:

```gams
Model exxon /all/;
...
Solve exxon maximizing profit using lp;
Solve exxon maximizing profit using lp;
```

we observe the following iteration counts:

```
SOLVE SUMMARY
MODEL     exxon        OBJECTIVE profit
TYPE      LP           DIRECTION MAXIMIZE
SOLVER    SNOPT        FROM LINE 278

**** SOLVER STATUS 1 NORMAL COMPLETION
**** MODEL STATUS 1 OPTIMAL
**** OBJECTIVE VALUE 2899.2528

RESOURCE USAGE, LIMIT 0.016 1000.000
ITERATION COUNT, LIMIT 24 10000

......
```

```
SOLVE SUMMARY
MODEL     exxon        OBJECTIVE profit
TYPE      LP           DIRECTION MAXIMIZE
```
The first solve takes 24 iterations, while the second solve needs exactly zero iterations.

Basis information is passed on using the marginals of the variables and equations. In general the rule is:

- \( X.M = 0 \): basic
- \( X.M \neq 0 \): nonbasic if level value is at bound, superbasic otherwise

A marginal value of \( \text{EPS} \) means that the numerical value of the marginal is zero, but that the status is nonbasic or superbasic. The user can specify a basis by assigning zero or nonzero values to the \( .M \) values. It is further noted that if too many \( .M \) values are zero, the basis is rejected. This happens for instance when two subsequent models are too different. This decision is made based on the value of the GAMS \texttt{bratio} option.

### 4.46.4 GAMS Options

The usual GAMS options (e.g. \texttt{reslim}, \texttt{sysout}) can be used to control GAMS/SNOPT. For more details, see section Controlling a Solver via GAMS Options. We highlight some of the details of this usage below for cases of special interest.

**iterlim**

Sets the minor iteration limit. SNOPT will stop as soon as the number of minor iterations exceeds the iteration limit, in which case the current solution will be reported.

**domlim**

Sets the domain error limit. Domain errors are evaluation errors in the nonlinear functions. An example of a domain error is trying to evaluate \( \sqrt{x} \) for \( x < 0 \). Other examples include taking logs of negative numbers, and evaluating the real power \( x^y \) for \( x < \epsilon \) (\( x^y \) is evaluated as \( \exp(y \log x) \)). When such an error occurs the count of domain errors is incremented: SNOPT will stop if this count exceeds the limit. If the limit has not been reached, reasonable estimates for the function (and derivatives, if requested) are returned and SNOPT continues. For example, in the case of \( \sqrt{x}, x < 0 \) a zero is passed back for the function value and a large value for the derivative. In many cases SNOPT will be able to recover from these domain errors, especially when they happen at some intermediate point. Nevertheless it is best to add appropriate bounds or linear constraints to ensure that these domain errors don’t occur. For example, when an expression \( \log(x) \) is present in the model, add a statement like \( x.lo = 0.001; \).

**bratio**

Ratio used in basis acceptance test. When a previous solution or solution estimate exists, GAMS automatically passes this solution to SNOPT so that it can reconstruct an advanced basis. When too many new (i.e. uninitialized with level and/or marginal values) variables or constraints enter the model, it may be better not to use existing basis information, but to instead crash a new basis. The \texttt{bratio} determines how quickly an existing basis is discarded. A value of 1.0 will discard any basis, while a value of 0.0 will retain any basis.
workfactor

By default, GAMS/SNOPT computes an estimate of the amount of workspace needed by SNOPT, and passes this workspace on to SNOPT for use in solving the model. This estimate is based on the model statistics: number of (nonlinear) equations, number of (nonlinear) variables, number of (nonlinear) nonzeroes, etc. In most cases this is sufficient to solve the model. In some rare cases SNOPT may need more memory, and the user can provide this by specifying a value of workfactor greater than 1. The computed memory estimate is multiplied by the workfactor to determine the amount of workspace made available to SNOPT for the solve.

workspace

This option is deprecated: use the workfactor option instead. The workspace option specifies the amount of memory, in MB, that SNOPT will use.

reform

This option controls the objective reformulation mechanism described in Section Objective function reconstruction. The default value of 100 will cause GAMS/SNOPT to try further substitutions along the diagonal after the objective variable has been removed. Any other value will disable this diagonal procedure.

4.46.5 SNOPT Options

The performance of GAMS/SNOPT is controlled by a number of parameters or “options.” Each option has a default value that should be appropriate for most problems. For special situations it is possible to specify non-default values for some or all of the options via the SNOPT option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

Note that the option file is not case sensitive. The tables below contain summary information about the SNOPT options, default values, and links to more detailed explanations.

</tbody>
</table>

**central difference interval** *(real)*: Not applicable: GAMS provides analytic derivatives

Default: $6.0e-6$

**check frequency** *(integer)*: Controls frequency of linear constraint satisfaction test

Every $i$th minor iteration after the most recent basis factorization, a numerical test is made to see if the current solution $x$ satisfies the general linear constraints (including linearized nonlinear constraints, if any). The constraints are of the form $Ax - s = b$, where $s$ is the set of slack variables. To perform the numerical test, the residual vector $r = b - Ax + s$ is computed. If the largest component of $r$ is judged to be too large, the current basis is refactorized and the basic variables are recomputed to satisfy the general constraints more accurately.

Check frequency 1 is useful for debugging purposes, but otherwise this option should not be needed.

Range: $[1, \infty)$

Default: 60
cold start (no value): Ignore advanced basis and use CRASH procedure

Requests that the CRASH procedure be used to choose an initial basis. This option takes precedence over the GAMS bratio option.

crash option (integer): Controls the basis crash algorithm

Except on restarts, a CRASH procedure is used to select an initial basis from certain rows and columns of the constraint matrix (\( A - I \)). The Crash option \( i \) determines which rows and columns of \( A \) are eligible initially, and how many times CRASH is called. Columns of \( -I \) are used to pad the basis where necessary.

If \( i \geq 1 \), certain slacks on inequality rows are selected for the basis first. (If \( i \geq 2 \), numerical values are used to exclude slacks that are close to a bound.) CRASH then makes several passes through the columns of \( A \), searching for a basis matrix that is essentially triangular. A column is assigned to “pivot” on a particular row if the column contains a suitably large element in a row that has not yet been assigned. (The pivot elements ultimately form the diagonals of the triangular basis.) For the remaining unassigned rows, slack variables are inserted to complete the basis.

By default, crash option 3 is used for linearly constrained problems and crash option 0 for problems with nonlinear constraints.

Default: auto: 0 or 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial basis will be a slack basis. The initial basis contains only slack variables: ( B = I ).</td>
</tr>
<tr>
<td>1</td>
<td>One phase CRASH. CRASH is called once, looking for a triangular basis in all rows and columns of the matrix ( A ).</td>
</tr>
<tr>
<td>2</td>
<td>Two phase CRASH. CRASH is called twice (if there are nonlinear constraints). The first call looks for a triangular basis in linear rows, and the iteration proceeds with simplex iterations until the linear constraints are satisfied. The Jacobian is then evaluated for the first major iteration and CRASH is called again to find a triangular basis in the nonlinear rows (retaining the current basis for linear rows).</td>
</tr>
<tr>
<td>3</td>
<td>Three phase CRASH. CRASH is called up to three times (if there are nonlinear constraints). The first two calls treat linear equalities and linear inequalities separately. As before, the last call treats nonlinear rows before the first major iteration.</td>
</tr>
</tbody>
</table>

crash tolerance (real): Allow crash procedure to ignore small elements in eligible columns

The Crash tolerance \( r \) allows the starting procedure CRASH to ignore certain small nonzeros in each column of \( A \). If \( a_{\text{max}} \) is the largest element in column \( j \), other nonzeros \( a_{ij} \) in the column are ignored if \( |a_{ij}| \leq a_{\text{max}} \times r \). (To be meaningful, \( r \) should be in the range \( 0 \leq r < 1 \).)

When \( r > 0.0 \), the basis obtained by CRASH may not be strictly triangular, but it is likely to be nonsingular and almost triangular. The intention is to obtain a starting basis containing more columns of \( A \) and fewer (arbitrary) slacks. A feasible solution may be reached sooner on some problems.

For example, suppose the first \( m \) columns of \( A \) are the matrix shown under LU_factor_tolerance, i.e. a tridiagonal matrix with entries \(-1, 2, -1\). To help CRASH choose all \( m \) columns for the initial basis, we would specify Crash tolerance \( r \) for some value of \( r > 0.5 \).
Range: $[0, 1]$
Default: 0.1

dervative linesearch \((no value)\): Linesearch method (safeguarded cubic interpolation) with use of derivatives

At each major iteration a linesearch is used to improve the merit function. A derivative linesearch uses safeguarded cubic interpolation and requires both function and gradient values to compute estimates of the step size $\alpha_k$.

difference interval \((real)\): Not applicable: GAMS provides analytic derivatives

This alters the interval $h_1$ that is used to estimate gradients by forward differences in the following circumstances:

- In the initial (“cheap”) phase of verifying the problem derivatives.
- For verifying the problem derivatives.
- For estimating missing derivatives.

In all cases, a derivative with respect to $x_j$ is estimated by perturbing that component of $x$ to the value $x_j + h_1(1 + |x_j|)$, and then evaluating $f_0(x)$ or $f(x)$ at the perturbed point. The resulting gradient estimates should be accurate to $O(h_1)$ unless the functions are badly scaled. Judicious alteration of $h_1$ may sometimes lead to greater accuracy. This option has limited use in a GAMS environment as GAMS provides analytical gradients.

Default: $1.5 \times 10^{-8}$

elastic weight \((real)\): Control for elastic mode

The elastic weight $\omega$ determines the initial weight $\gamma$ associated with problem $NP(\gamma)$. At any given major iteration $k$, elastic mode is started if the QP subproblem is infeasible or if the QP dual variables are larger in magnitude than $\omega(1 + \|g(x_k)\|_2)$, where $g$ is the objective gradient. In either case, the QP is re-solved in elastic mode with $\gamma = \omega(1 + \|g(x_k)\|_2)$.

Thereafter, $\gamma$ is increased (subject to a maximum allowable value) at any point that is optimal for problem $NP(\gamma)$, but not feasible for NP. After the $r$th such increase, $\gamma = \omega 10^r(1 + \|g(x_{k1})\|_2)$, where $x_{k1}$ is the iterate at which $\gamma$ was first needed.

Default: $1.0 \times 10^4$

expand frequency \((integer)\): Setting for anti-cycling mechanism

This option is part of the EXPAND anti-cycling procedure \cite{111} designed to make progress even on highly degenerate problems.

For linear models, the strategy is to force a positive step at every iteration, at the expense of violating the bounds on the variables by a small amount. Suppose that the minor feasibility tolerance is $\delta$ and the expand frequency is $k$. Over a period of $k$ iterations, the tolerance actually used by SNOPT increases from $0.5\delta$ to $\delta$ (in steps of $0.5\delta/k$).

For nonlinear models, the same procedure is used for iterations in which there is only one superbasic variable. (Cycling can occur only when the current solution is at a vertex of the feasible region.) Thus, zero steps are allowed if there is more than one superbasic variable, but otherwise positive steps are enforced.

At least every $k$ iterations, a resetting procedure eliminates any infeasible nonbasic variables. Increasing $k$ helps to reduce the number of these slightly infeasible nonbasic variables. However, it also diminishes the freedom to choose a large pivot element (see pivot tolerance).

Range: $[1, \infty]$
Default: 10000
factorization frequency (integer): Number of iterations between basis factorizations

At most $k$ basis changes will occur between factorizations of the basis matrix.

- With linear programs, the basis factors are usually updated every iteration. The default $k$ is reasonable for typical problems. Smaller values (say $k = 75$ or $k = 50$) may be more efficient on problems that are rather dense or poorly scaled.
- When the problem is nonlinear, fewer basis updates will occur as an optimum is approached. The number of iterations between basis factorizations will therefore increase. During these iterations a test is made regularly (according to the check frequency) to ensure that the general constraints are satisfied. If necessary the basis will be refactorized before the limit of $k$ updates is reached.

By default, the frequency is set to 100 for linear models and 50 otherwise.

Range: $[1, \infty]$  
Default: auto: 100 or 50

feasible point (no value): Ignore objective function and find a feasible point

The keyword feasible point means "Ignore the objective function" while finding a feasible point for the linear and nonlinear constraints. It can be used to check that the nonlinear constraints are feasible.

Default: turned off.

function precision (real): Relative accuracy with which the nonlinear functions are evaluated

The relative function precision $\epsilon_R$ is intended to be a measure of the relative accuracy with which the nonlinear functions can be computed. For example, if $f(x)$ is computed as $1000.56789$ for some relevant $x$ and if the first 6 significant digits are known to be correct, the appropriate value for $\epsilon_R$ would be $1.0e^{-6}$.

(Ideally the functions $f_0(x)$ or $f_i(x)$ should have magnitude of order 1. If all functions are substantially less than 1 in magnitude, $\epsilon_R$ should be the absolute precision. For example, if $f(x) = 1.23456789e^{-4}$ at some point and if the first 6 significant digits are known to be correct, the appropriate value for $\epsilon_R$ would be $1.0e^{-10}$.)

- The default value of $\epsilon_R$ is appropriate for simple analytic functions.
- In some cases the function values will be the result of extensive computation, possibly involving an iterative procedure that can provide rather few digits of precision at reasonable cost. Specifying an appropriate function precision may lead to savings, by allowing the linesearch procedure to terminate when the difference between function values along the search direction becomes as small as the absolute error in the values.

Default: $3.00e^{-13}$

hessian frequency (integer): How often the full Hessian is reset to the identity matrix

This option sets the frequency $i$ for resetting the full memory Hessian. For example, if hessian full memory is selected and $i$ BFGS updates have already been carried out, the Hessian approximation is reset to the identity matrix. (For certain problems, occasional resets may improve convergence, but in general they should not be necessary.)

Hessian Full Memory and Hessian Frequency = 20 have a similar effect to Hessian Limited Memory and Hessian Updates = 20, except that the latter retains the current diagonal during resets.

Default: 999999
**hessian full memory (no value):** Approximate Hessian is treated as a dense matrix

This option selects the full storage method for storing and updating the approximate Hessian. (SNOPT uses a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration.)

If **Hessian Full Memory** is specified, the approximate Hessian is treated as a dense matrix and the BFGS updates are applied explicitly. This option is most efficient when the number of nonlinear variables \( n_1 \) is not too large. In this case, the storage requirement is fixed and one can expect Q-superlinear convergence to the solution.

By default, this storage method is chosen when the number of nonlinear variables \( n_1 \leq 75 \).

**hessian limited memory (no value):** Limited-memory procedure is used to update a diagonal Hessian approximation

This option selects the limited memory storage method for storing and updating the approximate Hessian. (SNOPT uses a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration.)

**Hessian Limited Memory** should be used on problems where the number of nonlinear variables \( n_1 \) is large. In this case a limited-memory procedure is used to update a diagonal Hessian approximation \( H_r \) a limited number of times. (Updates are accumulated as a list of vector pairs. They are discarded at regular intervals after \( H_r \) has been reset to their diagonal.)

By default, this storage method is chosen when the number of nonlinear variables \( n_1 > 75 \).

**hessian updates (integer):** How often the limited memory Hessian is reset

If **hessian limited memory** is selected and \( i \) BFGS updates have already been carried out, all but the diagonal elements of the accumulated updates are discarded and the updating process starts again.

Broadly speaking, the more updates stored, the better the quality of the approximate Hessian. However, the cost of each QP iteration also increases with the number of updates. The default value is likely to give a robust algorithm without significant expense, but faster convergence can sometimes be obtained with significantly fewer updates (e.g., \( i = 5 \)).

Default: 10

**infinite bound (real):** Bounds larger than this number are considered Infinity

If \( r > 0 \), \( r \) defines the "infinite" bound \( \text{infBnd} \) in the definition of the problem constraints. Any upper bound greater than or equal to \( \text{infBnd} \) will be regarded as plus infinity (and similarly for a lower bound less than or equal to \( -\text{infBnd} \)). If \( r \leq 0 \), the default value is used.

Default: 1.0e20

**iterations limit (integer):** Minor iteration limit

The maximum number of minor iterations allowed (i.e., iterations of the simplex method or the QP algorithm), summed over all major iterations. This option, if set, overrides the GAMS iterlim specification.

Default: GAMS iterlim

**linesearch tolerance (real):** Controls accuracy of steplength selected
This controls the accuracy with which a steplength will be located along the direction of search at each iteration. At the start of each linesearch a target directional derivative for the merit function is identified. The linesearch tolerance \( t \) determines the accuracy to which this target value is approximated.

- Larger values like \( t = 0.9 \) request just moderate accuracy in the linesearch.
- If the nonlinear functions are cheap to evaluate, as is usually the case for GAMS models, a more accurate search may be appropriate; try \( t = 0.1, 0.01 \) or \( 0.001 \). The number of major iterations might decrease.
- If the nonlinear functions are expensive to evaluate, a less accurate search may be appropriate. In the case of running under GAMS where all gradients are known, try \( t = 0.99 \). The number of major iterations might increase, but the total number of function evaluations may decrease enough to compensate.

Range: \([0, 1]\)

Default: 0.1

**LU complete pivoting** (no value): LUSOL pivoting strategy

See **LU_partial_pivoting**.

**LU density tolerance** (real): Controls when to move to a dense factorization

The density tolerance \( r_1 \) is used during LUSOL’s basis factorization \( B = LU \). Columns of \( L \) and rows of \( U \) are formed one at a time, and the remaining rows and columns of the basis are altered appropriately. At any stage, if the density of the remaining matrix exceeds \( r_1 \), the Markowitz strategy for choosing pivots is terminated and the remaining matrix is factored by a dense \( LU \) procedure. Raising the density tolerance towards 1.0 may give slightly sparser \( LU \) factors, with a slight increase in factorization time.

See also **LU_singularity_tolerance**.

Range: \([0, 1]\)

Default: 0.6

**LU factor tolerance** (real): Trade-off between stability and sparsity in basis factorization

**LU factor tolerance** \( r_1 \)

**LU update tolerance** \( r_2 \)

These tolerances affect the stability and sparsity of the basis factorization \( B = LU \) during refactorization and updating, respectively. They must satisfy \( r_1, r_2 \geq 1.0 \). The matrix \( L \) is a product of matrices of the form

\[
\begin{pmatrix}
1 \\
\mu \\
1
\end{pmatrix}
\]

where the multipliers \( \mu \) satisfy \( |\mu| \leq r_i \). Smaller values of \( r_1 \) favor stability, while larger values favor sparsity.

- For large and relatively dense problems, smaller values of \( r_1 \) (e.g. \( r_1 = 3.0 \)) may give a useful improvement in stability without impairing sparsity to a serious degree.
For certain very regular structures (e.g., band matrices) it may be necessary to reduce $r_1$ and/or $r_2$ in order to achieve stability. For example, if the columns of $A$ include a submatrix of the form

$$
\begin{pmatrix}
2 & -1 & & & \\
-1 & 2 & -1 & & \\
& -1 & 2 & -1 & \\
& & & \ddots & \ddots & \ddots \\
& & & -1 & 2 & -1 \\
& & & & -1 & 2
\end{pmatrix},
$$

both $r_1$ and $r_2$ should be in the range $1.0 \leq r_i < 2.0$.

For linear models, the defaults are $r_1 = 100$ and $r_2 = 10$, while for nonlinear models both tolerances default to 3.99.

See also LU_update_tolerance.

Range: $[1, \infty]$  
Default: auto

**LU partial pivoting** *(no value)*: LUSOL pivoting strategy  

The LUSOL factorization implements a Markowitz-type search for pivots that locally minimizes fill-in subject to a threshold pivoting stability criterion. The rook pivoting and complete pivoting options are more expensive than partial pivoting but are more stable and better at revealing rank, as long as the LU_factor_tolerance is not too large (say $r_1 < 2.0$).

When numerical difficulties are encountered, SNOPT automatically reduces the LU tolerances toward 1.0 and switches (if necessary) to rook or complete pivoting before reverting to the default or specified options at the next refactorization. (With sysout on and system information enabled, relevant messages are output to the listing file.)

Default: yes

**LU rook pivoting** *(no value)*: LUSOL pivoting strategy  

See LU_partial_pivoting.

**LU singularity tolerance** *(real)*: Protection against ill-conditioned basis matrices  

The singularity tolerance $r_2$ helps guard against ill-conditioned basis matrices. After $B$ is refactorized, the diagonal elements of $U$ are tested as follows: if $|U_{jj}| \leq r_2$ or $|U_{jj}| < r_2 \max_i |U_{ij}|$, the $j$th column of the basis is replaced by the corresponding slack variable. (This is most likely to occur after a restart.)

See also LU_density_tolerance.

Default: $3.67e-11$

**LU update tolerance** *(real)*: Trade-off between stability and sparsity in basis factorization  

See LU_factor_tolerance for details.

Range: $[1, \infty]$  
Default: auto

**major feasibility tolerance** *(real)*: Feasibility tolerance for nonlinear constraints  

This tolerance $\epsilon_r$ specifies how accurately the nonlinear constraints should be satisfied. The default value of $1.0e-6$ is appropriate when the constraints are expected to have at least that accuracy.

Let $\text{rowerr}$ be the maximum nonlinear constraint violation, normalized by the size of the solution. It is required to satisfy

$$\text{rowerr} = \max_i \frac{\text{viol}_i}{\|x\|} \leq \epsilon_r,$$

where $\text{viol}_i$ is the violation of the $i$th nonlinear constraint.

In the GAMS/SNOPT iteration log, $\text{rowerr}$ appears as the quantity labeled "Feasibl". If some of the problem functions are known to be of low accuracy, a larger Major feasibility tolerance may be appropriate.

Default: $1.0e-6$

**major iterations limit (integer):** Max number of major iterations

This is the maximum number of major iterations allowed. It is intended to guard against an excessive number of linearizations of the constraints. By default it is set to $\max(1000, m)$.

Default: auto: $\max(1000, m)$

**major optimality tolerance (real):** Specifies the final accuracy of the dual variables

This tolerance $\epsilon_d$ specifies the final accuracy of the dual variables. On successful termination, SNOPT will have computed a solution $(x, s, \pi)$ such that

$$\max\text{Comp} = \max_j \frac{\text{Comp}_j}{\|\pi\|} \leq \epsilon_d,$$

where $\text{Comp}_j$ is an estimate of the complementarity slackness for variable $j$. The values $\text{Comp}_j$ are computed from the final QP solution using the reduced gradients $d_j = g_j - \pi^T a_j$ (where $g_j$ is the $j$th component of the objective gradient, $a_j$ is the associated column of the constraint matrix $(A - I)$ and $\pi$ is the set of QP dual variables):

$$\text{Comp}_j = \begin{cases} d_j \min\{x_j - l_j, 1\} & \text{if } d_j \geq 0; \\ -d_j \min\{u_j - x_j, 1\} & \text{if } d_j < 0. \end{cases}$$

In the GAMS/SNOPT iteration log, $\max\text{Comp}$ appears as the quantity labeled "Optimal".

Default: $1.0e-6$

**major print level (integer):** Amount of information printed during optimization (listing file)

This controls the amount of output to the GAMS listing file at each major iteration. This output is only visible if the `sysout` option is turned on. Major print level 1 gives normal output for linear and nonlinear problems, and Major print level 11 gives additional details of the Jacobian factorization that commences each major iteration. In general, the value specified may be thought of as a binary number of the form

```
Major print level    JFDXbs
```

where each letter stands for a digit that is either 0 or 1 as follows:

- $s$ single line that gives a summary of each major iteration. (This entry in `JFDXbs` is not strictly binary since the summary line is printed whenever `JFDXbs` $\geq 1$).
• b BASIS statistics, i.e., information relating to the basis matrix whenever it is refactorized. (This output is always provided if JFDXbs ≥ 10).
• X x_k, the nonlinear variables involved in the objective function or the constraints.
• D π_k, the dual variables for the nonlinear constraints.
• F F(x_k), the values of the nonlinear constraint functions.
• J J(x_k), the Jacobian.

To obtain output of any items JFDXbs, set the corresponding digit to 1, otherwise to 0.

If J=1, the Jacobian will be output column-wise at the start of each major iteration. Column j will be preceded by the value of the corresponding variable x_j and a key to indicate whether the variable is basic, superbasic or nonbasic. (Hence if J=1, there is no reason to specify X=1 unless the objective contains more nonlinear variables than the Jacobian.) A typical line of output is

3 1.250000D+01 BS 1 1.00000E+00 4 2.00000E+00

which would mean that x_3 is basic at value 12.5, and the third column of the Jacobian has elements of 1.0 and 2.0 in rows 1 and 4.

Major print level 0 suppresses most output, except for error messages.

Default: 1

major step limit (real): Limits the change in x during a linesearch

This parameter r limits the change in x during a linesearch. It applies to all nonlinear problems, once a "feasible solution" or "feasible subproblem" has been found.

1. A linesearch determines a step α over the range 0 < α ≤ β, where β is 1 if there are nonlinear constraints, or the step to the nearest upper or lower bound on x if all the constraints are linear. Normally, the first steplength tried is α_1 = min(1, β).

2. In some cases, such as f(x) = ae^{bx} or f(x) = ax^b, even a moderate change in the components of x can lead to floating-point overflow. The parameter r is therefore used to define a limit β = r(1 + ∥x∥)/∥p∥ (where p is the search direction), and the first evaluation of f(x) is at the potentially smaller steplength α_1 = min(1, β/β).

3. Wherever possible, upper and lower bounds on x should be used to prevent evaluation of nonlinear functions at meaningless points. The Major step limit provides an additional safeguard. The default value r = 2.0 should not affect progress on well behaved problems, but setting r = 0.1 or 0.01 may be helpful when rapidly varying functions are present. A "good" starting point may be required. An important application is to the class of nonlinear least-squares problems.

4. In cases where several local optima exist, specifying a small value for r may help locate an optimum near the starting point.

Default: 2.0

minor feasibility tolerance (real): Feasibility tolerance for all variables and linear constraints

SNOPT tries to ensure that all variables eventually satisfy their upper and lower bounds to within this tolerance t. This includes slack variables, so general linear constraints should also be satisfied to within t.

Feasibility with respect to nonlinear constraints is judged by the major feasibility tolerance.
• If the bounds and linear constraints cannot be satisfied to within \( t \), the problem is declared infeasible. Let \( s_{\text{Inf}} \) be the corresponding sum of infeasibilities. If \( s_{\text{Inf}} \) is quite small, it may be appropriate to raise \( t \) by a factor of 10 or 100. Otherwise, some error in the data should be suspected.

• Nonlinear functions will be evaluated only at points that satisfy the bounds and linear constraints. If there are regions where a function is undefined, every attempt should be made to eliminate these regions from the problem. For example, if \( f(x) = \sqrt{x_1} + \log x_2 \), it is essential to place lower bounds on both variables. If \( t = 1.0e-6 \), the bounds \( x_1 \geq 10^{-5} \) and \( x_2 \geq 10^{-4} \) might be appropriate. (The log singularity is more serious. In general, keep \( x \) as far away from singularities as possible.)

• If the model is scaled (see scale option), feasibility is defined in terms of the scaled problem.

• In reality, SNOPT uses \( t \) as a feasibility tolerance for satisfying the bounds on \( x \) and \( s \) in each QP subproblem. If the sum of infeasibilities cannot be reduced to zero, the QP subproblem is declared infeasible. SNOPT is then in elastic mode thereafter (with only the linearized nonlinear constraints defined to be elastic). See elastic weight for details.

Default: \( 1.0e-6 \)

**minor iterations limit** (*integer*): Max number of minor iterations between linearizations of nonlinear constraints

Minor iterations limit \( k \). If the number of minor iterations for the optimality phase of the QP subproblem exceeds \( k \), then all nonbasic QP variables that have not yet moved are frozen at their current values and the reduced QP is solved to optimality. Note that more than \( k \) minor iterations may be necessary to solve the reduced QP to optimality. These extra iterations are necessary to ensure that the terminated point gives a suitable direction for the linesearch. In the major iteration log, a \( t \) at the end of a line indicates that the corresponding QP was artificially terminated using the limit \( k \). Note that iterations limit defines an independent absolute limit on the total number of minor iterations (summed over all QP subproblems).

Default: 500

**minor print level** (*integer*): Amount of information printed during optimization (listing file)

This controls the amount of output to the GAMS listing file during solution of the QP subproblems. It is only useful if the GAMS sysout option is turned on. The value of \( k \) has the following effect:

- \( 0 \) No minor iteration output except error messages.
- \( \geq 1 \) A single line of output each minor iteration (controlled by print frequency).
- \( \geq 10 \) Basis factorization statistics generated during the periodic refactorization of the basis (see factorization frequency). Statistics for the first factorization of each major iteration are controlled by the major print level.

Default: 1

**new superbasics limit** (*integer*): Limit on new superbasics when a QP subproblem is solved

This option causes early termination of the QP subproblems if the number of free variables has increased significantly since the first feasible point. If the number of new superbasics is greater than new superbasics limit the nonbasic variables that have not yet moved are frozen and the resulting smaller QP is solved to optimality. In the major iteration log, a "T" at the end of a line indicates that the QP was terminated early in this way.

Default: 99
**nondervative linesearch** *(no value)*: Linensearch method (safeguarded quadratic interpolation) without use of derivatives

A **nondervative linesearch** can be slightly less robust on difficult problems, and it is recommended that the default **derivative linesearch** be used if the functions and derivatives can be computed at approximately the same cost. If the gradients are very expensive relative to the functions, a nondervative linesearch may give a significant decrease in computation time. In a GAMS environment **derivative linesearch** (the default) is more appropriate.

**partial price** *(integer)*: Number of segments in partial pricing strategy

This parameter sets the number of segments \( k \) using in partial pricing and is recommended for large problems that have significantly more variables than constraints. It reduces the work required for each "pricing" operation (i.e. when a nonbasic variable is selected to become superbasic).

- When \( k = 1 \), all columns of the constraint matrix \( (A - I) \) are searched.
- Otherwise, \( A \) and \( I \) are partitioned to give \( k \) roughly equal segments \( A_j, I_j \) (\( j = 1 \) to \( k \)). If the previous pricing search was successful on \( A_j, I_j \), the next search begins on the segments \( A_{j+1}, I_{j+1} \). (All subscripts here are modulo \( k \).)
- If a reduced gradient is found that is larger than some dynamic tolerance, the variable with the largest such reduced gradient (of appropriate sign) is selected to become superbasic. If nothing is found, the search continues on the next segments \( A_{j+2}, I_{j+2} \), and so on.
- **Partial price** \( t \) (or \( t/2 \) or \( t/3 \)) may be appropriate for time-stage models having \( t \) time periods.

The default is 10 for linear models and 1 for nonlinear models.

Range: \([1, \infty]\)

Default: **auto**

**penalty parameter** *(real)*: Initial penalty parameter

After a QP subproblem has been solved, new estimates of the NLP solution are computed using a linesearch on the augmented Lagrangian merit function. This functions contains penalty parameters, which may be increased to ensure descent.

Default: 0

**pivot tolerance** *(real)*: Used to keep the basis non-singular

During solution of QP subproblems, the pivot tolerance \( r \) is used to prevent columns entering the basis if they would cause the basis to become almost singular.

- When \( x \) changes to \( x + \alpha p \) for some search direction \( p \), a ratio test is used to determine which component of \( x \) reaches an upper or lower bound first. The corresponding element of \( p \) is called the pivot element.
- Elements of \( p \) are ignored (and therefore cannot be pivot elements) if they are smaller than the pivot tolerance \( r \).
- It is common for two or more variables to reach a bound at essentially the same time. In such cases, the **minor feasibility tolerance** (say \( t \)) provides some freedom to maximize the pivot element and thereby improve numerical stability. Excessively small values of \( t \) should therefore not be specified.
- To a lesser extent, the **expand frequency** (say \( f \)) also provides some freedom to maximize the pivot element. Excessively large values of \( f \) should therefore not be specified.
Default: $3.67 \times 10^{-11}$

**print frequency** *(integer)*: Number of iterations between each log line (listing file) →

Synonym: log_frequency

When `sysout` is turned on and minor print level is positive, a line of the QP iteration log will be printed on the listing file every $k$th minor iteration.

Range: $[1, \infty]$  

Default: 100

**proximal point method** *(integer)*: Controls proximal point method used for solving linear constraints →

Once the linear constraints are satisfied, the proximal point method chooses a linear feasible point that is closest to $x_0$, the initial point for the nonlinear variables. The idea is to both satisfy the linear constraints and stay close to the starting values provided for the nonlinear variables. This option is used to disable the proximal point method or to select the norm used.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | disable PPM  
Do not use the proximal point method. |
| 1     | one-norm  
Minimize the one-norm $\|x - x_0\|_1$. |
| 2     | two-norm  
Minimize the two-norm $\frac{1}{2}\|x - x_0\|_2^2$. |

**qpsolver** *(string)*: Controls method used for QP subproblems →

This specifies the method used to solve system (5) for the search directions in phase 2 of the QP subproblem.

- The Cholesky QP solver is the most robust, but may require a significant amount of computation if the number of superbasics is large.
- The quasi-Newton QP solver does not require the computation of the R at the start of each QP subproblem. It may be appropriate when the number of superbasics is large but relatively few major iterations are needed to reach a solution (e.g., if SNOPT is called with a warm start).  
- The conjugate-gradient QP solver is appropriate for problems with many degrees of freedom (say, more than 2000 superbasics).

Default: Cholesky
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| Cholesky | full Cholesky factor  
**QPSolver Cholesky** holds the full Cholesky factor $R$ of the reduced Hessian $Z^THZ$. As the minor iterations proceed, the dimension of $R$ changes with the number of superbasic variables. If the number of superbasic variables needs to increase beyond the value of reduced hessian dimension, the reduced Hessian cannot be stored and the solver switches to **QPSolver CG**. The Cholesky solver is reactivated if the number of superbasics stabilizes at a value less than the reduced hessian dimension. |
| QN      | quasi-Newton method  
**QPSolver QN** solves the QP using a quasi-Newton method similar to that of MINOS. In this case, $R$ is the factor of a quasi-Newton approximate Hessian. |
| CG      | conjugate-gradient method  
**QPSolver CG** uses an active-set method similar to **QPSolver QN**, but uses the conjugate-gradient method to solve all systems involving the reduced Hessian. |

**reduced hessian dimension (integer):** Size of Hessian matrix $i$  

Synonym: hessian_dim  

This specifies that an $i \times i$ triangular matrix $R$ is to be available for use by the **QPSolver Cholesky** option (to define the reduced Hessian according to $R^TR = Z^THZ$). The value of $i$ affects when **QPSolver CG** is activated. The default is computed internally by SNOPT, currently as $\min\{2000, n_1 + 1\}$.  

Range: $[1, \infty]$  

Default: **auto**  

**scale option (integer):** Controls problem scaling  

Three scale options are available. By default, option 2 is used for linear models and option 1 for nonlinear models. See also scale tolerance and scale print.  

Default: **auto**  

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | No scaling  
This is recommended if it is known that $x$ and the constraint matrix and Jacobian never have very large elements (say, larger than 100). |
| 1     | Scale linear variables  
Linear constraints and variables are scaled by an iterative procedure that attempts to make the matrix coefficients as close as possible to 1.0 (see Fourer [98]). This will sometimes improve the performance of the solution procedures. |
| 2     | Scale linear + nonlinear variables  
All constraints and variables are scaled by the iterative procedure. Also, an additional scaling is performed that takes into account columns of $(A - I)$ that are fixed or have positive lower bounds or negative upper bounds. If nonlinear constraints are present, the scales depend on the Jacobian at the first point that satisfies the linear constraints. **Scale option 2** should therefore be used only if (a) a good starting point is provided, and (b) the problem is not highly nonlinear. |

**scale print (no value):** Print scaling factors (listing file)  

Scale print causes the row-scales $r(i)$ and column-scales $c(j)$ to be printed. The scaled matrix coefficients are $\bar{a}_{ij} = a_{ij}c(j)/r(i)$, and the scaled bounds on the variables and slacks are $l_j = l_j/c(j)$, $u_j = u_j/c(j)$, where $c(j) \equiv r(j-n)$ if $j > n$.

The listing file will only show these values if the sysout option is turned on. See also scale option and scale tolerance.

scale tolerance (real): Scale tolerance $\leftrightarrow$

The scale tolerance $t$ affects how many passes might be needed through the constraint matrix. On each pass, the scaling procedure computes the ratio of the largest and smallest nonzero coefficients in each column:

$$\rho_j = \max_i |a_{ij}|/\min_i |a_{ij}| \quad (a_{ij} \neq 0).$$

If $\max_j \rho_j$ is less than $r$ times its previous value, another scaling pass is performed to adjust the row and column scales. Raising $r$ from 0.9 to 0.99 (say) usually increases the number of scaling passes through $A$. At most 10 passes are made.

See also scale option and scale print.

Range: [0, 1]

Default: 0.9

solution (string): Prints SNOPT solution (listing file) $\leftrightarrow$

This option causes the SNOPT solution file to be printed to the GAMS listing file, provided the sysout option is also turned on.

Default: turned off.

Default: NO

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>Turn off printing of solution</td>
</tr>
<tr>
<td>YES</td>
<td>Turn on printing of solution</td>
</tr>
</tbody>
</table>

start constraint check (integer): Can be used to reduce the range of finite-difference checks $\leftrightarrow$

If verify level is positive, this option can be used to abbreviate the verification of individual derivative elements. It is the starting column number for the check.

Range: [1, $\infty$]

Default: 1

start objective check (integer): Can be used to reduce the range of finite-difference checks $\leftrightarrow$

If verify level is positive, this option can be used to abbreviate the verification of individual derivative elements. It is the starting column number for the check.

Range: [1, $\infty$]

Default: 1
stop constraint check (integer): Can be used to reduce the range of finite-difference checks

If verify level is positive, this option can be used to abbreviate the verification of individual derivative elements. It is the ending column number for the check.

Range: [1, ∞]
Default: MAXINT

stop objective check (integer): Can be used to reduce the range of finite-difference checks

If verify level is positive, this option can be used to abbreviate the verification of individual derivative elements. It is the ending column number for the check.

Range: [1, ∞]
Default: MAXINT

summary frequency (integer): Number of iterations between each log line (log file)

If minor print level is positive, a line of the QP iteration log is output every kth minor iteration.

Range: [1, ∞]
Default: 100

superbasics limit (integer): Maximum number of superbasics

This places a limit on the storage allocated for superbasic variables. Ideally, i should be set slightly larger than the number of degrees of freedom expected at an optimal solution.

For linear programs, an optimum is normally a basic solution with no degrees of freedom. The default value of i is therefore 1. For nonlinear problems, the number of degrees of freedom is often called the "number of independent variables".

Normally, i need not be greater than n₁ + 1, where n₁ is the number of nonlinear variables. For many problems, i may be considerably smaller than n₁. This will save storage if n₁ is very large.

This parameter also sets the reduced hessian dimension, unless the latter is specified explicitly (and conversely). If neither parameter is specified, GAMS chooses values for both, based on problem characteristics.

Range: [1, ∞]
Default: 1

suppress parameters (no value): Suppress printing of parameters (listing file)

Normally SNOPT prints the option file as it is being read, and then prints a complete list of the available keywords and their final values. The suppress parameters option tells SNOPT not to print the full list. Used in conjunction with the sysout option.

system information (string): Provides additional information on the progress of the iterations (listing file)

The Yes option provides additional information on the progress of the iterations, including basis repair details when ill-conditioned bases are encountered and the LU factorization parameters are strengthened.

Default: NO
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>Turn off additional printing of information on progress of algorithm</td>
</tr>
<tr>
<td>YES</td>
<td>Turn on additional printing of information on progress of algorithm</td>
</tr>
</tbody>
</table>

**timing level (integer):** Amount of timing information (listing file)

Amount of timing information written to the listing file. Used in conjunction with the `sysout` option.

Range: [0, 3]

Default: 3

**unbounded objective value (real):** Determines when a problem is called unbounded

This parameter sets the value $f_{\text{max}}$ intended to detect unboundedness in nonlinear problems. See `unbounded step size` for the setting of $\alpha_{\text{max}}$.

During a line search, $f_0$ is evaluated at points of the form $x + \alpha p$, where $x$ and $p$ are fixed and $\alpha$ varies. If $|f_0|$ exceeds $f_{\text{max}}$ or $\alpha$ exceeds $\alpha_{\text{max}}$, iterations are terminated with the exit message **Problem is unbounded (or badly scaled)**.

Unboundedness in $x$ is best avoided by placing finite upper and lower bounds on the variables.

Default: 1.0e15

**unbounded step size (real):** Determines when a problem is called unbounded

This parameter sets the value $\alpha_{\text{max}}$ used in the unboundedness test: see `unbounded objective value` for details.

Default: 1.0e18

**verify level (integer):** Finite-difference checks on the derivatives

This option refers to finite-difference checks on the derivatives computed by the user-provided routines. Derivatives are checked at the first point that satisfies all bounds and linear constraints.

This option has limited use in a GAMS environment.

Default: -1

<table>
<thead>
<tr>

<tr>
<td>-1</td>
<td>Derivative checking is disabled</td>
</tr>
</tbody>
</table>

**violation limit (integer):** Limit on maximum constraint violation after the linesearch

This parameter $\tau$ is used to define an absolute limit on the magnitude of the maximum constraint violation after the line search. On completion of the line search, the new iterate
$x_{k+1}$ satisfies the condition

$$v_i(x_{k+1}) \leq \tau \max\{1, v_i(x_0)\},$$

where $x_0$ is the point at which the nonlinear constraints are first evaluated and $v_i(x)$ is the $i$th nonlinear constraint violation $v_i(x) = \max(0, l_i - F_i(x), F_i(x) - u_i)$.

The effect of this violation limit is to restrict the iterates to lie in an expanded feasible region whose size depends on the magnitude of $\tau$. This makes it possible to keep the iterates within a region where the objective is expected to be well-defined and bounded below. If the objective is bounded below for all values of the variables, then $\tau$ may be any large positive value.

Default: 10

**warm start** *(no value)*: Use advanced basis provided by GAMS

Use an advanced basis provided by GAMS. This option takes precedence over the GAMS **bratio** option.

### 4.46.6 The SNOPT log

When GAMS/SNOPT solves a linearly constrained problem the following log is visible on the screen:

GAMS prints the number of equations, variables and non-zero elements of the model it generated. This gives an indication of the size of the model. SNOPT then says how much memory it allocated to solve the model, based on an estimate. If the user had specified a workfactor of 3, there would be a message like

Work space estimate computed by solver -- 0.26 MB
Work space estimate adj by workfactor -- 0.77 MB
The SNOPT log shows the following columns:

**Major**

The current major iteration number.

**Minor**

The number of iterations required by both the feasibility and optimality phases of the QP subproblem. Generally, **Minor** will be 1 in the later iterations, since theoretical analysis predicts that the correct active set will be identified near the solution (see Section Description of the method)

**Step**

The step length \( \alpha \) taken along the current search direction \( p \). The variables \( x \) have just been changed to \( x + \alpha p \). On reasonably well-behaved problems, the unit step will be taken as the solution is approached.

**nObj**

The number of times the nonlinear objective function has been evaluated. **nObj** is printed as a guide to the amount of work required for the linesearch.

**nCon**

The number of times SNOPT evaluated the nonlinear constraint functions.

**Merit**

The value of the augmented Lagrangian merit function (6). This function will decrease at each iteration unless it was necessary to increase the penalty parameters (see Section Description of the method). As the solution is approached, **Merit** will converge to the value of the objective at the solution.

In elastic mode, the merit function is a composite function involving the constraint violations weighted by the elastic weight.

If the constraints are linear, this item is labeled **Objective**, the value of the objective function. It will decrease monotonically to its optimal value.

**Feasibl**

The value of **rowerr**, the maximum component of the scaled nonlinear constraint residual. The solution is regarded as acceptably feasible if **Feasibl** is less than the Major feasibility tolerance.

If the constraints are linear, all iterates are feasible and this entry is not printed.

**Optimal**

The value of **maxgap**, the maximum complementarity gap. It is an estimate of the degree of nonoptimality of the reduced costs. The solution is considered to be optimal if **Optimal** is less than the major optimality tolerance.

**nS**

The current number of superbasic variables.
Penalty

The Euclidean norm of the vector of penalty parameters used in the augmented Lagrangian merit function (not printed if the constraints are linear).

PD

A two-letter indication of the status of the convergence tests involving primal and dual feasibility of the iterates (see major feasibility tolerance and major optimality tolerance). Each letter is T if the test is satisfied, and F otherwise.

If either of the indicators is F when SNOPT terminates with 0 EXIT -- optimal solution found, the user should check the solution carefully.

The summary line may include additional code characters that indicate what happened during the course of the iteration.

c Central differences have been used to compute the unknown components of the objective and constraint gradients. This should not happen in a GAMS environment.

d During the linesearch it was necessary to decrease the step in order to obtain a maximum constraint violation conforming to the value of violation limit.

l The norm-wise change in the variables was limited by the value of the major step limit. If this output occurs repeatedly during later iterations, it may be worthwhile increasing the value of major step limit.

i If SNOPT is not in elastic mode, an "i" signifies that the QP subproblem is infeasible. This event triggers the start of nonlinear elastic mode, which remains in effect for all subsequent iterations. Once in elastic mode, the QP subproblems are associated with the elastic problem $NP(\gamma)$.

If SNOPT is already in elastic mode, an "i" indicates that the minimizer of the elastic subproblem does not satisfy the linearized constraints. (In this case, a feasible point for the usual QP subproblem may or may not exist.)

M An extra evaluation of the problem functions was needed to define an acceptable positive-definite quasi-Newton update to the Lagrangian Hessian. This modification is only done when there are nonlinear constraints.

M This is the same as "M" except that it was also necessary to modify the update to include an augmented Lagrangian term.

R The approximate Hessian has been reset by discarding all but the diagonal elements. This reset will be forced periodically by the hessian frequency and hessian updates keywords. However, it may also be necessary to reset an ill-conditioned Hessian from time to time.

r The approximate Hessian was reset after ten consecutive major iterations in which no BFGS update could be made. The diagonals of the approximate Hessian are retained if at least one update has been done since the last reset. Otherwise, the approximate Hessian is reset to the identity matrix.

s A self-scaled BFGS update was performed. This update is always used when the Hessian approximation is diagonal, and hence always follows a Hessian reset.

S This is the same as a "s" except that it was necessary to modify the self-scaled update to maintain positive definiteness.

n No positive-definite BFGS update could be found. The approximate Hessian is unchanged from the previous iteration.

t The minor iterations were terminated at the minor iterations limit.

u The QP subproblem was unbounded.

w A weak solution of the QP subproblem was found.

Finally SNOPT prints an exit message. See Section EXIT conditions.
4.46.6.1 EXIT conditions

When the solution procedure terminates, an EXIT -- message is printed to summarize the final result. Here we describe each message and suggest possible courses of action.

EXIT - Optimal Solution found, objective: xx.xx

The final point seems to be a solution. This means that $x$ is feasible (it satisfies the constraints to the accuracy requested), the reduced gradient is negligible, the reduced costs are optimal, and $R$ is nonsingular. In all cases, some caution should be exercised. For example, if the objective value is much better than expected, SNOPT may have obtained an optimal solution to the wrong problem! Almost any item of data could have that effect if it has the wrong value. Verifying that the problem has been defined correctly is one of the more difficult tasks for a model builder.

If nonlinearities exist, one must always ask the question: could there be more than one local optimum? When the constraints are linear and the objective is known to be convex (e.g., a sum of squares) then all will be well if we are minimizing the objective: a local minimum is a global minimum in the sense that no other point has a lower function value. (However, many points could have the same objective value, particularly if the objective is largely linear.) Conversely, if we are maximizing a convex function, a local maximum cannot be expected to be global, unless there are sufficient constraints to confine the feasible region.

Similar statements could be made about nonlinear constraints defining convex or concave regions. However, the functions of a problem are more likely to be neither convex nor concave. Our advice is always to specify a starting point that is as good an estimate as possible, and to include reasonable upper and lower bounds on all variables, in order to confine the solution to the specific region of interest. We expect modelers to know something about their problem, and to make use of that knowledge as they themselves know best.

One other caution about the "Optimal solution" message. Some of the variables or slacks may lie outside their bounds more than desired, especially if scaling was requested. If sysout is on, the listing file will contain several indicators of potential issues. Max Primal infeas indicates the largest bound infeasibility and which variable is involved. If it is too large, consider restarting with a smaller minor feasibility tolerance (say 10 times smaller) and perhaps a scale option of 0.

Similarly, Max Dual infeas indicates which variable is most likely to be at a non-optimal value. Broadly speaking, if

$$\text{Max Dual infeas}/\text{Norm of pi} = 10^{-d},$$

then the objective function would probably change in the $d$th significant digit if optimization could be continued. If $d$ seems too large, consider restarting with smaller values of major feasibility tolerance and minor feasibility tolerance.

Finally, Nonlinear constraint violn shows the maximum infeasibility for nonlinear rows. If it seems too large, consider restarting with a smaller major feasibility tolerance.

EXIT -- Feasible point found, objective: xx.xx

Occurs only if feasible point is enabled.

EXIT -- Requested accuracy could not be achieved, objective:

If the requested accuracy could not be achieved, a feasible solution has been found, but the requested accuracy in the dual infeasibilities could not be achieved. An abnormal termination has occurred, but SNOPT is within $10^{-2}$ of satisfying the major optimality tolerance. Check that the major optimality tolerance is not too small.
EXIT -- The problem is infeasible (infeasible linear constraints)

EXIT -- The problem is infeasible (infeasible linear equalities)

When the constraints are linear, the output messages are based on a relatively reliable indicator of infeasibility. Feasibility is measured with respect to the upper and lower bounds on the variables and slacks. Among all the points satisfying the general constraints $Ax - s = 0$, there is apparently no point that satisfies the bounds on $x$ and $s$. Violations as small as the minor feasibility tolerance are ignored, but at least one component of $x$ or $s$ violates a bound by more than the tolerance.

EXIT -- Nonlinear infeasibilities minimized

EXIT -- Infeasibilities minimized

When nonlinear constraints are present, infeasibility is much harder to recognize correctly. Even if a feasible solution exists, the current linearization of the constraints may not contain a feasible point. In an attempt to deal with this situation, when solving each QP subproblem, SNOPT is prepared to relax the bounds on the slacks associated with nonlinear rows.

If a QP subproblem proves to be infeasible or unbounded (or if the Lagrange multiplier estimates for the nonlinear constraints become large), SNOPT enters so-called "nonlinear elastic" mode. The subproblem includes the original QP objective and the sum of the infeasibilities—suitably weighted using the elastic weight parameter. In elastic mode, the nonlinear rows are made "elastic"—i.e., they are allowed to violate their specified bounds. Variables subject to elastic bounds are known as elastic variables. An elastic variable is free to violate one or both of its original upper or lower bounds. If the original problem has a feasible solution and the elastic weight is sufficiently large, a feasible point eventually will be obtained for the perturbed constraints, and optimization can continue on the subproblem. If the nonlinear problem has no feasible solution, SNOPT will tend to determine a "good" infeasible point if the elastic weight is sufficiently large. (If the elastic weight were infinite, SNOPT would locally minimize the nonlinear constraint violations subject to the linear constraints and bounds.) Unfortunately, even though SNOPT locally minimizes the nonlinear constraint violations, there may still exist other regions in which the nonlinear constraints are satisfied. Wherever possible, nonlinear constraints should be defined in such a way that feasible points are known to exist when the constraints are linearized.

EXIT -- Unbounded objective

EXIT -- Unbounded: Constraint violation limit reached

For linear problems, unboundedness is detected by the simplex method when a nonbasic variable can apparently be increased or decreased by an arbitrary amount without causing a basic variable to violate a bound. Adding a bound on the objective will allow SNOPT to find a solution, and inspection of this solution will show the variables that can become too large due to missing restrictions.

Very rarely, the scaling of the problem could be so poor that numerical error will give an erroneous indication of unboundedness. Consider using the scale option.

For nonlinear problems, SNOPT monitors both the size of the current objective function and the size of the change in the variables at each step. If either of these is very large (see unbounded step size and unbounded objective value), the problem is terminated and declared UNBOUNDED. To avoid large function values, it may be necessary to impose bounds on some of the variables in order to keep them away from singularities in the nonlinear functions.

The second message indicates an abnormal termination while enforcing the limit on the constraint violations. This exit implies that the objective is not bounded below in the feasible region defined by expanding the bounds by the value of the violation limit.
EXIT -- User Interrupt

The user pressed Ctrl-C or the Interrupt button in the Windows IDE.

EXIT -- Resource Interrupt

A time limit was hit. Increase the GAMS reslim option.

EXIT -- Too many iterations (exceeding ITERLIM)

EXIT -- Too many (minor) iterations

An iteration limit was reached. Most often this is cured by increasing the GAMS iterlim option. If an SNOPT option file was used, also the iterations limit may have been set too small.

Check the iteration log to be sure that progress was being made. If so, repeat the run with higher limits. If not, consider specifying new initial values for some of the nonlinear variables.

EXIT -- Major iteration limit reached

This indicates SNOPT was running out the limit on major iterations. This can be changed using the major iterations limit.

EXIT -- The superbasics limit is too small

The problem appears to be more nonlinear than anticipated. The current set of basic and superbasic variables have been optimized as much as possible and a PRICE operation is necessary to continue, but there are already as many superbasics as allowed (and no room for any more).

When increasing the superbasics limit, be aware that this also increases the reduced hessian dimension unless both options are set explicitly. This may increase the amount of memory required by SNOPT dramatically. Consider also increasing the amount memory available to SNOPT via the workfactor option, or setting a more moderate value for the reduced hessian dimension option and possibly getting slower convergence.

EXIT -- Current point cannot be improved

The algorithm could not find a better solution although optimality was not achieved within the optimality tolerance. Possibly scaling can lead to better function values and derivatives. Raising the major optimality tolerance will probably make this message go away. Try better scaling, better bounds or a better starting point.

EXIT -- Singular basis

The first factorization attempt found the basis to be structurally or numerically singular. (Some diagonals of the triangular matrix U were deemed too small.) The associated variables were replaced by slacks and the modified basis refactored, but singularity persisted. Try better scaling, better bounds or a better starting point.

EXIT -- Cannot satisfy the general constraints

The basic variables $x_B$ have been recomputed, given the present values of the superbasic and nonbasic variables. A step of "iterative refinement" has also been applied to increase the accuracy of $x_B$, but a row check has revealed that the resulting solution does not satisfy the QP constraints $Ax - s = b$ sufficiently well. Try better scaling, better bounds or a better starting point.

EXIT -- Ill-conditioned null-space basis
During computation of the reduced Hessian $Z^T H Z$, some column(s) of $Z$ continued to contain very large values. Try better scaling, better bounds or a better starting point.

**EXIT -- Incorrect objective derivatives**

**EXIT -- Incorrect constraint derivatives**

The derivatives are not deemed to be correct. This message should not occur using a GAMS model without external equations.

**EXIT -- Undefined function at the initial point**

**EXIT -- Undefined function at the first feasible point**

SNOPT was unable to proceed because the functions are undefined at the initial point or the first feasible point. Try to add better bounds or linear equations such that non-linear functions can be evaluated or use a better starting point.

**EXIT -- Unable to proceed into undefined region**

Repeated attempts to move into a region where the functions are not defined resulted in the change in variables being unacceptably small. At the final point, it appears that the only way to decrease the merit function is to move into a region where the problem functions are not defined.

Try to add better bounds or linear equations such that non-linear functions can be evaluated or use a better starting point.

**EXIT -- Function evaluation error limit**

The domain error limit was reached. Increase the GAMS domlim option, or even better add better bounds (or linear equations) such that functions and derivatives can be evaluated.

**EXIT -- Terminated during objective evaluation**

**EXIT -- Terminated during constraint evaluation**

**EXIT -- Terminated from monitor routine**

These messages indicate trouble evaluating the non-linear functions or derivatives. Usually these errors show a “Function evaluation error limit” message.

---

### 4.47 SolveEngine

#### 4.47.1 Introduction

GAMS/SolveEngine allows users to solve GAMS models using solvers from the Satalia SolveEngine. The SolveEngine aggregates different solution algorithms for optimization problems and automatically selects an algorithm that seems to suite best for a given model instance. Currently, LP and MIP problems can be handled by the SolveEngine.

The GAMS/SolveEngine link comes for free with any licensed GAMS system. Users must have an API key for the Satalia SolveEngine to submit jobs. The GAMS/SolveEngine link submits a GAMS model instance to the SolveEngine server, schedules it for processing, and waits until the problem has been solved.
4.47.2 Usage

To run GAMS/SolveEngine, specify to use solveengine as solver. For example, if one wishes to solve the trnsport.gms model, one would run

```bash
> gams trnsport.gms solver=solveengine
```

A SolveEngine API key is necessary to submit jobs to the SolveEngine. Once a user has registered for SolveEngine, the API key is available after login. To make GAMS/SolveEngine aware of this key, either set the environment variable SOLVEENGINE_APIKEY to the key string, or use the option apikey.

Currently, only the GAMS option reslim is supported by the GAMS/SolveEngine link. The limit set by reslim is passed on to the SolveEngine and applied there for the running solver. It can therefore take longer for the GAMS/SolveEngine run to finish than what is specified by reslim. Further, note that SolveEngine requires a minimal value of 60 seconds for the time limit. The option hardtimelimit can be used to set a time limit that is enforced on the GAMS side. When a running SolveEngine job is interrupted before it is completed (either by hitting any of the time limits or by receiving a user-interrupt signal (Ctrl+C)), no solution will be available.

All GAMS/SolveEngine specific options are described in the section Options.

4.47.3 Log

Running model trnsport using GAMS/SolveEngine gives the following log:

```bash
> gamslib trnsport
Copy ASCII : trnsport.gms
> gams trnsport.gms lp solveengine optfile 1
--- Job trnsport Start 07/14/17 15:00:27 24.9.0 r60947 LEX-LEG x86 64bit/Linux
GAMS 24.9.0 Copyright (C) 1987-2017 GAMS Development; All rights reserved
--- Starting compilation
--- trnsport.gms(69) 3 Mb
--- Starting execution: elapsed 0:00:00.001
--- trnsport.gms(45) 4 Mb
--- Generating LP model transport
--- trnsport.gms(66) 4 Mb
--- 6 rows 7 columns 19 non-zeroes
--- Executing SOLVEENGINE: elapsed 0:00:00.002
This is the GAMS link to Satalia SolveEngine.
Reading parameter(s) from "solveengine.opt"
>> apikey ***secret***
Finished reading from "solveengine.opt"
Submitting Job.
Scheduling Job. ID: 57636b79317861c7be20e9f0088d4136120f37ba
1.0s Job Status: queued
2.2s Job Status: completed
Retrieving results.
Status: optimal
Objective Value: 1.5367500000e+02
--- Restarting execution
--- trnsport.gms(66) 2 Mb
--- Reading solution for model transport
*** Solver did not provide marginals for model transport
***

*** Status: Normal completion
--- Job trnsport.gms Stop 07/14/17 15:00:30 elapsed 0:00:03.565
```
First, the options file `solveengine.opt` is read and echoed to the log. While doing so, echoing the API key itself is suppressed. Then a "job" is created on the SolveEngine server, to which the model instance is submitted. Next, the job is scheduled to be solved. Here, also the ID of the job on the SolveEngine server is printed. Further, a progress report on the solve status is printed. Finally, results are retrieved from SolveEngine and passed back to GAMS.

### 4.47.4 Options

The following options can be set via a solver options file:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>apikey</td>
<td>Satalia SolveEngine API key</td>
<td></td>
</tr>
<tr>
<td>debug</td>
<td>Enabling debug output</td>
<td>0</td>
</tr>
<tr>
<td>hardtimelimit</td>
<td>Hard timelimit that is applied to the time since the job has been submitted. If the job does not finish within this limit, it will be canceled by the GAMS/SolveEngine link.</td>
<td>∞</td>
</tr>
<tr>
<td>printjoblist</td>
<td>Prints list of SolveEngine jobs</td>
<td>0</td>
</tr>
<tr>
<td>verifycert</td>
<td>Whether to verify SSL certificate using the machines CA certificates storage</td>
<td>1</td>
</tr>
</tbody>
</table>

### 4.47.5 Troubleshooting

If submitting a job to the SolveEngine fails with an SSL certificate problem, then one may disable the corresponding check by using the option `verifycert`.

**Attention**

Disabling verification of the certificate makes the communication insecure as it cannot be ensured anymore that GAMS is indeed communicating with the Satalia SolveEngine server.

### 4.48 SoPlex

SoPlex (Sequential object-oriented simPlex) is an optimization package for solving linear programming problems (LPs) based on an advanced implementation of the primal and dual revised simplex algorithm. SoPlex is developed at the Zuse-Institute Berlin.

For more detailed information, we refer to [103] [163] [259] and the SoPlex web site.

#### 4.48.1 Usage

The following statement can be used inside your GAMS program to specify using SOPLEX

```plaintext
Option LP = SOPLEX; { or RMIP }
```

The above statement should appear before the Solve statement. If SoPlex was specified as the default solver during GAMS installation, the above statement is not necessary.
4.48.1.1 Specification of SoPlex Options

GAMS/SoPlex supports the GAMS parameters reslim and iterlim.

Setting the GAMS option integer1 to a nonzero value enables writing of detailed solution statistics to the log.

Setting the GAMS option integer3 to a nonzero value leads to writing the model instance to a file in LP or MPS format before starting the solution process (integer3=1 writes an MPS file, integer3=2 writes an LP files, integer3=4 writes SoPlex state files (.mps, .bas, .set); sum these values to write several files). The name of the output file is chosen to be the name of the GAMS model file with the extension .gms replaced. Setting the GAMS option integer2 to a nonzero value makes variable and equation names available when writing the LP or MPS files. These options may be useful for debugging purposes.

Options can be specified by a SoPlex options file. A SoPlex options file consists of one option or comment per line. A pound sign (#) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs).

A small example for a soplex.opt file is:

bool:rowboundflips = true
int:algorithm = 0
real:feastol = 1e-5

It causes GAMS/SoPlex to use bound flipping also for row representations, use the primal simplex, and use a primal feasibility tolerance of 1e-5.

4.48.2 List of SoPlex Options

In the following, we give a detailed list of all SoPlex options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>bool:acceptcycling</td>
<td>should cycling solutions be accepted during iterative refinement?</td>
<td>0</td>
</tr>
<tr>
<td>bool:computedegen</td>
<td>should the degeneracy be computed for each basis?</td>
<td>0</td>
</tr>
<tr>
<td>bool:decompositiondualsimplex</td>
<td>should the decomposition based dual simplex be used to solve the LP?</td>
<td>0</td>
</tr>
<tr>
<td>bool:ensureray</td>
<td>re-optimize the original problem to get a proof (ray) of infeasibility/unboundedness?</td>
<td>0</td>
</tr>
<tr>
<td>bool:explicitviol</td>
<td>Should violations of the original problem be explicitly computed in the decomposition simplex?</td>
<td>0</td>
</tr>
<tr>
<td>bool:fullperturbation</td>
<td>should perturbation be applied to the entire problem?</td>
<td>0</td>
</tr>
<tr>
<td>bool:lifting</td>
<td>should lifting be used to reduce range of nonzero matrix coefficients?</td>
<td>0</td>
</tr>
<tr>
<td>bool:persistentscaling</td>
<td>should persistent scaling be used?</td>
<td>1</td>
</tr>
<tr>
<td>bool:powerscaling</td>
<td>round scaling factors for iterative refinement to powers of two?</td>
<td>1</td>
</tr>
<tr>
<td>bool:ratfacjump</td>
<td>continue iterative refinement with exact basic solution if not optimal?</td>
<td>0</td>
</tr>
<tr>
<td>bool:rowboundflips</td>
<td>use bound flipping also for row representation?</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>bool:testdualinf</td>
<td>should dual infeasibility be tested in order to try to return a dual solution even if primal infeasible?</td>
<td>0</td>
</tr>
<tr>
<td>bool:usecompdual</td>
<td>should the dual of the complementary problem be used in the decomposition simplex?</td>
<td>0</td>
</tr>
<tr>
<td>int:algorithm</td>
<td>type of algorithm (0 - primal, 1 - dual)</td>
<td>1</td>
</tr>
<tr>
<td>int:decomp_displayfreq</td>
<td>the frequency that the decomposition based simplex status output is displayed.</td>
<td>50</td>
</tr>
<tr>
<td>int:decomp_iterlimit</td>
<td>the number of iterations before the decomposition simplex initialisation solve is terminated</td>
<td>100</td>
</tr>
<tr>
<td>int:decomp_maxaddedrows</td>
<td>maximum number of rows that are added to the reduced problem when using the decomposition based simplex</td>
<td>500</td>
</tr>
<tr>
<td>int:decompverbosity</td>
<td>the verbosity of decomposition based simplex (0 - error, 1 - warning, 2 - debug, 3 - normal, 4 - high, 5 - full).</td>
<td>0</td>
</tr>
<tr>
<td>int:displayfreq</td>
<td>display frequency</td>
<td>200</td>
</tr>
<tr>
<td>int:factor_update_max</td>
<td>maximum number of LU updates without fresh factorization (0 - auto)</td>
<td>0</td>
</tr>
<tr>
<td>int:factor_update_type</td>
<td>type of LU update (0 - eta update, 1 - Forrest-Tomlin update)</td>
<td>1</td>
</tr>
<tr>
<td>int:hyperpricing</td>
<td>mode for hyper sparse pricing (0 - off, 1 - auto, 2 - always)</td>
<td>1</td>
</tr>
<tr>
<td>int:iterlimit</td>
<td>iteration limit (-1 - no limit)</td>
<td>GAMS iterlim</td>
</tr>
<tr>
<td>int:leastsq_maxrounds</td>
<td>maximum number of conjugate gradient iterations in least square scaling</td>
<td>50</td>
</tr>
<tr>
<td>int:pricer</td>
<td>pricing method (0 - auto, 1 - dantzig, 2 - parmult, 3 - devex, 4 - quicksteep, 5 - steep)</td>
<td>0</td>
</tr>
<tr>
<td>int:printcondition</td>
<td>print condition number during the solve (0 - off, 1 - ratio estimate , 2 - sum estimate, 3 - product estimate, 4 - exact)</td>
<td>0</td>
</tr>
<tr>
<td>int:ratiotester</td>
<td>method for ratio test (0 - textbook, 1 - harris, 2 - fast, 3 - boundflipping)</td>
<td>3</td>
</tr>
<tr>
<td>int:reallimit</td>
<td>refinement limit (-1 - no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>int:representation</td>
<td>type of computational form (0 - auto, 1 - column representation, 2 - row representation)</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>int:scaler</td>
<td>scaling (0 - off, 1 - uni-equilibrium, 2 - bi-equilibrium, 3 - geometric, 4 - iterated geometric, 5 - least squares, 6 - geometric-equilibrium)</td>
<td>2</td>
</tr>
<tr>
<td>int:simplifier</td>
<td>simplifier (0 - off, 1 - auto)</td>
<td>1</td>
</tr>
<tr>
<td>int:stallreflimit</td>
<td>stalling refinement limit (-1 - no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>int:starter</td>
<td>crash basis generated when starting from scratch (0 - none, 1 - weight, 2 - sum, 3 - vector)</td>
<td>0</td>
</tr>
<tr>
<td>int:timer</td>
<td>type of timer (1 - cputime, aka. usertime, 2 - wallclock time, 0 - no timing)</td>
<td>2</td>
</tr>
<tr>
<td>int:verbosity</td>
<td>verbosity level (0 - error, 1 - warning, 2 - debug, 3 - normal, 4 - high, 5 - full)</td>

<tr>
<td>real:liftmaxval</td>
<td>lower threshold in lifting (nonzero matrix coefficients with smaller absolute value will be reformulated)</td>
<td>1024</td>
</tr>
<tr>
<td>real:liftminval</td>
<td>lower threshold in lifting (nonzero matrix coefficients with smaller absolute value will be reformulated)</td>
<td>0.000976562</td>
</tr>
<tr>
<td>real:maxscaleincr</td>
<td>maximum increase of scaling factors between refinements</td>
<td>1e+25</td>
</tr>
</tbody>
</table>
4.49 XA

4.49.1 Introduction

This document describes the GAMS/XA linear and mixed-integer programming solver. The GAMS/XA solver (here also simply referred to as XA) is based on Sunset Software Technology's XA Callable Library, an implementation of high performance solvers for LP and MIP problems.

XA implements primal simplex, dual simplex, and barrier algorithms for solving linear problems. The primal/dual simplex method is very robust, and in most cases you should get good performance, especially from a warm start. The barrier method is particularly efficient on large models. Both algorithms benefit from XA's presolver, which reduces the size of the model by removing redundant constraints, substituting constraints, etc.

In most cases, GAMS/XA should perform satisfactorily without using any options. However, if fine-tuning is necessary or desired, XA provides many options and parameters designed for this purpose. These options are accessible via GAMS option statements or via an XA-specific option file.

4.49.2 Usage

If you have installed the GAMS system and configured XA as the default LP, RMIP and MIP solver, all LP, RMIP and MIP models without a specific solver option will use XA. If you installed another solver as the default, you can explicitly request that a particular model be solved by XA by inserting the statement

```gams
option LP = xa; { or MIP or RMIP }
```

somewhere before the `solve` statement.

</tbody>
</table>
4.49.3 Memory Usage

By default, the GAMS/XA link computes an estimate of the amount of memory that will be required by the solver, and passes this on to the solver. The solver makes an allocation of this amount and then uses this memory during the course of program execution. Usually, this will be sufficient to solve the problem successfully. In some cases, though, the computed estimate will be too small, and GAMS/XA will indicate that a larger memory estimate is required. You will need to manually specify a larger memory estimate to solve the model.

A model-specified memory estimate can be made by adding the following line to your GAMS model before the solve statement:

\[ \text{<modelname>.workspace = xx;} \]

where xx is the amount of memory in Mbytes. You can also define the environment variable XAMEMORY to be the amount of memory to use, in Mbytes. The computed memory estimate is the default, and is used only if no manual estimate is specified. The model-specified workspace limit overrides the computed estimate, and the XAMEMORY environment variable takes precedence over both of these.

In an attempt to insure that all models solve without running out of memory, XA makes one final memory check and if the user supplied memory amount is below what XA would consider reasonable for that size of problem, XA will then increase your amount to XA's minimal value.

On multi-processor machines, XA will automatically detect and use all available processors (CPU's) when solving MIP models. The memory estimate computed adds 50% more memory per processor to take full advantage of these processors, but this is sometimes not enough memory for XA to multi-process. In this case, a larger estimate must be specified manually.

4.49.4 Semi-Continuous and Semi-Integer Variables

XA supports semi-continuous and semi-integer variable types. Semi-continuous variables are variables that are either at zero or greater than or equal to their lower bound. E.g. a pump motor if operating must run between 2400 and 5400 r.p.m., but it may be switched off as well. Investment levels must exceed a specific threshold or no investment is made.

All semi-continuous variables must have a lower bound specification, e.g., \( \text{speed.lo(i) = 100} \). Semi-integer variables must have an upper bound as well.

Prior to the introduction of these variable types, semi-continuous variables had to be emulated by adding one additional binary variable and one additional constraint for each semi-continuous variable. For models of any size, this approach very quickly increased the model's size beyond solvability. Now XA has implicitly defined these variables without requiring the addition of new variables and constraints to your model. This effectively increases the size of model that can be solved and does it in a very neat and clean way besides.

For example, to define variables 'a' and 'b' as semi-continuous enter:

\[ \text{SemiCont a , b ;} \]

or to define semi-integer variables -

\[ \text{SemiInt y1 , y2 ;} \]

Priority values (.prior suffix) can be associated with both semi-continuous and semi-integer variables. All the integer solving options are available for models with semi-continuous and semi-integer variables as well. For example, you can select solving strategies, \text{optcr} and \text{optca} values, etc.

The solve time complexity for semi-continuous variables is comparable with the solve times for binary models, while the semi-integer case compares to integer.
4.49.5 Branch and Bound Topics

XA is designed to solve a vast majority of LP problems using the default settings. In the integer case, however, the default settings may not result in optimal speed and reliability. By experimenting with the control parameters performance can be improved (or worsened!) dramatically.

4.49.5.1 Branching Priorities

Using priorities can significantly reduce the amount of time required to obtain a good integer solution. If your model has a natural order in time, or in space, or in any other dimension then you should consider using priority branching. For example, a multi-period production problem with inventory would use the period value as the priority setting for all variables indexed by period. In a layered chip manufacturing process, the priority assigned to binary variables would be top down or bottom up in that layer.

If priorities are given to binary, integer, or semi-continuous variables, then these are used to provide a user-specified order in which variables are branched. XA selects the variable with the highest priority (lowest numerical value) for branching and the Strategy determines the direction, up or down.

Priorities are assigned to variables using the .prior suffix. For example:

\[
\begin{align*}
\text{NAVY}.\text{PRIOROPT} & = 1 ; \\
... \\
\text{Z}.\text{PRIOR}(J, \text{"SMALL"}) & = 10 ; \\
\text{Z}.\text{PRIOR}(J, \text{"MEDIUM"}) & = 5 ; \\
\text{Z}.\text{PRIOR}(J, \text{"LARGE"}) & = 1 ;
\end{align*}
\]

The value 1 indicates the highest priority (branch first), and the value 10 the lowest priority (branch last). Valid priority values should range between -32000 and 32000. The default priority value is 16000.

4.49.5.2 Branching Strategies

Ten branch & bound strategies are provided to meet the demands of many different types of problems. Each strategy has five variations (six if you include the basic strategy, or "no variation") that affect the solve time, speed to first solution, and the search for the best integer solution. The order in which integer variables are processed during the search is important. This order is called the branching order of integer variables. Solution times can vary significantly with the method selected.

In general, XA will solve your MIP problems much faster when all model variables are given some kind of objective function value. This biases the basis in a specific direction and usually leads to satisfactory first integer solutions.

The strategy used can be changed by setting the strategy option in an XA options file.

<table>
<thead>
<tr>
<th>Branch &amp; Bound Strategy</th>
<th>Description of Selection Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Proprietary method. Default value. Excellent strategy, also add priority to integer variable and try 1P for additional performance gains.</td>
</tr>
<tr>
<td>2</td>
<td>Minimum change in the objective function. This strategy has not been very successful at solving MIP problems.</td>
</tr>
<tr>
<td>3</td>
<td>Priority based upon column order. This strategy probably does not have much meaning because you typically do not set the column order in GAMS</td>
</tr>
<tr>
<td>Branch &amp; Bound Strategy</td>
<td>Description of Selection Criteria</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td>4</td>
<td>Column closest to its integer bound. This strategy tends to send a variable to its lower bound.</td>
</tr>
<tr>
<td>6</td>
<td>Column always branches up (high). Second choice after 1. Excellent choice when your model is a multi-period problem; additional performance gains when priority value is equated with period number; also try 6P if using priorities.</td>
</tr>
<tr>
<td>7</td>
<td>Column always branches down (low). Useful if variable branched down doesn’t limit capacity or resources. One suggestion is to use priorities in the reverse order from that described in Strategy 6.</td>
</tr>
<tr>
<td>8</td>
<td>Column farthest from its integer bound. Next to Strategies 1 and 6 this is probably the next choice to try. Using priorities and variation P is also suggested.</td>
</tr>
<tr>
<td>9</td>
<td>Column randomly selected, useful when solving very large problems. Priority values helpful in multi-period models.</td>
</tr>
<tr>
<td>10</td>
<td>Apparent smoothest sides on the polytope. Priorities helpful.</td>
</tr>
</tbody>
</table>

Each XA B&B strategy has many variations. Sometimes these variations reduce the solution time but may not yield the optimal integer solution. If you are interested in obtaining a fast and 'good' integer solution (which may not be the optimal integer solution), try these variations. You should be aware, though, that using these variations will invalidate the best bound and optimality gap statistics printed by the link at the end of the solve. To choose a variation, either append its letter to the strategy number or add its offset to the strategy number. For example, to choose variations B and P of strategy 6, you could either set "strategy 6BP" or "strategy 1806".

<table>
<thead>
<tr>
<th>Variation</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>A (+100)</td>
<td>This variation reduces the amount of time XA spends estimating the value of a potential integer solution. The values calculated are rough estimates and may eliminate nodes that would lead to better integer solutions. Variation A may not appear with variation B.</td>
</tr>
<tr>
<td>B</td>
<td>This variation spends very little time calculating estimated integer solutions at each node and is the most radical in performance and integer solution value and may eliminate nodes that would lead to better integer solutions. Variation B may not appear with variation A.</td>
</tr>
<tr>
<td>C</td>
<td>Each time an improving integer solution is found XA splits the remaining node list in half based upon the length of the current list. This technique allows XA to search nodes that might not normally be explored. The reported integer solution value may not be the optimal integer solution because nodes may be eliminated that would lead to this solutions. Variation C may not appear with variation D.</td>
</tr>
<tr>
<td>D</td>
<td>Each time an improving integer solution is found XA splits the remaining node list based upon the difference in current projected objective and the best possible objective value divided by two. This technique allows XA to search nodes that might not normally be explored. The reported integer solution value may not be the optimal integer solution because nodes may be eliminated that would lead to this solutions. Variation D may not appear with variation C.</td>
</tr>
<tr>
<td>P</td>
<td>Each time a node is generated XA calculates the effects of each non-integer on future objective function values, which is calculation intensive. By assigning branching priorities to your integer variables XA will only perform this calculation on the non-integer variables with the lowest branching priority. This frequently reduces the number of calculations. Variation P may appear with any variation, but to be effective you must assign integer branching priorities.</td>
</tr>
</tbody>
</table>

If you wish to improve your solution times, you should experiment with different Strategies to determine which is best for your problems. We have found that Strategies 1 and 6 work quite well. Also try strategies
4.49 XA

1A, 1B, 6A, 6B, and 9. As you gain experience with these Strategies you will be able to make an informed choice.

4.49.5.3 Limitsearch Parameter

LIMITSEARCH is used to limit the number of nodes to search by implicitly or explicitly stating a bound on the value of an integer solution. The integer solution obtained, if any, will have a functional value no worse than LIMITSEARCH. The next integer solution will have a monotonically improving objective function value until an optimal integer solution is found and if verified.

If you can estimate the objective function value of a good integer solution, you can avoid nodes that lead to worse solutions and, consequently, speed up the search. However, too restrictive a value may lead to no integer solution at all, if an integer solution with an objective value better that the LIMITSEARCH value does not exist. If the search terminates with 'NO INTEGER SOLUTION', you must begin the search again with a less restrictive LIMITSEARCH value. The LIMITSEARCH command line parameter has three methods of specifying a lower limit on the objective function.

<table>
<thead>
<tr>
<th>LIMITSEARCH Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>##</td>
<td>Only search for integer solutions between this value and the 'optimal continuous' solution.</td>
</tr>
<tr>
<td>##%</td>
<td>Only search for integer solutions with ##% of the 'optimal continuous' solution.</td>
</tr>
<tr>
<td>(#%)</td>
<td>Solve for the integer solution that is within (#%) of the 'optimal integer solution'. This can reduce the search time significantly, but the reported integer solution may not be the optimal integer solution: it will only be within (#%) of it. This is similar to the GAMS optcr option, but setting optcr reports the actual gap: this is the recommended way to run GAMS/XA.</td>
</tr>
</tbody>
</table>

4.49.6 The XA Option File

The option file is typically called xa.opt. The following line in a GAMS model signals GAMS/XA to use the option file:

```
<modelname>.optfile = 1 ;
```

where modelname is the name of the model specified in the model statement. For instance:

```
model m /all/ ;
m.optfile = 1 ;
option LP = XA ;
solve m using LP minimize z ;
```

For more details on using solver option files, see the section on solver option files.

The XA option file allows you to solver-specific options that are not anticipated by GAMS. Where an XA option and a GAMS option both set the same thing, the setting in the XA option file takes precedence. Option file lines beginning with an asterisk * are comment lines. For example:
* Integer solving strategy.
  Strategy  6P
* Write log information to the screen every 5 seconds.
  Set  FreqLog  00:05
* Do NOT scale the problem.
  Set  Scale  No

The contents of the option file are echoed to the screen. If no options file is found where one is expected, a warning is sent to the log file and the solve continues.

Here is a list of available XA options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

<td>10</td>
</tr>
<tr>
<td></td>
<td>If an integer basis (.b01) file is reloaded to indicate branching direction</td>
<td></td>
</tr>
<tr>
<td></td>
<td>for the current XA solve, this branching advice is following until N</td>
<td></td>
</tr>
<tr>
<td></td>
<td>infeasible branches are made. After N infeasible branches, the standard</td>
<td></td>
</tr>
<tr>
<td></td>
<td>branching direction for the particular branch &amp; bound strategy is used.</td>
<td></td>
</tr>
<tr>
<td>set tctolerance</td>
<td>zero tolerance for technology coefficients</td>
<td>1e-7</td>
</tr>
<tr>
<td></td>
<td>The smallest technological coefficient allowed in your constraint matrix.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>This tolerance is useful when extensive calculations are performed on these</td>
<td></td>
</tr>
<tr>
<td></td>
<td>coefficients, where the results should be zero (but because of rounding</td>
<td></td>
</tr>
<tr>
<td></td>
<td>errors) ends up being something like 1.0e-15.</td>
<td></td>
</tr>
<tr>
<td>set timelimit</td>
<td>set the time limit</td>
<td>GAMS ResLim</td>
</tr>
<tr>
<td></td>
<td>Maximum time allowed for solving the problem. XA terminates if this limit</td>
<td></td>
</tr>
<tr>
<td></td>
<td>is exceeded, and if solving an integer problem the best integer solution</td>
<td></td>
</tr>
<tr>
<td></td>
<td>found thus far is returned. Wall clock time is used. If set too low,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>reported integer solutions may not be the optimal integer solution</td>
<td></td>
</tr>
<tr>
<td></td>
<td>because of premature termination.</td>
<td></td>
</tr>
<tr>
<td>set tolerance dual</td>
<td>dual feasibility tolerance</td>
<td>1e-7</td>
</tr>
<tr>
<td>set tolerance primal</td>
<td>primal feasibility tolerance</td>
<td>1e-7</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>set utol</td>
<td>upper tolerance for integrality: (i-utol,i+ltol) is integral</td>
<td>5e-6</td>
</tr>
<tr>
<td></td>
<td>The tolerances XA uses to decide that an integer column’s value is integral. For instance, you might consider using a UTOLERANCE of 0.02 (a boat 98% full is for all practical purposes really 100% full). But beware, these integer activities within the specified tolerances are used in calculating constraint relationships and the objective function value. For example, if LTOLERANCE = 0.001, UTOLERANCE = 0.05, and Y has a reported (rounded) activity of 4.0, then 3 * Y is in the range [3 * 3.95, 3 * 4.001].</td>
<td></td>
</tr>
<tr>
<td>set ypivot</td>
<td>zero tolerance for dual values when pivoting</td>
<td>1e-9</td>
</tr>
<tr>
<td></td>
<td>When selecting a column to leave the basis, columns with absolute marginal values less than ypivot are rejected. Pivoting in columns with very small values can lead to numeric instability and should be avoided when possible. Setting ypivot too large can lead to infeasible pivoting. Extreme caution should be exercised when changing this value because of the overall effect on problem feasibility.</td>
<td></td>
</tr>
<tr>
<td>stopafter</td>
<td>post-integer-feasible time limit for MIP models</td>
<td>GAMS Real3</td>
</tr>
<tr>
<td></td>
<td>Amount of time (hh:mm:ss) to continue solving after finding the first integer solution. Reported integer solution may not be the optimal integer solution because of premature termination. 0 disables this cheat.</td>
<td></td>
</tr>
<tr>
<td>strategy</td>
<td>controls the MIP search strategy</td>
<td>GAMS Integer1</td>
</tr>
<tr>
<td>tomps</td>
<td>write an MPS file (gams.mps) for the problem</td>
<td>no</td>
</tr>
<tr>
<td></td>
<td>Yes: Write problem in MPS format</td>
<td></td>
</tr>
<tr>
<td></td>
<td>No: Do not write an MPS formatted file</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Secure: Write problem in MPS format with names C0, C1, ... and R0, R1, ...</td>
<td></td>
</tr>
</tbody>
</table>

### 4.49.7 Iteration Log Formats

The iteration log is something many users watch closely, especially when solving MIP models. Setting Set FreqLog 0 suppresses the display of the iteration log. During LP iterations, the log format varies depending on the algorithm chosen. Its format is self-explanatory. The default MIP log looks like:

<table>
<thead>
<tr>
<th>Node</th>
<th>IIInf</th>
<th>ToGo.Map</th>
<th>Best.Obj</th>
<th>Cur.Obj</th>
<th>Int.Obj</th>
<th># Column +/- Iter</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>####</td>
<td>###</td>
<td>########</td>
<td>#######</td>
<td>#######</td>
<td># # # # # # #</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node</td>
</tr>
<tr>
<td>Active node, the smaller the better, value increases and decreases as the branch- and-bound proceeds.</td>
</tr>
<tr>
<td>IIInf</td>
</tr>
<tr>
<td>Number of discrete columns having fractional values. This number converges to 0 as XA approaches an integer solution.</td>
</tr>
<tr>
<td>ToGo.Map</td>
</tr>
<tr>
<td>A numeric picture of open nodes. The i'th digit (from the right) represents the number of open nodes in the i'th group of ten nodes. For example, 435 means: - 4 unexplored nodes between nodes 20 and 29. - 3 unexplored nodes between nodes 10 and 19. - 5 unexplored nodes between nodes 0 and 9.</td>
</tr>
<tr>
<td>Best.Obj</td>
</tr>
<tr>
<td>Best possible integer objective function. As the branch-and-bound algorithm proceeds this number bounds the Optimal Integer Solution. This number does not change very fast.</td>
</tr>
</tbody>
</table>
Use the `Set FreqLog` option to minimize the number of lines displayed. Logging each iteration can significantly slow down the solution process.

### 4.50 XPRESS

#### 4.50.1 Introduction

This document describes the GAMS/XPRESS linear and mixed-integer programming solver. The GAMS/XPRESS solver is based on the XPRESS Optimization Subroutine Library, and runs only in conjunction with the GAMS modeling system.

GAMS/XPRESS (also simply referred to as XPRESS) is a versatile, high-performance optimization system. The system integrates a powerful simplex-based LP solver, a MIP module with cut generation for integer programming problems and a barrier module implementing a state-of-the-art interior point algorithm for very large LP problems.

The GAMS/XPRESS solver is installed automatically with your GAMS system. Without a license, it will run in student or demonstration mode (i.e. it will solve small models only). If your GAMS license includes XPRESS, there is no size or algorithm restriction imposed by the license, nor is any separate licensing procedure required.

#### 4.50.2 Usage

To explicitly request that a model be solved with XPRESS, insert the statement

```
option LP = xpress; { or MIP, RMIP, QCP, MIQCP, or RMIQCP }
```

somewhere before the solve statement. If XPRESS has been selected as the default solver (e.g. during GAMS installation) for the model type in question, the above statement is not necessary.

The standard GAMS options (e.g. `iterlim`, `opter`) can be used to control XPRESS. For more details, see section Controlling a Solver via GAMS Options.

In addition, XPRESS-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

An example of a valid XPRESS option file is:

```plaintext
* sample XPRESS options file
algorithm simplex
presolve 0
IterLim 50000
```

In general this is enough knowledge to solve your models. In some cases you may want to use some of the XPRESS options to gain further performance improvements or for other reasons.
4.50 XPRESS

4.50.2.1 General

The options advBasis, algorithm, basisOut, mpsOutputFile, reform, reRun, and reslim control the behavior of the GAMS/XPRESS link. The options crash, extraPresolve, lpIterlimit, presolve, scaling, threads, and trace set XPRESS library control variables, and can be used to fine-tune XPRESS. See section General Options for more details of XPRESS general options.

4.50.2.2 LP

See section LP Options for more details of XPRESS library control variables which can be used to fine-tune the XPRESS LP solver.

4.50.2.3 MIP

In some cases, the branch-and-bound MIP algorithm will stop with a proven optimal solution or when unboundedness or (integer) infeasibility is detected. In most cases, however, the global search is stopped through one of the generic GAMS options:

1. iterlim (on the cumulative pivot count) or reslim (in seconds of CPU time),
2. optca & optcr (stopping criteria based on gap between best integer solution found and best possible) or
3. nodlim (on the total number of nodes allowed in the B&B tree).

It is also possible to set the maxNode and maxMipSol options to stop the global search: see section MIP Options for XPRESS control variables for MIP. The options loadMipSol, mipCleanup, mipTrace, mipTraceNode, and mipTraceTime control the behavior of the GAMS/XPRESS link on MIP models. The other options in section MIP Options set XPRESS library control variables, and can be used to fine-tune the XPRESS MIP solver.

4.50.2.4 MIP Solution Pool

Typically, XPRESS finds a number of integer feasible points during its global search, but only the final solution is available. The MIP solution pool capability makes it possible to store multiple integer feasible points (aka solutions) for later processing. The MIP solution pool operates in one of two modes: by default (solnpoolPop = 1) the global search is not altered, but with (solnpoolPop = 2) a selected set (potentially all) of the integer feasible solutions are enumerated.

The MIP enumeration proceeds until all MIP solutions are enumerated or cut off, or until a user-defined limit is reached. Whenever a new solution is generated by the enumerator, it is presented to the solution pool manager. If there is room in the pool, the new solution is added. If the pool is full, a cull round is performed to select a number of solutions to be thrown out - these solutions can be those stored in the pool and/or the new solution. Solutions can be selected for culling based on their MIP objective value and/or the overall diversity of the solutions in the pool. If neither is chosen, a default choice is made to throw out one solution based on objective values. Whenever a solution is thrown out based on its MIP objective, the enumeration space is pruned based on the cutoff defined by this objective value.

By default, the capacity of the pool is set very large, as is the number of cull rounds to perform, so selecting only solnpoolPop = 2 will result in full enumeration. However, many different strategies can be executed by setting the solution pool options. For example, to choose the N-best solutions, simply set the solution pool capacity to N. When the pool is full, new solutions will force a cull round, and the
default is to reject one solution based on its objective and update the cutoff accordingly. To generate all solutions with an objective as good as $X$, leave the pool capacity set at a high level but set the cutoff to $X$ using the `mipabscutoff` option. To return the $N$-first solutions, set the solution pool capacity to $N$ and `solnpoolCullRounds = 0`: as soon as the pool is full the enumeration will stop on the cull round limit.

A number of other strategies for controlling the solution pool behavior are possible by combining different options. Several working examples are provided in the GAMS Test Library in models `xpress03.gms`, `xpress04.gms`, and `xpress05.gms`.

See section MIP Solution Pool Options for XPRESS control variables for MIP Solution Pool.

### 4.50.2.5 Newton-Barrier

The barrier method is invoked by default for quadratic problems, and can be selected for linear models by using one of the options

```
algorithm   barrier
defaultalg  4
```

The barrier method is likely to use more memory than the simplex method. No warm start is done, so if an advanced basis exists, you may not wish to use the barrier solver.

See section Newton-barrier Options for XPRESS control variables for the Newton-Barrier method.

### 4.50.3 Options

The tables that follow contain the XPRESS options. They are organized by function (e.g. LP or MIP) and also by type: some options control the behavior of the GAMS/XPRESS link and will be new even to experienced XPRESS users, while other options exist merely to set control variables in the XPRESS library and may be familiar to XPRESS users.

#### 4.50.3.1 General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>advBasis</td>
<td>use advanced basis provided by GAMS</td>
<td>auto</td>
</tr>
<tr>
<td>algorithm</td>
<td>choose between simplex and barrier algorithm</td>
<td></td>
</tr>
<tr>
<td></td>
<td>This option is used to select the barrier method to solve LPs. By default the barrier method will do a crossover to find a basic solution.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>barrier: Use the barrier algorithm</td>
<td></td>
</tr>
<tr>
<td></td>
<td>simplex: Use the simplex algorithm</td>
<td></td>
</tr>
<tr>
<td>basisOut</td>
<td>directs optimizer to output an MPS basis file</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>In general this option is not used in a GAMS environment, as GAMS maintains basis information for you automatically.</td>
<td></td>
</tr>
<tr>
<td>crash</td>
<td>control for basis crashing procedure</td>
<td></td>
</tr>
<tr>
<td></td>
<td>A crash procedure is used to quickly find a good basis. This option is only relevant when no advanced basis is available.</td>
<td></td>
</tr>
<tr>
<td>deterministic</td>
<td>control for deterministic behavior of concurrent solves</td>
<td>1</td>
</tr>
<tr>
<td>extraPresolve</td>
<td>initial number of extra elements to allow for in the presolve</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The space required to store extra presolve elements is allocated dynamically, so it is not necessary to set this control. In some cases, the presolve may terminate early if this is not increased.</td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| lpIterLimit       | set the iteration limit for simplex solves  
For MIP models, this is a per-node iteration limit for the B&B tree. Overrides the iterlim option.                                                    |         |
| mpsNameLength     | maximum length of MPS names in characters  
Maximum length of MPS names in characters. Internally it is rounded up to the smallest multiple of 8. MPS names are right padded with blanks. Maximum value is 64. | none    |
| mpsOutputFile     | Name of MPS output file  
If specified XPRESS-MP will generate an MPS file corresponding to the GAMS model: the argument is the file name to be used. You can prefix the file name with an absolute or relative path. | none    |
| presolve          | sets presolve strategy  
0: presolve not applied  
1: presolve applied  
2: presolve applied, but redundant bounds are not removed  
3: presolve applied, and redundant bounds always removed | 1       |
| reform            | substitute out objective var and equ when possible                                                                                               | 1       |
| reRun             | rerun with primal simplex when not optimal/feasible  
Applies only in cases where presolve is turned on and the model is diagnosed as infeasible or unbounded. If rerun is nonzero, we rerun the model using primal simplex with presolve turned off in hopes of getting better diagnostic information. If rerun is zero, no good diagnostic information exists, so we return no solution, only an indication of unboundedness/infeasibility. | 0       |
| reslim            | overrides GAMS reslim option  
Sets the resource limit. When the solver has used more than this amount of CPU time (in seconds) the system will stop the search and report the best solution found so far. |         |
| scaling           | bitmap control for internal scaling algorithm  
Bitmap to determine how internal scaling is done. If set to 0, no scaling will take place. The default of 35 implies row and column scaling done by the maximum element method.  
bit 0 = 1: Row scaling  
bit 1 = 2: Column scaling  
bit 2 = 4: Row scaling again  
bit 3 = 8: Maximin  
bit 4 = 16: Curtis-Reid  
bit 5 = 32: Off implies scale by geometric mean, on implies scale by maximum element. Not applicable for maximin and Curtis-Reid scaling. | 1       |
| threads           | global default thread count  
Controls the number of threads to use. Positive values will be compared to the number of available cores detected and reduced if greater than this amount. Non-positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks.  
Range: [-∞, ∞] | 1       |
| trace             | turns on output of infeasibility diagnosis during presolve  
Control of the infeasibility diagnosis during presolve - if nonzero, infeasibility will be explained.                                                                                           |         |
| writePrtSol       | directs optimizer to output a "printsol" file                                                                                                      |         |

#### 4.50.3.3 MIP Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>backTrack</td>
<td>determines selection of next node in case of a full backtrack</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1: Unused</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>2: Select the node with the best estimated solution</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3: Select the node with the best bound on the solution</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4: Select the deepest node in the search tree (aka DFS)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5: Select the highest node in the search tree (aka BFS)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>6: Select the earliest node created</td>
<td></td>
</tr>
<tr>
<td></td>
<td>7: Select the latest node created</td>
<td></td>
</tr>
<tr>
<td></td>
<td>8: Select a node randomly</td>
<td></td>
</tr>
<tr>
<td></td>
<td>9: Select the node whose LP relaxation contains the fewest number of infeasible global entities</td>
<td></td>
</tr>
<tr>
<td></td>
<td>10: Combination of 2 and 9</td>
<td></td>

<tr>
<td></td>
<td>11: Combination of 2 and 4</td>
<td></td>
</tr>
<tr>
<td></td>
<td>12: Combination of 3 and 4</td>
<td></td>
</tr>
<tr>
<td>breadthFirst</td>
<td>determines number of nodes to include in a breadth-first search</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Used only if \texttt{nodeselection} = 4.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: ([1, \infty])</td>
<td></td>
</tr>
<tr>
<td>coverCuts</td>
<td>number of rounds of lifted cover inequalities at the top node</td>
<td></td>
</tr>
<tr>
<td></td>
<td>A lifted cover inequality is an additional constraint that can be particularly effective at reducing the size of the feasible region without removing potential integral solutions. The process of generating these can be carried out a number of times, further reducing the feasible region, albeit incurring a time penalty. There is usually a good payoff from generating these at the top node, since these inequalities then apply to every subsequent node in the tree search.</td>
<td></td>
</tr>
<tr>
<td>cutDepth</td>
<td>maximum depth in search tree at which cuts will be generated</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Generating cuts can take a lot of time, and is often less important at deeper levels of the tree since tighter bounds on the variables have already reduced the feasible region. A value of 0 signifies that no cuts will be generated.</td>
<td></td>
</tr>
<tr>
<td>cutFreq</td>
<td>frequency at which cuts are generated in the tree search</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If the depth of the node modulo \texttt{cutfreq} is zero, then cuts will be generated.</td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| cutStrategy | specifies the cut strategy  
An aggressive cut strategy, generating a greater number of cuts, will result in fewer nodes to be explored, but with an associated time cost in generating the cuts. The fewer cuts generated, the less time taken, but the greater subsequent number of nodes to be explored.  
-1: automatic  
0: no cuts  
1: conservative cut strategy  
2: moderate cut strategy  
3: aggressive cut strategy | -1      |
| gomCuts     | number of rounds of Gomory cuts at the top node  
Gomory cuts can always be generated if the current node does not yield an integral solution. However, they are usually not as effective as lifted cover inequalities in reducing the size of the feasible region. |         |
| heurThreads | number of threads for running parallel root node heuristics  
If positive, determines the number of root threads dedicated to running parallel heuristics. If 0, heuristics are run sequentially with the root LP solver and cutting. If -1, the threads control will be used as the default.  
Range: [-1, ∞] | 0       |
| loadMipSol  | loads a MIP solution (the initial point)  
If true, the initial point provided by GAMS will be passed to the optimizer to be treated as an integer feasible point. The optimizer uses the values for the discrete variables only: the level values for the continuous variables are ignored and are calculated by fixing the integer variables and reoptimizing. In some cases, loading an initial MIP solution can improve performance. In addition, there will always be a feasible solution to return. | 0       |
| maxMipSol   | maximum number of integer solutions in MIP tree search  
This specifies a limit on the number of integer solutions to be found (the total number, not necessarily the number of distinct solutions). 0 means no limit. |         |
| maxNode     | maximum number of nodes to explore in MIP tree search  
If the GAMS nodlim model suffix is set, that setting takes precedence. | maxint  |
| mipAbsCutoff| nodes with objective worse than this value are ignored  
If the user knows that they are interested only in values of the objective function which are better than some value, this can be assigned to `mipabs_cutoff`. This allows the Optimizer to ignore solving any nodes which may yield worse objective values, saving solution time. |         |
| mipAbsStop  | stopping tolerance for gap: if met XPRESS returns proven optimal  
The global search is stopped if the gap is reduced to this value. This check is implemented in the Optimizer library, and if the search is stopped on this check the Optimizer returns a status of proven optimal. For this reason you should use the GAMS `<modelname>.optca` parameter instead of this option. |         |
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>mipAddCutoff</td>
<td>amount to add to MIP incumbent to get the new cutoff</td>
<td>auto</td>
</tr>
<tr>
<td></td>
<td>Once an integer solution has been found whose objective function is equal to or better than <strong>mipAbsCutoff</strong>, improvements on this value may not be interesting unless they are better by at least a certain amount. If <strong>mipAddCutoff</strong> is nonzero, it will be added to <strong>mipAbsCutoff</strong> each time an integer solution is found which is better than this new value. This cuts off sections of the tree whose solutions would not represent substantial improvements in the objective function, saving processor time. Note that this should usually be set to a negative number for minimization problems, and positive for maximization problems. Notice further that the maximum of the absolute and relative cut is actually used.</td>
<td></td>
</tr>
<tr>
<td>mipCleanup</td>
<td>clean up the MIP solution (round-fix-solve) to get duals</td>

### 4.50.4 Helpful Hints

The comments below should help both novice and experienced GAMS users to better understand and make use of GAMS/XPRESS.

- **Infeasible and unbounded models** The fact that a model is infeasible/unbounded can be detected at two stages: during the presolve and during the simplex or barrier algorithm. In the first case we cannot recover a solution, nor is any information regarding the infeasible/unbounded constraint or variable provided (at least in a way that can be returned to GAMS). In such a situation, the GAMS link will automatically rerun the model using primal simplex with presolve turned off (this can be avoided by setting the rerun option to 0). It is possible (but very unlikely) that the simplex method will solve a model to optimality while the presolve claims the model is infeasible/unbounded (due to feasibility tolerances in the simplex and barrier algorithms).

- The barrier method does not make use of `iterlim`. Use `bariterlim` in an options file instead. The number of barrier iterations is echoed to the log and listing file. If the barrier iteration limit is reached during the barrier algorithm, XPRESS continues with a simplex algorithm, which will obey the `iterlim` setting.

- Semi-integer variables are not implemented in the link, nor are they supported by XPRESS; if present, they trigger an error message.

- **SOS1 and SOS2 variables** are required by XPRESS to have lower bounds of 0 and nonnegative upper bounds.
Chapter 5

Tools Manuals

A large number of tools are included in GAMS distribution. Below are a functional categorization of all tools, an alphabetically sorted list of all tools, and a brief description of each tool with their Supported Platforms.

5.1 Tools Category

All tools included in GAMS distribution are categorized as

5.1.1 GAMS Integrated Development Environments

There are two integrated model development environments including a general text editor with the ability to launch and monitor the compilation and execution of GAMS models: The GAMS IDE and GAMS Studio.

5.1.2 Data Exchange

A collection of tools that provide functionality to exchange data between GAMS and other data sources. This category contains tools for popular data sources and high-level programming environment and like databases (GDX2ACCESS, GDX2SQLITE, MDB2GMS, SQL2GMS), Matlab (GDXMRW), and R (GDXRRW). There are also tools for specialized systems like HAR (GDX2HAR and HAR2GDX), TROLL (GDXTROLL), and VEDA (GDX2VEDA).

5.1.2.1 Excel

Tools to exchange data with Microsoft Excel are grouped in a subcategory Excel. The tools in this category are GDX2XLS, GDXXRW, MSAPPAVAIL, XLS2GMS, XLSDUMP, and XLSTALK. Many of the tools described here use the GAMS Data eXchange facility GAMS Data eXchange (GDX).

5.1.3 GDX Service

A collection of tools that operate directly on GAMS Data eXchange (GDX) containers to e.g. compare (GDXDIFF), copy (GDXCOPY), merge (GDXMERGE), and rename (GDXRENAME).
5.1.4 Data Transformation

A collection of tools that perform very specific tasks that are awkward or inefficient to implement in GAMS directly. Through GAMS Data eXchange (GDX) and the execution of the tools in this category allow to perform complex tasks from a GAMS model like identifying eigenvalues or the inverse of a matrix.

The tools in this category are CHOLESKY, CSDP, EIGENVECTOR, EIGENVALUE, GDXRANK, INVERT, MCFILTER, SCENRED, and SCENRED2.

5.1.5 Other Tools

A collection of more exotic tools that can become handy in some some special circumstances. The tools in this category are ASK, BIB2GMS, CHK4UPD, ENDECRYPT, GAMS Posix Utilities, MODEL2TEX, and ShellExecute/ Most notably, the collection contains the tool MODEL2TEX to document the model algebra in LaTeX format.

5.2 List of Tools

The following table gives an alphabetically sorted list of all available tools.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASK</td>
<td>The utility can be used to get input from an user interactively.</td>
</tr>
<tr>
<td>BIB2GMS</td>
<td>Analyses BibTeX files with file extension .bib and writes GAMS source files that can be used to create various author, reference and cross reference reports.</td>
</tr>
<tr>
<td>CHK4UPD</td>
<td>Checks whether the user can update to a more recent GAMS version.</td>
</tr>
<tr>
<td>CHOLESKY</td>
<td>Calculates the Choheksy decomposition of a symmetric positive definite matrix,</td>
</tr>
<tr>
<td>CSDP</td>
<td>The semidefinite programming CSDP solver from COIN-OR. The communication with CSDP requires the setup of matrix data structures in a CSDP input file. In a sense a GAMS model functions as a matrix generator.</td>
</tr>
<tr>
<td>CSV2GDX</td>
<td>Reads a CSV file (comma separated values) and writes to a GDX file.</td>
</tr>
<tr>
<td>EIGENVALUE</td>
<td>Calculates eigenvalues of a symmetric matrix.</td>
</tr>
<tr>
<td>EIGENVECTOR</td>
<td>Calculates eigenvector of a symmetric matrix.</td>
</tr>
<tr>
<td>ENDECRYPT</td>
<td>A tool to encrypt and decrypt text files.</td>
</tr>
<tr>
<td>GAMS IDE</td>
<td>Classic Integrated Development Environment.</td>
</tr>
<tr>
<td>GAMS STUDIO</td>
<td>Integrated Development Environment.</td>
</tr>
<tr>
<td>GDX2ACCESS</td>
<td>Converts GDX data to MS Access tables.</td>
</tr>
<tr>
<td>GDX2HAR</td>
<td>Translates files between GDX and HAR format.</td>
</tr>
<tr>
<td>GDX2SQLITE</td>
<td>Dumps the complete contents of a GDX file into a SQLite2 database. From Amsterdam Optimization Modeling Group.</td>
</tr>
<tr>
<td>GDX2VEDA</td>
<td>Translates a GDX file into the VEDA format.</td>
</tr>
<tr>
<td>GDX2XLS</td>
<td>Converts GDX data into a MS Excel spreadsheet.</td>
</tr>
<tr>
<td>GDXCOPY</td>
<td>Converts a GDX file into different GDX formats.</td>
</tr>
<tr>
<td>GDXDIFF</td>
<td>Compares the data of symbols with the same name, type and dimension in two GDX files and writes the differences to a third GDX file.</td>
</tr>
<tr>
<td>GDXDUMP</td>
<td>Writes scalars, sets and parameters (tables) to standard output formatted as a GAMS program with data statements.</td>
</tr>
<tr>
<td>GDXMERGE</td>
<td>Combines multiple GDX files into one file. Symbols with the same name, dimension and type are combined into a single symbol of a higher dimension. The added dimension has the file name of the combined file as its unique element.</td>
</tr>
</tbody>
</table>
## 5.3 Supported Platforms

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GDXMRW</td>
<td>A suite of utilities to import/export data between GAMS and MATLAB and to call GAMS models from MATLAB and get results back into MATLAB.</td>
</tr>
<tr>
<td>GDXRANK</td>
<td>Reads one or more one dimensional parameters from a GDX file, sorts each parameter and writes the sorted indices as a one dimensional parameters to the output GDX file.</td>
</tr>
<tr>
<td>GDXRENAME</td>
<td>Replaces UEL strings in GDX files.</td>
</tr>
<tr>
<td>GDXRRW</td>
<td>An interface between GAMS and R. It includes functions to transfer data between GDX and R and a function to call GAMS from R.</td>
</tr>
<tr>
<td>GDXTROLL</td>
<td>Translates a GDX file into the TROLL format.</td>
</tr>
<tr>
<td>GDXVIEWER</td>
<td>Views and converts data contained in GDX files.</td>
</tr>
<tr>
<td>GDXXRW</td>
<td>Preferred utility to read and write MS Excel spreadsheet data.</td>
</tr>
<tr>
<td>GMSUNZIP</td>
<td>A copy of the decompression tool unzip from Info-ZIP prefixed with &quot;gms&quot; for clear identification.</td>
</tr>
<tr>
<td>GMSZIP</td>
<td>A copy of the compression and archiving tool zip from Info-ZIP prefixed with &quot;gms&quot; for clear identification.</td>
</tr>
<tr>
<td>HAR2GDX</td>
<td>Translates files between GDX and HAR format.</td>
</tr>
<tr>
<td>IDECMDS</td>
<td>Sends commands to the GAMSIDE.</td>
</tr>
<tr>
<td>INVERT</td>
<td>Inverts a matrix.</td>
</tr>
<tr>
<td>MCFILTER</td>
<td>Removal of duplicate and dominated points in a multi-criteria solution set.</td>
</tr>
<tr>
<td>MDB2GMS</td>
<td>Converts data from an MS Access database into a GAMS readable format.</td>
</tr>
<tr>
<td>MODELT2EX</td>
<td>Translates a GAMS model into LaTeX.</td>
</tr>
<tr>
<td>MPS2GMS</td>
<td>Translates an MPS file into an equivalent short generic GAMS program using a GDX file to store data.</td>
</tr>
<tr>
<td>MSAPPAVAIL</td>
<td>Checks if a MS Office Application is available.</td>
</tr>
<tr>
<td>POSIX</td>
<td>A collection of POSIX utilities which are usually available for Windows and the different Unix systems and therefore help to write platform independent scripts.</td>
</tr>
<tr>
<td>SCENRED</td>
<td>A tool for the reduction of scenarios that model random data processes of a stochastic program. From Humboldt-University Berlin.</td>
</tr>
<tr>
<td>SCENRED2</td>
<td>Scenred2 is a fundamental update of Scenred and offers a scenario tree construction algorithm. From Humboldt-University Berlin.</td>
</tr>
<tr>
<td>SHELLEXECUTE</td>
<td>Launches external programs from the command line.</td>
</tr>
<tr>
<td>SQL2GMS</td>
<td>Converts data from an SQL database into a GAMS readable format.</td>
</tr>
<tr>
<td>XLS2GMS</td>
<td>Converts spreadsheet data from a MS Excel spreadsheet into a GAMS readable format.</td>
</tr>
<tr>
<td>XLSDUMP</td>
<td>Writes all worksheets of a MS Excel workbook to a GDX file. Unlike gdxxrw, the program does not require that Excel is installed.</td>
</tr>
<tr>
<td>XLSTALK</td>
<td>Open/Close/Run macro in MS Excel.</td>
</tr>
</tbody>
</table>

5.4 ASK

Writing a GUI (Graphical User Interface) for a GAMS application requires some serious programming, and therefore place a burden on the knowledge and time of the modeler. In this section we show how
extremely simple user interfaces can be built using a few simple tools. The main purpose of these tools is to allow a developer quickly put an application together such that an end-user does not have to edit GAMS files. We assume the end-user runs a GAMS model from the GAMS-IDE.

The ASK utility can be used to get input from an end-user and the GDXViewer tool can be used to present end-results. Together these tools allow you to build a minimalist GUI without any programming.

5.4.1 Usage

ask <options>

where the options are

T=string

where the string identifies the type of input item to go after and can be

- integer - when one wants an integer number
- float - when one wants a real number
- radiobutton - when one wants a radio button choice
- combobox - when one wants a combo (drop down choice) box
- checklistbox - when one wants a check list box
- fileopenbox - when one wants the name of a file to open
- filesavebox - when one wants the name of a file to save

Example: T=integer

M="string"

where the string is the text to in the box.
Example: M="Enter a number"

O="filename"

where the filename is the name of a file in which to place the results for subsequent inclusion into GAMS
Example: O="file.inc"

D="string 1|string 2..."

where the "string 1|string 2|string 3|...|string n" gives the n strings to be associated with multiple choices when using checkbox, radiobutton, combobox, or checklistbox.
The individual strings are separated by the delimiter "|
Example: D="Small data set|Medium data set|Large data set"

E="number 1|number 2..."

where the "number 1|number 2|number 3|...|number n" gives the n numbers to be returned to GAMS associated with the choices made when using checkbox, radiobutton, combobox, or checklistbox. The individual numbers are separated by the delimiter "|
Example: E="1|2|3|4|5"

I="filepath"
where filepath gives the path in which to look for the file under the fileopenbox and filesavebox dialogues. If not specified this is the project directory. Example: I="C:\gams\mine"

F="filemask"

where filemask gives the mask for acceptable files under the fileopenbox and filesavebox dialogues. If not specified this is *. Example: I="*.gdx"

R="string"

where the string gives a line of GAMS code to place in the include file. This can contain a s parameter in which the information to return is substituted. Example: R="$include "%s"" or R="set i/1990+%s/;"

C="string"

A title for the dialogue box being used. Example: C="Box to ask for a file"

L=number

where the number gives a lower bound on a numeric entry. Example: L=15

U=number

where the number gives an upper bound on a numeric entry. Example: U=15

@"filename"

where filename gives the name of a file of input instructions containing the options above in this table. Example: @ask.opt

In addition a number by itself can be entered to put multiple entries into columns under the checkbox, radiobutton, combobox, or checklistbox entries.

### 5.4.2 Calling ASK utility from GAMS

The ASK utility is a simple tool to ask simple interactive questions to the end-user. For instance, if your model requires a scalar to be changed regularly, instead of letting the end-user change the .gms source file, it may be better to pop up a window, with a question text, where the required number can be entered. The ASK tool allows you to do this. As the ASK tool generates a standard GAMS include file, this file can then be used through a $include statement:

```gams
$call =ask T=integer M="Enter number of cities" o=n.inc Scalar n 'number of cities' / $include n.inc /; display n;
```

The $call statement will invoke the ASK tool. If ASK.EXE is not located in the GAMS system directory but placed somewhere else you may have to provide a path, as in:

```gams
$call =ask T=integer M="Enter number of cities" o=n.inc PATH=.../ASK
```
$call =d:\util\ask T=integer M="Enter number of cities" o=n.inc

The parameter T=integer indicates we want to ask for an integer number (T means type). The parameter M="text" specifies the question text. Finally O=filename sets the name of the include file that ASK should create.

When we run this GAMS fragment from the IDE, we will see:

After enter a number and hitting the OK button GAMS will continue. The listing file will demonstrate clearly how the include file was formed:

2 scalar n 'number of cities' /
INCLUDE D:\GAMS PROJECTS\ASK\N.INC
4 * Ask Import Filter Version 1.0, Nov. 1999
5 * Erwin Kalvelagen, GAMS Development Corp.
6 12
7 ;
8 display n;
Include File Summary
SEQ GLOBAL TYPE PARENT LOCAL FILENAME
1 1 INPUT 0 0 D:\GAMS PROJECTS\ASK\X.GMS
2 1 CALL 1 1 =ask T=integer M="Enter number of cities" o=n.inc
3 3 INCLUDE 1 3 \D:\GAMS PROJECTS\ASK\N.INC

In this case 12 was entered and the OK button was pressed. If the user pressed the CANCEL button, an error will be generated and the listing file will show that the CANCEL button was pressed:

2 scalar n 'number of cities' /
INCLUDE D:\GAMS PROJECTS\ASK\N.INC
4 * Ask Import Filter Version 1.0, Nov. 1999
5 * Erwin Kalvelagen, GAMS Development Corp.
6 12
7 ;
* **** $1
* **** LINE 4 INPUT D:\GAMS PROJECTS\ASK\X.GMS
* **** 1 Real number expected
8 display n;

In case you want to limit the integer that the user is allowed to enter you can specify a lower and an upperbound as in:

$call =ask T=integer M="Give integer, between 0 and 5" L=0 U=5 O=n1.inc
Scalar n1 'an integer 0..5' /
$include n1.inc
/;
display n1;

This will only accept values between 0 and 5.

To allow the user to specify a floating point number, we can use T=float. An example is:
The floating point popup window can be told to make sure the number entered is within certain bounds, using the \texttt{L=lowerbound} and \texttt{U=upperbound} syntax:

```gams
$call =ask T=float M="Give floating point number, no bounds" 0=x.inc
Scalar x 'real' /
$include x.inc /

display x;
```

Up to now, the include file generated by \texttt{ASK} just contained a single number. \texttt{ASK} can generate more complicated include files. Consider the example:

```gams
* import a set
$call =ask T=integer M="Give year between 1990 and 2010." C="My Title" L=1990 U=2010 R="set i /1990*%s/;" O=i.inc
$include i.inc
display i;
```

The parameters \texttt{C="caption"} and \texttt{R="resultstring"} are new. The caption is simple: it sets the name of the window. The result string is a string that is returned after \texttt{ASK} has substituted \texttt{s} for the result. I.e. if we enter \texttt{1991}, then the result written to the include file is \texttt{set i /1990*1991/;}

The listing file can be used to check the correct behavior:

```gams
1 * import a set
INCLUDE D:\GAMS PROJECTS\ASK\I.INC
4 * Ask Import Filter Version 1.0, Nov. 1999
5 * Erwin Kalvelagen, GAMS Development Corp.
6 set i /1990*1991/;
7 display i;
```

### 5.4.3 Radio Button

Radio buttons can be used through the parameter \texttt{T=radiobuttons} as in:

```gams
* import a number through radio buttons
$call =ask T=radiobuttons M="Choose single option" D="option 1|option 2|option 3|option 4|option 5" E="1|2|3|4|5" R="scalar n2 option /%s/;" o=n2.inc
$include n2.inc
display n2;
```
The parameter $D=^{\text{"option 1|option 2|option 3|option 4|option 5"}}^\text{specifies the text of the options shown. The list } E=^{\text{1|2|3|4|5}}^\text{gives the return (exit) strings when a certain option is chosen. I.e. if the second option is chosen in the list specified with the } D\text{ parameter, then the second string in the } E\text{ list is returned. The result is again substituted in the string specified in the } R\text{ parameter if it exists.}

In this example the command line became rather long and difficult to handle. In addition some Windows systems have restrictive maximum lengths for the command line. Therefore we offer the possibility to specify the command line arguments in a separate external text file. This text file is passed using

\@filename

. Assume the file ask.opt looks like:

T=radiobuttons
M=Choose single option
D=option 1|option 2|option 3|option 4|option 5|option 6|option 7|option 8|option 9|option 10
E=1|2|3|4|5|6|7|8|9|10
2
R=scalar n3 option /%s/;
0=n3.inc

Every command line parameter is specified on a separate line. Notice the strange option 2; this tells ASK to display the radio buttons in two columns. We can use this option file as follows:

* id, now 2 columns and using a parameter file
$call =ask @"ask.opt"
$include n3.inc
display n3;

The quotes around the filename are optional, and really only needed if the filename contains blanks.

If you want to keep all the logic in one place, then one can use GAMS to generate the option file. It is noted that it is not possible to use the PUT facility for this. I.e.:

File f /asktest.opt/;
puf f;
puf 'T=checklistbox'/
  'M=Choose multiple options'/
  'D=option 1|option 2|option 3|option 4|option 5'/
  'E=1|2|3|4|5'/
  'R=%s checked list box choice'/
  'O=k2.inc'/;
pufClose;
$call =ask @asktest.opt
Set k2 /
$include k2.inc
/;
display k2;

is not correct: the $call is handled at compile time, before the PUT statement has done its work. However, one could use the following:
5.4.4 Combo Box

The next type is \texttt{T=combobox} which also allows a single selection:

* import a number through a combo box

\begin{verbatim}
$call =ask T=combobox M="Choose single option" D="option 1|option 2|option 3|option 4|option 5" E="1|2|3|4|5"
#include n4.inc
display n4;
\end{verbatim}

As an example consider the case where the model comes with three data sets: a small one, a medium sized one and a large data set. Each data set is stored in a separate include file: \texttt{small.inc}, \texttt{medium.inc} and \texttt{large.inc}. We want to ask the user which data set should be used and the correct include file should be used. This can be accomplished by:

\begin{verbatim}
$echo 'T=combobox' > ask.opt
$echo 'M=choose data set' >> ask.opt
$echo 'D=Small data set|Medium data set|Large data set' >> ask.opt
$echo 'E=small.inc|medium.inc|large.inc' >> ask.opt
$echo 'R=\%s include file' >> ask.opt
$call =ask @ask.opt
#include dataset.inc
\end{verbatim}

Newer GAMS systems allow:
5.4 ASK

$onEcho > ask.opt
T=combobox
M=choose data set
D=Small data set|Medium data set|Large data set
E=small.inc|medium.inc|large.inc
R=$include %s
O=dataset.inc
$offEcho
$call =ask @ask.opt
$include dataset.inc

In this case dataset.inc will contain a single line: another include statement, which is either $include small.inc, $include medium.inc or $include large.inc.

5.4.5 List and Checklist Box

In some cases it may be useful to be able to select multiple items from a list. This can be done with T=listbox:

* import a set through a listbox
$call =ask T=listbox M="Choose multiple options" D="option 1|option 2|option 3|option 4|option 5" E="1|2|3|4|5"
Set k /
$include k.inc
/;
display k;

Selecting multiple entries involves holding down the CTRL key. Sometimes a convenient alternative is T=checklistbox:

* import a set through a checked listbox
$call =ask T=checklistbox M="Choose multiple options" D="option 1|option 2|option 3|option 4|option 5" E="1|2|3|4|5"
Set k2 /
$include k2.inc
/;
display k2;

When we select options 1, 3 and 5, the following include file is generated:

* Ask Import Filter Version 1.1, Aug. 2002
* Erwin Kalvelagen, GAMS Development Corp.
1 'checked list box choice'
3 'checked list box choice'
5 'checked list box choice'

which will populate the set k2 as follows:
1 * import a set through a checked listbox
3 set k2 /
INCLUDE D:\GAMS PROJECTS\ASK\K2.INC
5 * Ask Import Filter Version 1.1, Aug. 2002
6 * Erwin Kalvelagen, GAMS Development Corp.
7 1 'checked list box choice'
8 3 'checked list box choice'
9 5 'checked list box choice'
10 /
11 display k2;
---- 11 SET k2
1, 3, 5

The last type is the generic string type: T=string. This allows the user to enter any string, which is then copied to an include file as is.

5.4.6 File Open Dialog Box

The type T=fileopenbox will display a file open dialog box from which the user can select a file.

Related options are I=InitialDirectory and F=Filter. A complete example to ask for an include file could be:

```
$call =ask T=fileopenbox I="%system.fp%" F="select*.inc" o=fln.inc R="$include '%s'" C="Select include file" $include fln.inc
```

This will open a file open dialog box with the starting directory being the GAMS project/working directory (this is also where GAMS looks for include files by default). Only files with mask SELECT.*.INC are shown. The file FLN.INC will contain an include statement with the file the user has selected.

A related method would be:

```
$call =ask T=fileopenbox I="%system.fp%" F="select*.inc" o=fln.inc R="$setglobal incfile '%s'" C="Select include file"
$include fln.inc
```

where we use a $setglobal to set the macro incfile to contain the user-specified file name.

To let the user choose from a set of related GDX files, one could use something like:

```
$call =ask T=fileopenbox I="%system.fp%" F="myproject*.gdx" o=setgdxname.inc R="$setglobal gdxfile '%s'" C="Select GDX file"
$include setgdxname.inc
$gdxIn %gdxfile%
$load i
$load j
```

In case you want to ask for a filename of a file to be written, use the type T=filesavebox. E.g.:

```
$call =ask T=filesavebox I="%system.fp%" o=fln.inc R="$setglobal gdxfile '%s'" C="Specify gdx file"
$include fln.inc
Set i / a, b, c /;
execute_unload '%gdxfile%', i;
```

In case you want to ask for a directory, use the type T/selectdirectory. In this case the filter option F is ignored. E.g.:

```
$call =ask T=selectdirectory I="%system.fp%" o=fln.inc R="$setglobal myInputdir '%s'" C="Select directory"
$include fln.inc
$log Selected directory "%myInputdir%"
```
5.5 BIB2GMS

Analyses BibTeX files with file extension .bib and writes GAMS source files that can be used to create various author, reference and cross reference reports.

5.5.1 Usage

bib2gms bibinput [ option referencemap [key=value] ]

'Reads' BIB files and writes GAMS source files that can be used to create various author, reference and cross reference reports. The BibInput file usually contains many more entries than are needed for the specific GAMS application and the BIB document names need to be mapped into GAMS set elements. This mapping is specified in the ReferenceMap file.

Bib2gms will produce a number of gams include files and a GAMS main program that demonstrates the use of the include files.

5.5.2 Examples

bib2gms myfile.bib

bib2gms "my blanks.abc" R=mymap GmsFile="my gams.gms"

bib2gms bibin i = stem

The file ReferenceMap (R) contains the name of the BIB entries to be extracted from the BIB input file. If no (R) file names is given, all entries will be selected and the original BIB record names will be used. Each line contains the reference name of the entry to be included. You can enter a single name or the pair <gams> <bib> to rename the <bib> reference name to the new <gams> name.

Example of ReferenceMap file:

* lines staring with * or # are ignored
* empty lines are ignore as well
* spaces are ignored
* tabs , and . are all whitespace
r1 mybibref2
r2,mybibref5
r3.mybibref1
r4
* a single ref entry assumes the BIB record name is the same as the
* gams name, r4 r4
*
* The GAMS maintained master BIB file has references named g00001, g00002,...
* A reference name consisting of digits only will be renamed
* to form one of those g0000x names. For example:
r5 12

Output Files:

bib2gms.gms gams program that reads all include files shown below
### Quick guide to parameters:

<table>
<thead>
<tr>
<th>Key</th>
<th>Symbol</th>
<th>Abbrev.</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BibInput</td>
<td>B</td>
<td>Bib</td>
<td>BIB input file</td>
</tr>
<tr>
<td>ReferenceMap</td>
<td>R</td>
<td>Ref</td>
<td>BIB reference or extraction file</td>
</tr>
<tr>
<td>GmsFile</td>
<td>G</td>
<td>Gms</td>
<td>GAMS main program name</td>
</tr>
<tr>
<td>IncFiles</td>
<td>I</td>
<td>Inc</td>
<td>GAMS include file name stem</td>
</tr>
<tr>
<td>DoiStyle</td>
<td>D</td>
<td>Doi</td>
<td>Style of handling DOI entries (ignore, text, html)</td>
</tr>
</tbody>
</table>

### 5.6 CHK4UPD

The tool `chk4upd` checks if there is a newer version of GAMS available than the one you are running. It checks for the most recent version available as well as for the newest version you can run with your license in case your maintenance and support is expired.

By default it reads `gamslice.txt` located next to it. Alternatively, you can specify another license on the command line. In addition to the command line tool you will find an integration in the GAMS IDE at Help -> Check for GAMS Update.

### 5.7 CHOLESKY

`CHOLESKY` calculates the Cholesky decomposition of a symmetric positive definite matrix. Matrix decomposition $A=LL^T$.

#### 5.7.1 Usage

`cholesky gdxin i a gdxout L`

where

- **`gdxin`**
  
  name of gdxfile with matrix

- **`i`**
  
  name of set used in matrix
a

name of 2 dimensional parameter inside gdxin
gdxout

name of gdxfile for results (factor L)
L

name of 2 dimensional parameter inside gdxout

Calculates the Cholesky decomposition $A=LL^t$ of a symmetric positive definite matrix $A=a(i,j)$ where $i$ and $j$ are aliased sets. $L$ will contain the Cholesky factor $L(i,j)$.

5.7.2 Example

$onText
Finds the Cholesky decomposition $A=LL'$ of a positive definite symmetric matrix $A$ through an external program.

Erwin Kalvelagen, may 2008
$offText

Set i / i1*i5 /;
Alias (i,j);

Table a(i,j) 'original matrix'
  i1  i2  i3  i4  i5
  i1  64  48  24  8  8
  i2  48  72  42  54  36
  i3  24  42  89 107  95
  i4  8  54 107 210 186
  i5  8  36  95 186 187;

Parameter L(i,j) 'cholesky factor';
execute_unload 'a.gdx', i, a;
execute '=cholesky.exe a.gdx i a b.gdx L';
execute_load 'b.gdx', L;
display a, L;

* only lower triangular part of $A$ is used
*
Table a2(i,j) 'original matrix'
  i1  i2  i3  i4  i5
  i1  64
  i2  48  72
  i3  24  42  89
  i4  8  54 107 210
  i5  8  36  95 186 187;

Parameter L2(i,j) 'cholesky factor';
execute_unload 'a.gdx', i, a2;
execute '=cholesky.exe a.gdx i a2 b.gdx L2';
execute_load 'b.gdx', L2;
display a2, L2;
5.8 CSDP

The semidefinite programming CSDP solver from COIN-OR. The communication with CSDP requires the setup of matrix data structures in a CSDP input file. In a sense a GAMS model functions as a matrix generator.

5.8.1 Usage

csdp <input problem> [<final solution>] [<initial solution>]

<input problem>
the name of a file containing the SDP problem in SDPA sparse format.

<final solution>
the optional name of a file in which to save the final solution.

<initial solution>
the optional name of a file from which to take the initial solution.

See CSDP User’s Guide for more information.

5.9 CSV2GDX

CSV2GDX is a tool that reads a CSV file and writes to a GDX file. There are multiple ways to read CSV files (Comma Separated Values) inside GAMS (see Data Exchange with Text Files for instance), but a number of features available in CSV2GDX make it possible to read a CSV file where GAMS itself cannot be used. In addition to the syntax explanation and the basic functionalities demonstrated on some examples, this tutorial also discusses some advantages and disadvantages of CSV2GDX compared to the GAMS internal table statement.

5.9.1 Usage

CSV2GDX is called by specifying the CSV file and several options to define how to read the data.

csv2gdx filename {options}

Filename

The input file; the .csv file extension is assumed when no extension has been specified.

Parameters can also be read from a text file; the use of an external file for parameters is indicated by preceding the file name with a @ (at sign). When reading parameters from a text file, lines starting with an asterisk (*) will be ignored. See also Example 8.

5.9.2 Options

The following options can be used when calling CSV2GDX:
### Option Table

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acceptBadUels</td>
<td>N</td>
<td>Indicate if bad UELs are accepted or result in an error return code.</td>
</tr>
<tr>
<td>autoCol</td>
<td>none</td>
<td>Generate automatic UELs for each column.</td>
</tr>
<tr>
<td>autoRow</td>
<td>none</td>
<td>Generate automatic UELs for each row.</td>
</tr>
<tr>
<td>checkDate</td>
<td>N</td>
<td>Write GDX file only if the CSV file is more recent than the GDX file.</td>
</tr>
<tr>
<td>colCount</td>
<td>none</td>
<td>Number of columns in the input file.</td>
</tr>
<tr>
<td>decimalSep</td>
<td>Period</td>
<td>Specify a decimal separator.</td>
</tr>
<tr>
<td>fieldSep</td>
<td>Comma</td>
<td>Specify a field separator.</td>
</tr>
<tr>
<td>id</td>
<td>none</td>
<td>Identifier for the symbol in the GDX file.</td>
</tr>
<tr>
<td>index</td>
<td>none</td>
<td>Identify columns to get UELs from.</td>
</tr>
<tr>
<td>output</td>
<td>&lt;CSVFilename&gt;.gdx</td>
<td>Optional output filename.</td>
</tr>
<tr>
<td>password</td>
<td>none</td>
<td>Password for an encrypted input file.</td>
</tr>
<tr>
<td>storeZero</td>
<td>N</td>
<td>Indicate how zero values are handled.</td>
</tr>
<tr>
<td>text</td>
<td>none</td>
<td>Specify the column to get explanatory text from.</td>
</tr>
<tr>
<td>trace</td>
<td>1</td>
<td>Controls the amount of information written to the log.</td>
</tr>
<tr>
<td>useHeader</td>
<td>N</td>
<td>Indicate if the first row is a header row.</td>
</tr>
<tr>
<td>value</td>
<td>none</td>
<td>Specify the column to get the values from.</td>
</tr>
<tr>
<td>valueDim</td>
<td>N</td>
<td>Adds an extra dimension for values.</td>
</tr>
<tr>
<td>values</td>
<td>none</td>
<td>Specify the columns to get the values from.</td>
</tr>
</tbody>
</table>

### Note

- The user has to specify an identifier for the symbol in the GDX file within the parameter `id`, regardless of the data structure in the CSV file.
- `CSV2GDX` determines the number of columns in the CSV file from the header row or from the user defined input specified in the parameter `colCount`. Therefore, the user must enable the option `useHeader` or has to specify the number of columns within `colCount` in any case.

Some more detailed remarks on the options:

**acceptBadUels** = `boolean` (default=`N`)

This option specifies how to proceed, when a bad UEL (e.g., too long) is encountered. If set to `N`, reading is stopped, and an error is signaled. When set to `Y`, a valid UEL is made up and reading is continued.

**autoCol** = `string`

Generate automatic UELs for each column. The autoCol string is used as the prefix for the column label numbers. This option overrides the use of a header row. However, if there is a header row, one must skip the row by enabling `useHeader`. This option is demonstrated in Example 3.

**autoRow** = `string`
Generate automatic UELs for each row. The autoRow string is used as the prefix for the row label numbers. The generated unique elements will be used in the first index position shifting other elements to the right. Using autoRow can be helpful when there are no labels that can be used as unique elements but also to store entries that would be a duplicate entry without an unique row label. This option is demonstrated in Example 3.

`checkDate = boolean (default=N)`

Write GDX file only if the CSV file is more recent than the GDX file to save resources when running the model containing the CSV2GDX call multiple times. This option is demonstrated in Example 5.

`colCount = integer`

Number of columns in the input file. This parameter is required if there is no header row, since CSV2GDX determines the number of columns from the header row. This option is demonstrated in Example 3. Note that the lastCol constant cannot be used for the colCount option.

`decimalSep = [Period, Comma] (default=Period)`

Specify a decimal separator. The decimal is normally a period, but this parameter allows a comma as the decimal separator, too. Special values recognized are Eps, N/A resp. N/A, Inf, True, False, None, Null and Undef (case insensitive). A string that is not recognized as a valid number will be stored as Undef. This option is demonstrated in Example 2 and Example 6 (focusing on reading special values) for instance.

`fieldSep = [Comma, SemiColon, Tab] (default=Comma)`

Specify a field separator. Fields are normally separated by a comma, but this parameter allows some additional choices. Using tabs as delimiter should be avoided, since text editors act different on handling them. For instance, one must specify tabs in the GAMS IDE explicitly using %system.tab%:

```
$onEcho > tabSeparated.csv
USA%system.tab%100
GER%system.tab%70
$offEcho
```

$call csv2gdx tabSeparated.csv id=x fieldSep=tab index=1 colCount=2 value=lastCol

This option is demonstrated in Example 2 and Example 3 for instance.

`id = string`

Identifier for the symbol in the GDX file. Additional symbols, Dim1, Dim2, ... for the domain sets of the symbol id will be added automatically to the GDX file. Executing CSV2GDX without specifying an identifier will fail.

`index = list of columns`

Identify columns to get UELs from. The columns are represented as a list of integers separated by comma. For example `index=1,2,3,4` resp. `index=(1,2,3,4)`; in this case the notation `1..4` is allowed. Brackets can only be used on Windows systems. The index option is used in all examples.

`output = filename (default=<CSVFilename>.gdx)`
Optional output filename. If no output file is specified, `CSV2GDX` will use the input filename and change the file extension to `.gdx`. If no path is specified, the output file will be created in the current directory. This option is demonstrated in Example 2 for instance.

**password** = string

Password for an encrypted input file. Use `ENDECRYPT` to encrypt a file. This option is demonstrated in Example 7.

**storeZero** = boolean (default=N)

Indicate if zero values are ignored or written as EPS; an empty field is always ignored. This option is demonstrated in Example 6.

**text** = integer

Specify the column to get explanatory text from when reading a set. For example `text=5`. This option is demonstrated in Example 9.

**trace** = integer (default=1)

Controls the amount of information written to the log. Higher values will generate more output. Valid range is 0..3. Set `trace=0` to prevent writing any information to the log. This feature is demonstrated in Example 6.

**useHeader** = boolean (default=N)

Indicate if the first row is a header row. The fields in the header row of the columns specified within the values option will be used as UELs. A header row is not needed or should be ignored when using the `colCount` or `autoCol` option. To skip one existing header row while using `autoCol`, enable `useHeader`. This option is demonstrated in Example 1 and Example 2 for instance.

**value** = integer

Specify the column to get the values from. For example `value=5`. This option is demonstrated in Example 2.

**valueDim** = boolean (default=N)

Indicate if an extra dimension for values is added to the parameter even if there is just one value column. This is ignored, if there is no value column. This feature is demonstrated in Example 2.

**values** = list of columns

Specify the columns to get the values from. When using a list of columns for the values and `useHeader` enabled, each field in the first row of the columns is used as UEL to identify the values in those columns. See also `useHeader` and `autoCol` below. If the number of columns is unknown, the symbolic constant `lastCol` can be useful: `values=2..lastCol`. This option is demonstrated in Example 1 and Example 5 for instance.
5.9.3 Advances and limitations

Advances

- CSV2GDX enables the user to read CSV data where the table statement cannot be used without doing further preprocessing, e.g. in case of semicolon- or tab separated data or comma separated decimals.
- In general, CSV2GDX is a quite performant tool compared to the GAMS internal table statement.

Limitations

- Suppose we want to skip some rows while reading the data. For example, if the CSV file contains some reference information in a specific row which we do not want to be stored in the domain sets or in the parameter. However, skipping rows cannot be done with CSV2GDX.
- There might be CSV files with no header and varying, unknown length of rows. Since CSV2GDX determines the number of columns based on the header row or by setting the colCount option in advance, CSV2GDX might return incorrect results or the execution is aborted.
- Reading several parameters from a CSV file cannot be done directly within the CSV2GDX call. The data must be split later on as demonstrated in Example 4.
- CSV2GDX cannot read CSV files containing line breaks within a (quoted) field. You will either get an error message - "Quoted field not terminated with closing quote" - or the result might not be correct for unquoted fields, because the field content will be cut by the line break.

5.9.4 Getting Started

We introduce the basic functionalities of CSV2GDX on some simple examples. Note that many CSV files can be read inside GAMS directly using a table statement, but a number of features available in CSV2GDX enable the user to read a CSV file where the table statement cannot be used, e.g. reading files with semicolon separated data or if the decimals are separated by comma instead of a period.

5.9.4.1 Example 1 - Reading CSV Files with CSV2GDX

The first example of this collection demonstrates the key commands of CSV2GDX. For instance, consider the table statement of the model [transport] from the GAMS Model Library:

```
Table d(i,j) 'distance in thousands of miles'
    new-york  chicago  topeka
         seattle  2.5     1.7     1.8
         san-diego 2.5     1.8     1.4;
```

The data can be stored in distance.csv like this:
First of all, CSV2GDX is called now, to generate distance.gdx by processing the input file distance.csv:

csv2gdx distance.csv id=d index=1 values=2..lastCol useHeader=y

CSV2GDX generates one single parameter \( d \) and two domain sets from the input file. The name of the parameter in the GDX file must be declared within the id option, while the domain sets for this parameter will be labeled with Dim1 and Dim2 automatically. Column number one is specified as the first domain set within the index option. The values option is used to specify the column numbers 2, 3, 4 containing the data values. By enabling the useHeader option, the fields of the first row of the columns specified within the values option will be handled as the second domain set. If the number of columns is unknown in advance, one can use the lastCol constant in the values or index option.

However, to complete the declaration of the sets and parameter for the model trnsport, one must load the data from distance.gdx:

```
Set
  i 'canning plants'
  j 'markets';

$gdxIn distance.gdx
$load i = Dim1
$load j = Dim2

Parameter d(i,j) 'distance in thousands of miles';
$load d
$gdxIn
display i, j, d;
```

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx2] for reference.
5.9.4.2 Example 2 - Reading Semicolon separated Data

In this example, the distances from the previous example are stored as a list. We want to read the cities and the column containing the miles measurement. Note, that the fields are separated by semicolon and the decimals by comma. As described in Data Exchange with Text Files the CSV file must be preprocessed with the POSIX tools in advance to replace commas by dots and semicolons by commas to read the data directly using a simple table statement.

<table>
<thead>
<tr>
<th>i</th>
<th>j</th>
<th>miles</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>new-york</td>
<td>2,5</td>
</tr>
<tr>
<td>seattle</td>
<td>chicago</td>
<td>1,7</td>
</tr>
<tr>
<td>seattle</td>
<td>topeka</td>
<td>1,8</td>
</tr>
<tr>
<td>san-diego</td>
<td>new-york</td>
<td>2,5</td>
</tr>
<tr>
<td>san-diego</td>
<td>chicago</td>
<td>1,8</td>
</tr>
<tr>
<td>san-diego</td>
<td>topeka</td>
<td>1,4</td>
</tr>
</tbody>
</table>

The data will be stored as distanceOut.gdx by adding the output file option. One can specify the field and decimal separators within the fieldSep and decimalSep option. Domain sets for the parameter to be read are declared by index=1,2.

```bash
csv2gdx distance.csv output=distanceOut.gdx id=d fieldSep=semiColon decimalSep=comma index=1,2 useHeader=y value=3
```

In order to load the data from the GDX file, execute the commands from the previous example. However, note that Dim2 does not contain the UELs from the header row this time, but the unique elements of the second column specified in the index option. The option useHeader is enabled to indicate that there is a header row to be skipped when reading the values. Also note, that the symbol d in the GDX file has exactly two dimensions. It may be useful to add an additional dimension to the parameter dmod, e.g. if different measurement units for the distances may become relevant later on and need to be calculated (kilometer for instance).

This can be done by adding the option valueDim:

```bash
csv2gdx distance.csv output=distanceOut.gdx id=d fieldSep=semiColon decimalSep=comma index=1,2 useHeader=y value=3 valueDim=y
```

The option adds a third dimension to d. Now we want to add the distances in kilometer by calculating the values inside the model:

```bash
Set m 'measurement unit' / miles, km /;

Parameter dmod(i,j,m);

$gdxIn distanceOut.gdx
$load dmod = d
$gdxIn
display dmod;

dmod(i,j,'km') = 1.852*dmod(i,j,'miles');
display dmod;

Parameter d (valueDim disabled):
```
5.9 CSV2GDX

---- 36 PARAMETER d distance in thousands of miles

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.500</td>
<td>1.700</td>
<td>1.800</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.500</td>
<td>1.800</td>
<td>1.400</td>
</tr>
</tbody>
</table>

Parameter dmod resp. d with valueDim enabled before calculating further measurements:

---- 49 PARAMETER dmod

<table>
<thead>
<tr>
<th></th>
<th>miles</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle .new-york</td>
<td>2.500</td>
</tr>
<tr>
<td>seattle .chicago</td>
<td>1.700</td>
</tr>
<tr>
<td>seattle .topeka</td>
<td>1.800</td>
</tr>
<tr>
<td>san-diego .new-york</td>
<td>2.500</td>
</tr>
<tr>
<td>san-diego.chicago</td>
<td>1.800</td>
</tr>
<tr>
<td>san-diego.topeka</td>
<td>1.400</td>
</tr>
</tbody>
</table>

Parameter dmod with valueDim enabled after calculating the distances in kilometer inside the GAMS model:

---- 52 PARAMETER dmod

<table>
<thead>
<tr>
<th></th>
<th>miles</th>
<th>km</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle .new-york</td>
<td>2.500</td>
<td>4.630</td>
</tr>
<tr>
<td>seattle .chicago</td>
<td>1.700</td>
<td>3.148</td>
</tr>
<tr>
<td>seattle .topeka</td>
<td>1.800</td>
<td>3.334</td>
</tr>
<tr>
<td>san-diego .new-york</td>
<td>2.500</td>
<td>4.630</td>
</tr>
<tr>
<td>san-diego.chicago</td>
<td>1.800</td>
<td>3.334</td>
</tr>
<tr>
<td>san-diego .topeka</td>
<td>1.400</td>
<td>2.593</td>
</tr>
</tbody>
</table>

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx3] for reference.

5.9.4.3 Example 3 - Dealing with missing Labels and Duplicates

Missing Labels

The file EUCData.csv contains the extracted euclidean coordinates of the first nine cities of berlin52.tsp from TSPLib. You might want to import the data to calculate a complete distance matrix inside GAMS to find an optimal traveling salesman tour for instance.

565.0;575.0
25.0;185.0
345.0;750.0
945.0;685.0
845.0;655.0
880.0;660.0
25.0;230.0
525.0;1000.0
580.0;1175.0
There is no header row, neither a column with labels to serve as domain sets for the coordinates of the cities. However, CSV2GDX automatically generates UELs for columns and rows by adding ascending numbers to an user-defined prefix specified within the autoCol and autoRow option. Also note, because of the missing header, the number of columns in the file must be manually determined and declared within colCount.

```
java

csv2gdx EUCData.csv id=coord fieldSep=semiColon autoCol=x autoRow=city colCount=2 values=1,2
```

The rows will be labeled with city1...city9, the columns with x1 and x2.

Load the parameter and sets from the GDX file to calculate the complete distance matrix. The set Dim1 contains the UELs city1...city9 for the set i of cities, Dim2 is the set of axes/coordinates i.e. containing the elements x1 and x2 to represent the x-axis and y-axis:

```
Set
  i 'cities'
  axes 'x1 and x2 axes';

$gdxIn EUCData.gdx
$load i = Dim1
$load axes = Dim2

Parameter coord(i,axes) 'coordinate of city i';
$load coord
$gdxIn
display coord;
```

The display statement generates the following output:

```
----  43 PARAMETER coord coordinate of city i
           x1          x2
     city1  565.000   575.000
     city2    25.000   185.000
     city3  345.000   750.000
     city4  945.000   685.000
     city5  845.000   655.000
     city6  880.000   660.000
     city7    25.000   230.000
     city8  525.000 1000.000
     city9  580.000 1175.000
```

One could now easily proceed calculating a complete distance matrix:

```
Alias (i,j);

Parameter c(i,j) 'euclidean distance between city i and j';
c(i,j) = eDist(coord(i,"x1") - coord(j,"x1"),coord(i,"x2") - coord(j,"x2"));
```
Duplicates

In the previous example, using the autoCol and autoRow option had an additional benefit as we declared the set of the cities on the fly. However, one major advantage/purpose of these options is to prevent error messages or loss of data when reading rows with duplicate keys.

Consider the input file duplicates.csv:

```
red,red,1
red,red,2
red,green,3
blue,blue,4
```

Note the duplicate key in the first two rows. By the use of the autoRow parameter in the CSV2GDX call unique labels are added to each row. This way a GAMS program can store all data with duplicate keys and prepare for better error messages.

```
csv2gdx duplicates.csv id=data index=1,2 value=3 colCount=3 autoRow=row
```

Ascending numbers will be added to the 'row' prefix specified.

The data can be easily loaded into sets and parameter by executing the following lines:

```
Set
  row 'UELs generated by autoRow'
  color 'set of colors';
$gdxIn duplicates.gdx
$load row = Dim1
$load color = Dim2
$loadm color = Dim3

Parameter data(row,color,color);
$load data
$gdxIn
display row, color, data;
```

Note the usage of the $loadm command to merge all colors into one set of colors. The display statement generates the following output in the listing file:

```
---- 77 SET row UELs generated by autoRow
row1, row2, row3, row4

---- 77 SET color set of colors
red , blue , green
```
### 5.9.4.4 Example 4 - Reading several Parameters from a single Input File

This example demonstrates how to read the data from a single input file into different parameters. However, this cannot be done directly using the `CSV2GDX` tool, since `CSV2GDX` writes to a single parameter (see section limitations). For instance, an energy supplier plans to build new transmission lines from their power plants to some distribution stations. There are different stages for the transmissions lines. The relevant data to be read are the plant and station identifiers, the capacity bounds per transmission line on a certain stage and the associated cost. The data is all stored in a single file:

<table>
<thead>
<tr>
<th>plant;station;length;minCap;maxCap;stage;cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>p1;s1;100;50;100;1;1200</td>
</tr>
<tr>
<td>p1;s1;75;35;65;1;500</td>
</tr>
<tr>
<td>p1;s1;100;100;150;2;1800</td>
</tr>
<tr>
<td>p2;s1;150;50;100;1;1400</td>
</tr>
<tr>
<td>p2;s1;150;100;150;2;2000</td>
</tr>
<tr>
<td>p2;s1;150;150;200;3;2350</td>
</tr>
<tr>
<td>p2;s2;75;25;50;1;600</td>
</tr>
<tr>
<td>p2;s2;75;50;75;2;800</td>
</tr>
<tr>
<td>p3;s1;80;40;100;1;1050</td>
</tr>
</tbody>
</table>

Read `networkData.csv` with `CSV2GDX` by calling:

```bash
csv2gdx networkData.csv id=dataPar useHeader=y fieldSep=semiColon index=1,2,6 values=4,5,7
```

Note that the stage stored in column six is a domain set, too, while the length of the transmission line in the third column is of no interest. Since `CSV2GDX` writes to a single parameter, one must split the data later on into `minCap`, `maxCap` and `cost` for instance:

```plaintext
Parameter
dataPar
    minCap(plant,station,stage)
    maxCap(plant,station,stage)
    cost(plant,station,stage);
$gdxIn networkData.gdx
$load plant = Dim1
$load station = Dim2
```
$load stage  = Dim3
$load dataPar
$gdxIn

minCap(plant,station,stage) = dataPar(plant,station,stage,'minCap');
maxCap(plant,station,stage) = dataPar(plant,station,stage,'maxCap');
cost(plant,station,stage) = dataPar(plant,station,stage,'cost');

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx5] for reference.

5.9.4.5 Example 5 - Reading economic Data from the World Bank Data Catalog

This example demonstrates how to read some real CSV data from the World Bank Data Catalog. Suppose we want to read some time series data, e.g. GDP growth rates. The data is structured as follows (rows shortened for presentation):

We are not interested in the "Country Code", "Indicator Name" and "Indicator Code". Since the annual GDP rate per country is unique, the CSV2GDX call is quite easy despite the large number of columns. Note that there are only a few limitations of CSV2GDX, discussed in the section Advances and limitations. Empty fields in the data will always be ignored, causing no trouble at all if the field separators are set correctly.

csv2gdx GDPData.csv id=GDPG index=1 values=5..lastCol useHeader=y checkDate=y

The option checkDate is enabled to save resources if you run the model multiple times, as the GDX file is only written if the CSV file is more recent than the GDX file. To load the sets and parameter from the GDX file, execute the following commands:

Set country, year;
$gdxIn GDPData.gdx
$load country = Dim1
$load year  = Dim2

Parameter GDPRate(country,year);
$load GDPRate
$gdxIn
display country, year, GDPRate;

The display statement generates the following output in the listing file. Obviously, double quotes are removed from the fields of the value columns, but also from the index columns:
12 SET country

East Asia and Pacific, Europe and Central Asia, Latin America and the Caribbean, Middle East and North Africa, Afghanistan, Albania, Algeria, Angola

12 SET year

12 PARAMETER GDPR

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Europe and Central Asia</td>
<td>0.963</td>
<td>1.672</td>
<td>3.782</td>
<td>2.901</td>
<td>3.029</td>
<td>2.969</td>
</tr>
<tr>
<td>Latin America and the Caribbean</td>
<td>-0.562</td>
<td>-1.526</td>
<td>0.902</td>
<td>2.044</td>
<td>2.586</td>
<td>2.701</td>
</tr>
</tbody>
</table>

Note that the listings have been shortened for presentation. However, there is no data for the years 1999-2014.

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx6] for reference.

5.9.5 Additional Examples for extended Use

The examples in this section discuss some special features. Some topics were already mentioned briefly in the previous section like reading compressed and encrypted files or reading the CSV2GDX options from an external file.

5.9.5.1 Example 6 - Reading special Values

To illustrate how special values are interpreted, consider the following data:

one,two,three,four,five,six
red,red,,Undef,'3.3',red
red,red,"4.4",5.5,Eps,green
"red", 'green',7.7e+02,8.8*,-Inf,blue
blue,blue,10,0,NA,purple
brown,blue,true,false,N/A,green
black,red,None,Null,"True",blue

Calling CSV2GDX to read the data and write to GDX:

csv2gdx data.csv id=A index=1,2,6 values=3..5 useHeader=y storeZero=y trace=3

The GAMS log reports three occurrences of undefined values. Note that the amount of information written to the log was increased by setting the option trace=3.
--- call csv2gdx specialValues.csv id=A index=1,2,6 values=3..5 useHeader=y storeZero=y trace=3
CSV2GDX 25.2.0 r67638 ALFA Released 15Aug18 WEI x86 64bit/MS Windows
Header enabled, number of columns = 6
  1: one
  2: two
  3: three
  4: four
  5: five
  6: six
  2: |red|, |red|, ||, |Undef|, |'3.3'|, |red|
  3: |red|, |red|, |4.4|, |5.5|, |Eps|, |green|
  4: |red|, |'green'!, |7.7e+02|, |8.8°|, |-Inf|, |blue|
  5: |blue|, |blue|, |10|, |0|, |NA|, |purple|
Undef Count = 3, No errors, CSV2GDX time = 157ms

As mentioned in decimalSep, CSV2GDX fails to recognize the number 8.8 from the string 8.8° because of the unknown special character, while 7.7e+02 is interpreted as a number of course. Watch out if there are quotes in the values or index columns. The number 4.4 enclosed by double quotes is interpreted as a number, while '3.3' is not (as you can see in the log, the double quotes are eliminated, while the single quotes remain). In the first column, the double quotes enclosing the string red are removed, while the single quotes in the second column enclosing the string green are not removed. The zero value is stored as EPS by setting storeZero=y. Note that no error was reported, even though some of the values stored as Undef may cause some trouble in your model later on (use $onUndf to enable loading parameters with undefined values).

The booleans true and false in the second last row are represented by the numericals 1 resp. 0 within GAMS. The special values None and Null will be converted to 0. Since storeZero is enabled in this example, the value displayed for false, None and Null is EPS.

Suppose we want to declare the parameter A as: A(color,color,color,number). We can proceed as follows:

Set color, number;
$gdxIn data.gdx
$load color = Dim1
$loadm color = Dim2
$loadm color = Dim3
$load number = Dim4
Parameter A(color,color,color,number);
$onUndf
$load A
$offUndf
$gdxIn
display A;

Loading undefined values is enabled by adding $onUndf. This example is also part of the GAMS Data Utilities Library, see model [csv2gdx7] for reference.

5.9.5.2 Example 7 - Reading a compressed encrypted Input File

Reading a compressed input file is supported by CSV2GDX. The gzip program in the gbin sub-directory or ENDECRYPT must be used for compression. Call gzip to compress the CSV file by running the following command:
gzip compressMe.csv -c > compressedFile.csv.gz

Gzip writes to standard output by appending -c to keep the original file unchanged. The output is then redirected to compressedFile.csv.gz. To read the compressed file, call CSV2GDX with the same options as for processing the uncompressed file.

csv2gdx compressedFile.csv.gz output=unCompressedGzipFile.gdx id=d index=1 useHeader=y values=2..last

The data in this example is taken from Example 1.

While the main purpose of Endecrypt is about encrypting and decrypting files, it also compresses the file. If you want to compress a file with Endecrypt, do not specify an password file:

cat compressMe.csv | endecrypt -W compressedFile.csv

The option -W encrypts standard input and writes to compressedFile.csv. Although there will be no encryption because of the missing password file, one must set the option -W. You can read the compressed file with CSV2GDX:

csv2gdx compressedFile.csv output=unCompressedEndycryptFile.gdx id=d index=1 useHeader=y values=2..last

Note that there is no further file extension added.

By adding a password file (containing the password in the first line), Endecrypt encrypts and compresses the input file:

cat compressMe.csv | endecrypt -W compressedEncryptedFile.csv passwordFile.txt

The password file will be deleted. Execute the following command to read the compressed and encrypted file with CSV2GDX:

csv2gdx compressedEncryptedFile.csv output=unCompressedDecryptedFile.gdx password=Anton id=d index=1 useHeader=y values=2..last

The password option is added. You must set the password directly within the option, in this case ”Anton”, not the password file. Note that CSV2GDX does not support .gz, .7z etc. compressed files!

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx8] for reference.
5.9.5.3 Example 8 - Reading Options from an external File

This example demonstrates how to read the options from an external text file as already mentioned in section Filename. The file distance.csv from the Getting Started Example 1 will be processed with CSV2GDX while reading the options from an external text file named howToRead.txt.

```text
csv2gdx distance.csv @howToRead.txt
```

Swapping the order of the CSV filename and the instructions filename inside the call statement will cause an error. Note the leading @ (at sign) on the instructions file, containing the following options:

* These lines are interpreted as a comment
* This file specifies the options for reading distance.csv using CSV2GDX

```text
id = d
decimalSep = comma
index = i
useHeader = y
values = 2..lastCol
```

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx9] for reference.

5.9.5.4 Example 9 - Reading Set Elements with explanatory Text

In this example, we will demonstrate how to read explanatory text of set elements using the CSV2GDX option text.

Consider the input file data.csv:

```text
a1,b1,explanatory text of a1.b1,10
a1,b2,explanatory text of a1.b2,20
a2,b1,explanatory text of a2.b1,30
a2,b2,explanatory text of a2.b2,40
```

The set elements are stored in the first and second column, the explanatory text is stored in the third column and there is a fourth column containing some values. Suppose we want to read a two-dimensional set with explanatory text. By default, CSV2GDX does not read explanatory text, i.e. by running the following command:

```text
csv2gdx data.csv id=abOnlyUELs index=1,2 colCount=4
```

CSV2GDX creates a GDX file containing the two-dimensional set abOnlyUELs without explanatory text (needless to say, we did not specify a column to get the explanatory text from). By specifying the third column within the index option, i.e. index=1..3, the result will be a three-dimensional set (without explanatory text, too). Using the value option is not suitable, as the data type will be a parameter instead of a set (in addition, CSV2GDX expects numeric data, potentially leading to undefined values). We can read the explanatory text easily by specifying column three within the text option:

```text
csv2gdx data.csv id=abWithExpText index=1,2 text=3 colCount=4
```

The figure shows the set abOnlyUELs on the left without explanatory text and the set abWithExpText on the right.

Note that the text and value(s) options cannot be used at the same time (instead, use multiple CSV2GDX calls in scenarios when you wish to read set elements with explanatory text and parameters from a single data set).
5.10 EIGENVALUE

EIGENVALUE calculates eigenvalues of a symmetric matrix.

5.10.1 Usage

eigenvalue gdxin i a gdxout ev

where

  gdxin  
  name of gdxfile with matrix

  i  
  name of set used in matrix

  a  
  name of 2 dimensional parameter inside gdxin

  gdxout  
  name of gdxfile for results (eigenvalues)

  ev  
  name of 1 dimensional parameter inside gdxout

Calculates eigenvalues of symmetric matrix a(i,j) where i and j are aliased sets.

5.10.2 Example

$onText
Eigenvalue example.

octave:1> a=[9 1 1; 1 9 1; 1 1 9]
a =
 9 1 1
 1 9 1
 1 1 9

octave:2> eig(a)
an =
 8
 8
 11
$offText

Set i / i1*i3 /;

$onText

Octave: example.

octave:1> a=[9 1 1; 1 9 1; 1 1 9]
a =
 9 1 1
 1 9 1
 1 1 9

octave:2> eig(a)
an =
 8
 8
 11
$offText

Set i / i1*i3 /;

$offText

Alias (i,j);

Table a(i,j)
  i1  i2  i3
  i1  9  1  1
  i2  1  9  1
  i3  1  1  9;

Parameter e(i) 'eigenvalues';

execute_unload 'mat.gdx', i, a;
execute '=eigenvalue.exe mat.gdx i a ev.gdx e';
execute_load 'ev.gdx', e;

display a, e;

5.11 EIGENVECTOR

EIGENVECTOR calculates eigenvalues/vectors of a symmetric matrix.

5.11.1 Usage

eigenvector gdxin i a gdxout eval evec

where

  gdxin
      name of gdxfile with matrix

  i
      name of set used in matrix

  a
      name of 2 dimensional parameter inside gdxin

  gdxout
      name of gdxfile for results (eigenvalues)

  eval
      name of 1 dimensional parameter inside gdxout

  evec
      name of 2 dimensional parameter inside gdxout

Calculates eigenvalues/vectors of symmetric matrix a(i,j) where i and j are aliased sets. eval will contain the eigenvalues and evec will contain the eigenvectors.
5.11.2 Example

$onText
Eigenvector example.

octave:1> a = [1 2 4 7 11; 2 3 5 8 12; 4 5 6 9 13; 7 8 9 10 14; 11 12 13 14 15]
a =

5.12 ENDECRYPT

A tool to encrypt and decrypt text files.

5.12.1 Usage

endecrypt option xfile [passwdfile]

option

-W

to encrypt standard input and write to xfile

-R

to decrypt xfile and write to standard output

xfile

Text file to encrypt or decrypt.

passwdfile (optional)

First line is used as password; will be deleted after use

5.13 GAMS Studio

GAMS Studio is a completely new integrated development environment for GAMS, which is available for Windows, Mac OS X, and Linux. It is based on C++ and Qt.

5.13.1 Motivation

The classic GAMS IDE has been shipped with the GAMS system for the last 20 years and is still the workhorse for many GAMS programmers. However, the existing IDE does not provide all the features we see in modern development environments. Due to its underlying software technology, implementing new features in the current IDE turned out to be a poor option, so work on a new development environment started from scratch. GAMS Studio is based on C++ and Qt, which makes it fast, reliable, and platform independent (Windows, Mac OS X, and Linux).
5.13.2 Central Widgets

5.13.2.1 Welcome Page

The Welcome page is the starting point of GAMS Studio. It is designed to give quick access to common actions and to offer helpful information. It is divided into three columns.

On the very left there is a column labeled "Last Files" which lists all files that have been opened recently in Studio with the most recent file on top. A simple left click on an item in this list opens the corresponding file. The middle column named "Getting Started" offers useful actions and links for new users. The upper half contains shortcuts to create new files in user defined locations, open the GAMS Model Library Explorer or load the Transport example. The lower half has a link to the Studio introduction video on YouTube and two further links that open the integrated help view showing either this Studio documentation or the page with the GAMS tutorial overview. The rightmost column "Further Help" contains a link to the latest GAMS release notes, the GAMS World Forum for support and information about how to contact GAMS.

![Welcome page](image)

**Figure 5.1 Welcome page**

5.13.2.2 Code Editor

The Code Editor provides common functionality for editing with GAMS specific syntax highlighting. On the left side there is a special area displaying the line numbers and icons for links and errors generated by the compiler.
### 5.13.2.2.1 1. Basic Text Manipulation

<table>
<thead>
<tr>
<th>Keys</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl - Shift - L</td>
<td>Duplicate current line</td>
</tr>
<tr>
<td>Alt - Shift - L</td>
<td>Toggle selection to lower case</td>

<tr>
<td>Shift - F12</td>
<td>Stop currently running GAMS job</td>
</tr>
</tbody>
</table>

### 5.13.2.2.4 4. GAMS Shortcuts

<table>
<thead>
<tr>
<th>Keys</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>F1</td>
<td>Open the GAMS Help. If the word under the cursor is a GAMS keyword a search in the documentation document will be started</td>
</tr>
<tr>
<td>F6</td>
<td>Open GAMS Model Library Explorer</td>
</tr>
<tr>
<td>F7</td>
<td>Open Studio Settings</td>
</tr>
<tr>
<td>Ctrl - G</td>
<td>Goto specific line number</td>
</tr>
<tr>
<td>Ctrl - F</td>
<td>Open search and replace widget</td>
</tr>
</tbody>
</table>

### 5.13.2.2.5 5. GAMS Studio Dialogs

<table>
<thead>
<tr>
<th>Keys</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl - F2</td>
<td>Reset Studio to default visual settings (window position and -size, widget position and -visibility) Useful when a widget got lost or studio started on a disconnected monitor.</td>
</tr>
</tbody>
</table>

### 5.13.2.2.6 6. Studio Recovery  The Code Editor looks for parenthesis to the right then to the left of the cursor and marks valid and invalid nesting. Hitting F8 moves the cursor to the matching parenthesis keeping the state inside/outside. To select the block to the matching parenthesis hit Shift - F8.

### 5.13.2.2.7 Syntax Highlighting  The GAMS Studio syntax highlighter recognizes different kinds of source code like

- `$control option` with some special treatments (like $OffText, $OnText, etc.)
- `comments`, e.g. line comments and comment block
- `keywords` like declarations or loops
- `description` as descriptive text for identifiers
- `data statements` for identifiers or table data
- ...

### 5.13.2.2.8 Automatic closing of brackets and quote characters  This feature is meant to improve convenience for users typing source code. In GAMS, as in pretty much every other programming language, opening brackets or quote characters are followed at some point by a closing equivalent. So when a user types one of the following characters the matching closing character will also be inserted after the text cursor. This allows the user to easily type the content in between. When typing the closing
character which should be right after the cursor the already existing character will be jumped over. So when a user types the closing character by force of habit the autoclose feature does not interfere or causes syntax errors. Also possible is to make a text selection and then type a bracket or quote character. The selected text will then be surrounded by the chosen character pair. In the GAMS Studio under **Settings > Editor > ”Auto close opening brackets and quotes”** a switch is available to turn this auto-close feature off.

List of characters that trigger insertion of a closing character:

- (  
- {  
- [  
- "  
- '

Other editors also close the < character but in the GAMS language context it is used in a different way, making it unnecessary to be closed automatically (e.g. as a comparison operator). In some cases user might not like the closing character to be inserted automatically however, this is hard to predict. Other editors - like Qt Creator - check what the next character after the cursor is. Only a limited set of characters allows the automatic insertion of the closing character.

Following characters allow auto closing when being the next char after the text cursor:

- **Whitespaces**  
- ,  
- ;  
- )  
- ]  
- {  
- }

All others will prevent the insertion of characters.

**5.13.2.2.9 File Encoding**  When opening a file Studio tries to assume the valid file-encoding. As it is not possible to safely determine the encoding the **Edit > Encoding** menu assists. A selection of encodings is preselected. This selection can be changed using the **Select encoding** submenu. To reload a file using another codec the **reload with ...** submenu can be used. Finally with the **convert to ...** submenu the current file can be converted to another codec.
5.13.2.3 Listing Viewer

The Listing Viewer is used for displaying a **GAMS output or listing file (\*.lst)** which is generated when running a GAMS (.gms) file. The Listing Viewer consists of two sides. On the left side, the content of the listing file is presented in a tree structure that allows for convenient navigation within the listing file. The right side shows the listing file itself.

By clicking on a specific item in the tree on the left hand side, the listing file will automatically jump to the corresponding location. Changes of the cursor position in the listing file are dynamically reflected in the tree by selecting the item that belongs to the current section of the listing file.

![Listing Viewer showing trnsport.lst generated by running trnsport.gms from the GAMS Model Library](image)

5.13.2.4 GDX Viewer

The GDX Viewer is used to open and inspect **GDX (GAMS Data eXchange)** files. A GDX file contains GAMS symbols such as sets, parameters, variables, and equations in a binary format that serves as input and output to GAMS. The GDX Viewer layout consists of two sides. The left side displays the symbol table of the open GDX file in a table format. Every entry represents a symbol and consist of the following information:

- **Entry**: The index of the symbol
- **Name**: The identifier of the symbol
- **Type**: The type of the symbol (Alias, Equation, Parameter, Set, or Variable)
- **Dim**: The dimension of the symbol
- **Records**: The number of records of the symbol
- **Text**: The explanatory text of the symbol
Figure 5.3 Symbol table showing trnsport.gdx generated by running trnsport.gms from the GAMS Model Library

A specific column can be sorted by clicking on the respective column header. Clicking again toggles the sorting direction. The Symbol Search facility provides dynamic filtering of the list of symbols contained in the GDX file using wildcard syntax. By default, only the Name column is used. By selecting the All Columns check box the search considers all other columns as well. This can be useful if the exact symbol name is not known. The right side of the GDX Viewer displays the actual data of the symbol that is selected in the symbol table. Data can be displayed in either the List View or the Table View which can be toggled using the corresponding button in the lower part of the GDX Viewer.

5.13.2.4.1 List View  The List View is the default representation when looking at data using the GDX Viewer. The data is presented in the form of a table in which each row represents a record of the symbol. Each record consists of key columns corresponding to the symbols dimension. Depending on the symbol type, the value columns can vary as the following listing shows:

- **Set/Alias**: One value for explanatory text. Y if no explanatory text is available.
- **Parameter**: One numerical value.
- **Variable/Equation**: Five numerical values: Level, Marginal, Lower bound, Upper bound, Scale
The header allows to manipulate the displayed data in several ways. By left clicking on a column header, the corresponding column is sorted using a stable sort mechanism that does not change the order of equal entries. Clicking again changes the sorting direction. Due to the Extended Range Arithmetic used by GAMS, columns containing numerical data can contain special values. Those values are treated in a special way when being sorted:

- **-INF**: Smallest numerical value
- **EPS**: Treated as value very close but different from 0
- **+INF**: Largest numerical value
- **NA**: Treated as first non-numerical value (sorted as being greater than +INF)
- **UNDEF**: Sorted as being greater than NA
- **ACRONYMS**: Sorted as being greater than UNDEF. Relative order of acronyms is by their internal number

The order of columns can be changed by dragging a column header and dropping it at a different position. Dragging the border between column headers allows for resizing the width of the involved columns. Key columns offer a mechanism for applying a filter on the displayed labels. The filter for a key column can be opened either by right clicking on the column header or by left clicking on the filter icon. The Reset button in the lower part can be used to reset the view to defaults. This removes all filters and resets the applied sorting. The Squeeze Defaults checkbox can be used on variables and equations only in order to hide all columns that have the default value of the respective variable or equation type. The Value Columns menu allows to hide certain value columns of variables and equations explicitly. This is especially useful when using the Table View.

The filter dialog for a specific column shows all occurring labels of that column in a list. Per default all labels in all columns are visible. Shrinking the displayed data can be achieved by unchecking one or more labels. The filter is applied by clicking the Apply button. Instead of selecting labels manually one can also use the wildcard string filter in the upper part of the filter dialog. The filter is automatically applied to the list of labels. Matching labels will be selected while all others will be deselected. The Hide unselected
items checkbox can be used to automatically hide all deselected labels. This is especially useful for larger amounts of labels in combination with the wildcard string filter as only the matching labels will remain in the list while typing. The Select All and Deselect All buttons allow for selecting/deselecting all labels.

Figure 5.5 Filter dialog on column \( j \) for variable \( x \) in trnsport.gdx

5.13.2.4.2 Table View

Switching to the Table View is possible for symbols that have at least two dimensions. In this representation data is reshaped into a format where the labels of the last dimension are moved into the column header while the remaining dimensions go into the row header. The entries in the table are the numerical values (or explanatory text in case of GAMS sets) of the record with the corresponding labels of the headers. The following image shows the List View of a GAMS Parameter on the left side and its representation in the Table View on the right side:

Figure 5.6 Two dimensional parameter as List View and Table View

In case of GAMS variables and equations a virtual dimension for the five numerical values (Level, Marginal, Lower Bound, Upper Bound, Scale) is introduced and displayed in the column header. When looking at the data of variables or equations it is most of the time useful to visualize only a specific attribute like the variable levels. This can be achieved by using the Value Columns menu in the lower part of the GDX Viewer. The menu allows to hide specific attributes explicitly by disabling the corresponding checkboxes.

Both column and row header dimensions can be moved into different positions in order to reshape the table view. This can be done by performing a drag-and-drop operation that starts by clicking (and holding)
the left mouse button while the mouse cursor is located on the index that should be moved. Moving the mouse to an arbitrary location will bring up an drop indicator (in the form of a thin line) that previews the position in which the index will be dropped as soon as the mouse button is released. In general all index positions can be moved to arbitrary new locations, but there are a few restrictions:

- The (virtual) numerical dimension of variables and equations (Level, Marginal, Lower Bound, Upper Bound, Scale) can not be moved and is always the last dimension in the column header.
- If a header (column or row) runs out of dimensions, a dummy header (Value, Text) is introduced which can not be moved but can be used as a drop target for further drag-and-drop operations.

</tr>
</tbody>
</table>

Figure 5.7 The table view representation of a GAMS parameter during a drag-and-drop operation that will move the dragged dimension into the position indicated by the drop indicator (thin black line)

While filters that have been applied in the List View will also be applied to the Table View, sorting does not have any effect. The labels are sorted using the internal order which can not be changed by the user. For large data it is recommended to reduce the amount of visible records by applying filters in the List View and by disabling certain value columns in case of variables and equations. Once the data has been reduced, switching to the Table View allows to look at the data in a compact format.

5.13.2.4.3 Context Menu Right clicking on a symbols data opens the GDX Viewer context menu which allows to do the following actions:

- **Copy (comma-separated)** (Ctrl+C): Copy the current selection to clipboard using comma as separator
- **Copy (tab-separated)** (Ctrl+Shift+C): Copy the current selection to clipboard using tab as separator. Useful for pasting into spreadsheets
- **Auto Resize Columns** (Ctrl+R): Automatically adjust the width of the first visible 100 columns to their content. The first visible 500 rows are taken into account in order to calculate the width.
- **Copy (Select All)** (Ctrl+A): Select all data
5.13.2.5 Reference File Viewer

The Reference File Viewer is a useful tool to navigate the source code of GAMS models via a reference file, especially when multiple files are involved. A reference file contains all symbol references of GAMS model and is created using the rf parameter when running the model.

![Option to create a symbol reference file when running the model](image)

When the model is compiled, the reference file with ".ref" extension is created and can be opened either using the menu: File > Open or double-clicking the "RefFile" entry in the Output viewer:

![Output Viewer showing clickable entry for the reference file](image)

The Reference Viewer is categorized by a number of tabs:

![Reference File Viewer showing tabs and reference file information](image)

- **All Symbols** shows an alphabetical listing of all symbols used in the model.
• **Set, Acronym, Variable, Parameter, Equation, and Model** shows an alphabetical listing of symbols of the same type. See Data Types and Definitions for more details on GAMS data types.

• **File** shows an alphabetical listing of all file statements used in the model.

• **Function** shows a list of GAMS built-in functions that has been used in the model.

• **Unused** shows an alphabetical listing of all symbols that have been declared in the model but are not used anywhere.

• **File used** shows an alphabetical listing of all files used in the model including the full file path. A double-click on an file entry of the table will jump to the beginning of the reference file.

The number next to the tab name indicates how many symbols in the category, where the number of All Symbols tab sums up the number of symbols in all other tabs except Unused tab and File used tab. A click on a symbol entry of the table in every tab (except File used tab) will show the detailed reference list containing the reference location in the right hand side of the reference viewer. A mouse-over on an entry of the reference list will show the tooltip of file location and position with the file that has been referenced. A double-click on an entry of the reference list will jump to the position in the corresponding file that has been referenced.

The reference list is organized by the following reference types:

<table>
<thead>
<tr>
<th>Reference Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>declared</td>
<td>Declaration of the symbol.</td>
</tr>
<tr>
<td>defined</td>
<td>Defined using a data statement.</td>
</tr>
<tr>
<td>assigned</td>
<td>When the symbol appears on the left side of an assignment statement.</td>
</tr>
<tr>
<td>implicitly assigned</td>
<td>Implicit assignment like a variable in a model.</td>
</tr>
<tr>
<td>control</td>
<td>When the set is used as a control set.</td>
</tr>
<tr>
<td>reference</td>
<td>Referenced in a statement.</td>
</tr>
</tbody>
</table>

The detailed description of the reference types and their shorthand symbols can be found in Reference Types in GAMS Output.

Sort and Search referenced symbols

- **Sort**: A click on a table column header in the reference table will sort the symbol in the table by either Entry, Name, Type, Dim(ension), Domain, or Text.

- **Search**: An input in the Symbol Search box will search the symbol in the reference table by name. A search in all columns can be enabled by checking All Columns next to the Symbol Search box.

5.13.2.6 Tab Browser

The Tab Browser is accessible with a button next to the main tab bar or via the shortcut Ctrl+K. It opens a list of all open files and features a search input field. When opening the tab browser, the search field is already focused. Typing updates the list in real time. The enter key selects the first item in the list and opens it. It is also possible to use arrow up/down to navigate the list and select an item with enter. The filter supports wildcard syntax.
5.13 GAMS Studio

5.13.3 Dock Widgets

5.13.3.1 Project Explorer

The Project Explorer provides a group organization of files opened in Studio. The Project Explorer lists all files and their corresponding group in a flat hierarchical tree structure with Project Explorer as its root. A group entry is listed with the folder icon and its tooltip tells the location of the group in the file system. The runnable GAMS files (currently supported .gms and .inc) are listed with GAMS icon and the GDX files (.gdx) are given own icon to be identified faster. The tooltip of a file entry tells the location of the file in the file system. The file location and the group location can be explored using the default file system explorer via the context menu "Open location".

A group entry is created automatically when opening a file and a groups name is determined by the name of the opening file. When the group is created, Studio automatically adds certain files (.gdx and .lst with the same name as group name) into the group. By default the first runnable GAMS file in a group is considered the main file, marked with a green arrow over its GAMS icon. The tooltip of a group also tells which the current main file is. One group may contain multiple runnable GAMS files but only one runnable GAMS file is set as the main file. The main file can be changed to other runnable GAMS file in a group via the context menu "Set as main file".

The main file will be executed when pressing F9 or clicking the execute button (see how to set GAMS parameters and execute the main file in Toolbar and GAMS Parameter Editor). After executing the main file, the generated listing file (.lst) is added to its group and open the file in the output view. A clickable log line in the output may add the corresponding file into the group and open the file in Central Widgets area. Users can manually add more files to a group by right-clicking and choosing either "Add existing file" or "Add new file" from the context menu.

Files can also be removed from a group and group can be removed from Project Explorer via the two actions "Close group" and "Close file" from the context menu. The action "Close group" closes all files in the group if opened as well as removes all file entries and the group entry from the Project Explorer without actually touching the file on the file system. The action "Close file" closes the file if opened and removes the file entry group from the group. In case the closed file is the only entry in the group, the group is also closed accordingly. In case there are unsaved changes a message popup will appear, asking the user how to proceed.
It is possible to select multiple items in the project explorer. A selection always contains items of one kind, files or groups never both depending on the first selected item. The context menu then addresses all selected items.

Selected files can be dragged to another group. By dropping them they are moved to the destination group. Pressing the **CTRL** key creates a copy of the file-reference in that group (no file copy). If the group already contains a specific file it is just ignored.

Actions like rename, move, or delete from file system are currently not supported but will be added in the future.

5.13.3.2 Toolbar and GAMS Parameter Editor

The toolbar contains two parts: A quick access section and a combobox to enter GAMS Parameters to adjust how GAMS is executed for the current model (see **The GAMS Call and Command Line Parameters**). The quick access section contains buttons for common actions like **New**, **Open**, **Save**, **Redo**, **Undo**, to name some. The GAMS Parameter Editor provides a way to control and customize the execution of a GAMS model. The editor displays the parameters of the group of the file that is currently opened in **Central Widgets** (see also **Project Explorer** for group and its runnable files). The parameters can be typed into a combobox and the execution of a GAMS model can be carried out using the following pre-customized execution commands:

- **Run**: Choose **Run** or press **F9** to compile and execute GAMS statements in the main runnable file. This execution command is equivalent to running GAMS with the default option **action=CE** (Compile and Execution).

- **Run with GDX Creation**: Choose **Run with GDX Creation** or press **F10** to compile and execute GAMS statements in the main runnable file and create a GDX file with the name of the main runnable file and a gdx extension. This execution command is equivalent to running GAMS with the combination of the two options **action=CE** and **gdx=default**.

- **Compile**: Choose **Compile** or press **Shift - F9** to compile GAMS statements in the main runnable file. This execution command is equivalent to running GAMS with the option **action=C** (CompileOnly).

- **Compile with GDX Creation**: Choose **Compile with GDX Creation** or press **Shift - F10** to compile GAMS statements in the main runnable file and create a GDX file with the name of the main runnable file and a gdx extension. This execution command is equivalent to running GAMS with the combination of the two options **action=C** and **gdx=default**.

The pre-customized execution command will operate on the main file (marked with a little green arrow over the regular icon) of the active group (see how to manage the main file in section **Project Explorer**). In case GAMS parameters have been set they will be appended to the pre-customized commands. Just like the GAMS Terminal, when there are identical options with different values the last one "wins" and overwrites the previous ones. Thus it is possible for a user to change and override GAMS Studio default options, which can possibly lead to problems if done incorrectly. In this case Studio prints out a warning
message, informing users about potential problems. To debug what Studio does the full GAMS call parameters will be printed to the system log. After execution, the options will be added into the group history. All files in a group share one parameter history. The previous GAMS parameters can be recalled from the group history via the drop-down menu of the combo box. Switching the file opened in CentralWidgets will activate the different group history only when the group of the newly opened file is different from the group of the file before switch.

The parameters `curdir` and `workdir` behave slightly differently in Studio compared to the terminal. When using one of these options on the command line GAMS expects the gms file to be in the given folder. In Studio the path to the input file is always given as an absolute one. Therefore, there is no need to use the `inputDir` parameter to make the gms file accessible to GAMS if it is not in the specified working directory.

The toolbar provides a way to either interrupt or stop the currently running job when an execution of a GAMS model consumes a period of times:

- **Interrupt**: Click the **Interrupt** button or press **F12** to send an interrupt request to the running job in order to perform a graceful stop and collect an incumbent result back from the execution if the solver supports this feature. The command is enabled when there is a job that is currently running in the group and disabled when there is no currently running job in the group.

- **Stop**: Click the **Stop** button or press **Shift - F12** to send a request to stop the running job immediately. The command is enabled when there is a job that is currently running in the group and disabled when there is no currently running job in the group.

The Extended GAMS Parameter Editor allows to configure the GAMS parameters. The extended parameter editor is shown when the Show button next the parameter combobox is clicked or with the shortcut **Ctrl + Alt + L**. The editor can be hidden when the button is clicked again. When shown, the GAMS parameters from the parameter combobox will appear as a list of option entries in the left pane of the extended parameter editor, each entry contains the **Option Key** and **Option Value**. Note that the GAMS parameter combobox will be disabled when the extended parameter editor is shown and all editing has to be done in the extended parameter editor.

![Extended GAMS Parameter Editor](image)

**Figure 5.12** Extended GAMS Parameter Editor is shown when the button next to parameter combobox is clicked
The right pane of the extended editor displays the list of all valid option definitions, each contains **Option Name**, **Synonym**, **Default Value**, **Option Type**, and **Option Description**. The option definition entry with enumeration type (**EnumStr** or **EnumInt**) can be expanded to show all enumerated values of the option by clicking the bullet in front of the option entry, clicking the bullet again will hide all enumerated values of the option. Above the list of all valid option definitions is a search box (with placeholder text `Search Option...`) to allow a simple search through all option definitions. As a search keyword has been typed into the search box the results will be displayed in the list below. The search will perform on all fields of option definitions including enumerated values.

The extended parameter editor displays potential parameter errors in red color both in the combobox and in the left pane of the editor. When hovering a mouse over the error option key or value, a tooltip with more detailed explanation of the error appears. See **edit option key and value** on how to edit option key and Value that contains an error.

The followings describes all editing actions that can be performed via the extended parameter editor:

- **Edit option key and value**: double click on key cell to edit Option Key and on value cell to edit Option Value of the option entry. A drop-down list will suggest possible option keys and option values when possible. Press **Enter** to confirm the edit and press **Esc** to cancel the edit.
5.13 GAMS Studio

Figure 5.15 Option editor shows a drop-down list of all possible options started with 'o'

Figure 5.16 Option editor shows a drop-down list of all enumerated values of option 'action'

- **Add new option**: there are several ways to add a new option via extended parameter editor.
  - right click on the left pane of the option editor and choose **add new option** from the pop-up context menu
  - right click on the selected option entry of the option table and choose **add new option** from the pop-up context menu
  - click on the add new option button next to **option key** table header in the left pane

A new option entry will be added at the end of option entry table with dummy option key [KEY] and dummy option value [VALUE]. See **edit option key and value** on how to edit option key and Value.

It is also possible to add a new option from the right pane of the option editor by double clicking at the option definition entry in the right pane. The selected option definition entry will be added as a new option entry at the end of option table in the left pane. In case of double clicking an enumerated value entry of an option definition the option definition entry will be added as a new option with the selected enumerated value. Otherwise the default value of the option entry will be added.

Figure 5.17 Option with enumerated value added by double clicking at the selected entry in the right pane
• **Insert new option**: right click on the selected option entry and choose *insert new option*. A new option entry will be inserted before the selected option entry with dummy option key \([\text{KEY}]\) and dummy option value \([\text{VALUE}]\). See *edit option key and value* on how to edit option key and Value.

• **Move selected option up**: right click on the selected option entry and choose *move selected option up*. The selected option entry will be moved one position up the option entry table. This action will change the order of parameters.

• **Move selected option down**: right click on the selected option entry and choose *move selected option down*. The selected option entry will be moved one position down the option entry table. This action will change the order of parameters.

• **Remove selected option**: right click on the selected option entry and choose *remove selected option*. The selected option entry will be deleted from the option entry table.

• **Remove all options**: right click on the left pane of the extended editor and choose *remove all options*. All option entries will be deleted from the option entry table.

![Figure 5.18 A number of actions that can be performed via Extended Parameter Editor](image)

Press **F1** on an option entry in the extended parameter editor will activate the help page *The GAMS Call and Command Line Parameters* containing the detailed description of the option.

### 5.13.3.3 Integrated Help

The Help View is designed to integrate the navigation of the GAMS documentation into GAMS Studio. Press **F1** or choose *Help > Documentation* menu or check *View > Help* menu to start the Help View and browse the documentation. The start page of the Help View is the main document page available in the GAMS distribution that has been used to run GAMS Studio. See *Home* on how to always navigate back to the start page of the document. Click Close button or uncheck *View > Help* menu to dismiss the Help View. GAMS Studio will remember the last viewed page along with its browsing history until GAMS Studio is restarted.

The Help View starts in docking state for the first time and can be docked around the editor in the central widgets area by either dragging the view to the desired location. Studio will remember last state of the Help View before it was closed.
The Help View can also be floated by double clicking the title part of the Help View. Dragging or double clicking the title of the Help View again will dock the Help View.

Note that the Help View does not offer the full browsing features of a web browser. Though the help view offers a Open this page in Default Web Browser button to use the full features of a web browser.

An overview of Help features:
- **Home**: Start the start help page [GAMSDir]/docs/index.html

- **Back**: Back to previous page

- **Forward**: Go to next page

- **Reload**: Reload the content of this page

- **Stop**: Stop loading the content of this page

- **Bookmarks**:
  
  - **Bookmark this page**: Store the title of the page as the name of bookmark together with its location. The entry of the bookmark will appear below the Organize Bookmarks section. Click on an entry to jump to the page that has been bookmarked.

  ![Bookmark Dialog](image)

  - **Organize Bookmarks**: Open the bookmark dialog to edit or delete a bookmark entry. Right click on the selected entry in the bookmark table, then either load the selected bookmark in the Help View, or delete the selected bookmark. The selected bookmark Name and Location can be edited from the lower part of the bookmark dialog and press Enter. Press Esc to cancel the edit. Click close button to dismiss the bookmark dialog.
• **Zoom In**: Zoom in the page to increase the font size. Press Ctrl +, or Ctrl - Mousewheel Up or choose View > Zoom In menu to zoom in the page.

• **Zoom Out**: Zoom out the page to reduce the font size. Press Ctrl -, or Ctrl - Mousewheel Down or choose View > Zoom Out menu to zoom out the page.

• **Reset Zoom**: Reset the font size of the page to its original size. Press Ctrl 0 or choose View > Reset Zoom menu to reset zoom in the page.

• **Help Option**:
  - **View this page from** [https://www.gams.com/27/docs](https://www.gams.com/27/docs): Browse the same documentation on GAMS website. This, for example, allows to use more sophisticated search functionalities across all GAMS documentation of version 27.3 or to browse different version of documentation, or to browse the GAMS website from the Help View.
  
  - **Open in Default Web Browser**: Browse the same document in default web browser. As the help view does not offer the full features of a web browser, this allows to browse the documentation using the full web browser features in default web browser.
  
  - **Copy page URL to Clipboard**: Copy of the current page's URL to the clipboard. This, for example, help to see the URL of the currently viewed page of the document.
Find in page... : Press Ctrl - F or choose Edit > Search menu to activate a search at the bottom area of the Help View. Type in a word to be found in the page. The word found in the page will be highlighted as it has been typed in and the number of found occurrences will be highlighted in the scrollbar of the Help View. Click previous button to find the previous occurrence, and click next button or press Enter to find the next occurrence. Check Case Sensitivity box to find a word case sensitively. Highlighting the word stays as the document is navigated from page to page until the keyword is clear or the search is dismissed or the Help View is closed or invisible. Click the close button or press Esc to dismiss the search.

GAMS Documentation Center

The GAMS Documentation Center provides you with the technical information on getting started, using and maintaining our GAMS (General Algebraic Modeling System) products.

- Release Notes - 23.1.0 Data release (July 21, 2019)
- User’s Guide
- Installation and Licensing -Guides on installing GAMS for various platforms and using a GAMS license
- Tutorials and Examples - Step-by-step guides including a number of examples
- GAMS Language and Environment - Guide through components of GAMS language and the environment for executing a GAMS model
- Solver Manuals - Manuals of solvers available in the distribution
- Tools Manuals - Manuals of tools available in the distribution
- Application Programming Interfaces - Manuals of Application Programming Interfaces
- Glossary - An alphabetical list of GAMS terms
- Bibliography

The GAMS Documentation is also also available as PDF. However, note that the documentation is meant for consumption via an HTML viewer and only very limited effort has been spent to convert it to PDF, versions. Further, the PDF versions do not include detailed documentation on the APIs or the GAMS IDE.

Model Libraries

From the early stages of the development of GAMS we have collected models to be used in libraries of examples. Many of these are standard textbook examples and can be used in class or as problem formulations or to illustrate points about GAMS. Others are models that have been used in policy or sector analysis and are interesting for both the mathematics and the data they use. These model libraries are included with all GAMS systems and are also available online.

The following model libraries are available:

- Model Library - includes GAMS models representing interesting and sometimes classic problems, sourced from production and shipment by firms, investment planning, crop planting patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomic simulation model, applied general equilibrium, international trade in aluminum and copper, water distribution networks, and many more.
- Test Library - includes GAMS models developed for testing and quality control, both for the GAMS base modules and the many solvers distributed with the GAMS.

It is also possible to jump directly from Code Editor to the document page that describes Dollar Control Options or to the index page that lists entries related to Data Types and Definitions and Language Items in Code Editor, as well as from the parameter editor to the GAMS parameter described in The GAMS Call and Command Line Parameters:
• Press F1 on a **Dollar Control Option** within the editor will activate the page **Dollar Control Options** in the Help View and jump to the corresponding dollar control option described in **Dollar Control Options** chapter.

• Press F1 on a keyword in **Data Types and Definitions** or in **Language Items** within the editor to activate the **Index** Page in the Help View that lists the index entries related to the keyword.

• Press F1 on an option entry within the extended parameter editor to activate the help page displaying the detailed description of the option in **The GAMS Call and Command Line Parameters**.
Figure 5.21 Help View when press F1 on option entry 'output' in extended parameter editor

Figure 5.22 Help View when press F1 on option table entry 'Save' in extended parameter editor
5.13.4 Dialogs

5.13.4.1 Search and Replace

Pressing the **Ctrl - F** opens the Search and Replace window. Users can search specific files with it and do text replacement operations in the current file. Depending of which is the main file open in the editor, the search widget changes to visualize which actions are available. Due to technical limitations, .gdx files cannot be searched, also replacing in read-only file types (e.g. lst or ref) is deactivated. For reasons of performance the search stops when reaching 50000 search results. This is visualized in all places where the number of matches is shown by showing ”50000+” as the results number, indicating that there might be more results.

![Figure 5.23 Search window in its default configuration](image)

In the first row of the search widget from left to right the following items are located: Search field, which takes the search term and saves a list of recent searches. Next to it there is a "Find All" button which starts a search in a user defined scope. In the output pane of studio a table containing all matches will open. Items can be double clicked to perform a jump to the result. Information about the file, the location of the match, plus some context information are also shown. Right of "Find All" there are the find previous occurrence and find next occurrence buttons located, labeled "<" and ">" respectively. These will find and highlight the next word matching the search criteria either before or after the current text cursor position.

The next row houses items related to the replace functionality. Most of these are deactivated for files that are opened in read-only mode (e.g. .lst). First comes the replace input field where users can input the text which replaces the search term. "Replace All" replaces all matches in the currently selected scope at once but not before a pop-up is shown asking the user whether the replacement of n occurrences of X with Y is intended. In this pop-up the user can also decide to start a search instead, opening the results page showing all occurrences of the would-be replace action. The next button is "Replace" and works similarly to Find Next. On the very first click it selects the next match, without replacing anything. On the next click it replaces the current selection with the replacement term and jumps to the next match, selecting it. Users can use this to click through a file, replacing words while keeping an overview over what is actually changed. If the search options are set accordingly, the editor jumps to the next file eligible for replace actions. Both replacement actions can be undone by pressing either the undo button or hotkey **Ctrl - Z**. The button "Clear" on the far right clears all highlighted results and both text fields. A shortcut to clear all results is to press the **Esc** key in the **Code Editor**.

The last row contains options to narrow down a search. "Whole Words" excludes partial hits from matches. For example, when searching for "in" with the option checked only the word "in" is found but no occurrences in "information". "Case Sensitivity" sets if the case of letters in the search term matters. Reminder: The GAMS language is case insensitive, so this option can actually lead to incomplete results, depending on for what it is used. "Use Regex" activates an advanced search term interpretation mode and stands for *Regular Expressions*. When activated, instead of a single search term users can specify a pattern that matches an array of different words. [Click here](#) for further information about regular expressions.

The "File Pattern" drop-down menu can be used to filter the files to be searched. Using a wildcard syntax patterns of filenames can be specified. The drop-down menu comes with a few default options for GAMS
specific file types but can also be used to enter own patterns. Right next to it is another, non-editable drop down menu which works like a simpler filter. The scope of the search can be set here with four options available:

- "This File" limits the search to the currently active file and is the default. File patterns are ignored for this option.
- "This Group" searches all files that belong to the same group as the currently opened file. A group of files are all children of the same node in the Project Explorer.
- "Open Tabs" searches all files currently opened in the Studio editor (except gdx files).
- "All Files" searches all files that appear in the Project Explorer.

Tooltips are available for most items in the search window and contain further information like keyboard shortcuts.

5.13.4.1.1 Workflow Tips

- Edit a file, hit Ctrl - F to open the search widget. The search field is focused automatically so you can start typing your search term. Pressing the Enter-key is a shortcut for Find Next. Press Enter again or F3 to step through all matches. Press Shift - F3 to step backwards. Make changes to your document, press Ctrl - F again to re-focus the search widget without having to pick up the mouse.
- Enter a search term, press the Tab-key to move the focus to the next interface item which is "Find All". Press the Space-key to press the button and do a full search in the currently set scope. Pressing Enter here would still act as "Find Next" but this might depend on your operating system.
- The Esc-key will close the search widget. Pressing Esc again will clear all highlighted search results.
- Use groups or file prefixes when working with projects with many files. Use search filters to only search relevant files.

5.13.4.2 Model Library Explorer

The Model Library Explorer is used to search the different model libraries provided by GAMS and to retrieve their models in a convenient way. It can be opened either by choosing GAMS > Model Library Explorer from the menu or by hitting F6. Every library is presented in a separate tab.

The search facility in the upper part of the Model Library Explorer allows for dynamically searching all model libraries simultaneously using a wildcard syntax. As the search string is entered the results are applied directly to the tabs representing the different libraries. The parenthesis enclosed numbers indicate the number of models found for this specific library and the current search input. For a more sophisticated search syntax select the Regular Expression checkbox next to the search input.
Figure 5.24 Searching for trns in the Model Library Explorer

Beside a short description, several models have a longer and more detailed description available. Selecting a model and clicking on the Description button in the lower right corner opens a pop-up dialog showing further information about the model. A model can be opened either by clicking on the Load button, by double clicking or by selecting the model and pressing the Enter key.

5.13.4.2.1 User Libraries Additionally to the model libraries distributed by GAMS, it is possible to access user defined model libraries by providing a GLB file along with the corresponding files belonging to the models in the library. The Model Library Explorer looks into a specific location for user defined model libraries. This location can be accessed by opening the Settings dialog (File > Settings) and switching to the Misc. tab. The Open Location button will show the location where the Model Library Explorer tries to find user defined model libraries. Adding a new library is done by copying the required files into a subdirectory in this location. See Creating a User Library on how to create a custom model library. Newly added libraries require a restart of the Model Library Explorer to become visible.

5.13.4.3 Settings

The GAMS Studio settings dialog can be accessed via the File > Settings menu entry or with the hotkey F7. Users can change certain aspects of Studio like behavior or appearance. Settings are categorized loosely on three tab pages. On the first tab called "General" users can set the Default GAMS Studio workspace. This path is used as a default location for libraries imported from the Model Library Explorer. Automatically save modified files before GAMS run is an option that saves all modified files in the current group when the user starts a GAMS run. Thereby previously unsaved changes will be incorporated into that GAMS execution without the need for the user to go through all files and make sure that changes were saved manually. Jump to first compilation error is an automatism that aims to make working with Studio a little easier. When compilation errors occur, the editor and the log both jump to the first error detected if this option is activated.
The next tab labeled "Editor" contains many self explanatory appearance options. Most notably font settings which are shared between editor and log. Enable auto-indentation activates smart line break behavior. When pressing the Return-key a line break is inserted and the indentation of the line of origin is copied instead of moving the line to first column. Highlight current word under cursor without selection changes the highlighting behavior of word occurrences. While the default behavior highlights other occurrences of the same word when double clicking or selecting a word, activating this option changes the behavior so that everytime there is a word under the text cursor, it and it's other occurrences will be highlighted. Only full words and no partial matches are highlighted.

GAMS Studio always replaces inserted tabs with spaces. Tab stop size lets the user decide how many tabs will be inserted when pressing the Tab-key. Clear process log before GAMS execution empties the log before running a gms file. If deactivated old log output is kept but colored in a lighter gray so users are still able to identify that they are looking at an old run instead of the most current one. One can also decide if the log should be written to disk as well and if so, how many old versions of the same log should be kept on disk as backup. Note, that in addition to this log file written by Studio, one can instruct GAMS itself to write a log file using the GAMS parameter logOption, which could cause a file naming clash.

On the "Misc" tab a shortcut button is located that opens the user library folder. This folder can be used to store user generated model libraries, see User Libraries. There is also an option to set the maximum list size of last files used on the welcome page.

5.13.5 Command Line Options

GAMS Studio can be started with additional command line options that change the behavior or trigger certain functionality at start up time. The syntax for starting GAMS Studio from the command line is

```
studio [options] [files]
```

While files is one or more files to be opened by GAMS Studio, the following options can be supplied:

- `-?`, `-h`, `--help`: Displays the help.
- `-v`, `--version`: Displays version information.
- `--ignore-settings`: Ignore settings files. Studio will load with default settings without writing them.
- `--reset-settings`: Reset all settings to default. Studio will load with default settings and save them.
- `--reset-view`: Reset studio visually without resetting settings. Useful when a widget got lost or studio started on a disconnected monitor.

5.13.6 System Requirements

Compared to most of the GAMS system, GAMS Studio has some additional system requirements, which depend on the platform used. Also, additional information about technical requirements are listed at the GAMS Studio GitHub Wiki.
### 5.13.6.1 Linux

The Linux version of GAMS Studio is distributed as [AppImage](https://appimage.github.io/) and requires glibc 2.14 as well as [FUSE](https://fuse.sourceforge.net/) to be installed.

The GAMS Studio AppImage was tested and it was verified that it worked for the following Linux distributions (which are all under maintenance):

- Arch (current version)
- Debian 9
- Fedora 29
- openSUSE Leap 15 (Gnome + Wayland)
- openSUSE Leap 15 (KDE)
- openSUSE Tumbleweed
- Ubuntu 16.04 LTS
- Ubuntu 18.04 LTS

Other flavors might work as well, but were not tested. If you experience problems with a particular Linux distribution, please let us know.

### 5.13.6.2 Windows

The Windows version of GAMS Studio supports Windows 7 and above.

There are dependencies on certain Visual C++ libraries. These are present on most Windows systems but are missing on some. If you get a complaint about missing libraries on startup of GAMS Studio, please run the appropriate installer for these libraries, which can be found in the GAMS installation folder:

- 32-bit GAMS version: run `vcredist_x86.exe`, found in `[GAMS system]\apifiles\C++\lib\vs2013`, followed by `vcredist_x86.exe`, found in `[GAMS system]\apifiles\C++\lib\vs2015`
- 64-bit GAMS version: run `vcredist_x64.exe`, found in `[GAMS system]\apifiles\C++\lib\vs2017`

### 5.13.7 Comparing GAMS Studio and GAMSIDE

As mentioned above, the classic [GAMS IDE](https://www.gams.com/ide) has been shipped with the GAMS system for many years and is still the workhorse for many GAMS programmers. So it is still around and an alternative to GAMS Studio, especially since it has features, which are not available in GAMS Studio (yet), but it also lacks some features which are available in GAMS Studio. The following table gives a compact overview about most of the differences.

<table>
<thead>
<tr>
<th>GAMSIDE only</th>
<th>GAMS Studio only</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Supported Platforms</strong></td>
<td><strong>GDX Viewer</strong></td>
</tr>
<tr>
<td>- Windows</td>
<td>- Creating charts</td>
</tr>
<tr>
<td>- Linux</td>
<td>- Filtering</td>
</tr>
<tr>
<td>- Mac OS</td>
<td></td>
</tr>
<tr>
<td><strong>GAMSIDE only</strong></td>
<td><strong>GAMS Studio only</strong></td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>- Writing to Html/Excel</td>
<td>- Sorting by numerical value</td>
</tr>
<tr>
<td>- Heat-map functionality (aka Data Colors)</td>
<td></td>
</tr>
</tbody>
</table>

**Editor**

- Spell checker
- Open same file in different buffers
- Customize syntax coloring
- Recognize URLs and open them in the browser
- Different set of keyboard shortcuts

**Execution**

- Use different GAMS versions
- Use alternative license
- Set default options
- Execute program based on extension
- Solver selection menus
- Solver Option Editor

**Other**

- GDXXDiff
- Text Diff
- Delete 225a directories
- Script recording
- "MS DOS" button
- Find in Files (in given folders; independent of open files in the IDE)
- Email file
- Print
- Save test files in UNIX format
- Link to McCarl chm
- Minor options to customize (e.g. eolcom, margins, date format, ...)
- Update license file

---

**5.14 GDX2ACCESS**

**5.14.1 Overview**

**GDX2ACCESS** is a tool to dump the contents of a GDX file to an MS Access file (MDB or ACCDB format). Every identifier gets its own table in the database.
5.14.2 Usage

```plaintext
gdx2access inputFile {options}
```

The .gdx file extension of the inputFile can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

5.14.3 Options

Options are specified in an INI file and not directly on the command line. By default, the file gdx2access.ini located in the same directory as gdx2access.exe is consulted. If this file is not available, the program will continue using default settings (listed in the tables below).

It is also possible to tell the program to use a different INI file. This is done by using an extra argument of the form @iniFile. If you want to dump the contents of myFile.gdx to an MS Access file according to the options specified in a file called myIniFile.ini, run the following code:

```plaintext
gdx2access myFile.gdx @myIniFile.ini
```

In this case, the program will not read gdx2access.ini located in the same directory as gdx2access.exe, but rather myIniFile.ini in the current directory.

The INI file can contain two sections: [settings] and [debug]. A complete INI file with all possible settings looks like:

```plaintext
[settings]
scrdir=c:\tmp
inf=1.0e100
mininf=-1.0e100
eps=0.0
na=0.0
undf=0.0
scalarTable=1
etFlag=1
dbVersion=9
[debug]
method=5
thresholdCount=5
keepFiles=1
```

Note that the values above are not the default values for some options!

Section [settings]

Below some short descriptions for the options in the [settings] section:
### Option | Default | Description
--- | --- | ---
scrdir | `<windowstemp>` | Directory for temporary scratch files.
inf | `1.0e100` | The value used for GAMS special value +INF. See also the example Special value mapping.

- mininf | `-1.0e100` | The value used for GAMS special value -INF. See also the example Special value mapping.
eps | `0.0` | The value used for GAMS special value EPS. See also the example Special value mapping.
na | `0.0` | The value used for GAMS special value NA. See also the example Special value mapping.
undf | `0.0` | The value used for GAMS special value UNDEF. See also the example Special value mapping.
scalarTable | `0` | Possible values: 0 or 1. When set to 1, scalars of the same type are combined in a single table. The names for these tables are fixed: `ScalarParameter`, `ScalarEquation` and `ScalarVariable`. See also the example Special value mapping.
etFlag | `0` | Possible values: 0 or 1. When set to 1, include the text strings for sets containing element texts. See also the example Writing Explanatory Text to Database.
dbVersion | `0` | Specify the format of the output database. See also the example Writing Explanatory Text to Database.

- `- 0: Create database using current default format.`
- `- 9: Create a database in the Microsoft Access 2000 (.mdb) file format.
- `- 10: Create a database in the Microsoft Access 2002-2003 (.mdb) file format.
- `- 12: Create a database in the Microsoft Office Access 2007 (.accdb) file format.

### Section [debug]

Below some short descriptions for the options in the [debug] section:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
</table>
| method | `5` | Select an algorithm to insert data into the Access database.
| thresholdCount | `5` | When to change between algorithms while using method=4 or method=5. The default is 5 records.
| keepFiles | `0` | Possible values: 0 or 1. When set to 1, the program will not delete intermediate scratch files. |
5.14 GDX2ACCESS

5.14.4 Examples

5.14.4.1 Intro

Suppose we want to write the data of the [transport] model from the GAMS model library after solving to an MS Access data file. First of all, we solve the model by running the following command. Note that we will save the complete symbol table to a GDX file called transpor.gdx by adding the command line option gdx=transpor.

gams transpor gdx=transpor lo=2

The option lo=2 causes GAMS to save the log to an external file (in this case transpor.log), instead of writing it to the screen. In order to get an idea about the data at this point, we use the GDXDUMP tool to display the contents of the GDX file by running the following command:

gdxdump transpor.gdx symbols

By adding the GDXDUMP option symbols, we will only display the table of contents (shown below) rather than all data stored in transpor.gdx.

* GDX dump of transpor.gdx
* Library in use : C:\GAMS23.3
* Library version: GDX Library Nov 1, 2009 23.3.3 WIN 14596.15043 VIS x86/MS Windows
* File version : GDX Library Nov 1, 2009 23.3.3 WIN 14596.15043 VIS x86/MS Windows
* Producer : GAMS Base Module Nov 1, 2009 23.3.3 WIN 14929.15043 VIS x86/MS Windows
* File format : 7
* Compression : 0
* Symbols : 12
* Unique Elements: 5

</tbody>
</table>

Once we have a GDX file, we can use GDX2ACCESS to create a MDB or an ACCDB file. Versions of Microsoft Office prior to version 2007 use the file extension .mdb, while version 2007 and later versions use the file extension .accdb. We write all the data stored in the GDX file transpor.gdx to transpor.mdb resp. transpor.accdb by running the following code:

gdx2access transpor.gdx
Note that we do not referenced an INI file in the previous command in order to specify the options, i.e., GDX2ACCESS will consult the file gdx2access.ini located in the same directory as gdx2access.exe or, if the file does not exist, the tool will continue using the default settings (see Options). The information written to the log is shown below, including the identifiers of the symbols which are written to trnsport.accdb and the elapsed time per symbol and in total.

**GDX Access**

ALFA 23Mar10 23.4.0 WIN 16693.16738 VS8 x86/MS Windows

Creating C:\GAMS support\settext\temp1.accdb with Access: 0.48 seconds

Using temp directory C:\Users\Paul\AppData\Local\Temp\n
i. Insert: 0.00 seconds
j. Insert: 0.00 seconds
a. Insert: 0.00 seconds
b. Insert: 0.00 seconds
d. Dump: 0.00 seconds Load: 0.05 seconds
f. Insert: 0.00 seconds
c. Dump: 0.00 seconds Load: 0.05 seconds
x. Dump: 0.00 seconds Load: 0.03 seconds
z. Insert: 0.00 seconds
cost. Insert: 0.00 seconds
supply. Insert: 0.02 seconds
demand. Insert: 0.02 seconds

Renaming C:\GAMS support\settext\temp1.accdb -> trnsport.accdb

Total elapsed time: 0.92 seconds

The resulting ACCBD, opened with MS Access, is shown in Figure 1 (limited to the parameter c on the left and the variable x on the right).

As can be seen, every identifier is stored in its own table. For parameters like c, the value is stored in a column named value, while variables like x and equations have the columns level, marginal, lowerbound and upperbound. A possible additional field (scale for NLP’s, priority for MIP’s, stage for stochastic problems) is not exported. If needed, you can assign such a quantity to a parameter in GAMS before writing the GDX file. The complete process shown here can be automated as demonstrated in Example 1.

If no domain information is available for a symbol (like B in the code below), each index position gets a column and will be labeled automatically with dim1, dim2, etc. If domain information is available, the columns will use that information but keeping the names unique (like A in the code below). The small example below shows how the index positions are made unique using the (relaxed) domain information by adding an ascending number to the identifier.

```gams
Set i / i1*i5 /;
Alias (i,j,k);

Parameter A(i,i,i) 'domain informations, but the column name would not be unique';
A(i,j,k) = uniform(0,1);

Parameter B 'no domain information' / i1.i1 1, i1.i2 2, i2.i1 3, i2.i2 4 /;
execute_unload 'AB.gdx', A, B;
execute '=gdx2access AB.gdx';
```

The resulting database file, opened with MS Access, is shown in Figure 2 (parameter A on the left, parameter B on the right).
5.14 GDX2ACCESS

5.14.4.2 Example 1 - Dumping the Contents of trnsport.gdx

This example will solve the [trnsport] model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Access and MS Access is launched to inspect the results. This is a small example that should run very quickly.

execute '=gamslib trnsport';
execute '=gams trnsport lo=3 gdx=trnsport';
execute '=gdx2access trnsport.gdx';
execute '=ShellExecute trnsport.mdb';

Note: the equal signs in front of the external programs indicate we don’t go through a shell (e.g. command.com or cmd.exe). This will improve reliability in case the external program is not found. In such a case a proper error will be triggered. Without the ‘=’, such errors go undetected and the GAMS model will continue.

The command ShellExecute will launch Access to view the MDB file. This assumes that the version of Access installed is a version prior to version 2007. Later versions will generate a database with the extension .accdb and the ShellExecute command needs to be changed as follows:

* view generated file create
execute '=ShellExecute trnsport.accdb';

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample1] for reference.

5.14.4.3 Example 2 - Writing Explanatory Text to Database

In this example, we write a few sets to a GDX file; two of the sets written have explanatory text for set elements. We use the option etFlag to get this text saved in the Access database file along with the corresponding set elements. Without using the option, only the set tuples are saved in the database.

Running this example on a machine with Access 2007 or a later version installed will create a database with the .accdb file extension that cannot be read by an older version of Access. We use the dbVersion option to save the database in the MDB format. Both options must be specified in an user defined INI file within the settings section, see howToWrite.ini in the code below.

Set
  i   / i1 'one', i2 'two', i3 'three', i4 'four' /
  j   / j1*j4 /
  ij(i,j) / i1.j1 'red', i2.(j2,j3) 'green', i3.(j1,j2) 'blue' /;

$gdxOut example2.gdx
$unload i j ij
$gdxOut

$onEcho > howToWrite.ini
[settings]
etFlag=1
dbVersion=10
$offEcho

$call =gdx2access example2.gdx @howToWrite.ini%
When we open the database and inspect the table created from the set $ij$, we see the explanatory texts stored along with the corresponding set elements. The column containing the explanatory text will be labeled with `SetText` automatically. The column headers can be renamed as demonstrated in Example 5 - Renaming Fields.

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample2] for reference.

### 5.14.4.4 Example 3 - Dumping a large Table to Database

This is an artificial example where we generate a large identifier in GAMS: a parameter with a million elements. This parameter will be dumped to an MS Access Database afterwards. Note that the `GDX2ACCESS` execution will last several seconds. The resulting database file has approximately 36MB of size.

```plaintext
Set i / i1*i1000 /;
Alias (i,j);
Parameter p(i,j);
p(i,j) = uniform(-100,100);
execute_unload 'example3.gdx', p;
execute '=gdx2access example3.gdx';
```

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample3] for reference.

### 5.14.4.5 Example 4 - Special Value Mapping

To store special values like $+INF$, $-INF$, EPS, NA and UNDF in a numeric field in the database, `GDX2ACCESS` uses a mapping. This mapping can be changed by using an INI file (for the default values, see Options resp. the comments in the second code below). We will define a scalar for each special value in GAMS in order to demonstrate the `scalarTable` option in addition. By default, every scalar will be written to a new table. By activating the `scalarTable` option in the INI file, all scalars will be stored together in a single table.

```plaintext
$onEcho > howToWrite.ini
[settings]
inf=1
mininf=2
eps=3
na=4
undf=5
scalarTable=1
$offEcho
```

The usage of our previously customized INI file howToWrite.ini is indicated by the argument `@howToWrite.ini` within the `execute` statement.
## 5.14 GDX2ACCESS

$onUndf
Scalar
  pInf       / inf /
  mInf       / -inf /
  epsilon    / eps /
  notAvail   / na /
  undefined  / undf /
*/
save scalars in scalars.mdb in a single table named ScalarParameter using
* the scalarTable option
* special values are translated to default values:
* INF -> 1.0e100
* -INF -> -1.0e100
* EPS,NA,UNDF -> 0
execute_unload 'scalars.gdx', pInf, mInf, epsilon, notAvail, undefined;
execute 'gdx2access scalars.gdx @howToWrite.ini';

Note the $onUndf command in order to enter Undf values directly within the definition of the scalars. When we view the generated GDX file in the GAMS IDE or GAMS Studio, the special values are shown (note that the figure shows a parameter actually instead of five single scalars for a more compact presentation):

Viewing the resulting table in Access shows how the mapping for special values was applied (i.e. the GAMS special values have been substituted by our customized values defined in the INI file):

Note that the table will be named ScalarParameter automatically.

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample4] for reference.

### 5.14.4.6 Example 5 - Renaming Fields

GDX2ACCESS will use names like i, j, dim1, dim2, value etc. for the column headers in the resulting database file. In some cases, this may not be convenient, e.g. when more descriptive field names are required. In the following model, we will show how a small script in VBscript [1] can handle this task. The script will rename the columns i, j, and Value in table c to ifrom, jto, and transportcost. At first, the data is defined and dumped to an MicroSoft Access database. The VBscript named access.vbs is written at compile time and later executed at execution time in order to rename the column headers.

Set
  i 'canning plants' / seattle, san-diego /
  j 'markets'        / new-york, chicago, topeka /
Parameter
  a(i) 'capacity of plant i in cases'
     / seattle 350
     san-diego 600 /
  b(j) 'demand at market j in cases'
     / new-york 325
     chicago 300
topeka 275 /;

Table d(i,j) 'distance in thousands of miles'
   new-york  chicago  topeka
seattle      2.5     1.7     1.8
san-diego    2.5     1.8     1.4;

Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;

* export to gdx file.
execute_unload 'c.gdx', c;

* move to access database
* column names are i and j
execute '=gdx2access c.gdx';

* rename columns
execute '=cscript access.vbs';

* view results
execute '=shellexecute c.accdb';

$onEcho > access.vbs
'this is a VBscript script'
WScript.Echo "Running script: access.vbs"
set oa = CreateObject("Access.Application")
set oDAO = oa.DBEngine
Wscript.Echo "DAO Version: " & oDAO.version
Set oDB = oDAO.openDatabase("%system.fp%c.accdb")
Wscript.Echo "Opened : " & oDB.name
Set oTable = oDB.TableDefs.Item("c")
Wscript.Echo "Table : " & oTable.name
' rename fields
oTable.Fields.Item("i").name = "ifrom"
oTable.Fields.Item("j").name = "jto"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"
oDB.Close
Wscript.Echo "Done"
$offEcho

The resulting ACCBD, opened with MS Access, is shown in Figure 6 (parameter c before executing the VBScript on the left, parameter c after renaming the column headers on the right).

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample5] for reference.

5.14.5 References

   2018
5.15 GDX2HAR and HAR2GDX

GDX2HAR and HAR2GDX are translation Tools for GDX and HAR Files.

Mark Horridge, Centre of Policy Studies and the Impact Project, Monash University
Thomas F. Rutherford, Department of Economics, University of Colorado

The purpose of this document is to provide an overview of GDX2HAR and HAR2GDX translation tools. The GDX2HAR and HAR2GDX programs efficiently translate between HAR and GDX file formats, and their operation is straightforward. The examples covered in this document have been designed to illustrate potential difficulties which may arise and how these issues can be addressed.

5.15.1 Syntax

5.15.1.1 Syntax for GDX2HAR

gdx2har GDX_file_prefix [.gdx] [HAR_file_prefix [.har]] [/s]

Comments:

• gdx2har.exe is a Windows console application which runs on 32-bit versions of MSWindows (Win95 or later).

• The program requires gdxiomh.dll to be located in the same folder as gdx2har.exe.

• When only a single file is specified, the output file is GDX_file_prefix.HAR.

• Any (and all) single dimensional sets and all parameters in the GDX file are written to the HAR file. Variables, equations and multi-dimensional sets (tuples) in the GDX file are ignored.

• Sets in the GDX file are written as sets in the HAR file. Parameters from the GDX file are written as coefficients in the HAR file.

• The /s switch invokes strict enforcement of translation syntax. When this switch is specified, warning messages result in program termination without generation of any output.

• Warning messages are generated when incompatible features are encountered in the translation process, including names or set labels with more than 12 characters or other non-conforming syntax. (Set labels in GEMPACK may not begin with a numeric symbol).

Making sense of gdx2har requires some understanding of the underlying file formats. GAMS stores values for parameter matrices in GDX files using a sparse matrix format, so that a table like

<table>
<thead>
<tr>
<th></th>
<th>USA</th>
<th>France</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agriculture</td>
<td>411</td>
<td>87</td>
</tr>
<tr>
<td>Services</td>
<td>2831</td>
<td>365</td>
</tr>
<tr>
<td>SweetCorn</td>
<td>11</td>
<td>0</td>
</tr>
<tr>
<td>Truffles</td>
<td>0</td>
<td>68</td>
</tr>
<tr>
<td>Durian</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
is stored in a GDX file in a binary format corresponding to the following list:

"Agriculture" "USA" 411
"Agriculture" "France" 87
"Services" "USA" 2831
"Services" "France" 365
"SweetCorn" "USA" 11
"Truffles" "France" 68

The key point is that zero elements are not stored in the GDX format, and nor is explicit information about the domain of parameters as declared in the GAMS program which produced the GDX file. To work around this problem, GDX2HAR uses two strategies to infer the domain of a parameter:

1. **GDX2HAR** scans the descriptive text of parameters in the GDX file to see if an *explicit* header and domain have been provided. This information is identified by its enclosure in double square brackets, e.g.

   ```
   PARAMETER OUTPUT(i,r) Base year production [[Y:I*R]]
   ```

   The HAR information enclosed in double square brackets consists of the header key ("Y" in this example) and the domain defined with dimension sets separated by 's. The maximum length of a header key is 4 characters.

2. In the absence of explicit declaration in the descriptive text, **GDX2HAR** examines the labels of nonzero array elements which are stored in a GDX file to see if they correspond to a declared set. If the row or column set does not correspond to a set stored in the GDX file, a new set is created to define the coefficient domain in the HAR file. In the above example, if the GDX file contained sets defined as

   ```
   GOODS = [Agriculture,Services,SweetCorn,Truffles,Durian]
   ```

   and

   ```
   REGIONS = [USA,France]
   ```

   The **GDX2HAR** program would then correctly infer that the column set is REGIONS, but it would **not** conclude that the row set is GOODS. It would instead declare a new set

   ```
   SET1 = [Agriculture,Services,SweetCorn,Truffles]
   ```

   with which to dimension the data table in the HAR file. As illustrated in this example, the translation process can be problematic which parameters in the GDX file are not explicitly declared.

### 5.15.1.2 Syntax for HAR2GDX

```
har2gdx HAR_file_prefix [.har] [GDX_file_prefix [.gdx]] [/s]
```

**Comments:**

- **har2gdx.exe** is a Windows console application which run on 32-bit versions of MSWindows (Win95 or later).
- The program requires gdxiomh.dll to be located in the same folder as **gdx2har.exe**.
- When only a single file is specified, the output file is **HAR_file_prefix.GDX**.
- All sets and coefficients in the HAR file are written to the GDX file as sets and parameters, respectively.
- The `/s` switch invokes strict enforcement of translation syntax. When this switch is specified, warning messages result in program termination without generation of any output.
5.15 GDX2HAR and HAR2GDX

5.15.2 GDX2HAR Examples

5.15.2.1 Example 1: Default operation

This example shows how a GDX file can be written by a GAMS program and the results then transferred into a HAR file. In the small GAMS example two sets and three parameters are defined. The program output is then written to the GDX file. Set and parameter names are shorter than 12 characters and conform to GEMPACK syntax rules, so the translator retains all same names in the HAR file. In this case, set and parameter names have fewer than 4 characters, so the HEADER identifiers in the HAR file are identical to the GAMS names.

GDX2HAR infers domains of the parameters from the array elements, which are all non-zero in this case.

Set
i / a, b, c /
j / red, green, blue /;

Parameter
x 'Scalar value' / 1.5 /
y(i) 'Vector of values' / a 10.2, b 1.3, c 1.5 /
z(i,j) 'Matrix of random values';

z(i,j) = uniform(0,1);

This program may be stored as ex1.gms and then run from the command line as

gams ex1 gdx=ex1

If the program is executed from the GAMS IDE a GDX file can be generated by adding gdx=ex1 to the Additional Parameters box in the File/Options/Execute dialogue. The resulting GDX file can be opened in the GAMS IDE and appears as follows:

The GDX file can be translated into HAR format with the command:

gdx2har ex1 >ex1.log

As specified here, GDX2HAR program output (including warning messages) is written to ex1.log:

Running program: C:\GAMS21.0\GDX2HAR.EXE
Input file: H:\gdxhar\examples\ex1.gdx
Output file: H:\gdxhar\examples\ex1.har
Deleted existing file: H:\gdxhar\examples\ex1.har
Loaded GDX library: C:\GAMS21.0\gdxiomh.dll
Above is DLL version: _GAMS_GDX_V228_2003-05-07
GDX file was produced by:
  GAMS Rev 134 May 1, 2003 WIN.00.NA 21.0 134.000.041.VIS P3PC
  Using GDX library: _GAMS_GDX_V228_2003-05-07
GDX file contains 5 symbols and 6 set elements.
Reading GDX set "i".
Reading GDX set "j".
Reading GDX array "x".
Reading GDX array "y".
Reading GDX array "z".
Finished OK; created file: H:\gdxhar\examples\ex1.har

The resulting HAR file can be examined using the VIEWHAR utility:

Note that the HAR file contains the five items from the source GDX file as well as two additional sets named OGEL and NGEL. These sets are always provided to provide a consistent report in the event that set labels may have been translated.
5.15.2.2 Example 2: Missing sets are constructed.

In this example, sets are not written to the GDX file. GDX2HAR then generates the sets based on the nonzero patterns of the parameters. This example illustrates how a GDX file can be written and translated into HAR format within a GAMS program.

Set
i / a, b, c /
   j / red, green, blue /;

Parameter
x 'Scalar value' / 1.5 /
y(i) 'Vector of values' / a 10.2, b 1.3, c 1.5 /
z(i,j) 'Matrix of random values';

z(i,j) = uniform(0,1);

execute_unload 'ex2.gdx', x, y, z;
execute 'gdx2har ex2 > ex2.log';

The resulting HAR file appears as follows:

The sets titled Set1 and Set2 have been introduced by GDX2HAR and are stored in the HAR file under headers S1 and S2. GDX2HAR has inferred that y and z share the common dimension set1, but does not know that set1 was called "i" in the GAMS program.

5.15.2.3 Example 3: Zeros can create problems.

If one element of the w vector is zero, GDX2HAR does not assume that the coefficient is defined over set "i". Instead GDXHAR introduces a new set to define the domain.

Set i / a, b, c /

Parameter w(i) 'Vector of values' / a 10.2, c 1.5 /

execute_unload 'ex3.gdx', i, w;
execute 'gdx2har ex3 > ex3.log';

Above, the set Set1 contains only 2 members, a and c, corresponding to non-zero elements of w.

5.15.2.4 Example 4: EPS can be used to define a domain.

The GAMS language includes a special value EPS, standing for "epsilon," a infinitesimally small but nonzero number. When EPS is added to every element of an array over a given domain, then when that array is written to the GDX file the zeros become visible. The EPS values which are stored in the GDX file appear as a true zero in the translated HAR output file.
Set i / a, b, c /;

Parameter w(i) 'Vector of values' / a 10.2, c 1.5 /;

execute_unload 'ex3.gdx', i, w;
execute 'gdx2har ex3 > ex3.log';

* Add eps to create zeros which are "visible" in the
* GDX file:
  w(i) = w(i) + eps;

execute_unload 'ex4.gdx', i, w;
execute 'gdx2har ex4 > ex4.log';

5.15.2.5 Example 5: Explicit declaration of HAR coefficients.

As an alternative to adding EPS to all parameter values, the header and coefficient domain may be
specified in the GAMS declaration of a parameter. The HAR declaration is provided within double square
quotes, [[ ]].

In this example the GAMS parameter is 12 characters in length. This name may be used in the HAR file
to define the coefficient, but it may not be used as the header. (Headers are limited to four characters.) It
is possible to define a specific header and domain within the descriptor text of the GAMS parameter.

Set
  i / a, b, c /;
  j / red, green, blue /;

Parameter zs_long_name(i,j) 'Param with header and domain [[z:i*j]]';

* Note that missing rows are not a problem when the domain is explicitly
  specified:
  zs_long_name(i,j) = uniform(0,1);
  zs_long_name("b",j) = 0;

display zs_long_name;
execute_unload 'ex5.gdx', i, j, zs_long_name;
execute 'gdx2har ex5 > ex5.log';

5.15.2.6 Example 6: Long names are truncated

In GAMS, a set or parameter may have as many as 31 characters. GDX2HAR truncates such names to 12
characters.

Parameter GAMS_name_with_31_characters_OK 'A long GAMS identifier' / 1.5 /;
execute_unload 'ex6.gdx', GAMS_name_with_31_characters_OK;
execute 'gdx2har ex6 > ex6.log';

In this example GDX2HAR generates the following HAR file:

But issues the following warning message:

**** Warning: To conform with GEMPACK rules, GDX symbol
  GAMS_name_with_31_characters_OK was converted to GAMS_name_wi
5.15.2.7 Example 7: The GAMS symbol table controls set sequencing

Attention to the GAMS symbol table is needed if set sequences in the HAR file are to be in a particular order. Consider the following GAMS program:

Set
  r 'Selected South American countries' / ARG, BRA, COL, PER, BOL, URG /
  e 'Selected energy goods' / OIL, COL, GAS, ELE /

display e;

Parameter d(e,r) 'Energy demands';
d(e,r) = uniform(0,1);

execute_unload 'ex7.gdx', r, e, d;
execute 'gdx2har ex7 > ex7.log';

Note that the listing file output of this program presents set e is ordered in a sequence which differs from the declared sequence:

---- 5 SET e Selected energy goods

COL, OIL, GAS, ELE

The point is that GAMS orders all output rows and columns in accordance with the sequencing of the global symbol table. This aspect of GAMS carries over into HAR file generation. In this example, the order in which set e is displayed in the listing file is the same as the order in which the rows are sorted in the GDX and HAR files:

One way to control the global symbol table in a GAMS program is to declare a fictive set at the top of a program in which set elements are defined in the preferred sequence. For example, in the case of the previous program, the following declaration would produce the desired sequence of both sets R and E in the HAR file:

Set
  symbols / ARG, BRA, OIL, COL /
  r 'Selected South American countries' / ARG, BRA, COL, PER, BOL, URG /
  e 'Selected energy goods' / OIL, COL, GAS, ELE /

This produces a consistent ordering of both sets r and e, but this type of work-around may not always be possible. (See example 9 below.)

5.15.2.8 Example 8: Set elements may be truncated or revised.

Restrictions in GEMPACK on the length of set elements and the use of embedded blanks enforced by GDX2HAR. Also, GEMPACK does not allow for set elements to begin with a digit.

Set
  c / 'New York', 'San Francisco', 'Los Angeles' /
  t / 2000*2010 /

execute_unload 'ex8.gdx', c, t;
execute 'gdx2har ex8 > ex8.log';
With this example GDX2HAR produces the following warning message:

**** Warning: To conform with GEMPACK requirements,
the following GDX set elements were changed:

New York became NewYork
San Francisco became SanFrancisco
Los Angeles became LosAngeles
2000 became A2000
2001 became A2001
2002 became A2002
2003 became A2003
2004 became A2004
2005 became A2005
2006 became A2006
2007 became A2007
2008 became A2008
2009 became A2009
2010 became A2010
Reading GDX set "c".
Reading GDX set "t".
**** Warning: Some GDX set elements were changed.
There were 2 warnings.

GDX2HAR also alters identifiers to assure that they remain unique, for example, after truncation to 12 letters.

5.15.3 HAR2GDX Examples

5.15.3.1 Example 9: GlobalSet is provided by HAR2GDX to sequence the GAMS symbol table.

HAR2GDX constructs a symbol table which, where possible, provides properly sequenced arrays in the resulting GDX file. A simple example illustrates how this works. In the source HAR file there are two sets, COM and HAR. COM consists of [Cereals, OtherCrops, Power, Services], and IND contains [Agriculture, Nuclear, CoalFired, Services]. The HAR file contains a single numeric matrix, MAKE, which appears in VIEWHAR as follows:

When the HAR file ex9.har (from href="examples.zip" > examples.zip) is translated by HAR2GDX, the resulting GDX file contains three sets and one parameter array. The sets include COM and IND, as well as a GlobalSet which is inserted to provide a means of sorting the ata arrays into proper sequence. By virtue of the HAR2GDX global symbol table, the translated MAKE array appears in the GDXVIEWer as follows:

If, however, the global symbol table is ignored when the data is read into a GAMS program, as in the example:

Set
  COM(*) 'Set of commodities'
  IND(*) 'Set of industries';

$gdxIn make.gdx
$load com ind

Parameter make(com,ind) 'Make matrix';
$load make
display make;
Then the program develops a global symbol table in which set IND is ordered differently than in the source HAR file. The reason is that GAMS constructs a symbol table sequentially, so if COM is read before IND, then Services is introduced prior to Agriculture, Nuclear, and CoalFired:

```
---- 11 PARAMETER make Make matrix
       Services Agriculture Nuclear CoalFired
   Cereals 7.000
 OtherCrops 4.000
     Power  2.000   14.000
   Services 29.000
```

On the other hand, if GlobalSet is read first, then the GAMS set order (in this example) is identical to the HAR file order:

```
Set
   GlobalSet(*) 'Set provided by GDX2HAR to order symbol table'
   COM(*) 'Set of commodities'
   IND(*) 'Set of industries';

$gdxIn make.gdx
$load globalset com ind

Parameter make(com,ind) 'Make matrix';
$load make
display make;
```

```
---- 12 PARAMETER make Make matrix
          Agriculture Nuclear CoalFired Services
   Cereals 7.000
 OtherCrops 4.000
     Power  2.000 14.000
   Services 29.000
```

5.15.3.2 Example 10: Some GEMPACK datasets cannot be represented in GAMS without reordering sets.

The following is an example of a HAR file which cannot be translated to GAMS without reordering sets. Within ex10.har the sets IND and COM in this example are, respectively, \{A,B,C,D\} and \{D,C,B,A\}:

```
The HAR file can be translated to GDX, but this produces the following error message:
```

```
**** Warning: Inconsistent order: elements "D" and "C" in set COM
**** Warning: Inconsistent order: elements "C" and "B" in set COM
**** Warning: Inconsistent order: elements "B" and "A" in set COM
```

This message means that HAR2GDX was unable to construct a global symbol table which is ordered consistently with both HAR sets COM and IND. The translated data appears as:

```
Within the GDX file both COM and IND will be ordered \{A,B,C,D\}, and the elements of X are displayed in that order. Notice that values for particular array elements are translated correctly, e.g. \(X("A","B") = 14\) in both HAR and GDX files.
```
5.15.4 Concluding Remarks

GDX2HAR and HAR2GDX efficiently translate between HAR and GDX file formats. Although the examples above concentrate on potential problems, in practice both programs are generally easy to use. To avoid problems:

- if you are using GAMS to prepare a GDX file for translation to HAR, remember that GDX files do not naturally contain information about array domains – the sets over which the array is defined. To assist GDX2HAR, you should store associated sets in the GDX file and include domain information and a suggested header key in the "explicit text" description of each GAMS array declaration, as in example 5 above.

- if you are using GEMPACK to prepare a HAR file for translation to GDX, avoid creating sets which share common elements that are ordered differently. If you follow this rule, the GAMS user can use GlobalSet (prepared by HAR2GDX) to ensure that GAMS orders set elements in the same way as GEMPACK. See example 9 above.

- Try to use names (for arrays, sets and set elements) which are legal in both GEMPACK and GAMS. Identifiers of maximum length 10 with first character one of \[A..Z,a..z\] and remaining characters in \[A..Z,a..z,0..9\] will translate most smoothly.

5.16 GDX2SQLITE

A Tool to dump GDX contents into SQLite database file

Erwin Kalvelagen

November 30, 2015

5.16.1 Introduction

GDX2SQLITE.EXE is a tool to dump the complete contents of a GAMS GDX file (see GAMS Data eXchange (GDX)) into a SQLite database file (the website http://www.sqlite.org/ contains a wealth of information on SQLite).

A SQLite database is stored in a single file so it can be easily e-mailed or otherwise transmitted. The main advantages of using SQLite over other single file database systems such as MS Access is that SQLite is free and in the public domain and that it does not impose a 2 GB file size limit. For some large data sets this size limit present in MS Access and DBF database files causes problems. Another useful format is CSV files, but typically several CSV files are needed to store a data set stored in a GDX file. Many programs support reading SQLite database files, either through a native database access driver or via a standard ODBC interface. In summary: SQLite is a useful export format for GAMS solution data sets.

5.16.2 Usage

'GDX2SQLITE' is a command line tool that is best called from within a GAMS program using the $call or Execute statement, e.g.:

execute_unload "results.gdx", yield, price;
execute "gdx2sqlite -i results.gdx -o results.db";

The following options are available:
### Options

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i gdxinputfile</td>
<td>Specifies the input GDX file. Typically this is a file with a .gdx extension.</td>
</tr>
<tr>
<td>-o sqloutputfile</td>
<td>Specifies the output SQLite database. Typically this file has a .db extension.</td>
</tr>
<tr>
<td>-debug</td>
<td>This is an optional flag that will cause gdx2sqlite to print additional debugging information.</td>
</tr>
<tr>
<td>-expltext</td>
<td>This optional flag will export explanatory text for set elements.</td>
</tr>
<tr>
<td>-append</td>
<td>Don’t delete the database file before processing. This will allow adding new symbols in new tables. We will not allow adding data to existing tables.</td>
</tr>
<tr>
<td>-small</td>
<td>Write data strings in a separate table. A user-friendly SQL VIEW is created to hide the complexities of the joins.</td>
</tr>
<tr>
<td>-fast</td>
<td>Try to speed up writing the data using some non-standard pragmas. Using both -small -fast will write the data most efficiently.</td>
</tr>
<tr>
<td>-varchar</td>
<td>String columns will have the type VARCHAR(255) instead of TEXT.</td>
</tr>
</tbody>
</table>

An example of explanatory text is:

```plaintext
Set cty / AFG 'Afghanistan'
     AGO 'Angola'
     ALB 'Albania' /;
```

In GAMS set elements have a maximum length of 63 characters. Explanatory text has a maximum length of 255 characters.

### 5.16.3 How data is stored

#### 5.16.3.1 Gams issues

GAMS does not store zero values (or default records for variables and equations). Such non-existing records will not be exported to the GDX file and to the database either. To force a zero to be exported, set it to EPS in GAMS. E.g.:

```plaintext
p(i)$(p(i)=0) = EPS;
```

In case of doubt you are encouraged to inspect the GDX file.

#### 5.16.3.2 Sets

n-dimensional sets are stored as tables with n text columns. In case the option -expltext is used, another column may be added with explanatory text.
5.16 GDX2SQLITE

<table>
<thead>
<tr>
<th>GAMS</th>
<th>SQLite</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set month / jan, feb, mar / year / 2013, 2014 / date(year,month) / (2013,2014).{jan,feb,mar} /;</td>
<td>sqlite&gt;select * from month; month ---------- jan feb mar</td>
</tr>
<tr>
<td>execute_unload &quot;sets.gdx&quot;; execute &quot;gdx2sqlite -i sets.gdx -o sets.db&quot;;</td>
<td>sqlite&gt;select * from year; year ---------- 2013 2014</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Set month / jan 'january' feb 'fbruary' mar 'march' /;</td>
<td>sqlite&gt;select * from month; month expltext ---------- ---------- jan january feb fbruary mar march</td>
</tr>
<tr>
<td>execute_unload &quot;sets.gdx&quot;; execute &quot;gdx2sqlite -i sets.gdx -o sets.db -expltext&quot;;</td>
<td></td>
</tr>
</tbody>
</table>

5.16.3.3 Parameters

n-dimensional parameters will have n index columns plus a value column. Scalars are collected in a separate table.

<table>
<thead>
<tr>
<th>GAMS</th>
<th>SQLite</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set i / i1*i4 /; Parameter p(i); p(i) = uniform(0,1);</td>
<td>sqlite&gt;select * from p; i value ---------- 11 0.171747132 i2 0.843266708 i3 0.550375356 i4 0.301137904</td>
</tr>
<tr>
<td>Scalar s1 / 10 / s2 / 20 /;</td>
<td>sqlite&gt;select * from scalars; name value ---------- ---------- s1 10.0 s2 20.0</td>
</tr>
<tr>
<td>execute_unload &quot;data.gdx&quot;; execute &quot;gdx2sqlite -i data.gdx -o data.db&quot;;</td>
<td></td>
</tr>
</tbody>
</table>

5.16.3.4 Variables and Equations

n-dimensional variables and equations have besides n index columns also columns for the level, the lower and upper-bound and the marginal. Scalars are collected in the tables scalarvariables and scalarequations. Note that INF and -INF are mapped to $1.0\times10^{100}$ and $-1.0\times10^{100}$. The special value EPS is exported as zero. To be complete: UNDEF, NA and acronyms are exported as NULLs.
### 5.16.3.5 Fixing up names

A database table is not allowed to have columns with the same name. If a name clash is detected new names may be invented.

<table>
<thead>
<tr>
<th>GAMS</th>
<th>SQLite</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set i / i1*i4 /; Positive Variable x(i);</td>
<td>sqlite&gt; select * from x; i level lo up</td>
</tr>
<tr>
<td>x.l(i) = uniform(0,1);</td>
<td>marginal -------- -------- -------- --------</td>
</tr>
<tr>
<td>Variable z; z.m = 1;</td>
<td>i1 0.171747132 0.0</td>
</tr>
<tr>
<td>execute_unload &quot;data.gdx&quot;; execute</td>
<td>1.0e+100 0.0 12 0.843266708 0.0 1.0e+100</td>
</tr>
<tr>
<td>&quot;gdx2sqlite -i data.gdx -o data.db&quot;;</td>
<td>0.0 i3 0.550375356 0.0 1.0e+100 0.0 i4</td>
</tr>
<tr>
<td></td>
<td>0.301137904 0.0 1.0e+100 0.0</td>
</tr>
<tr>
<td></td>
<td>sqlite&gt; select * from scalarvariables; name</td>
</tr>
<tr>
<td></td>
<td>level lo up marginal -------- --------</td>
</tr>
<tr>
<td></td>
<td>-------- -------- -------- --------</td>
</tr>
<tr>
<td></td>
<td>i1 i2 i3 i4 i1 i2 i3 i4 i1 i2 i3 i4 i1 i2 i3 i4 i1 i2 i3 i4 i1 i2 i3 i4 i1 i2 i3 i4 i1 i2 i3 i4</td>
</tr>
</tbody>
</table>

### 5.16.3.6 Speeding up writing data

With the `-small` option we write data in a slightly different format. Instead of using strings for the GAMS indices we write integers. The integers can be looked up in a separate table `UELS` were the GAMS UELS (Unique Elements) are stored. We export an SQL view for each symbol to hide the complexities of the joins needed to replace the integers by strings.

The `-fast` option will set some SQLite pragmas that can speed up the inserts. Basically they will give up some consistency in case the program crashes, in which case the created database may be invalid.

For more information see: [http://yetanothermathprogrammingconsultant.blogspot.com/2014/07/a-little-bit-extra-fine-tuning.html](http://yetanothermathprogrammingconsultant.blogspot.com/2014/07/a-little-bit-extra-fine-tuning.html).

### 5.16.4 SQLite Browsers and compatible software

### 5.16.4.1 SQLite3.exe

From the distribution on [http://www.sqlite.org/download.html](http://www.sqlite.org/download.html) a command line tool is available that functions as shell for SQLite. An example session can look like:
C:\projects\impact3\sqlite\sqlite3.exe data.db
SQLite version 3.8.0.2 2013-09-03 17:11:13
Enter ".help" for instructions
Enter SQL statements terminated with a ";"
sqlite> .schema
CREATE TABLE [i](i TEXT);
CREATE TABLE [p](i TEXT,[i2] TEXT,[value] REAL);
sqlite> select * from p;
i1|i1|1.0
i2|i2|1.0
i3|i3|1.0
i4|i4|1.0
sqlite> .quit
C:\projects\impact3\sqlite>

5.16.4.2 SQLite Studio

A visual front-end can be downloaded from http://sqlitestudio.pl/.

5.16.4.3 SQLite Database Browser

Another visual browser is available from http://sqlitebrowser.sourceforge.net/.

5.16.4.4 SQLite and R

The statistical software R can conveniently use SQLite data, and can be called from a GAMS environment as follows:

$onText
Get data from GAMS into R via SQLite
$offText

$set IMPACTPATH c:\projects\impact3\impact_3\IMPACTv3.0
$set SCRIPT script.R
$set RPATH "C:\Program Files\R\R-3.0.2\bin\R.exe"
$set DB mapdata.db

Set cty;
$gdxIn %IMPACTPATH%\GDXs\Sets.gdx
$load cty
display cty;

Set maps / data1 'uniform random data between 0 and 1'
               data2 'uniform random data between 0 and 2' /;

Parameter mapdata(cty,maps);
mapdata(cty,"data1") = uniform(0,1);
mapdata(cty,"data2") = uniform(0,2);
execute_unload "mapdata.gdx";
execute "gdx2sqlite -i mapdata.gdx -o %DB% -expltext";
execute '"%RPATH%" --vanilla < %SCRIPT%';

$onEcho > %SCRIPT%
if (!require(RSQLite)) {
  install.packages("RSQLite", repos="http://cran.r-project.org")
  library(RSQLite)
}

sqlite<-dbDriver("SQLite")
db <- dbConnect(sqlite,"%DB%")
dbListTables(db)

maps<-dbGetQuery(db,"select * from maps")
maps

mapdata<-dbGetQuery(db,"select * from mapdata")
mapdata
$offEcho

5.16.4.5 SQLite and Python

Python has built-in support for SQLite:

import sqlite3

db = sqlite3.connect("turkey.db")

c = db.execute("select * from yieldl")
for row in c:
   print row

db.close()

5.16.4.6 SQLite ODBC Driver

ODBC is a database access layer for Windows. It allows many Windows programs that need to talk to databases to do this in a database independent manner. The SQLite ODBC driver can be downloaded from: http://www.ch-werner.de/sqliteodbc/.

5.16.4.7 SQLite and Excel

Excel can read SQLite database files through ODBC.

5.16.4.7.1 Import as Table  To import a table from a SQLite database perform the following steps:

1. Select the Data tab and choose Get External Data From Other Sources
2. Choose the Data Connection Wizard
3. Choose ODBC DSN
4. Select SQLite3Datasource
5. Enter the name and path of the database file and press OK.
6. Choose a table from the database.
7. Give this selection a name.
8. Choose Import as Table

The result is a table:

5.16.4.7.2 Import as Pivot Table The same steps can be used to import as Pivot Table. This way we can easily create summary reports, such as:

5.17 GDX2VEDA

Translates a GDX file into the VEDA format.

5.17.1 Usage

gdx2veda gdx vdd [run]

gdx
  GAMS GDX file
vdd
  VEDA Data Definition file
run
  VEDA Run identifier (optional)

The VEDA data file name and run identifier are either taken from the gdx file name or specified with the run name. Use "token with blanks" if needed.

5.17.2 Examples

This example dumps the gdx symbols:

gdx2veda mygdx

This example prints usage and example:

gdx2veda

To print more detailed help message:

gdx2veda --help

Add .csv to the run name to write in csv format
5.17.3 Detailed Help Message

5.17.3.1 VDD file Summary

[DataBaseName]
myveda

[Dimensions] cube dimensions
long_name tuple_element1 tuple_element2 ...

[DataEntries] data for the cube
long_name gams_name tuple_element1 tuple_element2 ...

[DimensionText] for generating .vde file (only for data in [DataEntries])
gams_set tuple_element1 tuple_element2 ...

[DimensionTextAll] for generating .vde file (also for data not in [DataEntries])
gams_set tuple_element1 tuple_element2 ...

[SubSets] for generating .vds file
sub_name gams_name tuple_element1 tuple_element2 ...

[ParentDimension] defines parent-child structure
parent_tab child_tab1 child_tab2 ...

[ParentDimensionTextAll] .vde file definitions with parent-child structure
2d_gams_set parent_tab child_tab
2d_gams_set child_tab parent_tab

[ParentSubSets] .vds file definitions with parent-child structure
sub_name 2d_gams_set parent_tab child_tab
sub_name 2d_gams_set child_tab parent_tab

[Options]
TupleSeparator "string" use a different separator symbol between tuple elements
ShowAllSeparators don't squeeze unnecessary separators
RelaxDimensionAll relax strict dimensionality checks in DimensionText(All) sections.
ValueDim n if n=2 write PV/DV value pairs for VEDA
SetsAllowed dim1 dim2 .. write SetsAllowed specification line to VEDA .vd file
Scenario scenarioSet specify the scenario set; a record with expl text goes to .vde
Format veda/csv specify the format of the data files
Not-0 attribute ... don't write records with zero values for these attributes

[SpecialValues]
EPS "string" value to be used for EPS
INF "string" value to be used for +INF
MINF "string" value to be used for -INF
NA "string" value to be used for NA
UNDEF "string" value to be used for UNDEF

<myveda>

is usually the application name which will be displayed on the top of the VEDA splash screen.
When a new VEDA database is created, a new folder with this name will appear:

...veda\database\mayveda_date_time.
Where data and time are the creation time stamp.

<tab_name>

corresponds to the tabs of your VEDA screen

Lines starting with * and empty lines are ignored. Blanks, commas and tabs are delimiters, blanks before and after delimiters are ignored. Quotes around data items are optional. The input data is NOT case sensitive.

5.17.3.2 Veda Data Definition file

Example of a Veda Data Definition file:

* Transport model

[DataBaseName]
myveda

[Dimensions]
* tab-name indices
Plants   i
Warehouses j
Links    ii jj

[DataEntries]
* veda_attribute gams_name tab1 tab2 ... for gams index 1, 2, ...
"x(i,j) duals" x.m i Warehouses
Shipments x.l i j
SupplyPrice supply.m i
DemandPrice demand.m j
TransportCost c i j
Distance d ii jj
Supply a i
Demand b j
TotalCost z.l
SupplyNodes i i
DemandNodes j j
Rate f

[DimensionText]
* gams_set tab
i i

[DimensionTextAll]
* gams_set tab
j j

[SubSets]
* sub_name gams_name tab
ii ic Plants
ii id i

Notes:

The long name from the [Dimensions] section can be used as a macro that expands to the tuples it defines. E.g. "Links" is identical to "ii jj".

In the [DataEntries] section a literal tuple element can be defined as /element/.

When ValueDim=2, the [DataEntries] section can contain X.LM entries, indicating both .L and .M needs to written as a pair.
5.18 GDX2XLS

A Tool to convert GDX data to MS Excel spreadsheets

Erwin Kalvelagen

June 10, 2005; December 6, 2006 This document describes the GDX2XLS utility which allows to convert data stored in a GDX file into Excel spreadsheets.

5.18.1 Overview

Note

The Windows GAMS distribution contains several tools to exchange data with MS-Excel: GDX2XLS, GDXXRW, XLS2GMS, and XLSDUMP. While we continue to include all four tools in our distribution, only GDXXRW is under active development. Therefore, we strongly recommend using GDXXRW for data exchange with Excel.

GDX2XLS is a tool to dump the complete contents of a GDX file to an MS Excel spreadsheet file (.xlsx or .xls file). Every identifier gets its own sheet in the .XLSX file. Excel 2007 or more recent versions will default to an xlsx file; versions before that default to the .xls file format. For instance when we save the results of the trnsport model from the model library:

C:\tmp>gamslib trnsport
Model trnsport.gms retrieved

C:\tmp>gams trnsport gdx=trnsport lo=2

C:\tmp>gdxdump trnsport.gdx symbols
  Symbol Dim  Type          Explanatory text
  1  a       1  Par capacity of plant i in cases
  2  b       1  Par demand at market j in cases
  3  c       2  Par transport cost in thousands of dollars per case
  4  cost    0  Equ define objective function
  5  d       2  Par distance in thousands of miles
  6  demand  1  Equ satisfy demand at market j
  7  f       0  Par freight in dollars per case per thousand miles
  8  i       1  Set canning plants
  9  j       1  Set markets
 10 supply  1  Equ observe supply limit at plant i
 11  x       2  Var shipment quantities in cases
 12  z       0  Var total transportation costs in thousands of dollars

C:\tmp>

The example shows how we copy the trnsport.gms model from the model library, and then solve it. The option gdx=filename will save the complete symbol table to a GDX file. The option lo=2 tells GAMS to save the log to a file (in this case trnsport.log) instead of writing it to the screen. The gdxdump will display the contents of the GDX file (the option symbols will only display the table of contents, rather than all data)

Once we have a GDX file we can use GDX2XLS to create an .XLSX file:
The resulting XLSX file, opened with MS Excel is shown in Figure 1. The first page is the Table of Contents page with all identifiers sorted alphabetically. When clicking on variable x, the sheet shown in Figure 2 is displayed.

The table of contents can be reached again by clicking on the TOC link in the top left corner. The complete process shown here can be automated as is shown in section Model gdx2xls1: import trnsport.gdx. As can be seen, every identifier is stored in its own sheet. Index positions get a column with labels showing their domains, or dim1, dim2, etc. if domain information is not available. By default scalar quantities are collected in a single sheet called scalar.

5.18.2 AutoFilter

By default the exported tables are organized in AutoFilter tables. This will allow you to easily make selections and sort the results. It is possible to set filters for different columns. Only the rows that meet the criteria will be shown. The columns used in the filter can be recognized by having a blue arrow instead of a black one in the drop down menu header. Sorting can also be performed on multiple columns: e.g. first sort on one column, then sort on a second column.

The autofilter generation can be turned off using an option in the .ini file.

5.18.3 Options

5.18.3.1 Default ini file

Options are specified in an .INI file. By default, the file gdx2xls.ini located in the same directory as gdx2xls.exe is consulted. If this file is not available, the program will continue using default settings.

5.18.3.2 Custom ini file

It is also possible to tell the program to use a different .ini file. This is done by using an extra argument of the form @inifile. An example would be:

C:\TMP> gdx2xls myfile.gdx @myinifile.ini

In this case the program will not read gdx2xls.ini located in the same directory as gdx2xls.exe but rather myinifile.ini in the current directory.

The ini file can contain two sections: [settings] and [colors]. A complete ini file with all possible settings looks like:
5.18.3.3 Settings section

A complete description for the [settings] section is:

<table>
<thead>
<tr>
<th>[settings]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inf=INF</td>
<td>Special values may need to be mapped to numeric values so the values can be used in formula's etc. This setting will specify the value for the GAMS INF quantity. The default is the string INF.</td>
</tr>
<tr>
<td>mininf=-INF</td>
<td>This is the mapped value for -INF. The default is -INF.</td>
</tr>
<tr>
<td>eps=EPS</td>
<td>This is the mapped value to be used for EPS. The default is EPS.</td>
</tr>
<tr>
<td>na=NA</td>
<td>This is the mapped value to be used for NA. The default is NA.</td>
</tr>
<tr>
<td>undf=UNDF</td>
<td>This is the mapped value to be used for UNDF. The default is UNDF.</td>
</tr>
<tr>
<td>scalarsheet=1</td>
<td>When this parameter is set to 1, GDX2XLS will generate a separate sheet to collect scalar parameters, scalar equations and scalar variables. This can reduce the number of sheets created with just a single data item. The name of the sheet is fixed: scalar. By default this option is turned on.</td>
</tr>
<tr>
<td>tableformatting=1</td>
<td>If this option is turned on, extra table formatting is used (adding colors, etc.) to make the tables look better. If this is not needed, this option can be turned off. Default: tableformatting=0.</td>
</tr>
<tr>
<td>toc=1</td>
<td>Whether or not to add a { Table of Contents} sheet. Default is to generate such a table.</td>
</tr>
<tr>
<td>sorttoc=1</td>
<td>Whether or not to sort the table of contents alphabetically. If turned off, the table will be displayed in the order in which the identifiers appear in the GDX file. Default is to sort.</td>
</tr>
<tr>
<td>autofilter=1</td>
<td>Automatically generate AutoFilter enabled tables in Excel.</td>
</tr>
<tr>
<td>freezeheader=1</td>
<td>Keep headers fixed so they don’t scroll off the screen.</td>
</tr>
<tr>
<td>indexformat=</td>
<td>Custom format for index columns. By default this is an empty string.</td>
</tr>
<tr>
<td>valueformat=</td>
<td>Custom format for value columns. By default this is an empty string.</td>
</tr>
</tbody>
</table>
An example of setting special values can be found in section Model gdx2xls4: special value mapping.

5.18.3.4 Colors section

A complete description for the [colors] section is:

<table>
<thead>
<tr>
<th>colors</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>header</td>
<td>The colorindex to be used as background for table headers. Default is 17.</td>
</tr>
<tr>
<td>body</td>
<td>The colorindex to be used as background for table bodies. Default is 19.</td>
</tr>
<tr>
<td>italics</td>
<td>The colorindex to be used for the font when writing explanatory text. The default is light grey (color index 48).</td>
</tr>
</tbody>
</table>

The [xmlcolors] section is used to specify colors in the XML file to be generated.

5.18.3.5 Custom formats

The format strings consists of four pieces:

`[format for $x>0$];[format for $x<0$];[format for $x=0$];[format for strings]`

An example given in the Excel help is:

`#,###.00_,[Red](#,###.00);0.00;"sales @`  

The codes used here have the following meaning:

<table>
<thead>
<tr>
<th>Formatting Characters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td># (number sign)</td>
<td>displays only significant digits and does not display insignificant zeros.</td>
</tr>
<tr>
<td>, (comma)</td>
<td>To display a comma as a thousands separator or to scale a number by a multiple of one thousand, include a comma in the number format.</td>
</tr>
<tr>
<td>0 (zero)</td>
<td>displays insignificant zeros if a number has fewer digits than there are zeros in the format.</td>
</tr>
<tr>
<td>_ (underscore)</td>
<td>To create a space the width of a character in a number format, include an underscore, followed by the character. For example, when you follow an underscore with a right parenthesis, such as _), positive numbers line up correctly with negative numbers that are enclosed in parentheses.</td>
</tr>
<tr>
<td>[color]</td>
<td>One of [Black], [Blue], [Cyan], [Green], [Magenta], [Red], [White], [Yellow].</td>
</tr>
<tr>
<td>@ (at sign)</td>
<td>Include an at sign (@) in the section where you want to display any text entered in the cell.</td>
</tr>
</tbody>
</table>

Additional formatting characters include:
### Formatting Characters

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>adds spaces for insignificant zeros on either side of the decimal point so that decimal points align when formatted with a fixed-width font, such as Courier New. You can also use ? for fractions that have varying numbers of digits.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conditions can be specified as follows: [Red]</td>
<td>[&lt;=100];[Blue]</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Exponent</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>To display numbers in scientific format, use exponent codes in a section, for example, E-, E+, e-, or e+.</td>
<td></td>
</tr>
</tbody>
</table>

A useful format is:

```plaintext
[settings]
valueformat=#.,????
```

which aligns numbers on the decimal point and depicts zero's as dots just as the listing file is doing.

### 5.18.4 Examples

#### 5.18.4.1 Model gdx2xls1: import trnsport.gdx

This example will solve the `trnsport.gms` model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Excel and MS Excel is launched to inspect the results. This is a small example that should run very quickly.

```plaintext
$onText
Test of GDX2XLS. Dumps all symbols of
trnsport.gms to trnsport.xlsx.
$offText
execute 'gamslib trnsport';
execute 'gams trnsport lo=3 gdx=trnsport';
execute 'gdx2xls trnsport.gdx';
execute 'shellExecute trnsport.xlsx';
```

Notes: the equal signs in from of the external programs indicate we don't go through a shell (e.g. `command.com` or `cmd.exe`). This will improve reliability in case the external program is not found. In such a case a proper error will be triggered. Without the '=' such errors go undetected and the GAMS model will continue.

The command `ShellExecute` will launch Excel to view the `.XLSX` file.

#### 5.18.4.2 Model gdx2xls2: import indus89.gdx

This example will solve the `indus89.gms` model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Excel and MS Excel is launched to inspect the results. This is a fairly large GDX file, with many identifiers, resulting in many sheets in the workbook.

```plaintext
$onText
Test of GDX2XLS. Dumps all symbols of
indus89.gms to indus89.xlsx. This takes
longer as there is a large number of symbols.
$offText
execute 'gamslib indus89';
execute 'gams indus89 lo=3 gdx=indus89';
execute 'gdx2xls indus89.gdx';
execute 'shellExecute indus89.xlsx';
```
5.18.4.3 Model gdx2xls3: a large table

This is an artificial example where we generate a large identifier in GAMS: a parameter with as many elements as the number of rows that Excel can handle.

$onText
Test of GDX2XLS. Single symbol with 65536-3=65533 records.
Maximum rows that XLS can handle is 65536; an XLSX file allows for slightly more than a million rows.
$offText

Set i / i1*i65533 /;

Parameter p(i);
p(i) = uniform(-100,100);
execute_unload 'test.gdx', p;
execute '=gdx2xls test.gdx';
execute '=ShellExecute test.xlsx';

If you create a spreadsheet with too many rows, the XLSX file writer will return OLE error 800A03EC. When generating an XML file, an error will occur when Excel loads the file.

5.18.4.4 Model gdx2xls4: special value mapping

To store special values like INF, EPS, NA in a numeric field in the database, GDX2XLS uses a mapping. This mapping can be changed using an INI file.

$onText
Test of GDX2XLS.
Check special value mapping.
$offText

$onEcho > m.ini
[settings]
inf=1.0e100
mininf=-1.0e100
eps=0.0
na=#NA!
undf=#UNDF!
$offEcho

Parameter p(*) / i1 inf, i2 -inf, i3 eps, i4 na /;
p('i5') = 1/0;
display p;

* save parameter p in p.xlsx
* special values are translated to default values:
execute_unload "p.gdx", p;
execute '=gdx2xls p.gdx';
execute '=shellExecute p.xlsx';

* save parameter p in q.xls using new mapping
* INF -> 1.0e100 (numeric)
Numeric values are important if you want Excel being able to operate on these numbers.

5.18.4.5 Model gdx2xls8: custom format

We use a custom value format to color the different values $x<0$, $x=0$, $x>0$ differently. Also align on the decimal point.

```gams
$onText
GDX2XLS example: use of custom format
$offText
$onEcho > mexls.ini
[settings]
valueformat=[Blue]#.????;[Red]-#.????;[Green]0.????;[Magenta]
$offEcho
execute '='gamslib mexls';
execute '='gams mexls lo=3 gdx=mexls';
execute '='gdx2xls mexls.gdx @mexls.ini';
execute '='shellExecute mexls.xlsx';
```

5.18.4.6 Model gdx2xls9: custom format 2

This uses the more useful custom format `valueformat=#.????` (see Figure 7).

```gams
$onText
GDX2XLS example: use of custom format
$offText
$onEcho > align.ini
[settings]
valueformat=#.????
$offEcho
execute '='gamslib mexls';
execute '='gams mexls lo=3 gdx=mexls';
execute '='gdx2xls mexls.gdx @align.ini';
execute '='shellExecute align.xlsx';
```
5.19 GDXCOPY

GDX files from different GAMS version can possibly be incompatible. A current GAMS system can read all older GDX file formats. The GDXCOPY utility provides a mechanism to convert GDX files to a format that different GAMS systems can read.

5.19.1 Usage

gdxcopy option inFile outDir

or

gdxcopy option -Replace inFile

The first form copies the converted files to a directory; the second form replaces the original file(s).

inFile

Single file or a file pattern with .gdx file extension.

outDir

The output directory.

Instead of converting the files explicitly using the GDXCOPY utility, files can also be converted by using the environment variable GDXCONVERT with values V5, V6 or V7. The values specified will be used together with the value of the environment variable GDXCOMPRESS to call GDXCOPY as soon as a GDX file is created.

The values of the environment variables can also be set using the GAMS parameters GDXCONVERT and GDXCOMPRESS.

Option:

<table>
<thead>
<tr>
<th>Option</th>
<th>Target format</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V5</td>
<td>Version 5</td>
</tr>
<tr>
<td>-V6U</td>
<td>Version 6 uncompressed</td>
</tr>
<tr>
<td>-V6C</td>
<td>Version 6 compressed</td>
</tr>
<tr>
<td>-V7U</td>
<td>Version 7 uncompressed</td>
</tr>
<tr>
<td>-V7C</td>
<td>Version 7 compressed</td>
</tr>
</tbody>
</table>

A current GAMS system can always handle older GDX file formats. The GDXCOPY utility provides a mechanism to convert GDX files to a prior format, so an older GAMS system can read these files.

Notes:

- Version 7 formatted files were introduced with version 22.6 of GAMS; version 6 formatted files were introduced with version 22.3 of GAMS. Prior versions used version 5.
• Some features introduced in version 7 of the GDX file format cannot be represented in older formats.
### 5.20 GDXDIFF

The **GDXDIFF** tool compares the data of symbols with identical name, type and dimension in two GDX files and writes the differences to a third GDX file. A summary report will be written to standard output.

#### 5.20.1 Usage

```
gdxdiff file1 file2 {diffile} {options}
```

The `.gdx` file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory. **GDXDIFF** requires two parameters, the file names of two GDX files. An optional third parameter is the name of the GDX difference file. Without the third parameter, the difference file will be `diffile.gdx` in the current directory.

`diffile = fileName` (default = `diffile.gdx`)

An optional name of the GDX difference file.

---

<table>
<thead>
<tr>
<th>Feature</th>
<th>Action taken</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimension &gt; 10</td>
<td>Symbol is ignored</td>
</tr>
<tr>
<td>Identifier longer than 31 characters</td>
<td>Truncated to 31 characters</td>
</tr>
<tr>
<td>Unique element longer than 31 characters</td>
<td>Truncated to 31 characters</td>
</tr>
<tr>
<td>Domain of a symbol</td>
<td>Domain is ignored</td>
</tr>
<tr>
<td>Aliased symbol</td>
<td>Symbol is entered as a set</td>
</tr>
<tr>
<td>Additional text for symbol</td>
<td>Additional text is ignored</td>
</tr>
</tbody>
</table>

- The Macintosh Intel-based system (DII) which was introduced with GAMS 22.6 does not support GDX conversion into formats version 6 and version 5.
- Solaris 9 or higher on Sun Sparc64 (SOX) which was introduced in GAMS 22.6 does not support GDX conversion into formats version 6 and version 5.

---

### 5.19.2 Example

In the example below we convert all GDX files to a compressed format for version 6.

```plaintext
dir
  1,219 t1.gdx
  1,740 t0.gdx
889,973 i.gdx
  1,740 pv.gdx
894,672 bytes

gdxcopy -v6c *.gdx newdir
dir newdir
  1,219 t1.gdx
  1,219 t0.gdx
203,316 i.gdx
  1,219 pv.gdx
206,973 bytes
```

---

### 5.20 GDXDIFF

The **GDXDIFF** tool compares the data of symbols with identical name, type and dimension in two GDX files and writes the differences to a third GDX file. A summary report will be written to standard output.
5.20.2 Options

The following options can be used when calling GDXDIFF:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Eps</td>
<td>0.0</td>
<td>Epsilon for comparison (absolute).</td>
</tr>
<tr>
<td>RelEps</td>
<td>0.0</td>
<td>Epsilon for comparison (relative).</td>
</tr>
<tr>
<td>field</td>
<td>all</td>
<td>Specify a single subfield (l, m, up, lo, prior, scale) of a variable or equation to be compared.</td>
</tr>
<tr>
<td>fldOnly</td>
<td>disabled</td>
<td>Write variables and equations as parameters for the selected subfield.</td>
</tr>
<tr>
<td>id</td>
<td>all</td>
<td>Define specific identifiers of the GDX files to be compared.</td>
</tr>
<tr>
<td>diffOnly</td>
<td>disabled</td>
<td>Controls if differences of variables and equations will be written as parameters or not.</td>
</tr>
<tr>
<td>cmpDefaults</td>
<td>disabled</td>
<td>Enables the comparison of default values.</td>
</tr>
<tr>
<td>cmpDomains</td>
<td>disabled</td>
<td>Enables the comparison of symbol domains.</td>
</tr>
<tr>
<td>matrixFile</td>
<td>disabled</td>
<td>Enables the comparison of GAMS matrix files in GDX format.</td>
</tr>
<tr>
<td>setDesc</td>
<td>Y</td>
<td>Control if associated text of matching set elements is compared.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the options:

- **Eps** = value (default = 0.0)

  Absolute difference for comparisons; see also Comparing numeric values. If the difference between two values exceeds Eps, a difference will be reported. The valid range is

- **RelEps** = value (default = 0.0)

  Relative difference for comparisons; see also Comparing numeric values. If the value of RelEps is exceeded, a difference will be reported.

- **field** = fieldName (default = all)

  The specified subfield is the only field used for deciding if a variable or equation is different. FieldName is one of the following: l, m, up, lo, prior, scale or all.

- **fldOnly** (disabled by default)

  Used in combination with the field option; The variables and equations will be written as parameters for the selected subfield. This option cannot be used in combination with diffOnly.

- **id** = identifier (default = all)

  Limits the comparison to one or more symbols; symbols not specified will be ignored. Multiple identifiers can be specified as: id=id1 id=id2 or as id="id1 id2". When using GDXDIFF from the menu bar in the GAMS IDE (Utilities), this option is not available.

- **diffOnly** (disabled by default)

  Differences for variables and equations will be written as parameters; each parameter will have an additional index which is used to store the field name. Only fields that are different will be written. This option cannot be used in combination with fldOnly.
cmpDefaults

Enables the comparison of default values. When using GDXDIFF from the menu bar in the GAMS IDE (Utilities), this option is not available.

cmpDomains (disabled by default)

Enable the comparison of symbol domains. Note that the difference are not listed in particular in the diffile. When using GDXDIFF from the menu bar in the GAMS IDE (Utilities), this option is not available.

matrixFile

This activates a special mode to compare GAMS matrix files in GDX format. This is mostly done for internal use. When using GDXDIFF from the menu bar in the GAMS IDE (Utilities), this option is not available.

setDesc = boolean (default = Y)

Enable or disable the comparison of associated texts for set elements.

Criterion for comparing numeric Values
The use of Eps and RelEps is best described by the code fragment below.

AbsDiff := Abs(V1 - V2);
if AbsDiff <= EpsAbsolute
then
  Result := true
else
  if EpsRelative > 0.0
  then
    Result := AbsDiff / (1.0 + DMin(Abs(V1), Abs(V2))) <= EpsRelative
  else
    Result := false;

Interpreting the Labels in the diffile
Only symbols with the same name, type and dimension will be compared. Tuples with different values are written to the GDX difference file, and a dimension is added to describe the difference using the following labels:

- ins1 indicates that the tuple only occurs in the first file.
- ins2 indicates that the tuple only occurs in the second file.
- dif1 indicates that the tuple occurs in both files; contains the value from the first file.
- dif2 indicates that the tuple occurs in both files; contains the value from the second file.
5.20.3 Examples

5.20.3.1 Compares two GDX Files and writes the Differences to a third GDX File

In the following example, the [transport] model is solved twice with different capacity data. GDX files are saved for each run, and compared afterwards using GDXDIF. The shipments variable is loaded into a new variable used for a display statement. We introduce four new unique elements that are used in the difference file.

* solve and write to unmodified.gdx before manipulating the data
solve transport using lp minimizing z;
execute_unload 'unmodified.gdx', a, x;

* manipulate the data and solve again, write to modified.gdx
a('seattle') = 1.2*a('seattle');
solve transport using lp minimizing z;
execute_unload 'modified.gdx', a, x;

execute 'gdxdiff unmodified modified diffile > %system.nullfile%';

* Declare symbols to hold the data for differences
Set difftags / dif1, dif2, ins1, ins2 /;
Variable xdiff(i,j,difftags);
Parameter adiff(i,difftags);

execute_load 'diffile' adiff=a, xdiff=x;
display a, xdiff.l;

The display statement generates the following output in the listing file:

---- 101 PARAMETER a capacity of plant i in cases
seattle 420.000, san-diego 600.000

---- 101 VARIABLE xdiff.L
dif1   dif2
seattle.new-york 50.000 120.000
san-diego.new-york 275.000 205.000

Alternatively, one can open the diffile in the GAMS IDE or GAMS Studio to display the differences.

This example is also part of the GAMS Data Utilities Library, see model [GDXDIFFExample16] for reference.

5.21 GDXDUMP

GDXDUMP is a tool to write scalars, sets, parameters (tables), variables and equations from a GDX file formatted as a GAMS program with data statements to standard output, GMS or CSV files. To write to a file, use the output redirection '>', provided by the operating system or the output option of GDXDUMP.
5.21 GDXDUMP

5.21.1 Usage

gdxdump filename {options}

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

5.21.2 Options

The table summarizes the options of GDXDUMP. Running GDXDUMP without any arguments will write the sets, parameters, scalars etc. to standard output formatted as a GAMS program with data statements.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>output</td>
<td>none</td>
<td>Specify the output filename.</td>
</tr>
<tr>
<td>version</td>
<td>disabled</td>
<td>Writing version information only.</td>
</tr>
<tr>

<td>+Inf</td>
<td>String to be used when writing the value for 'Positive Infinity'.</td>
</tr>
<tr>
<td>mInfOut</td>
<td>-Inf</td>
<td>String to be used when writing the value for 'Negative Infinity'.</td>
</tr>
<tr>
<td>UndfOut</td>
<td>Undf</td>
<td>String to be used when writing the value for 'Undefined'.</td>
</tr>
<tr>
<td>ZeroOut</td>
<td>0</td>
<td>String to be used when writing the value for 'Zero'.</td>
</tr>
</tbody>
</table>
Some more detailed remarks on the options:

**output** = `fileName` (default=none)

Write the output to a file. The .gms resp. the .csv file extension must be added when writing to GMS resp. CSV.

This option is demonstrated in **Writing GDX to CSV**.

**-version** (disabled by default)

Synonym: `-v`

Write version information only and terminate; all other options will be ignored.

**symb** = `identifier` (default=none)

Specify a single identifier in the GDX file to be written to standard output, GMS or CSV. When writing to CSV, one must specify the `symb` option.

This option is demonstrated in **Writing GDX to standard output and to GMS**.

**UelTable** = `identifier` (default=none)

Write all unique elements found in the GDX file to a set using the identifier specified as the name for the set.

This option is demonstrated in **Writing GDX to standard output and to GMS**.

**delim** = [period, comma, tab, blank, semiColon] (if format=normal: default=period, if format=csv: default=comma)

Selects a different delimiter to separate unique elements; period is the default when writing to standard output or GMS, while comma is the default when writing to CSV.

This option is demonstrated in **Writing GDX to CSV**.

**decimalSep** = [period, comma] (default=period)

Specify a decimal separator.

This option is demonstrated in **Writing GDX to CSV**.

**noHeader** (disabled by default)

Suppress the header information when writing a single symbol; only the data for the symbol will be written, not its declaration. The option is ignored when writing all symbols. When writing to CSV, the header row can be suppressed by enabling `noHeader`.

This option is demonstrated in **Adding double Quotes to an user defined Header when writing to CSV**.

**header** = `string` (default=none)
The string supplied replaces the default header written by the program to a CSV file. If an empty header is desired, the string can be empty; such a string can be written using two single quotes (header=""), while in general it is best to enclose the string with double quotes.

This option is demonstrated in Writing GDX to CSV and Adding double Quotes to an user defined Header when writing to CSV.

**noData** (disabled by default)

Only write the headers for the symbols; no data is written. The option is ignored when writing to CSV.

**CSVAllFields** (disabled by default)

When writing a variable or equation to CSV, all fields (level, marginal, lower, upper, and scale) will be written. Without this option, only the level will be written. When writing a set the option control the writing of the element text.

This option is demonstrated in Writing GDX to CSV.

**CSVSetText** (disabled by default)

When writing a set to CSV, the set element text will be written as the last column in the CSV file in addition to the set elements. Without this option, only the set elements will be written.

This option is demonstrated in Writing GDX to CSV.

**symbols** (disabled by default)

Generate an alphabetical list of all symbols in the GDX file (not valid when writing to CSV).

This option is demonstrated in Writing GDX to standard output and to GMS.

**symbolsAsSet** (disabled by default)

Generate a set declaration where the data represents basic information (symbol identifier, dimension, type, explanatory text) of all symbols in the GDX file (not valid when writing to CSV).

This option is demonstrated in Writing GDX to standard output and to GMS.

**symbolsAsSetDI** (disabled by default)

Generate a set declaration where the data represents basic information (symbol identifier, dimension, type, domain information) of all symbols in the GDX file (not valid when writing to CSV).

**domainInfo** (disabled by default)

Generate an alphabetical list of all symbols in the GDX file that includes domain information (not valid when writing to CSV). The column \texttt{DomInf} can have the following values:

- \texttt{N/A} - The function to get the type of domain information is not available
- \texttt{None} - No domain was specified (domain is the universe)
- \texttt{Relaxed} - The domain is relaxed, i.e. the identifiers shown do not necessarily represent one dimensional sets
- \texttt{Regular} - Regular domain; the identifiers shown are one dimensional sets

This option is demonstrated in Writing GDX to standard output and to GMS.
**setText** (disabled by default)

Show the set text (aka the associated set text or the set element text) in the GDX file (not valid when writing to CSV).

GDX allows a string of text to be associated with each element of a set. The universe of such strings stored for use in any particular GDX file (i.e. the set text list) can be shown with this option.

**format** = [normal, gamsbas, CSV] (default=normal)

Change the output format and the symbols written.

When using the gamsbas format, the program will not write the declarations for the symbols and only write the Level and Marginal assignment statements for the variables, and the Marginal assignment statements for equations.

The CSV format adds column headers to the output. By enabling the cDim option the unique elements of the last dimension of the symbol will be used as column headers for the values. If domain information is available, the column headers will be made unique if overlapping names have been used for the names of the index positions. If no domain information is available, the index names used will be of the form dim1, dim2, ...

In order to run **GDXDUMP**, one must specify a single symbol using the **symb** option when writing to CSV.

The gamsbas and CSV format is demonstrated in Writing GDX to standard output and to GMS resp. Writing GDX to CSV.

**dFormat** = [normal, hexponential, hexBytes] (default=normal)

Specify the numerical format in the output file.

**cDim** = [Y, N] (default = N)

Can be used when writing a CSV file; when enabled, the unique elements of the last dimension will be used as column headers for the values.

This option is demonstrated in Writing GDX to CSV.

**filterDef** = [Y, N] (default = Y)

When enabled, default values will be filtered and not written. This option is enabled by default. For example, if the Level field (.L) of a variable is zero, the value will not be written.

**EpsOut** = string (default = EPS)

String to be used when writing the value for 'Epsilon'.

**NaOut** = string (default = NA)

String to be used when writing the value for 'Not Available'.

**pInfOut** = string (default = +Inf)

String to be used when writing the value for 'Positive Infinity'.

This option is demonstrated in Writing GDX to CSV.

**mInfOut** = string (default = -Inf)

String to be used when writing the value for 'Negative Infinity'.

**UndfOut** = string (default = Undf)

String to be used when writing the value for 'Undefined'.

**zeroOut** = string (default = 0)

String to be used when writing the value for 'Zero'.

Note that GDX files can also be viewed using the GAMS IDE or GAMS Studio.
5.21.3 Examples

To demonstrate the features of GDXDUMP in the Writing GDX to standard output and to GMS and Writing GDX to CSV examples, we execute the model transport.gms ([TRNSPORT] from GAMS Model Library) initially to create the GDX file transport.gdx by using the GDX command line option. Afterwards, some important features of GDXDUMP are demonstrated.

```
gams transport gdx=transport
```

The figure shows the symbol listing of the GDX file in total and the variable x in particular, since those data is used quite often in the following examples:

All subfields of the variable x are shown in the next figure:

5.21.3.1 Writing GDX to standard output and to GMS

In this example, we will demonstrate the effect of some basic features of GDXDUMP.

While we write to standard output in the most sections of this example, one can also write the GDX file contents into a GAMS file using the following command to redirect the output:

```
gdxdump transport.gdx > GDXContents.gms
```

Alternatively, the output option can be used to specify an output filename.

Option symbols

This listing shown above can also be written to standard output by using the symbols option of GDXDUMP:

```
gdxdump transport symbols
```

The GDXDUMP program writes the following output (except for the numbering and the records column, the content is identical compared to the figure):

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Dim</th>
<th>Type</th>
<th>Records</th>
<th>Explanatory text</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
<td>Par</td>
<td>2</td>
<td>capacity of plant i in cases</td>
</tr>
<tr>
<td>2</td>
<td>b</td>
<td>Par</td>
<td>3</td>
<td>demand at market j in cases</td>
</tr>
<tr>
<td>3</td>
<td>c</td>
<td>Par</td>
<td>6</td>
<td>transport cost in thousands of dollars per case</td>
</tr>
<tr>
<td>4</td>
<td>cost</td>
<td>Equ</td>
<td>1</td>
<td>define objective function</td>
</tr>
<tr>
<td>5</td>
<td>d</td>
<td>Par</td>
<td>6</td>
<td>distance in thousands of miles</td>
</tr>
<tr>
<td>6</td>
<td>demand</td>
<td>Equ</td>
<td>3</td>
<td>satisfy demand at market j</td>
</tr>
<tr>
<td>7</td>
<td>f</td>
<td>Par</td>
<td>1</td>
<td>freight in dollars per case per thousand miles</td>
</tr>
<tr>
<td>8</td>
<td>i</td>
<td>Set</td>
<td>2</td>
<td>canning plants</td>
</tr>
<tr>
<td>9</td>
<td>j</td>
<td>Set</td>
<td>3</td>
<td>markets</td>
</tr>
<tr>
<td>10</td>
<td>supply</td>
<td>Equ</td>
<td>2</td>
<td>observe supply limit at plant i</td>
</tr>
<tr>
<td>11</td>
<td>x</td>
<td>Var</td>
<td>6</td>
<td>shipment quantities in cases</td>
</tr>
<tr>
<td>12</td>
<td>z</td>
<td>Var</td>
<td>1</td>
<td>total transportation costs in thousands of dollars</td>
</tr>
</tbody>
</table>

Option domainInfo

We use the domainInfo option to write some basic information including domain information (column DomInf) to standard output:
The GDXDUMP program writes the following output:

<table>
<thead>
<tr>
<th>SyNr</th>
<th>Type</th>
<th>DomInf</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Par</td>
<td>Regular</td>
<td>a(i)</td>
</tr>
<tr>
<td>4</td>
<td>Par</td>
<td>Regular</td>
<td>b(j)</td>
</tr>
<tr>
<td>7</td>
<td>Par</td>
<td>Regular</td>
<td>c(i,j)</td>
</tr>
<tr>
<td>10</td>
<td>Equ</td>
<td>None</td>
<td>cost</td>
</tr>
<tr>
<td>5</td>
<td>Par</td>
<td>Regular</td>
<td>d(i,j)</td>

Check the `domainInfo` option explanation linked above to get a full list of possible values for `DomInf` and their interpretation. In this example, the symbol dimensions were not specified (none) or they are defined on the one dimensional sets i and j (regular).

**Option symbolsAsSet**

Using the `symbolsAsSet` option one can write the information displayed by enabling the `symbols` option to a set declaration:

```plaintext
gdxdump trnsport symbolsAsSet
```

The GDXDUMP program writes the following:

```
alias (Symbol, Dim, Type, *)
set  .gdxitems(Symbol,Dim,Type) Items in the GDX file /
"i".1."Set" "canning plants",
"j".1."Set" "markets",
"a".1."Par" "capacity of plant i in cases",
"b".1."Par" "demand at market j in cases",
"d".2."Par" "distance in thousands of miles",
"f".0."Par" "freight in dollars per case per thousand miles",
"c".2."Par" "transport cost in thousands of dollars per case",
"x".2."Var" "shipment quantities in cases",
"z".0."Var" "total transportation costs in thousands of dollars",
"cost".0."Equ" "define objective function",
"supply".1."Equ" "observe supply limit at plant i",
"demand".1."Equ" "satisfy demand at market j"
/;
```

**Option symb**

One can write a single identifier from the GDX using the `symb` option:

```plaintext
gdxdump trnsport.gdx symb=x
```

The default output includes the declaration header and a data statement when writing a set or parameter. When writing a variable, the output includes the level and marginal subfields:
positive Variable x(i,j) shipment quantities in cases / 'seattle'. 'new-york'. L 50, 'seattle'. 'chicago'. L 300, 'seattle'. 'topeka'. M 0.036, 'san-diego'. 'new-york'. L 275, 'san-diego'. 'chicago'. M 0.00900000000000001, 'san-diego'. 'topeka'. L 275 /;

Note the default values are not written (for instance, zero values of the level or lower bound subfields are missing).

Option UelTable
Using the UelTable option one can write a set (named allUELs in this example) containing all unique elements of the GDX file:

```plaintext
gdxdump trnsp ort output=allUELs.gms UelTable=allUELs
```

The following set declaration will be part of the output file allUELs.gms:

```plaintext
Set allUELs / 'seattle', 'san-diego', 'new-york', 'chicago', 'topeka' /;
```

Format gamsbas
Using the format option one can write a variable or equation in the gamsbas format, i.e. there will be no declaration of the symbol and the level and marginal subfields will be written as assignments.

```plaintext
gdxdump trnsp ort format=gamsbas
```

GDXDUMP writes the following to standard output:

```plaintext
x.L ('seattle'. 'new-york') = 50 ;
x.L ('seattle'. 'chicago') = 300 ;
x.M ('seattle'. 'topeka') = 0.036 ;
x.L ('san-diego'. 'new-york') = 275 ;
x.M ('san-diego'. 'chicago') = 0.00900000000000001 ;
x.L ('san-diego'. 'topeka') = 275 ;

z.L = 153.675 ;
cost.M = 1 ;
supply.M ('seattle') = Eps ;
demand.M ('new-york') = 0.225 ;
demand.M ('chicago') = 0.153 ;
demand.M ('topeka') = 0.126 ;
```
5.21.3.2 Writing GDX to CSV

Next we specify CSV as the output format and demonstrate some simple features available when writing to CSV.

Writing to CSV

One can write to a CSV file by running the following command:

```
gdxdump trnsport.gdx output=varX.csv symb=x format=csv
```

By doing this, the level subfield of the variable x is written as a list to the file varX.csv specified in the output statement. The header row contains the domain set identifiers i and j of x and the field "Val":

```
"i","j","Val"
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275
```

Option cDim

Using the cDim option one can write the data as a table since the right most dimension is used as the column header:

```
gdxdump trnsport.gdx symb=x format=csv cDim=y
```

We did not specify an output file in this case, so the data will be written to standard output formatted as CSV:

The GDXDUMP program writes the following:

```
"i","new-york","chicago","topeka"
"seattle",50,300,0
"san-diego",275,0,275
```

Note the elements new-work, chicago and topeka are written to the header row, since they are elements of the most right dimension j.

Customizing the output: CSVAllFields, header, decimalSep, delim, pInfOut etc.

In this section, all subfields of the variable x are written to CSV and the representation is customized. The writing of subfields is enabled by CSVAllFields. In addition, the header option is used to overwrite the default header (as seen in the two previous paragraphs). For instance, we want to replace i with the term 'canning plants', j with the term 'markets' and "Val" with the term 'shipment quantities in cases', while we are fine with the default column labels for the level, marginal etc. subfields, but they will be overwritten, too. Therefore, we must specify them again manually in the header option. For some reason, the field separator is changed from comma (default) to semicolon and the decimal separator from period (default) to comma using the delim and decimalSep options. One can define the string written to CSV for special values of GAMS like +INF by using the corresponding option pInfOut, which might be useful for further processing of the CSV file.

```
gdxdump trnsport format=csv output=varX.csv symb=x CSVAllFields header="canning plants;markets;shipment quantities in cases;Level;Marginal;Lower;Upper;Scale" delim=semiColon decimalSep=comma pInfOut=1E+100
```
GDXDUMP creates the following output:

```
canning plants;markets;shipment quantities in cases;Level;Marginal;Lower;Upper;Scale
"seattle";"new-york";50;0;0;1E+100;1
"seattle";"chicago";300;0;0;1E+100;1
"seattle";"topeka";0;0,036;0;1E+100;1
"san-diego";"new-york";275;0;0;1E+100;1
"san-diego";"chicago";0;0,00900000000000001;0;1E+100;1
"san-diego";"topeka";275;0;0;1E+100;1
```

Note that the fields in the header are not enclosed by double quotes. This problem is addressed in the next section Adding double Quotes to an user defined Header when writing to CSV.

Customizing the output: CSVSetText

The set element text is the value of a set element. Often this is left out when defining sets, but for descriptive models often set element text is provided. When dumping a set to a CSV file the set element text is not written to the CSV file by default. The option CSVSetText enables the writing of the text. The model mexss.gms ([MEXSS] from GAMS Model Library) has a set i of steel plants with set element text.

```
Set i 'steel plants' / ahmsa 'altos hornos - monclova'
  fundidora 'monterrey'
  sicartsa 'lazaro cardenas'
  hylsa 'monterrey'
  hylsap 'puebla' /
```

When we create a GDX file and dump set i as CSV with defaults via the following commands

```
gamslib mexss
gams mexss a=c gdx=mexss
gdxdump mexss format=csv output=setI.csv symb=i header="steel_plants"
```

GDXDUMP creates the following output:

```
steel_plants
"ahmsa"
"fundidora"
"sicartsa"
"hylsa"
"hylsap"
```

If we add CSVSetText

```
gamslib mexss
gams mexss a=c gdx=mexss
gdxdump mexss format=csv output=setI.csv symb=i CSVSetText header="steel_plants,real_name"
```

GDXDUMP creates the following output:

```
steel_plants,real_name
"ahmsa","altos hornos - monclova"
"fundidora","monterrey"
"sicartsa","lazaro cardenas"
"hylsa","monterrey"
"hylsap","puebla"
```
5.21.4 Adding double Quotes to an user defined Header when writing to CSV

This sections describes a possible workaround for the following problem: Suppose one wish to write a parameter or variable from GDX to CSV, but with a non default header containing double quotes. For this purpose, one might try to use the header option of GDXDUMP to specify an user defined header. Though, there is no way to add double quotes enclosing the single fields using the header option, but this is a quite common standard in CSV files (for instance, if the fields contain reserved characters).

Initially, define the header you want to write to the CSV file and redirect the line to your final CSV file (which will be created at this point, an already existing file will be overwritten!). Note the double quotes enclosing the field content. Adding the single quotes is necessary in order to run the following statement from GAMS IDE (however, they will not be written to the file), while they must be omitted when using the command prompt.

$echo '"canning plants","markets","shipment quantities in cases"' > quotedHeader.csv

Afterwards, call GDXDUMP by specifying the GDX file, the single symbol x we want to write, the output format CSV and redirect the output to the file quotedHeader.csv:

$call gdxdump transport.gdx symb=x format=csv noHeader >> quotedHeader.csv

Appending the output of the recent GDXDUMP call to the already existing file quotedHeader.csv adds the data of x to the file and creates the following CSV file (note that one must prevent GDXDUMP to write the default header by using the command noHeader):

"canning plants","markets","shipment quantities in cases"
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275

5.22 GDXMERGE

The program GDXMERGE combines multiple GDX files into a single GDX file. Symbols with the same name, dimension and type are combined into a single symbol of a higher dimension. The added dimension has the file name of the combined file as its unique element.

5.22.1 Usage

gdxmerge filepattern1 filepattern2 .... filepatternN {options}

Each file pattern represents a file name or a wildcard representation using ? and *. A parameter of the form @filename will process the commands from the text file specified. The result of the GDXMERGE execution will be written to a file called merged.gdx, unless this default is overwritten by the output option.

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.
5.22 GDXMERGE

5.22.2 Options

The following options can be specified:

\[ \text{id} = <\text{ident1}>, <\text{ident2}>... \text{ (default = none)} \]

Only merge the symbols \text{ident1}, \text{ident2}, ...

\[ \text{exclude} = <\text{ident1}>, <\text{ident2}>... \text{ (default = none)} \]

Merge all symbols except for \text{ident1}, \text{ident2}', ...

\[ \text{big} = <\text{integer}> \]

The size for big symbols.

\[ \text{output} = \text{fileName} \text{ (default = merged.gdx)} \]

The optional output file name.

All symbols with matching type and dimension will be merged. By specifying the parameter \text{id}=<\text{ident1}>
the merge process will only be performed for the identifier(s) specified, while \text{exclude}=<\text{ident1}>
indicates that all symbols should be merged except for the ones specified in the \text{exclude} list. Note that the two options \text{id} and \text{exclude} are mutually exclusive.

By default, the program reads all GDX once and stores all data in memory before writing the merged.gdx file. The \text{big} parameter is used to specify a cutoff for symbols that will be written one at a time. Each symbol that exceeds the size will be processed by reading each GDX file and only process the data for that symbol. This can lead to reading the same GDX file many times, but it allows the merging of large data sets. The formula used to calculate the cutoff is:

\[ \text{dimension} \times \text{totalNumberOfElements}. \]

The calculated value is doubled for variables and equations.

In addition to the symbols written, a set is added to the GDX file representing all the files processed during the merge operation. The name of the set is \text{Merged_set_1}, and is made unique by changing the number. The explanatory text for each set element contains the date and time of the GDX file processed.

Note

- The file merged.gdx, or the file specified with the output parameter, will never be used in a merge operation even if the name matches a file pattern.
- Symbols with dimension 20 cannot be merged, because the resulting symbol will have dimension 21 which exceeds the maximum dimension allowed by GAMS.
5.22.3 Examples

5.22.3.1 Merging several GDX Files

In this example, we solve the \texttt{trnsport} model from the GAMS Model Library using different LP solvers. After each run, we write all symbols to a GDX file and merge the files into one file. The variable \texttt{X} is read from the merged file and displayed.

\begin{verbatim}
$call gamslib trnsport
$call gams trnsport lp=bdmlp gdx=bdmlp
$call gams trnsport lp=cplex gdx=cplex
$call gams trnsport lp=xpress gdx=xpress
$call gams trnsport lp=conopt gdx=conopt
$call gams trnsport lp=minos gdx=minos
$call gams trnsport lp=snopt gdx=snopt
$call gdxmerge *.gdx

Variable AllX(*,*,*);
$gdxIn merged.gdx
$load AllX=X
$gdxIn

option AllX:5:1:2;
display AllX.L;
\end{verbatim}

The display statement generates the following output in the listing file:

\begin{verbatim}
---- 22 VARIABLE AllX.L shipment quantities in cases

 seattle seattle san-diego san-diego
 new-york chicago new-york topeka

 bdmlp 50.00000 300.00000 275.00000 275.00000
 conopt 300.00000 325.00000 275.00000 275.00000
 cplex 50.00000 300.00000 275.00000 275.00000
 minos 50.00000 300.00000 275.00000 275.00000
 snopt 50.00000 300.00000 275.00000 275.00000
 xpress 300.00000 325.00000 275.00000 275.00000
\end{verbatim}

Note that the different solutions are combined into a single symbol of a higher dimension. The filenames (resp. the solver used) are added as unique elements.

Instead of using the display statement, we can also use the GAMS IDE or GAMS Studio to display the merged.gdx file. The following figure shows the contents of merged.gdx after selecting the level subfield of the variable to be displayed and arranging the display:

This example is also part of the GAMS Data Utilities Library, see model \texttt{GDXMERGEExample17} for reference.
5.23 GDXMRW

Interfacing GAMS and MATLAB. This document briefly describes GDXMRW (GDX-Matlab Read/Write), a suite of utilities to exchange data between GAMS and MATLAB. The software gives MATLAB users the ability to use all the optimization capabilities of GAMS, and allows visualization of GAMS models directly within MATLAB. The most recent version of GDXMRW is included as part of the current GAMS Distribution.

August 1, 2014:

5.23.1 Introduction

Optimization is becoming widely used in many application areas as can be evidenced by its appearance in software packages such as Excel and MATLAB. While the optimization tools in these packages are useful for small-scale nonlinear models (and to some extent for large linear models), the lack of a capability to compute automatic derivatives makes them impractical for large scale nonlinear optimization. In sharp contrast, modeling languages such as GAMS and AMPL have had such a capability for many years, and have been used in many practical large scale nonlinear applications.

On the other hand, while modeling languages have some capabilities for data manipulation and visualization (e.g., Rutherford’s GNUPLOT), specialized software tools like Excel and MATLAB are much better at these tasks.

This paper describes a link between GAMS and MATLAB. The aim of this link is two-fold. Firstly, it is intended to provide MATLAB users with a sophisticated nonlinear optimization capability. Secondly, the visualization tools of MATLAB are made available to a GAMS modeler in an easy and extendable manner so that optimization results can be viewed using any of the wide variety of plots and imaging capabilities that exist in MATLAB.

In order to enable this link between GAMS and MATLAB, we have implemented MATLAB callable functions that can efficiently import and export data to and from GAMS through GDX files. The simplest read and write functions, igdx and iwgd, deal with indexed parameters. Without getting into their precise meaning, these parameters are essentially indexed in each dimension by the sequence of integers from 1 to the size of that dimension. As an example of the read function, the following command in MATLAB will store the matrices A and B into the caller workspace after reading from the file foo1.gdx:

```matlab
>> irgdx('foo1','A','B');
```

Similarly, the call

```matlab
>> iwgd('foo2','C','D');
```
would write the matrices $C$ and $D$ (located in the MATLAB workspace) as indexed parameters into a file named \texttt{foo2.gdx}. Note that, many of the examples found in this manual are also part of the GAMS data utilities models library, referred to here as \texttt{datalib}. The statements above can be found in datalib example \texttt{gdxmrw_intro02_init}. For reading and writing more complex data such as sets, variables, equations, and non-indexed parameters, we can use the more sophisticated functions \texttt{rgdx} and \texttt{wdgx}. Further descriptions of these functions together with advanced use of \texttt{irgdx} and \texttt{iwgdx} are detailed in the rest of this paper.

In Section \textbf{Data Transfer}, we discuss the data transfer utilities that allow importing and exporting data between MATLAB and GDX files: \texttt{irgdx}, \texttt{iwgdx}, \texttt{rgdx}, \texttt{wdgx}. In Section \textbf{Extended use}, we give a few examples of the MATLAB and GAMS interface. In \textsc{APPENDIX A - Configuring GDXMRW}, we provide information about configuring GDXMRW and testing the utilities. In \textsc{APPENDIX B - Utility functions: gdxWhos and gdxInfo}, we describe additional utility functions, \texttt{gdxWhos} and \texttt{gdxInfo}, that allow viewing contents of GDX files in the MATLAB console. Finally, in \textsc{APPENDIX C - Calling GAMS model from MATLAB,} we discuss the \texttt{gams} function that with a single call initializes a GAMS model with MATLAB data, executes GAMS on the model, and returns results back into MATLAB.

### 5.23.2 Data Transfer

This paper describes a suite of tools for exchanging data between GAMS and MATLAB. This data exchange is accomplished via the GDX (i.e. the GAMS Data eXchange) interface and API. There are many advantages to using GDX, including platform independence, space and time efficiency in storing and accessing data, and a guarantee that all GDX data contains no duplicates and is free from any logical or syntax errors that might prevent it from being read into GAMS. The GDX interface is well tested, available to the public, and is the basis for most if not all of the GAMS data utilities.

In this section we discuss four MATLAB routines. The first two, \texttt{irgdx} and \texttt{iwgdx}, are the subject of sections \texttt{irgdx} and \texttt{iwgdx} and are used to quickly and simply read indexed parameters from a GDX file into MATLAB and vice versa. For an example use of these functions, a generic quadratic program function that mimics MATLAB's \texttt{quadprog} function is provided in datalib example \texttt{gdxmrw_qp3}. The \texttt{rgdx} and \texttt{wdgx} routines (sections \texttt{rgdx} and \texttt{wdgx}) are more sophisticated versions of the first two that can read and write more general GDX data, e.g. sets, variables, equations, and non-indexed parameters. To understand the structure of this GDX data, the material in section \textbf{Indexing with labels (UELs)} is essential.

#### 5.23.2.1 irgdx

\texttt{irgdx} is a specialized MATLAB function to do an efficient import of an indexed parameter from a GDX file. The \texttt{irgdx} call will not read non-indexed parameters; it can only read data recognized as an indexed data type. If a GDX file consists of both indexed and non-indexed data, \texttt{irgdx} can still read the indexed data. To see whether particular parameters in a GDX file are indexed, the \texttt{gdxWhos} function described in \textsc{APPENDIX B - Utility functions: gdxWhos and gdxInfo} can be used.

The syntax and functionality of \texttt{irgdx} closely resembles that of the MATLAB \texttt{load} function to import MATLAB formatted data, i.e data stored in MAT files. In \textbf{Basic syntax} and \textbf{Load symbols into output structure} we describe the basic modes of operation where the data read from GDX are either stored in the caller workspace or into a MATLAB structure on the left-hand side of an assignment. In \textbf{MATLAB sparse form}, we describe an optional specification that allows read results to be stored in MATLAB sparse form. Finally, in Subsection \textbf{Renaming}, we describe a simple syntax that allows the renaming of variables/parameters without the need to make expensive copies.
5.23.2.1.1 Basic syntax The basic syntax for \texttt{irgdx} is

\begin{verbatim}
irgdx('gdxFileName', 'sym1', 'sym2', ...);
\end{verbatim}

The above call will read the indexed parameters named \texttt{sym1}, \texttt{sym2}, and so on from the GDX file whose name is specified in the first argument and store the results in the MATLAB caller workspace. Only the GDX name argument is mandatory. If only this argument is specified (i.e. no symbol names are provided) then \texttt{all} of the indexed parameters stored in the GDX file will be loaded into the workspace. The GDX name can be specified with or without the \\
'.gdx' extension. Note that all of the input arguments must be specified in string form.

As an example of the above syntax, we can read the scalar \texttt{a0}, the vector \texttt{a1}, and the matrix \texttt{a2} from the file \texttt{idx1.gdx} with the following command:

\begin{verbatim}
>> irgdx('idx1_','a0','a1','a2');
\end{verbatim}

The three symbols are stored as MATLAB variables \texttt{a0}, \texttt{a1}, and \texttt{a2} in the caller workspace. If we want to read all the symbols from the file \texttt{idx1.gdx}, we simply call \texttt{irgdx} with only the file name:

\begin{verbatim}
>> irgdx('idx1_');
\end{verbatim}

5.23.2.1.2 Load symbols into output structure An alternative to storing the results in the MATLAB caller workspace is to return the results in a MATLAB structure. Here, the syntax is:

\begin{verbatim}
s = irgdx('gdxFileName', 'sym1', 'sym2', ...);
\end{verbatim}

This call will return the indexed parameters named \texttt{sym1}, \texttt{sym2}, and so on in the structure \texttt{s}, with fields \texttt{s.sym1}, \texttt{s.sym2}, and so on containing the values of the respective indexed parameters. The input arguments must all be in string form. Only the GDX name is mandatory; if only this argument is specified, all of the indexed parameters stored in the GDX file will be returned in the output structure. The GDX name can be specified with or without the \\
'.gdx' extension.

For example, the following call returns the values of parameter \texttt{a2} in the structure \texttt{s}:

\begin{verbatim}
>> s = irgdx('idx1_','a2');
>> s.a2
\end{verbatim}

\begin{verbatim}
ans =
50  50
50  50
\end{verbatim}

To return all the indexed parameters in the fields of the structure \texttt{s}, we would simply call \texttt{irgdx} with only the GDX name:

\begin{verbatim}
>> s = irgdx('idx1_');
\end{verbatim}

See datalib example \texttt{gdxmrw_irgdx01_init}.  

5.23.2.1.3 MATLAB sparse form  By default, irgdx will store results in MATLAB dense form. However, it is possible to use MATLAB sparse form for parameters with dimension less than or equal to 2; MATLAB's sparse storage scheme cannot handle matrices with more than 2 dimensions. Using sparse storage will allow for efficient import of especially large sparse indexed parameters. Note that in this context sparse does not refer to data represented in the form [i,j,...,val] but rather to MATLAB's internal sparse storage scheme. To store a particular symbol in MATLAB sparse form, one can simply append 's' to that symbol's name in the irgdx call. For example, the following call will store the parameter a2 into the caller's workspace in sparse form:

```
>> irgdx('idx1_','a2:s');
```

Note that if we want to store all the indexed parameters from a specified file in MATLAB sparse form, we would need to specify each symbol individually in order to append the 's' to each symbol's name.

5.23.2.1.4 Renaming  The details of this section are rather involved; it can be skipped without loss of continuity.

While an irgdx call will typically store results in the caller workspace or create field names in the output structure using the symbol names from the GDX file, it is possible to rename the outputs in MATLAB without making potentially expensive copies. To rename a symbol, we can take advantage of MATLAB's default copy-on-write mechanism: when an assignment occurs, the values assigned are not actually copied until one of the values (the original or the copy) is actually changed. For example, after executing the following two lines of code, the variable a2_new points to the same memory location as a2 and is not a separate copy of a2:

```
>> irgdx('idx1_','a2');
>> a2_new = a2;
```

If however the value of a2_new were changed after executing the above lines, MATLAB would then need to make a separate copy, at the cost of memory and time. Now, the command

```
>> clear a2;
```

immediately following the above code would complete the rename of a2 to a2_new as desired. Once a2 is cleared, we can change a2_new without needing to make a copy. Similarly, we can do a rename when we have an output structure:

```
>> s = irgdx('idx1_','a2');
>> s.a2_new = s.a2;
>> s = rmfield(s,'a2');
```

To convince ourselves that this code indeed does not require a copy, we can run the commands in the debug output format. That is, immediately after the assignment of s.a2 to s.a2_new in the above code (before using the rmfield function), we can run the following commands:

```
>> format debug;
>> s.a2
ans =
```

```
Structure address = 8c1eda0
```
Note that the pointer pr is the same for both outputs, implying that MATLAB does not make a separate copy prior to a write. A similar test can also be done when parameters are stored in workspace variables rather than a structure.

5.23.2.2 iwgdx

iwgdx is a function that creates a GDX file of indexed parameters from MATLAB data. Since iwgdx writes only indexed parameters to GDX, the input MATLAB data is simplified: no labels are required or implied. The input matrices can be stored in the usual (dense) scheme or using the MATLAB sparse scheme: iwgdx detects and handles the two cases automatically. Note that matrices represented in \([i,j,...,val]\) form are not acceptable as iwgdx input.

While the iwgdx function is patterned after the save function in MATLAB, there are important differences. Firstly, if only the file name is specified, the save function stores all variables in the caller workspace, while iwgdx creates an empty GDX file. The behavior of iwgdx in this case also differs from that of irgdx, which reads all parameters when only the file name is specified. Secondly, iwgdx has an additional pass by reference and renaming syntax, in which the parameter string name and values are passed as two consecutive arguments. In Subsection Basic syntax, we describe the basic syntax for iwgdx. In Subsection Pass by reference syntax, we introduce the pass by reference and renaming syntax. Finally, in Subsection Dimensionality specification, we describe an optional dimensionality specification that allows symbols to be written with a larger dimensionality than the default.

5.23.2.2.1 Basic syntax

The basic syntax for iwgdx is:

\[
iwgdx('fileName','sym1','sym2',...);
\]

The above call will write the values of the variables sym1, sym2, and so on in the MATLAB caller workspace into a GDX file with the name given by the first input argument. The file name can be specified with or without the '.gdx' extension. If a GDX file with the same name already exists, it will be overwritten. Note that a call with a single input argument (the GDX name) will raise a warning and will create an empty GDX file. This contrasts to the MATLAB save function, which writes all of the workspace variables when none are specified. In the basic form described here, all of the iwgdx input arguments are strings.

To illustrate, suppose the matrices a2 and a3 exist in the MATLAB caller workspace. We can write the results of these matrices into a file test.gdx with the following call:
If the file test.gdx already exists, it will be overwritten. Specifying only the file name will create an empty GDX file:

```matlab
>> iwgdx('test');
Warning: an empty gdx file was created.
```

### 5.23.2.2.2 Pass by reference syntax

When using the basic `iwgdx` syntax, a copy of the workspace variable to be written to GDX is made as part of the call. This is unavoidable: the MATLAB executable (MEX) interface only provides functions that return copies of workspace variables, most likely to avoid overwriting or corrupting data. However, an alternative, more efficient approach is possible by passing the numeric data as an argument. Essentially, the pointer to the data values are passed by reference and no copy is made. This could be especially useful when writing a large amount of data. An additional benefit of this syntax is the ability to write GDX parameters with different names than used in the MATLAB caller workspace. For example:

```matlab
>> iwgdx('test','s1',s1Mat,'s2',s2Mat);
```

In the above command, `s1` and `s2` are strings holding the GDX parameter names, while `s1Mat` and `s2Mat` are matrices containing the values to store. We can also use a mix of the basic syntax with the pass by reference syntax. For example:

```matlab
>> iwgdx('test','anew',a,'b','c',c);
```

This call would save matrix `a` as anew in GDX without making a copy, would internally make a copy of `b` while saving `b` to GDX, and would save `c` to GDX without renaming or making a copy.

We can do a timing test to see the performance difference between the basic syntax and the pass by reference syntax. The following commands create a 5000x5000 dense matrix consisting of random values in the workspace.

```matlab
>> clear;
>> randMat = rand(5000);
```

First, we do a timing test using the basic syntax:

```matlab
>> delete test.gdx; % delete file if it exists
>> tic;
>> iwgdx('test','randMat');
>> t1 = toc
```

```matlab
t1 =
      5.3346
```

Now, we do a timing test using the pass by reference syntax:

```matlab
>> delete test.gdx; % delete file if it exists
>> tic;
>> iwgdx('test','randMat',randMat);
>> t2 = toc
```

```matlab
t2 =
      5.1636
```

For the above example, the improvement in time performance is about 3%. Of course, the pass by reference call will also use only the half the memory compared to the basic call. We can expect further improvement in performance time and memory use for even larger data.
5.23.2.2.3 Dimensionality specification

It is possible to specify the number of dimensions (i.e., dimensionality) for the symbol written to GDX by appending ":n" to the variable/symbol name, where n is the desired dimensionality of the GDX symbol. This feature is motivated by two quirks of the MATLAB environment. Firstly, all scalars and vectors are stored in MATLAB as 2-dimensional matrices. For example:

```matlab
>> s0 = 100
>> s1 = [ 100 ]
```

results in two variables with identical storage schemes: 1x1 matrices. In the MATLAB environment this isn't a problem: things behave as you would expect them to, and the `isscalar`, `isvector`, and `ismatrix` calls are available to interrogate MATLAB about how it views variables. However, in GDX there is a distinction between a scalar (something with 0 dimensions), a parameter with 1 dimension and length 1, and a 1x1 parameter. We need to be able to create GDX files containing any or all of these.

Secondly, MATLAB "flattens" all variables by removing trailing dimensions whose size is 1. For example, after executing

```matlab
>> B = ones(2,2,2)
>> C = ones(2,2,2,1,1)
```

B and C will be identical 3-dimensional MATLAB arrays, yet we need to be able to create a 2x2x2x1x1 indexed parameter in GDX.

By default, `iwgdx` creates GDX parameters that are consistent with the MATLAB view of the data passed in. For example, executing

```matlab
>> d0 = ones(1,1)
>> d1 = ones(3,1)
>> d2 = ones(3,3)
>> iwgdx('dd','d0','d1','d2')
```

results in indexed parameters with 0, 1, and 2 dimensions, respectively, being written to GDX. However, if we want to write d0 as a vector or matrix or higher-dimensional array, we need to use the optional syntax to specify the dimensionality of the resulting symbol in GDX. For example:

```matlab
>> d0 = pi;
>> p1 = d0;
>> d1 = pi*ones(3,1);
>> p2 = d1;
>> d2 = pi*ones(3,3,1)
>> iwgdx('pp','d0','p1:1','d1','p2:2','d2','p3:3',d2)
```

will write the following symbols to GDX:

- The 0-dimensional symbol `d0`. This is the default behavior, consistent with the MATLAB view that `d0` is a scalar.
- The 1-dimensional symbol `p1`. The scalar variable `p1` was promoted to a 1-dimensional symbol by adding an additional singleton dimension.
- The 1-dimensional symbol `d1`. This is the default behavior, consistent with the MATLAB view that `d1` is a vector.
• The 2-dimensional symbol \( p_2 \). The vector variable \( p_2 \) was promoted to a 2-dimensional symbol by adding an additional singleton dimension.

• The 2-dimensional symbol \( d_2 \). This is the default behavior, consistent with the MATLAB view that \( d_2 \) is a matrix, i.e. the final singleton dimension is just removed.

• The 3-dimensional symbol \( p_3 \). The matrix variable \( d_2 \) was promoted to a 3-dimensional symbol by adding an additional singleton dimension. Independently, call-by-reference was used to rename \( d_2 \) to \( p_3 \).

Note that the dimensionality specified must always be a promotion, i.e. the dimensionality of the resulting GDX symbol is only increased from what it would be by default.

See datalib example gdxmrw_iwgdx01_init.

### 5.23.2.3 Indexing with labels (UELs)

To this point we have been looking at functions to read (irgdx, Section irgdx) and write (iwgdx, Section iwgdx) indexed parameters from and to GDX. Indexed parameters are convenient since their structure is essentially identical to that of MATLAB matrices. This structure can be encapsulated very simply as the number of dimensions and the size or extent of each dimension. Using indexed parameters, we do not need to be very concerned with the structure of the data since little structure exists. However, there is much more to GDX data than indexed parameters. If we want to read and write GDX data in more generality we will need to understand how labels or strings are used to reference GDX data and how these labels are organized within GDX.

In general, GAMS data is referenced with labels instead of with numbers, so that one references \( \text{demand('chicago')} \) instead of \( \text{demand(2)} \) in a GAMS model. These labels are also called Unique Element Labels, or UELs. The collection of UELs used in a model or in a GDX file is ordered internally and often referred to as the universe of UELs. For efficiency, it is not necessary to use labels internally in GDX or when using the GDX API. Instead, a correspondence or mapping between integers and labels is established initially and/or built up as labels are introduced, so that integers can be used in place of the UELs that reference the data. It is important to keep in mind that the labels are the key thing in referencing GDX data: when integer maps are used the integers are only used to efficiently represent the labels.

A similar scheme mapping integers to labels is used in the rgdx and wgdx routines for reading and writing general GDX data. In addition to the actual data values being stored, there will be a mapping passed to allow integers to be mapped to labels and vice versa. In some cases, where no mapping is passed and data are written to GDX, a default mapping (1 to ‘1’, 2 to ‘2’, etc.) may be used. When reading, the default mapping to use when passing back data is the universe mapping from the GDX, but it is possible to apply a filter. A filter can reduce the amount of data returned and also change the order of that data.

### 5.23.2.4 rgdx

\( \text{rgdx} \) is a MATLAB utility to import data from a GDX file. It takes structural input and returns data back in the form of a structure. This is a very flexible routine as it gives user control over the output data structure. \( \text{rgdx} \) can read a set/parameter/equation/variable from a GDX file and display results in either full/dense or sparse form. A user can also perform a filtered read to read only certain specific elements of a symbol. It can also perform compression to remove extra zeros.

This routine can take up to two arguments. The first argument is a string input containing the GDX file name. It can be with or without the ‘.gdx’ file extension. If you call this routine with only the GDX file name as an argument then the ‘uels’ field of output structure will be the global UEL of the GDX file and the rest of the fields of the output structure will be NULL. The second argument is a structure input containing information regarding the desired symbol. The syntax for this call looks like this:
\[ x = \text{rgdx('fileName', structure);} \]

As an example, we read a 3D parameter, 'test3' from 'sample.gdx'. Here we display this parameter in full format but without redundant zeros:

\[
\begin{align*}
\text{>> s.name} & = \text{'test3';} \\
\text{>> s.form} & = \text{'full';} \\
\text{>> s.compress} & = \text{true;} \\
\text{>> x} & = \text{rgdx('sample', s)} \\
\end{align*}
\]

\[
\text{x =}
\begin{align*}
\text{name: 'test3'} \\
\text{type: 'parameter'} \\
\text{dim: 3} \\
\text{val: [4x2x2 double]} \\
\text{form: 'full'} \\
\text{uels: {{1x4 cell} {1x2 cell} {1x2 cell}}} \\
\end{align*}
\]

\[
\begin{align*}
\text{>> x.val}
\text{ans(:,:,1) =}
\begin{bmatrix}
3 & 4 \\
4 & 5 \\
5 & 6 \\
6 & 7
\end{bmatrix} \\
\text{ans(:,:,2) =}
\begin{bmatrix}
4 & 5 \\
5 & 6 \\
6 & 7 \\
7 & 8
\end{bmatrix}
\end{align*}
\]

\[
\begin{align*}
\text{>> x.uels{1}}
\text{ans =}
\begin{bmatrix}
'1' & '2' & '3' & '4'
\end{bmatrix}
\end{align*}
\]

\[
\begin{align*}
\text{>> x.uels{2}}
\text{ans =}
\begin{bmatrix}
'j1' & 'j2'
\end{bmatrix}
\end{align*}
\]

\[
\begin{align*}
\text{>> x.uels{3}}
\text{ans =}
\begin{bmatrix}
'k1' & 'k2'
\end{bmatrix}
\end{align*}
\]

In the following subsections we will explain the input and output structures. Please note that except for the 'name' and 'uels' fields, all other string fields take case insensitive input. All boolean fields can also be entered as string values as well.
5.23.2.4.1 **Input structure**  To read a symbol from a GDX file we just need to know its name in string format. Thus, the only mandatory field of the input structure is 'name'. e.g.

```matlab
>> s.name = 'test3';
```

There are several other optional fields of the input structure that give user more control over the output structure. These optional fields are as follows:

1. **form**  
   This field represents the form of the output data. Output data can be either in 'full' or 'dense' form or it can be in \([i, j,\ldots, val]\) sparse form. We will label \([i, j,\ldots, val]\) as 'sparse'. A user can enter it as string input with value 'full' or 'sparse'. e.g.

```matlab
>> s.form = 'full';
```

By default the data will be in 'sparse' format. Note that this sparse format differs from MATLAB's internal sparse storage scheme that we referred to in prior sections for the \(ir\text{gdx}\) and \(i\text{w}\text{gdx}\) functions.

2. **compress**  
   By default the uels in the output structure will be a global UEL of the GDX file and the 'val' field data will be indexed to this UEL. The \(rg\text{d}x\) routine allows a user to remove rows and columns with all zeros from the 'val' data matrix and re-indexes the uels accordingly. This is called compression of the data. This can be achieved by setting compress as true in the input structure. Valid values for this field are true and false, either in logical form or in string form. e.g.

```matlab
>> s.compress = 'true';
```

However, we note that compressing the data can be dangerous because the size of the matrix that is read can be incorrect. Essentially, all zero rows and columns are removed, including those that might actually be part of the data values in the symbol matrix.

3. **uels**  
   This input field is used to perform a filtered read, i.e. output data matrix will contain values only corresponding to the entered uels. Filtered read is very useful if user just wants certain specific set of data. Uels should be entered in cell array form. It has to be in 1xN form with each column being a cell array representing the uels for that dimension. Each column can have strings, doubles or combinations of both. It also allows a user to enter double data in shorthand notation or a 1 x N matrix. For example, in the previous example we can perform a filtered read to get data corresponding to only the '1&prime', '3' elements of the first index of the parameter 'test3'. The following function is handy when one needs to generate a UEL listing for the input structure:

```matlab
>> guel = @(s,v) strcat(s,strsplit(num2str(v)));
```

Using the above function, we can create a listing of strings consisting of the string s appended to each number in the array v. Thus, instead of using the command

```matlab
>> s.uels = {{'1','3'},{'j1','j2'},{'k1','k2'}};
```

we can conveniently use the command

```matlab
>> s.uels = {guel('',[1,3]),guel('j',1:2),guel('k',1:2)};
```

The benefit of using the latter command will be more apparent when creating many elements in the listing. Now, as an example, suppose we would like to do a filtered read on the parameter called `test2` in `sample.gdx`. We could use the following commands:
```matlab
>> s.name = 'test3';
>> s.form = 'full';
>> s.compress = false;
>> s.uels = {guel('',[1,3]),guel('j',1:2),guel('k',1:2)};
>> x = rgdx('sample',s)

x =

    name: 'test3'
    type: 'parameter'
    dim: 3
    val: [2x2x2 double]
    form: 'full'
    uels: {{1x2 cell} {1x2 cell} {1x2 cell}}

>> x.val

ans(:,:,1) =

    3   4
    5   6

ans(:,:,2) =

    4   5
    6   7

Here it should be noted that we turned off compression while performing the filtered read. This is necessary because the filtered read will give data in accordance with the entered uels and the output uels will be the same as the input uels; thus compression is not possible.

4. field
This field is required when variables or equations are to be read from a GDX file. Sets and parameters in the GDX file do not have any field value but variables and equations have 5 fields namely, level, marginal, lower, upper, and scale. Thus, it may be useful to enter field as an input when reading an equation or a variable. A user can enter it as a string with valid values being 'l/m/up/lo/s'. e.g.

```matlab
>> s.field = 'm';
```

By default, the output will be the level value of a variable or an equation.

5. ts
This represents the text string associated with the symbol in the GDX file. If a user sets this field to be 'true', then the output structure will have one more string field 'ts' that contains the text string of the symbol. e.g.

```matlab
>> s.ts = true;
```

6. te
GAMS allows a modeler to enter text elements for a set. Similarly to the 'ts' field, if a user sets 'te' to be true in the input structure, then the output structure will contain one more field representing the text elements for that symbol. Please note that text elements only exist for 'sets'. e.g.

```matlab
>> s.te = true;
```
5.23.2.4.2 Output Structure  As mentioned earlier, output of the `rgdx` routine will be in structure form. This structure is very similar to the input structure. To get information regarding any symbol, we always need to display its basic characteristics, such as its name, type, value, uels, form, etc. An output structure will always have these fields:

1. name
   It is same as that entered in the input structure name field, i.e., the symbol name in the GDX file.

2. val
   It represents the value matrix of the symbol. To save MATLAB memory by default it will be in 'sparse' format. e.g.
   ```
   >> s = rmfield(s, 'form');
   >> s
   s =
   name: 'test3'
   compress: 0
   >> x = rgdx('sample', s)
   x =
   name: 'test3'
   type: 'parameter'
   dim: 3
   val: [16x4 double]
   form: 'sparse'
   uels: {{1x8 cell} {1x8 cell} {1x8 cell}}
   ```
   Here `val` is a 16x4 double matrix. As it is a parameter; thus the last column of the sparse matrix will represent the value and the rest (i.e. the first three columns) will represent its index. Please note that in the case of a 'set', the number of columns in the sparse matrix will be equal to its dimension, i.e., it will not have a column representing its value. Here, the presence of each row in the output 'val' field corresponds to the existence of a set element at that index. When a 'full' matrix output is specified, a 1 represents existence of a set element and a 0 otherwise.

3. form
   It represents the format in which the 'val' field is being displayed. As mentioned earlier it can be either in 'full' or 'sparse' form.

4. type
   While reading a symbol from a GDX file it is often very useful to know its type. The `rgdx` routine is designed to read set, parameter, variable and equation. This field will store this information as a string.

5. uels
   This represents the unique element listing of the requested symbol in the form of a cell array. It is a 1 x N cell array, where N is the dimension of the symbol. Each column of this array consists of string elements. By default, the output uels will be the same as the global uel of the GDX file, but it can be reduced to element specific local uels if `compress` is set to be true in the input structure. If a user is using a filtered read, i.e. calling `rgdx` with input uels, then the output uels will be essentially the same as the input uels.

6. dim
   It is a scalar value representing the dimension of the symbol.

   Apart from these necessary fields there are a few additional fields as well. They are as follows:

7. field
   If we are reading variables or equations, then it becomes useful to know which field we have read, i.e., l/m/up/lo/s. This information is displayed via this field in the form of a string.
8. ts
   It display the explanatory text string associated with the symbol. This field only exists in the output
   structure if the 'ts' field is set as 'true' in the input structure.

9. te
   It is an N dimensional cell array representing the text elements associated with each index of the set.
   This field only exists in the output structure if the 'te' field is set as true in the input structure
   and the symbol is a set.

See datalib example gdxmrw_rgdx01_init.

5.23.2.5 wgdx

wgdx is a MATLAB routine to create a GDX file containing data from MATLAB. Similar to the rgdx
routine, it takes a structure input and can write multiple symbols into a single GDX file with one call.
The first argument is the file name of the GDX file to be created in string format; it can be with or
without the '.gdx' file extension. The rest of the arguments are structures, each containing data for
different symbols to be written into the GDX file. The syntax for the call is:

```matlab
>> wgdx('fileName', s1, s2 ...);
```

If the GDX file already exists in the MATLAB current directory, wgdx will overwrite it; otherwise a new
file will be created. After a successful run, it doesn't return anything back into MATLAB. Most of the
fields of its input structures are the same as those of the rgdx output structure. In the example below, we
use the wgdx routine to create foo.gdx containing a set 'l' and a parameter 'par'.

```matlab
>> s.name = 'l';
>> s.uels = {{'i1', 'i2', 'i3'}, {'j1', 'j2'}};
>> c.name = 'par';
>> c.type = 'parameter';
>> c.val = eye(3);
>> c.form = 'full';
>> c.ts = '3 x 3 identity';
>> wgdx('foo', s, c)
```

The equivalent code in GAMS to create the above set 'l' is:

```gams
Set
   a / i1*i3 /
   b / j1*j2 /
   l(a,b);
   l(a,b) = yes;
```

In the next subsection we will explain the input fields in detail.
5.23.2.5.1 Input Structure  The necessary fields in an input structure to represent a symbol are given below:

1. name
   It is a string representing the name of the symbol.

2. val
   It represents the value matrix of the parameter or set. It can be entered in either full or sparse format, whichever is convenient to the user; the corresponding format must be specified in the 'form' field. By default the value matrix is assumed to be in sparse format.

3. type
   It is a string input to specify the type of the symbol. The \texttt{wgdx} routine can write a set or parameter into the GDX file. In the previous example, we didn’t specify the type for structure ‘s’ because by default it is assumed to be a set.

4. form
   This is a string input representing the format in which the val matrix has been entered. By default it is assumed that the data is specified in sparse format.

5. uels
   Similar to the \texttt{rgdx} uels field, this represents the local unique element listing of the symbol in an 1 x N cell array form. Each column of this cell array can contain string or double or both. Again we can make use of a handy function to create a UEL listing as mentioned previously in the section about \texttt{rgdx}:

   \begin{verbatim}
   >> guel = @(s,v) strcat(s,strsplit(num2str(v)));
   \end{verbatim}

   As an example, we create a set using this function and the \texttt{wgdx} routine:

   \begin{verbatim}
   >> s.name = 'l';
   >> s.uels = {guel('i',1:20),guel('j',1:40)};
   >> wgdx('foo',s);
   \end{verbatim}

   The above code will create \texttt{foo.gdx} that contains a 2 dimensional set ‘l’ with set elements for each of the specified uels. If a user would like to create a set with set elements only at specified indices, one could do so by entering the indices in the val field. e.g.

   \begin{verbatim}
   >> s.val = [1, 1; 2, 1; 3, 6; 4, 7];
   >> wgdx('foo',s);
   \end{verbatim}

   Now the above would result in a set with only elements existing in the indices specified in the val field. If a user enters a structure with only two fields, name and uels, as in the example given in the introduction of this section (structure s), then \texttt{wgdx} will create a full set corresponding to the global uels.

   The optional fields are:

6. dim
   This field is useful when a user wants to write a zero dimensional or 1 dimensional data in full format. As every data matrix in MATLAB is at least 2D, it becomes necessary to indicate its dimension for writing purposes.

7. ts
   This is the text string that goes with the symbol. If nothing is entered then 'MATLAB data from GDXMRW' will be written in the GDX file.

See datalib example gdxmrw wgdx01 init.
5.23.3 Extended use

In this section, we will discuss a few examples of the MATLAB and GAMS interface. We will give a
simple example of a nonlinear optimization problem that would benefit from this capability and describe
the steps that are needed in order to use our interface in this application.

- Special values
  Following example shows how special values are handled by this interface. It can be seen that rgdx
can retrieve all these values from GDX file and display them appropriately in MATLAB.

```matlab
>> s.name = 'special';
>> s.form = 'full';
>> s.compress = true;
>> x = rgdx('sample', s)

x =
  name: 'special'
  type: 'parameter'
  dim: 1
  val: [4x1 double]
  form: 'full'
  uels: {{1x4 cell}}

>> x.val

ans =
-Inf
NaN
3.141592653589793
Inf
```

- Variables and Equations
  In an optimization problem, we are not only interested in level value of variables and equations but
also in their marginal values, lower and upper bounds. This interface gives its user ability to read
any of these values into MATLAB. By default rgdx and gams routines will read the level value of
equations and variables but this can be changed very easily by using 'field' in input structure. In
gams call user can also specify this in '$set matout' statement. e.g.

```gams
$set matout "'matsol.gdx', x.m, dual.lo=dl ";
```

In this case the marginal value of variable 'x' will be read and lower bound of dual variable will be
read and stored in 'dl'.

- Text string and Text elements
  GAMS allows its user to enter text string and explanatory text elements and all GDX file contain
this information as well. Following example shows how to get these text elements in MATLAB.

```matlab
>> s1.name = 'el';
>> s1.te = true;
>> s1.ts = true;
>> s1.compress = true

s1 =
  name: 'el'
  te: 1
```
ts: 1
compress: 1

>> z = rgdx('sample', s1)

z =
    name: 'el'
    type: 'set'
    dim: 2
    val: [3x2 double]
    form: 'sparse'
    uels: {{1x2 cell} {1x2 cell}}
    ts: 'This is 2D set with text elements'
    te: {2x2 cell}

>> z.te
ans =
    'element1'    'element2'
    '2.j1'        []

>> z.val
ans =
    1  1
    1  2
    2  1

• String elements

One piece of information that may be needed within MATLAB is the modelstat and solvestat values generated by GAMS for the solves that it performed. This is easy to generate, and an example is given in do_status.m. This example is generated by taking the standard gamslib trnsport example, and adding the following lines to the end:

$set matout "matsol.gdx', returnStat, str ";

Set
    stat / modelstat, solvestat /
    str / 'grunt', '%system.title%' /;

Parameter returnStat(stat);
returnStat('modelstat') = transport.modelstat;
returnStat('solvestat') = transport.solvestat;
execute_unload %matout%

Note that the relevant status numbers are stored in GAMS into the parameter returnStat which is then written to matsol.gdx and read back into MATLAB using the rgdx call.

>> gamso.output = 'std';
>> gamso.form = 'full';
>> gamso.compress = true;
>> s = gams('trnsport')

s =
    1
    1
Advanced Use: Plotting

One of the key features of the GAMS/MATLAB interface is the ability to visualize optimization results obtained via GAMS within MATLAB. Some simple examples are contained with the program distribution. For example, a simple two dimensional plot with four lines can be carried out as follows. First create the data in GAMS and export it to MATLAB using the `gams` routine (see APPENDIX C - Calling GAMS model from MATLAB for a detailed description of this routine).

We make an assumption that the user will write the plotting routines in the MATLAB environment. To create the plot in MATLAB, the following sequence of MATLAB commands should be input (saved as `do_plot.m`).

```matlab
% The data is created using the following gams code.

$title Examples for plotting routines via MATLAB

$set matout "'matsol.gdx', a, t, j, sys ";

Set
    sys / 'system.title' /
    t / 1990*2030 /
    j / a, b, c, d /

Parameter a(t,j);
a("1990",j) = 1;

loop(t, a(t+1,j) = a(t,j)*(1 + 0.04*uniform(0.2,1.8)););

Parameter year(*);
year(t) = 1989 + ord(t);

* Omit some data in the middle of the graph:
a(t,j)$((year(t) > 1995)*(year(t) <= 2002)) = na;

execute_unload %matout%
```

The following figure is an example created using this utility (and the MATLAB command `print -djpeg simple`).
See datalib example GDXMRWPlotting01.

MATLAB supports extensive hard copy output or formats to transfer data to another application. For example, the clipboard can be used to transfer meta files in the PC environment, or encapsulated postscript files can be generated. The help print command in MATLAB details the possibilities on the current computing platform.

Scaling of pictures is also most effectively carried out in the MATLAB environment. The following code is an example of rescaling printed out. Note that the output of this routine is saved as a jpeg file "rescale.jpg".

```matlab
do_plot;
fpunits = get(gcf,'PaperUnits');
set(gcf,'PaperUnits','inches');
figpos = get(gcf,'Position');
pappos = get(gcf,'PaperPosition');
newpappos(1) = 0.25;
newpappos(2) = 0.25;
newpappos(3) = 4.0;
newpappos(4) = newpappos(3)*figpos(4)/figpos(3);
set(gcf,'PaperPosition',newpappos);
print -djpeg100 rescale.jpg
set(gcf,'PaperPosition',pappos);
set(gcf,'PaperUnits',fpunits);
```

Other examples of uses of the utility outlined in this paper can be found in the "m" files:

```matlab
do_ebl
plotngon
```

that are contained in the distribution.

5.23.4 Acknowledgements

The authors would like to thank Alexander Meeraus and Michael R. Bussieck of GAMS corporation for constructive comments on the design and improvement of this tool. Thanks to Rishabh Jain for work on an earlier version.

5.23.5 APPENDIX A - Configuring GDXMRW

5.23.5.1 Installation

This section describes the installation procedure for all types of machines. The following section describes the testing procedure for verifying a correct installation.

First of all, you need to install both MATLAB and GAMS on your machine. For brevity, we will assume that the GAMS system (installation) directory is (for Windows)

c:\GAMS
and for non-Windows systems:

/usr/local/gams

All of the utilities come as a part of the GAMS distribution, so to use them you have only to add the GAMS directory to the MATLAB path. One way to do this is from the MATLAB command prompt, as follows:

>> addpath 'C:GAMS'; savepath;

OR this can be done by following these steps:

1. Start MATLAB
2. Click on 'File' tab.
3. Now click on 'Set Path'
4. Click on 'Add Folder'
5. Select GAMS directory and click 'OK'.
6. Save it and then close it.

5.23.5.2 Testing

The GAMS system comes with some tests that you should run to verify the correct configuration and operation of the GDXMRW utilities. In addition, these tests create a log file that can be useful when things don't work as expected. To run the tests, carry out the following steps.

1. Create a directory to run the tests in, e.g.

   % mkdir \tmp

2. Extract the test models and supporting files from the GAMS test library into the test directory.

   % cd \tmp
   % testlib gdxmrw03
   % testlib gdxmrw04
   % testlib gdxmrw05
   % testlib gdxmrw06

3. Execute the GAMS files gdxmrw03, gdxmrw04, and gdxmrw06. The files gdxmrw03 and gdxmrw04 test that the rgdx and wgdx routines are working properly, and gdxmrw06 test irgdx and iwgdx. In addition to calling MATLAB in batch mode, they verify that the data are read and written as expected and give a clear indication of success or failure.

4. The GAMS file gdxmrw05 tests the gams MATLAB routine. Like the other tests, it can be run in batch mode. You can also run it interactively by starting MATLAB, making tmp the current directory, and running the script 'testinst.m'.

   >> testinst

In addition to messages indicating success or failure, this test produces a log file testinstlog.txt that will be useful in troubleshooting a failed test.
5.23.6 APPENDIX B - Utility functions: gdxWhos and gdxInfo

In this section, we'll describe two utilities, gdxWhos and gdxInfo, provided with GDXMRW that can be called from the MATLAB command prompt. The gdxWhos function is patterned loosely after the MATLAB function whos used to query .mat files. It provides information about symbols in a specified GDX file. The only input argument is the name of a GDX file, which can be with or without the '.gdx' extension. With no output argument, gdxWhos lists the symbols in the specified GDX file in the MATLAB command prompt. When used with an output argument, information about the symbols in the GDX file is returned as an array of structures. This meta-data can be used in a variety of ways and is especially useful when programming.

An example GDXWhos call without an output argument is shown below:

```
>> gdxWhos('idx1_.gdx');
Symbol info of GDX idx1_.gdx

Index Type Dim NRecs Name
1  Parameter 0 1     a0
2  Parameter 1 3     a1(5)
3  Parameter 2 4     a2(2,2)
4  Parameter 3 6     a3(3,5,2)
5  Parameter 10 256  a10(3,5,2,2,2,2,2,2,2,2)
```

The above output indicates that there are five indexed parameters in the file 'idx1_.gdx'. The way we can recognize an indexed parameter is by noticing numbered arguments of the parameters under the 'Name' column. For non-indexed data, the arguments will appear either as the name of a set or by a '*'. For example, the first three symbols are non-indexed and the last symbol is indexed in the output from this call:

```
>> gdxWhos('fake.gdx');
Symbol info of GDX fake.gdx

Index Type Dim NRecs Name
1  Set     1 3     i(*)
2  Parameter 1 3     a(i)
3  Set     1 3     d_i_m__3(*)
4  Parameter 1 3     aa(3)
```

The GDXInfo function is patterned after the gdxdump utility in GAMS. It lists and dumps all of the data values for each symbol in the specified GDX file to the MATLAB console. The only input argument is the name of a GDX file, which can be with or without the '.gdx' extension. It accepts no output arguments. It is especially useful to see the entire contents of smaller GDX files. To use the function, we could simply enter a command such as gdxInfo('idx1_.gdx') in the MATLAB command prompt, and the entire data contents would be displayed in the console. Further information about what is displayed can be found in the GAMS documentation of the gdxdump utility.

5.23.7 APPENDIX C - Calling GAMS model from MATLAB

Until now we have discussed the data Import/Export utility between MATLAB and GAMS. In this section, we will discuss a new MATLAB utility 'gams' that initializes a GAMS model with MATLAB data then executes GAMS on that model and bring the results back into MATLAB. This 'gams' routine is based on the same design as rgdx and wgdx but instead it does everything in one call. This routine can take multiple input arguments and can return multiple output arguments. Its standard syntax is as follows:
Here note that the first argument of gams is the GAMS model name plus any user specific command line settings. If a user wants to solve the given model (in this case found in qp.gms) using a different solver then it can be done by adding that solver to the GAMS model name as "qp nlp=baron". This feature allows a user to change the execution time behavior of the model.

The rest of the input arguments of GAMS are structures. Their positioning is not important. These structures are of two kinds: one is similar to the input structure of wgdx and the other structure has just two string fields, name and val. This latter structure is used to set or overwrite values in the model using the "$set" variables syntax of GAMS. We will explain it in detail a later section.

The first step is to generate a working GAMS model. For example, we can set up a simple model file to solve a quadratic program that minimizes $\frac{1}{2} x^T Q x + c^T x$ subject to $Ax \geq b$ and $x \geq 0$.

The GAMS model for this quadratic problem is as given in the following code.

```gams
$set matout '../matsol.gdx', x, dual, obj, returnStat 

Set
  i / 1*2 /
  j / 1*3 /;

Alias (j1,j);

Parameter
  Q(j,j1) / 1 .1 1.0
          2 .2 1.0
          3 .3 1.0 /
  A(i,j) / 1 .1 1.0
          1 .2 1.0
          1 .3 1.0
          2 .1 -1.0
          2 .3 1.0 /
  b(i)  / 1 1.0
          2 1.0 /
  c(j)  / 1 2.0 /

Variable obj;

Positive Variable x(j);

Equation cost, dual(i);

cost..    obj =e= 0.5*sum(j, x(j)*sum(j1, Q(j,j1)*x(j1))) + sum(j, c(j)*x(j));
dual(i).. sum(j, A(i,j)*x(j)) =g= b(i);

Model qp / cost, dual /

$if exist matdata.gms $include matdata.gms
solve qp using nlp minimizing obj;

Set stat / modelStat, solveStat /

Parameter returnStat(stat);
```
This GAMS qp model can be executed directly at the command prompt using the following command

```
gams qp (for Unix/Linux)
```

or

```
gams.exe qp (for Windows)
```

or the user can simply hit the run button in the GAMSIDE. The optimal value is 0.5. In order to run the same model within MATLAB and return the solution vector x back into the MATLAB workspace, no change is required to the GAMS file. In MATLAB, all you have to do is to execute the following command:

```
>> x = gams('qp');
```

This command will first collect the input structure data and create ‘matdata.gdx’ and ‘matdata.gms’ that contains include statements for the symbols written in a file matdata.gdx. In the previous example there is no structural input, so an empty ‘matdata.gdx’ file will be created and ‘matdata.gms’ will have just have a load statement for the GDX file but no load statements for any symbol. This is done to prevent any undesirable loading of data in the main model if there had already existed a ‘matdata.gdx’ or ‘matdata.gms file’. After creating these two files then the ‘gams’ routine will execute "gams qp" using a system call. When this model is executed, another file ‘matsol.gdx’ will be created because of the `execute_unload` statement in the last line of the model. Here it should be noted that any model that you want to execute using the MATLAB gams routine should contain something like

```
$set matout "'matsol.gdx', x, dual, obj, returnStat ";
```

either as the first line, or somewhere near the start of the model file. This is a standard gams $set statement, setting the value of the local variable 'matout'. The reason to have this statement near the start of the gms file is that the gams routine searches the file from the beginning for "$set matout" in the gms file. As these files can be very large, it is wise to have this statement near the start of the file. In this statement 'fileName' is the gdx file name that will be created containing symbols 'x1', 'x2', etc. These symbols can then be exported to MATLAB. The last line of the model should always be

```
execute_unload %matout%;
```

The purpose of setting the first and last line of the model in this manner is to specify what data the user wants to export to MATLAB in a “header” of the model. As MATLAB does not give any information about the output arguments except the number of expected arguments, we have to specify what data to export to MATLAB in the GAMS model with minimum modification to the existing model. In the previous example, there is only one output argument, thus the gams routine will get data for its first element from the output gdx file and store it in the MATLAB output argument.

If there is more than one output argument, e.g.,

```
>> [x, u] = gams('qp');
```

then the gams routine will read the output gdx file and store its first element information of the GDX file as the first output argument of MATLAB, i.e. ‘x,’ and the second element information of the GDX file in the second output argument of MATLAB, i.e. ‘u’ and so on. If the number of MATLAB output arguments is greater than the number of elements in the GDX file then gams will throw an error.

See datalib example gdxmrw_qp4.
5.23.7.1 Input Structure

As mentioned earlier, the \textit{gams} routine takes input arguments in structured form. It allows two different types of structure input. One contains the symbol data similar to the \textit{wgdx} input structure, to be exported to the GDX file. The other structure will just have two string fields 'name' and 'value'. Example use:

\begin{verbatim}
>> s.name = 'Q';
>> s.val = eye(3);
>> s.form = 'full';
>> m = struct('name','m','val','2');
>> [x] = gams('qpmcp',s, m);
\end{verbatim}

In this example both 's' and 'm' are structures but 'm' has only two fields and both are strings. The \textit{gams} routine will use the 's' structure to create a 'matdata.gdx' file and 'm' to modify the execution command line to include "--m=2" at the end i.e. a command that will executed will be "gams qpmcp --m=2"

The structure 's' is the same as the input structure for \textit{wgdx} but with two important differences. Firstly, it can be seen in the above example that 's' doesn't have a 'type' field. In \textit{wgdx} we assume the type to be 'set' by default, but in the \textit{gams} routine the type is assumed to be 'parameter' by default. The second change is an optional additional input field (in addition to those given in Section Input Structure) called "load".

- \textit{load}

It is a string input representing how the corresponding data will be loaded into the GAMS program. Depending on the value of the global option "gamso.input" (see next section) the input data will be read into GAMS in different ways. Suppose the input structure 's' has a 'name' field called 'foo'. By default (where gamso.input = 'compile'), the file matdata.gms will

\begin{verbatim}
$loadR foo
\end{verbatim}

The GAMS parameter (or set) foo will be replaced by the data that is in the 'matdata.gdx' container called 'foo'. If the data has been initialized before in the model, this will replace that initial data with the new data from 'matdata.gdx'. The option can also be explicitly set using

\begin{verbatim}
s.load = 'replace'
\end{verbatim}

There are two other compile time load options, namely 'initialize' and 'merge'. The first is only valid if the parameter values have not been initialized in the GAMS file, otherwise an error is thrown. It uses the GAMS syntax

\begin{verbatim}
$load foo
\end{verbatim}

The merge option is valid when the GAMS file being run has already initialized the parameter values. The new values in the MATLAB structure 's' are merged into the parameter simply overwriting existing values with the new values given. Explicitly, the 'matdata.gms' file contains the statement

\begin{verbatim}
$loadM foo
\end{verbatim}

to direct GAMS accordingly.

Finally, if gamso.input = 'exec', the loading will occur at execution time. In this case, \textit{s.load = 'initialize'} is not a valid input, the default setting is \textit{s.load = 'replace'} which carries out

\begin{verbatim}
execute_load "matdata.gdx" foo
\end{verbatim}

and the alternative setting \textit{s.load = 'merge'} carries out

\begin{verbatim}
execute_loadpoint "matdata.gdx" foo
\end{verbatim}

In this way, the data is loaded at execution time and performs an appropriate replace or merge.
5.23.7.2 Global input to change default behavior

Until now we have seen how to specify different input to the gams routine and in this section we will see how to change the default behavior of a gams call. This can be done by creating a structure 'gamso' in the current workspace and adding different fields to that structure. There are currently nine fields that can be set in that structure that affect the behavior of the program. Except the uels field, all other string fields take case insensitive data. These are as follows:

- **gamso.output**
  By default, output of the gams routine will be in structure form but it might be the case that a user is only interested in the data matrix, i.e., the val field of that structure. This can be done by setting `gamso.output` as 'std'. This will give only the value matrix as output. If this is not set to 'std' then output will be in the structure form described in the wgdx section.

  ```
  >> gamso.output = 'Std';
  >> x = gams('qp nlp=baron')
  x =
  0.5000
  ```

- **gamso.input**
  By default, the interface updates data at compile time. Thus, if execution time updates are made to the parameters before the line `$include matdata.gms` these may override the data that is provided in 'matdata.gms' (i.e. from the command line). This may not be desirable. If you wish to perform execution time updates to the data, you should set `gamso.input` to 'exec'.

- **gamso.write_data**
  If this is set to 'no', then all parameters on the call to gams are ignored, except the program name. This is useful for dealing with large datasets. Consider the following invocation:

  ```
  x = gams('largedata','A');
  y = gams('resolve','A');
  ```

  The first call generates a file 'matdata.gms' containing the elements of the matrix A for use in the largedata.gms program. The second call rewrites a new 'matdata.gms' file that again contains A. If we wish to save writing out A the second time we can use the following invocation:

  ```
  x = gams('largedata','A');
  gamso.write_data = 'no';
  y = gams('resolve','A');
  clear gamso;
  ```

  or the equivalent invocation:

  ```
  x = gams('largedata','A');
  gamso.write_data = 'no';
  y = gams('resolve');
  clear gamso;
  ```

- **gamso.show**
  This is only relevant on a Windows platform. This controls how the 'command box' that runs GAMS appears on the desktop. The three possible values are:

  - 'minimized' (default): The command prompt appears iconified on the taskbar.
  - 'invisible': No command prompt is seen.
  - 'normal': The command prompt appears on the desktop and focus is shifted to this box.
• \texttt{gamso.path}
  
  This option is used to specify fully qualified path for the gams executable. This is very useful if you have multiple versions of GAMS installed on your system and want to make sure which version you are running for the \texttt{gams} call. e.g.

  \begin{verbatim}
  >> gamso.path = 'C:\Program Files\GAMS23.4GAMS.exe';
  \end{verbatim}

  The output of \texttt{gams} is similar to \texttt{rgdx} but unlike the \texttt{rgdx gams} routine it doesn't take input specific to a particular symbol. Thus it becomes important to implement a way to change the default behavior of the output. This can be achieved by adding following field to the global structure \texttt{'gamso'}. All these fields behave similar to that described in \texttt{rgdx} and take the same input as of \texttt{rgdx}.

  • \texttt{gamso.compress}
  • \texttt{gamso.form}
  • \texttt{gamso.uels}
  • \texttt{gamso.field}

  This is a global option however.

\section*{5.24 GDXRANK}

A GAMS Utility for Ranking One-Dimensional Numeric Data.

\textbf{Thomas F. Rutherford}, Department of Economics, University of Colorado

\textbf{Paul van der Eijk}, GAMS Development Corporation

This utility consists of an executable file, \texttt{gdxrank.exe}, and a GAMS libinclude file, \texttt{rank.gms}. The former resides in the GAMS system directory, and the latter resides in the inclib/ subdirectory of GAMS system.

\subsection*{5.24.1 Usage}

\subsubsection*{5.24.1.1 Usage for GDXRANK}

GDXRANK reads one or more one dimensional parameters from a GDX file, sorts each parameter and writes the sorted indices as a one dimensional parameters to the output GDX file.

Usage:

\begin{verbatim}
gdxrank inputfile outputfile
\end{verbatim}

Each one dimensional parameter is read from the input file, sorted and the corresponding integer permutation index written to the output file using the same name for the symbol. GAMS special values such as \texttt{Eps}, \texttt{+Inf} and \texttt{-Inf} are recognized.

\subsubsection*{5.24.1.2 Usage for RANK}

\begin{verbatim}
$libInclude rank v s r [p]
\end{verbatim}

The first three arguments are required. The last is optional. These are defined as following:
<table>
<thead>
<tr>
<th>Type</th>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input:</td>
<td>(v(s))</td>
<td>Array of values to be ranked.</td>
</tr>
<tr>
<td></td>
<td>(s)</td>
<td>A one-dimensional set, the domain of array (v).</td>
</tr>
<tr>
<td>Output:</td>
<td>(r(s))</td>
<td>Rank order of element (v(s)), an integer between 1 and (\text{card}(s)), ranking from smallest to largest.</td>
</tr>
<tr>
<td>Optional: (input and output)</td>
<td>(p(\ast))</td>
<td>On input this vector specifies percentile levels to be computed. On output, it returns the linearly interpolated percentiles.</td>
</tr>
</tbody>
</table>

### 5.24.2 General Comments

- RANK only works for numeric data. You cannot sort sets.
- The first invocation must be outside of a loop or if block. This routine may be used within a loop or if block only if it is first initialized with blank invocations ("$LIBINCLUDE rank" in a context where set and parameter declarations are permitted (See Example 3).
- The following names are used within these routines and may not be used in the calling program:
  
  rank_tmp  rank_u  rank_p

- This routine returns rank values and does not return sorted vectors, however rank values are easily used to produce a sorted array. This can be done using computed "leads" and "lags" in GAMS' ordered set syntax, as illustrated in examples 1 and 3 below.

### 5.24.3 GDXRANK Example

In this example we sort a parameter, create a sorted version and verify that the sort worked correctly:

Set I / i1*i6 /;
Parameter A(I) / i1 +Inf, i2 -Inf, i3 Eps, i4 10, i5 30, i6 20 /;
display A;

* write symbol A to gdx file
execute_unload "rank_in.gdx", A;

* sort symbol; permutation index will be named A also
execute 'gdxrank rank_in.gdx rank_out.gdx';

* load the permutation index
Parameter AIndex(i);
execute_load "rank_out.gdx", AIndex=A;
display AIndex;

* create a sorted version
Parameter ASorted(i);
ASorted(i + (AIndex(i) - ord(i))) = A(i);
display ASorted;
* check that the result is sorted
Set C(i);
C(i) = yes$(ord(i) < card(i)) and (ASorted(i) > ASorted(i+1));

display C;
abort$(card(C) <> 0) 'sort failed';

5.24.4 RANK Example

5.24.4.1 Example 1: Rank a vector, and display the data in sorted order

Set
  i 'Set on which random data are defined' / a, b, d, c, e, f /
  k 'Ordered set for displaying sorted data' / 1*6 /;

Parameter
  x(i) 'Random data to be sorted'
  r(i) 'Rank values'
  s(k,i) 'Sorted data';

x(i) = uniform(0,1);
$libInclude rank x i r

display x;

* Generate a sorted list using the ordered set k.

* This assignment statement illustrates how the rank orders
* can be used to sort output for display in proper order. This
* statement uses GAMS support for computed "leads" and "lags"
* on the ordered set k. The loop is used to improve execution
* speed for larger dimensional sets:

loop(k$sameas(k,"1"),
  s(k+(r(i)-1),i) = x(i);
);

option s:3:0:1;
display s;

Example1 writes the following lines to ex1.lst:

---- 11 PARAMETER x Random data to be sorted
a 0.172,  b 0.843,  d 0.550,  c 0.301,  e 0.292,  f 0.224

---- 75 PARAMETER s Sorted data
1.a 0.172
2.f 0.224
3.e 0.292
4.c 0.301
5.d 0.550
6.b 0.843
Example 1 writes the following lines to ex1.lst:

```
---- 11 PARAMETER x Random data to be sorted
    a 0.172,  b 0.843,  d 0.550,  c 0.301,  e 0.292,  f 0.224

---- 75 PARAMETER s Sorted data
    1. a 0.172
    2. f 0.224
    3. e 0.292
    4. c 0.301
    5. d 0.550
    6. b 0.843
```

5.24.4.2 Example 2: Generate percentiles for a random vector

```
Set
    i 'Set on which random data are defined' / a, b, d, c, e /
    p 'Percentiles (all of them)' / 0*100 /
Parameter x(i) 'Random data to be sorted';
    * Generate the random data on set i:
        x(i) = uniform(0,1);
        display x;
Parameter
    r(i) 'Rank values'
    pct(*) 'Percentiles to be computed' / 20 20.0, median 50.0, 75 75.0 /;
    * Generate ranks and compute the specified percentiles (Note that
    * the rank array, r, is required, even if the values are not used.)
    $libInclude rank x i r pct
    * Display three percentiles:
        display pct;
```

The random data are displayed as follows in the listing file:

```
---- 11 PARAMETER x Random data to be sorted
    a 0.172,  b 0.843,  d 0.550,  c 0.301,  e 0.292
```

The interpolated percentiles are computed as follows:

```
---- 103 PARAMETER pct Percentiles
    20 0.268,  75 0.550,  median 0.301
```
The following code evaluates a full set of percentiles, from 1 to 100. The GAMS special value of EPS is used to represent zero in the percentile calculation. (Percentiles between zero and one are not permitted to avoid misunderstandings about how percentiles are scaled.)

\[
pct(p) = (\text{ord}(p) - 1) + \text{eps};
\]

\[
pct(\text{"median"}) = 0;
\]

\[
display \ pct;
\]

\[
$\text{libInclude rank x i r pct}
\]

\[
display \ pct;
\]

\[
* \text{Plot the results using GNUPLOT:}
\]

\[
\text{Set pl(p) / 20, 40, 60, 80, 100 /};
\]

\[
$\text{setGlobal domain p}$
\]

\[
$\text{setGlobal labels pl}$
\]

\[
$\text{libInclude plot pct}$
\]

5.24.4.3 Example 3: Use GDXRANK to report multisectoral Monte Carlo results

One of the most perplexing challenges in economic modeling with GAMS is to present multisectoral results in an easily interpreted format. One simple idea is to present sectoral results in a sorted sequence to make it easier to identify the most seriously affected sectors. The presentation of results in a multisectoral model is made even more challenging when model results are generated for a randomized set of scenarios. A summary of Monte Carlo results involves reporting both mean results and their sensitivity. One means of characterizing the sensitivity of model results is to report functions of the sample distribution such as the upper and lower quartiles.

In this example, I illustrate how gdxrank can be used to help report results from the Monte Carlo analysis of a multisectoral model.

Set
run 'Samples (potentially not all solved)' / 1*1000 /
i 'Sectors for which results are to be compared'/ELE, OLE, OLP, GAS, COA, OFU, FME, NFM, CHM, MWO, TPP
CNM, CLO, FOO, OTH, CON, AGF, RLW, TRK, PIP, MAR, AIR
TRO, TMS, PST, TRD, CAT, DIN, PSM, SSM, ECM, SCS, GEO, FIN, ADM /;

Parameter
v(run,i) 'Monte-Carlo results for all sectors';

* Load the sectoral results from the sensitivity analysis from a GDX file:
$gdxIn 'ex3.gdx'$load v

Set
s(run) 'Solved cases'
k 'Count used for quartiles' / i*1000 /
ki 'Count used for sectors' / i*100 /
qtl 'Quartiles (set)' / q25, q50, q75 /
imap(ki,i) 'Mapping from ordered list to sector labels';

Parameter
qvalue(i,*) 'Quartile values'
mean(i) 'Mean impact on sector i'
meanrank(i)  'Mean rank of sector i'
x(run)      'Vector used for sorting'
r(run)      'Rank values returned'
quartile(qtl) 'Quartiles (evaluated)'
qv(qtl)      'Quartiles (values)' / q25 25, q50 50, q75 75 /;

* Identify which scenarios have been solved (some of the runs
* may have failed):
s(run) = yes$(smax(i,abs(v(run,i))) <> 0);

* Evaluate means and support for results:
qvalue(i,"mean") = sum(s, v(s,i))/card(s);
qvalue(i,"min") = smin(s, v(s,i));
qvalue(i,"max") = smax(s, v(s,i));
display qvalue;

* Determine ranking of sectors by mean impact:
mean(i) = qvalue(i,"mean");
$libInclude rank mean i meanrank

* The following statement creates a tuple matching the ordered
* set, ki, to the set of sectors, i. In this tuple, the sequence of
* assignments corresponds to increasing mean impacts:
imap(ki+(meanrank(i)-ord(ki)),i) = yes;

* Evaluate quartiles of sectoral impacts for each sector:
loop(i,
x(s) = v(s,i);

* Load quartile with the percentiles to be
* evaluated (25th, 50th and 75th):
quartile(qtl) = qv(qtl);
$ libInclude rank x s r quartile

* Save the quartile values:
qvalue(i,qtl) = quartile(qtl);
);
display qvalue;

Parameter results(ki,i,*) 'Summary of impacts (sorted)';
results(ki,i,"mean")$imap(ki,i) = mean(i);
results(ki,i,qtl)$imap(ki,i) = qvalue(i,qtl);
display results;

The program produces the following display output:

<table>

</table>

The tabular report is helpful, but it does not convey the results as immediately as a picture. GNUPLOT's errorbar plot format is a convenient graphical format for portraying this information. The libinclude interface to GNUPLOT does not support this type of plot, so the continuation of the program produces the GNUPLOT command and data files before invoking the GNUPLOT program.

* Write out a GNUPLOT file to generate a chart of the results:

File kplt / ex3.gnu /;
put kplt;
kplt.lw = 0;

put "reset"/;
put 'set title "Sectoral Impacts with Quartiles"'/;
put "set linestyle 1 lt 8 lw 1 pt 8 ps 0.5"/;
put "set grid"/;
put 'set ylabel "% change"'/;
put "set xzeroaxis"/;
put "set bmargin 4"/;
put "set xlabel 'sector'"/;
put 'set xrange [1:', card(i), ']'/;
put @(file.cc-1) ')'/;
put "plot 'ex3.dat' notitle with errorbars ls 1"/;
putClose;

File kpltdat / ex3.dat /;
put kpltdat;
kpltdat.nr = 2;
5.24.4.4 Example 4: Repeated computation of percentiles within a loop

$title GAMS Program Illustrates Repeated Computation of Percentiles

$onText

Dear Prof Rutherford,

I am sorry to bother you again. If you recall I was having difficulty with the `rank` function. I wasn't able to run it in loop and use the 95th percentile value as a constraint in the next run of the loop, while also retaining a value of the 95th percentile for every iteration of the loop. [model below].

In the loop $libinclude rank call I ask GAMS to place the ranked values in pct, it only runs for 1 iteration before the 'user error' in rank. Whereas if I ask gams to put the ranked values in pct2, it runs for 2 iterations before saying 'user error'.

This must mean that the rank function only allows pct to be over-written once, after which it 'fills up' and generates a user error? How can I overcome this?

In your last email you though the problem was that the original values are being over written. So I introduced xparam95(iter). I think rank does not allow them to be overwritten.

I am only a novice and have been stuck on this for sometime, your help will be invaluable.

Kind regards,
Ashar
$offText

Set
iter 'Iterations' / iter1*iter10 /
week 'Weeks in the year' / 1*52 /
percentile 'Percentiles (all of them)' / 1*100 /
pctl(percentile) 'Percentiles to be computed' / 50, 75, 80, 95 /;

Parameter
z(week) 'Values to be sorted'
rnk(week) 'Rank values'
pct(*) 'Percentiles to be computed (input) and those values (output)'
pct0(*) 'Percentiles to be computed'
pctval(iter,*) 'Percentile values in successive iterations';

* Generate a "permanent copy" of the percentiles to be computed.
* This will be used to initialize pct before each call to rank;
pct0(percentile)$pctl(percentile) = ord(percentile);
* Assume that a model solution delivers the values;
z(week) = uniform(0,1);

* Assign the percentile values to be computed here:
pct(pctl) = pct0(pctl);

display 'Here are the INPUT values of PCT0 and PCT prior to the call to rank:', pct0, pct;

$libInclude rank z week rnk pct
display 'Here are the values of PCT0 and PCT after the call to rank:', pct0,
'Note that rank has changed the OUTPUT value of pct', pct;

* Do several iterations, computing percentiles in each step:

loop(iter,
* Substitute a call to the NLP solver by a call to the random
* number generator. In many applications, this substitution
* produces profoundly more sensible results.
* *
* solve catchment using nlp maximizing max;

    z(week) = uniform(0,1);

* If you want to retrieve percentile values, you need to reassign
* the percentiles that you wish to retrieve at this point in the
* program. If pct() were not reassigned at this point, the INPUT
* values would correspond to the OUTPUTs from the previous call.

    pct(pctl) = pct0(pctl);

$  libInclude rank z week rnk pct
    pctval(iter,pctl) = pct(pctl);
);
display pctval;

Output:

---- 58 Here are the INPUT values of PCT0 and PCT prior to the call to rank:

---- 58 PARAMETER pct0  Percentiles to be computed
   50 50.000,  75 75.000,  80 80.000,  95 95.000

---- 58 PARAMETER pct  Percentiles to be computed (input) and those values (output)
   50 50.000,  75 75.000,  80 80.000,  95 95.000

---- 153 Here are the values of PCT0 and PCT after the call to rank:

---- 153 PARAMETER pct0  Percentiles to be computed
   50 50.000,  75 75.000,  80 80.000,  95 95.000
5.24.4.5 Example 5: Use GDXRANK generating percentiles for heterogenous households.

$title Percentile ranking of household expenditure data with heterogenous household size

Set h / 0*100 /;

Parameter
  y(h) 'Aggregate expenditure associated with household type h'
  n(h) 'Number of persons associated with household type h'
  ypc(h) 'Per-capita expenditure of household type h'
  rank(h) 'Rank of household in per-capita expenditure';

* Assign some random values:
  y(h) = uniform(0.2,1.2);
  n(h) = uniform(1,6);
  ypc(h) = y(h)/n(h);

* Assign ranks to household based on per-capita expenditures:
$libInclude rank ypc h rank

* Now determine percentile ranking of the households taking into account
  * differences in numbers of members and household representation:
Set r 'Temporary set used for ranking' / r0*r100 /;

Parameter
  pcttmp(r) 'Temporary array for computing percentiles'
  pct(h) 'Percentile rankings for households';

Set r0(r) / r0 /;

* First, create an array with households assigned
loop((r0(r),h), pcttmp(r+(rank(h)-1)) = n(h));
loop(r,
  pcttmp(r) = pcttmp(r) + pcttmp(r-1));
pcttmp(r) = pcttmp(r)/sum(h, n(h));
Parameter ranking 'Ranking of households and expenditures';

\[
\text{loop}((r0(r),h), \text{pct}(h) = \text{pct}(r+(\text{rank}(h)-1)));
\]

\[
\text{Parameter ranking 'Ranking of households and expenditures'};
\]

\[
\text{loop}((r0(r),h), \text{ranking}(r+(\text{rank}(h)-1),h,"n") = n(h); \text{ranking}(r+(\text{rank}(h)-1),h,"ypc") = ypc(h); \text{ranking}(r+(\text{rank}(h)-1),h,"pct") = pct(h);}
\)

\[
\text{display ranking;}
\]

Output:

\[
\begin{array}{cccc}
\text{r0} & 0.43 & 5.662 & 0.044 & 0.018 \\
r1 & 0.8 & 5.682 & 0.047 & 0.036 \\
r2 & 0.58 & 4.477 & 0.052 & 0.050 \\
r3 & 0.14 & 5.742 & 0.058 & 0.068 \\
r4 & 0.55 & 4.815 & 0.063 & 0.083 \\
r5 & 0.65 & 3.702 & 0.063 & 0.094 \\
r6 & 0.61 & 5.880 & 0.064 & 0.113 \\
r7 & 0.54 & 4.463 & 0.064 & 0.127 \\
r80 & 0.62 & 1.134 & 0.640 & 0.991 \\
r99 & 0.10 & 1.673 & 0.716 & 0.997 \\
r100 & 0.73 & 1.053 & 1.076 & 1.000 \\
\end{array}
\]

5.25 GDXRENAME

The GDXRENAME program renames the unique elements in a GDX file using the unique elements from a second GDX file.

5.25.1 Usage

gdxrename data-file map-file {options}

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

The GDXRENAME utility renames the unique elements in the data-file using a two dimensional set called map in the map-file. The renaming of the unique elements only affects the string stored for each element, and does not change the data order for the symbols in the data-file. Because no data is changing in the data-file, only the strings for the unique elements, these changes are applied to the data-file directly and no new data-file is created.

\textbf{data-file = fileName} (default = none)

Name of the file where the renaming is to be applied.

\textbf{map-file = fileName} (default = none)

Name of the file where the map set appears containing the renaming tuples.
5.25.2 Options

_reverse_ (disabled by default)

Synonym: -r

Reverse the direction of the rename operation; see below

5.25.3 Example

A simple example, where the labels of the parameter A are renamed according to the map specified.

Set c / r, g, b, y /;
Parameter A(c);
A(c) = ord(c);
execute_unload 'data.gdx', A;
execute 'gdxdump data.gdx';
Set map(*,*) / r.red, g.green, b.blue, y.yellow /;
execute_unload 'map.gdx' map;
execute 'gdxrename data map';
Scalar rc;
rc = errorLevel;
abort$(rc <> 0) 'GDXRENAME execution error';
execute 'gdxdump data.gdx';

Symbol A before the rename:

Parameter A(*) /
'r' 1,
'g' 2,
'b' 3,
'y' 4 /;

Symbol A after the rename:

Parameter A(*) /
'red' 1,
'green' 2,
'blue' 3,
'yellow' 4 /;
5.26  GDXRRW

Interfacing GAMS and R

Michael C. Ferris (ferris@cs.wisc.edu), Computer Sciences Department, University of Wisconsin - Madison, 1210 West Dayton Street, Madison, Wisconsin 53706

Steven Dirkse (sdirkse@gams.com) GAMS Development Corp.

GDXRRW is a suite of utilities to import/export data between GAMS and R (both of which the user is assumed to have already) and to call GAMS conveniently from R. The software gives R users the ability to use all the optimization capabilities of GAMS, and allows visualization and other operations on GAMS data directly within R.

The GDXRRW tool is unique among the GDX interface utilities in that it is an R extension made available as an R package. As such, it is run as part of an R session or script, not as part of a GAMS run, and it follows the usual R package conventions.

1. Installation: The R software is designed to be easily extended. Thousands of extension packages are freely and conveniently available online and can be installed easily using a simple, standard procedure. The GDXRRW package is one of these. The latest version is available from the GDXRRW Wiki in both source and binary form, along with a FAQ list, some hints and tips on common problems and solutions, and other helpful content. For convenience, the source and binary packages are also available in the gdxrrw directory of the GAMS distribution.

2. Documentation: The GDXRRW documentation is installed as part of the GDXRRW package and is available from within R in the usual way. See the GDXRRW Wiki for details and hints.

3. Examples, tests, and data: Like many R packages, GDXRRW comes with examples and data that help a user get started using the package. The R help system and the GDXRRW Wiki provide pointers to these. The Wiki also provides hints on finding and running the thousands of lines of tests that come with the GDXRRW package.

5.27  GDXTROLL

gdxtroll reads TROLL data files into a GDX container.

5.27.1  Usage

gdxtroll in [out]

where

in

TROLL data text file (default extension is .txt)

out

GDX container file name (default in.gdx)

Accepts SPECS:NUMerlic and the following periodicities scalar NA, annual yyyyA, quartely yyyyQq, monthly yyyyMm weekly yyyyWwww (ISO 8601)
5.28 GDXVIEWER

5.28.1 Overview

GDXVIEWER is a tool to view and convert data contained in GDX files.

Besides inspecting a GDX file, gdxviewer allows you to export to a large number of data formats, including ASCII text, CSV, HTML, XML, database, and spreadsheet formats.

This tool is designed as an interactive Windows program, but it can also be operated through command line parameters.

5.28.2 Requirements

GDXVIEWER runs only on PC’s running Windows (95/98/NT/XP). The DLL GDXIO.DLL needs to be in the same location as GDXVIEWER.EXE. If XLS files are saved, MS Excel needs to be present. If MDB database files are saved, MS Access needs to be present.

If GDXIO.DLL is not found in the same directory as the executable gdxviewer.exe, the following window will be shown:

A simple way to make sure that GDXVIEWER has access to the GDXIO.DLL dynamic load library is to place gdxviewer.exe in the GAMS system directory, e.g. c:\program files\GAMS21.3.

5.28.3 Creating GDX files

GDX files are binary data files. They can contain sets, parameters (including scalars), equations and variables. These files can be generated by a number of tools: by GAMS itself, by utilities such as MDB2GMS, SQL2GMS, GDXXRW.

To save all data from a GAMS model into a GDX file you can use the GDX=fln command line parameter:

C:\> gams trnsport.gms GDX=trnsport.gdx

From the IDE you can specify the command line parameter GDX=trnsport.gdx in the parameter edit box.

To selectively place identifiers in a GDX file you can use the execute_unload statement:

Model transport / all /;
solve transport using lp minimizing z;
display x.l, x.m;
execute_unload 'results.gdx', i, j, x;

In this example the sets i and j and the variable x are saved to the GDX file results.gdx.

Other ways to create GDX files include:

- The MDB2GMS tool can be used to convert data stored in MS Access tables to GDX files
- The SQL2GMS tool can read data from virtually any SQL database (including any ODBC accessible database) and can create GDX files.
- The tool GDXXRW allows data from an Excel spreadsheet to be stored in a GDX file.
- $GDXOUT allows you to write data to a GDX file during GAMS compile time. This is not as useful as execute_unload but may have its use in special cases.
- You can write your own program to write a GDX file. There is an API and bindings for different languages such as Delphi, Kylix, VB6, VBA, VB.NET, C/C++, C#, Java, Fortran.
5.28.4 Viewing GDX files

After loading a GDX file in gdxviewer the content of the file is displayed in list view. The left-hand side of the window shows the index of the GDX file organized in a tree structure. When clicking on an identifier, the right-hand-side will display the actual data for the identifier.

When variables are shown, more information is available, such as bounds (lower and upper bounds) and marginals.

The GDX file can be loaded interactively using the File|Open menu, or it can be launched from the command line:

C:\> gdxviewer e:\models\transport.gdx

The command line specification can also be used to launch gdxviewer from within a GAMS model as in:

Model transport / all /;
solve transport using lp minimizing z;
display x.l, x.m;
execute_unload 'results.gdx', i, j, x;
execute '='gdxviewer results.gdx';

In this case gdxviewer.exe was located in the GAMS system directory, such that execute had no problems in finding it.

Note: there are alternative tools to view GDX files. The GAMS IDE has a built-in GDX file viewer (use File|Open) and there is a command line utility called GDXDUMP.

5.28.5 Exporting an identifier

When the right mouse button is clicked on an identifier a pop-up menu is presented that allows you to export an identifier to a number of target formats.

The same operation can be invoked from the File|Export menu:

5.28.6 Exporting to a Text File

The text file export facility (File|Export|Text File) will write a GAMS identifier to a standard ASCII text file. Such a text file can look like:

seattle new-york 2.5
seattle chicago 1.7
seattle topeka 1.8
san-diego new-york 2.5
san-diego chicago 1.8
san-diego topeka 1.4

The separator symbol can be set using the menu Options|Configuration|Text File:

Other options that involve the format of the text file being written are: Options|Configuration|Export and Options|Configuration|Special Values. Currently there are no facilities to write fixed format text files. If you need to write fixed format text files you can use the GAMS PUT statement.
5.28.7 Exporting to a CSV files

Comma-separated Values (File|Export|CSV File) is a popular format to exchange data between applications. An example of such a file is:

'new-york',325
'chicago',300
'topeka',275

Strings are surrounded by quotes and each field is separated by a comma. The precise format can be specified using the menu Options|Configuration|CSV File:

Other options that involve the format of the CSV file being written are: Options|Configuration|Export and Options|Configuration|Special Values.

5.28.8 Exporting to an XLS file

A GAMS identifier can be exported directly to an MS Excel spreadsheet using File|Export|Excel XLS File:

There are a few options available for this operation. Under Options|Configuration|Excel the following settings can be changed:

Other options that involve the format of the CSV file being written are: Options|Configuration|Export and Options|Configuration|Special Values. Exporting to Excel is only available if you have Microsoft Excel installed on your machine.

Note: We can write all symbols in the gdx file to Excel by specifying ID=* on the command line.

5.28.9 Exporting to an XLS Pivot Table

We can export to an XLS file and create a Pivot Table automatically (File|Export|Excel Pivot Table):

Pivot tables are a very convenient way to analyze multi-dimensional data.

The following options are available: Options|Configuration|Excel, Options|Configuration|Export and Options|Configuration|Special Values.

5.28.10 Exporting to a GAMS Include Files

The option File|Export|GAMS Include file will export an identifier to a GAMS include file format. An example of such an exported include file can look like:

Parameter d 'distance in thousands of miles'
    / seattle.new-york 2.5, san-diego.new-york 2.5
      seattle.chicago 1.7, san-diego.chicago 1.8
      seattle.topeka 1.8, san-diego.topeka 1.4 /;
5.28 GDXVIEWER

5.28.11 Exporting to an Access Tables

GDXVIEWER can export data directly to a table in an Access database using File|Export|Access (MDB or ACCDB) File. The name of the table will be the name of the parameter. If the table already exists, GDXVIEWER will try to create a new table with a slightly different name (e.g. d2, d3, ...).

An option Options|Configuration|Access allows you to set the length of the text fields where the GAMS indices are stored. This length is used when creating the table.

A feature added in version 2.9 is the possibility to use intermediate CSV (comma separated value) files instead of using direct SQL INSERT statements. The CSV files can be read into Access using a bulk operation and is therefore faster for large datasets. When using CSV files make sure double quotes are used (if single quotes are used they will become part of the data). The temporary CSV files will be written to the Windows TEMP directory (e.g. C:\WINDOWS\TEMP). When the import is done, these scratch files will be removed automatically. If you want to look at the CSV files that are being fed into Access, export the data to a CSV file.

5.28.12 Exporting to an SQL Table

It is possible to export data to SQL databases through ADO which includes all databases accessible through ODBC. The configuration information can be specified in Options|Configuration|SQL Database.

The Test Connection button will allow you to check the configuration and see if the database can be connected to.

The SQL data for double precision number is no always the same for each database. E.g. for MS Access you can use double while for MS SQL server you can use float.

When exporting data a new table is created with the name of the identifier. If such a table already exists, names like name2, name3, are tried.

5.28.13 Exporting to MS SQL Server

We can export to Microsoft SQL Server through the standard SQL export facility. However a special facility called BULK INSERT is only available through the specialized SQL Server export tool. BULK INSERT writes a TAB delimited text file to the Windows TEMP directory and subsequently calls BULK INSERT to load that file. This way is often much faster that using individual INSERT statements for each record.

5.28.14 Exporting to SQL Insert script

An SQL script with INSERT statements like:

```sql
```
can be generated with File|Export|SQL Insert script. The following settings in Options|Configuration|SQL Insert were used:

5.28.15 Exporting to SQL Update script

An SQL script with UPDATE statements like:

```sql
```
can be generated with File|Export|SQL Update script. The following settings in Options|Configuration|SQL Update were used:
5.28.16 Exporting HTML

GDXVIEWER can write an identifier to an HTML file using File|Export|HTML File.

The options relevant to this format are specified in Options|Configuration|HTML.

5.28.17 Exporting XML

GDXVIEWER can write an identifier to an XML file using File|Export|XML File.

The XML tags can be specified in Options|Configuration|XML.

5.28.18 Exporting fields

The menu Options|Configuration|Export allows you to set which fields are exported.

The following table gives the possibilities for exports:

<table>
<thead>
<tr>
<th></th>
<th>set</th>
<th>scalar</th>
<th>parameter</th>
<th>variable</th>
<th>equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Indices</td>
<td>+</td>
<td>+</td>
<td>+</td>
<td>+</td>
<td>+</td>
</tr>
<tr>
<td>Lower bound</td>
<td></td>
<td></td>
<td>+</td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>Level/Value</td>
<td>+</td>
<td>+</td>
<td>+</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Upper bound</td>
<td></td>
<td></td>
<td>+</td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>Marginal</td>
<td></td>
<td></td>
<td>+</td>
<td>+</td>
<td></td>
</tr>
</tbody>
</table>

5.28.19 Special Values

GAMS data can assume so called special values: -INF, +INF, EPS, NA, and UNDF. The meaning of these special values is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-INF</td>
<td>Minus infinity. Mostly used for non-binding lowerbounds.</td>
</tr>
<tr>
<td>+INF</td>
<td>Plus infinity. Mostly used for non-binding upperbounds.</td>
</tr>
<tr>
<td>EPS</td>
<td>Mostly used for marginals where it can indicate non-basic but numerically zero.</td>
</tr>
<tr>
<td>NA</td>
<td>Not available. Not often used.</td>
</tr>
<tr>
<td>UNDF</td>
<td>Undefined. Not often used.</td>
</tr>
</tbody>
</table>

When exporting GAMS identifiers we need to map such values to strings that the receiving program can understand. E.g. we could map {INF to 1.0e10 and +INF to +1.0e10. A good choice for EPS would be 0.0.

The mapping can be specified in Options|Configuration|Special Values:

When we export to a GAMS include file all special values are understood, so the mapping is not used. The defaults button will reset the mapping to their default values.
5.28 GDXVIEWER

5.28.20 Plotting Data

GDXVIEWER has a built-in facility to quickly plot data. It includes LINE, BAR and PIE charts, examples are shown below. The plots can be made through the menu File|Plot.

For multi-dimensional data it may be needed to take a “slice” of the data to make meaningful graphs. In the example above we plotted a two dimensional quantity \( v_f \) which looks like:

In this case we want to plot a pie graph of \( v_f(\ast, 'mexico-df') \) which can be specified in the index-selection tab:

5.28.21 Cube View

GDXVIEWER has a Cube View which allows to select rows and columns in a flexible way. In the example below we show a six dimensional variable where three dimensions are fixed, one dimension is chosen for the rows and two dimensions are chosen for the columns.

Below are some of the possibilities using parameter \( d(i,j) \) from the transport.gms model:

5.28.22 Exporting cubes

After creating a cube view, we can export that configuration by a right mouse click:

Exporting a cube will only export the selected slice (if certain dimensions are held fixed) and depending on the target format it will preserve the layout, e.g. an exported aligned text file can look like:

```
new-york  chicago  topeka
  seattle  2.5      1.7   1.8
  san-diego 2.5      1.8   1.4
```

Similarly, the XLS file can look like:

5.28.23 Commandline operation

The GDXViewer utility from version 2.3 accepts several command line parameters, so it can be used in a batch environment. When running in batch mode, the same configuration and option settings are used as for the interactive system and they can be changed by running GDXviewer interactively using the Options menu (the settings are saved in an INI file). It is advised to first run the program interactively until the results are as intended.

- **Single parameter** A single parameter is the filename of the GDX file. GDXViewer will load this file, and will continue to run interactively. Example: .

  Gdxviewer.exe test.gdx
• **XLS writing** To write an XLS file, one can use the syntax:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx xls=d:\tmp\result.xls id=x';
```

• **Text file writing** To write a text file, one can use the syntax:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx txt=d:\tmp\result.txt id=x';
```

• **CSV file writing** To write a CSV file, one can use the syntax:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx csv=d:\tmp\result.csv id=x';
```

• **HTML file writing** To write an HTML file, one can use the syntax:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx html=d:\tmp\result.html id=x';
```

• **XML file writing** To write an XML file, one can use the syntax:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx xml=d:\tmp\result.xml id=x';
```

• **GAMS include file writing** To write a GAMS include file, one can use the syntax:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx inc=d:\tmp\result.inc id=x';
```

• **Access MDB file writing** To write a Access MDB file, one can use the syntax:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx mdb=d:\tmp\result.mdb id=x';
```

• **Excel Pivot Table writing** To write a file containing a pivot table, one can use the syntax:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';
```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';

- SQL Database Table writing
To write a table to an SQL database, first interactively configure the connection to the database. The Export SQL Database option allows you to see if a connection succeeded and if the correct database was accessed. The configuration information is written to the SQLVIEWER.INI configuration file. The information in this file is used also when performing a batch command-line operation. The syntax is: i=inputfile.gdx sql id=x. A complete example is:

execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx sql id=x';

If you need to access several different databases, you can copy the file SQLVIEWER.INI (located in the directory where SQLVIEWER.EXE is placed). To tell GDXVIEWER to read a different INI file, you can say:

execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx ini=copy.ini sql id=x';

GDXVIEWER uses the MS Access and MS Excel applications as COM Object to write files in XLS (both XLS and PIVOT commands) or MDB format. Those applications may write to C:\My Documents in case no full path is specified. Other formats use the default GAMS working directory. In case when running under the IDE this is the location of the project file (*.GPR).

If a path or file name contains a blank, then it is possible to surround the name by double quotes as in:

execute_unload 'result.gdx',x;
execute 'gdxviewer.exe i=result.gdx csv="c:\my documents\result.csv" id=x';

Under windows 98 ME the call

execute 'gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';

will cause GAMS to continue while GDXVIEWER is executing. If we use:

execute '=gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';

GAMS will wait until gdxviewer.exe is terminated before executing more statements. This situation is different under other operating systems such as XP and NT.

5.28.24 Notes

GDX

GDX stands for Gams Data Exchange. It is a binary file format to get data in and out of GAMS.

5.29 GDXXRW

GDXXRW is a utility to read and write Excel spreadsheet data. GDXXRW can read multiple ranges in a spreadsheet and write the data to a GDX file, or read from a GDX file, and write the data to different ranges in a spreadsheet.
5.29.1 Usage

gdxxrw inputFile {outputFile} {options} [symbols]

Options and symbol specifications can also be read from a text file; the use of an option file is indicated by preceding the file name with a `@` (At sign.). When reading from a text file, lines starting with an asterisk (`*`) will be ignored and act as a comment.

Options and symbol specifications can also be read from an area in a spreadsheet; see index below.

Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory. The use of file names with embedded blanks is allowed as long as the file name is enclosed in double-quotes (").

Note: A small utility program is available to see if Excel is installed, to close an Excel file etc. See XLSTALK for more details. To read data from an Excel file without Excel installed see XLSDUMP.

5.29.2 Options

Describing the actions to be taken by GDXXRW requires passing a number of options and symbol specifications to the program. The ability of GDXXRW to process multiple actions in a single call makes the option passing and interpretation more complex.

There are four kinds of options:

1. **Immediate** Immediate options are recognized and processed before any other actions are taken and can only be specified once. Examples are:
   
   `input=` `output=` `trace=`

2. **Global** Global options are interpreted from left to right and affect every action that follows. The same option can be used multiple times to affect the actions that follow. Examples are:

   `skipEmpty=` `epsOut=`

3. **Symbol** A symbol definition introduces a new action for reading or writing a symbol. Examples are:

   `par=` `set=` `dSet=`

4. **Symbol attributes** Attributes specify additional information for the last symbol defined. Examples are:

   `dim=` `cDim=` `merge` `clear`

5.29.2.1 Immediate Options

Immediate options are recognized independent of their position on the command line. They are global and they can only be specified once.
<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>none</td>
<td>Specify the input filename (required).</td>
</tr>
<tr>
<td>output</td>
<td>inputFileName</td>
<td>Specify the output filename.</td>
</tr>
<tr>
<td>log</td>
<td>none</td>
<td>Specify the log filename.</td>
</tr>
<tr>
<td>logAppend</td>
<td>none</td>
<td>Appending the log information to the file specified.</td>
</tr>
<tr>
<td>index</td>
<td>none</td>
<td>Indicates reading the options and symbols directly from the spreadsheet.</td>
</tr>
<tr>
<td>password</td>
<td>none</td>
<td>Password for an encrypted input file.</td>
</tr>
<tr>
<td>rWait</td>
<td>0</td>
<td>Delay after opening a spreadsheet.</td>
</tr>
<tr>
<td>checkDate</td>
<td>disabled</td>
<td>Write GDX file only if the input file is more recent than the GDX file.</td>
</tr>
<tr>
<td>useRC</td>
<td>disabled</td>
<td>Use Row-Column notation to specify cells and ranges.</td>
</tr>
<tr>
<td>reCalc</td>
<td>N</td>
<td>Controls if recalcuations of cells inside Excel are executed after writing to the spreadsheet.</td>
</tr>
<tr>
<td>trace</td>
<td>1</td>
<td>Controls the amount of information written to the log.</td>
</tr>
<tr>
<td>maxDupeErrors</td>
<td>0</td>
<td>Maximum number of duplicate records allowed for a symbol.</td>
</tr>
<tr>
<td>updLinks</td>
<td>0</td>
<td>Updating of cells that refer to other spreadsheets.</td>
</tr>
<tr>
<td>runMarcos</td>
<td>0</td>
<td>Execution of Excel Auto macros.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the immediate options:

**input** = fileName (required, default = none)

Synonym: i

Either use the keywords **input** or **i** to specify the input file name anywhere on the command line or just specify the input file name without keyword at the first position behind **GDXXRW**. The file extension of the input file is required and determines the action taken by the program.

The extension .gdx for the input file will read data from a GDX file and write data to a spreadsheet. The extension .xls or .xlsx for the input file will read a spreadsheet and write the data to a .gdx file. In addition to the .xls and .xlsx input file extension, the following file extensions are also valid for spreadsheet input files: .wk1, .wk2, .wk3 and .dbf.

A file sharing conflict will arise when writing to a spreadsheet with the target file open in Excel. Either close the file in Excel before executing **GDXXRW**, or mark the spreadsheet as a shared workbook in Excel. To change the shared status of a workbook, use the Excel commands available under: **Tools**| **Share Workbook**.

Writing to a shared workbook can be painfully slow; simply closing the file and reopen the file after **GDXXRW** has finished is often a better option.

**output** = fileName (default = inputFileName)

Synonym: o

When an output file is not specified, the output file will be derived from the input file by changing the file extension of the input file and removing any path information. The file type, i.e. the file extension, depends on the installed version of Excel. Versions prior to Excel 2007 use the .xls file extension, later version use .xlsx. Excel 2007 can write .xls files, but in that case the output file has to be specified with an .xls file extension.
\textbf{log} = filename (default = none)

Specifies the filename of the log file. When omitted, log information will be written to standard output. When using \texttt{GDXXRW} in a GAMS model that is started from the GAMS IDE, the output will be written to the IDE process window.

\textbf{logAppend} = filename (default = none)

Using \texttt{logAppend} will add the log information to the end of the file specified. If the file does not exist yet, a new one will be created.

\textbf{index} = Excel Range

The \texttt{index} option is used to obtain the global options, symbols and symbol attributes specified by reading them from the spreadsheet directly. The parameters are read using the specified range, and treated as if they were specified directly on the command line. The first three columns of the range have a fixed interpretation: \texttt{dataType}, \texttt{Symbol identifier} and \texttt{dataRange}. The fourth and following columns can be used for additional parameters. The column header contains the keyword when necessary, and the cell content is used as the parameter value. See \texttt{Reading Spreadsheet using the Index Option} for instance.

\textbf{password} = string (default = none)

Specifies a password for a protected spreadsheet file.

\textbf{rWait} = integer (default = 0)

Introduce a delay (in milliseconds) after opening a spreadsheet before accessing the data. This parameter can be used to work around an issue we encountered that Excel indicated it was not ready.

\textbf{checkDate} (disabled by default)

When specified, no data will be written if the output file already exists and the file date for the output file is more recent than the file date for the input file. Provides a simple check to update the output file only if the input file has changed to save resources.

\textbf{useRC} (disabled by default)

Specify that all cell and range references use RC notation. So, instead of specifying the range Sheet1!A1:D6, one specifies Sheet1!R1C1:R6C4. When tracing is enabled, ranges will be reported in RC notation. This is a global option and applies to all cell references.

\textbf{reCalc} = flag (default = N)

Enable or disable the recalculations of cells inside Excel after writing to the spreadsheet. If there are many formulas in the spreadsheet the recalculation of cells can become very expensive and slowing down the writing process. By default, the recalculation is disabled and can be enabled via this option.

\textbf{trace} = integer (default = 1)
Sets the amount of information written to the log (for a better debugging). Higher values will generate more output. Valid range is 0..4.

0  Minimal information is included in the output
1  Message appears telling about each GDXXRW call indicating input file, output file and execution time
2  Message appears giving the level 1 output plus a listing for each symbol specified, indicating the type, sheet name, dimension, data range and the range of the row and column headers
3  Message appears giving the level 2 output plus cell ranges affected by reading, writing and clearing
4  Message appears giving the level 3 output plus cell addresses, and numerical or string values for every cell worked with

**maxDupeErrors** = integer (default = 0)

Sets the maximum number of duplicate records that is allowed when reading a spreadsheet and writing to a GDX file. The duplicate records for each symbol will be reported in the logfile, and if their accumulated number does not exceed the maximum specified using this option, the GDX file will not be deleted. This is a global option and applies to each symbol read from the spreadsheet.

The option is demonstrated in Reading Set from Lists with Duplication.

**updLinks** = integer (default = 0)

Specifies how links in a spreadsheet should be updated. The valid range is 0..3.

0  Doesn’t update any references
1  Updates external references but not remote references
2  Updates remote references but not external references
3  Updates both remote and external references

**runMacros** = integer (default = 0)

This option controls the execution of the 'Auto_open' and the 'Auto_close' macros when opening or closing a spreadsheet. Valid range is 0..3.

0  Doesn’t execute any macros
1  Executes Auto_open macro
2  Executes Auto_close macro
3  Executes Auto_open and Auto_close macro

### 5.29.2.2 Global Options

The following options affect the symbols that follow the option. They remain in effect unless they are redefined and used again for another symbol.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acronyms</td>
<td>0</td>
<td>Controls the handling of acronyms.</td>
</tr>
<tr>
<td>cMerge</td>
<td>0</td>
<td>Controls the handling of merged Excel ranges.</td>
</tr>
<tr>
<td>epsOut</td>
<td>Eps</td>
<td>String to be used when writing the value for 'Epsilon'.</td>
</tr>
<tr>
<td>filter</td>
<td>0</td>
<td>Set the Excel filter for symbols written to Excel.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>incRC</td>
<td>N</td>
<td>Include Excel row and column indices when a symbol is written to the GDX file.</td>
</tr>
<tr>
<td>mInfOut</td>
<td>-Inf</td>
<td>String to be used when writing the value for 'Negative infinity'.</td>
</tr>
<tr>
<td>NaIn</td>
<td>none</td>
<td>String to be used when reading a value for 'Not available'.</td>
</tr>
<tr>
<td>nameConv</td>
<td>N</td>
<td>Controls the interpretation of an Excel range.</td>
</tr>
<tr>
<td>NaOut</td>
<td>NA</td>
<td>String to be used when writing the value for 'Not available'.</td>
</tr>
<tr>
<td>pInfOut</td>
<td>+Inf</td>
<td>String to be used when writing the value for 'Positive infinity'.</td>
</tr>
<tr>
<td>resetOut</td>
<td>disabled</td>
<td>Reset the output strings for special values to their defaults.</td>
</tr>
<tr>
<td>squeeze</td>
<td>Y</td>
<td>Controls writing of default values of sub-fields of variables and equations resp. the handling of zero values within parameters when reading from spreadsheet.</td>
</tr>
<tr>
<td>skipEmpty</td>
<td>1</td>
<td>Number of empty rows or columns indicating the end of a block when reading from spreadsheet using the top left cell specification.</td>
</tr>
<tr>
<td>UndfOut</td>
<td>Undf</td>
<td>String to be used when writing the value for 'Undefined'.</td>
</tr>
<tr>
<td>allUELs</td>
<td>Y</td>
<td>Controls the handling of UELs without associated values in the data range.</td>
</tr>
<tr>
<td>zeroOut</td>
<td>0</td>
<td>String to be used when writing the value for 'Zero'.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the global options:

**acronyms = integer** (default = 0)

A non-zero value indicates that acronyms can be expected and should be processed.

If no acronym processing takes place, reading an identifier in the data section of a sheet will generate an error. Writing an acronym to a sheet will write the internal numerical representation of the acronym.

Processing acronyms:

When reading a spreadsheet, an identifier in the data section of the sheet will be interpreted as an acronym and will be written to the GDX file.

When writing to a spreadsheet, a data tuple containing an acronym will be stored using the corresponding identifier of the acronym.

**cMerge = integer** (default = 0)

Option indicating how to read an empty cell that is part of a merged Excel range. See Reading merged Excel Ranges with cMerge. Possible values and their interpretation are:

0 Leave the cell empty
1 Use merged value in row and column headers only
2 Use merged value in all cells

**epsOut = string** (default = Eps)

String to be used when writing the value for 'Epsilon'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet and Writing Parameter to Spreadsheet including Zero Values.

**filter = integer** (default = 0)
Adds basic Excel filter to the columns of the spreadsheet to display only those values matching some conditions. Using this option when reading an Excel file will result in an error. Specifying filter=1 will set an Excel filter for the row of labels that are closest to the data values. When there are multiple rows in a column header (cDim > 1) we can specify filter=x where x is a number of the range 2..cDim, indicating to use a row further away from the data values. See also Writing to Spreadsheet using a Filter.

\textbf{incRC} = \texttt{flag} (default = \texttt{N})

Valid only when reading a spreadsheet.

Include Excel row and column indices when a symbol is written to the GDX file. For example, when we write a parameter P with indices I and J, without this option it will be written as \( P(I, J) \). When incRC is enabled, the parameter will be written as \( P(\text{Excel Rows, } I, \text{Excel Columns, } J) \). Note that the sets \texttt{Excel Rows} and \texttt{Excel Columns} will be added to the GDX file automatically.

\textbf{mInfOut} = \textit{string} (default = \texttt{-Inf})

String to be used when writing the value for 'Negative infinity'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

\textbf{NaIn} = \textit{string} (default = none)

String to be used when reading a value for 'Not available'; this string is recognized in addition to the string 'NA' and is not case-sensitive. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

\textbf{nameConv} = \texttt{flag} (default = \texttt{N})

Synonym: nC

The naming convention parameter is used to change the interpretation of an Excel range that does not contain an '!' (exclamation mark). For details see Excel Ranges below.

\textbf{NaOut} = \textit{string} (default = \texttt{NA})

String to be used when writing the value for 'Not available'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

\textbf{pInfOut} = \textit{string} (default = \texttt{+Inf})

String to be used when writing the value for 'Positive infinity'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

\textbf{resetOut} (disabled by default)

Reset the output strings for special values to their defaults. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

\textbf{squeeze} = \texttt{flag} (default = \texttt{Y})

Synonym: sq

Writing to a spreadsheet:
The `squeeze` option affects the writing of sub-fields of variables and equations. A value for the field that is the default value for that type of variable or equation will not be written to the spreadsheet. For example, the default for `.l` (level value) is 0.0, and therefore zero will not be written to the spreadsheet. When we set `squeeze=n`, all values will be written to the spreadsheet.

The `squeeze` option for writing data is demonstrated in Reading Data from Spreadsheet and writing Data to Spreadsheet after Solve and Writing Parameter to Spreadsheet including Zero Values.

Reading a spreadsheet:

When the `squeeze` option is enabled, zero values for parameters will not be written to the GDX file. When the `squeeze` option is disabled, zero values will be written to the GDX file. In either case, empty cells, or cells containing blanks only, will never be written to the GDX file.

The `squeeze` option for reading data is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

**skipEmpty = integer (default = 1)**

Synonym: sE

The `skipEmpty` option can be used when reading a spreadsheet and the range is specified using the top left corner instead of a block range. The value defines the number of empty row or column cells signal the end of a block. Valid values are 0..n. If the range is specified using a block range, `skipEmpty` will be ignored. Blank rows or columns will be skipped automatically.

Note that `skipEmpty` is also valid when using the `merge` resp. `clear` options in order to write data to spreadsheet (in a specific order determined by matching row and column labels already stored in the spreadsheet).

See Skipping Empty Rows and Columns or Reading Multi-dimensional Parameter from Spreadsheet for instance.

**UndfOut = string (default = Undf)**

String to be used when writing the value for 'Undefined'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

**allUELs = flag (default = Y)**

Valid only when reading a spreadsheet.

When enabled, all unique elements found in a range will be entered in the GDX file. When disabled, only those unique elements that are used in conjunction with a value will be entered in the GDX file.

**zeroOut = string (default = 0)**

String to be used when writing the value for 'Zero'; by default this is '0'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.
5.29.2.3 Symbols

To write data to a spreadsheet or to a GDX file, one or more symbols and their associated Excel range need to be specified. See also Excel Ranges.

The general syntax for a symbol specification is:

\[
\text{dataType} = \text{symbolName} \{\text{symbolAttributes}\}
\]

Among the symbolAttributes, one specifies the dataRange, the dimensions of the symbol and some additional symbolOptions in general.

<table>
<thead>
<tr>
<th>dataTyp</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>par</td>
<td>Declare the symbol as parameter and define a individual name when reading from spreadsheet, or specify a parameter from a GDX file when writing to spreadsheet.</td>
</tr>
<tr>
<td>equ</td>
<td>Specify a sub-field of an equation from a GDX file when writing to spreadsheet.</td>
</tr>
<tr>
<td>var</td>
<td>Specify a sub-field of a variable from a GDX file when writing to spreadsheet.</td>
</tr>
<tr>
<td>set</td>
<td>Declare the symbol as set and define a individual name when reading from spreadsheet, or specify a set from a GDX file when writing to spreadsheet.</td>
</tr>
<tr>
<td>dSet</td>
<td>Declare the symbol as domain set and define a individual name when reading from spreadsheet, or specify a domain set from a GDX file when writing to spreadsheet.</td>
</tr>
<tr>
<td>text</td>
<td>Write the text specified to spreadsheet. One can also create hyperlinks, using the link resp. linkID statement.</td>
</tr>
<tr>
<td>textID</td>
<td>Write the explaynatory text of an identifier stored in the GDX file to spreadsheet.</td>
</tr>
<tr>
<td>hText</td>
<td>Write sections of the text specified to different cells in the horizontal direction (row).</td>
</tr>
<tr>
<td>vText</td>
<td>Write sections of the text specified to different cells in the vertical direction (column).</td>
</tr>
</tbody>
</table>

**par** = *GAMS Parameter*

Specify a GAMS parameter to be read from a GDX file and written to spreadsheet, or to be read from a spreadsheet and written to a GDX file.

When writing to a spreadsheet, special values such as Eps, NA and Inf will be written in ASCII. When reading data from a spreadsheet, the ASCII strings will be used to write the corresponding special values to the GDX file.

This datatype is used in the most examples. Reading parameters is demonstrated in Reading Parameter from Spreadsheet or Reading Multi-dimensional Parameter from Spreadsheet. Writing parameters from GDX to spreadsheet is demonstrated in Writing Parameter to Spreadsheet.

**equ** = *GAMS Equation*

**var** = *GAMS Variable*

A sub-field of a variable or equation can be written to a spreadsheet and should be specified as part of the symbolName. The fields recognized are .l (level), .m (marginal), .lo (lower bound), .up (upper bound), .prior (priority), and .scale (scale). The sub-field names are not case-sensitive. See also Reading Data from Spreadsheet and writing Data to Spreadsheet after Solve.

A sub-field of a variable or equation cannot be read from a spreadsheet and written to a GDX file.
\[ \text{set} = GAMS\_Set [\text{values} = \text{valueType}] \]

In GAMS we can define a set by specifying all its elements. In addition, each tuple can have an associated text. To read a set from a spreadsheet, the values option is used to indicate if there is any data, and if there is, if the data should be interpreted as associated text or as an indicator whether the tuple should be included in the set or not.

Reading sets is demonstrated in Reading Set from Spreadsheet or Reading Set Elements associated with Data or Text using the values Option (focusing on the values option) for instance. Writing sets from GDX to spreadsheet is demonstrated in Writing Set to Spreadsheet.

<table>
<thead>
<tr>
<th>valueType</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>Based on the range, row and column dimensions for the set, the program decides on the valueType to be used. This is the default for values.</td>
</tr>
<tr>
<td>noData</td>
<td>There is no data range for the set; all tuples will be included.</td>
</tr>
<tr>
<td>YN</td>
<td>Only those tuples will be included that have a data cell that is not empty and does not contain '0', 'N' or 'No'.</td>
</tr>
<tr>
<td>sparse</td>
<td>Only those tuples will be included that have a data cell that is not empty. The string in the data cell will be used as the associated text for the tuple.</td>
</tr>
<tr>
<td>dense</td>
<td>All tuples will be included. A string in the data cell will be used as the associated text for the tuple.</td>
</tr>
</tbody>
</table>

Due to backward compatibility, \text{valueType}=\text{string} or \text{all} are also recognized and are synonyms for \text{valueType}=\text{dense}. The following table summarizes which \text{valueType} will be used when reading a set, if a \text{valueType} was not specified:

<table>
<thead>
<tr>
<th>Range specification</th>
<th>rDim = 0 Or cDim = 0</th>
<th>rDim &gt; 0 And cDim &gt; 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top left corner only</td>
<td>dense</td>
<td>YN</td>
</tr>
<tr>
<td>A block, but the data range is empty</td>
<td>dense</td>
<td>YN</td>
</tr>
<tr>
<td>A block, and there is a data range</td>
<td>dense</td>
<td>YN</td>
</tr>
</tbody>
</table>

When writing to a spreadsheet, the entire set is written to the spreadsheet and the writing of the associated text is governed by the values option:

<table>
<thead>
<tr>
<th>valueType</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>If rDim=0 or cDim=0, auto means string, otherwise auto means YN.</td>
</tr>
<tr>
<td>noData</td>
<td>Neither associated text nor 'Y' is written for a set element.</td>
</tr>
<tr>
<td>YN</td>
<td>A 'Y' is written for a set element.</td>
</tr>
<tr>
<td>string</td>
<td>The associated text is written for a set element. If no text is stored with set element the cell will be empty.</td>
</tr>
</tbody>
</table>

Due to backward compatibility, \text{valueType}=\text{dense}, \text{sparse} or \text{all} are also recognized and are synonyms for \text{valueType}=\text{string}.

\[ dSet = GAMS\_Set \]
A domain set is used to read the domain of a set from a spreadsheet row or column. Either the row or the column dimension (\texttt{rDim} or \texttt{cDim}) should be set to '1' to specify a row or column for the set, resulting in a one-dimensional set. Duplicate labels in the range specified do not generate an error message. For instance, see also Reading Set from Lists with Duplication.

Note that reading explanatory text of set elements is not supported by \texttt{dSet}. In order to read explanatory text, use \texttt{set} instead. If there are duplicate set element labels in your data, use the \texttt{set} symbol specification while increasing the value of the immediate option \texttt{maxDupeErrors} to oppress an error message when reading duplicates.

\begin{verbatim}
\texttt{text = "String of characters" \{dataRange\}}
\texttt{textID = Identifier \{dataRange\}}
\end{verbatim}

Write the text to the cell specified in the DataRange. In addition, \texttt{textID} will write the explanatory text of the Identifier in the cell to the right of the dataRange.

A Text directive can be followed by a \texttt{link=Address} or \texttt{linkID=identifier} directive. Using \texttt{link} will create a hyperlink to an external page or to a cell in the spreadsheet, while \texttt{linkID} will create a hyperlink to the top left corner of the symbol specified. See Writing to Spreadsheet adding Text and Hyperlinks for instance.

\begin{verbatim}
\texttt{hText = "String of characters" \{dataRange\}}
\texttt{vText = "String of characters" \{dataRange\}}
\end{verbatim}

Write a string of characters in the horizontal direction for \texttt{hText} or vertical direction for \texttt{vText}. Text for the next cell is indicated by a comma. In order to write a comma as part of the text, the comma needs to be preceded by a backslash. See Writing Set to Spreadsheet for instance.

### 5.29.2.3.1 Symbol Attributes

The following options apply to the symbol preceding the option, and only affect that symbol:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataRange</td>
<td>Cell A1 of the first sheet</td>
<td>Specify the Excel range of the symbol for reading from spreadsheet or for writing to spreadsheet.</td>
</tr>
<tr>
<td>dim</td>
<td>2 when reading from spreadsheet Defined by the symbol dimension stored in the GDX file when writing to spreadsheet</td>
<td>Total dimension of the symbol.</td>
</tr>
<tr>
<td>cDim</td>
<td>1</td>
<td>Column dimension of the symbol.</td>
</tr>
<tr>
<td>rDim</td>
<td>\texttt{dim-1}</td>
<td>Row dimension of the symbol.</td>
</tr>
<tr>
<td>merge</td>
<td>disabled</td>
<td>When enabled, the data will be written in a specific order determined by matching row and column labels already stored in the spreadsheet.</td>
</tr>
<tr>
<td>clear</td>
<td>disabled</td>
<td>In addition to the effect of \texttt{merge}, already existing values in the data range of the spreadsheet are removed before writing.</td>
</tr>
<tr>
<td>colMerge</td>
<td>0</td>
<td>Determines the columns for which non-empty content of the previous cell will be used as content for the empty cell of a column.</td>
</tr>
</tbody>
</table>
Some more detailed remarks on the symbol attributes:

**dataRange**

\[ \text{rng} = \text{Excel Range} \]

The Excel Range for the data for the symbol. Note that an empty range is equivalent to the first cell of the first sheet.

**dimensions**

\[ \text{dim} = \text{integer} \]

The total dimension for the symbol.

\[ \text{cDim} = \text{integer} \]

Column dimension: the number of rows in the data range that will be used to define the labels for the columns. The first cDim rows of the data range will be used for labels.

\[ \text{rDim} = \text{integer} \]

Row dimension: the number of columns in the data range that will be used to define the labels for the rows. The first rDim columns of the data range will be used for the labels.

More about dimensions:

When reading data from a GDX file and writing to a spreadsheet, the dimension of the symbol is known. When reading a spreadsheet and writing to a GDX file, the dimension is not known.

The sum of cDim and rDim determine the dimension of the symbol. This dimension is used when writing data to a GDX file, and is used to verify the dimension of a symbol when reading from a GDX file.

When reading a GDX file, the dimension of a symbol is known, and therefore the cDim or rDim parameter can be omitted. If both cDim and rDim are omitted, the program assumes that cDim=1 and rDim=dim-1.

**symbolOptions**
The options below are only valid when reading a GDX file and writing to a spreadsheet.

By default, writing data to a spreadsheet will include the row and column labels in addition to the data. The row and column labels will appear in the same order as they appear in the GDX file.

**merge** (disabled by default)

Using the **merge** option assumes that the row and column labels are in the spreadsheet already. For each value read from the GDX file, the location of the row and column labels is used to update the spreadsheet. Using the **merge** option will force the data to be presented in a given order using the row and column labels. Spreadsheet cells for which there is no matching row/column pair will not be changed. The matching of labels is not case-sensitive. See also Writing to Spreadsheet with merge Option Example.

Note that the **skipEmpty** option value affects the reading of the row and column labels from spreadsheet in case of top left range specification (while **skipEmpty** is ignored in case of block range specification).

Warning: The **merge** or **clear** option will clear the Excel formulas in the rectangle used, even if the cells do not have matching row/column headings in the GDX file. Cells containing strings or numbers are not affected.

**clear** (disabled by default)

The **clear** option is similar as the **merge** option, except that the data range will be cleared before any data is written. See also Writing to Spreadsheet with clear Option Example.

**colMerge** = integer (default = 0)

The number of columns that will use a previous value in that column if the cell is empty. Can only be used when reading from a spreadsheet. See Reading empty Cells with colMerge.

**intAsText** = flag (default = Y)

Unique elements that are a proper integer can be written as text or as an integer value. The default is Y, which will write the unique element as a string. Note that this impacts the sorting order and can be used when using an Excel filter on a data range.

Ignoring Rows and Columns when reading from a spreadsheet

**ignoreRows** = rownr, rownr, rownr:rownr

**ignoreColumns** = colnr, colnr, colnr:colnr

Row numbers are represented by integers. Column numbers are represented by Excel column numbers, like A, CD, IV etc, or by integers.

Note

- Ignoring rows or columns is only allowed when reading a spreadsheet.
- The specification of ignored rows or columns follows the symbol specification and only applies to that symbol.
- When ignoring a column that would be part of an index if the column was not ignored, the range for the index will be extended for each column that is ignored. The same holds for ignored rows that are part of an index.

See also Ignoring Rows and Columns.
5.29.2.4 Syntax Elements

The most options are specified by using an integer, a string or a flag. Note that the options useRC, resetOut, checkDate, merge and clear are enabled or disabled by simply adding the keyword to your GDXXRW statement.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>An unsigned integer</td>
</tr>
<tr>
<td>string</td>
<td>A string of characters; a string can be quoted with single or double quotation marks.</td>
</tr>
<tr>
<td>flag</td>
<td>True values: 1, Y or Yes</td>
</tr>
<tr>
<td></td>
<td>False values: 0, N or No</td>
</tr>
<tr>
<td></td>
<td>(not case-sensitive)</td>
</tr>
</tbody>
</table>

5.29.2.5 Excel Ranges

An Excel Range is specified using the standard Excel notation: SheetName!CellRange.

When the SheetName! is omitted, the first sheet will be used. A CellRange is specified by using the TopLeft:BottomRight cell notation like A1:C12. When :BottomRight is omitted, the program will extend the range as far down and to the right as possible. (Using '..' in stead of ':' is supported.)

Excel also allows for named ranges; a named range includes a sheet name and a cell range. Before interpreting a range parameter, the string will be used to search for a pre-defined Excel range with that name. See Reading Parameter from Spreadsheet using pre-defined Excel Named Ranges for instance.

When writing to a spreadsheet and a sheet name has been specified that does not exist, a new sheet will be added to the workbook with that name. Reading a spreadsheet and using an unknown range or sheet name will result in an error.

The following table summarizes all possible input combinations and their interpretation:

<table>
<thead>
<tr>
<th>Input</th>
<th>Sheet used</th>
<th>Cell(s) used</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>First sheet</td>
<td>A1</td>
<td></td>
</tr>
<tr>
<td>!</td>
<td>First sheet</td>
<td>A1</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>First sheet</td>
<td>Name</td>
<td>When nc=0</td>
</tr>
<tr>
<td>Name</td>
<td>Name</td>
<td>A1</td>
<td>When nc=1</td>
</tr>
<tr>
<td>Name!</td>
<td>Name</td>
<td>A1</td>
<td></td>
</tr>
<tr>
<td>!Name</td>
<td>First sheet</td>
<td>Name</td>
<td></td>
</tr>
<tr>
<td>Name1!Name2</td>
<td>Name1</td>
<td>Name2</td>
<td></td>
</tr>
</tbody>
</table>

The term nc= refers to the nameConv option.

5.29.3 Return Codes

On success, GDXXRW will return 0 as error code. However, there might be an error which will be signaled with a specific return code in addition to an error message.
<table>
<thead>
<tr>
<th>Return Code</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error</td>
</tr>
<tr>
<td>1</td>
<td>Cannot write log</td>
</tr>
<tr>
<td>2</td>
<td>GDX error</td>
</tr>
<tr>
<td>3</td>
<td>No input file</td>
</tr>
<tr>
<td>4</td>
<td>Input file not found</td>
</tr>
<tr>
<td>5</td>
<td>Bad parameter</td>
</tr>
<tr>
<td>6</td>
<td>Read error</td>
</tr>
<tr>
<td>7</td>
<td>Problem loading GDX DLL</td>
</tr>
<tr>
<td>8</td>
<td>Symbol not found</td>
</tr>
<tr>
<td>9</td>
<td>Dimension different</td>
</tr>
<tr>
<td>10</td>
<td>Types different</td>
</tr>
<tr>
<td>11</td>
<td>Bad UELs</td>
</tr>
<tr>
<td>12</td>
<td>Bad output file</td>
</tr>
<tr>
<td>13</td>
<td>Problem opening Excel</td>
</tr>
<tr>
<td>14</td>
<td>Problem writing to Excel</td>
</tr>
<tr>
<td>15</td>
<td>Problem reading from Excel</td>
</tr>
<tr>
<td>16</td>
<td>Duplicate entry</td>
</tr>
<tr>
<td>17</td>
<td>Cannot add sheet</td>
</tr>
<tr>
<td>18</td>
<td>Bad cell value</td>
</tr>
<tr>
<td>19</td>
<td>Dimension conflict</td>
</tr>
<tr>
<td>20</td>
<td>Data exceeds range</td>
</tr>
<tr>
<td>21</td>
<td>Exceeds range or memory problem</td>
</tr>
<tr>
<td>22</td>
<td>Deprecated</td>
</tr>
<tr>
<td>23</td>
<td>Program aborted</td>
</tr>
<tr>
<td>24</td>
<td>Merge range empty</td>
</tr>
<tr>
<td>25</td>
<td>Too many columns skipped</td>
</tr>
<tr>
<td>26</td>
<td>Too many rows skipped</td>
</tr>
</tbody>
</table>

### 5.29.4 Warning

When executing `GDXXRW` twice and redirecting output to the same log file may result in a fatal error.

For example:

```
gdxxrw step1 parameters > logfile
gdxxrw step2 parameters > logfile
```

The execution of step2 may fail, because Excel will close the logfile in step1 in a delayed fashion, but return control to `GDXXRW` immediately. Using the `log` or `logAppend` parameter will avoid this problem.
5.29.5 Reading from Spreadsheet - Examples:

5.29.5.1 Reading Set from Spreadsheet

Assuming we want to read set elements from the first sheet of the spreadsheet file test.xlsx and write the data to test.gdx.

Either of the following two statements below reads the second row of set elements from the spreadsheet above:

```
gdxxrw exampleData.xlsx set=i1 rng=readingSets!A2:C2 cDim=1
```
```
gdxxrw exampleData.xlsx dSet=i1a rng=readingSets!A2:C2 cDim=1
```

When the output file is not specified, the output file will be derived from the input file by changing the file extension of the input file and removing any path information. Since all elements in the second row are unique, there is no need of increasing the maxDupeErrors parameter to avoid an error message when defining the symbol as set. By specifying the symbol directly as a dSet (domain set) in the second statement, duplicate labels would be removed without throwing an error. We set cDim to one so that the first row of the range is used for the labels of the set.

On the other hand if we want to read set elements listed in a column:

Either of the following two statements reads column A of set elements from the spreadsheet above:

```
gdxxrw exampleData.xlsx set=j1 rng=readingSets!A35:A37 rDim=1
```
```
gdxxrw exampleData.xlsx dSet=j1a rng=readingSets!A35:A37 rDim=1
```

Besides the range we also had to change the parameter rDim to indicate that the first column of the range is to be used for the labels.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample18] for reference.

5.29.5.2 Reading Set and Explanatory Text

Suppose we want to read the set elements in the ninth row and their associated text in the tenth row of the following spreadsheet:

We can read the set elements and their explanatory text by executing the command:

```
gdxxrw exampleData.xlsx set=i3 rng=readingSets!A9:E10 cDim=1
```

To read the explanatory text, we simple include the tenth row within the range of the symbol i3 and specify cDim=1. By doing this, the first row of the range, i.e. the elements of the ninth row, will be used as the set elements, while the tenth row will be interpreted as their associated text (depending on the values option specified. By default, the values option is set to dense in this example, i.e. all elements will be included and the string in the associated data cell will be used as explanatory text. See also Reading set elements associated with Data or Text for instance.).

Note here the explanatory text of the set element skipme2 is just a Y as it has a blank entry for the explanatory text.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample18] for reference.
5.29.5.3 Reading Set Elements associated with Data or Text using the values Option

When reading set elements from spreadsheet, the values option can be used to control whether elements and associated text are included in the set or not. We use the data displayed in the spreadsheet below to demonstrate the \texttt{yn}, \texttt{dense}, \texttt{sparse} and \texttt{noData} specifications:

The set element names are stored in the first row, the associated data cells in the second row.

1. \texttt{values=yn}
Run the following command to load those element names associated with nonzero data or yes without storing the data as explanatory text:

```bash
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=yn
```

The set \( A \) will contain the elements \( a, b, e, f, h, i, k \) and \( m \), since the elements \( c, d, g, j \) and \( l \) are associated with a zero, a blank or a no resp. \texttt{N} (case insensitive).

2. \texttt{values=dense}
This option must be specified, if we want to read all elements while using the strings in the data cells as explanatory text.

```bash
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=dense
```

3. \texttt{values=sparse}
To read in all elements having a non-empty data cell while interpreting the string in the data cell as explanatory text, run the following command:

```bash
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=sparse
```

The set \( A \) will contain all elements except for \( j \), since the associated data cell is empty.

4. \texttt{values=noData}
This option must be used, if we want to read all set elements while ignoring the data range. Especially, the data cells will not be interpreted as explanatory text. To read the elements from the range \( A1:M1 \), one could run the following command:

```bash
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M1 cDim=1
```

While all elements \( a - m \) will be included this way, the second row will be automatically interpreted as explanatory text (even though we specified only the first row within the \texttt{rng} statement). This might be not desirable at all in some situations, e.g. when reading the city names in the next example Reading Set from Data Tables, we do not want to have the numbers 5000, 6000 and 0 to be explanatory text for the city names. Run the following command to include all elements in your set without interpreting the cells in the second row as explanatory text:

```bash
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M1 cDim=1 values=noData
```

5. \texttt{values=auto} (default)
The second table within the description of the values options indicates which value type will be used by default based on the \texttt{rng}, \texttt{cDim} and \texttt{rDim} specifications for the set. For instance, when running the following command:

```bash
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1
```

the value type used is \texttt{dense}, since we specified a block range with a data row and \texttt{rDim} equals zero.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample9] for reference.
5.29.5.4  Reading Set from Data Tables

One may wish to load set elements from a data table. Given a spreadsheet segment like the following:

We can take the set across the top containing the elements cleveland, chicago and dallas with any of the following commands:

```
gdxxrw exampleData.xlsx set=i6  rng=readingSets!B20:D20  cDim=1  values=noData
gdxxrw exampleData.xlsx dSet=i6a  rng=readingSets!B20:D20  cDim=1
gdxxrw exampleData.xlsx set=i6c  rng=readingSets!B20:D21  cDim=1  values=noData
```

Note the usage of the values option in order to avoid reading the numbers as explanatory text. See also Reading set elements associated with Data or Text. However, this can also be avoided by declaring the symbol as a domain set using the symbol declaration dSet.

We can also take a set vertically from column A as follows:

```
gdxxrw exampleData.xlsx dSet=j4  rng=readingSets!A21:A23  rDim=1
```

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample18] for reference.

5.29.5.5  Reading Set from Lists with Duplication

One may wish to extract set elements from a spreadsheet where there is no unique list of elements that can be read but rather a list where some names are repeated. In the example below note that in rows 26 and 27 there are set element names but they are duplicated:

One can read this using dSet as follows:

```
gdxxrw exampleData.xlsx dSet=i7  rng=readingSets!B26:E26  cDim=1  dSet=i8  rng=readingSets!B27:E27  cDim=1
```

Both domain sets will be read within a single GDXXRW call. The rng and cDim specifications affect only the symbol that they are following directly.

It may be favored in some situation to use the set symbol instead (e.g. for reading explanatory text). To oppress an error message when reading sets with duplication, one must specify a sufficient large number within the maxDupeErrors option.

```
gdxxrw exampleData.xlsx maxDupeErrors=4  set=i7  rng=readingSets!B26:E26  cDim=1  values=noData  set=i8  rng=readingSets!B27:E27  cDim=1  values=noData
```

For the data in this example, four is a sufficient large number since there are two duplicates for the first and two duplicates for the second set within each range. Note the usage of the values option in order to avoid reading ‘cleveland’ as explanatory text for the elements of set i7 and to avoid reading the numbers as explanatory text for the elements of i8. See also Reading set elements associated with Data or Text for more informations about the values option.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample18] for reference.
5.29 GDXXRW

5.29.5.6 Reading Parameter from Spreadsheet

Assuming we want to read parameter data1 from the file Test1.xls and write the data to Test1.gdx.

The following statement reads parameter data1 from the spreadsheet above (using the par data type):

```gdx
gdxxrw Test1.xls par=data1 rng=A1:D3 cDim=1 rDim=1
```

The sheet name in a range can be omitted when it refers to the first sheet. The elements in the first row and first column of the data range will be used as labels for the two dimensional parameter data1 by defining cDim=1 and rDim=1 (see also cDim resp. rDim).

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample5] for reference.

5.29.5.7 Reading Parameter from Spreadsheet with Duplication

The same data as in the previous example, but organized differently. We use the dSet symbol specification instead of set to read set I (in column A) and set A (in column B), since there are duplicate entries in column A resp. column B.

The following statement reads parameter data2 from the spreadsheet above:

```gdx
gdxxrw Test1.xls par=data2 rng=EX2!A1 rDim=2 dSet=I rng=EX2!A1 rDim=1 dSet=A rng=EX2!B1 rDim=1
```

By setting rDim=2 for the parameter data2 we indicate to use the first two columns of the data range as the labels for the parameter values. Since the sheet does not contain further data, one can specify the ranges using the top left cell notation without hesitation.

When using a few symbols, the command line can become too long to be practical. In such case, use a text file to hold the parameters. A parameter file can contain multiple lines to increase readability and a line starting with an asterisk (*) will be ignored.

```gdx
* file example6.txt
par =data2 rng=EX2!A1 rDim=2
dSet=I rng=EX2!A1 rDim=1
dSet=A rng=EX2!B1 rDim=1
```

An option file is indicated by preceding the file name with a @ (At sign.).

```gdx
gdxxrw Test1.xls @example6.txt
```

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample6] for reference.

Note

- An option file can contain multiple lines to increase readability.
- When reading parameters from a text file, lines starting with an asterisk (*) will be ignored and act as a comment.
- An option file can also be written during the execution of a GAMS model using the GAMS Put Facility and the subsequent GDXXRW commands must use execute command so the put file is written before it is to be read (this would happen when using the compile time command $call to run GDXXRW).
5.29.5.8 Reading Multi-dimensional Parameter from Spreadsheet

This example illustrates how to read a four dimensional parameter from spreadsheet:

The strings in the first two columns and the first two rows of the data range A1:F6 shall be used as labels for the parameter values. Therefore, we define \( r\text{Dim}=2 \) and \( c\text{Dim}=2 \) (see also \( r\text{Dim} \) and \( c\text{Dim} \)). The parameter will be named data3 (within the \textit{par} declaration). Run the following command to read the data with GDXXRW:

\[
gdxxrw \text{Test1.xls par=data3 rng=EX3!A1:F6 rDim=2 cDim=2}
\]

Note that the data range was specified using the block range notation. However, it might be more comfortable to specify only the top left corner sometimes, but empty rows or columns may affect the reading process, i.e. GDXXRW might stop to early when encountering empty rows or columns or it will try to read data separated by empty rows or columns not being part of the data you wish to read. When we specify the range as a block, an empty row or column will always be ignored. When we specify the top left cell only, the \textit{skipEmpty} option can be used to ignore one or more empty rows or columns. However, for the data in this example, we do not need to ignore empty rows or columns within the data range, but suppose there is non-relevant data starting in column H. By default (\textit{skipEmpty}=1), GDXXRW would try to read the data starting in H. When we specify \textit{skipEmpty}=0 and cells A7, B7, G1 and G2 are empty, the range can be specified with the top left cell only in this example:

\[
gdxxrw \text{Test1.xls skipEmpty=0 par=data3 rng=EX3!A1 rDim=2 cDim=2}
\]

Since \textit{skipEmpty} is a global option, affecting every symbol that follows, we define it before declaring the parameter data3.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample7] for reference.

5.29.5.9 Reading Spreadsheet using the Index Option

The \textit{index} option is used to read a number of parameters and sets based on information stored in the spreadsheet itself. By doing this, the GDXXRW command becomes quit short and the informations on how to read the data can be written directly within the spreadsheet to increase readability. The first row of the range is used for column headings indicating additional parameters. We will discuss the results only briefly, because all other options used in this example were demonstrated before.

Suppose we want to read the parameters and sets from the following spreadsheet:

The informations about all parameters and sets are stored within the sheet index in the same spreadsheet file exampleData.xlsx as testIndex above:

The following statement reads parameters and sets from the spreadsheets using the \textit{index} option:

\[
gdxxrw \text{exampleData.xlsx output=gdxAll.gdx index=index!A1}
\]

We use the \textit{output} option to write the data to gdxAll.gdx for demonstration here. By default, GDXXRW would write to testIndex.gdx. Some brief remarks on the results:
- Elements of set $i_1$ and $i_1a$: trains, cars and planes. There is no explanatory text, since the data range (third row) is empty. We can use $\text{dim}=1$ equivalently to $\text{cDim}=1$ in this example, because by default, $\text{cDim}=1$ and $\text{rDim}=\text{dim}-1$. See also dimensions.

- When reading the sets $i_2$ and $i_3$, we are defining which elements and explanatory text will be stored by specifying the values option.

- The set $i_4$ will contain all elements of the thirteenth row. Afterwards, $\text{skipEmpty}$ is set to zero, affecting the reading of $i_4a$ and $i_5$. Unlike $i_4$, the sets $i_4a$ and $i_5$ will not contain the element houston, since $\text{skipEmpty}=0$ and the empty column signals GDXXRW to stop reading (note that the range is not defined using the block range specification). Since there is a data range for $i_5$, the strings city1 - city5 will be used as explanatory text by default. After reading $i_4a$ and $i_5$, $\text{skipEmpty}$ is reset to zero (default).

- Each of the sets $i_6$, $i_6a$ and $i_6b$ will contain the elements cleveland, chicago and dallas. There is no explanatory text for any of the sets in the GDX file, however, one must enforce this for the set $i_6$ with $\text{values}=\text{noData}$.

There are no interesting details for the remaining sets and parameters to discuss here. The complete example and the results displayed within GAMS can be found in the GAMS Data Utilities Library, see model [GDXXRWExample10] for reference.

Note

- The parameters and sets are read using the specifications within the myIndex sheet. They are treated as if they appeared directly on the command line.

- In the spreadsheet, the first three columns of the range have a fixed interpretation: DataType (par, set, dSet, equ, or var), Item name identifier and spreadsheet data range. The fourth and following columns can be used for additional parameters like $\text{dim}$, $\text{rDim}$, $\text{cDim}$, merge, clear and $\text{skipEmpty}$. The column header contains the keyword when necessary, and the cell content is used as the option value.

- When an entry appears in a column without a heading then it is directly copied into the GDXXRW option file. Thus in the example above the items in column G are directly copied into the file.

- Rows do not need to have entries in the first three columns if one just wants to enter persistent options such as $\text{skipEmpty}$ or some of the special character string re-definitions (as in row seven and ten from the spreadsheet above).

### 5.29.5.10 Reading Data from Spreadsheet and Loading into GAMS

One can use $\text{call}$ to execute the GDXXRW command in the GAMS code to read from spreadsheet at compilation time (the data is taken from the previous example):

```
$call gdxxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData
```

Getting a set from the spreadsheet into a GDX file is only half the battle. One must also use commands in GAMS to load the data as discussed in the chapter Using GAMS Data Exchange or GDX Files. At compile time this is done using:
Set i9;
* read/load set from data at compile time
$call gdxxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData
$gdxIn testIndex.gdx
$load i9

where the set must be declared in a set statement then one can if needed create the GDX file using GDXXRW, then one uses a $gdxIn to identify the source file and a $load to bring in the data.

Some users may wish to load sets at execution time. However, this is limited to subsets that are dynamic sets and cannot be used in domains. To do this one simply uses the statements as above, but substitutes execute in place of $call as follows:

Set i9(i6a);
* read/load set from data at execution time
execute 'gdxxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData'
execute_load 'testIndex' i9;

where the set i9 must be declared as a subset in a set statement (of i6a in this case), then one can if needed create the GDX file using execution time GDXXRW, and an execute_load to bring in the data with an identification of the GDX source file name. Note that we used the set i6a as superset, fitting best to the data from the previous example. However, one could also use the statement Set i9(∗);

One can load the universe of labels from a GDX file into a set at run-time using the syntax:

execute_load 'someFile', someSet=∗;

Note
In doing this, only labels known to the GAMS program will be loaded.

5.29.5.11 Reading empty Cells with colMerge

Suppose we want to read the four dimensional parameter from the following spreadsheet:

The cells B4, B5, C4 and D5 might be empty to avoid duplication, i.e., the non-empty content of the previous cell in the same column shall be used as content for the empty cell. In particular: the content of B3 shall be used for the content of B4 and B5, the content of C3 for C4 and the content of D4 for cell D5.

Reading the above spreadsheet using the following GAMS statement:

\[ \text{gdxxrw exampleData.xlsx par=A_d rng=colMerge!B2 rDim=3 cDim=1} \]

results in empty cells B4, B5, C4 and D5, causing troubles if you want to declare the parameter as \( A(\text{number,number,number,color}) \) certainly:

Adding the symbol attribute colMerge, we use the non-empty content of the previous cell in the same column as the content for the empty cell. Specifying \( \text{colMerge=2} \) will do this for the first two columns for instance.

\[ \text{gdxxrw exampleData.xlsx par=A_2 rng=colMerge!B2 rDim=3 cDim=1 colMerge=2} \]

Only the two entries corresponding to the cell D5 are still empty, since we do not specify all three columns within colMerge:
Note

A blank field displayed in GAMS Studio indicates an empty UEL. In the GAMS IDE, there would be an `<empty>` entry instead.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample20] for reference.

### 5.29.5.12 Reading merged Excel Ranges with cMerge

Suppose we want to read the three dimensional parameter from the following spreadsheet:

Note that the label 'red' is centered over the merged cells B1, C1 and D1 and label 'green' over the merged cells E1 and F1. Additionally, in the data range, the cells B3:C3 and B4:C4 are merged, too. The option cMerge can be used to control the way merged cells are handled. We will discuss the effect of the possible values for cMerge on the data presented above by running the following commands (an option file is used to increase readability):

```gams
$onEcho > howToRead.txt
cMerge=0 par=B_d rng=cMerge!A1 rDim=1 cDim=2
cMerge=1 par=B_1 rng=cMerge!A1 rDim=1 cDim=2
cMerge=2 par=B_2 rng=cMerge!A1 rDim=1 cDim=2
$offEcho
call gdxxrw exampleData.xlsx output=cMerge.gdx @howToRead.txt
```

We specify cMerge in advance, since it is a global option affecting every symbol that follows. Executing the three statements will create three different output files, all displayed in GAMS Studio:

Note

A blank field displayed in GAMS Studio indicates an empty UEL. In the GAMS IDE, there would be an `<empty>` entry instead.

Some remarks on the results:

**cMerge=0** (default)
Empty cells being part of a merged Excel range will remain empty. Thus, the cells C1, D1, F1, C3 and C4 from the spreadsheet above will remain empty when reading with GDXXRW. Since C3 and C4 are empty while being part of the data range, they won't show up in the GDX file. The values in the last column of the GDX file are useful to compare the results with the spreadsheet. For instance, the UELs of the value 5 are `a`, `<empty>` and `two`, since the cell F1 is empty, while A3 contains the string `a` and F2 the string `two`.

**cMerge=1**
The value of a merged range within a row or column header will be used for all cells being part of the merged range. Thus, the string 'red' will be used for the cells in the column header C1 and D1 and the string 'green' for the cell F1. Since C3 and C4 are part of the data range, they will remain empty and are not displayed in the GDX file. As you can see, there is no longer an empty UEL.
cMerge=2
The value of a merged range will be used for all cells being part of the merged range, i.e. cMerge=1 is extended to the data range. Therefore, the value 1 resp. 11 will be also used for the cell C3 resp. C4, appearing in the GDX file for the first time. Since there is no change in handling merged cells within the row or column header, all values have non-empty labels.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample20] for reference.

5.29.5.13 Skipping Empty Rows and Columns

By using the skipEmpty option, we can control the way blank rows or columns are handled and causes GDXXRW to either stop or skip over if a blank row or column is encountered when using the top left corner range specification instead of a block range. If the range is specified using the TopLeft:BottomRight cell notation (often referred as block range notation), empty rows or columns will be skipped automatically.

Suppose the data is stored in the following spreadsheet:

We can read this spreadsheet and skip blank rows and columns with the following command:

```
gdxxrw exampleData.xlsx par=A_d rng=skippingRC!A2 rDim=2 cDim=1
```
or

```
gdxxrw exampleData.xlsx se=1 par=A_1 rng=skippingRC!A2 rDim=2 cDim=1
```

Note that there will be no difference concerning the generated GDX files, since skipEmpty is set to one by default. On the other hand, if skipEmpty is set to zero

```
gdxxrw exampleData.xlsx se=0 par=A_0 rng=skippingRC!A2 rDim=2 cDim=1
```

the blanks terminate the read not reading the rail column and the san francisco.chicago row. After loading into GAMS the data become:

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample21] for reference.

Note

The skipEmpty option must appear before any par, set, dSet etc statements that use it and will persist for the rest of the statements in a command unless it is set to another value.
5.29.5.14 Ignoring Rows and Columns

We can use the options ignoreColumns and ignoreRows to ignore columns and rows when reading data for a symbol. Suppose we want to ignore the red colored rows and columns of the following spreadsheet, when reading the four dimensional parameter:

We can read this spreadsheet and ignore the red colored columns and rows with GDXXRW by running the following command:

gdxxrw exampleData.xlsx par=A rng=ignoringRCC1 cDim=2 rDim=2 ignoreRows=2,6 ignoreColumns=D,G

The options ignoreRows and ignoreColumns are symbol options and therefore must appear after the symbol specification, affecting only this particular symbol.

In the example above we ignored column D which would have been part of the index for the rows. So the range for the row index was extended with column E. The E column is no longer part of the data range. The treatment of the column index is similar. The second row would have been part of the column index, and now that the row is ignored, the next row becomes part of the column index and the third row is no longer part of the data range.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample21] for reference.

Note

The ignoreColumns and ignoreRows options appear after any par, set, dSet etc GDXXRW command instruction and only affect reading of that item.

5.29.5.15 Reading Parameter from Spreadsheet using pre-defined Excel Named Ranges

As mentioned in section Excel Ranges, the range of a symbol to be read can be defined by using named ranges. To name a cell range within Excel, simply select the cell range and type in the name you want to assign to this particular range by using the name-box next to the top left corner of your spreadsheet. Suppose we want to read the data in the range A1:D3 taken from the example Reading Parameter from Spreadsheet:

Instead of specifying the range explicitly by rng=A1:D3, we use the pre-defined named range 'parRange', i.e. rng=parRange. GDXXRW uses the string specified to search for a matching pre-defined named range first. In summary, run the following command to read the parameter data4 from the file Test1.xls:

gdxxrw Test1.xls par=data4 rng=parRange rDim=1 cDim=1

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample5] for reference.

Note

In Excel, one can assign a single name to several separated block ranges, e.g. assign the name 'disconnected' to the block ranges A1:D3 and F4:H5 (by holding 'Strg' while selecting the second block range and using the name-box to assign the name). However, such disconnected data cannot be read using the named-range specification.
5.29.6 Writing to Spreadsheet - Examples:

5.29.6.1 Unloading Data from GAMS before Writing to Spreadsheet

When writing to spreadsheet with GDXXRW, one must use commands in GAMS to place the data into the GDX file at first (see also Using GAMS Data Exchange or GDX files). When reading data, it is often desirable to use a $call command to run GDXXRW and the statements $gdxIn and $load afterwards to load the data, allowing also domain definitions (at compile time) for instance. This is hardly ever desirable or realizable when unloading and writing to a spreadsheet, for example, if one wish to write the solution after solving a model to spreadsheet. This should generally not be done at compile time so one should only use the execute and execute_unload commands at execution time as follows:

execute_unload 'test.gdx' someParameter;
execute 'gdxxrw test.gdx par=someParameter rng=A1'

where the execute_unload tells what data to place in the GDX file and determines the GDX source file name. The matching GDXXRW execution tells the name of the GDX file, the name of the spreadsheet (optional) and identifies the data to write.

See also Writing Set to Spreadsheet and Writing Parameter to Spreadsheet for demonstration.

Note

- One must be careful when using GDXXRW as each time the command is executed the GDX file is erased and only has the current contents and thus should be written just before if reusing the name.
- One also obtains output of sets using the command execute_unload where the GDX file automatically includes all sets associated with unloaded parameters, variables and equations without need to list the set element names.

5.29.6.2 Writing Set to Spreadsheet

At first, we will create a GDX file containing a simple set using the execute and execute_unloading directives. Most of the elements have an explanatory text:

Set x / element1 'explanatory text'
          element2
          element3 'previous element does not have explanatory text' /
;
execute_unload 'writingSet.gdx' x;

Of course, in this particular code section above, one could also use $gdxOut and $unload. The values option can be used to control whether explanatory text is written to the spreadsheet. We'll demonstrate all three possible values explicitly within a single GDXXRW execution:
Before executing this example, check if the Excel file (writingSet.xlsx) is open. If you run GDXXRW for writing a file sharing conflict will arise. To avoid this problem, either close the Excel file or use the Excel Tools menu to make this a shared notebook. After writing to the spreadsheet (still opened), use the Excel "File Save" command to verify the changes made.

By adding two additional commas within the hText statement, the cells B1, C1 and E1, F1 will be skipped when writing the text to the first row of the spreadsheet. If values=noData, neither explanatory text nor a Y are written to spreadsheet for the set elements. If values=yn, GDXXRW writes a Y for each set element to spreadsheet. To write the explanatory text, specify values=string.

Since cDim=0, the default option is string (see values). Imagine a two dimensional set, one could write the set in a table format, i.e. cDim=1 and rDim=1. By default, GDXXRW would write this set using the values=yn format.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample11b] for reference.

Note
- A workbook cannot in general be open unless you have made special provisions with an error signaled indicating a file sharing conflict will arise when the target file is open in Excel.
- To avoid the sharing conflict error the user must either close the file or indicate that the spreadsheet is a shared Excel workbook by using the Excel Tools Share Workbook dialogue.
- In an open shared workbook the contents are not updated until you have done a file save in Excel.
- Writing to a shared workbook can be painfully slow.
- In general, it is best to close the workbook.

5.29.6.3 Writing Parameter to Spreadsheet

At first, we create a GDX file, containing some random data:

* file makeData.gms
Set
  i / i1*i4 /
  j / j1*j4 /
  k / k1*k4 /;
Parameter V(i,j,k);
V(i,j,k)$ (uniform(0,1) < 0.30) = uniform(0,1);
When we run this GAMS model from the command prompt using the following statement, the file `writingPar.gdx` will be created at the end of the run.

```
GAMS makeData gdx=writingPar
```

Using the file `writingPar.gdx`, we can write to a spreadsheet:

```
Write parameter V to the first cell in the first sheet; because we only specify the top left corner of the sheet, the complete sheet can be used to store the data. We do not specify the row and column dimension, so they will be set to \texttt{rDim=2} and \texttt{cDim=1} by default. (See also \texttt{dimensions})
```

By using the following command (remember to close an already existing file `writingPar.xlsx` in advance or make it a shared notebook as discussed in the previous example):

```
gdxxrw writingPar.gdx output=writingPar.xlsx par=V rng=A1
```

The steps above can be combined in a single GAMS model using the `execute_unload` and `execute` statements as follows:

```
Set
  i / i1*i4 /,
  j / j1*j4 /,
  k / k1*k4 /;

Parameter V(i,j,k);
V(i,j,k)$(uniform(0,1) < 0.30) = uniform(0,1);
execute_unload 'writingPar.gdx', i, j, k, V;
execute 'gdxxrw writingPar.gdx par=V rng=A1';
```

The resultant spreadsheet looks like:

Note that if we only want to write the parameter \texttt{V}, there is no need to unload the sets \texttt{i}, \texttt{j} and \texttt{k} explicitly. The labels written to the columns \texttt{A} and \texttt{B} and to the first row are stored directly together with \texttt{V} in the GDX file.

This example is also part of the GAMS Data Utilities Library, see model \texttt{[GDXXRWEExample11b]} for reference.
5.29.6.4 Writing to Spreadsheet with merge Option

When writing to a spreadsheet one can control data handling and matching using the `merge` command line option. When `merge` is active, the only data that will be written to the spreadsheet are those data for which the element names match row and column labels that are in the spreadsheet already. Also under `merge`, spreadsheet cells for which there is no matching row/column pair will not be changed. This option might be very useful, e.g., if there is a fixed report layout/framework already in your spreadsheet file which should not be changed when writing the data from GAMS.

Suppose we want to write the parameter \( A \), already stored in data.gdx, to an existing spreadsheet:

In the following spreadsheet, there are row and column labels matching most of the data in the GDX file, except for the additional column header 'horse' and the non existing row labels 'san francisco.chicago':

Use the following commands to write the data from GDX to spreadsheet twice to different ranges for comparison:

```
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!B1:G4 rDim=2 cDim=1 merge
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!B8   rDim=2 cDim=1
```

Note that `merge` is a symbol option affecting only the symbol \( A \). The resultant spreadsheet looks like:

The parameter is written to the range B8-F12 without `merge` enabled, while the option is enabled when writing to the range B1:G4, respecting the data arrangement already existing. Note that the column and row orders vary and the san francisco - chicago row is missing since it is not mentioned in the labels within the spreadsheet before the merge operation, while the horse column is still present with it's data left alone, not being overwritten by the parameter.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample12] for reference.

Note

- Using the `merge` option will force the data to be presented in the order in which the row and column labels are entered already.
- GDX file contents that do not have matching row/column pair of named elements in the spreadsheet will be overlooked.
- A write under a `merge` option addressing a blank area of a spreadsheet will always be blank as there will not be matching set elements at all.
- The matching of labels is not case-sensitive.
- Warning: Enabling the `merge` option will clear the Excel formulas in the rectangle used, even if the cells do not have matching row/column headings in the GDX file. Cells containing strings or numbers are not affected.
5.29.6.5 Writing to Spreadsheet with clear Option

When writing to a spreadsheet one can also use the clear option to control data handling and matching. When clear is enabled, the only data that will be written to the spreadsheet are those data for which the element names match row and column labels that are in the spreadsheet already but all data and formulas in the target range will be removed.

Suppose the parameter A from the previous example is stored in data.gdx and there are row and column labels matching most of the data in the GDX file, except for the additional column header 'horse' and the non-existing row labels 'san francisco.chicago':

Use the following command to write to exampleData.xlsx with clear enabled:

```gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!I1 rDim=2 cDim=1 clear```

then the result is

The results are similar to those under merge but the old data in the column labeled 'horse' has been removed.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample12] for reference.

Note

- Using the clear option will force the data to be presented in the order in which the row and column labels are entered already.
- GDX file contents that do not have matching row/column pair of named elements in the spreadsheet will be overlooked.
- A write under a clear option addressing a blank area of a spreadsheet will always be blank as there will not be matching set elements.
- The matching of labels is not case-sensitive.
- Warning: The clear option will clear all Excel formulas and values in the rectangle used, even if the cells do not have matching row/column labels in the GDX file.

5.29.6.6 Writing to Spreadsheet using a Filter

In Excel, you can filter the data by some specified conditions so that only the data matching the conditions is displayed. This might be useful in some cases, e.g. it helps you to focus on the most relevant data within a large table of data. With GDXXRW you can add some basic filter to your spreadsheet when writing data from a GDX file.

The following example creates a small GDX file with some random data, which is used to write the symbol A to a spreadsheet later on with the filter option enabled.

Set

- `i / i1*i2 /`
- `j / j1*j2 /`
- `k / k1*k2 /`

Parameter A(i,j,k);
A(i,j,k) = uniform(0,1);
execute_unload 'test.gdx', A;
execute 'gdxxrw test.gdx filter=1 par=A rDim=1 cDim=2 rng=Sheet1!A1';
Since **filter** is a global option, it must be specified in advance of the symbols for which you want to add a filter. The default value is zero, i.e. no filter will be added. If there are multiple rows in the column header, i.e. **cDim** is greater than zero, the valid range for the filter option is 1..**cDim**.

The screenshot above shows the filter in Excel. When we specify **filter=2** in this example with two dimensions for the column header, the row with the filter moves away from the data range as illustrated below:

One could now filter the data, e.g. displaying only the values where the label of the first dimension is **i1** by selecting this value exclusively within the drop down menu of column A.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample15] for reference.

### 5.29.6.7 Writing to Spreadsheet adding Text and Hyperlinks

The following example illustrates the use of the **text directive**. Adding text and hyperlinks to your spreadsheet is useful to customize the output and to navigate more quickly through the data.

First, we write some data to a GDX file and we use the text directive to write text to various cells in the spreadsheet; some of the cells are hyperlinks to other locations. To increase readability, we'll use a parameter file **howToWrite.txt** to shorten the **GDXXRW** statement.

```plaintext
Set
  i / i1*i9 /
  j / j1*j9 /;

Parameter A(i,j);
A(i,j) = 10*ord(i) + ord(j);
execute_unload 'pv.gdx' A;

$onEcho > howToWrite.txt
  text="Link to data" rng=Index!A2 linkID=A
  text="Below the data for symbol A" rng=data!C2
  par=A rng=data!C4
  text="Back to index" rng=data!A1 link=Index!A1
  text="For more information visit GAMS" rng=data!C1 link=http://www.gams.com
$offEcho

execute 'gdxxrw pv.gdx output=pv.xls @howToWrite.txt'
```

We will write the text "Link to data" to the cell A2 of sheet Index. The option **linkID** is used to add a hyperlink to the range of the symbol A. In addition, we create a hyperlink "Back to index" in the cell A1 of sheet data using the **link** option pointing to the cell A1 of sheet Index. One can also specify links to external sources. For demonstration, we add a link to the GAMS homepage.

Below a screen shot showing both sheets data and Index created by the commands above:

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample16] for reference.
5.29.7  Reading and Writing, Extended Use - Examples:

5.29.7.1  Reads a Table from Spreadsheet, manipulates the Data and writes back to Spreadsheet

In the following example, we read data from a spreadsheet and save the data in a GDX file. Using the `gdxIn` and `load` GAMS directives, we load the data from the GDX file into GAMS afterwards. The GAMS program modifies the data and at the end of the run the data is saved in a new GDX file (tmp.gdx). The last step updates the spreadsheet with the modified parameter.

We read the spreadsheet and load the data from the resultant GDX file at compile time. The data modification and the unloading and writing process are done at execution time, using the `execute_unload` and `execute` directives:

```
$call gdxxrw test1.xls dSet=I rng=A2:A3 rDim=1 dSet=A rng=B1:D1 cDim=1 par=X rng=A1:D3 rDim=1 cDim=1
$gdxIn test1.gdx
Set I(*), A(*);
$load I A
Parameter X(I,A);
$load X
display I, A, X;
$gdxIn
X(I,A) = - X(I,A);
execute_unload 'tmp.gdx', I, A, X;
execute 'gdxxrw tmp.gdx output=test1.xls par=X rng=EX6!A1:D3 rDim=1 cDim=1';
```

The parameter is written to the sheet EX6. However, since we only write the parameter `X`, we do not necessarily have to unload the set `I` and `A`.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample13] for reference.

5.29.7.2  Reading Data from Spreadsheet and writing Data to Spreadsheet after Solve

In this example, we use a modified version of the [trnsport] model from the GAMS model library to demonstrate the process of reading data, defining and solving the model and writing a solution report to spreadsheet altogether. This example illustrates in particular:

- Compilation phase
- Read data from a spreadsheet and create a GDX file
- Loading sets from the GDX file
- Using the sets as a domain for additional declarations
- Reading additional data elements
- Execution phase
- Solve the model
- Write solution to a GDX file
- Use GDX file to update spreadsheet

A parameter file howToRead.txt is used to increase the readability of the GDXXRW call. Note that the dimension of the scalar we want to read is set to zero. The range of each parameter can be specified by using the top left corner only, since there are two empty rows separating the data blocks from each other and the default value of skipEmpty signals to stop reading if two empty rows occur.

```plaintext
$onEcho > howToRead.txt
dSet=i rng=A3:A4 rDim=1
dSet=j rng=B2:D2 cDim=1
par =a rng=A2 rDim=1 cDim=1
par =b rng=A13 rDim=1
par =f rng=A19 dim=0
$offEcho
$call gdxxrw TransportData.xls @howToRead.txt
$gdxIn TransportData.gdx

Set
  i(*) 'canning plants'
  j(*) 'markets';

$load i j
display i, j;

Parameter
  a(i) 'capacity of plant i in cases'
  b(j) 'demand at market j in cases'
  d(i,j) 'distance in thousands of miles';

Scalar f 'freight in dollars per case per thousand miles';
$load d a b f
$gdxIn

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;

Variable
  x(i,j) 'shipment quantities in cases'
  z 'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
  cost 'define objective function'
  supply(i) 'observe supply limit at plant i'
  demand(j) 'satisfy demand at market j';

  cost.. z =e= sum((i,j), c(i,j)*x(i,j));
  supply(i).. sum(j, x(i,j)) =l= a(i);
  demand(j).. sum(i, x(i,j)) =g= b(j);
```
Model transport / all /;
solve transport using lp minimizing z;
display x.l, x.m;
execute_unload 'TrnsportData.gdx', x;
execute 'gdxxrw TrnsportData.gdx output=TrnsportData.xls squeeze=n var=x.l rng=Sheet2!A1';

The solution is written to Sheet2 of the input file TrnsportData.xls by executing GDXXRW at execution time. The var statement is used in the symbol specification to write out the level of variable x. In order to write zero values, the squeeze option is disabled. Otherwise, the cells C4 and D3 remain blank.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample14] for reference.

5.29.7.3 Reading Special Values from Spreadsheet and writing to Spreadsheet

This example demonstrates the reading and writing of special values with GDXXRW.

Reading Special Values
Assuming we want to read the special values stored in the spreadsheet below:

The following statement reads parameter vIN from the spreadsheet above:

gdxxrw exampleData.xlsx output=specialValues.gdx NaIn=N/A squeeze=n par=vIN cDim=1 rng=specialValues!A1:S2

To affect the parameter vIN, the global options NaIn and squeeze (to display zero values in the GDX file) must be specified in advance.

The cells containing the strings Eps, +Inf, -Inf, Inf, NA and Undf are read in correctly. The division by zero error in the spreadsheet will be written as Undf. We defined a new string - 'N/A' - within the option NaIn to be recognized as NA additionally. Within GAMS, there is no directly comparable data type for 'None' and 'Null', so these strings will be interpreted as Undf. Note the importance of the cell format specified within Excel. For instance, the values for v13 and v14 are different, although both fields contain a Dollar sign, since the cell format of M2 is 'General', while the cell format of N2 is 'Currency'.

The boolean 'False' turns into zero after reading, while 'True' turns into -1. Note here, that this is independent whether the booleans are written as plain text within Excel or by using the formulas '='True()' resp. '='False()'!. We disabled squeeze in order to display the zero values for the elements v16, v18 and v19 in the GDX file.

Writing Special Values
Initially, we declare a parameter with special values and generate a GDX file from it:

$onUndf
Set v / v1*v7 /;
Parameter vOUT(v) / v1 Eps, v2 +Inf, v3 -Inf, v4 Inf, v5 Undf, v6 0.0, v7 NA /;
Scalar S / 0 /;
execute_unload 'specialValues.gdx', v, vOUT, S;
We will write the parameter vOUT to spreadsheet twice. At first to demonstrate the usage of EpsOut, plInfOut, mInfOut, UndfOut, zeroOut and NaOut, the second time to show the default settings when writing. Those output string options may be useful, if the GAMS default settings are not appropriate for your Excel calculations later on or to customize the representation of the values in Excel in general. Note that there is also a scalar declaration in order to demonstrate the different behavior when writing scalars and parameter with zero values to Excel while using the zeroOut option.

$onEcho > howToWrite.txt
* defining new strings to be used when writing special values:
EpsOut=0 plInfOut=+1E+100 mInfOut=-1E+100 UndfOut=undefined zeroOut=zero NaOut=notAvailable

* now write parameter vOUT with merge to force the column F containing set element "v6" and vOUT("v6"
set=v   rng=specialValues!A6:G6 cDim=1
par=vOUT rng=specialValues!A6:G7 cDim=1 merge
text="Special values of Parameter vOUT written with user defined output strings:" rng=specialValues!A5
text="Scalar S / 0 /:" rng=specialValues!I6
par=S rng=specialValues!I7

* reset the strings for special values back to default und write vOUT again
resetOut
set=v   rng=specialValues!A10:G10 cDim=1
par=vOUT rng=specialValues!A10:G11 cDim=1 merge
text="Special values of Parameter vOUT written with default output strings:" rng=specialValues!A9
text="Scalar S / 0 /:" rng=specialValues!I10
par=S rng=specialValues!I11
$offEcho

evaluate 'gdxxrw specialValues.gdx output=exampleData.xlsx @howToWrite.txt';

In order to increase readability when executing GDXXRW, we use a parameter file named howToWrite.txt and additionally, we write some text out to structure the Excel file. The range for the non-default values is A6:G7. We define the new strings to be used for the special values first, affecting the following symbols. To write the default values to the range A10:G11, we use the resetOut option to reset the output strings to default, otherwise, the new strings remain in effect, since they are global options.

As mentioned briefly above, the zeroOut option affects the scalar S and the parameter vOUT differently. While we get the expected result - 'zero' - for the scalar S, the cell F7 for the zero value of vOUT remains empty, since zero values of parameters are not even part of the GDX file in general (and cannot be added from your GAMS model; Note here, that the squeeze options only affects the writing of sub-fields of variables and equations). Therefore, cell F11 has no value, too. Though scalars with zero values are stored in the GDX file. We'll present a workaround for writing zero values of a parameter to spreadsheet in the next example Writing Parameter to Spreadsheet including Zero Values.

The complete example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample8] for reference.

Note

- When writing to a spreadsheet, special values such as Eps, NA, Undf and Inf will be written but this can be changed. When reading data from a spreadsheet, the ASCII strings for these special character strings will be used to write corresponding special values to the GDX file.
- Cells that are empty or zero will not be written to the GDX file.
5.29.7.4 Writing Parameter to Spreadsheet including Zero Values

There is no straight way to write zero values of a GAMS parameter to spreadsheet from your model using GDXXRW, since zero values of a parameter are not stored in the GDX file (see also the previous example Reading Special Values from Spreadsheet and writing to Spreadsheet). However, instead of the zero values one can store an EPS in the GDX file and instruct GDXXRW to use a zero when writing the value for EPS using the epsOut option afterwards as demonstrated below:

Set i / i1*i9 /;
Parameter A(i), Amod(i);
A(i) = uniformInt(0,1);

* Amod(i) = A(i) if A(i) <> 0 and Amod(i) = EPS if A(i) = 0
Amod(i) = EPS$(not A(i)) + A(i);

* Unload the unmodified and modified parameter and write to spreadsheet using an option file
execute_unload 'zeroPar1.gdx' A Amod;

$onEcho > howToWrite1.txt
text="Parameter A" rng=A1
par=A rng=A2
text="Modified Parameter Amod written with epsOut: 0" rng=A5
epsOut=0 par=Amod rng=A6
$offEcho
execute 'gdxxrw zeroPar1.gdx output=writingZeros.xlsx @howToWrite1.txt';

This approach is impracticable in the unlikely event that there are already EPS values in your parameter and you want to write these as EPS to your spreadsheet.

An alternate approach regarding variables while exploiting the squeeze option is demonstrated below (parameter A and set i refer to the data above):

Variable dummyPar(i);
dummyPar.l(i) = A(i);

* In order to write every entry of dummyPar in the spreadsheet, one must allocate
* a non-zero value to one of the variable attributes .m, .lo or .up
dummyPar.up(i) = 1;

* Unload the dummy variable and write the .l subfield to spreadsheet while disabling squeeze
execute_unload 'zeroPar2.gdx' dummyPar;

$onEcho > howToWrite2.txt
text="Variable dummyPar written with squeeze: n" rng=A9
squeeze=n var=dummyPar.l rng=A10
$offEcho
execute 'gdxxrw zeroPar2.gdx output=writingZeros.xlsx @howToWrite2.txt';

Creating the additional variable and the allocation of a non-zero value to one of the other variable attributes are the drawbacks of this approach. Note that we only declared the parameter Amod to keep the original data of A untouched in order to run the code in a single model and to write A to spreadsheet, too.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample19] for reference.
5.29 GDXXRW

5.29.7.5 Reading several Scalars from Spreadsheet

Suppose you want to read a large number of scalars (i.e. scalar names and their associated values) for your model from a spreadsheet file as shown below. Originally, the data was taken from the model \(\text{[indus89]}\) of the GAMS Model Library.

Natively, one could declare all scalars directly inside the model and read every single one of them with GDXXRW afterwards (the following code is shortened for representation):

Scalar baseyear, repco;

$call gdxxrw exampleData.xlsx output=indus89Scalars.gdx par=baseyear rng=indus89Scalars!B2 dim=0 par repco rng=indus89Scalars!B3 dim=0 trace=0
$gdxIn indus89Scalars.gdx
$load baseyear repco

However, the code would become quite long and circumstantially for this example, especially the GDXXRW statement, because every scalar must be specified individually. Therefore, we present a more sneaky way to tackle the problem. At first, the file mkScalar.gms is written. We declare a set and a parameter to hold the scalar names and their values. A simple GDXXRW call is used to read the names and values from the file indus89Scalars.xls. Afterwards, we load the data using $gdxIn and $load. The result of this is a single parameter containing the scalar values defined over a set containing the scalar names. However, this is not exactly what we are looking for. To transform this representation into several single scalar definitions, we use a simple loop over the set scalarNames and the Put Writing Facility to generate a file scalars.gms, containing those single scalar statements.

$onEchoV > mkScalar.gms
Set scalarNames;
Parameter scalarValues(scalarNames);

$call gdxxrw exampleData.xlsx output=indus89Scalars.gdx set=scalarNames rng=indus89Scalars!A2:A22 rDim=1 par=scalarValues rng=indus89Scalars!A2:B22 rDim=1
$ifE errorLevel<>0 $abort Problems reading sheet indus89Scalars with GDXXRW
$gdxIn indus89 Scalars.gdx
$load scalarNames scalarValues

File fs / 'scalars.gms' /;
put fs;
loop(scalarNames, put / 'Scalar ' scalarNames.tl ' / ' scalarValues(scalarNames):>20:10 ' /';');
$offEcho

$call gams mkScalar
$include scalars.gms

Calling the file mkScalar.gms will create the file scalars.gms, containing all those scalar statements (shortened for representation):

Scalar baseyear / 1988.0000000000 /;
Scalar repco / 2.5000000000 /;

Finally, the file scalars.gms is included to your model.

This example is also part of the GAMS Data Utilities Library, see model \(\text{[GDXXRWExample17]}\) for reference.
5.29.8 Changes in the Set Values Parameter

The following documents some changes that were made when reading a set using the values=string option. Reading a domain or a parameter was not affected by these changes.

To illustrate the various behaviors in different versions of GDXXRW, we are using the spreadsheet data as shown below, using the following call:

```
$call gdxxrw test.xlsx set=one rng=B2 rDim=1 values=string set=two rng=B1 rDim=1 cDim=1 values=string
```

We read the one dimensional set in column B by specifying the top-left corner of the data (cell B2) or the full range (B2..B5). A two dimensional set is read using the top-left corner of the data (cell B1) or the full range (B1..E5). Variations are introduced by specifying options for values to be string or yn or noData. The option value all is only available in later versions of GDXXRW and was used to introduce the same behavior as strings in earlier versions.

5.29.8.1 Chronological description of the changes made to the Values option:

- **GAMS versions prior to version 24.3:**
  values=string results in reading the data dense. The contents of a cell is used for the set associated text and an element is included even if the data cell is empty.

- **GAMS version 24.3.1**
  We changed the interpretation of string to mean that the set element was only to be included when the string data was not empty. Note below that element a4 is missing from the one-dimensional set and so are a1.b1, a2.b2 etc from the two-dimensional set. For the two-dimensional case this looked more or less how the GAMS compiler interprets a table statement. Unfortunately, the interpretation of empty data cells was also applied to one-dimensional sets leading to undesired results.

- **GAMS version 24.4.1**
  Recognizing that reading a set dense was no longer available, we introduced a new option values=all. This allowed us to read Excel data the same way as was possible before version 24.3.1 using the values=string i.e. reading the data dense and including all cells whether the data cell is empty or not and use the content of the data cell for the set associated texts.

- **GAMS version 24.4.6 (Current status)**
  We decided to remove some confusion with the interpretation of the values option by introducing the options dense and sparse and flagging the options strings and all as deprecated. Both strings and all are replaced with dense.

Backward compatibility issues.

With these changes we broke our in house rule not to introduce changes that break backward compatibility. Because of this, the user needs to change the parameters for the GDXXRW call or change the workbook data. The parameters for the call should be changed from values=string to values=dense for one-dimensional sets where we specify the top-left corner only. In case the data in the workbook needs to be changed, inserting a string to in the data cell will address the issue. In the example on the top of the page, inserting a 'Y' in cell C5.
5.30 INVERT

INVERT inverts a matrix.

5.30.1 Usage

invert gdxin i a gdxout inva

where

  gdxin
    name of gdxfile with matrix
  i
    name of set used in matrix
  a
    name of 2 dimensional parameter inside gdxin
  gdxout
    name of gdxfile for results (inverse matrix)
  inva
    name of 2 dimensional parameter inside gdxout

Calculates the inverse of a matrix $a(i,j)$, where $i$ and $j$ are aliased sets. The matrix inva in gdxout will contain the inverse.

5.30.2 Example

$onText
Finds the inverse of a matrix through an external program.
Erwin Kalvelagen, march 2005
Reference: model gauss.gms from the model library
http://www.gams.com/modlib/libhtml/gauss.htm
$offText

Set i /i1*i3 /;
Alias (i,j);

Table a(i,j) 'original matrix'
  i1  i2  i3
  i1  1   2   3
  i2  1   3   4
  i3  1   4   3;

Parameter inva(i,j) 'inverse of a';

execute_unload 'a.gdx', i, a;
execute '=invert.exe a.gdx i a b.gdx inva';
execute_load 'b.gdx', inva;

display a, inva;
5.31 MCFILTER

MCFilter filters duplicate and dominated points from a solution set.

5.31.1 Usage

mcfILTER InputFile

The input is a gdx file with the following data:

- parameter X(point, i)
  Points containing binary values; use EPS when all zero for a point
- parameter F(point, obj)
  Objectives for the points X; use EPS when all zero for a point
- parameter S(obj)
  Direction of each objective: 1=max,-1=min

The output will be a gdx file called InputFile_res.gdx with the same parameters but without duplicates and dominated points.

5.31.2 Example

* Generate random data to test MCFilter

Set
  Ri / R1*R65535 /
  Xi / X1*X16 /
  Fi / F1*F5 /

Parameter
  X(Ri,Xi) 'the binary variables'
  F(Ri,Fi) 'calculated F variables'
  S(Fi) 'sign on the F variables';

* The following points will be unique
  X(Ri,Xi) = mod(floor(Ri.ord/power(2, Xi.off)), 2);
  F(Ri,Fi) = uniform(1,2);
  S(Fi) = -1 + 2$(uniform(0,1) <= 0.5);

execute_unload 'testdata.gdx', X F S;
execute 'mcfilter testdata.gdx';

* The file testdata_res.gdx will contain the results

Below is the partial log after running the above model:

mcfilter v3.
Number of records = 65535
Number of X variables = 16
Number of F variables = 5
Loading GDX data = 156 ms
After X Filter, count = 65535
X Duplicate filter = 16 ms
After F Filter, count = 1070
F Dominance filter = 249 ms
Writing GDX data = 16 ms
5.32  MDB2GMS

Erwin Kalvelagen

5.32.1  Overview

**MDB2GMS** is a tool to convert data from an Microsoft Access database into GAMS readable format. The source is an MS Access database file (.mdb or .accdb) and the target is a GAMS Include File (.inc) or a GAMS GDX File (.gdx).

When running the executable mdb2gms.exe without command-line arguments, the tool will run interactively with a built-in GUI interface. Alternatively **MDB2GMS** can be run in **batch mode**, which is useful when running it directly from a GAMS model without user intervention using the `$call` command at compile time or the `execute` command at execution time.

Database tables can be considered as a generalization of a GAMS parameter. GAMS parameters have multiple index columns but just one value column. If the table is organized as multi-valued table, a UNION operation in the SQL statement can be used to generate the correct GAMS file.

There are no special requirements on the data types used in the database. The data is converted to strings, which is almost always possible. Data types like LONG BINARY may not be convertible to a string, in which case an exception will be raised. In general NULL’s should not be allowed to get into a GAMS data structure. The handling of NULL’s can be specified in an option.

Besides parameters it is also possible to generate set data.

5.32.2  Requirements

**MDB2GMS** runs only on Windows PC’s and with MS Access installed. MS Access comes with certain versions of MS Office, but some MS Office versions will not include Access. The actual retrieval of the database records is performed by DAO or Data Access Objects, an object layer for accessing the database. The actual database is the Jet engine, which performs the queries and retrieves the data. Also consider to use **SQL2GMS** instead of **MDB2GMS**, if MS Access is not installed on your system.

To use this tool effectively you will need to have a working knowledge of SQL in order to formulate proper database queries.

5.32.3  Batch Usage

**MDB2GMS** can be run in batch mode without user intervention from within the GAMS model by using the `$call` resp. `execute` statements or directly from command prompt while specifying all arguments in the command-line. A **MDB2GMS** batch call is of the following form:

```
mdb2gms inputFile outputFile queryString
```

A proper batch call will at least contain the following three command-line arguments:
1. The name of the MS Access database inputFile must be specified (.mdb or .accd format). Use the I argument to enter the file name, i.e. I=inputFile.

2. The name of outputFile, either an include file (.inc) or GDX file (.gdx), must be specified. Using an include file to store the results of the query is indicated by the option O, i.e. O=outputFile.inc, while the use of a GDX file is indicated by the option X, i.e. X=outputFile.gdx.

3. The SQL queryString, containing the SQL statement to be executed on the database, must be specified within the option Q, i.e. Q=queryString.

See also Command-line Arguments below for a complete list of all possible command-line arguments. Consider that the $call or execute usage is rather error prone and you will need to spend a little bit of time to get the call correct and reliable. Alternatively, use the interactive built-in GUI interface or enter the command-line arguments in an external text file in order to write a more structured and readable command. The use of an external parameter file is indicated by preceding the file name with a @ (At sign).

Also consider to take a look at the section Strategies, mentioning some of the drawbacks of the batch usage and how to overcome them.

If you only specify I=inputFile then the interactive user interface is started with an initial setting of the input file name edit box equal to the name given in the command-line argument. Only if an input file, an output file and a query string is provided, the call will be considered as batch invocation.

### 5.32.3.1 Command-line Arguments

The following table summarizes the command-line arguments that can be specified when using MDB2GMS directly from the GAMS model or command prompt.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Interpretation</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>inputFile</td>
<td>none</td>
<td>Specify the name of the input file (required).</td>
</tr>
<tr>
<td>O</td>
<td>outputIncludeFile</td>
<td>none</td>
<td>Specify the name of the output file (.inc). Either O= or X= must be specified (or both).</td>
</tr>
<tr>
<td>On</td>
<td>n-th outputIncludeFile</td>
<td>none</td>
<td>Match the nth query with the nth output file (.inc format) if multiple queries are used.</td>
</tr>
<tr>
<td>X</td>
<td>outputGDXFile</td>
<td>none</td>
<td>Specify the name of the output file (.gdx). Either O= or X= must be specified (or both).</td>
</tr>
<tr>
<td>Q</td>
<td>Query</td>
<td>none</td>
<td>This option can be used to specify a SQL query (required).</td>
</tr>
<tr>
<td>Qn</td>
<td>n-th Query</td>
<td>none</td>
<td>Match the nth query with the nth output file (.inc format) or with the nth set- or parameter name when writing to GDX if multiple queries are used.</td>
</tr>
<tr>
<td>S</td>
<td>setName</td>
<td>none</td>
<td>If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file.</td>
</tr>
<tr>
<td>Sn</td>
<td>n-th setName</td>
<td>none</td>
<td>Match the nth query with the nth set in the GDX file if multiple queries are used.</td>
</tr>
<tr>

<tr>
<td>W</td>
<td>Wiring</td>
<td>none</td>
<td>Maps database columns to GAMS index positions.</td>
</tr>
<tr>
<td>R</td>
<td>rowBatchSize</td>
<td>100</td>
<td>Row batch size; the default is 100 records.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the command-line arguments:

\[I = \text{string}(\text{inputFile}, \text{default} = \text{none})\]

This option is required and specifies the name of the .mdb or .accbd file containing the Access database. If the file contains blanks the name should be surrounded by double quotes. It is advised to use absolute paths, so Access has no confusion what file to open. On a network UNC Names can be used, and files from another computer can be accessed, e.g.

"\hostname\c\my documents\a.mdb."

This option is required for batch processing. To specify a path equal to the location where the .gms file is located, you can use:

\[I = \text{system.fpmydb.mdb}\]

This option is demonstrated in most examples, see Example 1 - Reading a single valued Table for instance.
O = string (outputIncludeFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter or set statement. Make sure the directory is writable. UNC Names can be used. An output file must be specified for batch operation: i.e. either O= or X= needs to be specified (or both). The include file will be an ASCII file that can be read by GAMS using the $include command within the data definition of a set, parameter or scalar. If the include file already exists, it will be overwritten. This option is demonstrated in most examples, see Example 1 - Reading a single valued Table for instance.

On = string (outputIncludeFile, default = none)

When using multiple queries in a single MDB2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition:

```plaintext
Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc
```

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

X = string (outputGDXFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS GDX file. Make sure the directory is writable. UNC names can be used. If the GDX file already exists it will be overwritten - it is not possible to append to a GDX file. An output file must be specified for batch operation: i.e. either O= or X= needs to be specified (or both). This option is demonstrated in Example 5 - Reading Set with Explanatory Text or Example 7 - Multi-Query Batch Example for instance.

Q = string (Query, default = none)

This option can be used to specify an SQL query. Queries can contain spaces and thus have to be surrounded by double quotes. For the exact syntax of the queries that is accepted by Access we refer to the documentation that comes with MS Access. The query is passed on directly to the Jet database engine, so the complete power and expressiveness of Access SQL is available. For an exact description of allowed expressions consult a text on MS Access.

One notable syntax feature is that when field names or table names contain blanks, they can be specified in square brackets. Examples:

```plaintext
Q="SELECT * FROM mytable"
Q="SELECT year, production FROM [production table]"
Q="SELECT [GAMS City], value FROM [example table], CityMapper
WHERE [Access City]=city"
```

This option is demonstrated in Example 1 - Reading a single valued Table for instance.

Qn = string (Query, default = none)
When using multiple queries in a single MDB2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition. In addition, you can match the results of a query with a specific set- or parameter name when writing to GDX.

Q1="SELECT a, b FROM table"
Q2="SELECT c, d FROM table"
Q1=ab.inc
Q2=cd.inc

or (GDX output file format - where several sets and parameters can be stored in a single file):

Q1="SELECT a, b FROM table"
P1=abParameter
Q2="SELECT c FROM table"
S2=cSet

Note the usage of the arguments Pn resp. Sn in order to store the results as parameter resp. set and to specify the name of the symbols. See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

S = string (setName, default = none)
If we write to a GDX file, use this option to specify the name of a set to be stored in the GDX file (containing the results of the query). This option is demonstrated in Example 4 - Reading a multi dimensional Set.

Sn = string (setName, default = none)
If multiple queries are used in a single MDB2GMS call while writing to a GDX file, use this option to specify the name of the nth set to be stored in the GDX file (containing the results of the nth query), e.g.

Q1="SELECT i FROM table"
S1=iSet
Q2="SELECT j FROM table"
S2=jSet

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

Y = string (setName, default = none)
If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. The last column specified within the select clause in the SQL statement will be used as explanatory text. This option is demonstrated in Example 5 - Reading Sets with Explanatory Text for instance.

Yn = string (setName, default = none)
If multiple queries are used in a single MDB2GMS call while writing to a GDX file, use this option to specify the name of the nth set (with explanatory text) to be stored in the GDX file (containing the results of the nth query), e.g.

Q1="SELECT i, explTextForSeti FROM table"
Y1=iSet
Q2="SELECT j, explTextForSetj FROM table"
Y2=jSet
The last column specified within the select clause in the SQL statements will be used as explanatory text.

\[ P = \text{string} \text{ (parameterName, default = none)} \]

If we write to a GDX file, use this option to specify the name of a parameter to be stored the GDX file (containing the results of the query).

\[ Pn = \text{string} \text{ (parameterName, default = none)} \]

If multiple queries are used in a single \texttt{MDB2GMS} call while writing to a GDX file, use this option to specify the name of the nth parameter to be stored in the GDX file (containing the results of the nth query), e.g.

\begin{verbatim}
Q1="SELECT i, j, value FROM table"
A1=ijValue
Q2="SELECT n, m, value FROM table"
A2=nmValue
\end{verbatim}

See also section \textit{Multi-Query Batch Usage} or \textit{Example 7 - Multi-Query Batch Example} for instance.

\[ D \text{ (Debug, default = disabled)} \]

This option can be used for debugging purposes. If specified the import filter will not run minimized but "restored", i.e. as a normal window. In addition the program will not terminate until the user clicks the Close button. This allows you to monitor possible errors during execution of \texttt{MDB2GMS}.

\[ B \text{ (Quote Blanks, default = disabled)} \]

If this parameter is specified, strings that have blanks in them will be quoted. If the string is already quoted this step is not performed. If the name contains an embedded single quote, the surrounding quotes will be double quotes. If the name already contains a double quote, the surrounding quotes will be single quotes. If both single and double quotes are present in the string, then all double quotes are replaced by single quotes and the surrounding quotes will be double quotes. By default this option is turned off. For more information see subsection \textit{Quotes}. This option only applies to an output include file.

\[ M \text{ (Mute, default = disabled)} \]

Run in modest or mute mode: no additional information, such as version number, number of rows in the data, elapsed time, used query etc. is written to the log and include file.

\[ L \text{ (Listing, default = disabled)} \]

Embed the data between the \$offListing and \$onListing dollar control options, so the data will not be listed in the listing file. This is a quick way to reduce the size of the listing file when including very large data files into the model. Otherwise the listing file would become too large to be handled comfortably.

\[ @fileName = \text{string} \text{ (fileName, default = none)} \]

Causes the program to read options from an external text file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if they were specified directly on the command-line. See also \textit{Command Files} for some further details.
5.32 MDB2GMS

N = string (fileName, default = mdb2gms.ini)

Use a different INI file than the standard mdb2gms.ini located in the same directory as the executable mdb2gms.exe.

F = string (formatString, default = none)

In special cases we can apply a format string on the include file output (not for GDX output). Each column in the result set is a string and can be represented by a $s$ in the format string.

W = string (wiring, default = none)

By using the $W$ option, one can map database columns to GAMS index positions. See model [Wiring] for reference.

R = integer (rowBatchSize, default = 100)

Row batch size; the default is 100 records. This option must be specified in an INI file when using the interactive mode of MDB2GMS.

5.32.3.2 Example 1 - Reading a single valued Table

Suppose we want to read the distances parameter of the [transport] model from the GAMS Model Library. The data is stored in the Microsoft Access Database format (file Sample.mdb).

The data can be queried with a simple SQL statement:

```
SELECT city1, city2, distance
FROM distances
```

By running the following MDB2GMS statement, the connection to the database Sample.mdb is established. In addition, the data will be queried and the results are written to a GAMS include file afterwards (.inc).

```
mdb2gms I=Sample.mdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
```

The MS Access database file name is specified using the argument I. Note that the string is enclosed by quotes, as the string contains blanks. The arguments Q and O are used to specify the query and the output file name (and format).

The generated include file distances.inc looks like:

```
* -----------------------------------------------------
* MDB2GMS 24.8.5 r61358 Released May 10, 2017 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* DAO version: 14.0
* Jet version: 4.0
* Database: F:\datalib\Sample.mdb
* Query: SELECT city1, city2, distance FROM distances
* -----------------------------------------------------
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----------------------------------------------------
```
The commented header section summarizes some information about the MDB2GMS resp. GAMS version and about the executed database query. The standard export format is to consider the last column as the value column (containing the distances) and the previous columns as the indices (containing the city names). The indices are separated by a dot, allowing the generated include file to be used as part of a parameter declaration statement in your GAMS model.

Retrieving the data using MDB2GMS from the database and including the queried data in your GAMS model within the parameter declaration statement (at compile time) can be combined in the following way:

Set
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /;

$call mdb2gms I=Sample.mdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
Parameter d(i,j) 'distance in thousands of miles' /
  $include distances.inc /
;

display d;

Finally, the values of the parameter d are displayed:

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.500</td>
<td>1.700</td>
<td>1.800</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.500</td>
<td>1.800</td>
<td>1.400</td>
</tr>
</tbody>
</table>

This example is also part of the GAMS Data Utilities Library, see model [Distances1] for reference. Note that the query results are written to a GDX file in addition.

5.32.3.3 Example 2 - Reading a multi valued Table

In this scenario, we want two read the three index columns year, loc, prod and the value columns sales and profit from the database file Sample.mdb. Therefore, we use two separate parameters and queries or alternatively a parameter with an extra index position (for sales resp. profit) and a UNION select.

Consider the table with two value columns sales and profit:

Two separate Parameters

A simple way to import this into GAMS is to use two parameters and two SQL queries. The SQL queries can look like:

```
SELECT year, loc, prod, sales
FROM data
SELECT year, loc, prod, profit
FROM data
```

We can generate a include file sales.inc by running the following command:

```
mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, sales FROM data" O=sales.inc
```
Note that we specify the first query in order to select the sales and the relevant index columns within the Q argument. The query results are written to sales.inc using the O argument. Analogously we generate an include file profit.inc by running the following command while specifying the second query in order to obtain the profits and the relevant index columns:

```
mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, profit FROM data" O=profit.inc
```

Retrieving the data using MDB2GMS from the database Sample.mdb and including the queried data in your GAMS model within the parameter declaration statements of sales and profit (at compile time) can be combined in the following way:

```
Set
  year 'years' / 1997*1998 /
  loc 'locations' / nyc, was, la, sfo /
  prd 'products' / hardware, software /;

$call mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, sales FROM data" O=sales.inc
Parameter sales(year,loc,prd) /
$include sales.inc
/;

$call mdb2gms I=Sample.mdb" Q="SELECT year, loc, prod, profit FROM data" O=profit.inc
Parameter profit(year,loc,prd) /
$include profit.inc
/;
```

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB1] for reference.

**Single Parameter with extra Index Position**

The operation can also be performed in one big swoop by using a different GAMS datastructure, i.e. a single parameter is defined with an extra index type to indicate the data type (sales or profit). The index and value columns will be selected by the following SQL statement. Note the UNION operation in order to combine the results and the strings 'sales' resp. 'profit' to identify the data type later on.

```
SELECT year, loc, prod, 'sales', sales
FROM data
UNION
SELECT year, loc, prod, 'profit', profit
FROM data
```

The data is accessed, queried and written to data.inc by running the following command:

```
mdb2gms @howToRead.txt
```

Note that usage of the external parameter file howToRead.txt shown below in order to increase the readability of the command (one argument per line, quotes can be omitted):

```
I=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc
```

The generated include file data.inc looks like (shortened for presentation):
Retrieving the data using **MDB2GMS** from the database and including the queried data in your GAMS model within the parameter declaration (at compile time) can be combined in the following way (note that the parameter has a fourth index `type` in order to access the data type `sales` resp. `profit`):

```plaintext
$onEcho > howToRead.txt
I=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc
$offEcho

Set
  year 'years' / 1997*1998 /
  loc 'locations' / nyc, was, la, sfo /
  prd 'products' / hardware, software /
  type 'data type' / sales, profit /;

$call mdb2gms @howToRead.txt
Parameter data(year,loc,prd,type) /
$include data.inc
```

This example is also part of the GAMS Data Utilities Library, see model [*SalesProfitDB2c*](#) for reference.
5.32.3.4 Example 3 - Reading a one dimensional Set

This example demonstrates how to read set elements of a one dimensional set from a single column of a MS Access database file. Suppose we want to read the column City1 (see table distances) in order to define the set $i$ in the GAMS model. Make sure elements are unique by using the distinct operation within the SQL statement (otherwise there will be an error when including the file within the set definition in the GAMS model, as some set elements will be redefined):

```sql
SELECT distinct(City1)
FROM distances
```

The include file city1.inc looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
  SAN-DIEGO  
  SEATTLE   
* -----------------------------------------------------
```

All steps (data access via MDB2GMS, set definition) can be combined:

```
$call mdb2gms I=Sample.mdb Q="SELECT distinct(city1) FROM distances" O=city_i.inc
Set i 'canning plants' /  
$include city_i.inc
/;

display i;
```

The display statement generates the following output in the listing file:

```
---- 56 SET i

  seattle , san-diego
```

5.32.3.5 Example 4 - Reading a multi dimensional Set

When reading a multi dimensional set from database and writing the results to an include file by using the O argument, one has to observe that the elements in the include file must have the correct format in order to be interpreted as element of a multi dimensional set. For instance, a line containing a b c is not recognized as a proper set element of a three dimensional set. In particular, one has to add periods between the single elements, i.e. a.b.c will be interpreted correctly.

There are different ways to add these periods explicitly within the SQL statement. E.g. add a dummy value field by adding a quoted blank to the select clause (index1, index2, index3 and dataTable are some placeholders):

```sql
SELECT index1, index2, index3, " " FROM dataTable
```

or by adding the periods explicitly within the select clause (|| or & depending on DBMS):
For instance, suppose we want to define a two dimensional set

Set ij(i,j) 'canning plants - markets';

based on the data of the table distances stored in Sample.mdb. The following \texttt{MDB2GMS} statement connects you to the database, queries the columns with the city names and adds an empty value field in order to create periods between the set elements:

\texttt{mdb2gms I=Sample.mdb Q="SELECT city1, city2, ' ' FROM distances" O=city\_ij.inc}

The include file \texttt{city\_ij.inc} looks like (header informations are removed in order to shorten the representation):

* -----------------------------------------------------
SEATTLE.NEW-YORK ' '
SAN-DIEGO.NEW-YORK ' '
SEATTLE.CHICAGO ' '
SAN-DIEGO.CHICAGO ' '
SEATTLE.TOPEKA ' '
SAN-DIEGO.TOPEKA ' '
* -----------------------------------------------------

Without adding the empty value field, the resulting include file would look like (shortened):

* -----------------------------------------------------
SEATTLE NEW-YORK
SAN-DIEGO NEW-YORK
* -----------------------------------------------------

Since the periods are missing, the lines are not recognized as valid elements of a two dimensional set. All steps can be combined in the following way:

Set
\begin{verbatim}
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /
\end{verbatim}

\$call mdb2gms I=Sample.mdb" Q="SELECT city1, city2, ' ' FROM distances" O=city\_ij.inc

Set ij(i,j) 'two dimensional set' /
\$include city\_ij.inc
/

display ij;
The display statement generates the following output in the listing file:

```
----  75 SET ij two dimensional set
       new-york  chicago  topeka
SAN-DIEGO        YES  YES  YES
SEATTLE           YES  YES  YES
```

Note that there is no need to add periods explicitly when reading multi dimensional sets, if the results are written only to a GDX file by using the \texttt{X} and \texttt{S} resp. \texttt{Y} arguments, i.e. there is no need to modify the query:

```
SELECT index1, index2, index3 FROM datatable
```

when using \texttt{MDB2GMS} in the following way:

```
mdb2gms I=Sample.mdb Q="SELECT index1, index2, index3 FROM datatable" X=setData.gdx S=setName
```

which will generate the file \texttt{setData.gdx} with a three dimensional set named \texttt{setName} containing the results of the query.

5.32.3.6 Example 5 - Reading Sets with Explanatory Text

In this example, we will demonstrate how to read set elements with explanatory text from a MS Access database file using \texttt{MDB2GMS}. In the first place, we are going to write the query results to an include file, afterwards we use the \texttt{Y} argument in order to store the query results as a set with explanatory text in a GDX file.

Note the blanks and the mixed quotes in the column containing the explanatory text. The data can be accessed by the following query:

```
SELECT setElement, explText
FROM  setData
```

Writing the Query Results in an include File

The last column in the select clause will be used as explanatory text. Take in mind to add the argument \texttt{B} in order to handle text strings with embedded blanks or quotes. The following GAMS code accesses the data and writes the results to an include file \texttt{setData.inc}:

```
$call mdb2gms I=Sample.mdb B Q="SELECT setElement, explText FROM setData" O=setData.inc
```

Set a /
Set a /;
The resulting include file will look like (header informations are removed in order to shorten the representation):

* -----------------------------------------------------
  firstSetElement "Explanatory text for the first 'set element'")
  secondSetElement 'Explanatory text for the second "set element"
  thirdSetElement "Explanatory text for the third 'set element'
  fourthSetElement 'Explanatory text for the fourth set element'
* -----------------------------------------------------

Note the handling of the quotes according to the description in B.

Writing the Query Results in a GDX File
When storing the results of the query as a set with explanatory text in a GDX file, there is no need to observe embedded blanks or quotes manually, instead one can use the Y argument. The last column specified in the select clause of the SQL statement will be interpreted as explanatory text. The following GAMS code accesses the data and writes the results to a GDX file setData.inc:

$call mdb2gms I=Sample.mdb Q="SELECT setElement, explText FROM setData" X=setData.gdx Y=set_b

Set b;
$gdxIn setData.gdx
$load b = set_b
$gdxIn

Note that the name of the set in the GDX file is set_b (specified within the Y argument), while the name of the GDX file was specified within the X argument.

5.32.3.7 Example 6 - Index Mapping

In some cases the index elements used in the database are not the same as in the GAMS model. E.g. consider the case where the GAMS model has defined a set as:

Set i / NY, DC, LA, SF /;

Now assume a data table looks like:

This means we have to map 'new york' to 'NY' etc. This mapping can be done in two places: either in GAMS or in the database.
5.32.3.7.1 Index Mapping done in GAMS When we export the table directly, we get the following include file (header informations are removed in order to shorten the representation):

* -----------------------------------------------------
  'new york' 100
  'los angeles' 120
  'san francisco' 105
  'washington dc' 102
* -----------------------------------------------------

Note that the single quotes are added by activating the option B (quote blanks), as the index elements contain blanks. Accessing the data, importing the resulting include file and converting it to a different index space can be done by the following GAMS code:

```gams
Set i / NY, DC, LA, SF /;
Set idb 'from database' / 'new york', 'washington dc', 'los angeles', 'san francisco' /;
$call mdb2gms I=Sample.mdb B O="city1.inc" Q="SELECT city, value FROM [example table]"
Parameter dbdata(idb) /
$include city1.inc
/;
Set mapindx(i,idb) / NY.'new york', DC.'washington dc', LA.'los angeles', SF.'san francisco' /;
Parameter data(i);
data(i) = sum(mapindx(i,idb), dbdata(idb));
display data;
```

The display statement generates the following output in the listing file:

```
---- 47 PARAMETER data
   NY 100.000,  DC 102.000, LA 120.000, SF 105.000
```

This example is also part of the GAMS Data Utilities Library, see model [IndexMapping1] for reference.

5.32.3.7.2 Index mapping done in Database The second approach is to handle the mapping inside the database. We can introduce a mapping table that looks like:

This table can be used in a join to export the data in a format we can use by executing the query:

```
SELECT [GAMS City], value
FROM example_table, CityMapper
WHERE CityMapper.[Access City]=example_table.city
```

The resulting include file looks like (header informations are removed in order to shorten the representation):
All steps can be combined in the GAMS model:

Set i / NY, DC, LA, SF /;

$onEcho > howToRead.txt
I=Sample.mdb
Q=SELECT [GAMS City], [value] FROM example_table, CityMapper WHERE CityMapper.[Access City]=example_table.city
O=city2.inc
$offEcho

$call mdb2gms @howToRead.txt
Parameter data(i) /
$include city2.inc
/;
display data;

The display statement generates the following output in the listing file:

---- 38 PARAMETER data
NY 100.000, DC 102.000, LA 120.000, SF 105.000

Note: MS Access allows table names with embedded blanks. In that case the table name can be surrounded by square brackets. Other databases may not allow this.

This example is also part of the GAMS Data Utilities Library, see model [IndexMapping2] for reference.

5.32.4 Multi-Query Batch Usage

In some cases a number of small queries need to be performed on the same database. However, several individual MDB2GMS execution can become expensive, since there is significant overhead in starting Access and opening the database. For these cases, we have added the option to do multiple queries in one call. To execute several queries in a single MDB2GMS call and write several GAMS include files containing the results of the queries, we can use the command-line arguments Qn and On. The structure of a multi-query call looks like:

I=sample.mdb
Q1=firstQuery
O1=outputFileName.inc

Q2=secondQuery
O2=outputFileName.inc

Q3=thirdQuery
O3=outputFileName.inc
The terms firstQuery, secondQuery etc. are placeholders for some SQL statements. We see that the argument Qn is matched by an argument Qn. That means that the results of the n-th query are written to the n-th output file.

In case we want to store the results of a multi-query call to a single GDX file, we can use the command-line arguments Qn, Sn, Pn and Yn. The structure of a multi-query call when writing to a GDX file looks like:

\[
\begin{align*}
I &= \text{sample.mdb} \\
X &= \text{sample.gdx} \\
Q1 &= \text{firstQuery} \\
S1 &= \text{setName} \\
Q2 &= \text{secondQuery} \\
S2 &= \text{setName} \\
Q3 &= \text{thirdQuery} \\
A3 &= \text{parameterName} \\
Q4 &= \text{fourthQuery} \\
A4 &= \text{setName}
\end{align*}
\]

Again, the terms firstQuery, secondQuery etc. are placeholders for some SQL statements. Here we see that a query Qn is matched by either a set name Sn or a parameter name Pn, i.e. the results of the first query will be stored as a set whose name is specified within the S1 argument, the results of the third query will be stored as a parameter whose name is specified within the P3 argument etc. The X argument is used to specify the name of the GDX file.

For a complete example see section Example 7 - Multi-Query Batch Example.

### 5.32.4.1 Example 7 - Multi-Query Batch Example

As an example database we use the following Access table (file Sample.mdb):

We want to extract the following information:

- The set year
- The set loc
- The set prd
- The parameter sales
- The parameter profit

**Output: Several include Files**

This can be accomplished using the following GAMS code with multiple queries in a single MDB2GMS call (note the usage of the distinct operator in the select clauses of the queries whose results will be used as sets in order to keep the set elements unique):
$onEcho > howToRead.txt
I=Sample.mdb
Q1=SELECT distinct(year) FROM data
O1=year.inc
Q2=SELECT distinct(loc) FROM data
O2=loc.inc
Q3=SELECT distinct(prod) FROM data
O3=prod.inc
Q4=SELECT prod, loc, year, sales FROM data
O4=sales.inc
Q5=SELECT prod, loc, year, profit FROM data
O5=profit.inc
$offEcho
$call =mdb2gms @howToRead.txt
Set y 'years' /
$include year.inc
/
Set loc 'locations' /
$include loc.inc
/
Set prd 'products' /
$include prod.inc
/
Parameter sales(prd,loc,y) /
$include sales.inc
/
display sales;

Parameter profit(prd,loc,y) /
$include profit.inc
/
display profit;

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB3] for reference.

Output: A single GDX File

The same example imported through a GDX file can look like:

$onEcho > howToRead.txt
I=Sample.mdb
X=Sample.gdx
Q1=SELECT distinct(year) FROM data
S1=year
Q2=SELECT distinct(loc) FROM data
S2=loc
Q3=SELECT distinct(prod) FROM data
S3=prd

Q4=SELECT prod, loc, year, sales FROM data
P4=sales

Q5=SELECT prod, loc, year, profit FROM data
P5=profit

$offEcho
$call =mdb2gms @howToRead.txt
$call =shellExecute gdxviewer Sample.gdx

Set
  y 'years'
  loc 'locations'
  prd 'products';

Parameter
  sales(prd,loc,y)
  profit(prd,loc,y);

$gdxIn Sample.gdx
$load y=year prd loc sales profit
$gdxIn

display sales, profit;

The call of the GDXViewer will display the GDX file in the stand-alone GDX viewer. This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB4] for reference.

5.32.5 Interactive Usage

When the tool is called without command-line parameters, it will startup interactively. Using it this way, one can specify the database file (.mdb or .accbd file), the query and the final destination file (a GAMS include file or a GDX file) using the built-in interactive environment. The main screen (see figure below) contains a number of buttons and edit boxes, which are explained below.

- **Input file (.mdb or .accbd)**. This is the combo box to specify the input file. See also inputFile for some more detailed remarks. The browse button can be used to launch a file open dialog which makes it easier to specify a file. The file may be located on a remote machine using the notation \\machine\directory\file.mdb.

- **Output GAMS Include file (*.inc)**. If you want to create a GAMS include file, then specify here the destination file. See also outputIncludeFile for some more detailed remarks.

- **Output GDX file (*.gdx)**. As an alternative to a GAMS include file, the tool can also generate a GDX file. One or both of the output files need to be specified. See also outputGDXFile for some more detailed notes.
• **SQL Query.** The SQL Query box is the place to provide the query. Note that the actual area for text can be larger than is displayed: use the cursor-keys to scroll. See also Q for some more detailed remarks. For an exact description of allowed expressions consult a text on MS Access.

• **Progress Memo.** This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.

• The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

• The **Tables button** will pop up a new window with the contents of the database file selected in the input file edit line. This allows you to see all table names and field names needed to specify a correct SQL query. An exception will be generated if no database file name is specified in the input edit line.

• The **Options button** will pop up a window where you can specify a number of options.

• Pressing the **Help button** will show this documentation.

• Pressing the **OK button** will execute the query and an include file or GDX file will be generated.

• Pressing the **Batch button** will give information on how the current query can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied to the clipboard. In the IDE press Ctr1-C or choose Edit|Paste to copy the contents of the clipboard to a GAMS text file.

• Pressing **Close button** will exit the application. The current settings will be saved in an INI file so when you run **MDB2GMS** again all current settings will be restored.

5.32.5.1 **Options**

The **Options** window can be created by pressing the options button:

The following options are available in the options window:

• **Quote blanks:** Quote strings if they contain blanks or embedded quotes. See also B for some more detailed notes.

• **Mute:** Don't include the extra informational text (such as used query etc.) in the include file.

• **No listing:** Surround the include file by $offListing and $onListing so that the data will not be echoed to the listing file. The equivalent command-line argument is L.
- **Format SQL:** If an SQL text is reloaded in the SQL Edit Box, it will be formatted: keywords will be printed in CAPS and the FROM and WHERE clause will be printed on their own line. If this check box is unchecked this formatting will not take place and SQL queries will be shown as is.

The following options are only needed in special cases:

- **NULL:** This radio box determines how NULL's are handled. A NULL in an index position or a value column will usually make the result of the query useless: the GAMS record will be invalid. To alert you on NULL's the default to throw an exception is a safe choice. In special cases you may want to map NULL's to an empty string or a 'NULL' string.

- **Output Lines:** By default output lines are created as follows: all first n-1 fields are considered indices and the last n-th column is the value. The format corresponding to this situation is '%s.%s.%s %s' (for a three dimensional parameter). In special cases you may want to tinker with the format string being used. The fields are all considered strings, so only use s as format placeholder. Make sure you specify exactly the same number of s's as there are columns in the result set.

The buttons have an obvious functionality:

- **OK button** will accept the changes made.

- **Cancel button** will ignore the changes made, and all option settings will revert to their previous values.

- **Help button** will show this help text.

### 5.32.6 Strategies

Including SQL statements to extract data from a database inside your model can lead to a number of difficulties:

- The database can change between runs, leading to results that are not reproducible. A possible scenario is a user calling you with a complaint: "the model is giving strange results". You run the model to verify and now the results are ok. The reason may be because the data in the database has changed.

- There is significant overhead in extracting data from a database. If there is no need to get new data from the database it is better to use a snapshot stored locally in a format directly accessible by GAMS.

- It is often beneficial to look at the extracted data. A first reason, is just to make sure the data arrived correctly. Another argument is that viewing data in a different way may lead to a better understanding of the data. A complete "under-the-hood" approach may cause difficulties in understanding certain model behavior.

Often it is a good strategy to separate the data extraction step from the rest of the model logic.

If the sub-models form a chain or a tree, like in:
we can conveniently use the save/restart facility. The individual submodel are coded as:

- **Step 0: sr0.gms**

```gams
$onText
step 0: data extraction from database
execute as: > gams sr0 save=s0
$offText

Set
i 'suppliers'
  j 'demand centers';

Parameter
  demand(j)
  supply(i)
  dist(i,j) 'distances';

$onEcho > howtoRead.txt
I=transportation.mdb
Q1=select name from suppliers
  O1=i.inc
Q2=select name from demandcenters
  O2=j.inc
Q3=select name,demand from demandcenters
  O3=demand.inc
Q4=select name,supply from suppliers
  O4=supply.inc
Q5=select supplier,demandcenter,distance from distances
  O5=dist.inc
$offEcho

$call =mdb2gms.exe @howtoRead.txt

Set i /
  $include i.inc
/

Set j /
  $include j.inc
/

Parameter demand /
  $include demand.inc
/

Parameter supply /
  $include supply.inc
/
```
Parameter dist /
$include dist.inc
/;

display i, j, demand, supply, dist;

- Step 1: sr1.gms

$onText
step 1: data manipulation step
execute as: > gams sr1 restart=s0 save=s1
$offText

Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*dist(i,j)/1000;

- Step 2: sr2.gms

$onText
step 2: model definition
execute as: > gams sr2 restart=s1 save=s2
$offText

Variable
  x(i,j) 'shipment quantities in cases'
  z 'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
  ecost 'define objective function'
  esupply(i) 'observe supply limit at plant i'
  edemand(j) 'satisfy demand at market j';

ecost.. z =e= sum((i,j), c(i,j)*x(i,j));
esupply(i).. sum(j, x(i,j)) =l= supply(i);
edemand(j).. sum(i, x(i,j)) =g= demand(j);

- Step 3: sr3.gms

$onText
step 3: model solution
execute as: > gams sr3 restart=s2 save=s3
$offText

option lp = cplex;

Model transport / all /
solve transport using lp minimizing z;

- Step 4: sr4.gms

$onText
step 4: report writing
execute as: > gams sr4 restart=s3
abort$(transport.modelStat <> 1) "model not solved to optimality";

display x.l, z.l;

A model that executes all steps can be written as:

execute 'gams.exe sr0 lo=3 save=s0';
abort$errorLevel "step 0 failed";

execute 'gams.exe sr1 lo=3 restart=s0 save=s1';
abort$errorLevel "step 1 failed";

execute 'gams.exe sr2 lo=3 restart=s1 save=s2';
abort$errorLevel "step 2 failed";

execute 'gams.exe sr3 lo=3 restart=s2 save=s3';
abort$errorLevel "step 3 failed";

execute 'gams.exe sr4 lo=3 restart=s3';
abort$errorLevel "step 4 failed";

If you only change the reporting step, i.e. generating some output using PUT statements, then you only need to change and re-execute step 4. If you change solver or solver options, then only steps 3 and 4 need to be redone. For a small model like this, this exercise may not be very useful, but when the model is large and every step is complex and expensive, this is a convenient way to achieve quicker turn-around times in many cases.

The model [MDBSr5] is also part of the GAMS Data Utilities Library.

In some cases the save/restart facility is not appropriate. A more general approach is to save the data from the database in a GDX file, which can then be used by other models. We can use the model from step 0 to store the data in a GDX file:

MDB2GDX1.gms

execute 'gams.exe sr0 lo=3 gdx=trnsport.gdx';
abort$errorLevel "step 0 failed";

execute 'gdxviewer.exe trnsport.gdx';

The model [MDB2GDX1] is also part of the GAMS Data Utilities Library.

We can also let MDB2GMS create the GDX file:

MDB2GDX2.gms

This model demonstrates how to store data from Access database (file Transportation.mdb) into a GDX file.
The first approach has the advantage that a complete audit record is available from the data moved from the database to the GDX file in the sr0.lst listing file. If someone ever wonders what came out of the database and how this was stored in the GDX file, that file gives the answer.

The model [MDB2GDX2] is also part of the GAMS Data Utilities Library.

To load the GDX data the following fragment can be used:

**GDXTRNSPORT.gms**

This model demonstrates how to load the transportation data from GDX file at compile time.

Set

i 'suppliers'
j 'demand centers';

Parameter
demand(j)
supply(i)
dist(i,j) 'distances';

$gdxIn transportation.gdx
$load i j demand supply dist

display i, j, demand, supply, dist;

**DBTimestamp1.gms**

In one application I had to retrieve data from the database each morning, at the first run of the model. The rest of the day, the data extracted that morning could be used. The following logic can implement this:
Retrieve data from data base first run each morning.

```
$onEcho > getdate.txt
I=%system.fp%transportation.mdb
Q=select day(now())
O=dbtimestamp.inc
$offEcho

$if not exist dbtimestamp.inc $call "echo 0 > dbtimestamp.inc"

Scalar dbtimestamp 'day of month when data was retrieved' /
$include dbtimestamp.inc
/

Scalar currentday 'day of this run';
currentday = gday(jnow);

display "compare", dbtimestamp, currentday;

if(dbtimestamp <> currentday,
   execute '=gams.exe sr0 lo=3 gdx=transportation.gdx';
   abort$errorLevel "step 0 (database access) failed";
   execute '=mdb2gms.exe @getdate.txt' );
```

The include file dbtimestamp.inc contains the day of the month (1,...,31) on which the data was extracted from the database. If this file does not exist, we initialize it with 0. We then compare this number with the current day of the month. If the numbers do not agree, we execute the database extraction step and rewrite the dbtimestamp.inc file. This last operation could be done using a PUT statement, but in this case we used an SQL statement.

The model [DBTimestamp1] is also part of the GAMS Data Utilities Library.

### 5.32.7 Command Files

Parameters can be specified in a command file. This is important if the length of the command-line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command-lines. Instead of specifying a long command-line as in:

```
$call =mdb2gms I="c:\My Documents\test.mdb" O="c:\My Documents\data.inc" Q="SELECT * FROM mytable"
```

we can use a command-line like:

```
$call =mdb2gms @"c:\My Documents\options.txt"
```

The command file

```
c:\My Documents\options.txt
```

can look like:
It is possible to write the command file from inside a GAMS model using the $echo command. The following example will illustrate this:

```
$set cmdfile "c:\windows\temp\commands.txt"
$echo "I=E:\models\labordata.mdb" >> "%cmdfile%"
$echo "O=E:\models\labor.INC" >> "%cmdfile%"
$echo "Q=SELECT * FROM labor" >> "%cmdfile%"
$call =mdb2gms @"%cmdfile%"
```

Parameter p /
$include "E:\models\labor.INC"
/;

display p;

Newer versions of GAMS allow the usage of the $onEcho and $offEcho commands:

```
$set cmdfile "c:\windows\temp\commands.txt"
$onEcho >> "%cmdfile%"
I=E:\models\labordata.mdb
O=E:\models\labor.INC
Q=SELECT * FROM labor
$offEcho
$call =mdb2gms @"%cmdfile%"
```

Parameter p /
$include "E:\models\labor.INC"
/;

display p;

Note that the quotes enclosing strings with blanks like `Q=SELECT * FROM labor` can be omitted when using an external parameter file.

If a query becomes very long, it is possible to spread it out over several lines. To signal a setting will continue on the next line insert the character `\` as the last character. E.g.:

```
Q=SELECT prod, loc, year, 'sales', sales FROM data 
UNION \nSELECT prod, loc, year, 'profit', profit FROM data
```

### 5.32.8 Notes

#### 5.32.8.1 GDX Files

A GDX file contains GAMS data in binary format. The following GAMS commands will operate on GDX files: `$gdxIn`, `$load`, `execute_load`, `execute_unload`. The GDX=filename command-line argument will save all data to a GDX file. A GDX file can be viewed in the GAMS IDE using File|Open.
5.32.8.2 UNC Names

UNC means Unified Naming Convention. UNC names are a Microsoft convention to name files across a network. The general format is:

```
\<server>\<share>\<path>\<file>
```

Examples:

```
\athlon\c\My Documents\MDB2GMS.rtf
```

5.32.8.3 Quotes

Examples of handling of indices when the option B for quoting strings containing blanks is used:

5.32.8.4 $CALL Command

The $call command in GAMS will execute an external program at compile time. There are two forms:

```
$call externalProgram
$call =externalProgram
```

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=' bypasses the command processor and directly executes the external program. We mention some of the differences:

1. Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE. If you want to execute these commands you will need to use the form $call externalProgram which uses the command processor.

2. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form $call externalProgram.

3. If it is important to stop with an appropriate error message if the external program does not exist, only use the form $call =externalProgram. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: $call =externalProgram.

4. When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: $call start /w externalWindowsProgram. Otherwise, it is preferred to use: $call =externalWindowsProgram.
Attention

In general it is recommended to use the $call =externalProgram version for its better error-handling.

When command line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

```
$call externalProgram parameter1 parameter2
$call =externalProgram parameter1 parameter2
```

The total length of the command line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

```
$call "external program" "parameter 1" "parameter 2"
$call ="external program" "parameter 1" "parameter 2"
```

It is noted that the first form needs additional quotes around the whole command line due to bugs in the parsing of the $call in GAMS. The second form work without additional quotes only if the = appears outside the double quotes.

### 5.32.8.5 Compile Time Commands

All $ commands in GAMS are performed at compile time. All other statements are executed at execution time. This means that a compile time command will be executed before an execution time command, even if it is below. As an example consider:

```
File batchfile / x.bat /
putClose batchfile "dir"/
$call x.bat
```

This fragment does not work correctly as already during compilation, the $call is executed, while the put statements are only executed after the compilation phase has ended and GAMS has started the execution phase. The above code can be fixed by moving the writing of the batch file to compilation time as in

```
$echo "dir" > x.bat
$call x.bat
```

or by moving the external program invocation to execution time:

```
File batchfile / x.bat /
putClose batchfile "dir"/
execute x.bat;
```

Notice that all $ commands do not include a semi-colon but are terminated by the end-of-line.
5.33 MODEL2TEX

A Tool to generate a documentation from GAMS source code in LaTeX format.

Clemens Westphal

Special thanks to Ingmar Schlecht for supporting us and sharing his `gamsToLatex` implementation.

5.33.1 Introduction

`MODEL2TEX` is a tool to generate a documentation from GAMS source code in LaTeX format. This LaTeX output can then be further processed in order to generate pretty output files like PDF. The tool can be found in the root directory of GAMS. The tool allows to document one specific model symbol inside of a GAMS program. The resulting documentation contains two parts. The first part shows a list of symbols that are used by the model. The second part shows the actual algebra of the used equations and information about the types of used variables. An optional third part can contain additional notes.

5.33.2 Usage

`MODEL2TEX` is a command line tool. The general command line usage is as follows:

`model2tex baseName [-h] [-m MODEL] [-f] [-o OUTPUT] [-e ENCODING]`

Since it operates on output files generated by GAMS, the first step is to generate the required files using the docfile option. In order to that, execute the following command line:

```
gams myModel.gms docfile=myModel
```

The second step is to call `MODEL2TEX`: On Windows the tool is shipped as an executable file. On Linux and Mac OS X, the original Python source code is distributed and used via the `model2tex.sh` script.

Windows:

```
model2tex myModel [-m MODEL] [-f] [-o OUTPUT] [-e ENCODING]
```

Linux/Mac OS X:

```
./model2tex.sh myModel [-m MODEL] [-f] [-o OUTPUT] [-e ENCODING]
```

The output file `myModel.tex` can be further processed for example by calling `pdflatex` in order to generate a PDF file.

```
pdflatex myModel.tex
```

5.33.3 Options

The following parameters can be used when calling `MODEL2TEX`:

---

5.33 Tools Manuals
### 5.33 MODEL2TEX

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-m model</td>
<td>Since MODEL2TEX generates documentation for one model symbol, the model name needs to be specified explicitly, if the GAMS file contains more than one model symbol.</td>
</tr>
<tr>
<td>-f</td>
<td>MODEL2TEX does not allow the occurrence of suffixes in equations. This option can be used in order to force the creation of the tex file by skipping the checks for suffixes.</td>
</tr>
<tr>
<td>-o output</td>
<td>Use this name for the generated TeX file instead of the base name.</td>
</tr>
<tr>
<td>-e encoding</td>
<td>Specify a different encoding. Default encoding is latin.</td>
</tr>
</tbody>
</table>

### 5.33.4 Using a JSON style file

MODEL2TEX automatically creates a JSON file that can be modified in order to customize the output. If you want to get the default settings back, just delete the generated JSON file and let MODEL2TEX create it again. The following list shows the available options in the JSON file:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fontSize</td>
<td>11</td>
<td>The size of the used font.</td>
</tr>
<tr>
<td>hrules</td>
<td>true</td>
<td>Horizontal rules are added between equations.</td>
</tr>
<tr>
<td>colors</td>
<td>black</td>
<td>Specifies the used colors in equations for variables, parameters, and sets.</td>
</tr>
<tr>
<td>landscape</td>
<td>false</td>
<td>Allows to change the page format to landscape.</td>
</tr>
<tr>
<td>noPowerFunc</td>
<td>false</td>
<td>Beside a power operator, GAMS offers several power functions. Setting this option to true will replace all power functions with the power operator.</td>
</tr>
<tr>
<td>reduceFrac</td>
<td>false</td>
<td>Try to resolve unbalanced fractions. This means that fractions with an unbalanced length of denominator and numerator will be changed in order to shrink the fraction.</td>
</tr>
<tr>
<td>reduceFracRatio</td>
<td>5.0</td>
<td>This number has only effect when reduceFrac is set to true. It specifies the ratio between denominator and numerator that is used as a threshold for reduceFrac.</td>
</tr>
<tr>
<td>latexDescription</td>
<td>false</td>
<td>Explanatory text for symbols is expected to be arbitrary text. In order to display the text correctly in LaTeX, some automatic adjustments are applied. If all explanatory text already contains valid LaTeX strings, this option can be enabled.</td>
</tr>
<tr>
<td>nameMap</td>
<td>the original names</td>
<td>This map allows to specify alternative names for symbols.</td>
</tr>
<tr>
<td>extraSymbols</td>
<td>empty list</td>
<td>On default, only the required symbols in a GAMS model symbol are contained in the generated LaTeX file. This list can be used in order to specify further symbols that should be included as well.</td>
</tr>
<tr>
<td>notes</td>
<td>empty list</td>
<td>Allows to specify additional notes for the documentation. Each list element will result in a new line.</td>
</tr>
</tbody>
</table>

### 5.33.5 Example

This example creates a PDF file for the pump model from the GAMS Model Library.

1. Retrieve model pump from GAMS Model Library

   ```bash
gamslib pump
   ```
2. Generate required doc files
   
   gams pump.gms docfile=pump

3. Generate the LaTeX files
   
   model2tex pump -m=pump

4. Generate PDF documentation
   
   pdflatex pump.tex

   The following pictures show snippets from the resulting PDF file:

5. Customizing the JSON style file In order to change the appearance of the PDF file, the generated
   JSON file `pump.json` can be modified. Changing the options in `pump.json` according to the picture
   and executing the commands from step 3 and 4 again will result in a customized PDF output.

5.34 MPS2GMS

Translates an MPS file into an equivalent short generic GAMS program using a GDX file to store data. A
number of solver specific extensions often used by CPLEX, MOSEK, OSL and XPRESS are recognized. Recently
introduced QP extensions QMATRIX, QUADOBJ, QSECTION and NAME/QSECTION/ENDATA are recognized as
well. Currently all Qsections are assumed to belong to the objective function only (quadratic constraints
are added to the objective function. The Mosek CSECTION extensions for QUAD and RQUAD cones are
recognized as well.

5.34.1 Usage

   mps2gms mpsfile [ gdxfile gmsfile [key=value] ]

   The MPS file is read in free format (no blanks in names). Row and column names can have up to 63
   characters and are tested for case sensitivity because row and column names become GAMS set members.

   GAMS Data Exchange (GDX) files, MPS files and matching GAMS source code can be written. Minimizing
   is the default.

   If no optimization direction is given, minimization will be assumed.

   MPS files may contain multiple section and objective functions. If none are specified the first one
   encountered will be used. Those keys are the same as the MPS type or section names: NAME, N, RHS,
   RANGES and BOUNDS.

   Quick guide to parameters:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPS</td>
<td>MPS file</td>
</tr>
<tr>
<td>GDX</td>
<td>GDX file</td>
</tr>
<tr>
<td>GMS</td>
<td>Name of GAMS program output file</td>
</tr>
<tr>
<td>NAME</td>
<td>name of MPS name section</td>
</tr>
<tr>
<td>N</td>
<td>name of objective function row</td>
</tr>
<tr>
<td>RHS</td>
<td>name of MPS Rhs section</td>
</tr>
<tr>
<td>RANGES</td>
<td>name of MPS Range section</td>
</tr>
<tr>
<td>BOUNDS</td>
<td>name of MPS Bounds section</td>
</tr>
<tr>
<td>MPSout</td>
<td>rewritten MPS file file</td>
</tr>
<tr>
<td>Trace</td>
<td>debugging options</td>
</tr>
</tbody>
</table>
5.34.2 Examples

mps2gms old.mps MpsOut=new.mps

mps2gms old.mps old.gdx old.gms RHS=somerhs N=MYOBJ

mps2gms old.mps old.gdx old.gms Name=MYModel

5.35 MSAPPAVAIL

Checks if a MS Office Application is available.

5.35.1 Usage

Project
Word

See how [cta] example from the GAMS model library uses this feature.
Starting with distribution 20.6 the GAMS system for Windows includes a collection of Posix utilities which are usually available for the different Unix systems and therefore help to write platform independent scripts. The following utilities are available:

- awk - Pattern scanning and processing language
- cat - Concatenate and print files
- cksun - Write file checksums and sizes
- cmp - Compare two files
- comm - Select or reject lines common to two files
- cp - Copy files
- cut - Cut out selected fields of each line of a file
- diff - Compare two files
- expr - Evaluate arguments as an expression
- fold - Fold lines
- gsort - Sort, merge, or sequence check text files
- grep - File pattern searcher
- gdate - Write the date and time
- head - Copy the first part of files
- join - Relational database operator
- mv - Move files
- od - Dump files in various formats
- paste - Merge corresponding or subsequent lines of files
- printf - Write formatted output
- rm - Remove directory entries
- sed - Stream editor
- sleep - Suspend execution for an interval
- tail - Copy the last part of a file
- tee - Duplicate standard input
- test - Evaluate expression
- tr - Translate characters
- uniq - Report or filter out repeated lines in a file
- wc - Word, line, and byte count
- xargs - Construct argument list(s) and invoke utility
Please note that the utilities "date" and "sort" have been renamed to "gdate" and "gsort" to avoid conflicts with the Windows commands "date" and "sort". For compatibility reasons the GNU implementation of awk called "gawk" has been renamed to "awk".

Please note that sed might crash if it runs against the memory limit. This only happens if the input is very big. If you experience this problem please use sed from the 'gbin_new' directory. This version does not suffer the memory leak.

The collection consists of native Windows ports of GNU implementation of these utilities taken from the Sourceforge. Detailed descriptions of the utilities can be found at the GNU website.

The Posix tools and in particular the awk utility can be used to transform a variety of different text inputs into GAMS readable input files. Examples can be found in the GAMS Model Library (Subject "GAMS Tools").

5.37 SCENRED

5.37.1 Release Notes

- May, 2002: Level 001 (GAMS Distribution 20.6)
  - GAMS/SCENRED introduced.

5.37.2 Introduction

Stochastic programs with recourse employing a discrete distribution of the random parameters become a deterministic programming problem. They can be solved by an appropriate optimization algorithm, ignoring the stochastic nature of (some or all) parameters.

SCENRED is a tool for the reduction of scenarios modeling the random data processes. The scenario reduction algorithms provided by SCENRED determine a scenario subset (of prescribed cardinality or accuracy) and assign optimal probabilities to the preserved scenarios. The reduced problem is then solved by a deterministic optimization algorithm provided by GAMS.

5.37.3 Scenario Reduction Algorithms

Many solution methods for stochastic programs employ discrete approximations of the uncertain data processes by a set of scenarios (i.e., possible outcomes of the uncertain parameters) with corresponding probabilities.

For most practical problems the optimization problem that contains all possible scenarios (the so-called deterministic equivalent program) is too large. Due to computational complexity and to time limitations this program is often approximated by a model involving a (much) smaller number of scenarios.

The reduction algorithms developed in [1,2] determine a subset of the initial scenario set and assign new probabilities to the preserved scenarios. All deleted scenarios have probability zero.

SCENRED contains three reduction algorithms: The Fast Backward method, a mix of Fast Backward/Forward methods and a mix of Fast Backward/Backward methods. In general, the computational performance (accuracy, running time) of the methods differ. For huge scenario trees the Fast Backward method has the best expected performance with respect to running time. The results of the Forward and Backward methods are more accurate, but at the expense of higher computing time. The Forward
method is the best algorithm when comparing accuracy, but it can only be recommended if the number of preserved scenarios is small (strong reduction). The combined methods improve the result of the Fast Backward method if the Forward or Backward method, respectively, can be completed within the running time limit. If no reduction method is selected, the method with the best expected performance with respect to running time is chosen.

The reduction algorithms exploit a certain probability distance of the original and the reduced probability measure. The probability distance trades off scenario probabilities and distances of scenario values. Therefore, deletion will occur if scenarios are close or have small probabilities.

The reduction concept is general and universal. No requirements on the stochastic data processes (e.g. the dependency or correlation structure of the scenarios, the scenario probabilities or the dimension of the process) or on the structure of the scenarios (e.g. tree-structured or not) are imposed. The reduction algorithms can be tailored to the stochastic model if the user provides additional information (How many decision stages are involved? Where do the random parameters enter the model – in objective and/or right hand sides and/or technology matrices?) The information is used to choose the probability distances (cf. Remark 1 in [1]).

References:

5.37.4 Using GAMS/SCENRED

The reduction algorithms require additional data preparation and reformulation of the GAMS program for the stochastic programming model.

GAMS offers great flexibility with respect to the organization of data specification, model definition and solve statements. The most common way to organize GAMS/SCENRED programs is shown below. Since the initial scenarios and a number of input parameters have to be passed to SCENRED, the corresponding components of the GAMS program have to be defined before the SCENRED call. The reduced scenarios have to be defined before the equations of the (reduced) stochastic programming model are used in a solve statement. Therefore the SCENRED call can be placed anywhere between the definitions of the GAMS parameters and the solve statement of the reduced stochastic programming model.

When building or modifying a model for use with GAMS/SCENRED the following steps should be taken:

- Analyse the GAMS program of the stochastic programming model.
  Since the initial scenarios and a number of input parameters have to be passed to SCENRED (see Section The SCENRED Input File), one must identify the corresponding components of the GAMS model and create or calculate them if they do not already exist.

- Reformulate the GAMS program.
  Check if the model can handle varying scenario or node probabilities, and whether the equations are defined in terms of a (possibly reduced) tree. If the model doesn't already contain a scenario tree, one should be added. If it does, it is a simple task to rewrite the equation definitions (and possibly other statements too) in terms of a subset of the original nodes or tree.

- Add the statements for passing the initial set of scenarios to SCENRED, for the execution of SCENRED and for the import of the reduced scenarios from SCENRED.
A reduction of the initial scenarios makes sense only if we are able to generate that part of the model that corresponds to the preserved scenarios (i.e. the reduced subtree). This is done by declaring a subset of the nodes in the original tree. The parameters and equations are declared over the original node set, but are defined over only the subtree. This will be illustrated by an example later in the section.

Further, one should verify that the model can handle changing probabilities. Many practical models involve scenarios with equal probabilities. This property will not be maintained by the probabilities in the reduced subtree.

### ORGANIZATION OF GAMS/SCENRED PROGRAMS

<table>
<thead>
<tr>
<th>Component</th>
<th>Contents</th>
</tr>
</thead>
</table>
| 1. DATA   | * set & parameter declarations and definitions  
|           | * $libinclude scenred.gms  
|           | * assignments displays |
| 2. SCENRED CALL | * export the initial scenarios from GAMS to SCENRED  
|           | * execute SCENRED  
|           | * import the reduced scenarios from SCENRED to GAMS |
| 3. MODEL  | * variable declaration  
|           | * equation declarations  
|           | * equation definitions (using sets from reduced tree)  
|           | * model definition & solution |

Prior to calling SCENRED, you should include the declaration of the SCENRED input and output parameters and the definition of the sets they are indexed by from the GAMS include library:

```
$libinclude scenred.gms
```

Once you have created all the inputs to SCENRED and assigned values to them, you are ready to write the SCENRED GDX data input file, write the SCENRED options file, call SCENRED, and read the reduced tree data from the SCENRED GDX data output file (see Section The SCENRED Input File, Section SCENRED Options and the Option File, and Section The SCENRED Output File). Assuming your model is formulated to use a subtree of the original, you can now continue with the solve and any subsequent reporting.

SCENRED is executed by issuing the statement

```
execute 'scenred optfilename';
```

where `optfilename` is the name of the SCENRED option file.

As an example, consider the `srkandw` model in the GAMS model library, and the `kand` model upon which it is based (get these from the modlib now!). To produce `srkandw` from `kand`, we first reformulate the original to allow for solution over a reduced tree. To do this, we introduce a subset of the node set: set `sn(n)` ‘nodes in reduced tree’; For convenience and clarity, we introduce a second subset at the same time, the set of leaf nodes: set `leaf(n)` ‘leaf nodes in original tree’; as well as some code to compute this set based on the existing time-node mapping. We also declare a new parameter, the probabilities for the reduced tree: parameter `sprob(n)` ‘node probability in reduced tree’; Once these are declared, we can quickly edit the equation definitions so that they run only over the reduced subtree: we simply substitute the reduced probabilities `sprob` for the original `prob`, and the reduced node set `sn` for the original node set `n`. Note that the declaration of the equations does not change.

This example illustrates one other change that may be required: the stochastic data must be in parameters having the node set as their last index. This is not the case in the `kand` model, so we simply reversed the indices in the `dem` parameter to meet the requirement in `srkandw`. It is also possible to create a transposed copy of the original data and pass that the SCENRED if the original data cannot be changed conveniently.
5.37.5 The SCENRED Input File

The SCENRED input file contains the initial scenarios and their stochastic parameter data, as well as statistics describing this input and (possibly) options to control the SCENRED run. This input file has a special binary format; it is a GDX (GAMS Data Exchange) file. The name of the SCENRED input file is assigned in the option file (see Section SCENRED Options and the Option File).

The scalar inputs to SCENRED are collected in the one-dimensional parameter ScenRedParms, the first parameter stored in the SCENRED input file. Some of the elements of ScenRedParms are required (e.g. statistics for the input tree) while others are optional (e.g. the run time limit). SCENRED will stop if a required element is missing or out of range.

Table 1 Required ScenRedParms elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_leaves</td>
<td>the number of initial scenarios or leaves of the scenario tree (i.e., before the reduction)</td>
</tr>
<tr>
<td>num_nodes</td>
<td>number of nodes in the initial tree (the number of scenarios if not tree-structured)</td>
</tr>
<tr>
<td>num_random</td>
<td>Number of random variables assigned to a scenario or node, i.e., the dimension of the random data process</td>
</tr>
<tr>
<td>num_time_steps</td>
<td>Length of a path from the root node to a leaf of the scenario tree, i.e., the number of time steps involved</td>
</tr>
</tbody>
</table>

Table 2 Optional ScenRedParms elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>red_num_leaves</td>
<td>specifies the desired number of preserved scenarios or leaves</td>
<td>none</td>
</tr>
<tr>
<td>red_percentage</td>
<td>specifies the desired reduction in terms of the relative distance between the initial and reduced scenario trees (a real between 0.0 and 1.0)</td>
<td>none</td>
</tr>
<tr>
<td>num_stages</td>
<td>Set the number of branching levels of the scenario tree, i.e., the number of stages of the model -1. Hence num_stages=1 if no branching occurs, i.e., the values of the scenarios differ for all time steps</td>
<td>1</td>
</tr>
<tr>
<td>where_random</td>
<td>An integer indicating where the randomness enters the model. The value is interpreted as a digit map computed using the formula 100∗inObj + 10∗inRHS + inMatrix, where inObj is 1 if the objective contains random parameters and 0 otherwise, inRHS is 1 if the right-hand side contains random parameters and 0 otherwise, and inMatrix is 1 if the constraint matrix contains random coefficients and 0 otherwise.</td>
<td>10 (random right-hand side)</td>
</tr>
<tr>
<td>reduction_method</td>
<td>Select a reduction method: 0: automatic (best expected performance with respect to running time) 1: Fast Backward method 2: Mix of Fast Backward/Forward methods 3: Mix of Fast Backward/Backward methods</td>
<td>0</td>
</tr>
<tr>
<td>run_time_limit</td>
<td>Defines a limit on the running time in seconds</td>
<td>none</td>
</tr>
<tr>
<td>report_level</td>
<td>Control the content of the SCENRED log file: 0: Standard SCENRED log file 1: Additional information about the tree</td>
<td>0</td>
</tr>
</tbody>
</table>
A few comments on the parameters `red_percentage` and `red_num_leaves` are in order. At least one of these values must be set. The value of `red_percentage` will be ignored if the parameter `red_num_leaves` is non-zero. Otherwise, the tree will not be reduced if `red_percentage=0`, while the reduction of the tree will be maximal (i.e. only one scenario will be kept) if `red_percentage=1`. A numeric value of 0.5 means that the reduced tree maintains 50% of the information contained in the original tree. The reduction algorithms are skipped if `red_num_leaves=num_leaves` or if `red_num_leaves=0` and `red_percentage=0`. These values can be assigned if the user wishes to run the scenario tree diagnostic.

The second data element in the input file is the set of nodes making up the scenario tree. Note that the cardinality of this set is part of `ScenRedParms`.

The third data element is the ancestor mapping between the nodes. This mapping determines the scenario tree. Note that the mapping can be either an ancestor mapping (i.e. child-parent) or a successor mapping (parent-child). By default, SCENRED expects an ancestor mapping. If the check for this fails, it looks for a successor mapping.

The fourth data element is the parameter of probabilities for the nodes in the original tree. It is only required that probabilities for the scenarios (i.e. the leaf nodes) be provided, but the parameter can contain probabilities for the non-leaf nodes as well.

The remaining elements in the input data file specify the parameter(s) that comprise the random values assigned to the initial scenarios, or to the nodes of the scenario tree. There can be more than one such parameter, included in any order. The only requirement is that the node set be the final index in each of these parameters.

Table 3 summarizes the content of the SCENRED input file. Please keep in mind that the order of the entries must not be altered!

<table>
<thead>
<tr>
<th>No.</th>
<th>Symbol</th>
<th>Type</th>
<th>Dimension</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>ScenRedParms</code></td>
<td>Parameter</td>
<td>1</td>
<td>scalar SCENRED input</td>
</tr>
<tr>
<td>2</td>
<td>(any name)</td>
<td>Set</td>
<td>1</td>
<td>nodes in the scenario tree</td>
</tr>
<tr>
<td>3</td>
<td>(any name)</td>
<td>Set</td>
<td>2</td>
<td>the ancestor set</td>
</tr>
<tr>
<td>4</td>
<td>(any name)</td>
<td>Parameter</td>
<td>1</td>
<td>node probabilities; at least for the leaves</td>
</tr>
<tr>
<td>≥ 5</td>
<td>(any name)</td>
<td>Parameter</td>
<td>≥ 1</td>
<td>random values assigned to the nodes</td>
</tr>
</tbody>
</table>

To create the SCENRED data input file, the GAMS `execute_unload` statement is used. This statement is used to transfer GAMS data to a GDX file at execution time. As an example, to create a GDX file with the 4 required input parameters and one parameter `demand` containing the stochastic data, you might have the following statement:

```gams
execute_unload 'sr_input.gdx', ScenRedParms, node, ancestor, prob, demand;
```

### 5.37.6 SCENRED Options and the Option File

When the SCENRED executable is run, it takes only one argument on the command line: the name of the SCENRED option file. The option file is a plain text file. Typically, it is used to specify at least the names of the SCENRED data input and output files. The option file must be created by the SCENRED user (typically via the GAMS put facility during the GAMS run). The syntax for the SCENRED option file is

```gams
optname value or optname = value
```
with one option on each line. Comment lines start with an asterix and are ignored.

Some of the SCENRED options may be specified in two places: as elements of the `ScenRedParms` parameter of the SCENRED input file, or as entries in the options file. These parameters have been summarized in Table 2. If an option is set in both these places, the value in the option file takes precedence of over the value from `ScenRedParms`. In addition, the parameters in Table 4 can only be specified in the option file.

**Table 4 Options - optfile only**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>input.gdx</td>
<td>Name of the SCENRED data input file</td>
<td>xllink.gdx</td>
</tr>
<tr>
<td>output.gdx</td>
<td>Name of the SCENRED data output file</td>
<td>scenred.gdx</td>
</tr>
<tr>
<td>log_file</td>
<td>Name of the SCENRED log file</td>
<td>scenred.log</td>
</tr>
</tbody>
</table>

## 5.37.7 The SCENRED Output File

The SCENRED output file contains the reduced scenario tree and the `ScenRedReport` parameter. Like the input file, the output file has a special binary format; it is a GDX (GAMS Data Exchange) file.

The first data element in the output file is the `ScenRedReport` parameter containing the scalar outputs and statistics from the SCENRED run. The elements of this parameter are summarized in Table 5. The second data element is the parameter containing the probabilities of the nodes in the reduced scenario tree. These node probabilities are required to construct the reduced tree. The third and final data element is the ancestor map for the reduced scenario tree. This map can be read from the GDX file, or the reduced tree can be built from the original one by using the reduced probabilities. The content of the data output file is summarized in Table 6.

**Table 5 ScenRedReport elements**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScenRedWarnings</td>
<td>number of SCENRED warnings</td>

</tr>
</tbody>
</table>
| reduction_method | reduction method used: 0: the program stopped before it could select a method
|                 | 1: Fast Backward method                              |
|                 | 2: Mix of Fast Backward/Forward methods               |
|                 | 3: Mix of Fast Backward/Backward methods              |

**Table 6 Content of the SCENRED Output File**

<table>
<thead>
<tr>
<th>No.</th>
<th>Symbol</th>
<th>Type</th>
<th>Dimension</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ScenRedReport</td>
<td>Parameter</td>
<td>1</td>
<td>report of the SCENRED run</td>
</tr>
<tr>
<td>2</td>
<td>red_prob</td>
<td>Parameter</td>
<td>1</td>
<td>node probabilities for the reduced scenarios</td>
</tr>
<tr>
<td>3</td>
<td>red_ancestor</td>
<td>Set</td>
<td>2</td>
<td>the ancestor map for the reduced scenarios</td>
</tr>
</tbody>
</table>
To read the SCENRED data output file, the GAMS \texttt{execute_load} statement is used. This statement is used to transfer GDX data to GAMS at execution time. As an example, to read a GDX file named \texttt{sr_output.gdx} created by SCENRED, you might have the following statement:

\begin{verbatim}
execute_load 'sr_output.gdx', ScenRedReport, sprob=red_prob, sanc=red_ancestor;
\end{verbatim}

In the statement above, the equal sign = is used to indicate that the data in the GDX parameter \texttt{red_prob} should be read into the GAMS parameter \texttt{sprob}, and the data in the GDX set \texttt{red_ancestor} should be read into the GAMS set \texttt{sanc}.

5.37.8 Diagnostic Check of Scenario Trees

When SCENRED reads its input data, it performs a number of checks to verify that the data is correct. The diagnostic checks of the input parameters include:

- consistency of the desired input parameters with the contents of the SCENRED input file (number of nodes, number of leaves, number of time steps, number of random values assigned to a node)
- range check of desired input parameters and options
- check of scenario and node probabilities
- check of the ancestor matrix (check the orientation of the graph, check if the graph contains a cycle, check if the graph contains incomplete forests or scenarios, check the consistency of the parameter \texttt{num_time_steps} with the ancestor matrix)

The following errors in the specification of the scenario tree cause SCENRED to skip the reduction algorithms:

- The input files cannot be opened.
- Not all required input parameters are given.
- The required input parameters are not consistent with the contents of the SCENRED input file.
- The required input parameters are out of range.
- Missing or negative scenario probabilities (probabilities of leaves).
- The ancestor set contains too many entries (more than \(2^{\texttt{num_nodes}}\)).
- SCENRED detects a cycle in the ancestor set.
- SCENRED detects incomplete scenarios in the ancestor set.
- Run time limit reached

5.37.9 SCENRED Errors and Error Numbers

When SCENRED encounters a serious error in the input files or in the scenario tree, it sends an error message to the screen and to the log file. These messages always start with

\begin{verbatim}
**** SCENRED run-time error ... 
\end{verbatim}

The number of SCENRED errors are contained in the parameter \texttt{ScenRedReport} of the SCENRED output file (if it could be created). The occurrence of an error can also be detected from the last line that SCENRED sends to the screen:

\begin{verbatim}
**** SCENRED ErrCode=... 
\end{verbatim}

The numerical values of \texttt{ErrCode} and their meaning are given below.
<table>
<thead>
<tr>
<th>ErrCode</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(for internal use)</td>
</tr>
<tr>
<td>2</td>
<td>fatal error while reading from SCENRED input file</td>
</tr>
<tr>
<td>3</td>
<td>fatal error while writing to SCENRED output file</td>
</tr>
<tr>
<td>4</td>
<td>fatal error while reading from SCENRED option file</td>
</tr>
<tr>
<td>5</td>
<td>log file cannot be opened</td>
</tr>
<tr>
<td>6</td>
<td>a memory allocation error occurred</td>
</tr>
<tr>
<td>7</td>
<td>there are missing input parameters</td>
</tr>
<tr>
<td>8</td>
<td>could not access the GAMS names for the nodes</td>
</tr>
<tr>
<td>9</td>
<td>(for internal use)</td>
</tr>
<tr>
<td>10</td>
<td>ancestor set not given or contains too many entries</td>
</tr>
<tr>
<td>11</td>
<td>node probabilities cannot be not read or are wrong</td>
</tr>
<tr>
<td>12</td>
<td>random values for the nodes cannot be read</td>
</tr>
<tr>
<td>13</td>
<td>input parameters are out of range</td>
</tr>
<tr>
<td>14</td>
<td>ancestor set contains a cycle</td>
</tr>
<tr>
<td>15</td>
<td>incomplete scenarios or forests detected</td>
</tr>
<tr>
<td>16</td>
<td>fatal error in reduction algorithm (not enough memory)</td>
</tr>
<tr>
<td>17</td>
<td>running time limit reached</td>
</tr>
</tbody>
</table>

5.37.10 SCENRED Warnings

SCENRED warnings are caused by misspecification of the initial scenarios that can be possibly fixed. When SCENRED encounters such an error in the input files or in the scenario tree, it sends a message to the screen and to the log file. These messages always start with

**** SCENRED Warning . . .

The following list gives an overview of the cases that produce warnings, and the action taken by SCENRED in these cases.

- The user assigned an option value that is out of range.
  **Action:** Assign the default value.

- Both parameters `red_num_leaves` and `red_percentage` are assigned nontrivial values.
  **Action:** The value of `red_percentage` will be ignored.

- The scenario probabilities (probabilities of leaves) do not sum up to 1.
  **Action:** The scenario probabilities are rescaled. Assign new probabilities to the remaining (inner) nodes that are consistent with the scenario probabilities.

- Missing probabilities of inner nodes.
  **Action:** Assign node probabilities that are consistent with the scenario probabilities.

- The ancestor set contains more than one ancestor for a node.
  **Action:** SCENRED assumes to be given a successor set instead of an ancestor set (i.e., the transpose of an ancestor matrix. This means that the graph corresponding to the ancestor set has the wrong orientation). SCENRED starts the tree diagnostic for the successor set. The reduced tree will be defined in terms of a successor set as well (if the successor set passes the tree diagnostic and if SCENRED locates no fatal error during the run).

- The fast backward method delivered a result, but the result cannot be improved by the forward or backward method (running time limit reached).
  **Action:** Use the result of the fast backward method.
5.38 SCENRED2

5.38.1 Introduction

Scenred2 is a fundamental update of the well-known scenario reduction software Scenred. A lot of new features come along with the latest release version. Beside updates and extensions concerning the control of the scenario reduction action an all new device for scenario tree construction has been implemented in Scenred2. Moreover, a lot of visualization functions to plot scenario trees and scenario processes linked to the free Gnuplot plotting software are available with Scenred2 now.

Table: Summary of basic new functions in Scenred2

<table>
<thead>
<tr>

<td>Command Line Interface</td>
</tr>
</tbody>
</table>

5.38.2 Using Gams/Scenred2

Successful applying Scenred or Scenred2 requires a special formulation of the stochastic programming model within the Gams program. Probabilistic information must be given by a set of nodes implying a certain ancestor structure including a well-defined root node. Note that the usage of Gams/Scenred2 is basically the same as the usage of Gams/Scenred. Hence, it is recommended for new users to look at the Scenred documentation first. All details about how to organize your Gams program, how to run Scenred from the Gams program by using the gdx interface, and, of course, examples can be found in that documentation.

The Gams/Scenred2 link provides the same gdx interface. But, due to new features some small changes in controlling the options are needed. Scenred2 supports now two types of option files. The first one is the SR-Command-File which must be passed to Scenred2 together with the Scenred2 call. The second one, the SR-Option-File includes more specific options to control the selected scenario reduction or scenario construction methods and can be declared in the SR-Command-File.

5.38.2.1 SR-Command-File

The command file includes the basic specifications. These are input/output gdx file names, the log file name, all other file names which are needed for diverse visualization and output options. It also includes the name of the SR-Option-File.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_file</td>
<td>specify a log file name</td>
<td>yes</td>
</tr>
<tr>
<td>input.gdx</td>
<td>specify the gdx input file for Scenred</td>
<td>yes</td>
</tr>
<tr>
<td>output.gdx</td>
<td>specify the gdx output file of Scenred</td>
<td>yes</td>
</tr>
<tr>
<td>sr_option</td>
<td>specify a SR-Option-File</td>
<td>no</td>
</tr>
<tr>
<td>visual_init</td>
<td>specify a name for visualization of input tree</td>
<td>no</td>
</tr>
<tr>
<td>visual_red</td>
<td>specify a name for visualization of reduced/constructed tree</td>
<td>no</td>
</tr>
<tr>
<td>plot_scen</td>
<td>specify a name for visualization of scenario processes</td>
<td>no</td>
</tr>
<tr>
<td>out_scen</td>
<td>specify a file for scenario data output in fan format</td>
<td>no</td>
</tr>
<tr>
<td>out_tree</td>
<td>specify a file for scenario data output in tree format</td>
<td>no</td>
</tr>
</tbody>
</table>
ScenRed2 must be called together with a command file, which contains at least all required options. The data exchange via the gdx interface and the ScenRed2 call from the Gams program is of the form (be careful with the meanings and right order of gdx symbols):

```plaintext
execute_unload 'sрин.gdx', ScenRedParms, n, ancestor, prob, random;
execute 'scenred2 scenred.cmd';
execute_load 'sרוут.gdx', ScenRedReport, ancestor=red_ancestor, prob=red_prob;
```

For example, the command file could be the following (note the compatible gdx file names):

```plaintext
* scenred command file 'scenred.cmd'
log_file sr.log
input_gdx sрин.gdx
output_gdx sroit.gdx
sr_option scenred.opt
visual_red tree
out_scen raw.dat
```

### 5.38.2.2 ScenRedParms

With the symbol list of the parameter ScenRedParms and the SR-Option-File all necessary information regarding the ScenRed2 run can be assigned. The Gams parameter ScenRedParms can easily included to the Gams program by the statement:

```plaintext
$libInclude scenred2
```

Of course, the include must be stated before calling ScenRed2. After that statement all supported parameters can be assigned, but at least all required parameters regarding the input scenarios. By the symbols of the parameter ScenRedParms you make also the decision of what features you exactly want to use with ScenRed2. Moreover, some other useful parameters for the ScenRed2 run are included in the symbol list of the parameter ScenRedParms.

**Table:** Supported ScenRed2 parameters in ScenRedParms

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_time_steps</td>
<td>path length from root to leaf</td>
<td>yes</td>
</tr>
<tr>

</tr>
<tr>
<td>num_stages</td>
<td>number stages</td>
<td>no</td>
</tr>
<tr>
<td>run_time_limit</td>
<td>time limit in seconds</td>
<td>no</td>
</tr>
<tr>
<td>report_level</td>
<td>report level: more messages by higher values</td>
<td>no</td>
</tr>
<tr>
<td>scen_red</td>
<td>scenario reduction command</td>
<td>no</td>
</tr>
<tr>
<td>tree_con</td>
<td>tree construction command</td>
<td>no</td>
</tr>
<tr>
<td>visual_init</td>
<td>visualization initial tree</td>
<td>no</td>
</tr>
<tr>
<td>visual_red</td>
<td>visualization reduced (constructed) tree</td>
<td>no</td>
</tr>
<tr>
<td>plot_scen</td>
<td>visualization scenario processes</td>
<td>no</td>
</tr>
<tr>
<td>out_scen</td>
<td>output of scenario raw data</td>
<td>no</td>
</tr>
</tbody>
</table>
To enable some options assign a value to the parameter. A parameter value of zero (default) disables an option. Note that when running Scenred2 either scenario reduction or scenario tree construction can be performed. Hence, only `scen_red` or `tree_con` should be used at once.

**Example:**

The following statements describe a possible example setup for proceeding the scenario tree construction with visualization of the scenario tree and output of the scenarios to a raw data file afterwards. Note that for the visualization and the scenario output the name of output files must be specified in the SR-Command-File. Otherwise a warning will inform you about not selected file names.

```plaintext
* general parameters
ScenRedParms('num_leaves') = 100;
ScenRedParms('num_nodes') = 200;
ScenRedParms('num_time_steps') = 5;
ScenRedParms('num_random') = 2;
ScenRedParms('report_level') = 2;
ScenRedParms('run_time_limit') = 30;

* execution commands
ScenRedParms('tree_con') = 1;
ScenRedParms('visual_red') = 1;
ScenRedParms('out_scen') = 1;
```

Scenred2 can also be used for plotting tasks only. Disable both the `scen_red` and `tree_con` option and use one or more visualization options only (see also Section Visualization for more details regarding visualizations).

### 5.38.2.3 SR-Option-File

The SR-Option-File is the more specific option file and will be passed to Scenred2 by the `sr_option` statement specified in the SR-Command-File. It serves as control unit for available methods provided by Scenred2. The supported options depend on what kind of method is called with Scenred2. A detailed list of all options together with examples are given below for both the scenario reduction and the scenario construction devices (see Sections Scenario Reduction and Scenario Tree Construction, respectively). Note that certain parameters can be assigned by using both ScenRedParms and the SR-Option-File. In case of having parameters defined twice a warning by Scenred2 will generated to inform you.

### 5.38.3 Scenario Reduction

The scenario reduction device consists of approved methods for reducing the model size by reducing the number of scenarios in an optimal way. Here it doesn't make any difference whether the input data is structured as scenario tree or not. But note, the classical scenario reduction approach is actually developed for two-stage models. Extensions for the multistage case are planned in the near future. To learn more about the mathematical theory see, for example,

With Scenred2 the most popular and accurate reduction algorithms of forward and backward type are maintained further on. New options make it possible to proceed with the scenario reduction more individual. The most important new parameter is given by the option `metric_type` which allows to control the reduction process by different type of probability distances. Altogether three distances can be selected (see Table below). All probability distances are associated with a special order specification which can be set by the new option `order`. Both options replace the old option `where_random` which is not used any longer.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>red_num_leaves</code></td>
<td>desired number of scenarios (integer)</td>
</tr>
<tr>
<td><code>red_percentage</code></td>
<td>relative accuracy (number from 0.0 to 1.0)</td>
</tr>
<tr>
<td><code>reduction_method</code></td>
<td>1 - Forward, 2 - Backward, 0 - Default</td>
</tr>
<tr>
<td><code>metric_type</code></td>
<td>1 - Transport (default), 2 - Fortet-Mourier, 3 - Wasserstein</td>
</tr>
<tr>
<td><code>p_norm</code></td>
<td>choice of norm (example: 0 - max, 1 - sum, 2 - Euclidian)</td>
</tr>
<tr>
<td><code>scaling</code></td>
<td>0 - scaling off, 1 - scaling on (default)</td>
</tr>
<tr>
<td><code>order</code></td>
<td>metric order (integer, default is 1)</td>
</tr>
</tbody>
</table>

Example:

For example, a valid SR-Option-File is the following:

```plaintext
* scenred option file
reduction_method 1
red_percentage 0.3
metric_type 2
order 2
p_norm 1
scaling 0
```

Lines starting with the star symbol (route symbol can be used too) provide comment lines. The star symbol can also be used to out comment and disable certain options.

### 5.38.4 Scenario Tree Construction

Scenario tree construction is the outstanding all new device of Scenred2. It allows to construct scenario trees as accurate input for multistage stochastic programs (cf. H. Heitsch and W. Römisch, Scenario tree modeling for multistage stochastic programs, Mathematical Programming, 118:371–406, 2009). The input are individual scenarios in form of a fan which must be allocated before calling Scenred2. A lot of options are offered to control the tree construction process. Note that in some cases due to sensibility of certain parameters some tuning is indispensable for producing good results.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>construction_method</code></td>
<td>1 - forward, 2 - backward</td>
</tr>
<tr>
<td><code>reduction_method</code></td>
<td>1 - forward, 2 - backward, used within the iteration</td>
</tr>
<tr>
<td><code>first_branch</code></td>
<td>time period of first branch (integer)</td>

</tbody>
</table>
The Table above displays the main options to control the tree construction process. They are very similar to the reduction options. The role of the option `red_percentage` is here to prescribe a total epsilon accuracy (level) for the approximation scheme. But the approximation scheme is based on stagewise approximations which requires a splitting of the total level to the stages. Two strategies are offered by Scenred2 a linear and an exponential mapping of the total level to the intermediate levels. Use option `eps_growth` to select one of them. Both strategies allow a second tuning parameter `eps_evolution` which effects the slope of the epsilon splitting.

Even though this kind of control may generate good results for many applications, sometimes a more individual control can be needed. For example, some applications require a localization of branching stages. Moreover, to setup approximation bounds directly to stages can be very useful. To this end the standard options are extended by a new section environment.

5.38.4.1 Additional options - The section environment

An alternative control for the accurate constructions is provided by using the section environment. The section environment aims to establish a better monitoring of the construction process. There are overall three section types supported by Scenred2 with the same syntax.

**Branching control:**

This section environment allows to specify branching points, i.e., an explicit selection of stages serving for branching. For example, use

```plaintext
section branching
  2
  4
  6
end
```

to allow branching only at time period 2, 4, and 6. Note that each stage statement must be placed in one line. But stages can be merged. A shorter formulation of the same contents can be written in closed form

```plaintext
section branching
  2*6 2
end
```

This statement reads branching within time periods from period 2 to period 6 with increment 2 steps. Both assignments can be combined and should be used together with the `red_percentage` option.

**Epsilon control:**

In the similar way by the epsilon section it is possible to assign epsilon tolerances for the stage approximations explicitly. This environment overcomes difficulties at times coming across with the automatic epsilon control. Note that this environment disables the option `red_percentage`. For example, use

```plaintext
section epsilon
  2 0.04
  3*4 0.03
  5 0.02
  6 0.01
end
```
to control the approximation scheme by assigning different epsilon values per stage. Note that the value 0.03 is assigned to time period 3 and 4 in the example.

**Node control:**

The node control is the most specific control you have over the tree construction. With this environment the number of nodes of the tree which will generated can be assigned for each time stage explicitly. For example, use

```plaintext
section num_nodes
  1 1
  2*3 5
  4*5 10
  6 15
end
```

The syntax is the same as before. Note that only one section environment can be use at once. In particular, only the first section environment detected in the option file is used. The section environment can be out commented like a standard option too.

**Experimental option:**

There is one other useful option to speed up computations when building different scenario trees from exactly the same input data. In this case the scenario distances needed to compute the trees could be saved to a external file at the first run and reloaded at later runs. Hence, the distances must be calculated only once. For example, use the option

```plaintext
write_distance dist.sr2
```

to save the computed distances to the file 'dist.sr2'. To reload them at next run use the option

```plaintext
read_distance dist.sr2
```

The option is classified as experimental since no validation of the input file takes place. Before using this option, please ensure that the distances loaded with the `read_distance` option are the right ones.

**Example:**

Finally, look at the following example to see a valid SR-Option-File which can be passed to the scenario tree construction:

```plaintext
* tree construction option file

construction_method  2
reduction_method  1
order  1
scaling  0

section epsilon
  2*4  0.1
  5  0.2
  6  0.1
end
```
5.38 SCENRED2

5.38.4.2 Example problems 'srtree.gms' and 'srpchase.gms'

Small example problems has been included to the GAMS Model Library.

The implementation can be found in the Gams programs 'srtree.gms' and 'srpchase.gms'. It might help you to practice in building scenario trees using Gams/Scenred2. The problem 'srtree.gms' converts a fan format scenario representation into a tree format representation and then reduces the tree size. The problem 'srpchase.gms' is to solve a simple stochastic purchase problem involving three stages. Sample scenarios which are generated from a fixed distribution using a random value generator serve as input for the tree construction.

5.38.5 Visualization

Visualization is another all new feature of Scenred2. In this section an easy way for making plots of scenario processes and tree structures is described. To this end you need the free Gnuplot software or any other plotting software which allows plotting directly from simple data files.

The concept of plotting tasks is the following. For each plot two files are generated, a Gnuplot access file (name.plt) and a raw data file (name.dat). The access file contains basic Gnuplot options and it can be adjusted for individual liking afterwards. The default output is the display. The supported plotting commands are

visual_init, visual_red, plot_scen

for plotting the initial tree structure, the reduced/constructed tree structure, and the scenario process(es), respectively.

Example:

For example, to visualize the constructed tree use the option

visual_red tree

within the SR-Command-File to specify the name for the output and activate the ScenRedParms parameter

ScenRedParms('visual_red') = 1;

in the Gams program. The result are the output files 'tree.plt' and 'tree.dat'. To compute the picture now you simply open the file 'tree.plt' with Gnuplot from the directory, where both output files are located (that should be the working directory). Alternatively, from the command line prompt call

>gnuplot tree.plt

Gnuplot will automatically generate the picture. Feel free to change any option in the Gnuplot access file for individual requirements. See also the Gnuplot manual for more details. In particular, to compute a well-scaled encapsulated postscript picture (eps), you simply have to uncomment a few lines in the Gnuplot option file above and to open it with Gnuplot once again.

With the command plot_scen the scenario process(es) can be visualized. Note that Scenred2 generates Gnuplot access and data files according to the number of random values.
5.38.6 Command Line Interface

The command line interface allows to run Scenred2 stand alone without using Gams. In this case the input for scenario reduction and scenario tree construction is handled by special input data files. The command file will be extended by the parameters having with the ScenRedParms otherwise.

To execute Scenred2 from the command line prompt together with a specified command file (which is required again), for example, call

```
>scenred2 command.file -nogams
```

To avoid diverse error messages do not forget the '-nogams' option to switch off the Gams interface. The command file can include some of the following options.

```
report_level <integer>
runtime_limit <integer>
read_scen <input file>
scen_red <option file>
tree_con <option file>
visual_init <name>
visual_red <name>
plot_scen <name>
out_scen <file name>
out_tree <file name>
```

The denotation is not accidental the same as in case of using the Gams interface. The meaning of a certain option is maintained for the command line interface. To compute any scenario reduction or scenario tree construction the same SR-Option-Files are supported. It remains to clarify the data input format which comes across with the new read_scen command.

5.38.6.1 Data input format

To feed Scenred2 with data the scenario parameters must be passed by the read_scen command. Two types of input file formats are accepted.

a) The tree format:

This file is a formatted data file including all information of the input scenarios tree. It must have a header with dimension information and the scenario data separated for each node. The header includes the type declaration, the number of nodes, and the number of random values.

The data part starts with the key word DATA (do not forget). The tree data has to be ordered node by node. For every node the following information is expected separated by white spaces: The unique predecessor node (root node points to itself) followed by the node probability and followed by the assigned number of random data values. All information to one node should be written to one line (only for clearness reasons). Comment lines are allowed.

Match the following conventions:

- Nodes are identified by a sequence of integer numbers.
- The root node is expected to be the node '1'.
- The predecessor of root is '1' too, i.e., the root points to itself.
• All nodes numbers require a canonical order by stages and scenarios (see example).

Example:

# input tree example for scenred

TYPE TREE

NOD[ES 9
RANDOM 4

DATA

* PRED PROB RAND-1 RAND-2 RAND-3 RAND-4
1 1.0 42.5 9.1 7.5 120.0
1 1.0 39.8 11.2 8.4 90.0
2 1.0 37.6 14.0 6.3 110.0
3 0.5 38.9 12.4 8.1 130.0
3 0.5 35.7 13.8 7.5 120.0
4 0.25 40.3 14.9 7.2 120.0
4 0.25 38.4 15.2 8.9 100.0
5 0.3 37.6 14.9 9.3 80.0
5 0.2 36.3 12.8 10.3 90.0

END

b) The fan format:

A scenario fan serves as input for the scenario tree construction but it can be used also for the scenario reduction. The scenario fan represents a special form of a scenario tree, where we consider individual scenarios merged to a collective root node (the root node can also be viewed here as some kind of artificial node).

Accordingly, the fan input file is a formatted data file including all information of the scenarios in individual form now. It must have a similar header with dimension information and the scenario data separated now for each scenario. The header gets the type declaration \texttt{FAN} instead of \texttt{TREE} and includes the number of scenarios, the number of time periods, and the number of random values. The data part is opened again with the \texttt{DATA} key word.

Every scenario is specified by a dataset including the scenario probability first followed by the different random values in ascending order w.r.t. time periods. All entries must be separated by a white space. Comment lines can be placed by the star and route symbols again. Note that in case of having an undetermined root node the mean of random values will taken for the first time period to appoint a unique root node. The example tree represented as input in scenario fan format is displayed in the next example.

Example:
# input fan example for scenred

**TYPE**  FAN

**TIME**  5  
**SCEN**  4  
**RANDOM**  4

**DATA**

| 0.2500 | 42.5  | 9.1  | 7.5  | 120.0 |
| 0.2500 | 39.8  | 11.2 | 8.4  | 90.0  |
| 0.2500 | 37.6  | 14.0 | 6.3  | 110.0 |
| 0.2500 | 38.9  | 12.4 | 8.1  | 130.0 |
| 0.2500 | 40.3  | 14.9 | 7.2  | 120.0 |

| 0.2500 | 42.5  | 9.1  | 7.5  | 120.0 |
| 0.2500 | 39.8  | 11.2 | 8.4  | 90.0  |
| 0.2500 | 37.6  | 14.0 | 6.3  | 110.0 |
| 0.2500 | 38.9  | 12.4 | 8.1  | 130.0 |
| 0.2500 | 38.4  | 15.2 | 8.9  | 100.0 |

| 0.3000 | 42.5  | 9.1  | 7.5  | 120.0 |
| 0.3000 | 39.8  | 11.2 | 8.4  | 90.0  |
| 0.3000 | 37.6  | 14.0 | 6.3  | 110.0 |
| 0.3000 | 35.7  | 13.8 | 7.5  | 120.0 |
| 0.3000 | 37.6  | 14.9 | 9.3  | 80.0  |

| 0.2000 | 42.5  | 9.1  | 7.5  | 120.0 |
| 0.2000 | 39.8  | 11.2 | 8.4  | 90.0  |
| 0.2000 | 37.6  | 14.0 | 6.3  | 110.0 |
| 0.2000 | 35.7  | 13.8 | 7.5  | 120.0 |
| 0.2000 | 36.3  | 12.8 | 10.3 | 90.0  |

**END**

Note that even though all scenarios coincide at the first three time periods, in this example, the scenarios will represented by one node each for every time period by the fan input format. The exception is the first time period, where a unique root node is expected in general and, therefore, only one node is assigned. The following picture shows the structure of the scenario fan which is generated by the example input.
5.38.6.2 Data Export

Scenred2 allows to export scenario data after computing the scenario reduction or scenario tree construction to external data files. Data export is available for both the Gams and the command line interface. To export data from Scenred2 two output options `out.tree` and `out.scen` can be use. These options generate data files according to the tree and fan format, respectively. The name of the data files will be specified in the SR-Command-File. When using the Gams interface the options must be connected by activating the corresponding ScenRedParms parameter, additionally.

5.38.7 A Simplified Interface to Scenred2: $libinclude runscenred2

While the previously described interface between GAMS and Scenred2 provides a maximum of flexibility, it also is rather complex and error-prone. The GAMS utility `runscenred2` tries to hide most of the mechanics of the GAMS/Scenred2 interface. The call to `runscenred2` looks as follows:

```
$libInclude runscenred2 myprefix tree_con n tree p rtree rp rv1 rv2
```

Table: runscenred2 Arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 <code>myprefix</code></td>
<td>base name for files used with Scenred2</td>
</tr>
<tr>
<td>2 <code>tree_con</code> or <code>scen_red</code></td>
<td>select Scenred2 action: tree construction or scenario reduction</td>
</tr>
<tr>
<td>3 <code>n</code></td>
<td>the set of nodes in the tree</td>
</tr>
<tr>
<td>4 <code>tree</code></td>
<td>the set of ancestor relations describing the tree</td>
</tr>
<tr>
<td>5 <code>p</code></td>
<td>the parameter containing the node probabilities</td>
</tr>
<tr>
<td>6 <code>rtree</code></td>
<td>the set of ancestor relations of the reduced tree (output)</td>
</tr>
<tr>
<td>7 <code>rp</code></td>
<td>the parameter containing the node probabilities for the reduced tree (output)</td>
</tr>
<tr>
<td>8 <code>rv1, rv2</code></td>
<td>parameters containing random values of the nodes</td>
</tr>
</tbody>
</table>

The table above describes the arguments of the `runscenred2` call. Arguments 3, 4, 5, 8 and following correspond to the symbols that need to be exported to the Scenred2 data input file (done with the `execute_unload` call in the complex interface). The output arguments 6 and 7 correspond to the symbols imported from te Scenred2 data output file (done with the `execute_load` call in the complex interface). The parameters `ScenRedParms` and `ScenRedReport` are invisibly communicated with Scenred2.

The second argument instructs Scenred2 either to construct a tree (`tree_con`) or to reduce a tree (`scen_red`).

Instead of providing an explicit name for all the different files in the Scenred2 command file, the first argument determines the name of all files using a simple naming scheme. The following name scheme is observed:

<table>
<thead>
<tr>
<th>Filename</th>
<th>Command option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sr2myprefix.log</td>
<td>log_file</td>
<td>log file name</td>
</tr>
<tr>
<td>sr2myprefix_in.gdx</td>
<td>input_gdx</td>
<td>gdx input file name</td>
</tr>
<tr>
<td>sr2myprefix_out.gdx</td>
<td>output.gdx</td>
<td>gdx output file name</td>
</tr>
<tr>
<td>sr2myprefix.opt</td>
<td>sr_option</td>
<td>option file name</td>
</tr>
<tr>
<td>sr2myprefix_vl.plt</td>
<td>visual_init</td>
<td>file name for visualization of input tree</td>
</tr>
</tbody>
</table>
The first three files (log file, input gdx and output gdx) are always used. The only optional input file sr_option is read by Scenred2 if ScenRedParms('sroption')=1. When you create this file, make sure to use the proper file name. The output files are created by Scenred2 if the corresponding option is set to 1 in ScenRedParms, e.g. ScenRedParms('out_tree')=1.

In addition to a simpler communication of data between GAMS and Scenred2, the newer versions of GAMS/Scenred2 (starting with GAMS distribution 23.1) release the user of setting required fields in the ScenRedParms parameter: num_time_steps, num_leaves, num_nodes, and num_random. GAMS/Scenred2 calculates these numbers from its input data. In case the user still sets these fields, Scenred2 will ensure that the internally calculated numbers and the user provided numbers match.

5.39 ShellExecute

A Tool for Launching External Programs.

Erwin Kalvelagen

March 25, 2004:

5.39.1 Overview

shellexecute is a small wrapper program for the ShellExecute Windows API call. It allows you to spawn an external program based on the file type of the document to open.

GAMS provides the execute statement to execute external programs. In some cases we want to let the system figure out what application to start for a given document. This can be accomplished with shellexecute. For instance, when we call:

> shellexecute demo.html

Windows will launch the web browser and show demo.html. This works correctly, irrelevant whether the user installed Microsoft Internet Explorer or Netscape’s web browser.

5.39.2 Usage

The command line for shellexecute looks like:

shellexecute [/verb=vvv] [/showcmd=flag] [/dir=ddd] filename args

The filename is either a document (e.g. demo.html or book1.xls) or an application (e.g. winword.exe or notepad). If a document is provided, the associated application will be launched. If a directory name is provided the windows explorer will be launched.

If additional parameters are specified they are considered as command line parameters for the process to be spawned.

The following options are recognized:

- /verb=vvv Specifies the action to be performed. The allowed actions are application dependent. Some commonly available verbs include:
If no verb is specified the default command for the file class will be used (in many cases this is open).

- /showcmd=flag Flag that specifies how an application is to be displayed when it is opened. The actual behavior is up to the launched program. The possible values are:

<table>
<thead>
<tr>
<th>showcmd</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW_HIDE</td>
<td>Hides the window and activates another window.</td>
</tr>
<tr>
<td>SW_MAXIMIZE</td>
<td>Maximizes the specified window.</td>
</tr>
<tr>
<td>SW_MINIMIZE</td>
<td>Minimizes the specified window and activates the next top-level window in the $z$-order.</td>
</tr>
<tr>
<td>SW_RESTORE</td>
<td>Activates and displays the window. If the window is minimized or maximized, Windows restores it to its original size and position. An application should specify this flag when restoring a minimized window.</td>
</tr>
<tr>
<td>SW_SHOW</td>
<td>Activates the window and displays it in its current size and position.</td>
</tr>
<tr>
<td>SW_SHOWMAXIMIZED</td>
<td>Activates the window and displays it as a maximized window.</td>
</tr>
<tr>
<td>SW_SHOWMINIMIZED</td>
<td>Activates the window and displays it as a minimized window.</td>
</tr>
<tr>
<td>SW_SHOWMINNOACTIVE</td>
<td>Displays the window as a minimized window. The active window remains active.</td>
</tr>
<tr>
<td>SW_SHOWNA</td>
<td>Displays the window in its current state. The active window remains active.</td>
</tr>
<tr>
<td>SW_SHOWNOACTIVATE</td>
<td>Displays a window in its most recent size and position. The active window remains active.</td>
</tr>
<tr>
<td>SW_SHOWNORMAL</td>
<td>Activates and displays a window. If the window is minimized or maximized, Windows restores it to its original size and position. An application should specify this flag when displaying the window for the first time.</td>
</tr>
</tbody>
</table>

The default is **SW_SHOWNORMAL**.

- /dir=ddd the default directory for the sub-process.

In many cases you will not need to use any options.

### 5.39.3 Examples

Below are some examples of ShellExecute. It is noted that much of the behavior is depending on the file associations that are installed on your machine. These file associations can be inspected and changed with the Windows Explorer, see Figure 1.

#### 5.39.3.1 Spawning a web browser

```bash
> shellextuce turkey.html
```
5.39.3.2 Spawning notepad

> shellexecute trnspirit.txt

If a different program is associated with a .TXT file, a different program will be launched. In my case notepad will be launched due to the file association shown in Figure 1.

5.39.3.3 Spawning the GAMS IDE to view a GDX file

> shellexecute trnspirit.gdx

5.39.3.4 Spawning Excel

> shellexecute test.xls

5.39.3.5 Calling shellexecute from GAMS

execute '=shellexecute trnspirit.html';

5.39.3.6 A complete GAMS example

The following model is the trnspirit model from the model library. We write the solution both to an HTML file and a CSV file. HTML is standard ASCII and is easily written using the PUT facility. CSV is even easier, as setting the FILE suffix csv.pc=5; will automatically generate comma separated values. The web browser is launched to view the HTML file, while Excel will be spawned to view the CSV file.

$title A Transportation Problem (TRNSPORT,SEQ=1)

5.40 SQL2GMS

Erwin Kalvelagen

5.40.1 Overview

SQL2GMS is a tool to convert data from an SQL database into GAMS readable format. The source is any data source accessible through Microsoft’s Data Access components including ADO, ODBC and OLEDB. The target is a GAMS Include File (.inc) or a GAMS GDX File (.gdx).

When running the executable sql2gms.exe without command line arguments, the tool will run interactively with a built-in GUI interface. Alternatively SQL2GMS can be run in batch mode, which is useful when running it directly from a GAMS model without user intervention using the $call command at compile time or the execute command at execution time.

Database tables can be considered as a generalization of a GAMS parameter. GAMS parameters have multiple index columns but just one value column. If the table is organized as multi-valued table, a UNION operation in the SQL statement can be used to generate the correct GAMS file.

There are no special requirements on the data types used in the database. The data is converted to strings, which is almost always possible. Data types like LONG BINARY may not be convertible to a string, in which case an exception will be raised. In general NULL’s should not be allowed to get into a GAMS data structure. The handling of NULL’s can be specified in an option.

Besides parameters it is also possible to generate set data.

If you need to read data from an MS Access database or MS Excel spreadsheet, the accompanying tools MDB2GMS or XLS2GMS resp. GDXXRW may be more appropriate. In some cases it may be more useful to use SQL2GMS to read from Access and Excel data sources.

5.40.2 Requirements

SQL2GMS runs only on Windows PC's with MDAC (Microsoft Data Objects) installed. In many cases this will be installed on your computer. Otherwise it can be downloaded from the Microsoft Download Center (direct link to MDAC).

In order to use SQL2GMS effectively, you will need to have a working knowledge of SQL in order to formulate proper database queries. In addition you will need some knowledge on how to connect to your database using ODBC or ADO.
5.40.3 Batch Usage

SQL2GMS can be run in batch mode without user intervention from within the GAMS model by using the `$call` resp. `execute` statements or directly from command prompt while specifying all arguments in the command-line. A SQL2GMS batch call is of the following form:

`sql2gms connectionString outputFile queryString`

A proper call will at least contain the following three command-line arguments:

1. The name of the database and the instruction for connecting to the database must be specified within the connectionString, which is indicated by the option C, i.e. `C=connectionString`.

2. The name of outputFile, either an include file (.inc) or GDX file (.gdx), must be specified. Using an include file to store the results of the query is indicated by the option O, i.e. `O=outputFile.inc`, while the use of a GDX file is indicated by the option X, i.e. `X=outputFile.gdx`.

3. The SQL queryString, containing the SQL statement to be executed on the database, must be specified within the option Q, i.e. `Q=queryString`.

See also Command-line Arguments below for a complete list of all possible command-line arguments. Consider that the `$call` or `execute` usage is rather error prone and you will need to spend a little bit of time to get the call correct and reliable. Alternatively, use the interactive built-in GUI interface or enter the command-line arguments in an external text file in order to write a more structured and readable command. The use of an external parameter file is indicated by preceding the file name with a @ (At sign).

Also consider to take a look at the section Strategies, mentioning some of the drawbacks of the batch usage and how to overcome them.

5.40.3.1 Command-line Arguments

The following table summarizes the command-line arguments that can be specified when using SQL2GMS directly from the GAMS model or command prompt.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Interpretation</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>connectionString</td>
<td>none</td>
<td>Specify the connectionString (required).</td>
</tr>
<tr>
<td>O</td>
<td>outputIncludeFile</td>
<td>none</td>
<td>Specify the name of the output file (.inc). Either O= or X= must be specified (or both).</td>
</tr>
<tr>
<td>On</td>
<td>nth outputIncludeFile</td>
<td>none</td>
<td>Match the nth query with the nth output file (.inc format) if multiple queries are used.</td>
</tr>
<tr>
<td>X</td>
<td>outputGDXFile</td>
<td>none</td>
<td>Specify the name of the output file (.gdx). Either O= or X= must be specified (or both).</td>
</tr>
<tr>
<td>Q</td>
<td>Query</td>
<td>none</td>
<td>This option can be used to specify a SQL query (required).</td>
</tr>
<tr>
<td>Qn</td>
<td>nth query</td>
<td>none</td>
<td>Match the nth query with the nth output file (.inc) format or with the nth set- or parameter name when writing to GDX if multiple queries are used.</td>
</tr>
<tr>
<td>Argument</td>
<td>Interpretation</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>------------------------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>S</td>
<td>setName</td>
<td>none</td>
<td>If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file.</td>
</tr>
<tr>
<td>Sn</td>
<td>nth setName</td>
<td>none</td>
<td>Match the nth query with the nth set in the GDX file if multiple queries are used.</td>
</tr>
<tr>
<td>Y</td>
<td>setName (with expl. text)</td>
<td>none</td>
<td>If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. Use this argument to store a set with explanatory text.</td>
</tr>
<tr>
<td>Yn</td>
<td>nth setName (with expl. text)</td>
<td>none</td>
<td>Match the nth query with the nth set (with explanatory text) in the GDX file if multiple queries are used.</td>
</tr>
<tr>
<td>A</td>
<td>parameterName</td>
<td>none</td>
<td>If we write to a GDX file, use this option to specify the name of a parameter to be used inside the GDX file.</td>
</tr>
<tr>
<td>An</td>
<td>nth parameterName</td>
<td>none</td>
<td>Match the nth query with the nth parameter in the GDX file if multiple queries are used.</td>
</tr>
<tr>
<td>L</td>
<td>Listing</td>
<td>disabled</td>
<td>Controls if the data is embedded in the listing file.</td>
</tr>
<tr>
<td>M</td>
<td>Mute</td>
<td>disabled</td>
<td>Controls if additional information is written to the log and include file.</td>
</tr>
<tr>
<td>B</td>
<td>Quote Blanks</td>
<td>disabled</td>
<td>Quote strings if they contain blanks or embedded quotes.</td>
</tr>
<tr>
<td>@fileName</td>
<td>ext. options file</td>
<td>none</td>
<td>Causes the program to read options from an external text file.</td>
</tr>
<tr>
<td>N</td>
<td>iniFileName</td>
<td>sql2gms.ini</td>
<td>Indicates the usage of a different INI file.</td>
</tr>
<tr>
<td>T1</td>
<td>connectionTimeOut</td>
<td>15</td>
<td>Indicates how long to wait while establishing a connection before terminating the attempt and generating an error.</td>
</tr>
<tr>
<td>T2</td>
<td>commandTimeOut</td>
<td>30</td>
<td>Indicates how long to wait while executing a command before terminating the attempt and generating an error.</td>
</tr>
<tr>
<td>T</td>
<td>timeOut</td>
<td>none</td>
<td>Sets both T1 and T2.</td>
</tr>
<tr>
<td>D</td>
<td>Debug</td>
<td>disabled</td>
<td>Generate debug information.</td>
</tr>
<tr>
<td>E</td>
<td>Empty sets</td>
<td>disabled</td>
<td>Allow an empty result set; without this option an empty result set will generate an error.</td>
</tr>
<tr>
<td>R</td>
<td>rowBatchSize</td>
<td>100</td>
<td>Row batch size; the default is 100 records.</td>
</tr>
<tr>
<td>P</td>
<td>Password</td>
<td>none</td>
<td>Specify a password for the database.</td>
</tr>
<tr>
<td>W</td>
<td>Wiring</td>
<td>none</td>
<td>Maps database columns to GAMS index positions.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the command-line arguments:

\[ C = string \text{ (connectionString, default = none)} \]
This option is required and specifies which database is to be used and how SQL2GMS talks to the database. A collection of valid connection strings can be found in section Connection Strings. Often the connection string will need to be surrounded by quotes, as in: C=“DSN=sample”. This option is demonstrated in all examples, see Example 1 - Reading a single valued Table for instance.

\[O = string\] (outputIncludeFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter or set statement. Make sure the directory is writable. UNC names can be used. An output file must be specified for batch operation: i.e. either \[O=\] or \[X=\] needs to be specified (or both). The include file will be an ASCII file that can be read by GAMS using the $include command within the data definition of a set, parameter or scalar. If the include file already exists, it will be overwritten. This option is demonstrated in Example 1 - Reading a single valued Table for instance.

\[On = string\] (outputIncludeFile, default = none)

When using multiple queries in a single SQL2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition:

\[Q1=“SELECT a, b FROM table”\]
\[O1=ab.inc\]
\[Q2=“SELECT c, d FROM table”\]
\[O2=cd.inc\]

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

\[X = string\] (outputGDXFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS GDX file. Make sure the directory is writable. UNC names can be used. If the GDX file already exists it will be overwritten - it is not possible to append to a GDX file. An output file must be specified for batch operation: i.e. either \[O=\] or \[X=\] needs to be specified (or both). This option is demonstrated in Example 5 - Reading Set with Explanatory Text or Example 7 - Multi-Query Batch Example for instance.

\[Q = string\] (query, default = none)

This option can be used to specify an SQL query. Queries can contain spaces and thus have to be surrounded by double quotes. For the exact syntax of the queries that is accepted by the database we refer to the documentation that comes with your RDBMS (Relational DataBase Management System). The query is passed on directly to the RDBMS so the complete power and expressiveness of SQL is available including stored procedures etc. For an exact description of allowed expressions consult a text on your database system. This option is demonstrated in Example 1 - Reading a single valued Table for instance.

\[Qn = string\] (query, default = none)

When using multiple queries in a single SQL2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition. In addition, you can match the results of a query with a specific set- or parameter name when writing to GDX.
Q1="SELECT a, b FROM table"
Q1=ab.inc
Q2="SELECT c, d FROM table"
Q2=cd.inc

or (GDX output file format - where several sets and parameters can be stored in a single file):

Q1="SELECT a, b FROM table"
A1=abParameter
Q2="SELECT c FROM table"
S2=cSet

Note the usage of the arguments An resp. Sn in order to store the results as parameter resp. set and to specify the name of the symbols. See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

S = string (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be stored in the GDX file (containing the results of the query). This option is demonstrated in Example 4 - Reading a multi dimensional Set.

Sn = string (setName, default = none)

If multiple queries are used in a single SQL2GMS call while writing to a GDX file, use this option to specify the name of the nth set to be stored in the GDX file (containing the results of the nth query), e.g.

Q1="SELECT i FROM table"
S1=iSet
Q2="SELECT j FROM table"
S2=jSet

See section Multi-Query Batch Usage and Example 7 - Multi-Query Batch Example for instance.

Y = string (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. The last column specified within the select clause in the SQL statement will be used as explanatory text. This option is demonstrated in Example 5 - Reading Sets with Explanatory Text for instance.

Yn = string (setName, default = none)

If multiple queries are used in a single SQL2GMS call while writing to a GDX file, use this option to specify the name of the nth set (with explanatory text) to be stored in the GDX file (containing the results of the nth query), e.g.

Q1="SELECT i, explTextForSeti FROM table"
Y1=iSet
Q2="SELECT j, explTextForSetj FROM table"
Y2=jSet

The last column specified within the select clause in the SQL statements will be used as explanatory text.

A = string (parameterName, default = none)
If we write to a GDX file, use this option to specify the name of a parameter to be stored the GDX file (containing the results of the query).

Note: `MDB2GMS` uses P, but P was already taken in `SQL2GMS` for specifying the password.

An = string (parameterName, default = none)

If multiple queries are used in a single `SQL2GMS` call while writing to a GDX file, use this option to specify the name of the nth parameter to be stored in the GDX file (containing the results of the nth query), e.g.

Q1="SELECT i, j, value FROM table"
A1=ijValue
Q2="SELECT n, m, value FROM table"
A2=nmValue

See section Multi-Query Batch Usage and Example 7 - Multi-Query Batch Example for instance.

L (Listing, disabled by default)

Embed the data between the \$offListing and \$onListing dollar control options, so the data will not be listed in the listing file. This is a quick way to reduce the size of the listing file when including very large data files into the model. Otherwise the listing file would become too large to be handled comfortably.

M (Mute, disabled by default)

Controls if additional information (GAMS and `SQL2GMS` version numbers, number of rows in the data, elapsed time, used query etc.) is written to the log and include file.

B (Quote Blanks, disabled by default)

Quote strings if they contain blanks or embedded quotes. If a string does not contain a blank or embedded quotes, it will remain unquoted. If the string contains a single quote the quotes applied will be double quotes and if the string contains already a double quote, the surrounding quotes will be single quotes. In the special case that the string contains both, the double quotes are replaced by single quotes. For more information see subsection Quotes. This option only applies to an output include file.

@fileName = string (fileName, default = none)

Causes the program to read options from an external text file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if they were specified directly on the command-line. See also Parameter Files for some further details.

N = string (fileName, default = none)

Use a different INI file than the standard sql2gms.ini located in the same directory as the executable sql2gms.exe.

T1 = integer (connectionTimeOut, default = 15)

Indicates how long to wait while establishing a connection before terminating the attempt and generating an error. The value sets, in seconds, how long to wait for the connection to open. Default is 15. If you set the property to zero, ADO will wait indefinitely until the connection is opened. A value of -1 indicates that the default value is to be used. Note: the provider needs to support this functionality.
\[ T2 = integer \ (commandTimeOut, \ default = 30) \]

Indicates how long to wait while executing a command before terminating the attempt and generating an error. The value sets, in seconds, how long to wait for a command to execute. Default is 30. If you set the property to zero, ADO will wait indefinitely until the execution is complete. A value of -1 indicates that the default value is to be used. Note: the provider needs to support this functionality.

\[ T = integer \ (timeOut, \ default = none) \]

Sets both \( T1 \) and \( T2 \).

\( D \) (Debug, disabled by default)

Generate debug information. This option must be specified in an INI file when using the interactive mode of SQL2GMS.

\( E \) (Empty sets, disabled by default)

Allow an empty result set; without this option an empty result set will generate an error. This option must be specified in an INI file when using the interactive mode of SQL2GMS.

\( R = integer \ (rowBatchSize, \ default = 100) \)

Row batch size; the default is 100 records. This option must be specified in an INI file when using the interactive mode of SQL2GMS.

\( P = string \ (password, \ default = none) \)

Specify a password for the database.

\( W = string \ (wiring, \ default = none) \)

By using the \( W \) option, one can map database columns to GAMS index positions. See model [Wiring] for reference (note that MDB2GMS is used to access the MS Access database instead of SQL2MDB, however this does not affect the wiring specification).

### 5.40.3.2 Example 1 - Reading a single valued Table

Suppose we want to read the distances parameter of the [transport] model from the GAMS Model Library. The data is stored in the Microsoft Access Database format (file Sample.mdb).

The data can be queried with a simple SQL statement:

\[
\text{SELECT city1, city2, distance} \\
\text{FROM distances}
\]

By running the following SQL2GMS statement, the connection to the database Sample.mdb is established. In addition, the data will be queried and the results are written to a GAMS include file afterwards (.inc).

\[
\text{sql2gms} \ C=\text{"Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb"} \ Q=\text{"SELECT city1, city2, distance} \\
\text{FROM distances"}
\]
The connection string is specified using the argument C. Note that the string is enclosed by quotes, as the string contains blanks. The database file name Sample.mdb is also specified within the connection string. For more information on how to connect to your database, see section Connection Strings. The arguments Q and O are used to specify the query and the output file name (and format).

The generated include file distances.inc looks like:

```
* -----------------------------------------------------
* SQL2GMS 3.0 25.2.0 r67636 ALFA Released 15Aug18 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* ADO version: 10.0
* Connection string: Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb
* Provider: MSDASQL
* Query: SELECT city1, city2, distance FROM distances
* -----------------------------------------------------

SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4

* -----------------------------------------------------
```

The commented header section summarizes some information about the SQL2GMS resp. GAMS version and about the executed database query. The standard export format is to consider the last column as the value column (containing the distances) and the previous columns as the indices (containing the city names). The indices are separated by a dot, allowing the generated include file to be used as part of a parameter declaration statement in your GAMS model.

Retrieving the data using SQL2GMS from the database and including the queried data in your GAMS model within the parameter declaration statement (at compile time) can be combined in the following way:

```gams
Set
   i 'canning plants' / seattle, san-diego /
   j 'markets' / new-york, chicago, topeka /;
$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT city1, city2, distance FROM distances"
Parameter d(i,j) 'distance in thousands of miles' /
   $include distances.inc
;
display d;
```

Finally, the values of the parameter d are displayed:

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.500</td>
<td>1.700</td>
<td>1.800</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.500</td>
<td>1.800</td>
<td>1.400</td>
</tr>
</tbody>
</table>

This example is also part of the GAMS Data Utilities Library, see model [Distances2] for reference. Note that the query results are written to a GDX file in addition.
Example 2 - Reading a multi valued Table

In this scenario, we want to read the three index columns `year`, `loc`, `prod` and the value columns `sales` and `profit` from the database file Sample.mdb. Therefore, we use two separate parameters and queries or alternatively a parameter with an extra index position (for `sales` resp. `profit`) and a UNION select.

Consider the table with two value columns `sales` and `profit`:

**Two separate Parameters**

A simple way to import this into GAMS is to use two parameters and two SQL queries. The SQL queries can look like:

```sql
SELECT year, loc, prod, sales
FROM data
SELECT year, loc, prod, profit
FROM data
```

We can generate an include file `sales.inc` by running the following command:

```bash
sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" Q="SELECT year, loc, prod, sales FROM data" O=sales.inc
```

Note that we specify the first query in order to select the `sales` and the relevant index columns within the `Q` argument. The query results are written to `sales.inc` using the `O` argument. Analogously we generate a include file `profit.inc` by running the following command while specifying the second query in order to obtain the `profits` and the relevant index columns:

```bash
sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" Q="SELECT year, loc, prod, profit FROM data" O=profit.inc
```

Retrieving the data using SQL2GMS from the database Sample.mdb and including the queried data in your GAMS model within the parameter declaration statements of `sales` and `profit` (at compile time) can be combined in the following way:

```gams
Set
eyear 'years' / 1997*1998 /
loc 'locations' / nyc, was, la, sfo /
prd 'products' / hardware, software /;
$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" Q="SELECT year, loc, prod, sales FROM data" Parameter sales(year,loc,prd) /
$include sales.inc /;
$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" Q="SELECT year, loc, prod, profit FROM data" Parameter profit(year,loc,prd) /
$include profit.inc /;
```

**Single Parameter with extra Index Position**

The operation can also be performed in one big swoop by using a different GAMS datastructure, i.e. a single parameter is defined with an extra index position to indicate the data type (`sales` or `profit`). The index and value columns will be selected by the following SQL statement. Note the UNION operation in order to combine the results and the strings 'sales' resp. 'profit' to identify the data type later on.
SELECT year, loc, prod, 'sales', sales
FROM data
UNION
SELECT year, loc, prod, 'profit', profit
FROM data

The data is accessed, queried and written to data.inc by running the following command:

sql2gms @howToRead.txt

Note that usage of the external parameter file howToRead.txt shown below in order to increase the readability of the command (one argument per line, quotes can be omitted):

C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc

The generated include file data.inc looks like (shortened for presentation):

* -----------------------------------------------------
* SQL2GMS 3.0 25.2.0 r67636 ALFA Released 15Aug18 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* ADO version: 10.0
* Connection string: DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb
* Provider: MSDASQL
* Query: SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
* -----------------------------------------------------

1997.la.hardware.profit 8
1997.la.hardware.sales 80
1997.la.software.profit 16
1997.la.software.sales 60
1997.nyc.hardware.profit 5
1997.nyc.hardware.sales 110
1997.nyc.software.profit 10
1997.nyc.software.sales 100
1997.sfo.hardware.profit 9
1997.sfo.hardware.sales 80
1997.sfo.software.profit 10
1997.sfo.software.sales 50
1998.la.hardware.profit 6
1998.la.hardware.sales 70

Retrieving the data using SQL2GMS from the database and including the queried data in your GAMS model within the parameter declaration (at compile time) can be combined in the following way (note that the parameter has a fourth index type in order to access the data type sales resp. profit):
5.40 SQL2GMS

$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc
$offEcho

Set
ty "years" / 1997*1998 /
loc "locations" / nyc, was, ia, sfo /
prd "products" / hardware, software /
type "data type" / sales, profit /

$call sql2gms @howToRead.txt
Parameter data(year,loc,prd,type) /
$include data.inc
/

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB5] for reference.

5.40.3.4 Example 3 - Reading a one dimensional Set

This example demonstrates how to read set elements of a one dimensional set from a single column of a database file. Suppose we want to read the column City1 (see table distances) in order to define the set i in the GAMS model. Make sure elements are unique by using the distinct operation within the SQL statement (otherwise there will be an error when including the file within the set definition in the GAMS model, as some set elements will be redefined):

```
SELECT distinct(City1)
FROM distances
```

The include file city1.inc looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
* SAN-DIEGO
* SEATTLE
* -----------------------------------------------------
```

All steps (data access via SQL2GMS, set definition) can be combined:

```
$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT distinct(city1) FROM distances"
Set i 'canning plants' /
$include city_i.inc
/

display i;
```

The display statement generates the following output in the listing file:

```
---- 56 SET i
seattle , san-diego
```
5.40.3.5  Example 4 - Reading a multi dimensional Set

When reading a multi dimensional set from database and writing the results to an include file by using the O argument, one has to observe that the elements in the include file must have the correct format in order to be interpreted as element of a multi dimensional set. For instance, a line containing a b c is not recognized as a proper set element of a three dimensional set. In particular, one has to add periods between the single elements, i.e. a.b.c will be interpreted correctly.

Depending on your DBMS (DataBase Management System), these periods must be added explicitly in a different way within the SQL statement. E.g. add a dummy value field by adding a quoted blank to the select clause (index1, index2, index3 and dataTable are some placeholders):

```
SELECT index1, index2, index3, " " FROM dataTable
```

or by adding the periods explicitly within the select clause (|| or & depending on DBMS):

```
SELECT index1&'.'&index2&'.'&index3 FROM dataTable
SELECT index1||'.'||index2||'.'||index3 FROM dataTable
```

For instance, suppose we want to define a two dimensional set

Set ij(i,j) 'canning plants - markets';

based on the data of the table distances stored in Sample.mdb. The following SQL2GMS statement connects you to the database, queries the columns with the city names and adds an empty value field in order to create periods between the set elements:

```
sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT city1, city2, ' ' FROM distances" O=city_ij.inc
```

The include file city_ij.inc looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
SEATTLE.NEW-YORK ' ' 
SAN-DIEGO.NEW-YORK ' ' 
SEATTLE.CHICAGO ' ' 
SAN-DIEGO.CHICAGO ' ' 
SEATTLE.TOPEKA ' ' 
SAN-DIEGO.TOPEKA ' ' 
* -----------------------------------------------------
```

Without adding the empty value field, the resulting include file would look like (shortened):

```
* -----------------------------------------------------
SEATTLE NEW-YORK 
SAN-DIEGO NEW-YORK 
* -----------------------------------------------------
```
Since the periods are missing, the lines are not recognized as valid elements of a two dimensional set. All steps can be combined in the following way:

```
Set
canning plants / seattle, san-diego /
markets / new-york, chicago, topeka /;

$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT city1, city2, ' ' FROM distances" O=city_ij.inc

Set ij(i,j) 'two dimensional set' /
$include city_ij.inc
/;

display ij;

The display statement generates the following output in the listing file:

```
---- 75 SET ij two dimensional set

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAN-DIEGO</td>
<td>YES</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>SEATTLE</td>
<td>YES</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>
```

Note that there is no need to add periods explicitly when reading multi dimensional sets, if the results are written only to a GDX file by using the X and S resp. Y arguments, i.e. there is no need to modify the query:

```
SELECT index1, index2, index3 FROM datatable
```

when using SQL2GMS in the following way:

```
sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT index1, index2, index3 FROM datatable"
```

which will generate the file setData.gdx with a three dimensional set named setName containing the results of the query.
5.40.3.6 Example 5 - Reading Sets with Explanatory Text

In this example, we will demonstrate how to read set elements with explanatory text from a database file using SQL2GMS. In the first place, we are going to write the query results to an include file, afterwards we use the Y argument in order to store the query results as a set with explanatory text in a GDX file.

Note the blanks and the mixed quotes in the column containing the explanatory text. The data can be accessed by the following query:

```
SELECT setElement, explText
FROM  setData
```

Writing the Query Results in an include File

The last column in the select clause will be used as explanatory text. Take in mind to add the argument B in order to handle text strings with embedded blanks or quotes. The following GAMS code accesses the data and writes the results to an include file setData.inc:

```
$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" B Q="SELECT setElement, explText FROM setData" O=setData.inc
```

The resulting include file will look like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
firstSetElement "Explanatory text for the first 'set element'
secondSetElement 'Explanatory text for the second "set element"
thirdSetElement "Explanatory text for the third 'set element'
fourthSetElement 'Explanatory text for the fourth set element'
* -----------------------------------------------------
```

Note the handling of the quotes according to the description in B.

Writing the Query Results in a GDX File

When storing the results of the query as a set with explanatory text in a GDX file, there is no need to observe embedded blanks or quotes manually, instead one can use the Y argument. The last column specified in the select clause of the SQL statement will be interpreted as explanatory text. The following GAMS code accesses the data and writes the results to a GDX file setData.inc:

```
$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT setElement, explText FROM setData" X=setData.gdx Y=set_b
```

Set b;
$gdxIn setData.gdx
$load b = set_b
$gdxIn

Note that the name of the set in the GDX file is set_b (specified within the Y argument), while the name of the GDX file was specified within the X argument.
5.40.3.7 Example 6 - Index Mapping

In some cases the index elements used in the database are not the same as in the GAMS model. E.g., consider the case where the GAMS model has defined a set as:

Set i / NY, DC, LA, SF /;

Now assume a data table looks like:

This means we have to map ‘new york’ to ‘NY’ etc. This mapping can be done in two places: either in GAMS or in the database.

5.40.3.7.1 Index Mapping done in GAMS When we export the table directly, we get the following include file (header informations are removed in order to shorten the representation):

* -----------------------------------------------------
'new york' 100
'los angeles' 120
'san francisco' 105
'washington dc' 102
* -----------------------------------------------------

Note that the single quotes are added by activating the option B (quote blanks), as the index elements contain blanks. Accessing the data, importing the resulting include file and converting it to a different index space can be done by the following GAMS code:

Set i / NY, DC, LA, SF /;

Set idb 'from database' / 'new york', 'washington dc', 'los angeles', 'san francisco' /;

$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" B O="city1.inc" Q="SELECT city, value FROM [example table]"
Parameter dbdata(idb) /
$include city1.inc /
Set mapindx(i,idb) / NY.'new york', DC.'washington dc', LA.'los angeles', SF.'san francisco' /;

Parameter data(i);
data(i) = sum(mapindx(i,idb), dbdata(idb));
display data;

The display statement generates the following output in the listing file:

---- 47 PARAMETER data

NY 100.000, DC 102.000, LA 120.000, SF 105.000

This example is also part of the GAMS Data Utilities Library, see model [IndexMapping3] for reference.
5.40.3.7.2 Index mapping done in Database  The second approach is to handle the mapping inside the database. We can introduce a mapping table that looks like:

This table can be used in a join to export the data in a format we can use by executing the query:

```sql
SELECT [GAMS City], value
FROM example_table, CityMapper
WHERE CityMapper.[Access City]=example_table.city
```

The resulting include file looks like (header informations are removed in order to shorten the representation):

```plaintext
* -----------------------------------------------------
  la 120
  ny 100
  sf 105
  dc 102
* -----------------------------------------------------
```

All steps can be combined in the GAMS model:

```gams
Set i / NY, DC, LA, SF /;
$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb
Q=SELECT [GAMS City], [value] FROM example_table, CityMapper WHERE CityMapper.[Access City]=example_table.city
O=city2.inc
$offEcho
$call sql2gms @howToRead.txt
Parameter data(i) /
$include city2.inc
/;
display data;
```

The display statement generates the following output in the listing file:

```plaintext
---  38 PARAMETER data
NY 100.000,  DC 102.000,  LA 120.000,  SF 105.000
```

**Note:** MS Access allows table names with embedded blanks. In that case the table name can be surrounded by square brackets. Other databases may not allow this.

This example is also part of the GAMS Data Utilities Library, see model [IndexMapping4] for reference.
5.40 SQL2GMS

5.40.4 Multi-Query Batch Usage

In some cases a number of small queries need to be performed on the same database. However, several individual SQL2GMS execution can become expensive, since there is significant overhead in starting Access and opening the database. For these cases, we have added the option to do multiple queries in one call. To execute several queries in a single SQL2GMS call and write several GAMS include files containing the results of the queries, we can use the command-line arguments Qn and On. The structure of a multi-query call looks like:

\[
\begin{align*}
C & = \text{DRIVER}={\text{Microsoft Access Driver (*.mdb)}};\text{dbq}=\text{sample.mdb} \\
Q1 & = \text{firstQuery} \\
O1 & = \text{outputFileName.inc} \\
Q2 & = \text{secondQuery} \\
O2 & = \text{outputFileName.inc} \\
Q3 & = \text{thirdQuery} \\
O3 & = \text{outputFileName.inc}
\end{align*}
\]

The terms firstQuery, secondQuery etc. are placeholders for some SQL statements. We see that the argument Qn is matched by an argument On. That means that the results of the n-th query are written to the n-th output file.

In case we want to store the results of a multi-query call to a single GDX file, we can use the command-line arguments Qn, Sn, An and Yn. The structure of a multi-query call when writing to a GDX file looks like:

\[
\begin{align*}
C & = \text{DRIVER}={\text{Microsoft Access Driver (*.mdb)}};\text{dbq}=\text{sample.mdb} \\
X & = \text{sample.gdx} \\
Q1 & = \text{firstQuery} \\
S1 & = \text{setName} \\
Q2 & = \text{secondQuery} \\
S2 & = \text{setName} \\
Q3 & = \text{thirdQuery} \\
A3 & = \text{parameterName} \\
Q4 & = \text{fourthQuery} \\
A4 & = \text{setName}
\end{align*}
\]

Again, the terms firstQuery, secondQuery etc. are placeholders for some SQL statements. Here we see that a query Qn is matched by either a set name Sn or a parameter name An (the letter P was taken already: it is used to specify a password), i.e. the results of the first query will be stored as a set whose name is specified within the S1 argument, the results of the third query will be stored as a parameter whose name is specified within the A3 argument etc. The X argument is used to specify the name of the GDX file.

For a complete example see section Example 7 - Multi-Query Batch Example.
5.40.4.1 Example 7 - Multi-Query Batch Example

As an example database we use the following Access table (file Sample.mdb):

We want to extract the following information:

- The set year
- The set loc
- The set prd
- The parameter sales
- The parameter profit

Output: Several include Files

This can be accomplished using the following GAMS code with multiple queries in a single SQL2GMS call (note the usage of the distinct operator in the select clauses of the queries whose results will be used as sets in order to keep the set elements unique):

```
$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb
Q1=SELECT distinct(year) FROM data
  O1=year.inc
Q2=SELECT distinct(loc) FROM data
  O2=loc.inc
Q3=SELECT distinct(prd) FROM data
  O3=prod.inc
Q4=SELECT prd, loc, year, sales FROM data
  O4=sales.inc
Q5=SELECT prd, loc, year, profit FROM data
  O5=profit.inc
$offEcho
$call =sql2gms @howToRead.txt
Set y 'years' /
  $include year.inc
/
Set loc 'locations' /
  $include loc.inc
/
Set prd 'products' /
  $include prod.inc
/
Parameter sales(prd,loc,y) /
  $include sales.inc
/
display sales;
```
Parameter profit(prd,loc,y) /
$include profit.inc
/;
display profit;

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB6] for reference.

**Output: A single GDX File**

The same example imported through a GDX file can look like:

```plaintext
$onEcho > howToRead.txt
C=Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb
X=Sample.gdx
Q1=SELECT distinct(year) FROM data
S1=year
Q2=SELECT distinct(loc) FROM data
S2=loc
Q3=SELECT distinct(prod) FROM data
S3=prd
Q4=SELECT prod, loc, year, sales FROM data
A4=sales
Q5=SELECT prod, loc, year, profit FROM data
A5=profit
$offEcho
$call =sql2gms @howToRead.txt
$call =shell Execute gdxviewer Sample.gdx

Set
  y 'years'
  loc 'locations'
  prd 'products';

Parameter
  sales(prd,loc,y)
  profit(prd,loc,y);

$gdxIn sample.gdx
$load y=year prd loc sales profit
$gdxIn

display sales, profit;
```

The call of the **GDX Viewer** will display the GDX file in the stand-alone GDX viewer. This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB7] for reference.
5.40.5 **Interactive Usage**

When the tool is called without command-line arguments, it will startup interactively. Using it this way, one can specify options such as the connection string, the query and the final destination file (a GAMS include file or a GDX file) using the built-in interactive environment. The main screen (see figure below) contains a number of buttons and edit boxes, which are explained below.

- **Output GAMS Include file (*.inc)**. If you want to create a GAMS include file, then specify here the destination file. See also `outputIncludeFile` for some more detailed remarks.

- **Output GDX file (*.gdx)**. As an alternative to a GAMS include file, the tool can also generate a GDX file. One or both of the output files need to be specified. See also `outputGDXFile` for some more detailed notes.

- **SQL Query.** The SQL Query box is the place to provide the query. Note that the actual area for text can be larger than is displayed: use the cursor-keys to scroll. See also `Q` for some more detailed notes.

- **Progress Memo.** This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.

- The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

- The **Tables button** will pop up a new window with the contents of the database file selected in the input file edit line. This allows you to see all table names and field names needed to specify a correct SQL query. An exception will be generated if no database file name is specified in the input edit line.

- The **Options button** will pop up a window where you can specify a number of options. The connection string is an important option, which needs to be set correctly before a query can be submitted successfully.

- Pressing the **Help button** will show this documentation.

- Pressing the **OK button** will execute the query and an output file will be generated.

- The **Batch button** will give information on how the current extract command can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied onto the clipboard. In the IDE press **Ctrl-C** or choose **Edit|Paste** to copy the contents of the clipboard to a GAMS text file.

- Pressing the **Close button** will exit the application. The current settings will be saved in an INI file so when you run `SQL2GMS` again all current settings will be restored.
5.40.5.1 Options

The **Options** window can be created by pressing the options button:

The following options are available in the options window:

- **User name:** Here you can specify the user name for logging in to the RDBMS. For databases without user authentication, this can be left empty.

- **Password:** This edit box allows you to specify the password for the database system. The characters are echoed as an '∗'.

- **Connection String:** The connection string determines how SQL2GMS talks to the database. For more informations see **Connection Strings**.

- **ODBC Data Sources/Drivers:** This drop down list can be used to compose a connection string when an ODBC data source or driver is involved. The list will show all configured data sources and all available ODBC drivers.

- **Quote blanks:** Quote strings if they contain blanks or embedded quotes. See also B for some more detailed notes.

- **Mute:** Don't include the extra informational text (such as used query etc.) in the include file. The equivalent command-line argument is M.

- **No listing:** Surround the include file by $offListing and $onListing so that the data will not be echoed to the listing file. The equivalent command-line argument is L.

- **Format SQL:** If an SQL text is reloaded in the SQL Edit Box, it will be formatted: keywords will be printed in CAPS and the FROM and WHERE clause will be printed on their own line. If this check box is unchecked this formatting will not take place and SQL queries will be shown as is.

The following options are only needed in special cases:

- **NULL:** This radio box determines how NULL's are handled. A NULL in an index position or a value column will usually make the result of the query useless: the GAMS record will be invalid. To alert you on NULL's the default to throw an exception is a safe choice. In special cases you may want to map NULL's to an empty string or a 'NULL' string.

- **Time-out** values for connection time and command execution time expressed in seconds. If -1 is specified then it will use the default value which is 15 seconds for the connection and 30 for the commands. See also T1, T2 resp. T for some more detailed notes.

The following buttons have an obvious functionality:

- **OK button** will accept the changes made.
• **Cancel button** will ignore the changes made and all option settings will revert to their previous values.

• **Help button** will show this documentation.

• **Test Connection** will try to make a connection to the database using the given connection string.

If the settings are correct you will see something like:

The following options can only be specified in an INI file; there is no interactive equivalent:

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td></td>
<td>Generate debug output</td>
</tr>
<tr>
<td>E</td>
<td></td>
<td>Allow an empty result set; without this option an empty result set will generate an error</td>
</tr>
<tr>
<td>R</td>
<td>integer</td>
<td>Row batch size; the default is 100 records</td>
</tr>
</tbody>
</table>

### 5.40.6 Connection Strings

The connection string determines to which database the tool will try to connect. You can give simply the name of an ODBC Data Source or provide much more elaborate connection strings. Here is an example list:

- **ODBC Examples**

- **OLE DB Examples**

- **MS Remote Examples**

For more information consult the documentation with your database driver. ODBC drivers can be had from several sources: Microsoft delivers ODBC with a number of drivers; database providers may have likely an ODBC driver for their RDBMS available and finally there are a number of third party ODBC drivers available (e.g. from [http://www.easysoft.com](http://www.easysoft.com)).

### 5.40.7 ODBC Examples

In this section we show a few examples using **SQL2GMS** with ODBC data sources.
5.40.7.1 ODBC Driver Manager

To configure ODBC data sources use the ODBC Data Source Administrator. This tool can be invoked from the Start button menu: Settings | Control Panel, and click on the ODBC Data Sources icon:

Under Windows XP the sequence is: Control Panel | Performance and Maintenance | Administrative Tools and click on the Data Sources (ODBC) icon. Under Windows 10, access the Control Panel at first, type 'odbc' in the top right box and select either 'Set up ODBC data sources (32-bit)' or 'Set up ODBC data sources (64-bit)'. The ODBC Data Source Administrator tool looks like:

To create a new data source, click the Add button, select a driver, give it a name (this is the DSN name) and configure the data source.

5.40.7.2 Example 8 - Reading from an MS Access Database

There are several ways to export data from an SQL database into a GAMS include file:

1. Export a CSV (Comma Separated Values) file using Access Export. See also CSV Files.
2. Use the MDB2GMS tool.
3. Use SQL2GMS with a configured ODBC data source. The connection string will look like:
   "DSN=mydsn".
4. Use SQL2GMS with a DSN-less ODBC connection. In this case we need to specify both the driver and the location of the database file explicitly in the connection string. The connection string will look like:
   "Driver=\{Microsoft Access Driver (*.mdb)};Dbq=D:\data\mydata.mdb".
5. Use SQL2GMS with an OLE DB driver. The connection string can look like:
   "Provider=Microsoft.Jet.OLEDB.4.0;Data Source=D:\data\mydata.mdb"

5.40.7.3 Example 9 - Reading from an MS Excel Spreadsheet

There are numerous ways to export data from an Excel spreadsheet into a GAMS include file:

1. Export a CSV (Comma Separated Values) file using Excel Export.
2. Use the XLS2GMS tool.
3. Use the GDXXRW tool.
4. Use SQL2GMS with an Excel ODBC connection. An example is shown below.
Consider the spreadsheet ExcelDist.xls:

After configuring a data source ExcelDist that uses the Excel ODBC driver and points to the .xls file containing the above sheet, we can use the connection string: "DSN=ExcelDist". With the database browser we see:

I.e. the table name is Sheet1$. We now can formulate the query: SELECT city1, city2, distance FROM [Sheet1$]. We need the brackets to protect the funny table name. The result is (header removed in order to shorten the presentation=:

```
* -----------------------------------------------------
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOEKA 1.8
SAN-DIEGO.TOEKA 1.4
* -----------------------------------------------------
```

Although other tools are often more convenient to use, this approach is useful if you need to select a subsection of the spreadsheet table. It is easy to select just a few columns or rows from a table using a properly formulated SQL query. The skeleton would be: SELECT columns_to_extract FROM [sheet1$] WHERE rows_to_extract.

An example of a more complex spreadsheet is (profit.xls):

A DSN-less connection string would be: "DRIVER=Microsoft Excel Driver (*.xls); DBQ=d:\gams\projects\sql2gms\ver2.0\profit.xls". The browser will show:

A possible query that maps the two value columns into a GAMS parameter is:

```
SELECT year, loc, prod, 'sales', sales
FROM [profitdata$]
UNION
SELECT year, loc, prod, 'profit', profit
FROM [profitdata$]
```

The result is (shortened for presentation):

```
* -----------------------------------------------------
1997.la.hardware.profit 8
1997.la.hardware.sales 80
1997.la.software.profit 16
1997.la.software.sales 60
1997.nyc.hardware.profit 5
1997.nyc.hardware.sales 110
1997.nyc.software.profit 10
1997.nyc.software.sales 100
1997.sfo.hardware.profit 9
1997.sfo.hardware.sales 80
1997.sfo.software.profit 10
1997.sfo.software.sales 50
1997.was.hardware.profit 7
1997.was.hardware.sales 120
1997.was.software.profit 20
1997.was.software.sales 70
1998.la.hardware.profit 6
1998.la.hardware.sales 70
* -----------------------------------------------------
```

This example is also part of the GAMS Data Utilities Library, see model [Excel] for reference.
5.40.7.4 Example 10 - Reading from a Text File

Microsoft delivers ODBC with a text file driver which allows you to read a text file as if it is a database table.

A fixed format file such as:

<table>
<thead>
<tr>
<th>City1</th>
<th>City2</th>
<th>Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEATTLE</td>
<td>NEW-YORK</td>
<td>2.5</td>
</tr>
<tr>
<td>SAN-DIEGO</td>
<td>NEW-YORK</td>
<td>2.5</td>
</tr>
<tr>
<td>SEATTLE</td>
<td>CHICAGO</td>
<td>1.7</td>
</tr>
<tr>
<td>SAN-DIEGO</td>
<td>CHICAGO</td>
<td>1.8</td>
</tr>
<tr>
<td>SEATTLE</td>
<td>TOPEKA</td>
<td>1.8</td>
</tr>
<tr>
<td>SAN-DIEGO</td>
<td>TOPEKA</td>
<td>1.4</td>
</tr>
</tbody>
</table>

can be read using Fixed Length setting of the text driver:

The resulting include file will look like:

```
* -----------------------------------------------------
* SQL2GMS Version 2.0, January 2004
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* ADO version:    2.7
* Connection string: DSN=text
* Query:          SELECT city1, city2, distance FROM odbcdata.txt
* Provider:       MSDASQL
* -----------------------------------------------------
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----------------------------------------------------
```

Note that the text file is specified directly within the FROM clause.

A CSV file can be interpreted as a table as well, or any other separated format. We will try to read:

```
City1;City2;Distance
SEATTLE;NEW-YORK;2.5
SAN-DIEGO;NEW-YORK;2.5
SEATTLE;CHICAGO;1.7
SAN-DIEGO;CHICAGO;1.8
SEATTLE;TOPEKA;1.8
SAN-DIEGO;TOPEKA;1.4
```

This can be read using:

The actual formats used are stored by ODBC in an INI file schema.ini (located in the directory of the data files) which can be inspected directly:
5.40.8 Strategies

Including SQL statements to extract data from a database inside your model can lead to a number of difficulties:

- The database can change between runs, leading to results that are not reproducible. A possible scenario is a user calling you with a complaint: "the model is giving strange results". You run the model to verify and now the results are ok. The reason may be because the data in the database has changed.

- There is significant overhead in extracting data from a database. If there is no need to get new data from the database it is better to use a snapshot stored locally in a format directly accessible by GAMS.

- It is often beneficial to look at the extracted data. A first reason, is just to make sure the data arrived correctly. Another argument is that viewing data in a different way may lead to a better understanding of the data. A complete "under-the-hood" approach may cause difficulties in understanding certain model behavior.

Often it is a good strategy to separate the data extraction step from the rest of the model logic.

If the sub-models form a chain or a tree, like in:

Data Extraction --> Data Manipulation --> Model Definition --> Model Solution --> Report Writing

we can conveniently use the save/restart facility. The individual submodel are coded as:

- Step 0 - Data Extraction: sr0.gms
\$onText
step 0: data extraction from database
execute as: > gams sr0 save=s0
\$offText

Set
i 'suppliers'
j 'demand centers';

Parameter
demand(j)
supply(i)
dist(i,j) 'distances';

\$onEcho > howtoRead.txt
C=Provider=Microsoft.Jet.OLEDB.4.0;Data Source=%system.fp%transportation.mdb
Q1=SELECT name FROM suppliers
O1=i.inc
Q2=SELECT name FROM demandcenters
O2=j.inc
Q3=SELECT name,demand FROM demandcenters
O3=demand.inc
Q4=SELECT name, supply FROM suppliers
O4=supply.inc
Q5=SELECT supplier, demandcenter, distance FROM distances
O5=dist.inc
\$offEcho

\$call =sql2gms.exe @howtoRead.txt

Set i /
$include i.inc
/;

Set j /
$include j.inc
/;

Parameter demand /
$include demand.inc
/;

Parameter supply /
$include supply.inc
/;

Parameter dist /
$include dist.inc
/;

display i, j, demand, supply, dist;

- Step 1 - Data Manipulation: sr1.gms
Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*dist(i,j)/1000;

• Step 2 - Model Definition: sr2.gms

Variable x(i,j) 'shipment quantities in cases'
z 'total transportation costs in thousands of dollars';

Positive Variable x;

Equation ecost 'define objective function'
esupply(i) 'observe supply limit at plant i'
edemand(j) 'satisfy demand at market j';
ecost.. z =e= sum((i,j), c(i,j)*x(i,j));
esupply(i).. sum(j, x(i,j)) =l= supply(i);
edemand(j).. sum(i, x(i,j)) =g= demand(j);

• Step 3 - Model Solution: sr3.gms

Model transport / all /
solve transport using lp minimizing z;

• Step 4 - Report Writing: sr4.gms

display x.l, z.l;

A model that executes all steps can be written as:
execute 'gams.exe sr0 lo=3 save=s0';
abort$errorLevel "step 0 failed";

execute 'gams.exe sr1 lo=3 restart=s0 save=s1';
abort$errorLevel "step 1 failed";

execute 'gams.exe sr2 lo=3 restart=s1 save=s2';
abort$errorLevel "step 2 failed";

execute 'gams.exe sr3 lo=3 restart=s2 save=s3';
abort$errorLevel "step 3 failed";

execute 'gams.exe sr4 lo=3 restart=s3';
abort$errorLevel "step 4 failed";

If you only change the reporting step, i.e. generating some output using PUT statements, then you only need to change and re-execute step 4. If you change solver or solver options, then only steps 3 and 4 need to be redone. For a small model like this, this exercise may not be very useful, but when the model is large and every step is complex and expensive, this is a convenient way to achieve quicker turn-around times in many cases.

The model [SQLSr5] is also part of the GAMS Data Utilities Library.

In some cases the save/restart facility is not appropriate. A more general approach is to save the data from the database in a GDX file, which can then be used by other models. We can use the model from step 0 to store the data in a GDX file:

**SQL2GDX1.gms**

```
$onText
Store data from Access database into a GDX file.
$offText

execute 'gams.exe sr0 lo=3 gdx=trnsport.gdx';
abort$errorLevel "step 0 failed";

execute 'gdxviewer.exe trnsport.gdx';
```

The model [SQL2GDX1] is also part of the GAMS Data Utilities Library.

We can also let SQL2GMS create the GDX file:

**SQL2GDX2.gms**

```
$onText
Store data from Access database into a GDX file.
$offText

$onEcho > howToRead.txt
C=Provider=Microsoft.Jet.OLEDB.4.0;Data Source=%system.fp%transportation.mdb
X=%system.fp%transportation.gdx
Q1=SELECT name FROM suppliers
S1=i
Q2=SELECT name FROM demandcenters
```
The first approach has the advantage that a complete audit record is available from the data moved from
the database to the GDX file in the sr0.lst listing file. If someone ever wonders what came out of the
database and how this was stored in the GDX file, that file gives the answer.

The model [SQL2GDX2] is also part of the GAMS Data Utilities Library.

To load the GDX data the following fragment can be used:

**GDXTRANSPORT.gms**

This model demonstrates how to load the transportation data from GDX file at compile time.

```plaintext
Set
   i 'suppliers'
   j 'demand centers';

Parameter
   demand(j)
   supply(i)
   dist(i,j) 'distances';

$gdxIn transportation.gdx
$load i j demand supply dist
$gdxIn

display i, j, demand, supply, dist;
```

**DBTimestamp2.gms**

In one application I had to retrieve data from the database each morning, at the first run of the model.
The rest of the day, the data extracted that morning could be used. The following logic can implement
this:

```plaintext
$onText
Retrieve data from database first run each morning.
$offText

$onEcho > getdate.txt
C=Provider=Microsoft.Jet.OLEDB.4.0;Data Source=%system.fp%transportation.mdb
Q=select day(now())
O=dbtimestamp.inc
$offEcho
```
$if not exist dbtimestamp.inc $call "echo 0 > dbtimestamp.inc"

Scalar dbtimestamp 'day of month when data was retrieved' /
$include dbtimestamp.inc /

Scalar currentday 'day of this run';
currentday = gday(jnow);
display "compare", dbtimestamp, currentday;

if(dbtimestamp<>currentday,
   execute ' =gams.exe sr0 lo=3 gdx=transportation.gdx';
   abort$errorLevel "step 0 (database access) failed";

   execute ' =sql2gms.exe @getdate.txt'
);

The include file dbtimestamp.inc contains the day of the month (1,...,31) on which the data was extracted from the database. If this file does not exist, we initialize it with 0. We then compare this number with the current day of the month. If the numbers do not agree, we execute the database extraction step and rewrite the dbtimestamp.inc file. This last operation could be done using a PUT statement, but in this case we used an SQL statement.

The model [DBTimestamp2] is also part of the GAMS Data Utilities Library.

### 5.40.9 Parameter Files

Parameters can be specified in an external parameter file. This is important if the length of the command-line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command-lines. Instead of specifying a long command line as in:

```
$call =sql2gms C="DSN=sample" O="c:\My Documents\data.inc" Q="SELECT * FROM mytable"
```

we can use a command line like:

```
$call =sql2gms @"c:\My Documents\options.txt"
```

The parameter file

```
c:\My Documents\options.txt
```

can look like:

```
C=DSN=sample
O=c:\My Documents\data.inc
Q=SELECT * FROM mytable
```
It is possible to write the parameter file from inside a GAMS model using the `$echo` command. The following example will illustrate this:

```gams
$set cmdfile "c:\windows\temp\commands.txt"
$echo "C=DSN=sample" > "\%cmdfile\%
$echo "O=E:\models\labor.INC" >> "\%cmdfile\%
$echo "Q=SELECT * FROM labor" >> "\%cmdfile\%
$call =sql2gms @"\%cmdfile\%"

Parameter p /
$include "E:\models\labor.INC"
/;
display p;
```

Newer versions of GAMS allow the usage of the `$onEcho` and `$offEcho` commands:

```gams
$set cmdfile "c:\windows\temp\commands.txt"
$onEcho > "\%cmdfile\%
C=DSN=sample
O=E:\models\labor.INC
Q=SELECT * FROM labor
$offEcho

$call =sql2gms @"\%cmdfile\%"

Parameter p /
$include "E:\models\labor.INC"
/;
display p;
```

If a query becomes very long, it is possible to spread it out over several lines. To signal a setting will continue on the next line insert the character `\` as the last character. E.g.:

```gams
Q=SELECT prod, loc, year, 'sales', sales FROM data \ 
UNION \ 
SELECT prod, loc, year, 'profit', profit FROM data
```

5.40.10 Notes

5.40.10.1 ADO

ActiveX Data Objects. Microsoft's data-access object model. An object-oriented architecture for accessing data stored in SQL databases and related data sources. Accessible from a large number of host languages such as VB, C++, Delphi. Supersedes ODBC. Many SQL databases provide ADO access through either OLEDB or ODBC.
5.40.10.2 ODBC

An API and driver manager system for accessing data stored in an RDBMS. The API provides applications a way to talk to databases while the driver manager application allows users to install, configure and manage ODBC drivers for different databases.

5.40.10.3 OLEDB

Driver architecture for SQL databases. A driver is called a OLE DB provider. This is used from ADO.

5.40.10.4 UNC Names

UNC means Unified Naming Convention. UNC names are a Microsoft convention to name files across a network. The general format is:

```\<server>\<share>\<path>\<file>```

Examples:

```\athlon\c\My Documents\sql2gms.rtf```

5.40.10.5 GDX Files

A GDX file contains GAMS data in binary format. The following GAMS commands will operate on GDX files: `$gdxIn`, `$load`, `execute_load`, `execute_unload`. The `GDX=filename` command-line option will save all data to a GDX file. A GDX file can be viewed in the GAMS IDE using `File|Open`.

5.40.10.6 MDB2GMS

MDB2GMS is a tool to import tables from MS Access databases. This utility directly uses MS Access and DAO (Data Access Objects) resulting in a somewhat simpler interface. It is not needed to specify a connection string, but just a .mdb file. The query mechanism is similar: a query is sent as it is to the database server and the result set is translated into a GAMS representation. For more information see MDB2GMS.

5.40.10.7 XLS2GMS

XLS2GMS is a tool to import data from an Excel spreadsheet. It considers the content of a selected range as GAMS source code. For more information XLS2GMS.
5.40.10.8 GDXXRW

GDXXRW is a utility to read and write Excel spreadsheet data. GDXXRW can read multiple ranges in a spreadsheet and write the data to a GDX file, or read from a GDX file, and write the data to different ranges in a spreadsheet. For more information GDXXRW.

5.40.10.9 Quotes

Examples of handling of indices when the option B for quoting strings containing blanks is used:

5.40.10.10 $CALL Command

The $call command in GAMS will execute an external program at compile time. There are two forms:

$call externalProgram

$call =externalProgram

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=' bypasses the command processor and directly executes the external program. We mention some of the differences:

1. Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE. If you want to execute these commands you will need to use the form $call externalProgram which uses the command processor.

2. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form $call externalProgram.

3. If it is important to stop with an appropriate error message if the external program does not exist, only use the form $call =externalProgram. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: $call =externalProgram.

4. When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: $call start /w externalWindowsProgram. Otherwise, it is preferred to use: $call =externalWindowsProgram.

Attention

In general it is recommended to use the $call =externalProgram version for its better error-handling.

When command-line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

$call externalProgram parameter1 parameter2
$call =externalProgram parameter1 parameter2

The total length of the command-line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

$call "external program" "parameter 1" "parameter 2",
$call ="external program" "parameter 1" "parameter 2"

It is noted that the first form needs additional quotes around the whole command-line due to bugs in the parsing of the $call in GAMS. The second form work without additional quotes only if the = appears outside the double quotes.
Compile Time Commands

All \$ commands in GAMS are performed at compile time. All other statements are executed at execution time. This means that a compile time command will be executed \textbf{before} an execution time command, even if it is below. As an example consider:

File batchfile / x.bat /;
putClose batchfile "dir"/;
\$call x.bat

This fragment does not work correctly as already during compilation, the \$call is executed, while the put statements are only executed after the compilation phase has ended and GAMS has started the execution phase. The above code can be fixed by moving the writing of the batch file to compilation time as in

\$echo "dir" > x.bat
\$call x.bat

or by moving the external program invocation to execution time:

File batchfile / x.bat /;
putClose batchfile "dir"/;
execute x.bat;

Notice that all \$ commands do not include a semi-colon but are terminated by the end-of-line.

\section{XLS2GMS}

Erwin Kalvelagen, GAMS Development Corp

2.4 May 2004:

\subsection{Overview}

Note

The Windows GAMS distribution contains several tools to exchange data with MS-Excel: GDX2XLS, GDXXRW, XLS2GMS, and XLSDUMP. While we continue to include all four tools in our distribution, only GDXXRW is under active development. Therefore, we strongly recommend using GDXXRW for data exchange with Excel.

XLS2GMS is a tool to convert spreadsheet data from a Microsoft Excel spreadsheet into GAMS readable format. The source is a MS Excel spreadsheet file (*.XLS) and the target is a GAMS Include File.

When running the executable \texttt{XLS2GMS.EXE} without command line parameters the tool will run \texttt{interactively} with a built-in GUI interface. Alternatively XLS2GMS can be run in \texttt{batch mode} which is useful when calling it directly from a GAMS model using the \$call command.

The philosophy of the tool is to consider the content of a spreadsheet as \texttt{Text}. This text can contain GAMS statements, or parts of GAMS statements (e.g. the data part of a table statement). The text is exported to a GAMS include file where some spacing is introduced to maintain cell boundaries. This allows tables to be exported directly to GAMS include files.
5.41.2 Requirements

**XLS2GMS** runs only on PC's running Windows (95/98/NT/XP) and with MS Excel installed. Microsoft Excel is included in the MS Office suite.

5.41.3 Converting spreadsheet data to GAMS data

Spreadsheet data are often differently organized than is suitable for import into a GAMS model. In some cases the data is scattered around different sheets, and in a format that is not compatible with a more structured multi-dimensional parameter as are used in a GAMS model. To export spreadsheet data to GAMS parameters, tools will either require a strict format to be used inside the spreadsheet or they will need to offer a complex specification step where the data representation in the spreadsheet is described so that it can be understood by the tool. This tool will use the first approach: the modeler is required to lay-out the data in the spreadsheet in a well defined format. Instead of defining a new format, we use the GAMS language syntax as the required representation. In effect the spreadsheet is considered as an alternative editor for GAMS source code.

As an example consider the GAMS table in the model [TRNSPORT] which is part of the GAMS model library:

```plaintext
Table d(i,j) 'distance in thousands of miles'
       new-york  chicago  topeka
seattle  2.5   1.7   1.8
san-diego 2.5   1.8   1.4;
```

This table can be expressed comfortably in a spreadsheet as follows:

**XLS2GMS** can convert this table into a GAMS include file, which results in:

```
* -----------------------------------------------------
* XLS2GMS Version 2.4, May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----------------------------------------------------
* Application: Microsoft Excel
* Version: 9.0
* Workbook: D:\gams projects\xls2gms\ver2.0\Book2.xls
* Sheet: Sheet1
* Range: $A$1:$D$3
* -----------------------------------------------------
  new-york  chicago  topeka
seattle   2.5   1.7   1.8
san-diego 2.5   1.8   1.4
* -----------------------------------------------------

The tool will try to keep cells in a column aligned so that table statements can be used in the GAMS model. The above file book2.inc can be imported directly into a GAMS model by:

```
Table d(i,j) 'distance in thousands of miles'
$include book2.inc
```

```
As the tool does not expect any special formatting, we could have include the table statement in the spreadsheet, as in:

This would result in:

```
* -----------------------------------------------------
* XLS2GMS Version 2.4, May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----------------------------------------------------
* Application: Microsoft Excel
* Version: 9.0
* Workbook: D:\gams projects\xls2gms\ver2.0\Book3.xls
* Sheet: Sheet1
* Range: $A$1:$D$5
* -----------------------------------------------------
table d(i,j) 'distance in thousands of miles'
    new-york chicago topeka
    seattle 2.5 1.7 1.8
    san-diego 2.5 1.8 1.4
;  
* -----------------------------------------------------
```

In some cases the data will need to be copied and massaged to fit into the above format. It is convenient to add a sheet dedicated for this purpose to your workbook. This interface sheet can be filled either manually, with formulas that automatically update values, or by macro’s (either recorded or programmed in VBA).

### 5.41.4 Importing sets

Sets can be directly imported if they are organized vertically. The following picture shows a spreadsheet with two sets with elements \{a,b,c\} organized vertically (A1:A3) and horizontally (B5:D5).

The first set can be imported directly using:

```
Set i /
$call =xls2gms r=a1:a3 i=book4.xls o=set1.inc
$include set1.inc
/;

display i;
```

The second set is somewhat more difficult, as we need to add a separating comma between the elements. This can be accomplished by:

```
Set j /
$call =xls2gms r=b5:d5 s="," i=book4.xls o=set2.inc
$include set2.inc
/;

display j;
```

This will generate the include file:
5.41.5 Importing sets and tables

The table can be considered to contain three pieces of GAMS data:

- The set \( i \) (seattle, san-diego)
- The set \( j \) (new-york, chicago, topeka)
- The distances

All this information can be read as follows:

```gams
Set i /
$call =xls2gms r=a3:a4 i=book3.xls o=seti.inc
$include seti.inc
/

Set j /
$call =xls2gms r=b2:d2 s="," i=book3.xls o=setj.inc
$include setj.inc
/

Table d(i,j)
$call =xls2gms r=a2:d4 i=book3.xls o=pard.inc
$include pard.inc
;

display i, j, d;
```

The above $call statements can be combined onto one as follows:

```gams
$onEcho > book3a.txt
i=%system.fp%book3.xls
r1=a3:a4
o1=seti.inc
r2=b2:d2
o2=setj.inc
s2="",
r3=a2:d4
o3=pard.inc
$offEcho
```
$call =xls2gms @book3a.txt

Set i / $include seti.inc /

Set j / $include setj.inc /

Table d(i,j) $include pard.inc ;

display i, j, d;

The command file generated by the $onecho statement looks like:

i=E:\wtools\ver000\examples\book3.xls
r1=a3:a4
o1=seti.inc
r2=b2:d2
o2=setj.inc
s2=","
r3=a2:d4
o3=pard.inc

5.41.6 Multidimensional parameters

Consider the data table:

In this spreadsheet the first two columns are index columns. To make this valid GAMS syntax we need to insert a dot between the index elements. A simple way is to insert a (narrow) column with a dot in each cell. This way we can import this table as:

Set
  l 'livestock types' / sheep, goat, angora, cattle, buffalo, mule, poultry /
  cl 'livestk comm' / meat, milk, wool, hide, egg /
  ty 'time periods - years' / 1974*1979 /

$onEcho > yield.txt
i=%system.fp%yield.xls
R=data!B2:J23
O=yield.inc
$offEcho

$call =xls2gms @yield.txt

Table yieldtl(l,cl,ty) 'livestock "yield" time series (kg per head)'
$include yield.inc
;

display yieldtl;
5.41.7 Interactive use

When the tool is called without command line parameters, it will startup interactively. Using it this way, one can specify the spreadsheet file (.XLS file), the range and the final destination file (a GAMS include file) using the built-in interactive environment. The main screen contains a number of buttons and edit boxes, which are explained below.

- **Input file (*.XLS)**. This is the combo box to specify the input file. The file must be a valid MS Excel spreadsheet file (*.XLS). The browse button can be used to launch a file open dialog which makes it easier to specify a file. The file may be located on a remote machine using the notation \machine\directory\file.xls.

- **Range**. The range can be left empty in which case the whole first sheet is taken. Otherwise the range can be a single cell (e.g. A1), a block (e.g. B2:J23), or a region within a sheet (e.g. Sheet1!A1:C10). The range can also be a name if the spreadsheet contains named ranges. The browse button will start Excel allowing you to interactively select a range.

- **Output GAMS Include file (*.INC)**. If you want to create a GAMS include file, then specify here the destination file. The include file will be an ASCII file that can be read by GAMS using the $include command. If the include file already exists, it will be overwritten.

- **Progress Memo**. This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.

- The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

- **options button** will pop up a window where you can specify a number of options.

- **help button** will show this help.

- the **OK button** is pressed the query will be executed and an include file will be generated.

- the **batch button** will give information on how the current extract command can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied onto the clipboard. In the IDE press Ctrl-C or choose Edit|Paste to copy the contents of the clipboard to a GAMS text file.

- the **close button** will exit the application. The current settings will be saved in an INI file so when you run XLS2GMS again all current settings will be restored.

5.41.8 Options

The **Options** window can be created by pressing the options button:

The following options are available in the options window:

- **Quote blanks**: Quote strings if they contain blanks or embedded quotes. If a string does not contain a blank or embedded quotes, it will remain unquoted. If the string contains a single quote the quotes applied will be double quotes and if the string contains already a double quote, the surrounding quotes will be single quotes. (In the special case the string contains both, double quotes are replaced by single quotes). For more information see this example.

- **Mute**: Don't include the extra informational text (such as used query etc.) in the include file.

- **No listing**: Surround the include file by $offlisting and $onlisting so that the data will not be echoed to the listing file. This can be useful for very large data files, where the listing file would become too large to be handled comfortably.
• **Separator.** This option allows you to set a separator string to be written between cell entries. By default this is a blank. In some cases it can be useful to make this a comma. See example for an example where this is used to import sets. Note: when this option is set to an empty string, the results may not be syntactically correct for GAMS. As it is difficult to see the difference between a single blank and an empty string, the user interface will give some feedback for these cases. When an empty string is used, a warning is written to the include file.

• **Range Separator.** Multiple ranges can be separated by a range separator symbol. By default this is a semi-colon. When certain non-US locales are used, the semi-colon is a list separator symbol which can be used in multi-area ranges. In case of such a conflict, it is possible to change the range separator symbol.

• **Append.** Append to the output file.

• **Browse Read-Only.** When the Browse Range button is pressed, we launch Excel and try to load the currently specified input file. If this option is checked then the input file is loaded as read-only. If this option is not checked the file is loaded normally, in which case you can change and save it.

The buttons have an obvious functionality:

• **OK button** will accept the changes made.

• **Cancel button** will ignore the changes made, and all option settings will revert to their previous values.

• **Help button** will show this help text.

5.41.9 **Batch use**

When calling **XLS2GMS** directly from GAMS we want to specify all command and options directly from the command line or from a command file. An example is:

```
C:\tmp>xls2gms "I=c:\My Documents\test.xls" O=test.inc
```

This call will perform its task without user intervention. The batch facility can be used from inside a GAMS model, e.g.:

```
Table c(i,j) 'data from spreadsheet' / 
$call =xls2gms I=C:\tmp\test.xls O=C:\tmp\data.inc R=B1:E10 
$include C:\tmp\data.inc 
/
```

The `$call` statement is rather error prone and you will need to spend a little it of time to get the call correct and reliable.

All the possible command line options are listed in command line arguments section. A proper batch call will at least contain the following command line parameters:

1. `I=inputfilename`
2. `O=outputincludefile`

If you only specify `I=inputfilename` then the interactive user interface is started with an initial setting of the input file name edit box equal to the name given in the command line argument. Only if an input file and an output file is provided, the call will be considered a batch invocation.

5.41.10 **Command-line Arguments**
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I=inputfile</td>
<td>This option is required and specifies the name of the .XLS file containing the Access database. If the file contains blanks the name should be surrounded by double quotes. It is advised to use absolute paths, so Access has no confusion what file to open. If only the file name is used without a path, the file is searched in the current directory (this is the project directory when running under the IDE). On a network UNC names can be used, and files from another computer can be accessed, e.g. &quot;\hostname\c\my documents\a.xls.&quot; This option is required for batch processing.</td>
</tr>
<tr>
<td>O=outputincludefile</td>
<td>The option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter statement. Make sure the directory is writable. UNC names can be used. An output file must be specified for batch operation.</td>
</tr>
<tr>
<td>R=range</td>
<td>range is an optional argument. If not specified the whole first sheet is taken. Otherwise the range can be a single cell (e.g. A1), a block (e.g. B2:J23), or a region within a sheet (e.g. Sheet1!A1:C10). To specify a whole sheet use: Sheet2!. The range can also be a name if the spreadsheet contains named ranges. Both global names (e.g. R=rangename) and sheet specific range names (e.g. R=Sheet2!rangename) are recognized. To select multiple ranges in one go, you can specify: R=range1;range2;range3. This is just a short-hand for three separate invocations of xls2gms. A multiple-area range can be specified by R=area1,area2,area3. Before exporting, a new range is created consisting of the union of the areas. This can be used to drop certain rows or columns from a table.</td>
</tr>
<tr>
<td>D</td>
<td>Debug. This option can be used for debugging purposes. If specified the import filter will run minimized but &quot;restored&quot;, i.e. as a normal window. In addition the program will not terminate until the user clicks the Close button. This allows you to monitor possible errors during execution of xls2gms.</td>
</tr>
<tr>
<td>B</td>
<td>If this parameter is specified, strings that have blanks in them will be quoted. If the string is already quoted this step is not performed. If the name contains an embedded single quote, the surrounding quotes will be double quotes. If the name already contains a double quote, the surrounding quotes will be single quotes. If both single and double quotes are present in the string, then all double quotes are replaced by single quotes and the surrounding quotes will be double quotes. By default this option is turned off.</td>
</tr>
<tr>
<td>M</td>
<td>Run in modest or mute mode: no additional information, such as version number etc. is written to the listing file.</td>
</tr>
<tr>
<td>L</td>
<td>Embed the data in $offlisting, $onlisting. A quick way to reduce the size of the listing file.</td>
</tr>
<tr>
<td>@filename @&quot;file name&quot;</td>
<td>Causes the program to read options from a file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if it were specified on the command line.</td>
</tr>
<tr>
<td>N=inifilename</td>
<td>Use a different Inifile than the standard xls2gms.ini located in the same directory as the executable xls2gms.exe.</td>
</tr>
<tr>
<td>A</td>
<td>Append to output files instead of overwriting them.</td>
</tr>
<tr>
<td>G=&quot;x&quot;</td>
<td>Sets the range separator symbol</td>
</tr>
<tr>
<td>S=&quot;x&quot;</td>
<td>Sets the output separator symbol</td>
</tr>
</tbody>
</table>

As invocations of xls2gms are reasonably expensive (a copy of Excel is started), there is a way to optimize related calls. From version 1.4, xls2gms allows multiple ranges to be read and multiple include files to be written in one swoop. The syntax is best explained by showing an illustrative example:

```
$call =xls2gms I=c:\tmp\x.xls R1=range1 R1=range2 R2=range3 O1=c:\tmp\f1.inc O2=c:\tmp\f2.inc
```
In this example the ranges 'range1' and 'range2' are written to the file 'f1.inc' while the range 'range3' will go to file 'f2.inc'. In general the ranges specified with Rn will be written to the file specified with On. If multiple ranges are specified, they are written sequentially to the output file.

$call =xls2gms I=c:\tmp\x.xls R=range1 R=range2 O=c:\tmp\f1.inc

In this example the ranges 'range1' and 'range2' are written to 'f1.inc'.

5.41.11 $CALL command

The $CALL command in GAMS will execute an external program at compile time. There are two forms:

$call externalprogram

$call =externalprogram

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=', bypasses the command processor and directly executes the external program. We mention some of the differences:

- Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE.
- If you want to execute these commands you will need to use the form $call externalprogram which uses the command processor. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form $call =externalprogram.
- If it is important to stop with an appropriate error message if the external program does not exist, only use the form $call =externalprogram. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: $call =externalprogram.
- When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: $call start /w externalwindowsprogram. Otherwise, it is preferred to use: $call =externalwindowsprogram.

Attention

In general it is recommended to use the $call =externalprogram version for its better error-handling.

When command line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

$call externalprogram parameter1 parameter2

$call =externalprogram parameter1 parameter2

The total length of the command line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

$call "external program" "parameter 1" "parameter 2"

$call ="external program" "parameter 1" "parameter 2"

It is noted that the first form needs additional quotes around the whole command line due to bugs in the parsing of the $call in GAMS. The second form work without additional quotes only if the = appears outside the double quotes.
5.41.12 Command files

Parameters can be specified in a command file. This is important if the length of the command line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command lines. Instead of specifying a long command line as in:

```
$call =xls2gms "I:\My Documents\test.xls" O="\My Documents\data.inc" R="Sheet2!A1:F15"
```

we can use a command line like:

```
$call =xls2gms @"c:\My Documents\options.txt"
```

The command file `c:\My Documents\options.txt` can look like:

```
I=c:\My Documents\test.xls
O=c:\My Documents\data.inc
R=Sheet2!A1:F15
```

It is possible to write the command file from inside a GAMS model using the $echo command. The following example will illustrate this:

```
$set cmdfile "trnsport.txt"
$echo "I=trnsport.xls" > "%cmdfile%"
$echo "O=trnsport.inc" >> "%cmdfile%"
$call =xls2gms "%cmdfile%"

$include trnsport.inc
```

Newer versions of GAMS allow:

```
$set cmdfile trnsport.txt
$onEcho > "%cmdfile%"
I=trnsport.xls
O=trnsport.inc
$offEcho
$call =xls2gms "%cmdfile%"

$include trnsport.inc
```

5.41.13 Multiple-area ranges and post-processing

The following fragment is from a spreadsheet from Unesco:

Assume we want to extract the 1990 percentage distribution of current expenditure for the countries Algeria through Congo. The range to select is not a contiguous area but consists of several pieces. In Excel we can use the mouse and the Ctrl key to make a multiple selection:

The range is `A10,E10:G10,A14:A19,E14:G19,A21:A26,E21:G26`, where the comma's indicate the range is a multiple-area range. In this case we have six pieces. It is important that Excel understands that the union of the pieces forms a rectangular area. If this is not the case an error will be raised. (You can check this yourself by selecting a multi-area range and copying it to a new sheet: this operation will fail if the areas together don't form a rectangle).

The extracted text file will look like:
This file is not completely suitable for using in a GAMS model. The following edits would need to be made:

1. The header labels should get rid of the trailing dot.
2. Cells with ... should be replaced by blanks.
3. Cells with ./ should be replaced by blanks.

In the GAMS distribution a subdirectory gbin contains lots of interesting Unix utilities. Some of these are very suited to do string processing on text files, such as sed and awk. In this case we can use sed with some substitution commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s/prim./prim /</td>
<td>Replace &quot;prim.&quot; by &quot;prim &quot;. We need to be careful to keep the table alignment correctly, so we replace the dot by a blank instead of just removing the dot. A dot is a special character in sed (it means &quot;any character&quot;) so we escape it by specifying &quot;.&quot;.</td>
</tr>
<tr>
<td>s/Sec./sec /</td>
<td>Replace &quot;Sec.&quot; by &quot;sec &quot;.</td>
</tr>
<tr>
<td>s/Tert./tert /</td>
<td>Replace &quot;Tert.&quot; by &quot;tert &quot;.</td>
</tr>
<tr>
<td>s/.... /g</td>
<td>Replace &quot;...&quot; by &quot; &quot;. The dots are escaped. We add g to indicate there may be multiple instances on a line that must be replaced.</td>
</tr>
<tr>
<td>s/./.. /g</td>
<td>Replace &quot;/.&quot; by &quot;. Both dots and &quot;/&quot; needs to be escaped.</td>
</tr>
</tbody>
</table>

The complete GAMS formulation can look like:

```gams
$onText
New version XLS2GMS ver 2.1 can handle multiple-area ranges.
```
Set
c 'countries'
   / Algeria, Angola, Benin, Botswana, 'Burkina Faso', Burundi, Cameroon
   'Cape Verde', 'Central African Republic', Chad, Comoros, Congo /
exp 'percentage distribution of current expenditure'
   / prim, sec, tert /;

$onEcho > commands.txt
I=%system.fp%unesco.xls
R=A10,E10:G10,A14:A19,E14:G19
O=unesco.inc
B
$offEcho

$call =xls2gms @commands.txt

$onEcho > sedcommands.txt
s/prim\.\./prim /
s/Sec\.\./sec /
s/Tert\.\./tert /
s/\..\..\./ /g
s/\..\./\./ /g
$offEcho

$call sed.exe -f sedcommands.txt unesco.inc > unescox.inc

Table distr(c,exp)
$include unescox.inc
;
display distr;

5.42 XLSDUMP

Note
The Windows GAMS distribution contains several tools to exchange data with MS-Excel: GDX2XLS, GDXXRW, XLS2GMS, and XLSDUMP. While we continue to include all four tools in our distribution, only GDXXRW is under active development. Therefore, we strongly recommend using GDXXRW for data exchange with Excel.

This program will write all worksheets of an Excel workbook to a gdx file. Unlike GDXXRW, the program does not require that Excel is installed. Windows platforms only.

5.42.1 Usage

XLSDump infile outfile

where

   infile
       A valid Excel workbook

   outfile
       Optional. The output gdx file. If no output file is specified, the name of the input file will be used to construct the name the output file.
5.42.2 Example

Consider the following working file 'test2.xlsx'.

Converting this workbook using xlsdump:

```
xlsdump test2.xlsx
```

Will generate the file test2.gdx. Showing this gdx file in the GAMS IDE:

The parameter VF:

5.43 XLSTALK

XLSTalk is not a GDX utility, but as the program is often used with GDXXRW, it is discussed here.

5.43.1 Usage

```
xlstalk <option> {-V} <file> {<parameters>}
```

where

\(<\text{file}>\)

Excel file name with file extension

\(<\text{option}>\)

One of the following options; see following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
<th>Parameter</th>
<th>Return code</th>
</tr>
</thead>
<tbody>
<tr>
<td>-A</td>
<td>Test if Excel is running</td>
<td></td>
<td>0 Excel not running 1 Excel is running</td>
</tr>
<tr>
<td>-C</td>
<td>Close file; do not save changes.</td>
<td>&lt;file&gt;</td>
<td></td>
</tr>
<tr>
<td>-E</td>
<td>Test if file exists</td>
<td>&lt;file&gt;</td>
<td>0 File does not exist 1 File exists</td>
</tr>
<tr>
<td>-M</td>
<td>Status of file</td>
<td>&lt;file&gt;</td>
<td>0 Not open in Excel 1 File is open and is not modified 2 File is open and has been modified</td>
</tr>
<tr>
<td>-O</td>
<td>Open file but do not reload</td>
<td>&lt;file&gt;</td>
<td></td>
</tr>
<tr>
<td>-Q</td>
<td>Quit Excel if no workbooks have been modified</td>
<td>&lt;file&gt;</td>
<td>0 Excel is closed 1 Excel is still running</td>
</tr>
<tr>
<td>-R</td>
<td>Run a macro</td>
<td>&lt;file&gt; {&lt;macro-name&gt; &lt;macro-param&gt;}</td>
<td></td>
</tr>
<tr>
<td>-S</td>
<td>Save and close the file</td>
<td>&lt;file&gt;</td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Action</td>
<td>Parameter</td>
<td>Return code</td>
</tr>
<tr>
<td>--------</td>
<td>-------------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-V</td>
<td>Verbose mode</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-W</td>
<td>Wait for the user to close the file</td>
<td>&lt;file&gt;</td>
<td></td>
</tr>
</tbody>
</table>
| -X     | Excel version                 |             | 0 Excel is not installed  
1 Excel is installed; version 2003 or earlier  
2 Excel is installed; version 2007 or later |

### 5.43.2 Example

In GAMS, the return value can be obtained by using 'errorlevel'.

execute 'xlstalk.exe -X';

Scalar x;
    x = errorLevel;
    display x;
Chapter 6

Application Programming Interfaces

The Application Programming Interfaces (APIs) to GAMS allow the seamless integration of GAMS into an application. The APIs by provides appropriate classes for the interaction with GAMS. The GAMSDatabase class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the GAMSJob class and by using the GAMSModelInstance class a sequence of closely related model instances can be solved in the most efficient way. Note that the GAMS object-oriented API was not designed to offer modeling capability. The model needs to be formulated in GAMS and passed on to the GAMSJob class.

Four versions of object-oriented GAMS APIs:

- **.NET API** works with .NET framework 4 (Visual Studio 2010),
- **C++ API** works with C++11 or later,
- **Java API** works with Java SE 7 or later, and
- **Python API** works with Python 2.7 (in addition 3.4 and 3.6 on some Supported Platforms).

In addition to the object-oriented GAMS APIs, there exist expert-level (or low-level) GAMS APIs in which its usage requires advanced knowledge of GAMS component libraries. See Executing GAMS from other Environments if you want to execute GAMS directly from an application without using APIs.

### 6.1 Object-oriented APIs

The Reference Manuals give an overview of the features provided by GAMS APIs, release notes, and a list of all classes with descriptions. The Tutorials provide an overview of the basic functionality of the GAMS APIs and the Examples provides a list of examples available with GAMS distribution with detailed description. See also Release Notes and Supported Platforms.

### 6.1.1 Reference Manuals

The GAMS APIs reference manuals give an overview of the features provided by GAMS APIs, release notes, and a list of all classes with descriptions.

- **.NET API**
- **C++ API**
- **Java API**
- **Python API**
6.1.2 Tutorials

GAMS API Tutorials provide an overview of basic functionalities of GAMS APIs and allow a user to get started to work with the GAMS API.

- .NET API Tutorial
- C++ API Tutorial
- Java API Tutorial
- Python API Tutorial

6.1.3 Examples

There are several examples available for the different programming languages: .NET, C++, Java, and Python. Below we give a description of each example together with its link to the detailed page in different languages.

<table>

These examples are available with the GAMS distribution in [Path/To/GAMS]/apifiles/ directory. In that directory, the file readme.txt describes how to build and execute these examples. A GAMS script to compile and execute each example is available in [Path/To/GAMS]/apilib_ml/ directory with a table of contents.

6.1.3.1 Alias

The Object-oriented API does not have the concept of a GAMS alias. An alias cannot be entered into a GAMSDatabase by API methods. Nevertheless, if the GAMSDatabase is loaded from a GDX container (e.g. the GAMSJob.OutDB), the database can contain aliases. Such an alias can be retrieved as a GAMSSet and consists of the elements of the aliased set. The method to find out if a GAMSSet in a GAMSDatabase is indeed an alias is to check if the symbol name is different from the lookup name (i.e. bool isAlias = db.GetSet("ii").Name != "ii"). This example model goes through the logic of how aliases are handled in the Object-oriented API.

See Alias example in [ .NET, Java, Python].

6.1.3.2 Benders2Stage

This example implements a simple Benders decomposition method for a stochastic linear program. The underlying model implements a simple distribution system with stochastic demand data. This example actually consists of two programs: A sequential and a parallel implementation. In the sequential version, the master and the subproblems are implemented with the GAMSModelInstance object which allows resolving the model with modified input without regenerating the model. A GAMSModelInstance has a fixed model rim, so this provides a challenge for Benders master problem because every iteration adds new constraints (the Benders cuts) to the master. We get around this limitation of GAMSModelInstance by initializing the GAMSModelInstance of the master with a fixed number of empty (i.e. non-binding) placeholders constraints and during the run of the algorithm turn these placeholder constraints into valid Benders cuts. The parallel version extends the Benders2Stage example by solving the independent subproblems in parallel. For that we need to instantiate a separate GAMSModelInstance for each parallel worker. We use the efficient GAMSModelInstance.CopyInstance method to accomplish this in the most effective way. The number of demand scenarios can be larger than the number of parallel workers. The distribution of work is handles through a work queue. The parallel execution of the subproblems is done in separate threads (the MT in the name of the example stands for Multi Threading), so there is very little overhead from disk activity.

See Benders2Stage example in [ .NET, Java, Python] and Bender2StageMT example in [ .NET, Java, Python].

6.1.3.3 Clad

This example demonstrates how to implement a complex termination criterion for a difficult MIP using GAMS/Cplex. We would like to achieve a globally optimal solution (relative gap 0%) but if solution time becomes larger than n1 seconds, we can compromise for a 10% gap, and if this is not achieved after n2 seconds, we compromise for a 20% gap, and again if this is not accomplished in n3 seconds we take whatever the solver has done so far and terminate the solve. This is implemented by executing GAMSJob.run in an independent thread and providing new tolerances for the relative gap in the main thread by supplying new GAMS/Cplex option files and triggers the processing of the new tolerance option by GAMS/Cplex through the GAMSJob.Interrupt method.

See Clad example in [ .NET, Java, Python].
6.1.3.4 CutStock

This example contains two programs that implement a column generation approach to solve the cutting stock problem. In the program SimpleCutsock, the column generation scheme has been implemented in GAMS. Moreover, the GAMS model with the input and output data has been wrapped in a class that separates all interaction with GAMS from the driving application. In the second example, the column generation approach has been entirely implemented in the program using GAMSJob for the master and GAMSModelInstance for the pricing problem. GAMS is used to build the master and pricing problems. The logic of the column generation method is in the application program.

See Cutstock Model example in [.NET, Java, Python], SimpleCutsock example in [.NET, Java, Python], and Custock example in [.NET, Java, Python].

6.1.3.5 Domain Checking

Enforcing referential integrity also known in the GAMS lingo as domain checking is an essential and important part of GAMS. The Object-oriented API does a delayed domain checking of symbols. So you can add records to a domain controlled parameter (e.g. p(j)) even though the GAMSSet i does not contain the label (yet). The user can trigger an explicit check of the referential integrity by calling the GAMSDatabase.CheckDomains (or GAMSSymbol.CheckDomains). The Object-oriented API provides methods to access the records that violate the referential integrity (see GAMSDatabaseDomainViolation for details). Domain checking is implicitly done when the GAMSDatabase is exported to a GDX file via the GAMSDatabase.Export method or for databases provided in the GAMSJob.Run method. The implicit domain check can be suppressed (and left to GAMS when importing data) via the GAMSDatabase.SuppressAutoDomainChecking property. This example demonstrates how to trigger domain checking and how to access the records that violate the referential integrity.

See Domain checking example in [.NET, C++, Java, Python].

6.1.3.6 GUI Examples

Modern development frameworks like Microsoft’s Visual Studio, Python, and Java allow to quickly build graphical user interfaces. Every example consists of a simple GUI that provides data entry, executing of a GAMSJob and graphically represents the results of a GAMS model.

- **CutstockGUI**: This example allows to either load data from a database or to enter data manually. A cutting stock problem is solved by using both the GAMSJob and the GAMSModelInstance class in order to implement a decomposition approach. See also CutStock Example. See this example in [.NET].

- **InterruptGUI**: This small example demonstrates how to run a GAMS model in a graphical user interface. This has all rudimentary features we know from the GAMS IDE: starting a job, capture the GAMS log in a window, and providing a button to interrupt. The underlying mechanism to interrupt the job is similar to the Interrupt Example (GAMSJob.Interrupt), but the trigger mechanism is very different. See this example in [.NET, Java, Python].

- **FarmGUI**: For this farming model, the input data can be entered directly into several tables. The GAMS model itself is executed by using one single GAMSJob instance. Results are displayed in different charts and tables. See this example in [.NET].

- **TransportGUI**: In this example a series of transportation problems is solved using GAMSModelInstance. Data can be entered into tables or can be loaded from a database. When data is entered into a table, related tables are updated automatically. Results are shown in tables and/or a bar chart. See also Transport Model Sequence Example. See this example in [.NET, Java].
6.1.3.7 GAMS Remote Object

This example demonstrates how to implement a simple GAMS Server. The example has two parts: GAMSServer and GAMSClient. The example is configured to run the client and server on the same machine, but can easily be altered to run on different machines. Both client and server need access to the GAMSRemoteClass that implements the server. The method to communicate is very simple. The client sets up the ingredients for a GAMSJob (model text, GDX input, parameters) and sends them serialized (via a byte representation of the GDX and parameter file) to the server. The server recreates the GAMS objects from the serialized representations, runs the model, and ships GAMSJob.OutDB serialized back to the client for further processing.

See GAMSServer example in [.NET] and GAMSClient in [.NET].

6.1.3.8 Interrupt

Ctrl-C in a regular console application results in the interrupt of the entire job. GAMS users are used to the fact that Ctrl-C interrupts a solve but then continues with the execution of the remaining GAMS job. The example demonstrates how to alter some console properties to get this behavior of Ctrl-C.

See Interrupt example in [.NET, Java, Python].

6.1.3.9 Markowitz

This is a small graphical program that plots the efficient frontier of Markowitz’ portfolio selection problem with the two objectives return and risk. The example utilizes the GAMSModelInstance class to solve the parameterized objective max lambda*return - (1-lambda)*risk in the most efficient way.

See Markowitz example in [.NET, Python].

6.1.3.10 MessageReceiver Window

The little example demonstrates how to implement a custom visual log. From GAMS one can send messages to the form started by this program via the put_utility "winmsg". The form also understands some commands (a message that starts with @) to save the content of the form, to put the content into the clipboard, or to terminate the program. The MessageReceiverWindow is also distributed as an executable in the GAMS system directory ready to be used. The model mrw01 in the GAMS Test Library demonstrates the use of the program.

See MessageReceiver Window example in [.NET].

6.1.3.11 Special Values

This example shows how special values of the programming language (e.g. infinity) percolate down to GAMS. Infinity and NaN (not a number) are well defined. The GAMS Undefined and EPS need special considerations.

See Special Values example in [.NET, Java, Python].
6.1.3.12 Transport Model Sequence

This set of examples demonstrates the use of the Object-oriented API on the simple transport model `transport.gms : A Transportation Problem [transport]`. The detailed description of the various examples is provided in the Object-oriented API tutorials in the GAMS documentation.

See Transport Model example in [.NET, C++, Java, Python].

6.1.3.13 Traveling Salesman Problem

This example demonstrates how to use a GAMSModelInstance to implement the subtour elimination algorithm for the Traveling Salesman Problem (TSP) problem. Similar to Benders2Stage example, we have a placeholder for the subtour elimination constraint that gets generated in each iteration of the algorithm. In contrast to the Benders example, here we regenerate the GAMSModelInstance if the original number of placeholders was not big enough. We continue this process until all subtours are eliminated.

See Traveling Salesman Problem example in [.NET, Java, Python].

6.1.3.14 Unit Test

This example contains all the unit tests we run on the .Net Object-oriented API. See Unit Test example in [.NET].

6.1.3.15 Warehouse

This example demonstrates how to solve a simple GAMS model to assign stores to warehouses for different data sets in parallel. The model has been parameterized. The data can be derived from a few numbers namely the number of warehouses, stores, and some fixed cost scalar. The results of the model are written into a single result database that is protected across the parallel threads via a mutex.

See Warehouse example in [.NET, C++, Java, Python].

6.1.4 Release Notes

GAMS API Release Notes provide an overview of changes to the GAMS APIs in releases of the GAMS distribution.

- .NET API Release Notes
- Java API Release Notes
- Python API Release Notes

6.1.5 Supported Platforms
6.2 Expert-Level APIs

In addition to the object-oriented GAMS API, there exist expert-level (or low-level) APIs to some component libraries of the GAMS system. These APIs are used internally in GAMS for a long time and help in the deployment of GAMS models. While they offer high performance and flexibility, they also require advanced knowledge and it is recommended that the object-oriented GAMS API is used if possible. The expert-level APIs are offered for C, C#, Delphi, Fortran, Java, Python, and Visual Basic.

The DCT, GEV, and GMO components are mainly used to build solver links to GAMS (see, e.g., the GAMSLinks project at COIN-OR for the interfaces to Bonmin, Cbc, Couenne, Ipopt, and SCIP). In fact, all professional GAMS solver links are based on these components. They provide access to an instance of a model generated by a `solve` statement. If you plan to build advanced algorithms for models or need to solve a sequence of very similar models these components might represent an alternative to an implementing using the GAMS language.

While we also strive for backward compatibility with our component libraries, but programming interfaces are commonly subject to change, so programs based on these APIs might require adjustment when updating to a new GAMS version. The Release Notes have a section on these API changes.

Overviews of the exported function in pseudo code are available in the following summary pages:

- **CFG API** (GAMS Configuration Object)
- **DCT API** (GAMS Dictionary Object)
- **GAMSx API** (GAMS Execution Object)
- **GDX API** (GAMS Data Exchange Object) with additional information available as PDF and CHM.
- **GEV API** (GAMS Environment Object) with additional GAMS Environment Object Options.
- **GMO API** (GAMS Modeling Object) with additional information on philosophy and design.
- **IDX API** (GAMS IDX Object)
- **OPT API** (GAMS Option Object)

* Fortran API files are based on C code to load dynamic libraries. For Windows pure Fortran API files for Intel and Lahey Fortran compilers are included.

6.3 C++ API

GAMS C++ API provides a convenient way to exchange input data and model results with in-memory representation of data (GAMSDatabase), and to create and run GAMS models (GAMSJob) that can be customized by GAMS options (GAMSOptions). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (GAMSModelInstance).

6.4 Java API

GAMS Java API provides a Java programming interface to the General Algebraic Model System (GAMS). GAMS Java API objects allow a convenient way to exchange input data and model results with in-memory representation of data (GAMSDatabase), and to create and run GAMS models (GAMSJob) that can be customized by GAMS options (GAMSOptions). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (GAMSModelInstance).

The underlying GAMS engine relies to some extent on file based communication (e.g. the listing file) and other unmanaged resources. The use of external resources in the Java environment requires special attention. Hence, some objects need to be properly disposed before the Java garbage collector does its job.

A GAMS program can include other source files (e.g. $include), load data from GDX files (e.g. $GDXIN or execute $load), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base object GAMSWorkspace manages the anchor to the file system.

With the exception of GAMSWorkspace the objects in the gams namespace cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the GAMSModelInstance class).
6.5 Python API

Note

If you use multiple instances of the GAMSWorkspace in parallel, you should avoid using the same WorkingDirectory. Otherwise you may end up with conflicting file names.

Currently only CplexD, Gurobi, and SoPlex fully utilize the power of solving GAMSModelInstances. Some solvers will not work in a multi-threaded application using GAMSModelInstances. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. Cplex, note there is a thread safe version of Cplex called CplexD which lack some minor features e.g. support for BCH framework). Moreover, GAMSModelInstances are not available for quadratic model types (QCP, MIQCP, RMIQCP).

This version of the GAMS Java API also does not provide support for the following GAMS components: acronyms, GAMS compilation/execution errors, structured access to listing file, and solver options.

6.5 Python API

The gams namespace provides objects to interact with the General Algebraic Modeling System (GAMS). Objects in this namespace allow convenient exchange of input data and model results (GamsDatabase), help to create and run GAMS models (GamsJob), that can be customized by GAMS options (GamsOptions). Furthermore, it introduces a way to solve a sequence of closely related model instances in the most efficient way (GamsModelInstance).

A GAMS program can include other source files (e.g. $include), load data from GDX files (e.g. $GDXIN or execute$load), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base class GamsWorkspace manages the anchor to the file system. If external file communication is not an issue in a particular Python application, temporary directories and files will be managed by objects in the namespace.

With the exception of GamsWorkspace the objects in the gams namespace cannot be accessed across different threads unless the instance is locked. The classes themself are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the GamsModelInstance class).

Note

If you use multiple instances of the GamsWorkspace in parallel, you should avoid using the same working directory. Otherwise you may end up with conflicting file names.

This version of the gams namespace lacks support for the following GAMS components:

Acronyms, support for GAMS compilation/execution errors (GamsJob.run just throws an exception), structured access to listing file, and proper support for solver options.

Currently only CplexD, Gurobi, and SoPlex fully utilize the power of solving GamsModelInstances. Some solvers will not even work in a multi-threaded application using GamsModelInstances. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. Cplex, note there is a thread safe version of Cplex called CplexD which lack some minor features e.g. support for BCH framework). Moreover, GamsModelInstances are not available for quadratic model types (QCP, MIQCP, RMIQCP).
6.6 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS C# API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known transportation problem. These examples introduce several API features step by step.

- **Getting Started** A quick introduction about how to create and configure C# project
- **Important Classes of the API** Overview of some fundamental classes of the GAMS C# API
- **How to use API** An extensive set of examples how to use API components

6.6.1 Getting Started

This section takes you through the basic steps of creating and configuring a C# project in Visual Studio 2010 for use with the GAMS C# API. At the end of this section there is also a paragraph about Mono as an alternative to Microsoft Visual Studio.

6.6.1.1 Open a new Project

After opening Microsoft Visual Studio you can open the New Project wizard by choosing **File > New > Project** from the ribbon menu and type a name for your application, e.g. GAMSApplication.

6.6.1.2 Add a Reference to a Project

Once you opened the project add a reference by a right click on **References** inside the solution explorer. Then choose **Add Reference**, and select the **Browse** tab. Next navigate to the location where you installed GAMS.net4.dll, typically the GAMS system directory, e.g. C:\GAMS\win32\27.3. Then choose GAMS.net4.dll and click **OK**.
6.6.1.3 Solving your first Model

This section illustrates how a model from the GAMS model library can be imported and solved.

Open a new project and reference the GAMS.net4.dll in your project as explained above. Open Program.cs which should be part of your project and replace the content by:

```csharp
using System;
using System.IO;
using System.Collections.Generic;
using System.Text;
using GAMS;

namespace TransportSeq
{
    class Transport0
    {
        static void Main(string[] args)
        {
            GAMSWorkspace ws = new GAMSWorkspace();
            ws.GamsLib("trnsport");

            // create a GAMSJob from file and run it with default settings
            GAMSJob t0 = ws.AddJobFromFile("trnsport.gms");
            t0.Run();

            Console.WriteLine("Ran with Default:");
            foreach (GAMSVariableRecord rec in t0.OutDB.GetVariable("z"))
            Console.WriteLine("z=" + t0.OutDB.GetVariable("z").LastRecord().Level);
        }
    }
}
```
Then click the highlighted button from figure (a) down below or press F5 to start debugging. You can also start the program without debugging by pressing Control + F5 or choosing Debug > Start Without Debugging from the ribbon menu as illustrated in figure (b).

Figure (a)

Figure(b)

By following the latter instruction the command line shell remains open and show the produced output.

6.6.1.4 Mono

The GAMS .NET API works also on non-Windows platforms where no Visual Studio is available. It can be used for example with the open source .Net framework Mono (http://www.mono-project.com). Mono offers a IDE that could be used similarly to Visual Studio. If one prefers to compile and execute from a shell, the following code shows how this can be done using the example Transport1 which comes with the GAMS system (this assumes that xbuild and mono are in the PATH):

```
cd <GAMS Dir>/apifiles/CSharp/Transport1
xbuild /t:rebuild /p:Configuration=Release Transport1.csproj
mono bin/Release/Transport1.exe ../../..
```

6.6.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of examples.

- GAMS Namespace
- GAMSWorkspace Class
- GAMSJob Class
- GAMSDatabase Class
- GAMSOptions Class
- GAMSModelInstance Class

6.6.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the C# API. <GAMS system directory>/apifiles/CSharp contains a file TransportSeq.sln that can be opened in Microsoft Visual Studio. The contained projects deal with the well-known transportation problem. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to choose the GAMS system (Transport1)
- How to export data to GDX (TransportGDX)
- How to import data from GDX (TransportGDX)
6.6.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing Transport1.exe with C:/GAMS/win64/27.3 we use the 64-bit version of GAMS 27.3 to run Transport1 even if our default GAMS system might be a different one. This is managed by the following code:

```csharp
... GAMSWorkspace ws;
if (Environment.GetCommandLineArgs().Length > 1)
    ws = new GAMSWorkspace(systemDirectory: Environment.GetCommandLineArgs()[1]);
else
    ws = new GAMSWorkspace();
...```

Remember that the bitness of the GAMS system has to match the bitness of your .NET program.
6.6.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented .NET API offers much more than exchanging data between .NET and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GAMSDatabase. We assume that the data to be exported is available in .NET data structures.

```csharp
List<string> plants = new List<string>()
{
    "Seattle", "San-Diego"
};
List<string> markets = new List<string>()
{
    "New-York", "Chicago", "Topeka"
};
Dictionary<string, double> capacity = new Dictionary<string, double>()
{
    { "Seattle", 350.0 }, { "San-Diego", 600.0 }
};
Dictionary<string, double> demand = new Dictionary<string, double>()
{
    { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
Dictionary<Tuple<string, string>, double> distance = new Dictionary<Tuple<string, string>, double>()
{
    { new Tuple<string,string>("Seattle", "New-York"), 2.5 },
    { new Tuple<string,string>("Seattle", "Chicago"), 1.7 },
    { new Tuple<string,string>("Seattle", "Topeka"), 1.8 },
    { new Tuple<string,string>("San-Diego", "New-York"), 2.5 },
    { new Tuple<string,string>("San-Diego", "Chicago"), 1.8 },
    { new Tuple<string,string>("San-Diego", "Topeka"), 1.4 }
};

Different GAMS symbols are represented using different .NET data structures. The data for the GAMS sets is represented using lists of strings (e.g. plants and markets). On the other hand, GAMS parameters are represented by dictionaries (e.g. capacity and demand). Note that the representation of the two dimensional parameter distance uses tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with .NET data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.AddDatabase.

```csharp
// prepare a GAMSDatabase with data from the C# data structures
GAMSDatabase db = ws.AddDatabase();
```

We start adding GAMS sets using the method GAMSDatabase.AddSet which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A foreach-loop iterates through plants and adds new records to the recently created GAMSSet instance i using GAMSSet.AddRecord.

```csharp
// add 1-dimensional set 'i' with explanatory text 'canning plants' to the GAMSDatabase
GAMSSet i = db.AddSet("i", 1, "canning plants");
foreach (String p in plants)
i.AddRecord(p);
```

GAMSParameter instances can be added by using the method GAMSDatabase.AddParameter. It has the same signature as GAMSDatabase.AddSet. Anyhow, in this example we use an overload of the method which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.
As soon as all data is prepared in the GAMSDatabase, the method GAMSDatabase.Export can be used to create a GDX file.

```
// export the GAMSDatabase to a GDX file with name 'data.gdx' located in the 'workingDirectory' of the GAMSWorkspace
db.Export("data.gdx");
```

### 6.6.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using `GAMSWorkspace.AddDatabaseFromGDX`. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```
// add a new GAMSDatabase and initialize it from the GDX file just created
GAMSDatabase db2 = ws.AddDatabaseFromGDX("data.gdx");
```

Reading the data from the GAMSSet `i` into a list can be done as follows:

```
// read data from symbols into .NET data structures
List<string> plants2 = new List<string>();
foreach (GAMSSetRecord item in db2.GetSet("i"))
    plants2.Add(item.Key(0));
```

A new list `plants2` is created. `i` is retrieved by calling `GAMSDatabase.GetSet` on `db2`. The returned GAMSSet object can be iterated using a foreach-loop to access the records of the set. Each record is of type GAMSSetRecord and can be asked for its keys.

You can do the same for GAMSParameters. Instead of creating a list, we want to have the data in the form of a dictionary. GAMSParameterRecords can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter `a` into a `Dictionary<string, double>`.

```
Dictionary<string, double> capacity2 = new Dictionary<string, double>();
foreach (GAMSParameterRecord item in db2.GetParameter("a"))
    capacity2.Add(item.Key(0), item.Value);
```

For multi dimensional symbols, we choose the dictionary keys to be tuples instead of string.

```
Dictionary<Tuple<string, string>, double> distance2 = new Dictionary<Tuple<string, string>, double>();
foreach (GAMSParameterRecord item in db2.GetParameter("d"))
    distance2.Add(new Tuple<string, string>(item.Key(0), item.Key(1)), item.Value);
```
6.6.3.4 How to run a GAMSJob from file (Transport1)

Here we load the model transport from the GAMS Model Library. In doing so it is made available in the current working directory and can be loaded by the GAMSWorkspace.AddJobFromFile Method afterwards. Apparently this method also works with any other gms file you might have created on your own as long as it is located in the current working directory. Then the GAMSJob t1 is defined from that file and run by the GAMSJob.Run method.

The following lines create the solution output and illustrate the usage of the GAMSJob.OutDB property to get access to the GAMSDatabase created by the Run method. To retrieve the content of variable x we use the GAMSVariableRecord class and the GAMSDatabase.GetVariable method.

```csharp
...
ws.GamsLib("trnsport");
// create a GAMSJob from file and run it with default settings
GAMSJob t1 = ws.AddJobFromFile("trnsport.gms");
t1.Run();
Console.WriteLine("Ran with Default:");
foreach (GAMSVariableRecord rec in t1.OutDB.GetVariable("x"))
    Marginal);
...
```

6.6.3.5 How to specify the solver (Transport1)

The solver can be specified via the GAMSOptions class and the GAMSWorkspace.AddOptions method. The GAMSOptions.AllModelTypes property sets xpress as default solver for all model types which the solver can handle.

```csharp
...
// run the job again with another solver
using (GAMSOptions opt = ws.AddOptions())
{
    opt.AllModelTypes = "xpress";
    t1.Run(opt);
}
...
```

6.6.3.6 How to run a job with a solver option file (Transport1)

At first we use the StreamWriter to create the file xpress.opt which will be used as solver option file and is stored in the current working directory. Then we write algorithm=barrier to this file and specify the barrier algorithm as algorithm before we close the solver option file. We choose xpress as solver just like in the preceding example and set the GAMSOptions.OptFile Property to 1 to tell the solver to look for a solver option file.

```csharp
...
using (GAMSOptions opt = ws.AddOptions())
{
    optFile.WriteLine("algorithm=barrier");
    optFile.Close();
    opt.AllModelTypes = "xpress";
    opt.OptFile = 1;
    t1.Run(opt);
}
...
6.6.3.7 How to use include files (Transport2)

In this example, as in many preceding, the data text and the model text are separated into two different strings. Note that these strings `GetDataText` and `GetModelText` are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```csharp
{
    writer.Write(GetDataText());
}
```

Afterwards we create a GAMSJob using the `GAMSWorkspace.AddJobFromString` method. The `GAMSOptions.Defines` field is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line.

```csharp
using (GAMSOptions opt = ws.AddOptions())
{
    GAMSJob t2 = ws.AddJobFromString(GetModelText());
    opt.Defines.Add("incname", "tdata");
    t2.Run(opt);
}
```

Note that the string `GetModelText` contains the following lines to read in the data.

```csharp
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
```

6.6.3.8 How to read data from string and export to GDX (Transport3)

We read the data from the string `GetDataText` as we did in the preceding example. Note that this contains no solve statement but only data definition in GAMS syntax. By running the corresponding GAMSJob a GAMSDatabase is created that is available via the `GAMSJob.OutDb` property. We can use the `GAMSDatabase.Export` method to write the content of this database to a gdx file `tdata.gdx`.

```csharp
GAMSJob t3 = ws.AddJobFromString(GetDataText());
t3.Run();
```

6.6.3.9 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in Transport2 - How to use include files (Transport2).

```csharp
t3 = ws.AddJobFromString(GetModelText());
using (GAMSOptions opt = ws.AddOptions())
{
    opt.Defines.Add("gdxincname", "tdata");
    opt.AllModelTypes = "xpress";
    t3.Run(opt);
}
```

Note that there are some changes in `GetModelText` due to the usage of a GDX file instead of an include file.

```csharp
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
```
6.6 Tutorial

6.6.3.10 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two GAMSJobs t3a and t3b where the first one contains only the data and the second one contains only the model without data. After running t3a the corresponding OutDB can be read in directly just like a gdx file. Note that the database needs to be passed to the GAMSJob.Run method as additional argument.

```csharp
... using (GAMSOptions opt = ws.AddOptions())
{
    GAMSJob t3a = ws.AddJobFromString(GetDataText());
    GAMSJob t3b = ws.AddJobFromString(GetModelText());
    t3a.Run();
    opt.Defines.Add("gdxincname", t3a.OutDB.Name);
    opt.AllModelTypes = "xpress";
    t3b.Run(opt, t3a.OutDB);
    ...
}
...```

6.6.3.11 How to define data using C# data structures (Transport4)

We use the List<T> class, the Dictionary<TKey, TValue> class and the Tuple<T1, T2> class to define C# data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```csharp
... List<string> plants = new List<string>()
{ "Seattle", "San-Diego" }
; List<string> markets = new List<string>()
{ "New-York", "Chicago", "Topeka" }
; Dictionary<string, double> capacity = new Dictionary<string, double>()
{ { "Seattle", 350.0 }, { "San-Diego", 600.0 } }
; Dictionary<string, double> demand = new Dictionary<string, double>()
{ { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 } }
; Dictionary<Tuple<string, string>, double> distance = new Dictionary<Tuple<string, string>, double>()
{ { new Tuple<string, string> ("Seattle", "New-York"), 2.5 },
  { new Tuple<string, string> ("Seattle", "Chicago"), 1.7 },
  { new Tuple<string, string> ("Seattle", "Topeka"), 1.8 },
  { new Tuple<string, string> ("San-Diego", "New-York"), 2.5 },
  { new Tuple<string, string> ("San-Diego", "Chicago"), 1.8 },
  { new Tuple<string, string> ("San-Diego", "Topeka"), 1.4 } }
...```

6.6.3.12 How to prepare a GAMSDatabase from C# data structures (Transport4)

At first we create an empty GAMSDatabase db using the GAMSWorkspace.AddDatabase method. Afterwards we prepare the database. To add a set to the database we use the GAMSSet class and the GAMSDatabase.AddSet method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our C# data structure and add them by using the GAMSSet.AddRecord method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2.

The GAMSJob can be run like explained in the preceding example about implicit database communication.

6.6.3.13 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following two lines of code conduct several operations. While the first line simply creates a GAMS Checkpoint, the second one uses the GAMSWorkspace.AddJobFromString method to create a GAMSJob containing the model text and data but no solve statement. In contrast to the preceding examples it runs the job immediately using the GAMSJob.Run method. Furthermore, it passes an additional checkpoint argument to the Run method. That means the GAMSCheckpoint cp captures the state of the GAMSJob.

```csharp
... GAMSCheckpoint cp = ws.AddCheckpoint();
... ws.AddJobFromString(GetModelText()).Run(cp);
...
```

This creates the same checkpoint as for example the following code snippet:

```csharp
GAMSCheckpoint cp = ws.AddCheckpoint();
GAMSJob t5a = ws.AddJobFromString(GetModelText());
t5a.Run(cp);
```

6.6.3.14 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function GetModelText() contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```csharp
Scalar bmult demand multiplier /1/;
... demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
... Scalar ms 'model status', ss 'solve status';
...
```

We create a list with eight different values for this demand multiplier.

```csharp
... Scalar bmult demand multiplier /1/;
... bmult = repeat(1,8);
... demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
... Scalar ms 'model status', ss 'solve status';
...`
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };

For each entry of that list we create a GAMSJob t5 using the GAMSWorkspace.AddJobFromString method. Besides the string which resets the demand multiplier bmult, specifies the solve statement and assigns values to the scalars ms and ss we pass the checkpoint cp as additional argument. This results in a GAMSJob combined from the checkpoint plus the content provided by the string.

We run the GAMSJob and echo some interesting data from the OutDB using the GAMSDatabase.getParameter and GAMSDatabase.GetVariable methods, the GAMSParameter.FindRecord and GAMSVariable.FindRecord methods plus the GAMSParameterRecord.Value property and the GAMSVariableRecord.Level property.

```java
... foreach (double b in bmultlist)
    { GAMSJob t5 = ws.AddJobFromString("bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;", cp);
      t5.Run();
      Console.WriteLine("Scenario bmult=" + b + ":");
      Console.WriteLine(" Modelstatus: " + t5.OutDB.GetParameter("ms").FindRecord().Value);
      Console.WriteLine(" Solvestatus: " + t5.OutDB.GetParameter("ss").FindRecord().Value);
      Console.WriteLine(" Obj: " + t5.OutDB.GetVariable("z").FindRecord().Level);
    }
... 
```

Note

Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

6.6.3.15 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs known from Transport5 in parallel. We initialize the GAMSCheckpoint cp and introduce a demand multiplier as we did before:

```java
... GAMSCheckpoint cp = ws.AddCheckpoint();
ws.AddJobFromString(GetModelText()).Run(cp);
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

Furthermore, we introduce a new object ioMutex that will be used to avoid mixed up output from the parallel jobs. For each element b from the list of demand multipliers we call a delegate of the function RunScenario. Note that these calls are parallel!

```java
...
// run multiple parallel jobs using the created GAMSCheckpoint
Object ioMutex = new Object();
System.Threading.Tasks.Parallel.ForEach(bmultlist, delegate(double b) { RunScenario(ws, cp, ioMutex, b); })
...
```

In function RunScenario a GAMSJob is created and run just like in the preceding example of Transport5. The output section is also the same except for the fact that it is marked as critical section by the lock keyword. That means the delegates of RunScenario are running in parallel but the output block of different delegates cannot be executed in parallel since it is 'locked' by the same object ioMutex for all delegates.
static void RunScenario(GAMSWorkspace ws, GAMSCheckpoint cp, object ioMutex, double b)
{
    GAMSJob t6 = ws.AddJobFromString("bmult=" + b + "; solve transport min z use lp; ns=transport.modelstat; ss=transport.solvestat; ", cp);
    t6.Run();
    // we need to make the output a critical section to avoid messed up report information
    lock (ioMutex)
    {
        Console.WriteLine("Scenario bmult=" + b + ":");
        Console.WriteLine(" Modelstatus: " + t6.OutDB.GetParameter("ms").FindRecord().Value);
        Console.WriteLine(" Solvestatus: " + t6.OutDB.GetParameter("ss").FindRecord().Value);
        Console.WriteLine(" Obj: " + t6.OutDB.GetVariable("z").FindRecord().Level);
    }
}

While the output in Transport5 is strictly ordered subject to the order of the elements of bmultlist, in Transport6 the output blocks might change their order but the blocks describing one scenario are still appearing together due to the lock keyword.

If you want a further impression of the impact of the lock keyword, just rerun Transport6 but comment out the lock as follows and compare the output.

...//lock (ioMutex)
//{
    Console.WriteLine("Scenario bmult=" + b + ":");
    Console.WriteLine(" Modelstatus: " + t6.OutDB.GetParameter("ms").FindRecord().Value);
    Console.WriteLine(" Solvestatus: " + t6.OutDB.GetParameter("ss").FindRecord().Value);
    Console.WriteLine(" Obj: " + t6.OutDB.GetVariable("z").FindRecord().Level);
//}
...

6.6.3.16 How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)

In Transport7 the usage of GAMS::GAMSModelInstance is demonstrated.

At first checkpoint cp is created as in the preceding examples. Then we create the GAMSModelInstance mi using the GAMSCheckpoint.AddModelInstance method. Note that the GAMSJob again contains no solve statement and the demand multiplier is already included with default value 1.

GAMSCheckpoint cp = ws.AddCheckpoint();
GAMSJob t7 = ws.AddJobFromString(GetModelText());
t7.Run(cp);
GAMSModelInstance mi = cp.AddModelInstance();
...

6.6.3.17 How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)

A GAMSModelInstance uses a SyncDB to maintain the data. We define bmult as GAMSParameter using the GAMSDatabase.AddParameter method and specify gurobi as solver. Afterwards the GAMSModelInstance is instantiated with arguments opt and GAMSModifier bmult. The GAMSModifier means that bmult is modifiable while all other parameters, variables and equations of ModelInstance mi stay unchanged. We use the GAMSParameter.AddRecord method to assign a value to bmult that can be varied afterwards using the GAMSParameter.FirstRecord method to reproduce our well-known example with different demand multipliers.
6.6.3.18 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a GAMSModelInstance just like in the next to last example. We define \( x \) as GAMSVariable and its upper bound as GAMSParameter \( xup \). At the following instantiate method GAMSModifier has three arguments. The first one says that \( x \) is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GAMSParameter that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```csharp
... 
mi = cp.AddModelInstance();
GAMSVariable x = mi.SyncDB.AddVariable("x", 2, VarType.Positive, "");
GAMSParameter xup = mi.SyncDB.AddParameter("xup", 2, "upper bound on x");
mi.Instantiate("transport use lp min z", modifiers: new GAMSModifier(x, UpdateAction.Upper, xup));
foreach (GAMSSetRecord i in t7.OutDB.GetSet("i"))
    foreach (GAMSSetRecord j in t7.OutDB.GetSet("j"))
    {
        xup.Clear();
        xup.AddRecord(i.Keys[0], j.Keys[0]).Value = 0;
        mi.Solve();
        Console.WriteLine("Scenario link blocked: " + i.Keys[0] + " - " + j.Keys[0]);
        Console.WriteLine(" Modelstatus: " + mi.ModelStatus);
        Console.WriteLine(" Solvestatus: " + mi.SolveStatus);
        Console.WriteLine(" Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
    }
... 
```

6.6.3.19 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a GAMSCheckpoint \( cp \) from a GAMSJob. Then we define a queue that represents the different values of the demand multiplier. A queue follows the first-in-first-out-principle. The objects queueMutex and ioMutex are used later to avoid messed up output. Then we call two delegates of the function ScenSolve in parallel that get the same queue as argument.

```csharp
... 
GAMSCheckpoint cp = ws.AddCheckpoint();
ws.AddJobFromString(GetModelText()).Run(cp);
Queue<double> bmultQueue = new Queue<double>(new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 });
Object queueMutex = new Object();
Object ioMutex = new Object();
Parallel.For(0, 2, delegate(int i) { ScenSolve(ws, cp, bmultQueue, queueMutex, ioMutex); });
... 
```
In function ScenSolve we create and instantiate a GAMSModelInstance as in the preceding examples and make \texttt{bmult} modifiable. The two delegates of the function extract the elements of the queue using \texttt{bmultQueue.Dequeue}. Note that we chose \texttt{cplexd} as solver because it is thread safe (gurobi would also be possible). Once the queue is empty the loop terminates.

```csharp
private static void ScenSolve(GAMSWorkspace ws, GAMSCheckpoint cp, Queue<double> bmultQueue, Object queueMutex, Object ioMutex, int i)
{
    GAMSModelInstance mi = cp.AddModelInstance();
    GAMSParameter bmult = mi.SyncDB.AddParameter("bmult", 0, "demand multiplier");
    GAMSOptions opt = ws.AddOptions();
    opt.AllModelTypes = "cplexd";
    mi.Instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
    bmult.AddRecord().Value = 1.0;
    while (true)
    {
        double b;
        // dynamically get a bmult value from the queue instead of passing it to the different threads at
        // creation time
        lock (queueMutex)
        {
            if(0 == bmultQueue.Count)
                return;
            b = bmultQueue.Dequeue();
        }
        bmult.FirstRecord().Value = b;
        mi.Solve();
        // we need to make the output a critical section to avoid messed up report informations
        lock (ioMutex)
        {
            Console.WriteLine("Scenario bmult=" + b + ":");
            Console.WriteLine(" Modelstatus: " + mi.ModelStatus);
            Console.WriteLine(" Solvestatus: " + mi.SolveStatus);
            Console.WriteLine(" Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
        }
    }
}
```

6.6.3.20 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a GAMSDatabase. We call a function \texttt{ReadFromAccess} that finally returns a GAMSDatabase as shown below.

```csharp
...
GAMSDatabase db = ReadFromAccess(ws);
...
```

The data we are going to read can be found in `<GAMS system directory>\apifiles\Data\transport.accdb`. It might be helpful to open this file for a better understanding. The function begins with the creation of an empty GAMSDatabase. Afterwards we connect to the MS Access database by first specifying the provider and then defining the aforementioned file as data source. The \texttt{OleDbConnection} represents an open connection to a data source. The following lines initialize the connection and use a try and a catch block for potential exceptions, i.e. errors that occur during application execution. To finally read in GAMS sets and parameters we call the functions \texttt{ReadSet} and \texttt{ReadParameter}. We will use several classes of the \texttt{System.Data.OleDb} namespace that are documented here. Furthermore, we recommend the \texttt{OLE DB Tutorial}.

```csharp
static GAMSDatabase ReadFromAccess(GAMSWorkspace ws)
{
    GAMSDatabase db = ws.AddDatabase();
    // connect to database
    string strAccessConn = "Provider=Microsoft.ACE.OLEDB.12.0;Data Source=..\..\..\..\..\..\Data\transport.accdb";
    OleDbConnection connection = null;
```
6.6 Tutorial

try
{
    connection = new OleDbConnection(strAccessConn);
}
catch (Exception ex)
{
    Console.WriteLine("Error: Failed to create a database connection. 
{0}", ex.Message);
    Environment.Exit(1);
}

// read GAMS sets
ReadSet(connection, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
ReadSet(connection, db, "SELECT Market FROM Market", "j", 1, "markets");

// read GAMS parameters
ReadParameter(connection, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
ReadParameter(connection, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
ReadParameter(connection, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");

return db;

The function ReadSet incorporates a try and a catch block. In the try block we prepare the reading from the MS Access file. Then we add a set symbol to the GAMSDatabase that is filled with the data from the MS Access file afterwards. The function ReadParameter works quite similar.

static void ReadSet(OleDbConnection connect, GAMSDatabase db, string strAccessSelect, string setName, int setDim, string setExp = "")
{
    try
    {
        OleDbCommand cmd = new OleDbCommand(strAccessSelect, connect);
        connect.Open();
        OleDbDataReader reader = cmd.ExecuteReader();

        if (reader.FieldCount != setDim)
        {
            Console.WriteLine("Number of fields in select statement does not match setDim");
            Environment.Exit(1);
        }

        GAMSSet i = db.AddSet(setName, setDim, setExp);
        string[] keys = new string[setDim];
        while (reader.Read())
        {
            for (int idx = 0; idx < setDim; idx++)
            {
                keys[idx] = reader.GetString(idx);
            }
            i.AddRecord(keys);
        }
    }
    catch (Exception ex)
    {
        Console.WriteLine("Error: Failed to retrieve the required data from the DataBase. 
{0}", ex.Message);
        Environment.Exit(1);
    }
    finally
    {
        connect.Close();
    }
}

Once we read in all the data we can create a GAMSJob from the GAMSDatabase and run it as usual.

6.6.3.21 How to fill a GAMSDatabase by reading from MS Excel (Transport10)

This example illustrates how to read data from Excel, or to be more specific, from <GAMS system directory>\apifiles\Data\transport.xls. The model is given as string without data like in in many examples before. At first we have to add
The following lines address the different worksheets and read in the contained data. Afterwards we make an error check to ensure that the number of plants and markets is the same in all worksheets.

```csharp
Excel.Worksheet capacity = (Excel.Worksheet)wb.Worksheets.get_Item("capacity");
range = capacity.UsedRange;
Array capacityData = (Array)range.Cells.Value;
int iCount = capacity.UsedRange.Columns.Count;
Excel.Worksheet demand = (Excel.Worksheet)wb.Worksheets.get_Item("demand");
range = demand.UsedRange;
Array demandData = (Array)range.Cells.Value;
int jCount = range.Columns.Count;
Excel.Worksheet distance = (Excel.Worksheet)wb.Worksheets.get_Item("distance");
range = distance.UsedRange;
Array distanceData = (Array)range.Cells.Value;
// number of markets/plants have to be the same in all spreadsheets
Debug.Assert((range.Columns.Count - 1) == jCount && (range.Rows.Count - 1) == iCount,
"Size of the spreadsheets doesn't match");
```

If you have problems to see through the steps above, adding the following output section right after `wb.Close()` might be helpful to understand where which data is stored.

```csharp
for (int ii = 1; ii <= iCount; ii++)
{
    Console.WriteLine("capacityData(1, " + ii + ") = " + capacityData.GetValue(1, ii));
    Console.WriteLine("capacityData(2, " + ii + ") = " + capacityData.GetValue(2, ii));
}
```

Now we can create the `GAMSWorkspace` as usual and afterwards create a `GAMSDatabase` and fill it with the workbook data as follows:
6.6 Tutorial

```csharp
GMSDatabase db = ws.AddDatabase();
GMSSet Set1 = db.AddSet("i", 1, "Plants");
GMSSet j = db.AddSet("j", 1, "Markets");
GMSParameter capacityParam = db.AddParameter("a", 1, "Capacity");
GMSParameter demandParam = db.AddParameter("b", 1, "Demand");
GMSParameter distanceParam = db.AddParameter("d", 2, "Distance");
for (int ic = 1; ic <= iCount; ic++)
{
    Set1.AddRecord((string)capacityData.GetValue(1, ic));
    capacityParam.AddRecord((string)capacityData.GetValue(1, ic)).Value = (double)capacityData.GetValue(2, ic);
}
for (int jc = 1; jc <= jCount; jc++)
{
    j.AddRecord((string)demandData.GetValue(1, jc));
    demandParam.AddRecord((string)demandData.GetValue(1, jc)).Value = (double)demandData.GetValue(2, jc);
    for (int ic = 1; ic <= iCount; ic++)
    {
        distanceParam.AddRecord((string)distanceData.GetValue(ic + 1, 1), (string)distanceData.GetValue(1, jc + 1)).Value = (double)distanceData.GetValue(ic + 1, jc + 1);
    }
}
```

Note that we can name sets and parameters just like in the database but we don't have to. Now we finally set up the database and can run our `GAMSJob` as usual.

```csharp
... using (GAMSOptions opt = ws.AddOptions())
{
    GAMSJob t10 = ws.AddJobFromString(GetModelText());
    opt.Defines.Add("gdxincname", db.Name);
    opt.AllModelTypes = "xpress";
    t10.Run(opt, db);
    foreach (GAMSVariableRecord rec in t10.OutDB.GetVariable("x"))
    {
    }
}
```

6.6.3.22 How to create and use a save/restart file (Transport11)

In Transport11 we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a `GAMSCheckpoint`.

In the main function we start with the creation of a folder called `tmp` that internally is denoted as `wDir`. Then we call the function `CreateSaveRestart`.

```csharp
... string wDir = Path.Combine('.', "tmp");
CreateSaveRestart(Path.Combine(wDir, "tbase"));
```

In function `CreateSaveRestart` we choose the path of the file given as argument as working directory, so it should be `wDir`. Then we create a `GAMSJob` from a string. Note that the string given via `GetBaseModelText()` contains the basic definitions of sets without giving them a content (that is what `@onempty` is used for). Afterwards we specify a `GAMSOption` to only compile the job but do not execute it. Then we create a `checkpoint` that is initialized by the following run of the `GAMSJob` and stored in the file given as argument to the function. This becomes possible because the `AddCheckpoint` method accepts identifiers as well as file names as argument.
static void CreateSaveRestart(string cpFileName)
{
    GAMSWorkspace ws;
    if (Environment.GetCommandLineArgs().Length > 1)
        ws = new GAMSWorkspace(workingDirectory: Path.GetDirectoryName(cpFileName), systemDirectory:
            Environment.GetCommandLineArgs()[1]);
    else
        ws = new GAMSWorkspace(workingDirectory: Path.GetDirectoryName(cpFileName));
    GAMSJob j1 = ws.AddJobFromString(GetBaseModelText());
    GAMSOptions opt = ws.AddOptions();
    opt.Action = GAMSOptions.EAction.CompileOnly;
    GAMSCheckpoint cp = ws.AddCheckpoint(Path.GetFileName(cpFileName));
    j1.Run(opt, cp);
    opt.Dispose();
}

So what you should keep in mind before we return to further explanations of the main function is, that
now the file tbase in folder tmp which is denoted as wDir contains a checkpoint. Now in the main function
we define some data using C# data structures as we already did in Transport4 before we create the
GAMSWorkspace with working directory wDir.

Afterwards we set up the GAMSDatabase like we already did in Transport4. Once this is done we run a
GAMSJob using this data plus the checkpoint stored in file tbase.

Note that the string from which we create job t4 is different to the one used to prepare the checkpoint
stored in tbase and is only responsible for reading in the data from the GAMSDatabase correctly. The
entire model definition is delivered by the checkpoint cpBase which is equal to the one we saved in tbase.

6.7 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS C++
API. It allows the user to start immediately working with the API by providing a set of small examples
based on the well-known transportation problem. These examples introduce several API features step
by step. The GAMS distribution comes with a pre compiled binary version of the GAMS C++ API
on Windows, Mac OS X and Linux. Furthermore, the C++ API itself and the provided examples are
published under MIT license and are hosted at the GAMS GitHub organization. Therefore it is possible to
compile the library manually (e.g. if a certain compiler is required) The GAMS C++ API is compatible
with C++ 11 and is implemented using the Qt framework

- **Getting Started** A quick introduction about how to create and configure a C++ project using Qt
  Creator
- **Important Classes of the API** Overview of some fundamental classes of the GAMS C++ API
- **How to use API** An extensive set of examples how to use API components
6.7 Tutorial

6.7.1 Getting Started

This section guides you through the basic steps of compiling and running a program from scratch using either Qt Creator or Microsoft Visual Studio. If you want to have a look at the API itself you can directly start with the How to use API section instead. Note that you need to use at least C++ 11 in order to be able to use the GAMS C++ API. While this tutorial uses Qt Creator and Microsoft Visual Studio, other IDE's can be used as well.

Note

When using the pre compiled binary distribution of the GAMS C++ API as done in this section, one needs to use a compiler that is compatible with the one that was used during compilation of the library. Depending on the platform, different versions of the pre build binaries can be found under <GAMS system directory>/apifiles/C++/lib In GAMS versions before 25.0 the binaries can be found under <GAMS system directory>.

6.7.1.1 Getting Started using Qt Creator

After opening Qt Creator click on File > New File or Project. Choose Qt Console Application and click on Choose.... On the next page fill in the name and the location of the new project and click on Next. Select the kits you want to use for the project and click on Next. If you use the precompiled library on Windows, you need to use MSVC2013 Confirm the creation of the new project by clicking on Finish.

As soon as the project is created open the file GAMSApplication.pro by double clicking on it in the pane on the left hand side. Add the following two lines to the .pro file:

unix : LIBS += -ldl -L$(HOME)/gams/gams24_9_linux.x64.sfx -lgamscpp
win32: LIBS += -LC:\GAMS\win64\24.9 -lgamscpp
INCLUDEPATH += C:\GAMS\win64\24.9\apifiles\C++\api

Note

Depending on your operating system and the location of your GAMS system you need to adjust the paths respectively. Furthermore, all pre build binaries are always located at <GAMS system directory>/apifiles/C++/lib, if GAMS 25.0 (or higher) is used. This location may contain additional sub directories, like <GAMS system directory>/apifiles/C++\lib\vs2013. In case a previous version of GAMS is used the binaries are located at <GAMS system directory>.

Save the changes, right click on the project and choose Run qmake.

The last step of creating a first small example is to write code that makes use of the GAMS C++ API. Open the file main.cpp and replace the content of the file with the following lines of code:

```cpp
#include "gams.h"
#include <iostream>
using namespace gams;
using namespace std;

int main(int argc, char* argv[])
{
  GAMSWorkspace ws;
  ws.gamsLib("trnsport");

  // create a GAMSJob from file and run it with default settings
  GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
  t1.run();
  for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
    cout << "x(" << rec.key(0) << "," << rec.key(1) << ") : level=" << rec.level() << " marginal="<
    << rec.marginal() << endl;
}
```

Make sure that MSVC2013 64bit is chosen as kit using the Release mode.

Click on the play button below to run (and compile) the small example. If everything works, you should see the output of the example displaying results of the solved transportation problem.
6.7.1.2 Getting Started using Visual Studio 2013

After opening Visual Studio click on File > New > Project .... Choose Win32 Console Application and fill in the name and the location of the project and click on Next.

Turn off the Precompiled header and confirm with Finish in order to create the project.

As soon as the project is loaded, open the Configuration Manager:

Change the Active solution configuration to Release and the Active solution platform to x64.

The next step is to configure the project to find the GAMS C++ API. Right click on the project and choose Properties from the context menu. Go to Configuration Properties > C/C++ > General and add <GAMS system directory>\apifiles\C++\api to Additional Include Directories.

Go to Configuration Properties > Linker > General and add your <GAMS system directory> to Additional Library Directories (e.g. C:\gams\win64\24.9). Make sure that %%(AdditionalLibraryDirectories) is present as shown in the following picture.

Note

Please mind that the pre build binaries are always located at <GAMS system directory>\apifiles\C++\lib, if GAMS 25.0 (or higher) is used. This location may contain additional sub directories, like <GAMS system directory>\apifiles\C++\lib\vs2013. In case a previous version of GAMS is used the binaries are located at <GAMS system directory>.

Choose Input and add gamscpp.lib to Additional Dependencies and make sure that %%(AdditionalDependencies) is present as well.

The last required configuration step is to add a post-build event that copies required files next to the generated executable. Click on Build Events > Post-Build Event and add the following code to Command Line. Note that you might need to adjust the used path depending on the location of your GAMS installation:

xcopy /Y "C:\gams\win64\24.9\gamscpp.dll" "$OutDir"
xcopy /Y "C:\gams\win64\24.9\Qt*.dll" "$OutDir"

Open the file GAMSApplication.cpp and replace its content by the following code:

```cpp
#include "gams.h"
#include <iostream>
using namespace gams;
using namespace std;

int main(int argc, char* argv[])
{
    GAMSWorkspace ws;
    ws.gamsLib("transport");

    // create a GAMSJob from file and run it with default settings
    GAMSJob t1 = ws.addJobFromFile("transport.gms");
    t1.run();
    for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
        cout << "x(" << rec.key(0) << "," << rec.key(1) << ") = " << rec.level() << " marginal=" << rec.marginal() << endl;
}
```

Click on DEBUG > Start Without Debugging in order to compile and run the example. If everything works, you should see the output of the example displaying results of the solved transportation problem.
6.7.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the gams namespace. Their usage is demonstrated by an extensive set of examples.

- gams Namespace
- gams::GAMSWorkspace Class
- gams::GAMSJob Class
- gams::GAMSDatabase Class
- gams::GAMSOptions Class
- gams::GAMSModelInstance Class
- gams::GAMSSymbol Class

6.7.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the C++ API. `<GAMS system directory>/apifiles/C++` contains the Qt project `examples.pro` and several Visual Studio solutions for different versions of Visual Studio (e.g. `examples-vs2013.sln`, `examples-vs2015.sln`, `examples-vs2017.sln`). The code snippets that are explained in this tutorial are taken from these examples. Furthermore there is a `CMakeLists.txt` file that can be used for building the examples using CMake. The well-known transportation problem is discussed step by step and each example introduces new elements of the GAMS C++ API.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to choose the GAMS system (Transport1)

- How to prepare a GAMSDatabase from C++ data structures (Transport4)
- How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)
- How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)
- How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)
• How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)
• How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)
• How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)
• How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)
• How to fill a GAMSDatabase by reading from MS Access (Transport9)
• How to fill a GAMSDatabase by reading from MS Excel (Transport10)
• How to create and use a save/restart file (Transport11)

6.7.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on
your machine, the desired system can be specified via an additional argument when the workspace is created.
When running the examples, we can provide an additional command line argument in order to define the
GAMS system directory that should be used. By executing Transport1.exe with C:/GAMS/win64/27.3
we use the 64-bit version of GAMS 27.3 to run Transport1 even if our default GAMS system might be a
different one. This is managed by the following code:

```c++
GAMSWorkspaceInfo wsInfo;
if (argc > 1)
  wsInfo.setSystemDirectory(argv[1]);
GAMSWorkspace ws(wsInfo);
```

Remember that the bitness of the GAMS system has to match the bitness of your C++ program.

6.7.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented C++ API offers much more than exchanging data between C++ and
GDX, a common use case is the export and import of GDX files. The central class for this purpose is
GAMSDatabase. We assume that the data to be exported is available in C++ data structures.

```c++
vector<string> plants = {
  "Seattle", "San-Diego"
};
vector<string> markets = {
  "New-York", "Chicago", "Topeka"
};
map<string, double> capacity = {
  {"Seattle", 350.0 }, {"San-Diego", 600.0 }
};
map<string, double> demand = {
  {"New-York", 325.0 }, {"Chicago", 300.0 }, {"Topeka", 275.0 }
};
map<tuple<string, string>, double> distance = {
  {make_tuple("Seattle", "New-York"), 2.5 },
  {make_tuple("Seattle", "Chicago"), 1.7 },
  {make_tuple("Seattle", "Topeka"), 1.8 },
  {make_tuple("San-Diego", "New-York"), 2.8 },
  {make_tuple("San-Diego", "Chicago"), 1.8 },
  {make_tuple("San-Diego", "Topeka"), 1.4 }
};
```
Different GAMS symbols are represented using different C++ data structures. The data for the GAMS sets is represented using vectors of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by maps (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with C++ data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.addDatabase.

```cpp
// create new GAMSDatabase instance
GAMSDatabase db = ws.addDatabase();
```

We start adding GAMS sets using the method `GAMSDatabase.addSet` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created GAMSSet instance `i` using `GAMSSet.addRecord`.

```cpp
// add 1-dimensional set 'i' with explanatory text 'canning plants' to the GAMSDatabase
GAMSSet i = db.addSet("i", 1, "canning plants");
for (string p: plants)
    i.addRecord(p);
```

GAMSParameter instances can be added by using the method `GAMSDatabase.addParameter`. It has the same signature as `GAMSDatabase.addSet`. Anyhow, in this example we use an overload of the method which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```cpp
// add parameter 'a' with domain 'i'
GAMSParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (string p: plants)
    a.addRecord(p).setValue(capacity[p]);
```

As soon as all data is prepared in the GAMSDatabase, the method `GAMSDatabase.doExport` can be used to create a GDX file.

```cpp
// export the GAMSDatabase to a GDX file with name 'data.gdx' located in the 'workingDirectory' of the GAMSWorkspace
db.doExport("data.gdx");
```

### 6.7.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using `GAMSWorkspace.addDatabaseFromGDX`. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```cpp
// add a new GAMSDatabase and initialize it from the GDX file just created
GAMSDatabase db2 = ws.addDatabaseFromGDX("data.gdx");
```

Reading the data from the GAMSSet `i` into a vector can be done as follows:
A new vector `iNew` is created. `i` is retrieved by calling `GAMSDatabase.getSet` on `db2`. The returned `GAMSSet` object can be iterated using a for-loop to access the records of the set. Each record is of type `GAMSSetRecord` and can be asked for its keys.

You can do the same for `GAMSParameters`. Instead of creating a vector, we want to have the data in the form of a map. `GAMSParameterRecords` can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter `a` into a `map<string, double>`.

```cpp
map<string, double> aNew;
for (GAMSParameterRecord rec : db2.getParameter("a"))
    aNew[rec.key(0)] = rec.value();
...
```

For multi dimensional symbols, we choose the map keys to be tuples instead of string. We access the individual keys by index and generate a tuple using `make_tuple`.

```cpp
map<tuple<string, string>, double> dNew;
for (GAMSParameterRecord rec : db2.getParameter("d"))
    dNew[make_tuple(rec.key(0), rec.key(1))] = rec.value();
...
```

Scalars can be read into a variable of type `double` by accessing the value of the first and only record.

```cpp
double fNew = db2.getParameter("f").firstRecord().value();
...
```

### 6.7.3.4 How to run a GAMSJob from file (Transport1)

At first we create a `GAMSWorkspace`. Afterwards we load the model `trnsport` from the GAMS Model Library. In doing so it is made available in the current working directory and can be loaded by the `GAMSWorkspace.AddJobFromFile` Method afterwards. Apparently this method also works with any other `gms` file you might have created on your own as long as it is located in the current working directory. Then the `GAMSJob t1` is defined from that file and run by the `GAMSJob.run` method. The following lines create the solution output and illustrate the usage of the `GAMSJob.outDB` method to get access to the `GAMSDatabase` created by the `run` method. To retrieve the content of variable `x` we use the `GAMSVariableRecord` class and the `GAMSDatabase.getVariable` method.

```cpp
GAMSWorkspace ws;
ws.gamsLib("trnsport");
// create a GAMSJob from file and run it with default settings
GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
// Default run
t1.run();
cout << "Run with Defaults:" << endl;
for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
    cout << rec.key(0) << "," << rec.key(1) << ":" << " " << rec.level() << " marginal" << rec.marginal() << endl;
```
6.7 Tutorial

6.7.3.5 How to specify the solver (Transport1)

The solver can be specified via the GAMSOptions class and the `GAMSWorkspace.addOptions` method. The `GAMSOptions.setAllModelTypes` method sets `xpress` as default solver for all model types which the solver can handle.

```gams
// Run the job again with another solver
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("xpress");
t1.run(opt);
```

6.7.3.6 How to run a job with a solver option file (Transport1)

At first create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. We choose xpress as solver just like in the preceding example and call `GAMSOptions.setOptFile` in order to tell the solver to look for a solver option file.

```gams
// Run the job with a solver option file
ofstream xpressopt(ws.workingDirectory() + cPathSep + "xpress.opt");
xpressopt << "algorithm=barrier" << endl;
xpressopt.close();

opt.setAllModelTypes("xpress");
opt.setOptFile(1);
t1.run(opt);
```

6.7.3.7 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings provided by the methods `getDataText` and `getModelText` are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```gams
// Run the job with another solver
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("xpress");
t1.run(opt);
```

Afterwards we create a `GAMSJob` using the `GAMSWorkspace.addJobFromString` method. The `GAMSOptions.setDefine` method is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line.

```gams
GAMSOptions opt = ws.addOptions();
GAMSJob t2 = ws.addJobFromString(getModelText());
opt.setDefine("incname", "tdata");
t2.run(opt);
```

Note that the string provided by `getModelText` contains the following lines to read in the data.

```gams
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
```
6.7.3.8 How to read data from string and export to GDX (Transport3)

We read the data from the string provided by `getDataText` as we did in the preceding example. Note that this contains no solve statement but only data definition in GAMS syntax. By running the corresponding GAMSJob a GAMSDatabase is created that is available via the GAMSJob.outDb method. We can use the GAMSDatabase.doExport method to write the content of this database to a gdx file `tdata.gdx`.

```gams
// data from a string with GAMS syntax with explicit export to GDX file
GAMSJob t3 = ws.addJobFromString(getDataText());
t3.run();
t3.outDB().doExport(ws.workingDirectory() + cPathSep + "tdata.gdx");
```

6.7.3.9 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in Transport2 - How to use include files (Transport2).

```gams
...  
t3 = ws.addJobFromString(getModelText());
GAMSOptions opt = ws.addOptions();
opt.setDefine("gdxincname", "tdata");
opt.setAllModelTypes(“xpress”);
t3.run(opt);
...
```

Note that there are some changes in `getModelText` due to the usage of a GDX file instead of an include file.

```gams
$if not set gdxincname $abort ‘no include file name for data file provided’
$gdxin %gdxincname%
$load i j a b d f
$gdxin
```

6.7.3.10 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two GAMSJobs `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding `outDB` can be read in directly just like a gdx file. Note that the database needs to be passed to the GAMSJob.run method as additional argument.

```gams
...  
GAMSJob t3a = ws.addJobFromString(getDataText());
GAMSJob t3b = ws.addJobFromString(getModelText());
t3a.run();
opt.setDefine("gdxincname", t3a.outDB().name());
t3b.run(opt, t3a.outDB());
...
6.7 Tutorial

6.7.3.11 How to define data using C++ data structures (Transport4)

We use the `vector<T>` and `map<Key, Value>` to define C++ data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```c++
... vector<string> plants = {
    "Seattle", "San-Diego"
};
vector<string> markets = {
    "New-York", "Chicago", "Topeka"
};
map<string, double> capacity = {
    "Seattle", 350.0 }, {
    "San-Diego", 600.0 
};
map<string, double> demand = {
    "New-York", 325.0 }, {
    "Chicago", 300.0 }, {
    "Topeka", 275.0 
};
map<tuple<string, string>, double> distance = {
    make_tuple("Seattle", "New-York"), 2.5,
    make_tuple("Seattle", "Chicago"), 1.7,
    make_tuple("Seattle", "Topeka"), 1.8,
    make_tuple("San-Diego", "New-York"), 2.5,
    make_tuple("San-Diego", "Chicago"), 1.8,
    make_tuple("San-Diego", "Topeka"), 1.4
};
...
```

6.7.3.12 How to prepare a GAMSDatabase from C++ data structures (Transport4)

At first we create an empty GAMSDatabase `db` using the `GAMSWorkspace.addDatabase` method. Afterwards we prepare the database. To add a set to the database we use the `GAMSSet` class and the `GAMSDatabase.addSet` method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our C++ data structure and add them by using the `GAMSSet.addRecord` method. We do pretty much the same thing for the parameters.

Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that the scalars can be treated as parameter with dimension 0.

The GAMSDJob can be run like explained in the preceding example about implicit database communication.

```c++
... GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "canning plants");
for (string p: plants)
    i.addRecord(p);
...
GAMSPParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (string p: plants)
    a.addRecord(p).setValue(capacity[p]);
...
GAMSPParameter d = db.addParameter("d", "distance in thousands of miles", i, j);
for (auto t : distance)
    d.addRecord(get<0>(t.first), get<1>(t.first)).setValue(t.second);
GAMSPParameter f = db.addParameter("f", "freight in dollars per case per thousand miles");
f.addRecord().setValue(90);
// run a job using data from the created GAMSDatabase
GAMSJob t4 = ws.addJobFromString(getModelText());
GAMSOptions opt = ws.addOptions();
opt.setDefine("gdxincname", db.name());
opt.setAllModelTypes("xpress");
t4.run(opt, db);
...
6.7.3.13 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following two lines of code conduct several operations. While the first line simply creates a GAMS checkpoint, the second one uses the GAMSWorkspace.addJobFromString method to create a GAMSJob containing the model text and data but no solve statement. In contrast to the preceding examples it runs the job immediately using the GAMSJob.run method. Furthermore, it passes an additional checkpoint argument to the run method. That means the GAMSCheckpoint cp captures the state of the GAMSJob.

```
GAMSCheckpoint cp = ws.addCheckpoint();
ws.addJobFromString(getModelText()).run(cp);
```

6.7.3.14 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function getModelText() contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```
Scalar bmult demand multiplier /1/;
... demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
Scalar ms 'model status', ss 'solve status';
... Scalar bmult 'demand multiplier';
```

We create a vector with eight different values for this demand multiplier.

```
vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
```

For each entry of the vector we create a GAMSJob t5 using the GAMSWorkspace.addJobFromString method. Besides the string which resets the demand multiplier bmult, specifies the solve statement and assigns values to the scalars ms and ss we pass the checkpoint cp as additional argument. This results in a GAMSJob combined from the checkpoint plus the content provided by the string.

We run the GAMSJob and echo some interesting data from the outDB using the GAMSDatabase.getParameter and GAMSDatabase.getVariable methods, the GAMSParameter.findRecord and GAMSVariable.findRecord methods plus the GAMSParameterRecord.value and the GAMSVariableRecord.level methods.

```
for (double b : bmultlist)
{
  GAMSJob t5 = ws.addJobFromString("bmult=" + to_string(b) + "; solve transport min z use lp;
ms=transport.modelstat; ss=transport.solvestat;", cp);
t5.run();
cout << "Scenario bmult" << b << ";" << endl;
cout << " Modelstatus: " << t5.outDB().getParameter("ms").findRecord().value() << endl;
cout << " Solvestatus: " << t5.outDB().getParameter("ss").findRecord().value() << endl;
cout << " Obj: " << t5.outDB().getVariable("z").findRecord().level() << endl;
}
```

Note

Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.
6.7.3.15 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs we already know from Transport5 in parallel. We create a GAMSCheckpoint cp and initialize it by running a GAMSJob. Furthermore we introduce a demand multiplier as we did before.

```
GAMSCheckpoint cp = ws.addCheckpoint();
ws.addJobFromModelString(getModelText()).run(cp);
vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
```

Furthermore, we introduce a new object ioMutex that will be used to avoid mixed up output from the parallel jobs. For each element b from the vector of demand multipliers we create a thread executing the runScenario method.

```
// run multiple parallel jobs using the created GAMSCheckpoint
mutex ioMutex;
vector<thread> v;
for(double b : bmultlist)
    v.emplace_back([&ws, cp, &ioMutex, b](
        runScenario(&ws, cp, &ioMutex, b));)
for (auto& t : v)
    t.join();
```

In function runScenario a GAMSJob is created and run just like in the preceding example of Transport5. The output section is also the same except for the fact that it is locked by using a lock guard on the ioMutex. That means the threads of runScenario are running in parallel but the output block of different threads cannot be executed in parallel since it is locked using the same ioMutex.

```
void Transport6::runScenario(GAMSWorkspace* ws, const GAMSCheckpoint& cp, mutex* ioMutex, double b)
{
    auto t6 = ws->addJobFromModelString("bmult=" + to_string(b) + "; solve transport min z use lp;
    ms=transport.modelstat; ss=transport.solvestat;", cp);
    t6.run();
    // we need to make the output a critical section to avoid messed up report information
    lock_guard<mutex> lck(*ioMutex);
    cout << "Scenario bmult" << b << ":" << endl;
    cout << " Modelstatus: " << t6.outDB().getParameter("ms").findRecord().value() << endl;
    cout << " Solvestatus: " << t6.outDB().getParameter("ss").findRecord().value() << endl;
    cout << " Obj: " << t6.outDB().getVariable("z").findRecord().level() << endl;
}
```

While the output in Transport5 is strictly ordered subject to the order of the elements of bmultlist, in Transport6 the output blocks might change their order but the blocks describing one scenario are still appearing together due to the lock guard mechanism.

If you want a further impression of the impact of the lock guard, just rerun Transport6 but comment out the lock guard as follows and compare the output.

```
void Transport6::runScenario(GAMSWorkspace* ws, const GAMSCheckpoint& cp, mutex* ioMutex, double b)
{
    auto t6 = ws->addJobFromModelString("bmult=" + to_string(b) + "; solve transport min z use lp;
    ms=transport.modelstat; ss=transport.solvestat;", cp);
    t6.run();
    // we need to make the output a critical section to avoid messed up report information
    lock_guard<mutex> lck(*ioMutex);
    cout << "Scenario bmult" << b << ":" << endl;
    cout << " Modelstatus: " << t6.outDB().getParameter("ms").findRecord().value() << endl;
    cout << " Solvestatus: " << t6.outDB().getParameter("ss").findRecord().value() << endl;
    cout << " Obj: " << t6.outDB().getVariable("z").findRecord().level() << endl;
}
```

...
6.7.3.16 How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)

In Transport7 the usage of `gams::GAMSModelInstance` is demonstrated.

At first we create a checkpoint `cp` as in the preceding examples. Then we create the GAMSModelInstance `mi` using the `GAMSCheckpoint.addModelInstance` method. Note that the `GAMSJob` again contains no solve statement and the demand multiplier is already included with default value 1.

```cpp
... GAMSCheckpoint cp = ws.addCheckpoint(); GAMSJob t7 = ws.addJobFromString(getModelText()); t7.run(cp); GAMSModelInstance mi = cp.addModelInstance(); ...
```

6.7.3.17 How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)

A GAMSModelInstance uses a syncDB to maintain the data. We define `bmult` as GAMSParameter using the `GAMSDatabase.addParameter` method and specify `cplexd` as solver. Afterwards the GAMSModelInstance is instantiated with three arguments: the solve statement, the `GAMSOptions` object `opt` and `bmult`. The `GAMSModifier` means that `bmult` is modifiable while all other parameters, variables and equations of GAMSModelInstance `mi` stay unchanged.

We use the `GAMSParameter.addRecord` method to assign a value to `bmult` that can be varied afterwards using the `GAMSParameter.firstRecord` method to reproduce our well-known example with different demand multipliers.

```cpp
... GAMSModelInstance mi = cp.addModelInstance(); GAMSParameter bmult = mi.syncDb().addParameter("bmult", 0, "demand multiplier"); GAMSOptions opt = ws.addOptions(); opt.setAllModelTypes("cplexd"); // instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable mi.instantiate("transport use lp min z", opt, GAMSModifier(bmult)); bmult.addRecord().setValue(1.0); vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 }; for (double b : bmultlist) { bmult.firstRecord().setValue(b); mi.solve(); cout << "Scenario bmult= " << b << ": " << endl; cout << " Modelstatus: " << mi.modelStatusAsString() << endl; cout << " Solvestatus: " << mi.solveStatusAsString() << endl; cout << " Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl; }
```

6.7.3.18 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a GAMSModelInstance and define `x` as GAMSVariable and its upper bound as GAMSParameter `xup`. At the following instantiate method `GAMSModifier` has three arguments. The first one says that `x` is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GAMSParameter that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.
6.7 Tutorial

6.7.3.19 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a GAMSCheckpoint \( cp \) from a GAMSJob. Then we define a vector that represents the different values of the demand multiplier. While \( \text{ioMutex} \) is used to avoid messed up output, \( \text{vectorMutex} \) synchronizes the access to the vector. Then we start multiple thread executing the method \( \text{scenSolve} \). The number of parallel executed threads is specified by \( \text{nrThreads} \). All threads share the same vector that provides the different values for \( \text{bmult} \).

```cpp
void Transport8::scenSolve(GAMSWorkspace* ws, GAMSCheckpoint* cp, vector<double>* bmultVector, std::mutex* vectorMutex, std::mutex* ioMutex)
{
    unique_lock<std::mutex> vectorLock(*vectorMutex);
    GAMSModelInstance mi = cp->addModelInstance();
    vectorLock.unlock();
    GAMSParameter bmult = mi.syncDb().addParameter("bmult", "demand multiplier");
    GAMSOptions opt = ws->addOptions();
    opt.setAllModelTypes("cplexd");
    // instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable
    mi.instantiate("transport use lp min z", opt, GAMSModifier(bmult));
    bmult.addRecord().setValue(1.0);
    while (true)
    {
        double b;
    }
}
```

In \( \text{scenSolve} \) we create and instantiate a GAMSModelInstance as in the preceding examples and make \( \text{bmult} \) modifiable. As long as \( \text{bmultVector} \) is not empty, an elements is taken and removed from the vector. The value is used for the scalar \( \text{bmult} \). Note that we chose \( \text{cplexd} \) as solver because it is thread safe (gurobi would also be possible). Once the vector is empty the loop terminates.
// dynamically get a bmult value from the vector instead of passing it to the different threads at
creation time
vectorLock.lock();
if (bmultVector->empty())
    return;
b = bmultVector->back();
bmultVector->pop_back();
vectorLock.unlock();
bmult.firstRecord().setValue(b);
mi.solve();

// we need to make the output a critical section to avoid messed up report informations
unique_lock<mutex> ioLock(*ioMutex);
cout << "Scenario bmult=" << b << ":" << endl;
cout << " Modelstatus: " << mi.modelStatus() << endl;
cout << " Solvestatus: " << mi.solveStatus() << endl;
cout << " Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
ioLock.unlock();
}
}

6.7.3.20 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a GAMSDatabase. It can only be run on Windows since it makes use of the Microsoft Access Driver. Furthermore the example makes use of the Qt SQL module. Note that you need to have Microsoft Access installed and that its bitness needs to match the bitness of your GAMS version. In the example we call a function readFromAccess that finally returns a GAMSDatabase as shown below.

... GAMSDatabase db = readFromAccess(ws);
...

The data we are going to read can be found in <GAMS system directory>\apifiles\Data\transport.accdb. It might be helpful to open this file for a better understanding. The function begins with the creation of an empty GAMSDatabase. Afterwards we create a QSqlDatabase, specify the connection string and open the connection to the database. If opening the connection was successful, data is read from the database into the GAMSDatabase using the methods readSet and readParameter.

GAMSDatabase readFromAccess(GAMSWorkspace ws)
{
    GAMSDatabase db = ws.addDatabase();
    QSqlDatabase sqlDb = QSqlDatabase::addDatabase("QODBC", "readConnection");
    QString strAccessConn = ("Driver={Microsoft Access Driver (*.mdb, *.accdb)};DBQ=" + ws.systemDirectory() + cPathSep + "apifiles" + cPathSep + "Data" + cPathSep + "transport.accdb").c_str();
    sqlDb.setDatabaseName(strAccessConn);
    if(sqlDb.open())
    {
        // read GAMS sets
        readSet(sqlDb, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
        readSet(sqlDb, db, "SELECT Market FROM Market", "j", 1, "markets");

        // read GAMS parameters
        readParameter(sqlDb, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
        readParameter(sqlDb, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
        readParameter(sqlDb, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
        sqlDb.close();
    }
    else
    {
        cout << "Error: Failed to create a database connection. " << sqlDb.lastError().text().toStdString() << endl;
        exit(1);
    }
    return db;
}
The function `readSet` creates a `QSqlQuery` that reads data from a table of the Access database. A `GAMSSet` is created and populated with the data.

```cpp
void readSet(QSqlDatabase sqlDb, GAMSDatabase db, string strAccessSelect, string setName, int setDim, string setExp = "")
{
    QSqlQuery query(sqlDb);
    if (!query.exec(strAccessSelect.c_str()))
    {
        cout << "Error executing query on set'" << setName << "'" << endl;
        cout << query.lastError().text().toStdString() << endl;
        exit(1);
    }
    if (query.size() && (query.record().count() != setDim))
    {
        cout << "Number of fields in select statement does not match setDim" << endl;
        exit(1);
    }
    GAMSSet i = db.addSet(setName, setDim, setExp);
    vector<string> keys = vector<string>(setDim);
    while (query.next())
    {
        for (int idx = 0; idx < setDim; idx++)
            keys[idx] = query.value(idx).toString().toStdString();
        i.addRecord(keys);
    }
}
```

Once we read in all the data we can create a `GAMSJob` from the `GAMSDatabase` and run it as usual. Finally the results are written to `transport.accdb`.

**6.7.3.21 How to fill a GAMSDatabase by reading from MS Excel (Transport10)**

This example illustrates how to read data from Excel, or to be more specific, from `<GAMS system directory>/apifiles/Data/transport.xls`. It can only be run on Windows. Note that you need to have Microsoft Excel installed and that its bitness needs to match the bitness of your GAMS version. The model is given as string without data like in in many examples before. At first we have to add

```bash
#include <QAxObject>
#include <Windows.h>
```

to be able to use the `QAxObject` class, which serves as a wrapper for COM objects. Furthermore we include `Windows.h` to access the functions `CoInitialize` and `CoUninitialize`. In the `main` function we open the aforementioned file to get access to its content. Note that we need to call `CoInitialize(0)` first in order to initialize ActiveX. We create an instance of the class `QAxObject` and use the `querySubObject` method multiple times to get to the sheets of the workbook.

```cpp
QAxObject* excel = new QAxObject( "Excel.Application", 0 );
QAxObject* workbooks = excel->querySubObject( "Workbooks" );
QAxObject* workbook = workbooks->querySubObject( "Open(const QString&)", fileName );
QAxObject* sheets = workbook->querySubObject( "Worksheets" );
```

The method `sheetToParameter` is used in order to transfer data from the workbook into `GAMSPParameter` instances. In order to determine from which sheet the actual data needs to be read, the method takes the `QAxObject` instance referring to the sheets and the actual sheet name. A new `GAMSPParameter` is added to the `GAMSDatabase` object `db` using `set1` and `set2` as domains. The next step is to determine the number of columns and the number of rows used. The `for` loop reads the actual data, adds the records to the new `GAMSPParameter` and sets their values.
GAMSParameter sheetToParameter(QAxObject* sheets, string sheetName, GAMSDatabase db, string paramName, string paramText, GAMSSet set1, GAMSSet set2)
{
    QAxObject* sheet = sheets->querySubObject( "Item( string )", sheetName.c_str() );
    vector<GAMSDomain> sets = {set1, set2};
    GAMSSet param = db.addParameter(paramName, paramText, sets);
    QAxObject* usedrange = sheet->querySubObject( "UsedRange" );
    QAxObject* columns = usedrange->querySubObject("Columns");
    int intCols = columns->property("Count").toInt();
    QAxObject* rows = usedrange->querySubObject("Rows");
    int intRows = rows->property("Count").toInt();

    for (int j = 2; j <= intCols; j++) {
        string namej = sheet->querySubObject("Cells( int, int )", 1, j)->dynamicCall("Value()").toString().toStdString();
        for (int i = 2; i <= intRows; ++i)
        {
            string namei = sheet->querySubObject("Cells( int, int )", i, 1)->dynamicCall("Value()").toString().toStdString();
            GAMSParameterRecord rec = param.addRecord(namei, namej);
            double value = sheet->querySubObject("Cells( int, int )", i, j)->dynamicCall("Value()").toDouble();
            rec.setValue(value);
        }
    }
    return param;
}

After all required data was read from the workbook, we need to close it and quit the Excel application.

workbook->dynamicCall("Close()");
excel->dynamicCall("Quit()");

Now we can create and run the GAMSJob using the created GAMSDatabase as usual.

GAMSOptions opt = ws.addOptions();
GAMSJob t10 = ws.addJobFromString(getModelText());
opt.setDefine("gdxincname", db.name());
opt.setAllModelTypes("xpress");
t10.run(opt, db);
for (GAMSVariableRecord record : t10.outDB().getVariable("x"))
{
    cout << "x(" << record.key(0) << ", " << record.key(1) << ") = " << record.level() << " marginal = " << record.marginal() << endl;
}

Finally we need to call 'CoUninitialize' in order to close the COM library.

::CoUninitialize();

6.7.3.22 How to create and use a save/restart file (Transport11)

In Transport11 we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a GAMSCheckpoint. We start by creating the save/restart file by calling createSaveRestart.

std::string cpName = "tbase";
createSaveRestart(argc, argv, cpName);
In function createSaveRestart we choose the checkpointName as relative path to the current directory in order to create a GAMSWorkspace. Then we create a GAMSJob from a string. Note that the string given via getBaseModelText() contains the basic definitions of sets without giving them a content (that is what $onempty is used for). Afterwards we specify a GAMSOption to only compile the job without executing it. Then we create a checkpoint cp that is initialized by the following run of the GAMSJob and stored in the file given as argument to the function. This becomes possible because the addCheckpoint method accepts identifiers as well as file names as argument.

```cpp
void createSaveRestart(int argc, char* argv[], const string &checkpointName)
{
    GAMSWorkspaceInfo wsInfo;
    if (argc > 1)
        wsInfo.setSystemDirectory(argv[1]);
    wsInfo.setWorkingDirectory(".", +cPathSep + checkpointName);
    GAMSWorkspace ws(wsInfo);
    GAMSJob j1 = ws.addJobFromString(getBaseModelText());
    GAMSOptions opt = ws.addOptions();
    opt.setAction(GAMSOptions::EAction::CompileOnly);
    auto checkpoint = ws.workingDirectory() + cPathSep + checkpointName;
    GAMSCheckpoint cp = ws.addCheckpoint(checkpoint);
    j1.run(opt, cp);
}
```

So what you should keep in mind before we return to further explanations of the main function is, that now the file tbase in folder tbase contains a checkpoint. Now in the main function we define some data using C++ data structures as we already did in Transport4 before we create another GAMSWorkspace.

```cpp
GAMSWorkspaceInfo wsInfo;
if (argc > 1)
    wsInfo.setSystemDirectory(argv[1]);
wsInfo.setWorkingDirectory(".", +cPathSep + cpName);
GAMSWorkspace ws(wsInfo);
...`

Afterwards we set up the GAMSDatabase like we already did in Transport4. Once this is done we run a GAMSJob using this data plus the checkpoint stored in file tbase.

```cpp
GAMSCheckpoint cpBase = ws.addCheckpoint("tbase");
GAMSOptions opt = ws.addOptions();
GAMSJob t4 = ws.addJobFromString(getModelText(), cpBase);
opt.setDefine("gdxincname", db.name());
opt.setAllModelTypes("xpress");
t4.run(opt, db);
for (auto record : t4.outDB().getVariable("x"))
    cout << "x(" << record.key(0) << "," << record.key(1) << "): level=" << record.level() << 
marginal=" << record.marginal() << endl;
...`

Note that the string from which we create job t4 is different to the one used to prepare the checkpoint stored in tbase and is only responsible for reading in the data from the GAMSDatabase correctly. The entire model definition is delivered by the checkpoint cpBase which is equal to the one we saved in tbase.

### 6.7.4 How to use the pre configured example projects

Depending on the operating system, the GAMS C++ API comes with example project configurations for different development tools like CMake, qmake and Visual Studio. They provide an easy way of building and running the distributed GAMS C++ examples and are located in `<GAMS system directory>/apifiles/C++`. 
6.7.4.1 CMake

Windows:
Create build directory

```
  cd <GAMS system directory>|apifiles|C++
mkdir build && cd build
```

Run CMake and build project

```
  cmake -G "Visual Studio 12 2013 Win64" -config Release -DVSVERSION:STRING=vs2013 ..
  msbuild.exe examples.sln /p:Configuration=Release
```

Note
For other Visual Studio versions, the generator-name (-G) needs to be adjusted (see cmake documentation). Leave out the arch flag("Win64") for 32-bit builds

All generated executables can now be found in the CMake build directory. The exact path depends on the project name and the config setting. Assuming the solution was build with -config Release, a transport1.exe executable is located in `<GAMS system directory>|apifiles|C++|build|transport1|Release`. Therefore you can use the following commands to execute the transport1 example:

```
  cd transport1|Release
  set PATH=%PATH%;<GAMS system directory>|apifiles|C++|lib|vs2013
  transport1.exe
```

Linux:
Create build directory

```
  cd <GAMS system directory>|apifiles|C++
mkdir build && cd build
```

Run CMake and build project

```
  cmake ..
  make
```

All generated executables can now be found in the CMake build directory. For every project a subdirectory is created. Assuming you want to execute the transport1 example, use the following commands:

```
  cd transport1
  export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<GAMS system directory>|apifiles|C++|lib
  ./transport1
```

Mac OS X:
Create build directory

```
  cd <GAMS system directory>|apifiles|C++
mkdir build && cd build
```

Run CMake and build project

```
  cmake ..
  make
```

All generated executables can now be found in the CMake build directory. For every project a subdirectory is created. Assuming you want to execute the transport1 example, use the following commands:

```
  cd transport1
  export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:<GAMS system directory>|apifiles|C++|lib
  ./transport1
```
6.7.4.2 qmake

Building the examples can be done by using Qt Creator. Open `<GAMS system directory>\apifiles\C++\examples.pro` with Qt Creator. After the project is loaded, click on Build > Build All in order to compile and link the project. After the build process has carried out, select a subproject and click on Build > Run in order to execute the chosen example.

Alternatively you can run qmake using the command line.

**Windows:**

Create build directory

```
cd <GAMS system directory>\apifiles\C++
mkdir build && cd build
```

Run qmake and build project

```
qmake ..\examples.pro VSVERSION=vs2013
nmake
```

**Note**

For other supported Visual Studio versions change the value of VSVERSION.

All generated executables can now be found in the qmake output directory. In order to execute an example (e.g. transport1) run the following commands:

```
cd ..\bin
set PATH=%PATH%;<GAMS system directory>\apifiles\C++\lib\vs2013
transport1.exe
```

**Linux and Mac OS X:**

In order to run qmake on Linux and Mac OS X refer to the description of using CMake above and call qmake instead of cmake.

6.7.4.3 Microsoft Visual Studio

The Visual Studio solutions are available for Windows only. Open the solution file that matches the version of your Visual Studio installation (e.g. `<GAMS system directory>\apifiles\C++\examples-vs2013.sln`).

As soon as the solution is loaded, click on Build > Configuration Manager and adjust the Active solution configuration and the Active solution platform. The solution configuration needs to be set to Release for using the distributed binaries of the GAMS C++ API. Note that the platform needs to match the version of your GAMS installation.

The examples Transport9 and Transport10 require a Qt installation. If you do not have one, you need to disable these projects. Right click on a project in the Solution Explorer and choose Unload Project from the context menu.

Click on Build > Build Solution in order to compile and link the examples.

**Note**

In some cases the build might return with xcopy errors. Just build the project again. Make sure that you don’t do a rebuild.

In order to run an example, click on Debug > Start Without Debugging. This will execute the current StartUp project. Changing the StartUp project can be achieved by right clicking on a project in the Solution Explorer and choosing Set as StartUp Project.
6.8 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Java API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known transportation problem. These examples introduce several API features step by step.

- **Getting started** A quick introduction about how to compile and run a program from command line or an IDE
- **Important Classes of the API** Overview of some fundamental classes of the GAMS Java API
- **How to use API** An extensive set of examples describing how to use API components

6.8.1 Getting started

A Java program that uses GAMS Java API requires at least Java SE 7 (Since 25.0) to compile and run. For all platforms, assume GAMS system has been installed at [PathToGAMS] directory, called GAMS directory. The directory [PathToGAMS] denotes the path setting according to your GAMS installation on targeted platforms. For instance

- on Windows-based platforms with GAMS distribution 27.3 (32 bits) installed, [PathToGAMS] denotes C:\GAMS\win32\27.3
- on Unix-based platforms with GAMS distribution 27.3 (64 bits) installed, [PathToGAMS] denotes /usr/gams/gams27.3_linux_x64_64_sfx

All GAMS Java API classes are contained within one single jar file GAMSJavaAPI.jar with a namespace com.gams.api. The jar file is distributed with the current GAMS distribution and located at

- on Windows-based platforms:
  
  [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar

- on Unix-based platforms:
  
  [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

There are two different approaches of how to use the GAMS Java API. Either the Java source files can be edited with any common editor and compiled from command line or a Java IDE can be used. The following sections give a quick introduction about the different possibilities.

6.8.1.1 Compiling a Program

To compile a Java program, one usually provides the following information to Java compiler:

- the directory(ies) containing all required Java class files
- the directory to place the generated class files
- the name of the Java source file

A Java program that uses GAMS Java API requires class files that are contained in GAMSJavaAPI.jar for compilation.
6.8 Tutorial

6.8.1.1 Compiling a Program from Command Line  To compile a Java program that uses GAMS Java API, for instance HelloAPI.java, at the command line:

```
javac -cp [CLASSPATH] -d [TARGETDIR] HelloAPI.java
```

where

- [CLASSPATH] is 'GAMSJavaAPI.jar' with its location, as it contains classes files that are used by the program.
- On Windows-based platform, [CLASSPATH] denotes [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar
- On Unix-based platforms, [CLASSPATH] denotes [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

- [TARGETDIR] is the directory to place the generated classe file.

Please note that it is possible to add [CLASSES PATH] to your CLASSPATH environment variable of the operating system as an alternative to specifying -cp [CLASSES PATH]. Also note that -d [TARGETDIR] is optional. In case -d [TARGETDIR] is omitted and the compilation is successful, the class file will be generated and located under the current directory.

To compile other programs, change the arguments accordingly. See also How to compile and run examples from the GAMS system directory.

6.8.1.2 Compiling a Program from Java IDE  In case of compiling a program under a Java IDE (for instance, Eclipse, NetBeans, or IntelliJ), the location of the jar file GAMSJavaAPI.jar shall be added into the Java build path of the IDE’s project properties.

For an Eclipse user, see How to import an Eclipse Java Project from the GAMS system directory.

6.8.2 Running a Program

To run a Java program, one usually provide the following information to Java Virtual Machine:

- the directory(ies) containing all required Java classes
- the directory(ies) containing all required shared libraries
- the name of an entry point class (in most case containing main method)

A Java program that uses GAMS Java API requires a number of shared libraries for establishing a connection with GAMS software components during run time. These shared libraries are platform dependent and they are located at [PathToGAMS]/apifiles/Java/api directory.
6.8.1.2.1 Running a Program from Command Line  To run a Java program that uses GAMS Java API, for instance HelloAPI.class containing in [TARGETDIR] directory, at the command line type:

```
java -cp [CLASSPATH] HelloAPI
```

where

[CLASSPATH] is the list of two paths, a path of 'GAMSJavaAPI.jar' and a path of targeted directory containing 'HelloAPI.class', separated by path separator on the targeted platform.

On Windows-based platform, [CLASSESPATHS] denotes

```
[PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar;[TARGETDIR]
```

On Unix-based platform, [CLASSESPATHS] denotes

```
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar:[TARGETDIR]
```

HelloAPI is the name of an entry point class containing main method.

Please note that it is possible to add [CLASSPATH] to your CLASSPATH environment variable of the operating system as an alternative to specify -cp [CLASSPATH].

Most operations performed by GAMS Java API such as gdx or options operations require shared libraries (located in the folder [PathToGAMS]/apifiles/Java/api by default) when running a program. In case no java.library.path has been specified when running a program, the Java API will determine the path of the shared libraries from the java class path containing GAMSJavaAPI.jar.

Note that it is also possible to pass the following argument to Java Virtual Machine:

```
-Djava.library.path=[LIBRARYPATH]
```

where [LIBRARYPATH] describes the list of paths containing all required shared libraries (as previously mentioned, it is [PathToGAMS]/apifiles/Java/api by default). In such case, the Java API will give priority to the java library path when loading all required JNI libraries during run time. The java API will raise an exception when either the java virtual machine fails to load the required libraries from the specified java library path or there is a version conflict of shared libraries during run time.

To run other programs, change the arguments accordingly. See also How to compile and run examples from the GAMS system directory.

6.8.1.2.2 Running a Program from Java IDE  In case of running a program under a Java IDE (for instance, Eclipse, NetBeans, or IntelliJ), it is possible to set the necessary arguments via the properties of the IDE project.

For an Eclipse user, see How to import an Eclipse Java Project from the GAMS system directory.
6.8.1.3 Setting Up Your Environment

Since 24.3, the GAMS system directory can be specified within the program during run time. Therefore the setting up of execution environment before running a program is no longer required (see also Release Notes 24.3).

Nevertheless, it is still possible to preconfigure the GAMS system directory before running a program and use the default workspace setting within a program. In the default setting, GAMS system directory is not specified by a user within the program. The directory will be searched during run time from environment variable in the following order (depends on the target platform):

- On Windows-based platform: first from PATH environment variable. If not found, from the platform windows registry gams.location,
- On Mac-based platform: first from PATH environment variable. If not found, from DYLD_LIBRARY_PATH,
- On other Unix-based platform: from PATH environment variable. If not found, from LD_LIBRARY_PATH.

The following examples illustrate how to add [PathToGAMS] into the environment variable PATH on different platforms:

- On Windows 2000, XP, Vista, or Windows 7 desktop:
  > right-click on 'My Computer'
  > choose 'Properties' (alternatively, click on 'System' icon in the control panel)
  > click on 'Advanced' tab (or 'Advance system settings')
  > click on 'Environment Variables'
  > edit 'PATH' by adding [PathToGAMS] to the variable using a semi-colon as a separator.

- On Window-based platform via command line terminal:
  ```
  set PATH=[PathToGAMS];%PATH%
  ```

- On Unix-based platform via command line terminal using Bourne shell and its derivatives:
  ```
  export PATH=[PathToGAMS]:${PATH}
  ```

- On Unix-based platform via command line terminal using C Shell:
  ```
  setenv PATH [PathToGAMS]:${PATH}
  ```

6.8.1.4 How to compile and run examples from the GAMS system directory

GAMS provides several examples to demonstrate how to use GAMS Java API. These examples are located in the [PathToGAMS]/apifiles/Java directory containing various examples based on the different optimization problems. The following explanations guide you through the compilation and execution process of one example based on the well-known transportation problem, assuming that Java Runtime System is already installed on your machine.

For instance, Transport1.java under the directory [PathToGAMS]/apifiles/Java/transport demonstrates how to retrieve GAMS transport model from GAMS Model Library, execute the model with various GAMS options, and extract results after execution.

To compile Transport1.java at the command line under the directory [PathToGAMS]/apifiles/Java/transport:
javac -cp [CLASSPATH] -d [TARGETDIR] Transport1.java

where

[CLASSPATH] is a location of ’GAMSJavaAPI.jar’, as it contains classes files that are used by ’Transport1.java’.
On Windows-based platform, [CLASSPATH] denotes
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar;
On Unix-based platforms, [CLASSESPATHS] denotes
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

[TARGETDIR] is the destination directory to place the generated classed file.

As Transport1.java is declared under package com.gams.examples.transport, the output class file will be located in [TARGETDIR] under the directory structure corresponding to package information. This means the compiled output file Transport1.class is located under:

• [TARGETDIR]/com\gams\examples\transport on Windows-based platform, or
• [TARGETDIR]/com/gams/examples/transport on Unix-based platforms.

To run Transport1.class from the command line:

java -cp [CLASSPATH] com.gams.examples.transport.Transport1

where

[CLASSPATH] is the list of two paths, ’GAMSJavaAPI.jar’ with its path and a directory containing ’Transport1.class’ and (in this case [TARGETDIR] from the compilation step), separated by path separator on the targeted platform.
On Windows-based platform, [CLASSESPATHS] denotes
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar;[TARGETDIR]
On Unix-based platforms, [CLASSESPATHS] denotes
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar:[TARGETDIR]

Please note that the path [TARGETDIR] can be either absolute or relative path representing the directory that contains Transport1.class.

To compile and run other examples under the directory [PathToGAMS]/apifiles/Java, adjust the arguments accordingly.

See How to use API for detailed explanations on the series of transportation problem examples located in the folder [PathToGAMS]/apifiles/Java/transport.
6.8.1.5 How to import an Eclipse Java Project from the GAMS system directory

Since GAMS version 24.2 there is an prepared Java project that can be imported into Eclipse. The project is located in folder \[PathToGAMS]/apifiles/Java/Eclipse and contains the examples based on the transportation problem. The following explanations guide you through the import and preparation process, assuming that the Eclipse Java IDE is already installed on your machine.

To import the project located in folder \[PathToGAMS]/apifiles/Java/Eclipse into the workspace:

1. Open the Eclipse IDE with the chosen workspace location, click on File menu and choose Import.
2. In the Import window, choose General > Existing Projects into Workspace then click Next.
3. In the next page of Import window, click Browse.. and select the folder with the prepared project ([PathToGAMS]/apifiles/Java/Eclipse) as root directory.
   We recommend to check for option Copy projects into workspace. Click Finish to finish the Import window.
4. Now the project is imported, and appears in the Package Explorer window on the left hand side of the IDE (shown below with its elements expanded).
5. As every example in the project requires GAMS Java API classes files to compile (all classes are packaged in GAMSJavaAPI.jar located in the folder [PathToGAMS]/apifiles/Java/api), you need to tell eclipse where to find GAMSJavaAPI.jar. To do this, either click on the project then choose Project > Properties or right click on the project name and choose Properties.
6. The Properties window of the project appears. Click Java Build Path on the left of the window, choose Libraries tab, choose Add External JARs... select GAMSJavaAPI.jar located in the folder [PathToGAMS]/apifiles/Java/api to be opened. and click OK to finish adding [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar to Java Build Path.
7. Now all the java files should be successfully compiled without errors except for Transport10 (unsuccessful compilation is denoted with red x mark in front of the file name). This is because Transport10 requires an additional jexcelapi JAR file jxl.jar from jexcelapi. It can be downloaded and unzipped the downloaded archive into a local directory e.g. C:\tools. Then the jar file C:\tools\jexcelapi\jxl.jar can be added to the the Java Build Path of the project in a similar way as explained in 6.
8. To run a transport example, for example Transport1, you need to create a Run Configuration. To do this, either click Run menu and choose Run Configurations... or open the drop down menu next to the run button and click on Run Configurations.... Then create a new run configuration by either press the New button in the left hand side of the window or right click at Java Application in the left hand side of the window and choose New.
9. The run configuration for Transport1 appears.
   For each run configuration it is possible to configure the execution of a program, such as the arguments of the virtual machine, class paths, environment variables and so on.
   For instance, to specify the java.library.path for Transport1 run configuration, choose Arguments tab in the run configuration and specify -Djava.library.path=[PathToGAMS]/apifiles/Java/api as one of the VM arguments. Then Click Apply and Run.

Note that the run configuration described in 8. and 9. is needed to be set for every single example. Once this is done you should be able to use the run configuration to repeat the execution of all the transport examples.

For a more detailed explanations on each transport examples see How to use API.
6.8.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of examples. All GAMS Java API classes are contained within one single jar file \texttt{GAMSJavaAPI.jar} with a namespace \texttt{com.gams.api}. It provides objects to interact with the General Algebraic Modeling System (GAMS). Objects in this namespace allow convenient exchange of input data and model results (GAMSDatabase) and help to create and run GAMS models (GAMSJob), that can be customized by GAMS options (GAMSOptions). Furthermore, it introduces a way to solve a sequence of closely related models in the most efficient way (GAMSModelInstance).

Other classes are GAMSWorkspace, GAMSOptions, GAMSSymbol, and GAMSException.

6.8.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the Java API. \texttt{[PathToGAMS]/apifiles/Java/transport} contains multiple examples dealing with the well-known transportation problem. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to choose the GAMS system (Transport1)
- How to export data to GDX (TransportGDX)
- How to import data from GDX (TransportGDX)
- How to run a GAMSJob from file (Transport1)
- How to retrieve a solution from an output database (Transport1)
- How to specify the solver using GAMSOptions (Transport1)
- How to run a job with a solver option file (Transport1)
- How to use include files (Transport2)
- How to set a non-default working directory (Transport3)
- How to read data from string and export to GDX (Transport3)
- How to run a job using data from GDX (Transport3)
- How to run a job using implicit database communication (Transport3)
- How to define data using Java data structures (Transport4)
- How to prepare a GAMSDatabase from Java data structures (Transport4)
- How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)
- How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)
- How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)
- How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)
- How to modify a parameter of a GAMSModelInstance using GAMSMODifier (Transport7)
- How to modify a variable of a GAMSModelInstance using GAMSMODifier (Transport7)
- How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)
- How to fill a GAMSDatabase by reading from MS Access (Transport9)
- How to fill a GAMSDatabase by reading from MS Excel (Transport10)
- How to create and use a save/restart file (Transport11)
6.8.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing Transport1 with C:/GAMS/win64/27.3 we use the 64-bit version of GAMS 27.3 to run Transport1 even if our default GAMS system might be a different one. This is managed by the following code:

```java
...
GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
if (args.length > 0)
    wsInfo.setSystemDirectory( args[0] );
GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
...
```

Remember that the bitness of the GAMS system has to match the bitness of your Java Runtime Environment.

6.8.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented Java API offers much more than exchanging data between Java and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GAMSDatabase. We assume that the data to be exported is available in Java data structures.

```java
...
List<String> plants = Arrays.asList(“Seattle”, “San-Diego”);
List<String> markets = Arrays.asList(“New-York”, “Chicago”, “Topeka”);
Map<String, Double> capacity = new HashMap<String, Double>();
    capacity.put(“Seattle”, Double.valueOf(350.0));
    capacity.put(“San-Diego”, Double.valueOf(600.0));
Map<String, Double> demand = new HashMap<String, Double>();
    demand.put(“New-York”, Double.valueOf(325.0));
    demand.put(“Chicago”, Double.valueOf(300.0));
    demand.put(“Topeka”, Double.valueOf(275.0));
Map<Vector<String>, Double> distance = new HashMap<Vector<String>, Double>();
    distance.put( new Vector<String>(Arrays.asList(new String[]{“Seattle”, “New-York”})), Double.valueOf(2.5));
    distance.put( new Vector<String>(Arrays.asList(new String[]{“Seattle”, “Chicago”})), Double.valueOf(1.7));
    distance.put( new Vector<String>(Arrays.asList(new String[]{“Seattle”, “Topeka”})), Double.valueOf(1.8));
    distance.put( new Vector<String>(Arrays.asList(new String[]{“San-Diego”, “New-York”})), Double.valueOf(2.5));
    distance.put( new Vector<String>(Arrays.asList(new String[]{“San-Diego”, “Chicago”})), Double.valueOf(1.8));
    distance.put( new Vector<String>(Arrays.asList(new String[]{“San-Diego”, “Topeka”})), Double.valueOf(1.4));
...
```

Different type of GAMS symbols are represented using different Java data structures. The data for the GAMS sets is represented using List of Strings (e.g. plants and markets). On the other hand, GAMS parameters are represented by Map (e.g. capacity and demand). Note that the representation of the two dimensional parameter distance uses Vectors for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with Java data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.addDatabase.
// create new GAMSDatabase instance
GAMSDatabase db = ws.addDatabase();

We start adding GAMS sets using the method GAMSDatabase.addSet which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through plants and adds new records to the recently created GAMSSet instance i using GAMSSet.addRecord.

GAMSSet i = db.addSet("i", 1, "canning plants");
for(String p : plants)
  i.addRecord(p);

GAMSParameter instances can be added by using the method GAMSDatabase.addParameter. In this example we use the overloaded method which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

GAMSParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (String p : plants)
  a.addRecord(p).setValue( capacity.get(p) );

As soon as all data is prepared in the GAMSDatabase, the method GAMSDatabase.export can be used to create a GDX file.

db.export("data.gdx");

6.8.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using GAMSWorkspace.addDatabaseFromGDX. The method takes a path to a GDX file and creates a GAMSDatabase instance.

GAMSDatabase gdxdb = ws.addDatabaseFromGDX("data.gdx");

Reading the data from the GAMSSet i into a List of Strings can be done as follows:

List<String> gdxPlants = new ArrayList<String>();
for(GAMSSetRecord rec : gdxdb.getSet("i"))
  gdxPlants.add(rec.getKey(0));

A new List gdxPlants is created. i is retrieved by calling GAMSDatabase.getSet on gdxdb. The returned GAMSSet object can be iterated using a for-loop to access the records of the set. Each record is of type GAMSSetRecord and can be asked for its keys.

You can do the same for GAMSParameter. Instead of creating a List, we want to have the data in the form of a Map. GAMSParameterRecord can not only be asked for its keys, but also for its value. The following code snippet shows how to read the one dimensional parameter a into a Map<String, Double>.
Map<String, Double> gdxCapacity = new HashMap<String, Double>();
for(GAMSParameterRecord rec : gdxdb.getParameter("a")
    gdxCapacity.put(rec.getKey(0), rec.getValue());
}

For a key of multi dimensional symbol, we choose Vector of String instead of String.

Map<Vector<String>, Double> gdxDistance = new HashMap<Vector<String>, Double>();
for(GAMSParameterRecord rec : gdxdb.getParameter("d")
    gdxDistance.put( new Vector<String>( Arrays.asList(new String[]{
        rec.getKey(0), rec.getKey(1)} ) ), rec
        .getValue());
}

Scalar can be read into a variable of type double by accessing the value of the first and only record.

double gdxFreight = gdxdb.getParameter("f").getFirstRecord().getValue();

6.8.3.4 How to run a GAMSJob from file (Transport1)

At first we create our workspace using GAMSWorkspace ws = new GAMSWorkspace();. Afterward we can create a GAMSJob t1 using the addJobFromGamsLib method and run it.

Apparently you can create a GAMSJob with any other gms file you might have created on your own as long as it is located in the current working directory. Then the GAMSJob t1 can be defined using the GAMSJob.addJobFromFile method.

// create GAMSWorkspace "ws" with default working directory
// (the directory named with current date and time under System.getProperty("java.io.tmpdir"))
GAMSWorkspace ws = new GAMSWorkspace();

// create GAMSJob "t1" from "transport" model in GAMS Model Libraries
GAMSJob t1 = ws.addJobFromGamsLib("transport");
// run GAMSJob "t1"
t1.run();

See also Transport1.java.

6.8.3.5 How to retrieve a solution from an output database (Transport1)

The following lines create the solution output and illustrate the usage of the GAMSJob.OutDB property to get access to the GAMSDatabase created by the run method. To retrieve the content of variable x we use the getVariable method and the GAMSVariableRecord class.

System.out.println("Ran with Default:");
GAMSVariable x = t1.OutDB().getVariable("x");
for (GAMSVariableRecord rec : x)
{ System.out.print("x(" + rec.getKeys()[0] + ", " + rec.getKeys()[1] + ") = ");
    System.out.print("level = " + rec.getLevel());
    System.out.print("marginal = " + rec.getMarginal());
}

See also Transport1.java.
6.8.3.6 How to specify the solver using GAMSOptions (Transport1)

The solver can be specified via the GAMSOptions class and the GAMSWorkspace.addOptions method. The GAMSOptions.setAllModelTypes property sets xpress as default solver for all model types which the solver can handle. Then we run our GAMSJob t1 with the new GAMSOptions.

```java
// create GAMSOptions "opt1"
GAMSOptions opt1 = ws.addOptions();
// set all model types of "opt1" for "xpress"
opt1.setAllModelTypes("xpress");
// run GAMSJob "t1" with GAMSOptions "opt1"
t1.run(opt1);
```

See also Transport1.java.

6.8.3.7 How to run a job with a solver option file (Transport1)

At first we create the file xpress.opt with content algorithm=barrier which will be used as solver option file and is stored in the current working directory. Afterward we use a GAMSOptions just like in the preceding example and GAMSOptions.setOptFile property to 1 to tell the solver to look for a solver option file.

```java
// write file "xpress.opt" under GAMSWorkspace's working directory
try {
    BufferedWriter optFile = new BufferedWriter(new FileWriter(
        ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "xpress.opt"));
    optFile.write("algorithm=barrier");
    optFile.close();
} catch (IOException e) {
    e.printStackTrace();
    System.exit(-1);
}
// create GAMSOptions "opt2"
GAMSOptions opt2 = ws.addOptions();
// set all model types of "opt2" for "xpress"
opt2.setAllModelTypes("xpress");
// for "opt2", use "xpress.opt" as solver's option file
opt2.setOptFile(1);
// run GAMSJob "t2" with GAMSOptions "opt2"
t1.run(opt2);
```

See also Transport1.java.

6.8.3.8 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings data and model are using GAMS syntax.

At first we write an include file tdata.gms that contains the data but not the model text:

```java
try {
    BufferedWriter file = new BufferedWriter(new FileWriter(
        ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "tdata.gms"));
    file.write(data);
    file.close();
} catch (IOException e) {
    e.printStackTrace();
    System.exit(-1);
}
```
Afterwards we create a **GAMSJob** using the **GAMSWorkspace.addJobFromString** method. **GAMSOptions.defines** is used like the 'double dash' GAMS parameters, i.e. it corresponds to **--incname=tdata** on the command line where incname is used as name for the include file in the **model** string.

```java
...
// create GAMSJob "t2" from the "model"
GAMSJob t2 = ws.addJobFromString(model);
// create GAMSOption "opt" and define "incname" as "tdata"
GAMSOptions opt = ws.addOptions();
opt.defines("incname", "tdata");
// run GAMSJob "t2" with GAMSOptions "opt"
t2.run(opt);
...
```

The string model contains the following lines to read in the data.

```java
...
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
...
```

See also **Transport2.java**.

### 6.8.3.9 How to set a non-default working directory (Transport3)

At first we create a new directory. Once this is done we can use this directory when creating the **GAMSWorkspace** and make it the working directory.

```java
...
// create a directory
File workingDirectory = new File(System.getProperty("user.dir"), "Transport3");
workingDirectory.mkdir();
// create a workspace
GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());
GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
...
```

See also **Transport3.java**.

### 6.8.3.10 How to read data from string and export to GDX (Transport3)

We read the data from the string data. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding **GAMSJob** a **GAMSDatabase** is created that is available via the **GAMSJob.OutDB** property. We can use the **GAMSDatabase.export** method to write the content of this database to a gdx file **tdata.gdx**.

```java
...
// Create and run a job from a data file, then explicitly export to a GDX file
gamsJob t3 = ws.addJobFromString(data);
t3.run();
t3.OutDB().export( ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "tdata.gdx" );
...
```

See also **Transport3.java**.
6.8.3.11 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in Transport2 - How to use include files (Transport2).

... // run a job using an instance of GAMSOptions that defines the data include file
t3 = ws.addJobFromString(model);
GAMSOptions opt = ws.addOptions();
opt.defines("gdxincname", "tdata");
t3.run(opt);
...

Note that there are some minor changes in model due to the usage of a gdx instead of an include file.

... $if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
...

See also Transport3.java.

6.8.3.12 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two GAMSJobs t3a and t3b where the first one contains only the data and the second one contains only the model without data. After running t3a the corresponding OutDB can be read in directly just like a gdx file. Note that the database needs to be passed to the GAMSJob.run method as additional argument.

... GAMSVariable x = t3.OutDB().getVariable("x");
for (GAMSVariableRecord rec : x)
    System.out.println("x(" + rec.getKeys()[0] + ", " + rec.getKeys()[1] + "): level=" + rec.getLevel() + ", marginal=" + rec.getMarginal());
System.out.println();

// similar to the previous run but without exporting database into a file
GAMSJob t3a = ws.addJobFromString(data);
GAMSJob t3b = ws.addJobFromString(model);
opt = ws.addOptions();
t3a.run();
opt.defines("gdxincname", t3a.OutDB().getName());
t3b.run(opt, t3a.OutDB());
...

See also Transport3.java.
6.8.3.13 How to define data using Java data structures (Transport4)

We use the `List<E>` class and the `Map<Key,Value>` to define Java data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```java
// prepare input data
List<String> plants = Arrays.asList("Seattle", "San-Diego");
List<String> markets = Arrays.asList("New-York", "Chicago", "Topeka");
Map<String, Double> capacity = new HashMap<String, Double> {
    capacity.put("Seattle", Double.valueOf(350.0));
    capacity.put("San-Diego", Double.valueOf(600.0));
};
Map<String, Double> demand = new HashMap<String, Double> {
    demand.put("New-York", Double.valueOf(325.0));
    demand.put("Chicago", Double.valueOf(300.0));
    demand.put("Topeka", Double.valueOf(275.0));
};
Map<Vector<String>, Double> distance = new HashMap<Vector<String>, Double> {
    distance.put(
        new Vector<String>(Arrays.asList(new String[] {"Seattle", "New-York"})),
        Double.valueOf(2.5));
    distance.put(
        new Vector<String>(Arrays.asList(new String[] {"Seattle", "Chicago"})),
        Double.valueOf(1.7));
    distance.put(
        new Vector<String>(Arrays.asList(new String[] {"Seattle", "Topeka"})),
        Double.valueOf(1.8));
    distance.put(
        new Vector<String>(Arrays.asList(new String[] {"San-Diego", "New-York"})),
        Double.valueOf(2.5));
    distance.put(
        new Vector<String>(Arrays.asList(new String[] {"San-Diego", "Chicago"})),
        Double.valueOf(1.8));
    distance.put(
        new Vector<String>(Arrays.asList(new String[] {"San-Diego", "Topeka"})),
        Double.valueOf(1.4));
};
 ...
```

See also `Transport4.java`.

6.8.3.14 How to prepare a GAMSDatabase from Java data structures (Transport4)

At first we create an empty `GAMSDatabase db` using the `GAMSWorkspace.addDatabase` method. Afterwards we prepare the database. To add a set to the database we use the `GAMSSet` class and the `GAMSDatabase.addSet` method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Java data structure and add them by using the `GAMSSet.addRecord` method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that scalars can be treated as parameter with dimension 0.

The `GAMSJob` can be run like explained in the preceding example about implicit database communication.

```java
// add a database and add input data into the database
GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "canning plants");
for(String p : plants)
    i.addRecord(p);
GAMSSet j = db.addSet("j", 1, "markets");
for(String m : markets)
    j.addRecord(m);
GAMSSet a = db.addParameter("a", 1, "capacity of plant i in cases");
for (String p : plants)
    a.addRecord(p).setValue(capacity.get(p));
```
GAMSParameter b = db.addParameter("b", 1, "demand at market j in cases");
for(String m : markets)
    b.addRecord(m).setValue( demand.get(m) );
GAMSParameter d = db.addParameter("d", 2, "distance in thousands of miles");
for(Vector<String> vd : distance.keySet())
    d.addRecord(vd).setValue( distance.get(vd).doubleValue() );
GAMSParameter f = db.addParameter("f", 0, "freight in dollars per case per thousand miles");
f.addRecord().setValue( 90 );

// create and run a job from the model and read gdx include file from the database
GAMSJob t4 = ws.addJobFromString(model);
GAMSOptions opt = ws.addOptions();
opt.defines("gdxincname", db.getName());
t4.run(opt, db);

See also Transport4.java.

6.8.3.15 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following lines of code conduct several operations. While the first line simply creates a GAMSCheckpoint, the second one uses the GAMSWorkspace.addJobFromString method to create a GAMSJob containing the model text and data but no solve statement. Afterwards the run method gets the GAMSCheckpoint as argument. That means the GAMSCheckpoint cp captures the state of the GAMSJob.

... 
GAMSCheckpoint cp = ws.addCheckpoint();
GAMSJob t5 = ws.addJobFromString(model);
t5.run(cp);
...

See also Transport5.java.

6.8.3.16 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function model contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

... 
Scalar bmult demand multiplier /1/;
...
  demand(j) .. sum(i, x(i,j)) =g= bmult*b(j); 
...
Scalar ms 'model status', ss 'solve status';
...

In Transport5 we create a list with eight different values for this demand multiplier.

... 
  double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 }; 
...
For each entry of that list we create a **GAMSJob** `t5` using the `GAMSWorkspace.addJobFromString` method. Besides another string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a **GAMSJob** combined from the checkpoint plus the content provided by the string. We run the **GAMSJob** and echo some interesting data from the `OutDB` using the `GAMSDatabase.getParameter` and `GAMSDatabase.getVariable` methods, the `GAMSParameter.findRecord` and `GAMSVariable.findRecord` methods plus the `GAMSParameterRecord.getValue` property and the `GAMSVariableRecord.getLevel` method.

```java
...
// create a new GAMSJob that is initialized from the GAMSCheckpoint
for(double b : bmultlist)
{
    t5 = ws.addJobFromString(
        "bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvstatus;",
        cp);
    t5.run();
    System.out.println("Scenario bmult=" + b + ":");
    System.out.println(" Modelstatus: " + GAMSGlobals.ModelStat.lookup((int) t5.OutDB().getParameter("ms").findRecord().getValue()));
    System.out.println(" Solvestatus: " + GAMSGlobals.SolveStat.lookup((int)t5.OutDB().getParameter("ss").findRecord().getValue()));
    System.out.println(" Obj: " + t5.OutDB().getVariable("z").findRecord().getLevel());
}
...
```

**Note**

Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

See also **Transport5.java**.

### 6.8.3.17 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs known from **Transport5** in parallel. We initialize the **GAMSCheckpoint** `cp` and introduce a demand multiplier as we did before:

```java
...
GAMSJob t6 = ws.addJobFromString(model);
t6.run(cp);
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

Furthermore, we introduce a new object `lockObject` that will be used to avoid mixed up output from the parallel jobs. We create one scenario for each entry of `bmultlist` and cause a thread to begin execution.

```java
... // run multiple parallel jobs using the created checkpoint
Object lockObject = new Object();
Scenario[] scenarios = new Scenario[bmultlist.length];
for (int i=0; i<bmultlist.length; i++)
{
    scenarios[i] = new Scenario(ws, cp, lockObject, bmultlist[i]);
    scenarios[i].start();
}
...
In class `Scenario` a `GAMSJob t6` is created and run just like in the preceding example of `Transport5`. The output section is also the same except for the fact that it is 'locked' by the object `lockObject` which means that the output section cannot be executed simultaneously for multiple demand multipliers.

```java
static class Scenario extends Thread {
    GAMSWorkspace workspace;
    GAMSCheckpoint checkpoint;
    Object lockObject;
    double bmult;
    public Scenario(GAMSWorkspace ws, GAMSCheckpoint cp, Object lockObj, double b) {
        workspace = ws;
        checkpoint = cp;
        lockObject = lockObj;
        bmult = b;
    }
    public void run() {
        GAMSJob t6 = workspace.addJobFromString("bmult=" + bmult + "; solve transport min z use lp;
ms=transport.modelstat; ss=transport.solvestat;",
               checkpoint);
        t6.run();
        synchronized (lockObject) {
            System.out.println("Scenario bmult=" + bmult + ":");
            System.out.println(" Modelstatus: " + GAMSGlobals.ModelStat.lookup((int)t6.OutDB().getParameter("ms").findRecord().getValue()));
            System.out.println(" Solvestatus: " + GAMSGlobals.SolveStat.lookup((int)t6.OutDB().getParameter("ss").findRecord().getValue()));
            System.out.println(" Obj: " + t6.OutDB().getVariable("z").findRecord().getLevel());
        }
    }
}
```

While the output in `Transport5` is strictly ordered subject to the order of the elements of `bmultlist` in `Transport6` the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `lockObject`.

If you want a further impression of the impact of the `lockObject`, just rerun `Transport6` but comment out the lock as follows and compare the output.

```java
// synchronized (lockObject)
// {
    System.out.println("Scenario bmult=" + bmult + ":");
    System.out.println(" Modelstatus: " + GAMSGlobals.ModelStat.lookup((int)t6.OutDB().getParameter("ms").findRecord().getValue()));
    System.out.println(" Solvestatus: " + GAMSGlobals.SolveStat.lookup((int)t6.OutDB().getParameter("ss").findRecord().getValue()));
    System.out.println(" Obj: " + t6.OutDB().getVariable("z").findRecord().getLevel());
// }
```

See also `Transport6.java`. 
6.8.3.18 How to create a `GAMSModelInstance` from a `GAMSCheckpoint` (Transport7)

In `Transport7` the usage of `com::gams::api::GAMSModelInstance` is demonstrated.

At first checkpoint `cp` is created as in the preceding examples. Then we create the `GAMSModelInstance mi` using the `GAMSCheckpoint.addModelInstance` method. Note that the `GAMSJob` again contains no solve statement and the demand multiplier is already included with default value 1.

```java
GAMSCheckpoint cp = ws.addCheckpoint();
// initialize a checkpoint by running a job
GAMSJob t7 = ws.addJobFromString(model);
t7.run(cp);
GAMSModelInstance mi = cp.addModelInstance();
```

See also `Transport7.java`.

6.8.3.19 How to modify a parameter of a `GAMSModelInstance` using `GAMSModifier` (Transport7)

A `GAMSModelInstance` uses a `SyncDB` to maintain the data. We define `bmult` as `GAMSParameter` using the `GAMSParameter` method and specify gurobi as solver. Afterwards the `GAMSModelInstance` is instantiated with 3 arguments, the solve statement, `GAMSOptioons opt` and `GAMSModifier bmult`. The `GAMSModifier` means that `bmult` is modifiable while all other parameters, variables and equations of ModelInstance `mi` stay unchanged. We use the `GAMSParameter.addRecord` method and the `setValue` function to assign a value to `bmult`. That value can be varied afterwards using the `GAMSParameter.getFirstRecord` method to reproduce our well-known example with different demand multipliers.

```java
GAMSParameter bmult = mi.SyncDB().addParameter("bmult", 0,"demand multiplier");
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("gurobi");
// instantiate the ModelInstance and pass a model definition and Modifier to declare bmult mutable
mi.instantiate(\"transport use lp min z\", opt, new GAMSModifier(bmult));
bmult.addRecord().setValue(1.0);
```

```java
double[] bmultlist = new double[] { 0.6, 0.7 , 0.8, 0.9, 1.0,1.1, 1.2, 1.3 };
for (double b : bmultlist) {
    bmult.getFirstRecord().setValue( b );
    mi.solve();
    System.out.println("Scenario bmult=" + b + ":");
    System.out.println("Modelstatus: "+ mi.getModelStatus());
    System.out.println(" Solvestatus: "+ mi.getSolveStatus());
    System.out.println(" Obj: "+ mi.SyncDB().getVariable(\"z\").findRecord().getLevel());
}
```

See also `Transport7.java`.  

6.8.3.20 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a GAMSModelInstance just like in the next to last example. We define \( x \) as GAMSVariable and its upper bound as GAMSParameter \( \text{xup} \). At the following instantiate method GAMSModifier has 3 arguments. The first one says that \( x \) is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GAMSParameter that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```java
...
mi = cp.addModelInstance();
GAMSVariable x = mi.SyncDB().addVariable("x", 2, GAMSGlobals.VarType.POSITIVE, "");
GAMSParameter xup = mi.SyncDB().addParameter("xup", 2, "upper bound on x");

// instantiate the ModelInstance and pass a model definition and Modifier to declare upper bound of X mutable
mi.instantiate("transport use lp min z", new GAMSModifier(x, GAMSGlobals.UpdateAction.UPPER, xup));

for (GAMSSetRecord i : t7.OutDB().getSet("i"))
{
    for (GAMSSetRecord j : t7.OutDB().getSet("j"))
    {
        xup.clear();
        String[] keys = { i.getKeys()[0], j.getKeys()[0] };
        xup.addRecord(keys).setValue(0);
        mi.solve();
        System.out.println("Scenario link blocked: " + i.getKeys()[0] + " - " + j.getKeys()[0]);
    }
}
```

See also Transport7.java.

6.8.3.21 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a GAMSCheckpoint \( cp \) from a GAMSJob. Then we define a queue that represents the different values of the demand multiplier. A queue follows the first-in-first-out principle. The object IOLockObject is used later to avoid messed up output. Then we call Scenarios multiple times in parallel. The number of parallel calls is specified by numberOfWorkers.

```java
...
GAMSJob t8 = ws.addJobFromString(model);
t8.run(cp);

Queue<Double> bmultQueue = new LinkedList<Double>(
    Arrays.asList(Double.valueOf(0.6), Double.valueOf(0.7), Double.valueOf(0.8),
      Double.valueOf(0.9), Double.valueOf(1.0), Double.valueOf(1.1),
      Double.valueOf(1.2), Double.valueOf(1.3) )
);

// solve multiple model instances in parallel
Object IOLockObject = new Object();
int numberOfWorkers = 2;
Scenarios[] scenarios = new Scenarios[numberOfWorkers];
for (int i=0; i<numberOfWorkers; i++)
{
    scenarios[i] = new Scenarios( ws, cp, bmultQueue, IOLockObject, i );
    scenarios[i].start();
}
```

...
In class Scenarios we create and instantiate a GAMSModelInstance as in the preceding examples and make parameter bmult modifiable. Note that we chose cplexd as solver because it is thread safe (gurobi would also be possible). Once the queue is empty the loop terminates.

```java
... static class Scenarios extends Thread {
    GAMSWorkspace workspace;
    GAMSCheckpoint checkpoint;
    Object IOLockObject;
    Queue<Double> bmultQueue;
    int workerNumber;
    public Scenarios(GAMSWorkspace ws, GAMSCheckpoint cp, Queue<Double> que, Object IOLockObj, int i) {
        workspace = ws;
        checkpoint = cp;
        IOLockObject = IOLockObj;
        bmultQueue = que;
        workerNumber = i;
    }
    public void run() {
        GAMSModelInstance mi = checkpoint.addModelInstance();
        {
            GAMSParameter bmult = mi.SyncDB().addParameter("bmult", 0, "demand multiplier");
            GAMSOptions opt = workspace.addOptions();
            opt.setAllModelTypes("cplexd");
            // instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare
            bmult mutable
            mi.instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
            bmult.addRecord().setValue( 1.0 );
            while (true)
                double b = 0.0;
                // dynamically get a bmult value from the queue instead of passing it to the different
                threads at creation time
                synchronized (bmultQueue)
                    if (bmultQueue.isEmpty())
                        break;
                    else
                        b = bmultQueue.remove();
                bmult.getFirstRecord().setValue(b);
                mi.solve();
                // we need to make the output a critical section to avoid messed up report informations
                synchronized (IOLockObject)
                    {
                        System.out.println("#"+workerNumber+" Scenario bmult=" + b + ":");
                        System.out.println(" Modelstatus: "+mi.getModelStatus());
                        System.out.println(" Solvestatus: "+mi.getSolveStatus());
                        System.out.println(" Obj: " + mi.SyncDB().getVariable("z").findRecord().getLevel());
                    }
        }
    }
}
...
```

See also Transport8.java.

6.8.3.22 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a GAMSDatabase (on Windows platform only). There are a few prerequisites required to run Transport9 successfully.

- Install a Microsoft access driver on your machine (if none is available) as the driver must be loaded at runtime to connect to a data source file.
To access the data source file go to Control Panel\System and Security\Administrative Tools\Data Sources (ODBC) and set up a data source name (DSN) as "transportdsn", leave out user ID and password, and select [PathToGAMS]/apfiles/Data/transport.accdb as the data source file.

Note that an architecture mismatch between the Driver and Application might cause problems.

We call a function readDataFromAccess that finally returns a GAMSDatabase as shown below.

```java
GAMSDatabase db = readDataFromAccess(ws);
```

The function readDataFromAccess begins with the creation of an empty database. Afterwards we set up a connection to the MS Access database by specifying the aforementioned data source name (DSN). To finally read in GAMS sets and parameters we call the functions readSet and readParameter.

```java
static GAMSDatabase readDataFromAccess(GAMSWorkspace ws) {
    GAMSDatabase db = ws.addDatabase();
    try {
        // loading the jdbc odbc driver
        Class.forName("sun.jdbc.odbc.JdbcOdbcDriver");
        // creating connection to database
        Connection c = DriverManager.getConnection("jdbc:odbc:transportdsn","","");
        // read GAMS sets
        readSet(c, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
        readSet(c, db, "SELECT Market FROM Market", "j", 1, "markets");
        // read GAMS parameters
        readParameter(c, db, "SELECT Plant, Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
        readParameter(c, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
        readParameter(c, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
        c.close();
    } catch (ClassNotFoundException e) {
        System.err.println("Error: Failed to find a driver for the database.");
        e.printStackTrace();
        System.exit(-1);
    } catch (SQLException e) {
        System.err.println("Error: Failed to retrieve data from the database.");
        e.printStackTrace();
        System.exit(-1);
    }
    return db;
}
```

The function readSet adds a set to the GAMSDatabase that is filled with the data from the MS Access file afterwards. The function readParameter works quite similar.

```java
static void readSet(Connection c, GAMSDatabase db, String queryString, String setName, int setDimension, String setExplanatoryText) throws SQLException {
    Statement st = c.createStatement();
    ResultSet rs = st.executeQuery(queryString);
    ResultSetMetaData rsmd = rs.getMetaData();
    if (rsmd.getColumnCount() != setDimension) {
        System.err.println("Error: Number of fields in select statement does not match setDimension.");
        c.close();
        System.exit(-1);
    }
    GAMSSet set = db.addSet(setName, setDimension, setExplanatoryText);
    String[] keys = new String[setDimension];
    while (rs.next()) {
        for (int idx=0; idx < setDimension; idx++)
            keys[idx] = rs.getString(idx+1);
        set.addRecord(keys);
    }
    st.close();
}
```
Once we read in all the data we can create a GAMSJob from the GAMSDatabase and run it as usual.

See also Transport9.java.

6.8.3.23 How to fill a GAMSDatabase by reading from MS Excel (Transport10)

This example illustrates how to read data from Excel, or to be more specific, from \PathToGAMS\apifiles\Data\transport.xls. At first we have to add an additional jar file to the [CLASSESPATH] since we use the Java Excel API which can be downloaded from jexcelapi. We unzipped the Java Excel API folder in C:\tools. To compile and run on a Windows platform from the command line go to C:\GAMS\win64\24.1\apifiles\Java\transport and use:

```
javac -cp C:\GAMS\win64\GAMS_VERSION\apifiles\Java\GAMSJavaAPI.jar;C:\tools\jexcelapi\jxl.jar; -d . Transport10.java
```

and

```
java -cp C:\GAMS\win64\GAMS_VERSION\apifiles\Java\api\GAMSJavaAPI.jar;C:\tools\jexcelapi\jxl.jar; com.gams.examples.transport.Transport10
```

If you are using an IDE like Eclipse add C:\tools\jexcelapi\jxl.jar to the class path as explained in the Compiling a Program from Java IDE and Running a Program from Java IDE section.

The model is given as string without data like in many examples before and the Excel file transport.xls is located at [gamsdir]\apifiles\Data.

At first we define the input string and create the corresponding input file.

```java
String input = gamsdir + "\apifiles\" +
GAMSGlobals.FILE_SEPARATOR + "Data" + GAMSGlobals.FILE_SEPARATOR + "transport.xls";
File inputFile = new File(input);
```

The following lines address the different worksheets and read in the contained data.

```java
try {
  Workbook w = Workbook.getWorkbook(inputFile);
  Sheet capacity = w.getSheet("capacity");
  capacityData = new String[capacity.getRows()][capacity.getColumns()];
  for (int j = 0; j < capacity.getColumns(); j++)
    for (int i = 0; i < capacity.getRows(); i++)
      capacityData[i][j] = capacity.getCell(j, i).getContents();
  Sheet demand = w.getSheet("demand");
  demandData = new String[demand.getRows()][demand.getColumns()];
  for (int j = 0; j < demand.getColumns(); j++)
    for (int i = 0; i < demand.getRows(); i++)
      demandData[i][j] = demand.getCell(j, i).getContents();
  Sheet distance = w.getSheet("distance");
  distanceData = new String[distance.getRows()][distance.getColumns()];
  for (int j = 0; j < distance.getColumns(); j++)
    for (int i = 0; i < distance.getRows(); i++)
      distanceData[i][j] = distance.getCell(j, i).getContents();
  w.close();
} catch (IOException e) {
  e.printStackTrace();
} catch (BiffException e) {
  e.printStackTrace();
}
```

Now we can create the **GAMSWorkspace** as usual and afterwards create a **GAMSDatabase** and fill it with the workbook data as follows:

```java
GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "Plants");
GAMSSet j = db.addSet("j", 1, "Markets");
GAMSParameter capacityParam = db.addParameter("a", 1, "Capacity");
GAMSParameter demandParam = db.addParameter("b", 1, "Demand");
GAMSParameter distanceParam = db.addParameter("d", 2, "Distance");
for (int ic = 0; ic < iCount; ic++)
    i.addRecord( capacityData[0][ic] );
    capacityParam.addRecord( capacityData[0][ic] ).setValue( Double.valueOf(capacityData[1][ic]).doubleValue() );
for (int jc = 0; jc < jCount; jc++)
    j.addRecord( demandData[0][jc] );
    demandParam.addRecord( demandData[0][jc] ).setValue( Double.valueOf(demandData[1][jc]).doubleValue() );
String[] data = null;
for (int ic = 0; ic < iCount; ic++)
    data = new String[] { distanceData[ic+1][0], distanceData[0][jc+1] };
    distanceParam.addRecord( data ).setValue( Double.valueOf(distanceData[ic+1][jc+1]) );
```

Note that we can name sets and parameters just like in the database but we don't have to. Now we can run our **GAMSJob** as usual.

```java
GAMSOptions opt = ws.addOptions();
GAMSJob t10 = ws.addJobFromString(model);
opt.defines("gdxincname", db.getName());
opt.setAllModelTypes("xpress");
t10.run(opt, db);
```

See also **Transport10.java**.

### 6.8.3.24 How to create and use a save/restart file (Transport11)

In **Transport11** we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a **GAMSCheckpoint**. From the main function we call the function **CreateSaveRestart** giving it the current working directory and the desired file name as arguments.

```java
CreateSaveRestart( workingDirectory, "tbase" );
```

In function **CreateSaveRestart** create a workspace with the given working directory. Then we create a **GAMSJob** from a string. Note that the string given via **baseModel** contains the basic definitions of sets without giving them a content (that is what **$onempty** is used for). Afterwards we specify a **GAMSOptions** to only compile the job but do not execute it. Then we create a checkpoint **cp** that is initialized by the following run of the **GAMSJob** and stored in the file given as argument to the function, in our case **tbase**. This becomes possible because the **addCheckpoint** method accepts identifiers as well as file names as argument.
static void CreateSaveRestart(File workingDirectory, String cpFileName)
{
    GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
    wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());

    GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
    GAMSJob j1 = ws.addJobFromString(baseModel);
    GAMSOptions opt = ws.addOptions();
    opt.setAction(GAMSOptions.EAction.CompileOnly);
    GAMSCheckpoint cp = ws.addCheckpoint(cpFileName);
    j1.run(opt, cp);
    opt.dispose();
}

So what you should keep in mind before we return to further explanations of the main function is, that
the file tbase is now in the current working directory and contains a checkpoint. Now in the main function
we define some data using Java data structures as we already did in Transport4 before we create the
GAMSWorkspace and a GAMSDatabase.

... GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());

GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
GAMSDatabase db = ws.addDatabase();
...

Afterwards we set up the GAMSDatabase like we already did in Transport4. Once this is done we
run a GAMSJob using this data plus the checkpoint stored in file tbase.

... GAMSCheckpoint cpBase = ws.addCheckpoint("tbase");

GAMSOptions opt = ws.addOptions();
GAMSJob t11 = ws.addJobFromString(model, cpBase);
opt.defines("gdxincname", db.getName());
opt.setAllModelTypes("xpress");
t11.run(opt, db);
...

Note that the string from which we create job t11 is different to the one used to prepare the checkpoint
stored in tbase and is only responsible for reading in the data from the GAMSDatabase correctly.
The entire model definition is delivered by the checkpoint cpBase which is equal to the one we saved in
tbase.

See also Transport11.java.

6.9 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Python
API. It allows the user to start immediately working with the API by providing a set of small examples
based on the well-known transportation problem. These examples introduce several API features step
by step.

- Getting started A quick introduction about how to run a program
- Important Classes of the API Overview of some fundamental classes of the GAMS Python API
- How to use the API An extensive set of examples describing how to use API components
6.9.1 Getting started

The object oriented GAMS Python API is built on top of the different low level component API's and provides convenient access to GAMS from within Python. Examples using the API are located in api\files/Python while the API itself is found in api\files/Python/api for Python 2.7, in api\files/Python/api_26 for Python 2.6 (Windows and Linux only), in api\files/Python/api_34 for Python 3.4 and in api\files/Python/api_36 for Python 3.6. The bitness of the Python version has to be the same as the bitness of the GAMS system. Assuming that the current directory is \&lt;Path/To/GAMS\&gt;/api\files/Python the API can be used as follows:

- Installing the API and the required low level API's to Python site-packages:
  
  ```
  cd api && python setup.py install && cd ..
  ```

  If the API is installed, then the GAMS system directory may need to be locatable by the dynamic library loader. This would require setting (DY)LD_LIBRARY_PATH on Linux/OS X (see below).

- Using the API without installing:

  ```
  export PYTHONPATH=api (on windows: set PYTHONPATH=api)
  ```

- Running the transport1.py example:

  ```
  python transport1.py
  ```

6.9.1.1 Specifying a GAMS System Directory

There are several ways to specify which system directory should be used. On all platforms, the system directory can be specified in the GamsWorkspace constructor. If no system directory is specified by the user, The API tries to find one automatically:

- Windows: Try to find a system directory in the Windows registry.
- Linux: Try to find a system directory in the PATH first. If none was found, search LD_LIBRARY_PATH.
- OS X: Try to find a system directory in the PATH first. If none was found, search DYLD_LIBRARY_PATH.

The environment variables can be set as follows:

Linux/OS X:

```bash
export PATH=<Path/To/GAMS>:$PATH
```

Linux:

```bash
export LD_LIBRARY_PATH=<Path/To/GAMS>:$LD_LIBRARY_PATH
```

OS X:

```bash
export DYLD_LIBRARY_PATH=<Path/To/GAMS>:$DYLD_LIBRARY_PATH
```

Note

On Linux and Mac OS X it is recommended to specify the PATH only instead of (DY)LD_LIBRARY_PATH since this might cause problems loading the correct version of certain modules (e.g. gdx).
6.9 Tutorial

6.9.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of examples in the How to use the API section.

- gams::workspace::GamsWorkspace Class
- gams::execution::GamsJob Class
- gams::database::GamsDatabase Class
- gams::options::GamsOptions Class
- gams::execution::GamsModelInstance Class

6.9.3 How to use the API

The GAMS distribution provides several examples that illustrate the usage of the Python API.

[GAMSDIR]/apifiles/Python contains multiple examples dealing with the well-known transportation problem. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to import packages/modules from the GAMS Python API (transport1.py)
- How to choose the GAMS system (transport1.py)
- How to export data to GDX (transport_gdx.py)
- How to import data from GDX (transport_gdx.py)
- How to run a GamsJob from file (transport1.py)
- How to retrieve a solution from an output database (transport1.py)
- How to specify the solver using GamsOptions (transport1.py)
- How to run a job with a solver option file (transport1.py)
- How to use include files (transport2.py)
- How to read data from string and export to GDX (transport3.py)
- How to run a job using data from GDX (transport3.py)
- How to run a job using implicit database communication (transport3.py)
- How to define data using Python data structures (transport4.py)
- How to prepare a GamsDatabase from Python data structures (transport4.py)
- How to initialize a GamsCheckpoint by running a GamsJob (transport5.py)
- How to initialize a GamsJob from a GamsCheckpoint (transport5.py)
- How to run multiple GamsJobs in parallel using a GamsCheckpoint (transport6.py)
- How to create a GamsModelInstance from a GamsCheckpoint (transport7.py)
- How to modify a parameter of a GamsModelInstance using GamsModifier (transport7.py)
- How to modify a variable of a GamsModelInstance using GamsModifier (transport7.py)
- How to use a queue to solve multiple GamsModelInstances in parallel (transport8.py)
- How to fill a GamsDatabase by reading from MS Access (transport9.py)
- How to fill a GamsDatabase by reading from MS Excel (transport10.py)
- How to create and use a save/restart file (transport11.py)
6.9.3.1 How to import packages/modules from the GAMS Python API (transport1.py)

If you followed the instructions from the Getting started section and installed the GAMS Python API there should be a directory `{PYTHONDIR}\Lib\site-packages\gams` that contains the required packages and modules. We simply import all of them using

```python
from gams import *
```

Conventional Python packages/modules can by imported like that:

```python
import os
import sys
```

6.9.3.2 How to choose the GAMS system (transport1.py)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. If we type `python transport1.py C:/GAMS/win64/27.3` we use the 64-bit version of GAMS 27.3 to run transport1.py even if our default GAMS system might be a different one. This is managed by the following code:

```python
...
if len(sys.argv) > 1:
    ws = GamsWorkspace(system_directory = sys.argv[1])
else:
    ws = GamsWorkspace()
...
```

Remember that the bitness of the GAMS system has to match the bitness of your Python version.

6.9.3.3 How to export data to GDX (transport_gdx.py)

Although the Object-oriented Python API offers much more than exchanging data between Python and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GamsDatabase. We assume that the data to be exported is available in Python data structures.

```python
...
plants = [ "Seattle", "San-Diego" ]
markets = [ "New-York", "Chicago", "Topeka" ]
capacity = { "Seattle": 350.0, "San-Diego": 600.0 }
demand = { "New-York": 325.0, "Chicago": 300.0, "Topeka": 275.0 }
distance = { ("Seattle", "New-York") : 2.5,
            ("Seattle", "Chicago") : 1.7,
            ("Seattle", "Topeka") : 1.8,
            ("San-Diego", "New-York") : 2.5,
            ("San-Diego", "Chicago") : 1.8,
            ("San-Diego", "Topeka") : 1.4
        }
...
```

Different GAMS symbols are represented using different Python data structures. The data for the GAMS sets is represented using Python lists of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by Python dictionaries (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses Python tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with standard Python data structures.

A new GamsDatabase instance can be created using GamsWorkspace.add_database.
# create new GamsDatabase instance
db = ws.add_database()

We start adding GAMS sets using the method GamsDatabase.add_set which takes the name and the
dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through
`plants` and adds new records to the recently created GamsSet instance `i` using GamsSet.add_record.

```python
# add 1-dimensional set 'i' with explanatory text 'canning plants' to the GamsDatabase
i = db.add_set("i", 1, "canning plants")
for p in plants:
    i.add_record(p)
```

GamsParameter instances can be added by using the method GamsDatabase.add_parameter. It
has the same signature as GamsDatabase.add_set. Anyhow, in this example we use Gams-
Database.add_parameter_dc instead which takes a list of GamsSet instances instead of the dimension for
creating a parameter with domain information.

```python
# add parameter 'a' with domain 'i'
a = db.add_parameter_dc("a", [i], "capacity of plant \textit{i} in cases")
for p in plants:
    a.add_record(p).value = capacity[p]
```

As soon as all data is prepared in the GamsDatabase, the method GamsDatabase.export can be used to
create a GDX file.

```python
# export the GamsDatabase to a GDX file with name 'data.gdx' located in the 'working
directory' of the GamsWorkspace
db.export("data.gdx")
```

### 6.9.3.4 How to import data from GDX (transport_gdx.py)

Data can be imported from a GDX file using GamsWorkspace.add_database_from_gdx. The method takes
a path to a GDX file and creates a GamsDatabase instance.

```python
# add a new GamsDatabase and initialize it from the GDX file just created
db2 = ws.add_database_from_gdx("data.gdx")
```

Reading the data from the GamsSet `i` into a list can be done as follows:

```python
# read data from symbols into Python data structures
i = [ rec.keys[0] for rec in db2['i'] ]
```

A Python list is created using list comprehensions. `i` is retrieved by querying the GamsDatabase `db2`. The returned GamsSet object can be iterated using a for-loop to access the records of the set. Each record
is of type GamsSetRecord and can be asked for its keys.

You can do the same for GamsParameters. Instead of creating a Python list, we want to have the data in
the form of a Python dictionary. GamsParameterRecords can not only be asked for their keys, but also
for their value. The following code snippet shows how to read the one dimensional parameter `a` into a Python dictionary.
The slightly more complicated syntax above is only used for compatibility reasons with Python 2.6. For Python 2.7 and later, it is possible to use dict comprehensions.

For multi dimensional symbols, we choose the Python dictionary keys to be tuples instead of string. We access the keys as usual, but do not address a specific key. Instead, we take the whole list of keys and turn it into a tuple.

Scalars can be read into a Python identifier by accessing the value of the first and only record.

### 6.9.3.5 How to run a GamsJob from file (transport1.py)

At first we create our workspace using `ws = GamsWorkspace()`. Afterwards we load the `transp`ort model from the GAMS model library which puts the corresponding gms file in our working directory. Apparently you can create a GamsJob with any other gms file you might have created on your own as long as it is located in the current working directory. Then the GamsJob `t1` can be defined using the `add_job_from_file` method and afterwards we run the job.

### 6.9.3.6 How to retrieve a solution from an output database (transport1.py)

The following lines create the solution output and illustrate the usage of the GamsJob.out_db property to get access to the GamsDatabase created by the run method. To retrieve the content of variable `x` we use squared brackets that internally call the get_symbol method.

Note that instead of using the squared brackets we could also use
6.9.3.7 How to specify the solver using GamsOptions (transport1.py)

The solver can be specified via the GamsOptions class and the GamsWorkspace.add_options method. The GamsOptions.all_model_types property sets xpress as default solver for all model types that can be handled by the solver. Then we run our GamsJob t1 with the new GamsOption.

```python
...
    opt = ws.add_options()
    opt.all_model_types = "xpress"
    t1.run(opt)
...
```

6.9.3.8 How to run a job with a solver option file (transport1.py)

At first we create the file xpress.opt with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterwards we use a GamsOption just like in the preceding example and set GamsOption.optfile property to 1 to tell the solver to look for a solver option file.

```python
...
    file = open(os.path.join(ws.working_directory, "xpress.opt"), "w")
    file.write("algorithm=barrier")
    file.close()
    opt.optfile = 1
    t1.run(opt)
...
```

6.9.3.9 How to use include files (transport2.py)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings accessed via functions get_data_text and get_model_text are using GAMS syntax. At first we write an include file tdata.gms that contains the data but not the model text and save it in our current working directory.

```python
...
    file = open(os.path.join(ws.working_directory, "tdata.gms"), "w")
    file.write(get_data_text())
    file.close()
...
```

Afterwards we create a GamsJob using the GamsWorkspace.add_job_from_string method. GamsOptions.defines is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line where incname is used as name for the include file in get_model_text as shown below.

```python
...
    t2 = ws.add_job_from_string(get_model_text())
    opt = ws.add_options()
    opt.defines["incname"] = "tdata"
    t2.run(opt)
...
```

The string get_model_text contains the following lines to read in the data.

```python
...
$if not set incname $abort 'no include file name for data file provided'
$include [incname]
...
```
6.9.3.10  How to read data from string and export to GDX (transport3.py)

We read the data from the string accessed via function `get_data_text`. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding GamsJob a GamsDatabase is created that is available via the GamsJob.out.db property. We can use the GamsDatabase.export method to write the content of this database to a gdx file `tdata.gdx` in the current working directory.

```python
... t3 = ws.add_job_from_string(get_data_text())
    t3.run()
    t3.out_db.export(os.path.join(ws.working_directory, "tdata.gdx"))
...```

6.9.3.11  How to run a job using data from GDX (transport3.py)

This works quite similar to the usage of an include file explained in How to use include files (transport2.py).

```python
... t3 = ws.add_job_from_string(get_model_text())
    opt = ws.add_options()
    opt.defines["gdxincname"] = "tdata"
    opt.all_model_types = "xpress"
    t3.run(opt)
...```

Note that there are some minor changes in `get_model_text` compared to preceding examples due to the usage of a gdx instead of an include file.

```bash
... $if not set gdxincname $abort 'no include file name for data file provided'
    $gdxin %gdxincname%
    $load i j a b d f
    $gdxin ...
```

6.9.3.12  How to run a job using implicit database communication (transport3.py)

This example does basically the same as the two preceding examples together. We create two GamsJobs `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding `out.db` can be read in directly just like a gdx file.

Note that the database needs to be passed to the GamsJob.run method as additional argument.

```python
... t3a = ws.add_job_from_string(get_data_text())
    t3b = ws.add_job_from_string(get_model_text())
    t3a.run()
    opt.defines["gdxincname"] = t3a.out_db.name
    t3b.run(opt, databases=t3a.out_db)
...```

6.9.3.13  How to define data using Python data structures (transport4.py)

We use squared brackets (Python Lists) to define the sets and curly brackets (Python Dictionaries) for the parameter definition.

```python
... plants = ['Seattle', 'San-Diego']
    markets = ["New-York", "Chicago", "Topeka"]
    capacity = {"Seattle": 350.0, "San-Diego": 600.0}
    demand = {"New-York": 325.0, "Chicago": 300.0, "Topeka": 275.0}
    distance = {("Seattle", "New-York") : 2.5,
                    ("Seattle", "Chicago") : 1.7,
                    ("Seattle", "Topeka") : 1.8,
                    ("San-Diego", "New-York") : 2.5,
                    ("San-Diego", "Chicago") : 1.8,
                    ("San-Diego", "Topeka") : 1.4}
...```
6.9.3.14 How to prepare a GamsDatabase from Python data structures (transport4.py)

At first we create an empty GamsDatabase db using the GamsWorkspace.add_database method. Afterwards we prepare the database. To add a set to the database we use the GamsSet class and the GamsDatabase.add_set method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Python data structure and add them by using the GamsSet.add_record method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2.

The GamsJob can be run like explained in the preceding example How to run a job using implicit database communication (transport3.py).

```
...
  db = ws.add_database()
  i = db.add_set("i", 1, "canning plants")
  for p in plants:
    i.add_record(p)
  j = GamsSet(db, "j", 1, "markets")
  for m in markets:
    j.add_record(m)
  a = GamsParameter(db, "a", 1, "capacity of plant i in cases")
  for p in plants:
    a.add_record(p).value = capacity[p]
  b = GamsParameter(db, "b", 1, "demand at market j in cases")
  for m in markets:
    b.add_record(m).value = demand[m]
  d = GamsParameter(db, "d", 2, "distance in thousands of miles")
  for k, v in distance.iteritems():
    d.add_record(k).value = v
  f = GamsParameter(db, "f", 0, "freight in dollars per case per thousand miles")
  f.add_record().value = 90
  t4 = GamsJob(ws, source=get_model_text())
  opt = GamsOptions(ws)
  opt.defines["gdxincname"] = db.name
  opt.all_model_types = "xpress"
  t4.run(opt, databases = db)
...
```

6.9.3.15 How to initialize a GamsCheckpoint by running a GamsJob (transport5.py)

The following lines of code conduct several operations. While the first line simply creates a GamsCheckpoint, the second one uses the GamsWorkspace.add_job_from_string method to create a GamsJob containing the model text and data but no solve statement. Afterwards the run method gets the GamsCheckpoint as argument. That means the GamsCheckpoint cp captures the state of the GamsJob.

```
...
  cp = ws.add_checkpoint()
  t5 = ws.add_job_from_string(get_model_text())
  t5.run(checkpoint=cp)
...
```
6.9.3.16 How to initialize a GamsJob from a GamsCheckpoint (transport5.py)

Note that the string returned from function get_model_text contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```plaintext
... 
Scalar bmult demand multiplier /1/; 
... 
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ; 
... 
Scalar ms 'model status', ss 'solve status'; 
... 
```

In transport5.py we create a list with eight different values for this demand multiplier.

```plaintext
... 
bmultlist = [ 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 ] 
... 
```

For each entry of that list we create a GamsJob t5 using the GamsWorkspace.add_job_from_string method. Besides another string which resets the demand multiplier bmult, specifies the solve statement and assigns values to the scalars ms and ss we pass the checkpoint cp as additional argument. This results in a GamsJob combined from the checkpoint plus the content provided by the string.

We run the GamsJob and print some interesting data from the out_db.

```plaintext
... 
for b in bmultlist:
    t5 = ws.add_job_from_string("bmult=" + str(b) + "; solve transport min z use lp; 
ms="transport.modelstat; ss=transport.solvestat;">", cp)
    t5.run()
    print "Scenario bmult=" + str(b) + ";": 
    print " Modelstatus: "+ str(t5.out_db["ms"].find_record().value) 
    print " Solvestatus: "+ str(t5.out_db["ss"].find_record().value) 
    print " Obj: " + str(t5.out_db["z"].find_record().level) 
... 
```

NOTE: Some of the demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

6.9.3.17 How to run multiple GamsJobs in parallel using a GamsCheckpoint (transport6.py)

This example illustrates how to run the jobs known from transport5.py in parallel. We initialize the GamsCheckpoint cp and introduce a demand multiplier as we did before:

```plaintext
... 
cp = ws.add_checkpoint() 
t6 = ws.add_job_from_string(get_model_text()) 
t6.run(checkpoint=cp) 
bmultlist = [ 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 ] 
... 
```

Furthermore, we introduce a lock object io_lock that will be used to avoid mixed up output from the parallel jobs. We create one scenario for each entry of bmultlist and cause a thread to begin execution.
io_lock = threading.Lock()
threads = {} 
for b in bmultlist:
    threads[b] = threading.Thread(target=run_scenario, args=(ws, cp, io_lock, b))
    threads[b].start()
for b in bmultlist:
    threads[b].join()

In function run_scenario a GamsJob t6 is created and run just like in the preceding example of transport5.py. The output section is also the same except for the fact that it is 'locked' by the object io_lock which means that the output section cannot be executed simultaneously for multiple demand multipliers.

def run_scenario(workspace, checkpoint, io_lock, b):
    t6 = workspace.add_job_from_string("bmult=" + str(b) + "; solve transport min z use lp;
    ms=transport.modelstat; ss=transport.solvestat;", checkpoint)
    t6.run() 
    # we need to make the output a critical section to avoid messed up report informations
    io_lock.acquire()
    print "Scenario bmult=" + str(b) + ":"
    print " Modelstatus: " + str(t6.out_db["ms"]()[].value)
    print " Solvestatus: " + str(t6.out_db["ss"]()[].value)
    print " Obj: " + str(t6.out_db["z"]()[().level])
    io_lock.release()

While the output in transport5.py is strictly ordered subject to the order of the elements of bmultlist in transport6.py the output blocks might change their order but the blocks describing one scenario are still appearing together due to the io_lock object.

6.9.3.18 How to create a GamsModelInstance from a GamsCheckpoint (transport7.py)

In transport7.py the usage of GamsModelInstance is demonstrated.

At first checkpoint cp is created as in the preceding examples. Note that the GamsJob t7 again contains no solve statement and the demand multiplier is already included with default value 1. We create the GamsModelInstance mi using the GamsCheckpoint.add_modelinstance method.

... 
    cp = ws.add_checkpoint()
    t7 = ws.add_job_from_string(get_model_text())
    t7.run(checkpoint=cp)
    mi = cp.add_modelinstance()
...

6.9.3.19 How to modify a parameter of a GamsModelInstance using GamsModifier (transport7.py)

A GamsModelInstance uses a sync_db to maintain the data. We define bmult as GamsParameter using the GamsDatabase.add_parameter method and specify gurobi as solver. Afterwards the GamsModelInstance is instantiated with 3 arguments, the solve statement, GamsModifier bmult and GamsOptions opt. The GamsModifier means that bmult is modifiable while all other parameters, variables and equations of GamsModelInstance mi stay unchanged. We use the GamsParameter.add_record method to assign a value to bmult. That value can be varied afterwards using the GamsParameter.first_record method to reproduce our well-known example with different demand multipliers.

... bmult = mi.sync_db.add_parameter("bmult", 0, "demand multiplier")
opt = ws.add_options()
opt.all_model_types = "gurobi"

mi.instantiate("transport use lp min z", GamsModifier(bmult), opt)

bmult.add Record().value = 1.0
bmultlist = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3]
for b in bmultlist:
    bmult.first_record().value = b
    mi.solve()
    print "Scenario bmult=" + str(b) + ":"
    print " Modelstatus: " + str(mi.model_status)
    print " Solvestatus: " + str(mi.solver_status)
    print " Obj: " + str(mi.sync_db.get_variable("z").find_record().level)

6.9.3.20 How to modify a variable of a GamsModelInstance using GamsModifier (transport7.py)

We create a GamsModelInstance using the GamsCheckpoint.add_modelinstance method. Afterwards we define \( x \) as GamsVariable and a GamsParameter \( x_{up} \) that will be used as upper bound for \( x \). At the following instantiate method GamsModifier has 3 arguments. The first one says that \( x \) is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GamsParameter that holds the new value, in this case \( x_{up} \).

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

... mi = cp.add_modelinstance()
x = mi.sync_db.add_variable("x", 2, VarType.Positive)
xup = mi.sync_db.add_parameter("xup", 2, "upper bound on x")

mi.instantiate("transport use lp min z", GamsModifier(x, UpdateAction.Upper, xup))
mi.solve()

for i in t7.out_db["i"]: for j in t7.out_db["j"]:
xup.clear()
xup.add_record((i.keys[0], j.keys[0])).value = 0
mi.solve()
print "Scenario link blocked: " + i.keys[0] + " - " + j.keys[0]
print " Modelstatus: " + str(mi.model_status)
print " Solvestatus: " + str(mi.solver_status)
print " Obj: " + str(mi.sync_db["z"].find_record().level)

6.9.3.21 How to use a queue to solve multiple GamsModelInstances in parallel (transport8.py)

We initialize a GamsCheckpoint \( cp \) from a GamsJob. Then we define a list that represents the different values of the demand multiplier. That list will be used like a queue where we extract the last element first. The objects \( \text{list}\_\text{lock} \) and \( \text{io}\_\text{lock} \) are used later to avoid multiple reading of one demand multiplier and messed up output. Then we call function \( \text{scen}\_\text{solve} \) multiple times in parallel. The number of parallel calls is specified by \( \text{nr}\_\text{workers} \).

... cp = ws.add_checkpoint()
t8 = ws.add_job_from_string(get_model_text())
t8.run(checkpoint=cp)
bmult_list = [1.3, 1.2, 1.1, 1.0, 0.9, 0.8, 0.7, 0.6]
list_lock = threading.Lock()
In function scen_solve we create and instantiate a GamsModelInstance as in the preceding examples and make parameter bmult modifiable. Note that we choose cplexd as solver because it is thread safe (gurobi would also be possible).

We have two critical sections that are locked by the objects list_lock and io_lock. Note that the pop method removes and returns the last element from the list and deletes it. Once the list is empty the loop terminates.

```
...  
def scen_solve(workspace, checkpoint, bmult_list, list_lock, io_lock):
    mi = checkpoint.add_modelinstance()
    bmult = mi.sync_db.add_parameter("bmult", 0, "demand multiplier")
    opt = ws.add_options()
    opt.all_model_types = "cplexd"

    # instantiate the GamsModelInstance and pass a model definition and GamsModifier to declare bmult mutable
    mi.instantiate("transport use lp min z", GamsModifier(bmult), opt)
    bmult.add_record().value = 1.0

    while True:
        # dynamically get a bmult value from the queue instead of passing it to the different threads at creation time
        list_lock.acquire()
        if 0 == len(bmult_list):
            list_lock.release()
            return
        b = bmult_list.pop()
        list_lock.release()
        bmult.first_record().value = b
        mi.solve()

        # we need to make the output a critical section to avoid messed up report informations
        io_lock.acquire()
        print "Scenario bmult=" + str(b) + ":",
        print "Modelstatus: " + str(mi.model_status)
        print "Solvestatus: " + str(mi.solver_status)
        print "Obj: " + str(mi.sync_db.get_variable("z").find_record().level)
        io_lock.release()

    ...  
```

### 6.9.3.22 How to fill a GamsDatabase by reading from MS Access (transport9.py)

This example illustrates how to import data from Microsoft Access to a GamsDatabase. There are a few prerequisites required to run transport9.py successfully.

- We import pyodbc which can be downloaded from [http://code.google.com/p/pyodbc/](http://code.google.com/p/pyodbc/).
- Note that an architecture mismatch might cause problems. The bitness of your MS Access, Python, pyodbc and GAMS should be identical.

We call a function `read_data_from_access` that finally returns a GamsDatabase as shown below.

```
...  
db = read_data_from_access(ws)
...  
```
The function `read_from_access` begins with the creation of an empty database. Afterwards we set up a connection to the MS Access database `transport.accdb` which can be found in `[GAMSDIR]\apifiles\Data`. To finally read in GAMS sets and parameters we call the functions `read_set` and `read_parameter` that are explained down below.

```python
... def read_from_access(ws):
    db = ws.add_database()
    # connect to database
    str_access_conn = 'DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};DBQ=..\Data\transport.accdb'
    try:
        connection = pyodbc.connect(str_access_conn)
    except Exception as ex:
        print "Error: Failed to create a database connection. \n{0}".format(ex)
        sys.exit(1)
    # read GAMS sets
    read_set(connection, db, "SELECT Plant FROM plant", "i", 1, "canning plants")
    read_set(connection, db, "SELECT Market FROM Market", "j", 1, "markets")
    # read GAMS parameters
    read_parameter(connection, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases")
    read_parameter(connection, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases")
    read_parameter(connection, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles")
    connection.close()
    return db
...
```

The function `read_set` adds a set to the GamsDatabase that is filled with the data from the MS Access file afterwards. The function `read_parameter` works quite similar.

```python
... def read_set(connection, db, query_string, set_name, set_dim, set_exp=""):
    try:
        cursor = connection.cursor()
        cursor.execute(query_string)
        data = cursor.fetchall()
        if len(data[0]) != set_dim:
            print "Number of fields in select statement does not match setDim"
            sys.exit(1)
        i = db.add_set(set_name, set_dim, set_exp)
        for row in data:
            keys = []
            for key in row:
                keys.append(str(key))
            i.add_record(keys)
    except Exception as ex:
        print "Error: Failed to retrieve the required data from the DataBase.\n{0}".format(ex)
        sys.exit(1)
    finally:
        cursor.close()
...
```

Once we read in all the data we can create a GamsJob from the GamsDatabase and run it as usual.

### 6.9.3.23 How to fill a GamsDatabase by reading from MS Excel (transport10.py)

This example illustrates how to read data from Excel, or to be more specific, from `[GAMSDIR]\apifiles\Data\transport.xls`.

At first you have to download an additional package from [https://pypi.python.org/pypi/xlrd](https://pypi.python.org/pypi/xlrd), e.g. to C:\Users\[USERNAME]\Downloads. Unzip the package and run the following code from command line:

```
cd C:\Users\[Username]\Downloads\xlrd-0.9.2 & & python setup.py install & & cd [GAMSDIR]\apifiles\Python
```
Now you should be able to find the directory `xlrd` in `[PYTHONDIR]\Lib\site-packages` and to run `transport10.py`.

In `transport10.py` the model is given as string without data like in many examples before and the Excel file `transport.xls` is located at `[GAMSDIR]\apifiles\Data`. At first we define the workbook to read from and the different sheet names. To ensure to have the same number of markets and plants in all spreadsheets, we conduct a little test that checks for the number of rows and columns. Our workspace is only created if this test yields no errors.

```python
... wb = open_workbook(‘..\Data\transport.xls’) capacity = wb.sheet_by_name(‘capacity’) demand = wb.sheet_by_name(‘demand’) distance = wb.sheet_by_name(‘distance’) # number of markets/plants have to be the same in all spreadsheets assert (distance.ncols-1 == demand.ncols) and (distance.nrows-1 == capacity.ncols), ‘Size of the spreadsheets doesn’t match’ ...
```

Now we can create a GamsDatabase and read in the data contained in the different worksheets. We iterate over the columns and read in the set names and the corresponding parameter values.

```python
...
  db = ws.add_database()
  i = db.add_set(‘i’, 1, ‘Plants’) j = db.add_set(‘j’, 1, ‘Markets’) capacity_param = db.add_parameter(‘a’, 1, ‘Capacity’) demand_param = db.add_parameter(‘b’, 1, ‘Demand’) distance_param = db.add_parameter(‘d’, 2, ‘Distance’) for cx in range(capacity.ncols):
    i.add_record(str(capacity.cell_value(rowx=0, colx=cx))) capacity_param.add_record(str(capacity.cell_value(rowx=0, colx=cx))).value = capacity.cell_value(rowx=1, colx=cx)

  for cx in range(demand.ncols):
    j.add_record(str(demand.cell_value(rowx=0, colx=cx)))
    demand_param.add_record(str(demand.cell_value(rowx=0, colx=cx))).value = demand.cell_value(rowx=1, colx=cx)

  for cx in range(1, distance.ncols):
    for rx in range(1, distance.nrows):
      keys = (str(distance.cell_value(rowx=rx, colx=0)), str(distance.cell_value(rowx=0, colx=cx)))
      distance_param.add_record(keys).value = distance.cell_value(rowx=rx, colx=cx)

...
```

Note that we can name sets and parameters just like in the database but we don’t have to. Now we can run our GamsJob as usual.

```python
...
  t10 = ws.add_job_from_string(get_model_text())
  opt = ws.add_options()
  opt.defines[‘gdxincname’] = db.name
  opt.all_model_types = ‘xpress’
  t10.run(opt, databases=db)
  for rec in t10.out_db[‘x’]:
    print “x(‘“ + rec.keys[0] + “’, ‘“ + rec.keys[1] + “’): level=” + str(rec.level) + “ marginal=” + str(rec.marginal) + “

```
6.9.3.24  How to create and use a save/restart file (transport11.py)

In transport11.py we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a GamsCheckpoint.

We create a directory tmp with internal identifier w_dir in the directory we are currently in (usually [GAMSDIR]\apifiles\Python). This file will be used as working directory later. From the main function we call the function create_save_restart giving it directory tmp and the desired name for the save/restart file (tbase) as arguments.

```python
...     w_dir = os.path.join('.', 'tmp')
     create_save_restart(os.path.join(w_dir, 'tbase'));
...
```

In function create_save_restart we create a workspace with the given working directory (w_dir refers to tmp). Then we create a GamsJob from a string. Note that the string given via get_base_model_text contains the basic definitions of sets without giving them a content (that is what $onempty is used for). Afterwards we specify a GamsOption to only compile the job but do not execute it. Then we create a checkpoint cp that is initialized by the following run of the GamsJob and stored in the file given as argument to the function, in our case tbase. This becomes possible because the add_checkpoint method accepts identifiers as well as file names as argument.

```python
...     def create_save_restart(cp_file_name):
         if len(sys.argv) > 1:
             ws = GamsWorkspace(os.path.dirname(cp_file_name), sys.argv[1])
         else:
             ws = GamsWorkspace(os.path.dirname(cp_file_name))

             j1 = ws.add_job_from_string(get_base_model_text())
             opt = ws.add_options()
             opt.action = Action.CompileOnly
             cp = ws.add_checkpoint(os.path.basename(cp_file_name))
             j1.run(opt, cp)
         del opt
...
```

So what you should keep in mind before we return to further explanations of the main function is, that the file tbase is now in the current working directory and contains a checkpoint that will work exactly like a restart file.

In the main function we define some data using Python data structures as we already did in transport4.py before we create the GamsWorkspace and a GamsDatabase.

```python
...     if len(sys.argv) > 1:
         ws = GamsWorkspace(w_dir, sys.argv[1])
     else:
         ws = GamsWorkspace(w_dir)

     db = ws.add_database()
...
```

Afterwards we set up the GamsDatabase like we already did in transport4.py. Once this is done we run a GamsJob using this data plus the checkpoint stored in file tbase.

```python
...     cp_base = ws.add_checkpoint("tbase")
     t4 = ws.add_job_from_string(get_model_text(), cp_base)
     opt = ws.add_options()
     opt.defines["gdxincname"] = db.name
     opt.all_model_types = "xpress"
     t4.run(opt, databases=db)
...
```

Note that the string from which we create job t11 is different to the one used to prepare the checkpoint stored in tbase and is only responsible for reading in the data from the GamsDatabase correctly. The entire model definition is delivered by the checkpoint cp_base which is equal to the one we saved in tbase.
6.10 Release Notes

6.10.1 25.0.1

Changes for GAMSSymbol and GAMSSymbolRecord: Both classes got the IEquatable<T> Interface. As a result the behavior of the Equals function as well as the == and != operators were modified. For both classes Equals and == returns now true, if the internal data reference is the same. Here is an example:

```csharp
GAMSVariable x1 = t1.OutDB.GetVariable("x");
GAMSVariable x2 = t1.OutDB.GetVariable("x");

if(x1 == x2)
    Console.WriteLine("x1==x2");
else
    Console.WriteLine("x1!=x2");
if (x1.Equals(x2))
    Console.WriteLine("x1 equals x2");
else
    Console.WriteLine("x1 does not equal x2");
```

In previous versions we got this output:

```
x1!=x2
x1 does not equal x2
```

Now we get:

```
x1==x2
x1 equals x2
```

6.10.2 24.9.1

- New functions GAMSWorkspace.AddJobFromApiLib, GAMSWorkspace.AddJobFromNoaLib to create GAMSJob from models from the GAMS API Library and the Nonlinear Optimization Applications Library

6.10.3 24.8.1

- New option GAMSOptions.ErrorLog: Max error message lines written to the log for each error

6.10.4 24.7.4

- GAMSModelInstance.Instantiate: Skip creation of GDX file, which was unreachable from within the API anyway

6.10.5 24.7.1

- GAMSWorkspace.AddJobFromFile: Throw an exception if given file does not exist
6.10.6 24.5.4

- Fixed a bug with the property GAMSOptions.IDir

6.10.7 24.5.2

- Fixed a bug that lead to a crash on Linux (using Mono) when the GAMS system directory is a symbolic link

6.10.8 24.5.1

- New functions GAMSWorkspace.ApiLib and GAMSWorkspace.NoaLib that can be used to retrieve models from the GAMS API Library and the Nonlinear Optimization Applications Library

6.10.9 24.4.2

- New property GAMSSymbol.DomainsAsString: Domains of Symbol, each element is a string
  
  Note: If the domain is an alias in GAMS, this call will return the name of the Alias, not the name of the aliased Set

- Disable unwanted debug output from Couenne when running with GAMSModelInstance

6.10.10 24.4.1

- Modified handling of GAMS Aliases:
  
  - If we ask for the number of GAMSSymbols in a GAMSDatabase, theAliases will be excluded
  - If we iterate over all GAMSSymbols in a GAMSDatabase, Aliases will be skipped
  - If we ask explicitly for an Alias in a GAMSDatabase (GAMSDatabase.GetSet("a") with a being an Alias) we will get a reference to the GAMSSet referenced by the Alias, not the Alias itself
  
  Note: Aliases can appear in a GAMSDatabase only, if it was initialized by a GDX file containing an Alias.

6.10.11 24.3.2

- Make more GAMS options available through the GAMSOptions class:
  
  - GAMSOptions.AppendExpand: Expand file append option
  - GAMSOptions.AppendOut: Output file append option
  - GAMSOptions.DumpOpt: Writes preprocessed input to the file input.dmp
  - GAMSOptions.DumpParms: GAMS parameter logging
  - GAMSOptions.ErrMsg: Placing of compilation error messages
  - GAMSOptions.Expand: Expanded (include) input file name
  - GAMSOptions.FErr: Alternative error message file
  - GAMSOptions.JobTrace: Job trace string to be written to the trace file at the end of a Gams job
- GAMSOptions.LimCol: Maximum number of columns listed in one variable block
- GAMSOptions.LimRow: Maximum number of rows listed in one equation block
- GAMSOptions.LogLine: Amount of line tracing to the log file
- GAMSOptions.On115: Generate errors for unknown unique element in an equation
- GAMSOptions.Output: Output file
- GAMSOptions.PageContr: Output file page control option
- GAMSOptions.PageSize: Output file page size (=0 no paging)
- GAMSOptions.PageWidth: Output file page width
- GAMSOptions.Reference: Symbol reference file
- GAMSOptions.ScriptExit: Program or script to be executed at the end of a GAMS run
- GAMSOptions.Suppress: Compiler listing option
- GAMSOptions.Symbol: Symbol table file
- GAMSOptions.TraceLevel: Solvestate threshold used in conjunction with a=GT

6.10.12 24.3.1

- GAMSJob.Run creates OutDB now even if it throws a GAMSExceptionExecution
- New function GAMSSymbolRecord.Key(int index): Retrieve key of GAMSSymbolRecord on position index
- GAMSMModelInstance.Solve also works now for solvers which require a subsolver, e.g. Dicopt
- GAMSDatabase.Export registers real domains in GDX file now if possible, before relaxed domains were registered always
- GAMSSymbol.CopySymbol works for the Universe of a GAMSDatabase (GAMSDatabase.GetSet("*")) now, when copying into the Universe, a merge will be performed
- Fix default value for systemDirectory argument in GAMSWorkspace constructor when using MONO: If no value is given, first the PATH and then the (DY)LD_LIBRARY_PATH is checked for a valid GAMS system directory

6.10.13 24.2.3

- Fix memory leak in GAMSDatabase

6.10.14 24.2.2

- Fixed a bug regarding the subtype of equations and their default records, when the equation was added to a GamsDatabase from the API
- Fix GAMSEnum.GAMSExitCode
- Make sure that GAMSMModelInstance.Instantiate() does not solve the model, but only prepares everything required for the following Solve()
6.10.15 24.2.1

- New version of function GAMSWorkspace.AddOptions creating an instance of GAMSOptions initialized by an existing option file
- New properties: GAMSWorkspace.APIVersion, GAMSWorkspace.APIMajorRelNumber, GAMSWorkspace.APIMinorRelNumber and GAMSWorkspace.APIGOLDRelNumber
- New property GAMSWorkspace.MyEPS: Reset value to be stored in and read from GAMSDatabase for Epsilon, default is double.Epsilon
- New function GAMSOptions.Export: Write GAMSOptions into a parameter file
- Switching type of property GAMSOptions.NoNewVarEqu from Integer to Enum (ENoNewVarEqu)

6.10.16 24.1.1

- GAMSDatabase:
  - New function CheckDomains: Check for all symbols if all records are within the specified domain of the symbol
  - New function GetDatabaseDVs: Return all GAMSDatabaseDomainViolations
  - New property SuppressAutoDomainChecking: Controls whether domain checking is called in GAMSDatabase export
  - New variants of the functions AddEquation, AddParameter, AddSet, AddVariable: Allow to specify domain information
  - Function Compact becomes obsolete and will be dropped in future
- GAMSModelInstance:
  - New function CopyModelInstance: Copies a ModelInstance to a new ModelInstance which gets constructed at this call
  - New function Interrupt: Sends interrupt signal to running GAMSModelInstance
- GAMSModifier:
  - Allow to define SymbolUpdateType for each GAMSModifier separately
- GAMSSymbol (GAMSEquation, GAMSParameter, GAMSSet, GAMSVariable):
  - New function CheckDomains: Check if all records are within the specified domain of the symbol
  - New function CopyToArray: Copies values of a dense symbol into a dense array
  - New function CopyToSqdArray: Copies values of a sparse symbol into a squeezed array
  - New function CopySparseToDenseArray: Copies values of a sparse symbol into a dense array
  - New function CopyFromDenseArray: Copies values from dense array into a symbol
  - New function CopySliceFromDenseArray: Copies values from slice of dense array into a symbol
  - New function GetSymbolDVs: Return all GAMSSymbolDomainViolations
  - New function MergeRecord: Finds record in GAMSSymbol if it exists, adds it if not
  - New property Domains: Domains of Symbol, each element is either a GAMSSet (real domain) or a string (relaxed domain)
- GAMSWorkspace:
  - Change the Debug parameter from a Boolean flag to an enum type called DebugLevel
6.10 Release Notes

- The Debug parameter can be overwritten by the system environment variable "GAMSOOAPI-DEBUG" if set to one of the following: Off, KeepFiles, ShowLog, Verbose.
- Improve performance significantly for function AddDatabase(GAMSDatabase)
- New functions: AddJobFromGamsLib, AddJobFromTestLib, AddJobFromEmpLib, AddJobFromDataLib and AddJobFromFinLib
- New properties: Version, MajorRelNumber, MinorRelNumber and GOLDRelNumber
- New optional parameter inModelName for functions AddDatabaseFromGDX/AddDatabase: GAMS string constant that is used to access this database

- Add new sub class of GAMSEException: GAMSExceptionExecution. This provides additional info about the reason of the failed execution.

6.10.17 24.0.2

- Add new function GAMSSymbol.CopySymbol which copys all records from one to another GAMSSymbol
- Label and symbol lookup is now case insensitive
- Fixed handling of infinite bounds for GAMSModifiers

6.10.18 24.0.1

- Add function Interrupt to GAMSJob
- Do not throw an exception when hitting an Alias with the GAMSDatabaseEnumerator or GetSymbol function but return the aliased GAMSSet

6.10.19 23.9.3

- Constructor of GAMSWorkspace now appends conditionally the GAMS system directory to the PATH environment variable. This fixes a problem with applications that create and dispose many GAMSWorkspace instances.

6.10.20 23.9.2

- GAMSModelInstance.Instantiate is now thread-safe
- Additional flag createOutDB for method GAMSJob.Solve which allows to switch off automatic outDB creation
- Fix a problem with parallel execution of GAMSModelInstances in Debug mode
- Add new class GAMSEException
- Add tighter restriction on adding symbols to GAMSModelInstance.SyncDB
- Add new class GAMSModelInstanceOpt to customize method GAMSModelInstance.Solve
  - GAMSModelInstanceOpt.Debug: produces a gams.gms, jacobian.gdx and dictmap.gdx allowing inspection of the model instance solved in the GAMSModelInstance.Solve method
  - GAMSModelInstanceOpt.NoMatchLimit: controls the maximum number of accepted unmatched scenario records before terminating the solve
  - GAMSModelInstanceOpt.OptFile: allows to choose solver option for GAMSModelInstance.Solve
  - GAMSModelInstanceOpt.Solver: allows to choose solver for GAMSModelInstance.Solve
- Add GAMSWorkspace.ScratchFilePrefix to prefix all scratch files created by GAMS.Net
- GAMSJob no longer implements IDisposable
6.11 Release Notes

6.11.1 25.1.1 (May 2018)

- Changed the naming scheme of a temporary working directory to be created from 'yyyyM-Mdd_HHmmss' to the prefixed 'gams_' (defined by `GAMSGlobal.workingDirectoryPrefix`), in case no working directory has been specified.

- Fixed the behavior when GAMSDatabase is added with the name that already exists, now GAMSException will be raised. (see `GAMSWorkspace.addDatabase(String databaseName)` and `GAMSWorkspace.addDatabaseFromGDX(String gdxFileName, String databaseName)`)

- Calls on `GAMSWorkspace.finalize` and `GAMSSymbolIterator.finalize` are no longer available. As calling a finalizer method can arbitrarily delay the reclamation of object instances and potentially create unpredictable outcome. Whenever the object is no longer needed it is recommended to explicitly dispose the object rather than to rely on the Java garbage collector to do the job. See `GAMSDatabase.dispose`, `GAMSModelInstance.dispose`, and `GAMSOptions.dispose`.

- All Java native interfaces to Expert-Level APIs are now included in the distributed `GAMSJavaAPI.jar`, located under the `[Path/To/GAMS]/apifiles/Java/api/` directory.

6.11.2 25.0.1 (January 2018)

- The minimum version requirement of Java Runtime Environment for using with GAMS Java API is now Java SE 7.

- New `TransportGDX` example to demonstrate how to import and export GDX files.

- Removed `GAMSSymbol.compact`, deprecated since 24.8.1 (December 2016).

- Changed equivalence behavior of `GAMSSymbol` and `GAMSSymbolRecord` objects. As a result, two symbol objects with the same internal reference are now equivalent, similar to symbol record objects:
  - Two symbols are equivalent if and only if they have the same internal reference.
  - Two symbol records are equivalent if and only if they have the same internal reference.

  The behavior of operator `==` remains unchanged. The following example illustrates the new equivalence behavior:

  ```java
  GAMSVariable x1 = db.getVariable("x");
  GAMSVariable x2 = db.getVariable("x");
  GAMSVariable x3 = x1;
  assertTrue(x1.equals(x2)); // true, previously false
  assertFalse(x1 == x2); // false, previously false
  assertTrue(x1.equals(x3)); // true, previously true
  assertTrue(x1 == x3); // true, previously true
  ```

6.11.3 24.8.1 (December 2016)

- Deprecated `GAMSSymbol.compact` and the method will be removed in the next major release.

- an exception or an error thrown by `GAMSWorkspace.finalize` and `GAMSSymbolIterator.finalize` now must be caught or declared to be thrown. Note that an explicit call on one of these two methods is not recommended unless it is necessary to do so.
6.11.4 24.7.4 (September 2016)

- **GAMSModelInstance.instantiate**: Skip creation of GDX file, which was unreachable from within the API anyway

6.11.5 24.7.1 (March 2016)

- Fixed a bug with the property **GAMSOptions.defines**: When too many entries were added, all of them were ignored.

6.11.6 24.5.1 (August 2015)

- New examples
  - Clad at [Path/To/GAMS]/apifiles/Java/clad/Clad.java
  - SpecialValues at [Path/To/GAMS]/apifiles/Java/specialvalues/SpecialValues.java
- New functions **GAMSWorkspace.addJobFromApiLib** and **GAMSWorkspace.addJobFromNoaLib** that can be used to retrieve models from GAMS API Library and **Nonlinear Optimization Applications Library**.

6.11.7 24.4.2 (March 2015)

- New property **GAMSSymbol.getDomainsAsString**: get domains of symbol, each element is a string
  
  **Note**: If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set.

- Disable unwanted debug output from Couenne when running with **GAMSModelInstance**

- Change naming scheme of gdx output scratch file to sequence number.

6.11.8 24.4.1 (December 2014)

- Modify the handling of GAMS Aliases in the object oriented APIs:
  
  - If we ask for the number of **GAMSSymbol** in a **GAMSDatabase**, the Aliases will be excluded.
  
  - If we iterate over all **GAMSSymbol** in a **GAMSDatabase**, Aliases will be skipped.
  
  - If we ask explicitly for an Alias in a **GAMSDatabase** (**GAMSDatabase.getSet**("a") with a being an Alias) we will get a reference to the **GAMSSet** referenced by the Alias, not the Alias itself.
  
  **Note**:
  
  * Aliases can appear in a **GAMSDatabase** only, if it was initialized by a GDX file containing an Alias.
  
  * The new example **Alias** at [Path/To/GAMS]/apifiles/Java/alias/Alias.java demonstrates this new behavior.
6.11.9 24.3.3 (September 2014)

Fixed

- a location of listing file when creating a job from (full-path) file without giving a job name

6.11.10 24.3.2 (August 2014)

- Make more GAMS options available through the **GAMSOptons** class:
  - GAMSOptons.EAppendExpand (enum, getter, and setter): Expand file append option
  - GAMSOptons.EAppendOut (enum, getter, and setter): Output file append option
  - GAMSOptons.EDumpOpt (enum, getter, and setter): Writes preprocessed input to the file input.dmp
  - GAMSOptons.EDumpParms (enum, getter, and setter): GAMS parameter logging
  - GAMSOptons.EErrMsg (enum, getter, and setter): Placing of compilation error messages
  - GAMSOptons.EAppendExpand (getter, and setter): Expanded (include) input file name
  - GAMSOptons.FErr (getter, and setter): Alternative error message file
  - GAMSOptons.JobTrace (getter, and setter): Job trace string to be written to the trace file at the end of a Gams job
  - GAMSOptons.LimCol (getter, and setter): Maximum number of columns listed in one variable block
  - GAMSOptons.LimRow (getter, and setter): Maximum number of rows listed in one equation block
  - GAMSOptons.ELLogLine (enum, getter, and setter): Amount of line tracing to the log file
  - GAMSOptons.EOn115 (enum, getter, and setter): Generate errors for unknown unique element in an equation
  - GAMSOptons.Output (getter, and setter): Output file
  - GAMSOptons.EPageContr (enum, getter, and setter): Output file page control option
  - GAMSOptons.PageSize (getter, and setter): Output file page size (=0 no paging)
  - GAMSOptons.PageWidth (getter, and setter): Output file page width
  - GAMSOptons.Reference (getter, and setter): Symbol reference file
  - GAMSOptons.ScriptExit (getter, and setter): Program or script to be executed at the end of a GAMS run
  - GAMSOptons.ESuppress (enum, getter, and setter): Compiler listing option
  - GAMSOptons.Symbol (getter, and setter): Symbol table file
  - GAMSOptons.TraceLevel (getter, and setter): Solvestat threshold used in conjunction with a=GT

6.11.11 24.3.1 (July 2014)

New

- **Transport14** example at [Path/To/GAMS]/apifiles/Java/transport/Transport14.java.
- **GAMSSymbolRecord.getKey** method: to retrieve key of **GAMSWorkspace** on specified position index.
6.11 Release Notes

Changed

- no longer necessary to set up environment variable before running a program
  - possible to specify the GAMS system directory during run time using `GAMSWorkspace-Info.setSystemDirectory(String directory)` and `GAMSWorkspace(GAMSWorkspaceInfo info)`

- no longer necessary to specify `-Djava.library.path` when running a program
  - if `java.library.path` is specified, the shared libraries will be loaded from `java.library.path`
  - otherwise the shared libraries will be loaded from the class path that contains `GAMSJavaAPI.jar`.

- when exporting a database to GDX: a symbol with real domains from now on will be registered

- in `GAMSJob.run`: always creates output database `OutDB` even if `GAMSExecutionException` has been raised.

- in `GAMSSymbol.copySymbol` when copy into the Universe symbol (`GAMSDatabase.getSet("*")`) of a `GAMSDatabase`: merge operation will be performed.

- in `GAMSWorkspace` default constructor: API will apply the default setting, that is, finding GAMS system directory from environment variable in the following order (depends on the target platform):
  - Windows: first from `PATH` environment variable. If not found, from the platform windows registry `gams.location`,
  - Mac OS: first from `PATH` environment variable. If not found, from `DYLD_LIBRARY_PATH`,
  - Unix: from `PATH` environment variable. If not found, from `LD_LIBRARY_PATH`.

- in non-default `GAMSWorkspace` constructor:
  - user can specify a GAMS system directory during run time, API will not search for a GAMS system directory from an environment variable.
  - in case the specified system directory is null or user specify other workspace attributes but a system directory, API will apply the default setting (see changed in `GAMSWorkspace` default constructor above).

Fixed

- API memory leak issue in `GAMSDatabaseIterator`.
- a bug when reading an option file on Unix platform with non-standard locale

Removed

- all deprecated classes and methods since 24.1.

6.11.12 24.2.3 (May 2014)

Fixed

- API memory leak issue in `GAMSDatabase`.
- a bug in `GAMSDatabase.getDatabaseDomainViolations`. 
6.11.13  24.2.2 (March 2014)

Changed

- null string is treated as an invalid key for all record operations of `GAMSSymbol`.

Fixed

- a bug when creating `GAMSDatabase` from source database.
- a bug when initializing a variable type in `GAMSVariable`.
- a bug in `GAMSSymbol`: methods `getVarType` and `getEquType`.
- `GAMSModelInstance.instantiate`: make sure that the method does not solve the model, but only prepares everything required for the following `GAMSModelInstance.solve`.

6.11.14  24.2.1 (December 2013)

New

- tutorial: (GAMS_java_Tutorial.pdf) under <Path/To/GAMS>/docs/API. From the GAMSIDE this document can be accessed at Help -> Docs -> API.
- method in `GAMSGlobal.Globals.SpecialValues`: `setValue`, to set a GAMS special value
- method in `GAMSGlobal.Globals.SpecialValues`: `export`, to write an option into a parameter file
- methods in `GAMSWorkspace`: `addOptions` to create a `GAMSGlobal.Globals.SpecialValues` object from either another object or an option file
- methods in `GAMSWorkspace`: `getAPIVersion`, `getAPIMajorReleaseNumber`, `getAPIMinorReleaseNumber`, and `getAPIGoldReleaseNumber`, to retrieve API version number

Changed

- default value of `GAMSGlobal.Globals.SpecialValues`: `NAN`, `PLUS_INF`, `MINUS_INF`, and `EPS`

Fixed

- a bug when running a job with an input directory `IDir` added into `GAMSGlobal.Globals.SpecialValues` object.
6.11.15 24.1.3 (July 2013)

Improve data iterator

- New classes:
  - GAMSDatabaseIterator implements java.util.Iterator
  - GAMSSymbolIterator implements java.util.Iterator
- Deprecated Interface:
  - GAMSSymbolIterable, replaced by GAMSDatabaseIterator and GAMSSymbolIterator
- Changes in GAMSDatabase:
  - GAMSDatabase implements GAMSDatabaseIterator instead of GAMSSymbolIterable
  - deprecated the implemented methods of GAMSSymbolIterable: next(), hasnext(), and remove()
- Changes in GAMSSymbol:
  - GAMSSymbol implements GAMSSymbolIterator instead of GAMSSymbolIterable
  - deprecated the implemented methods of GAMSSymbolIterable: next(), hasnext(), and remove()
- New methods in GAMSSymbolRecord:
  - moveNext: to iterate to the next record using the current data iterator criterion
  - movePrevious: to iterate to the previous record using the current data iterator criterion

Update example:

- Transport12 at [Path/To/GAMS]/apifiles/Java/transport/Transport12.java

6.11.16 24.1.1 (May 2013)

Changes in GAMSDatabase:

- deprecates the compact method, as it has no effect anymore.

Changes in GAMSGlobals:

- the default value of working directory has been changed from System.getProperty("user.dir") to System.getProperty("java.io.tmpdir").

Changes in GAMSMModelInstance:

- deprecates the instantiate(GAMSOptions options), instantiate(GAMSModifier[]), and instantiate(GAMSOptions, GAMSModifier[]) methods and replaced by instantiate(String, GAMSModifier ...) and instantiate(String, GAMSOptions, GAMSModifier ...) methods

Changes in GAMSWorkspace and GAMSWorkspaceInfo:
• deprecates boolean debug flag and replaced by a debug level flag (type of a new class GAMS-Globals.DebugLevel).

• allows an override of debug level flag from an environment variable GAMS00APIDebug

New methods in GAMSDatabase:

• GAMSDatabase.addEquation, addParameter, addSet, and addVariable: to add symbols with domain information.

• checkDomains: to check whether or not all records of all symbols are within the specified domain of the symbols.

• getDatabaseDomainViolations: to retrieve a domain violation information as a list of GAMS-DatabaseDomainViolation objects.

• isAutoDomainCheckingSuppressed and suppressAutoDomainChecking: to control whether domain checking will be called when exporting a database.

New class GAMSDatabaseDomainViolation:

• contains domain violation information of all symbols (if any) in the database.

• returns call from a new method GAMSDatabase.getDatabaseDomainViolations.

New enumeration class GAMSGlobals.DebugLevel:

• defines values of different GAMS Debug Levels.

New methods in GAMSMModelInstance:

• copyModelInstance: to copy a GAMSMModelInstance object.

• interrupt: to send an interrupt signal to a running GAMSMModelInstance object.

New enumerated value of GAMSMModelInstance.SymbolUpdateType:

• GAMSMModelInstance.SymbolUpdateType.INHERIT: to specify GAMSMModelInstance.SymbolUpdateType separately for each GAMSMModifier.

New methods in GAMSMModifier:

• constructor: to specify SymbolUpdateType for each GAMSMModifier object.

• getUpdateType: to retrieve SymbolUpdateType property of the object.

New methods in GAMSSSymbol:

• checkDomains: to check whether or not all records of the symbol are within the specified domain.

• getDomains: to retrieve a list of domains of the symbol, each element is either a GAMSSet (real domain) or a String (relaxed domain).
• **getSymbolDomainViolations**: to retrieve a domain violation information as a list of GAMSSymbolDomainViolation objects.

• **mergeRecord**: to add a new symbol record in case the record does not exist.

New class  **GAMSSymbolDomainViolation**:

• contains domain violation information of the symbol (if any).

• returns call from a new method  **GAMSSymbol.getSymbolDomainViolations**.

New methods in  **GAMSWorkspace**

• **getGAMSVersion**: to retrieve information about GAMS Version.

• **getGoldReleaseNumber**: to retrieve GAMS GOLD Release Number.

• **getMajorReleaseNumber**: to retrieve GAMS Major Release Number.

• **getMinorReleaseNumber**: to retrieve GAMS Minor Release Number.

Fixed a bug when iterating through the records of a **GAMSSymbol**

Changes of location of examples:

• **Bender Examples**: from [Path/To/GAMS]/apifiles/Java/Benders*.java to [Path/To/GAMS]/apifiles/Java/benders/Benders*.java

• **Cutstock**: from [Path/To/GAMS]/apifiles/Java/Cutstock.java to [Path/To/GAMS]/apifiles/Java/cutstock/Cutstock.java

• **ConsoleInterrupt**: from [Path/To/GAMS]/apifiles/Java/ConsoleInterrupt.java to [Path/To/GAMS]/apifiles/Java/interrupt/ConsoleInterrupt.java

• **Transport Examples**: from [Path/To/GAMS]/apifiles/Java/Transport*.java to [Path/To/GAMS]/apifiles/Java/transport/Transport*.java

• **Warehouse**: from [Path/To/GAMS]/apifiles/Java/Warehouse.java to [Path/To/GAMS]/apifiles/Java/warehouse/Warehouse.java

New examples:

• **SimpleCutstock** at [Path/To/GAMS]/apifiles/Java/cutstock/SimpleCutstock.java

• **DomainCheck** at [Path/To/GAMS]/apifiles/Java/domain/DomainCheck.java

• **Transport13** at [Path/To/GAMS]/apifiles/Java/transport/Transport13.java

• **Tsp** at [Path/To/GAMS]/apifiles/Java/tsp/Tsp.java

6.11.17  24.0.2 (February 2013)

New method in  **GAMSSymbol**

• added new method  **copySymbol**.
6.11.18 24.0.1 (December 2012)

This release contains a beta version of the object-oriented Java API that can be used to control GAMS from a Java program. It allows the seamless integration of GAMS into Java by providing appropriate classes for the interaction with GAMS. GAMS Java API objects allow a convenient way to exchange input data and model results with in-memory representation of data (\texttt{GAMSDatabase}), and to create and run GAMS models (\texttt{GAMSJob}) that can be customized by GAMS options (\texttt{GAMSOOptions}). Furthermore, they introduce a way to solve a sequence of closely related model instances in the more efficient way (\texttt{GAMSModelInstance}).

- A Java program that uses object-oriented Java API requires at least Java SE 5 to compile and run.
- All classes are distributed within one single jar file \texttt{GAMSJavaAPI.jar} with a namespace \texttt{com.gams.api}, located under the \texttt{[Path/To/GAMS]/apifiles/Java/api/} directory.
- Java program examples are distributed with namespace \texttt{com.gams.examples}, located under \texttt{[Path/To/GAMS]/apifiles/Java/} directory.
- Installation and detailed documents can be found in \texttt{[Path/To/GAMS]/apifiles/readme.txt} and \texttt{[Path/To/GAMS]/docs/API/GAMS\_java.pdf}.
- Javadoc for \texttt{GAMSJavaAPI.jar} can be found under \texttt{[Path/To/GAMS]/apifiles/java/api/javadoc} directory.

6.12 Release Notes

6.12.1 25.0.1

- Added implementation of \_eq\_() and \_ne\_() to classes \texttt{GamsSymbol} and \texttt{GamsSymbolRecord} and its derived classes. As a result the behavior of the operators == and != has changed. == returns now \texttt{True}, if the internal data reference is the same. The behavior of is remains unchanged.
- New example \texttt{transport\_gdx.py} that shows how to import and export GDX files.
- Added description of example \texttt{transport\_gdx.py} to the tutorial.

6.12.2 24.9.2

- Fixed a bug in the setup script that prevented files from being installed in the correct location in certain cases.

6.12.3 24.9.1

- New functions \texttt{GamsWorkspace.add\_job\_from\_apilib}, \texttt{GamsWorkspace.add\_job\_from\_noalib} to create \texttt{GamsJob} from models from the GAMS API Library and the Nonlinear Optimization Applications Library
- Added a version check for the setup.py scripts to avoid unintentional installation of wrong versions
6.12.4  24.8.4

- Added support for Python 3.6
- Fixed a bug in GamsJob.run() that prevented the underlying GAMS model from terminating, if executables spawned by GAMS generate log output that is not captured.

6.12.5  24.8.1

- The option GamsOptions.errorlog was renamed as GamsOptions.errorlog in order to indicate it as public. The option sets the maximum error message lines written to the log for each error.

6.12.6  24.7.4

- Added support for Python 3.4 on Mac OS X
- Skip creation of a GDX file in GamsModelInstance.instantiate that was unreachable from within the API.
- Fixed a problems with Exceptions in GamsWorkspace.

6.12.7  24.7.2

- Fixed a minor bug regarding the names of GamsJob listing files.

6.12.8  24.7.1

- Fixed a bug with the property GamsOptions.defines: When too many entries were added, all of them were ignored.
- Fixed a memory leak in GamsDatabase.

6.12.9  24.6.1

- New Python example transport8a.py

6.12.10  24.5.2

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. The property GamsWorkspace.system_directory now always returns the canonical path with all symbolic links resolved.
6.12.11  24.5.1

- Added support for Python 3.4 (Windows and Linux only)
  - The examples have been changed to be compatible with all supported Python versions
- New Python example special_values.py.
- New Python example clad.py.
- New functions GamsWorkspace.noalib and GamsWorkspace.apilib that can be used to retrieve models from the NOALIB and the APILIB

6.12.12  24.4.2

- Fixed a bug in the constructor of all subclasses of _GamsSymbol that occurred when the explanatory text was omitted.
- Disable unwanted debug output from Couenne when running with GamsModelInstance
- New property _GamsSymbol.domains_as_strings: Domains of Symbol, each element is a string. Note: If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set
- Fixed potential problem with GamsModelInstance used with BARON.

6.12.13  24.4.1

- Fixed a bug in GamsDatabase.merge_record that prevented the function from creating a record if none was found.
- We changed the handling of GAMS Aliases in the object oriented APIs:
  - If we ask for the number of GamsSymbols in a GamsDatabase, the Aliases will be excluded.
  - If we iterate over all GamsSymbols in a GamsDatabase, Aliases will be skipped.
  - If we ask explicitly for an Alias in a GamsDatabase (GamsDatabase.get_set("a") with a being an Alias) we will get a reference to the GamsSet referenced by the Alias, not the Alias itself.
  - Note: Aliases can appear in a GamsDatabase only, if it was initialized by a GDX file containing an Alias.
  - The new Python example alias.py demonstrates this new behavior.

6.12.14  24.3.2

- Make more GAMS options available through the GamsOptions class (Removed leading underscores of property identifiers):
  - GamsOptions.appendexpand: Expand file append option
  - GamsOptions.appendout: Output file append option
  - GamsOptions.dumpopt: Writes preprocessed input to the file input.dmp
  - GamsOptions.dumpparms: GAMS parameter logging
  - GamsOptions.errmsg: Placing of compilation error messages
  - GamsOptions.expand: Expanded (include) input file name
  - GamsOptions.ferr: Alternative error message file
- GamsOptions.jobtrace: Job trace string to be written to the trace file at the end of a Gams job
- GamsOptions.limcol: Maximum number of columns listed in one variable block
- GamsOptions.limrow: Maximum number of rows listed in one equation block
- GamsOptions.logline: Amount of line tracing to the log file
- GamsOptions.on115: Generate errors for unknown unique element in an equation
- GamsOptions.output: Output file
- GamsOptions.pagecontr: Output file page control option
- GamsOptions.pagesize: Output file page size (=0 no paging)
- GamsOptions.pagewidth: Output file page width
- GamsOptions.reference: Symbol reference file
- GamsOptions.scriptexit: Program or script to be executed at the end of a GAMS run
- GamsOptions.suppress: Compiler listing option
- GamsOptions.symbol: Symbol table file
- GamsOptions.tracelevel: Solvestat threshold used in conjunction with a=GT

6.12.15 24.3.1

- On Linux and OS X: LD_LIBRARY_PATH and DYLD_LIBRARY_PATH do not need to contain a GAMS system directory anymore. Anyway, if no system directory is specified in the GamsWorkspace constructor, PATH and LD_LIBRARY_PATH/DYLD_LIBRARY_PATH is used to find a GAMS system directory. The order is as follows:
  - Linux: If no system directory is specified in the GamsWorkspace constructor, check PATH first. If no system directory was found, check LD_LIBRARY_PATH
  - OS X: If no system directory is specified in the GamsWorkspace constructor, check PATH first. If no system directory was found, check DYLD_LIBRARY_PATH
  - Windows: If no system directory is specified in the GamsWorkspace constructor, check registry.
- GamsJob.run creates out.db now even if it throws a GamsExceptionExecution
- New example transport14
- New function GamsSymbolRecord.key(int index): Retrieve key of GamsSymbolRecord on position index
- GamsModelInstance.solve now also works for solvers which require a subsolver, e.g. Dicopt

6.12.16 24.2.3

- Fix memory leak in GamsDatabase

6.12.17 24.2.2

- Fixed a bug regarding the subtype of equations and their default records, when the equation was added to a GamsDatabase from the API.
- Fixed a bug in GamsSymbol.delete_record.
- Fixed GamsExitCode.
- Make sure that GamsModelInstance.instantiate() does not solve the model, but only prepares everything required for the following solve()
6.12.18 24.2.1

- Add tutorial (GAMS_python_Tutorial.pdf) to <Path/To/GAMS>/docs/API. From the GAMSIDE this document can be accessed at Help -> Docs -> API.
- New parameter opt_file in function GamsWorkspace.add_options allows to create an instance of GamsOptions that is initialized by an existing option file.
- New function GamsOptions.export: Write GamsOptions into a parameter file.
- New property GamsWorkspace.my_eps: Reset value to be stored in and read from GamsDatabase for Epsilon.
- New class NoNewVarEqu providing static fields to set option nonewvarreq.
- Fixed a bug in _GamsSymbol.add_record() that occurred when using empty strings as keys.
- Fixed a bug in GamsModelInstance.solve() that affected the logging behavior.
- The following functions throw an exception, when a wrong data type is passed for the keys/slice parameter: delete_record, find_record, add_record, merge_record, first_record, last_record. Valid data types are str, list, tuple and their subclasses.

6.12.19 24.1.1

- New examples: markowitz.py, tsp.py, transport13.py, simple_cutstock.py, domain_checking.py.
- New facility for GamsSymbols with domain information:
  - GamsDatabase:
    * New functions add_parameter_dc, add_variable_dc, add_equation_dc and add_set_dc: Create GamsSymbols with domain information.
    * New function check_domains: Check for all symbols if all records are within the specified domain of the symbol.
    * New function get_database_dvs: Return all GamsDatabaseDomainViolations.
    * New property suppress_auto_domain_checking: Controls whether domain checking is called in GamsDatabase export.
  - _GamsSymbol and its derived classes:
    * New function check_domains: Check if all records are within the specified domain of the symbol.
    * New function get_symbol_dvs: Return all GamsDatabaseDomainViolations.
    * New property domains: Domains of Symbol, each element is either a GamsSet (real domain) or a string (relaxed domain).
  - New classes GamsDatabaseDomainViolation and GamsSymbolDomainViolation that are returned by GamsDatabase.get_database_dvs and _GamsSymbol.get_symbol_dvs.
- New functions in GamsModelInstance:
  - copy_modelinstance: Copies a GamsModelInstance to a new GamsModelInstance which gets constructed at this call.
  - interrupt: Sends interrupt signal to running GamsModelInstance.
• New function in \_GamsSymbol and its derived classes: merge_record finds a record if it exists and adds it if not

• New functions in GamsWorkspace: add_job_from_gamslib, add_job_from_testlib, add_job_from_emplib, add_job_from_datelib and add_job_from_finlib

• New properties in GamsWorkspace: version, major_rel_number, minor_rel_number, gold_rel_number

• New optional parameter in model name for functions add_database from gdx/add_database in GamsWorkspace: GAMS string constant that is used to access this database

• Changed the debug argument passed to the GamsWorkspace constructor. Use members of class DebugLevel: Off, KeepFiles, ShowLog and Verbose instead of True and False

• New sub class of GamsException: GamsExceptionExecution, which provides additional info about the reason of the failed execution

• Allow to define SymbolUpdateType for each GamsModifier seperately

• Significant performance improvement for function GamsWorkspace.add_database when creating from an already existing database

• Changed the unicode settings on Linux from UCS2 to UCS4

• The Debug parameter of GamsWorkspace can be overwritten by the system environment variable "GAMSOOAPIDEBUG" if set to one of the following: Off, KeepFiles, ShowLog, Verbose

• The compact method of GamsDatabase is obsolete and has no effect anymore. It will be removed in the future.

• Fixed a bug in GamsModelInstance.solve()

• Fixed a bug in GamsDatabase, where the special value for undefined was set to 0 instead of 1.0E300 (SV_UNDEF)

• Fixed a bug when iterating through the records of a GamsSymbol

6.12.20 24.0.2

• Added new function \_GamsSymbol.copy_symbol which copies all records from one to another GamsSymbol

• Label and symbol lookup is now case insensitive

• Fixed handling of infinite bounds for GamsModifiers

6.12.21 24.0.1

This release contains a beta version of the object-oriented Python API that can be used to control GAMS from within Python 2.7. It allows the seamless integration of GAMS into Python by providing appropriate classes for the interaction with GAMS. The GamsDatabase class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the GamsJob class and by using the GamsModelInstance class a sequence of closely related model instances can be solved in an efficient way. To use this API see the Getting started section.

6.14  GAMS Modeling Object Design

This document gives a brief introduction to GAMS’ new model-solver API, including a description of its design goals and philosophy. This document is not intended to be used as a user's manual but rather to give a picture of what the new API can do and a description of some of the conceptual underpinnings for the new API.

Further material: Presentation at ICS 2011

6.14.1 Introduction

Historically, there have been a number of different GAMS solver interface libraries, i.e. libraries that enabled a solver to get all required information from a GAMS model, compute the solution, and return the solution, status information, and other information (e.g. solver log messages, nonlinear function evaluation error messages, node counts, time used) to GAMS. Each library was unique in some way, e.g. in the computer language or subset of GAMS model types it supported. Each library had its own advantages and disadvantages, but all of them were feature-poor and supported a limited scheme of operation: GAMS/Base would write scratch files containing the model to be solved, the GAMS solver link executable would use one of the solver interface libraries to read the model from scratch file and write a solution file, and GAMS/Base would read this solution file. While this scheme worked for many years it was inconvenient for the library user, difficult to maintain, slow, and a barrier to further development.

To address these issues and others, GAMS developed a new model-solver interface library, called GMO (GAMS Model Object), and a companion library called GEV (GAMS Environment Object). The two libraries are distinct and help to separate the purely model-specific tasks and information handled by GMO from the computing and solver environment that the model will be solved in, handled by GEV. The two libraries are typically used together and we will sometimes refer to them as simply GMO. For legacy reasons the new libraries support the old file-based scheme to communicate a model through scratch files.

In what follows, we first describe the basic structure, organization, and usage of GMO (Basic organization). Client applications can be split into two types: those defining or updating the model (Modeler Access to GMO) and those passing the model to a solver (Solver Access to GMO). We next describe some ways to update a model in Updating a GMO instance.

6.14.2 Basic organization

In this section we outline the basic organization of GMO. GMO is implemented as a shared library that interfaces to different languages via language-specific header files and interface code. The header files and code are included in source form with the GAMS distribution. Since the interface code employs dynamic loading, each GMO session begins with a call to initialize the required shared library (i.e. load it and all its symbols) and return an empty model object.

The next step is to load a model into the model object. This is typically done with a single wrapper call, as in the case of loading a model from model scratch files prior to solving in one of the GAMS solver links. It is also possible build up a model from scratch with a sequence of calls to provide the model column-wise or row-wise. If the model is built up column-wise or row-wise, additional information (e.g. about nonlinearities) may be passed to the object after the basic structure is built up. Once the model is complete, a finalization routine is called. This routine prepares the model object for efficient access by the user. Typically the model does not change after this point. There are exceptions to this (see Updating a GMO instance), but they usually involve small modifications to the existing model (like adding alternative bounds) or the addition of constraints and variables that require the re-finalization of the model.

When a model is fully loaded, the GMO client can start accessing the model. Typically the GMO client doing this will be a solver, but other clients (e.g. the CONVERT solver, the Examiner utility, or a model
structure browser) exist also. In addition to querying the model, the client can also request that the
model be presented or viewed in various different ways. For example, GMO can be requested to use an
objective function or an objective variable. Most types of information are available immediately when the
model is loaded, but some type of queries (e.g. Hessians, alternative QP forms) are less common and
relatively expensive in time and/or space: these require that an initialization routine be called before the
information is requested. Once the client has completed its work it reports on the solution found, if any.
Typically, the model object is destroyed at this point. Model access by a client, especially solvers, is an
important topic that is discussed in Solver Access to GMO.

The variety of data that go into the interface library when a model is defined and that a solver can request
during solution is large, but the data can be divided into two types - data defining the model (e.g.
number of rows and columns, coefficients, nonlinear functions) and data defining the solver environment (e.g.
available and default GAMS solvers, license info, algorithm tolerances and limits). It is sometimes useful to
separate these two types of data, so that it is possible to define and work with a model without specifying
anything about the environment it exists in. The environment can be specified separately, and multiple
models can make use of the same basic environment. To facilitate this, the solver interface is in two parts:
the GMO interface deals with model-specific information and the GEV interface with information about
the environment. The two environments are linked, since they are typically used together, with one (or
multiple) models existing in one environment, but the separation makes it possible to define a model
without defining its environment, etc. Since the bulk of the information and the code lies with GMO,
we usually speak of the two libraries as one, called GMO, but it is worth remembering that GEV is a
separate object.

6.14.3 Solver Access to GMO

One of the primary purposes of GMO is to provide convenient, efficient access to the model. GAMS links
to many solvers, each solver link using GMO to access the model in different ways, so there is a wide
array of possible methods to access the model in GMO. We describe them in this section.

There are multiple but equivalent views possible for the same model. For example, the model can be
formulated with an objective function or with an objective variable. Free rows can be removed or left
in, and the rows and/or columns can be permuted. Prior to accessing the model, the solver link can
choose what view it would like to use. The view can be changed later, but since this can obviate the data
obtained previously, the choice of view is usually made early on and left unchanged. Moreover, a view can
be stored and restored in case multiple users access the same model.

All solvers will need to get basic information about a model - simple things like row and column counts,
nonzero counts, etc. These are available via simple access routines. Since the model is essentially fixed
(assuming the view does not change), basic information is pre-computed when the model takes its final
form and is available at essentially no cost. Information about the rows and columns (e.g. variable level
values, marginal values, variable priorities, row types) is also available, either for single rows/cols or in an
array for all rows/cols at once.

For linear models, the only information left to get is the matrix of coefficients. This is available in a
number of different forms e.g. column-wise or row-wise, either as a complete matrix returned with one call
or as separate rows or columns returned via many calls. For nonlinear models, there are more variants on
this theme: calls to return the function value or the function value and derivatives, calls for constraints and
calls for the objective function. You can request that the nonlinear model be treated as its linearization
around a certain point. There are also routines to do interval evaluations of functions and gradients. The
GMO library prepares the model object to handle all these calls efficiently when the model takes its final
form.

Nonlinear models present several additional challenges. When NL functions are evaluated, mathematical
errors can occur (e.g. sqrt(-1)). GMO supports different ways to log and handle these errors. Some
algorithms will require or want 2nd-order information. Since this can be relatively expensive to compute,
the solver must first call an initialization routine specifying what is desired (e.g. only Hessian-vector
products, Lagrangian Hessian, single-row Hessians) and potentially a limit on the memory dedicated to computing Hessians. After this initialization, 2nd-order information is available.

Once the solver finishes, the solution (if any) and related status values must be reported back to GMO. There are a number of convenience routines included in GMO for this purpose.

A convenient interface was and is an important design goal for GMO, especially in the area of solver access to the model. Convenience takes many forms: a number of ways to get the same model data in order to support a variety of different solver libraries, self-contained calls with minimal requirements on previous setup for correct behavior, and a modern interface adhering to design principles like information hiding, encapsulation, and an object model. By keeping these goals at the fore when designing GMO we have made accessing the model convenient and efficient, which greatly simplifies the task of building a correctly-functioning solver link.

6.14.4 Modeler Access to GMO

In normal operation the modeler creates a model in GAMS source form and the GAMS/Base module handles all the details necessary to build up model instances in GMO. However, there are cases (e.g. solving a model many times over with different scenario data) where it is useful to access and modify a GMO instance outside of GAMS/Base. GMO provides routines to support this, specifically routines to update the model (see Updating a GMO instance), solve the model with one of the GAMS solvers available as part of the GAMS environment and GEV, and retrieve the solution.

Access to a GMO instance is usually done using integer indices, \([1..m]\) for the rows and \([1..n]\) for the columns. However, it is also possible to reference rows and columns using the notation from the original GAMS model, e.g. \(x('seattle','topeka')\) or \(demand('chicago')\). This is more convenient when specifying what data should be updated to define a new scenario. In order to update a model instance in this case, it is useful to have a convenient, efficient way to translate row and column indices from one form to the other. This translation is done by the model dictionary interface DCT.

The DCT API provides information about the variables, equations, and sets used to define the GMO model instance. In addition, given a row or column index, it will translate this index into the equation or variable name and the list of set labels that correspond to this index. It will also do the inverse operation, translating an equation/variable name and list of labels into a row or column index. GAMS builds models in a way that makes this translation very efficient.

This organization is also useful when updating models to create new scenarios. Models are organized so that:

- There is one ordered universe of all labels appearing in the variables and equations of a given model. The order for the labeling does not change from symbol to symbol within a model.
- All of the columns in a model corresponding to a given variable are contiguous. (Ditto for rows and equations)
- The columns corresponding to a given variable are sorted by their index labels, using the universal order, with the left-most index varying slowest. (Ditto for rows and equations)
- GDX data is sorted in the same way: sorted by index label order, left-most index varying slowest. This can be very useful, provided the model and the GDX data use the same label ordering.

Using the various GAMS component libraries, it is possible to create a model updating interface that is both convenient for the user (by using the symbolic names referenced in the GAMS source) and efficient in updating the model data.
6.14 GAMS Modeling Object Design

6.14.5 Updating a GMO instance

There are several possible ways to modify a model contained in a GMO instance. By updating, we mean an actual model change, rather than a change in the view that doesn't alter the set of solutions.

In perhaps the simplest case, the user can specify alternate variable bounds, as is useful when implementing a branch and bound code. The original bounds are retained in this case, so that the model can be reverted to the original bounds with a single call.

It is possible to linearize a model around a given point. This requires no information from the point to linearize around and can be undone easily. This is almost a change in view but since the solutions of the original and linearized models may be quite different we can also consider this a model update.

Many algorithms (e.g. outer approximation, Benders decomposition, Danzig-Wolfe decomposition) involve the addition of rows, and columns incident on these rows, to a core model. Such algorithms can be implemented effectively using GMO by taking advantage of GMO facilities to add rows and columns. There will be only a small amount of work required to prepare the GMO instance for use after each round of additional rows and columns. Note that all the changes to the model in this case are additions: the existing structure and data are left as is.

Finally, there are facilities in GMO to update variable bounds (as mentioned before), variable types (e.g. to relax single discrete variables), and the right-hand-side of constraints. The user cannot directly modify matrix coefficients. There is a much better way to safely update exogenous data in a model: GAMS can provide a model instance in which GAMS parameters are visible and can be updated. A reevaluation of the expressions in the models provides the updated matrix elements. The underlying concept is also used in Gather-Update-Solve-Scatter (GUSS) and described in more detail in this paper. This is a powerful tool to efficiently do e.g. Monte-Carlo simulation without the need for GAMS to regenerate the entire model over and over.
