5.13.5 Appendix B - Error Messages

1. ERROR in MODEL.STO: kwd, word1, word2 was not matched in first realization of block
   The specification of the stochastic parameters is incorrect. The stochastic parameter has not been
   specified in the specification of the first outcome of the block. When specifying the first outcome of
   a block always include all stochastic parameters corresponding to the block.

2. Option word1 word2 not supported
   You specified an input distribution in the stochastic file that is not supported. Check the DECIS
   manual for supported distributions.

3. Error in time file
   The time file is not correct. Check the file MODEL.TIM. Check the DECIS manual for the form of
   the time file.

4. ERROR in MODEL.STO: stochastic RHS for objective, row name2
   The specification in the stochastic file is incorrect. You attempted to specify a stochastic right-hand
   side for the objective row (row name2). Check file MODEL.STO.

5. ERROR in MODEL.STO: stochastic RHS in master, row name2
   The specification in the stochastic file is incorrect. You attempted to specify a stochastic right-hand
   side for the master problem (row name2). Check file MODEL.STO.

6. ERROR in MODEL.STO: col not found, name1
   The specification in the stochastic file is incorrect. The entry in the stochastic file, name1, is not
   found in the core file. Check file MODEL.STO.

7. ERROR in MODEL.STO: invalid col/row combination, (name1/name2)
   The stochastic file (MODEL.STO) contains an incorrect specification.

8. ERROR in MODEL.STO: no nonzero found (in B or D matrix) for col/row (name1, name2)
   There is no nonzero entry for the combination of name1 (col) and name2(row) in the B-matrix or in
   the D-matrix. Check the corresponding entry in the stochastic file (MODEL.STO). You may want
   to include a nonzero coefficient for (col/row) in the core file (MODEL.COR).

9. ERROR in MODEL.STO: col not found, name2
   The column name you specified in the stochastic file (MODEL.STO) does not exist in the core file
   (MODEL.COR). Check the file MODEL.STO.

10. ERROR in MODEL.STO: stochastic bound in master, col name2
    You specified a stochastic bound on first-stage variable name2. Check file MODEL.STO.

11. ERROR in MODEL.STO: invalid bound type (kwd) for col name2
    The bound type, kwd, you specified is invalid. Check file MODEL.STO.

12. ERROR in MODEL.STO: row not found, name2
    The specification in the stochastic file is incorrect. The row name, name2, does not exist in the core
    file. Check file MODEL.STO.

13. ERROR: problem infeasible
    The problem solved (master- or subproblem) turned out to be infeasible. If a subproblem is infeasible,
    you did not specify the problem as having the property of "complete recourse". Complete recourse
    means that whatever first-stage decision is passed to a subproblem, the subproblem will have a
    feasible solution. It is the best way to specify a problem, especially if you use a sampling based
    solution strategy. If DECIS encounters a feasible subproblem, it adds a feasibility cut and continues
    the execution. If DECIS encounters an infeasible master problem, the problem you specified is
    infeasible, and DECIS terminates. Check the problem formulation.

14. ERROR: problem unbounded
    The problem solved (master- or subproblem) turned out to be unbounded. Check the problem
    formulation.
15. ERROR: error code: inform
The solver returned with an error code from solving the problem (master- or subproblem). Consult the users’ manual of the solver (MINOS or CPLEX) for the meaning of the error code, inform. Check the problem formulation.

16. ERROR: while reading SPECS file
The MINOS specification file (MINOS.SPC) contains an error. Check the specification file. Consult the MINOS user’s manual.

17. ERROR: reading mps file, mpsfile
The core file mpsfile (i.e., MODEL.COR) is incorrect. Consult the DECIS manual for instructions regarding the MPS format.

18. ERROR: row 1 of problem is not a free row
The first row of the problem is not a free row (i.e., is not the objective row). In order to make the first row a free row, set the row type to be 'N'. Consult the DECIS manual for the MPS specification of the problem.

19. ERROR: name not found = nam1, nam2
There is an error in the core file (MODEL.COR). The problem cannot be decomposed correctly. Check the core file and check the model formulation.

20. ERROR: matrix not in staircase form
The constraint matrix of the problem as specified in core file (MODEL.COR) is not in staircase form. The first-stage rows and columns and the second-stage rows and columns are mixed within each other. Check the DECIS manual as to how to specify the core file. Check the core file and change the order of rows and columns.
5.13.6 DECIS License and Warranty

The software, which accompanies this license (the "Software") is the property of Gerd Infanger and is protected by copyright law. While Gerd Infanger continues to own the Software, you will have certain rights to use the Software after your acceptance of this license. Except as may be modified by a license addendum, which accompanies this license, your rights and obligations with respect to the use of this Software are as follows:

- You may
  1. Use one copy of the Software on a single computer,
  2. Make one copy of the Software for archival purposes, or copy the software onto the hard disk of your computer and retain the original for archival purposes,
  3. Use the Software on a network, provided that you have a licensed copy of the Software for each computer that can access the Software over that network. After a written notice to Gerd Infanger, transfer the Software on a permanent basis to another person or entity, provided that you retain no copies of the Software and the transferee agrees to the terms of this agreement.

- You may not
  1. Copy the documentation, which accompanies the Software,
  2. Sublicense, rent or lease any portion of the Software,
  3. Reverse engineer, de-compile, disassemble, modify, translate, make any attempt to discover the source code of the Software, or create derivative works from the Software.

5.13.6.1 Limited Warranty:

Gerd Infanger warrants that the media on which the Software is distributed will be free from defects for a period of thirty (30) days from the date of delivery of the Software to you. Your sole remedy in the event of a breach of the warranty will be that Gerd Infanger will, at his option, replace any defective media returned to Gerd Infanger within the warranty period or refund the money you paid for the Software. Gerd Infanger does not warrant that the Software will meet your requirements or that operation of the Software will be uninterrupted or that the Software will be error-free.

THE ABOVE WARRANTY IS EXCLUSIVE AND IN LIEU OF ALL OTHER WARRANTIES, WHETHER EXPRESS OR IMPLIED, INCLUDING THE IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT.

5.13.6.2 Disclaimer of Damages:

REGARDLESS OF WHETHER ANY REMEDY SET FORTH HEREIN FAILS OF ITS ESSENTIAL PURPOSE, IN NO EVENT WILL GERD INFANGER BE LIABLE TO YOU FOR ANY SPECIAL, CONSEQUENTIAL, INDIRECT OR SIMILAR DAMAGES, INCLUDING ANY LOST PROFITS OR LOST DATA ARISING OUT OF THE USE OR INABILITY TO USE THE SOFTWARE EVEN IF GERD INFANGER HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

IN NO CASE SHALL GERD INFANGER'S LIABILITY EXCEED THE PURCHASE PRICE FOR THE SOFTWARE. The disclaimers and limitations set forth above will apply regardless of whether you accept the Software.
5.13.6.3 General:

This Agreement will be governed by the laws of the State of California. This Agreement may only be modified by a license addendum, which accompanies this license or by a written document, which has been signed by both you and Gerd Infanger. Should you have any questions concerning this Agreement, or if you desire to contact Gerd Infanger for any reason, please write:

5.14 DICOPT

Author

Ignacio E. Grossmann, Jagadisan Viswanathan, Aldo Vecchietti; Engineering Research Design Center, Carnegie Mellon University, Pittsburgh, PA
Ramesh Raman, Erwin Kalvelagen; GAMS Development Corporation, Washington D.C.

5.14.1 Introduction

DICOPT is a program for solving mixed-integer nonlinear programming (MINLP) problems that involve linear binary or integer variables and linear and nonlinear continuous variables. While the modeling and solution of MINLP optimization problems has not yet reached the stage of maturity and reliability achieved by linear, integer, or non-linear programming modeling, these problems still have rich areas of application. For example, they often arise in engineering design, management sciences, and finance. DICOPT (DIscrete and Continuous OPTimizer) was developed by J. Viswanathan and Ignacio E. Grossmann at the Engineering Design Research Center (EDRC) at Carnegie Mellon University. The program is based on the extensions of the outer-approximation algorithm for the equality relaxation strategy. The MINLP algorithm inside DICOPT solves a series of NLP and MIP sub-problems. These sub-problems can be solved using any NLP (Nonlinear Programming) or MIP (Mixed-Integer Programming) solver that runs under GAMS. The performance will heavily depend on the choice of the selected subsolvers.

Although the algorithm has provisions to handle non-convexities, it does not necessarily obtain the global optimum.

The GAMS/DICOPT system has been designed with two main goals in mind:

- to build on existing modeling concepts, introduce a minimum of extensions to the existing modeling language, and provide upward compatibility to ensure easy transition from existing modeling applications to nonlinear mixed-integer formulations
- to use existing optimizers to solve the DICOPT sub-problems. This allows one to match the best algorithms to the problem at hand and guarantees that any new development and enhancements in the NLP and MIP solvers become automatically and immediate available to DICOPT.
5.14.2 Requirements

In order to use **DICOPT** you will need to have access to a licensed GAMS BASE system as well as at least one licensed MIP solver and one licensed NLP solver. For difficult models it is advisable to also have access to multiple solvers.

5.14.3 How to Run a Model with GAMS/DICOPT

**DICOPT** is only able to solve MINLP and MIQCP models. If you did not specify **DICOPT** as the default solver you can use the following statement in your GAMS model:

```
option minlp = dicopt;
```

This should appear before the solve statement. **DICOPT** automatically uses the default MIP and NLP solver to solve its sub-problems. One can override this with GAMS statements like:

```
option nlp = conopt;  { or any other nlp solver }
option mip = gurobi;  { or any other mip solver }
```

These options can also be specified on the command line:

```
> gams mymodel minlp=dicopt nlp=conopt mip=gurobi
```

In the Integrated Development Environment (IDE) the command line option can be specified in the edit line in the right upper corner of the main window.

Possible NLP solvers include **conopt**, **ipopt**, **knitro**, **minos**, and **snopt**. Possible MIP solvers include **cplex**, **gurobi**, and **xpress**.

With an option file it is even possible to use alternate solvers in different cycles. Section **DICOPT Options** explains this in detail.

5.14.4 Overview of DICOPT

**DICOPT** solves models of the form:

\[
\begin{align*}
\text{min or max} & \quad f(x, y) \\
\text{subject to} & \quad g(x, y) \sim b \\
& \quad \ell_x \leq x \leq u_x \\
& \quad y \in [\ell_y, \ldots, u_y]
\end{align*}
\]  

(MINLP)

where \(x\) are the continuous variables and \(y\) are the discrete variables. The symbol \(\sim\) is used to denote a vector of relational operators \(\leq, =, \geq\). The constraints can be either linear or non-linear. Bounds \(\ell\) and \(u\) on the variables are handled directly. \([x]\) indicates the smallest integer, greater than or equal to \(x\). Similarly, \([-x]\) indicates the largest integer, less than or equal to \(x\). The discrete variables can be either integer variables or binary variables.
5.14 DICOPT

5.14.5 The Algorithm

The algorithm in DICOPT is based on three key ideas:

- Outer Approximation
- Equality Relaxation
- Augmented Penalty

Outer Approximation refers to the fact that the surface described by a convex function lies above the tangent hyper-plane at any interior point of the surface. (In 1-dimension, the analogous geometrical result is that the tangent to a convex function at an interior point lies below the curve). In the algorithm outer-approximations are attained by generating linearizations at each iterations and accumulating them in order to provide successively improved linear approximations of nonlinear convex functions that underestimate the objective function and overestimate the feasible region.

Equality Relaxation is based on the following result from non-linear programming. Suppose the MINLP problem is formulated in the form:

\[
\begin{align*}
\text{minimize or maximize} & \quad f(x) + c^T y \\
\text{subject to} & \quad G(x) + Hy \sim b \\
& \quad \ell \leq x \leq u \\
& \quad y \in \{0, 1\}
\end{align*}
\]

i.e. the discrete variables are binary variables and they appear linearly in the model.

Let \( y^{(0)} \) be any fixed binary vector and let \( x^{(0)} \) be the solution of the corresponding NLP subproblem:

\[
\begin{align*}
\text{minimize} & \quad c^T y^{(0)} + f(x) \\
\text{subject to} & \quad A y^{(0)} + h(x) = 0 \\
& \quad B y^{(0)} + g(x) \leq 0 \\
& \quad \ell \leq x \leq u
\end{align*}
\]

Further let

\[
T^{(0)} = \text{diag}(t_{i,i}) \\
t_{i,i} = \text{sign}(\lambda_i)
\]

where \( \lambda_i \) is the Lagrange multiplier of the \( i \)-th equality constraint.

If \( f \) is pseudo-convex, \( h \) is quasi-convex, and \( g \) is quasi-convex, then \( x^0 \) is also the solution of the following NLP:

\[
\begin{align*}
\text{minimize} & \quad c^T y^{(0)} + f(x) \\
\text{subject to} & \quad T^{(0)}(A y^{(0)} + h(x)) \leq 0 \\
& \quad B y^{(0)} + g(x) \leq 0 \\
& \quad \ell \leq x \leq u
\end{align*}
\]

In colloquial terms, under certain assumptions concerning the convexity of the nonlinear functions, an equality constraint can be relaxed to be an inequality constraint. This property is used in the MIP master problem to accumulate linear approximations.
Augmented Penalty refers to the introduction of (non-negative) slack variables on the right hand sides of the just described inequality constraints and the modification of the objective function when assumptions concerning convexity do not hold.

The algorithm underlying DICOPT starts by solving the NLP in which the 0-1 conditions on the binary variables are relaxed. If the solution to this problem yields an integer solution the search stops. Otherwise, it continues with an alternating sequence of nonlinear programs (NLP) called subproblems and mixed-integer linear programs (MIP) called master problems. The NLP subproblems are solved for fixed 0-1 variables that are predicted by the MIP master problem at each (major) iteration. For convex problems the master problem also provides a lower bound on the objective function. This lower bound (in the case of minimization) increases monotonically as iterations proceed due to the accumulation of linear approximations. Note that in the case of maximization this bound is an upper bound which can be used as a stopping criterion through a DICOPT option stop 1 (see section DICOPT Options). Another stopping criterion that tends to work very well for non-convex problems (and even for convex problems) is based on the heuristic: stop as soon as the NLP subproblems start worsening (i.e. the current NLP subproblem has an optimal objective function that is worse than the previous NLP subproblem). This stopping criterion relies on the use of the augmented penalty, and is used in the description of the algorithm below. This is also the default stopping criterion in the implementation of DICOPT. The algorithm can be stated briefly as follows:

1. Solve the NLP relaxation of the MINLP program. If \( y^{(0)} = y \) is integer, stop(integer optimum found). Else continue with step 2.
2. Find an integer point \( y^{(1)} \) with an MIP master problem that features an augmented penalty function to find the minimum over the convex hull determined by the half-spaces at the solution \((x^{(0)}, y^{(0)})\).
3. Fix the binary variables \( y = y^{(1)} \) and solve the resulting NLP. Let \((x^{(1)}, y^{(1)})\) be the corresponding solution.
4. Find an integer solution \( y^{(2)} \) with a MIP master problem that corresponds to the minimization over the intersection of the convex hulls described by the half-spaces of the KKT points at \( y^{(0)} \) and \( y^{(1)} \).
5. Repeat steps 3 and 4 until there is an increase in the value of the NLP objective function. (Repeating step 4 means augmenting the set over which the minimization is performed with additional linearizations - i.e. half-spaces - at the new KKT point).

In the MIP problems integer cuts are added to the model to exclude previously determined integer vectors \( y^{(1)}, y^{(2)}, ..., y^{(K)} \).

For a detailed description of the theory and references to earlier work, see [193] [110] [52].

The algorithm has been extended to handle general integer variables and integer variables appearing nonlinearly in the model.

### 5.14.6 Modeling

#### 5.14.6.1 Relaxed Model

Before solving a model with DICOPT, the user is strongly advised to experiment with the relaxed model where the integer restrictions are ignored. This is the RMINLP model. As the DICOPT will start solving the relaxed problem and can use an existing relaxed optimal solution, it is a good idea to solve the RMINLP always before attempting to solve the MINLP model, i.e., the following fragment is not detrimental with respect to performance:
The second \texttt{SOLVE} statement will only be executed if the first \texttt{SOLVE} was successful, i.e., if the model status was one (optimal) or two (locally optimal).

In general it is not a good idea to try to solve an MINLP model if the relaxed model cannot be solved reliably. As the RMINLP model is a normal NLP model, some obvious points of attention are:

- Scaling. If a model is poorly scaled an NLP solver may not be able find the optimal or even a feasible solution. Some NLP solvers have automatic scaling algorithms, but often it is better to attack this problem on the modeling level. The GAMS scaling facility can help in this respect.

- Starting point. If a poor starting point is used, the NLP solver may not be able to find a feasible or optimal solution. A starting point can be set by setting level values, e.g. \texttt{X.L = 1;} . The GAMS default levels are zero, which is often not a good choice.

- Adding bounds. Add bounds so that all functions can be properly evaluated. If you have a function $\sqrt{x}$ or $\log(x)$ in the model, you may want to add a bound \texttt{X.LO=0.001;} . If a function like $\log(f(x))$ is used, you may want to introduce an auxiliary variable and equation $y = f(x)$ with an appropriate bound \texttt{Y.LO=0.001;} .

In some cases the relaxed problem is the most difficult model. If more than one NLP solver is available you may want to try them in a sequence:
In this fragment we first try to solve the relaxed model using CONOPT. If that fails we try MINOS, and if that solve also fails we try SNOPT.

It is worthwhile to spend some time getting the relaxed model to solve reliably and speedily. In most cases, modeling improvements in the relaxed model, such as scaling, will also benefit the subsequent NLP sub-problems. In general these modeling improvements turn out to be rather solver independent: changes that improve the performance with CONOPT will also help solving the model with MINOS.

5.14.6.2 OPTCR and OPTCA

The DICOPT algorithm assumes that the integer sub-problems are solved to optimality. The GAMS options for OPTCR and OPTCA are therefore ignored: subproblems are solved with both tolerances set to zero. If you want to solve a MIP sub-problem with an optimality tolerance you can use the DICOPT option file to set OPTCR or OPTCA. For more information see section DICOPT Options.

For models with many discrete variables, it may be necessary to introduce an OPTCR or OPTCA option in order to solve the model in acceptable time. For models with a limited number of integer variables the default to solve MIP sub-models to optimality may be acceptable.

5.14.6.3 Integer Formulations

A number of MIP formulations are not very obvious and pose a demand on the modeler’s knowledge and experience. A good overview of integer programming modeling is given in [202].

Many integer formulations use a so-called big- $M$ construct. It is important to choose small values for those big- $M$ numbers. As an example consider the fixed charge problem where $y_i \in \{0,1\}$ indicate if facility $i$ is open or closed, and where $x_i$ is the production at facility $i$. Then the cost function can be modeled as:

$$
C_i = f_i y_i + v_i x_i
$$

$$
x_i \leq M_i y_i
$$

$$
y_i \in \{0,1\}
$$

$$
0 \leq x_i \leq \text{cap}_i
$$

where $f_i$ is the fixed cost and $v_i$ the variables cost of operating a facility $i$. In this case the chosen $M_i$ should be large enough that $x_i$ is not restricted if $y_i = 1$. On the other hand, it should be as small as possible. This leads to a choice to have $M_i$ equal to the (tight) upperbound of variable $x_i$ (i.e. the capacity $\text{cap}_i$ of facility $i$).

5.14.6.4 Non-smooth Functions

GAMS alerts NLP modelers against the use of non-smooth functions such as $\min()$, $\max()$, $\text{smin}()$, $\text{smax}()$ and $\text{abs}()$. In order to use these functions, a non-linear program needs to be declared as a DNLP model instead of a regular NLP model:

```gams
option dnlp=conopt;
model m /all/;
solve m minimizing z using dnlp;
```
This construct will warn the user that problems may arise due to the use of non-smooth functions.

A possible solution is to use a smooth approximation. For instance, the function \( f(x) = |x| \) can be approximated by \( g(x) = \sqrt{x^2 + \varepsilon} \) for some \( \varepsilon > 0 \). This approximation does not contain the point \((0,0)\). An alternative approximation can be devised that has this property:

\[
f(x) \approx \frac{2x}{1 + e^{-x/\delta}} - x
\]

MINLP models do not have such protection against non-smooth functions, but the use of such functions is just as problematic here. It is possible to use discrete variables with MINLP models in order to model if-then-else situations. For instance, in the case of the absolute value we can replace \( x \) by \( x^+ - x^- \) and \( |x| \) by \( x^+ + x^- \) by using:

\[
\begin{align*}
x &= x^+ - x^- \\
|x| &= x^+ + x^- \\
x^+ &\leq \delta M \\
x^- &\leq (1 - \delta) M \\
x^+, x^- &\geq 0 \\
\delta &\in \{0, 1\}
\end{align*}
\]

where \( \delta \) is a binary variable.

5.14.7 GAMS Options

GAMS options are specified in the GAMS model source, using either the option statement or a model suffix.

5.14.7.1 The OPTION Statement

An option statement sets a global parameter. An option statement should appear before the solve statement, as in:

```gams
model m /all/;
option iterlim=100;
solve m using minlp minimizing z;
```

Option statements that affect the behavior of DICOPT are listed below:

- **option domlim = n;**
  This option sets a limit on the total accumulated number of non-linear function evaluation errors that are allowed while solving the NLP subproblems or inside DICOPT itself. An example of a function evaluation error or domain error is taking the square root of a negative number. This situations can be prevented by adding proper bounds. The default is zero, i.e. no function evaluation errors are allowed.

In case a domain error occurs, the listing file will contain an appropriate message, including the equation that is causing the problem. For instance:

```
**** ERRORS(S) IN EQUATION loss(cc,sw)
    2 instance(s) of - UNDEFINED REAL POWER (RETURNED  0.0E+00)
```
If such errors appear you can increase the DOMLIM limit, but often it is better to prevent the errors from occurring in the first place. In many cases this can be accomplished by adding appropriate bounds. Sometimes extra variables and equations need to be added to accomplish this. For instance, with an expression like \( \log(x - y) \), you may want to introduce a variable \( z > \varepsilon \) and an equation \( z = x - y \), so that the expression can be rewritten as \( \log(z) \).

- **option iterlim = n;**
  This option sets a limit on the total accumulated (minor) iterations performed in the MIP and NLP subproblems.

- **option minlp = dicopt;**
  This option selects DICOPT to solve MINLP problems.

- **option mip = s;**
  This option sets the MIP solver to be used for the MIP master problems. Note that changing from one MIP solver to another can lead to different results, and may cause DICOPT to follow a different path.

- **option nlp = s;**
  This option sets the NLP solver to be used for the NLP sub-problems. Note that changing from one NLP solver to another can lead to different results, and may cause DICOPT to follow a different path.

- **option optca = x;**
  This option is ignored. MIP master problems are solved to optimality unless specified differently in the DICOPT option file.

- **option optcr = x;**
  This option is ignored. MIP master problems are solved to optimality unless specified differently in the DICOPT option file.

- **option reslim = x;**
  This option sets a limit on the total accumulated time (in seconds) spent inside DICOPT and the subsolvers.

- **option sysout = on;**
  This option will print extra information to the listing file.

In the list above (and in the following) \( n \) indicates an integer number. GAMS will also accept fractional values, which will be rounded. Options marked with an \( x \) parameter expect a real number. Options with an \( s \) parameter expect a string argument.

### 5.14.7.2 The Model Suffix

Some options are set by assigning a value to a model suffix, as in:

```gams
model m /all/;
  m.optfile=1;
solve m using minlp minimizing z;
```

Model suffixes that affect the behavior of DICOPT are listed below:

- **m.dictfile = 1;**
  This option tells GAMS to write a dictionary file containing information about GAMS identifiers (equation and variables names). Such information is needed when the DICOPT option nlptracelevel is used, otherwise the option can be ignored.
• `m.iterlim = n;`
  Sets the total accumulated (minor) iteration limit. This option overrides the global iteration limit
  set by an option statement, e.g.,

  ```
  model m /all/;
  m.iterlim = 100;
  option iterlim = 1000;
  solve m using minlp minimizing z;
  ```

  will cause DICOPT to use an iteration limit of 100.

• `m.optfile = 1;`
  This option instructs DICOPT to read an option file `dicopt.opt`. This file should be located in the
  current directory (or the project directory when using the GAMS IDE). The contents of the option
  file will be echoed to the listing file and to the screen (the log file):

  ```
  --- DICOPT: Reading option file D:\MODELS\SUPPORT\DICOPT.OPT
  > maxcycles 10
  --- DICOPT: Starting major iteration 1
  ```

  If the option file does not exist, the algorithm will proceed using its default settings. An appropriate
  message will be displayed in the listing file and in the log file:

  ```
  --- DICOPT: Reading option file D:\MODELS\SUPPORT\DICOPT.OPT
  --- DICOPT: File does not exist, using defaults...
  --- DICOPT: Starting major iteration 1
  ```

• `m.optfile = n;`
  If `n > 1` then the option file that is read is called `dicopt.op n` (for `n = 2,...,9`) or `dicopt.o n` (for
  `n = 10,...,99`). E.g. `m.optfile=2;` will cause DICOPT to read `dicopt.op2`.

• `m.prioropt = 1;`
  This option turns on the use of priorities on the discrete variables. Priorities influence the branching
  order chosen by the MIP solver during solution of the MIP master problems. The use of priorities
  can greatly impact MIP solver performance. The priorities themselves have to be specified using
  the `.prior` variables suffix, e.g. `x.prior(i,j) = ord(i);`. Contrary to intuition, variables with a
  lower value for their priority are branched on before variables with a higher priority, i.e., the most
  important variables should get lower priority values.

• `m.reslim = x;`
  Sets the total accumulated time limit. This option overrides the global time limit set by an option
  statement.

### 5.14.8 DICOPT Options

This sections describes the options that can be specified in the DICOPT option file. This file is usually
called `dicopt.opt`. The `optfile` model suffix must be set to tell DICOPT to read this file:

```
model m /all/;
    m.optfile=1;
    solve m using minlp minimizing z;
```

The option file is searched for in the current directory, or in the project directory when the IDE is used.

The option file is a standard text file, with a single option on each line. All options are case-insensitive. A
line is a comment line if it starts with an asterisk, `*` in column one. A valid option file can look like:
* stop only on infeasible MIP or hitting a limit
stop 0
* use minos to solve first NLP sub problem
* and conopt for all subsequent ones
nlpsolver minos conopt

A convenient way to write the option file from within a GAMS model is to use the following construct:

```
$onecho > dicopt.opt
stop 0
nlpsolver minos conopt
$offecho
```

This will make the model self-contained. Notice, however, that this overwrites an existing file `dicopt.opt`.

Available DICOPT options are listed below:

### 5.14.8.1 Algorithmic options

<table>

</tbody>
</table>
### 5.14.8.6 Detailed Options Description

**continue (integer):** How to proceed in case of NLP errors

This option can be used to let DICOPT continue in cases of NLP solver failure. The preferred approach is to fix the model so that NLP subproblems solve without problems. In some cases, however, (partial) failures of an NLP solver in solving the NLP subproblems can be ignored, as DICOPT may recover later on. Adding the option `continue 0` during model debugging enables DICOPT to function in a more specific way.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | Stop on solver failure  
Stop on solver failure. DICOPT will terminate when an NLP subproblem cannot be solved to optimality. Some NLP solvers terminate with a status other than optimal if not all of the termination criteria are met. For instance, the change in the objective function is negligible (indicating convergence) but the reduced gradients are not within the required tolerance. Such a solution may or may not be close to the (local) optimum. Using `continue 0` will prevent DICOPT from accepting such a solution. |
| 1     | Accept non-optimal feasible solutions  
NLP subproblem failures resulting in a non-optimal but feasible solutions are accepted. Sometimes an NLP solver cannot make further progress towards meeting all optimality conditions, although the current solution is feasible. Such a solution can be accepted by this option. |
| 2     | Ignore infeasible solutions  
NLP subproblem failures resulting in a non-optimal but feasible solution are accepted (as in option `continue 1`). NLP subproblem failures resulting in an infeasible solution are ignored. The corresponding configuration of discrete variables is forbidden to be used again. An integer cut to accomplish this is added to subsequent MIP master problems. Note that the relaxed NLP solution should be feasible. This setting is the default. |

**convex (boolean):** If enabled, the defaults for a number of other options are set to values appropriate to convex MINLPs

If this option is enabled, the default option values will be changed such that DICOPT will stop on crossover (`stop` set to 1), linearizations from infeasible NLP subproblems will be added to the MIP master problem (`infeasder` set to 1), penalty relaxation is no longer applied to linearizations (`weight` set to `maxdouble`), and the feasibility pump is run if there are no semicontinuous or semiinteger variables and no special ordered sets (`feaspump` set to 1).

Default: 0

**domlim (string):** List of allowed number of domain errors

---

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fp_timelimit</code></td>
<td>Time limit</td>
<td><code>maxdouble</code></td>
</tr>
<tr>
<td><code>fp_transfercuts</code></td>
<td>Whether to transfer cuts from the Feasibility Pump MIP to the DICOPT MIP (all except from the round in which the FP MIP became infeasible)</td>
<td>1</td>
</tr>
</tbody>
</table>
domlim $i_1 \ldots i_n$. Sets a limit of the number of function and derivative evaluation errors for a particular cycle. A number of $-1$ means that the global GAMS option domlim is used. The last number $i_n$ sets a domain error limit for all cycles $n, n+1, \ldots$.

Example: domlim 0 100 0
The NLP solver in the second cycle is allowed to make up to 100 evaluation errors, while all other cycles must be solved without evaluation errors.

The default is to use the global GAMS domlim option.

**epsmip** *(real)*: Tolerance on test on monotonic improvement of MIP master problem

This option can be used to relax the test on MIP objective functions. The objective function values of the MIP master problems should form a monotonic worsening curve. This is not the case if the MIP master problems are not solved to optimality. If the options OPTCR or OPTCA are set to a nonzero value, this test is bypassed. If the test fails, DICOPT will fail with a message:

The MIP solution became better after adding integer cuts. Something is wrong. Please check if your model is properly scaled. Also check your big M formulations -- the value of M should be relatively small. This error can also occur if you used a MIP solver option file with a nonzero OPTCR or OPTCA setting. In that case you may want to increase the EPSMIP setting using a DICOPT option file.

The value of

$$\frac{\text{PreviousObj} - \text{CurrentObj}}{1 + |\text{PreviousObj}|}$$

is compared against epsmip. In case the test fails but you want DICOPT to continue anyway, you may want to increase the value of epsmip. The current values used in the test (previous and current MIP objective, epsmip) are printed along with the above message to provide information about how much you should increase epsmip to pass the test. Normally, you should not have to change this value.

Default: $1.0e^{-6}$

**epsx** *(real)*: Tolerance for integer values when loading relaxed solution

This tolerance is used to distinguish integer variables that are set to an integer value by the user, or integer variables that are fractional. See the option relaxed.

Default: $1.0e^{-3}$

**feaspump** *(integer)*: Whether to run the Feasibility Pump

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not run the Feasibility Pump</td>
</tr>
<tr>
<td>1</td>
<td>Run the Feasibility Pump if there are no semicontinuous or semiinteger variables and no special ordered sets</td>
</tr>
<tr>
<td>2</td>
<td>Always run the Feasibility Pump</td>
</tr>
</tbody>
</table>

**fp_acttol** *(real)*: Tolerance on when to consider an equation as active
**fp_cutoffdecr** *(real)*: Additional relative decrement of cutoff value for the original objective function

Default: 0.1

**fp_dumpsprob** *(boolean)*: Whether to dump subproblems (NLPs and MIPs) into GAMS files

Default: 0

**fp_integercuts** *(integer)*: Whether to add integer cuts after an NLP subproblem has been solved to optimality

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use integer cuts</td>
</tr>
<tr>
<td>1</td>
<td>Use integer cuts only for mixed-binary problems</td>
</tr>
<tr>
<td>2</td>
<td>Always use integer cuts</td>
</tr>
</tbody>
</table>

**fp_iterlimit** *(integer)*: Major Iteration limit

Default: 20

**fp_mipgap** *(real)*: Optimality tolerance (relative gap) to use for solving MIP projection problem

Default: 0.01

**fp_projcuts** *(boolean)*: Whether to add cut derived from projection of MIP solution onto NLP feasible set

Default: 1

**fp_projectrotol** *(real)*: Tolerance on when to consider optimal value of projection problem as zero, which may trigger the solution of a Sub-NLP

Default: 1E-4

**fp_sollimit** *(integer)*: Stop when a number of (improving) solutions has been bound

Default: maxint

**fp_stalllimit** *(integer)*: Stop when no improving solution has been bound for a number of FP iterations, -1 to disable

Range: {-1, ..., ∞}

Default: 5

**fp_subsolverlog** *(boolean)*: Whether to show the log of subsolvers

Default: 0

**fp_timelimit** *(real)*: Time limit

Default: maxdouble
**fp_transfercuts** *(boolean)*: Whether to transfer cuts from the Feasibility Pump MIP to the DICOPT MIP (all except from the round in which the FP MIP became infeasible) ←

Default: 1

**infbnd** *(real)*: Bound to use for unbounded integer variables in integer cuts ←

Value to use for missing bounds on discrete variables when constructing integer cuts.

Default: 10000

**infeasder** *(integer)*: Use derivatives of infeasible nonlinear subproblems ←

This option is to determine whether linearizations of infeasible NLP subproblems are added or not added to the MIP master problem.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No linearizations of infeasible NLP subproblems. This is the default option in which no linearizations are added in the infeasible NLP subproblems. In this case a simple integer cut is added to remove from consideration the 0-1 vector that gave rise to the infeasible NLP. Since this may slow the convergence, it is recommended to reformulate the MINLP with &quot;elastic&quot; constraints (i.e., adding slacks to infeasible constraints and adding a penalty for them in the objective) to ensure that the NLP subproblems are mathematically feasible.</td>
</tr>
<tr>
<td>1</td>
<td>Add linearization for infeasible NLP subproblems. This will add linearizations derived from the infeasible NLP subproblem to the master problem. This option is recommended to speed up convergence when the MINLP is known to be convex (i.e. its continuous relaxation is convex). The possibility of cutting-off the global optimum is increased if it is used for a nonconvex MINLP.</td>
</tr>
</tbody>
</table>

**maxcycles** *(integer)*: Maximum number of cycles ←

The maximum number of cycles or major iterations performed by DICOPT.

Default: 20

**mipiterlim** *(string)*: List of iteration limits ←

`mipiterlim i1 i2 ... in` sets an iteration limit on individual MIP master problems. The last number `in` is valid for all subsequent cycles `n, n + 1, ...`. A number of `−1` indicates that there is no (individual) limit on the corresponding MIP master problem. A global iteration limit is maintained through the GAMS option `iterlim`.

Example: `mipiterlim 10000 -1`

The first MIP master problem cannot use more than 10000 iterations, while subsequent MIP master problems are not individually restricted.

Example: `mipiterlim 10000`

Sets an iteration limit of 10000 on all MIP master problems.

When this option is used it is advised to have the option `continue` set to its default of 2. The default for this option is not to restrict iteration counts on individual solves of MIP master problems. The default for this option is not to restrict iteration counts on individual solves of MIP master problems.
mipoptfile (string): List of option files for MIP solver

mipoptfile $s_1 \ s_2 \ldots \ s_n$ specifies the option file to be used for the MIP master problems. Several option files can be specified, separated by a blank. If a digit 1 is entered the default option file for the MIP solver in question is being used. The digit 0 indicates that no option file is to be used. The last option file is also used for subsequent MIP master problems.

Example: \texttt{mipoptfile mip.opt mip2.opt 0}  
This option will cause the first MIP master problem solver to read the option file \texttt{mip.opt} and the second one to read the option file \texttt{mip2.opt}; subsequent MIP master problem solvers will not use any option file.

Example: \texttt{mipoptfile 1}  
This will cause the MIP solver for all MIP subproblems to read a default option file (e.g. \texttt{cplex.opt}, \texttt{xpress.opt}, \texttt{gurobi.opt} etc.).

Option files are located in the current directory (or the project directory when using the IDE). The default is not to use an option file.

mipreslim (string): List of resource limits

mipreslim $x_1 \ x_2 \ldots \ x_n$ sets a resource (time) limit on individual MIP master problems. The last number $x_n$ is valid for all subsequent cycles $n, n+1, \ldots$. A number $-1.0$ means that the corresponding MIP master problem is not individually time restricted. A global time limit is maintained through the GAMS option \texttt{reslim}.

Example: \texttt{mipreslim -1 10000 -1}  
The MIP master problem in cycle 2 cannot use more than 100 seconds, while subsequent MIP master problems are not individually restricted.

Example: \texttt{mipreslim 1000}  
Sets a time limit on all MIP master problems of 1000 seconds.

When this option is used it is advised to have the option \texttt{continue} set to its default of 2. The default for this option is not to restrict individually the time a solver can spent on the MIP master problem.

mipsolver (string): List of MIP solvers

This option specifies with MIP solver to use for the MIP master problems.

Example: \texttt{mipsolver cplex xpress}  
This instructs \texttt{DICOPT} to use Cplex for the first MIP and XPRESS for the second and subsequent MIP problems. The last entry may be used for more than one problem.

The names to be used for the solvers are the same as one uses in the GAMS statement \texttt{OPTION MIP=...}; The default is to use the default MIP solver. Note that changing from one MIP solver to another can lead to different results, and may cause \texttt{DICOPT} to follow a different path.

nlpiterlim (string): List of iteration limits

nlpiterlim $i_1 \ i_2 \ldots \ i_n$ sets an iteration limit on individual NLP subproblems. The last number $i_n$ is valid for all subsequent cycles $n, n+1, \ldots$. A number of $-1$ indicates that there is no (individual) limit on the corresponding NLP subproblem. A global iteration limit is maintained through the GAMS option \texttt{reslim}. 
Example: `nlpiterlim 1000 -1`  
The first (relaxed) NLP subproblem cannot use more than 1000 iterations, while subsequent NLP subproblems are not individually restricted.

Example: `nlpiterlim 1000`  
Sets an iteration limit of 1000 on all NLP subproblems.

When this option is used it is advised to have the option `continue` set to its default of 2. This default does not restrict the amount of iterations an NLP solver can spend on an NLP subproblem, other than the global iteration limit.

**nlpoptfile** *(string)*: List of option files for NLP solver  

`nlpoptfile s_1 s_2 ... s_n` specifies the option file to be used for the NLP subproblems. Several option files can be specified, separated by a blank. If a digit 1 is entered, the default option file for the NLP solver in question is being used. The digit 0 indicates that no option file is to be used. The last option file is also used for subsequent NLP subproblems.

Example: `nlpoptfile nlp.opt nlp2.opt 0`  
This option will cause the first NLP subproblem solver to read the option file `nlp.opt` and the second one to read the option file `nlp2.opt`; subsequent NLP subproblem solvers will not use any option file.

Example: `nlpoptfile 1`  
This will cause the NLP solver for all NLP subproblems to read a default option file (e.g. `conopt.opt`, `minos.opt`, `snopt.opt` etc.).

Option files are located in the current directory (or the project directory when using the IDE). The default is not to use an option file.

**nlpreslim** *(string)*: List of resource limits  

`nlpreslim x_1 x_2 ... x_n` sets a resource (time) limit on individual NLP subproblems. The last number `x_n` is valid for all subsequent cycles `n, n+1, ...`. A number `-1.0` means that the corresponding NLP subproblem is not individually time restricted. A global time limit is maintained through the GAMS option `reslim`.

Example: `nlpreslim 100 -1`  
The first (relaxed) NLP subproblem can not use more than 100 seconds, while subsequent NLP subproblems are not individually restricted.

Example: `nlpreslim 1000`  
Sets a time limit of 1000 seconds on all NLP subproblems.

When this option is used it is advised to have the option `continue` set to its default of 2. This default does not restrict the time an NLP solver can spend on an NLP subproblem (other than the global resource limit).

**nlpsolver** *(string)*: List of NLP solvers  

`nlpsolver s_1 s_2 ... s_n`. This option specifies which NLP solver to use for the NLP subproblems.

Example: `nlpsolver conopt minos snopt`  
tells DICOPT to use CONOPT for the relaxed NLP, MINOS for the second NLP subproblem, and SNOPT for the third and subsequent ones. The last entry is used for more than one subproblem: for all subsequent ones DICOPT will use the last specified solver.
The names to be used for the solvers are the same as those used in the GAMS statement `OPTION NLP=...;`. The default is to use the default NLP solver. Note that changing from one NLP solver to another can lead to different results, and may cause DICOPT to follow a different path.

**nlptracefile (string):** Base name of trace files

Name of the files written if the option `nlptracelevel` is set. Only the stem is needed: if the name is specified as `nlptracefile nlptrace`, then files of the form `nlptrace.001`, `nlptrace.002`, etc. are written. These files contain the settings of the integer variables so that NLP subproblems can be investigated independently of DICOPT.

Default: `nlptrace`

**nlptracelevel (integer):** Trace level

This sets the level for NLP tracing, which writes a file for each NLP sub-problem, so that NLP sub-problems can be investigated outside the DICOPT environment. See also the option `DICOPT.nlptracefile "nlptracefile"`. By including a trace file in your original problem and changing it into an MINLP problem, the subproblem will be solved directly by an NLP solver. This option only works if the names in the model (names of variables and equations) are exported by GAMS. This can be accomplished by using the `m.dictfile` model suffix, as in `m.dictfile=1;`. In general it is more convenient to use the CONVERT solver to generate isolated NLP models (see section Model Debugging).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | No trace info is written  
No trace files are written. This is the default. |
| 1     | GAMS file with fixed integer variables  
A GAMS file for each NLP subproblem is written which fixes the discrete variables. |
| 2     | Include levels of continuous variables  
As `nlptracelevel 1`, but in addition level values of the continuous variables are written. |
| 3     | Include all levels and marginals  
As `nlptracelevel 2`, but in addition marginal values for the equations and variables are written. |

**optca (string):** List of OPTCA values

`optca x_1 x_2 ... x_n`. The absolute optimality criterion for the MIP master problems. The GAMS option `optca` is ignored, as, by default, DICOPT wants to solve MIP master problems to optimality. It is possible to stop the MIP solver earlier to allow it to solve a large problem, by specifying a value for `optca` or `optcr` in a DICOPT option file. With setting a value for `optca`, the MIP solver is instructed to stop as soon as the gap between the best possible integer solution and the best found integer solution is less than `x`, i.e. stop as soon as

$$|\text{BestFound} - \text{BestPossible}| \leq x$$

It is possible to specify a different `optca` value for each cycle. The last number `x_n` is valid for all subsequent cycles `n, n+1, ...`

Example: `optca 10`

Stop the search in all MIP problems as soon as the absolute gap is less than 10.
Example: optca 0 10 0
Sets a nonzero optca value of 10 for cycle 2, while all other MIP master problems are solved to optimality.

The default is zero.

optcr (string): List of OPTCR values ←

optcr x_1 x_2 \ldots x_n. The relative optimality criterion for the MIP master problems. The GAMS option optcr is ignored, as by default DICOPT wants to solve MIP master problems to optimality. To allow it to solve a large problem it is possible to stop the MIP solver earlier by specifying a value for optca or optcr in a DICOPT option file. With setting a value for optcr, the MIP solver is instructed to stop as soon as the relative gap between the best possible integer solution and the best found integer solution is less than x, i.e., stop as soon as

\[
\frac{|\text{BestFound} - \text{BestPossible}|}{|\text{BestPossible}|} \leq x
\]

Note that the relative gap cannot be evaluated if the best possible integer solution is zero. In these cases the absolute optimality criterion optca can be used. It is possible to specify a different optcr value for each cycle. The last number x_n is valid for all subsequent cycles n, n + 1, \ldots.

Example: optcr 0.1
Stop the search in all the MIP problems as soon as the relative gap is smaller than 10%.

Example: optcr 0 0.01 0
Sets a nonzero optcr value of 1% for cycle 2, while all other MIP master problems are solved to optimality.

The default is zero.

relaxed (integer): How to start DICOPT ←

In some cases it may be possible to use a known configuration of the discrete variables. Some users have very difficult problems, where the relaxed problem cannot be solved but where NLP sub-problems with the integer variables fixed are much easier. If a reasonable integer configuration is known in advance in these cases we can bypass the relaxed NLP and tell DICOPT to directly start with this integer configuration. The integer variables need to be specified by the user before the solve statement by assigning values to the levels, as in \texttt{Y.L(I) = INITVAL(I);}.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Start with all integers fixed to the starting value</td>
</tr>
<tr>
<td></td>
<td>The first NLP sub-problem will be executed with all integer variables fixed to the values specified by the user. If you don’t assign a value to an integer variable, it will retain its current value, which is zero by default.</td>
</tr>
<tr>
<td>1</td>
<td>Start with relaxed NLP</td>
</tr>
<tr>
<td></td>
<td>The first NLP problem is the relaxed NLP problem: all integer variables are relaxed between their bounds. This is the default.</td>
</tr>
<tr>
<td>2</td>
<td>Start with mixture of fixed and relaxed integers</td>
</tr>
<tr>
<td></td>
<td>The first NLP subproblem will be executed with some variables fixed and some relaxed. The program distinguishes the fixed from the relaxed variables by comparing the initial values against the bounds and the tolerance allowed \texttt{EPSX}. \texttt{EPSX} has a default value of 1.e-3. This can be changed through the option file.</td>
</tr>
</tbody>
</table>
**solvelink** *(integer)*: Solvelink for NLP and MIP subsolver

This option defines the solvelink used for the NLP and MIP subsolver.

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Call NLP and MIP solver via script</td>
</tr>
<tr>
<td>2</td>
<td>Call NLP and MIP solver via module</td>
</tr>
<tr>
<td>5</td>
<td>Call NLP and MIP solver in memory</td>
</tr>
</tbody>
</table>

**stop** *(integer)*: Stopping criterion

This option defines the stopping criterion to be used. The search is always stopped when the (minor) iteration limit (the *iterlim* option), the resource limit (the *reslim* option), or the major iteration limit (see *maxcycles*) is hit or when the MIP master problem becomes infeasible.

Note: In general a higher number stops earlier, although in some cases stopping rule 2 may terminate the search earlier than rule 1. Section Modeling shows some experiments with these stopping criteria.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stop on maxcycles</td>
</tr>
<tr>
<td>1</td>
<td>Stop on crossover</td>
</tr>
<tr>
<td>2</td>
<td>Stop on worsening</td>
</tr>
<tr>
<td>3</td>
<td>Stop on crossover or worsening</td>
</tr>
</tbody>
</table>

- **Stop on maxcycles**
  Do not stop unless an iteration limit, resource limit, or major iteration limit is hit or an infeasible MIP master problem becomes infeasible. This option can be used to verify that DICOPT does not stop too early when using one of the other stopping rules. In general it should not be used on production runs, as in general DICOPT will often find the optimal solution using one of the more optimistic stopping rules. Do not stop unless an iteration limit, resource limit, or major iteration limit is hit or an infeasible MIP master problem becomes infeasible. This option can be used to verify that DICOPT does not stop too early when using one of the other stopping rules. In general it should not be used on production runs, as in general DICOPT will find often the optimal solution using one of the more optimistic stopping rules.

- **Stop on crossover**
  Stop as soon as the bound defined by the objective of the last MIP master problem is worse or close (w.r.t. GAMS option *optcr*) to the best NLP solution found (a crossover occurred). For convex problems this gives a global solution, provided the weights are large enough and *optcr* is set to 0. This stopping criterion should only be used if it is known or it is very likely that the nonlinear functions are convex. In the case of non-convex problems the bounds of the MIP master problem are not rigorous. Therefore, the global optimum can be cut off with the setting *stop* 1.

- **Stop on worsening**
  Stop as soon as the NLP subproblems stop improving. This worsening criterion is a heuristic. For non-convex problems in which valid bounds can not be obtained the heuristic often works very well. Even on convex problems, in many cases it terminates the search very early while providing an optimal or a very good integer solution. The criterion is not checked before major iteration three.

- **Stop on crossover or worsening**
  Stop as soon as a crossover occurs or when the NLP subproblems start to worsen. (This is a combination of 1 and 2).
5.14 DICOPT

usexinit (boolean): Use the user initial point as starting point for all NLP solves

Default: 0

weight (real): Penalty parameter, set above 1e20 to disable penalty relaxation

The value of the penalty coefficients.

Default: 1000

5.14.9 DICOPT Output

DICOPT generates lots of output on the screen. DICOPT itself and also the NLP and MIP solvers that handle the sub-problems write messages to the screen. The most important part is the last part of the screen output.

In this section we will discuss the output DICOPT writes to the screen and the listing file using the model procsel.gms (this model is part of the GAMS model library). A DICOPT log is written and the reason why DICOPT terminated is explained.

--- DICOPT: Terminating...
--- DICOPT: Stopped on NLP worsening

The search was stopped because the objective function of the NLP subproblems started to deteriorate.

--- DICOPT: Best integer solution found: 1.923099
--- Restarting execution
--- PROCESL.GMS(98) 0 Mb
--- Reading solution for model process
*** Status: Normal completion

Notice that the integer solutions are provided by the NLP's except for major iteration one (the first NLP is the relaxed NLP). For all NLP's except the relaxed one the binary variables are fixed, according to a pattern determined by the previous MIP which operates on a linearized model. The integer solutions marked with a '<' are an improvement. We see that the NLP in cycle 4 starts to deteriorate, and DICOPT stops based on its default stopping rule.

Note that if the criterion stop 1 had been used the search would have been terminated at iteration 3. The reason is that the upper bound to the profit predicted by the MIP (1.42129) exceeds the best current NLP solution (1.9231). Since it can be shown that the MINLP involves convex nonlinear functions, 1.9231 is the global optimum and the criterion stop 1 is rigorous.

A similar output can be found in the listing file:

In case the DICOPT run was not successful, or if one of the subproblems could not be solved, the listing file will contain all the status information provided by the solvers of the subproblems. For each iteration the configuration of the binary variables will also be printed. This extra information can also be requested via the GAMS option:

```
option sysout = on;
```
5.14.10 Special Notes

This section covers some special topics of interest to users of DICOPT.

5.14.10.1 Stopping Rule

Although the default stopping rule behaves quite well in practice there some cases where it terminates too early. In this section we discuss the use of the stopping criteria.

When we run the example procsel.gms with stopping criterion 0, we see the following DICOPT log:

--- DICOPT: Starting major iteration 10
--- DICOPT: Search terminated: infeasible MIP master problem
--- DICOPT: Log File:

--- DICOPT: Terminating...
--- DICOPT: Stopped on infeasible MIP

The search was stopped because the last MIP problem was infeasible. DICOPT will not be able to find a better integer solution.

--- DICOPT: Best integer solution found: 1.923099
--- Restarting execution
--- procsel.gms(98) 0 Mb
--- Reading solution for model process
*** Status: Normal completion

This example shows some behavioral features that are not uncommon for other MINLP models. First, DICOPT often finds the best integer solution in the first few major iterations. Second, in many cases as soon as the NLP's start to give worse integer solution no better integer solution will be found. This observation is the motivation to make stopping option 2, where DICOPT stops as soon as the NLP's start to deteriorate, the default stopping rule. In this example DICOPT would have stopped in major iteration 4 (you can verify this in the previous section). In many cases this will give the best integer solution. For this problem, DICOPT has indeed found the global optimum.
Based on experience with other models, we find that the default stopping rule (stop when the NLP becomes worse) performs well in practice. In many cases it finds the global optimum solution for both convex and non-convex problems. In some cases, however, it may provide a sub-optimal solution. In those cases where you want more reassurance that no good integer solutions are missed you can use one of the other stopping rules.

Changing the MIP or NLP solver can change the path that DICOPT follows, since the sub-problems may have non-unique solutions. The optimum stopping rule for a particular problem depends on the MIP and NLP solvers used.

The bounds of the MIP master problem are not rigorous in the case of non-convex problems. Therefore, the global optimum can be cut-off with \texttt{stop 1}. However, this option is the best stopping criterion for convex problems.

5.14.10.2 Solving the NLP Problems

Using a combination of NLP solvers has been found effective in cases where the relaxed NLP and/or the other NLP sub-problems are very difficult. For example, MINOS has many more difficulties to establish if a model is infeasible, so one would like to use CONOPT for NLP subproblems that are either infeasible or barely feasible. The \texttt{nlpsolver} option can be used to specify the NLP solver to be used for each iteration.

Infeasible NLP sub-problems can be problematic for DICOPT. Those subproblems cannot be used to form a new linearization. Effectively only the current integer configuration is excluded from further consideration by adding appropriate integer cuts, but otherwise an infeasible NLP sub-problem provides no useful information to be used by the DICOPT algorithm. If your model shows many infeasible NLP sub-problems you can try to use the \texttt{infeasder} option. Otherwise a strategy that can help is to introduce explicit slack variables and add them with a penalty to the objective function.

Assume your model is of the form:

\[
\begin{align*}
\min & \quad f(x, y) \\
& \quad g(x, y) \sim b \\
& \quad \ell \leq x \leq u \\
& \quad y \in \{0, 1\}
\end{align*}
\]

where \(\sim\) is a vector of relational operators \(\{\leq, =, \geq\}\). \(x\) are continuous variables and \(y\) are the binary variables. If many of the NLP subproblems are infeasible, we can try the following \texttt{elastic} formulation:

\[
\begin{align*}
\min & \quad f(x, y) + M \sum_i (s_i^+ + s_i^-) \\
& \quad y = y^B + s^+ - s^- \\
& \quad g(x, y) \sim b \\
& \quad \ell \leq x \leq u \\
& \quad 0 \leq y \leq 1 \\
& \quad 0 \leq s^+, s^- \leq 1 \\
& \quad y^B \in \{0, 1\}
\end{align*}
\]

I.e., the variables \(y\) are relaxed to be continuous with bounds \([0, 1]\), and binary variables \(y^B\) are introduced that are related to the variables \(y\) through a set of the slack variables \(s^+, s^-\). The slack variables are added to the objective with a penalty parameter \(M\). The choice of a value for \(M\) depends on the size of \(f(x, y)\), on the behavior of the model, etc. Typical values are 100 or 1000.
5.14.10.3 Solving the MIP Master Problems

MIP master problems may become expensive to solve when there are many discrete variables. One of the first things to try is to see if a different MIP solver can solve your particular problems more efficiently.

Different formulations can have dramatic impact on the performance of MIP solvers. Therefore it is advised to try out several alternative formulations. The use of priorities can have a big impact on some models. It is possible to specify a nonzero value for `OPTCA` and `OPTCR` in order to prevent the MIP solver from spending an unacceptable long time proving optimality of MIP master problems.

If the MIP master problem is infeasible the `DICOPT` solver will terminate. In this case you may want to try the same reformulation discussed in the previous paragraph.

5.14.10.4 Feasibility Pump

The feasibility pump is similar to the Outer-approximation, but its objective is to completely focus on finding good feasible solutions rather than optimal ones. The main idea of this algorithm is to decompose the original mathematical programming problem in two parts: integer feasibility and constraint feasibility. By solving an MIP subproblem its solution is an integer feasible solution, which may violate the constraints; and by solving a continuous relaxation of the original MINLP (NLP subproblem) the solution is constraint feasible but might not be integral. By minimizing in successive iterations the distance between these two types of solutions it is expected to achieve a solution that is both constraint and integral feasible.

The feasibility pump can be used as a standalone solver for convex MINLP problems. This is achieved by iteratively applying the method, while including a bound to the objective function. This bound is obtained by the best known solution and an epsilon improvement. This will result in the global optimum of a convex MINLP [28]. The drawback of this algorithm is that it may require many iterations, since each time the objective function is restricted to improve only by epsilon.

In DICOPT, the feasibility pump can be applied before the Outer-approximation method by setting option `feaspump`. In the feasibility pump, large improvements in the objective function are enforced at each iteration (option `fp_cutoffdecr`). After the method finishes, all the cuts and the best known solution are passed to the Outer-approximation method to prove optimality. More details on the implementation of the feasibility pump in DICOPT can be found in [19].

5.14.10.5 Model Debugging

In this paragraph we discuss a few techniques that can be helpful in debugging your MINLP model.

- Start with solving the model as an `RMINLP` model. Make sure this model solves reliably before solving it as a proper `MINLP` model. If you have access to different NLP solvers, make sure the `RMINLP` model solves smoothly with all NLP solvers. `CONOPT`, especially, can generate useful diagnostics such as Jacobian elements (i.e. matrix elements) that become too large.
- Try different NLP and MIP solvers on the subproblems. Example: use the GAMS statement `OPTION NLP=KNITRO;` to solve all NLP subproblem using the solver `KNITRO`.
- The GAMS option statement `OPTION SYSOUT = ON;` can generate extra solver information that can be helpful for diagnosing problems.
- If many of the NLP subproblems are infeasible, add slacks as described in section `Solving the NLP Problems`.
- Run `DICOPT` in pedantic mode by using the `DICOPT` option: `CONTINUE 0`. Make sure all NLP subproblems solve to optimality.
• Don't allow any nonlinear function evaluation errors, i.e. keep the DOMLIM limit at zero. See the discussion on DOMLIM in section The OPTION Statement.

• If you have access to another MINLP solver such as AlphaECP, SHOT, or SBB or even global solvers like Antigone or BARON, try to use a different solver on your model. To select another solver (here SBB) use the following GAMS option statement: OPTION MINLP=SBB;.

• Individual NLP or MIP subproblems can be extracted from the MINLP by using the CONVERT solver, which will write a model in scalar GAMS notation that can then be solved using any GAMS NLP or MIP solver. E.g., to generate the second NLP subproblem, you can use the following DICOPT option: NLPSOLVER CONOPT CONVERT. The model will be written to the file GAMS.GMS. A disadvantage of this technique is that some precision is lost due to the fact that files are being written in plain ASCII. The advantage is that you can visually inspect these files and look for possible problems such as poor scaling.

5.15 EXAMINER

5.15.1 Introduction

This document describes GAMS/Examiner, a tool for examining points and making an unbiased, independent assessment of their merit. In short, it checks if solutions are really solutions. As an example, it can take a solution point reported as optimal by a solver and examine it for primal feasibility, dual feasibility, and optimality. Examiner has a number of different modes, allowing it to check the input point from GAMS/Base as well as the solution passed by a solver back to GAMS.

Many of the tests done by Examiner (perhaps all of them!) are already being done by the GAMS solvers, so Examiner is in a sense redundant. However, the ability to make an independent, transparent check of a solver's solution is very useful in solver development, testing, and debugging. It is also useful when comparing the solutions returned by two different solvers. Finally, a tool like the Examiner allows one to examine solutions using different optimality tolerances and optimality criteria in a way that is not possible when working with the solvers directly.

GAMS/Examiner is installed automatically with your GAMS system. Without a full GAMS/Base license, examiner will run in student or demonstration mode (i.e. it will examine small models only).

5.15.2 Usage

Examiner can be used with all supported model types. Since Examiner doesn't really solve any problems, it is not a good choice for a default solver, and when installing GAMS it does not appear as an option in the list of possible solver defaults. However, you can choose Examiner via the command line:

    gams transport LP=examiner;

or via a GAMS option statement

    option LP=examiner;
somewhere before the solve statement.

Since Examiner is not really a solver, many of the usual GAMS options controlling solvers have no impact on it. However, the sysout option is interpreted in the usual way.

The optimality checks done in Examiner are first-order optimality checks done at a given point. A discussion here of these conditions and all they imply would be redundant: any good intro text in optimization will cover them. For linear programming, first-order optimality is all one needs to prove global optimality. For nonlinear programming, these conditions may or may not be necessary or sufficient for optimality; this depends on the convexity of the feasible set and objective and the form of the constraints. For integer programming models, these checks only make sense if we turn the global problem into a local one by adding bounds to the model, essentially fixing each discrete variable to its current value: these bounds are added automatically by Examiner.

Examiner runs in two basic modes of operation: it can examine the input point passed from GAMS/Base to the solver, and it can examine the point passed from the solver back to GAMS. Each mode can be used independent of the other. By default it will operate in the first mode, examining the initial “solution” passed to it by GAMS, but only if GAMS indicates it is passing an advanced basis to the solver (cf. the GAMS User Guide and the bratio option). If you wish to use the second solver-check mode, you may specify an appropriate subsolver using the subsolver option (see section Options). If no subsolver is selected, the default solver for the model type being solved is used. In most cases you will want to use an option file to specify exactly what type of examination you wish to perform. The rules for using an option file are described in The Solver Options File.

5.15.2.1 Solution Points: Definition

There are a number of different ways a solution point can be defined. Of course the different definitions will typically result in the same points being produced, but there are cases where this will not be precisely so. Since Examiner is intended to explore and analyze these cases, we must make these definitions precise. The following four points are defined and used in Examiner:

1. The gamspoint is the input point provided by GAMS to Examiner. The GAMS input point includes level & marginal values for the rows and columns: Examiner uses these exactly as given.

2. The initpoint is determined by the variable levels (primal vars) and equation marginals (dual vars) provided by GAMS to Examiner. These values are used to compute the equation levels and variable marginals / reduced costs using the function evaluator in Examiner, rather than using the values passed in by GAMS.

3. The solupoint is similar to the initpoint: it uses the variable levels (primal vars) and equation marginals (dual vars) to compute the equation levels and variable marginals. The variable levels and equation marginals used are those returned by the subsolver.

4. The solvpoint is the point returned by the subsolver. The subsolver returns both level and marginal values for the rows and columns: Examiner uses these, exactly as given.

5.15.2.2 Checks Performed

There are a number of checks that can be performed on any of the solution points. By default, Examiner tries to choose the appropriate checks. For example, if a primal simplex solver returns a model status of nonoptimal, the only checks that make sense are feasibility in the primal variables and constraints. However, this automatic choice of appropriate checks is not possible when checking points passed in from GAMS/Base.

1. Primal variable feasibility: check that all primal variables are within bounds.
2. **Primal constraint feasibility**: check that all primal constraints are satisfied.

3. **Dual variable feasibility**: check that all dual variables are within bounds.

4. **Dual constraint feasibility**: check that all dual constraints are satisfied.

5. **Primal complementary slackness**: check complementarity between the primal variables and the dual constraints / reduced costs.

6. **Dual complementary slackness**: check complementarity between the dual variables / equation marginals and the equation slacks.

7. **Equilibrium condition complementarity**: check complementarity of the equation/variable pairs in complementarity models (MCP, MPEC).

The checks above are implemented with default tolerances. These tolerances can be changed via an option file (see section Options).

Different ways exist to check the items mentioned above. For example, different norms can be used to measure the error of the residual when checking for primal feasibility. Currently, we have only implemented one way to make these checks.

For optimization models, it is possible to define a merit function that measures how well a given point satisfies conditions 1 through 6 above. Such a function is always nonnegative, and its value represents the error between the given point and a true solution. If such an input point is well-defined (e.g. if only one point is selected for examination) then Examiner will compute the merit function value at this point and return it in the RObj model attribute.

### 5.15.2.3 Scaling

By default, Examiner makes its checks on the original, unscaled model. In many cases, however, it is important to take scaling into account. Consider the effect of row scaling on the simple constraint $x^2 \leq 9$ where $x = 3.5$. Multiplying this constraint through by large or small constants changes the amount of the constraint violation proportionately, but the distance to feasibility is not changed. Applying row scaling to the original model eliminates this problem.

Most solvers scale a model before solving it, so any feasibility or optimality checks and tolerances are applied to the scaled model. The process of unscaling the model can result in a loss of feasibility or optimality. Even though we do not have access to the scales applied by the solver and cannot precisely construct the same scaled model, we can get a better idea of how the solver performed by looking at a model scaled by Examiner than by looking at the original.

It is also interesting to see what the model scaling looks like, even if we do not apply the scales to do the Examiner checks. If the row scales are in a nice range, say $[.1,100]$, we can have some confidence that the model is well-scaled. In contrast, if the row scales are in the range $[1,1e8]$ we may question the precision of the solution provided.

For each row, Examiner computes the true row scale as

$$\max_j (\|RH_{ij}\|, \max_j (\|A_{ij}\| \cdot \max (1, \|x_j\|)))$$

In this way variables with a large level value lead to large scale factors. To make the scale factor independent of the variable values, use an option file line of "AbsXScale 0". This replaces the term $\max (1, \|x_j\|)$ above with 1.

Since the user may wish to limit the size of the scale factors applied, the true row scales are projected onto the scale factor bounds to get the applied scale factors. The scale factors are applied when making a scaled check by dividing the rows by the scale factors and multiplying the corresponding Lagrange multipliers by these same factors. When making unscaled checks information about the true scales is still included in the output to give the user a hint about potential scaling issues.

Note that the scaled and unscaled checks are made independently. By default only the unscaled checks are performed. If you turn the scaled checks on via an option file line "scaled 1", this will not turn off the unscaled checks. You will need an option file line of "unscaled 0" to turn off unscaled checks.
### 5.15.3 Options

The following options control the behavior of GAMS/Examiner. Many of these are boolean (i.e. on/off) options. In this case, zero indicates off, nonzero on. For details on how to create and use an option file, see the section on the Solver Option File.

### 5.16 GAMSCHK

Abridged GAMSCHK USER DOCUMENTATION - Version 1.1
A System for Examining the Structure and Solution Properties of GAMS Model Instances

Author

Bruce A. McCarl, Professor, Department of Agricultural Economics, Texas A&M University

Date

April 2013
5.16 GAMSCHK

5.16.1 GAMSCHK USER DOCUMENTATION

This document describes procedures designed to aid users who wish to examine empirical GAMS models for possible flaws. The conceptual basis for many of the routines herein is supplied in McCarl and Spreen, and McCarl et.al.

The function of the specific components of GAMSCHK are to:

- List coefficients for user selected equations and/or variables using the DISPLAYCR procedure.
- List the characteristics of selected groups of variables and/or equations using MATCHIT.
- List the characteristics of equation and variable blocks using BLOCKLIST.
- Examine a GAMS model to see whether any variables and equations contain specification errors using ANALYSIS.
- Generate schematics depicting the characteristics of coefficients by variable and equation blocks using BLOCKPIC.
- Generate a schematic for small GAMS models or portions of larger models depicting the location of coefficients by sign and magnitude using PICTURE.
- Reconstruct the reduced cost of variables and the activity within equations after a model solution using POSTOPT.
- Help resolving problems with unbounded or infeasible models using NONOPT and ADVISORY.

5.16.2 General Notes on Package Usage

GAMSCHK must replace a solver. This is done using a GAMS option statement of the form:

```gams
OPTION LP= GAMSCHK;
```

or

```gams
OPTION NLP=GAMSCHK;
```

or

```gams
OPTION MIP=GAMSCHK;
```

which replaces either the solver of the particular model type with GAMSCHK. In turn, the user will invoke the solver using the statement:

```gams
SOLVE MODELNAME USING LP MINIMIZING OBJNAME;
```

where MODELNAME is the name used in the GAMS MODEL statement; OBJNAME is the objective variable name for the model; and the type of solver that GAMSCHK has replaced which must also be able to solve this type of problem (LP, NLP, MIP, ...) is identified. The following are examples of GAMS sequences which can be added to the GAMS file:

```gams
OPTION NLP=GAMSCHK;
SOLVE TRANSPORT USING NLP MINIMIZING Z;
```

or

```gams
OPTION LP=GAMSCHK;
SOLVE FEED USING LP MINIMIZING COST;
```

or

```gams
OPTION MIP=GAMSCHK;
SOLVE RESOURCE USING MIP MAXIMIZING PROFIT;
```
5.16.2.1 Selecting a Procedure and Providing Input - the *.GCK File

GAMSCHK requires that the user indicate which procedures are to be employed. This is specified through the use of the *.GCK file where the * refers to the filename from the GAMS execution instruction. The general form of that file is:

FIRST PROCEDURE NAME
   ITEM SELECTION INPUT

SECOND PROCEDURE NAME
   ITEM SELECTION INPUT

Spaces and capitalization are ignored in this input. For example, a *.GCK file could look like

DISPLAYCR
  variables
     SELL(*,*,FANCY)
  makeetable
Invariables
     transport(plant2,*,fancy)
Equations
     objT
     notthere
in equations
     resourceq(plant1)
PICTURE

The first procedure name in this case is DISPLAYCR and the following 10 lines indicate the items to be selected. Then, we also request PICTURE. Selection entries are treated using several assumptions. In particular:

1. If the *.GCK file is empty then it is assumed that the BLOCKPIC procedure is selected.
2. Spaces maybe freely used in the GCK input file.
3. Upper, lower, or mixed case input is accepted.
4. GAMSCHK recognizes certain words. These words are listed in Appendix A: Reserved Names and cannot be used as variable or equation names.

5.16.2.2 The *.GCK file: General Notes on Item Selection

Some of the procedures permit selection of variables, equations or functions. Specifically, the DISPLAYCR, PICTURE, POSTOPT, and MATCHIT procedures accept input identifying the variables and equations to be utilized. Also NONOPT accepts limited input controlling its function. General observations about the selection requests are

1. Variables can be chosen by entering the word VARIABLE or VARIABLES possibly with a modifier, followed by variable selection statements.

---

2 Thus, if the GAMS instructions are in the file called MYMODEL, and GAMS is invoked using the DOS command GAMS MYMODEL, then the GCK file would be called MYMODEL.GCK. If GAMS instructions are on the filename with a period in it then the name up to the period will be used, i.e., the GCK file associated with MYMODEL.IT would be MYMODEL.GCK
2. Variables can also be selected using the INEQUATION or INEQUATIONS syntax followed by names of equations. Use of this syntax results in selection of variables with coefficients in the named equations.

3. Equations are selected by entering the keyword, EQUATION or EQUATIONS possibly with a modifier, followed by equation selection statements.

4. Equations can also be selected using the INVARIABLE or INVARIABLES syntax followed by names of variables. Use of this syntax results in selection of equations in which the named variables have coefficients.

5. Certain item selection modifier keywords can be used depending on procedure. The INTERSECT keyword works with procedures DISPLAYCR and POSTOPT. The INEQUATION and INVARIABLE keywords work with procedures DISPLAYCR, PICTURE and POSTOPT. LISTEQUATION and LISTVARIABLE keywords work with the MATCHIT procedure. INSOLUTION, NOTINSOLUTION, BINDING, and NOTBINDING keywords work with POSTOPT. The keywords VERBOSE and IDENTIFY work with NONOPT.

6. If variable or equation names do not follow the keyword, then usually all variables or equations are assumed selected.

When variables or equations are to be selected after an item selection keyword, a number of input conventions apply. These conventions are:

1. If a variable or equation name is entered without any following parentheses, then all cases for that variable or equation are selected.

2. The selection entries identify specific elements from among the sets over which the variables and equations are defined. In specifying these elements one can use various wild card entries as discussed below or an element name. Note GAMS set or subset names cannot be used. Set membership information is not available to the GAMSCHK routines.

3. Wild cards can be used to select items. An "*" will select any item. For example, "B*" will select anything starting with a B. "A?B" will select anything beginning with A, ending with B with one intervening alpha numeric character.

4. When individual elements are specified, you need not enclose them in quotes (".").

5. Quotes must be specified to include set item names with spaces, and special characters. In that case wild cards do not work and all input up to the next quote is simply copied.

6. When the selected item has more dimensions than specified, then all later dimensions are handled as if a wild card were specified. For example, when a variable X is defined with reference to 4 sets in the GAMS instructions, but only 3 parameters are specified in the GAMSCHK input, then the request is handled as if all elements of the 4th are desired.

7. When the selected item has less dimensions in GAMS than in the item selection input, then all additional dimensions are ignored. Thus, when a variable X is defined with reference to 3 sets in GAMS, but 4 parameters are specified in the item selection file, then the 4th specification is ignored.

8. Multiple selection statements can appear on successive lines of the *.GCK file. Output is ordered according to the way items are found in the GAMS file which is determined by the ordering of variables, equations, and set elements in the original GAMS input.

9. Error messages will be generated when an entry cannot be matched to a GAMS element.

10. Examples include
<table>
<thead>
<tr>
<th>Example</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>X(*,CLEVELAND)</td>
<td>which indicates that X will be selected for any element of the first set</td>
</tr>
<tr>
<td></td>
<td>where the element in the second set equals CLEVELAND</td>
</tr>
<tr>
<td>X(SEATTLE)</td>
<td>when X is two dimensional selects all cases where the first set element</td>
</tr>
<tr>
<td></td>
<td>is SEATTLE</td>
</tr>
<tr>
<td>X(SEATTLE,CHICAGO,Z)</td>
<td>when X is two dimensional selects the case where the first set element</td>
</tr>
<tr>
<td></td>
<td>equals SEATTLE, and the second element equals CHICAGO. The third</td>
</tr>
<tr>
<td></td>
<td>is ignored.</td>
</tr>
<tr>
<td>X</td>
<td>all X's will be selected</td>
</tr>
<tr>
<td>X(S*, C.O, Z)</td>
<td>when X is three dimensional selects where all X's with first element</td>
</tr>
<tr>
<td></td>
<td>starting with S, second element beginning with C and ending with O</td>
</tr>
<tr>
<td></td>
<td>and third element Z will be selected.</td>
</tr>
<tr>
<td>*</td>
<td>all variables or equations will be selected</td>
</tr>
<tr>
<td>{empty selection set}</td>
<td>all variables or equations will be selected</td>
</tr>
</tbody>
</table>

5.16.2.3 Procedure Output

In all cases the output generated by the procedure will be written to the * .LST file associated with the GAMS call. Thus, if the file is called MODEL with the * .GCK file (MODEL.GCK), then all output will be on MODEL.LST.

5.16.2.4 Nonlinear Terms

GAMS models examined with GAMSCHK may involve nonlinear terms. In such cases, GAMSCHK uses the value of the nonlinear term sent forth from GAMS which is an accurate marginal, not total value. GAMS develops this value based on the current level value of the variable. This will either be: a) the starting point selected by GAMS, if the model has not been solved, or b) the current solution value, if the model has been solved. The most accurate portrayals of the coefficients will be generated after the model has been solved through a GAMS SOLVE command before invoking GAMSCHK. Some cases may require a solution and/or the specification of a good starting point before using GAMSCHK. Also, nonlinear terms potentially cause misleading coefficients as those values are local marginal, not global, values determined by the current levels of the variables. Nonlinear terms are marked with *** in the DISPLAYCR, POSTOPT, and NONOPT output.

5.16.2.5 Entering Comments in the * .GCK File

The * .GCK file has been programmed so that users can enter comments. These comments can take one of two forms. Comments that begin with a hash mark are copied to the output when the program runs. Comments which begin with a question mark are simply overlooked. Thus, one can temporarily comment GAMSCHK selection statements making them inactive by putting in question marks. If multiple procedures are being run or if some sort of output is decided to screen in the computer output then the hash marks can be entered.

5.16.2.6 Controlling Page Width in the * .GCK File

When running multiple procedures, in particular the pictures with other procedures, it is often desirable to have some procedures run with wide page widths, but the rest with a narrower page width. The GCK file provides the option to narrow the page width using a PW= command. In particular, what one can do is run GAMS with a large page width, i.e. run GAMS BLOCK pw=200, then insert in the GCK file instructions which narrow that page width for selected procedures. Users should note that the page width can never be made any wider than the default page width when running with GAMS. Information in excess of the page width will be ignored. Thus, if the model is run under the default status which has a page width of 75 characters then GAMSCHK will reduce the page width down to the maximum page width allowed. Consequently, the pw= command can only be used to narrow the page width from the default page width, not increase it.
5.16.2.7 Running Multiple Procedures

GAMSCHK can run multiple procedures during one job. This is done by simply stacking the sequence of the commands in the .GCK file.

5.16.3 Use of the Procedures

The following section describes the procedures available in GAMSCHK and their input requirements.

5.16.3.1 DISPLAYCR

Brief Purpose: DISPLAYCR displays all coefficients from the empirical model for a set of user selected equations and variables. All nonzero coefficients under each selected variable or in each selected equation are displayed with the associated variable or equation name and coefficient value. The selection entries may refer to all terms in equations under variables or only those coefficients at the intersection of the selected variables and equations.

Usage Notes: This option mirrors the GAMS LIMCOL and LIMROW options, but allows the user to select the specific items to be displayed. Partial displays within a variable or equation are also allowed using INTERSECT. Use of VARIABLE and EQUATION keywords followed by selection statements allows one to select variables and equations. Use of the INVARIABLE command allows users to select the equations which are associated with a particular variable. For example, if one is having trouble with a particular variable and wants to look at competition in the equations in which it appears, then selecting the variable under the INVARIABLE command will display the complete contents of all the equations in which the selected variables have coefficients. Similarly, the INEQUATION command will display the complete contents of all variables which fall in a particular equation. Nonlinear terms are marked with ***. When the keyword INTERSECT is found then only the coefficients at the intersection of the specified equations and variables are selected. Use of INTERSECT with the INVARIABLE syntax results in the named variables and the equations in which they fall being selected. Similarly, use of INTERSECT with the INEQUATION syntax results in selection of the named equations and the variables which fall in those equations.

Note that when GAMS internal scaling features are employed the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: The keyword DISPLAYCR is entered followed by optional lines of item selection input identifying the variables and equations to be displayed. This file can contain the keywords VARIABLE, INVARIABLE, EQUATION, and INEQUATION, with each followed by a specification of the items to be selected using the procedure input specification conventions that were described above. The keyword INTERSECT can also be used. Several special cases are relevant:

- If none of the above keywords are found after DISPLAYCR and another procedure name does not follow, then the input is assumed to identify variables.
- If input is found but the VARIABLE or INEQUATION keyword cannot be found then no variables are assumed selected.
- If the VARIABLE keyword is entered, but is followed by the end of file or an Appendix A reserved word and INEQUATION does not appear, then all variables are assumed selected.
- If the EQUATION or INVARIABLE keyword cannot be found, then no equations are assumed selected.
- If the EQUATION keyword is entered, but is followed by the end of the file or a reserved word and the INVARIABLE command does not occur, then all equations are assumed selected.
• The keyword INVARIABLE is allowed. It should be followed by variable selection statements. In turn, DISPLAYCR selects all equations which have nonzero entries under the INVARIABLE selections.

• The keyword INEQUATION may be used. It should be followed by equation selection statements. In turn, DISPLAYCR selects all variables which have nonzero entries in the INEQUATION selections.

• The keyword INTERSECT causes only coefficients at the intersection of the specified equations and variables to be displayed. This occurs for all specifications in this run of DISPLAYCR. One should use DISPLAYCR again if some intersecting and some non-intersecting displays are desired.

• When INTERSECT appears along with INVARIABLE, the named variable is selected along with all the equations in which it falls. Similarly, when INTERSECT and INEQUATION appear then all the named equations and the variables appearing in them are selected.

5.16.3.2 MATCHIT

Brief Purpose: MATCHIT retrieves the names and characteristics of selected variables and equations. The characteristics reported tell whether the items are nonlinear as well as reporting scaling characteristics and counts of the coefficients. MATCHIT will summarize the items which match a request or list all the items individually.

Usage Notes: The input to MATCHIT can include the keywords VARIABLE and EQUATION along with those keywords with the prefix LIST attached. When the LIST prefix is not used, the procedure summarizes the characteristics of all items which match the item requests counting the number of matching items, the number of those items which are nonlinear, the total coefficients under or in those items, the number of positive, negative, and nonlinear coefficients that fall under or in those items. This does not list the names of the individual items which match. If the LIST prefix is used (entering LISTVARIABLE or LISTEQUATION) then the individual matching items are printed in the order in which they are encountered. For each matching item the information tells whether it is nonlinear, how many total coefficients it has, the count of positive, negative, and nonlinear coefficients falling under it, and the minimum and maximum absolute values of coefficients under it (excluding the objective function coefficient).

Note that when GAMS internal scaling features are employed then by default scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: This file contains the keyword MATCHIT, followed by optional item selection input data. The optional input identifies the variables and equations to be displayed. This input can contain the keywords VARIABLE or LISTVARIABLE followed by a specification of the variables to be selected using the procedure input specification conventions that were described above. This can be followed by the keyword EQUATION or LISTEQUATION and the specified entries.

Several special cases are relevant:

• If the procedure name is not followed by any selection input, then a count of all variables and equations appears.

• If the input is found, but the input does not begin with VARIABLE, EQUATION, LISTVARIABLE, or LISTEQUATION keywords, then the input is assumed to contain variable names.

• If the VARIABLE keyword is entered, but is not followed by variable selection statements, and LISTVARIABLE does not appear, then all variables are assumed selected.

• If the EQUATION or LISTEQUATION keyword cannot be found, then equations are assumed selected.
• If the EQUATION keyword is entered, but is not followed by equation selection statements or a LISTEQUATION entry, then all equations are assumed selected.

• The keyword LISTVARIABLE is allowed. It should be followed by variable selection statements. In turn, MATCHIT lists all variables which fall under the request.

• The keyword LISTEQUATION may also be used. It should be followed by equation selection statements. In turn, MATCHIT lists all equations which fall under the request.

5.16.3.3 ANALYSIS

Brief Purpose: Analyzes the structure of all variables and equations. Information is given on errors involving obvious model misspecifications causing redundancy, zero variable values, infeasibility, unboundedness, or obvious constraint relaxations in linear programs. The checks are those identified in Tables 1, 2 and 3.

Usage Notes: The analysis tests given in Tables 1 and 2 are utilized to determine if individual variables or equations in the model possess obvious specification errors. One test, for example, considers whether or not in a maximization problem a variable appears which has a positive return in the objective function, but no coefficients in the constraints indicating an obviously unbounded model. Similarly, information is provided on whether certain equations can never be satisfied. For example, tests examine whether an equality equation appears with a negative right hand side and all positives on the left hand side. Also tests see whether the bounds on variables preclude equation satisfaction or make equations redundant (Table 3). In ANALYSIS these tests are applied to each and every variable and equation. The BLOCKPIC and BLOCKLIST routines utilize the tests on a block by block basis. Thus, the messages will be triggered only if every variable or equation in that block has the same problem. Also interactions between variables and equations are not checked so ANALYSIS only finds flaws contained in individual variables/equations.

Input File: The keyword ANALYSIS is all that is accepted.

5.16.3.4 BLOCKLIST

Brief Purpose: The BLOCKLIST procedure displays the number and characteristics of the items in each GAMS variable and equation block.

Usage Notes: The characteristic information gives:

1. The variable sign restriction or equation inequality type.
2. The number of variables or equations in this block;
3. The number of variables or equations with at least one nonlinear term in this block.
4. The number of positive coefficients under the variables or in the equations.
5. The number of negative coefficients under the variables or in the equations.
6. The number of nonlinear coefficients under the variables or in the equations.
7. The largest coefficient in absolute value in this block;
8. The smallest coefficient in absolute value in this block. Analysis tests are also performed as discussed under the ANALYSIS procedure.

Note that when GAMS internal scaling features are employed, the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: No input other than the procedure name is needed.
5.16.3.5 BLOCKPIC

**Brief Purpose:** Generates model schematics and scaling information. The schematics depict coefficient signs, total and average number of coefficients within each GAMS equation and variable block.

**Usage Notes:** These schematics are designed to aid users in identifying flaws in coefficient placement and sign. The summary information on problem scaling characteristics is designed to help users in scaling data. The scaling information is usually reported after any GAMS scaling (using the variablename.scale and equationname.scale features) but before solver scaling. (The user can change whether descaling is done - see the options file). Analysis tests are done using the procedures in Tables 1 and 2.

Note that when GAMS internal scaling features are employed the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

**Input File:** The keyword BLOCKPIC is all that is recognized.

5.16.3.6 PICTURE

**Brief Purpose:** Generates a schematic depicting the location, sign and magnitude of coefficients for selected variables and equations. Users can use this schematic to help identify flaws in coefficient placement, magnitude, or sign. Reports are also generated on the number of individual elements in the pictured portions of each variable and equation.

**Usage Notes:** This output can be quite large, so PICTURE should only be used for small models or model components. Note that when GAMS internal scaling features are employed, the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

**Input File:** Optional input instructions may appear after the PICTURE keyword. This input selects the variables and equations to be included. Only coefficients at the intersection of the selected variables and equations are portrayed. The selected item in the .GCK file can contain the keywords VARIABLE, or INvariable followed by a specification of the selected variables using the procedure input specification conventions above. This can be followed by the keywords EQUATION or INEquation and the specified entries. Several special cases are also relevant:

- If the VARIABLE or INEQUATION keywords cannot be found, then all variables are assumed selected.
- If the EQUATION or INVARIABLE keywords cannot be found, then all equations are assumed to selected.
- If the none of the VARIABLE, INVARIABLE, EQUATION, or INEQUATION keywords are found, everything is pictured and all other input is ignored.
- When the INVARIABLE keyword is used, then all equations in which those variables have coefficients are selected along with the named variables.
- When the INEQUATION keyword is used, then all variables which have coefficients in the named equations are selected along with the named equations.
5.16.3.7 POSTOPT

**Brief Purpose:** Does post optimality computations. In that capacity POSTOPT either:

- Reconstructs the reduced cost of variables after a GAMS model solution. Modelers can use this information to discover why certain variables are nonbasic or why certain shadow prices take on particular values, or
- Reconstructs the usage and supply across an equation after a GAMS model solution. Modelers can use this information to discover why certain variables or slacks take on particular values, as well as to find out where items within equations are produced and/or used.

**Usage Notes:** POSTOPT uses essentially the same input conventions as does DISPLAYCR. Thus, the usage notes in that selection are also relevant here. In addition:

1. POSTOPT requires a solution has been obtained GAMSCHK will automatically cause a solver to be invoked unless suppressed by the options file;
2. Nonlinear terms may not be accurate in the row sums as their marginal value not their total value is used but GAMS will have adjusted the right-hand sides for their presence; and
3. Attention can be restricted to only certain types of variables or equations. Variables that are INSOLUTION (Nonzero or with Zero marginals), NOTINSOLUTION (zero with a nonzero marginal) can be requested, BINDING or NONBINDING equations can be focused on.

Note that when GAMS internal scaling features are employed, the default option is that the unscaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

**Input File:** An optional input file is read in, indicating the specific variables desired using the conventions explained under DISPLAYCR above. In addition:

- One can enter INSOLUTION to restrict attention to variables which are nonzero or have zero marginals.
- One can enter NOTINSOLUTION to restrict attention to zero variables.
- The above entries restrict alteration in all VARIABLE or INEQUATION selection statements in a POSTOPT run.
- One can enter BINDING to only consider equations with zero slack. Similarly, NONBINDING considers equations with nonzero slack.
- The above equation specifications restrict all sections by all EQUATION or INVARIABLES items in a POSTOPT run.

5.16.3.8 ADVISORY

**Brief Purpose:** To identify variables which could be unbounded or equations and variable bounds which could cause a model to be infeasible.

**Usage Notes:** The ADVISORY procedure causes a presolution report on the set of all: a) variables which could be unbounded and/or b) equations and variable bounds which could cause infeasibility. The tests used are summarized in Table 3. This procedure identifies all variables which would need to be bounded as well as all constraints which need artificial variables if one wishes to diagnose problems in a model. The same output is also generated by NONOPT but the ADVISORY version does not require a solution.

**Input file:** Just the word ADVISORY
5.16.3.9 NONOPT

**Brief Purpose:** To help diagnose unbounded and infeasible models.

**Usage Notes:** The NONOPT procedure can be used in either an informative mode or with models which terminate as unbounded or infeasible. NONOPT will look through an optimal model reporting all variables which may be potentially unbounded or infeasible and all equations which may be infeasible using the checks explained under the ADVISORY section. Also in an unbounded model NONOPT can report the names of unbounded or infeasible variables or equations as well as either budgeting or row summing them. NONOPT runs after a solution and causes a solve to occur.

**Input File:** NONOPT may be followed by optional keywords IDENTIFY or VERBOSE. The IDENTIFY keyword causes GAMSCHK to report potential unbounded variables and/or infeasible equations. VERBOSE causes full budgets and row summing as done by the POSTOPT procedure on infeasible equations, and/or variables as well as unbounded variables and/or equations. Only the last encountered of the VERBOSE or IDENTIFY keywords will be obeyed. The details on these options are as follows:

1. If the IDENTIFY keyword is used, then the rules in Table 3 are applied to the model. Identify also anticipates that large upper bounds and/or artificial variables may be present. In an optimal condition all variable and equation levels that have exponents greater than the user supplied level filter in the options file (or 6 by default) are identified as items which could be involved with an unbounded model. Similarly, all variables or equations with marginals greater in exponent than the user supplied marginal exponent filter will be identified as items potentially involved with an infeasible model.

2. When the VERBOSE keyword is read then all variables and equations which are listed as nonoptimal or infeasible are treated using the budgeting and row summing aspects of POSTOPT.

3. When no keyword is found and the model solution is not optimal then the nonoptimal equations, infeasible equations and/or nonoptimal variables automatically listed.

5.16.4 Options File

GAMSCHK accepts an option file controlling solver choice (when needed); descaling; and size of the nonoptimal filters; the number of variable and column blocks selection entries allowed. The file is called GAMSCHK.OPT

5.16.4.1 Solver Choice Options

GAMSCHK calls for the solution of the problem when the POSTOPT or NONOPT procedures are used. In doing this, GAMSCHK internally selects the default GAMS solver for a problem class. Users may override this choice using the solver options file. Users may also force or suppress the solution process.

There are 16 solver related keywords allowed in the options file. These are as follows:

<table>
<thead>
<tr>
<th>OPTION</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>LP</td>
<td>Gives name of solver for LP problems</td>

<tr>
<td>OPTFILE</td>
<td>Solver options file number</td>
</tr>
</tbody>
</table>

In the first five cases, the option name is followed by the name of one of the licensed solvers. If the options file is empty, then the default solver will be used. If a solver name is given, then that solver will be used provided it matches the name of a solver GAMS recognizes.

5.16.4.2 When Should I Use SOLVE or NOSOLVE

Ordinarily GAMSCHK will cause a solver to be used if either the POSTOPT or the NONOPT options are used. However, users can force solutions under other cases or suppress solutions if desired.

One should only force a solution (using the SOLVE option) when one wishes to use the solution information after GAMSCHK is done either to examine the solution output or do post optimality calculations. Forcing a solution will not cause GAMSCHK to have improved representations of nonlinear terms. That will only occur when a SOLVE statement is executed before the SOLVE statement involving GAMSCHK.

5.16.4.3 Control of Number of Variable and Row Selections Allowed

The GAMSCHK program uses an upper estimate on the number of variable or equation blocks. In rare circumstances users may wish to override this choice. The options for this are:

<table>
<thead>
<tr>
<th>OPTION</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARBLOCK</td>
<td>Maximum number of variable blocks allowed</td>
</tr>
<tr>
<td>EQUBLOCK</td>
<td>Maximum number of equation blocks allowed</td>
</tr>
</tbody>
</table>

These options are followed by a number, but should not be routinely used.

5.16.4.4 Scaling

GAMS users may be utilizing internal features which involve scaling through the Model-name.SCALEOPT=1, VariableName.SCALE, and EquationName.SCALE options. GAMSCHK can work with these options to create output which reflects scaled, unscaled or partially unscaled output. In particular, the command DESCALE can be entered with one of three options: NEVER, ALL, or PART. If you enter NEVER, then none of the model output will be descaled. If you enter ALL, then all of the model output will be descaled. The third option is to use PART. In that case the NONOPT and POSTOPT output will be descaled whereas scaled information will be displayed for PICTURE, BLOCKPIC, BLOCKLIST, MATCHIT and DISPLAYCR. The PART option allows investigation of scaling. If you do not enter a DESCALE option then all information will be reported as if the PART option was chosen.
5.16.4.5 NONOPT Filters

The NONOPT model in "IDENTIFY" mode checks through a model solution to identify large marginals and/or large variable values. The limits on these checks are provided by two options:

<table>
<thead>
<tr>
<th>OPTION</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEVELFILT</td>
<td>Numerical value of exponent on &quot;unbounded levels&quot;</td>
</tr>
<tr>
<td>MARGFILT</td>
<td>Numerical value of exponent on &quot;infeasible marginals&quot;</td>
</tr>
</tbody>
</table>

These options provide upper bounds on the exponents of the absolute values for the levels and marginals. They are followed by an integer which gives the exponent. Thus, entries like

```
LEVELFILT 7
MARGFILT 7
```

will cause the reporting of all marginals and levels which are greater in absolute value than $10^7$.

5.16.4.6 Example Options File

The GAMSCHK option file is called GAMSCHK.OPT. An example of a file could look like the following 6 lines:

```
LP SOPLEX
MIP CBC
VARBLOCK 50
SOLVE
DESCALE PART
LEVELFILT 4
```

5.16.4.7 Solver Options File

One other important aspect regarding the options file involves the use of a problem solver options file when a solver such as SOPLEX, CBC, IPOPT etc. is also being used. As seen above the GAMSCHK.OPT does not recognize option commands such as those which would be submitted to the programming model solvers - SOPLEX for example. In all cases GAMSCHK will cause the default option file for the solver to be used when invoking the solver. Thus if SOPLEX and the options file is invoked is being used, SOPLEX options are controlled by the option file SOPLEX.OPT while GAMSCHK.OPT controls GAMSCHK operation. Users can change the number of the solver options file being used by using the OPTFILE parameter in the options file. OPTFILE 2 would cause use of solver options file .OP2.

5.16.5 Known Bugs

There are a few bugs that can cause GAMSCHK to report improper outputs or results. A list of the known bugs, their symptoms and a remedy is given below.
<table>
<thead>
<tr>
<th>Symptom</th>

<tr>
<td>GAMSCHK won’t run</td>
<td>Files are not properly installed</td>
<td>Recheck installation. If still doesn’t work report to author</td>
</tr>
<tr>
<td>Zero shadow prices when using NOSOLVE</td>
<td>Old version of GAMS solvers or Shadow prices suppressed</td>
<td>Try changing GAMSCOMP.TXT lines 2 or 0 to 12 or 10, if that doesn’t work update GAMS.</td>
</tr>
</tbody>
</table>

5.16.6 Tables

Table 1: Conditions under which a modeler should be advised of potential difficulty for equations without nonlinear terms.

- **a/** The PS cases indicate, because the variables in this equation follow this pattern, that:
  1. The variables appearing with nonzeros in this equation are forced to equal zero.
  2. This equation can never be satisfied and is obviously infeasible.
  3. This equation is redundant. The nonnegativity conditions are a stronger restriction.
- **b/** In the examples x denotes indexed non-negative variables, y indexed non-positive variables, and z a single unrestricted variable.
- **c/** Here and in the cases below at least one nonzero must occur.
- **d/** These entries give examples of the problem covered by each warning. Namely, in the first case examining only the nonnegative variables suppose all those variables have signs ≥ 0 but the right-hand-side is zero. Thus, we have X ≥ 0 and X ≤ 0 which implies X = 0. A warning is generated in that case.
- **e/** Only one coefficient is allowed.

5.16.10 GAMSCHK References

- McCarl, B.A. GAMSCHK. Older version of GAMSCHK User Documentation with additional GAMS examples.
5.17  Gurobi 9

Gurobi Optimization, www.gurobi.com

5.17.1  Introduction

The Gurobi suite of optimization products include state-of-the-art simplex and parallel barrier solvers for linear programming (LP) and quadratic programming (QP), parallel barrier solver for quadratically constrained programming (QCP), as well as parallel mixed-integer linear programming (MILP), mixed-integer quadratic programming (MIQP) and mixed-integer quadratically constrained programming (MIQCP) solvers.

The Gurobi MIP solver includes shared memory parallelism, capable of simultaneously exploiting any number of processors and cores per processor. The implementation is deterministic: two separate runs on the same model will produce identical solution paths.

While numerous solving options are available, Gurobi automatically calculates and sets most options at the best values for specific problems. All Gurobi options available through GAMS/Gurobi are summarized at the end of this chapter.

We offer a GAMS/Gurobi-Link license that works in combination with a Gurobi callable library license from Gurobi Optimization Inc.

Finally, a bare-bone interface to the LP and MIP solver of Gurobi is available under the name OSIGUROBI. Note that OSIGUROBI lacks several features of the GAMS/Gurobi-Link. It comes free of charge with any GAMS system.

5.17.2  How to Run a Model with Gurobi

The following statement can be used inside your GAMS program to specify using Gurobi

```
Option LP = Gurobi; { or MIP or RMIP or QCP or MIQCP or RMIQCP }
```

The above statement should appear before the `solve` statement. If Gurobi was specified as the default solver during GAMS installation, the above statement is not necessary.

5.17.3  Overview of GAMS/Gurobi

5.17.3.1  Linear, Quadratic and Quadratic Constrained Programming

Gurobi can solve LP and convex QP problems using several alternative algorithms, while the only choice for solving convex QCP is the parallel barrier algorithm. The majority of LP problems solve best using Gurobi’s state-of-the-art dual simplex algorithm, while most convex QP problems solve best using the parallel barrier algorithm. Certain types of LP problems benefit from using the parallel barrier or the primal simplex algorithms, while for some types of QP, the dual or primal simplex algorithm can be a better choice. If you are solving LP problems on a multi-core system, you should also consider using the concurrent optimizer. It runs different optimization algorithms on different cores, and returns when the first one finishes.
GAMS/Gurobi also provides access to the Gurobi infeasibility finder. The infeasibility finder takes an infeasible linear program and produces an irreducibly inconsistent set of constraints (IIS). An IIS is a set of constraints and variable bounds which is infeasible but becomes feasible if any one member of the set is dropped. GAMS/Gurobi reports the IIS in terms of GAMS equation and variable names and includes the IIS report as part of the normal solution listing. The infeasibility finder is activated by the option IIS. Another option for analyzing infeasible model the FeasOpt option which instructs GAMS/Gurobi to find a minimal feasible relaxation of an infeasible model. See section Feasible Relaxation for details.

GAMS/Gurobi supports sensitivity analysis (post-optimality analysis) for linear programs which allows one to find out more about an optimal solution for a problem. In particular, objective ranging and constraint ranging give information about how much an objective coefficient or a right-hand-side and variable bounds can change without changing the optimal basis. In other words, they give information about how sensitive the optimal basis is to a change in the objective function or the bounds and right-hand side. GAMS/Gurobi reports the sensitivity information as part of the normal solution listing. Sensitivity analysis is activated by the option Sensitivity.

The Gurobi presolve can sometimes diagnose a problem as being infeasible or unbounded. When this happens, GAMS/Gurobi can, in order to get better diagnostic information, rerun the problem with presolve turned off. The rerun without presolve is controlled by the option ReRun. In default mode only problems that are small (i.e. demo sized) will be rerun.

Gurobi can either presolve a model or start from an advanced basis or primal/dual solution pair. Often the solve from scratch of a presolved model outperforms a solve from an unpresolved model started from an advanced basis/solution. It is impossible to determine a priori if presolve or starting from a given advanced basis/solution without presolve will be faster. By default, GAMS/Gurobi will automatically use an advanced basis or solution from a previous solve statement. The GAMS BRatio option can be used to specify when not to use an advanced basis/solution. The GAMS/Gurobi option UseBasis can be used to ignore or force a basis/solution passed on by GAMS (it overrides BRatio). In case of multiple solves in a row and slow performance of the second and subsequent solves, the user is advised to set the GAMS BRatio option to 1.

5.17.3.2 Mixed-Integer Programming

The methods used to solve pure integer and mixed integer programming problems require dramatically more mathematical computation than those for similarly sized pure linear or quadratic programs. Many relatively small integer programming models take enormous amounts of time to solve.

For problems with discrete variables, Gurobi uses a branch and cut algorithm which solves a series of subproblems, LP subproblems for MILP, QP subproblems for MIQP, and QCP subproblems or LP outer approximation subproblems for MIQCP. Because a single mixed integer problem generates many subproblems, even small mixed integer problems can be very compute intensive and require significant amounts of physical memory. With option nonConvex Gurobi can also solve nonconvex (MI)QP and (MI)QCP problems using a spatial branch-and-bound method.

GAMS/Gurobi supports Special Order Sets of type 1 and type 2 as well as semi-continuous and semi-integer variables.

You can provide a known solution (for example, from a MIP problem previously solved or from your knowledge of the problem) to serve as the first integer solution.

If you specify some or all values for the discrete variables together with GAMS/Gurobi option MipStart, Gurobi will check the validity of the values as an integer-feasible solution. If this process succeeds, the solution will be treated as an integer solution of the current problem.

The Gurobi MIP solver includes shared memory parallelism, capable of simultaneously exploiting any number of processors and cores per processor. The implementation is deterministic: two separate runs on the same model will produce identical solution paths.
5.17.3.3 Nonlinear Programming

Gurobi is not a general purpose nonlinear programming solver, but it is able to handle certain nonlinear constraints by reformulating them into supported linear and/or quadratic constraints. These constraints are:

- **MAX constraint:**
  
  \[ \text{eq1. } r = \max(x_1, x_2, x_3, \ldots, c); \]
  \[ \text{eq2. } r = \text{smax}(i, x(i)); \]

- **MIN constraint:**
  
  \[ \text{eq1. } r = \min(x_1, x_2, x_3, \ldots, c); \]
  \[ \text{eq2. } r = \text{smin}(i, x(i)); \]

- **AND constraint:**
  
  \[ \text{eq1. } r = \text{b1 and b2 and b3 and \ldots}; \]
  \[ \text{eq2. } r = \text{sand}(i, b(i)); \]

- **OR constraint:**
  
  \[ \text{eq1. } r = \text{b1 or b2 or b3 or \ldots}; \]
  \[ \text{eq2. } r = \text{sor}(i, b(i)); \]

- **ABS constraint:**
  
  \[ \text{eq. } r = \text{abs}(x); \]

- **EXP constraint:**
  
  \[ \text{eq1. } r = \exp(x); \]
  \[ \text{eq2. } r = x^a; \]
  \[ \text{eq3. } r = a^x; \]

  Here, \( a > 0 \) and for eq3 the lower bound of \( x \) must be nonnegative.

- **LOG constraint:**
  
  \[ \text{eq1. } r = \log(x); \]
  \[ \text{eq2. } r = \log_2(x); \]
  \[ \text{eq3. } r = \log_{10}(x); \]

- **SIN / COS / TAN constraint:**
  
  \[ \text{eq1. } r = \sin(x); \]
  \[ \text{eq2. } r = \cos(x); \]
  \[ \text{eq3. } r = \tan(x); \]

- **NORM constraint:**
  
  \[ \text{eq. } r = \text{edist}(x_1, x_2, x_3, \ldots); \]

  Note that a 2-norm constraint can lead to a non-convex quadratic model which is much harder to solve than a convex quadratic or linear model.

- **POLY constraint:**
  
  \[ \text{eq. } r = \text{poly}(x, a_0, a_1, a_2, \ldots); \]
Nonlinear constraints must perfectly match one of the above forms. Otherwise, GAMS/Gurobi will raise a capability error. For example, it is not possible to interchange left-hand-side and right-hand-side of the above constraints.

GAMS/Gurobi offers a second approach to specify nonlinear constraints via linear constraints combined with .genconstrtype. These further support 0-NORM, 1-NORM and INF-NORM constraints.

### 5.17.3.4 Feasible Relaxation

The Infeasibility Finder identifies the causes of infeasibility by means of inconsistent set of constraints (IIS). However, you may want to go beyond diagnosis to perform automatic correction of your model and then proceed with delivering a solution. One approach for doing so is to build your model with explicit slack variables and other modeling constructs, so that an infeasible outcome is never a possibility. An automated approach offered in GAMS/Gurobi is known as FeasOpt (for Feasible Optimization) and turned on by parameter FeasOpt in a GAMS/Gurobi option file.

With the FeasOpt option GAMS/Gurobi accepts an infeasible model and selectively relaxes the bounds and constraints in a way that minimizes a weighted penalty function. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

By default all equations are candidates for relaxation and weighted equally but none of the variables can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the .feaspref option. The input value denotes the users willingness to relax a constraint or bound. The more likely it will be that a given bound or constraint will be relaxed. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed. It is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a GAMS/Gurobi solver option file using dot options. The syntax is:

```
(variable or equation).feaspref(value)
```

For example, suppose we have a GAMS declaration:

```plaintext
Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);
```

Then, the relaxation preference in the gurobi.opt file can be specified by:

```
feasopt 1
v.feaspref   1
v.feaspref('i1',*) 2
v.feaspref('i1','j2') 0
e.feaspref(*,'j1') 0
e.feaspref('i5','j4') 2
```
First we turn the feasible relaxation on. Furthermore, we specify that all variables $v(i,j)$ have preference of 1, except variables over set element $i1$, which have a preference of 2. The variable over set element $i1$ and $j2$ has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords `variables` or `equations` instead of the individual variable and equations names (e.g. `variables.feaspref 1`).

The parameter `FeasOptMode` allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter `FeasOptMode` indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a sum of required relaxations; as the number of constraints and bounds required to be relaxed; as a sum of the squares of required relaxations).

Please check description of parameter `FeasOptMode` for details. Also check example models `feasopt*` in the GAMS Model library.

### 5.17.3.5 Parameter Tuning Tool

The Gurobi Optimizer provides a wide variety of parameters that allow you to control the operation of the optimization engines. The level of control varies from extremely coarse-grained (e.g., the `Method` parameter, which allows you to choose the algorithm used to solve continuous models) to very fine-grained (e.g., the `MarkowitzTol` parameter, which allows you to adjust the precise tolerances used during simplex basis factorization). While these parameters provide a tremendous amount of user control, the immense space of possible options can present a significant challenge when you are searching for parameter settings that improve performance on a particular model. The purpose of the Gurobi tuning tool is to automate this search.

The Gurobi tuning tool performs multiple solves on your model, choosing different parameter settings for each, in a search for settings that improve runtime. The longer you let it run, the more likely it is to find a significant improvement.

A number of tuning-related parameters allow you to control the operation of the tuning tool. The most important is probably `TuneTimeLimit`, which controls the amount of time spent searching for an improving parameter set. Other parameters include `TuneTrials` (which attempts to limit the impact of randomness on the result), `TuneResults` (which limits the number of results that are returned), and `TuneOutput` (which controls the amount of output produced by the tool).

While parameter settings can have a big performance effect for many models, they aren’t going to solve every performance issue. One reason is simply that there are many models for which even the best possible choice of parameter settings won’t produce an acceptable result. Some models are simply too large and/or difficult to solve, while others may have numerical issues that can’t be fixed with parameter changes.

Another limitation of automated tuning is that performance on a model can experience significant variations due to random effects (particularly for MIP models). This is the nature of search. The Gurobi algorithms often have to choose from among multiple, equally appealing alternatives. Seemingly innocuous changes to the model (such as changing the order of the constraint or variables), or subtle changes to the algorithm (such as modifying the random number seed) can lead to different choices. Often times, breaking a single tie in a different way can lead to an entirely different search. We’ve seen cases where subtle changes in the search produce 100X performance swings. While the tuning tool tries to limit the impact of these effects, the final result will typically still be heavily influenced by such issues.

The bottom line is that automated performance tuning is meant to give suggestions for parameters that could produce consistent, reliable improvements on your models. It is not meant to be a replacement for efficient modeling or careful performance testing.
5.17.3.6 Compute Server

The Gurobi Compute Server allows you to use one or more servers to offload all of your Gurobi computations.

Gurobi compute servers support queuing and load balancing. You can set a limit on the number of simultaneous jobs each compute server will run. When this limit has been reached, subsequent jobs will be queued. If you have multiple compute servers, the current job load is automatically balanced among the available servers. By default, the Gurobi job queue is serviced in a First-In, First-Out (FIFO) fashion. However, jobs can be given different priorities. Jobs with higher priorities are then selected from the queue before jobs with lower priorities.

Gurobi Compute Server licenses and software are not included in GAMS/Gurobi. Contact Gurobi directly to inquire about the software and license.

5.17.3.7 Distributed Parallel Algorithms

Gurobi Optimizer implements a number of distributed algorithms that allow you to use multiple machines to solve a problem faster. Available distributed algorithms are:

- A **distributed MIP solver**, which allows you to divide the work of solving a single MIP model among multiple machines. A manager machine passes problem data to a set of worker machines in order to coordinate the overall solution process.

- A **distributed concurrent solver**, which allows you to use multiple machines to solve an LP or MIP model. Unlike the distributed MIP solver, the concurrent solver doesn't divide the work associated with solving the problem among the machines. Instead, each machine uses a different strategy to solve the whole problem, with the hope that one strategy will be particularly effective and will finish much earlier than the others. For some problems, this concurrent approach can be more effective than attempting to divide up the work.

- **Distributed parameter tuning**, which automatically searches for parameter settings that improve performance on your optimization model. Tuning solves your model with a variety of parameter settings, measuring the performance obtained by each set, and then uses the results to identify the settings that produce the best overall performance. The distributed version of tuning performs these trials on multiple machines, which makes the overall tuning process run much faster.

These distributed parallel algorithms are designed to be almost entirely transparent to the user. The user simply modifies a few parameters, and the work of distributing the computation to multiple machines is handled behind the scenes by Gurobi.

5.17.3.7.1 Specifying the Worker Pool  Once you’ve set up a set of one or more distributed workers, you should list at least one of their names in the WorkerPool parameter. You can provide either machine names or IP addresses, and they should be comma-separated.

You can provide the worker access password through the WorkerPassword parameter. All servers in the worker pool must have the same access password.
5.17.3.7.2 Requesting Distributed Algorithms Once you've set up the worker pool through the appropriate parameters, the last step to use a distributed algorithm is to set the `TuneJobs`, `ConcurrentJobs`, or `DistributedMIPJobs` parameter. These parameters are used to indicate how many distinct tuning, concurrent, or distributed MIP jobs should be started on the available workers.

If some of the workers in your worker pool are running at capacity when you launch a distributed algorithm, the algorithm won’t create queued jobs. Instead, it will launch as many jobs as it can (up to the requested value), and it will run with these jobs.

These distributed algorithms have been designed to be nearly indistinguishable from the single machine versions. Our hope is that, if you know how to use the single machine version, you’ll find it straightforward to use the distributed version. The distributed algorithms respect all of the usual parameters. For distributed MIP, you can adjust strategies, adjust tolerances, set limits, etc. For concurrent MIP, you can allow Gurobi to choose the settings for each machine automatically or specify a set of options. For distributed tuning, you can use the usual tuning parameters, including `TuneTimeLimit`, `TuneTrails`, and `TuneOutput`.

There are a few things to be aware of when using distributed algorithms, though. One relates to relative machine performance. Distributed algorithms work best if all of the workers give very similar performance. For example, if one machine in your worker pool were much slower than the others in a distributed tuning run, any parameter sets tested on the slower machine would appear to be less effective than if they were run on a faster machine. Similar considerations apply for distributed MIP and distributed concurrent. We strongly recommend that you use machines with very similar performance. Note that if your machines have similarly performing cores but different numbers of cores, we suggest that you use the `Threads` parameter to make sure that all machines use the same number of cores.

Logging for distributed MIP is very similar to the standard MIP logging. The main differences are in the progress section. The header for the standard MIP logging looks like this:

```
Nodes | Current Node | Objective Bounds | Work
Expl Unexpl | Obj Depth IntInf | Incumbent BestBd Gap | It/Node Time
```

By contrast, the distributed MIP header looks like this:

```
Nodes | Utilization | Objective Bounds | Work
Expl Unexpl | Active Sync Comm | Incumbent BestBd Gap | It/Node Time
```

You’ll note that columns three through five show different information. In the distributed MIP log, these columns give information about the utilization of the distributed workers, expressed as percentages. The first of these columns shows the fraction of the preceding time period (the time since the previous progress log line) that the workers spent actively processing MIP nodes. The second column shows the time the workers spent waiting for other workers to complete tasks assigned to them. The final column shows the time spent communicating data between machines. The numbers sum to 100%.

Here is an example of a distributed MIP progress log:

```
Nodes | Utilization | Objective Bounds | Work
Expl Unexpl | Active Sync Comm | Incumbent BestBd Gap | It/Node Time
* 0 - 157344.61033 - - - 0s
* 0 - 41359.940833 - - - 0s
* 0 - 25050.545455 - - - 0s
* 0 - 18150.083886 - - - 0s
* 0 - 14372.871258 - - - 0s
* 0 - 13725.475382 - - - 0s
```
One thing you may find in the progress section is that node counts may not increase monotonically. In this example, a solution found at node 261 is reported before a solution found at node 0. Distributed MIP tries to create a single, unified view of node numbers, but with multiple machines processing nodes independently, possibly at different rates, some inconsistencies are inevitable.

Another difference is the line that indicates that the distributed ramp-up phase is complete. At this point, the distributed strategy transitions from a concurrent approach to a distributed approach. The log line indicates which worker was the winner in the concurrent approach. Distributed MIP continues by dividing the partially explored MIP search tree from this worker among all of the workers.

Another difference in the distributed log is in the summary section. The distributed MIP log includes a breakdown of how runtime was spent:

Runtime breakdown:
  Active: 13.73s (75%)
  Sync: 1.16s (6%)
  Comm: 3.45s (19%)

This is an aggregated view of the utilization data that is displayed in the progress log lines. In this example, the workers spent 75% of runtime actively working on MIP nodes, 6% waiting to synchronize with other workers, and 19% communicating data between machines.

The installation instructions for the Gurobi Remote Services can be found on Gurobi’s web page www.gurobi.com.

5.17.3.7.3 Gurobi Instant Cloud An alternative to setting up your own pool of machines is to use the Gurobi Instant Cloud. You only need a GAMS/Gurobi link license when you solve your problems in the Gurobi Instant Cloud. The cost for the Gurobi license is paid on a per use basis directly to Gurobi. If you follow through the steps on the Gurobi web site, you eventually get the names of the machines Gurobi has started for you in the cloud. In order to use these machines from GAMS/Gurobi, you need to provide a Gurobi license with access instructions for the Gurobi Instant Cloud (detailed instructions for configuring the client license file).
5.17.3.8 Solution Pool

While the default goal of the Gurobi Optimizer is to find one proven optimal solution to your model, with a possible side-effect of finding other solutions along the way, the solver provides a number of parameters that allow you to change this behavior.

By default, the Gurobi MIP solver will try to find one proven optimal solution to your model. It will typically find multiple sub-optimal solutions along the way, which can be retrieved later. However, these solutions aren't produced in a systematic way. The set of solutions that are found depends on the exact path the solver takes through the MIP search. You could solve a MIP model once, obtaining a set of interesting sub-optimal solutions, and then solve the same problem again with different parameter settings, and find only the optimal solution.

To store (some of the) solutions found along the way, you can enable the Solution Pool feature by setting option solnpool. If you'd like more control over how solutions are found and retained, the Gurobi Optimizer has a number of parameters available for this. The first and simplest is PoolSolutions, which controls the size of the solution pool. Changing this parameter won't affect the number of solutions that are found - it simply determines how many of those are retained.

You can use the PoolSearchMode parameter to control the approach used to find solutions. In its default setting (0), the MIP search simply aims to find one optimal solution. Setting the parameter to 1 causes the MIP search to expend additional effort to find more solutions, but in a non-systematic way. You will get more solutions, but not necessarily the best solutions. Setting the parameter to 2 causes the MIP to do a systematic search for the n best solutions. For both non-default settings, the PoolSolutions parameter sets the target for the number of solutions to find.

If you are only interested in solutions that are within a certain gap of the best solution found, you can set the PoolGap parameter. Solutions that are not within the specified gap are discarded.

Obtaining an OPTIMAL optimization return status when using PoolSearchMode=2 indicates that the MIP solver succeeded in finding the desired number of best solutions, or it proved that the model doesn't have that many distinct feasible solutions. If the solver terminated early (e.g., due to a time limit), you PoolObjBound attribute (printed to the log) to evaluate the quality of the solutions that were found. This attribute gives a bound on the objective of any solution that isn't already in the solution pool. The difference between this attribute and ObjBound is that the latter gives a bound on the objective for any solution, and which is often looser than PoolObjBound. The PoolObjBound attribute gives a bound on the objective of undiscovered solutions. Further tree exploration won't find better solutions. You can use this bound to get a count of how many of the n best solutions you found: any solutions whose objective values are at least as good as PoolObjBound are among the n best.

5.17.3.8.1 Solution Pool Example

Let's continue with a few examples of how these parameters would be used. Imagine that you are solving a MIP model with an optimal (minimization) objective of 100. Further imagine that, using default settings, the MIP solver finds four solutions to this model with objectives 100, 110, 120, and 130.

If you set the PoolSolutions parameter to 3 and solve the model again, the MIP solver would discard the worst solution and return with 3 solutions in the solution pool. If you instead set the PoolGap parameter to value 0.2, the MIP solver would discard any solutions whose objective value is worse than 120 (which would also leave 3 solutions in the solution pool).

If you set the PoolSearchMode parameter to 2 and the PoolSolutions parameter to 10, the MIP solver would attempt to find the 10 best solutions to the model. An OPTIMAL return status would indicate that either (i) it found the 10 best solutions, or (ii) it found all feasible solutions to the model, and there were fewer than 10. If you also set the PoolGap parameter to a value of 0.1, the MIP solver would try to find 10 solutions with objective no worse than 110. While this may appear equivalent to asking for 10 solutions and simply ignoring those with objective worse than 110, the solve will typically complete significantly faster with this parameter set, since the solver does not have to expend effort looking for solutions beyond the requested gap.
5.17.3.8.2 Solution Pool Subtleties There are a few subtleties associated with finding multiple solutions that we'll cover now.

Continuous Variables

One subtlety arises when considering multiple solutions for models with continuous variables. Specifically, you may have two solutions that take identical values on the integer variables but where some continuous variables differ. By choosing different points on the line between these two solutions, you actually have an infinite number of choices for feasible solutions to the problem. To avoid this issue, we define two solutions as being equivalent if they take the same values on all integer variables (and on all continuous variables that participate in SOS constraints). A solution will be discarded if it is equivalent to another solution that is already in the pool.

Optimality Gap

The interplay between the optimality gap (MIPGap or MIPGapAbs) and multiple solutions can be a bit subtle. When using the default PoolSearchMode, a non-zero optimality gap indicates that you are willing to allow the MIP solver to declare a solution optimal, even though the model may have other, better solutions. The claim the solver makes upon termination is that no other solution would improve the incumbent objective by more than the optimality gap. Terminating at this point is ultimately a pragmatic choice - we'd probably rather have the true best solution, but the cost of reducing the optimality gap to zero can often be prohibitive.

This pragmatic choice can produce a bit of confusion when finding multiple optimal solutions. Specifically, if you ask for the n best solutions, the optimality gap plays a similar role as it does in the default case, but the implications may be a bit harder to understand. Specifically, a non-zero optimality gap means that you are willing to allow the solver to declare that it has found the n best solutions, even though there may be solutions that are better than those that were returned. The claim in this case is that any solution not among the reported n best would improve on the objective for the worst among the n best by less than the optimality gap.

If you want to avoid this source of potential confusion, you should set the optimality gap to 0 when using PoolSearchMode=2.

Logging

If you browse the log from a MIP solve with PoolSearchMode set to a non-default value, you may see the lower bound on the objective exceed the upper bound. This can't happen with the default PoolSearchMode - if you are only looking for one optimal solution, the search is done as soon as the lower bound reaches the upper bound. However, if you are looking for the n best solutions, you have to prove that the model has no solution better than the n-th best. The objective for that n-th solution could be much worse than that of the incumbent. In this situation, the log file will include a line of the form:

Optimal solution found at node 123 - now completing solution pool...

Distributed MIP

One limitation that we should point out related to multiple solutions is that the distributed MIP solver has not been extended to support non-default PoolSearchMode settings. Distributed MIP will typically produce many more feasible solutions than non-distributed MIP, but there's no way to ask it to find the n best solutions.
5.17.3.9 Multiple Objectives

While typical optimization models have a single objective function, real-world optimization problems often have multiple, competing objectives. For example, in a production planning model, you may want to both maximize profits and minimize late orders, or in a workforce scheduling application, you may want to both minimize the number of shifts that are short-staffed while also respecting worker’s shift preferences.

The main challenge you face when working with multiple, competing objectives is deciding how to manage the tradeoffs between them. Gurobi provides tools that simplify the task: Gurobi allows you to blend multiple objectives, to treat them hierarchically, or to combine the two approaches. In a blended approach, you optimize a weighted combination of the individual objectives. In a hierarchical or lexicographic approach, you set a priority for each objective, and optimize in priority order. When optimizing for one objective, you only consider solutions that would not degrade the objective values of higher-priority objectives. Gurobi allows you to enter and manage your objectives, to provide weights for a blended approach, or to set priorities for a hierarchical approach. Gurobi will only solve multi-objective models with strictly linear objectives. Moreover, for continuous models, Gurobi will report a primal only solution (not dual information).

Following the workforce application the specifications of the objectives would be done as follows:

```
equations defObj, defNumShifts, defSumPreferences;
variables obj, numShifts, sumPreferences;

defObj.. obj =e= numShifts - 1/100*sumPreferences;
defNumShifts.. numShifts =e= ...;
defSumPreferences.. sumPreferences =e= ...;

model workforce /all/;
solve workforce minimizing obj using mip;
```

With the default setting GUROBI will solve the blended objective. Using the parameter MultObj GUROBI will use a hierarchical approach. A hierarchical or lexicographic approach assigns a priority to each objective, and optimizes for the objectives in decreasing priority order. At each step, it finds the best solution for the current objective, but only from among those that would not degrade the solution quality for higher-priority objectives. The priority is specified by the absolute value of the objective coefficient in the blended objective function (defObj). In the example, the numShifts objective with coefficient 1 has higher priority than the sumPreferences objective with absolute objective coefficient 1/100. The sign of the objective coefficient determines the direction of the particular objective function. So here numShifts will be minimized (same direction as on the solve statement) while sumPreferences will be maximized. GAMS needs to identify the various objective functions, therefore the objective variables can only appear in the blended objective functions and in the particular objective defining equation.

By default, the hierarchical approach won’t allow later objectives to degrade earlier objectives. This behavior can be relaxed through a pair of attributes: ObjNRelTol and ObjNAbsTol. By setting one of these for a particular objective, you can indicate that later objectives are allowed to degrade this objective by the specified relative or absolute amount, respectively. In our earlier example, if the optimal value for numShifts is 100, and if we set ObjNAbsTol for this objective to 20, then the second optimization step maximizing sumPreferences would find the best solution for the second objective from among all solutions with objective 120 or better for numShifts. Note that if you modify both tolerances, later optimizations would use the looser of the two values (i.e., the one that allows the larger degradation).
5.17.4 GAMS Options

The following GAMS options are used by GAMS/Gurobi:

Option BRatio = x;

Determines whether or not to use an advanced basis. A value of 1.0 causes GAMS to instruct Gurobi not to use an advanced basis. A value of 0.0 causes GAMS to construct a basis from whatever information is available. The default value of 0.25 will nearly always cause GAMS to pass along an advanced basis if a solve statement has previously been executed. This GAMS option is overridden by the GAMS/Gurobi option UseBasis.

Option IterLim = n;

Sets the simplex iteration limit. Simplex algorithms will terminate and pass on the current solution to GAMS. For MIP problems, if the number of the cumulative simplex iterations exceeds the limit, Gurobi will terminate. This GAMS option is overridden by the GAMS/Gurobi option IterationLimit.

Option NodLim = x;

Maximum number of nodes to process for a MIP problem. This GAMS option is overridden by the GAMS/Gurobi option NodeLimit.

Option OptCA = x;

Absolute optimality criterion for a MIP problem. The OptCA option asks Gurobi to stop when

$$|BP - BF| < \text{OptCA}$$

where $BF$ is the objective function value of the current best integer solution while $BP$ is the best possible integer solution. This GAMS option is overridden by the GAMS/Gurobi option MipGapAbs.

Option OptCR = x;

Relative optimality criterion for a MIP problem. Notice that Gurobi uses a different definition than GAMS normally uses. The OptCR option asks Gurobi to stop when

$$|BP - BF| < |BF| \times \text{OptCR}$$

where $BF$ is the objective function value of the current best integer solution while $BP$ is the best possible integer solution. The GAMS definition is:

$$|BP - BF| < |BP| \times \text{OptCR}$$

This GAMS option is overridden by the GAMS/Gurobi option MipGap.

Option ResLim = x;

Sets the time limit in seconds. The algorithm will terminate and pass on the current solution to GAMS. Gurobi measures time in wall time on all platforms. Some other GAMS solvers measure time in CPU time on some Unix systems. In case resLim assumes its default value (1e+10) Gurobi will use its own default (infinity). This GAMS option is overridden by the GAMS/Gurobi option TimeLimit.
Option SysOut = On;

Will echo Gurobi messages to the GAMS listing file. This option may be useful in case of a solver failure.

*ModelName*.Cutoff = x;

Cutoff value. When the branch and bound search starts, the parts of the tree with an objective worse than x are deleted. This can sometimes speed up the initial phase of the branch and bound algorithm. This GAMS option is overridden by the GAMS/Gurobi option CutOff.

*ModelName*.OptFile = 1;

Instructs GAMS/Gurobi to read the option file. The name of the option file is *gurobi.opt*.

*ModelName*.PriorOpt = 1;

Instructs GAMS/Gurobi to use the priority branching information passed by GAMS through variable suffix values *variable.prior*.

5.17.5 Summary of GUROBI Options

5.17.5.1 Termination options

<table>
<thead>
<tr>
<th>Option</th>

5.17.5.12 The GAMS/Gurobi Options File

The GAMS/Gurobi options file consists of one option or comment per line. An asterisk (\*) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by any amount of white space (blanks or tabs).

Following is an example options file *gurobi.opt*.

```
simplexpricing 3
method 0
```

It will cause Gurobi to use quick-start steepest edge pricing and will use the primal simplex algorithm.

5.17.6 GAMS/Gurobi Log File

Gurobi reports its progress by writing to the GAMS log file as the problem solves. Normally the GAMS log file is directed to the computer screen.

The log file shows statistics about the presolve and continues with an iteration log.

For the simplex algorithms, each log line starts with the iteration number, followed by the objective value, the primal and dual infeasibility values, and the elapsed wall clock time. The dual simplex uses a bigM approach for handling infeasibility, so the objective and primal infeasibility values can both be very large during phase I. The frequency at which log lines are printed is controlled by the DisplayInterval option. By default, the simplex algorithms print a log line roughly every five seconds, although log lines can be delayed when solving models with particularly expensive iterations.

The simplex screen log has the following appearance:

```
Presolve removed 977 rows and 1539 columns
Presolve changed 3 inequalities to equalities
Presolve time: 0.078000 sec.
Presolved: 1748 Rows, 5030 Columns, 32973 Nonzeros

<table>
<thead>
<tr>

<td>0.000000e+00</td>
<td>0.000000e+00</td>
<td>2s</td>
</tr>
</tbody>
</table>

Solved in 5624 iterations and 1.69 seconds
Optimal objective 1.148696610e+05
```

The barrier algorithm log file starts with barrier statistics about dense columns, free variables, nonzeros in \( AA' \) and the Cholesky factor matrix, computational operations needed for the factorization, memory estimate and time estimate per iteration. Then it outputs the progress of the barrier algorithm in iterations with the primal and dual objective values, the magnitude of the primal and dual infeasibilities and the magnitude of the complementarity violation. After the barrier algorithm terminates, by default, Gurobi will perform crossover to obtain a valid basic solution. It first prints the information about pushing the dual and primal superbasic variables to the bounds and then the information about the simplex progress until the completion of the optimization.

The barrier screen log has the following appearance:
Presolve removed 2394 rows and 3412 columns
Presolve time: 0.09s
Presolved: 3677 Rows, 8818 Columns, 30934 Nonzeros
Ordering time: 0.20s

Barrier statistics:
Dense cols : 10
Free vars : 3
AA’ NZ : 9.353e+04
Factor NZ : 1.139e+06 (roughly 14 MBytes of memory)
Factor Ops : 7.388e+08 (roughly 2 seconds per iteration)

Solved in 2043 iterations and 2.00 seconds
Optimal objective 1.126639605e+07

For MIP problems, the Gurobi solver prints regular status information during the branch and bound search. The first two output columns in each log line show the number of nodes that have been explored so far in the search tree, followed by the number of nodes that remain unexplored. The next three columns provide information on the most recently explored node in the tree. The solver prints the relaxation objective value for this node, followed by its depth in the search tree, followed by the number of integer variables with fractional values in the node relaxation solution. The next three columns provide information on the progress of the global MIP bounds. They show the objective value for the best known integer feasible solution, the best bound on the value of the optimal solution, and the gap between these lower and upper bounds. Finally, the last two columns provide information on the amount of work performed so far. The
first column gives the average number of simplex iterations per explored node, and the next column gives
the elapsed wall clock time since the optimization began.

At the default value for option DisplayInterval, the MIP solver prints one log line roughly every five
seconds. Note, however, that log lines are often delayed in the MIP solver due to particularly expensive
nodes or heuristics.

Presolve removed 12 rows and 11 columns
Presolve tightened 70 bounds and modified 235 coefficients
Presolve time: 0.02s
Presolved: 114 Rows, 116 Columns, 424 Nonzeros
Objective GCD is 1

5.17.7 Detailed Descriptions of GUROBI Options

aggfill (integer): Allowed fill during presolve aggregation

Controls the amount of fill allowed during presolve aggregation. Larger values generally lead
to presolved models with fewer rows and columns, but with more constraint matrix non-zeros.

The default value chooses automatically, and usually works well.

Default: -1

aggregate (integer): Presolve aggregation control

Default: 1

barconvtol (real): Barrier convergence tolerance

The barrier solver terminates when the relative difference between the primal and dual objective values is less than the specified tolerance.

Default: $1e^{-08}$

**barcorrectors** (integer): Central correction limit

The default value is chosen automatically, depending on problem characteristics.

Default: $-1$

**barhomogeneous** (integer): Barrier homogeneous algorithm

Determines whether to use the homogeneous barrier algorithm. At the default setting (-1), it is only used when barrier solves a node relaxation for a MIP model. Setting the parameter to 0 turns it off, and setting it to 1 forces it on. The homogeneous algorithm is useful for recognizing infeasibility or unboundedness. It is a bit slower than the default algorithm.

Default: $-1$

</table>

**barqcpcrontol** (real): Barrier QCP convergence tolerance

When solving a QCP model, the barrier solver terminates when the relative difference between the primal and dual objective values is less than the specified tolerance. Tightening this tolerance may lead to a more accurate solution, but it may also lead to a failure to converge.

Default: $1e^{-06}$

**bestbdstop** (real): Best objective bound to stop

Terminates as soon as the engine determines that the best bound on the objective value is at least as good as the specified value.

Default: maxdouble

**bestobjstop** (real): Best objective value to stop
Terminate as soon as the engine finds a feasible solution whose objective value is at least as good as the specified value.

Default: mindouble

**bqpcuts (integer):** BQP cut generation

Default: -1

</tr>
</tbody>
</table>

**branchdir (integer):** Branch direction preference

This option allows more control over how the branch-and-cut tree is explored. Specifically, when a node in the MIP search is completed and two child nodes, corresponding to the down branch and the up branch are created, this parameter allows you to determine whether the MIP solver will explore the down branch first, the up branch first, or whether it will choose the next node based on a heuristic determination of which sub-tree appears more promising.

Default: 0

</tr>
</tbody>
</table>

**concurrentjobs (integer):** Enables distributed concurrent solver

Enables distributed concurrent optimization, which can be used to solve LP or MIP models on multiple machines. A value of $n$ causes the solver to create $n$ independent models, using different parameter settings for each. Each of these models is sent to a distributed worker for processing. Optimization terminates when the first solve completes. Use the WorkerPool parameter to provide a list of available distributed workers.

By default, Gurobi chooses the parameter settings used for each independent solve automatically. The intent of concurrent MIP solving is to introduce additional diversity into the MIP search.
By bringing the resources of multiple machines to bear on a single model, this approach can sometimes solve models much faster than a single machine.

Default: 0

**concurrentmip** *(integer)*: Enables concurrent MIP solver

This parameter enables the concurrent MIP solver. When the parameter is set to value $n$, the MIP solver performs $n$ independent MIP solves in parallel, with different parameter settings for each. Optimization terminates when the first solve completes. Gurobi chooses the parameter settings used for each independent solve automatically. The intent of concurrent MIP solving is to introduce additional diversity into the MIP search. This approach can sometimes solve models much faster than applying all available threads to a single MIP solve, especially on very large parallel machines.

The concurrent MIP solver divides available threads evenly among the independent solves. For example, if you have 6 threads available and you set ConcurrentMIP to 2, the concurrent MIP solver will allocate 3 threads to each independent solve. Note that the number of independent solves launched will not exceed the number of available threads.

The concurrent MIP solver produces a slightly different log from the standard MIP solver. The log only provides periodic summary information. Each concurrent MIP log line shows the objective for the best feasible solution found by any of the independent solves to that point, the best objective bound proved by any of the independent solves, and the relative gap between these two values. Gurobi also includes node counts from one of the independent solves, as well as elapsed times, to give some indication of forward progress.

Default: 1

**covercuts** *(integer)*: Cover cut generation

See the description of the global Cuts parameter for further information.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>

<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

**crossover** *(integer)*: Barrier crossover strategy

Use value 0 to disable crossover; the solver will return an interior solution. Other options control whether the crossover algorithm tries to push primal or dual variables to bounds first, and then which simplex algorithm is used once variable pushing is complete. Options 1 and 2 push dual variables first, then primal variables. Option 1 finishes with primal, while option 2 finishes with dual. Options 3 and 4 push primal variables first, then dual variables. Option 3 finishes with primal, while option 4 finishes with dual. The default value of -1 chooses automatically.

Default: -1

**crossoverbasis** *(integer)*: Crossover initial basis construction strategy

Default: -1
<table>
<thead>

</tbody>
</table>

**cutaggpasses** *(integer)*: Constraint aggregation passes performed during cut generation

A non-negative value indicates the maximum number of constraint aggregation passes performed during cut generation. See the description of the global Cuts parameter for further information.

Default: -1

**cutoff** *(real)*: Objective cutoff

Optimization will terminate if the engine determines that the optimal objective value for the model is worse than the specified cutoff. This option overwrites the GAMS cutoff option.

Default: maxdouble

**cutpasses** *(integer)*: Root cutting plane pass limit

Default: -1

**cuts** *(integer)*: Global cut generation control

The parameters, Cuts, CliqueCuts, CoverCuts, FlowCoverCuts, FlowPathCuts, GUBCoverCuts, ImpliedCuts, InfProofCuts, MIPSepCuts, MIRCuts, ModKCuts, NetworkCuts, GomoryPasses, StrongCGCuts, SubMIPCuts, CutAggPasses and ZeroHalfCuts, affect the generation of MIP cutting planes. In all cases except GomoryPasses and CutAggPasses, a value of -1 corresponds to an automatic setting, which allows the solver to determine the appropriate level of aggressiveness in the cut generation. Unless otherwise noted, settings of 0, 1, and 2 correspond to no cut generation, conservative cut generation, or aggressive cut generation, respectively. The Cuts parameter provides global cut control, affecting the generation of all cuts. This parameter also has a setting of 3, which corresponds to very aggressive cut generation. The other parameters override the global cuts parameter (so setting Cuts to 2 and CliqueCuts to 0 would generate all cut types aggressively, except clique cuts which would not be generated at all. Setting Cuts to 0 and GomoryPasses to 10 would not generate any cuts except Gomory cuts for 10 passes).

Default: -1

</tr>
<tr>
<td>3</td>
<td>Very aggressive</td>
</tr>
</tbody>
</table>

**degenmoves** *(integer)*: Degenerate simplex moves

Limits degenerate simplex moves. These moves are performed to improve the integrality of the current relaxation solution. By default, the algorithm chooses the number of moves to perform automatically.
Changing the value of this parameter can help performance in cases where an excessive amount of time is spent after the initial root relaxation has been solved but before the cut generation process or the root heuristics have started.

Default: -1

**disconnected (integer)**: Disconnected component strategy

A MIP model can sometimes be made up of multiple, completely independent sub-models. This parameter controls how aggressively we try to exploit this structure. A value of 0 ignores this structure entirely, while larger values try more aggressive approaches. The default value of -1 chooses automatically. This only affects mixed integer programming (MIP) models.

Default: -1

<table>
<thead>
<tr>

</tbody>
</table>

**displayinterval (integer)**: Frequency at which log lines are printed

Default: 5

**distributedmipjobs (integer)**: Enables the distributed MIP solver

Enables distributed MIP. A value of \( n \) causes the MIP solver to divide the work of solving a MIP model among \( n \) machines. Use the `WorkerPool` parameter to provide the list of available machines.

Default: 0

**.dofuncpieceerror (real)**: Error allowed for PWL translation of function constraints

Default: 1e-3

**.dofuncpiecelength (real)**: Piece length for PWL translation of function constraints

The default length behavior for piecewise-linear approximation of a function constraint is controlled by `funcPieceLength`. This dot option `.dofuncPieceError` allows to overwrite the default behavior by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: 1e-2

**.dofuncpieceratio (real)**: Control whether to under- or over-estimate function values in PWL approximation

The default ratio behavior for piecewise-linear approximation of a function constraint is controlled by `funcPieceRatio`. This dot option `.dofuncPieceError` allows to overwrite the default behavior by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: -1

**.dofuncpieces (integer)**: Sets strategy for PWL function approximation

The dot option `.dofuncpieces` allows to specify the strategy for piecewise-linear approximation of function constraints. This option is particularly useful when working with piecewise-linear functions in MIP models.

Default: -1
The default strategy for performing a piecewise-linear approximation of a function constraint is set by `funcPieces`. This dot option .do`funcPieces` allows to overwrite the default strategy by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

`dofuncpieceerror` The default error behavior for piecewise-linear approximation of a function constraint is controlled by `funcPieceError`. This dot option .do`funcPieceError` allows to overwrite the default behavior by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

`dualreductions` (boolean): Disables dual reductions in presolve

Default: 1

`dumpbcsol` (string): Dump incumbents to GDX files during branch-and-cut

The content of this string option is used as a file stem for GDX point files. The file name gets completed by the solution number. So if this option has been set to `mysol` then GDX files containing the new solution with the names `mysol0.gdx`, `mysol1.gdx`, ... will be created. The number of GDX files created depends on the number of solutions Gurobi finds during branch-and-cut.

`feasibilitytol` (real): Primal feasibility tolerance

All constraints must be satisfied to a tolerance of `FeasibilityTol`.

Range: \([1e-09, 0.01]\]

Default: \(1e-06\)

`feasopt` (boolean): Computes a minimum-cost relaxation to make an infeasible model feasible

With `Feasopt` turned on, a minimum-cost relaxation of the right hand side values of constraints or bounds on variables is computed in order to make an infeasible model feasible. It marks the relaxed right hand side values and bounds in the solution listing.

Several options are available for the metric used to determine what constitutes a minimum-cost relaxation which can be set by option `FeasOptMode`.

Feasible relaxations are available for all problem types.

Default: 0
feasoptmode (integer): Mode of FeasOpt

The parameter FeasOptMode allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter FeasOptMode indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the minimality of the relaxation (as a sum of required relaxations; as the number of constraints and bounds required to be relaxed; as a sum of the squares of required relaxations).

Default: 0

</tbody>
</table>

.feaspref (real): feasibility preference

You can express the costs associated with relaxing a bound or right hand side value during a FeasOpt run through the .feaspref option. The syntax for dot options is explained in the Introduction chapter of the Solver Manual. The input value denotes the user’s willingness to relax a constraint or bound. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed.

Default: 1

feasrelaxbigm (real): Big-M value for feasibility relaxations

When relaxing a constraint in a feasibility relaxation, it is sometimes necessary to introduce a big-M value. This parameter determines the default magnitude of that value.

Default: 1e+06
**fixoptfile** (string): Option file for fixed problem optimization

**flowcovercuts** (integer): Flow cover cut generation

See the description of the global Cuts parameter for further information.

Default: -1

<table>

</tr>
</tbody>
</table>

**freegamsmodel** (boolean): Preserves memory by dumping the GAMS model instance representation temporarily to disk

In order to provide the maximum amount of memory to the solver this option dumps the internal representation of the model instance temporarily to disk and frees memory. This option only works with SolveLink=0 and only for models without quadratic constraints.

Default: 0

**funcmaxval** (real): Maximum value for x and y variables in function constraints

Very large values in piecewise-linear approximations can cause numerical issues. This parameter limits the bounds on the variables that participate in function constraints. Specifically, if x or y participate in a function constraint, any bound larger than funcMaxVal (in absolute value) will be truncated.

Default: 1e+06

**funcpieceerror** (real): Error allowed for PWL translation of function constraint

If the **funcPieces** parameter is set to value -1 or -2, this parameter provides the maximum allowed error (absolute for -1, relative for -2) in the piecewise-linear approximation.

Default: 0.001

**funcpiecelength** (real): Piece length for PWL translation of function constraint
If the `funcPieces` parameter is set to value 1, this parameter gives the length of each piece of the piecewise-linear approximation.

Default: 0.01

`funcpieceratio (real)`: Controls whether to under- or over-estimate function values in PWL approximation

This option controls whether the piecewise-linear approximation of a function constraint is an underestimate of the function, an overestimate, or somewhere in between. A value of 0 will always underestimate, while a value of 1 will always overestimate. A value in between will interpolate between the underestimate and the overestimate. A special value of -1 chooses points that are on the original function.

Default: -1

`funcpieces (integer)`: Sets strategy for PWL function approximation

</tbody>
</table>

`.genconstrtype (integer)`: General constraint type

Mathematical programming has traditionally defined a set of fundamental constraint types: variable bound constraints, linear constraints, quadratic constraints, integrality constraints, and SOS constraints. These are typically treated directly by the underlying solver (although not always), and are fundamental to the overall algorithm.

Gurobi accepts a number of additional constraint types, which we collectively refer to as general constraints. These are typically not treated directly by the solver. Rather, they are transformed by presolve into mathematically equivalent sets of constraints (and variables), chosen from among the fundamental types listed above. These general constraints are provided as a convenience to users. If such constraints appear in your model, but if you prefer to reformulate them yourself using fundamental constraint types instead, you can certainly do so. However, note that Gurobi can sometimes exploit information contained in the other constraints in the model to build a more efficient formulation than what you might create. Gurobi does not allow general logical constraints but needs the constraint with a single operator (either `max` or `min` or ...). In order to pass the general constraint type to Gurobi we interpret a linear constraint plus the value of the `GenConstrType` option. Such a linear constraint has a resultant variable (r or rb) on the left hand side of `=`E=`) and the variables involved in the operation on the right hand side:

**MAX constraint:**

`eqMax.. r =e= max(x1,x2,x3,c);`

is represented in the following form:
eqMax.. r =e= x1+x2+x3+c;
with GAMS/GUROBI option eqMax.GenConstrType=1.

MIN constraint:
eqMin.. r =e= min(x1,x2,x3,c);
is represented in the following form:
eqMin.. r =e= x1+x2+x3+c;
with GAMS/GUROBI option eqMin.GenConstrType=2.

ABS constraint:
eqAbs.. r =e= abs(x1);
is represented in the following form:
eqAbs.. r =e= x1;
with GAMS/GUROBI option eqAbs.GenConstrType=3.

AND constraint:
eqAnd.. br =e= b1 and b2 and b3 and b4;
is represented in the following form:
eqAnd.. br =e= b1+b2+b3+b4;
with GAMS/GUROBI option eqAnd.GenConstrType=4.

OR constraint:
eqOr.. br =e= b1 or b2 or b3 or b4;
is represented in the following form:
eqOr.. br =e= b1+b2+b3+b4;
with GAMS/GUROBI option eqOr.GenConstrType=5.

EXPA constraint:
eqExpA.. r =e= a**x1;
is represented in the following form:
eqExpA.. r =e= x1+a;
with GAMS/GUROBI option eqExpA.GenConstrType=6.

LOGA constraint:
eqLogA.. r =e= log(x1)/log(a);
is represented in the following form:
eqLogA.. r =e= x1+a;
with GAMS/GUROBI option eqLogA.GenConstrType=7.

POW constraint:

eqPow.. r =e= x1**a;

is represented in the following form:

eqPow.. r =e= x1+a;

with GAMS/GUROBI option eqPow.GenConstrType=8.

EXP constraint:

eqExp.. r =e= exp(x1);

is represented in the following form:

eqExp.. r =e= x1;

with GAMS/GUROBI option eqExp.GenConstrType=9.

LOG constraint:

eqLog.. r =e= log(x1);

is represented in the following form:

eqLog.. r =e= x1;

with GAMS/GUROBI option eqLog.GenConstrType=10.

SIN constraint:

eqSin.. r =e= sin(x1);

is represented in the following form:

eqSin.. r =e= x1;

with GAMS/GUROBI option eqSin.GenConstrType=11.

COS constraint:

eqCos.. r =e= cos(x1);

is represented in the following form:

eqCos.. r =e= x1;

with GAMS/GUROBI option eqCos.GenConstrType=12.

TAN constraint:

eqTan.. r =e= tan(x1);

is represented in the following form:
eqTan.. r =e= x1;

0-NORM constraint:

eqNorm0.. r =e= norm0(x1,x2,x3);
is represented in the following form:

eqNorm0.. r =e= x1 + x2 + x3;
with GAMS/GUROBI option eqNorm0.GenConstrType=14.

1-NORM constraint:

eqNorm1.. r =e= norm1(x1,x2,x3);
is represented in the following form:

eqNorm1.. r =e= x1 + x2 + x3;
with GAMS/GUROBI option eqNorm1.GenConstrType=15.

2-NORM constraint:

eqNorm2.. r =e= norm2(x1,x2,x3);
is represented in the following form:

eqNorm2.. r =e= x1 + x2 + x3;
with GAMS/GUROBI option eqNorm2.GenConstrType=16. Note that a 2-norm constraint can lead to a non-convex quadratic model which is much harder to solve than a convex quadratic or linear model.

INF-NORM constraint:

eqNormInf.. r =e= normInf(x1,x2,x3);
is represented in the following form:

eqNormInf.. r =e= x1 + x2 + x3;
with GAMS/GUROBI option eqNormInf.GenConstrType=17.

Note that for the AND and OR constraint the resultant variable needs to be a binary variable.
The default value for parameter GenConstrType of a constraint is 0 marking it as a regular constraint (linear or quadratic).
Default: 0

gomorypasses (integer): Root Gomory cut pass limit ←

A non-negative value indicates the maximum number of Gomory cut passes performed. See the description of the global Cuts parameter for further information.

Default: -1

gubcovercuts (integer): GUB cover cut generation ←

See the description of the global Cuts parameter for further information.

Default: -1
heuristics (real): Turn MIP heuristics up or down

Larger values produce more and better feasible solutions, at a cost of slower progress in the best bound.

Range: [0, 1]

Default: 0.05

iis (boolean): Run the Irreducible Inconsistent Subsystem (IIS) finder if the problem is infeasible

Default: 0

iismethod (integer): IIS method

Chooses the IIS method to use. Method 0 is often faster, while method 1 can produce a smaller IIS. Method 2 ignores the bound constraints. Method 3 will return the IIS for the LP relaxation of a MIP model if the relaxation is infeasible, even though the result may not be minimal when integrality constraints are included. The default value of -1 chooses automatically.

Default: -1

impliedcuts (integer): Implied bound cut generation

See the description of the global Cuts parameter for further information.

Default: -1

improvestartgap (real): Trigger solution improvement

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify an optimality gap at which the MIP solver will switch to this strategy. For example, setting this parameter to 0.1 will cause the MIP solver to switch once the relative optimality gap is smaller than 0.1.

Default: 0
\textbf{improvestartnodes (real):} Trigger solution improvement $\leftrightarrow$

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify the node count at which the MIP solver switches to a solution improvement strategy. For example, setting this parameter to 10 will cause the MIP solver to switch strategies once the node count is larger than 10.

Default: \texttt{maxdouble}

\textbf{improvestarttime (real):} Trigger solution improvement $\leftrightarrow$

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify a time limit when the MIP solver will switch to this strategy. For example, setting this parameter to 10 will cause the MIP solver to switch 10 seconds after starting the optimization.

Default: \texttt{maxdouble}

\textbf{infproofcuts (integer):} Infeasibility proof cut generation $\leftrightarrow$

Controls infeasibility proof cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the \texttt{Cuts} parameter.

Default: -1

\textbf{integralityfocus (boolean):} Set the integrality focus $\leftrightarrow$

One unfortunate reality in MIP is that integer variables don’t always take exact integral values. While this typically doesn’t create significant problems, in some situations the side-effects can be quite undesirable. The best-known example is probably a trickle flow, where a continuous variable that is meant to be zero when an associated binary variable is zero instead takes a non-trivial value. More precisely, given a constraint \( y = 1 \leq \M b \), where \( y \) is a non-negative continuous variable, \( b \) is a binary variable, and \( M \) is a constant that captures the largest possible value of \( y \), the constraint is intended to enforce the relationship that \( y \) must be zero if \( b \) is zero. With the default integer feasibility tolerance, the binary variable is allowed to take a value as large as \( 1e^{-5} \) while still being considered as taking value zero. If the \( M \) value is large, then the \( M b \) upper bound on the \( y \) variable can be substantial.

Reducing the value of the \texttt{intFeasTol} parameter can mitigate the effects of such trickle flows, but often at a significant cost, and often with limited success. The \texttt{integralityFocus} parameter provides a better alternative. Setting this parameter to 1 requests that the solver work harder to try to avoid solutions that exploit integrality tolerances. More precisely, the solver tries to find solutions that are still (nearly) feasible if all integer variables are rounded to exact integral values. We should say that the solver won’t always succeed in finding such solutions, and that this setting introduces a modest performance penalty, but the setting will significantly reduce the frequency and magnitude of such violations.

Default: 0

<table>

.lazy (integer): Lazy constraints value

Determines whether a linear constraint is treated as a lazy constraint. At the beginning of the MIP solution process, any constraint whose Lazy attribute is set to 1, 2, or 3 (the default value is 0) is removed from the model and placed in the lazy constraint pool. Lazy constraints remain inactive until a feasible solution is found, at which point the solution is checked against the lazy constraint pool. If the solution violates any lazy constraint, the solution is discarded and one or more of the violated lazy constraints are pulled into the active model.

Larger values for this attribute cause the constraint to be pulled into the model more aggressively. With a value of 1, the constraint can be used to cut off a feasible solution, but it won't necessarily be pulled in if another lazy constraint also cuts off the solution. With a value of 2, all lazy constraints that are violated by a feasible solution will be pulled into the model. With a value of 3, lazy constraints that cut off the relaxation solution are also pulled in.

Any constraint whose Lazy attribute is set to -1 is treated as a user cut; it is removed from the model and placed in the user cut pool. User cuts may be added to the model at any node in the branch-and-cut search tree to cut off relaxation solutions.

The main difference between user cuts and lazy constraints is that the former are not allowed to cut off integer-feasible solutions. In other words, they are redundant for the MIP model, and the solver is free to decide whether or not to use them to cut off relaxation solutions. The hope is that adding them speeds up the overall solution process. Lazy constraints have no such restrictions. They are essential to the model, and the solver is forced to apply them whenever a solution would otherwise not satisfy them.
Only affects MIP models. Lazy constraints are only active if option LazyConstraints is enabled and are specified through the option lazy. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: 0

lazyconstraints (boolean): Indicator to use lazy constraints

Default: 0

liftprojectcuts (integer): Lift-and-project cut generation

Controls lift-and-project cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the Cuts parameter.

Default: -1

lpwarmstart (integer): Warm start usage in simplex

Controls whether and how Gurobi uses warm start information for an LP optimization. The non default setting of 2 is particularly useful for communicating advanced start information while retaining the performance benefits of presolve.

As a general rule, setting this parameter to 0 ignores any start information and solves the model from scratch. Setting it to 1 (the default) uses the provided warm start information to solve the original, unpresolved problem, regardless of whether presolve is enabled. Setting it to 2 uses the start information to solve the presolved problem, assuming that presolve is enabled. This involves mapping the solution of the original problem into an equivalent (or sometimes nearly equivalent) crushed solution of the presolved problem. If presolve is disabled, then setting 2 still prioritizes start vectors, while setting 1 prioritizes basis statuses. Taken together, the LPWarmStart parameter setting, the LP algorithm specified by Gurobi's Method parameter, and the available advanced start information determine whether Gurobi will use basis statuses only, basis statuses augmented with information from start vectors, or a basis obtained by applying the crossover method to the provided primal and dual start vectors to jump start the optimization.

When Gurobi's Method parameter requests the barrier solver, primal and dual start vectors are prioritized over basis statuses (but only if you provide both). These start vectors are fed to the crossover procedure. This is the same crossover that is used to compute a basic solution from the interior solution produced by the core barrier algorithm, but in this case crossover is started from arbitrary start vectors. If you set the LPWarmStart parameter to 1, crossover will be invoked on the original model using the provided vectors. Any provided basis information will not be used in this case. If you set LPWarmStart to 2, crossover will be invoked on the presolved model using crushed start vectors. If you set the parameter to 2 and provide a basis but no start vectors, the basis will be used to compute the corresponding primal and dual solutions on the original model. Those solutions will then be crushed and used as primal and dual start vectors for the crossover, which will then construct a basis for the presolved model. Note that for all of these settings and start combinations, no barrier algorithm iterations are performed.

The simplex algorithms provide more warm-starting options, with a parameter value of 1, simplex will start from a provided basis, if available. Otherwise, it uses a provided start vector to refine the crash basis it computes.

With a value of 2, simplex will use the crushed start vector on the presolved model to refine the crash basis. This is true regardless of whether the start is derived from start vectors or a starting basis from the original model. The difference is that if you provide an advanced basis, the basis will be used to compute the corresponding primal and dual solutions on the original model from which the primal or dual start on the presolved model will be derived.

Note: Only affects linear programming (LP) models.

Default: 1
**markowitztol** *(real)*: Threshold pivoting tolerance

Used to limit numerical error in the simplex algorithm. A larger value may avoid numerical problems in rare situations, but it will also harm performance.

Range: [0.0001, 0.999]

Default: 0.0078125

**memlimit** *(real)*: Memory limit

Limits the total amount of memory (in GB, i.e., $10^9$ bytes) available to Gurobi. If more is needed, Gurobi will fail with an OUT_OF_MEMORY error.

Default: maxdouble

**method** *(integer)*: Algorithm used to solve continuous models

Synonyms: lpmethod rootmethod

Algorithm used to solve continuous models or the root node of a MIP model. Options are:
-1=automatic, 0=primal simplex, 1=dual simplex, 2=barrier, 3=concurrent, 4=deterministic concurrent, 5=deterministic concurrent simplex.

In the current release, the default Automatic (-1) setting will typically choose non-deterministic concurrent (Method=3) for an LP, barrier (Method=2) for a QP or QCP, and dual (Method=1) for the MIP root node. Only the simplex and barrier algorithms are available for continuous QP models. Only primal and dual simplex are available for solving the root of an MIQP model. Only barrier is available for continuous QCP models.

Concurrent optimizers run multiple solvers on multiple threads simultaneously, and choose the one that finishes first. Method=3 and Method=4 will run dual simplex, barrier, and sometimes primal simplex (depending on the number of available threads). Method=5 will run both primal and dual simplex. The deterministic options (Method=4 and Method=5) give the exact same result each time, while Method=3 is often faster but can produce different optimal bases when run multiple times.

The default setting is rarely significantly slower than the best possible setting, so you generally won’t see a big gain from changing this parameter. There are classes of models where one particular algorithm is consistently fastest, though, so you may want to experiment with different options when confronted with a particularly difficult model.

Note that if memory is tight on an LP model, you should consider using the dual simplex method (Method=1). The concurrent optimizer, which is typically chosen when using the default setting, consumes a lot more memory than dual simplex alone.

Default: -1

minrelnodes (integer): Minimum relaxation heuristic control

Number of nodes to explore in the minimum relaxation heuristic. Note that this heuristic is only applied at the end of the MIP root, and only when no other root heuristic finds a feasible solution.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

The default value automatically chooses whether to apply the heuristic. It will only rarely choose to do so.

Default: $-1$

mipfocus (integer): Set the focus of the MIP solver

Default: 0

mipgap (real): Relative MIP optimality gap

The MIP engine will terminate (with an optimal result) when the gap between the lower and upper objective bound is less than $\text{MipGap}$ times the upper bound.

Range: $[0, \infty]$  

Default: GAMS optcr

mipgapabs (real): Absolute MIP optimality gap

The MIP solver will terminate (with an optimal result) when the gap between the lower and upper objective bound is less than $\text{MIPGapAbs}$.

Range: $[0, \infty]$  

Default: GAMS optca

mipsepcuts (integer): MIP separation cut generation

See the description of the global Cuts parameter for further information.

Default: $-1$

**mipstopexpr (string):** Stop expression for branch and bound

If the provided logical expression is true, the branch-and-bound is aborted. Supported values are: resusd, nodusd, objest, objval. Supported operators are: +, -, *, /, ^, %, !=, ==, <=, >=, >, ==, !, &&, ||, (, ), abs, ceil, exp, floor, log, log10, pow, sqrt. Example: nodusd >= 1000 && abs(objest - objval) / abs(objval) < 0.1

**miptrace (string):** Filename of MIP trace file

More info is available in chapter Solve trace.

**miptracenode (integer):** Node interval when a trace record is written

Default: 100

**miptracetime (real):** Time interval when a trace record is written

Default: 1

**miqcpmethod (integer):** Method used to solve MIQCP models

Controls the method used to solve MIQCP models. Value 1 uses a linearized, outer-approximation approach, while value 0 solves continuous QCP relaxations at each node. The default setting (-1) chooses automatically.

Default: -1

<table>

**modkcuts (integer):** Mod-k cut generation

...
See the description of the global \texttt{Cuts} parameter for further information.

Default: \texttt{-1}

\textbf{multimipstart} (\textit{string}): Use multiple (partial) mipstarts provided via gdx files

Specifies (multiple) GDX files with values for the variables. Each file is treated as one initial guess for the MIP start. These MIP starts are added in addition to the initial guess provided by the level attribute. A MIP start GDX file can be created, for example, by using the command line option \texttt{savepoint}.

This option further allows to add partial MIP starts where some variable level records are not given. GUROBI will then try to construct a full MIP start out of it. In order to not provide a certain variable level record, simply not include that record in the GDX file or set the level value to NA or UNDEF.

This option requires \texttt{mipstart} enabled.

\textbf{multiobjmethod} (\textit{integer}): Warm-start method to solve for subsequent objectives

When solving a continuous multi-objective model using a hierarchical approach, the model is solved once for each objective. The algorithm used to solve for the highest priority objective is controlled by the \texttt{Method} parameter. This parameter determines the algorithm used to solve for subsequent objectives. As with the \texttt{Method} parameters, values of 0 and 1 use primal and dual simplex, respectively. A value of 2 indicates that warm-start information from previous solves should be discarded, and the model should be solved from scratch (using the algorithm indicated by the \texttt{Method} parameter). The default setting of \texttt{-1} usually chooses primal simplex.

Default: \texttt{-1}

\textbf{multiobjpre} (\textit{integer}): Initial presolve on multi-objective models

Controls the initial presolve level used for multi-objective models. Value 0 disables the initial presolve, value 1 applies presolve conservatively, and value 2 applies presolve aggressively. The default \texttt{-1} value usually applies presolve conservatively. Aggressive presolve may increase the chance of the objective values being slightly different than those for other options.

Default: \texttt{-1}

\textbf{multobj} (\textit{boolean}): Controls the hierarchical optimization of multiple objectives

Default: 0

\textbf{names} (\textit{boolean}): Indicator for loading names

Default: 1

<table>

**nlpheur (boolean):** Controls the NLP heuristic for non-convex quadratic models

The NLP heuristic uses a non-linear barrier solver to find feasible solutions to non-convex quadratic models. It can often find solutions much more quickly than the alternative, but in some cases it can consume significant runtime without producing a solution.

Note: Only affects non-convex quadratic models.

Default: 1

**nodefiledir (string):** Directory for MIP node files

Determines the directory into which nodes are written when node memory usage exceeds the specified NodelfileStart value.

Default: .

**nodefilestart (real):** Memory threshold for writing MIP tree nodes to disk

Controls the point at which MIP tree nodes are written to disk. Whenever node storage exceeds the specified value (in GBytes), nodes are written to disk.

Default: maxdouble

**nodelimit (real):** MIP node limit

Default: maxdouble

**nodemethod (integer):** Method used to solve MIP node relaxations

Algorithm used for MIP node relaxations. Note that barrier is not an option for MIQP node relaxations.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic</td>
</tr>
<tr>
<td>0</td>
<td>Primal simplex</td>
</tr>

<td>Barrier</td>
</tr>
</tbody>
</table>

**nonconvex (integer):** Control how to deal with non-convex quadratic programs

Sets the strategy for handling non-convex quadratic objectives or non-convex quadratic constraints. With setting 0, an error is reported if the original user model contains non-convex quadratic constructs. With setting 1, an error is reported if non-convex quadratic constructs could not be discarded or linearized during presolve. With setting 2, non-convex quadratic
problems are solved by means of translating them into bilinear form and applying spatial branching. The default -1 setting is currently equivalent to 1, and may change in future releases to be equivalent to 2.

Default: -1

norelheurtime (real): Limits the amount of time (in seconds) spent in the NoRel heuristic

Limits the amount of time (in seconds) spent in the NoRel heuristic. This heuristic searches for high-quality feasible solutions before solving the root relaxation. It can be quite useful on models where the root relaxation is particularly expensive. Note that this parameter will introduce non-determinism - different runs may take different paths. Use norelheurwork parameter for deterministic results.

Default: 0

norelheurwork (real): Limits the amount of work performed by the NoRel heuristic

Limits the amount of work spent in the NoRel heuristic. This heuristic searches for high-quality feasible solutions before solving the root relaxation. It can be quite useful on models where the root relaxation is particularly expensive. The work metric used in this parameter is tough to define precisely. A single unit corresponds to roughly a second, but this will depend on the machine, the core count, and in some cases the model. You may need to experiment to find a good setting for your model.

Default: 0

normadjust (integer): Simplex pricing norm

Chooses from among multiple pricing norm variants. The default value of -1 chooses automatically.

Default: -1

numericfocus (integer): Set the numerical focus

The NumericFocus parameter controls the degree to which the code attempts to detect and manage numerical issues. The default setting makes an automatic choice, with a slight preference for speed. Settings 1-3 increasingly shift the focus towards being more careful in numerical computations. With higher values, the code will spend more time checking the numerical accuracy of intermediate results, and it will employ more expensive techniques in order to avoid potential numerical issues.

Default: 0

objnabstol (string): Allowable absolute degradation for objective

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is ObjNAbstol ObjVarName value.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value \( z \) when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most ObjNAbstol.

objnreltol (string): Allowable relative degradation for objective
This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is `ObjNRelTol ObjVarName value`.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value $z$ when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most $ObjNRelTol \times |z|$.

**objscale (real): Objective scaling**

Divides the model objective by the specified value to avoid numerical errors that may result from very large objective coefficients. The default value of 0 decides on the scaling automatically. A value less than zero uses the maximum coefficient to the specified power as the scaling (so `ObjScale=-0.5` would scale by the square root of the largest objective coefficient).

Range: $[-1, \infty]$  
Default: 0

**optimalitytol (real): Dual feasibility tolerance**

Reduced costs must all be larger than `OptimalityTol` in the improving direction in order for a model to be declared optimal.

Range: `[1e-09, 0.01]`  
Default: `1e-06`

**.partition (integer): Variable partition value**

The MIP solver can perform a solution improvement heuristic using user-provided partition information. The provided partition number can be positive, which indicates that the variable should be included when the correspondingly numbered sub-MIP is solved, 0 which indicates that the variable should be included in every sub-MIP, or -1 which indicates that the variable should not be included in any sub-MIP. Variables that are not included in the sub-MIP are fixed to their values in the current incumbent solution.

To give an example, imagine you are solving a model with 400 variables and you set the partition attribute to -1 for variables 0-99, 0 for variables 100-199, 1 for variables 200-299, and 2 for variables 300-399. The heuristic would solve two sub-MIP models: sub-MIP 1 would fix variables 0-99 and 300-399 to their values in the incumbent and solve for the rest, while sub-MIP 2 would fix variables 0-99 and 200-299.

The parameter `PartitionPlace` controls the use of the heuristic. The partition numbers are specified through the option `.partition`. The syntax for `dot options` is explained in the Introduction chapter of the Solver Manual.

Default: 0

**partitionplace (integer): Controls when the partition heuristic runs**

This option works in combination with the `Partition` number for variables. Setting this option and providing some partitions enables the partitioning heuristic, which uses large-neighborhood search to try to improve the current incumbent solution.

This parameter determines where that heuristic runs. Options are:

- Before the root relaxation is solved (16)
• At the start of the root cut loop (8)
• At the end of the root cut loop (4)
• At the nodes of the branch-and-cut search (2)
• When the branch-and-cut search terminates (1)

The parameter value is a bit vector, where each bit turns the heuristic on or off at that place. The numerical values next to the options listed above indicate which bit controls the corresponding option. Thus, for example, to enable the heuristic at the beginning and end of the root cut loop (and nowhere else), you would set the 8 bit and the 4 bit to 1, which would correspond to a parameter value of 12.

The recommended value is 15 which indicates that every option except the first one listed above is enabled.

Default: 15

**perturbvalue** *(real)*: Simplex perturbation magnitude

Range: \([0, \infty]\)

Default: 0.0002

**poolgap** *(real)*: Relative gap for solutions in pool

Determines how large a gap to tolerate in stored solutions. When this parameter is set to a non-default value, solutions whose objective values exceed that of the best known solution by more than the specified (relative) gap are discarded. For example, if the MIP solver has found a solution at objective 100, then a setting of **PoolGap=0.2** would discard solutions with objective worse than 120 (assuming a minimization objective).

Default: maxdouble

**poolgapabs** *(real)*: Absolute gap for solutions in pool

Determines how large a (absolute) gap to tolerate in stored solutions. When this parameter is set to a non-default value, solutions whose objective values exceed that of the best known solution by more than the specified (absolute) gap are discarded. For example, if the MIP solver has found a solution at objective 100, then a setting of **PoolGapAbs=20** would discard solutions with objective worse than 120 (assuming a minimization objective).

Default: maxdouble

**poolsearchmode** *(integer)*: Choose the approach used to find additional solutions

With the default setting (**PoolSearchMode=0**), the MIP solver tries to find an optimal solution to the model. It keeps other solutions found along the way, but those are incidental. By setting this parameter to a non-default value, the MIP search will continue after the optimal solution has been found in order to find additional, high-quality solutions. With a setting of 2, it will find the n best solutions, where n is determined by the value of the **PoolSolutions** parameter. With a setting of 1, it will try to find additional solutions, but with no guarantees about the quality of those solutions. The cost of the solve will increase with increasing values of this parameter.

Once optimization is complete, the **PoolObjBound** attribute (printed to the log) can be used to evaluate the quality of the solutions that were found. For example, a value of **PoolObjBound=100** indicates that there are no other solutions with objective better 100, and thus that any known solutions with objective better than 100 are better than any as-yet undiscovered solutions.

Default: 0
**poolsolutions** *(integer)*: Number of solutions to keep in pool

Determines how many MIP solutions are stored. For the default value of PoolSearchMode, these are just the solutions that are found along the way in the process of exploring the MIP search tree. For other values of PoolSearchMode, this parameter sets a target for how many solutions to find, so larger values will impact performance.

Default: 10

**precrush** *(boolean)*: Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model

Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model. This parameter is turned on when you use BCH with Gurobi.

Default: 0

**predeprrow** *(integer)*: Presolve dependent row reduction

Controls the presolve dependent row reduction, which eliminates linearly dependent constraints from the constraint matrix. The default setting (-1) applies the reduction to continuous models but not to MIP models. Setting 0 turns the reduction off for all models. Setting 1 turns it on for all models.

Default: -1

**predual** *(integer)*: Presolve dualization

Depending on the structure of the model, solving the dual can reduce overall solution time. The default setting uses a heuristic to decide. Setting 0 forbids presolve from forming the dual, while setting 1 forces it to take the dual. Setting 2 employs a more expensive heuristic that forms both the presolved primal and dual models (on two threads), and heuristically chooses one of them.

Default: -1

**premiqcpform** *(integer)*: Format of presolved MIQCP model

Option 0 leaves the model in MIQCP form, so the branch-and-cut algorithm will operate on a model with arbitrary quadratic constraints. Option 1 always transforms the model into MISOCP form; quadratic constraints are transformed into second-order cone constraints. Option 2 always transforms the model into disaggregated MISOCOP form; quadratic constraints are transformed into rotated cone constraints, where each rotated cone contains two terms and involves only three variables.

Default: -1

</tbody>
</table>

**prepasses** *(integer)*: Presolve pass limit

Limits the number of passes performed by presolve. The default setting (-1) chooses the number of passes automatically.
**preqlinearize (integer):** Presolve Q matrix linearization

Options 1 and 2 attempt to linearize quadratic constraints or a quadratic objective, potentially transforming an MIQP or MIQCP model into an MILP. Option 1 focuses on getting a strong LP relaxation. Option 2 aims for a compact relaxation. Option 0 always leaves Q matrices unmodified. The default setting (-1) chooses automatically.

**presos1bigm (real):** Controls largest coefficient in SOS1 reformulation

Controls the automatic reformulation of SOS1 constraints into binary form. SOS1 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values increase the chances that an SOS1 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of -1 chooses a threshold automatically. You should set the parameter to 0 to shut off SOS1 reformulation entirely, or a large value to force reformulation.

Range: [-1, 1e+10]

Default: -1

**presos1encoding (integer):** Controls SOS1 reformulation

Controls the automatic reformulation of SOS1 constraints. Such constraints can be handled directly by the MIP branch-and-cut algorithm, but they are often handled more efficiently by reformulating them using binary or integer variables. There are several different ways to perform this reformulation; they differ in their size and strength. Smaller reformulations add fewer variables and constraints to the model. Stronger reformulations reduce the number of branch-and-cut nodes required to solve the resulting model.

Options 0 and 1 of this parameter encode an SOS1 constraint using a formulation whose size is linear in the number of SOS members. Option 0 uses a so-called multiple choice model. It
usually produces an LP relaxation that is easier to solve. Option 1 uses an incremental model. It often gives a stronger representation, reducing the amount of branching required to solve harder problems.

Options 2 and 3 of this parameter encode the SOS1 using a formulation of logarithmic size. They both only apply when all the variables in the SOS1 are non-negative. Option 3 additionally requires that the sum of the variables in the SOS1 is equal to 1. Logarithmic formulations are often advantageous when the SOS1 constraint has a large number of members. Option 2 focuses on a formulation whose LP relaxation is easier to solve, while option 3 has better branching behaviour.

The default value of -1 chooses a reformulation for each SOS1 constraint automatically. Note that the reformulation of SOS1 constraints is also influenced by the PreSOS1BigM parameter. To shut off the reformulation entirely you should set that parameter to 0.

Default: -1

**presos2bign** *(real)*: Controls largest coefficient in SOS2 reformulation

Controls the automatic reformulation of SOS2 constraints into binary form. SOS2 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values increase the chances that an SOS2 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of 0 disables the reformulation. You can set the parameter to -1 to choose an automatic approach, or a large value to force reformulation.

Range: [-1, 1e+10]

Default: -1

**presos2encoding** *(integer)*: Controls SOS2 reformulation

Controls the automatic reformulation of SOS2 constraints. Such constraints can be handled directly by the MIP branch-and-cut algorithm, but they are often handled more efficiently by reformulating them using binary or integer variables. There are several different ways to perform this reformulation; they differ in their size and strength. Smaller reformulations add fewer variables and constraints to the model. Stronger reformulations reduce the number of branch-and-cut nodes required to solve the resulting model.

Options 0 and 1 of this parameter encode an SOS2 constraint using a formulation whose size is linear in the number of SOS members. Option 0 uses a so-called multiple choice model. It usually produces an LP relaxation that is easier to solve. Option 1 uses an incremental model. It often gives a stronger representation, reducing the amount of branching required to solve harder problems.

Options 2 and 3 of this parameter encode the SOS2 using a formulation of logarithmic size. They both only apply when all the variables in the SOS2 are non-negative. Option 3 additionally requires that the sum of the variables in the SOS2 is equal to 1. Logarithmic formulations are often advantageous when the SOS2 constraint has a large number of members. Option 2 focuses on a formulation whose LP relaxation is easier to solve, while option 3 has better branching behaviour.

The default value of -1 chooses a reformulation for each SOS2 constraint automatically. Note that the reformulation of SOS2 constraints is also influenced by the PreSOS2BigM parameter. To shut off the reformulation entirely you should set that parameter to 0.

Default: -1

**presparsify** *(integer)*: Presolve sparsify reduction

This reduction can sometimes significantly reduce the number of nonzero values in the presolved model.

Default: -1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Disable the presolve sparsify reduction</td>

</tr>
</tbody>
</table>

**printoptions** *(boolean)*: List values of all options to GAMS listing file

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not list option values to GAMS listing file</td>
</tr>
<tr>
<td>1</td>
<td>List option values to GAMS listing file</td>
</tr>
</tbody>
</table>

**.prior** *(real)*: Branching priorities

GAMS allows to specify priorities for discrete variables only. Gurobi can detect that continuous variables are implied discrete variables and can utilize priorities. Such priorities can be specified through a GAMS/Gurobi solver option file. The syntax for dot options is explained in the Introduction chapter of the Solver Manual. The priorities are only passed on to Gurobi if the model attribute priorOpt is turned on.

Default: 1

**projimpliedcuts** *(integer)*: Projected implied bound cut generation

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Moderate</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

**psdtol** *(real)*: Positive semi-definite tolerance

Positive semi-definite tolerance (for QP/MIQP). Sets a limit on the amount of diagonal perturbation that the optimizer is allowed to automatically perform on the Q matrix in order to correct minor PSD violations. If a larger perturbation is required, the optimizer will terminate stating the problem is not PSD.

Range: [0, \( \infty \)]

Default: 1e-06
**pumppasses** (*integer*): Feasibility pump heuristic control

Note that this heuristic is only applied at the end of the MIP root.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

Default: -1

**qcpdual** (*boolean*): Compute dual variables for QCP models

Determines whether dual variable values are computed for QCP models. Computing them can add significant time to the optimization, so you should turn this parameter to 0 if you do not need them.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not compute dual for QCP problem</td>
</tr>
<tr>
<td>1</td>
<td>Compute dual for QCP problem</td>
</tr>
</tbody>
</table>

**qextractalg** (*integer*): quadratic extraction algorithm in GAMS interface

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic</td>
</tr>
<tr>
<td>1</td>
<td>ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.</td>
</tr>
<tr>
<td>2</td>
<td>DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.</td>
</tr>
</tbody>
</table>

**quad** (*integer*): Quad precision computation in simplex

Enables or disables quad precision computation in simplex. The -1 default setting allows the algorithm to decide.

Default: -1

**readparams** (*string*): Read Gurobi parameter file

**relaxliftcuts** (*integer*): Relax-and-lift cut generation

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Conservative</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>
rerun (integer): Resolve without presolve in case of unbounded or infeasible 

In case Gurobi reports *Model was proven to be either infeasible or unbounded*, this option decides about a resolve without presolve which will determine the exact model status. If the option is set to *auto*, which is the default, and the model fits into demo limits, the problems is resolved.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>No</td>
</tr>
<tr>
<td>0</td>
<td>Auto</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

rins (integer): RINS heuristic 

Default value (-1) chooses automatically. A value of 0 shuts off RINS. A positive value \( n \) applies RINS at every \( n \)-th node of the MIP search tree.

Default: -1

rltcuts (integer): RLT cut generation

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Conservative</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

rngrestart (string): Write GAMS readable ranging information file 

If the extension specified is `.gdx`, a GDX file is exported, and a GAMS file otherwise.

scaleflag (integer): Model scaling

Controls model scaling. By default, the rows and columns of the model are scaled in order to improve the numerical properties of the constraint matrix. The scaling is removed before the final solution is returned. Scaling typically reduces solution times, but it may lead to larger constraint violations in the original, unscaled model. Turning off scaling *ScaleFlag=0* can sometimes produce smaller constraint violations. Choosing a more aggressive scaling option *ScaleFlag=2* can sometimes improve performance for particularly numerically difficult models.

Default: -1

seed (integer): Modify the random number seed

Modifies the random number seed. This acts as a small perturbation to the solver, and typically leads to different solution paths.

Default: 0

sensitivity (boolean): Provide sensitivity information

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not provide sensitivity information</td>
</tr>
<tr>
<td>1</td>
<td>Provide sensitivity information</td>
</tr>
</tbody>
</table>

**sifting** (*integer*): Sifting within dual simplex

Enables or disables sifting within dual simplex. Sifting is often useful for LP models where the number of variables is many times larger than the number of constraints. With a *Moderate* setting, sifting will be applied to LP models and to the root node for MIP models. With an *Aggressive* setting, sifting will be also applied to the nodes of a MIP. Note that this parameter has no effect if you aren’t using dual simplex. Note also that sifting will be skipped in cases where it is obviously a worse choice, even when sifting has been selected.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Moderate</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

**siftmethod** (*integer*): LP method used to solve sifting sub-problems

Note that this parameter only has an effect when you are using dual simplex and sifting has been selected (either by the automatic method, or through the *Sifting* parameter).

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>

</tr>
<tr>
<td>2</td>
<td>Devex</td>
</tr>
<tr>
<td>3</td>
<td>Quick-Start Steepest Edge</td>
</tr>
</tbody>
</table>

**solfiles** (*string*): Location to store intermediate solution files

During the MIP solution process, multiple incumbent solutions are typically found on the path to finding a proven optimal solution. Setting this parameter to a non-empty string causes these solutions to be written to files (in .sol format) as they are found. The MIP solver will
append \_\_n.sol to the value of the parameter to form the name of the file that contains solution number \_\_n. For example, setting the parameter to value solutions/mymodel will create files mymodel\_0.sol, mymodel\_1.sol, etc., in directory solutions.

solnpooldumpfile (string): Controls export of alternate MIP solutions

The GDX file specified by this option will contain a set call index that contains the names of GDX files with the individual solutions. For details see example model dumpsol in the GAMS Test Library. The option PoolSolutions, PoolSearchModel, and PoolGap control the search for alternative solutions. Please also refer to the section Solution Pool.

solnpoolmerge (string): Controls export of alternate MIP solutions for merged GDX solution file

Similar to SolnPool this option stores multiple alternative solutions to a MIP problem, but in a single GDX file. The GDX file specified by this option will contain all variables with an additional first index (determined through SolnPoolPrefix) as parameters. The option PoolSolutions, PoolSearchModel, and PoolGap control the search for alternative solutions. Please also refer to the section Solution Pool.

solnpoollimitsol (integer): Maximum number of variable symbols when writing merged GDX solution file

Default: 10

solnpoolprefix (string): First dimension of variables for merged GDX solution file or file name prefix for GDX solution files

Default: soln

solutionlimit (integer): MIP feasible solution limit

Default: maxint

solvedumpfile (boolean): Indicator for solving the fixed problem for a MIP to get a dual solution

Default: true

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not solve the fixed problem</td>
</tr>
<tr>
<td>1</td>
<td>Solve the fixed problem</td>
</tr>
</tbody>
</table>

startnodelimit (integer): Node limit for MIP start sub-MIP

This parameter limits the number of branch-and-bound nodes explored when completing a partial MIP start. The default value of -1 uses the value of the SubMIPNodes parameter. A value of -2 means to only check full MIP starts for feasibility and to ignore partial MIP starts. A value of -3 shuts off MIP start processing entirely. Non-negative values are node limits.

Default: -1

strongcgcuts (integer): Strong-CG cut generation

Controls Strong Chvátal-Gomory (Strong-CG) cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the Cuts parameter.

Default: -1
submipcuts (integer): Sub-MIP cut generation

See the description of the global Cuts parameter for further information.

Default: -1

submipnodes (integer): Nodes explored by sub-MIP heuristics

Limits the number of nodes explored by the heuristics, like RINS. Exploring more nodes can produce better solutions, but it generally takes longer.

Default: 500

symmetry (integer): Symmetry detection

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Conservative</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

threads (integer): Number of parallel threads to use

Default number of parallel threads allowed for any solution method. Non-positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks.

Default: GAMS threads

timelimit (real): Time limit

Default: GAMS reslim

tunecleanup (real): Enables a tuning cleanup phase

Enables a cleanup phase at the end of tuning. The parameter indicates the percentage of total tuning time to devote to this phase, with a goal of reducing the number of parameter changes required to achieve the best tuning result.

Default: 0

tunecriterion (integer): Specify tuning criterion

Modifies the tuning criterion for the tuning tool. The primary tuning criterion is always to minimize the runtime required to find a proven optimal solution. However, for MIP models that don't solve to optimality within the specified time limit, a secondary criterion is needed. Set this parameter to 1 to use the optimality gap as the secondary criterion. Choose a value of 2 to use the objective of the best feasible solution found. Choose a value of 3 to use the best objective bound. Choose 0 to ignore the secondary criterion and focus entirely on minimizing the time to find a proven optimal solution. The default value of -1 chooses automatically.

Default: -1

tunejobs (integer): Enables distributed tuning
Enables distributed parallel tuning, which can significantly increase the performance of the tuning tool. A value of $n$ causes the tuning tool to distribute tuning work among $n$ parallel jobs. These jobs are distributed among a set of workers. Use the WorkerPool parameter to provide a list of available workers.

Note that distributed tuning is most effective when the workers have similar performance. Distributed tuning doesn’t attempt to normalize performance by worker, so it can incorrectly attribute a boost in performance to a parameter change when the associated setting is tried on a worker that is significantly faster than the others.

Default: 0

tunemetric (integer): Metric to aggregate results into a single measure

A single tuning run typically produces multiple timing results for each candidate parameter set, either as a result of performing multiple trials, or tuning multiple models, or both. This parameter controls how these results are aggregated into a single measure. The default setting (-1) chooses the aggregation automatically; setting 0 computes the average of all individual results; setting 1 takes the maximum.

Default: -1

tuneoutput (integer): Tuning output level

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No output</td>
</tr>
<tr>
<td>1</td>
<td>Summary output only when a new best parameter set is found</td>
</tr>
<tr>
<td>2</td>
<td>Summary output for each parameter set that is tried</td>
</tr>
<tr>
<td>3</td>
<td>Summary output, plus detailed solver output, for each parameter set tried</td>
</tr>
</tbody>
</table>

tuneresults (integer): Number of improved parameter sets returned

The tuning tool often finds multiple parameter sets that produce better results than the baseline settings. This parameter controls how many of these sets should be retained when tuning is complete. The default value retains the best results that were found for each count of changed parameters. In other words, it retains the best result for one changed parameter, for two changed parameter, etc. Results that aren’t on the efficient frontier are discard.

Default: -1

tunetargetmipgap (real): A target gap to be reached

A target gap to be reached. As soon as the tuner has found parameter settings that allow Gurobi to reach the target gap for the given model(s), it stops trying to improve parameter settings further. Instead, the tuner switches into the cleanup phase (see TuneCleanup parameter).

Default: 0

tunetargettime (real): A target runtime in seconds to be reached

A target runtime in seconds to be reached. As soon as the tuner has found parameter settings that allow Gurobi to solve the model(s) within the target runtime, it stops trying to improve parameter settings further. Instead, the tuner switches into the cleanup phase (see TuneCleanup parameter).

Default: 0.005
**tunetimelimit** *(real)*: Time limit for tuning

Limits total tuning runtime (in seconds). The default setting (-1) chooses a time limit automatically.

Default: -1

**tunetrials** *(integer)*: Perform multiple runs on each parameter set to limit the effect of random noise

Performance on a MIP model can sometimes experience significant variations due to random effects. As a result, the tuning tool may return parameter sets that improve on the baseline only due to randomness. This parameter allows you to perform multiple solves for each parameter set, using different Seed values for each, in order to reduce the influence of randomness on the results. The default value of 0 indicates an automatic choice that depends on model characteristics.

Note: Only affects mixed integer programming (MIP) models

Default: 0

**Tuning** *(string)*: Parameter Tuning

Invokes the Gurobi parameter tuning tool. The mandatory value following the keyword specifies a GAMS/Gurobi option file. All options found in this option file will be used but not modified during the tuning. A sequence of file names specifying existing problem files may follow the option file name. The files can be in MPS, REW, LP, RLP, and ILP format created by the WriteProb option. Gurobi will tune the parameters either for the problem provided by GAMS (no additional problem files specified) or for the suite of problems listed after the GAMS/Gurobi option file name without considering the problem provided by GAMS. The result of such a run is the updated GAMS/Gurobi option file with a tuned set of parameters. In case the option TuneResults is larger than 1, GAMS/Gurobi will create a sequence of GAMS/Gurobi option files. The solver and model status returned to GAMS will be NORMAL COMPLETION and NO SOLUTION. Tuning is incompatible with advanced features like FeasOpt of GAMS/Gurobi.

**usebasis** *(integer)*: Use basis from GAMS

If UseBasis is not specified, GAMS (via option BRatio) decides if the starting basis or a primal/dual solution is given to Gurobi. If UseBasis is explicitly set in an option file then the basis or a primal/dual solution is passed to Gurobi independent of the GAMS option BRatio. Please note, if Gurobi uses a starting basis presolve will be skipped.

Default: GAMS bratio

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

<td>Strong Branching</td>
</tr>
</tbody>
</table>

**varhint** *(boolean)*: Guide heuristics and branching through variable hints

If you know that a variable is likely to take a particular value in high quality solutions of a MIP model, you can provide this information as a hint. If **VarHint** option is active, GAMS/Gurobi will pass variable levels rounded to the nearest integer as hints to Gurobi if their level is within **TryInt** of an integer. The closer the level is to the rounded integer the higher your level of confidence in this hint. Internally this is recalculated into a Gurobi variable hint priority:

\[
m = \max(10^{-6}, 1 - |x.l - \lfloor x.l \rfloor|)\]

The Gurobi MIP solver will use these variable hints in a number of different ways. Hints will affect the heuristics that Gurobi uses to find feasible solutions, and the branching decisions that Gurobi makes to explore the MIP search tree. In general, high quality hints should produce high quality MIP solutions faster. In contrast, low quality hints will lead to some wasted effort, but shouldn’t lead to dramatic performance degradations.

Variables hints and **MIP starts** are similar in concept, but they behave in very different ways. If you specify a MIP start, the Gurobi MIP solver will try to build a single feasible solution from the provided set of variable values. If you know a solution, you should use a MIP start to provide it to the solver. In contrast, variable hints provide guidance to the MIP solver that affects the entire solution process. If you have a general sense of the likely values for variables, you should provide them through variable hints.

Default: 0

**workerpassword** *(string)*: Password for distributed worker cluster

When using a distributed algorithm (the distributed concurrent MIP solver or distributed tuning), this parameter allows you to specify the password for the workers listed in the **WorkerPool** parameter.

**workerpool** *(string)*: Distributed worker cluster

When using a distributed algorithm (distributed MIP, distributed concurrent, or distributed tuning), this parameter allows you to specify a Remote Services cluster that will provide distributed workers. You should also specify the access password for that cluster, if there is one, in the **WorkerPassword** parameter.

You can provide a comma-separated list of machines for added robustness. If the first node in the list is unavailable, the client will attempt to contact the second node, etc.

To give an example, if you have a Remote Services cluster that uses port 61000 on a pair of machines named server1 and server2, you could set WorkerPool to `server1:61000,server2:61000`.

**worklimit** *(real)*: Work limit
Limits the total work expended (in work units).

In contrast to the TimeLimit, work limits are deterministic. This means that on the same hardware and with the same parameter and attribute settings, a work limit will stop the optimization of a given model at the exact same point every time. One work unit corresponds very roughly to one second on a single thread, but this greatly depends on the hardware on which Gurobi is running and the model that is being solved.

Note that optimization may not stop immediately upon hitting the work limit. It will stop when the optimization is next in a deterministic state, and it will then perform the required additional computations of the attributes associated with the terminated optimization. As a result, the Work attribute may be larger than the specified WorkLimit upon completion, and repeating the optimization with a WorkLimit set to the Work attribute of the stopped optimization may result in additional computations and a larger attribute value.

Default: `maxdouble`

writeparams (string): Write Gurobi parameter file

writeprob (string): Save the problem instance

zerohalfcuts (integer): Zero-half cut generation

See the description of the global `Cuts` parameter for further information.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Auto</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Conservative</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive</td>
</tr>
</tbody>
</table>

zeroobjnodes (integer): Zero objective heuristic control

Note that this heuristic is only applied at the end of the MIP root, and only when no other root heuristic finds a feasible solution.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

Default: -1

5.17.8 Setting up a GAMS/Gurobi-Link license

The GAMS/Gurobi-Link requires two licenses:

- A GAMS license with components GAMS/GUROBI-Link and GAMS BASE (to generate models beyond the demo limits)
A Gurobi license which you need to get directly from Gurobi

An attempt to use the GAMS/Gurobi solver with a GAMS/Gurobi-Link license but without a properly set up Gurobi license will result in a licensing error with a message describing the problem. For example, the following message is sent to the log when attempting to solve a model with dimensions beyond the community limits:

--- Executing GUROBI (Solvelink=2): elapsed 0:00:00.047
Gurobi 32.2.0 rc62c018 Released Aug 26, 2020 WEI x86 64bit/MS Window
Gurobi link license.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)

Starting with GAMS distribution 24.7, even demo sized models require a license from Gurobi. An attempt to solve a demo sized model without a Gurobi license installed results in:

--- Executing GUROBI (Solvelink=2): elapsed 0:00:00.016
Gurobi 32.2.0 rc62c018 Released Aug 26, 2020 WEI x86 64bit/MS Window
*** This solver runs with a demo license. No commercial use.
GAMS/Gurobi demo/community requires a Gurobi license from Gurobi Optimization.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)

To make the GAMS/Gurobi-Link work you do not need to download or install the Gurobi software but only your Gurobi license. GAMS will use it's own Gurobi DLL/shared library, so the Gurobi license has to be valid for the Gurobi version GAMS uses. You can download your Gurobi license from www.gurobi.com. Log in to your Gurobi account and go to Download & Licenses -> Your Gurobi licenses.

Now click on the license you want to download and click on Get License Details. On the license detail page, copy the grbgetkey command on the bottom.

Paste the grbgetkey command to a command/terminal prompt. Your GAMS system directory contains the grbgetkey program, so to make sure it is found you should open the terminal via GAMS Studio or add your GAMS system directory to the path variable. After running the grbgetkey command, you will be asked where you would like to save your Gurobi license.

$ ./grbgetkey [...]
info : grbgetkey version 9.0.3, build v9.0.3rc0
info : Contacting Gurobi key server...
info : Key for license ID [...] was successfully retrieved
info : License expires at the end of the day on 2021-08-31
info : Saving license key...

In which directory would you like to store the Gurobi license key file?
[hit Enter to store it in /opt/gurobi]: /home/nb/gurobilic

info : License [...] written to file /home/nb/gurobilic/gurobi.lic
info : You may have saved the license key to a non-default location
info : You need to set the environment variable GRB_LICENSE_FILE before you can use this license key
info : GRB_LICENSE_FILE=/home/nb/gurobilic/gurobi.lic
Once you have saved your gurobi.lic file, you need to make GAMS/Gurobi aware of that license via environment variable GRB_LICENSE_FILE. The environmentVariables section in the GAMS configuration file (available as of GAMS version 31.1.0) is a convenient way to set the GRB_LICENSE_FILE environment variable. This can either be done by manually opening and editing the gmsconfig.yaml file which can be found in one of the standard locations or via the corresponding GAMS Configuration Editor in GAMS Studio. As a result, the configuration file should contain an entry for environment variable GRB_LICENSE_FILE that points to the Gurobi license, e.g.

```yaml
environmentVariables:
  [...]  
  - GRB_LICENSE_FILE:
    value: /home/nb/gurobilic/gurobi.lic
  [...] 
```

As an alternative you could also set GRB_LICENSE_FILE via the usual OS-specific ways to set environment variables.

To test whether the license setup has been successful, you can solve a model from the GAMS Model library, e.g. [INDUS89], where you should get the following output.

```
$ gamslib indus89
Copy ASCII : indus89.gms
$ gams indus89 lp gurobi

```

Note

To install a Gurobi license key as described above, the grbgetkey program needs to be able to communicate with the Gurobi website. If it fails to work, the grbprobe program which can also be found in your GAMS system directory may be used to retrieve the required hardware information which then needs to be manually submitted to the Gurobi Website (detailed instructions can be found [here](#)).
5.18 Gather-Update-Solve-Scatter (GUSS)

5.18.1 Introduction

The purpose of this chapter is to detail an extension of the GAMS modeling system that allows collections of models (parameterized exogenously by a set of samples or indices) to be described, instantiated, and solved efficiently.

As a specific example, we consider the parametric optimization problem $P(s)$ defined by:

$$\min_{x \in X(s)} f(x; s) \text{ s.t. } g(x; s) \leq 0 \quad (5.16)$$

where $s \in S = \{1, \ldots, K\}$. Note that each scenario $s$ represents a different problem for which the optimization variable is $x$. The form of the constraint set as given above is simply for concreteness; equality constraints and range and bound constraints are trivial extensions of the above framework. Clearly the problems $P(s)$ are interlinked. We intend to show how such problems can be easily specified within GAMS, and detail one type of algorithmic extension that can exploit the nature of the linkage. Other extensions of GAMS allow solves to be executed in parallel or by using grid computing resources. Note that in our description we will use the terms indexed, parameterized, and scenario somewhat interchangeably. An extended version of this chapter containing several examples is available as a paper at http://www.gams.com/modlib/adddocs/gusspaper.pdf.

5.18.2 Design Methodology

One of the most important functions of GAMS is to build a model instance from the collection of equations (i.e. an optimization model defined by the GAMS keyword MODEL) and corresponding data (consisting of the content of GAMS (sub)sets and parameters). Such a model instance is constructed or generated when the GAMS execution system executes a SOLVE statement. The generated model instance is passed to a solver which searches for a solution of this model instance and returns status information, statistics, and a (primal and dual) solution of the model instance. After the solver terminates, GAMS brings the solution back into the GAMS database, i.e. it updates the level (.L) and marginal (.M) fields of variable and equation symbols used in the model instance. Hence, the SOLVE statement can be interpreted as a complex operator against the GAMS database. The model instance generated by a SOLVE statement only lives during the execution of this one statement, and hence has no representation within the GAMS language. Moreover, its structure does fit the relational data model of GAMS. A model instance consists of vectors of bounds and right hand sides, a sparse matrix representation of the Jacobian, a representation of the non-linear expressions that allow the efficient calculation of gradient vectors and Hessian matrices, and so on.

This chapter is concerned with solving collections of models that have similar structure but modified data. As an example, consider a linear program of the form:

$$\min c^T x \text{ s.t. } Ax \geq b, \quad \ell \leq x \leq u.$$ 

The data in this problem is $(A, b, c, \ell, u)$. Omitting some details, the following code could be used within GAMS to solve a collection of such linear programs in which each member of the collection has a different $A$ matrix and lower bound $\ell$:

Set i / ... /, j / ... /;
Parameter A(i,j), b(i);
Variable x(j), z, ...;
Equation e(i), ...;
e(i).. sum(j, A(i,j)*x(j)) =g= b(i);
...
model mymodel /all/;

Set s / s1*s10 /;
Parameter
  A_s(s,i,j) 'Scenario data'
  xlo_s(s,j) 'Scenario lower bound for variable x'
  xl_s(s,j) 'Scenario solution for x.l'
  em_s(s,i) 'Scenario solution for e.m';
Loop(s,
  A(i,j) = A_s(s,i,j);
  x.lo(j) = xlo_s(s,j);
  solve mymodel min z using lp;
  xl_s(s,j) = x.l(j);
  em_s(s,i) = e.m(i);
);

Summarizing, we solve one particular model (mymodel) in a loop over s with an unchanged model rim (i.e. the same individual variables and equations) but with different model data and different bounds for the variables. The change in model data for a subsequent solve statement does not depend on the previous model solutions in the loop.

The purpose of this new Gather-Update-Solve-Scatter (GUSS) manager is to provide syntax at the GAMS modeling level that makes an instance of a problem that provides limited access to treat that instance as an object, and allows the modeler to update portions of it iteratively. Specifically, we provide syntax that gives a list of data changes to an instance, and allows these changes to be applied sequentially to the instance (which is then solved without returning to GAMS). Thus, we can simulate a limited set of actions to be applied to the model instance object and retrieve portions of the solution of these changed instances back in the modeling environment. Such changes can be done to any model type in GAMS, including nonlinear problems and mixed integer models. However, the only changes we allow are to named parameters appearing in the equations and lower and upper bounds used in the model definition.

Thus, in the above example GUSS allows us to replace lines 15-21 by

Set dict / s. scenario. ''
  A. param. A_s
  x. lower. xlo_s
  x. level. xl_s
  e. marginal. em_s /;
solve mymodel min z using lp scenario dict;

The three dimensional set dict (you can freely choose the name of this symbol) contains mapping information between symbols in the model (in the first position) and symbols that supply required update data or store solution information (in the third position), and the type of update/storing (in the second position). An exception to this rule is the tuple with label scenario in the second position. This tuple determines the symbol (in the first position) that is used as the scenario index. This scenario symbol can be a multidimensional set. A tuple in this set represents a single scenario. The remaining tuples in the set dict can be grouped into input and output tuples. Input tuples determine the modifications of the model instance prior to solving, while output tuples determine which part of the solution gets saved away. The following keywords can be used in the second position of the set dict:

<table>
<thead>
<tr>
<th>Type</th>
<th>Keywords</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input:</td>
<td>param</td>
<td>Supplies scenario data for a parameter used in the model</td>
</tr>
<tr>
<td></td>
<td>lower</td>
<td>Supplies scenario lower bounds for a variable</td>
</tr>
<tr>
<td></td>
<td>upper</td>
<td>Supplies scenario upper bounds for a variable</td>
</tr>
<tr>
<td></td>
<td>fixed</td>
<td>Supplies scenario fixed bounds for a variable</td>
</tr>
<tr>
<td>Output:</td>
<td>level</td>
<td>Stores the levels of a scenario solution of variable or equation</td>
</tr>
<tr>
<td></td>
<td>marginal</td>
<td>Stores the marginals of a scenario solution of variable or equation</td>
</tr>
</tbody>
</table>
Sets in the model cannot be updated. GUSS works as follows: GAMS generates the model instance for the original data. As with regular `SOLVE` statements, all the model data (e.g. parameter A) needs to be defined at this time. The model instance with the original data is also called the base case. The solution of the base case is reported back to GAMS in the regular way and is accessible via the regular `.L` and `.M` fields after the `SOLVE` statement. After solving the base case, the update data for the first scenario is applied to the model. The tuples with `lower`, `upper`, `fixed` update the bounds of the variables, whereas the tuples with `param` update the parameters in the model.

The scenario index `s` needs to be the first index in the parameters mapped in the `set dict`. The update of the model parameters goes far beyond updating the coefficients of the constraint matrix/objective function or the right hand side of an equation, as one can do with some other systems. GAMS stores all the necessary expressions of the constraints with the model instance, so the change in the constraint matrix coefficient is the result of an expression evaluation. For example, consider a term in the calculation of the cost for shipping a variable amount of goods `x(i,j)` between cities `i` and `j`. The expression for shipping cost is `d(i,j)*f*x(i,j)`, i.e. the distance between the cities times a freight rate `f` times the variable amount of goods. In order to find out the sensitivity of the solution with respect to the freight rate `f`, one can solve the same model with different values for `f`. In a matrix representation of the model one would need to calculate the coefficient of `x(i,j)` which is `d(i,j)*f`, but with GUSS it is sufficient to supply different values for `f` that potentially result in many modified coefficients on the matrix level. GUSS evaluates the shipping cost term and communicates the resulting matrix coefficient to the solver reliably behind the scenes.

After the variable bound and the model parameter updates have been applied and the resulting updates to the model instance data structures (e.g. constraint matrix) has been determined, the modified model instance is passed to the solver. Some solvers (e.g. Cplex, Gurobi, SoPlex, and Xpress) allow modifying a model instance. In these cases GUSS only communicates the changes from the previous model instance to the solver. This reduces the amount of data communicated to the solver and also, in the case of an LP model, allows the solver to restart from an advanced basis and its factorization. In the case of an NLP model, this provides initial values. After the solver determines the solution of a model instance, GUSS stores the part of the solution requested by the output tuples of `dict` to some GAMS parameters and continues with the next scenario. GUSS emphasizes on speed and only works with solvers that allow to communicate the model instance through memory, Hence, the following solvers cannot be used as subsolvers of GUSS: ALPHAECP, BARON, CONVERT, DECISC, DECISM, DICOPT, EXAMINER, GAMSCHK, JAMS, KESTREL, LOGMIP, MILES, MPSGE, NLPEC, PATHNLP, SBB, and XA.

### 5.18.3 GUSS Options

The execution of GUSS can be parameterized using some options. Options are not passed through a solver option file but via another tuple in the `dict` set. The keyword in the second position of this tuple is `opt`. A one dimensional parameter is expected in the first position (or the label `''`). This parameter may contain some of the following labels with values:

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OptfileInit</td>
<td>Option file number for the first solve (default from GAMS OptFile setting)</td>
</tr>
<tr>
<td>Optfile</td>
<td>Option file number for subsequent solves (default 0)</td>
</tr>
<tr>
<td>LogOption</td>
<td>Determines amount of log output:</td>
</tr>
<tr>
<td></td>
<td>0 - Moderate log (default)</td>
</tr>
<tr>
<td></td>
<td>1 - Minimal log</td>
</tr>
<tr>
<td></td>
<td>2 - Detailed log</td>
</tr>
<tr>
<td>NoHotStart</td>
<td>Disable hot start capability in solver that supports hot starts (default 0)</td>
</tr>
<tr>
<td>NoMatchLimit</td>
<td>Limit of unmatched scenario records (default 0)</td>
</tr>
<tr>
<td>RestartType</td>
<td>Determines restart point for the scenarios</td>
</tr>
<tr>
<td></td>
<td>0 - Restart from last solution (default)</td>
</tr>
<tr>
<td></td>
<td>1 - Restart from solution of base case</td>
</tr>
<tr>
<td></td>
<td>2 - Restart from input point</td>
</tr>
</tbody>
</table>
### Options

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SkipBaseCase</strong></td>
<td>Switch for solving the base case (0 solves the base case)</td>
</tr>
<tr>
<td><strong>ReportLastScen</strong></td>
<td>Switch for reporting the solution of the last scenario rather than solution of the base case (default 0)</td>
</tr>
<tr>
<td><strong>SolveEmpty</strong></td>
<td>Limit of solved empty scenarios, afterwards empty scenarios will be skipped (default 0)</td>
</tr>
<tr>
<td><strong>UpdateType</strong></td>
<td>Scenario update mechanism: 0 - Set everything to zero and apply changes (default) 1 - Reestablish base case and apply changes 2 - Build on top of last scenario and apply changes</td>
</tr>
</tbody>
</table>

For the example model above the **UpdateType** setting would mean:

- **UpdateType=0**: \( \text{loop}(s, A(i,j) = A_s(s,i,j)) \)
- **UpdateType=1**: \( \text{loop}(s, A(i,j) = A_{base}(i,j); A(i,j) = A_s(s,i,j)) \)
- **UpdateType=2**: \( \text{loop}(s, A(i,j) = A_s(s,i,j)) \)

The option **SkipBaseCase=1** allows the user to skip the base case. This means only the scenarios are solved and there is no solution reported back to GAMS in the traditional way. The third position in the opt-tuple can contain a parameter for storing the scenario solution attribute information, e.g. model and solve status, or needs to have the label '' . The labels to store solution status information must be known to GAMS, so one needs to declare a set with such labels. A convenient way to enter these attributes is via `System.GUSSModelAttributes`:

```gams
Set ma 'GUSS Model Attributes' / System.GUSSModelAttributes /; display ma;

---- 1 SET ma GUSS Model Attributes
ModelStat, SolveStat, NumInfes, SumInfes, IterUsd
ResUsd, ObjVal, NodUsd, ObjEst, DomUsd
RObj, MaxInfes, MeanInfes
```

The following example shows how to use some of the GUSS options and the use of a parameter to store some solution status information:

```gams
Set h solution headers / System.GUSSModelAttributes /;
Parameter
  o / SkipBaseCase 1, UpdateType 1, Optfile 1 /
  r_s(s,h) Solution status report;
Set dict / s. scenario. ''
  o. opt. r_s
  a. param. a_s
  x. lower. xlo_s
  x. level. xl_s
  e. marginal. em_s /;
solve mymodel min z using lp scenario dict;
```

Please note that the domain set of the solution status report attributes (here \( h \)) must only contain model attributes known to GUSS. If this domain (unless the domain in *) contains a label unknown to GUSS, a compilation error is triggered.
5.18.4 Implementation Details

This section describes some technical details that may provide useful insight in case of unexpected behavior.

Because GUSS changes all model parameters mentioned in the `dict` set to variables, a linear model can produce some non-linear instructions (e.g. \( d(i,j) \cdot f \cdot x(i,j) \) becomes a non-linear expression since \( f \) becomes a variable in the model instance given to GUSS). This also explains why some models compile without complaint, but if the model is used in the context of GUSS, the compile time check of the model will fail because a parameter that is turned into a variable can no longer be used in that way. For example, suppose the model contains a constraint \( e(i) .. \text{sum}(j A(i,j), ...) \). If \( A(i,j) \) is a parameter in the regular model, the compiler will not complain, but if \( A \) becomes a parameter that shows up in the first position of a `param` tuple in the `dict` set, the GAMS compiler will turn \( A \) into a variable and complain that an endogenous variable cannot be used in a `$`-condition.

The sparsity pattern of a model can be greatly affected by GUSS. In a regular model instance GAMS will only generate and pass on non-zero matrix elements of a constraint \( e(i) .. \text{sum}(j, A(i,j) \cdot x(j)) ... \), so the sparsity of \( A \) determines the sparsity of the generated model instance. GUSS allows to use this constraint with different values for \( A \) hence GUSS cannot exclude any of the pairs \( (i,j) \) and generate a dense matrix. The user can enforce some sparsity by explicitly restricting the \( (i,j) \) pairs: \( e(i) .. \text{sum}(ij(i,j), A(i,j) \cdot x(j)) ... \)

Attention

While GUSS is available for many model types quadratic models require special attention. Linear solvers that have been extended to cover (convex) quadratic models, e.g. Cplex, Gurobi, Mosek, Xpress, do not work properly if the modifying parameter affects the left hand side of linear equations or any modifications of quadratic equations. Bound updates as well as changes of the right hand side of linear constraints are okay (see the example of the quadratic support vector machine below). Unfortunately, detecting if a quadratic model is okay or not for a given solver is at the moment difficult to detect, so use caution with quadratic models in combination with such (linear) solvers.

The actual change of the GAMS language required for the implementation of GUSS is minimal. The only true change is the extension of the `SOLVE` statement with the term `SCENARIO dict`. Existing language elements have been used to store symbol mapping information, options, and model result statistics. Some parts of the GUSS presentation look somewhat unnatural, e.g. since `dict` is a three dimensional `set` the specification the scenario `set` using keyword `scenario` requires a third dummy label `'`. However, this approach gives maximum flexibility for future extension, allows reliable consistency checks at compile and execution time, and allows the user to delay the commitment for significant and permanent syntax changes of a developing method to handle model instances at a GAMS language level.

5.18.5 Applications

5.18.5.1 Cross Validation in GAMS via GUSS

Cross validation is a statistical/machine learning technique that aims to evaluate the generalizability of a classifier (or other decision) process. It does this by setting aside a portion of the data for testing, and uses the remaining data entries to produce the classifier. The testing data is subsequently used to evaluate how well the classifier works. Cross validation performs this whole process a number of times in order to estimate the true power of the classifier.

Ten-fold cross validation is a special case, where the original data is split into ten pieces, and cross validation is performed using each of these ten pieces as the testing set. Thus, the training process is performed ten times, each of which uses the data obtained by deleting the testing set from the whole dataset. We show below how to carry this out using the Gather-Update-Solve-Scatter (GUSS) facility in GAMS.

A paper with the title "GUSS: Solving Collections of Data Related Models within GAMS" that contains two additional application examples for GUSS is available [here](#).
5.18.5.1.1 GUSS formulation in GAMS  

The following example compares the two formulations for a feature-selection model under cross-validation using data files `a_data.inc` and `b_data.inc`. The actual source code for both of these GAMS formulations is available [here](#).

Original GAMS formulation (without the GAMS/DEA interface):

```gams
$title Ten-fold cross validation example
$eolcom !

$setglobal num_folds 10

set a 'set for category 1' /1*1505/
  b 'set for category 2' /1*957/
  o 'observations' /1*14/
  p 'folds to perform' /1*%num_folds%/ 
  f 'maximum features to select' /1*10/

* Read in the data from the data files
parameter a_data(a, o) / $offlisting
  $include "a_data.inc" $onlisting /;

parameter b_data(b, o) / $offlisting
  $include "b_data.inc" $onlisting /;

set a_test(p, a), b_test(p, b) 'testing sets'
  a_trai(a), b_trai(b) 'training sets';

* Define problem
scalar w_tol /1/
  features /6/;

positive variables a_err(a), sla(a)
  b_err(b), slb(b);

variables c,
  weight(o),
  gamma;

binary variable y(o);

equations w_def1(o),
  w_def2(o),
  y_def,
  c_def,
  a_def(a),
  b_def(b);

w_def1(o).. 
  weight(o) =l= w_tol*y(o);
w_def2(o).. 
```

weight(o) = g = -w_tol*y(o);

y_def..  
   sum(o, y(o)) = e = features;

c_def..  
   c = e = sum(a, a_err(a)) + sum(b, b_err(b));

a_def(a)..  
   -sum(o, a_data(a, o)*weight(o)) + gamma + 1 = l = a_err(a) + sla(a);

b_def(b)..  
   sum(o, b_data(b, o)*weight(o)) - gamma + 1 = l = b_err(b) + slb(b);

model train /all/;

$batinclude gentestset.inc "p,a" "p,b"

set headers 'report' / modelstat, solvestat, objval /;
parameter rep(p,headers);
train.optfile = 0;
option limrow=0, limcol=0, solprint=silent, mip=xpress,
   solvelink=%Solvelink.LoadLibrary%, optcr=0, optca=0;

$echo loadmipsol=1 > xpress.opt

loop(p,
   a_err.up(a) = inf; a_err.up(a)$a_test(p,a) = 0;
   b_err.up(b) = inf; b_err.fx(b)$b_test(p,b) = 0;
   sla.fx(a) = 0; sla.up(a)$a_test(p,a) = inf;
   slb.fx(b) = 0; slb.up(b)$b_test(p,b) = inf;
   solve train using mip minimizing c;
   train.optfile = 1; ! use mipstart for the second run
   rep(p,'modelstat') = train.modelstat;
   rep(p,'solvestat') = train.solvestat;
   rep(p,'objval') = train.objval;
);

display rep;

Options file for the original formulation: xpress.opt

loadmipsol=1

The batinclude file gentestset.inc gives instructions for generating the testing sets. It produces a_test and b_test that detail which equations are left out on solve p.

The actual model is set up to include all the data points in the equations a_def and b_def. To delete the equations that correspond to the test set, we introduce nonnegative slack variables into all the equations. We then set the upper bounds of the slack variables to zero in equations corresponding to the training set, and to infinity in equations corresponding to the testing set. At the same time we fix the error measures a_err and b_err belonging to the testing set by setting their upper bounds to zero. Thus the testing set equations are always satisfiable by choice of the slack variables alone - essentially they are discarded from the model as required. An alternative formulation could "include" the data equations that you need in each scenario, but the update from one scenario to the next in the defining data is much larger.

Cross validation formulated using GUSS: This model essentially mimics what the standard model does, but the implementation of the solver loop behind the scenes is much more efficient, and the consequences are that are clear to see if you execute both model runs. The changes are in the last 40 lines of the GAMS code.
$title Ten-fold cross validation example

    sum(o, y(o)) =e= features;

c_def..
c = \sum(a, a_{err}(a)) + \sum(b, b_{err}(b));

a_{def}(a).
-\sum(o, a_{data}(a, o)\times weight(o)) + \gamma + 1 \leq a_{err}(a) + sla(a);

b_{def}(b).
\sum(o, b_{data}(b, o)\times weight(o)) - \gamma + 1 \leq b_{err}(b) + slb(b);

model train /all/;
train.optfile = 1;

$batinclude gentestset.inc "p,a" "p,b"

parameter wval(p,o), gval(p);

set headers 'report' / modelstat, solvestat, objval /;
parameter
    scenrep(p,headers)
    scopt(*) / SkipBaseCase 1, Optfile 1, LogOption 2 /;

set dict / p. scenario.''
    scopt. opt. scenrep
    a_err. upper. aupper
    b_err. upper. bupper
    sla. upper. afree
    slb. upper. bfree
    weight.level. wval
    gamma. level. gval /

$echo loadmipsol=1 > xpress.opt

Parameter aupper(p,a), bupper(p,b), afree(p,a), bfree(p,b);

aupper(p,a)$(not a_test(p,a)) = inf;
bupper(p,b)$(not b_test(p,b)) = inf;

afree(p,a)$a_test(p,a) = inf;
bfree(p,b)$b_test(p,b) = inf;

option mip=xpress, optcr=0, optca=0;
solve train using mip minimizing c scenario dict;
display scenrep, gval;

Firstly, parameters aupper, bupper, afree and bfree are used to set the bounds on the error and slack variables in the testing set equations respectively. The setting of the upper bounds are governed by the syntax shown in the controlling set dict. Furthermore, the output of the classifier (v, gamma) for each fold of the cross validation uses the dict set to place results into the parameters wval and gval respectively. Finally, the GUSS options are used to guarantee that the subsequent solves are instructed to process solver options (Optfile 1) which instruct the solver to use the previous solution to start the branch-and-cut process (loadmipsol=1).

The complete data and model files for this example are found in (galaxy zip archive). The data and model for a second instance based on the Wisconsin Diagnostic Breast Cancer Database is downloadable as (wdbc zip archive).

5.18.5.1.2 Quadratic Programs

GUSS is not limited to linear programs, but can be used more generally. Simple (indexed) quadratic models can be solved using GUSS. The following example illustrates
the use of GUSS for quadratic programs. In this example, a support vector machine is used to determine
a linear classifier that separates data into two categories. We use the following model:

\[
\begin{align*}
\text{Min}_{w,g,z} & \quad (1/2)\|w\|^2 + Cz^Tz \\
\text{subject to} & \quad D(Aw - g) + z \geq 1 \\
& \quad z \geq 0
\end{align*}
\] (5.17)

Here, \(A\) is a matrix containing the training data (patients by features) and \(D\) is a diagonal matrix with
values +1 or −1 (each denoting one of the two classes). \(C\) is a parameter weighting the importance of
maximizing the margin between the classes \((2/\|w\|_2)\) versus minimizing the misclassification error \((z)\).
The solution \(w\) and \(g\) are used to define a separating hyperplane \(\{x | w^Tx = g\}\) to classify (unseen) data
points.

As given, the standard linear support vector machine is not a slice model per se. It becomes a slice model
under cross-validation training, where it is solved multiple times on different pieces of data. In this case,
only the data \(A\) and \(D\) vary between solves, appropriately fitting the definition of a slice model.

The data for this example comes from the Wisconsin Diagnosis Breast Cancer Database, and is available
here. The data was converted to the GAMS file wdbc.gms, which defines \(A\) and \(D\). The actual
source code for the following GAMS formulation is available here.

The GUSS formulation for quadratic svm:

```
$title Ten-fold cross validation example using GUSS
$eolcom

$setglobal num_folds 10

set p /1*%num_folds%/; ! folds to perform

! Read in data
$include "wdbc.gms"

set test(p,i); ! testing set

! Define problem
parameter C /1/;
positive variables z(i);
variables obj, w(k), gamma, slack(i);

equations obj_def, sep_def(i);

obj_def.. obj =e= 1/2*sum(k, sqr(w(k))) + C*sum(i, z(i));
sep_def(i).. D(i)*(sum(k, A(i,k)*w(k)) - gamma) + z(i) + slack(i) =g= 1;

model train /all/;

! Generate testing sets (to be deleted in each problem)
loop(p,
$batinclude gentestset2.inc "p,i"
);

set headers report / modelstat, solvestat, objval /
parameter
  scenrep(p,headers)
  scopt / SkipBaseCase 1, LogOption 2 /
```
Because the problem is quadratic, we must use a quadratic program solver. The variable values for weight and gamma could be saved for later testing using the same method as detailed above for the linear case.

The batinclude file `gentestset2.inc` is very similar to `gentestset.inc` from the earlier cross-validation examples. In `gentestset2.inc`, though, only one set is being dealt with rather than two. The complete source GAMS code for this formulation is available in this zip archive.

### 5.18.5.2 DEA Modeling in GAMS via GUSS

Data Envelopment Analysis (DEA) models can be solved most efficiently in GAMS using the Gather-Update-Solve-Scatter (GUSS) facility. This is the preferred method since release 23.7 of GAMS and hence the GAMS/DEA solver is no longer available.

A paper with the title “GUSS: Solving Collections of Data Related Models within GAMS” that contains two additional application examples for GUSS is available here.

#### 5.18.5.2.1 Introduction

The basic (CCR) DEA model is a collection of models indexed by $k$ and defined by

\[
\begin{align*}
\max_{u,v} & \quad u^T Y_{*,k} \\
\text{subject to} & \quad v^T X_{*,k} = 1 \\
& \quad u^T Y \leq v^T X \\
& \quad u, v \geq 0
\end{align*}
\]

where $X, Y$ are data matrices.

Without using GUSS in GAMS, a model would be defined and solved in a loop over $k$, requiring the model to be generated multiple times with different instances for each value of $k$. GUSS is an alternative (and more efficient) way to define the individual programs and pass them to any underlying GAMS solver. In this way, individual programs are not re-generated, but are instead defined as data modifications of each other. This reduces overall model generation time. Further, previous solutions can be used as starting points in later solves to speed up overall processing time.

Some DEA examples compare the two formulations. The actual source code for both of these formulations is available here.
5.18.5.2.2 DEA Examples  Original GAMS formulation (without GUSS): In all these models the model setup and data are given at the top of the file and the code of interest is in the last 10 or so lines. In this setting we loop over the set k and change the data in the objective function and the first constraint of the model explicitly before each solve. We only output a minimal summary of the solution.

$title Data Envelopment Analysis - DEA
$context

Data Envelopment Analysis (DEA) is a technique for measuring the relative performance of organizational units where presence of multiple inputs and outputs makes comparison difficult.

\[
\text{efficiency} = \frac{\text{weighted sum of output}}{\text{weighted sum of input}}
\]

Find weights that maximize the efficiency for one unit while ensuring that no other units has an efficiency < 1 using these weights. A primal and dual formulation is presented.

Dyson, Thanassoulis, and Boussofiane, A DEA Tutorial.

The DEA problem formulated using GUSS: In this setting, the solve statement includes an extra keyword
scenario that points to a new set called dict. The contents of this set are directives to GUSS that state
the scenario index is k, the parameter slice is populated from the parameter data and the values of the
variable eff are stored into the parameter eff_k for each scenario solved. More details follow below.

    eff .level. eff_k
    scopt .opt. scenrep /

slice(j) = 0; option lp=cplex;
solve dea using lp max eff scenario dict;
display scenrep,eff_k;

In the GUSS version we indicate the collection of models to be solved using the set dict. The first element of dict determines the set to be used for the scenario (collection) index, in this case k. The second element of dict then details that in each scenario k, the parameter slice is instantiated using a slice of the parameter data. Essentially, this corresponds to the GAMS statement:

\[
slice(j) = data(k,j)
\]

Note the scenario index k must appear as the first index of the parameter data. The third element of dict allows the modeler to collect information from each solve and store it into a GAMS parameter. Essentially, the third element of dict corresponds to the GAMS statement:

\[
eff_k(k) = eff.l
\]
that gets executed immediately after the solve of scenario \( k \).

More complex scenario models can also be formulated using GUSS, including multiple equations being updated. This is shown by the dual of the basic DEA model, given by

\[
\begin{align*}
\min_{z, \lambda} & \quad z \\
\text{subject to} & \quad X^* \lambda \leq zX_{*,k} \quad \text{(objective)} \\
& \quad Y^* \lambda \geq Y_{*,k} \quad \text{(slice constraint)} \\
& \quad \lambda \geq 0 \quad \text{(core constraint)} \\
\end{align*}
\]

The next example compares the two formulations for this model. The actual source code for both of these formulations is available [here](#).

**Original GAMS formulation (without GUSS):**

Extensions of these models to formulations with weighted outputs or variable returns to scale are easy to
formulate with the scenario solver within GAMS. This extended model can be downloaded [here].

The **DEA model** in the model library is similar to the extended model, but does not make use of GUSS.

### 5.19 HiGHS

**HiGHS** is an optimization package for solving continuous and mixed-integer linear programming problems
(LPs and MIPs) using simplex, interior-point, and branch-and-cut algorithms. HiGHS is developed by the
Edinburgh Research Group in Optimization.

For more detailed information on the implemented simplex method, we refer to [98].

#### 5.19.1 Usage

The following statement can be used inside your GAMS program to specify using HiGHS

```
Option MIP = HIGHS; { or LP or RMIP }
```

The above statement should appear before the Solve statement. If HiGHS was specified as the default
solver during GAMS installation, the above statement is not necessary.
5.19 HiGHS

5.19.1.1 Specification of HiGHS Options

GAMS/HiGHS supports the GAMS parameters reslim, iterlim, nodlim, optca, optcr, cutoff, and threads.

Options can be specified by a HiGHS options file. A HiGHS options file consists of one option or comment per line. A pound sign (#) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs).

A small example for a highs.opt file is:

```plaintext
solver = ipm
ipm_optimality_tolerance = 1e-6
run_crossover = false
```

It causes HiGHS to use an interior point solver for an LP solve, increases the optimality tolerance to $10^{-6}$, and turns off crossover to a basis solution.

5.19.2 List of HiGHS Options

In the following, we give a detailed list of all HiGHS options.

### 5.20 IPOPT and IPOPTH

**COIN-OR IPOPT** (Interior Point Optimizer) is an open-source solver for large-scale nonlinear programming (NLP). The code has been written primarily by Andreas Wächter.

IPOPT implements an interior point line search filter method for nonlinear programming models which functions can be nonconvex, but should be twice continuously differentiable. For more information on the algorithm we refer to [144] [196] [195] [197] [194] and the [IPOPT documentation]. Most of the IPOPT documentation in the section was taken from the IPOPT manual [104].

#### 5.20.1 Available linear solvers

The performance and robustness of IPOPT on larger models heavily relies on the used solver for sparse symmetric indefinite linear systems.

GAMS/IPOPT includes the sparse solver [MUMPS] [8] [9] (currently the default), and MKL PARDISO [166] [167]. In the commercially licensed GAMS/IPOPTH version, also the Harwell Subroutine Library (HSL) solvers MA27, MA57, HSL_MA86, and HSL_MA97 are available and MA27 is used by default.

MUMPS, MA57, HSL_MA86, and HSL_MA97 use METIS for matrix ordering [103], see also the [METIS manual]. METIS is copyrighted by the regents of the University of Minnesota.

IPOPT and IPOPTH can exploit parallelization of the linear solvers MKL Pardiso, HSL MA86, and HSL MA97 and the linear algebra routines (see next section).

The linear solver is chosen by the `linear_solver` option. Benchmarks have shown that MA57 and HSL_MA97 are often able to outperform MA27 on larger instances. Further, PARDISO often allows for performance that is better than MUMPS and similar to the HSL solvers. If IPOPT fails to solve an instance with PARDISO, it’s worth to try changing the options `pardisomkl_order` and `pardisomkl_max_iterative_refinement_steps`.

It is also possible to use the linear solver PARDISO from the [PARDISO Solver Project] or the [HSL routines] with GAMS/IPOPT if a user provides libraries that can be loaded at runtime. PARDISO from the PARDISO Solver Project can provide performance that exceeds the one of PARDISO from Intel MKL. To build the HSL routines, COIN-OR project ThirdParty-HSL may be useful. See also options `linear_solver`, `linear_system_scaling`, `nlp_scaling_method`, `pardisolib`, and `hsllib`. Note that it is your responsibility to ensure that you are entitled to download and use these routines!
5.20.2 The linear algebra library

The IPOPT library distributed by GAMS and most of the linear solvers used by IPOPT use the Intel oneAPI Math Kernel Library (MKL), which provides a fast and parallel implementation of linear algebra routines (BLAS/LAPACK) and the linear solver PARDISO. MKL chooses an internal code path that provides the best possible performance for the used CPU type. As a consequence, results can be different when changing from one CPU to another. By setting an environment variable, the code path to use can be set by the user. See the Intel MKL documentation regarding Conditional Numerical Reproducibility for more details.

Intel MKL has been optimized for use with Intel CPUs. On CPUs from other vendors, MKL may not use an internal code path that could provide a better performance on that CPU. For example, it may not use AVX2 instructions on an AMD CPU that provides AVX2.

To gain more insight into the use of MKL in GAMS/IPOPT, one may set the environment variable MKL_VERBOSE to 1. This will print out information about the MKL library used, functions being called, time spend there, etc.

5.20.3 Usage

The following statement can be used inside your GAMS program to specify using IPOPT

```
Option NLP = IPOPT;  { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```

The above statement should appear before the Solve statement. If IPOPT was specified as the default solver during GAMS installation, the above statement is not necessary.

To use IPOPTH, the statement should be

```
Option NLP = IPOPTH;  { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```

5.20.3.1 Specification of Options

IPOPT has many options that can be adjusted for the algorithm (see Section List of IPOPT Options). Options are all identified by a string name, and their values can be of one of three types: Number (real), Integer, or String. Number options are used for things like tolerances, integer options are used for things like maximum number of iterations, and string options are used for setting algorithm details, like the NLP scaling method. Options can be set by creating a ipopt.opt file in the directory you are executing IPOPT.

The ipopt.opt file is read line by line and each line should contain the option name, followed by whitespace, and then the value. Comments can be included with the # symbol. For example, the following is a valid ipopt.opt file:

```
# This is a comment

# Turn off the NLP scaling
nlp_scaling_method none

# Change the initial barrier parameter
mu_init 1e-2

# Set the max number of iterations
max_iter 500
```

GAMS/IPOPT understands currently the following GAMS parameters: reslim (time limit), iterlim (iteration limit), domlim (domain violation limit). Further the option threads can be used to control the number of threads used in the linear algebra routines and the linear solver.
5.20.3.2 Warmstarting IPOPT

As an interior point solver, it is difficult to warm start IPOPT. By default, only the level values of the variables are passed as starting point to IPOPT. Setting the IPOPT option `warm_start_init_point` to `yes` enables that also dual values for variables and constraints are passed to IPOPT.

However, the expected behavior that IPOPT finishes within one iteration if optimal primal and dual values are passed is not reached this way, yet. This is, because IPOPT by default moves any initial value that is close to a bound into the interior. The amount on how much the initial point is moved can be controlled by various `bound_push` and `bound_frac` options. To make IPOPT accept an optimal primal/dual solution within one iteration, it should be sufficient to set the following options:

```
warm_start_init_point       yes
warm_start_bound_push       1e-9
warm_start_bound_frac       1e-9
warm_start_slack_bound_push 1e-9
warm_start_slack_bound_frac 1e-9
warm_start_mult_bound_push  1e-9
```

Further, it can be useful to specify that IPOPT can use a less central path in its first iterations by reducing the value of option `mu_init`. This option is only used if option `mu_strategy` is set to "monotone", so the option file entries would be

```
mu_strategy monotone
mu_init 0.0001
```

Finally, IPOPT by default checks whether it should scale the problem. The computed scaling depends on the starting point, which can be undesired when warmstarting. Thus, it may be useful to turn off scaling via option `nlp_scaling_method`:

```
nlp_scaling_method none
```

If a modified but structurally equivalent problem instance is solved, e.g., via GUSS, option `warm_start_init_point` is automatically set to "yes" for every solve following the first one. If this is not desired, `warm_start_init_point` should explicitly be set to "no" in an IPOPT options file.

5.20.4 Output

This section describes the standard IPOPT console output. The output is designed to provide a quick summary of each iteration as IPOPT solves the problem.

Before IPOPT starts to solve the problem, it displays the problem statistics (number of nonzero-elements in the matrices, number of variables, etc.). Note that if you have fixed variables (both upper and lower bounds are equal), IPOPT may remove these variables from the problem internally and not include them in the problem statistics.

Following the problem statistics, IPOPT will begin to solve the problem and you will see output resembling the following,

```
iter    objective   inf_pr   inf_du  lg(mu)    ||d||    lg(rg)   alpha_du  alpha_pr  ls
0       1.6109693e+01 1.12e+01 5.28e-01 0.00 0.000e+00 - 0.00e+00 0.00e+00 0
1       1.8029749e+01 9.90e-01 6.62e+00 0.10 2.05e+00 - 2.14e-01 1.00e+00 1
2       1.8719906e+01 1.25e-02 9.04e+00 -2.2 5.94e-02 2.0 8.04e-01 1.00e+00 1
```
and the columns of output are defined as

**item**

The current iteration count. This includes regular iterations and iterations while in restoration phase. If the algorithm is in the restoration phase, the letter \( r \) will be appended to the iteration number.

**objective**

The unscaled objective value at the current point. During the restoration phase, this value remains the unscaled objective value for the original problem.

**inf\_pr**

The unscaled constraint violation at the current point. This quantity is the infinity-norm (max) of the (unscaled) constraint violation. During the restoration phase, this value remains the constraint violation of the original problem at the current point. The option `inf_pr_output` can be used to switch to the printing of a different quantity. During the restoration phase, this value is the primal infeasibility of the original problem at the current point.

**inf\_du**

The scaled dual infeasibility at the current point. This quantity measure the infinity-norm (max) of the internal dual infeasibility (Eq. (4a) in [197]), including inequality constraints reformulated using slack variables and problem scaling. During the restoration phase, this is the value of the dual infeasibility for the restoration phase problem.

**lg(mu)**

\( \log_{10} \) of the value of the barrier parameter \( \mu \).

**\|d\|**

The infinity norm (max) of the primal step (for the original variables \( x \) and the internal slack variables \( s \)). During the restoration phase, this value includes the values of additional variables, \( p \) and \( n \) in Eq. (10) of [197].

**lg(rg)**

\( \log_{10} \) of the value of the regularization term for the Hessian of the Lagrangian in the augmented system (\( \delta_w \) in Eq. (26) of [197]). A dash (\(-\)) indicates that no regularization was done.

**alpha\_du**

The stepsize for the dual variables (\( \alpha^z_k \) in Eq. (14c) of [197]).

**alpha\_pr**

The stepsize for the primal variables (\( \alpha_k \) in Eq. (14a) of [197]). The number is usually followed by a character for additional diagnostic information regarding the step acceptance criterion:

- \( f \): f-type iteration in the filter method w/o second order correction
- \( F \): f-type iteration in the filter method w/ second order correction
- \( h \): h-type iteration in the filter method w/o second order correction
- \( H \): h-type iteration in the filter method w/ second order correction
- \( k \): penalty value unchanged in merit function method w/o second order correction
• \( K \): penalty value unchanged in merit function method w/ second order correction
• \( n \): penalty value updated in merit function method w/o second order correction
• \( N \): penalty value updated in merit function method w/ second order correction
• \( R \): Restoration phase just started
• \( w \): in watchdog procedure
• \( s \): step accepted in soft restoration phase
• \( t/T \): tiny step accepted without line search
• \( r \): some previous iterate restored

\[ \text{ls} \]

The number of backtracking line search steps (does not include second-order correction steps).

Note that the step acceptance mechanisms in IPOPT consider the barrier objective function (Eq. (3a) in [197]) which is usually different from the value reported in the \text{objective} column. Similarly, for the purposes of the step acceptance, the constraint violation is measured for the internal problem formulation, which includes slack variables for inequality constraints and potentially scaling of the constraint functions. This value, too, is usually different from the value reported in \text{infpr}. As a consequence, a new iterate might have worse values both for the objective function and the constraint violation as reported in the iteration output, seemingly contradicting globalization procedure.

When the algorithm terminates, IPOPT will output a message to the screen. The following is a list of the possible output messages and a brief description.

**Optimal Solution Found.**

This message indicates that IPOPT found a (locally) optimal point within the desired tolerances.

**Solved To Acceptable Level.**

This indicates that the algorithm did not converge to the "desired" tolerances, but that it was able to obtain a point satisfying the "acceptable" tolerance level as specified by \text{acceptable-\star} options. This may happen if the desired tolerances are too small for the current problem.

**Feasible point for square problem found.**

This message is printed if the problem is "square" (i.e., it has as many equality constraints as free variables) and IPOPT found a point that is feasible w.r.t. \text{constr\_viol\_tol}. It may, however, not be feasible w.r.t. \text{tol}.

**Converged to a point of local infeasibility. Problem may be infeasible.**

The restoration phase converged to a point that is a minimizer for the constraint violation (in the \( \ell_1 \)-norm), but is not feasible for the original problem. This indicates that the problem may be infeasible (or at least that the algorithm is stuck at a locally infeasible point). The returned point (the minimizer of the constraint violation) might help you to find which constraint is causing the problem. If you believe that the NLP is feasible, it might help to start the optimization from a different point.

**Search Direction is becoming Too Small.**

This indicates that IPOPT is calculating very small step sizes and making very little progress. This could happen if the problem has been solved to the best numerical accuracy possible given the current scaling.

**Iterates divering; problem might be unbounded.**
This message is printed if the max-norm of the iterates becomes larger than the value of the option `diverging_iterates_tol`. This can happen if the problem is unbounded below and the iterates are diverging.

Stopping optimization at current point as requested by user.

This message is printed if either an interrupt signal was received (e.g., Ctrl+C was pressed) or the domain violation limit is reached.

Maximum Number of Iterations Exceeded.

This indicates that IPOPT has exceeded the maximum number of iterations as specified by the IPOPT option `max_iter` or the GAMS option `iterlim`.

Maximum wallclock time exceeded.

This indicates that IPOPT has exceeded the maximum number of wallclock seconds as specified by the IPOPT option `max_wall_time` or the GAMS option `reslim`.

Maximum CPU time exceeded.

This indicates that IPOPT has exceeded the maximum number of CPU seconds as specified by the IPOPT option `max_cpu_time`.

Restoration Failed!

This indicates that the restoration phase failed to find a feasible point that was acceptable to the filter line search for the original problem. This could happen if the problem is highly degenerate, does not satisfy the constraint qualification, or if an external or extrinsic function in GAMS provides incorrect derivative information.

Error in step computation!

This messages is printed if IPOPT is unable to compute a step towards a new iterate and the current iterate is not acceptable for the specified tolerances.

A possible reason is that a search direction could not be computed despite several attempts to modify the iteration matrix. Usually, the value of the regularization parameter then becomes too large.

Another reason is that the feasibility restoration phase could not be activated because the current iterate is not infeasible. Reasons for this again include that the problem is highly degenerate, badly scaled, or does not satisfy the constraint qualification. Before IPOPT 3.14, this resulted in a Restoration_Failed status code with message ”Restoration phase is called at almost feasible point...”.

Problem has too few degrees of freedom.

This indicates that your problem, as specified, has too few degrees of freedom. This can happen if you have too many equality constraints, or if you fix too many variables (IPOPT removes fixed variables by default, see also the option `fixed_variable_treatment`).

Not enough memory.

An error occurred while trying to allocate memory. The problem may be too large for your current memory and swap configuration. Sometimes it can help to choose a different linear solver.

INTERNAL ERROR: Unknown SolverReturn value - Notify IPOPT Authors.

An unknown internal error has occurred. Please notify the authors of the GAMS/IPOPT link or IPOPT (refer to support@gams.com).
5.20.4.1 Diagnostic Tags for IPOPT

To print additional diagnostic tags for each iteration of IPOPT, set the options print_info_string to yes. With this, a tag will appear at the end of an iteration line with the following diagnostic meaning that are useful to flag difficulties for a particular IPOPT run. The following is a list of possible strings:

- !: Tighten resto tolerance if only slightly infeasible, see Sec. 3.3 in [197]
- A: Current iteration is acceptable (alternate termination)
- a: Perturbation for PD Singularity can't be done, assume singular, see Sec. 3.1 in [197]
- C: Second Order Correction taken, see Sec. 2.4 in [197]
- Dh: Hessian degenerate based on multiple iterations, see Sec. 3.1 in [197]
- Dhj: Hessian/Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [197]
- Dj: Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [197]
- δx: δx perturbation too large, see Sec. 3.1 in [197]
- e: Cutting back α due to evaluation error (in backtracking line search)
- F−: Filter should be reset, but maximal resets exceeded, see Sec. 2.3 in [197]
- F+: Resetting filter due to last few rejections of filter, see Sec. 2.3 in [197]
- L: Degenerate Jacobian, δc already perturbed, see Sec. 3.1 in [197]
- l: Degenerate Jacobian, δc perturbed, see Sec. 3.1 in [197]
- M: Magic step taken for slack variables (in backtracking line search)
- Nh: Hessian not yet degenerate, see Sec. 3.1 in [197]
- Nhj: Hessian/Jacobian not yet degenerate, see Sec. 3.1 in [197]
- Nj: Jacobian not yet degenerate, see Sec. 3.1 in [197]
- NW: Warm start initialization failed (in Warm Start Initialization)
- q: PD system possibly singular, attempt to improve solution quality, see Sec. 3.1 in [197]
- R: Solution of restoration phase, see Sec. 3.3 in [197]
- s: PD system singular, see Sec. 3.1 in [197]
- S: PD system possibly singular, accept current solution, see Sec. 3.1 in [197]
- T: Square Problem. Set multipliers to zero (default initialization routine)
- Tmax: Trial θ is larger than θmax (filter parameter, Eq. (21) in [197])
- W: Watchdog line search procedure successful, see Sec. 3.2 in [197]
- w: Watchdog line search procedure unsuccessful, stopped, see Sec. 3.2 in [197]
- Wb: Undoing most recent SR1 update, see Sec. 5.4.1 in [23]
- We: Skip Limited-Memory Update in restoration phase, see Sec. 5.4.1 in [23]
- Wp: Safeguard B0 = σI for Limited-Memory Update, see Sec. 5.4.1 in [23]
- Wr: Resetting Limited-Memory Update, see Sec. 5.4.1 in [23]
- Ws: Skip Limited-Memory Update since sTy is not positive, see Sec. 5.4.1 in [23]
- WS: Skip Limited-Memory Update since Δx is too small, see Sec. 5.4.1 in [23]
- y: Dual infeasibility, use least square multiplier update (during IPOPT algorithm)
- z: Apply correction to bound multiplier if too large (during IPOPT algorithm)
## 5.20.5 List of IPOPT Options

</tbody>
</table>

### 5.20.5.11 Step Calculation
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>fast_step_computation</td>
<td>Indicates if the linear system should be solved quickly.</td>
<td>no</td>
</tr>
<tr>
<td>first_hessian_perturbation</td>
<td>Size of first x-s perturbation tried.</td>
<td>0.0001</td>
</tr>
<tr>
<td>jacobian_regularization_value</td>
<td>Size of the regularization for rank-deficient constraint Jacobians.</td>
<td>1e-08</td>
</tr>
<tr>
<td>max_hessian_perturbation</td>
<td>Maximum value of regularization parameter for handling negative curvature.</td>
<td>1e+20</td>
</tr>
<tr>
<td>max_refinement_steps</td>
<td>Maximum number of iterative refinement steps per linear system solve.</td>
<td>10</td>
</tr>
<tr>
<td>mehrotra_algorithm</td>
<td>Indicates whether to do Mehrotra's predictor-corrector algorithm.</td>
<td>no</td>
</tr>
<tr>
<td>min_hessian_perturbation</td>
<td>Smallest perturbation of the Hessian block.</td>
<td>1e-20</td>
</tr>
<tr>
<td>min_refinement_steps</td>
<td>Minimum number of iterative refinement steps per linear system solve.</td>
<td>1</td>
</tr>
<tr>
<td>neg_curv_test_reg</td>
<td>Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).</td>
<td>yes</td>
</tr>
<tr>
<td>neg_curv_test_tol</td>
<td>Tolerance for heuristic to ignore wrong inertia.</td>
<td>0</td>
</tr>
<tr>
<td>perturb_dec_fact</td>
<td>Decrease factor for x-s perturbation.</td>
<td>0.333333</td>
</tr>
<tr>
<td>perturb_inc_fact</td>
<td>Increase factor for x-s perturbation.</td>
<td>8</td>
</tr>
<tr>
<td>perturb_inc_fact_first</td>
<td>Increase factor for x-s perturbation for very first perturbation.</td>
<td>100</td>
</tr>
<tr>
<td>jacobian_regularization_exponent</td>
<td>Exponent for mu in the regularization for rank-deficient constraint Jacobians.</td>
<td>0.25</td>
</tr>
<tr>
<td>perturb_always_cd</td>
<td>Active permanent perturbation of constraint linearization.</td>
<td>no</td>
</tr>
<tr>
<td>residual_improvement_factor</td>
<td>Minimal required reduction of residual test ratio in iterative refinement.</td>
<td>1</td>
</tr>
<tr>
<td>residual_ratio_max</td>
<td>Iterative refinement tolerance.</td>
<td>1e-10</td>
</tr>
<tr>
<td>residual_ratio_singular</td>
<td>Threshold for declaring linear system singular after failed iterative refinement.</td>
<td>1e-05</td>
</tr>
</tbody>
</table>

### 5.20.5.12 Restoration Phase

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>bound_mult_reset_threshold</td>
<td>Threshold for resetting bound multipliers after the restoration phase.</td>
<td>1000</td>
</tr>
<tr>
<td>constr_mult_reset_threshold</td>
<td>Threshold for resetting equality and inequality multipliers after restoration phase.</td>
<td>0</td>
</tr>
<tr>
<td>evaluate_orig_obj_at_resto_trial</td>
<td>Determines if the original objective function should be evaluated at restoration phase trial points.</td>
<td>yes</td>
</tr>
<tr>
<td>expect_infeasible_problem</td>
<td>Enable heuristics to quickly detect an infeasible problem.</td>
<td>no</td>
</tr>
<tr>
<td>expect_infeasible_problem_ctol</td>
<td>Threshold for disabling &quot;expect_infeasible_problem&quot; option.</td>
<td>0.001</td>
</tr>
<tr>
<td>expect_infeasible_problem_ytol</td>
<td>Multiplier threshold for activating &quot;expect_infeasible_problem&quot; option.</td>
<td>1e+08</td>
</tr>
<tr>
<td>required_infeasibility_reduction</td>
<td>Required reduction of infeasibility before leaving restoration phase.</td>
<td>0.9</td>
</tr>
</tbody>
</table>
### 5.20.5.13 Hessian Approximation

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>hessian_approximation</td>
<td>Indicates what Hessian information is to be used.</td>
<td>exact</td>
</tr>

### 5.20.6 Detailed Options Description

**accept_after_max_steps** *(advanced)*: Accept a trial point after maximal this number of steps even if it does not satisfy line search conditions. ←

Setting this to -1 disables this option.

Range: {-1, ..., ∞}

Default: -1

**accept_every_trial_step**: Always accept the first trial step. ←

Setting this option to "yes" essentially disables the line search and makes the algorithm take aggressive steps, without global convergence guarantees.

Range: yes, no

Default: no

**acceptable_compl_inf_tol**: "Acceptance" threshold for the complementarity conditions. ←

Absolute tolerance on the complementarity. "Acceptable" termination requires that the max-norm of the (unscaled) complementarity is less than this threshold; see also acceptable_tol.

Range: (0, ∞]

Default: 0.01

**acceptable_constr_viol_tol**: "Acceptance" threshold for the constraint violation. ←

Absolute tolerance on the constraint violation. "Acceptable" termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold; see also acceptable_tol.

Range: (0, ∞]

Default: 0.01
acceptable_dual_inf_tol: "Acceptance" threshold for the dual infeasibility. 

Absolute tolerance on the dual infeasibility. "Acceptable" termination requires that the (max-norm of the unscaled) dual infeasibility is less than this threshold; see also acceptable_tol.

Range: \((0, \infty]\)

Default: \(1e+10\)

acceptable_iter: Number of "acceptable" iterates before triggering termination. 

If the algorithm encounters this many successive "acceptable" iterates (see "acceptable_tol"), it terminates, assuming that the problem has been solved to best possible accuracy given round-off. If it is set to zero, this heuristic is disabled.

Range: \(\{0, ..., \infty\}\)

Default: 0

acceptable_obj_change_tol: "Acceptance" stopping criterion based on objective function change. 

If the relative change of the objective function (scaled by Max\(1,|f(x)|\)) is less than this value, this part of the acceptable tolerance termination is satisfied; see also acceptable_tol. This is useful for the quasi-Newton option, which has trouble to bring down the dual infeasibility.

Range: \([0, \infty]\)

Default: \(1e+20\)

acceptable_tol: "Acceptable" convergence tolerance (relative). 

Determines which (scaled) overall optimality error is considered to be "acceptable". There are two levels of termination criteria. If the usual "desired" tolerances (see tol, dual_inf_tol etc) are satisfied at an iteration, the algorithm immediately terminates with a success message. On the other hand, if the algorithm encounters "acceptable_iter" many iterations in a row that are considered "acceptable", it will terminate before the desired convergence tolerance is met. This is useful in cases where the algorithm might not be able to achieve the "desired" level of accuracy.

Range: \((0, \infty]\)

Default: \(1e-06\)

adaptive_mu_globalization: Globalization strategy for the adaptive mu selection mode. 

To achieve global convergence of the adaptive version, the algorithm has to switch to the monotone mode (Fiacco-McCormick approach) when convergence does not seem to appear. This option sets the criterion used to decide when to do this switch. (Only used if option "mu_strategy" is chosen as "adaptive".)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>kkt-error</td>
<td>nonmonotone decrease of kkt-error</td>
</tr>
<tr>
<td>obj-constr-filter</td>
<td>2-dim filter for objective and constraint violation</td>
</tr>
<tr>
<td>never-monotone-mode</td>
<td>disables globalization</td>
</tr>
</tbody>
</table>

Default: obj-constr-filter
adaptive_mu_kkt_norm_type (advanced): Norm used for the KKT error in the adaptive mu globalization strategies.

When computing the KKT error for the globalization strategies, the norm to be used is specified with this option. Note, this option is also used in the QualityFunctionMuOracle.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-norm</td>
<td>use the 1-norm (abs sum)</td>

</tr>
<tr>
<td>max-norm</td>
<td>use the infinity norm (max)</td>
</tr>
<tr>
<td>2-norm</td>
<td>use 2-norm</td>
</tr>
</tbody>
</table>

Default: 2-norm-squared

adaptive_mu_kkterror_red_fact (advanced): Sufficient decrease factor for "kkt-error" globalization strategy.

For the "kkt-error" based globalization strategy, the error must decrease by this factor to be deemed sufficient decrease.

Range: (0, 1)

Default: 0.9999

adaptive_mu_kkterror_red_iters (advanced): Maximum number of iterations requiring sufficient progress.

For the "kkt-error" based globalization strategy, sufficient progress must be made for "adaptive_mu_kkterror_red_iters" iterations. If this number of iterations is exceeded, the globalization strategy switches to the monotone mode.

Range: {0, ..., ∞}

Default: 4

adaptive_mu_monotone_init_factor (advanced): Determines the initial value of the barrier parameter when switching to the monotone mode.

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode and fixed_mu_oracle is chosen as "average_compl", the barrier parameter is set to the current average complementarity times the value of "adaptive_mu_monotone_init_factor".

Range: (0, ∞]

Default: 0.8

adaptive_mu_restore_previous_iterate (advanced): Indicates if the previous accepted iterate should be restored if the monotone mode is entered.

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode, it can either start from the most recent iterate (no), or from the last iterate that was accepted (yes).

Range: yes, no

Default: no

alpha_for_y: Method to determine the step size for constraint multipliers (alpha_y).

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>primal</td>
<td>use primal step size</td>
</tr>
<tr>

</tr>
<tr>
<td>dual-and-full</td>
<td>use the dual step size, and full step if $\Delta x \leq \alpha_{\text{for}_y_tol}$</td>
</tr>
<tr>
<td>acceptor</td>
<td>Call LSAcceptor to get step size for $y$</td>
</tr>
</tbody>
</table>

Default: primal

**alpha_for_y_tol:** Tolerance for switching to full equality multiplier steps.  
This is only relevant if "alpha_for_y" is chosen "primal-and-full" or "dual-and-full". The step size for the equality constraint multipliers is taken to be one if the max-norm of the primal step is less than this tolerance.

Range: $[0, \infty]$  
Default: 10

**alpha_min_frac** *(advanced):* Safety factor for the minimal step size (before switching to restoration phase).  
This is gamma_alpha in Eqn. (20) in the implementation paper.

Range: $(0, 1)$  
Default: 0.05

**alpha_red_factor** *(advanced):* Fractional reduction of the trial step size in the backtracking line search.

At every step of the backtracking line search, the trial step size is reduced by this factor.

Range: $(0, 1)$  
Default: 0.5

**barrier_tol_factor:** Factor for mu in barrier stop test.

The convergence tolerance for each barrier problem in the monotone mode is the value of the barrier parameter times "barrier_tol_factor". This option is also used in the adaptive mu strategy during the monotone mode. This is kappa_epsilon in implementation paper.

Range: $(0, \infty]$  
Default: 10

**bound_frac:** Desired minimum relative distance from the initial point to bound.

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: $(0, 0.5]$  
Default: 0.01

**bound_mult_init_method:** Initialization method for bound multipliers

This option defines how the iterates for the bound multipliers are initialized. If "constant" is chosen, then all bound multipliers are initialized to the value of "bound_mult_init_val". If "mu-based" is chosen, the each value is initialized to the the value of "mu_init" divided by the corresponding slack variable. This latter option might be useful if the starting point is close to the optimal solution.
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>constant</td>
<td>set all bound multipliers to the value of bound_mult_init_val</td>
</tr>
<tr>
<td>mu-based</td>
<td>initialize to mu_init/x_slack</td>
</tr>
</tbody>
</table>

Default: constant

**bound_mult_init_val**: Initial value for the bound multipliers. ↔

All dual variables corresponding to bound constraints are initialized to this value.

Range: \((0, \infty]\)

Default: 1

**bound_mult_reset_threshold**: Threshold for resetting bound multipliers after the restoration phase. ↔

After returning from the restoration phase, the bound multipliers are updated with a Newton step for complementarity. Here, the change in the primal variables during the entire restoration phase is taken to be the corresponding primal Newton step. However, if after the update the largest bound multiplier exceeds the threshold specified by this option, the multipliers are all reset to 1.

Range: \([0, \infty]\)

Default: 1000

**bound_push**: Desired minimum absolute distance from the initial point to bound. ↔

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Range: \((0, \infty]\)

Default: 0.01

**bound_relax_factor**: Factor for initial relaxation of the bounds. ↔

Before start of the optimization, the bounds given by the user are relaxed. This option sets the factor for this relaxation. Additional, the constraint violation tolerance constr_viol_tol is used to bound the relaxation by an absolute value. If it is set to zero, then then bounds relaxation is disabled. See Eqn.(35) in implementation paper. Note that the constraint violation reported by Ipopt at the end of the solution process does not include violations of the original (non-relaxed) variable bounds. See also option honor_original_bounds.

Range: \([0, \infty]\)

Default: 1e-10

**check_derivatives_for_naninf**: Indicates whether it is desired to check for Nan/Inf in derivative matrices ↔
Activating this option will cause an error if an invalid number is detected in the constraint Jacobians or the Lagrangian Hessian. If this is not activated, the test is skipped, and the algorithm might proceed with invalid numbers and fail. If test is activated and an invalid number is detected, the matrix is written to output with print_level corresponding to J_MORE DETAILED; so beware of large output!

Range: yes, no
Default: no

**compl_inf_tol:** Desired threshold for the complementarity conditions. ↔

Absolute tolerance on the complementarity. Successful termination requires that the max-norm of the (unscaled) complementarity is less than this threshold.

Range: $(0, \infty]$  
Default: $0.0001$

**constr_mult_init_max:** Maximum allowed least-square guess of constraint multipliers. ↔

Determines how large the initial least-square guesses of the constraint multipliers are allowed to be (in max-norm). If the guess is larger than this value, it is discarded and all constraint multipliers are set to zero. This options is also used when initializing the restoration phase. By default, "resto.constr_mult_init_max" (the one used in RestoIterateInitializer) is set to zero.

Range: $[0, \infty]$  
Default: $1000$

**constr_mult_reset_threshold:** Threshold for resetting equality and inequality multipliers after restoration phase. ↔

After returning from the restoration phase, the constraint multipliers are recomputed by a least square estimate. This option triggers when those least-square estimates should be ignored.

Range: $[0, \infty]$  
Default: $0$

**constr_viol_tol:** Desired threshold for the constraint and variable bound violation. ↔

Absolute tolerance on the constraint and variable bound violation. Successful termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold. If option bound_relax_factor is not zero 0, then Ipopt relaxes given variable bounds. The value of constr_viol_tol is used to restrict the absolute amount of this bound relaxation.

Range: $(0, \infty]$  
Default: $1e-06$

**constraintViolationNormType (advanced):** Norm to be used for the constraint violation in the line search. ↔

Determines which norm should be used when the algorithm computes the constraint violation in the line search.
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-norm</td>
<td>use the 1-norm</td>
</tr>
<tr>
<td>2-norm</td>
<td>use the 2-norm</td>
</tr>
<tr>
<td>max-norm</td>
<td>use the infinity norm</td>
</tr>
</tbody>
</table>

Default: 1-norm

**corrector_compl_avrg_red_fact (advanced):** Complementarity tolerance factor for accepting corrector step. ←

This option determines the factor by which complementarity is allowed to increase for a corrector step to be accepted. Changing this option is experimental.

Range: \((0, \infty]\)

Default: 1

**corrector_type (advanced):** The type of corrector steps that should be taken. ←

If “mu_strategy” is “adaptive”, this option determines what kind of corrector steps should be tried. Changing this option is experimental.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>no corrector</td>
</tr>
<tr>
<td>affine</td>
<td>corrector step towards (\mu=0)</td>
</tr>
<tr>
<td>primal-dual</td>
<td>corrector step towards current (\mu)</td>
</tr>
</tbody>
</table>

Default: none

**delta (advanced):** Multiplier for constraint violation in the switching rule. ←

See Eqn. (19) in the implementation paper.

Range: \((0, \infty]\)

Default: 1

**dependency_detection_with_rhs (advanced):** Indicates if the right hand sides of the constraints should be considered in addition to gradients during dependency detection ←

Range: yes, no

Default: no

**dependency_detector (advanced):** Indicates which linear solver should be used to detect linearly dependent equality constraints. ←

This is experimental and does not work well.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>don't check; no extra work at beginning</td>
</tr>
<tr>
<td>mumps</td>
<td>use MUMPS</td>
</tr>
</tbody>
</table>
diverging_iterates_tol: Threshold for maximal value of primal iterates. ↔

If any component of the primal iterates exceeded this value (in absolute terms), the optimization is aborted with the exit message that the iterates seem to be diverging.

Range: \((0, \infty]\)

Default: \(1e+20\)

dual_inf_tol: Desired threshold for the dual infeasibility. ↔

Absolute tolerance on the dual infeasibility. Successful termination requires that the max-norm of the (unscaled) dual infeasibility is less than this threshold.

Range: \((0, \infty]\)

Default: 1

eta_phi (advanced): Relaxation factor in the Armijo condition. ↔

See Eqn. (20) in the implementation paper.

Range: \((0, 0.5]\)

Default: \(1e-08\)

evaluate_orig_obj_at_resto_trial: Determines if the original objective function should be evaluated at restoration phase trial points. ↔

Enabling this option makes the restoration phase algorithm evaluate the objective function of the original problem at every trial point encountered during the restoration phase, even if this value is not required. In this way, it is guaranteed that the original objective function can be evaluated without error at all accepted iterates; otherwise the algorithm might fail at a point where the restoration phase accepts an iterate that is good for the restoration phase problem, but not the original problem. On the other hand, if the evaluation of the original objective is expensive, this might be costly.

Range: yes, no

Default: yes

expect_infeasible_problem: Enable heuristics to quickly detect an infeasible problem. ↔

This option is meant to activate heuristics that may speed up the infeasibility determination if you expect that there is a good chance for the problem to be infeasible. In the filter line search procedure, the restoration phase is called more quickly than usually, and more reduction in the constraint violation is enforced before the restoration phase is left. If the problem is square, this option is enabled automatically.

Range: yes, no

Default: no

expect_infeasible_problem_ctol: Threshold for disabling "expect_infeasible_problem" option. ↔
If the constraint violation becomes smaller than this threshold, the "expect_infeasible_problem" heuristics in the filter line search are disabled. If the problem is square, this option is set to 0.

Range: \([0, \infty]\)
Default: 0.001

**expect_infeasible_problem_ytol:** Multiplier threshold for activating "expect_infeasible_problem" option.

If the max norm of the constraint multipliers becomes larger than this value and "expect_infeasible_problem" is chosen, then the restoration phase is entered.

Range: \((0, \infty]\)
Default: 1e+08

**fast_step_computation:** Indicates if the linear system should be solved quickly.

If enabled, the algorithm assumes that the linear system that is solved to obtain the search direction is solved sufficiently well. In that case, no residuals are computed to verify the solution and the computation of the search direction is a little faster.

Range: yes, no
Default: no

**filter_margin_fact (advanced):** Factor determining width of margin for obj-constr-filter adaptive globalization strategy.

When using the adaptive globalization strategy, "obj-constr-filter", sufficient progress for a filter entry is defined as follows: \(\text{new obj} < \text{(filter obj)} - \text{filter_margin_fact} \times \text{(new constr-viol)}\) OR \(\text{new constr-viol} < \text{(filter constr-viol)} - \text{filter_margin_fact} \times \text{(new constr-viol)}\). For the description of the "kkt-error-filter" option see "filter_max_margin".

Range: \((0, 1]\)
Default: 1e-05

**filter_max_margin (advanced):** Maximum width of margin in obj-constr-filter adaptive globalization strategy.

Range: \((0, \infty]\)
Default: 1

**filter_reset_trigger (advanced):** Number of iterations that trigger the filter reset.

If the filter reset heuristic is active and the number of successive iterations in which the last rejected trial step size was rejected because of the filter, the filter is reset.

Range: \(\{1, ..., \infty\}\)
Default: 5

**first_hessian_perturbation:** Size of first x-s perturbation tried.

The first value tried for the x-s perturbation in the inertia correction scheme. This is \(\delta_0\) in the implementation paper.

Range: \((0, \infty]\)
Default: 0.0001

**fixed_mu_oracle:** Oracle for the barrier parameter when switching to fixed mode.

Determines how the first value of the barrier parameter should be computed when switching to the "monotone mode" in the adaptive strategy. (Only considered if "adaptive" is selected for option "mu_strategy").
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>probing</td>
<td>Mehrotra’s probing heuristic</td>
</tr>
<tr>
<td>loqo</td>
<td>LOQO’s centrality rule</td>
</tr>
<tr>
<td>quality-function</td>
<td>minimize a quality function</td>
</tr>
<tr>
<td>average_compl</td>
<td>base on current average complementarity</td>
</tr>
</tbody>
</table>

Default: average_compl

**fixed_variable_treatment**: Determines how fixed variables should be handled. ←

The main difference between those options is that the starting point in the "make_constraint" case still has the fixed variables at their given values, whereas in the case "make_parameter(nodual)" the functions are always evaluated with the fixed values for those variables. Also, for "relax_bounds", the fixing bound constraints are relaxed (according to" bound_relax_factor"). For all but "make_parameter_nodual", bound multipliers are computed for the fixed variables.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>make_parameter</td>
<td>Remove fixed variable from optimization variables</td>
</tr>
<tr>
<td>make_parameter_nodual</td>
<td>Remove fixed variable from optimization variables and do not compute bound multipliers for fixed variables</td>
</tr>
<tr>
<td>make_constraint</td>
<td>Add equality constraints fixing variables</td>
</tr>
<tr>
<td>relax_bounds</td>
<td>Relax fixing bound constraints</td>
</tr>
</tbody>
</table>

Default: make_parameter

**gamma_phi (advanced)**: Relaxation factor in the filter margin for the barrier function. ←

See Eqn. (18a) in the implementation paper.

Range: (0, 1)

Default: 1e-08

**gamma_theta (advanced)**: Relaxation factor in the filter margin for the constraint violation. ←

See Eqn. (18b) in the implementation paper.

Range: (0, 1)

Default: 1e-05

**hessian_approximation**: Indicates what Hessian information is to be used. ←

This determines which kind of information for the Hessian of the Lagrangian function is used by the algorithm.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>exact</td>
<td>Use second derivatives provided by the NLP.</td>
</tr>
<tr>
<td>limited-memory</td>
<td>Perform a limited-memory quasi-Newton approximation</td>
</tr>
</tbody>
</table>

Default: exact
**hessian_approximation_space** *(advanced):* Indicates in which subspace the Hessian information is to be approximated.  

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>nonlinear-variables</td>
<td>only in space of nonlinear variables.</td>
</tr>
<tr>
<td>all-variables</td>
<td>in space of all variables (without slacks)</td>
</tr>
</tbody>
</table>

Default: nonlinear-variables

**honor_original_bounds:** Indicates whether final points should be projected into original bounds.  

Ipopt might relax the bounds during the optimization (see, e.g., option "bound_relax_factor"). This option determines whether the final point should be projected back into the user-provide original bounds after the optimization. Note that violations of constraints and complementarity reported by Ipopt at the end of the solution process are for the non-projected point.

Range: yes, no

Default: no

**hsllib:** Name of library containing HSL routines for load at runtime

Range: string

Default: libhsl.so (Linux), libhsl.dylib (macOS), libhsl.dll (Windows)

**inf_pr_output:** Determines what value is printed in the "inf_pr" output column.

Ipopt works with a reformulation of the original problem, where slacks are introduced and the problem might have been scaled. The choice "internal" prints out the constraint violation of this formulation. With "original" the true constraint violation in the original NLP is printed.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>internal</td>
<td>max-norm of violation of internal equality constraints</td>
</tr>
<tr>
<td>original</td>
<td>maximal constraint violation in original NLP</td>
</tr>
</tbody>
</table>

Default: original

**jac_e_constant:** Indicates whether to assume that all equality constraints are linear

Activating this option will cause Ipopt to ask for the Jacobian of the equality constraints only once from the NLP and reuse this information later.

Range: yes, no

Default: no

**jac_d_constant:** Indicates whether to assume that all inequality constraints are linear

Activating this option will cause Ipopt to ask for the Jacobian of the inequality constraints only once from the NLP and reuse this information later.

Range: yes, no

Default: no
**jacobian_regularization_exponent** *(advanced)*: Exponent for $\mu$ in the regularization for rank-deficient constraint Jacobians. 

This is $\kappa_c$ in the implementation paper.

Range: $[0, \infty]$  
Default: 0.25

**jacobian_regularization_value**: Size of the regularization for rank-deficient constraint Jacobians. 

This is $\bar{\delta_c}$ in the implementation paper.

Range: $[0, \infty]$  
Default: $1 \times 10^{-8}$

**kappa_d** *(advanced)*: Weight for linear damping term (to handle one-sided bounds). 

See Section 3.7 in implementation paper.

Range: $[0, \infty]$  
Default: $1 \times 10^{-5}$

**kappa_sigma** *(advanced)*: Factor limiting the deviation of dual variables from primal estimates. 

If the dual variables deviate from their primal estimates, a correction is performed. See Eqn. (16) in the implementation paper. Setting the value to less than 1 disables the correction.

Range: $(0, \infty]$  
Default: $1 \times 10^{10}$

**kappa_soc** *(advanced)*: Factor in the sufficient reduction rule for second order correction. 

This option determines how much a second order correction step must reduce the constraint violation so that further correction steps are attempted. See Step A-5.9 of Algorithm A in the implementation paper.

Range: $(0, \infty]$  
Default: 0.99

**least_square_init_duals**: Least square initialization of all dual variables

If set to yes, Ipopt tries to compute least-square multipliers (considering ALL dual variables). If successful, the bound multipliers are possibly corrected to be at least $\text{bound\_mult\_init\_val}$. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP. This overwrites option "bound\_mult\_init\_method".

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>use $\text{bound_mult_init_val}$ and least-square equality constraint multipliers</td>
</tr>
<tr>
<td>yes</td>
<td>overwrite user-provided point with least-square estimates</td>
</tr>
</tbody>
</table>

Default: no
least_square_init_primal: Least square initialization of the primal variables

If set to yes, Ipopt ignores the user provided point and solves a least square problem for the primal variables (x and s) to fit the linearized equality and inequality constraints. This might be useful if the user doesn’t know anything about the starting point, or for solving an LP or QP.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>take user-provided point</td>
</tr>
<tr>
<td>yes</td>
<td>overwrite user-provided point with least-square estimates</td>
</tr>
</tbody>
</table>

Default: no

limited_memory_augSolver (advanced): Strategy for solving the augmented system for low-rank Hessian.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>sherman-morrison</td>
<td>use Sherman-Morrison formula</td>
</tr>
<tr>
<td>extended</td>
<td>use an extended augmented system</td>
</tr>
</tbody>
</table>

Default: sherman-morrison

limited_memory_init_val: Value for B0 in low-rank update.

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Range: (0, ∞]

Default: 1

limited_memory_init_val_max: Upper bound on value for B0 in low-rank update.

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Range: (0, ∞]

Default: 1e+08

limited_memory_init_val_min: Lower bound on value for B0 in low-rank update.

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Range: (0, ∞]

Default: 1e-08

limited_memory_initialization: Initialization strategy for the limited memory quasi-Newton approximation.

Determines how the diagonal Matrix B_0 as the first term in the limited memory approximation should be computed.
### 5.20 IPOPT and IPOPTH

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>scalar1</td>
<td>( \sigma = s^\top T_y/s^\top T_s )</td>
</tr>
<tr>
<td>scalar2</td>
<td>( \sigma = y^\top T_y/s^\top T_y )</td>
</tr>
<tr>
<td>scalar3</td>
<td>arithmetic average of scalar1 and scalar2</td>
</tr>
<tr>
<td>scalar4</td>
<td>geometric average of scalar1 and scalar2</td>
</tr>
<tr>
<td>constant</td>
<td>( \sigma = \text{limited_memory_init_val} )</td>
</tr>
</tbody>
</table>

Default: scalar1

**limited_memory_max_history**: Maximum size of the history for the limited quasi-Newton Hessian approximation. ←

This option determines the number of most recent iterations that are taken into account for the limited-memory quasi-Newton approximation.

Range: \( \{0, ..., \infty\} \)

Default: 6

**limited_memory_max_skipping**: Threshold for successive iterations where update is skipped. ←

If the update is skipped more than this number of successive iterations, the quasi-Newton approximation is reset.

Range: \( \{1, ..., \infty\} \)

Default: 2

**limited_memory_special_for_resto**: Determines if the quasi-Newton updates should be special during the restoration phase. ←

Until Nov 2010, Ipopt used a special update during the restoration phase, but it turned out that this does not work well. The new default uses the regular update procedure and it improves results. If for some reason you want to get back to the original update, set this option to "yes".

Range: yes, no

Default: no

**limited_memory_update_type**: Quasi-Newton update formula for the limited memory quasi-Newton approximation. ←

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bfgs</td>
<td>BFGS update (with skipping)</td>
</tr>
<tr>
<td>sr1</td>
<td>SR1 (not working well)</td>
</tr>
</tbody>
</table>

Default: bfgs

**line_search_method (advanced)**: Globalization method used in backtracking line search ←

Only the "filter" choice is officially supported. But sometimes, good results might be obtained with the other choices.
### Filter method

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>filter</td>
<td>Filter method</td>
</tr>
<tr>
<td>cg-penalty</td>
<td>Chen-Goldfarb penalty function</td>
</tr>
<tr>
<td>penalty</td>
<td>Standard penalty function</td>
</tr>
</tbody>
</table>

Default: filter

#### linear_scaling_on_demand

Flag indicating that linear scaling is only done if it seems required.

This option is only important if a linear scaling method (e.g., mc19) is used. If you choose "no", then the scaling factors are computed for every linear system from the start. This can be quite expensive. Choosing "yes" means that the algorithm will start the scaling method only when the solutions to the linear system seem not good, and then use it until the end.

Range: yes, no

Default: yes

#### linear_solver

Linear solver used for step computations.

Determines which linear algebra package is to be used for the solution of the augmented linear system (for obtaining the search directions). Note, that MA27, MA57, MA86, and MA97 are included with a commercially supported GAMS/IpoptH license only. To use MA27, MA57, MA86, or MA97 with GAMS/Ipopt, or to use HSL_MA77, a HSL library needs to be provided by the user. To use Pardiso from pardiso-project.org, a Pardiso library needs to be provided by the user. **ATTENTION**: Before Ipopt 3.14 (GAMS 36), value pardiso specified to use Pardiso from Intel MKL. With GAMS 36, this value has been renamed to pardisomkl.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ma27</td>
<td>IpoptH: use the Harwell routine MA27; Ipopt: load the Harwell routine MA27 from user-provided library</td>
</tr>
<tr>
<td>ma57</td>
<td>IpoptH: use the Harwell routine MA57; Ipopt: load the Harwell routine MA57 from user-provided library</td>
</tr>
<tr>
<td>ma77</td>
<td>load the Harwell routine HSL_MA77 from user-provided library</td>
</tr>
<tr>
<td>ma86</td>
<td>IpoptH: use the Harwell routine HSL_MA86; Ipopt: load the Harwell routine HSL_MA86 from user-provided library</td>
</tr>
<tr>
<td>ma97</td>

<td>load the Pardiso package from pardiso-project.org from user-provided library at runtime</td>
</tr>
<tr>
<td>pardisomkl</td>
<td>use the Pardiso package from Intel MKL</td>
</tr>
<tr>
<td>mumps</td>
<td>use the Mumps package</td>
</tr>
</tbody>
</table>

Default: ma27, if IpoptH, otherwise mumps

#### linear_system_scaling

Method for scaling the linear system.

Determines the method used to compute symmetric scaling factors for the augmented system (see also the "linear_scaling_on_demand" option). This scaling is independent of the NLP problem scaling. Note, that MC19 is included with a commercially supported GAMS/IpoptH license only. To use MC19 with GAMS/Ipopt, a HSL library needs to be provided by the user.
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>no scaling will be performed</td>
</tr>
<tr>
<td>mc19</td>
<td>IpoptH: use the Harwell routine MC19; Ipopt: load the Harwell routine MC19 from user-provided library</td>
</tr>
<tr>
<td>slack-based</td>
<td>use the slack values</td>
</tr>
</tbody>
</table>

Default: mc19, if IpoptH, otherwise none

**ma27_ignore_singularity (advanced)**: Whether to use MA27's ability to solve a linear system even if the matrix is singular.

Setting this option to "yes" means that Ipopt will call MA27 to compute solutions for right hand sides, even if MA27 has detected that the matrix is singular (but is still able to solve the linear system). In some cases this might be better than using Ipopt's heuristic of small perturbation of the lower diagonal of the KKT matrix.

Range: yes, no

Default: no

**ma27_la_init_factor**: Real workspace memory for MA27.

The initial real workspace memory = la_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by ma27_meminc_factor if required.

Range: [1, ∞]

Default: 5

**ma27_liw_init_factor**: Integer workspace memory for MA27.

The initial integer workspace memory = liw_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by ma27_meminc_factor if required.

Range: [1, ∞]

Default: 5

**ma27_meminc_factor**: Increment factor for workspace size for MA27.

If the integer or real workspace is not large enough, Ipopt will increase its size by this factor.

Range: [1, ∞]

Default: 2

**ma27_pivtol**: Pivot tolerance for the linear solver MA27.

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: (0, 1)

Default: 1e-08

**ma27_pivtolmax**: Maximum pivot tolerance for the linear solver MA27.
Ipopt may increase pivtol as high as ma27.pivtolmax to get a more accurate solution to the linear system.

Range: (0, 1)
Default: 0.0001

**ma27.print_level**: Debug printing level for the linear solver MA27

0: no printing; 1: Error messages only; 2: Error and warning messages; 3: Error and warning messages and terse monitoring; 4: All information.

Range: {0, ..., 4}
Default: 0

**ma27.skip_inertia_check** *(advanced)*: Whether to always pretend that inertia is correct.

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no
Default: no

**ma57.automatic_scaling**: Controls whether to enable automatic scaling in MA57

For higher reliability of the MA57 solver, you may want to set this option to yes. This is ICNTL(15) in MA57.

Range: yes, no
Default: no

**ma57.block_size**: Controls block size used by Level 3 BLAS in MA57BD

This is ICNTL(11) in MA57.

Range: {1, ..., ∞}
Default: 16

**ma57.node_amalgamation**: Node amalgamation parameter

This is ICNTL(12) in MA57.

Range: {1, ..., ∞}
Default: 16

**ma57.pivot_order**: Controls pivot order in MA57

This is ICNTL(6) in MA57.

Range: {0, ..., 5}
Default: 5

**ma57.pivtol**: Pivot tolerance for the linear solver MA57
A smaller number pivots for sparsity, a larger number pivots for stability.

Range: \((0, 1)\)
Default: \(1e-08\)

\textbf{ma57.pivtolmax}: Maximum pivot tolerance for the linear solver MA57.

Ipopt may increase pivtol as high as \texttt{ma57.pivtolmax} to get a more accurate solution to the linear system.

Range: \((0, 1)\)
Default: 0.0001

\textbf{ma57.pre alloc}: Safety factor for work space memory allocation for the linear solver MA57.

If 1 is chosen, the suggested amount of work space is used. However, choosing a larger number might avoid reallocation if the suggest values do not suffice.

Range: \([1, \infty)\]
Default: 1.05

\textbf{ma57.print level}: Debug printing level for the linear solver MA57

0: no printing; 1: Error messages only; 2: Error and warning messages; 3: Error and warning messages and terse monitoring; \(\geq 4\): All information.

Range: \(\{0, ..., \infty\}\)
Default: 0

\textbf{ma57.small pivot flag}: Handling of small pivots

If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient. This is ICNTL(16) in MA57.

Range: \(\{0, ..., 1\}\)
Default: 0

\textbf{ma77.buffer.lpage}: Number of scalars per MA77 in-core buffer page in the out-of-core solver MA77

Must be at most \texttt{ma77.file.size}.

Range: \(\{1, ..., \infty\}\)
Default: 4096

\textbf{ma77.buffer.npage}: Number of pages that make up MA77 buffer

Number of pages of size \texttt{buffer.lpage} that exist in-core for the out-of-core solver MA77.

Range: \(\{1, ..., \infty\}\)
Default: 1600
**ma77_file_size**: Target size of each temporary file for MA77, scalars per type

MA77 uses many temporary files, this option controls the size of each one. It is measured in the number of entries (int or double), NOT bytes.

Range: \{1, ..., \infty\}

Default: 2097152

**ma77_maxstore**: Maximum storage size for MA77 in-core mode

If greater than zero, the maximum size of factors stored in core before out-of-core mode is invoked.

Range: \{0, ..., \infty\}

Default: 0

**ma77_nemin**: Node Amalgamation parameter

Two nodes in elimination tree are merged if result has fewer than ma77_nemin variables.

Range: \{1, ..., \infty\}

Default: 8

**ma77_order**: Controls type of ordering used by MA77

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>amd</td>
<td>Use the HSL_MC68 approximate minimum degree algorithm</td>
</tr>
<tr>
<td>metis</td>
<td>Use the MeTiS nested dissection algorithm (if available)</td>
</tr>
</tbody>
</table>

Default: metis

**ma77_print_level**: Debug printing level for the linear solver MA77

\(<0: \text{no printing}; 0: \text{Error and warning messages only}; 1: \text{Limited diagnostic printing}; >1: \text{Additional diagnostic printing.}

Range: \{-\infty, ..., \infty\}

Default: -1

**ma77_small**: Zero Pivot Threshold

Any pivot less than ma77_small is treated as zero.

Range: \[0, \infty\]

Default: 1e-20

**ma77_static**: Static Pivoting Threshold
See MA77 documentation. Either ma77_static=0.0 or ma77_static>ma77_small. ma77_static=0.0 disables static pivoting.

Range: [0, ∞]
Default: 0

**ma77_u:** Pivoting Threshold ↔

See MA77 documentation.

Range: [0, 0.5]
Default: 1e-08

**ma77_umax:** Maximum Pivoting Threshold ↔

Maximum value to which u will be increased to improve quality.

Range: [0, 0.5]
Default: 0.0001

**ma86_nemin:** Node Amalgamation parameter ↔

Two nodes in elimination tree are merged if result has fewer than ma86_nemin variables.

Range: {1, ..., ∞}
Default: 32

**ma86_order:** Controls type of ordering ↔

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tbody>
</table>
Default: mc64

**ma86_small**: Zero Pivot Threshold

Any pivot less than ma86_small is treated as zero.

Range: \([0, \infty]\)

Default: 1e-20

**ma86Static**: Static Pivoting Threshold

See MA86 documentation. Either ma86_static=0.0 or ma86_static>ma86_small. ma86_static=0.0 disables static pivoting.

Range: \([0, \infty]\)

Default: 0

**ma86_u**: Pivoting Threshold

See MA86 documentation.

Range: \([0, 0.5]\)

Default: 1e-08

**ma86_umax**: Maximum Pivoting Threshold

Maximum value to which u will be increased to improve quality.

Range: \([0, 0.5]\)

Default: 0.0001

**ma97_nemin**: Node Amalgamation parameter

Two nodes in elimination tree are merged if result has fewer than ma97_nemin variables.

Range: \(\{1, ..., \infty\}\)

Default: 8

**ma97_order**: Controls type of ordering

<tr>
<td>od_hd</td>
<td>Combination of on_demand and high_delay</td>
</tr>
<tr>
<td>od_hd_reuse</td>
<td>Combination of on_demand_reuse and high_delay_reuse</td>
</tr>
</tbody>
</table>

Default: never

**ma97_u**: Pivoting Threshold

See MA97 documentation.

Range: [0, 0.5]

Default: 1e-08

**ma97_umax**: Maximum Pivoting Threshold

See MA97 documentation.

Range: [0, 0.5]

Default: 0.0001

**max_cpu_time**: Maximum number of CPU seconds.
A limit on CPU seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding message.

Range: \((0, \infty]\)
Default: \(1e+20\)

**max_filter_resets** *(advanced)*: Maximal allowed number of filter resets

A positive number enables a heuristic that resets the filter, whenever in more than "filter_reset_trigger" successive iterations the last rejected trial steps size was rejected because of the filter. This option determine the maximal number of resets that are allowed to take place.

Range: \(\{0, ..., \infty\}\)
Default: 5

**max_hessian_perturbation**: Maximum value of regularization parameter for handling negative curvature.

In order to guarantee that the search directions are indeed proper descent directions, Ipopt requires that the inertia of the (augmented) linear system for the step computation has the correct number of negative and positive eigenvalues. The idea is that this guides the algorithm away from maximizers and makes Ipopt more likely converge to first order optimal points that are minimizers. If the inertia is not correct, a multiple of the identity matrix is added to the Hessian of the Lagrangian in the augmented system. This parameter gives the maximum value of the regularization parameter. If a regularization of that size is not enough, the algorithm skips this iteration and goes to the restoration phase. This is \(\delta_w^{\max}\) in the implementation paper.

Range: \((0, \infty]\)
Default: \(1e+20\)

**max_iter**: Maximum number of iterations.

The algorithm terminates with a message if the number of iterations exceeded this number.

Range: \(\{0, ..., \infty\}\)
Default: GAMS iterlim

**max_refinement_steps**: Maximum number of iterative refinement steps per linear system solve.

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the maximum number of iterative refinement steps.

Range: \(\{0, ..., \infty\}\)
Default: 10

**max_resto_iter** *(advanced)*: Maximum number of successive iterations in restoration phase.

The algorithm terminates with an error message if the number of iterations successively taken in the restoration phase exceeds this number.

Range: \(\{0, ..., \infty\}\)
Default: 3000000
max_soc: Maximum number of second order correction trial steps at each iteration. 

Choosing 0 disables the second order corrections. This is p^{\text{max}} of Step A-5.9 of Algorithm A in the implementation paper.

Range: \{0, ..., \infty\}

Default: 4

max_soft_resto_iters (advanced): Maximum number of iterations performed successively in soft restoration phase.

If the soft restoration phase is performed for more than so many iterations in a row, the regular restoration phase is called.

Range: \{0, ..., \infty\}

Default: 10

max_wall_time: Maximum number of walltime clock seconds.

A limit on walltime clock seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding message.

Range: (0, \infty]

Default: GAMS reslim

mehrotra_algorithm: Indicates whether to do Mehrotra's predictor-corrector algorithm.

If enabled, line search is disabled and the (unglobalized) adaptive mu strategy is chosen with the "probing" oracle, and "corrector_type=affine" is used without any safeguards; you should not set any of those options explicitly in addition. Also, unless otherwise specified, the values of "bound_push", "bound_frac", and "bound_mult_init_val" are set more aggressive, and sets "alpha_for_y=bound_mult". The Mehrotra's predictor-corrector algorithm works usually very well for LPs and convex QPs.

Range: yes, no

Default: no

min_hessian_perturbation: Smallest perturbation of the Hessian block.

The size of the perturbation of the Hessian block is never selected smaller than this value, unless no perturbation is necessary. This is delta_w^{\text{min}} in implementation paper.

Range: [0, \infty]

Default: 1e-20

min_refinement_steps: Minimum number of iterative refinement steps per linear system solve.

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the minimum number of iterative refinements (i.e. at least "min_refinement_steps" iterative refinement steps are enforced per right hand side.)

Range: \{0, ..., \infty\}

Default: 1

mu_allow_fast_monotone_decrease (advanced): Allow skipping of barrier problem if barrier test is already met.
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Take at least one iteration per barrier problem even if the barrier test is already met for the updated barrier parameter</td>
</tr>
<tr>
<td>yes</td>
<td>Allow fast decrease of mu if barrier test it met</td>
</tr>
</tbody>
</table>

Default: yes

**mu_init**: Initial value for the barrier parameter. ←

This option determines the initial value for the barrier parameter (mu). It is only relevant in the monotone, Fiacco-McCormick version of the algorithm. (i.e., if "mu_strategy" is chosen as "monotone")

Range: $$(0, \infty)$$

Default: 0.1

**mu_linear_decrease_factor**: Determines linear decrease rate of barrier parameter. ←

For the Fiacco-McCormick update procedure the new barrier parameter mu is obtained by taking the minimum of $\mu \times \text{mu_linear_decrease_factor}$ and $\mu^{\text{superlinear_decrease_power}}$. This is kappa_mu in implementation paper. This option is also used in the adaptive mu strategy during the monotone mode.

Range: $$(0, 1)$$

Default: 0.2

**mu_max**: Maximum value for barrier parameter. ←

This option specifies an upper bound on the barrier parameter in the adaptive mu selection mode. If this option is set, it overwrites the effect of mu_max_fact. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: $$(0, \infty)$$

Default: 100000

**mu_max_fact**: Factor for initialization of maximum value for barrier parameter. ←

This option determines the upper bound on the barrier parameter. This upper bound is computed as the average complementarity at the initial point times the value of this option. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: $$(0, \infty)$$

Default: 1000

**mu_min**: Minimum value for barrier parameter. ←

This option specifies the lower bound on the barrier parameter in the adaptive mu selection mode. By default, it is set to the minimum of 1e-11 and min("tol","compl_inf_tol")/("barrier_tol_factor"+1), which should be a reasonable value. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: $$(0, \infty)$$

Default: 1e-11

**mu_oracle**: Oracle for a new barrier parameter in the adaptive strategy. ←

Determines how a new barrier parameter is computed in each "free-mode" iteration of the adaptive barrier parameter strategy. (Only considered if "adaptive" is selected for option "mu_strategy").
5.20 IPOPT and IPOPTH

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>probing</td>
<td>Mehrotra's probing heuristic</td>
</tr>
<tr>
<td>logq</td>
<td>LOQO's centrality rule</td>
</tr>
<tr>
<td>quality-function</td>
<td>minimize a quality function</td>
</tr>
</tbody>
</table>

Default: quality-function

**mu_strategy**: Update strategy for barrier parameter. ➔

Determines which barrier parameter update strategy is to be used.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>monotone</td>
<td>use the monotone (Fiacco-McCormick) strategy</td>
</tr>
<tr>
<td>adaptive</td>
<td>use the adaptive update strategy</td>
</tr>
</tbody>
</table>

Default: adaptive

**mu_superlinear_decrease_power**: Determines superlinear decrease rate of barrier parameter. ➔

For the Fiacco-McCormick update procedure the new barrier parameter mu is obtained by taking the minimum of \( \mu^*\mu_{\text{linear\_decrease\_factor}} \) and \( \mu^\theta \mu_{\text{superlinear\_decrease\_power}} \). This is \( \theta \mu \) in implementation paper. This option is also used in the adaptive mu strategy during the monotone mode.

Range: \((1, 2)\)

Default: 1.5

**mu_target**: Desired value of complementarity. ➔

Usually, the barrier parameter is driven to zero and the termination test for complementarity is measured with respect to zero complementarity. However, in some cases it might be desired to have Ipopt solve barrier problem for strictly positive value of the barrier parameter. In this case, the value of “mu_target” specifies the final value of the barrier parameter, and the termination tests are then defined with respect to the barrier problem for this value of the barrier parameter.

Range: \([0, \infty]\)

Default: 0

**mumps dep tol** *(advanced)*: Threshold to consider a pivot at zero in detection of linearly dependent constraints with MUMPS. ➔

This is CNTL(3) in MUMPS.

Range: real

Default: 0

**mumps_mem_percent**: Percentage increase in the estimated working space for MUMPS. ➔
When significant extra fill-in is caused by numerical pivoting, larger values of `mumps_mem_percent` may help use the workspace more efficiently. On the other hand, if memory requirements are too large at the very beginning of the optimization, choosing a much smaller value for this option, such as 5, might reduce memory requirements.

Range: \( \{0, \ldots, \infty\} \)
Default: 1000

**mumps_permutingscaling:** Controls permuting and scaling in MUMPS

This is ICNTL(6) in MUMPS.

Range: \( \{0, \ldots, 7\} \)
Default: 7

**mumps_pivot_order:** Controls pivot order in MUMPS

This is ICNTL(7) in MUMPS.

Range: \( \{0, \ldots, 7\} \)
Default: 7

**mumps_pivtol:** Pivot tolerance for the linear solver MUMPS

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: \([0, 1]\)
Default: 1e-06

**mumps_pivtolmax:** Maximum pivot tolerance for the linear solver MUMPS

Ipopt may increase pivtol as high as pivtolmax to get a more accurate solution to the linear system.

Range: \([0, 1]\)
Default: 0.1

**mumps_print_level:** Debug printing level for the linear solver MUMPS

0: no printing; 1: Error messages only; 2: Error, warning, and main statistic messages; 3: Error and warning messages and terse diagnostics; \( \geq 4\): All information.

Range: \( \{0, \ldots, \infty\} \)
Default: 0

**mumps_scaling:** Controls scaling in MUMPS

This is ICNTL(8) in MUMPS.

Range: \([-2, \ldots, 77]\)
Default: 77

**neg_curv_test_reg:** Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).
5.20 IPOPT and IPOPTH

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>yes</td>
<td>use primal regularization with the inertia-free curvature test</td>
</tr>
<tr>
<td>no</td>
<td>use original IPOPT approach, in which the primal regularization is ignored</td>
</tr>
</tbody>
</table>

Default: yes

**neg_curv_test_tol**: Tolerance for heuristic to ignore wrong inertia. 

If nonzero, incorrect inertia in the augmented system is ignored, and Ipopt tests if the direction is a direction of positive curvature. This tolerance is alpha_n in the paper by Zavala and Chiang (2014) and it determines when the direction is considered to be sufficiently positive. A value in the range of [1e-12, 1e-11] is recommended.

Range: \([0, \infty]\)

Default: 0

**nlp_scaling_constr_target_gradient** *(advanced)*: Target value for constraint function gradient size.

If a positive number is chosen, the scaling factors for the constraint functions are computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max_gradient for the constraint functions.

Range: \([0, \infty]\)

Default: 0

**nlp_scaling_max_gradient**: Maximum gradient after NLP scaling.

This is the gradient scaling cut-off. If the maximum gradient is above this value, then gradient based scaling will be performed. Scaling parameters are calculated to scale the maximum gradient back to this value. (This is \(g_{\text{max}}\) in Section 3.8 of the implementation paper.) Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Range: \((0, \infty]\)

Default: 100

**nlp_scaling_method**: Select the technique used for scaling the NLP.

Selects the technique used for scaling the problem internally before it is solved. For user-scaling, the parameters come from the NLP.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>no problem scaling will be performed</td>
</tr>
<tr>
<td>gradient-based</td>
<td>scale the problem so the maximum gradient at the starting point is (nlp_scaling_max_gradient)</td>
</tr>
<tr>
<td>equilibration-based</td>
<td>scale the problem so that first derivatives are of order 1 at random points (GAMS/Ipopt: requires user-provided library with HSL routine MC19)</td>
</tr>
</tbody>
</table>

Default: gradient-based if GAMS scaleopt is not set, otherwise none

**nlp_scaling_min_value**: Minimum value of gradient-based scaling values.
This is the lower bound for the scaling factors computed by gradient-based scaling method. If some derivatives of some functions are huge, the scaling factors will otherwise become very small, and the (unscaled) final constraint violation, for example, might then be significant. Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Range: [0, \infty]
Default: 1e-08

\textbf{nlp\_scaling\_obj\_target\_gradient (advanced):} Target value for objective function gradient size. 

If a positive number is chosen, the scaling factor for the objective function is computed so that the gradient has the max norm of the given size at the starting point. This overrides \texttt{nlp\_scaling\_max\_gradient} for the objective function.

Range: [0, \infty]
Default: 0

\textbf{nu\_inc (advanced):} Increment of the penalty parameter.

Range: (0, \infty]
Default: 0.0001

\textbf{nu\_init (advanced):} Initial value of the penalty parameter.

Range: (0, \infty]
Default: 1e-06

\textbf{obj\_max\_inc (advanced):} Determines the upper bound on the acceptable increase of barrier objective function.

Trial points are rejected if they lead to an increase in the barrier objective function by more than \texttt{obj\_max\_inc} orders of magnitude.

Range: (1, \infty]
Default: 5

\textbf{pardiso\_iter\_coarse\_size (advanced):} Maximum Size of Coarse Grid Matrix

DPARM(3)
Range: \{1, ..., \infty\}
Default: 5000

\textbf{pardiso\_iter\_dropping\_factor (advanced):} dropping value for incomplete factor

DPARM(5)
Range: (0, 1)
Default: 0.5

\textbf{pardiso\_iter\_dropping\_schur (advanced):} dropping value for sparsify schur complement factor
DPARM(6)
Range: (0, 1)
Default: 0.1

**pardiso_iter_inverse_norm_factor** *(advanced):* \( \leftarrow \)

DPARM(8)
Range: \((1, \infty]\)
Default: 5e+06

**pardiso_iter_max_levels** *(advanced):* Maximum Size of Grid Levels \( \leftarrow \)

DPARM(4)
Range: \(\{1, \ldots, \infty\}\)
Default: 10

**pardiso_iter_max_row_fill** *(advanced):* max fill for each row \( \leftarrow \)

DPARM(7)
Range: \(\{1, \ldots, \infty\}\)
Default: 10000000

**pardiso_iter_relative_tol** *(advanced):* Relative Residual Convergence \( \leftarrow \)

DPARM(2)
Range: (0, 1)
Default: 1e-06

**pardiso_iterative** *(advanced):* Switch for iterative solver in Pardiso library \( \leftarrow \)

Range: yes, no
Default: no

**pardiso_matching_strategy**:
Matching strategy to be used by Pardiso \( \leftarrow \)

This is IPAR(13) in Pardiso manual.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>complete</td>
<td>Match complete (IPAR(13)=1)</td>
</tr>
<tr>
<td>complete+2x2</td>
<td>Match complete+2x2 (IPAR(13)=2)</td>
</tr>
<tr>
<td>constraints</td>
<td>Match constraints (IPAR(13)=3)</td>
</tr>
</tbody>
</table>

Default: complete+2x2
**pardiso_max_droptol_corrections** *(advanced):* Maximal number of decreases of drop tolerance during one solve.  

This is relevant only for iterative Pardiso options.

Range: \{1, ..., ∞\}

Default: 4

**pardiso_max_iter** *(advanced):* Maximum number of Krylov-Subspace Iteration  

DPARM(1)

Range: \{1, ..., ∞\}

Default: 500

**pardiso_max_iterative_refinement_steps**: Limit on number of iterative refinement steps.  

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: \{-∞, ..., ∞\}

Default: 0

**pardiso_msglvl**: Pardiso message level  

This is MSGlvl in the Pardiso manual.

Range: \{0, ..., ∞\}

Default: 0

**pardiso_order**: Controls the fill-in reduction ordering algorithm for the input matrix.

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>yes</td>
<td>Only redo symbolic factorization when elements were perturbed if also the inertia was wrong</td>
</tr>
</tbody>
</table>

Default: no

**pardiso_repeated_perturbation_means_singular** *(advanced):* Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization. 

Range: yes, no

Default: no

**pardiso_skip_inertia_check** *(advanced):* Whether to pretend that inertia is correct. 

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

**pardisolib:** Name of library containing Pardiso routines (from pardiso-project.org) for load at runtime

Range: string

Default: libpardiso.so (Linux), libpardiso.dylib (macOS), libpardiso.dll (Windows)

**pardismkl_matching_strategy:** Matching strategy to be used by Pardiso

This is IPAR(13) in Pardiso manual.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>complete</td>
<td>Match complete (IPAR(13)=1)</td>

<td>Match constraints (IPAR(13)=3)</td>
</tr>
</tbody>
</table>

Default: complete+2x2

**pardismkl_max_iterative_refinement_steps:** Limit on number of iterative refinement steps.

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: \(-\infty, ..., \infty\)

Default: 1

**pardismkl_msglvl:** Pardiso message level
This is MSGLVL in the Pardiso manual.

Range: \( \{0, \ldots, \infty\} \)

Default: 0

**pardisomkl_order**: Controls the fill-in reduction ordering algorithm for the input matrix.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>amd</td>
<td>minimum degree algorithm</td>
</tr>
<tr>
<td>one</td>
<td>undocumented</td>
</tr>
<tr>
<td>metis</td>
<td>MeTiS nested dissection algorithm</td>

<tr>
<td>pmetis</td>
<td>parallel (OpenMP) version of MeTiS nested dissection algorithm</td>
</tr>
</tbody>
</table>

Default: metis

**pardisomkl_redo_symbolic_fact_only_if_inertia_wrong (advanced)**: Toggle for handling case when elements were perturbed by Pardiso.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Always redo symbolic factorization when elements were perturbed</td>
</tr>
<tr>
<td>yes</td>
<td>Only redo symbolic factorization when elements were perturbed if also the inertia was wrong</td>
</tr>
</tbody>
</table>

Default: no

**pardisomkl_repeated_perturbation_means_singular (advanced)**: Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization.

Range: yes, no

Default: no

**pardisomkl_skip_inertia_check (advanced)**: Whether to pretend that inertia is correct.

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

**perturb_always_cd (advanced)**: Active permanent perturbation of constraint linearization.

Enabling this option leads to using the \( \delta_c \) and \( \delta_d \) perturbation for the computation of every search direction. Usually, it is only used when the iteration matrix is singular.

Range: yes, no

Default: no

**perturb_dec_fact**: Decrease factor for x-s perturbation.
The factor by which the perturbation is decreased when a trial value is deduced from the size of the most recent successful perturbation. This is kappa_w^- in the implementation paper.

Range: (0, 1)
Default: 0.333333

perturb_inc_fact: Increase factor for x-s perturbation. ←

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of all perturbations except for the first. This is kappa_w^+ in the implementation paper.

Range: (1, ∞]
Default: 8

perturb_inc_fact_first: Increase factor for x-s perturbation for very first perturbation. ←

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of the very first perturbation and allows a different value for the first perturbation than that used for the remaining perturbations. This is bar_kappa_w^+ in the implementation paper.

Range: (1, ∞]
Default: 100

print_advanced_options (advanced): whether to print also advanced options ←

Range: yes, no
Default: no

print_eval_error: Switch to enable printing information about function evaluation errors into the GAMS listing file. ←

Range: no, yes
Default: yes

print_frequency_iter: Determines at which iteration frequency the summarizing iteration output line should be printed. ←

Summarizing iteration output is printed every print_frequency_iter iterations, if at least print_frequency_time seconds have passed since last output.

Range: \{1, ..., ∞\}
Default: 1

print_frequency_time: Determines at which time frequency the summarizing iteration output line should be printed. ←

Summarizing iteration output is printed if at least print_frequency_time seconds have passed since last output and the iteration number is a multiple of print_frequency_iter.

Range: [0, ∞]
Default: 0
**print_info_string**: Enables printing of additional info string at end of iteration output.  

This string contains some insider information about the current iteration. For details, look for "Diagnostic Tags" in the Ipopt documentation.

Range: yes, no

Default: no

**print_level**: Output verbosity level.  

Sets the default verbosity level for console output. The larger this value the more detailed is the output.

Range: \{0, ..., 12\}

Default: 5

**print_options_mode**: format in which to print options documentation  

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>Ordinary text</td>
</tr>
<tr>
<td>latex</td>
<td>LaTeX formatted</td>
</tr>
<tr>
<td>doxygen</td>
<td>Doxygen (markdown) formatted</td>
</tr>
</tbody>
</table>

Default: text

**print_timing_statistics**: Switch to print timing statistics.  

If selected, the program will print the time spend for selected tasks. This implies timing_statistics=yes.

Range: yes, no

Default: no

**quality_function_balancing_term** *(advanced)*: The balancing term included in the quality function for centrality.  

This determines whether a term is added to the quality function that penalizes situations where the complementarity is much smaller than dual and primal infeasibilities. Only used if option "mu_oracle" is set to "quality-function".

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>no balancing term is added</td>
</tr>
<tr>
<td>cubic</td>
<td>$\text{Max}(0,\text{Max}(\text{dual inf, primal inf})-\text{compl})^3$</td>
</tr>
</tbody>
</table>

Default: none

**quality_function_centrality** *(advanced)*: The penalty term for centrality that is included in quality function.  

This determines whether a term is added to the quality function to penalize deviation from centrality with respect to complementarity. The complementarity measure here is the $\text{x}_i$ in the Loqo update rule. Only used if option "mu_oracle" is set to "quality-function".

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>no balancing term is added</td>
</tr>
<tr>

Default: none

**quality_function_max_section_steps**: Maximum number of search steps during direct search procedure determining the optimal centering parameter. 

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: \{0, ..., \infty\}

Default: 8

**quality_function_norm_type (advanced)**: Norm used for components of the quality function.

Only used if option "mu_oracle" is set to "quality-function".

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-norm</td>
<td>use the 1-norm (abs sum)</td>
</tr>
<tr>

</tr>
<tr>
<td>max-norm</td>
<td>use the infinity norm (max)</td>
</tr>
<tr>
<td>2-norm</td>
<td>use 2-norm</td>
</tr>
</tbody>
</table>

Default: 2-norm-squared

**quality_function_section_qf_tol (advanced)**: Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space).

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: [0, 1)

Default: 0

**quality_function_section_sigma_tol (advanced)**: Tolerance for the section search procedure determining the optimal centering parameter (in sigma space).

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: [0, 1)

Default: 0.01

**recale_y**: Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates.

This asks the algorithm to recompute the multipliers, whenever the current infeasibility is less than reccale_y_feas_tol. Choosing yes might be helpful in the quasi-Newton option. However, each recalculation requires an extra factorization of the linear system. If a limited memory quasi-Newton option is chosen, this is used by default.
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>use the Newton step to update the multipliers</td>
</tr>
<tr>
<td>yes</td>
<td>use least-square multiplier estimates</td>
</tr>
</tbody>
</table>

Default: no

**recale_y_feas_tol**: Feasibility threshold for recomputation of multipliers.  

If recalc_y is chosen and the current infeasibility is less than this value, then the multipliers are recomputed.

Range: $(0, \infty)$

Default: $1e-06$

**replace_bounds** *(advanced)*: Whether all variable bounds should be replaced by inequality constraints

This option must be set for the inexact algorithm.

Range: yes, no

Default: no

**report_mininfeas_solution**: Switch to report intermediate solution with minimal constraint violation to GAMS if the final solution is not feasible.

This option allows to obtain the most feasible solution found by Ipopt during the iteration process, if it stops at a (locally) infeasible solution, due to a limit (time, iterations, ...), or with a failure in the restoration phase.

Range: no, yes

Default: no

**required_infeasibility_reduction**: Required reduction of infeasibility before leaving restoration phase.

The restoration phase algorithm is performed, until a point is found that is acceptable to the filter and the infeasibility has been reduced by at least the fraction given by this option.

Range: $[0, 1)$

Default: 0.9

**residual_improvement_factor** *(advanced)*: Minimal required reduction of residual test ratio in iterative refinement.

If the improvement of the residual test ratio made by one iterative refinement step is not better than this factor, iterative refinement is aborted.

Range: $(0, \infty]$  

Default: 1

**residual_ratio_max** *(advanced)*: Iterative refinement tolerance
Iterative refinement is performed until the residual test ratio is less than this tolerance (or until "max_refinement_steps" refinement steps are performed).

Range: \((0, \infty]\)

Default: 1e-10

**residual_ratio_singular** *(advanced)*: Threshold for declaring linear system singular after failed iterative refinement. ⇐

If the residual test ratio is larger than this value after failed iterative refinement, the algorithm pretends that the linear system is singular.

Range: \((0, \infty]\)

Default: 1e-05

**resto_failure_feasibility_threshold** *(advanced)*: Threshold for primal infeasibility to declare failure of restoration phase. ⇐

If the restoration phase is terminated because of the "acceptable" termination criteria and the primal infeasibility is smaller than this value, the restoration phase is declared to have failed. The default value is actually \(1e2 \times \text{tol}\), where \(\text{tol}\) is the general termination tolerance.

Range: \([0, \infty]\)

Default: 0

**resto_penalty_parameter** *(advanced)*: Penalty parameter in the restoration phase objective function. ⇐

This is the parameter \(\rho\) in equation (31a) in the Ipopt implementation paper.

Range: \((0, \infty]\)

Default: 1000

**resto_proximity_weight** *(advanced)*: Weighting factor for the proximity term in restoration phase objective. ⇐

This determines how the parameter \(\zeta\) in equation (29a) in the implementation paper is computed. \(\zeta\) here is \(\text{resto_proximity_weight} \times \sqrt{\mu}\), where \(\mu\) is the current barrier parameter.

Range: \([0, \infty]\)

Default: 1

**rho** *(advanced)*: Value in penalty parameter update formula. ⇐

Range: \((0, 1]\)

Default: 0.1

**s_max** *(advanced)*: Scaling threshold for the NLP error. ⇐
See paragraph after Eqn. (6) in the implementation paper.

Range: \((0, \infty]\)

Default: 100

**s_phi** *(advanced) :* Exponent for linear barrier function model in the switching rule.

See Eqn. (19) in the implementation paper.

Range: \((1, \infty]\)

Default: 2.3

**s_theta** *(advanced) :* Exponent for current constraint violation in the switching rule.

See Eqn. (19) in the implementation paper.

Range: \((1, \infty]\)

Default: 1.1

**sigma_max** *(advanced) :* Maximum value of the centering parameter.

This is the upper bound for the centering parameter chosen by the quality function based barrier parameter update. Only used if option "mu_oracle" is set to "quality-function".

Range: \((0, \infty]\)

Default: 100

**sigma_min** *(advanced) :* Minimum value of the centering parameter.

This is the lower bound for the centering parameter chosen by the quality function based barrier parameter update. Only used if option "mu_oracle" is set to "quality-function".

Range: \([0, \infty]\)

Default: 1e-06

**skip_corr_if_neg_curv** *(advanced) :* Whether to skip the corrector step in negative curvature iteration.

The corrector step is not tried if negative curvature has been encountered during the computation of the search direction in the current iteration. This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Range: yes, no

Default: yes

**skip_corr_in_monotone_mode** *(advanced) :* Whether to skip the corrector step during monotone barrier parameter mode.

The corrector step is not tried if the algorithm is currently in the monotone mode (see also option "barrier_strategy"). This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Range: yes, no

Default: yes
**slack_bound_frac**: Desired minimum relative distance from the initial slack to bound.  

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)  

Range: (0, 0.5]  
Default: 0.01

**slack_bound_push**: Desired minimum absolute distance from the initial slack to bound.  

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)  

Range: (0, \infty]  
Default: 0.01

**slack_move** *(advanced)*: Correction size for very small slacks.  

Due to numerical issues or the lack of an interior, the slack variables might become very small. If a slack becomes very small compared to machine precision, the corresponding bound is moved slightly. This parameter determines how large the move should be. Its default value is `mach_\text{eps}^{3/4}`. See also end of Section 3.5 in implementation paper - but actual implementation might be somewhat different.  

Range: [0, \infty]  
Default: 1.81899e-12

**soc_method**: Ways to apply second order correction  

This option determines the way to apply second order correction. 0 is the method described in the implementation paper. 1 is the modified way which adds alpha on the rhs of x and s rows.  

Range: \{0, ..., 1\}  
Default: 0

**soft_resto_pdeerror_reduction_factor**: Required reduction in primal-dual error in the soft restoration phase.  

The soft restoration phase attempts to reduce the primal-dual error with regular steps. If the damped primal-dual step (damped only to satisfy the fraction-to-the-boundary rule) is not decreasing the primal-dual error by at least this factor, then the regular restoration phase is called. Choosing “0” here disables the soft restoration phase.  

Range: [0, \infty]  
Default: 0.9999

**start_with_resto**: Whether to switch to restoration phase in first iteration.  

Setting this option to “yes” forces the algorithm to switch to the feasibility restoration phase in the first iteration. If the initial point is feasible, the algorithm will abort with a failure.  

Range: yes, no  
Default: no
**tau_min** *(advanced)*: Lower bound on fraction-to-the-boundary parameter tau. 

This is tau_min in the implementation paper. This option is also used in the adaptive mu strategy during the monotone mode.

Range: (0, 1)
Default: 0.99

**theta_max_fact** *(advanced)*: Determines upper bound for constraint violation in the filter. 

The algorithmic parameter theta_max is determined as theta_max_fact times the maximum of 1 and the constraint violation at initial point. Any point with a constraint violation larger than theta_max is unacceptable to the filter (see Eqn. (21) in the implementation paper).

Range: (0, \( \infty \)]
Default: 10000

**theta_min_fact** *(advanced)*: Determines constraint violation threshold in the switching rule. 

The algorithmic parameter theta_min is determined as theta_min_fact times the maximum of 1 and the constraint violation at initial point. The switching rules treats an iteration as an h-type iteration whenever the current constraint violation is larger than theta_min (see paragraph before Eqn. (19) in the implementation paper).

Range: (0, \( \infty \)]
Default: 0.0001

**timing_statistics**: Indicates whether to measure time spend in components of Ipopt and NLP evaluation.

The overall algorithm time is unaffected by this option.

Range: yes, no
Default: no

**tiny_step_tol** *(advanced)*: Tolerance for detecting numerically insignificant steps. 

If the search direction in the primal variables (x and s) is, in relative terms for each component, less than this value, the algorithm accepts the full step without line search. If this happens repeatedly, the algorithm will terminate with a corresponding exit message. The default value is 10 times machine precision.

Range: [0, \( \infty \)]
Default: 2.22045e-15

**tiny_step_y_tol** *(advanced)*: Tolerance for quitting because of numerically insignificant steps. 

If the search direction in the primal variables (x and s) is, in relative terms for each component, repeatedly less than tiny_step_tol, and the step in the y variables is smaller than this threshold, the algorithm will terminate.

Range: [0, \( \infty \)]
Default: 0.01
5.20 IPOPT and IPOPTH

**tol**: Desired convergence tolerance (relative).

Determines the convergence tolerance for the algorithm. The algorithm terminates successfully, if the (scaled) NLP error becomes smaller than this value, and if the (absolute) criteria according to "dual_inf_tol", "constr_viol_tol", and "compl_inf_tol" are met. This is epsilon_tol in Eqn. (6) in implementation paper. See also "acceptable_tol" as a second termination criterion. Note, some other algorithmic features also use this quantity to determine thresholds etc.

Range: $(0, \infty]$

Default: $1e^{-08}$

**warm_start_bound_frac**: same as bound_frac for the regular initializer

Range: $(0, 0.5]$.

Default: $0.001$

**warm_start_bound_push**: same as bound_push for the regular initializer

Range: $(0, \infty]$

Default: $0.001$

**warm_start_init_point**: Warm-start for initial point

Indicates whether this optimization should use a warm start initialization, where values of primal and dual variables are given (e.g., from a previous optimization of a related problem.)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>do not use the warm start initialization</td>
</tr>
<tr>
<td>yes</td>
<td>use the warm start initialization</td>
</tr>
</tbody>
</table>

Default: yes, if run on modified model instance (e.g., from GUSS), otherwise no

**warm_start_mult_bound_push**: same as mult_bound_push for the regular initializer

Range: $(0, \infty]$

Default: $0.001$

**warm_start_mult_init_max**: Maximum initial value for the equality multipliers.

Range: real

Default: $1e+06$

**warm_start_slack_bound_frac**: same as slack_bound_frac for the regular initializer

Range: $(0, 0.5]$

Default: $0.001$

**warm_start_slack_bound_push**: same as slack_bound_push for the regular initializer
Range: \((0, \infty]\)
Default: 0.001

**warm_start_target_mu (advanced):** \(\leftarrow\)

Experimental!

Range: real
Default: 0

**watchdog_shortened_iter_trigger:** Number of shortened iterations that trigger the watchdog. \(\leftarrow\)

If the number of successive iterations in which the backtracking line search did not accept the first trial point exceeds this number, the watchdog procedure is activated. Choosing "0" here disables the watchdog procedure.

Range: \(\{0, \ldots, \infty\}\)
Default: 10

**watchdog_trial_iter_max:** Maximum number of watchdog iterations. \(\leftarrow\)

This option determines the number of trial iterations allowed before the watchdog procedure is aborted and the algorithm returns to the stored point.

Range: \(\{1, \ldots, \infty\}\)
Default: 3

### 5.21 JAMS and LogMIP

#### 5.21.1 Introduction

EMP (Extended Mathematical Programming) is not a solver but an (experimental) framework for automated mathematical programming reformulations. The idea behind EMP is that new upcoming types of models which currently cannot be solved reliably are reformulated into models of established math programming classes in order to use mature solver technology. At this stage, EMP supports the modeling of Bilevel Programs, Variational Inequalities, Disjunctive Programs, Extended Nonlinear Programs and Embedded Complementarity Systems.

Extended mathematical programs are collections of functions and variables joined together using specific optimization and complementarity primitives. EMP annotates the existing relationships within a model to facilitate higher level structure identification. A specific implementation of this framework is outlined that reformulates the original GAMS model automatically using directives contained in an "empinfo" file into an equivalent model that can be solved using existing GAMS solvers.

The reformulation is done by the solver JAMS which currently is the only solver that is capable of handling EMP models. Examples showing how to use the EMP framework and the solver JAMS are made available through the GAMS EMP Library which is included in the GAMS Distribution. In order to generate a copy of and EMPLIB model, one can use the library facility of the GAMS IDE, or execute the command line directive `emplib <modelname>`, where modelname is the (stem of the) file containing the model.

EMP has been developed jointly by Michael Ferris of UW-Madison, Ignacio Grossmann of Carnegie Mellon University, and GAMS Development Corporation. EMP and JAMS come free of charge with any licensed GAMS system but require a subsolver to solve the generated models.
5.21.2 JAMS: a reformulation tool

EMP models are currently processed by the JAMS solver. The solver JAMS creates a scalar version of the given GAMS model. This scalar version of the model is then solved by an appropriate subsolver. By default, there are no reformulations carried out, so the model generated is simply a GAMS scalar form of the model the actual subsolver will process. The subsolver used is by default the currently specified solver for the given model type.

5.21.2.1 The JAMS Option File

As with any GAMS solver, JAMS has an option file, typically called jams.opt. A JAMS option subsolver is available to change the subsolver used for the reformulated model, along with an option to utilize a subsolver option file (subsolveropt).

The actual scalar version of the model can also be seen by the modeler using the option filename. For example, the option file

```
subsolver path
subsolveropt 1
filename mcpmod.gms
```

when applied to an EMP model that is a complementarity problem will create a file called mcpmod.gms in the current directory and solve that model using the solver PATH utilizing any options for PATH that are specified in path.opt. The scalarized model is not particularly useful to look at since all of the original variables have been renamed into a scalar form. The mapping between original variables and the ones used in the scalar version of the model is given in a dictionary file that can also be seen by the modeler using the dict option. If a user simply wants to generate this scalar model, then the option terminate will not solve the generated model.

After the scalar version of the model is solved, the solution values are mapped back into the original namespace and returned to the modeler as usual in the listing file. The JAMS option margtol allows the modeler to suppress reporting marginals that have (absolute) values smaller than this tolerance.

Obviously, all of the above functionality is not of much value: the key part of JAMS is to interpret additional directives to take the original model and produce a reformulated scalar model. This is carried out using an “empinfo” file. The syntax and use of this file is the content of the remaining sections of this document.

The option EMPInfoFile allows the user to specify the path and name of a file containing additional EMP information. The syntax of this file is described by examples elsewhere in this document and in section Empinfo file details. There is a subtlety that should be mentioned when a user writes this file in the default location in the GAMS scratch directory of the current run specified in the gams file using:

```
file empinfo / '%emp.info%' /;
```

wherein certain additional formatting instructions are given. If instead, the file handle is given by:

```
file empinfo / 'empinfo.txt' /;
```

for example, then to produce the same file the following lines must be added to the gams source file:

```
empinfo.pc = 8;
empinfo.pw = 255;
```

The following tables list all available options.

5.21.2.2 Reformulation Options
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>KeepObj</td>
<td>Keep original objective function and variables in generated MCP model. This option is only valid for reformulations into complementarity systems. If KeepObj is set the generated MCP program will incorporate the original objective function and the Karush-Kuhn-Tucker condition of the original objective variable.</td>
<td>0</td>
</tr>
<tr>
<td>MargTol</td>
<td>Only report marginals with an absolute value above the tolerance</td>
<td>1e-6</td>
</tr>
<tr>
<td>ObjVarName</td>
<td>Name of objective variable in generated model.</td>
<td>objvar</td>
</tr>
</tbody>
</table>

#### 5.21.2.3 General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompModel</td>
<td>Complementarity model (MCP or VI) to generate for equilibrium problems.</td>
<td>mcp</td>
</tr>
<tr>
<td>Dict</td>
<td>Generate a dictionary file that maps original variable and equation names to the ones of the scalar JAMS model.</td>
<td>dict.txt</td>
</tr>
<tr>
<td>DisjBinRelax</td>
<td>Relax requirement that disjunction variables are binary.</td>
<td>0</td>
</tr>
<tr>
<td>EMPInfoFile</td>
<td>Path and name of file containing additional EMP information as disjunctions, perpendiculares, bilevel characterization etc. By default, the file is expected to exist in the GAMS scratch directory of the current run (gams.scrdir). If this option is used, EMP searches for the file based on the provided relative or absolute path. In case of a given relative path, it is assumed to be relative to the working directory.</td>
<td></td>
</tr>
<tr>
<td>FileName</td>
<td>Filename of generated scalar reformulated GAMS model.</td>
<td>emp.gms</td>
</tr>
<tr>
<td>ImplVarModel</td>
<td>Reformulation model to generate for implicit variables.</td>
<td>switching</td>
</tr>
<tr>
<td>NLConsToFunc</td>
<td>Stick nonlinear constraints into functional part when generating a VI model for equilibrium problems</td>
<td>0</td>
</tr>
<tr>
<td>SharedEqu</td>
<td>Allow shared equations in equilibrium problems</td>
<td>0</td>
</tr>
<tr>
<td>SubSolvePar</td>
<td>User defined GAMS parameters for subsolve</td>
<td></td>
</tr>
<tr>
<td>SubSolver</td>
<td>Subsolver used to solve the reformulated model. The subsolver chosen has to be suitable for the chosen reformulation type. The user can also provide a solver related option file, see SubSolverOpt.</td>
<td></td>
</tr>
<tr>
<td>SubSolverOpt</td>
<td>Optfile value to pass to the subsolver</td>
<td>1</td>
</tr>
<tr>
<td>Terminate</td>
<td>Generate the GAMS source code of the reformulated model in a file and terminate without solving the model.</td>
<td>0</td>
</tr>
<tr>
<td>UserPFFile</td>
<td>Filename of extra GAMS options when running the reformulated GAMS model.</td>
<td></td>
</tr>
<tr>
<td>ZipDebug</td>
<td>Zip-file name to create if the internal GAMS model fails</td>
<td>none</td>
</tr>
</tbody>
</table>
5.21.3 Forming Optimality Conditions: NLP2MCP

The first nontrivial use of the JAMS solver is to automatically generate the first order conditions of a linear or nonlinear program; essentially we reformulate the optimization problem as a mixed complementarity problem (MCP). The "empinfo" file to do this simply contains the following line:

```
modeltype mcp
```

Behind the scenes, JAMS forms the Lagrangian of the nonlinear program and then forms its Karush-Kuhn-Tucker optimality conditions. To be clear, given the original nonlinear program

\[
\begin{align*}
\min_x f(x) \text{ s.t. } & g(x) \leq 0, \ h(x) = 0, \\
\end{align*}
\]

the Lagrangian is:

\[
L(x, \lambda, \mu) = f(x) - \langle \lambda, g(x) \rangle - \langle \mu, h(x) \rangle.
\]

The first order conditions are the following MCP:

\[
\begin{align*}
0 &= \nabla_x L(x, \lambda, \mu) \perp x \text{ free} \\
0 &\geq -\nabla_\lambda L(x, \lambda, \mu) \perp \lambda \leq 0 \\
0 &= -\nabla_\mu L(x, \lambda, \mu) \perp \mu \text{ free}
\end{align*}
\]

A specific example is:

\[
\begin{align*}
\min_{x,y,z} & -3x + y \\
\text{s.t.} & \quad x + y \leq 1, \ x + y - z = 2, \ x, y \geq 0
\end{align*}
\]

which is found in the EMPLIB model `nlp2mcp`:

Positive Variables x, y;
Variables f, z;
Equations g, h, defobj;
\[
\begin{align*}
g.. & \quad x + y =e= 1; \\
h.. & \quad x + y - z =e= 2; \\
defobj.. & \quad f =e= -3x + y; \end{align*}
\]

model comp / defobj, g, h /;
file info / '%emp.info%' /;
putclose info / 'modeltype mcp';
solve comp using emp minimizing f;

The putclose line writes out the default "empinfo" file whose location is provided in the system string `%emp.info%`. Armed with this additional information, the EMP tool automatically creates the following MCP:

\[
\begin{align*}
0 &\leq -3 - \lambda - \mu \perp x \geq 0 \\
0 &\leq 1 - \lambda - \mu \perp y \geq 0 \\
0 &= \mu \perp z \text{ free} \\
0 &\geq x + y - 1 \perp \lambda \leq 0 \\
0 &= x + y - z - 2 \perp \mu \text{ free}.
\end{align*}
\]
5.21.4 Soft Constraints

In many cases, we wish to relax certain constraints in a model during solution (to help identify feasibility issues for example). As an example, consider the problem

\[
\begin{align*}
\min_{x_1, x_2, x_3} & \quad \exp(x_1) \\
\text{s.t.} & \quad \log(x_1) = 1, \\
& \quad x_2^2 \leq 2, \\
& \quad x_1/x_2 = \log(x_3), \\
& \quad 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0,
\end{align*}
\]

which can be formulated in GAMS as

```gams
$title simple example of ENLP
Variables obj, x1, x2, x3;
Equations f0, f1, f2, f3, f4;
f0.. obj =e= exp(x1);
f1.. log(x1) =e= 1;
f2.. sqrt(x2) =g= 2;
f3.. x1/x2 =e= log(x3);
f4.. 3*x1 + x2 =l= 5;
x1.lo = 0; x2.lo = 0;
model enlpemp /all/;
x1.l = 1; x2.l = 1; x3.l = 1;
solve enlpemp using nlp min obj;
```

5.21.4.1 Reformulation as a classical NLP

Soft constraints allow us to treat certain equations in the model as "soft" by removing the constraints and adding a penalty term to the objective function. Explicitly, we replace the above problem by:

\[
\begin{align*}
\min_{x_1, x_2, x_3, w} & \quad \exp(x_1) + 5 \|\log(x_1) - 1\|^2 + 2 \max(x_2^2 - 2, 0) \\
\text{s.t.} & \quad x_1/x_2 = \log(x_3), \\
& \quad 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0.
\end{align*}
\]

In this problem, we still force \( x_1/x_2 = \log(x_3) \), but apply a least squares penalty to \( \log(x_1) - 1 \) and a smaller one-sided penalization to \( x_2^2 - 2 \).

The above formulation is nonsmooth due to the "max" term in the objective function; in practice we would replace this by:

\[
\begin{align*}
\min_{x_1, x_2, x_3, w} & \quad \exp(x_1) + 5 (\log(x_1) - 1)^2 + 2w \\
\text{s.t.} & \quad x_1/x_2 = \log(x_3), \\
& \quad 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\
& \quad w \geq x_2^2 - 2, w \geq 0
\end{align*}
\]

and recover a standard form NLP.

The "empinfo" file:

```gams
modeltype NLP
adjustequ f1 sqr 5
f2 maxz 2
```

coupled with replacing the last line with

```gams
solve enlpemp using emp min obj;
```

achieves this goal. The parameter values provide the penalty coefficients above.
5.21 JAMS and LogMIP

5.21.4.2 Reformulation as an MCP

As an alternative, we can rewrite the problem as an MCP, also dealing explicitly with the nonsmoothness. The "empinfo" file is given by:

```
modeltype NLP
adjustequ
f1 sqr 5
f2 maxz 2
```

and this generates the following MCP:

\[
\begin{align*}
0 &= \log(x_1) - 1 + y_1/10 \quad \perp \quad y_1 \text{ free}, \\
0 &\leq x_2^2 - 2 \quad \perp \quad y_2 \geq 0, \\
0 &= x_1/x_2 - \log(x_3) \quad \perp \quad y_3 \text{ free}, \\
0 &\geq 3x_1 + x_2 - 5 \quad \perp \quad y_4 \leq 0, \\
0 &\leq \exp(x_1) - y_1/x_1 - y_3/x_2 - 3y_4 \quad \perp \quad x_1 \geq 0, \\
0 &\leq -2y_2x_2 + x_1y_3/x_2^2 - y_4 \quad \perp \quad x_2 \geq 0, \\
0 &= y_3/x_3 \quad \perp \quad x_3 \text{ free},
\end{align*}
\]

where \( y \) represent the multipliers.

A complete description of the process to derive this MCP will be given later in section Extended Nonlinear Programs.

5.21.5 Bilevel Programs

Mathematical programs with optimization problems in their constraints have a long history in operations research including [15] [29] [71]. New codes are being developed that exploit this structure, at least for simple hierarchies, and attempt to define and implement algorithms for their solution.

The simplest case is that of bilevel programming, where an upper level problem depends on the solution of a lower level optimization. For example:

\[
\begin{align*}
\min_{x,y} & \quad f(x,y) \\
\text{s.t.} & \quad g(x,y) \leq 0, \\
& \quad y \text{ solves } \min_y v(x,y) \text{ s.t. } h(x,y) \geq 0.
\end{align*}
\]

Often, the upper level is referred to as the "leader", while the lower level is the "follower".

This problem can be reformulated as a Mathematical Program with Complementarity Constraints (MPCC) by replacing the lower level optimization problem by its first order optimality conditions:

\[
\begin{align*}
\min_{x,y} & \quad f(x,y) \\
\text{s.t.} & \quad g(x,y) \leq 0, \\
0 &= \nabla_y v(x,y) - \lambda^T \nabla_y h(x,y) \quad \perp \quad x \text{ free} \\
0 &\leq h(x,y) \quad \perp \quad \lambda \geq 0.
\end{align*}
\]

We find a solution of the MPCC, not of the bilevel program. This approach allows the MPCC to be solved using the NLPEC code, for example. Note that this reformulation is potentially problematic. First order
conditions require theoretical assumptions to be necessary and sufficient for local optimality. There may be cases where the lower level problem has multiple local solutions, but the modeler really was interested in the global solution. The approach here may not produce this solution, even if a global solver is used within NLPEC.

The following example is Example 5.1.1, page 197 from [15]. Mathematically, the problem is

$$\begin{align*}
\min_{x,y} & \quad x - 4y \\
\text{s.t.} & \quad y \text{ solves } \min y \\
& \quad x + y \geq 3 \\
& \quad 2x - y \geq 0 \\
& \quad -2x - y \geq -12 \\
& \quad -3x + 2y \geq -4
\end{align*}$$

and the EMPLIB model bard511 contains the following code:

```plaintext
Positive variables x, y;
Variables objout, objin;
equations defout, defin, e1, e2, e3, e4;
defout.. objout =e= x - 4*y;
defin.. objin =e= y;
e1.. x + y =g= 3;
e2.. 2*x - y =g= 0;
e3.. -2*x - y =g= -12;
e4.. -3*x + 2*y =g= -4;
model bard / all /;
$echo bilevel x min objin y defin e1 e2 e3 e4 > "%emp.info%"
solve bard using emp minimizing objout;
```

Note that first the functions that form the objectives and constraints of the model are defined and the model is assembled. The `$echo` line writes the "empinfo" file and states that the lower level problem involves the objective `objin` which is to be minimized by choice of variables `y` subject to the constraints specified in (`defin`), `e1`, `e2`, `e3`, and `e4`.

Note that the variables `x` are declared to be variables of the upper level problem and this example has no upper level constraints `g`. Having written the problem in this way, the MPCC is generated automatically, and passed on to a solver. In the case where that solver is NLPEC, a further reformulation of the model is carried out to convert the MPCC into an equivalent NLP or a parametric sequence of NLP's.

Further examples of bilevel models in EMPLIB are named: bard*, ccmg74, ccmg153, flds*, jointc1, jointc2, mirrlees, transbp.

The EMP model type allows multiple lower level problems to be specified within the bilevel format. An example of this is given in EMPLIB as ccmg71. The equations and objectives are specified in the normal manner; the only change is the definition of the "empinfo" file, shown below:

```plaintext
... defh1.. h1 =e= sqr(u1-x1) + sqr(u2-x2) + sqr(u3-x3) + sqr(u4-x4);
e1.. 3*u1 + u2 + 2*u3 + u4 =e= 6;
...
$echo > "%emp.info%"
bilevel x1 x2 x3 x4
min h1 u1 u2 u3 u4 defh1 e1
min h2 v1 v2 v3 v4 defh2 e2
$offecho
```

This corresponds to a bilevel program with two followers, both solving minimization problems. The first follower minimizes the objective function `h1` (defined in `defh1`) over the variables `u1`, `u2`, `u3`, and `u4` subject to the constraint given in `e1`. The second followers problem is defined analogously next. Note that `h1` involves the variables `x1`, `x2`, `x3`, and `x4` that are optimization variables of the leader. The constraint in `e1` could also include these variables, and also the variables `v1`, `v2`, `v3`, or `v4` of the second follower, but all of these would be treated as parameters by the first follower.

The actual model (ccmg71) in EMPLIB uses a shortcut notation:

```plaintext
... defh1.. h1 =e= sqr(u1-x1) + sqr(u2-x2) + sqr(u3-x3) + sqr(u4-x4);
```

Further examples of bilevel models in EMPLIB are named: bard*, ccmg74, ccmg153, flds*, jointc1, jointc2, mirrlees, transbp.
In the followers problem, the 'w' notation indicates that this agent will optimize over all the variables used in defh1 and e1 that are not under the control of any other follower or the leader. In this case, this means u1, u2, u3, and u4. To avoid confusion, it is recommended that the modeler explicitly names all the variables in each followers problem as shown before.

5.21.6 Variational Inequalities

A variational inequality $VI(F,X)$ is to find $x \in X$:

$$\langle F(x), (z - x) \rangle \geq 0, \text{ for all } z \in X.$$ 

Here $X$ is a closed (frequently assumed convex) set, defined for example as

$$X = \{ x \mid x \geq 0, h(x) \geq 0 \}.$$ 

Note that the first-order (minimum principle) conditions of a nonlinear program

$$\min_{z \in X} f(z)$$

are precisely of this form with $F(x) = \nabla f(x)$.

It is well known that such problems can be reformulated as complementarity problems when the set $X$ has the representation

$$X = \{ x \mid x \geq 0, h(x) \geq 0 \}$$

by introducing multipliers $\lambda$ on the constraints $h(x) \geq 0:

$$0 \leq F(x) - \langle \lambda, \nabla h(x) \rangle \perp x \geq 0$$

$$0 \leq h(x) \perp \lambda \geq 0.$$ 

If $X$ has a different representation, this construction would be modified appropriately.

A simple two dimensional example may be useful to improve understanding. Let

$$F(x) = \begin{bmatrix} x_1 + 2 \\ x_1 + x_2 - 3 \end{bmatrix}, \quad X = \{ x \geq 0 \mid x_1 + x_2 \leq 1 \},$$

so that $F$ is an affine function, but $F$ is not the gradient of any function $f : \mathbb{R}^2 \to \mathbb{R}$. For this particular data, $VI(F,X)$ has a unique solution $x = (0, 1)$.

Set J / 1, 2 /;
Positive Variable x(J) 'vars, perp to f(J)';
Equations F(J), h;
F(J).. (x('1') + 2)*$sameas(J,'1') + (x('1') + x('2') - 3)*$sameas(J,'2') =n= 0 ;
h.. x('1') + x('2') =l= 1;
model simpleVI / F, h/;
pUTCLOSE fx 'vi F x h';
solve simpleVI using emp;

Note that the first lines of this file define the $F$ and $h$ using standard GAMS syntax and include the defining equations in the model simpleVI. The extension is the annotation "empinfo" file that indicates certain equations are to be treated differently by the EMP tool. The annotation simply says that the model is a VI (vi) that pairs F with x and that the remaining (unpaired) equations form the constraint set X. (Alternative notation allows the keyword vi to be replaced by vifunc.) Thus, model equations F define a function F that is to be part of a variational inequality, while the equations h define constraints of X. It is also acceptable in this setting to use the "empinfo" file defined by:
In this case, by default, any equations that are given in the model statement but not included as a pair in the \textit{vi} statement are automatically used to form $X$. An alternative way to write this model without using \texttt{sameas} is given in \texttt{EMPLIB} as \texttt{affinevi}.

Some subtleties related to VI's are demonstrated in the \texttt{EMPLIB} model \texttt{zerofunc}. In this model, the set $X$ is defined using variables $y$ and $z$, for which $z$ does not appear in the definition of $F \equiv F_y$. In this case, the variable $z$ is then matched with a "0" function. The "empinfo" file can be written in a number of different ways:

\texttt{putclose fx 'vi F_y y';}

or

\texttt{putclose fx 'vi z F_y y';}

or

\texttt{putclose fx 'vi z F_y y gCons';}

or

\texttt{putclose fx 'vi F_z z F_y y gCons';}

where $F_z$ simply defines the zero function. To some extent, our preferred notation is the one listed third: it explicitly includes all the variables and constraints that are present in the model and does not require the modeler to define $F_z$ at all.

Further example models in \texttt{EMPLIB} are \texttt{simplevi}, \texttt{simplevi2}, \texttt{simplevi3}, \texttt{target}, \texttt{traffic}, \texttt{traffic2}, and \texttt{transvi}.

Note also that the lower level problems of a bilevel program could be VI's instead of optimization problems - these problems are called Mathematical Programs with Equilibrium Constraints (MPEC) in the literature. Note that since MPCC is a special case of MPEC, the GAMS model type MPEC covers both. An example demonstrating this setup is given in \texttt{EMPLIB} as \texttt{multmpec}. The actual model to solve is:

$$\begin{align*}
\min_{z, u, v, w} & z \\
\text{s.t.} & \exp(z) + w = 2, z \geq 1 \\
& (u, v) \text{ solves } VI([v + w + z - 1; u - \log(v)], \{(u, v) \mid u \geq 0, v \geq 0\}) \\
& w \text{ solves } VI(w + z + 3, \{w \mid w \text{ free}\})
\end{align*}$$

Note that the two VI's (due to the definitional sets) correspond respectively to a complementarity problem:

$$
\begin{align*}
0 \leq v + w + z - 1 & \perp u \geq 0 \\
0 \leq u - \log(v) & \perp v \geq 0
\end{align*}
$$

and a linear equation:

$$w + z + 3 = 0$$
The actual GAMS code is as follows:

Positive Variable u;
Variables v, w, z;
Equations f1, f2, f3, h;
f1.. v + w + z =n= 1;
f2.. u =n= log(v);
f3.. w + z =n= -3;
h.. exp(z) + w =e= 2;
v.lo = 0; v.l = 1; z.lo = 1;
model mpecmod /all/;
$onecho > %emp.info%
bilevel
vi f1 u
f2 v
vi f3 w
$offecho
solve mpecmod using emp min z;

The initial level value for v \((v.l = 1)\) is needed to protect the evaluation of log(v). The two complementarity problems are specified in the empinfo file (it is not really necessary to split these VI's apart, but it may give information to a solver that can be exploited). It is of course possible to write the MPCC directly in GAMS using the model type MPEC instead of EMP.

### 5.21.7 Embedded Complementarity Systems

A different type of embedded optimization model that arises frequently in applications is:

\[
\begin{align*}
\max \quad & f(x, y) \\
\text{s.t.} \quad & g(x, y) \leq 0 \quad (\perp p \geq 0) \\
& H(x, y, p) = 0 \quad (\perp y \text{ free})
\end{align*}
\]

Note the difference here: the optimization problem is over the variable \(x\), and is parameterized by the variable \(y\). The choice of \(y\) is fixed by the (auxiliary) complementarity relationships depicted here by \(H\). Note that the \(H\) equations are not part of the optimization problem, but are essentially auxiliary constraints to tie down remaining variables in the model.

A specific example is:

\[
\begin{align*}
\max \quad & x \\
\text{s.t.} \quad & x + y \leq 1 \\
& -3x + y = 0.5 \quad (\perp y \text{ free})
\end{align*}
\]

which is found in the EMPLIB model \texttt{simpequil2}: Variables y;
Positive variables x;
Equations optcons, vicons;
optcons.. x + y =l= 1;
vicons.. -3*x + y =e= 0.5;
model comp / optcons, vicons /;
file info / '%emp.info%' /;
put info / 'equilibrium';
put / 'max x optcons';
putclose / 'vi vicons y';
solve comp using emp;

In order that this model can be processed correctly as an EMP, the modeler provides additional annotations to the model defining equations in an "empinfo" file. Specifically, first it is indicated that the problem is an equilibrium problem involving one or more agent problems. Next, the first agent is defined as an optimizer (over \(x\)). Finally, the second agent is defined as solving a VI in \(y\). Armed with this additional information, the EMP tool automatically creates the following MCP:

\[
\begin{align*}
0 \leq -1 + p & \perp x \geq 0 \\
0 \leq 1 - x - y & \perp p \geq 0 \\
0 = -3x + y - 0.5 & \perp y \text{ free},
\end{align*}
\]
(which is formed by the steps we outline below). EMP explicitly enforces the rule that every variable and constraint is under the control of exactly one agent. Thus a constraint or a variable cannot appear in both the max problem and the VI problem.

The above example is slightly simpler than the general form described above in which \( H \) is a function of \( x, y, \) and \( p, \) the multiplier on the constraint of the optimization problem. The problem is that we do not have that variable around in the model code if we only specify the optimization problem there. This occurs for example in the classical PIES Model due to Hogan. In this setting, the problem is described by a linear program

\[
\begin{align*}
\min_{x} & \quad c^T x \\
\text{s.t.} & \quad Ax = q(p) \\
& \quad Bx = b \\
& \quad x \geq 0
\end{align*}
\]

in which the quantity \( q \) is a function of \( p, \) which is a multiplier on one of the LP constraints. To do this in EMP, we simply add the annotation:

```plaintext
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'emp.info'/;
put myinfo 'equilibrium';
put 'min obj c o ct ot lt ht defobj dembal cmbal ombal lmbal hmbal ruse';
putclose 'dualvar p dembal';
solve piesemp using emp;
```

where `dembal` is the name of the constraint for which \( p \) needs to be the multiplier. The full model is found in the EMPLIB model `pies`. Two final points: the `dualvar` directive identifies the variable \( p \) with the multiplier on the `dembal` constraint, and all variables and constraints must be owned by a single agent. In this case, since there is only one agent (the minimizer), all constraints of the model are explicitly claimed, along with all variables except for \( p. \) However, next, \( p \) is identified with the `dembal` constraint, which is owned by the min agent, and hence \( p \) is also owned by that agent.

There are several shorthands possible here. The first is that the explicit statement of variables can be replaced by the `'*'` form:

```plaintext
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'emp.info'/;
put myinfo 'equilibrium';
put 'min obj * defobj dembal cmbal ombal lmbal hmbal ruse';
```

Alternatively, an even shorter version is possible since there is only one agent present in this model, namely:

```plaintext
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'emp.info'/;
putclose myinfo 'dualvar p dembal';
solve piesemp using emp minimizing obj;
```

Note that in this form, all the variables and constraints of the original model are included in the (single) agents problem, and the original variable \( p \) is identified in the constructed MCP with the multiplier on the `dembal` constraint.

In the general case where the "empinfo" file contains all three lines:

```plaintext
min x optcons
vi vicons y
dualvar p optcons
```

namely that the function \( H \) that is defined in `vicons` is complementary to the variable \( y \) (and hence the variable \( y \) is a parameter to the optimization problem), and furthermore that the dual variable associated with the equation `optcons` in the optimization problem is one and the same as the variable \( p \) used to define \( H, \) the EMP tool automatically creates the following MCP:

\[
\begin{align*}
0 &= \nabla_x L(x, y, p) \quad \perp x \text{ free} \\
0 &\geq -\nabla_p L(x, y, p) \quad \perp p \leq 0 \\
0 &= H(x, y, p) \quad \perp y \text{ free},
\end{align*}
\]
where the Lagrangian is defined as
\[ L(x, y, p) = f(x, y) - \langle p, g(x, y) \rangle. \]

Essentially, this MCP consists of the first order optimality conditions of the optimization problem, coupled with the VI that is the second agents problem. An example that does both of these things together is provided in EMPLIB as \texttt{scarfemp-primal}.

Note that since the PIES model has no \( y \) variables, this is a special case of the general form in which the second agents (VI) problem is simply not present.

Example models are \texttt{ferris43}, \texttt{flipper pies}, \texttt{scarfemp-dual}, \texttt{simpequil}, \texttt{transecs}, and \texttt{transeql}.

### 5.21.8 MOPECs

MOPECs (Multiple Optimization Problems with Equilibrium Constraints) are a simple conceptual extension of the aforementioned embedded complementarity system. Instead of having a single optimizing agent and a variational inequality, one instead allows multiple optimizing agents coupled with an equilibrium constraint (the variational inequality).

Perhaps the most popular use of this formulation is where competition is allowed between agents. A standard method to deal with such cases is via the concept of Nash Games. In this setting \( x^* \) is a Nash Equilibrium if
\[ x_i^* \in \arg \min_{x_i \in X_i} \ell_i(x_i, x_{-i}^*, q), \forall i \in I, \]
where \( x_{-i} \) are other players decisions and the quantities \( q \) are given exogenously, or via complementarity:
\[ 0 \leq H(x, q) \perp q \geq 0. \]

This mechanism is extremely popular in economics, and Nash famously won the Nobel Prize for his contributions to this literature.

This format is again an EMP, more general than the example given above in two respects. Firstly, there is more than one optimization problem specified in the embedded complementarity system. Secondly, the parameters in each optimization problem consist of two types. Firstly, there are the variables \( q \) that are tied down by the auxiliary complementarity condition and hence are treated as parameters by the \( i \)th Nash player. Also there are the variables \( x_{-i} \) that are treated as parameters by the \( i \)th Nash player, but are treated as variables by a different player \( j \).

While we do not specify the syntax here for these issues, \texttt{EMPLIB} provides examples that outline how to carry out this matching within GAMS. Finally, two points of note: first it is clear that the resulting model is a complementarity problem and can be solved using PATH, for example. Secondly, performing the conversion from an embedded complementarity system or a Nash Game automatically is a critical step in making such models practically useful.

We note that there is a large literature on discrete-time finite-state stochastic games: this has become a central tool in analysis of strategic interactions among forward-looking players in dynamic environments. The model of dynamic competition in an oligopolistic industry given in \cite{55} is exactly in the format described above, and has been used extensively in applications such as advertising, collusion, mergers, technology adoption, international trade and finance. Ongoing work aims to use the EMP format to model these problems.
5.21.9 Extended Nonlinear Programs

Optimization models have traditionally been of the form (NLP). Specialized codes have allowed certain problem structures to be exploited algorithmically, for example simple bounds on variables. However, for the most part, assumptions of smoothness of \( f, g \) and \( h \) are required for many solvers to process these problems effectively. In a series of papers, Rockafellar and colleagues [152] [153] [154] have introduced the notion of extended nonlinear programming, where the (primal) problem has the form:

\[
\min_{x \in X} f(x) + \theta(g_1(x), \ldots, g_m(x)).
\]

In this setting, \( X \) is assumed to be a nonempty polyhedral set, and the functions \( f, g_1, \ldots, g_m \) are smooth. The function \( \theta \) can be thought of as a generalized penalty function that may well be nonsmooth. However, when \( \theta \) has the form

\[
\theta(u) = \sup_{y \in Y} \{ \langle y, u \rangle - k(y) \},
\]

a computationally exploitable and theoretically powerful framework can be developed based on conjugate duality. A key point for computation and modeling is that the function \( \theta \) can be fully described by defining the set \( Y \) and the function \( k \). Furthermore, from a modeling perspective, an extended nonlinear program can be specified simply by defining the functions \( f, g_1, \ldots, g_m \) in the manner already provided by the modeling system, with the additional issue of simply defining \( Y \) and \( k \). Conceptually, this is not much harder than what is carried out already, but leads to significant enhancements to the types of models that are available. Once a modeler determines which constraints are treated via which choice of \( k \) and \( Y \), the EMP model interface automatically forms an equivalent variational inequality or complementarity problem. As we show later, there may be alternative formulations that are computationally more appealing; such reformulations can be generated using different options to JAMS.

5.21.9.1 Forms of \( \theta \)

The EMP model type makes the problem format (ENLP) available to users in GAMS. As special cases, we can model piecewise linear penalties, least squares, and \( L_1 \) approximation problems, as well as the notion of soft and hard constraints.

For ease of exposition, we now describe a subset of the types of functions \( \theta \) that can be generated by particular choices of \( Y \) and \( k \). In many cases, the function \( \theta \) is separable, that is

\[
\theta(u) = \sum_{i=1}^{m} \theta_i(u_i),
\]

so we can either specify \( \theta_i \) or \( \theta \) itself.

Extended nonlinear programs include the classical nonlinear programming form (NLP) as a special case. This follows from the observation that if \( K \) is a closed convex cone, and we let \( \psi_K \) denote the “indicator function” of \( K \) defined by:

\[
\psi_K(u) = \begin{cases} 0 & \text{if } u \in K, \\ \infty & \text{else,} \end{cases}
\]

then (NLP) can be rewritten as:

\[
\min_x f(x) + \psi_K((g(x), h(x)), \quad K = \mathbb{R}_-^m \times \{0\}^p,
\]

where \( m \) and \( p \) are the dimensions of \( g \) and \( h \) respectively and \( \mathbb{R}_-^m = \{ u \in \mathbb{R}^m \mid u \leq 0 \} \). An elementary calculation shows that

\[
\psi_K(u) = \sup_{v \in \mathbb{R}^p} \langle u, v \rangle,
\]
where $K^\circ = \{ u \mid \langle u, v \rangle \leq 0, \forall v \in K \}$ is the polar cone of the given cone $K$. Thus, when $\theta(u) = \psi_K(u)$ we simply take $k \equiv 0$ and $Y = K^\circ$. In our example, $K^\circ = \mathbb{R}^m_+ \times \mathbb{R}^p$. To some extent, this is just a formalism that allows us to claim the classical case as a specialization; however when we take the cone $K$ to be more general than the polyhedral cone used above, we can generate conic programs for example.

The second example involves a piecewise linear function $\theta$: Formally, for $u \in \mathbb{R}$,

$$\theta(u) = \begin{cases} \rho u & \text{if } u \geq 0, \\ \sigma u & \text{else.} \end{cases}$$

In this case, simple calculations prove that $\theta$ has the form $(\theta \text{ con})$ for the choices $k \equiv 0$ and $Y = [\sigma, \rho]$.

The special case where $\sigma = -\rho$ results in

$$\theta(u) = \rho |u| .$$

This allows us to model nonsmooth $L_1$ approximation problems. Another special case results from the choice of $\sigma = -\gamma$, $\rho = 0$, whereby

$$\theta(u) = \gamma \max\{-u, 0\} .$$

This formulation corresponds to a soft penalization on an inequality constraint, namely if $\theta(-g_1(x))$ is used then nothing is added to the objective function if $g_1(x) \leq 0$, but $\gamma g_1(x)$ is added if the constraint $g_1(x) \leq 0$ is violated. Contrast this to the classical setting above, where $\infty$ is added to the objective if the inequality constraint is violated. It is interesting to see that truncating the set $Y$, which amounts to bounding the multipliers, results in replacing the classical constraint by a linearized penalty.

The third example involves a more interesting choice of $k$. If we wish to replace the "absolute value" penalization given above by a quadratic penalization (as in classical least squares analysis), that is

$$\theta(u) = \gamma u^2$$

then a simple calculation shows that we should take

$$k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = \mathbb{R} .$$

By simply specifying this different choice of $k$ and $Y$ we can generate such models easily and quickly within the modeling system. Note, however, that the reformulation we would use in $\theta(u) = \rho |u|$ and $\theta(u) = \gamma u^2$ are very different as we shall explain in the simple example below. Furthermore, in many applications it has become popular to penalize violations using a quadratic penalty only within a certain interval, afterwards switching to a linear penalization (chosen to make the penalty function $\theta$ continuously differentiable - see [99] ). That is:

$$\theta(u) = \begin{cases} \gamma u - \frac{1}{2} \gamma^2 & \text{if } u \geq \gamma \\ \frac{1}{2} u^2 & \text{if } u \in [-\gamma, \gamma] \\ -\gamma u + \frac{1}{2} \gamma^2 & \text{else.} \end{cases}$$

Such functions arise from quadratic $k$ and simple bound sets $Y$. In particular, the somewhat more general function

$$\theta(u) = \begin{cases} \gamma \beta^2 + \rho (u - \beta) & \text{if } u \geq \beta \\ \gamma u^2 & \text{if } u \in [\alpha, \beta] \\ \gamma \alpha^2 + \sigma (u - \alpha) & \text{else} \end{cases}$$

arises from the choice of

$$k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = [\sigma, \rho] ,$$

with $\alpha = \frac{\sigma}{2\gamma}$ and $\beta = \frac{\rho}{2\gamma}$.

The final example that we give is that of $L_\infty$ penalization. This example is different to the examples given above in that $\theta$ is not separable. However, straightforward calculation can be used to show

$$\theta(u) = \max_{i=1,\ldots,m} u_i$$

results from the choice of

$$k \equiv 0 \text{ and } Y = \left\{ y \in \mathbb{R}^m \mid y \geq 0, \sum_{i=1}^m y_i = 1 \right\} ,$$

that is, $Y$ is the unit simplex.
5.21.9.2 Underlying theory

The underlying structure of \( \theta \) leads to a set of extended optimality conditions and an elegant duality theory. This is based on an extended form of the Lagrangian:

\[
L(x, y) = f(x) + \sum_{i=1}^{m} y_{i} g_{i}(x) - k(y)
\]

\[x \in X, y \in Y\]

Note that the Lagrangian \( L \) is smooth - all the nonsmoothness is captured in the \( \theta \) function. The theory is an elegant combination of calculus arguments related to \( g_{i} \) and its derivatives, and variational analysis for features related to \( \theta \).

It is shown in [153] that under a standard constraint qualification, the first-order conditions of (ENLP) are precisely in the form of the following variational inequality:

\[
\text{VI} \left( \begin{bmatrix} \nabla_x L(x, y) \\ -\nabla_y L(x, y) \end{bmatrix}, X \times Y \right). \tag{ENLP VI}
\]

When \( X \) and \( Y \) are simple bound sets, this is simply a complementarity problem.

Note that EMP exploits this result. In particular, if an extended nonlinear program of the form (ENLP) is given to EMP, then the optimality conditions (ENLP VI) are formed as a variational inequality problem and can be processed as outlined above. For a specific example, we cite the fact that if we use the (classical) choice \( k \equiv 0 \) and \( Y = K^{\circ} \), then the optimality conditions of (ENLP) are precisely the standard complementarity problem given as (ENLP VI). While this is of interest, we believe that other choices of \( k \) and \( Y \) may be more useful and lead to models that have more practical significance.

Under appropriate convexity assumptions on this Lagrangian, it can be shown that a solution of the VI (ENLP VI) is a saddle point for the Lagrangian on \( X \times Y \). Furthermore, in this setting, the saddle point generates solutions to the primal problem (ENLP) and its dual problem:

\[
\max_{y \in Y} d(y), \quad \text{where} \quad d(y) = \inf_{x \in X} L(x, y),
\]

with no duality gap.

Unfortunately, the perturbations \( y \) in Rockafellar's theory are precisely the negative of those used throughout the GAMS system. Thus, we need to replace \( y \) by \(-y\) throughout in the above to recover the same multipliers as those GAMS uses.

5.21.9.3 A simple example

As an example, consider the problem

\[
\min_{x_1, x_2, x_3} \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2\max(x_2^2 - 2, 0)
\]
\[\text{s.t. } x_1/x_2 = \log(x_3),
\]
\[3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0.\]

In this problem, we would take

\[
X = \{ x \in \mathbb{R}^3 \mid 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \}.
\]
The function $\theta$ essentially treats 3 separable pieces:

$$g_1(x) = \log(x_1) - 1,$$
$$g_2(x) = x_2^2 - 2,$$
$$g_3(x) = x_1/x_2 - \log(x_3).$$

A classical problem would force $g_1(x) = 0$, $g_2(x) \leq 0$, and $g_3(x) = 0$, while minimizing $f(x) = \exp(x_1)$. In our problem, we still force $g_3(x) = 0$, but apply a (soft) least squares penalty on $g_1(x)$ and a smaller one-sided penalization on $g_2(x)$. The above formulation is nonsmooth due to the "max" term in the objective function; in practice we could replace this by:

$$\min_{x_1,x_2,x_3,w} \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2w$$

s.t. $x_1/x_2 = \log(x_3)$,

$$3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0$$

$$w \geq x_2^2 - 2, w \geq 0$$

and recover a standard form NLP. If the penalty on $g_1(x)$ would be replaced by a one-norm penalization (instead of least squares), we would have to play a similar game, moving the function $g_1(x)$ into the constraints and adding additional variable(s). To some extent, this seems unnatural - a modeler should be able to interchange the penalization without having to reformulate the problem from scratch. The proposed extended NLP would not be reformulated at all by the modeler, but allows all these "generalized constraints" to be treated in a similar manner within the modeling system. The actual formulation would take:

$$\theta(u) = \theta_1(u_1) + \theta_2(u_2) + \theta_3(u_3)$$

where

$$\theta_1(u_1) = 5u_1^2,$$
$$\theta_2(u_2) = 2 \max(u_2, 0),$$
$$\theta_3(u_3) = \psi_{[0]}(u_3).$$

The discussion above allows us to see that

$$Y = -(\mathbb{R} \times [0, 2] \times \mathbb{R}),$$
$$k(y) = \frac{1}{20}y_1^2 + 0 + 0.$$

The corresponding Lagrangian is the smooth function:

$$\mathcal{L}(x, y) = f(x) - \sum_{i=1}^{3} y_i g_i(x) - k(y).$$

The corresponding VI (ENLP VI) can almost be formulated in GAMS (except that the linear constraint in $X$ cannot be handled currently except by introducing a $\theta_4(x)$). Thus

$$g_4(x) = 3x_1 + x_2 - 5, \theta_4(u) = \psi_{\mathbb{R}_-},$$

resulting in the following choices for $Y$ and $k$:

$$Y = -(\mathbb{R} \times [0, 2] \times \mathbb{R} \times \mathbb{R}_+),$$
$$k(y) = \frac{1}{20}y_1^2 + 0 + 0 + 0.$$

Since $X$ and $Y$ are now simple bound sets, (ENLP VI) is now a complementarity problem and can be solved for example using PATH. A simple "empinfo" file details the choices of $Y$ and $k$ from the implemented library:

```
Adjustequ
e1 sqr 5
e2 MaxZ 2
```
5.21.9.4 Reformulation as a classical NLP

Suppose

$$\theta(u) = \sup_{y \in Y} \{ \langle u, y \rangle - \frac{1}{2} \langle y, Qy \rangle \}$$

for a polyhedral set $Y \subseteq \mathbb{R}^m$ and a symmetric positive semidefinite $Q \in \mathbb{R}^{m \times m}$ (possibly $Q = 0$).

Suppose further that

$$X = \{ x \mid Rx \leq r \}, Y = \{ y \mid S^T y \leq s \},$$

$$Q = DJ^{-1}D^T, \quad F(x) = (g_1(x), \ldots, g_m(x)),$$

where $J$ is symmetric and positive definite (for instance $J = I$). Then, as outlined by [154], the optimal solutions $\bar{x}$ of (ENLP) are the $\bar{x}$ components of the optimal solutions $(\bar{x}, \bar{z}, \bar{w})$ to

$$\min f(x) + \langle s, z \rangle + \frac{1}{2} \langle w, Jw \rangle$$

s.t. $Rx \leq r, z \geq 0, F(x) - Sz - Dw = 0.$

The multiplier on the equality constraint in the usual sense is the multiplier associated with $\bar{x}$ in the extended Lagrangian for (ENLP). (Note that a Cholesky factorization may be needed to determine $D$.)

It may be better to solve this reformulated NLP than to solve the VI (ENLP VI). However, it is important that we can convey all types of nonsmooth optimization problems to a solver as smooth optimization problems, and hence it is important to communicate the appropriate structure to the solver interface. We believe that specifying $Y$ and $k$ is a theoretically sound way to do this.

5.21.10 Disjunctive Programs (LogMIP)

There are many ways that the EMP model type can be used for further extensions to the modeling capabilities of a given system. In particular, the procedures outlined in [190] for disjunctive programming extensions are also implemented within the EMP model type.

The disjunctive programming procedures are also known as the LogMIP 2.0 solver for solving linear and nonlinear disjunctive programming problems involving binary variables and disjunction definitions for modeling discrete choices. While the modeling and solution of these disjunctive optimization problems has not yet reached the stage of maturity and reliability as LP, MIP and NLP modeling, these problems have a rich area of applications.

LogMIP 2.0 has been developed by Dr. Aldo Vecchietti from INGAR (Santa Fe, Argentina) and Professor Ignacio E. Grossmann from Carnegie Mellon University (Pittsburgh, USA), and supersedes its previous version, LogMIP 1.0 (GAMS releases 22.6 (December 2007) to 23.6 (December 2010)). Changes in version 2.0 are at the level of language, where now the EMP syntax and modeltype is used, and at the level of solvers, where Big-M and convex-hull relaxations are combined. For more information see the website http://www.logmip.ceride.gov.ar/ and the documentation http://www.logmip.ceride.gov.ar/files/pdfs/newUserManual.pdf.

One simple example to highlight the disjunctive programming feature is the notion of an ordering of tasks, namely that either job $i$ completes before job $j$ starts or the converse, i.e., that the jobs cannot overlap. Such a disjunction can be specified using an empinfo file containing lines:

```
disjunction * seq(i,j) else seq(j,i)
```

In such an example, one can implement a Big-M method, employ indicator constraints, or utilize a convex hull reformulation. The convex hull reformulation is the default strategy; to utilize the Big-M formulation, the additional option
default bigm 1000

would add binary variables and constraints to impose the disjunction using a Big-M value of 1000. Alternatively, the option setting

default indic

writes out a model and an option file that implements a reformulation using indicator constraints, which can be handled by the solvers CPLEX, SCIP, and XPRESS. The EMPLIB model sequence is sequencing model that implements all of these options.

More complicated (nonlinear) examples make the utility of this approach clearer. The design of a multiproduct batch plan with intermediate storage described in [189] and a synthesis problem involving 8 processes from [186] are also included in the EMP model library. As a final example, the gasoline emission model outlined in [72] is precisely in the form that could exploit the features of EMP related to (nonlinear) disjunctive programming.

5.21.11 Empinfo file details

We have explained above many of the standard vectorized ways to write an "empinfo" file. The "empinfo" file has a vectorized format and a more powerful (but more complex) scalar version. We describe some of the features of the scalar version in this section.

An example of the use of the scalar syntax is given below

```plaintext
file info / '%emp.info%' /;
pit info / 'equilibrium';
loop(h,
   put / 'min' obj(h) /;
   loop(j, put x(h,j)); put /;
   loop(k, put z(h,k));
   put / costdef(h) /;
   loop(i, put nodebal(h,i)); put /;
);
loop(a, put 'vi',flowdef(a),f(a) /);
```

This is an example of a MOPEC in which the optimization agents are indexed by $h$ and each of these agents control variables $x_{hj}$ and $z_{hk}$. The objective function for each $h$ is defined in `costdef`, the constraints of each minimization problem are defined in `nodebal`, and the equilibrium constraints that link all the optimization problems are a VI defined by variables $f_a$ and functions within `flowdef`. Sometimes it is necessary to use syntax that generates the "tl" fields of sets, but this seems only necessary when abnormal side conditions are needed.

The format of the empinfo file is given below:

```
Disjunction [chull [big eps] | bigM [big eps threshold] | indic]
   [NOT] var|* [NOT] {equ} {ELSEIF [NOT] var|* [NOT] {equ}} [ELSE [NOT] {equ}]
Default [chull [big eps] | bigM [big eps threshold] | indic]
ParallelStep1 {equ|*}
AdjustEqu equ abs|sqr|maxz|... {weight}
```
5.22 KESTREL - Remote Solver Execution on NEOS Servers

5.22.1 Background

The Kestrel client/server is a way of sending your GAMS solve job to be solved via the NEOS Server from within your usual GAMS modeling environment and receiving results that can be processed as with any local solver. Starting with distribution 23.7 the Kestrel solver is part of the GAMS distribution. The solve statement using the GAMS/KESTREL solver invokes a client program that sends your problem to a solver running on one of the NEOS Server's remote computers. The results from the NEOS Server are eventually returned through Kestrel to GAMS, where you can view and manipulate them locally in the usual way. The introduction below covers everything you need to know to start using GAMS/KESTREL. Further information about more advanced features and other uses of Kestrel can be found at the Kestrel page on the NEOS Server. Please also make you familiar with the NEOS optimization service terms of use before submitting jobs via GAMS/KESTREL.

5.22.1.1 Kestrel and IBM DOcloud

With GAMS 24.6 the GAMS/Kestrel client has been adjusted to work with IBM's cloud service Decision Optimization on Cloud (DOcloud). When the Kestrel option docloudurl is set, the generated model instance will be automatically translated into an MPS format and send to DOcloud and solved by Cplex in IBM's cloud. So no GAMS/Cplex license is required on your local machine. You as a user need to register with IBM on the web page mentioned about and pay IBM for the solution time spend in IBM's cloud. IBM provides details how to get started with DOcloud.

5.22.2 Using GAMS/KESTREL

The Kestrel solver can be used to solve a GAMS model remotely. For example, consider the transport model. It can be solved locally in GAMS through the following statements,

```plaintext
model transport /all/;
solve transport using lp minimizing z;
```
which specify the \texttt{transport} model and solve it with the default linear programming solver. We can add an option statement to the code to explicitly specify the solver. For example, if we change the linear programming solver to GAMS/MINOS, the code becomes

\begin{verbatim}
model transport /all/;
option lp=minos;
solve transport using lp minimizing z;
\end{verbatim}

To solve the same problem remotely through the NEOS Server, we simply change the linear programming solver to Kestrel. In addition we have to provide an email address. This can be specified either in an option file or by setting the environment variable \texttt{NEOS_EMAIL}. In order to set this permanently, it is recommended to add \texttt{NEOS_EMAIL} to your \texttt{gamsconfig.yaml} file.

Without an option file Kestrel will submit the model instance to the NEOS server and use the default LP solver on NEOS.

\begin{verbatim}
option lp=kestrel;
solve transport using lp minimizing z;
\end{verbatim}

We can support a Kestrel option file and determine the solver on the NEOS server:

\begin{verbatim}
transport.optfile=1;
option lp=kestrel;
solve transport using lp minimizing z;
$echo email jdoe@jeangreyhigh.edu > kestrel.opt
$echo kestrel_solver minos >> kestrel.opt
\end{verbatim}

The statement \texttt{transport.optfile=1} specifies that an options file, called \texttt{kestrel.opt}, will be used. The options file contains the email address, the remote solver name as well as any options for the remote solver. We instruct the Kestrel solver to use GAMS/MINOS as the remote solver by writing the following \texttt{kestrel.opt} file:

\begin{verbatim}
email jdoe@jeangreyhigh.edu
kestrel_solver minos
\end{verbatim}

If you do not know what solvers are available via GAMS/KESTREL on NEOS, submitting a job with a nonexistent solver set will return a list of enabled solvers. If you want to change the URL of the server, you can specify the option \texttt{neos_server}. The complete format of the parameter is \texttt{protocol://host:port}.

A subsequent run of the code through the GAMS interpreter results in the transport model being solved through the NEOS Server with the GAMS/MINOS solver. Once the job is submitted to the NEOS Server, a job number, password, and Web address are displayed to the screen, which provide information on accessing the job and viewing the intermediate output, for example,

--- Executing KESTREL
Job has been submitted to Kestrel
Kestrel/NEOS Job number : 93478
Kestrel/NEOS Job password : utiwtxTK
Check the following URL for progress report :
https://neos-server.org/neos/cgi-bin/nph-neos-solver.cgi?admin=results&jobnumber=93478&pass=utiwtxTK
To look at the solver's output while it is running, point your browser at the URL given in the Kestrel output as shown above, and click on View Intermediate Results in the web page that appears. This will take you to another page that shows all of the output produced by the solver for your problem so far. To track the solver’s progress, simply update this page periodically.

If the NEOS Server or the network becomes unavailable after the submission, a particular job can be retrieved by setting both the kestrel job and kestrel password in the options file.

```plaintext
kestrel_solver minos
kestrel_job 93478
kestrel_password utiwtxTK
```

Re-issuing the command `gams transport` with this options file will retrieve the results for the specified job number.

By specifying `neos_username` and `neos_user_password` in the option file, you can submit an authenticated job using your NEOS user account. Authenticated jobs will appear in your user account on the NEOS website.

```plaintext
neos_username username
neos_user_password password
```

### 5.22.2.1 Using GAMS/KESTREL with IBM DOcloud

In order to use GAMS/Kestrel to solve model instances with Cplex on IBM's DOcloud, the only thing that needs to be done is to provide a different option file. The option `docloud_url` triggers the submission to IBM's DOcloud rather than NEOS. You need an account on DOcloud (and pay IBM for the Cplex solution time in their cloud). Some additional account information needs to be specified in the Kestrel option `docloud_key`. The use of Cplex in DOcloud is limited to solve a model instance, special options that are available in the GAMS/Cplex system, like IIS or FeasOpt cannot be used (yet) through Kestrel/DOcloud. Moreover, for problems with discrete variables, only the primal solution is returned. If you want to specify Cplex options this needs to be done with a Cplex parameter file which is quite different from the GAMS/Cplex option file. You can use a GAMS/Cplex option file and have the additional option `WriteParam` to produce such a Cplex parameter file. The Cplex parameter file might have a few more options compared to the GAMS/Cplex option file because some GAMS options set Cplex parameters. Please note that you can produce the Cplex parameter file with GAMS/Cplex even if you do not have a license for GAMS/Cplex as long as you run a demo sized model (e.g. from the GAMS Model Library) to produce the Cplex parameter file. The following GAMS/Cplex optfile

```plaintext
lpmethod 4
advind 0
eprhs 1e-4
scaind 1
writeparam cplex.prm
```

produces the Cplex parameter file `cplex.prm` which can be submitted to Kestrel/DOcloud via the option `docloud_prmfile`:

```plaintext
CPLEX Parameter File Version 12.6.3.0
CPX_PARAM_ADVIND 0
CPX_PARAM_EPRHS 1.00000000000000e-04
CPX_PARAM_SIMDISPLAY 2
CPX_PARAM_SCAIND 1
CPX_PARAM_TILIM 1.00000000000000e+03
CPX_PARAM_LPMETHOD 4
CPX_PARAM_THREADS 1
CPX_PARAM_PARALLELMODE 1
```
Users of GAMS/Kestrel on platforms other than Windows, Linux, or macOS have to manually provide a Python 3 installation that has access to the following modules:

- GAMS Python API
- IBM DOcloud Python package.

5.23 KNITRO

5.23.1 Introduction

Artelys Knitro is a software package for finding local solutions of both continuous (i.e. smooth) optimization problems, with or without constraints, and discrete optimization problems with integer or binary variables. Even though Knitro has been designed for solving large-scale general problems, it is efficient for solving all of the following classes of optimization problems:

- unconstrained,
- bound constrained,
- equality constrained,
- systems of nonlinear equations,
- least squares problems,
- linear programming problems (LPs),
- quadratic programming problems (QP),
- general (inequality) constrained problems,
- (convex) mixed integer nonlinear programs (MINLP) of moderate size.

The Knitro package provides the following features:

- Efficient and robust solution of small or large problems,
- Solvers for both continuous and discrete problems,
- Derivative-free, 1st derivative and 2nd derivative options,
- Both interior-point (barrier) and active-set optimizers,
- Both feasible and infeasible versions,
- Both iterative and direct approaches for computing steps,

The problems solved by Knitro have the form

\[
\begin{align*}
\text{minimize} & \quad f(x) \\
\text{subject to} & \quad c^L \leq c(x) \leq c^U \\
& \quad b^L \leq x \leq b^U,
\end{align*}
\]

(1a) (1b) (1c)

where the variables $x$ can be continuous, binary, or integer. This allows many forms of constraints, including bounds on the variables. Knitro requires that the functions $f(x)$ and $c(x)$ be smooth functions.
Knitro implements both state-of-the-art interior-point and active-set methods for solving nonlinear optimization problems. In the interior method (also known as a barrier method), the nonlinear programming problem is replaced by a series of barrier sub-problems controlled by a barrier parameter $\mu$. The algorithm uses trust regions and a merit function to promote convergence. The algorithm performs one or more minimization steps on each barrier problem, then decreases the barrier parameter, and repeats the process until the original problem (1) has been solved to the desired accuracy.

Knitro provides two procedures for computing the steps within the interior point approach. In the version known as Interior/CG each step is computed using a projected conjugate gradient iteration. This approach differs from most interior methods proposed in the literature in that it does not compute each step by solving a linear system involving the KKT (or primal-dual) matrix. Instead, it factors a projection matrix, and uses the conjugate gradient method, to approximately minimize a quadratic model of the barrier problem.

The second procedure for computing the steps, which we call Interior/Direct, always attempts to compute a new iterate by solving the primal-dual KKT matrix using direct linear algebra. In the case when this step cannot be guaranteed to be of good quality, or if negative curvature is detected, then the new iterate is computed by the Interior/CG procedure.

Knitro also implements an active-set sequential linear-quadratic programming (SLQP) algorithm which we call Active. This method is similar in nature to a sequential quadratic programming method but uses linear programming sub-problems to estimate the active-set at each iteration. This active-set code may be preferable when a good initial point can be provided, for example, when solving a sequence of related problems.

For problems with discrete variables, Knitro provides two variants of the branch and bound algorithm. The first is a standard implementation, while the second is specialized for convex, mixed-integer nonlinear problems.

We encourage the user to try all algorithmic options to determine which one is more suitable for the application at hand. For guidance on choosing the best algorithm see section Algorithm Options.

For a detailed description of the algorithm implemented in Interior/CG see [30] and for the global convergence theory see [31]. The method implemented in Interior/Direct is described in [198]. The Active algorithm is described in [33] and the global convergence theory for this algorithm is in [34]. An important component of Knitro is the HSL routine MA27 [92] which is used to solve the linear systems arising at every iteration of the algorithm. In addition, the Active Set algorithm in Knitro may make use of the COIN-OR Clp linear programming solver module. The version used in Knitro may be downloaded from http://www.artelys.com/tools/clp/.

5.23.2 Usage

Basic details of solver usage, including how to choose Knitro as the solver and how to use a solver-specific option file, are part of Chapter Solver Usage.

As an NLP solver, Knitro can also be used to solve linear programs (LP), and both convex and nonconvex quadratic programs (QCP).
5.23.3 GAMS Options

The following GAMS options are used by the GAMS/Knitro link:

- **Option ResLim = x;**
  
  Sets the time limit in seconds. If this limit is exceeded the solver will terminate and pass on the current solution to GAMS. See also reslim in section GAMS options.

- **Option SysOut = On;**
  
  This option sends additional Knitro messages to the GAMS listing file. It is useful in case of a solver failure or to get algorithmic details. See also sysout in section GAMS options.

- **ModelName.optCA = x;**
  
  Absolute gap stop criterion for a discrete problem. The Knitro option mip_opt_gap_abs takes its default from this value. See also optca in section GAMS options.

- **ModelName.optCR = x;**
  
  Relative gap stop criterion for a discrete problem. The Knitro option mip_opt_gap_rel takes its default from this value. See also optcr in section GAMS options.

5.23.4 Summary of Knitro Options

The Knitro options file *knitro.opt* allows the user to easily set options controlling Knitro's behavior. Options are set by specifying a keyword and a corresponding value on a line in the *knitro.opt* file. Lines that begin with a # character are treated as comments and blank lines are ignored. For example, to set the maximum allowable number of iterations to 500, one could use the following options file:

```
mxit 500
```

5.23.4.1 General options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>algorithm</td>
<td>Indicates which algorithm to use to solve the problem</td>
<td>0</td>
</tr>
<tr>
<td>blasoption</td>
<td>Specifies the BLAS/LAPACK function library to use for basic vector and matrix computations</td>
<td>1</td>
</tr>
<tr>
<td>blasoptionlib</td>
<td>Specifies a dynamic library name that contains object code for BLAS/LAPACK functions</td>
<td></td>
</tr>
<tr>
<td>bndrange</td>
<td>Specifies max limits on the magnitude of constraint and variable bounds</td>
<td>1e+20</td>
</tr>
<tr>
<td>cg_maxit</td>
<td>Determines the maximum allowable number of inner conjugate gradient (CG) iterations per Knitro minor iteration</td>
<td>-1</td>
</tr>
<tr>
<td>cg_pmem</td>
<td>Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner</td>
<td>10</td>
</tr>
<tr>
<td>cg_precond</td>
<td>Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>----------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>cg_stoptol</td>
<td>Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves</td>
<td>0.01</td>
</tr>
<tr>
<td>convex</td>
<td>Declare the problem as convex by setting to 1 or non-convex by setting to 0</td>
<td>-1</td>
</tr>
<tr>
<td>cpuplatform</td>
<td>This option can be used to specify the target instruction set architecture for the machine on which Knitro is running</td>
<td>-1</td>
</tr>
<tr>
<td>datacheck</td>
<td>Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure)</td>
<td>0</td>
</tr>
<tr>
<td>delta</td>
<td>Specifies the initial trust region radius scaling factor used to determine the initial trust region size</td>
<td>1</td>
</tr>
<tr>
<td>honorbnds</td>
<td>Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization</td>
<td>-1</td>
</tr>
<tr>
<td>initpenalty</td>
<td>Specifies the initial penalty parameter used in the Knitro merit functions</td>

<tr>
<td><code>xtol_iters</code></td>
<td>The optimization process will terminate if the relative change in the solution estimate is less than <code>xtol</code> for <code>xtol_iters</code> consecutive iterations</td>
<td><code>0</code></td>
</tr>
</tbody>
</table>

### 5.23.4.4 Barrier options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bar_conic_enable</code></td>
<td>Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm)</td>
<td>-1</td>
</tr>
<tr>
<td><code>bar_directinterval</code></td>
<td>Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra</td>
<td>-1</td>
</tr>
<tr>
<td><code>bar_feasible</code></td>
<td>Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms</td>
<td>0</td>
</tr>
<tr>
<td><code>bar_feasmodetol</code></td>
<td>Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible</td>
<td><code>0.0001</code></td>
</tr>
<tr>
<td><code>bar_initmu</code></td>
<td>Specifies the initial value for the barrier parameter $\mu$ used with the barrier algorithms</td>
<td>-1</td>
</tr>
<tr>
<td><code>bar_initpi_mpec</code></td>
<td>Specifies the initial value for the MPEC penalty parameter $\pi$ used when solving problems with complementarity constraints using the barrier algorithms</td>
<td>0</td>
</tr>
<tr>
<td><code>bar_initpt</code></td>
<td>Indicates initial point strategy for $x$, slacks and multipliers when using a barrier algorithm</td>
<td>0</td>
</tr>
<tr>
<td><code>bar_linsys</code></td>
<td>Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps</td>
<td>-1</td>
</tr>
<tr>
<td><code>bar_linsys_storage</code></td>
<td>Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps</td>
<td>-1</td>
</tr>
<tr>
<td><code>bar_maxcorrectors</code></td>
<td>Specifies the maximum number of corrector steps allowed for primal-dual steps</td>
<td>-1</td>
</tr>
<tr>
<td><code>bar_maxcrossit</code></td>
<td>Specifies the maximum number of crossover iterations before termination</td>
<td>0</td>
</tr>
<tr>
<td><code>bar_maxrefactor</code></td>
<td>Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step</td>
<td>-1</td>
</tr>
<tr>
<td><code>bar_mpec_heuristic</code></td>
<td>Specifies whether or not to use a heuristic approach when solving MPEC models with the barrier algorithm</td>
<td>0</td>
</tr>

</tbody>
</table>

### 5.23.4.6 MIP options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>mip_branchrule</td>
<td>Specifies which branching rule to use for MIP branch and bound procedure</td>
<td>0</td>
</tr>
<tr>
<td>mip_clique</td>
<td>Specifies rules for adding clique cuts</td>
<td>0</td>
</tr>
<tr>
<td>mip_cutfactor</td>
<td>This value specifies a limit on the number of cuts added to a node subproblem</td>
<td>1</td>
</tr>
<tr>
<td>mip_cutoff</td>
<td>This value specifies the objective cutoff value for MIP</td>
<td>maxdouble</td>
</tr>
<tr>
<td>mip_cutting_plane</td>
<td>Specifies when to apply the cutting plane procedure</td>
<td>0</td>
</tr>
<tr>
<td>mip_gub_branch</td>
<td>Specifies whether or not to branch on generalized upper bounds (GUBs)</td>
<td>0</td>
</tr>
<tr>
<td>mip_heuristic_diving</td>
<td>Specifies whether or not to enable the MIP diving heuristic</td>
<td>-1</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td><code>mip_heuristic_feaspump</code></td>
<td>Specifies whether or not to enable the MIP feasibility pump heuristic</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_lns</code></td>
<td>Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_maxit</code></td>
<td>Specifies the maximum number of iterations to allow for MIP heuristic, if one is enabled</td>
<td>100</td>
</tr>
<tr>
<td><code>mip_heuristic_misqp</code></td>
<td>Specifies whether or not to enable the MIP MISQP heuristic</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_mpec</code></td>
<td>Specifies whether or not to enable the MIP MPEC heuristic</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_strategy</code></td>
<td>Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_heuristic_terminate</code></td>
<td>Specifies the condition for terminating the MIP heuristic</td>
<td>1</td>
</tr>
<tr>
<td><code>mip_implications</code></td>
<td>Specifies whether or not to add constraints to the MIP derived from logical implications</td>
<td>1</td>
</tr>
<tr>
<td><code>mip_integer_tol</code></td>
<td>This value specifies the threshold for deciding whether or not a variable is determined to be an integer</td>
<td>1e-08</td>
</tr>
<tr>
<td><code>mip_intvar_strategy</code></td>
<td>Specifies how to handle integer variables</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_knapsack</code></td>
<td>Specifies rules for adding MIP knapsack cuts</td>
<td>1</td>
</tr>
<tr>
<td><code>mip_liftproject</code></td>
<td>Specifies rules for adding lift and project cuts</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_lpalg</code></td>
<td>Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch and bound procedure</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_maxnodes</code></td>
<td>Specifies the maximum number of nodes explored (0 means no limit)</td>
<td>GAMS nodlim</td>
</tr>
<tr>
<td><code>mip_maxsolves</code></td>
<td>Specifies the maximum number of subproblem solves allowed (0 means no limit)</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_maxtime_cpu</code></td>
<td>Specifies the maximum allowable CPU time in seconds for the complete MIP solution</td>
<td>100000000</td>
</tr>
<tr>
<td><code>mip_maxtime_real</code></td>
<td>Specifies the maximum allowable real time in seconds for the complete MIP solution</td>
<td>GAMS reslim</td>
</tr>
<tr>
<td><code>mip_method</code></td>
<td>Specifies which MIP method to use</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_mir</code></td>
<td>Specifies rules for adding mixed integer rounding cuts</td>
<td>-1</td>
</tr>
<tr>
<td><code>mip_multistart</code></td>
<td>Use to enable MIP multi-start at the branch-and-bound level</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_nodealg</code></td>
<td>Specifies which algorithm to use for standard node subproblem solves in MIP (same options as <code>algorithm</code> user option)</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_numthreads</code></td>
<td>Specify the number of threads to use for MIP branch and bound (when <code>mip_method</code> = 1)</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_opt_gap_abs</code></td>
<td>The absolute optimality gap stop tolerance for MIP</td>
<td>GAMS optca</td>
</tr>
<tr>
<td><code>mip_opt_gap_rel</code></td>
<td>The relative optimality gap stop tolerance for MIP</td>
<td>GAMS optcr</td>
</tr>
<tr>
<td><code>mip_outinterval</code></td>
<td>Specifies node printing interval for <code>mip_outlevel</code> when <code>mip_outlevel</code> &gt; 0</td>
<td>0</td>
</tr>
<tr>
<td><code>mip_outlevel</code></td>
<td>Specifies how much MIP information to print</td>
<td>2</td>
</tr>
<tr>
<td><code>mip_pseudoinit</code></td>
<td>Specifies the method used to initialize pseudo-costs corresponding to variables that have not yet been branched on in the MIP method</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>mip_relaxable</td>
<td>Specifies whether integer variables are relaxable</td>
<td>1</td>
</tr>
<tr>
<td>mip_restart</td>
<td>Specifies whether to enable the MIP restart procedure</td>
<td>1</td>
</tr>
<tr>
<td>mip_rootalg</td>
<td>Specifies which algorithm to use for the root node solve in MIP</td>
<td>0</td>
</tr>
<tr>
<td>mip_rounding</td>
<td>Specifies the MIP rounding rule to apply</td>
<td>-1</td>
</tr>
<tr>
<td>mip_selectdir</td>
<td>Specifies the MIP node selection direction rule (for tiebreakers) for choosing the next node in the branch and bound tree</td>
<td>0</td>
</tr>
<tr>
<td>mip_selectrule</td>
<td>Specifies the MIP select rule for choosing the next node in the branch and bound tree</td>
<td>0</td>
</tr>
<tr>
<td>mip_strong_candlim</td>
<td>Specifies the maximum number of candidates to explore for MIP strong branching</td>
<td>128</td>
</tr>
<tr>
<td>mip_strong_level</td>
<td>Specifies the maximum number of tree levels on which to perform MIP strong branching</td>
<td>10</td>
</tr>
<tr>
<td>mip_strong_maxit</td>
<td>Specifies the maximum number of iterations to allow for MIP strong branching solves</td>
<td>1000</td>
</tr>
<tr>
<td>mip_terminate</td>
<td>Specifies conditions for terminating the MIP algorithm</td>
<td>0</td>
</tr>
<tr>
<td>mip_zerohalf</td>
<td>Specifies rules for adding zero-half cuts</td>
<td>0</td>
</tr>
</tbody>
</table>

5.23.4.7 Multi-algorithm options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ma_maxtime_cpu</td>
<td>Specifies, in seconds, the maximum allowable CPU time before termination for the multi-algorithm (&quot;MA&quot;) procedure (algorithm=5)</td>
<td>100000000</td>
</tr>
<tr>
<td>ma_maxtime_real</td>
<td>Specifies, in seconds, the maximum allowable real time before termination for the multi-algorithm (&quot;MA&quot;) procedure (algorithm=5)</td>
<td>100000000</td>
</tr>
<tr>
<td>ma_outsub</td>
<td>Enable writing algorithm output to files for the multi-algorithm (algorithm=5) procedure</td>
<td>0</td>
</tr>
<tr>
<td>ma_terminate</td>
<td>Define the termination condition for the multi-algorithm (algorithm=5) procedure</td>
<td>1</td>
</tr>
</tbody>
</table>

5.23.4.8 Multi-start options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ms_deterministic</td>
<td>Indicates whether Knitro multi-start procedure will be deterministic (when ms_terminate = 0)</td>
<td>1</td>
</tr>
<tr>
<td>ms_enable</td>
<td>Indicates whether Knitro will solve from multiple start points to find a better local minimum</td>
<td>0</td>
</tr>
<tr>
<td>ms_maxbndrange</td>
<td>Specifies the maximum range that an unbounded variable can take when determining new start points</td>
<td>1000</td>
</tr>
<tr>
<td>ms_maxsolves</td>
<td>Specifies how many start points to try in multi-start</td>
<td>0</td>
</tr>
<tr>
<td>ms_maxtime_cpu</td>
<td>Specifies, in seconds, the maximum allowable CPU time before termination</td>
<td>100000000</td>
</tr>
<tr>
<td>ms_maxtime_real</td>
<td>Specifies, in seconds, the maximum allowable real time before termination</td>
<td>100000000</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>ms_numthreads</td>
<td>Specify the number of threads to use for multi-start (when ms_enable = 1)</td>
<td>0</td>
</tr>
<tr>
<td>ms_num_to_save</td>
<td>Specifies the number of distinct feasible points to save in a file named knitro_mspoints</td>
<td>0</td>
</tr>
<tr>
<td>ms_outsub</td>
<td>Enable writing algorithm output to files for the parallel multi-start procedure</td>
<td>0</td>
</tr>
<tr>
<td>ms_savetol</td>
<td>Specifies the tolerance for deciding if two feasible points are distinct</td>
<td>1e-06</td>
</tr>
<tr>
<td>ms_seed</td>
<td>Seed value used to generate random initial points in multi-start; should be a non-negative integer</td>
<td>0</td>
</tr>
<tr>
<td>ms_startptrange</td>
<td>Specifies the maximum range that each variable can take when determining new start points</td>
<td>1e+20</td>
</tr>
<tr>
<td>msterminate</td>
<td>Specifies the condition for terminating multi-start</td>
<td>0</td>
</tr>
</tbody>
</table>

5.23.4.9 Parallelism options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>blas_numthreads</td>
<td>Specify the number of threads to use for BLAS operations when blasoption = 1</td>
<td>0</td>
</tr>
<tr>
<td>conic_numthreads</td>
<td>Specify the number of threads to use for operations in the conic algorithm (when bar_conic_enable = 1)</td>
<td>0</td>
</tr>
<tr>
<td>linsolver_numthreads</td>
<td>Specify the number of threads to use for linear system solve operations when linsolver = 6</td>
<td>0</td>
</tr>
<tr>
<td>threads</td>
<td>default thread count</td>
<td>GAMS threads</td>
</tr>
</tbody>
</table>

5.23.4.10 Output options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>outappend</td>
<td>Specifies whether output should be started in a new file, or appended to existing files</td>
<td>0</td>
</tr>
<tr>
<td>oudir</td>
<td>Specifies a single directory as the location to write all output files</td>
<td></td>
</tr>
<tr>
<td>outlev</td>
<td>Controls the level of output produced by Knitro</td>
<td>2</td>
</tr>
<tr>
<td>outmode</td>
<td>Specifies where to direct the output from Knitro</td>
<td>0</td>
</tr>
<tr>
<td>outname</td>
<td>Use to specify a custom filename when output is written to a file using outmode</td>
<td></td>
</tr>
<tr>
<td>out_csvinfo</td>
<td>Controls whether or not to generates a file knitro_solve</td>
<td>0</td>
</tr>
<tr>
<td>out_csvname</td>
<td>Use to specify a custom csv filename when using out_csvinfo</td>
<td></td>
</tr>
<tr>
<td>out_hints</td>
<td>Specifies whether to print diagnostic hints (e.g. about user option settings) after solving</td>
<td>1</td>
</tr>
</tbody>
</table>

5.23.4.11 Tuner options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>tuner</td>
<td>Indicates whether to invoke the Knitro-Tuner</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>tuner_maxtime_cpu</td>
<td>Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner</td>
<td>100000000</td>
</tr>
<tr>
<td>tuner_maxtime_real</td>
<td>Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner</td>
<td>100000000</td>
</tr>
<tr>
<td>tuner_optionsfile</td>
<td>Can be used to specify the location of a Tuner options file</td>
<td></td>
</tr>
<tr>
<td>tuner_outsub</td>
<td>Enable writing additional Tuner subproblem solve output to files for the Knitro-Tuner procedure (tuner=1)</td>
<td>0</td>
</tr>
<tr>
<td>tuner_terminate</td>
<td>Define the termination condition for the Knitro-Tuner procedure (tuner=1)</td>
<td>0</td>
</tr>
</tbody>
</table>

5.23.5 Detailed Descriptions of Knitro Options

**act_lpfeastol (real):** Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms

\[\text{Range: } [0, \infty]\]

Default: 1e-08

**act_lppenalty (integer):** Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(all) penalize all constraints.</td>
</tr>
<tr>
<td>2</td>
<td>(nonlinear) penalize only nonlinear constraints.</td>
</tr>
<tr>
<td>3</td>
<td>(dynamic) dynamically choose which constraints to penalize.</td>
</tr>
</tbody>
</table>

**act_lppresolve (boolean):** Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(off) presolve turned off for LP subproblems.</td>
</tr>
<tr>
<td>1</td>
<td>(on) presolve turned on for LP subproblems.</td>
</tr>
</tbody>
</table>

**act_parametric (integer):** Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms

Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms. A parametric approach will solve a sequence of closely related LPs instead of one LP. It may increase the cost of an active-set iteration, but perhaps lead to convergence in fewer iterations.

Default: 1
**act_qpalg (integer):** Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms

Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms. This option has no effect on the Interior/Direct and Interior/CG algorithms.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) do not use a parametric solve (i.e. solve a single LP).</td>
</tr>
<tr>
<td>1</td>
<td>(maybe) use a parametric solve sometimes.</td>
</tr>
<tr>
<td>2</td>
<td>(yes) always try a parametric solve.</td>
</tr>
</tbody>
</table>

**act_qppenalty (integer):** Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) let Knitro automatically decide.</td>
</tr>
<tr>
<td>0</td>
<td>(none) do not penalize constraints in QP subproblems.</td>
</tr>
<tr>
<td>1</td>
<td>(all) penalize all constraints in QP subproblems.</td>
</tr>
</tbody>
</table>

**algorithm (integer):** Indicates which algorithm to use to solve the problem

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) let Knitro automatically choose an algorithm, based on the problem characteristics.</td>
</tr>
<tr>
<td>1</td>
<td>(direct) use the Interior/Direct algorithm.</td>
</tr>
<tr>
<td>2</td>
<td>(cg) use the Interior/CG algorithm.</td>
</tr>
<tr>
<td>3</td>
<td>(active) use the Active Set algorithm.</td>
</tr>
<tr>
<td>4</td>
<td>(sqp) use the SQP algorithm.</td>
</tr>
<tr>
<td>5</td>
<td>(multi) run all algorithms, perhaps in parallel (see Algorithms).</td>
</tr>
</tbody>
</table>

**bar_conic_enable (integer):** Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm)

Default: -1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>0</td>
<td>(none) Do not apply any special treatment for conic constraints.</td>
</tr>
<tr>
<td>1</td>
<td>(soc) Apply special treatments for any Second Order Cone (SOC) constraints identified in the model.</td>
</tr>
</tbody>
</table>

**bar_directinterval** *(integer)*: Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra

Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra. This option is only valid for the Interior/Direct algorithm and may be useful on problems where Knitro appears to be taking lots of conjugate gradient steps. Setting `bar_directinterval` to 0 will try to enforce that only direct steps are taken which may produce better results on some problems.

Range: \{-1, ..., \infty\}

Default: -1

**bar_feasible** *(integer)*: Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms

Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms. Note This option can only be used with the Interior/Direct and Interior/CG algorithms. If `bar_feasible = stay` or `bar_feasible = get_stay`, this will activate the feasible version of Knitro. The feasible version of Knitro will force iterates to strictly satisfy inequalities, but does not require satisfaction of equality constraints at intermediate iterates. This option and the honorbnds option may be useful in applications where functions are undefined outside the region defined by inequalities. The initial point must satisfy inequalities to a sufficient degree; if not, Knitro may generate infeasible iterates and does not switch to the feasible version until a sufficiently feasible point is found. Sufficient satisfaction occurs at a point $x$ if it is true for all inequalities that $cl + tol \leq c(x) \leq cu - tol$ The constant tol is determined by the option `bar_feasmodetol`. If `bar_feasible = get` or `bar_feasible = get_stay`, Knitro will place special emphasis on first trying to get feasible before trying to optimize.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) No special emphasis on feasibility.</td>
</tr>
<tr>
<td>1</td>
<td>(stay) Iterates must satisfy inequality constraints once they become sufficiently feasible.</td>
</tr>
<tr>
<td>2</td>
<td>(get) Special emphasis is placed on getting feasible before trying to optimize.</td>
</tr>
<tr>
<td>3</td>
<td>(get_stay) Implement both options 1 and 2 above.</td>
</tr>
</tbody>
</table>

**bar_feasmodetol** *(real)*: Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible

Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible. The tolerance applies to all inequality constraints in the problem. This option only has an effect if option `bar_feasible = stay` or `bar_feasible = get_stay`.

Range: [0, \infty]

Default: 0.0001
bar_initmu (real): Specifies the initial value for the barrier parameter $\mu$ used with the barrier algorithms

Specifies the initial value for the barrier parameter $\mu$ used with the barrier algorithms. This option has no effect on the Active Set algorithm.

Range: $[-\infty, \infty]$

Default: -1

bar_inipi_mpec (real): Specifies the initial value for the MPEC penalty parameter $\pi$ used when solving problems with complementarity constraints using the barrier algorithms

Specifies the initial value for the MPEC penalty parameter $\pi$ used when solving problems with complementarity constraints using the barrier algorithms. If this value is non-positive, then Knitro uses an internal formula to initialize the MPEC penalty parameter.

Range: $[0, \infty]$

Default: 0

bar_initpt (integer): Indicates initial point strategy for x, slacks and multipliers when using a barrier algorithm

Indicates initial point strategy for x, slacks and multipliers when using a barrier algorithm. Note, this option only alters the initial x values if the user does not specify an initial x. This option has no effect on the Active Set algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(convex) Initialization designed for convex models.</td>
</tr>
<tr>
<td>2</td>
<td>(nearbnd) Initialization strategy that stays closer to the bounds.</td>
</tr>
<tr>
<td>3</td>
<td>(central) Initialization strategy that is more central on double-bounded variables.</td>
</tr>
</tbody>
</table>

bar_linsys (integer): Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps

Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps. Eliminating more elements results in a smaller dimensional linear system (but also one that is, perhaps, less numerically stable). The bounds option may be preferable for very large problems with many bounded variables. The ineq option may generate significant speedups on models where the number of variables is small, but the number of inequality constraints is large.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose the linear system form.</td>
</tr>
<tr>
<td>0</td>
<td>(full) Use the full linear system.</td>
</tr>
<tr>
<td>1</td>
<td>(slacks) Eliminate the slack variables.</td>
</tr>
<tr>
<td>2</td>
<td>(bounds) Eliminate the slack variables and bounds.</td>
</tr>
<tr>
<td>3</td>
<td>(ineqs) Eliminate the slack variables, bounds, and some inequalities.</td>
</tr>
</tbody>
</table>
**bar_linsys_storage** *(integer)*: Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps

Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps. The `lowmem` option uses one storage location for multiple linear systems. As a result it may use much less memory, but also may be less efficient when the Interior/Direct algorithm takes a lot of CG steps. The `normal` option uses separate storage for different linear systems.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose the linear system storage approach.</td>
</tr>
<tr>
<td>1</td>
<td>(lowmem) Use common storage for multiple linear systems.</td>
</tr>
<tr>
<td>2</td>
<td>(normal) Use separate storage for different linear systems.</td>
</tr>
</tbody>
</table>

**bar_maxcorrectors** *(integer)*: Specifies the maximum number of corrector steps allowed for primal-dual steps

Specifies the maximum number of corrector steps allowed for primal-dual steps. If the value is positive and the algorithm used is Interior/Direct, then Knitro may add at most `bar_maxcorrectors` corrector steps to the primal-dual step to try to stay closer to the central path. This may speed up convergence on some models (although it may make the cost per iteration a little more expensive). If the value is negative, Knitro automatically determines the maximum number of corrector steps to apply.

Range: \{-∞, ..., ∞\}

Default: -1

**bar_maxcrossit** *(integer)*: Specifies the maximum number of crossover iterations before termination

Specifies the maximum number of crossover iterations before termination. If the value is positive and the algorithm in operation is Interior/Direct or Interior/CG, then Knitro will crossover to the Active Set algorithm near the solution. The Active Set algorithm will then perform at most `bar_maxcrossit` iterations to get a more exact solution. If the value is 0, no Active Set crossover occurs and the interior-point solution is the final result. If Active Set crossover is unable to improve the approximate interior-point solution, then Knitro will restore the interior-point solution. In some cases (especially on large-scale problems or difficult degenerate problems) the cost of the crossover procedure may be significant – for this reason, crossover is disabled by default. Enabling crossover generally provides a more accurate solution than Interior/Direct or Interior/CG.

Range: \{0, ..., ∞\}

Default: 0

**bar_maxrefactor** *(integer)*: Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step

Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step. If this value is set to -1, it will use a dynamic strategy. These refactorizations are performed if negative curvature is detected in the model. Rather than reverting to a CG step, the Hessian matrix is modified in an attempt to make the subproblem convex and then the KKT system is refactorized. Increasing this value will make the Interior/Direct algorithm less likely to take CG steps. If the Interior/Direct
algorithm is taking a large number of CG steps (as indicated by a positive value for “CGits” in the output), this may improve performance. This option has no effect on the Active Set algorithm.

Range: \{-1, ..., \infty\}

Default: \(-1\)

**bar_mpec_heuristic** (boolean): Specifies whether or not to use a heuristic approach when solving MPEC models with the barrier algorithm

Specifies whether or not to use a heuristic approach when solving MPEC models with the barrier algorithm. In some cases enabling this heuristic can speedup the convergence to the solution and provide a more precise solution on MPEC models (i.e., models with complementarity constraints).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not enable the heuristic for MPEC models.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Enable the heuristic for MPEC models.</td>
</tr>
</tbody>
</table>

**bar_murule** (integer): Indicates which strategy to use for modifying the barrier parameter \(\mu\) in the barrier algorithms

Indicates which strategy to use for modifying the barrier parameter \(\mu\) in the barrier algorithms. Not all strategies are available for both barrier algorithms, as described below. This option has no effect on the Active Set algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(monotone) Monotonically decrease the barrier parameter. Available for both barrier algorithms.</td>
</tr>
<tr>
<td>2</td>
<td>(adaptive) Use an adaptive rule based on the complementarity gap to determine the value of the barrier parameter. Available for both barrier algorithms.</td>
</tr>
<tr>
<td>3</td>
<td>(probing) Use a probing (affine-scaling) step to dynamically determine the barrier parameter. Available only for the Interior/Direct algorithm.</td>
</tr>
<tr>
<td>4</td>
<td>(dampmpc) Use a Mehrotra predictor-corrector type rule to determine the barrier parameter, with safeguards on the corrector step. Available only for the Interior/Direct algorithm.</td>
</tr>
<tr>
<td>5</td>
<td>(fullmpc) Use a Mehrotra predictor-corrector type rule to determine the barrier parameter, without safeguards on the corrector step. Available only for the Interior/Direct algorithm.</td>
</tr>
<tr>
<td>6</td>
<td>(quality) Minimize a quality function at each iteration to determine the barrier parameter. Available only for the Interior/Direct algorithm.</td>
</tr>
</tbody>
</table>

**bar_penaltycons** (integer): Indicates whether a penalty approach is applied to the constraints

Indicates whether a penalty approach is applied to the constraints. Using a penalty approach may be helpful when the problem has degenerate or difficult constraints. It may also help
to more quickly identify infeasible problems, or achieve feasibility in problems with difficult constraints. This option has no effect on the Active Set algorithm.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>0</td>
<td>(none) No constraints are penalized.</td>
</tr>
<tr>
<td>2</td>
<td>(all) A penalty approach is applied to all general constraints.</td>
</tr>
<tr>
<td>3</td>
<td>(equalities) Apply a penalty approach to equality constraints only.</td>
</tr>
</tbody>
</table>

**bar_penaltyrule (integer):** Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate

Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate. This option has no effect on the Active Set algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(single) Use a single penalty parameter in the merit function to weight feasibility versus optimality.</td>
</tr>
<tr>
<td>2</td>
<td>(flex) Use a more tolerant and flexible step acceptance procedure based on a range of penalty parameter values.</td>
</tr>
</tbody>
</table>

**bar_refinement (boolean):** Specifies whether to try to refine the barrier solution for better precision

Specifies whether to try to refine the barrier solution for better precision. If enabled, once the optimality conditions are satisfied, Knitro will apply an additional refinement/postsolve phase to try to obtain more precision in the barrier solution. The effect is similar to the effect of enabling bar_maxcrossit, but it is usually much more efficient since it does not involve switching to the Active Set algorithm.

Default: 0

**bar_relaxcons (integer):** Indicates whether a relaxation approach is applied to the constraints

Indicates whether a relaxation approach is applied to the constraints. Using a relaxation approach may be helpful when the problem has degenerate or difficult constraints. This option has no effect on the Active Set algorithm.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) No constraints are relaxed.</td>
</tr>
<tr>
<td>1</td>
<td>(eqs) A relaxation approach is applied to general equality constraints.</td>
</tr>
<tr>
<td>2</td>
<td>(ineqs) A relaxation approach is applied to general inequality constraints.</td>
</tr>
<tr>
<td>3</td>
<td>(all) A relaxation approach is applied to all general constraints.</td>
</tr>
</tbody>
</table>

**bar_slackboundpush (real):** Specifies the amount by which the barrier slack variables are initially
pushed inside the bounds ←

Specifies the amount by which the barrier slack variables are initially pushed inside the bounds. A smaller value may be preferable when warm-starting from a point close to the solution.

Range: \([-\infty, \infty]\)

Default: \(-1\)

**bar_switchobj** (integer): Indicates which objective function to use when the barrier algorithms switch to a pure feasibility phase ←

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) No (or zero) objective.</td>
</tr>
<tr>
<td>1</td>
<td>(scalarprox) Proximal point objective with scalar weighting.</td>
</tr>
<tr>
<td>2</td>
<td>(diagprox) Proximal point objective with diagonal weighting.</td>
</tr>
</tbody>
</table>

**bar_switchrule** (integer): Indicates whether or not the barrier algorithms will allow switching from an optimality phase to a pure feasibility phase ←

Indicates whether or not the barrier algorithms will allow switching from an optimality phase to a pure feasibility phase. This option has no effect on the Active Set algorithm.

Default: \(-1\)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-1)</td>
<td>(auto) Let Knitro determine the switching procedure.</td>
</tr>
<tr>
<td>0</td>
<td>(never) Never switch to feasibility phase.</td>
</tr>
<tr>
<td>2</td>
<td>(moderate) Allow switches to feasibility phase.</td>
</tr>
<tr>
<td>3</td>
<td>(aggressive) Use a more aggressive switching rule.</td>
</tr>
</tbody>
</table>

**bar_watchdog** (boolean): Specifies whether to enable watchdog heuristic for barrier algorithms ←

Specifies whether to enable watchdog heuristic for barrier algorithms. In general, enabling the watchdog heuristic makes the barrier algorithms more likely to accept trial points. Specifically, the watchdog heuristic may occasionally accept trial points that increase the merit function, provided that subsequent iterates decrease the merit function.

Default: 0

**bfgs_scaling** (integer): Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation ←

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(dynamic) Dynamically choose which scaling to use.</td>
</tr>
<tr>
<td>1</td>
<td>(invhess) The scaling approximates the scale of the inverse Hessian.</td>
</tr>
<tr>
<td>2</td>
<td>(hess) The scaling approximates the scale of the Hessian.</td>
</tr>
</tbody>
</table>
blasoption (integer): Specifies the BLAS/LAPACK function library to use for basic vector and matrix computations

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(knitro) Use Knitro built-in functions.</td>
</tr>
<tr>
<td>1</td>
<td>(intel) Use Intel Math Kernel Library (MKL) functions on available platforms.</td>
</tr>
<tr>
<td>2</td>
<td>(dynamic) Use the dynamic library specified with option blasoptionlib.</td>
</tr>
<tr>
<td>3</td>
<td>(blis) Use BLIS functions on available platforms (currently not available on Windows OS).</td>
</tr>
</tbody>
</table>

blasoptionlib (string): Specifies a dynamic library name that contains object code for BLAS/LAPACK functions

Specifies a dynamic library name that contains object code for BLAS/LAPACK functions. The library must implement all the functions declared in the file include/blas_lapack.h.

blas_numthreads (integer): Specify the number of threads to use for BLAS operations when blasoption = 1

Range: \( \{0, \ldots, \infty\} \)

Default: 0

bndrange (real): Specifies max limits on the magnitude of constraint and variable bounds

Specifies max limits on the magnitude of constraint and variable bounds. Any constraint or variable bounds whose magnitude is greater than or equal to bndrange will be treated as infinite by Knitro. Using very large, finite bounds is discouraged (and is generally an indication of a poorly scaled model).

Range: \([0, \infty]\)

Default: 1e+20

cg_maxit (integer): Determines the maximum allowable number of inner conjugate gradient (CG) iterations per Knitro minor iteration

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Let Knitro automatically determine a value.</td>
</tr>
<tr>
<td>0</td>
<td>Knitro will set a maximum value based on the problem size.</td>
</tr>
<tr>
<td>n</td>
<td>At most n&gt;0 CG iterations may be performed during one minor iteration of Knitro.</td>
</tr>
</tbody>
</table>

cg_pmem (integer): Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner

Default: 10
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>At most n&gt;0 nonzero elements per column.</td>
</tr>
</tbody>
</table>

**cg_precond** *(boolean)*: Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Not applied.</td>
</tr>
<tr>
<td>1</td>
<td>(chol) Preconditioner is applied.</td>
</tr>
</tbody>
</table>

**cg_stoptol** *(real)*: Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves

Range: $[0, \infty]$  
Default: 0.01

**conic_numthreads** *(integer)*: Specify the number of threads to use for operations in the conic algorithm (when bar_conic_enable = 1)

Specify the number of threads to use for operations in the conic algorithm (when bar_conic_enable = 1). 0 Let Knitro choose the number of threads (currently sets conic_numthreads based on numthreads). n>0 Use n threads for the conic solver.

Range: $\{0, ..., \infty\}$  
Default: 0

**convex** *(integer)*: Declare the problem as convex by setting to 1 or non-convex by setting to 0

Declare the problem as convex by setting to 1 or non-convex by setting to 0. Otherwise, Knitro will try to determine this automatically, but may only be able to do so for simple model forms such as QPs or QCQPs. If your model is specified as (or automatically determined to be) convex, this will cause Knitro to apply specializations and tunings that are often beneficial for convex models to speed up the solution. Currently this option is only active for the Interior/Direct algorithm, but may be applied to other algorithms in the future.

Range: $\{-1, ..., 1\}$  
Default: -1

**cpuplatform** *(integer)*: This option can be used to specify the target instruction set architecture for the machine on which Knitro is running

This option can be used to specify the target instruction set architecture for the machine on which Knitro is running. This can be used, for example, to try to produce more consistent Knitro performance across various architectures (at the expense of, perhaps, slower performance on some platforms). This option is currently only used for the Intel Math Kernel Library (MKL) functions used inside Knitro.

Range: $\{-1, ..., 5\}$  
Default: -1
**datacheck (boolean):** Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure).

Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure). The datacheck may have a non-trivial cost for large problems.

Default: 0

**delta (real):** Specifies the initial trust region radius scaling factor used to determine the initial trust region size.

Range: $[1e^{-14}, \infty)$

Default: 1

**feastol (real):** Specifies the final relative stopping tolerance for the feasibility error.

Specifies the final relative stopping tolerance for the feasibility error. Smaller values of feastol result in a higher degree of accuracy in the solution with respect to feasibility.

Range: $[0, \infty)$

Default: $1e^{-06}$

**feastolabs (real):** Specifies the final absolute stopping tolerance for the feasibility error.

Synonym: feastol.abs

Specifies the final absolute stopping tolerance for the feasibility error. Smaller values of feastol.abs result in a higher degree of accuracy in the solution with respect to feasibility.

Range: $[0, \infty)$

Default: 0.001

**findiff_estnoise (integer):** This option can be used to enable an estimate of the noise in the model when using finite-difference gradients.

This option can be used to enable an estimate of the noise in the model when using finite-difference gradients. This noise estimate can then be used to set a finite-difference steplength appropriate for the estimated noise level. This can improve performance on models with noise (e.g. noisy black-box optimization models). The cost of the noise estimation procedure is usually a few extra function evaluations.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not enable any noise estimation procedure for finite-difference gradients.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Enable noise estimation procedure for finite-difference gradients.</td>
</tr>
<tr>
<td>2</td>
<td>(withcurv) Enable noise estimation and curvature factor for finite-difference gradients.</td>
</tr>
</tbody>
</table>

**findiff_relstepsize (real):** Specifies the relative step size used for finite-difference gradients during the optimization.
Specifies the relative stepsize used for finite-difference gradients during the optimization. This option sets the stepsize for all variables. Note that this option has no affect on the finite-difference derivatives computed for the derivative checker (default values are always used here). It is only used for the finite-difference derivatives computed during the optimization.

Range: \([-\infty, \infty]\)

Default: 0

`findiff.terminate` (boolean): This option specifies the termination criteria when using finite-difference gradients

This option specifies the termination criteria when using finite-difference gradients. The optimality (or KKT) conditions for nonlinear optimization depend on gradient values of the nonlinear objective and constraint functions. When using finite-difference gradients (e.g. `gradopt > 1`), there will typically be small errors in the computed gradients that will limit the precision in the solution (and the ability to satisfy the optimality conditions). By default, Knitro will try to estimate these finite-difference gradient errors and terminate when it seems that no more accuracy in the solution is possible. The solution will be treated as optimal as long as it is feasible and the optimality conditions are satisfied either by the optimality tolerances (`opttol` and `opttol.abs`) or the error estimates. On some problems, the error estimates may result in extra function evaluations on some iterations, but will often prevent extra iterations that produce no significant improvement in the solution. This special termination can be disabled by setting `findiff.terminate = 0` (none).

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none)  No special criteria; use the standard stopping conditions.</td>
</tr>
<tr>
<td>1</td>
<td>(errest) Allow termination based on estimates of the finite-difference error (when no more significant progress is likely).</td>
</tr>
</tbody>
</table>

`fstopval` (real): Used to implement a custom stopping condition based on the objective function value

Used to implement a custom stopping condition based on the objective function value. Knitro will stop and declare that a satisfactory solution was found if a feasible objective function value at least as good as the value specified by `fstopval` is achieved. This stopping condition is only active when the absolute value of `fstopval` is less than `objrange`.

Range: \([-\infty, \infty]\)

Default: `maxdouble`

`ftol` (real): The optimization process will terminate if the relative change in the objective function is less than `ftol` for `ftol.liters` consecutive feasible iterations

Range: \([0, \infty]\)

Default: `1e-15`

`ftol.liters` (integer): The optimization process will terminate if the relative change in the objective function is less than `ftol` for `ftol.liters` consecutive feasible iterations

Range: \(\{1, ..., \infty\}\)

Default: 5

`gradopt` (integer): Specifies how to compute the gradients of the objective and constraint functions

Default: 1
### hessopt (integer)

Specifies how to compute the (approximate) Hessian of the Lagrangian

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto)</td>
</tr>
<tr>
<td>1</td>
<td>(exact) User provides a routine for computing the exact Hessian.</td>
</tr>
<tr>
<td>2</td>
<td>(bfgs) Knitro computes a (dense) quasi-Newton BFGS Hessian.</td>
</tr>
<tr>
<td>3</td>
<td>(sr1) Knitro computes a (dense) quasi-Newton SR1 Hessian.</td>
</tr>
<tr>
<td>5</td>
<td>(product) User provides a routine to compute the Hessian-vector products.</td>
</tr>
<tr>
<td>6</td>
<td>(lbfgs) Knitro computes a limited-memory quasi-Newton BFGS Hessian (its size is determined by the option lmsize).</td>
</tr>
<tr>
<td>7</td>
<td>(gauss_newton) Knitro computes a Gauss-Newton approximation of the hessian (available for least-squares only, and default value for least-squares)</td>
</tr>
</tbody>
</table>

Default: 0

### honorbnds (integer)

Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization

Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization. This option and the bar_feasible option may be useful in applications where functions are undefined outside the region defined by inequalities.

Default: -1

### infefastol (real)

Specifies the (relative) tolerance used for declaring infeasibility of a model

Specifies the (relative) tolerance used for declaring infeasibility of a model. Smaller values of infefastol make it more difficult to satisfy the conditions Knitro uses for detecting infeasible models. If you believe Knitro incorrectly declares a model to be infeasible, then you should try a smaller value for infefastol.

Range: $[0, \infty]$.

Default: $1e^{-08}$

### infefastol_iters (integer)

The optimization process will terminate if the relative change in the feasibility error is less than infefastol for infefastol_iters consecutive infeasible iterations

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Knitro automatically determine the best setting.</td>
</tr>
<tr>
<td>0</td>
<td>(no) Knitro does not require that the bounds on the variables be satisfied at intermediate iterates.</td>
</tr>
<tr>
<td>1</td>
<td>(always) Knitro enforces that the initial point and all subsequent solution estimates satisfy the bounds on the variables.</td>
</tr>
<tr>
<td>2</td>
<td>(initpt) Knitro enforces that the initial point satisfies the bounds on the variables.</td>
</tr>
</tbody>
</table>
1932 Solver Manuals

Range: \{1, ..., \infty\}

Default: 50

\textbf{initpenalty} (\textit{real}): Specifies the initial penalty parameter used in the Knitro merit functions

Specifies the initial penalty parameter used in the Knitro merit functions. The Knitro merit functions are used to balance improvements in the objective function versus improvements in feasibility. A larger initial penalty value places more weight initially on feasibility in the merit function.

Range: \[0, \infty\]

Default: 10

\textbf{initvalues} (\textit{integer}): Enable use of initial guess for levels and marginals (subsequent solves)

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Using no initial values</td>
</tr>
<tr>
<td>1</td>
<td>Using all initial values</td>
</tr>
<tr>
<td>2</td>
<td>Using only non-default initial values</td>
</tr>
</tbody>
</table>

\textbf{initvalues0} (\textit{integer}): Enable use of initial guess for levels and marginals (first solve)

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Using no initial values</td>
</tr>
<tr>
<td>1</td>
<td>Using all initial values</td>

<tr>
<td>2</td>
<td>Using only non-default initial values</td>
</tr>
</tbody>
</table>

\textbf{linesearch} (\textit{integer}): Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate

Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate. This option has no effect on the Interior/CG or Active Set algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(backtrack) Use a simple backtracking scheme.</td>
</tr>
<tr>
<td>2</td>
<td>(interpolate) Use a cubic interpolation scheme.</td>
</tr>
<tr>
<td>3</td>
<td>(weakwolfe) Use a linesearch that satisfies the weak Wolfe conditions (unconstrained only).</td>
</tr>
</tbody>
</table>

\textbf{linesearch_maxtrials} (\textit{integer}): Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step
Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step. This option has no effect on the Interior/CG or Active Set algorithm.

Range: \( \{0, ..., \infty\} \)

Default: 3

**linsolver** (integer): Indicates which linear solver to use to solve linear systems arising in Knitro algorithms

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the linear solver.</td>
</tr>
<tr>
<td>1</td>
<td>(internal) Not currently used; reserved for future use. Same as auto for now.</td>
</tr>
<tr>
<td>2</td>
<td>(hybrid) Use a hybrid approach where the solver chosen depends on the particular linear system which needs to be solved.</td>
</tr>
<tr>
<td>3</td>
<td>(qr) Use a dense QR method. This approach uses LAPACK QR routines. Since it uses a dense method, it is only efficient for small problems. It may often be the most efficient method for small problems with dense Jacobians or Hessian matrices.</td>
</tr>
<tr>
<td>4</td>
<td>(ma27) Use the HSL MA27 sparse symmetric indefinite solver.</td>
</tr>
<tr>
<td>5</td>
<td>(ma57) Use the HSL MA57 sparse symmetric indefinite solver.</td>
</tr>
<tr>
<td>6</td>
<td>(mklpardiso) Use the Intel MKL PARDISO (parallel, deterministic) sparse symmetric indefinite solver.</td>
</tr>
<tr>
<td>7</td>
<td>(ma97) Use the HSL MA97 (parallel, deterministic) sparse symmetric indefinite solver.</td>
</tr>
<tr>
<td>8</td>
<td>(ma86) Use the HSL MA86 (parallel, non-deterministic) sparse symmetric indefinite solver.</td>
</tr>
</tbody>
</table>

**linsolver_maxitref** (integer): Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro

Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro. Iterative refinement steps may be applied when there are significant errors (e.g., large residuals) in the linear system solves. Applying more iterative refinement steps may improve the numerical accuracy of the linear solves at extra cost.

Range: \( \{0, ..., \infty\} \)

Default: 2

**linsolver_numthreads** (integer): Specify the number of threads to use for linear system solve operations when **linsolver** = 6

Range: \( \{0, ..., \infty\} \)

Default: 0

**linsolver_ooc** (integer): Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when **linsolver** = mklpardiso

Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when **linsolver** = mklpardiso. This option is only active when **linsolver** = mklpardiso.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not use Intel MKL PARDISO out-of-core option.</td>
</tr>
<tr>
<td>1</td>
<td>(maybe) Maybe solve out-of-core depending on how much space is needed.</td>
</tr>
<tr>
<td>2</td>
<td>(yes) Solve linear systems out-of-core when using Intel MKL PARDISO.</td>
</tr>
</tbody>
</table>

**linsolver_pivottol (real):** Specifies the initial pivot threshold used in factorization routines

Specifies the initial pivot threshold used in factorization routines. The value should be in the range \([0, \ldots, 0.5]\) with higher values resulting in more pivoting (more stable factorizations). Values less than 0 will be set to 0 and values larger than 0.5 will be set to 0.5. If `linsolver_pivottol` is non-positive, initially no pivoting will be performed. Smaller values may improve the speed of the code but higher values are recommended for more stability (for example, if the problem appears to be very ill-conditioned).

Range: \([0, 0.5]\]

Default: \(1e-08\)

**lmsize (integer):** Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option

Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option. The value must be between 1 and 100 and is only used with `hessopt = 6`. Larger values may give a more accurate, but more expensive, Hessian approximation. Smaller values may give a less accurate, but faster, Hessian approximation. When using the limited memory BFGS approach it is recommended to experiment with different values of this parameter.

Range: \(\{1, \ldots, 100\}\)

Default: 10

**maxfevals (integer):** Specifies the maximum number of function evaluations before termination

Specifies the maximum number of function evaluations before termination. Values less than zero imply no limit.

Range: \(\{-\infty, \ldots, \infty\}\)

Default: \(-1\)

**maxit (integer):** Specifies the maximum number of iterations before termination

Synonym: iterlim

Default: GAMS iterlim

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</thead>
<tbody>
<tr>
<td>0</td>
<td>Let Knitro automatically choose a value based on the problem type. Currently Knitro sets this value to 10000 for LPs/NLPs and 3000 for MIP problems.</td>
</tr>
<tr>
<td>n</td>
<td>At most (n&gt;0) iterations may be performed before terminating.</td>
</tr>
</tbody>
</table>

**maxtime_cpu (real):** Specifies, in seconds, the maximum allowable CPU time before termination
Range: $[0, 100000000]$
Default: $100000000$

**maxtime_real** *(real)*: Specifies, in seconds, the maximum allowable real time before termination

Synonym: reslim

Range: $[0, 100000000]$
Default: GAMS reslim

**ma_maxtime_cpu** *(real)*: Specifies, in seconds, the maximum allowable CPU time before termination for the multi-algorithm ("MA") procedure *(algorithm=5)*

Range: $[0, \infty]$
Default: $100000000$

**ma_maxtime_real** *(real)*: Specifies, in seconds, the maximum allowable real time before termination for the multi-algorithm ("MA") procedure *(algorithm=5)*

Range: $[0, \infty]$
Default: $100000000$

**ma_outsub** *(boolean)*: Enable writing algorithm output to files for the multi-algorithm *(algorithm=5)* procedure

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not write detailed algorithm output to files.</td>
</tr>
<tr>
<td>1</td>
<td>Write detailed algorithm output to files named knitro_ma_*_.log.</td>
</tr>
</tbody>
</table>

**ma terminate** *(integer)*: Define the termination condition for the multi-algorithm *(algorithm=5)* procedure

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Terminate after all algorithms have completed.</td>
</tr>
<tr>
<td>1</td>
<td>Terminate at first locally optimal solution.</td>
</tr>
<tr>
<td>2</td>
<td>Terminate at first feasible solution estimate.</td>
</tr>
<tr>
<td>3</td>
<td>Terminate at first solution estimate of any type.</td>
</tr>
</tbody>
</table>

**mip_branchrule** *(integer)*: Specifies which branching rule to use for MIP branch and bound procedure

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><em>(auto)</em> Let Knitro automatically choose the branching rule.</td>
</tr>
<tr>
<td>value</td>
<td>meaning</td>
</tr>
<tr>
<td>-------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>1</td>
<td>(most_frac) Use most fractional (most infeasible) branching.</td>
</tr>
<tr>
<td>2</td>
<td>(pseudocost) Use pseudo-cost branching.</td>
</tr>
<tr>
<td>3</td>
<td>(strong) Use strong branching (see options <code>mip_strong_candlim</code>, <code>mip_strong_level</code> and <code>mip_strong_maxit</code> for further control of strong branching procedure).</td>
</tr>
</tbody>
</table>

**mip_clique (integer):** Specifies rules for adding clique cuts

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Do not add clique cuts.</td>
</tr>
<tr>
<td>1</td>
<td>(root) Add cuts derived from equalities at the root node only.</td>
</tr>
<tr>
<td>2</td>
<td>(tree) Add cuts derived from equalities at every node depending on the solution of the relaxation and the cut generation strategy.</td>
</tr>
<tr>
<td>3</td>
<td>(all) Add cuts derived from equalities combining both root and tree cut generations.</td>
</tr>
</tbody>
</table>

**mip_cutfactor (real):** This value specifies a limit on the number of cuts added to a node subproblem

This value specifies a limit on the number of cuts added to a node subproblem. If non-negative, a maximum of `mip_cutfactor` times the number of constraints is possibly appended.

Range: \([0, \infty]\)

Default: 1

**mip_cutoff (real):** This value specifies the objective cutoff value for MIP

Range: \([-\infty, \infty]\)

Default: maxdouble

**mip_cutting_plane (boolean):** Specifies when to apply the cutting plane procedure

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) No cutting plane procedure enabled.</td>
</tr>
<tr>
<td>1</td>
<td>(root) Perform cutting plane procedure at the root node only.</td>
</tr>
</tbody>
</table>

**mip_gub_branch (boolean):** Specifies whether or not to branch on generalized upper bounds (GUBs)

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not branch on GUBs.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Allow branching on GUBs.</td>
</tr>
</tbody>
</table>

**mip_heuristic_diving (integer):** Specifies whether or not to enable the MIP diving heuristic

Specifies whether or not to enable the MIP diving heuristic. This option is a bit-valued option where various diving heuristics can be enabled by activating the corresponding bit value as described below. Setting this option to -1 will use an automatic setting and setting the value to 0 will disable all diving heuristics. Otherwise, set this parameter value to the sum of the values for the individual diving heuristics you wish to enable. For example, to enable only the "fractional" and "linesearch" diving heuristics, you would set this option value to 9 (summing 1 for fractional and 8 for linesearch).

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro determine automatically from mip_heuristic_strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(bit 0) Enable fractional diving heuristic.</td>
</tr>
<tr>
<td>2</td>
<td>(bit 1) Enable vector length diving heuristic.</td>
</tr>
<tr>
<td>4</td>
<td>(bit 2) Enable coefficient diving heuristic.</td>
</tr>
<tr>
<td>8</td>
<td>(bit 3) Enable linesearch diving heuristic.</td>
</tr>
<tr>
<td>16</td>
<td>(bit 4) Enable guided diving heuristic.</td>
</tr>
</tbody>
</table>

**mip_heuristic_feaspump (integer):** Specifies whether or not to enable the MIP feasibility pump heuristic

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro determine automatically from mip_heuristic_strategy.</td>
</tr>
<tr>
<td>0</td>
<td>(off) Feasibility pump heuristic is not applied.</td>
</tr>
<tr>
<td>1</td>
<td>(on) Feasibility pump heuristic is enabled.</td>
</tr>
</tbody>
</table>

**mip_heuristic_lns (integer):** Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics

Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics. This option is a bit-valued option where various LNS heuristics can be enabled by activating the corresponding bit value as described below. Setting this option to -1 will use an automatic setting and setting the value to 0 will disable all LNS heuristics. Otherwise, set this parameter value to the sum of the values for the individual LNS heuristics you wish to enable. For example, to enable both the "RENS" and "RINS" LNS heuristics, you would set this option value to 3 (summing 1 for RENS and 2 for RINS).

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro determine automatically from mip_heuristic_strategy.</td>
</tr>
<tr>
<td>1</td>
<td>(bit 0) Enable relaxation enforced neighborhood search (RENS) heuristic.</td>
</tr>
<tr>
<td>2</td>
<td>(bit 1) Enable relaxation induced neighborhood search (RINS) heuristic.</td>
</tr>
</tbody>
</table>

**mip_heuristic_maxit (integer):** Specifies the maximum number of iterations to allow for MIP heuristic, if one is enabled

Range: \{0, ..., \infty\}

Default: 100
mip_heuristic_misqp (integer): Specifies whether or not to enable the MIP MISQP heuristic

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro determine automatically from mip_heuristic_strategy.</td>
</tr>
<tr>
<td>0</td>
<td>(off) MISQP heuristic is not applied.</td>
</tr>
<tr>
<td>1</td>
<td>(on) MISQP heuristic is enabled.</td>
</tr>
</tbody>
</table>

mip_heuristic_mpec (integer): Specifies whether or not to enable the MIP MPEC heuristic

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro determine automatically from mip_heuristic_strategy.</td>
</tr>
<tr>
<td>0</td>
<td>(off) MPEC heuristic is not applied.</td>
</tr>
<tr>
<td>1</td>
<td>(on) MPEC heuristic is enabled.</td>
</tr>
</tbody>
</table>

mip_heuristic_strategy (integer): Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro choose the heuristic strategy to apply (if any).</td>
</tr>
<tr>
<td>0</td>
<td>(none) No heuristic search applied.</td>
</tr>
<tr>
<td>1</td>
<td>(basic) Apply basic heuristics.</td>
</tr>
<tr>
<td>2</td>
<td>(advanced) Apply more advanced heuristics.</td>
</tr>
<tr>
<td>3</td>
<td>(extensive) Apply most extensive heuristics.</td>
</tr>
</tbody>
</table>

mip_heuristicTerminate (integer): Specifies the condition for terminating the MIP heuristic

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(feasible) Terminate at first feasible point or iteration limit (whichever comes first).</td>
</tr>
<tr>
<td>2</td>
<td>(limit) Always run to the iteration limit.</td>
</tr>
</tbody>
</table>

mip_implications (boolean): Specifies whether or not to add constraints to the MIP derived from logical implications

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not add constraints from logical implications.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Knitro adds constraints from logical implications.</td>
</tr>
</tbody>
</table>
**mip_integer_tol** *(real)*: This value specifies the threshold for deciding whether or not a variable is determined to be an integer

Range: [0, 1]

Default: 1e-08

**mip_intvar_strategy** *(integer)*: Specifies how to handle integer variables

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) No special treatment applied.</td>
</tr>
<tr>
<td>1</td>
<td>(relax) Relax all integer variables.</td>
</tr>
<tr>
<td>2</td>
<td>(mpec) Convert all binary variables to complementarity constraints.</td>
</tr>
</tbody>
</table>

**mip_knapsack** *(integer)*: Specifies rules for adding MIP knapsack cuts

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Do not add knapsack cuts.</td>
</tr>
<tr>
<td>1</td>
<td>(ineqs) Add knapsack cuts derived from linear (in)equalities at the root node only.</td>
</tr>
<tr>
<td>2</td>
<td>(lifted) Add lifted separation cuts derived at every node from the solution of the relaxation.</td>
</tr>
<tr>
<td>3</td>
<td>(all) Add both root node cuts from (in)equalities and lifted separation cuts.</td>
</tr>
</tbody>
</table>

**mip_liftproject** *(boolean)*: Specifies rules for adding lift and project cuts

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Do not add lift and project cuts.</td>
</tr>
<tr>
<td>1</td>
<td>(root) Add lift and project cuts at the root node only.</td>
</tr>
</tbody>
</table>

**mip_lpalg** *(integer)*: Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch and bound procedure

Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch and bound procedure. LP subproblems may arise if the problem is a mixed integer linear program (MILP), or if using **mip_method** = HQG. (Nonlinear programming subproblems use the algorithm specified by the **algorithm** option.)

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose an algorithm, based on the problem characteristics.</td>
</tr>
<tr>
<td>1</td>
<td>(direct) Use the Interior/Direct (barrier) algorithm.</td>
</tr>
<tr>
<td>2</td>
<td>(cg) Use the Interior/CG (barrier) algorithm.</td>
</tr>
<tr>
<td>3</td>
<td>(active) Use the Active Set (simplex) algorithm.</td>
</tr>
</tbody>
</table>
**mip_maxnodes** *(integer)*: Specifies the maximum number of nodes explored (0 means no limit) →

Synonym: nodlim

Range: \(\{0, \ldots, \infty\}\)

Default: GAMS nodlim

**mip_maxsolves** *(integer)*: Specifies the maximum number of subproblem solves allowed (0 means no limit) →

Range: \(\{0, \ldots, \infty\}\)

Default: 0

**mip_maxtime_cpu** *(real)*: Specifies the maximum allowable CPU time in seconds for the complete MIP solution →

Specifies the maximum allowable CPU time in seconds for the complete MIP solution. Use `maxtime_cpu` to additionally limit time spent per subproblem solve.

Range: \([0, \infty]\)

Default: 100000000

**mip_maxtime_real** *(real)*: Specifies the maximum allowable real time in seconds for the complete MIP solution →

Specifies the maximum allowable real time in seconds for the complete MIP solution. Use `maxtime_real` to additionally limit time spent per subproblem solve.

Range: \([0, \infty]\)

Default: GAMS reslim

**mip_method** *(integer)*: Specifies which MIP method to use →

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro automatically choose the method.</td>
</tr>
<tr>
<td>1</td>
<td>(BB) Use the standard branch and bound method.</td>
</tr>
<tr>
<td>2</td>
<td>(HQG) Use the hybrid Quesada-Grossman method (for convex, nonlinear problems only).</td>
</tr>
<tr>
<td>3</td>
<td>(MISQP) Use mixed-integer SQP method (allows for non-relaxable integer variables).</td>
</tr>
</tbody>
</table>

**mip_mir** *(integer)*: Specifies rules for adding mixed integer rounding cuts →

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro decide whether to add mixed integer rounding cuts.</td>
</tr>
<tr>

</tr>
</tbody>
</table>

**mip_nodealg** *(integer):* Specifies which algorithm to use for standard node subproblem solves in MIP (same options as algorithm user option)

Range: {0, ..., 5}

Default: 0

**mip_numthreads** *(integer):* Specify the number of threads to use for MIP branch and bound (when **mip_method** = 1)

Specify the number of threads to use for MIP branch and bound (when **mip_method** = 1). 0 Let Knitro choose the number of threads. n > 0 Use n threads for the MIP branch and bound.

Range: {0, ..., ∞}

Default: 0

**mip_opt_gap_abs** *(real):* The absolute optimality gap stop tolerance for MIP

Synonym: optca

Range: [-1, ∞]

Default: GAMS optca

**mip_opt_gap_rel** *(real):* The relative optimality gap stop tolerance for MIP

Synonym: optcr

Range: [-1, ∞]

Default: GAMS optcr

**mip_outinterval** *(integer):* Specifies node printing interval for **mip_outlevel** when **mip_outlevel** > 0

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Let Knitro decide.</td>

</tr>
</tbody>
</table>
mip_outlevel (integer): Specifies how much MIP information to print

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Do not print any MIP node information.</td>
</tr>
<tr>
<td>1</td>
<td>(iters) Print one line of output for every node.</td>
</tr>
<tr>
<td>2</td>
<td>(iterstime) Also print accumulated time for every node.</td>
</tr>
<tr>
<td>3</td>
<td>(root) Also print detailed log from root node solve.</td>
</tr>
</tbody>
</table>

mip_pseudoinit (integer): Specifies the method used to initialize pseudo-costs corresponding to variables that have not yet been branched on in the MIP method

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Let Knitro automatically choose the method.</td>
</tr>
<tr>
<td>1</td>
<td>Initialize using the average value of computed pseudo-costs.</td>

<tr>
<td>1</td>
<td>(up) Choose the up (i.e. (&gt;=) node first.</td>
</tr>
</tbody>
</table>

**mip_selectrule (integer)**: Specifies the MIP select rule for choosing the next node in the branch and bound tree

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(auto) Let Knitro choose the node selection rule.</td>
</tr>
<tr>
<td>1</td>
<td>(depth_first) Search the tree using a depth first procedure.</td>
</tr>
<tr>
<td>2</td>
<td>(best_bound) Select the node with the best relaxation bound.</td>
</tr>
<tr>
<td>3</td>
<td>(combo_1) Use depth first unless pruned, then best bound.</td>
</tr>
</tbody>
</table>

**mip_strong_candlim (integer)**: Specifies the maximum number of candidates to explore for MIP strong branching

Range: \([-\infty, ..., \infty]\)

Default: 128

**mip_strong_level (integer)**: Specifies the maximum number of tree levels on which to perform MIP strong branching

Range: \([-\infty, ..., \infty]\)

Default: 10

**mip_strong_maxit (integer)**: Specifies the maximum number of iterations to allow for MIP strong branching solves

Range: \([-\infty, ..., \infty]\)

Default: 1000

**mip_terminate (integer)**: Specifies conditions for terminating the MIP algorithm

Default: 0
### Mip_Zerohalf

**mip_zerohalf (integer):** Specifies rules for adding zero-half cuts

- **Default:** 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Do not add zero-half cuts.</td>
</tr>
<tr>
<td>1</td>
<td>(root) Add cuts derived from equalities at the root node only.</td>
</tr>
<tr>
<td>2</td>
<td>(tree) Add cuts derived from equalities at every node depending on the solution of the relaxation and the cut generation strategy.</td>
</tr>
<tr>
<td>3</td>
<td>(all) Add cuts derived from equalities combining both root and tree cut generations.</td>
</tr>
</tbody>
</table>

### Ms_Deterministic

**ms_deterministic (boolean):** Indicates whether Knitro multi-start procedure will be deterministic (when ms_termine = 0)

- **Default:** 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) multithreaded multi-start is non-deterministic.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) multithreaded multi-start is deterministic (when ms_termine = 0).</td>
</tr>
</tbody>
</table>

### Ms_Enable

**ms_enable (boolean):** Indicates whether Knitro will solve from multiple start points to find a better local minimum

- **Default:** 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Knitro solves from a single initial point.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Knitro solves using multiple start points.</td>
</tr>
</tbody>
</table>

### Ms_Maxbndrange

**ms_maxbndrange (real):** Specifies the maximum range that an unbounded variable can take when determining new start points

Specifies the maximum range that an unbounded variable can take when determining new start points. If a variable is unbounded in one or both directions, then new start point values are restricted by the option. If $x_i$ is such a variable, then all initial values satisfy $\max\{l_i, x_i^0 - \text{ms_maxbndrange}/2\} \leq x_i \leq \min\{u_i, x_i^0 + \text{ms_maxbndrange}/2\}$, where $x_i^0$ is the initial value of $x_i$ provided by the user, and $l_i$ and $u_i$ are the variable bounds (possibly infinite) on $x_i$. This option has no effect unless ms_enable = yes.

- **Range:** $[-\infty, \infty]$

- **Default:** 1000

### Ms_Maxsolves

**ms_maxsolves (integer):** Specifies how many start points to try in multi-start

Specifies how many start points to try in multi-start. This option has no effect unless ms_enable = yes.

- **Default:** 0
Let Knitro automatically choose a value based on the problem size. The value is \( \min(200, 10 N) \), where \( N \) is the number of variables in the problem.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Let Knitro automatically choose a value based on the problem size. The value is ( \min(200, 10 N) ), where ( N ) is the number of variables in the problem.</td>
</tr>
<tr>
<td>( n )</td>
<td>Try ( n &gt; 0 ) start points.</td>
</tr>
</tbody>
</table>

**ms_maxtime_cpu (real):** Specifies, in seconds, the maximum allowable CPU time before termination

Specifies, in seconds, the maximum allowable CPU time before termination. The limit applies to the operation of Knitro since multi-start began; in contrast, the value of *maxtime_cpu* limits how long Knitro iterates from a single start point. Therefore, *ms_maxtime_cpu* should be greater than *maxtime_cpu*. This option has no effect unless *ms_enable = yes*.

Range: \([-\infty, \infty]\)

Default: 100000000

**ms_maxtime_real (real):** Specifies, in seconds, the maximum allowable real time before termination

Specifies, in seconds, the maximum allowable real time before termination. The limit applies to the operation of Knitro since multi-start began; in contrast, the value of *maxtime_real* limits how long Knitro iterates from a single start point. Therefore, *ms_maxtime_real* should be greater than *maxtime_real*. This option has no effect unless *ms_enable = yes*.

Range: \([-\infty, \infty]\)

Default: 100000000

**ms_numthreads (integer):** Specify the number of threads to use for multi-start (when *ms_enable = 1*)

Specify the number of threads to use for multi-start (when *ms_enable = 1*). 0 Let Knitro choose the number of threads (currently sets *ms_numthreads* based on numthreads). \( n > 0 \) Use \( n \) threads for the multi-start (solve \( n \) problems in parallel).

Range: \( \{0, ..., \infty\} \)

Default: 0

**ms_num_to_save (integer):** Specifies the number of distinct feasible points to save in a file named knitro_mspoints

Specifies the number of distinct feasible points to save in a file named knitro_mspoints.log. Each point results from a Knitro solve from a different starting point, and must satisfy the absolute and relative feasibility tolerances. The file stores points in order from best objective to worst. Points are distinct if they differ in objective value or some component by the value of *ms_savetol* using a relative tolerance test. This option has no effect unless *ms_enable = yes*.

Range: \( \{0, ..., \infty\} \)

Default: 0

**ms_outsub (boolean):** Enable writing algorithm output to files for the parallel multi-start procedure

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not write detailed algorithm output to files.</td>
</tr>
<tr>
<td>1</td>
<td>Write detailed algorithm output to files named knitro_ms_*log.</td>
</tr>
</tbody>
</table>

**ms_savetol** (*real*): Specifies the tolerance for deciding if two feasible points are distinct

Specifies the tolerance for deciding if two feasible points are distinct. Points are distinct if they differ in objective value or some component by the value of *ms_savetol* using a relative tolerance test. A large value can cause the saved feasible points in the file knitro_mspoints.log to cluster around more widely separated points. This option has no effect unless *ms_enable* = yes. and *ms_num_to_save* is positive.

Range: $[-\infty, \infty]$

Default: $1e-06$

**ms_seed** (*integer*): Seed value used to generate random initial points in multi-start; should be a non-negative integer

Range: $\{0, ..., \infty\}$

Default: 0

**ms_startptrange** (*real*): Specifies the maximum range that each variable can take when determining new start points

Specifies the maximum range that each variable can take when determining new start points. If a variable has upper and lower bounds and the difference between them is less than or equal to *ms_startptrange*, then new start point values for the variable can be any number between its upper and lower bounds. If the variable is unbounded in one or both directions, or the difference between bounds is greater than *ms_startptrange*, then new start point values are restricted by the option. If $x_i$ is such a variable, then all initial values satisfy $\max\{b^L_i, x^0_i - \tau\} \leq x_i \leq \min\{b^U_i, x^0_i + \tau\}, \tau = \min\{ms\_startptrange/2, ms\_maxbndrange/2\}$ where $x^0_i$ is the initial value of $x_i$ provided by the user, and $b^L_i$ and $b^U_i$ are the variable bounds (possibly infinite) on $x_i$. This option has no effect unless *ms_enable* = yes.

Range: $[-\infty, \infty]$

Default: $1e+20$

**ms_terminate** (*integer*): Specifies the condition for terminating multi-start

Specifies the condition for terminating multi-start. This option has no effect unless *ms_enable* = yes.

Default: 0

</tr>
</tbody>
</table>
names (boolean): Enable to pass variable and equation names to Knitro

Default: 0

ncvx_qcqp_init (integer): Specifies the initialization strategy used for non-convex QPs and QCQPs

Specifies the initialization strategy used for non-convex QPs and QCQPs. In particular, these strategies may be more likely to cause Knitro to find global or better local solutions on non-convex quadratic programs (QPs) or non-convex quadratically constrained quadratic programs (QCQPs).

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Knitro will automatically determine the strategy.</td>
</tr>
<tr>
<td>0</td>
<td>(none) No special initialization strategy is used.</td>
</tr>
<tr>
<td>1</td>
<td>(linear) Initialize by solving a linear relaxation.</td>
</tr>
<tr>
<td>2</td>
<td>(hybrid) Initialize by solving a hybrid formulation.</td>
</tr>
<tr>
<td>3</td>
<td>(penalty) Initialize by solving a penalty formulation.</td>
</tr>
<tr>
<td>4</td>
<td>(cvxquad) Initialize by solving a convex quadratic relaxation.</td>
</tr>
</tbody>
</table>

newpoint (integer): Specifies additional action to take after every iteration in a solve of a continuous problem

Specifies additional action to take after every iteration in a solve of a continuous problem. An iteration of Knitro results in a new point that is closer to a solution. The new point includes values of x and Lagrange multipliers lambda. The "newpoint" feature in Knitro is currently only available for continuous problems (solved via KNsolve()).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(none) Knitro takes no additional action.</td>
</tr>
<tr>
<td>1</td>
<td>(saveone) Knitro writes x and lambda to the file knitro_newpoint.log. Previous contents of the file are overwritten.</td>
</tr>
<tr>
<td>2</td>
<td>(saveall) Knitro appends x and lambda to the file knitro_newpoint.log. Warning: this option can generate a very large file. All iterates, including the start point, crossover points, and the final solution are saved.</td>
</tr>
</tbody>
</table>

objrange (real): Specifies the extreme limits of the objective function for purposes of determining unboundedness

Specifies the extreme limits of the objective function for purposes of determining unboundedness. If the magnitude of the objective function becomes greater than objrange for a feasible iterate, then the problem is determined to be unbounded and Knitro proceeds no further.

Range: [0, ∞]

Default: 1e+20

option_file (string): additional option file name - read only by KNITRO solver lib
**opttol** *(real)*: Specifies the final relative stopping tolerance for the KKT (optimality) error

Specifies the final relative stopping tolerance for the KKT (optimality) error. Smaller values of **opttol** result in a higher degree of accuracy in the solution with respect to optimality.

Range: \([0, \infty]\)

Default: \(1e-06\)

**opttolabs** *(real)*: Specifies the final absolute stopping tolerance for the KKT (optimality) error

Synonym: **opttol-abs**

Specifies the final absolute stopping tolerance for the KKT (optimality) error. Smaller values of **opttolabs** result in a higher degree of accuracy in the solution with respect to optimality.

Range: \([0, \infty]\)

Default: \(0.001\)

**outappend** *(boolean)*: Specifies whether output should be started in a new file, or appended to existing files

Specifies whether output should be started in a new file, or appended to existing files. The option affects knitro.log. It does not affect knitro_newpoint.log, which is controlled by option newpoint.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Erase any existing files when opening for output.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Append output to any existing files.</td>
</tr>
</tbody>
</table>

**outdir** *(string)*: Specifies a single directory as the location to write all output files

Specifies a single directory as the location to write all output files. The option should be a full pathname to the directory, and the directory must already exist.

**outlev** *(integer)*: Controls the level of output produced by Knitro

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

<tr>
<td>2</td>
<td>(iter,10) Print basic information every 10 iterations.</td>
</tr>
<tr>
<td>3</td>
<td>(iter) Print basic information at each iteration.</td>
</tr>
<tr>
<td>4</td>
<td>(iter_verbose) Print basic information and the function count at each iteration.</td>
</tr>
<tr>
<td>5</td>
<td>(iter,x) Print all the above, and the values of the solution vector x.</td>
</tr>
<tr>
<td>6</td>
<td>(all) Print all the above, and the values of the constraints c at x and the Lagrange multipliers lambda.</td>
</tr>
</tbody>
</table>

**outmode** *(integer)*: Specifies where to direct the output from Knitro

---
Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(screen) Output is directed to standard out (e.g., screen).</td>
</tr>
<tr>
<td>1</td>
<td>(file) Output is sent to a file named knitro.log.</td>
</tr>
<tr>
<td>2</td>
<td>(both) Output is directed to both the screen and file knitro.log.</td>
</tr>
</tbody>
</table>

**outname (string):** Use to specify a custom filename when output is written to a file using **outmode**

Default: 0

**output_time (boolean):** print output on where time is used

Default: 0

**out_csvinfo (boolean):** Controls whether or not to generates a file knitro_solve

Controls whether or not to generates a file knitro_solve.csv containing solve information in comma separated format.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) No solution information file is generated.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) The knitro_solve.csv solution file is generated.</td>
</tr>
</tbody>
</table>

**out_csvname (string):** Use to specify a custom csv filename when using **out_csvinfo**

**out_hints (boolean):** Specifies whether to print diagnostic hints (e.g. about user option settings) after solving

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not print any hints.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Print diagnostic hints on occasion.</td>
</tr>
</tbody>
</table>

**presolve (boolean):** Determine whether or not to use the Knitro presolver to try to simplify the model by removing variables or constraints

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) Do not use the Knitro presolver.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Enable the Knitro presolver.</td>
</tr>
</tbody>
</table>

**presolveop_tighten (integer):** Determine whether or not to enable the Knitro presolve operation to tighten variable bounds
Default: \(-1\)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Automatically determined (may depend on the algorithm).</td>
</tr>
<tr>
<td>0</td>
<td>(none) Do not tighten variable bounds (unless it removes a constraint).</td>
</tr>
<tr>
<td>1</td>
<td>(varbnd) Enable tightening variable bounds always.</td>
</tr>
</tbody>
</table>

**presolve_initpt** \((integer)\): Control whether the Knitro presolver can shift a user-supplied initial point

Default: \(-1\)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose whether to allow shifting.</td>
</tr>
<tr>
<td>0</td>
<td>(noshift) Do not allow presolver to shift user-supplied initial point.</td>
</tr>
<tr>
<td>1</td>
<td>(linshift) Allow presolver to shift user-supplied initial point if it only appears in linear constraints.</td>
</tr>
<tr>
<td>2</td>
<td>(anyshift) Allow presolver to shift any user-supplied initial point.</td>
</tr>
</tbody>
</table>

**presolve_level** \((integer)\): Set the level of presolve operations to enable through the Knitro presolver

Set the level of presolve operations to enable through the Knitro presolver. A higher presolve level enables more complex presolve operations.

Default: \(-1\)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>(auto) Let Knitro automatically choose the presolve level.</td>
</tr>
<tr>
<td>1</td>
<td>(level1) Enable the most basic presolve operations.</td>
</tr>
<tr>
<td>2</td>
<td>(level2) Enable more advanced presolve operations.</td>
</tr>
</tbody>
</table>

**presolve_passes** \((integer)\): Set a maximum limit on the number of passes through the Knitro presolve operations

Range: \(\{0, \ldots, \infty\}\)

Default: 10

**presolve_tol** \((real)\): Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model

Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model. If you believe the Knitro presolver is incorrectly modifying the model, use a smaller value for this tolerance (or turn the presolver off).

Range: \([0, \infty]\)

Default: \(1e-06\)

**qextractalg** \((integer)\): quadratic extraction algorithm in GAMS interface

Default: 0
restarts (integer): Specifies whether or not to enable automatic restarts in Knitro

Specifies whether or not to enable automatic restarts in Knitro. When enabled, if a Knitro algorithm seems to be converging slowly or not converging, the algorithm will automatically restart, which may help with convergence.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No automatic restarts allowed.</td>
</tr>
<tr>
<td>n</td>
<td>At most n&gt;0 automatic restarts may be performed.</td>
</tr>
</tbody>
</table>

restarts_maxit (integer): When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No iteration limit on restarts enforced.</td>
</tr>
<tr>
<td>n</td>
<td>At most n&gt;0 iterations are allowed without convergence before enforcing an automatic restart, if restarts are enabled.</td>
</tr>
</tbody>
</table>

scale (integer): Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables

Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables. If scaling is performed, internal computations, including some aspects of the optimality tests, are based on the scaled values, though the feasibility error is always computed in terms of the original, unscaled values.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) No scaling is performed.</td>
</tr>
<tr>
<td>1</td>
<td>(user_internal) User provided scaling is used if defined, otherwise Knitro internal scaling is applied.</td>
</tr>
<tr>
<td>2</td>
<td>(user_none) User provided scaling is used if defined, otherwise no scaling is applied.</td>
</tr>
<tr>
<td>3</td>
<td>(internal) Knitro internal scaling is applied.</td>
</tr>
</tbody>
</table>

soc (integer): Specifies whether or not to try second order corrections (SOC)

Specifies whether or not to try second order corrections (SOC). A second order correction may be beneficial for problems with highly nonlinear constraints.
Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) No second order correction steps are attempted.</td>
</tr>
<tr>
<td>1</td>
<td>(maybe) Second order correction steps may be attempted on some iterations.</td>
</tr>
<tr>
<td>2</td>
<td>(yes) Second order correction steps are always attempted if the original step is rejected and there are nonlinear constraints.</td>
</tr>
</tbody>
</table>

strat_warm_start (boolean): Specifies whether or not to invoke a warm-start strategy

Specifies whether or not to invoke a warm-start strategy. A warm-start strategy may be beneficial when an initial point close to the solution can be provided. For example, this may occur when solving a sequence of closely related problems, and the solution from one problem can be used to initialize (or warm-start) the next problem in the sequence. The Knitro warm-start strategy will use this information to tune the algorithms to try to converge more quickly in this case. If the initial point is not sufficiently close to the solution, or is too infeasible, the warm-start strategy may not be helpful. This option is currently only used for the Knitro barrier/interior-point algorithms. In this case it may also be useful to experiment with different (smaller than default) values for the initial barrier parameter bar_initmu. In general, the closer the initial point is to the solution, the smaller this value should be (Knitro will try by default to initialize this to a good value when applying a warm-start strategy).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(no) No warm-start strategy is applied.</td>
</tr>
<tr>
<td>1</td>
<td>(yes) Knitro will apply a warm-start strategy with special tunings.</td>
</tr>
</tbody>
</table>

threads (integer): default thread count

Synonyms: gthreads numthreads

Controls the number of threads to use. Non-positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks.

By default, Knitro decides automatically how to use the threads specified. For example, if the multi-start method is enabled, it can run in parallel threads. If the multi-algorithm algorithm=5 is selected, the different algorithms can be run in parallel threads if threads are allocated. In case only one algorithm is running, multiple threads can be allocated to the MKL BLAS library or to the PARDISO linear solver via the threads option: see the blasoption, par_blasnumthreads, and par_lssnumthreads options for details.

Range: \{-\infty, \ldots, \infty\}

Default: GAMS threads

tuner (boolean): Indicates whether to invoke the Knitro-Tuner

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(off) Do not invoke the Knitro-Tuner.</td>
</tr>
<tr>
<td>1</td>
<td>(on) Invoke the Knitro-Tuner.</td>
</tr>
</tbody>
</table>
**tuner_maxtime_cpu (real):** Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner.

Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner. The limit applies to the operation of Knitro since the Knitro-Tuner began. In contrast, the value of `maxtime_cpu` places a time limit on each individual Knitro-Tuner solve for a particular option setting. Therefore, `tuner_maxtime_cpu` should be greater than `maxtime_cpu`. This option has no effect unless `tuner = on`.

Range: $[0, \infty]$  
Default: 100000000

**tuner_maxtime_real (real):** Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner.

Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner. The limit applies to the operation of Knitro since the Knitro-Tuner began. In contrast, the value of `maxtime_real` places a time limit on each individual Knitro-Tuner solve for a particular option setting. Therefore, `tuner_maxtime_real` should be greater than `maxtime_real`. This option has no effect unless `tuner = on`.

Range: $[0, \infty]$  
Default: 100000000

**tuner_optionsfile (string):** Can be used to specify the location of a Tuner options file.

**tuner_outsub (integer):** Enable writing additional Tuner subproblem solve output to files for the Knitro-Tuner procedure (tuner=1).

Default: 0  

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not write detailed solve output to files.</td>
</tr>
<tr>
<td>1</td>
<td>Write summary solve output to a file named knitro_tuner_summary.log.</td>
</tr>
<tr>
<td>2</td>
<td>Write detailed individual solve output to files named knitro_tuner_*_.log.</td>
</tr>
</tbody>
</table>

**tuner_terminate (integer):** Define the termination condition for the Knitro-Tuner procedure (tuner=1).

Default: 0  

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Terminate after all solves have completed.</td>
</tr>
<tr>
<td>1</td>
<td>Terminate at first locally optimal solution.</td>
</tr>
<tr>
<td>2</td>
<td>Terminate at first feasible solution estimate.</td>
</tr>
<tr>
<td>3</td>
<td>Terminate at first solution estimate of any type.</td>
</tr>
</tbody>
</table>

**xtol (real):** The optimization process will terminate if the relative change in all components of the solution point estimate is less than `xtol` for `xtol_iters`.
The optimization process will terminate if the relative change in all components of the solution point estimate is less than `xtol` for `xtol_iters` consecutive iterations. If using the Interior/Direct or Interior/CG algorithm and the barrier parameter is still large, Knitro will first try decreasing the barrier parameter before terminating.

Range: \([0, \infty]\)

Default: \(1e-12\)

\(\text{xtol} \text{ } \text{integer}\): The optimization process will terminate if the relative change in the solution estimate is less than \(\text{xtol}\) for \(\text{xtol}\) consecutive iterations.

The optimization process will terminate if the relative change in the solution estimate is less than \(\text{xtol}\) for \(\text{xtol}\) consecutive iterations. If set to 0, Knitro chooses this value based on the solver and context. Currently Knitro sets this value to 3 unless the MISQP algorithm is being used, in which case the value is set to 1 by default.

Range: \([0, \ldots, \infty]\)

Default: 0

5.23.6 Knitro Termination Test and Optimality

5.23.6.1 Continuous problems

The first-order conditions for identifying a locally optimal solution of the problem (1) are:

\[
\nabla_x L(x, \lambda) = \nabla f(x) + \sum_{i=1}^{m} \lambda_i^c \nabla c_i(x) + \sum_{j=1}^{n} \lambda_j^b \nabla b_j(x) = 0
\]

\[
\lambda_i^c \min[(c_i(x) - c_i^L), (c_i^U - c_i(x))] = 0, \quad i = 1 \ldots m
\]

\[
\lambda_j^b \min[(x_j - b_j^L), (b_j^U - x_j)] = 0, \quad j = 1 \ldots n
\]

\[
c_i^L \leq c_i(x) \leq c_i^U, \quad i = 1 \ldots m
\]

\[
b_j^L \leq x_j \leq b_j^U, \quad j = 1 \ldots n
\]

where \(\mathcal{I}\) and \(\mathcal{B}\) represent the sets of indices corresponding to the general inequality constraints and non-fixed variable bound constraints respectively, \(\lambda_i^c\) is the Lagrange multiplier corresponding to constraint \(c_i(x)\), and \(\lambda_j^b\) is the Lagrange multiplier corresponding to the simple bounds on \(x_j\). There is exactly one Lagrange multiplier for each constraint and variable. The Lagrange multiplier may be restricted to take on a particular sign depending on the corresponding constraint or variable bounds.

In Knitro we define the feasibility error (\(\text{FeasErr}\)) at a point \(x^k\) to be the maximum violation of the constraints of (1), i.e.,

\[
\text{FeasErr} = \max_{i=1 \ldots m, j=1 \ldots n} (0, (c_i^L - c_i(x^k)), (c_i(x^k) - c_i^U), (b_j^L - x_j^k), (x_j^k - b_j^U))
\]

while the optimality error (\(\text{OptErr}\)) is defined as the maximum violation of the first three conditions of (3)

\[
\text{OptErr} = \max_{i=1 \ldots m, j=1 \ldots n} (\|\nabla_x L(x^k, \lambda^k)\|_{\infty}, \lambda_i^c \min[(c_i(x) - c_i^L), (c_i^U - c_i(x))], \lambda_j^b \min[(x_j - b_j^L), (b_j^U - x_j)])
\]
The remaining conditions on the sign of the multipliers are enforced explicitly throughout the optimization. In order to take into account problem scaling in the termination test, the following scaling factors are defined:

\[
\tau_1 = \max(1, (c_i^L - c_i(x^0)), (c_i(x^0) - c_i^U), (b_j^L - x_j^0), (x_j^0 - b_j^U)),
\]

\[
\tau_2 = \begin{cases} 
\max(1, \|\nabla f(x^k)\|_{\infty}), & \text{for constrained problems}, \\
\max(1, \min(|f(x^k)|, \|\nabla f(x^0)\|_{\infty})), & \text{for unconstrained problems}, 
\end{cases}
\]

where \(x^0\) represents the initial point. The special treatment for unconstrained problems is necessary, as for these problems, \(\|\nabla f(x^k)\|_{\infty} \to 0\) as a solution is approached, thus \(\max(1, \|\nabla f(x^k)\|_{\infty})\) would not be effective.

Knitro stops and declares **Locally optimal solution found** if the following stopping conditions are satisfied:

\[
\text{FeasErr} \leq \max(\tau_1 \ast \text{feastol, feastolabs}) \quad (4)
\]

\[
\text{OptErr} \leq \max(\tau_2 \ast \text{opttol, opttolabs}) \quad (5)
\]

where \(\text{feastol, opttol, feastolabs and opttolabs}\) are user-defined options (see section **Usage**).

This stopping test is designed to give the user much flexibility in deciding when the solution returned by Knitro is accurate enough. One can use a purely scaled stopping test (which is the recommended and default option) by setting \(\text{feastolabs}\) and \(\text{opttolabs}\) equal to \(0.0e0\). Likewise, an absolute stopping test can be enforced by setting \(\text{feastol}\) and \(\text{opttol}\) equal to \(0.0e0\).

**Unbounded problems**

Since by default Knitro uses a relative/scaled stopping test it is possible for the optimality conditions to be satisfied for an unbounded problem. For example, if \(\tau_2 \to \infty\) while the optimality error \(\text{OptErr}\) stays bounded, condition (5) will eventually be satisfied for some \(\text{opttol}>0\). If you suspect that your problem may be unbounded, using an absolute stopping test will allow Knitro to detect this.

### 5.23.6.2 Discrete problems

Algorithms for solving versions of (1) where one or more of the variables are restricted to take on only discrete values, proceed by solving a sequence of continuous relaxations, where the discrete variables are relaxed such that they can take on any continuous value. The *global* solutions \(f(x^g)\) of these relaxed problems provide a lower bound on the optimal objective value for problem (1) (upper bound if maximizing). If a feasible point is found for problem (1) that satisfies the discrete restrictions on the variables, then this provides an upper bound on the optimal objective value of problem (1) (lower bound if maximizing). We will refer to these feasible points as *incumbent* points and denote the objective value at an incumbent point by \(f(x^I)\). Assuming all the continuous subproblems have been solved to global optimality (if the problem is convex, all local solutions are global solutions), an optimal solution of problem (1) is verified when the lower bound and upper bound are equal.

Knitro declares optimality for a discrete problem when the gap between the best (i.e., largest) lower bound \(f(x^g)\) and the best (i.e., smallest) upper bound \(f(x^I)\) is less than a threshold determined by the user options \(\text{mip\_opt\_gap\_abs}\) and \(\text{mip\_opt\_gap\_rel}\). Specifically, Knitro declares optimality when either

\[
f(x^I) - f(x^g) \leq \text{mip\_integral\_gap\_abs}
\]
or

\[ f(x_I) - f(x_R) \leq \text{mip\_integral\_gap\_rel} \cdot \max(1, |f(x_I)|), \]

where \text{mip\_opt\_gap\_abs} and \text{mip\_opt\_gap\_rel} are typically small positive numbers. Since these termination conditions assume that the continuous subproblems are solved to global optimality and Knitro only finds local solutions of nonconvex, continuous optimization problems, they are only reliable when solving convex, mixed integer problems. The integrality gap \( f(x_I) - f(x_R) \) should be non-negative although it may become slightly negative from roundoff error, or if the continuous subproblems are not solved to sufficient accuracy. If the integrality gap becomes largely negative, this may be an indication that the model is nonconvex, in which case Knitro may not converge to the optimal solution, and will be unable to verify optimality (even if it claims otherwise).

Note that the default values for \text{mip\_opt\_gap\_abs} and \text{mip\_opt\_gap\_rel} are taken from the GAMS options \text{optCA} and \text{optCR}, but an explicit setting of \text{mip\_opt\_gap\_abs} or \text{mip\_opt\_gap\_rel} will override those.

5.23.7 Knitro Output

If \text{outlev}=0 then all printing of output is suppressed. The description below assumes the default output level (\text{outlev}=2) except where indicated:

Nondefault Options:

This output lists all user options (see section Usage) which are different from their default values. If nothing is listed in this section then all user options are set to their default values.

Problem Characteristics:

The output begins with a description of the problem characteristics.

Iteration Information - Continuous Problems:

An iteration, in the context of Knitro, is defined as a step which generates a new solution estimate (i.e., a successful step). The columns of the iteration log are as follows:

- \text{Iter} Iteration number.
- \text{fCount} The cumulative number of function evaluations, only included if (\text{outlev}>3)
- \text{Objective} Gives the value of the objective function at the current iterate.
- \text{FeasErr} Gives a measure of the feasibility violation at the current iterate.
- \text{OptErr} Gives a measure of the violation of the Karush-Kuhn-Tucker (KKT) (first-order) optimality conditions (not including feasibility) at the current iterate.
- ||\text{Step}|| The 2-norm length of the step (i.e., the distance between the new iterate and the previous iterate).
- \text{CG its} The number of Projected Conjugate Gradient (CG) iterations required to compute the step.

If \text{outlev}=2, information is printed every 10 major iterations. If \text{outlev}=3 information is printed at each major iteration. If \text{outlev}>4 addition information is included in the log.

Iteration Information - Discrete Problems:

By default, the GAMS/Knitro link prints a log line at every 10th node. This frequency can be changed via the \text{mip\_outinterval} option. To turn off the node log completely, set the \text{mip\_outlevel} option to 0. The columns of the iteration log for discrete models are as follows:
- **Node** The node number. If an integer feasible point was found at a given node, it is marked with a *
- **Left** The current number of active nodes left in the branch and bound tree.
- **Iinf** The current number of active nodes left in the branch and bound tree.
- **Objective** Gives the value of the objective function at the solution of the relaxed subproblem solved at the current node. If the subproblem was infeasible or failed, this is indicated. Additional symbols may be printed at some nodes if the node was pruned (pr), integer feasible (f), or an integer feasible point was found through rounding (r).
- **Best relaxatn** The value of the current best relaxation (lower bound on the solution if minimizing).
- **Best incumbent** The value of the current best integer feasible point (upper bound on the solution if minimizing).

**Termination Message:** At the end of the run a termination message is printed indicating whether or not the optimal solution was found and if not, why the solver terminated. Below is a list of some possible termination messages.

- **EXIT: Locally optimal solution found.**
  Knitro found a locally optimal point which satisfies the stopping criterion (see section Knitro Termination Test and Optimality) for more detail on how this is defined. If the problem is convex (for example, a linear program), then this point corresponds to a globally optimal solution.

- **EXIT: Iteration limit reached.**
  The iteration limit was reached before being able to satisfy the required stopping criteria.

- **EXIT: Convergence to an infeasible point. Problem appears to be locally infeasible.**
  The algorithm has converged to an infeasible point from which it cannot further decrease the infeasibility measure. This happens when the problem is infeasible, but may also occur on occasion for feasible problems with nonlinear constraints or badly scaled problems. It is recommended to try various initial points. If this occurs for a variety of initial points, it is likely the problem is infeasible.

- **EXIT: Problem appears to be unbounded.**
  The objective function appears to be decreasing without bound, while satisfying the constraints.

- **EXIT: Current point cannot be improved.**
  No more progress can be made. If the current point is feasible it is likely it may be optimal, however the stopping tests cannot be satisfied perhaps because of degeneracy, ill-conditioning or bad scaling.

- **EXIT: Current point cannot be improved. Point appears to be optimal, but desired accuracy could not be achieved.**
  No more progress can be made, but the stopping tests are close to being satisfied (within a factor of 100) and so the current approximate solution is believed to be optimal.

- **EXIT: Time limit reached.**
  The time limit was reached before being able to satisfy the required stopping criteria.

- **EXIT: Evaluation error.**
  This termination value indicates that an evaluation error occurred (e.g., divide by 0, taking the square root of a negative number), preventing the optimization from continuing.

- **EXIT: Not enough memory available to solve problem.**
This termination value indicates that there was not enough memory available to solve the problem.

**Final Statistics:**

Following the termination message some final statistics on the run are printed. Both relative and absolute error values are printed.

**Solution Vector/Constraints:**

If `outlev=5`, the values of the solution vector are printed after the final statistics. If `outlev=6`, the final constraint values are also printed before the solution vector and the values of the Lagrange multipliers (or dual variables) are printed next to their corresponding constraint or bound.

### 5.23.8 Algorithm Options

#### 5.23.8.1 Automatic

By default, Knitro will automatically try to choose the best optimizer for the given problem based on the problem characteristics.

#### 5.23.8.2 Interior/Direct

If the Hessian of the Lagrangian is ill-conditioned or the problem does not have a large-dense Hessian, it may be advisable to compute a step by directly factoring the KKT (primal-dual) matrix rather than using an iterative approach to solve this system. Knitro offers the Interior/Direct optimizer which allows the algorithm to take direct steps by setting `algorithm=1`. This option will try to take a direct step at each iteration and will only fall back on the iterative step if the direct step is suspected to be of poor quality, or if negative curvature is detected.

Using the Interior/Direct optimizer may result in substantial improvements over Interior/CG when the problem is ill-conditioned (as evidenced by Interior/CG taking a large number of Conjugate Gradient iterations). We encourage the user to try both options as it is difficult to predict in advance which one will be more effective on a given problem. In each case, also experiment with the `bar_murule` option, as it is difficult to predict which update rule will work best.

**NOTE:** Since the Interior/Direct algorithm in Knitro requires the explicit storage of a Hessian matrix, this version can only be used with Hessian options, `hessopt=1, 2, 3` or `6`. It may not be used with Hessian options, `hessopt=4` or `5`, which only provide Hessian-vector products. Both the Interior/Direct and Interior/CG methods can be used with the `bar_feasible` option.

#### 5.23.8.3 Interior/CG

Since Knitro was designed with the idea of solving large problems, the Interior/CG optimizer in Knitro offers an iterative Conjugate Gradient approach to compute the step at each iteration. This approach has proven to be efficient in most cases and allows Knitro to handle problems with large, dense Hessians, since it does not require factorization of the Hessian matrix. The Interior/CG algorithm can be chosen by setting `algorithm=2`. It can use any of the Hessian options as well as the `bar_feasible` option.
5.23.8.4 Active Set

Knitro includes an active-set Sequential Linear-Quadratic Programming (SLQP) optimizer. This optimizer is particular advantageous when "warm starting" (i.e., when the user can provide a good initial solution estimate, for example, when solving a sequence of closely related problems). This algorithm is also the preferred algorithm for detecting infeasible problems quickly. The Active Set algorithm can be chosen by setting \texttt{algorithm=3}. It can use any of the Hessian options.

5.23.9 Other Knitro special features

This section describes in more detail some of the more important special features of Knitro and provides some guidance on how use them so that Knitro runs most efficiently for the problem at hand.

5.23.9.1 Second derivative options

The default version of Knitro assumes that exact second derivatives of the objective function and constraint functions can be computed. If this is possible and the cost of computing the second derivatives is not overly expensive, it is highly recommended to use exact second derivatives. However, Knitro also offers other options which are described in detail below.

**(Dense) Quasi-Newton BFGS**
The quasi-Newton BFGS option uses gradient information to compute a symmetric, \textit{positive-definite} approximation to the Hessian matrix. Typically this method requires more iterations to converge than the exact Hessian version. However, since it is only computing gradients rather than Hessians, this approach may be more efficient in many cases. This option stores a \textit{dense} quasi-Newton Hessian approximation so it is only recommended for small to medium problems (\(n < 1000\)). The quasi-Newton BFGS option can be chosen by setting options value \texttt{hessopt=2}.

**(Dense) Quasi-Newton SR1**
As with the BFGS approach, the quasi-Newton SR1 approach builds an approximate Hessian using gradient information. However, unlike the BFGS approximation, the SR1 Hessian approximation is not restricted to be positive-definite. Therefore the quasi-Newton SR1 approximation may be a better approach, compared to the BFGS method, if there is a lot of negative curvature in the problem since it may be able to maintain a better approximation to the true Hessian in this case. The quasi-Newton SR1 approximation maintains a \textit{dense} Hessian approximation and so is only recommended for small to medium problems (\(n < 1000\)). The quasi-Newton SR1 option can be chosen by setting options value \texttt{hessopt=3}.

**Finite-difference Hessian-vector product option**
If the problem is large and gradient evaluations are not the dominate cost, then Knitro can internally compute Hessian-vector products using finite-differences. Each Hessian-vector product in this case requires one additional gradient evaluation. This option can be chosen by setting options value \texttt{hessopt=4}. This option is generally only recommended if the exact gradients are provided.

**NOTE:** This option may not be used when \texttt{algorithm=1}.

**Exact Hessian-vector products**
In some cases the problem which the user wishes to solve may have a large, dense Hessian which makes it impractical to store or work with the Hessian directly. The performance of this option should be nearly identical to the exact Hessian option but requires much less storage. This option can be chosen by setting options value \texttt{hessopt=5}.

**NOTE:** This option may not be used when \texttt{algorithm=1}.

**Limited-memory Quasi-Newton BFGS**
The limited-memory quasi-Newton BFGS option is similar to the dense quasi-Newton BFGS option described above. However, it is better suited for large-scale problems since, instead of storing a dense Hessian approximation, it only stores a limited number of gradient vectors used to approximate the Hessian. In general it requires more iterations to converge than the dense quasi-Newton BFGS approach but will be much more efficient on large-scale problems. This option can be chosen by setting options value \texttt{hessopt=6}. 

\[
\begin{align*}
\text{5.23 KNITRO} & \quad 1959
\end{align*}
\]
5.23.9.2 Feasible version

Knitro offers the user the option of forcing intermediate iterates to stay feasible with respect to the inequality constraints (it does not enforce feasibility with respect to the equality constraints however). Given an initial point which is sufficiently feasible with respect to all inequality constraints and selecting $\text{bar\_feasible} = 1$, forces all the iterates to strictly satisfy the inequality constraints throughout the solution process. For the feasible mode to become active the iterate $x$ must satisfy

$$cl + tol \leq c(x) \leq cu - tol$$

(21)

for all inequality constraints (i.e., for $cl \neq cu$). The tolerance $tol > 0$ by which an iterate must be strictly feasible for entering the feasible mode is determined by the parameter $\text{bar\_feasmodetol}$ which is $1.0e^{-4}$ by default. If the initial point does not satisfy (21) then the default infeasible version of Knitro will run until it obtains a point which is sufficiently feasible with respect to all the inequality constraints. At this point it will switch to the feasible version of Knitro and all subsequent iterates will be forced to satisfy the inequality constraints.

For a detailed description of the feasible version of Knitro see [32].

NOTE: This option may only be used when $\text{algorithm}=2$.

5.23.9.3 Honor Bounds

By default Knitro does not enforce that the simple bounds on the variables (1c) are satisfied throughout the optimization process. Rather, satisfaction of these bounds is only enforced at the solution. In some applications, however, the user may want to enforce that the initial point and all intermediate iterates satisfy the bounds $bl \leq x \leq bu$. This can be enforced by setting $\text{honorbnds}=1$.

5.23.9.4 Crossover

Interior-point (or barrier) methods are a powerful tool for solving large-scale optimization problems. However, one drawback of these methods is that they do not always provide a clear picture of which constraints are active at the solution. In general they return a less exact solution and less exact sensitivity information. For this reason, Knitro offers a crossover feature in which the interior-point method switches to the Active Set method at the interior-point solution estimate, in order to ”clean up” the solution and provide more exact sensitivity and active set information. The crossover procedure is controlled by the $\text{bar\_maxcrossit}$ option. If this option is greater than 0, then Knitro will attempt to perform $\text{bar\_maxcrossit}$ Active Set crossover iterations after the interior-point method has finished, to see if it can provide a more exact solution. This can be viewed as a form of post-processing. If $\text{bar\_maxcrossit}$ is not positive, then no crossover iterations are attempted.

The crossover procedure will not always succeed in obtaining a more exact solution compared with the interior-point solution. If crossover is unable to improve the solution within $\text{bar\_maxcrossit}$ crossover iterations, then it will restore the interior-point solution estimate and terminate. By default, Knitro will then print a message indicating that it was unable to improve the solution within the iterations allowed. In this case, you may want to increase the value of $\text{bar\_maxcrossit}$ and try again. If Knitro determines that the crossover procedure will not succeed, no matter how many iterations are tried, then a message of the form Crossover mode unable to improve solution. will be printed.

The extra cost of performing crossover is problem dependent. In most small or medium scale problems, the crossover cost is a small fraction of the total solve cost. In these cases it may be worth using the crossover procedure to obtain a more exact solution. On some large scale or difficult degenerate problems, however, the cost of performing crossover may be significant. It is recommended to experiment with this option to see whether improvement in the exactness of the solution is worth the additional cost.
5.23.9.5 Tuner

The Knitro-Tuner can help you identify some non-default options settings that may improve performance on a particular model or set of models. The Knitro tuner is enabled with the tuner option and controlled via the tuner family of options. If you are unsure about what Knitro options should be tuned to try to improve performance, you can run the default Knitro-Tuner by simply setting the option tuner=1 when solving with Knitro. This will cause Knitro to run your model with a variety of automatically determined option settings, and report some statistics at the end. Any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.

If you have some ideas about which Knitro options you want to tune, you can tell Knitro which options you want it to tune, as well as specify the values for particular options that you want Knitro to explore. This can be done by specifying a Tuner options file. A Tuner options file is a simple text file that is similar to a standard Knitro options file, with some important differences:

- You can define multiple values (separated by spaces) for each option. This tells Knitro the values you want it to explore.
- You can specify an option name without any values. This will tell Knitro to explore all possible option values for that option. This only works for options that have a finite set of possible option value settings.
- A Tuner options file is loaded via the tuner_optionsfile option.

All possible combinations of options/values specified in a Tuner options file will be explored by Knitro, while any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.

5.23.9.6 Solving Systems of Nonlinear Equations

Knitro is quite effective at solving systems of nonlinear equations. To solve a square system of nonlinear equations using Knitro one should specify the nonlinear equations as equality constraints (i.e., constraints with \( cl = cu \)), and specify the objective function (1a) as zero (i.e., \( f(x) = 0 \)).

5.23.9.7 Solving Least Squares Problems

There are two ways of using Knitro for solving problems in which the objective function is a sum of squares of the form

\[
f(x) = \frac{1}{2} \sum_{j=1}^{q} r_j(x)^2.\]

If the value of the objective function at the solution is not close to zero (the large residual case), the least squares structure of \( f \) can be ignored and the problem can be solved as any other optimization problem. Any of the Knitro options can be used.

On the other hand, if the optimal objective function value is expected to be small (small residual case) then Knitro can implement the Gauss-Newton or Levenberg-Marquardt methods which only require first derivatives of the residual functions, \( r_j(x) \), and yet converge rapidly. To do so, the user need only define the Hessian of \( f \) to be

\[
\nabla^2 f(x) = J(x)^T J(x),
\]

where

\[
J(x) = \begin{bmatrix}
\frac{\partial r_j}{\partial x_i} \\
\end{bmatrix} \quad j = 1, 2, \ldots, q \quad i = 1, 2, \ldots, n.
\]
The actual Hessian is given by

\[ \nabla^2 f(x) = J(x)^T J(x) + \sum_{j=1}^{q} r_j(x) \nabla^2 r_j(x); \]

the Gauss-Newton and Levenberg-Marquardt approaches consist of ignoring the last term in the Hessian.

Knitro will behave like a Gauss-Newton method by setting `algorithm=1`, and will be very similar to the classical Levenberg-Marquardt method when `algorithm=2`. For a discussion of these methods see, for example, [143].

## 5.24 LINDO and LINDOGlobal

### 5.24.1 Introduction

GAMS/LINDO finds guaranteed globally optimal solutions to general nonlinear problems with continuous and/or discrete variables. GAMS/LINDO supports most mathematical functions, including functions that are nonsmooth, such as `abs(x)` and or even discontinuous, such as `floor(x)`. Nonlinear solvers employing methods like successive linear programming (SLP) or generalized reduced gradient (GRG) return a local optimal solution to an NLP problem. However, many practical nonlinear models are non-convex and have more than one local optimal solution. In some applications, the user may want to find a global optimal solution.

The LINDO global optimization procedure (GOP) employs branch-and-cut methods to break an NLP model down into a list of subproblems. Each subproblem is analyzed and either a) is shown to not have a feasible or optimal solution, or b) an optimal solution to the subproblem is found, e.g., because the subproblem is shown to be convex, or c) the subproblem is further split into two or more subproblems which are then placed on the list. Given appropriate tolerances, after a finite, though possibly large number of steps a solution provably global optimal to tolerances is returned. Traditional nonlinear solvers can get stuck at suboptimal, local solutions. This is no longer the case when using the global solver.

GAMS/LINDO can automatically linearize a number of nonlinear relationships, such as `max(x,y)`, through the addition of constraints and integer variables, so the transformed linearized model is mathematically equivalent to the original nonlinear model. Keep in mind, however, that each of these strategies will require additional computation time. Thus, formulating models, so they are convex and contain a single extremum, is desirable. In order to decrease required computing power and time it is also possible to disable the global solver and use GAMS/LINDO like a regular nonlinear solver.

GAMS/LINDO has a multistart feature that restarts the standard (non-global) nonlinear solver from a number of intelligently generated points. This allows the solver to find a number of locally optimal points and report the best one found. This alternative can be used when global optimization is costly. A user adjustable parameter controls the maximum number of multistarts to be performed.

LINDO automatically detects problem type and uses an appropriate solver, e.g., if you submit an LP model to LINDO, it will be solved as an LP at LP speed, regardless of what you said in the "solve using" statement. With the NLP parameter `NLP_QUADECHK` turned on, LINDO can detect hidden quadratic expressions and automatically recognize convex QCPs, as well as second-order cones (SOCP), like in Value-at-Risk models, allowing dramatically faster solution times via the barrier solver. When such models have integer variables, LINDO would use the barrier solver to solve all subproblems leading to significantly improved solution times when compared to the case with the standard NLP solver.
5.24.1.1 Licensing and software requirements

In order to use GAMS/LINDOGlobal, two licenses are required: a GAMS/LINDOGlobal license and a GAMS/CONOPT license. The additional CONOPT license requirement exists because LINDOGlobal uses CONOPT to solve the nonlinear subproblems. The GAMS/LINDOGlobal license places upper limits on the model size of 3,000 variables and 2,000 constraints.

To use GAMS/LINDO, only a GAMS/LINDO license is required. It imposes no upper limit on the model size and includes the capability to solve stochastic models (see section Stochastic Programming (SP) in GAMS/Lindo).

Neither the GAMS/LINDO nor the GAMS/LINDOGlobal license includes the Barrier solver option. The Barrier option is enabled via a separate license for the GAMS/MOSEK barrier solver.

5.24.1.2 Running GAMS/LINDO

GAMS/LINDO is capable of solving models of the following types: EMP (stochastic), LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP and MINLP. If GAMS/LINDO is not specified as the default solver for these models, it can be invoked by issuing one of the following commands before the solve statement:

```gams
option xxx=lindo;
option xxx=lindoglobal;
```

where `xxx` is one of: EMP, LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP, or MINLP.

You can also find global optima to math programs with equilibrium or complementarity constraints, type MPEC, by using the GAMS/NLPEC translator in conjunction with LINDO. You use NLPEC to translate complementarities into standard mathematical statements, e.g. \( h \cdot y = 0 \), and then use LINDO as the DNLP(Discontinuous Nonlinear) solver to solve the translated model. The following little GAMS model illustrates:

```gams
$title simple mpec example
variable f, x1, x2, y1, y2; positive
variable y1; y2.lo = -1; y2.up = 1;
equations cost, g, h1, h2;
cost..  f =E=  x1 + x2;
g..  sqr(x1) + sqr(x2) =L= 1;
h1..  x1 =G=  y1 - y2 + 1;
h2..  x2 + y2 =N= 0;
* declare h and y complementary
model example / cost, g, h1.y1, h2.y2 /;

option mpec=nlpec;
option dnlp=lindo;
solve example using mpec min f;
```

5.24.2 Supported nonlinear functions

GAMS/LINDO supports most nonlinear functions in global mode, including +, -, *, /, floor, modulo, sign, min, max, sqrt, exp, power, ln, log, sqrt, abs, cos, sin, tan, cosh, sinh, tanh, arccos, arcsin, arctan and logic expressions AND, OR, NOT, and IF. Be aware that using highly nonconvex functions may lead to long solve times.
5.24.3 Diagnosis of Infeasible or Unbounded Models

GAMS/LINDO offers two diagnostic tools, that can help users debug infeasible or unbounded optimization models. These tools can be called after the solver reports an infeasible or unbounded status for the model. When activating IIS Lindo finds an irreducible infeasible set (IIS) of constraints, whereas setting IUS, makes Lindo find an irreducible unbounded set (IUS) of variables. An IIS is a set of constraints that are infeasible taken together, but every strict subset is feasible. Similarly, an IUS is a set of unbounded variables such that fixing any one of them would make the model bounded. The IIS or IUS portion of the model will generally be much smaller than the original model. Thus, the user can track down formulation or data entry errors quickly. By isolating the source of infeasibility or unboundedness, the user can correct the model data such as right-hand side values, objective coefficients, senses of the constraints, and column bounds. Note that the IUS option is available for LPs only.

5.24.3.1 Infeasible Models

GAMS/Lindo's IIS option activates the IIS finder, after a model was tried to be solved and the solver returned a ”no feasible solution” message. For an LP, if an infeasible basis is not resident in the solver, the IIS finder cannot initiate the process to isolate an IIS. This can occur if the infeasibility is detected in the pre-solver before a basis is created, or the barrier solver has terminated without performing a basis crossover. To obtain an IIS for such cases, the pre-solve option will be turned off automatically and the model gets optimized again.

The constraints and bounds in the IIS are further classified into two disjoint sets: a necessary set and a sufficient set. The sufficient set refers to a crucial subset of the IIS in the sense that removing any one of its members from the entire model renders the model feasible. Note that not all infeasible models have sufficient sets. The necessary set contains those constraints and bounds that are likely to contribute to the overall infeasibility of the entire model. Thus, the necessary set requires a correction in at least one member to make the original model feasible. A constraint that has been marked as sufficient has a high probability of containing an error. In fact, if the model contains only one bad coefficient, the constraint containing it will be marked as sufficient.

To control the level of analysis when locating an IIS, one can set the option IIS_ANALYZE_LEVEL.

5.24.3.2 Unbounded Linear Programs

GAMS/Lindo's IUS option is similar to the IIS option, except that it is used to track down the source of an unbounded solution in a linear program. This tool analyzes the model and isolates an "irreducibly unbounded set" (IUS) of variables. As in the infeasibility case, the IUS is partitioned into sufficient and necessary sets to indicate the role of the member variables for the unboundedness of the overall model.

The variables in the sufficient set are crucial in the sense that fixing any of these variables makes the overall model bounded. However, fixing the variables in the necessary set does not ensure that there are no other sets of unbounded variables that cause unboundedness for the overall model.

To control the level of analysis when locating an IUS, one can set the option IUS_ANALYZE_LEVEL.
5.24.4 GAMS/LINDO output

The log output below is obtained for the NLP model mhw4d.gms from the GAMS model library using LINDO's global solver.

5.24.5 The GAMS/LINDO Options

GAMS/LINDO offers a diverse range of user-adjustable parameters to control the behavior of its solvers. While the default values of these parameters work best for most purposes, there may be cases the users prefer to work with different settings for a subset of the available parameters. This section gives a list of available GAMS/LINDO parameters, categorized by type, along with their brief descriptions. A more detailed description is given in the section that follows.
5.24.5.1 GAMS/LINDO Options File

In order to set GAMS/LINDO options, you need to set up an option file `lindo.opt` or `lindoglobal.opt` in your GAMS project directory. You must indicate in the model that you want to use the option file by inserting before the solve statement, the line:

```plaintext
<modelname>.optfile = 1;
```

where

```plaintext
<modelname>
```

is the name of the model referenced in the model statement. The option file is in plain text format containing a single GAMS/LINDO option per line. Each option identifier is followed by its target value with space or tab characters separating them. The lines starting with `*` character are treated as comments.

A sample option file `lindo.opt` looks like below

```plaintext
* Use(1) or Disable(0) global optimization for NLP/MINLP models
USEGOP 0

* Enable Multistart NLP solver
NLP_SOLVER 9

* Allow a maximum of 3 multistart attempts
NLP_MAXLOCALSEARCH 3

* Set an overall time limit of 200 secs.
SOLVER_TIMLMT 200
```

<tr>
<td>MIP_DELTA</td>
<td>near-zero value used in linearizing nonlinear expressions</td>
<td>1e-6</td>
</tr>
<tr>
<td>MIP_DUAL_SOLUTION</td>
<td>flag for computing dual solution of LP relaxation</td>
<td>0</td>
</tr>
<tr>
<td>MIP_FP_ITRLIM</td>
<td>iteration limit for feasibility pump heuristic</td>
<td>500</td>
</tr>
<tr>
<td>MIP_FP_MODE</td>
<td>mode for the feasibility pump heuristic</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_FP_OPT_METHOD</td>
<td>optimization and reoptimization method for feasibility pump heuristic</td>
<td>0</td>
</tr>
<tr>
<td>MIP_FP_TIMLIM</td>
<td>time limit for feasibility pump heuristic</td>
<td>1800</td>
</tr>
<tr>
<td>MIP_FP_WEIGHT</td>
<td>weight of the objective function in the feasibility pump</td>
<td>1</td>
</tr>
<tr>
<td>MIP_GENERAL_MODE</td>
<td>general strategy in solving MIPs</td>
<td>0</td>
</tr>
<tr>
<td>MIP_HEUELEVEL</td>
<td>specifies heuristic used to find integer solution</td>
<td>3</td>
</tr>
<tr>
<td>MIP_HEUMINTIMLIM</td>
<td>minimum time in seconds to be spent in finding heuristic solutions</td>
<td>0</td>
</tr>
<tr>
<td>MIP_HEU_DROP_OBJ</td>
<td>flag for whether to use without OBJ heuristic</td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------</td>

<td>MIP_INTTOL</td>
<td>absolute integer feasibility tolerance</td>
<td>1e-6</td>
</tr>
<tr>
<td>MIP_ITRLIM</td>
<td>iteration limit for branch and bound</td>
<td>infinity</td>
</tr>
<tr>
<td>MIP_KBEST_USE_GOP</td>
<td>specifies whether to use gop solver in MIP KBest</td>
<td>0</td>
</tr>
<tr>
<td>MIP_KEEPINMEM</td>
<td>flag for keeping LP bases in memory</td>
<td>1</td>
</tr>
<tr>
<td>MIP_LBIGM</td>
<td>Big-M value used in linearizing nonlinear expressions</td>
<td>10000</td>
</tr>
<tr>
<td>MIP_LSOLTIMLIM</td>
<td>time limit until finding a new integer solution</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_MAKECUT_INACTIVE_COUNT</td>
<td>threshold for times a cut could remain active after successive reoptimization</td>
<td>10</td>
</tr>
<tr>
<td>MIP_MAXCUTPASS_TOP</td>
<td>number passes to generate cuts on the root node</td>
<td>200</td>
</tr>
<tr>
<td>MIP_MAXCUTPASS_TREE</td>
<td>number passes to generate cuts on the child nodes</td>
<td>2</td>
</tr>
<tr>
<td>MIP_MAXNONIMP_CUTPASS</td>
<td>number of passes allowed in cut-generation that does not improve current relaxation</td>
<td>3</td>
</tr>
<tr>
<td>MIP_MAXNUM_MIP_SOL_STORAGE</td>
<td>maximum number of k-best solutions to store</td>
<td>1</td>
</tr>
<tr>
<td>MIP_MINABSOBJSTEP</td>
<td>value to update cutoff value each time a mixed integer solution is found</td>
<td>0</td>
</tr>
<tr>
<td>MIP_NODESELRULE</td>
<td>specifies the node selection rule</td>
<td>0</td>
</tr>
<tr>
<td>MIP_NUM_THREADS</td>
<td>number of parallel threads to use by the parallel MIP solver</td>
<td>1</td>
</tr>
<tr>
<td>MIP_PARA_FP</td>
<td>flag for whether to use parallelization on the feasibility pump heuristic</td>
<td>1</td>
</tr>
<tr>
<td>MIP_PARA_FP_MODE</td>
<td>flag for the mode of parallel feasibility pump</td>
<td>0</td>
</tr>
<tr>
<td>MIP_PARA_INIT_NODE</td>
<td>number of initial nodes for MIP parallelization</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_PARA_ITR_MODE</td>
<td>flag for iteration mode in MIP parallelization</td>
<td>1</td>
</tr>
<tr>
<td>MIP_PARA_RND_ITRLMT</td>
<td>iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations</td>
<td>2.0</td>
</tr>
<tr>
<td>MIP_PARA_SUB</td>
<td>flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing</td>
<td>1</td>
</tr>
<tr>
<td>MIP_PEROPTTOL</td>
<td>MIP relative optimality tolerance in effect after MIP_AOPTTIMLIM seconds</td>
<td>1e-5</td>
</tr>
<tr>
<td>MIP_PERSPECTIVEREFORM</td>
<td>flag for whether to use Perspective Reformulation</td>
<td>1</td>
</tr>
<tr>
<td>MIP_POLISH_ALPHA_TARGET</td>
<td>proportion solutions in the pool to initiate a polishing-task at the current node</td>
<td>0.6</td>
</tr>
<tr>
<td>MIP_POLISH_MAX_BRANCH_COUNT</td>
<td>maximum number of branches to polish</td>
<td>2000</td>
</tr>
<tr>
<td>MIP_POLISH_NUM_BRANCH_NEXT</td>
<td>number of branches to polish in the next round</td>
<td>4000</td>
</tr>
<tr>
<td>MIP_PREHEU_DFE_VSTLIM</td>
<td>limit for the variable visit in depth first enumeration</td>
<td>200</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>MIP_PREHEU_LEVEL</td>
<td>heuristic level for the prerelax solver</td>
<td>0</td>
</tr>
<tr>
<td>MIP_PREHEU_TC_ITERLIM</td>
<td>iteration limit for the two change heuristic</td>
<td>30000000</td>
</tr>
<tr>
<td>MIP_PREHEU_VAR_SEQ</td>
<td>sequence of the variable considered by the prerelax heuristic</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_PRELEVEL</td>
<td>controls the amount and type of MIP presolving at root node</td>
<td>3070</td>
</tr>
<tr>
<td>MIP_PRELEVEL_TREE</td>
<td>amount and type of MIP presolving at tree nodes</td>
<td>1214</td>
</tr>
<tr>
<td>MIP_PRE_ELIM_FILL</td>
<td>controls fill-in introduced by eliminations during pre-solve</td>
<td>100</td>
</tr>
<tr>
<td>MIP_PSEUDOCOST_RULE</td>
<td>specifies the rule in pseudocost computations for variable selection</td>
<td>0</td>
</tr>
<tr>
<td>MIP_PSEUDOCOST_WEIGT</td>
<td>weight in pseudocost computations for variable selection</td>
<td>1.5625e-05</td>
</tr>
<tr>
<td>MIP_REDCOSTFIX_CUTOFF</td>
<td>cutoff value as a percentage of the reduced costs</td>
<td>0.9</td>
</tr>
<tr>
<td>MIP_REDCOSTFIX_CUTOFF_TREE</td>
<td>cutoff value as a percentage of the reduced costs at tree nodes</td>
<td>0.9</td>

<tr>
<td>MIP_RELINTTOL</td>
<td>relative integer feasibility tolerance</td>
<td>8e-6</td>
</tr>
<tr>
<td>MIP_RELOPTTOL</td>
<td>MIP relative optimality tolerance</td>
<td>GAMS OptCR</td>
</tr>
<tr>
<td>MIP_REOPT</td>
<td>optimization method to use when doing reoptimization</td>
<td>0</td>
</tr>
<tr>
<td>MIP_SCALING_BOUND</td>
<td>maximum difference between bounds of an integer variable for enabling scaling</td>
<td>10000</td>
</tr>
<tr>
<td>MIP_SOLLIM</td>
<td>integer solution limit for MIP solver</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_SOLVERTYPE</td>
<td>optimization method to use when solving mixed-integer models</td>
<td>0</td>
</tr>
<tr>
<td>MIP_STRONGBRANCHDONUM</td>
<td>minimum number of variables to try the strong branching on</td>
<td>3</td>
</tr>
<tr>
<td>MIP_STRONGBRANCHLEVEL</td>
<td>depth from the root in which strong branching is used</td>
<td>10</td>
</tr>
<tr>
<td>MIP_SWITCHFAC_SIM_IPM_TIME</td>
<td>factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method</td>
<td>-1</td>
</tr>
<tr>
<td>MIP_SYMMETRY_MODE</td>
<td>specifies mip symmetry handling methods</td>
<td>0</td>

</tbody>
</table>

5.24.7 Detailed Descriptions of GAMS/Lindo Options

**CHECKRANGE** *(string)*: calculate feasible range for variables

If this option is set, Lindo calculates the feasible range (determined by an upper and lower bound) for every variable in each equation while all other variables are fixed to their level. If set, the value of this option defines the name of the GDX file where the results are written to.

For every combination of equation- and variable block there will be one symbol in the format *EquBlock_VarBlock(equ_Ind_1, ..., equ_Ind_M, var_Ind_1, ..., var_Ind_N, directions)*.

Default: range.gdx

**CORE_ORDER_BY_STAGE** *(integer)*: order nontemporal models or not
Order non-temporal models or not.

Default: 1

**DECOMPOSITION_TYPE** (integer): decomposition to be performed on a linear or mixed integer model

This refers to the type of decomposition to be performed on a linear or mixed integer model.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tbody>
</table>
**GOP_ABSOPTTOL** *(real)*: absolute optimality tolerance

Synonym: ABSOPTTOL

This value is the GOP absolute optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: GAMS OptCA

**GOP_ALGREFORMMD** *(integer)*: algebraic reformulation rule for a GOP

Synonym: ALGREFORMMD

This controls the algebraic reformulation rule for a GOP. The algebraic reformulation and analysis is very crucial in building a tight convex envelope to enclose the nonlinear/nonconvex functions. A lower degree of overestimation on convex envelopes helps increase the convergence rate to the global optimum.

Default: 18

<table>
<thead>
<tr>

</tbody>
</table>

**GOP_BBSRCHMD** *(integer)*: node selection rule in GOP branch-and-bound

Synonym: BBSRCHMD

This specifies the node selection rule for choosing between all active nodes in the GOP branch-and-bound tree when solving global optimization programs.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Depth first search</td>
</tr>
<tr>
<td>1</td>
<td>Choose node with worst bound</td>
</tr>
</tbody>
</table>

**GOP_BNDLIM** *(real)*: max magnitude of variable bounds used in GOP convexification

Synonym: BNDLIM

This value specifies the maximum magnitude of variable bounds used in the GOP convexification. Any lower bound smaller than the negative of this value will be treated as the negative of this value. Any upper bound greater than this value will be treated as this value. This helps the global solver focus on more productive domains.

Default: 1e10

**GOP_BOXTOL** *(real)*: minimal width of variable intervals

Synonym: BOXTOL

This value specifies the minimal width of variable intervals in a box allowed to branch.

Default: 1e-6
GOP_BRANCHMD (integer): direction to branch first when branching on a variable

Synonym: BRANCHMD

This specifies the direction to branch first when branching on a variable. The branch variable is selected as the one that holds the largest magnitude in the measure.

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Absolute width</td>
</tr>
<tr>
<td>1</td>
<td>Locally relative width</td>

<tr>
<td>4</td>
<td>Absolute violation between the function and its convex envelope at the convex minimum</td>
</tr>
<tr>
<td>5</td>
<td>Relative violation between the function and its convex envelope at the convex minimum</td>
</tr>
</tbody>
</table>

GOP_BRANCH_LIMIT (integer): limit on the total number of branches to be created in GOP tree

Synonym: BRANCH_LIMIT

This is the limit on the total number of branches to be created during branch-and-bound in GOP tree. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible solution was found, it will be installed as the incumbent (best known) solution.

Range: \{-1, ..., \infty\}

Default: -1

GOP_CMINLP (integer): flag indicating if GOP exploits convex MINLP model

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

GOP_CONIC_REFORM (integer): flag indicating if GOP explore conic reformulation

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

GOP_CORELEVEL (integer): strategy of GOP branch-and-bound

Synonym: CORELEVEL

This controls the strategy of GOP branch-and-bound procedure.
Default: 14
### GOP_DECOMPPTMD

**Type:** (integer)

**Description:** decomposition point selection rule in GOP branch-and-bound

**Synonym:** DECOMPPTMD

This specifies the decomposition point selection rule. In the branch step of GOP branch-and-bound, a branch point M is selected to decompose the selected variable interval [Lb, Ub] into two subintervals, [Lb, M] and [M, Ub].

**Default:** 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>LP convex relaxation</td>
</tr>
<tr>
<td>+4</td>
<td>NLP solving</td>
</tr>
<tr>
<td>+8</td>
<td>Box Branching</td>
</tr>
</tbody>
</table>

### GOP_DELTATOL

**Type:** (real)

**Description:** delta tolerance in GOP convexification

**Synonym:** DELTATOL

This value is the delta tolerance in the GOP convexification. It is a measure of how closely the additional constraints added as part of convexification should be satisfied.

**Default:** 1e-7

### GOP_FLTTOL

**Type:** (real)

**Description:** floating-point tolerance

**Synonym:** FLTTOL

This value is the GOP floating-point tolerance. It specifies the maximum rounding errors in the floating-point computation.

**Default:** 1e-10

### GOP_HEU_MODE

**Type:** (integer)

**Description:** heuristic used in global solver

**Synonym:** HEU_MODE

This specifies the heuristic used in the global solver to find a good solution. Typically, if a heuristic is used, this will put more efforts in searching for good solutions, and less in bound tightening.

**Default:** 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No heuristic is used</td>
</tr>
<tr>
<td>1</td>
<td>A simple heuristic is used</td>
</tr>
</tbody>
</table>

### GOP_ITRLIM

**Type:** (real)

**Description:** GOP iteration limit
Synonym: ITRLIM

This is the total iteration limit (including simplex, barrier and nonlinear iteration) summed over branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\]
Default: infinity

**GOP_ITRLIM_JPM** (*real*): total barrier iteration limit summed over all branches in GOP

Synonym: ITRLIM_JPM

This is the total barrier iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\]
Default: -1

**GOP_ITRLIM_NLP** (*real*): total nonlinear iteration limit summed over all branches in GOP

Synonym: ITRLIM_NLP

This is the total nonlinear iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\]
Default: -1

**GOP_ITRLIM_SIM** (*real*): total simplex iteration limit summed over all branches in GOP

Synonym: ITRLIM_SIM

This is the total simplex iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: \([-1, \infty]\]
Default: -1

**GOP_LIM_MODE** (*integer*): flag indicating which heuristic limit on sub-solver in GOP is based

Synonym: LIM_MODE

This is a flag indicating which heuristic limit on sub-solver in GOP is based.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No limit</td>
</tr>
<tr>
<td>1</td>
<td>Time based limit</td>
</tr>
<tr>
<td>2</td>
<td>Iteration based limit</td>
</tr>
<tr>
<td>3</td>
<td>Both time and iteration based limit</td>
</tr>
</tbody>
</table>
**GOP_LINEARZ** *(integer)*: flag indicating if GOP exploits linearizable model

This is a flag indicating if GOP exploits linearizable model.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exploit linearizable model</td>
</tr>
<tr>
<td>1</td>
<td>Do not exploit linearizable model</td>
</tr>
</tbody>
</table>

**GOP_LSOLBRANLIM** *(integer)*: branch limit until finding a new nonlinear solution

Synonym: LSOLBRANLIM

This value controls the branch limit until finding a new nonlinear solution since the last nonlinear solution is found. The default value is -1, which means no branch limit is imposed.

Range: \{-1, ..., \infty\}

Default: -1

**GOP_MAXWIDMD** *(integer)*: maximum width flag for the global solution

Synonym: MAXWIDMD

This is the maximum width flag for the global solution. The GOP branch-and-bound may continue contracting a box with an incumbent solution until its maximum width is smaller than **GOP_WIDTOL**.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The maximum width criterion is suppressed</td>
</tr>
<tr>
<td>1</td>
<td>The maximum width criterion is performed</td>
</tr>
</tbody>
</table>

**GOP_MULTILINEAR** *(integer)*: flag indicating if GOP exploits multi linear feature

This is a flag indicating if GOP exploits multi linear feature.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

**GOP_NUM_THREADS** *(integer)*: number of parallel threads to be used when solving a nonlinear model with the global optimization solver

This value specifies the number of parallel threads to be used when solving a nonlinear model with the global optimization solver.

Default: 1
**GOP_OBJ_THRESHOLD** (*real*): threshold of objective value in the GOP solver

This value specifies the threshold of objective value in the GOP solver. For min problem, if current incumbent solution is less than the threshold GOP solver will stop.

Range: $[-1e+30, \infty]$  
Default: $-1e+30$

**GOP_OPTCHKMD** (*integer*): criterion used to certify the global optimality

Synonym: OPTCHKMD

This specifies the criterion used to certify the global optimality. When this value is 0, the absolute deviation of objective lower and upper bounds should be smaller than **GOP_ABSOPTTOL** at the global optimum. When its value is 1, the relative deviation of objective lower and upper bounds should be smaller than **GOP_RELOPTTOL** at the global optimum. 2 means either absolute or relative tolerance is satisfied at global optimum.

Default: 2

**GOP_OPT_MODE** (*integer*): mode for GOP optimization

Synonym: OPT_MODE

This specifies the mode for GOP optimization.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Global search for a feasible solution (thus a feasibility certificate)</td>
</tr>
<tr>
<td>1</td>
<td>Global search for an optimal solution</td>
</tr>
<tr>
<td>2</td>
<td>Global search for an unboundedness certificate</td>
</tr>
</tbody>
</table>

**GOP_POSTLEVEL** (*integer*): amount and type of GOP postsolving

Synonym: POSTLEVEL

This controls the amount and type of GOP post-solving. The default value is: $6 = 2+4$ meaning to do both of the below options.

Default: 6

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Apply LSgetBestBound</td>
</tr>
<tr>
<td>+4</td>
<td>Reoptimize variable bounds</td>
</tr>
</tbody>
</table>

**GOP_PRELEVEL** (*integer*): amount and type of GOP presolving

Synonym: PRELEVEL

This controls the amount and type of GOP pre-solving. The default value is: $30 = 2+4+8+16$ meaning to do all of the below options.

Default: 30
GOP QUAD_METHOD (integer): specifies if the GOP solver should solve the model as a QP when applicable

Default: −1

GOP RELBRNDMD (integer): reliable rounding in the GOP branch-and-bound

Synonym: RELBRNDMD

This controls the reliable rounding rule in the GOP branch-and-bound. The global solver applies many suboptimizations to estimate the lower and upper bounds on the global optimum. A rounding error or numerical instability could unintentionally cut off a good solution. A variety of reliable approaches are available to improve the precision.

Default: 0

GOP RELOPTTOL (real): relative optimality tolerance

Synonyms: OPTTOL RELOPTTOL

This value is the GOP relative optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: GAMS OptCR

GOP SOLLIM (integer): integer solution limit for GOP branch-and-bound

Range: \{-1, ..., ∞\}

Default: -1

GOP SUBOUT MODE (integer): substituting out fixed variables

Synonym: SUBOUT_MODE

This is a flag indicating whether fixed variables are substituted out of the instruction list used in the global solver.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not substitute out fixed variables</td>
</tr>
<tr>
<td>1</td>
<td>Substitute out fixed variables</td>
</tr>
</tbody>
</table>

**GOP_TIMLIM** (*integer*): time limit in seconds for GOP branch-and-bound

Synonym: TIMLIM

This is the time limit in seconds for GOP branch-and-bound.

Range: \{-1, ..., \infty\}

Default: GAMS ResLim

**GOP_USEBNDLIM** (*integer*): max magnitude of variable bounds flag for GOP convexification

Synonym: USEBNDLIM

This value is a flag for the parameter **GOP_BNDLIM**.

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use the bound limit on the variables</td>
</tr>
<tr>
<td>1</td>
<td>Use the bound limit right at the beginning of global optimization</td>
</tr>
<tr>
<td>2</td>
<td>Use the bound limit after the initial local optimization if selected</td>
</tr>
</tbody>
</table>

**GOP_WIDTOL** (*real*): maximal width of variable intervals

Synonym: WIDTOL

This value specifies the maximal width of variable intervals for a box to be considered as an incumbent box containing an incumbent solution. It is used when **GOP_MAXWIDMD** is set at 1.

Default: $1e^{-4}$

**IIS** (*boolean*): run the IIS finder if the problem is infeasible

Default: 0

**IIS_ANALYZE_LEVEL** (*integer*): controls the level of analysis when locating an IIS

Default: 1

</tbody>
</table>

**IPM**\_**BASIS**\_**REL**\_**TOL**\_**S** (*real*): maximum relative dual bound violation allowed in an optimal basic solution

Maximum relative dual bound violation allowed in an optimal basic solution.

Default: $1e^{-12}$

**IPM**\_**BASIS**\_**TOL**\_**S** (*real*): maximum absolute dual bound violation in an optimal basic solution

Maximum absolute dual bound violation in an optimal basic solution.

Default: $1e^{-7}$

**IPM**\_**BASIS**\_**TOL**\_**X** (*real*): maximum absolute primal bound violation allowed in an optimal basic solution

Maximum absolute primal bound violation allowed in an optimal basic solution.

Default: $1e^{-7}$

**IPM**\_**BI**\_**LU**\_**TOL**\_**REL**\_**PIV** (*real*): relative pivot tolerance used in the LU factorization in the basis identification procedure

Relative pivot tolerance used in the LU factorization in the basis identification procedure.

Range: \([0, 0.999999]\]

Default: $1e^{-2}$

**IPM**\_**CHECK**\_**CONVEXITY** (*integer*): flag to check convexity of a quadratic program using barrier solver

This is a flag to check convexity of a quadratic program using barrier solver.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Check convexity only without solving the model</td>
</tr>
<tr>
<td>0</td>
<td>Use barrier solver to check convexity</td>

<tr>
<td>1</td>
<td>Do not use barrier solver to check convexity</td>
</tr>
</tbody>
</table>

**IPM**\_**CO**\_**TOL**\_**INFEAS** (*real*): maximum bound infeasibility tolerance for Conic solver

Maximum bound infeasibility tolerance for Conic solver.

Default: $1e^{-10}$

**IPM**\_**MAX**\_**ITERATIONS** (*integer*): ipm iteration limit
Controls the maximum number of iterations allowed in the interior-point optimizer.

Default: 1000

**IPM_NUM_THREADS** *(integer)*: number of threads to run the interior-point optimizer on

Number of threads to run the interior-point optimizer on. This value should be less than or equal to the actual number of processors or cores on a multi-core system.

Default: 1

**IPM_OFF_COL_TRH** *(integer)*: extent for detecting the offending columns in the Jacobian of the constraint matrix

Controls the extent for detecting the offending columns in the Jacobian of the constraint matrix. 0 means no offending columns will be detected. 1 means offending columns will be detected. In general, increasing the parameter value beyond the default value of 40 does not improve the result.

Default: 40

**IPM_TOL_DFEAS** *(real)*: dual feasibility tolerance

Dual feasibility tolerance used for linear and quadratic optimization problems.

Default: 1e-8

**IPM_TOL_DSAFE** *(real)*: controls the initial dual starting point

Controls the initial dual starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the dual variables associated with constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: [1e-4, $\infty$]

Default: 1

**IPM_TOL_INFEAS** *(real)*: infeasibility tolerance

This is the tolerance to declare the model primal or dual infeasible using the interior-point optimizer. A smaller number means the optimizer gets more conservative about declaring the model infeasible.

Default: 1e-10

**IPM_TOL_MU_RED** *(real)*: relative complementarity gap tolerance

Relative complementarity gap tolerance.

Default: 1e-16

**IPM_TOL_PATH** *(real)*: how close to follow the central path

Controls how close the interior-point optimizer follows the central path. A large value of this parameter means the central path is followed very closely. For numerically unstable problems it might help to increase this parameter.

Range: [0, 0.5]

Default: 1e-8
IPM_TOL_PFEAS *(real)*: primal feasibility tolerance →

Primal feasibility tolerance used for linear and quadratic optimization problems.

Default: $1e^{-8}$

IPM_TOL_PSAFE *(real)*: controls the initial primal starting point →

Controls the initial primal starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: $[1e^{-2}, \infty]$  
Default: 1

IPM_TOL_REL_STEP *(real)*: relative step size to the boundary →

Relative step size to the boundary for linear and quadratic optimization problems.

Range: $[0, 0.999999]$  
Default: 0.9999

IUS *(boolean)*: run the IUS finder if the problem is unbounded →

Default: 0

IUS_ANALYZE_LEVEL *(integer)*: controls the level of analysis when locating an IUS →

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

LP_AIJ_ZEROTOL *(real)*: coefficient matrix zero tolerance →

Default: $2.22045e^{-16}$

LP_BIGM *(real)*: big-M for phase-I →

Default: $1e6$

LP_BNDINF *(real)*: big-M to truncate lower and upper bounds in single phase dual-simplex →

Default: $1e15$

LP_DPSWITCH *(integer)*: specifies whether LP primal-dual simplex switch is enabled or not →

Range: $\{0, ..., 1\}$  
Default: 1

LP_DRATIO *(integer)*: controls the dual min-ratio strategy →
Range: \{0, ..., 2\}

Default: 1

**LP\_DYNOBJFACT** *(real)*: Dynamic obj factor

Range: \([0, 1]\)

Default: 0.75

**LP\_DYNOBJMODE** *(integer)*: Dynamic obj mode

Default: 0

**LP\_ITRLMT** *(integer)*: simplex iteration limit

Synonym: SPLEX\_ITRLMT

Range: \([-1, ..., \infty]\)

Default: infinity

**LP\_PIV\_BIGTOL** *(real)*: simplex maximum pivot tolerance

Default: 1e-5

**LP\_PIV\_ZEROTOL** *(real)*: simplex pivot zero tolerance

Default: 1e-8

**LP\_PPARTIAL** *(integer)*: primal simplex partial pricing method

Range: \{0, ..., 3\}

Default: 0

**LP\_PRELEVEL** *(integer)*: controls the amount and type of LP pre-solving

This controls the amount and type of LP pre-solving to be used.

Default: 126

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Simple pre-solving</td>
</tr>
<tr>
<td>+4</td>
<td>Probing</td>
</tr>
<tr>
<td>+8</td>
<td>Coefficient reduction</td>

<td>Elimination</td>
</tr>
<tr>
<td>+32</td>
<td>Dual reductions</td>
</tr>
<tr>
<td>+64</td>
<td>Use dual information</td>
</tr>
<tr>
<td>+512</td>
<td>Maximum pass</td>
</tr>
</tbody>
</table>

**LP\_RATRANGE** *(integer)*: controls the number of pivot-candidates to consider when searching for a stable pivot in LU decomposition

Range: \{1, ..., \infty\}
Default: 4

**LP_SCALE** *(integer):* scaling flag  
Synonym: SPLEX_SCALE

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Scaling is suppressed</td>
</tr>
<tr>
<td>1</td>
<td>Scaling is performed</td>
</tr>
</tbody>
</table>

**LP_SPRINT_COLFACT** *(integer):* maximum number of columns in Sprint as a factor of number of rows  
Range: \{1, ..., \infty\}

Default: 10

**LP_SPRINT_MAXPASS** *(integer):* maximum number of passes in Sprint method  
Range: \{1, ..., \infty\}

Default: 100

**LP_SPRINT_SUB** *(integer):* LP method for subproblem in Sprint method  
Default: 0

**MIP_ASCUTTOL** *(real):* MIP absolute cut tolerance  
This is the MIP absolute cut tolerance. If the value is less than or equal to zero, it will use the internal decided tolerace, otherwise it will use this value as the absolute tolerance for adding cuts.

Range: [-1.0, \infty]

Default: -1.0

**MIP_ASOPTTOL** *(real):* MIP absolute optimality tolerance  
This is the MIP absolute optimality tolerance. Solutions must beat the incumbent by at least this absolute amount to become the new, best solution.

Default: GAMS OptCA

**MIP_ADDCUTOBJTOL** *(real):* required objective improvement to continue generating cuts  
This specifies the minimum required improvement in the objective function for the cut generation phase to continue generating cuts.

Default: 1.5625e-5

**MIP_ADDCUTPER** *(real):* percentage of constraint cuts that can be added  

This determines how many constraint cuts can be added as a percentage of the number of original rows in an integer programming model.

Default: 0.75

**MIP_ADDCUTPER_TREE** *(real)*: percentage of constraint cuts that can be added at child nodes

This determines how many constraint cuts can be added at child nodes as a percentage of the number of original rows in an integer programming model.

Default: 0.5

**MIP_AGGCUTLIM_TOP** *(integer)*: max number of constraints involved in derivation of aggregation cut at root node

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the root node. The default is .1, which means that the solver will decide.

Range: \(-1, ..., \infty\)

Default: -1

**MIP_AGGCUTLIM_TREE** *(integer)*: max number of constraints involved in derivation of aggregation cut at tree nodes

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the tree nodes. The default is .1, which means that the solver will decide.

Range: \(-1, ..., \infty\)

Default: -1

**MIP_ANODES_SWITCH_DF** *(integer)*: threshold on active nodes for switching to depth-first search

This specifies the threshold on active nodes for switching to depth-first search rule.

Default: 50000

**MIP_AOPTTIMLIM** *(integer)*: time in seconds beyond which the relative optimality tolerance will be applied

This is the time in seconds beyond which the relative optimality tolerance, **MIP_PEROPTTOL** will be applied.

Default: 100

**MIP_BIGM_FOR_INTTOL** *(real)*: threshold for which coefficient of a binary variable would be considered as big-M

This value specifies the threshold for which the coefficient of a binary variable would be considered as big-M (when applicable).

Default: \(1e8\)

**MIP_BRANCHDIR** *(integer)*: first branching direction

This specifies the direction to branch first when branching on a variable.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Always branch up first</td>
</tr>
<tr>
<td>2</td>
<td>Always branch down first</td>
</tr>
</tbody>
</table>

**MIP_BRANCHRULE** *(integer)*: rule for choosing the variable to branch

This specifies the rule for choosing the variable to branch on at the selected node.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Basis rounding with pseudo reduced costs</td>
</tr>
<tr>
<td>2</td>
<td>Maximum infeasibility</td>
</tr>
<tr>
<td>3</td>
<td>Pseudo reduced costs only</td>
</tr>
<tr>
<td>4</td>
<td>Maximum coefficient only</td>
</tr>
<tr>
<td>5</td>
<td>Previous branching only</td>
</tr>
</tbody>
</table>

**MIP_BRANCH_LIMIT** *(integer)*: limit on the total number of branches to be created during branch and bound

This is the limit on the total number of branches to be created during branch-and-bound. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: \{-1, ..., \infty\}

Default: -1

**MIP_BRANCH_Prio** *(integer)*: controls how variable selection priorities are set and used

This controls how variable selection priorities are set and used.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>If the user has specified priorities then use them Otherwise let LINDO API decide</td>
</tr>
<tr>
<td>1</td>
<td>If user has specified priorities then use them Overwrite users choices if necessary</td>
</tr>
<tr>
<td>2</td>
<td>If user has specified priorities then use them Otherwise do not use any priorities</td>
</tr>
<tr>
<td>3</td>
<td>Let LINDO API set the priorities and ignore any user specified priorities</td>
</tr>
<tr>
<td>4</td>
<td>Binaries always have higher priority over general integers</td>
</tr>
</tbody>
</table>

**MIP_CUTDEPTH** *(integer)*: threshold value for the depth of nodes in the branch and bound tree

This controls a threshold value for the depth of nodes in the B&B tree, so cut generation will be less likely at those nodes deeper than this threshold.

Default: 8

**MIP_CUTFREQ** *(integer)*: frequency of invoking cut generation at child nodes
This controls the frequency of invoking cut generation at child nodes. The default value is 10, indicating that the MIP solver will try to generate cuts at every 10 nodes.

Default: 10

**MIP.CUTLEVEL.TOP** *(integer)*: combination of cut types to try at the root node when solving a MIP

This controls the combination of cut types to try at the root node when solving a MIP. Bit settings are used to enable the various cut types.

Default: 57342

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tbody>
</table>

**MIP.CUTLEVEL.TREE** *(integer)*: combination of cut types to try at child nodes in the branch and bound tree when solving a MIP

This controls the combination of cut types to try at child nodes in the B&B tree when solving a MIP.

Default: 53246

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>GUB cover</td>
</tr>
<tr>
<td>+4</td>

<td>Soft Knapsack Cuts</td>
</tr>
</tbody>
</table>
**MIP_CUTOFFOBJ** *(real)*: defines limit for branch and bound

If this is specified, then any part of the branch-and-bound tree that has a bound worse than this value will not be considered. This can be used to reduce the running time if a good bound is known.

Default: \(1e30\)

**MIP_CUTTIMLIM** *(integer)*: time to be spent in cut generation

This controls the total time to be spent in cut generation throughout the solution of a MIP. The default value is -1, indicating that no time limits will be imposed when generating cuts.

Range: \([-1, ..., \infty]\)

Default: -1

**MIP_DELTA** *(real)*: near-zero value used in linearizing nonlinear expressions

This refers to a near-zero value used in linearizing nonlinear expressions.

Default: \(1e-6\)

**MIP_DUAL_SOLUTION** *(integer)*: flag for computing dual solution of LP relaxation

This flag controls whether the dual solution to the LP relaxation that yielded the optimal MIP solution will be computed or not.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not calculate dual solution for LP relaxation</td>
</tr>
<tr>
<td>1</td>
<td>Calculate dual solution for LP relaxation</td>
</tr>
</tbody>
</table>

**MIP_FP_ITRLIM** *(integer)*: iteration limit for feasibility pump heuristic

This is the iteration limit in seconds for feasibility pump heuristic. A value of -1 means no iteration limit is imposed.

Default: 500

**MIP_FP_MODE** *(integer)*: mode for the feasibility pump heuristic

Controls the mode for the feasibility pump heuristic.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On until the first solution</td>
</tr>
<tr>
<td>2</td>
<td>Try to get more than one solution</td>
</tr>
</tbody>
</table>

**MIP_FP_OPT_METHOD** *(integer)*: optimization and reoptimization method for feasibility pump
heuristic←

This specifies optimization and reoptimization method for feasibility pump heuristic.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Primal simplex</td>
</tr>
<tr>
<td>2</td>
<td>Dual simplex</td>
</tr>
<tr>
<td>3</td>
<td>Barrier</td>
</tr>
</tbody>
</table>

MIP_FP_TIMLIM (real): time limit for feasibility pump heuristic←

This is the time limit in seconds for feasibility pump heuristic. A value of -1 implies no time limit is imposed.

Default: 1800

MIP_FP_WEIGHT (real): weight of the objective function in the feasibility pump←

Controls the weight of the objective function in the feasibility pump.

Range: [0, 1]

Default: 1

MIP_GENERAL_MODE (integer): general strategy in solving MIPs←

This value specifies the general strategy in solving MIPs.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>+2</td>
<td>Disable all time-driven events for reproducibility of runs</td>
</tr>
<tr>
<td>+16</td>
<td>Disable cut generation before branching</td>
</tr>
</tbody>
</table>

MIP_HEULEVEL (integer): specifies heuristic used to find integer solution←

This specifies the heuristic used to find the integer solution. Possible values are: 0: No heuristic is used. 1: A simple heuristic is used. Typically, this will find integer solutions only on problems with a certain structure. However, it tends to be fast. 2: This is an advanced heuristic that tries to find a "good" integer solution fast. In general, a value of 2 seems to not increase the total solution time and will find an integer solution fast on many problems. A higher value may find an integer solution faster, or an integer solution where none would have been found with a lower level. Try level 3 or 4 on "difficult" problems where 2 does not help. Higher values cause more time to be spent in the heuristic. The value may be set arbitrarily high. However, >20 is probably not worthwhile. MIP_HEUMINTIMLIM controls the time to be spent in searching heuristic solutions.

Default: 3

MIP_HEUMINTIMLIM (integer): minimum time in seconds to be spent in finding heuristic solutions←
This specifies the minimum time in seconds to be spent in finding heuristic solutions to the MIP model. \texttt{MIP.HEULEVEL} controls the heuristic used to find the integer solution.

Default: 0

\textbf{MIP.HEU.DROP.OBJ (integer):} flag for whether to use without OBJ heuristic

This is a flag for whether to use without OBJ heuristic.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

\textbf{MIP.HEU.MODE (integer):} heuristic used in MIP solver

This controls the MIP heuristic mode.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides when to stop the heuristic</td>
</tr>
<tr>
<td>1</td>
<td>Solver uses a pre-specified time limit to stop the heuristic.</td>
</tr>
<tr>
<td>2</td>
<td>Solver uses a pre-specified iteration limit to stop the heuristic</td>
</tr>
</tbody>
</table>

\textbf{MIP.INTTOL (real):} absolute integer feasibility tolerance

An integer variable is considered integer feasible if the absolute difference from the nearest integer is smaller than this.

Default: 1e-6

\textbf{MIP.ITRLIM (real):} iteration limit for branch and bound

This is the total LP iteration limit summed over all branches for branch-and-bound. Range for The default value is -1, which means no iteration limit is imposed. If this iteration limit is reached, branch-and-bound will stop and the best feasible integer solution found will be installed as the incumbent (best known) solution.

Range: [-1, \infty]

Default: infinity

\textbf{MIP.KBEST.USE.GOP (integer):} specifies whether to use gop solver in MIP KBest

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

\textbf{MIP.KEEPINMEM (integer):} flag for keeping LP bases in memory
If this is set to 1, the integer pre-solver will try to keep LP bases in memory. This typically gives faster solution times, but uses more memory. Setting this parameter to 0 causes the pre-solver to erase bases from memory.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not keep LP bases in memory</td>
</tr>
<tr>
<td>1</td>
<td>Keep LP bases in memory</td>
</tr>
</tbody>
</table>

**MIP_LBIGM** (*real*): Big-M value used in linearizing nonlinear expressions

This refers to the Big-M value used in linearizing nonlinear expressions.

Default: 10000

**MIP_LSOLTIMLIM** (*integer*): time limit until finding a new integer solution

Range: \{-1, ..., ∞\}

Default: -1

**MIP_MAKECUT_INACTIVE_COUNT** (*integer*): threshold for times a cut could remain active after successive reoptimization

This value specifies the threshold for the times a cut could remain active after successive reoptimization during branch-and-bound. If the count is larger than the specified level the solver will inactive the cut.

Default: 10

**MIP_MAXCUTPASS_TOP** (*integer*): number passes to generate cuts on the root node

This controls the number passes to generate cuts on the root node. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.

Default: 200

**MIP_MAXCUTPASS_TREE** (*integer*): number passes to generate cuts on the child nodes

This controls the number passes to generate cuts on the child nodes. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.

Default: 2

**MIP_MAXNONIMP_CUTPASS** (*integer*): number of passes allowed in cut-generation that does not improve current relaxation

This controls the maximum number of passes allowed in cut-generation that does not improve the current relaxation.

Default: 3

**MIP_MAXNUM_MIP_SOL_STORAGE** (*integer*): maximum number of k-best solutions to store
This specifies the maximum number of k-best solutions to store. Possible values are positive integers.

Default: 1

**MIP_MINABSOBJSTEP** *(real)*: value to update cutoff value each time a mixed integer solution is found

This specifies the value to update the cutoff value each time a mixed integer solution is found.

Default: 0

**MIP_NODESELRULE** *(integer)*: specifies the node selection rule

This specifies the node selection rule for choosing between all active nodes in the branch-and-bound tree when solving integer programs. Possible selections are: 0: Solver decides (default). 1: Depth first search. 2: Choose node with worst bound. 3: Choose node with best bound. 4: Start with best bound. If no improvement in the gap between best bound and best integer solution is obtained for some time, switch to: if (number of active nodes < 10000) Best estimate node selection (5). else Worst bound node selection (2). 5: Choose the node with the best estimate, where the new objective estimate is obtained using pseudo costs. 6: Same as (4), but start with the best estimate.

Default: 0

</tbody>
</table>

**MIP_NUM_THREADS** *(integer)*: number of parallel threads to use by the parallel MIP solver

This parameter specifies the number of parallel threads to use by the parallel MIP solver. Possible values are positive integers. The default is 1 implying that the parallel solver is disabled.

Range: \{1, \ldots, \infty\}

Default: 1

**MIP_PARA_FP** *(integer)*: flag for whether to use parallelization on the feasibility pump heuristic

This is a flag for whether to use parallelization on the feasibility pump heuristic.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>

MIP_PARA_FP_MODE (integer): flag for the mode of parallel feasibility pump

This is a flag for the mode of parallel feasibility pump.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Terminate when all threads finish</td>
</tr>
<tr>
<td>1</td>
<td>Terminate as soon as the master thread finishes</td>
</tr>
</tbody>
</table>

MIP_PARA_INIT_NODE (real): number of initial nodes for MIP parallelization

This value specifies the number of initial nodes for MIP parallelization.

Range: [-1, ∞]

Default: -1

MIP_PARA_ITR_MODE (integer): flag for iteration mode in MIP parallelization

This is a flag for iteration mode in MIP parallelization.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Each thread terminates as soon as arrives iteration limit</td>
</tr>
<tr>
<td>1</td>
<td>Each thread terminates until all threads get iteration limit</td>
</tr>
</tbody>
</table>

MIP_PARA_RND_ITRLMT (real): iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations

This value specifies the iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations.

Default: 2.0

MIP_PARA_SUB (integer): flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing

This is a flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

MIP_PEROPTTOL (real): MIP relative optimality tolerance in effect after MIP_AOPTTIMLIM seconds

This is the MIP relative optimality tolerance that will be in effect after T seconds following the start. The value T should be specified using the MIP_AOPTTIMLIM parameter.

Default: 1e-5
**MIP_PERSPECTIVE_REFORM** *(integer)*: flag for whether to use Perspective Reformulation

This is the flag for whether to use Perspective Reformulation.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>On</td>
</tr>
</tbody>
</table>

**MIP_POLISH_ALPHA_TARGET** *(real)*: proportion solutions in the pool to initiate a polishing-task at the current node

This value specifies the proportion solutions in the pool to initiate a polishing-task at the current node.

Range: [0.01, 0.99]

Default: 0.6

**MIP_POLISH_MAX_BRANCH_COUNT** *(integer)*: maximum number of branches to polish

This value specifies the maximum number of branches to polish.

Default: 2000

**MIP_POLISH_NUM_BRANCH_NEXT** *(integer)*: number of branches to polish in the next round

This value specifies the number of branches to polish in the next round.

Default: 4000

**MIP_PREHEU_DFE_VSTLIM** *(integer)*: limit for the variable visit in depth first enumeration

Limit for the variable visit in depth first enumeration.

Default: 200

**MIP_PREHEU_LEVEL** *(integer)*: heuristic level for the prerelax solver

The heuristic level for the prerelax solver.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Nothing</td>
</tr>
<tr>
<td>1</td>
<td>One-change</td>
</tr>
<tr>

<tr>
<td>3</td>
<td>Depth first enumeration</td>
</tr>
</tbody>
</table>

**MIP_PREHEU_TC_ITERLIM** *(integer)*: iteration limit for the two change heuristic

Iteration limit for the two change heuristic.

Default: 30000000
MIP_PREHEU_VAR_SEQ (integer): sequence of the variable considered by the prerelax heuristic

The sequence of the variable considered by the prerelax heuristic.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Backward</td>
</tr>
<tr>
<td>1</td>
<td>Forward</td>
</tr>
</tbody>
</table>

MIP_PRELEVEL (integer): controls the amount and type of MIP pre-solving at root node

This controls the amount and type of MIP pre-solving at root node.

Default: 3070

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Simple pre-solving</td>
</tr>
<tr>
<td>+4</td>

<td>Maximum pass</td>
</tr>
<tr>
<td>+2048</td>
<td>Similar row</td>
</tr>
</tbody>
</table>

MIP_PRELEVEL_TREE (integer): amount and type of MIP pre-solving at tree nodes

This controls the amount and type of MIP pre-solving at tree nodes.

Default: 1214

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Simple pre-solving</td>
</tr>
<tr>
<td>+4</td>

<tr>
<td>+512</td>
<td>Coef Probe Lifting</td>
</tr>
<tr>
<td>+1024</td>
<td>Maximum pass</td>
</tr>
</tbody>
</table>

MIP_PRE_ELIM_FILL (integer): controls fill-in introduced by eliminations during pre-solve

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly
more than the original model.

Default: 100

**MIP_PSEUDOCOST_RULE (integer)**: specifies the rule in pseudocost computations for variable selection

This specifies the rule in pseudocost computations for variable selection.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Only use min pseudo cost</td>
</tr>
<tr>
<td>2</td>
<td>Only use max pseudo cost</td>
</tr>
<tr>
<td>3</td>
<td>Use quadratic score function and the pseudo cost weight</td>
</tr>
<tr>
<td>4</td>
<td>Same as 3 without quadratic score</td>
</tr>
</tbody>
</table>

**MIP_PSEUDOCOST_WEIGHT (real)**: weight in pseudocost computations for variable selection

This specifies the weight in pseudocost computations for variable selection.

Default: 1.5625e-05

**MIP_REDCOSTFIX_CUTOFF (real)**: cutoff value as a percentage of the reduced costs

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic.

Default: 0.9

**MIP_REDCOSTFIX_CUTOFF_TREE (real)**: cutoff value as a percentage of the reduced costs at tree nodes

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic at tree nodes.

Default: 0.9

**MIP_RELINTTOL (real)**: relative integer feasibility tolerance

An integer variable is considered integer feasible if the difference between its value and the nearest integer value divided by the value of the nearest integer is less than this.

Default: 8e-6

**MIP_RELOPTTOL (real)**: MIP relative optimality tolerance

This is the MIP relative optimality tolerance. Solutions must beat the incumbent by at least this relative amount to become the new, best solution.

Default: GAMS OptCR

**MIP_REOPT (integer)**: optimization method to use when doing reoptimization

This specifies which optimization method to use when doing reoptimization from a given basis.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use primal method</td>
</tr>
<tr>
<td>2</td>
<td>Use dual simplex</td>
</tr>
<tr>
<td>3</td>
<td>Use barrier solver</td>
</tr>
</tbody>
</table>

**MIP_SCALING_BOUND** *(integer):* maximum difference between bounds of an integer variable for enabling scaling ←

This controls the maximum difference between the upper and lower bounds of an integer variable that will enable the scaling in the simplex solver when solving a subproblem in the branch-and-bound tree.

Default: 10000

**MIP_SOLLIM** *(integer):* integer solution limit for MIP solver ←

Range: \{-1, ..., \infty\}

Default: -1

**MIP_SOLVERTYPE** *(integer):* optimization method to use when solving mixed-integer models ←

This specifies the optimization method to use when solving mixed-integer models.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use Branch and Bound only</td>
</tr>
<tr>
<td>2</td>
<td>Use Enumeration and Knapsack solver only</td>
</tr>
</tbody>
</table>

**MIP_STRONGBRANCHDONUM** *(integer):* minimum number of variables to try the strong branching on ←

This value specifies the minimum number of variables, among all the candidates, to try the strong branching on.

Default: 3

**MIP_STRONGBRANCHLEVEL** *(integer):* depth from the root in which strong branching is used ←

This specifies the depth from the root in which strong branching is used. The default value of 10 means that strong branching is used on a level of 1 to 10 measured from the root. Strong branching finds the real bound for branching on a given variable, which, in most cases, requires a solution of a linear program and may therefore also be quite expensive in computing time. However, if used on nodes close to the root node of the tree, it also gives a much better bound for that part of the tree and can therefore reduce the size of the branch-and-bound tree.

Default: 10

**MIP_SWITCHFAC_SIM_IPM_TIME** *(real):* factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method ←
This specifies the (positive) factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method. A value of -1.0 means that no time limit is imposed.

Range: \([-1, \infty]\)

Default: -1

**MIP_SYMMETRY_MODE (integer):** specifies mip symmetry handling methods

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use symmetries</td>
</tr>
<tr>
<td>1</td>
<td>Adding symmetry breaking cuts</td>
</tr>
<tr>
<td>2</td>
<td>Orbital fixing</td>
</tr>
</tbody>
</table>

**MIP_TIMLIM (integer):** time limit in seconds for integer solver

This is the time limit in seconds for branch-and-bound. The default value is -1, which means no time limit is imposed. However, the value of \(\text{SOLVER\_TIMLMT}\) will be applied to each continuous subproblem solve. If the value of this parameter is greater than 0, then the value of \(\text{SOLVER\_TIMLMT}\) will be disregarded. If this time limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: \([-1, ..., \infty]\)

Default: GAMS ResLim

**MIP_TOPOPT (integer):** optimization method to use when there is no previous basis

This specifies which optimization method to use when there is no previous basis.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use primal method</td>
</tr>
<tr>
<td>2</td>
<td>Use dual simplex</td>
</tr>
<tr>
<td>3</td>
<td>Use barrier solver</td>
</tr>
</tbody>
</table>

**MIP_TREEREORDERLEVEL (integer):** tree reordering level

This specifies the tree reordering level.

Default: 10

**MIP_TREEREORDERMODE (integer):** tree reordering mode

This specifies the tree reordering mode.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Use tree reordering only for subproblems</td>
</tr>
<tr>
<td>2</td>
<td>Use tree reordering for subproblems and the main bnb loop only when LP status is infeasible</td>
</tr>
<tr>
<td>3</td>
<td>Not use tree reordering</td>
</tr>
<tr>
<td>4</td>
<td>Use tree reordering based on MIP_TREEREORDERLEVEL</td>
</tr>
</tbody>
</table>

**MIP_USECUTOFFOBJ** *(integer)*: flag for using branch and bound limit $\leftarrow$

This is a flag for the parameter `MIP_CUTOFFOBJ`. If you do not want to lose the value of the parameter `MIP_CUTOFFOBJ`, this provides an alternative to disabling the cutoff objective.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use current cutoff value</td>
</tr>
<tr>
<td>1</td>
<td>Use current cutoff value</td>
</tr>
</tbody>
</table>

**MIP_USE_CUTS_HEU** *(integer)*: controls if cut generation is enabled during MIP heuristics $\leftarrow$

This flag controls if cut generation is enabled during MIP heuristics. The default is -1 (i.e. the solver decides).

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Do not use cut heuristic</td>
</tr>
<tr>
<td>1</td>
<td>Use cut heuristic</td>
</tr>
</tbody>
</table>

**MIP_USE_ENUM_HEU** *(integer)*: frequency of enumeration heuristic $\leftarrow$

This specifies the frequency of enumeration heuristic.

Default: 4

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off</td>
</tr>
<tr>
<td>1</td>
<td>Only at top (root) node without cuts</td>
</tr>
<tr>
<td>2</td>
<td>Both at top (root) and tree nodes without cuts</td>
</tr>
<tr>
<td>3</td>
<td>Same as 1 with cuts</td>
</tr>
<tr>
<td>4</td>
<td>Same as 2 with cuts</td>
</tr>
</tbody>
</table>

**MIP_USE_INT_ZERO_TOL** *(integer)*: controls if all MIP calculations would be based on absolute integer feasibility tolerance $\leftarrow$

This flag controls if all MIP calculations would be based on the integrality tolerance specified by `MIP_INTTOL`.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not base MIP calculations on MIP_INTTOL</td>
</tr>
<tr>
<td>1</td>
<td>Base MIP calculations on MIP_INTTOL</td>
</tr>
</tbody>
</table>

**MULTITHREAD\_MODE** (integer): threading mode

This parameter controls the threading mode for solvers with multithreading support.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Try parallel mode but if it is not available try concurrent mode</td>
</tr>
<tr>
<td>2</td>
<td>Try parallel mode only</td>
</tr>
<tr>
<td>3</td>
<td>Try concurrent mode but if it is not available try parallel mode</td>
</tr>
<tr>
<td>4</td>
<td>Try concurrent mode only</td>
</tr>
</tbody>
</table>

**NLP\_AUTODERIV** (integer): defining type of computing derivatives

This is a flag to indicate if automatic differentiation is the method of choice for computing derivatives and select the type of differentiation.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Finite Differences approach will be used</td>
</tr>
<tr>
<td>1</td>
<td>Forward type of Automatic Differentiation will be used</td>
</tr>
<tr>
<td>2</td>
<td>Backward type of Automatic Differentiation will be used</td>
</tr>
</tbody>
</table>

**NLP\_AUTOHESS** (integer): flag for using Second Order Automatic Differentiation for solving NLP

This is a flag to indicate if Second Order Automatic Differentiation will be performed in solving a nonlinear model. The second order derivatives provide an exact/precise Hessian matrix to the SQP algorithm, which may lead to less iterations and better solutions, but may also be quite expensive in computing time for some cases.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use Second Order Automatic Differentiation</td>
</tr>
<tr>
<td>1</td>
<td>Use Second Order Automatic Differentiation</td>
</tr>
</tbody>
</table>

**NLP\_CONIC\_REFORM** (integer): determines if to explore conic reformulation

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>
**NLP_CUTOFFOBJ (real):** as soon as any multi-start thread achieves this value all threads stop

If the current best objective of the NLP being solved in a multistart run is better than this value, the solver will terminate early without exhausting the maximum number of multistarts. This is a way of saving computer time if the current best solution is sufficiently attractive.

Range: \([-1e30, \infty]\)

Default: \(-1e30\)

**NLP_DERIV_DIFFTYPE (integer):** flag indicating the technique used in computing derivatives with finite differences

This is a flag indicating the technique used in computing derivatives with Finite Differences.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Use forward differencing method</td>
</tr>
<tr>
<td>2</td>
<td>Use backward differencing method</td>
</tr>
<tr>
<td>3</td>
<td>Use center differencing method</td>
</tr>
</tbody>
</table>

**NLP_FEASCHK (integer):** how to report results when solution satisfies tolerance of scaled but not original model

This input parameter specifies how the NLP solver reports the results when an optimal or local-optimal solution satisfies the feasibility tolerance (NLP_FEASTOL) of the scaled model but not the original (descaled) one.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform no action accept the final solution</td>
</tr>
<tr>
<td>1</td>
<td>Declare the model status as FEASIBLE if maximum violation in the unscaled model is not higher than 10 times NLP_FEASTOL</td>
</tr>
<tr>
<td>2</td>
<td>Declare the model status as UNKNOWN if maximum violation in the unscaled model is higher than NLP_FEASTOL</td>
</tr>
</tbody>
</table>

**NLP_FEASTOL (real):** feasibility tolerance for nonlinear constraints

This is the feasibility tolerance for nonlinear constraints. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: \(1e-6\)

**NLP_INF (real):** numeric infinity for nonlinear models

Specifies the numeric infinity for nonlinear models. Possible values are positive real numbers. Smaller values could cause numerical problems.

nlp_ipm2grg This is a flag to switch from IPM solver to the standard NLP (GRG) solver when IPM fails due to numerical errors.

Default: \(1e30\)
**NLP_IPM2GRG** (integer): switch from IPM solver to GRG solver when IPM fails due to numerical errors

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not switch</td>
</tr>
<tr>
<td>1</td>
<td>Switch</td>
</tr>
</tbody>
</table>

**NLP_ITERS_PER_LOGLINE** (integer): number of nonlinear iterations to elapse before next progress message

Number of nonlinear iterations to elapse before next progress message.

Range: \( \{1, \ldots, \infty\} \)

Default: 10

**NLP_ITRLMT** (integer): nonlinear iteration limit

This controls the iteration limit on the number of nonlinear iterations performed.

Range: \( \{-1, \ldots, \infty\} \)

Default: GAMS IterLim

**NLP_LINEARZ** (integer): extent to which the solver will attempt to linearize nonlinear models

This determines the extent to which the solver will attempt to linearize nonlinear models.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>No linearization occurs</td>
</tr>
<tr>
<td>2</td>
<td>Linearize ABS MAX and MIN functions</td>
</tr>
<tr>
<td>3</td>
<td>Same as option 2 plus IF AND OR NOT and all logical operators are linearized</td>
</tr>
</tbody>
</table>

**NLP_LINEARZ_WBCONSISTENT** (integer): determines if linearization process is consistent with WB/excel calculation

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**NLP_MAXLOCALSEARCH** (integer): maximum number of local searches

This controls the maximum number of local searches (multistarts) when solving a NLP using the multistart solver.

Default: 5
**NLP_MAXLOCALSEARCH_TREE** (integer): maximum number of multistarts

Maximum number of multistarts (at tree nodes)

Default: 1

**NLP_MAX_RETRY** (integer): maximum number refinement retries to purify the final NLP solution

Maximum number refinement retries to purify the final NLP solution.

Range: \{-1, ..., \infty\}

Default: 5

**NLP_MSW_EUCDIST_THRES** (real): euclidean distance threshold in multistart search

Euclidean distance threshold in multistart search

Default: 0.001

**NLP_MSW_FILTMODE** (integer): filtering mode to exclude certain domains during sampling in multistart search

Filtering mode to exclude certain domains during sampling in multistart search.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>+1</td>
<td>Filter-out the points around known KKT or feasible points previously visited</td>
</tr>
<tr>
<td>+2</td>
<td>Filter-out the points whose p are in the vicinity of p(x)</td>
</tr>
<tr>
<td>+4</td>
<td>Filter-out the points in the vicinity of x where x are initial points of all previous local optimizations</td>
</tr>
<tr>
<td>+8</td>
<td>Filter-out the points whose p(.) values are below a dynamic threshold tolerance</td>
</tr>
</tbody>
</table>

**NLP_MSW_MAXNOIMP** (integer): maximum number of consecutive populations to generate without any improvements

Maximum number of consecutive populations to generate without any improvements.

Range: \{-1, ..., \infty\}

Default: -1

**NLP_MSW_MAXPOP** (integer): maximum number of populations to generate in multistart search

Maximum number of populations to generate in multistart search.

Range: \{-1, ..., \infty\}

Default: -1

**NLP_MSW_MAXREF** (integer): maximum number of reference points to generate trial points in multistart search

Maximum number of reference points to generate trial points in multistart search.
Maximum number of reference points in the solution space to generate trial points in multistart search.

Range: \{-1, ..., \infty\}

Default: -1

**NLP_MSW_NORM** *(integer)*: norm to measure the distance between two points in multistart search

Norm to measure the distance between two points in multistart search.

Range: \{-1, ..., \infty\}

Default: 2

**NLP_MSW_NUM_THREADS** *(integer)*: number of parallel threads to be used when solving an NLP model with the multistart solver

This value specifies the number of parallel threads to be used when solving an NLP model with the multistart solver.

Default: 1

**NLP_MSW_OVERLAP_RATIO** *(real)*: rate of replacement in successive populations

This value specifies the rate of replacement in successive populations. Higher values favours survival of points in the parent population.

Range: \([0.0, 1.0]\)

Default: 0.1

**NLP_MSW_POXDIST THRES** *(real)*: penalty function neighborhood threshold in multistart search

Penalty function neighborhood threshold in multistart search

Default: 0.01

**NLP_MSW_PREPMODE** *(integer)*: preprocessing strategies in multistart solver

This value specifies the preprocessing strategies in multistart solver.

Default: -1

<table>
<thead>

</table>
**NLP_MSW_RG_SEED** (*integer*): random number generator seed for the multistart solver

This value specified the random number generator seed for the multistart solver.

Default: 1019

**NLP_MSW_SOLIDX** (*integer*): index of the multistart solution to be loaded

Index of the multistart solution to be loaded main solution structures.

Default: 0

**NLP_MSW_XKKTRAD_FACTOR** (*real*): KKT solution neighborhood factor in multistart search

KKT solution neighborhood factor in multistart search

Default: 0.85

**NLP_MSW_XNULRAD_FACTOR** (*real*): initial solution neighborhood factor in multistart search

Initial solution neighborhood factor in multistart search

Default: 0.5

**NLP_PRELEVEL** (*integer*): controls the amount and type of NLP pre-solving

This controls the amount and type of NLP pre-solving.

Default: 126

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+2</td>
<td>Simple pre-solving</td>

</tbody>
</table>

**NLP_PSTEP_FINITEDIFF** (*real*): value of the step length in computing the derivatives using finite differences

This controls the value of the step length in computing the derivatives using finite differences.

Default: 5e-7

**NLP_QUADCHK** (*integer*): flag for checking if NLP is quadratic

This is a flag indicating if the nonlinear model should be examined to check if it is a quadratic model.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not check if NLP is quadratic</td>
</tr>
<tr>
<td>1</td>
<td>Check if NLP is quadratic</td>
</tr>
</tbody>
</table>
**NLP_REDTOL** (*real*): tolerance for the gradients of nonlinear functions

This is the tolerance for the gradients of nonlinear functions. The (projected) gradient of a function is considered to be the zero-vector if its norm is below this tolerance.

Default: $1 \text{e}^{-7}$

**NLP_SOLVER** (*integer*): type of nonlinear solver

This value determines the type of nonlinear solver.

Default: 7

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Solver decides</td>

</tbody>
</table>

**NLP_SOLVE_AS_LP** (*integer*): flag indicating if the nonlinear model will be solved as an LP

This is a flag indicating if the nonlinear model will be solved as an LP. 1 means that an LP using first order approximations of the nonlinear terms in the model will be used when optimizing the model with the LSoptimize() function.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NLP will not be solved as LP</td>
</tr>
<tr>
<td>1</td>
<td>NLP will be solved as LP</td>
</tr>
</tbody>
</table>

**NLPSTALLITRLMT** (*integer*): iteration limit before a sequence of non-improving NLP iterations is declared as stalling

This specifies the iteration limit before a sequence of non-improving NLP iterations is declared as stalling, thus causing the solver to terminate.

Default: 100

**NLP_STARTPOINT** (*integer*): flag for using initial starting solution for NLP

This is a flag indicating if the nonlinear solver should accept initial starting solutions.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use initial starting solution for NLP</td>
</tr>
<tr>
<td>1</td>
<td>Use initial starting solution for NLP</td>
</tr>
</tbody>
</table>

**NLP_SUBSOLVER** (*integer*): type of nonlinear subsolver
This controls the type of linear solver to be used for solving linear subproblems when solving nonlinear models.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Primal simplex method</td>
</tr>
<tr>
<td>2</td>
<td>Dual simplex method</td>
</tr>
<tr>
<td>3</td>
<td>Barrier solver with or without crossover</td>
</tr>
</tbody>
</table>

**NLP_USECUTOFFOBJ** *(integer)*: flag to use parameter NLP_CUTOFFOBJ

This is a flag for the parameter NLP_CUTOFFOBJ. The value of 0 means NLP_CUTOFFOBJ will be ignored, else it will be used as specified.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>

</tr>
</tbody>
</table>

**NLP_USE_CRASH** *(integer)*: flag for using simple crash routines for initial solution

This is a flag indicating if an initial solution will be computed using simple crash routines.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use simple crash routines</td>
</tr>
<tr>
<td>1</td>
<td>Use simple crash routines</td>
</tr>
</tbody>
</table>

**NLP_USE_LINDO_CRASH** *(integer)*: flag for using advanced crash routines for initial solution

This is a flag indicating if an initial solution will be computed using advanced crash routines.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use advanced crash routines</td>
</tr>
<tr>
<td>1</td>
<td>Use advanced crash routines</td>

**NLP_USE_SDP** *(integer)*: flag to use SDP solver for POSD constraint

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1</td>
<td>Yes</td>
</tr>
</tbody>
</table>
NLP_USE_SELCON(eval) (integer): flag for using selective constraint evaluations for solving NLP

This is a flag indicating if selective constraint evaluations will be performed in solving a nonlinear model.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use selective constraint evaluations</td>
</tr>
<tr>
<td>1</td>
<td>Use selective constraint evaluations</td>

</tbody>
</table>

NLP_USE_SLP (integer): flag for using sequential linear programming step directions for updating solution

This is a flag indicating if sequential linear programming step directions should be used in updating the solution.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Do not use sequential linear programming step directions</td>
</tr>
<tr>
<td>1</td>
<td>Use sequential linear programming step directions</td>
</tr>
</tbody>
</table>

NLP_USE_STEEPEDGE (integer): flag for using steepest edge directions for updating solution

This is a flag indicating if steepest edge directions should be used in updating the solution.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use steepest edge directions</td>
</tr>
<tr>
<td>1</td>
<td>Use steepest edge directions</td>
</tr>
</tbody>
</table>

NUM_THREADS (integer): number of parallel threads to be used

Synonym: gthreads

Number of threads to use in the solver routine to be called. It is a solver-independent parameter which internally sets solver-specific threading parameters automatically.

Range: \{1, ..., \infty\}

Default: GAMS Threads

PROB_TO_SOLVE (integer): controls whether the explicit primal or dual form of the given LP problem will be solved

This flag controls whether the explicit primal or dual form of the given LP problem will be solved.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Explicit primal form</td>
</tr>
<tr>
<td>2</td>
<td>Explicit dual form</td>
</tr>
</tbody>
</table>

**PROFILER_LEVEL (integer):** specifies the profiler level to break down the total cpu time into.

Specifies the profiler level to break down the total cpu time into.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Profiler is off</td>
</tr>
<tr>
<td>+1</td>
<td>Enable for simplex solver</td>
</tr>
<tr>
<td>+2</td>
<td>Enable for integer solver</td>
</tr>
<tr>
<td>+4</td>
<td>Enable for multistart solver</td>
</tr>
<tr>
<td>+8</td>
<td>Enable for global solver</td>
</tr>
</tbody>
</table>

**READPARAMS (string):** read Lindo parameter file

**REPORTEVSOl (no value):** solve and report the expected value solution

Default: 0

**SAMP_CDSINC (real):** correlation matrix diagonal shift increment

Correlation matrix diagonal shift increment.

Default: 1e-6

**SAMP_NCM_CUTOBJ (real):** objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem

Objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem.

Default: 1e-30

**SAMP_NCM_DSTORAGE (integer):** flag to enable or disable sparse mode in NCM computations

Flag to enable/disble sparse mode in NCM computations.

Range: \{-1, ..., ∞\}

Default: -1

**SAMP_NCM_ITERLIM (integer):** iteration limit for NCM method

Iteration limit for NCM method.

Default: 100

**SAMP_NCM_METHOD (integer):** bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem

---

{5.24 LINDO and LINDOGlobal 2021}
Bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem.

Default: 5

**SAMP_NCM_OPTTOL (real):** optimality tolerance for NCM method

Optimality tolerance for NCM method.

Default: 1e-7

**SAMP_SCALE (integer):** flag to enable scaling of raw sample data

Flag to enable scaling of raw sample data.

Default: 0

**SOLVER_CONCURRENT_OPTMODE (integer):** controls if simplex and interior-point optimizers will run concurrently

Controls if simplex and interior-point optimizers will run concurrently, 0 means no concurrent runs will be performed, 1 means both optimizers will run concurrently if at least two threads exist in system, 2 means both optimizers will run concurrently.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no concurrent runs</td>
</tr>
<tr>
<td>1</td>
<td>run concurrently if at least 2 threads exist</td>
</tr>
<tr>
<td>2</td>
<td>run concurrently</td>
</tr>
</tbody>
</table>

**SOLVER_CUTOFFVAL (real):** solver will exit if optimal solution is worse than this

If the optimal objective value of the LP being solved is shown to be worse than this (e.g., if the dual simplex method is being used), then the solver will exit without finding a feasible solution. This is a way of saving computer time if there is no sufficiently attractive solution. **SOLVER_USECUTOFFVAL** needs to be set to 1 to activate this value.

Default: 0

**SOLVER_FEASTOL (real):** feasibility tolerance

This is the feasibility tolerance. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: 1e-7

**SOLVER_IPMSOL (integer):** basis crossover flag for barrier solver

This flag controls whether a basis crossover will be performed when solving LPs with the barrier solver. A value of 0 indicates that a crossover to a basic solution will be performed. If the value is 1, then the barrier solution will be left intact. For example, if alternate optima exist, the barrier method will return a solution that is, loosely speaking, the average of all alternate optima.

Default: 0
### Value | Meaning
--- | ---
0 | Perform crossover to basis solution
1 | Leave barrier solution intact

**SOLVER_IUSOL** (*integer*): flag for computing basic solution for infeasible model

This is a flag that, when set to 1, will force the solver to compute a basic solution to an infeasible model that minimizes the sum of infeasibilities and a basic feasible solution to an unbounded problem from which an extreme direction originates. When set to the default of 0, the solver will return with an appropriate status flag as soon as infeasibility or unboundedness is detected. If infeasibility or unboundedness is declared with presolver’s determination, no solution will be computed.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Return appropriate status if infeasibility is encountered</td>
</tr>
<tr>
<td>1</td>
<td>Force the solver to compute a basic solution to an infeasible model</td>
</tr>
</tbody>
</table>

**SOLVER_METHOD** (*integer*): specifies the method to use when generic solver is invoked

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FREE</td>
</tr>
<tr>
<td>1</td>
<td>PSIMPLEX</td>
</tr>
<tr>

</tr>
<tr>
<td>10</td>
<td>SBD</td>
</tr>
<tr>
<td>11</td>
<td>SPRINT</td>
</tr>
<tr>
<td>12</td>
<td>GA</td>
</tr>
</tbody>
</table>

**SOLVER_MODE** (*integer*): controls some of the advanced strategies when solving LPs

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+1</td>
<td>add distinct basic solutions to the pool of alternate optimal solutions</td>
</tr>
<tr>
<td>+2</td>
<td>add edge/nonbasic solutions to the pool of alternate optimal solutions</td>
</tr>
<tr>
<td>+4</td>
<td>favor basic solutions with integer values when choosing solutions to add to the pool of alternate optimal solutions</td>
</tr>
</tbody>
</table>

**SOLVER_OPTTOL** (*real*): dual feasibility tolerance
This is the optimality tolerance. It is also referred to as the dual feasibility tolerance. A dual slack (reduced cost) is considered violated if it violates its lower bound by the optimality tolerance.

Default: 1e-7

**SOLVER_PRE_ELIM_FILL** *(integer)*: fill-in introduced by the eliminations during pre-solve

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly more than the original model.

Default: 1000

**SOLVER_RESTART** *(integer)*: starting basis flag

This is the starting basis flag. 1 means LINDO API will perform warm starts using any basis currently in memory. 0 means LINDO API will perform cold starts discarding any basis in memory and starting from scratch.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Perform cold start</td>
</tr>
<tr>
<td>1</td>
<td>Perform warm start</td>
</tr>
</tbody>
</table>

**SOLVER_TIMLMT** *(integer)*: time limit in seconds for continous solver

This is a time limit in seconds for the LP solver. The default value of -1 imposes no time limit.

Range: \{-1, ..., ∞\}

Default: GAMS ResLim

**SOLVER_USECUTOFFVAL** *(integer)*: flag for using cutoff value

This is a flag for the parameter **SOLVER_CUTOFFVAL**

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not use cutoff value</td>
</tr>
<tr>
<td>1</td>
<td>Use cutoff value</td>
</tr>
</tbody>
</table>

**SPLEX_DPRICING** *(integer)*: pricing option for dual simplex method

This is the pricing option to be used by the dual simplex method.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides the dual pricing method</td>
</tr>
<tr>
<td>0</td>
<td>Partial pricing</td>
</tr>
<tr>
<td>1</td>
<td>Steepest edge</td>
</tr>
</tbody>
</table>
**SPLEX_DUAL_PHASE** *(integer)*: controls the dual simplex strategy

This controls the dual simplex strategy, single-phase versus two-phase.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>1</td>
<td>Single-phase</td>
</tr>
<tr>
<td>2</td>
<td>Two-phase</td>
</tr>
</tbody>
</table>

**SPLEX_PPRICING** *(integer)*: pricing option for primal simplex method

This is the pricing option to be used by the primal simplex method.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides the primal pricing method</td>
</tr>
<tr>
<td>0</td>
<td>Partial pricing</td>
</tr>
<tr>
<td>1</td>
<td>Devex</td>
</tr>
</tbody>
</table>

**SPLEX_REFACFRQ** *(integer)*: number of simplex iterations between two consecutive basis refactorizations

This is a positive integer scalar referring to the simplex iterations between two consecutive basis refactorizations. For numerically unstable models, setting this parameter to smaller values may help.

Default: 100

**STOC_ABSOPTTOL** *(real)*: absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver

Absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. Possible values are reals in (0,1) interval.

Default: GAMS OptCA

**STOC_ADD_MPI** *(integer)*: flag to use add-instructions mode when building deteq

Flag to use add-instructions mode when building deteq.

Default: 0

**STOC_ALD_DUAL_FEASTOL** *(real)*: dual feasibility tolerance for ALD

Dual feasibility tolerance for ALD.

Default: 1e-4

**STOC_ALD_DUAL_STEPLEN** *(real)*: dual step length for ALD
Dual step length for ALD.
Default: 0.9

**STOC_ALD_INNER_ITER_LIM** (integer): inner loop iteration limit for ALD

Inner loop iteration limit for ALD.
Default: 1000

**STOC_ALD_OUTER_ITER_LIM** (integer): outer loop iteration limit for ALD

Outer loop iteration limit for ALD.
Default: 200

**STOC_ALD_PRIMAL_FEASTOL** (real): primal feasibility tolerance for ALD

Primal feasibility tolerance for ALD.
Default: 1e-4

**STOC_ALD_PRIMAL_STEPLEN** (real): primal step length for ALD

Primal step length for ALD.
Default: 0.5

**STOC_AUTOAGG** (integer): flag to enable or disable autoaggregation

Flag to enable or disable autoaggregation.
Default: 1

**STOC_BENCHMARK_SCEN** (integer): benchmark scenario to compare EVPI and EVMU against

Benchmark scenario to compare EVPI and EVMU against.
Range: \([-2, ..., \infty]\)
Default: -2

**STOC_BIGM** (real): big-M value for linearization and penalty functions

Big-M value for linearization and penalty functions.
Default: 1e7

**STOC_BUCKET_SIZE** (integer): bucket size in Benders decomposition

Bucket size in Benders decomposition. Possible values are positive integers or (-1) for solver decides.
Range: \([-1, ..., \infty]\)
Default: -1

**STOC_CALC_EVPI** (integer): flag to enable or disable calculation of EVPI

Flag to enable/disable calculation of lower bounds on EVPI.
Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>disable</td>
</tr>
<tr>
<td>1</td>
<td>enable</td>
</tr>
</tbody>
</table>

STOC\_CORRELATION\_TYPE (integer): correlation type associated with correlation matrix

Correlation type associated with the correlation matrix.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Target correlation</td>
</tr>
<tr>
<td>0</td>
<td>Pearson correlation</td>
</tr>
<tr>
<td>1</td>
<td>Kendall correlation</td>
</tr>
<tr>
<td>2</td>
<td>Spearman correlation</td>
</tr>
</tbody>
</table>

STOC\_DEQOPT (integer): method to solve the DETEQ problem

This specifies the method to use when solving the deterministic equivalent.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver decides</td>
</tr>
<tr>
<td>10</td>
<td>Use simple Benders Decomposition</td>
</tr>
</tbody>
</table>

STOC\_DETEQ\_TYPE (integer): type of deterministic equivalent

Type of deterministic equivalent to be used by the solver. Implicit determinisitic equivalent is valid for linear and integer models only.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Implicit determinisitic equivalent</td>
</tr>
<tr>
<td>1</td>
<td>Explicit determinisitic equivalent</td>
</tr>
</tbody>
</table>

STOC\_DS\_SUBFORM (integer): subproblem formulation to use in DirectSearch

This parameter specifies the type of subproblem formulation to be used in heuristic search.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solver decides</td>
</tr>
<tr>
<td>0</td>
<td>Perform heuristic search in the original solution space</td>
</tr>
<tr>
<td>1</td>
<td>Perform heuristic search in the space of discrete variables coupled with optimizations in the linear space</td>
</tr>
</tbody>
</table>
**STOC_ELIM_FXVAR** *(integer)*: flag to enable elimination of fixed variables from deteq MPI

Flag to enable elimination of fixed variables from deteq MPI.

Default: 1

**STOC_INFBND** *(real)*: value to truncate infinite bounds at non-leaf nodes

Value to truncate infinite bounds at nonleaf nodes.

Default: 1e9

**STOC_ITER_LIM** *(integer)*: iteration limit for stochastic solver

Iteration limit for stochastic solver. Possible values are positive integers or (-1) no limit.

Range: \{-1, ..., \infty\}

Default: infinity

**STOC_MAP_MPI2LP** *(integer)*: flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements

Flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements.

Default: 0

**STOC_MAX_NUMSCENS** *(integer)*: maximum number of scenarios before forcing automatic sampling

Maximum number of scenarios before forcing automatic sampling. Possible values are positive integers.

Default: 40000

**STOC_METHOD** *(integer)*: stochastic optimization method to solve the model

Stochastic optimization method to solve the model.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Solve with the method chosen by the solver</td>
</tr>
<tr>
<td>0</td>
<td>Solve the deterministic equivalent (DETEQ)</td>
</tr>
<tr>
<td>1</td>
<td>Solve with the Nested Benders Decomposition (NBD) method</td>
</tr>
</tbody>
</table>

**STOC_NAMEDATA_LEVEL** *(integer)*: name data level

Name data level.

Default: 1

**STOC_NODELP_PRELEVEL** *(integer)*: presolve level solving node-models

Presolve level solving node-models.

Default: 0
### STOC\_NSAMPLE\_PER\_STAGE (string): list of sample sizes per stage (starting at stage 2)

Comma separated list of sample sizes per stage. The sample size of stage 1 is assumed to be 1 so that this list starts with stage 2.

### STOC\_NSAMPLE\_SPAR (integer): common sample size per stochastic parameter

Common sample size per stochastic parameter. Possible values are positive integers.

Range: \{-1, ..., \infty\}

Default: -1

### STOC\_NSAMPLE\_STAGE (integer): common sample size per stage

Common sample size per stage.

Range: \{-1, ..., \infty\}

Default: -1

### STOC\_NUM\_THREADS (integer): number of parallel threads

This value specifies the number of parallel threads to be used when solving a stochastic programming model.

Default: 1

### STOC\_RELOPTTOL (real): relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver

Relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. Possible values are reals in \( (0,1) \) interval.

Default: GAMS OptCR

### STOC\_REL\_DSTEPTOL (real): dual-step tolerance

This value specifies the dual-step tolerance in decomposition based algorithms.

Default: 1e-7

### STOC\_REL\_PSTEPTOL (real): primal-step tolerance

This value specifies the primal-step tolerance in decomposition based algorithms.

Default: 1e-8

### STOC\_REOPT (integer): reoptimization method to solve the node-models

Reoptimization method to solve the node-models.

Default: 0

**STOC_SBD_MAXCUTS** *(integer)*: max cuts to generate for master problem

Max cuts to generate for master problem.

Range: \{-1, \ldots, \infty\}

Default: -1

**STOC_SBD_NUMCANDID** *(integer)*: maximum number of candidate solutions to generate at SBD root

Maximum number of candidate solutions to generate at SBD root.

Range: \{-1, \ldots, \infty\}

Default: -1

**STOC_SBD_OBJCUTFLAG** *(integer)*: flag to enable objective cut in SBD master problem

Flag to enable objective cut in SBD master problem.

Default: 1

**STOC_SBD_OBJCUTVAL** *(real)*: RHS value of objective cut in SBD master problem

RHS value of objective cut in SBD master problem.

Default: 1e-30

**STOC_SHARE_BEGSTAGE** *(integer)*: stage beyond which node-models are shared

Stage beyond which node-models share the same model structure. Possible values are positive integers less than or equal to number of stages in the model or \((-1)\) for solver decides.

Range: \([-1, \, \infty]\)

Default: \(-1\)

\textbf{STOC\_TIME\_LIM} \textit{(real)}: time limit for stochastic solver

Time limit for stochastic solver. Possible values are nonnegative real numbers or -1 for solver decides.

Range: \([-1, \, \infty]\)

Default: GAMS ResLim

\textbf{STOC\_TOPOPT} \textit{(integer)}: optimization method to solve the root problem

Optimization method to solve the root problem.

5.24.8 Stochastic Programming (SP) in GAMS/Lindo

GAMS/Lindo can also solve stochastic programming models. The syntax to set up an SP problem in GAMS is explained in the chapter Stochastic Programming (SP) with EMP. The options to control LINDO's stochastic solver are described in the subsection SP Options.
5.25 MILES

Thomas F. Rutherford, University of Colorado

5.25.1 Abstract

MILES is a solver for nonlinear complementarity problems and nonlinear systems of equations. The solver can be accessed through GAMS to solve MPSGE or MCP models. This paper documents the solution algorithm, user options, and solver output. The purpose of the paper is to provide users of MILES an overview of how the solver works so that they can use it effectively.

5.25.2 Introduction

MILES is a Fortran-based solver for nonlinear complementarity problems and nonlinear systems of equations. The solution procedure is a generalized Newton method with a backtracking line search. This code is based on an algorithm investigated by Mathiesen (1985) who proposed a modeling format and sequential method for solving economic equilibrium models. The method is closely related to algorithms proposed by Robinson (1975), Hogan (1977), Eaves (1978) and Josephy (1979). In this implementation, subproblems are solved as linear complementarity problems (LCPs), using an extension of Lemke’s almost-complementary pivoting scheme in which upper and lower bounds are represented implicitly. The linear solver employs the basis factorization package LUSOL, developed by Gill et al. (1991).

The class of problems for which MILES may be applied are referred to as ”generalized” or ”mixed” complementarity problems, which is defined as follows:

Given: \( F : \mathbb{R}^n \rightarrow \mathbb{R}^n \), \( \ell, u \in \mathbb{R}^n \)

Find: \( z, w, v \in \mathbb{R}^n \)

such that \( F(z) = w - v \)
\( \ell \leq z \leq u, \ w \geq 0, \ v \geq 0 \)
\( w^T(z - \ell) = 0 \), \( v^T(u - z) = 0 \).

When \( \ell = -\infty \) and \( u = \infty \) MCP reduces to a nonlinear system of equations. When \( \ell = 0 \) and \( u = +\infty \), the MCP is a nonlinear complementarity problem. Finite dimensional variational inequalities are also MCP. MCP includes inequality-constrained linear, quadratic and nonlinear programs as special cases, although for these problems standard optimization methods may be preferred. MCP models which are not optimization problems encompass a large class of interesting mathematical programs. Specific examples of MCP formulations are not provided here. See Rutherford (1992a) for MCP formulations arising in economics. Other examples are provided by Harker and Pang (1990) and Dirkse (1993).

There are two types of GAMS models which can be presented to MILES:

1. MILES may be used to solve computable general equilibrium models generated by MPSGE as a GAMS subsystem. In the MPSGE language, a model-builder specifies classes of nonlinear functions using a specialized tabular input format embedded within a GAMS program. Using benchmark quantities and prices, MPSGE automatically calibrates function coefficients and generates nonlinear equations and Jacobian matrices. Large, complicated systems of nonlinear equations may be implemented and analyzed very easily using this interface to MILES. An introduction to general equilibrium modeling with GAMS/MPSGE is provided by Rutherford (1992a).
2. MILES may be accessed as a GAMS solver for mixed complementarity problems (MCP). If more than one MCP solver is available \(^3\), the statement `OPTION MCP = MILES;` tells GAMS to use MILES as the MCP solution system. When problems are presented to MILES using the MCP format, the user specifies nonlinear functions using GAMS matrix algebra and the GAMS compiler automatically generates the Jacobian functions. An introduction to the GAMS/MCP modeling format is provided by Rutherford (1992b).

The purpose of this document is to provide users of MILES with an overview of how the solver works so that they can use the program more effectively. Section The Newton Algorithm introduces the Newton algorithm. Section Lemke’s Method with Implicit Bounds describes the implementation of Lemke’s algorithm which is used to solve linear subproblems. Section The Options File defines switches and tolerances which may be specified using the options file. Section Log File Output interprets the run-time log file which is normally directed to the screen. Section Status File Output interprets the status file and the detailed iteration reports which may be generated. Section Termination Messages lists and suggests remedies for abnormal termination conditions.

5.25.3 The Newton Algorithm

The iterative procedure applied within MILES to solve nonlinear complementarity problems is closely related to the classical Newton algorithm for nonlinear equations. This first part of this section reviews the classical procedure. A thorough introduction to these ideas is provided by Dennis and Schnabel (1983). For a practical perspective, see Press et al. (1986).

Newton algorithms for nonlinear equations begin with a local (Taylor series) approximation of the system of nonlinear equations. For a point \( z \) in the neighborhood of \( \bar{z} \), the system of nonlinear functions is linearized:

\[
LF(z) = F(\bar{z}) + \nabla F(\bar{z})(z - \bar{z}).
\]

Solving the linear system \( LF(z) = 0 \) provides the Newton direction from \( \bar{z} \) which is given by \( d = -\nabla F^{-1} F(\bar{z}) \).

Newton iteration \( k \) begins at point \( z^k \). First, the linear model formed at \( z^k \) is solved to determine the associated "Newton direction", \( d^k \). Second, a line search in direction \( d^k \) determines the scalar steplength and the subsequent iterate: \( z^{k+1} = z^k + \lambda d^k \). An Armijo or "back-tracking" line search initially considers \( \lambda = 1 \). If \( \| F(z^k + \lambda d^k) \| \leq \| F(z^k) \| \), the step size \( \lambda \) is adopted, otherwise is multiplied by a positive factor \( \alpha \), \( \alpha < 1 \), and the convergence test is reapplied. This procedure is repeated until either an improvement results or \( \lambda < \lambda_0 \). When \( \lambda_0 = 0 \), a positive step is taken provided that \(^4\)

\[
\frac{d}{d\lambda} \| F(z^k + \lambda d^k) \| < 0.
\]

Convergence theory for this algorithm is quite well developed. See, for example, Ortega and Rheinboldt (1970) or Dennis and Schnabel (1983). The most attractive aspect of the Newton scheme with the backtracking line search is that in the neighborhood of a well-behaved fixed point, \( \lambda = 1 \) is the optimal step length and the rate of convergence can be quadratic. If this method finds a solution, it does so very quickly.

The application of Newton methods to nonlinear complementarity problems involves a modification of the search direction. Here, \( d \) solves a linear complementarity problem (LCP) rather than a linear system of equations. For iteration \( k \), \( d \) solves:

\(^3\)There is one other MCP solver available through GAMS: PATH (Ferris and Dirkse,1992)

\(^4\)\( \alpha \) and \( \lambda_0 \) correspond to user-specified tolerances ‘DMPFAC’ and ‘MINSTP’, respectively
\[
F(z^k) + \nabla F(z^k) d - w + v = 0
\]

\[
\ell \leq d + z^k \leq u, \ w \geq 0, \ v \geq 0
\]

\[
w^T (d + z^k - \ell) = v^T (u - d - z^k) = 0.
\]

Conceptually, we are solving for \(d\), but in practice MILES solves the linear problem in terms of the original variables \(z = z^k + d\):

\[
F(z^k) - \nabla F(z^k) z_k + \nabla F(z^k) z = w - v
\]

\[
\ell \leq z \leq u, \ w \geq 0, \ v \geq 0
\]

\[
w^T (z - \ell) = 0, \ v^T (u - z) = 0.
\]

After computing the solution \(z\), MILES sets \(d^k = z - z^k\).

The linear subproblem incorporates upper and lower bounds on any or all of the variables, assuring that the iterative sequence always remains within the bounds: \(\ell \leq z^k \leq u\). This can be helpful when, as is often the case, \(F()\) is undefined for some \(z \in \mathbb{R}^n\).

Convergence of the Newton algorithm applied to MCP hinges on three questions:

1. Does the linearized problem always have a solution?
2. If the linearized problem has a solution, does Lemke's algorithm find it?
3. Is it possible to show that the computed direction \(d^k\) will provide an "improvement" in the solution?

Only for a limited class of functions \(F()\) can all three questions be answered in the affirmative. For a much larger class of functions, the algorithm converges in practice but convergence is not "provable".

The answer to question 3. depends on the choice of a norm by which an improvement is measured. The introduction of bounds and complementarity conditions makes the calculation of an error index more complicated. In MILES, the deviation associated with a candidate solution \(z, \epsilon(z)\), is based on a measure of the extent to which \(z, w\) and \(v\) violate applicable upper and lower bounds and complementarity conditions.

---

\(^5\)Kaneko (1978) provides some convergence theory for the linearized subproblem
5.25.3.1 Evaluating Convergence

Let $\delta^L_i$ and $\delta^U_i$ be indicator variables for whether $z_i$ is off its lower or upper bound. These are defined as

$$\delta^L_i = \min(1, (z_i - \ell_i)^+) \quad \text{and} \quad \delta^U_i = \min(1, (u_i - z_i)^+).$$

Given $z$, MILES uses the value of $F(z)$ to implicitly define the slack variables $w$ and $v$:

$$w_i = F_i(z)^+, \quad v_i = (-F_i(z))^+.$$

There are two components to the error term associated with index $i$, one corresponding to $z_i$'s violation of upper and lower bounds:

$$\varepsilon^B_i = (z_i - u_i)^+ + (\ell_i - z_i)^+$$

and another corresponding to violations of complementarity conditions:

$$\varepsilon^C_i = \delta^L_i w_i + \delta^U_i v_i.$$

The error assigned to point $z$ is then taken:

$$\varepsilon(z) = \|\varepsilon^B(z) + \varepsilon^C(z)\|_p$$

for a pre-specified value of $p = 1, 2$ or $+\infty$.  

5.25.4 Lemke's Method with Implicit Bounds

A mixed linear complementarity problem has the form:

Given: $M \in \mathbb{R}^{n \times n}$, $q, \ell, u \in \mathbb{R}^n$

Find: $z, w, v \in \mathbb{R}^n$

such that $Mz + q = w - v,$

$\ell \leq z \leq u,$ $w \geq 0,$ $v \geq 0,$

$w^T(z - \ell) = 0,$ $v^T(u - z) = 0.$

In the Newton subproblem at iteration $k$, the LCP data are given by $q = F(z^k) - \nabla F(z^k)z^k$ and $M = \nabla F(z^k)$.

---

6 In the following $x^+ = \max(x, 0)$

7 Parameter $p$ may be selected with input parameter ‘NORM’. The default value for $p$ is $+\infty$. 

5.25 MILES

5.25.4.1 The Working Tableau

In MILES, the pivoting scheme for solving the linear problem works with a re-labeled linear system of the form:

$$\begin{align*}
B x^B + N x^N &= q,
\end{align*}$$

where $x^B \in R^n$, $x^N \in R^{2n}$, and the tableau $[B|N]$ is a conformal "complementary permutation" of $[-M\mid I \mid -I]$. That is, every column $i$ in $B$ must either be the $i$th column of $M, I$ or $-I$, while the corresponding columns $i$ and $i+n$ in $N$ must be the two columns which were not selected for $B$.

To move from the problem defined in terms of $z, w$, and $v$ to the problem defined in terms of $x^B$ and $x^N$, we assign upper and lower bounds for the $x^B$ variables as follows:

$$
x^B_i = \begin{cases} 
\ell_i, & \text{if } x^B_i = z_i \\
0, & \text{if } x^B_i = w_i \text{ or } v_i,
\end{cases}
$$

$$
x^B_i = \begin{cases} 
ut_i, & \text{if } x^B_i = z_i \\
\infty, & \text{if } x^B_i = w_i \text{ or } v_i.
\end{cases}
$$

The values of the non-basic variables $x^N_i$ and $x^N_{i+n}$ are determined by the assignment of $x^B_i$:

$$
x^B_i = \begin{cases} 
z_i \Rightarrow \begin{cases} 
x^N_i = w_i = 0 \\
x^N_{i+n} = v_i = 0
\end{cases} \\
w_i \Rightarrow \begin{cases} 
x^N_i = z_i = \ell_i \\
x^N_{i+n} = v_i = 0
\end{cases} \\
v_i \Rightarrow \begin{cases} 
x^N_i = w_i = 0 \\
x^N_{i+n} = z_i = u_i.
\end{cases}
\end{cases}
$$

In words: if $z_i$ is basic then both $w_i$ and $v_i$ equal zero. If $z_i$ is non-basic at its lower bound, then $w_i$ is possibly non-zero and $v_i$ is non-basic at zero. If $z_i$ is non-basic at its upper bound, then $v_i$ is possibly non-zero and $w_i$ is non-basic at zero.

Conceptually, we could solve the LCP by evaluating $3^n$ linear systems of the form:

$$
x^B = B^{-1} \left( q - N x^N \right).
$$

Lemke’s pivoting algorithm provides a procedure for finding a solution by sequentially evaluating some (hopefully small) subset of these $3^n$ alternative linear systems.
5.25.4.2 Initialization

Let $B^0$ denote the initial basis matrix. The initial values for basic variables are then:

$$\hat{x}^B = (B^0)^{-1}(q - N \tilde{x}^N).$$

If $\hat{x}^B \leq \bar{x}^B \leq \tilde{x}^B$, then the initial basis is feasible and the complementarity problem is solved. Otherwise, MILES introduces an artificial variable $z_0$ and an artificial column $\tilde{h}$. Basic variables are then expressed as follows:

$$x^B = \hat{x}^B - \tilde{h}z_0,$$

where $\tilde{h}$ is the "transformed artificial column" (the untransformed column is $h = B^0\tilde{h}$). The coefficients of $\tilde{h}$ are selected so that:

1. The values of "feasible" basis variables are unaffected by $z_0$: ($x_i^B \leq x_i^B \leq \tilde{x}_i^B \Rightarrow \tilde{h}_i = 0$).
2. The "most infeasible" basic variable ($i = p$) is driven to its upper or lower bound when $z_0 = 1$:

$$\tilde{h}_p = \begin{cases} \frac{\hat{x}_p^B - \bar{x}_p^B}{\bar{x}_p^B - \tilde{x}_p^B}, & \text{if } \bar{x}_p^B > \tilde{x}_p^B \\ \frac{\bar{x}_p^B - \hat{x}_p^B}{\tilde{x}_p^B - \hat{x}_p^B}, & \text{if } \tilde{x}_p^B < \hat{x}_p^B. \end{cases}$$

3. All other infeasible basic variables assume values between their upper and lower bounds when $z_0$ increases to 1:

$$x_i^B = \begin{cases} 1 + x_i^B, & \text{if } x_i^B > -\infty, \quad \hat{x}_i^B = +\infty \\ \frac{x_i^B + \tilde{x}_i^B}{2}, & \text{if } x_i^B > -\infty, \quad \hat{x}_i^B < +\infty \\ \bar{x}_i^B - 1, & \text{if } x_i^B = -\infty, \quad \hat{x}_i^B < +\infty. \end{cases}$$

5.25.4.3 Pivoting Rules

When $z_0$ enters the basis, it assumes a value of unity, and at this point (barring degeneracy), the subsequent pivot sequence is entirely determined. The entering variable in one iteration is determined by the exiting basic variable in the previous iteration. For example, if $z_i$ were in $B^0$ and introducing $z_0$ caused $z_i$ to move onto its lower bound, then the subsequent iteration introduces $w_i$. Conversely, if $w_i$ were in $B^0$ and $z_0$ caused $w_i$ to fall to zero, the subsequent iteration increases $z_i$ from $\ell_i$. Finally, if $v_i$ were in $B^0$ and $z_0$’s introduction caused $v_i$ to fall to zero, the subsequent iteration decreases $z_i$ from $u_i$.

Table 1: Pivot Sequence Rules for Lemke's Algorithm with Implicit Bounds

<table>
<thead>
<tr>
<th>N</th>
<th>Exiting Variable</th>
<th>Entering Variable</th>
<th>Change in Non-basic Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>$z_i$ at lower bound</td>
<td>$w_i$ increases from 0</td>
<td>$x_i^N = z_i = \ell_i$</td>
</tr>
<tr>
<td>II</td>
<td>$z_i$ at upper bound</td>
<td>$v_i$ increases from 0</td>
<td>$x_i^N = z_i = u_i$</td>
</tr>
<tr>
<td>III</td>
<td>$w_i$ at 0</td>
<td>$z_i$ increases from $\ell_i$</td>
<td>$x_i^N = x_{i+n}^N = 0$</td>
</tr>
<tr>
<td>IV</td>
<td>$v_i$ at 0</td>
<td>$z_i$ decreases from $u_i$</td>
<td>$x_i^N = x_{i+n}^N = 0$</td>
</tr>
</tbody>
</table>

8In Miles, $B^0$ is chosen using the initially assigned values for $z$. When $z_i \leq \ell_i$, then $x_i^B = w_i$; when $z_i \geq u_i$, then $x_i^B = v_i$; otherwise $x_i^B = z_i$.

9The present version of the code simply sets $B^0 = -I$ and $x^B = w$ when the user-specified basis is singular. A subsequent version of the code will incorporate the algorithm described by Austracher, Lee, and Rutherford [1992] for coping with singularity.
The full set of pivoting rules is displayed in Table 1. One difference between this algorithm and the original Lemke (type III) pivoting scheme (see Lemke (1965), Garcia and Zangwill (1981), or Cottle and Pang (1992)) is that structural variables ($z_i$'s) may enter or exit the basis at their upper bound values. The algorithm, therefore, must distinguish between pivots in which the entering variable increases from a lower bound and those in which the entering variable decreases from an upper bound.

Another difference with the "usual" Lemke pivot procedure is that an entering structural variable may move from one bound to another. When this occurs, the subsequent pivot introduces the corresponding slack variable. For example, if $z_i$ is increased from $\ell_i$ to $u_i$ without driving a basic variable infeasible, then $z_i$ becomes non-basic at $u_i$, and the subsequent pivot introduces $v_i$. This type of pivot may be interpreted as $z_i$ entering and exiting the basis in a single step.\footnote{If all structural variables are subject to finite upper and lower bounds, then no $z_i$ variables may be part of a homogeneous solution adjacent to a secondary ray. This does not imply, however, that secondary rays are impossible when all $z_i$ variables are bounded, as a ray may then be comprised of $w_i$ and $v_i$ variables.}

In theory it is convenient to ignore degeneracy, while in practice degeneracy is unavoidable. The present algorithm does not incorporate a lexicographic scheme to avoid cycling, but it does implement a ratio test procedure which assures that when there is more than one candidate, priority is given to the most stable pivot. The admissible set of pivots is determined on both an absolute pivot tolerance ($\text{ZTOLPV}$) and a relative pivot tolerance ($\text{ZTOLRP}$). No pivot with absolute value smaller than $\min(\text{ZTOLPV}, \text{ZTOLRP} \| V \|)$ is considered, where $\| V \|$ is the norm of the incoming column.

### 5.25.4.4 Termination on a Secondary Ray

Lemke’s algorithm terminates normally when the introduction of a new variable drives $z_0$ to zero. This is the desired outcome, but it does not always happen. The algorithm may be interrupted prematurely when no basic variable "blocks" an incoming variable, a condition known as "termination on a secondary ray". In anticipation of such outcomes, MILES maintains a record of the value of $z_0$ for successive iterations, and it saves basis information associated with the smallest observed value, $z^*_0$. (In Lemke’s algorithm, the pivot sequence is determined without regard for the effect on $z_0$, and the value of the artificial variable may follow an erratic (non-monotone) path from its initial value of one to the final value of zero.)

When MILES encounters a secondary ray, a restart procedure is invoked in which the set of basic variables associated with $z^*_0$ are reinstalled. This basis (augmented with one column from the non-basic triplet to replace $z_0$) serves as $B^0$, and the algorithm is restarted. In some cases this procedure permits the pivot sequence to continue smoothly to a solution, while in other cases may only lead to another secondary ray.

### 5.25.5 The Options File

The standard GAMS options (e.g. iterlim, reslim) can be used to control MILES. For more details, see section Controlling a Solver via GAMS Options.

In addition, MILES-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

The following is a typical MILES options file:

\begin{verbatim}
ITLIMT = 50
CONTOL = 1.0E-8
LUSIZE = 16
\end{verbatim}

In the remainder of this section we describe the MILES options and give their default values.

### 5.25.6 Log File Output

The log file is intended for display on the screen in order to permit monitoring progress. Relatively little output is generated.

A sample iteration log is displayed in **Table 2**. This output is from two cases solved in succession. This and subsequent output comes from program `TRNSP.FOR` which calls the MILES library directly. (When MILES is invoked from within GAMS, at most one case is processed at a time.)

The first line of the log output gives the MILES program date and version information. This information is important for bug reports.

The line beginning "Work space..." reports the amount of memory which has been allocated to solve the model - 10K for this example. Thereafter is reported the initial deviation together with the name of the variable associated with the largest imbalance ($\epsilon_B + \epsilon_C$). The next line reports the convergence tolerance.

The lines beginning 0 and 1 are the major iteration reports for those iterations. the number following the iteration number is the current deviation, and the third number is the Armijo step length. The name of the variable complementary to the equation with the largest associated deviation is reported in parenthesis at the end of the line.

Following the final iteration is a summary of iterations, refactorizations, and final deviation. The final message reports the solution status. In this case, the model has been successfully processed ("Solved.").

5.25.7 Status File Output

The status file reports more details regarding the solution process than are provided in the log file. Typically, this file is written to disk and examined only if a problem arises. Within GAMS, the status file appears in the listing only following the GAMS statement `OPTION SYSOUT=ON;`.

The level of output to the status file is determined by the options passed to the solver. In the default configuration, the status file receives all information written to the log file together with a detailed listing of all switches and tolerances and a report of basis factorization statistics.

When output levels are increased from their default values using the options file, the status file can receive considerably more output to assist in debugging. Table 3 - Table 6 present a status file generated with `LEVOUT=3` (maximum), `PIVLOG=T`, and `LCPECH=T`.

The status file begins with the same header as the log file. Thereafter is a complete echo-print of the user-supplied option file when one is provided. Following the core allocation report is a full echo-print of control parameters, switches and tolerance as specified for the current run.

Table 4 continues the status file. The iteration-by-iteration report of variable and function values is produced whenever `LEVOUT >= 2`. Table 4 also contains an LCP echo-print. This report has two sections: `$\text{ROWS}$ and `$\text{COLUMNS}$`. The four columns of numbers in the `$\text{ROWS}$` section are the constant vector \((q)\), the current estimate of level values for the associated variables \((z)\), and the lower and upper bounds vectors \((\ell \text{ and } u)\). The letters \(L\) and \(U\) which appear between the \(\text{ROW}\) and \(\text{Z}\) columns are used to identify variables which are non-basic at their lower and upper bounds, respectively. In this example, all upper bounds equal \(+\infty\), so no variables are non-basic at their upper bound.

By convention, only variable (and not equation names) appear in the status file. An equation is identified by the corresponding variable. We therefore see in the `$\text{COLUMNS}$` section of the matrix echo-print, the row names correspond to the names of \(z\) variables. The names assigned to variables \(z_i\), \(w_i\) and \(v_i\) are...
$$z = <\text{name }i>, w = <\text{name }i>, \text{ and } v = <\text{name }i>, \text{ as shown in the $\text{\$COLUMNS}$ section. The nonzeros for } w = <\> \text{ and } v = <\> \text{ variables are not shown because they are assumed to be } -/ + I.$$

The status file output continues on Table 5 where the first half of the table reports output from the matrix scaling procedure, and the second half reports the messages associated with initiation of Lemke’s procedure.

The “lu6chk warning” is a LUSOL report. Thereafter are two factorization reports. Two factorizations are undertaken here because the first basis was singular, so the program installs all the lower bound slacks in place of the matrix defined by the initial values, $z$.

Following the second factorization report, at the bottom of Table 5 is a summary of the initial pivot. “Infeasible in 3 rows.” indicates that $\tilde{h}$ contains 3 nonzero elements. “Maximum infeasibility” reports the largest amount by which a structural variable violates an upper or lower bound. ”Artificial column with 3 elements.” indicates that the vector $h = B^0 \tilde{h}$ contains 3 elements (note that in this case $B^0 = -I$ because the initial basis was singular, hence the equivalence between the number of nonzeros in $\tilde{h}$ and $h$.)

Table 6 displays the final section of the status file. At the top of the table is the Lemke iteration log. The columns are interpreted as follows:

- **ITER** is the iteration index beginning with 0.
- **STATUS** is a statistic representing the efficiency of the Lemke path. Formally, status is the ratio of the minimum number of pivots from $B_0$ to the current basis divided by the actual number of pivots. When the status is 1, Lemke’s algorithm is performing virtually as efficiently as a direct factorization (apart from the overhead of basis factor updates.)
- **Z%** indicates the percentage of columns in the basis are ”structural” ($z$’s).
- **Z0** indicates the value of the artificial variable. Notice that in this example, the artificial variable declines monotonically from its initial value of unity.
- **ERROR** is a column in which the factorization error is reported, when it is computed. For this run, ITCH=30 and hence no factorization errors are computed.
- **INFEAS** is a column in which the magnitude of the infeasibility introduced by the artificial column (defined using the box-norm) is reported. (In MILES the cover vector $h$ contains many different nonzero values, not just 1’s; so there may be a large difference between the magnitude of the artificial variable and the magnitude of the induced infeasibility.
- **PIVOTS** reports the pivot magnitude in both absolute terms (the first number) and relative terms (the second number). The relative pivot size is the ratio of the pivot element to the norm of the incoming column.
- **IN/OUT** report the indices (not names) of the incoming and outgoing columns for every iteration. Notice that Lemke’s iteration log concludes with variable $z_0$ exiting the basis.

The convergence report for iteration 1 is no different from the report written to the log file, and following this is a second report of variable and function values. We see here that a solution has been obtained following a single subproblem. This is because the underlying problem is, in fact, linear.

The status file (for this case) concludes with an iteration summary identical to the log file report and a summary of how much CPU time was employed overall and within various subtasks. (Don’t be alarmed if the sum of the last five numbers does not add up to the first number - some cycles are not monitored precisely.)

**5.25.8 Termination Messages**

**Basis factorization error in INVERT.** An unexpected error code returned by LUSOL. This should normally not occur. Examine the status file for a message from LUSOL 11.

11Within GAMS, insert the line "OPTION SYSOUT=ON;" prior to the solve statement and resubmit the program in order to pass the MILES solver status file through to the listing.
**Failure to converge.** Two successive iterates are identical - the Newton search direction is not defined. This should normally not occur.

**Inconsistent parameters** $\text{ZTOLZ0}$, $\text{ZTOLZE}$. $\text{ZTOLZ0}$ determines the smallest value loaded into the cover vector $h$, whereas $\text{ZTOLZE}$ is the feasibility tolerance employed in the Harris pivot selection procedure. If $\text{ZTOLZ0} < -\text{ZTOLZE}$, Lemke's algorithm cannot be executed because the initial basis is infeasible.

**Insufficient space for linearization.** Available memory is inadequate for holding the nonzeros in the Jacobian. More memory needs to be allocated. If there is insufficient space for the (Jacobi) matrix, there is far too little memory for holding the LU factors of the same matrix.

**Insufficient space to invert.** More memory needs to be allocated for basis factors. Increase the value of $\text{LUSIZE}$ in the options file, or assign a larger value to `<model>.workspace`.

**Iteration limit exceeded.** This can result from either exceeding the major (Newton) or minor (Lemke) iterations limit. When MILES is invoked from GAMS, the cumulative Lemke iteration limit can be set with the statement `<model>.iterlim = xx>;`. The Newton iteration limit is 100 by default, and it can be modified only through the `ITLIMT` option.

**Resource interrupt.** Elapsed CPU time exceeds options parameter `RESLIM`. To increase this limit, either add `RESLIM = xxx` in the options file or add a GAMS statement `<model>.RESLIM = xxx;`.

**Singular matrix encountered.** Lemke's algorithm has been interrupted due to a singularity arising in the basis factorization, either during a column replacement or during a refactorization. For some reason, a restart is not possible.

**Termination on a secondary ray.** Lemke's algorithm terminated on a secondary ray. For some reason, a restart is not possible.

**Unknown termination status.** The termination status flag has not been set, but the code has interrupted. Look in the status file for a previous message. This termination code should not happen often.

Philip E. Gill; Department of Mathematics, University of California, San Diego, La Jolla, CA

5.26.1 Introduction

This document describes the GAMS interface to MINOS which is a general purpose nonlinear programming solver. For a quad-precision MINOS, see quadMINOS.

GAMS/MINOS is a specially adapted version of the solver that is used for solving linear and nonlinear programming problems in a GAMS environment.

GAMS/MINOS is designed to find solutions that are locally optimal. The nonlinear functions in a problem must be smooth (i.e., their first derivatives must exist). The functions need not be separable. Integer restrictions cannot be imposed directly.

A certain region is defined by the linear constraints in a problem and by the bounds on the variables. If the nonlinear objective and constraint functions are convex within this region, any optimal solution obtained will be a global optimum. Otherwise there may be several local optima, and some of these may not be global. In such cases the chances of finding a global optimum are usually increased by choosing a starting point that is "sufficiently close", but there is no general procedure for determining what "close" means, or for verifying that a given local optimum is indeed global.

Linearly constrained models are solved with a very efficient and reliable reduced gradient technique that takes advantage of the sparsity of the model. Models with nonlinear constraints are solved with a method that iteratively solves subproblems with linearized constraints and an augmented Lagrangian objective function. This iterative scheme implies that only the final, optimal solution is sure to be feasible w.r.t the nonlinear constraints. This is in contrast to the feasible path method used by some other NLP solvers, e.g., CONOPT. MINOS and CONOPT are very complementary to each other as they employ very different algorithms. See MINOS vs CONOPT for a comparison of the two solvers.

GAMS allows you to specify values for many parameters that control GAMS/MINOS, and with careful experimentation you may be able to influence the solution process in a helpful way. All MINOS options available through GAMS/MINOS are summarized at the end of this document.
5.26.2 How to Run a Model with GAMS/MINOS

MINOS is capable of solving many types of models, including LP, NLP, DNLP and QCP. If MINOS is not specified as the default solver for the desired model type (e.g. NLP), then the following statement can be used in your GAMS model to select MINOS:

\[
\text{option nlp=minos;}
\]

The option statement should appear before the `solve` statement.

To be complete, we mention that the solver can be also specified on the command line, as in:

\[
> \text{gams camcge nlp=minos}
\]

This will override the global default, but if an algorithm option has been specified inside the model, then that specification takes precedence.

5.26.3 Overview of GAMS/MINOS

GAMS/MINOS is a system designed to solve large-scale optimization problems expressed in the following form:

\[
\text{NLP : minimize } \quad \min F(x) + c^T x + d^T y \quad (1)
\]

\[
\text{subject to } \quad f(x) + A_1 y \sim b_1 \quad (2)
\]

\[
A_2 x + A_3 y \sim b_2 \quad (3)
\]

\[
\ell \leq \begin{pmatrix} x \\ y \end{pmatrix} \leq u \quad (4)
\]

where the vectors \( c, d, b_1, b_2, \ell, u \) and the matrices \( A_1, A_2, A_3 \) are constant, \( F(x) \) is a smooth scalar function, and \( f(x) \) is a vector of smooth functions. The \( \sim \) signs mean that individual constraints may be defined using \( \leq, = \) or \( \geq \) corresponding to the GAMS constructs \( =L=, =E= \) and \( =G= \).

The components of \( x \) are called the nonlinear variables, and the components of \( y \) are the linear variables. Similarly, the equations in (2) are called the nonlinear constraints, and the equations in (3) are the linear constraints. Equations (2) and (3) together are called the general constraints.

Let \( m_1 \) and \( n_1 \) denote the number of nonlinear constraints and variables, and let \( m \) and \( n \) denote the total number of (general) constraints and variables. Thus, \( A_3 \) has \( m - m_1 \) rows and \( n - n_1 \) columns. The constraints (4) specify upper and lower bounds on all variables. These are fundamental to many problem formulations and are treated specially by the solution algorithms in GAMS/MINOS. Some of the components of \( \ell \) and \( u \) may be \( -\infty \) or \( +\infty \) respectively, in accordance with the GAMS use of \( -\text{INF} \) and \( +\text{INF} \).

The vectors \( b_1 \) and \( b_2 \) are called the right-hand side, and together are denoted by \( b \).
5.26.3.1 Linear Programming

If the functions $F(x)$ and $f(x)$ are absent, the problem becomes a linear program. Since there is no need to distinguish between linear and nonlinear variables, we use $x$ rather than $y$. GAMS/MINOS converts all general constraints into equalities, and the only remaining inequalities are simple bounds on the variables. Thus, we write linear programs in the form

\[
\text{LP : minimize } c^T x \\
\text{subject to } Ax + Is = 0 \\
\ell \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u
\]

where the elements of $x$ are your own GAMS variables, and $s$ is a set of slack variables: one for each general constraint. For computational reasons, the right-hand side $b$ is incorporated into the bounds on $s$.

In the expression $Ax + Is = 0$ we write the identity matrix explicitly if we are concerned with columns of the associated matrix $(A \ I)$. Otherwise we will use the equivalent notation $Ax + s = 0$.

GAMS/MINOS solves linear programs using a reliable implementation of the primal simplex method [41], in which the constraints $Ax + Is = 0$ are partitioned into the form

\[
Bx_B + Nx_N = 0,
\]

where the basis matrix is square and nonsingular. The elements of $x_B$ and $x_N$ are called the basic or nonbasic variables respectively. Together they are a permutation of the vector

\[
\begin{pmatrix} x \\ s \end{pmatrix}.
\]

Normally, each nonbasic variable is equal to one of its bounds, and the basic variables take on whatever values are needed to satisfy the general constraints. (The basic variables may be computed by solving the linear equations $Bx_B = Nx_N$.) It can be shown that if an optimal solution to a linear program exists, then it has this form.

The simplex method reaches such a solution by performing a sequence of iterations, in which one column of $B$ is replaced by one column of $N$ (and vice versa), until no such interchange can be found that will reduce the value of $c^T x$.

As indicated nonbasic variables usually satisfy their upper and lower bounds. If any components of $x_B$ lie significantly outside their bounds, we say that the current point is infeasible. In this case, the simplex method uses a Phase 1 procedure to reduce the sum of infeasibilities to zero. This is similar to the subsequent Phase 2 procedure that optimizes the true objective function $c^T x$.

If the solution procedures are interrupted, some of the nonbasic variables may lie strictly between their bounds $\ell_j < x_j < u_j$. In addition, at a "feasible" or "optimal" solution, some of the basic variables may lie slightly outside their bounds: $\ell_j - \delta < x_j < \ell_j$ or $u_j < x_j < u_j + \delta$ where $\delta$ is a feasibility tolerance (typically $10^{-6}$). In rare cases, even nonbasic variables might lie outside their bounds by as much as $\delta$.

GAMS/MINOS maintains a sparse $LU$ factorization of the basis matrix $B$, using a Markowitz ordering scheme and Bartels-Golub updates, as implemented in the Fortran package LUSOL [82] (see [16] [17] [147] [148] ). The basis factorization is central to the efficient handling of sparse linear and nonlinear constraints.
5.26.3.2 Problems with a Nonlinear Objective

When nonlinearities are confined to the term \( F(x) \) in the objective function, the problem is a linearly constrained nonlinear program. GAMS/MINOS solves such problems using a reduced-gradient algorithm \[203\] combined with a quasi-Newton algorithm that is described in [139]. In the reduced-gradient method, the constraints \( Ax + Is = 0 \) are partitioned into the form

\[
Bx_B + Sx_S + Nx_N = 0
\]

where \( x_s \) is a set of superbasic variables. At a solution, the basic and superbasic variables will lie somewhere between their bounds (to within the feasibility tolerance \( \delta \), while nonbasic variables will normally be equal to one of their bounds, as before. Let the number of superbasic variables be \( s \), the number of columns in \( S \). (The context will always distinguish \( s \) from the vector of slack variables.) At a solution, \( s \) will be no more than \( n_1 \), the number of nonlinear variables. In many practical cases we have found that \( s \) remains reasonably small, say 200 or less, even if \( n_1 \) is large.

In the reduced-gradient algorithm, \( x_s \) is regarded as a set of ”independent variables” or ”free variables” that are allowed to move in any desirable direction, namely one that will improve the value of the objective function (or reduce the sum of infeasibilities). The basic variables can then be adjusted in order to continue satisfying the linear constraints.

If it appears that no improvement can be made with the current definition of \( B, S \) and \( N \), some of the nonbasic variables are selected to be added to \( S \), and the process is repeated with an increased value of \( s \). At all stages, if a basic or superbasic variable encounters one of its bounds, the variable is made nonbasic and the value of \( s \) is reduced by one.

A step of the reduced-gradient method is called a minor iteration. For linear problems, we may interpret the simplex method as being the same as the reduced-gradient method, with the number of superbasic variable oscillating between 0 and 1.

A certain matrix \( Z \) is needed now for descriptive purposes. It takes the form

\[
\begin{pmatrix}
-B^{-1}S \\
I \\
0
\end{pmatrix}
\]

though it is never computed explicitly. Given an \( LU \) factorization of the basis matrix \( B \), it is possible to compute products of the form \( Zq \) and \( Z^Tg \) by solving linear equations involving \( B \) or \( B^T \). This in turn allows optimization to be performed on the superbasic variables, while the basic variables are adjusted to satisfy the general linear constraints.

An important feature of GAMS/MINOS is a stable implementation of a quasi-Newton algorithm for optimizing the superbasic variables. This can achieve superlinear convergence during any sequence of iterations for which the \( B, S, N \) partition remains constant. A search direction \( q \) for the superbasic variables is obtained by solving a system of the form

\[
R^T R q = -Z^T g
\]

where \( g \) is a gradient of \( F(x) \), \( Z^T g \) is the reduced gradient, and \( R \) is a dense upper triangular matrix. GAMS computes the gradient vector \( g \) analytically, using automatic differentiation. The matrix \( R \) is updated in various ways in order to approximate the reduced Hessian according to \( R^T R \approx Z^T H Z \) where \( H \) is the matrix of second derivatives of \( F(x) \) (the Hessian).

Once \( q \) is available, the search direction for all variables is defined by \( p = Zq \). A line search is then performed to find an approximate solution to the one-dimensional (w.r.t. \( \alpha \)) problem

\[
\begin{align*}
\text{minimize} & \quad F(x + \alpha p) \\
\text{subject to} & \quad 0 < \alpha < \beta
\end{align*}
\]
where $\beta$ is determined by the bounds on the variables. Another important piece in GAMS/MINOS is a step-length procedure used in the linesearch to determine the step-length $\alpha$ (see [80]). The number of nonlinear function evaluations required may be influenced by setting the Linesearch tolerance, as discussed in Section Detailed Description of MINOS Options.

As in a linear programming solver, an equation $B^T\pi = gB$ is solved to obtain the dual variables or shadow prices $\pi$ where $gB$ is the gradient of the objective function associated with basic variables. It follows that $gB - B^T\pi = 0$. The analogous quantity for superbasic variables is the reduced-gradient vector $Z^Tg = gs - s^T\pi$; this should also be zero at an optimal solution. (In practice its components will be of order $r||\pi||$ where $r$ is the optimality tolerance, typically $10^{-6}$, and $||\pi||$ is a measure of the size of the elements of $\pi$.)

### 5.26.3.3 Problems with Nonlinear Constraints

If any of the constraints are nonlinear, GAMS/MINOS employs a project Lagrangian algorithm, based on a method due to [150], see [140]. This involves a sequence of major iterations, each of which requires the solution of a linearly constrained subproblem. Each subproblem contains linearized versions of the nonlinear constraints, as well as the original linear constraints and bounds.

At the start of the $k^\text{th}$ major iteration, let $x_k$ be an estimate of the nonlinear variables, and let $\lambda_k$ be an estimate of the Lagrange multipliers (or dual variables) associated with the nonlinear constraints. The constraints are linearized by changing $f(x)$ in equation (2) to its linear approximation:

$$f'(x, x_k) = f(x_k) + J(x_k)(x - x_k)$$

or more briefly

$$f' = f_k + J_k(x - x_k)$$

where $J(x_k)$ is the Jacobian matrix evaluated at $x_k$. (The $i$-th row of the Jacobian is the gradient vector of the $i$-th nonlinear constraint function. As with the objective gradient, GAMS calculates the Jacobian using automatic differentiation).

The subproblem to be solved during the $k$-th major iteration is then

$$\text{minimize } F(x) + c^Tx + d^Ty - \lambda_k^T(f - f') + 0.5\rho(f - f')^T(f - f') \tag{5}$$

subject to

$$f' + A_1y \sim b_1 \tag{6}$$
$$A_2x + A_3y \sim b_2 \tag{7}$$
$$\ell \leq \begin{pmatrix} x \\ y \end{pmatrix} \leq u \tag{8}$$

The objective function (5) is called an augmented Lagrangian. The scalar $\rho$ is a penalty parameter, and the term involving $\rho$ is a modified quadratic penalty function.

GAMS/MINOS uses the reduced-gradient algorithm to minimize (5) subject to (6) – (8). As before, slack variables are introduced and $b_1$ and $b_2$ are incorporated into the bounds on the slacks. The linearized constraints take the form

$$\begin{pmatrix} J_k & A_1 \\ A_2 & A_3 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \begin{pmatrix} s_1 \\ s_2 \end{pmatrix} = \begin{pmatrix} J_k x_k - f_k \end{pmatrix}$$

This system will be referred to as $Ax + Is = 0$ as in the linear case. The Jacobian $J_k$ is treated as a sparse matrix, the same as the matrices $A_1$, $A_2$, and $A_3$.

In the output from GAMS/MINOS, the term Feasible subproblem indicates that the linearized constraints have been satisfied. In general, the nonlinear constraints are satisfied only in the limit, so that feasibility and optimality occur at essentially the same time. The nonlinear constraint violation is printed every major iteration. Even if it is zero early on (say at the initial point), it may increase and perhaps fluctuate before tending to zero. On "well behaved problems", the constraint violation will decrease quadratically (i.e., very quickly) during the final few major iterations.
5.26.4 Modeling Issues

Formulating nonlinear models requires that the modeler pays attention to some details that play no role when dealing with linear models.

5.26.4.1 Starting Points

The first issue is specifying a starting point. It is advised to specify a good starting point for as many nonlinear variables as possible. The GAMS default of zero is often a very poor choice, making this even more important.

As an (artificial) example consider the problem where we want to find the smallest circle that contains a number of points \((x_i, y_i):\)

Example:

\[
\begin{align*}
\text{minimize} & \quad r \\
\text{subject to} & \quad (x_i - a)^2 + (y_i - b)^2 \leq r^2, \quad r \geq 0.
\end{align*}
\]

This problem can be modeled in GAMS as follows.

```gams
set i 'points' /p1*p10/;
parameters
  x(i) 'x coordinates',
  y(i) 'y coordinates';
  * fill with random data
  x(i) = uniform(1,10);
  y(i) = uniform(1,10);
variables
  a 'x coordinate of center of circle'
  b 'y coordinate of center of circle'
  r 'radius';
equations
  e(i) 'points must be inside circle';
e(i).. sqr(x(i)-a) + sqr(y(i)-b) =l= sqr(r);
  r.lo = 0;
model m /all/;
option nlp=minos;
solve m using nlp minimizing r;
```

Without help, MINOS will not be able to find an optimal solution. The problem will be declared infeasible. In this case, providing a good starting point is very easy. If we define

\[
\begin{align*}
  x_{\min} &= \min_i x_i, \\
  y_{\min} &= \min_i y_i, \\
  x_{\max} &= \max_i x_i, \\
  y_{\max} &= \max_i y_i,
\end{align*}
\]
then good estimates are

\[ a = \frac{x_{\min} + x_{\max}}{2}, \]
\[ b = \frac{y_{\min} + y_{\max}}{2}, \]
\[ r = \sqrt{\left(a - x_{\min}\right)^2 + \left(b - y_{\min}\right)^2}. \]

Thus we include in our model:

```plaintext
parameters xmin,ymin,xmax,ymax;
xmin = smin(i, x(i));
ymin = smin(i, y(i));
xmax = smax(i, x(i));
ymax = smax(i, y(i));

* set starting point
a.l = (xmin+xmax)/2;
b.l = (ymin+ymax)/2;
r.l = sqrt( sqr(a.l-xmin) + sqr(b.l-ymin) );
```

and now the model solves very easily.

Level values can also be set away from zero implicitly as a result of assigning bounds. When a variable is bounded away from zero, for instance by the statement \( Y.LO = 1; \), the implicit projection of variable levels onto their bounds that occurs when a model is solved will initialize \( Y \) away from zero.

### 5.26.4.2 Bounds

Setting appropriate bounds can be very important to steer the algorithm away from uninteresting areas, and to prevent function evaluation errors from happening.

If your model contains a real power of the form \( x^{**y} \) it is important to add a bound \( x > 0.001 \), as real exponentiation is evaluated in GAMS as \( \exp(y \log(x)) \). In some cases one cannot write a bound directly, e.g. if the equation is \( z = x^{f(y)} \). In that case it is advised to introduce an extra variable and equation:

\[
\begin{align*}
z &= x^\vartheta \\
\vartheta &= f(y) \\
\vartheta &\geq \varepsilon
\end{align*}
\]

(Note that the functions \( \text{SQR}(x) \) and \( \text{POWER}(x, k) \) are integer powers and do not require \( x \) to be positive).

If the model produces function evaluation errors adding bounds is prefered to raising the \( \text{DOMLIM} \) limit.

Bounds in GAMS are specified using \( X.LO(i) = 0.001 \) and \( X.UP(i) = 1000 \).

### 5.26.4.3 Scaling

Although MINOS has some facilities to scale the problem before starting to optimize it, it remains an important task for the modeler to provide a well-scaled model. This is especially the case for nonlinear models. GAMS has special syntax features to specify row and column scales that allow the modeler to keep the equations in a most natural form. For more information consult the GAMS User's Guide.
5.26.4.4 The Objective Function

The first step GAMS/MINOS performs is to try to reconstruct the objective function. In GAMS, optimization models minimize or maximize an objective variable. MINOS however works with an objective function. One way of dealing with this is to add a dummy linear function with just the objective variable. Consider the following GAMS fragment:

```gams
obj.. z =e= sum(i, sqr(resid(i)));
model m /all/;
solve m using nlp minimizing z;
```

This can be cast in form NLP (equations (1) − (4)) by saying minimize \( z \) subject to \( z = \sum_i resid_i^2 \) and the other constraints in the model. Although simple, this approach is not always preferable. Especially when all constraints are linear it is important to minimize \( \sum_i resid_i^2 \) directly. This can be achieved by a simple reformulation: \( z \) can be substituted out. The substitution mechanism carries out the formulation if all of the following conditions hold:

- the objective variable \( z \) is a free continuous variable (no bounds are defined on \( z \)),
- \( z \) appears linearly in the objective function,
- the objective function is formulated as an equality constraint,
- \( z \) is only present in the objective function and not in other constraints.

For many models it is very important that the nonlinear objective function be used by MINOS. For instance the model [CHEM] from the model library solves in 21 iterations. When we add the bound

```gams
energy.lo = 0;
```

to the objective variable `energy` and thus prevent it from being substituted out, MINOS will not be able to find a feasible point for the given starting point.

This reformulation mechanism has been extended for substitutions along the diagonal. For example, the GAMS model

```gams
Variables x,y,z;
Equations e1,e2;
e1..z =e= y;
e2..y =e= sqr(1+x);
model m /all/;
option nlp=minos;
solve m using nlp minimizing z;
```

will be reformulated as an unconstrained optimization problem

\[
\text{minimize } f(x) = (1 + x)^2.
\]

These additional reformulations can be turned off by using the statement `option reform = 0;` (see Section GAMS Options).
5.26.5 GAMS Options

The standard GAMS options (e.g. iterlim, domlim) can be used to control GAMS/MINOS. For more details, see section Controlling a Solver via GAMS Options. We highlight some of the details of this usage below for cases of special interest.

**iterlim**

Sets the minor iteration limit. MINOS will stop as soon as the number of minor iterations exceeds the iteration limit and report the current solution.

**domlim**

Sets the domain error limit. Domain errors are evaluation errors in the nonlinear functions. An example of a domain error is trying to evaluate \( \sqrt{x} \) for \( x < 0 \). Other examples include taking logs of negative numbers, and evaluating the real power \( x^y \) for \( x < \varepsilon \) (\( x^y \) is evaluated as \( \exp(y \log x) \)). When such an error occurs the count of domain errors is incremented: MINOS will stop if this count exceeds the limit. If the limit has not been reached, reasonable estimates for the function (and derivatives, if requested) are returned and MINOS continues. For example, in the case of \( \sqrt{x}, x < 0 \) a zero is passed back for the function value and a large value for the derivative. In many cases MINOS will be able to recover from these domain errors, especially when they happen at some intermediate point. Nevertheless it is best to add appropriate bounds or linear constraints to ensure that these domain errors don't occur. For example, when an expression \( \log(x) \) is present in the model, add a statement like \( x.lo = 0.001; \).

**bratio**

Ratio used in basis acceptance test. When a previous solution or solution estimate exists, GAMS automatically passes this solution to MINOS so that it can reconstruct an advanced basis. When too many new (i.e. uninitialized with level and/or marginal values) variables or constraints enter the model, it may be better not to use existing basis information, but to instead crash a new basis. The \textbf{bratio} determines how quickly an existing basis is discarded. A value of 1.0 will discard any basis, while a value of 0.0 will retain any basis.

**workfactor**

By default, GAMS/MINOS computes an estimate of the amount of workspace needed by MINOS, and passes this workspace on to MINOS for use in solving the model. This estimate is based on the model statistics: number of (nonlinear) equations, number of (nonlinear) variables, number of (nonlinear) nonzeroes, etc. In most cases this is sufficient to solve the model. In some rare cases MINOS may need more memory, and the user can provide this by specifying a value of workfactor greater than 1. The computed memory estimate is multiplied by the workfactor to determine the amount of workspace made available to MINOS for the solve.

**workspace**

The workspace option is deprecated: use the workfactor option instead. The workspace option specifies the amount of memory, in MB, that MINOS will use.

**reform**

This option controls the objective reformulation mechanism described in Section The Objective Function. The default value of 100 will cause GAMS/MINOS to try further substitutions along the diagonal after the objective variable has been removed. Any other value will disable this diagonal procedure.
5.26.6 Summary of MINOS Options

The performance of GAMS/MINOS is controlled by a number of parameters or "options." Each option has a default value that should be appropriate for most problems. For special situations it is possible to specify non-standard values for some or all of the options through the MINOS option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

Note that the option file is not case sensitive. Examples for using the option file can be found at the end of this section. The tables below contain summary information about the MINOS options, default values, and links to more detailed explanations.

5.26.6.1 Output related options

5.26.6.5 Examples of GAMS/MINOS Option File

The following example illustrates the use of certain options that might be helpful for “difficult” models involving nonlinear constraints. Experimentation may be necessary with the values specified, particularly if the sequence of major iterations does not converge using default values.

* These options might be relevant for very nonlinear models.
  - Major damping parameter 0.2 * may prevent divergence.
  - Minor damping parameter 0.2 * if there are singularities
    * in the nonlinear functions.
  - Penalty parameter 10.0 * or 100.0 perhaps—a value
    * higher than the default.
  - Scale linear variables * (This is the default.)

Conversely, nonlinearly constrained models that are very nearly linear may optimize more efficiently if some of the cautious defaults are relaxed:

* Suggestions for models with MILDLY nonlinear constraints
  - Completion Full
  - Penalty parameter 0.0 * or 0.1 perhaps—a value
    * smaller than the default.
    * Scale one of the following
  - Scale all variables * if starting point is VERY GOOD.
  - Scale linear variables * if they need it.
  - Scale No * otherwise.

Most of the options should be left at their default values for any given model. If experimentation is necessary, we recommend changing just one option at a time.

5.26.7 Special Notes

5.26.7.1 Modeling Hints

Unfortunately, there is no guarantee that the algorithm just described will converge from an arbitrary starting point. The concerned modeler can influence the likelihood of convergence as follows:
• Specify initial activity levels for the nonlinear variables as carefully as possible (using the GAMS suffix .L).

• Include sensible upper and lower bounds on all variables.

• Specify a *Major damping parameter* that is lower than the default value, if the problem is suspected of being highly nonlinear

• Specify a *Penalty parameter* \( \rho \) that is higher than the default value, again if the problem is highly nonlinear.

In rare cases it may be safe to request the values \( \lambda_k = 0 \) and \( \rho = 0 \) for all subproblems, by specifying *Lagrangian=No*. However, convergence is much more likely with the default setting, *Lagrangian=Yes*. The initial estimate of the Lagrange multipliers is then \( \lambda_0 = 0 \), but for later subproblems \( \lambda_k \) is taken to be the Lagrange multipliers associated with the (linearized) nonlinear constraints at the end of the previous major iteration.

For the first subproblem, the default value for the penalty parameter is \( \rho = 100.0/m_1 \) where \( m_1 \) is the number of nonlinear constraints. For later subproblems, \( \rho \) is reduced in stages when it appears that the sequence \( \{x_k, \lambda_k\} \) is converging. In many cases it is safe to specify \( \lambda = 0 \), particularly if the problem is only mildly nonlinear. This may improve the overall efficiency.

### 5.26.7.2 Storage

GAMS/MINOS uses one large array of memory for most of its workspace. The implementation places no fixed limit on the size of a problem or on its shape (many constraints and relatively few variables, or *vice versa*). In general, the limiting factor will be the amount of physical memory available on a particular machine, and the amount of computation time one is willing to spend.

Some detailed knowledge of a particular model will usually indicate whether the solution procedure is likely to be efficient. An important quantity is \( m \), the total number of general constraints in (2) and (3). The amount of workspace required by GAMS/MINOS is roughly 100\( m \) doubles, or 800\( m \) bytes for workspace. A further 300K bytes, approximately, are needed for the program itself, along with buffer space for several files. Very roughly, then, a model with \( m \) general constraints requires about \( (m + 300) \) K bytes of memory.

Another important quantity is \( n \), the total number of variables in \( x \) and \( y \). The above comments assume that \( n \) is not much larger than \( m \), the number of constraints. A typical ratio for \( n/m \) is 2 or 3.

If there are many nonlinear variables (i.e., if \( n_1 \) is large), much depends on whether the objective function or the constraints are highly nonlinear or not. The degree of nonlinearity affects \( s \), the number of superbasic variables. Recall that \( s \) is zero for purely linear problems. We know that \( s \) need never be larger than \( n_1 + 1 \). In practice, \( s \) is often very much less than this upper limit.

In the quasi-Newton algorithm, the dense triangular matrix \( R \) has dimension \( s \) and requires about \( s^2/2 \) words of storage. If it seems likely that \( s \) will be very large, some aggregation or reformulation of the problem should be considered.

### 5.26.8 The GAMS/MINOS Log File

MINOS writes different logs for LPs, NLPs with linear constraints, and NLPs with non-linear constraints. In this section, a sample log file is shown for each case, and the messages that appear are explained.
5.26.8.1 Linear Programs

MINOS uses a standard two-phase simplex method for LPs. In the first phase, the sum of the infeasibilities at each iteration is minimized. Once feasibility is attained, MINOS switches to phase 2 where it minimizes (or maximizes) the original objective function. The different objective functions are called the phase 1 and phase 2 objectives. Notice that the marginals in phase 1 are with respect to the phase 1 objective. This means that if MINOS interrupts in phase 1, the marginals are "wrong" in the sense that they do not reflect the original objective.

*** Status: Normal completion

The first line that is written by MINOS is the version string: GAMS/MINOS Aug 18, 2010 23.5.2 WIN 19143.19383 VS8 x86/MS Windows This line identifies which version of the MINOS libraries and links you are using, and is only to be deciphered by GAMS support personnel.

After some advertisement text we see the amount of work space (i.e. memory) that is allocated: 1.60 Mb. When MINOS is loaded, the amount of memory needed is first estimated. This estimate is based on...
statistics like the number of rows, columns and non-zeros. This amount of memory is then allocated and the problem loaded into MINOS.

The columns have the following meaning:

**Itn**

Iteration number.

**ninf**

Number of infeasibilities. If nonzero the current iterate is still infeasible.

**sinf**

The sum of the infeasibilities. This number is minimized during Phase I. Once the model is feasible this number is zero.

**objective**

The value of the objective function: \( z = \sum c_i x_i \). In phase II this number is maximized or minimized. In phase I it may move in the wrong direction.

The final line indicates the exit status of MINOS.

### 5.26.8.2 Linearly Constrained NLP's

The log is basically the same as for linear models. The only difference is that not only matrix rows and columns need to be loaded, but also instructions for evaluating functions and gradients.

The log for the problem **WEAPONS** is as follows:

EXIT - Optimal Solution found, objective: 191.7346

--- Restarting execution
Two sets of iterations, major and minor, are now reported. A description of the various columns present in this log file follows:

**Major**

A major iteration involves linearizing the nonlinear constraints and performing a number of minor iterations on the resulting subproblem. The objective for the subproblem is an augmented Lagrangian, not the true objective function.

**Minor**

The number of minor iterations performed on the linearized subproblem. If it is a simple number like 90, then the subproblem was solved to optimality. Here, 2T means that the subproblem was terminated. In general the T is not something to worry about. Other possible flags are I and U, which mean that the subproblem was infeasible or unbounded. MINOS may have difficulty if these keep occurring.

**Step**

The step size taken towards the solution suggested by the last major iteration. Ideally this should be 1.0, especially near an optimum. If the subproblem solutions are widely different, MINOS may reduce the step size under control of the Major Damping parameter.

**Objective**

The objective function for the original nonlinear program.

**Feasible**

Primal infeasibility, indicating the maximum non-linear constraint violation.

**Optimal**

The maximum dual infeasibility, measured as the maximum departure from complementarity. If we call $d_j$ the reduced cost of variable $x_j$, then the dual infeasibility of $x_j$ is $d_j \times \min\{x_j - \ell_j, 1\}$ or $-d_j \times \min\{u_j - x_j, 1\}$ depending on the sign of $d_j$.

**nsb**

Number of superbasics. If the model is feasible this number cannot exceed the superbasic limit, which may need to be reset to a larger number if the numbers in this column become larger.

**ncon**

The number of times MINOS has evaluated the nonlinear constraints and their derivatives.

**penalty**

The current value of the penalty parameter in the augmented Lagrangian (the objective for the subproblems). If the major iterations appear to be converging, MINOS will decrease the penalty parameter. If there appears to be difficulty, such as unbounded subproblems, the penalty parameter will be increased.

**BSswp**

Number of basis swaps: the number of $(B \rightarrow S)$ (i.e. basic vs. superbasic) changes.

Note: The CAMCGE model (like many CGE models or other almost square systems) can better be solved with the MINOS option Start Assigned Nonlinears Basic.
5.26.9 Detailed Description of MINOS Options

The following is an alphabetical list of the keywords that may appear in the GAMS/MINOS options file, and a description of their effect. Options not specified will take the default values shown.

check frequency (integer): Controls frequency of linear constraint satisfaction test

Every $i$th iteration after the most recent basis factorization, a numerical test is made to see if the current solution $x$ satisfies the general linear constraints (including linearized nonlinear constraints, if any). The constraints are of the form $Ax + s = 0$ where $s$ is the set of slack variables. To perform the numerical test, the residual vector $r = Ax + s$ is computed. If the largest component of $r$ is judged to be too large, the current basis is refactorized and the basic variables are recomputed to satisfy the general constraints more accurately.

Range: $\{1, ..., \infty\}$

Default: 60

completion (string): Completion level for subproblems (full/partial)

When there are nonlinear constraints, this determines whether subproblems should be solved to moderate accuracy (partial completion) or to full accuracy (full completion). GAMS/MINOS implements the option by using two sets of convergence tolerances for the subproblems. Use of partial completion may reduce the work during early major iterations, unless the Minor iterations limit is active. The optimal set of basic and superbasic variables will probably be determined for any given subproblem, but the reduced gradient may be larger than it would have been with full completion. An automatic switch to full completion occurs when it appears that the sequence of major iterations is converging. The switch is made when the nonlinear constraint error is reduced below $100 \ast (\text{Row tolerance})$, the relative change in $\text{Lambda}_k$ is 0.1 or less, and the previous subproblem was solved to optimality. Full completion tends to give better Lagrange-multiplier estimates. It may lead to fewer major iterations, but may result in more minor iterations.

Default: FULL

crash option (integer): Controls the basis crash algorithm

If a restart is not being performed, an initial basis will be selected from certain columns of the constraint matrix ($A I$). The value of the parameter $i$ determines which columns of $A$ are eligible. Columns of $I$ are used to fill gaps where necessary. If $i > 0$, three passes are made through the relevant columns of $A$, searching for a basis matrix that is essentially triangular. A column is assigned to pivot on a particular row if the column contains a suitably large element in a row that has not yet been assigned. (The pivot elements ultimately form the diagonals of the triangular basis). Pass 1 selects pivots from free columns (corresponding to variables with no upper and lower bounds). Pass 2 requires pivots to be in rows associated with equality ($=\text{E}=\$) constraints. Pass 3 allows the pivots to be in inequality rows. For remaining (unassigned) rows, the associated slack variables are inserted to complete the basis.

Default: 3

**crash tolerance (real):** Allow crash procedure to ignore small elements in eligible columns

The crash tolerance $r$ allows the starting procedure CRASH to ignore certain small nonzeros in each column of $A$. If $a_{max}$ is the largest element in column $j$, other nonzeros $a_{ij}$ in the column are ignored if $|a_{ij}| < a_{max} \times r$. To be meaningful, the parameter $r$ should be in the range $0 \leq r < 1$. When $r > 0.0$ the basis obtained by CRASH may not be strictly triangular, but it is likely to be nonsingular and almost triangular. The intention is to obtain a starting basis containing more columns of $A$ and fewer (arbitrary) slacks. A feasible solution may be reached sooner on some problems. For example, suppose the first $m$ columns of $A$ are the matrix shown under LU factor tolerance; i.e., a tridiagonal matrix with entries -1, 4, -1. To help CRASH choose all $m$ columns for the initial basis, we could specify Crash tolerance $r$ for some value of $r > 0.25$.

Range: [0, 1.0]

Default: 0.1

**debug level (integer):** Controls amount of debug information written

This causes various amounts of information to be output. Most debug levels will not be helpful to GAMS users, but they are listed here for completeness. Note that you will need to use the GAMS statement `OPTION SYSOUT=on;` to echo the MINOS listing to the GAMS listing file.

- **debug level 0**
  No debug output.
- **debug level 2** (or more)
  Output from `M5SETX` showing the maximum residual after a row check.
- **debug level 40**
  Output from `LU8RPC` (which updates the LU factors of the basis matrix), showing the position of the last nonzero in the transformed incoming column.
- **debug level 50**
  Output from `LU1MAR` (which updates the LU factors each refactorization), showing each pivot row and column and the dimensions of the dense matrix involved in the associated elimination.
- **debug level 100**
  Output from `M2BFAC` and `M5LOG` listing the basic and superbasic variables and their values at every iteration.

Default: 0

**expand frequency (integer):** Setting for anti-cycling mechanism

This option is part of an anti-cycling procedure designed to guarantee progress even on highly degenerate problems. For linear models, the strategy is to force a positive step at every iteration, at the expense of violating the bounds on the variables by a small amount. Suppose the specified feasibility tolerance is $\delta$ and the expand frequency is $k$. Over a period of $k$ iterations, the tolerance actually used by GAMS/MINOS increases from $0.5\delta$ to $\delta$ (in steps $0.5\delta/k$). For nonlinear models, the same procedure is used for iterations in which there is only one superbasic variable. (Cycling can occur only when the current solution is
at a vertex of the feasible region.) Thus, zero steps are allowed if there is more than one
superbasic variable, but otherwise positive steps are enforced. At least every $k$ iterations, a
resetting procedure eliminates any infeasible nonbasic variables. Increasing $k$ helps to reduce
the number of these slightly infeasible nonbasic variables. However, it also diminishes the
freedom to choose a large pivot element (see Pivot tolerance).

Range: $\{1, ..., \infty\}$

Default: 10000

**factorization frequency** *(integer)*: Number of iterations between basis factorizations

At most $i$ basis updates will occur between factorizations of the basis matrix. With linear
programs, basis updates usually occur at every iteration. The default $i$ is reasonable for typical
problems. Higher values up to $i = 200$ (say) may be more efficient on problems that are
extremely sparse and well scaled. When the objective function is nonlinear, fewer basis updates
will occur as an optimum is approached. The number of iterations between basis factorizations
will therefore increase. During these iterations a test is made regularly (according to the Check
frequency) to ensure that the general constraints are satisfied. If necessary the basis will be
re-factorized before the limit of $i$ updates is reached. When the constraints are nonlinear, the
Minor iterations limit will probably preempt $i$.

Range: $\{1, ..., \infty\}$

Default: 100

**feasibility tolerance** *(real)*: Feasibility tolerance for linear constraints

When the constraints are linear, a feasible solution is one in which all variables, including
slacks, satisfy their upper and lower bounds to within the absolute tolerance $r$. (Since
slacks are included, this means that the general linear constraints are also satisfied within $r$.)
GAMS/MINOS attempts to find a feasible solution before optimizing the objective function.
If the sum of infeasibilities cannot be reduced to zero, the problem is declared infeasible. Let
$SINF$ be the corresponding sum of infeasibilities. If $SINF$ is quite small, it may be appropriate
to raise $r$ by a factor of 10 or 100. Otherwise, some error in the data should be suspected.
If $SINF$ is not small, there may be other points that have a significantly smaller sum of
infeasibilities. GAMS/MINOS does not attempt to find a solution that minimizes the sum.
If Scale option $= 1$ or 2, feasibility is defined in terms of the scaled problem (since it is then
more likely to be meaningful). A nonlinear objective function $F(x)$ will be evaluated only at
feasible points. If there are regions where $F(x)$ is undefined, every attempt should be made to
eliminate these regions from the problem. For example, for a function $F(x) = \sqrt{x_1} + \log(x_2)$,
it should be essential to place lower bounds on both variables. If Feasibility tolerance $= 10^{-6}$,
the bounds $x_1 > 10^{-5}$ and $x_2 > 10^{-4}$ might be appropriate. (The log singularity is more serious;
in general, keep variables as far away from singularities as possible.) If the constraints are
nonlinear, the above comments apply to each major iteration. A feasible solution satisfies the
current linearization of the constraints to within the tolerance $r$. The associated subproblem
is said to be feasible. As for the objective function, bounds should be used to keep $x$ more
than $r$ away from singularities in the constraint functions $f(x)$. At the start of major iteration
$k$, the constraint functions $f(x_k)$ are evaluated at a certain point $x_k$. This point always satisfies
the relevant bounds ($l < x_k < u$), but may not satisfy the general linear constraints. During
the associated minor iterations, $F(x)$ and $f(x)$ will be evaluated only at points $x$ that satisfy
the bound and the general linear constraints (as well as the linearized nonlinear constraints).
If a subproblem is infeasible, the bounds on the linearized constraints are relaxed temporarily,
in several stages. Feasibility with respect to the nonlinear constraints themselves is measured
against the Row tolerance (not against $r$). The relevant test is made at the start of a major
iteration.

Default: $1.0e-6$
hessian dimension (integer): Size of Hessian matrix

This specifies that an \( r \times r \) triangular matrix \( R \) is to be available for use by the quasi-Newton algorithm. The matrix \( R \) approximates the reduced Hessian in that \( R^T R \) approximates \( Z^T H Z \). Suppose there are \( s \) superbasic variables at a particular iteration. Whenever possible, \( r \) should be greater than \( s \). If \( r > s \), the first \( s \) columns of \( R \) will be used to approximate the reduced Hessian in the normal manner. If there are no further changes to the set of superbasic variables, the rate of convergence will ultimately be superlinear. If \( r < s \), a matrix of the form

\[
R = \text{diag}(R_r, D)
\]

will be used to approximate the reduced Hessian, where \( R_r \) is an \( r \times r \) upper triangular matrix and \( D \) is a diagonal matrix of order \( s - r \). The rate of convergence will no longer be superlinear (and may be arbitrarily slow). The storage required is of the order \( \text{sqr}(r)/2 \), i.e., quadratic in \( r \). In general, \( r \) should be a slight over-estimate of the final number of superbasic variables, whenever storage permits. It need never be larger than \( n_1 + 1 \), where \( n_1 \) is the number of nonlinear variables. For many problems it can be much smaller than \( n_1 \). If \( \text{Superbasics limit} \) \( s \) is specified, the default value of \( r \) is the same number, \( s \) (and conversely). This is a safeguard to ensure super-linear convergence wherever possible. If neither \( r \) nor \( s \) is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: \( \{1, \ldots, \infty\} \)

Default: 1

iterations limit (integer): Minor iteration limit

The maximum number of minor iterations allowed (i.e., iterations of the simplex method or the reduced-gradient method). This option, if set, overrides the GAMS ITERLIM specification. If \( i = 0 \), no minor iterations are performed, but the starting point is tested for both feasibility and optimality.

Default: GAMS iterlim

lagrangian (string): Determines form of objection function in the linearized subproblems

This determines the form of the objective function used for the linearized subproblems. The default value \text{yes} \ is highly recommended. The \text{Penalty parameter} \ value is then also relevant. If \text{No} is specified, the nonlinear constraint functions will be evaluated only twice per major iteration. Hence this option may be useful if the nonlinear constraints are very expensive to evaluate. However, in general there is a great risk that convergence may not occur.

Default: \text{YES}

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{NO}</td>
<td>Nondefault value (not recommended)</td>
</tr>
<tr>
<td>\text{YES}</td>
<td>Default value (recommended)</td>
</tr>
</tbody>
</table>

linesearch tolerance (real): Controls accuracy of steplength selected

For nonlinear problems, this controls the accuracy with which a steplength \( \alpha \) is located in the one-dimensional problem

\[
\begin{align*}
\text{minimize} & \quad F(x+\alpha p) \\
\text{subject to} & \quad 0 < \alpha \leq \beta 
\end{align*}
\]
A linesearch occurs on most minor iterations for which $x$ is feasible. (If the constraints are nonlinear, the function being minimized is the augmented Lagrangian.) $r$ must be a real value in the range $0.0 < r < 1.0$. The default value $r = 0.1$ requests a moderately accurate search. It should be satisfactory in most cases. If the nonlinear functions are cheap to evaluate, a more accurate search may be appropriate: try $r = 0.01$ or $r = 0.001$. The number of iterations should decrease, and this will reduce total run time if there are many linear or nonlinear constraints. If the nonlinear function are expensive to evaluate, a less accurate search may be appropriate; try $r = 0.5$ or perhaps $r = 0.9$. (The number of iterations will probably increase but the total number of function evaluations may decrease enough to compensate.)

Range: $[0, 1.0]$

Default: 0.1

**log frequency (integer):** Controls iteration logging to listing file

In general, one line of the iteration log is printed every $i$th minor iteration. A heading labels the printed items, which include the current iteration number, the number and sum of feasibilities (if any), the subproblem objective value (if feasible), and the number of evaluations of the nonlinear functions. A value such as $i = 10$, $100$ or larger is suggested for those interested only in the final solution. *Log frequency 0* may be used as shorthand for *Log frequency 99999*. If *Print level* $> 0$, the default value of $i$ is 1. If *Print level* $= 0$, the default value of $i$ is 100. If *Print level* $= 0$ and the constraints are nonlinear, the minor iteration log is not printed (and the *Log frequency* is ignored). Instead, one line is printed at the beginning of each major iteration.

Range: \{1, ..., $\infty$\}

Default: 100

**LU complete pivoting (no value):** LUSOL pivoting strategy

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say $< 2.0$).

**LU density tolerance (real):** When to use dense factorization

The density tolerance is used during LUSOL’s basis factorization $B=LU$. Columns of $L$ and rows of $U$ are formed one at a time, and the remaining rows and columns of the basis are altered appropriately. At any stage, if the density of the remaining matrix exceeds this tolerance, the Markowitz strategy for choosing pivots is terminated and the remaining matrix is factored by a dense $LU$ procedure. Raising the tolerance towards 1.0 may give slightly sparser factors, with a slight increase in factorization time.

Range: $[0, 1.0]$

Default: 0.5

**LU factor tolerance (real):** Trade-off between stability and sparsity in basis factorization

This tolerance affects the stability and sparsity of the basis factorization $B = LU$ during factorization. The value $r$ specified must satisfy $r \geq 1.0$.

- The default value $r = 100.0$ usually strikes a good compromise between stability and sparsity.
- For large and relatively dense problems, a larger value may give a useful improvement in sparsity without impairing stability to a serious degree.
- For certain very regular structures (e.g., band matrices) it may be necessary to set $r$ to a value smaller than the default in order to achieve stability.

Range: $[1.0, \infty)$

Default: 100.0

**LU partial pivoting** *(no value)*: LUSOL pivoting strategy

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say $< 2.0$).

**LU rook pivoting** *(no value)*: LUSOL pivoting strategy

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say $< 2.0$).

**LU singularity tolerance** *(real)*: Protection against ill-conditioned basis matrices

When the basis is refactorized, the diagonal elements of $U$ are tested as follows: if $|U_{jj}| < r$ or $|U_{pj}| < r \cdot \max_i |U_{ii}|$, the $j$th column of the basis is replaced by the corresponding slack variable. (This is most likely to occur after a restart, or at the start of a major iteration.) In some cases, the Jacobian matrix may converge to values that make the basis very ill-conditioned, causing the optimization to progress very slowly (if at all). Setting $r = 1.0^{-11}$, say, may help cause a judicious change of basis.

Default: $1.0e-11$

**LU update tolerance** *(real)*: Trade-off between stability and sparsity in basis updating

This tolerance affects the stability and sparsity of the basis factorization $B = LU$ during updates. The value $r$ specified must satisfy $r > 1.0$.

- The default value $r = 10.0$ usually strikes a good compromise between stability and sparsity.
- For large and relatively dense problems, $r = 25.0$ (say) may give a useful improvement in sparsity without impairing stability to a serious degree.
- For certain very regular structures (e.g., band matrices) it may be necessary to set $r$ to a value smaller than the default in order to achieve stability.

Range: $[1.0, \infty)$

Default: 10.0

**major damping parameter** *(real)*: Prevents large relative changes between subproblem solutions
The parameter may assist convergence on problems that have highly nonlinear constraints. It is intended to prevent large relative changes between subproblem solutions \((x_k, \lambda_k)\) and \((x_{k+1}, \lambda_{k+1})\). For example, the default value 2.0 prevents the relative change in either \(x_k\) or \(\lambda_k\) from exceeding 200 percent. It will not be active on well behaved problems. The parameter is used to interpolate between the solutions at the beginning and end of each major iteration. Thus \(x_{k+1}\) and \(\lambda_{k+1}\) are changed to \(x_k + \sigma (x_{k+1} - x_k)\) and \(\lambda_k + \sigma (\lambda_{k+1} - \lambda_k)\) for some step-length \(\sigma < 1\). In the case of nonlinear equations (where the number of constraints is the same as the number of variables) this gives a damped Newton method. This is a very crude control. If the sequence of major iterations does not appear to be converging, one should first re-run the problem with a higher Penalty parameter (say 10 or 100 times the default \(\rho\)). (Skip this re-run in the case of nonlinear equations: there are no degrees of freedom and the value of \(\rho\) is irrelevant.) If the subproblem solutions continue to change violently, try reducing \(r\) to 0.2 or 0.1 (say). For implementation reasons, the shortened step to \(\sigma\) applies to the nonlinear variables \(x\), but not to the linear variables \(y\) or the slack variables \(s\). This may reduce the efficiency of the control.

Default: 2.0

**major iterations** (integer): Max number of major iterations

The maximum number of major iterations allowed. It is intended to guard against an excessive number of linearizations of the nonlinear constraints, since in some cases the sequence of major iterations may not converge. The progress of the major iterations can be best monitored using *Print level 0* (the default).

Default: 50

**minor damping parameter** (real): Limit change in \(x\) during linesearch

This parameter limits the change in \(x\) during a linesearch. It applies to all nonlinear problems, once a feasible solution or feasible subproblem has been found. A linesearch of the form

\[
\min_{\alpha} F(x + \alpha \cdot p)
\]

is performed over the range \(0 < \alpha < \beta\), where \(\beta\) is the step to the nearest upper or lower bound on \(x\). Normally, the first step length tried is \(\alpha_1 = \min(1, \beta)\). In some cases, such as \(F(x) = ae^{bx}\) or \(F(x) = ax^b\), even a moderate change in the components of \(x\) can lead to floating-point overflow. The parameter \(r\) is therefore used to define a limit

\[
\beta_2 = r(1 + ||x||/||p||)
\]

and the first evaluation of \(F(x)\) is at the potentially smaller steplength \(\alpha_1 = \min(1, \beta, \beta_2)\). Wherever possible, upper and lower bounds on \(x\) should be used to prevent evaluation of nonlinear functions at meaningless points. The *Minor damping parameter* provides an additional safeguard. The default value \(r = 2.0\) should not affect progress on well behaved problems, but setting \(r = 0.1\) or 0.01 may be helpful when rapidly varying functions are present. A good starting point may be required. An important application is to the class of nonlinear least squares problems. In cases where several local optima exist, specifying a small value for \(r\) may help locate an optimum near the starting point.

Default: 2.0

**minor iterations** (integer): Max number of minor iterations between linearizations of nonlinear constraints

The maximum number of minor iterations allowed. It is intended to guard against an excessive number of linearizations of the nonlinear constraints, since in some cases the sequence of major iterations may not converge. The progress of the major iterations can be best monitored using *Print level 0* (the default).

Default: 50
The maximum number of feasible minor iterations allowed between successive linearizations of the nonlinear constraints. A moderate value (e.g., \( 20 \leq i \leq 50 \)) prevents excessive efforts being expended on early major iterations, but allows later subproblems to be solved to completion. The limit applies to both infeasible and feasible iterations. In some cases, a large number of iterations (say \( K \)) might be required to obtain a feasible subproblem. If good starting values are supplied for variables appearing nonlinearly in the constraints, it may be sensible to specify a limit \( > K \), to allow the first major iteration to terminate at a feasible (and perhaps optimal) subproblem solution. If a good initial subproblem is arbitrarily interrupted by a small limit, the subsequent linearization may be less favorable than the first.

In general it is unsafe to specify a value as small as \( i = 1 \) or \( 2 \). Even when an optimal solution has been reached, a few minor iterations may be needed for the corresponding subproblem to be recognized as optimal. The Iteration limit provides an independent limit on the total minor iterations (across all subproblems). If the constraints are linear, only the Iteration limit applies: the minor iterations value is ignored.

Default: 40

**Multiple price (integer):** Multiple pricing

Pricing refers to a scan of the current non-basic variables to determine which, if any, are eligible to become (super)basic. The multiple pricing parameter \( k \) controls the number of entering variables to choose: the \( k \) best non-basic variables are selected for admission to the set of (super)basic variables. The default \( k = 1 \) is best for linear programs, since an optimal solution will have zero superbasic variables. **Warning:** If \( k > 1 \), GAMS/MINOS will use the reduced-gradient method rather than the simplex method, even on purely linear problems. The subsequent iterations do not correspond to the efficient minor iterations carried out by commercial linear programming systems using multiple pricing. (In the latter systems, the classical simplex method is applied to a tableau involving \( k \) dense columns of dimension \( m \), and \( k \) is therefore limited for storage reasons typically to the range \( 2 \leq k \leq 7 \).) GAMS/MINOS varies all superbasic variables simultaneously. For linear problems its storage requirements are essentially independent of \( k \). Larger values of \( k \) are therefore practical, but in general the iterations and time required when \( k > 1 \) are greater than when the simplex method is used (\( k = 1 \)). On large nonlinear problems it may be important to set \( k > 1 \) if the starting point does not contain many superbasic variables. For example, if a problem has 3000 variables and 500 of them are nonlinear, the optimal solution may well have 200 variables superbasic. If the problem is solved in several runs, it may be beneficial to use \( k = 10 \) (say) for early runs, until it seems that the number of superbasics has leveled off. If Multiple price \( k \) is specified, it is also necessary to specify Superbasic limit \( s \) for some \( s > k \).

Range: \{1, ..., ∞\}

Default: 1

**Optimality tolerance (real):** Reduced gradient optimality check

This is used to judge the size of the reduced gradients \( d_j = g_j - pi^T a_j \), where \( g_j \) is the gradient of the objective function corresponding to the \( j^{th} \) variable, \( a_j \) is the associated column of the constraint matrix (or Jacobian), and \( pi \) is the set of dual variables. By construction, the reduced gradients for basic variables are always zero. Optimality will be declared if the reduced gradients for nonbasic variables at their lower or upper bounds satisfy \( d_j / ||pi|| \geq -r \) or \( d_j / ||pi|| \leq r \) respectively, and if \( d_j / ||pi|| \leq r \) for superbasic variables. The \( ||pi|| \) is a measure of the size of the dual variables. It is included to make the tests independent of a scale factor on the objective function. The quantity actually used is defined by

\[
\sigma = \text{sum}(i, \text{abs}(pi(i))), ||pi|| = \max\{\sigma \text{/sqrt}(m), 1\}
\]

so that only large scale factors are compensated for. As the objective scale decreases, the optimality test tends to become an absolute (instead of a relative) test.

Default: 1.0e-6
**partial price (integer):** Number of segments in partial pricing strategy

This parameter is recommended for large problems that have significantly more variables than constraints. It reduces the work required for each pricing operation (when a nonbasic variable is selected to become basic or superbasic). When \( i = 1 \), all columns of the constraints matrix \((A \ I)\) are searched. Otherwise, \( A_j \) and \( I \) are partitioned to give \( i \) roughly equal segments \( A_j, I_j \) (\( j = 1 \) to \( i \)). If the previous search was successful on \( A_{j-1}, I_{j-1} \), the next search begins on the segments \( A_j, I_j \). (All subscripts here are modulo \( i \).) If a reduced gradient is found that is larger than some dynamic tolerance, the variable with the largest such reduced gradient (of appropriate sign) is selected to become superbasic. (Several may be selected if multiple pricing has been specified.) If nothing is found, the search continues on the next segments \( A_{j+1}, I_{j+1} \) and so on. Partial price \( t \) (or \( t/2 \) or \( t/3 \)) may be appropriate for time-stage models having \( t \) time periods.

Range: \( \{1, ..., \infty\} \)

Default: 10

**penalty parameter (real):** Used in modified augmented Lagrangian

This specifies the value of \( \rho \) in the modified augmented Lagrangian. It is used only when \( \text{Lagrangian} = \text{yes} \) (the default setting). For early runs on a problem with unknown characteristics, the default value should be acceptable. If the problem is known to be highly nonlinear, specify a large value, such as 10 times the default. In general, a positive value of \( \rho \) may be necessary to ensure convergence, even for convex programs. On the other hand, if \( \rho \) is too large, the rate of convergence may be unnecessarily slow. If the functions are not highly nonlinear or a good starting point is known, it will often be safe to specify penalty parameter 0.0. When solving a sequence of related problems, initially, use a moderate value for \( \rho \) (such as the default) and a reasonably low Iterations and/or major iterations limit. If successive major iterations appear to be terminating with radically different solutions, the penalty parameter should be increased. (See also the Major damping parameter.) If there appears to be little progress between major iterations, it may help to reduce the penalty parameter.

Default: automatic

**print level (integer):** Controls amount of information printed during optimization

This varies the amount of information that will be output during optimization. Print level 0 sets the default log and summary frequencies to 100. It is then easy to monitor the progress of the run. Print level 1 (or more) sets the default log and summary frequencies to 1, giving a line of output for every minor iteration. Print level 1 also produces basis statistics, i.e., information relating to LU factors of the basis matrix whenever the basis is re-factorized. For problems with nonlinear constraints, certain quantities are printed at the start of each major iteration. The option value is best thought of as a binary number of the form

\[ \text{Print level JFLXB} \]

where each letter stands for a digit that is either 0 or 1. The quantities referred to are:

- **B** Basis statistics, as mentioned above
- **X** \( x_k \), the nonlinear variables involved in the objective function or the constraints.
- **L** \( \lambda_{k} \), the Lagrange-multiplier estimates for the nonlinear constraints. (Suppressed if \( \text{Lagrangian}=\text{No} \), since then \( \lambda_{k} = 0 \).)
- **F** \( f(x_k) \), the values of the nonlinear constraint functions.
- **J** \( J(x_k) \), the Jacobian matrix.
To obtain output of any item, set the corresponding digit to 1, otherwise to 0. For example, 
*Print level 10* sets \( X = 1 \) and the other digits equal to zero; the nonlinear variables will be 
printed each major iteration. If \( J = 1 \), the Jacobian matrix will be output column-wise at the 
start of each major iteration. Column \( j \) will be preceded by the value of the corresponding 
variable \( x_j \) and a key to indicate whether the variable is basic, superbasic or nonbasic. (Hence 
if \( J = 1 \), there is no reason to specify \( X = 1 \) unless the objective contains more nonlinear 
variables than the Jacobian.) A typical line of output is

\[
3 \ 1.250000D+01 \ \text{BS} \ 1 \ 1.00000D+00 \ 4 \ 2.00000D+00
\]

which would mean that \( x_3 \) is basic at value 12.5, and the third column of the Jacobian has 
elements of 1.0 and 2.0 in rows 1 and 4. (Note: the GAMS/MINOS row numbers are usually 
different from the GAMS row numbers; see the Solution option.)

Default: 0

**radius of convergence (real):** controls final reduction of penalty parameter \( \rho \)

This determines when the penalty parameter \( \rho \) will be reduced, assuming \( \rho \) was initially 
positive. Both the nonlinear constraint violation (see ROWERR below) and the relative 
change in consecutive Lagrange multiplier estimates must be less than \( r \) at the start of a major 
itration before \( \rho \) is reduced or set to zero. A few major iterations later, full completion 
will be requested if not already set, and the remaining sequence of major iterations should 
converge quadratically to an optimum.

Default: 0.01

**row tolerance (real):** Accuracy requirement for nonlinear rows \( \epsilon \)

This specifies how accurately the nonlinear constraints should be satisfied at a solution. The 
default value is usually small enough, since model data is often specified to about this accuracy. 
Let \( \text{ROWERR} \) be the maximum component of the residual vector \( f(x) + A_1 y - b_1 \), normalized 
by the size of the solution. Thus

\[
\text{ROWERR} = \frac{||f(x) + A_1 y - b_1||_\infty}{(1 + \text{XNORM})}
\]

where \( \text{XNORM} \) is a measure of the size of the current solution \( (x, y) \). The solution is considered 
 to be feasible if \( \text{ROWERR} <= r \). If the problem functions involve data that is known to be of 
low accuracy, a larger Row tolerance may be appropriate.

Default: 1.0e-6

**scale all variables (no value):** Synonym to scale option 2 \( \epsilon \)

**scale linear variables (no value):** Synonym to scale option 1 \( \epsilon \)

**scale no (no value):** Synonym to scale option 0 \( \epsilon \)

**scale nonlinear variables (no value):** Synonym to scale option 2 \( \epsilon \)

**scale option (integer):** Scaling \( \epsilon \)

*Scale Yes* sets the default. (*Caution:* If all variables are nonlinear, *Scale Yes* unexpectedly does 
nothing, because there are no linear variables to scale). *Scale No* suppresses scaling (equivalent 
to *Scale Option 0*). If nonlinear constraints are present, *Scale option 1* or *0* should generally 
be tried at first. *Scale option 2* gives scales that depend on the initial Jacobian, and should 
therefore be used only if (a) a good starting point is provided, and (b) the problem is not 
highly nonlinear.

Default: 1
<table>
<thead>
<tr>

<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No scaling&lt;br&gt; If storage is at a premium, this option should be used.</td>
</tr>
<tr>
<td>1</td>
<td>Scale linear variables&lt;br&gt; Linear constraints and variables are scaled by an iterative procedure that attempts to make the matrix coefficients as close as possible to 1.0 (see [5]). This will sometimes improve the performance of the solution procedures. Scale linear variables is an equivalent option.</td>
</tr>
<tr>
<td>2</td>
<td>Scale linear + nonlinear variables&lt;br&gt; All constraints and variables are scaled by the iterative procedure. Also, a certain additional scaling is performed that may be helpful if the right-hand side $b$ or the solution $x$ is large. This takes into account columns of $(A I)$ that are fixed or have positive lower bounds or negative upper bounds. Scale nonlinear variables or Scale all variables are equivalent options.</td>
</tr>
</tbody>
</table>

**scale print** *(no value)*: Print scaling factors ←

This causes the row-scales $r(i)$ and column-scales $c(j)$ to be printed. The scaled matrix coefficients are $\hat{a}_{ij} = a_{ij}c(j)/r(i)$. The scaled bounds on the variables and slacks are $\hat{b}_j = b_j/c(j)$ and $\hat{u}_j = u_j/c(j)$, where $c(j) = r(j - n)$ if $j > n$. If a Scale option has not already been specified, **Scale print** sets the default scaling.

**scale print tolerance** *(real)*: Scale print flag and set tolerance ←

See **Scale Tolerance**. This option also turns on printing of the scale factors.

Range: [0, 1.0]  
Default: 0.9

**scale tolerance** *(real)*: Scale tolerance ←

All forms except **Scale option** may specify a tolerance $r$ where $0 < r < 1$ (for example: **Scale Print Tolerance** = 0.99). This affects how many passes might be needed through the constraint matrix. On each pass, the scaling procedure computes the ratio of the largest and smallest nonzero coefficients in each column:

$$\rho_{ij} = \max_i |a_{ij}|/\min_i |a_{ij}| \quad (a_{ij} \neq 0)$$

If $\max_j \rho_{ij}$ is less than $r$ times its previous value, another scaling pass is performed to adjust the row and column scales. Raising $r$ from 0.9 to 0.99 (say) usually increases the number of scaling passes through $A$. At most 10 passes are made. If a **Scale option** has not already been specified, **Scale tolerance** sets the default scaling.

Range: [0, 1.0]  
Default: 0.9

**scale yes** *(no value)*: Synonym to scale option 1 ←

**solution** *(string)*: Prints MINOS solution ←

This controls whether or not GAMS/MINOS prints the final solution obtained. There is one line of output for each constraint and variable. The lines are in the same order as in the GAMS solution, but the constraints and variables labeled with internal GAMS/MINOS numbers rather than GAMS names. (The numbers at the left of each line are GAMS/MINOS column numbers, and those at the right of each line in the rows section are GAMS/MINOS slacks.) The GAMS/MINOS solution may be useful occasionally to interpret certain messages that occur during the optimization, and to determine the final status of certain variables (basic, superbasic or nonbasic).

Default: NO
**start assigned nonlinear**s *(string)*: Starting strategy when there is no basis

This option affects the starting strategy when there is no basis (i.e., for the first solve or when the GAMS statement `option bratio = 1` is used to reject an existing basis.) This option applies to all nonlinear variables that have been assigned nondefault initial values and are strictly between their bounds. Free variables at their default value of zero are excluded. Let \( K \) denote the number of such assigned nonlinear variables.

Default: **SUPERBASIC**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUPERBASIC</td>
<td>Default Specify <em>superbasic</em> for highly nonlinear models, as long as ( K ) is not too large (say ( K &lt; 100 )) and the initial values are good.</td>
</tr>
<tr>
<td>BASIC</td>
<td>Good for square systems Specify <em>basic</em> for models that are essentially square (i.e., if there are about as many general constraints as variables).</td>
</tr>
<tr>
<td>NONBASIC</td>
<td>Specify <em>nonbasic</em> if ( K ) is large.</td>
</tr>
<tr>
<td>ELIGIBLE FOR CRASH</td>
<td>Specify <em>Eligible for Crash</em> for linear or nearly linear models. The nonlinear variables will be treated in the manner described under <em>Crash</em> option.</td>
</tr>
</tbody>
</table>

**subspace tolerance** *(real)*: Determines when nonbasics becomes superbasic

This controls the extent to which optimization is confined to the current set of basic and superbasic variables (Phase 4 iterations), before one or more nonbasic variables are added to the superbasic set (Phase 3). The parameter \( r \) must be a real number in the range \( 0 < r <= 1 \). When a nonbasic variable \( x_j \) is made superbasic, the resulting norm of the reduced-gradient vector (for all superbasics) is recorded. Let this be \( \|Z^T g_0\| \). (In fact, the norm will be \( |d_j| \), the size of the reduced gradient for the new superbasic variable \( x_j \).) Subsequent Phase 4 iterations will continue at least until the norm of the reduced-gradient vector satisfies \( \|Z^T g_0\| < r \|Z^T g_0\| \) is the size of the largest reduced-gradient component among the superbasic variables.) A smaller value of \( r \) is likely to increase the total number of iterations, but may reduce the number of basic changes. A larger value such as \( r = 0.9 \) may sometimes lead to improved overall efficiency, if the number of superbasic variables has to increase substantially between the starting point and an optimal solution. Other convergence tests on the change in the function being minimized and the change in the variables may prolong Phase 4 iterations. This helps to make the overall performance insensitive to larger values of \( r \).

Range: \([0, 1.0]\)

Default: 0.5

**summary frequency** *(integer)*: Controls iteration logging to summary (log file)

A brief form of the iteration log is output to the MINOS summary file (i.e. the GAMS log file). In general, one line is output every \( r \)th minor iteration. In an interactive environment, the output normally appears at the terminal and allows a run to be monitored. If something looks wrong, the run can be manually terminated. The summary frequency controls summary output in the same way as the log frequency controls output to the print file. A value such as
Summary Frequency = 10 or 100 is often adequate to determine if the solve is making progress. If Print level = 0, the default value of Summary Frequency is 100. If Print level > 0, the default value of Summary Frequency is 1. If Print level = 0 and the constraints are nonlinear, the Summary Frequency is ignored. Instead, one line is printed at the beginning of each major iteration.

Range: \{1, \ldots, \infty\}

Default: 100

superbasics limit (integer): Maximum number of superbasics

This places a limit on the storage allocated for superbasic variables. Ideally, the parameter $i$ should be set slightly larger than the number of degrees of freedom expected at an optimal solution. For linear problems, an optimum is normally a basic solution with no degrees of freedom. (The number of variables lying strictly between their bounds is not more than $m$, the number of general constraints.) The default value of $i$ is therefore 1. For nonlinear problems, the number of degrees of freedom is often called the number of independent variables. Normally, $i$ need not be greater than $n_1 + 1$, where $n_1$ is the number of nonlinear variables. For many problems, $i$ may be considerably smaller than $n_1$. This will save storage if $n_1$ is very large. This parameter also sets the Hessian dimension, unless the latter is specified explicitly (and conversely). If neither parameter is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: \{1, \ldots, \infty\}

Default: 1

unbounded objective value (real): Determines when a problem is called unbounded

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

$$\min_{\alpha} F(x + \alpha p)$$

If $|F|$ exceeds the parameter $r$ or if $\alpha$ exceeds the unbounded stepsize, iterations are terminated with the exit message PROBLEM IS UNBOUNDED (OR BADLY SCALED). If singularities are present, unboundedness in $F(x)$ may be manifested by a floating-point overflow (during the evaluation of $F(x + \alpha p)$, before the test against $r$ can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the Minor damping parameter.

Default: 1.0e20

unbounded step size (real): Determines when a problem is called unbounded

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

$$\min_{\alpha} F(x + \alpha p)$$

If $\alpha$ exceeds the parameter $r$ or if $|F|$ exceeds the unbounded objective value, iterations are terminated with the exit message PROBLEM IS UNBOUNDED (OR BADLY SCALED). If singularities are present, unboundedness in $F(x)$ may be manifested by a floating-point overflow (during the evaluation of $F(x + \alpha p)$, before the test against $r$ can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the Minor damping parameter.

Default: 1.0e10
**verify constraint gradients** *(no value)*: Synonym to verify level 2 ←

**verify gradients** *(no value)*: Synonym to verify level 3 ←

**verify level** *(integer)*: Controls verification of gradients ←

This option controls the finite-difference check performed by MINOS on the gradients (first derivatives) computed by GAMS for each nonlinear function. GAMS computes gradients analytically, and the values obtained should normally be taken as correct.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
</table>
| 0     | Cheap test  
Only a cheap test is performed, requiring three evaluations of the nonlinear objective and two evaluations of the nonlinear constraints. **Verify No** is an equivalent option. |
| 1     | Check objective  
A more reliable check is made on each component of the objective gradient. **Verify objective gradients** is an equivalent option. |
| 2     | Check Jacobian  
A check is made on each column of the Jacobian matrix associated with the nonlinear constraints. **Verify constraint gradients** is an equivalent option. |
| 3     | Check objective and Jacobian  
A detailed check is made on both the objective and the Jacobian. **Verify, Verify gradients**, and **Verify Yes** are equivalent options. |
| -1    | No check |

**verify no** *(no value)*: Synonym to verify level 0 ←

**verify objective gradients** *(no value)*: Synonym to verify level 1 ←

**verify yes** *(no value)*: Synonym to verify level 3 ←

**weight on linear objective** *(real)*: Composite objective weight ←

This option controls the so-called composite objective technique. If the first solution obtained is infeasible, and if the objective function contains linear terms, and the objective weight \( w \) is positive, this technique is used. While trying to reduce the sum of infeasibilities, the method also attempts to optimize the linear portion of the objective. At each infeasible iteration, the objective function is defined to be

\[
\text{minimize}_x \sigma w(c^T x) + \text{(sum of infeasibilities)}
\]

where \( \sigma = 1 \) for minimization and \( \sigma = -1 \) for maximization and \( c \) is the linear portion of the objective. If an optimal solution is reached while still infeasible, \( w \) is reduced by a factor of 10. This helps to allow for the possibility that the initial \( w \) is too large. It also provides dynamic allowance for the fact the sum of infeasibilities is tending towards zero. The effect of \( w \) is disabled after five such reductions, or if a feasible solution is obtained. This option is intended mainly for linear programs. It is unlikely to be helpful if the objective function is nonlinear.

Default: 0.0
5.26.10 Exit Conditions

This section discusses the exit codes printed by MINOS at the end of the optimization run.

EXIT – Optimal solution found

This is the message we all hope to see! It is certainly preferable to every other message. Of course it is quite possible that there are model formulation errors, which will (hopefully) lead to unexpected objective values and solutions. The reported optimum may be a local, and other much better optima may exist.

EXIT – The problem is infeasible

When the constraints are linear, this message can probably be trusted. Feasibility is measured with respect to the upper and lower bounds on the variables (the bounds on the slack variables correspond to the GAMS constraints). The message tells us that among all the points satisfying the general constraints \( Ax + s = 0 \), there is apparently no point that satisfies the bounds on \( x \) and \( s \). Violations as small as the FEASIBILITY TOLERANCE are ignored, but at least one component of \( x \) or \( s \) violates a bound by more than the tolerance.

Note: Although the objective function is the sum of the infeasibilities, this sum will usually not have been minimized when MINOS recognizes the situation and exits. There may exist other points that have significantly lower sum of infeasibilities.

When nonlinear constraints are present, infeasibility is much harder to recognize correctly. Even if a feasible solution exists, the current linearization of the constraints may not contain a feasible point. In an attempt to deal with this situation MINOS may relax the bounds on the slacks associated with nonlinear rows. This perturbation is allowed a fixed number of times. Normally a feasible point will be obtained relative to the perturbed constraints, and optimization can continue on the subproblem. However, if several consecutive subproblems require such perturbation, the problem is terminated and declared INFEASIBLE. Clearly this is an ad-hoc procedure. Wherever possible, nonlinear constraints should be defined in such a way that feasible points are known to exist when the constraints are linearized.

EXIT – The problem is unbounded (or badly scaled)

For linear problems, unboundedness is detected by the simplex method when a nonbasic variable can apparently be increased by an arbitrary amount without causing a basic variable to violate a bound. A simple way to diagnose such a model is to add an appropriate bound on the objective variable.

Very rarely, the scaling of the problem could be so poor that numerical error will give an erroneous indication of unboundedness. Consider using the SCALE option.

For nonlinear problems, MINOS monitors both the size of the current objective function and the size of the change in the variables at each step. If either of these is very large (as judged by the UNBOUNDED parameter), the problem is terminated and declared UNBOUNDED. To avoid large function values, it may be necessary to impose bounds on some of the variables in order to keep them away from singularities in the nonlinear functions.

EXIT – User Interrupt

This exit code is a result of interrupting the optimization process by hitting Ctrl-C. Inside the IDE this is accomplished by hitting the Interrupt button. The solver will finish its current iteration, and return the current solution. This solution can be still intermediate infeasible or intermediate non-optimal.

EXIT – Too many iterations
The iteration limit was hit. Either the ITERLIM, or in some cases the ITERATIONS LIMIT or MAJOR ITERATION LIMIT was too small to solve the problem. In most cases increasing the GAMS ITERLIM option will resolve the problem. In other cases you will need to create a MINOS option file and set a MAJOR ITERATION LIMIT. The listing file will give more information regarding what limit was hit.

The GAMS iteration limit is displayed in the listing file under the section SOLVE SUMMARY. If the ITERLIM was hit, the message will look like:

```
ITERATION COUNT, LIMIT  10001  10000
```

**EXIT – Resource Interrupt**

The solver hit the RESLIM resource limit, which is a time limit. It returned the solution at that time, which may be still intermediate infeasible or intermediate non-optimal.

The GAMS resource limit is displayed in the listing file under the section SOLVE SUMMARY. If the GAMS RESLIM was hit, the message will look like:

```
RESOURCE USAGE, LIMIT  1001.570  1000.000
```

**EXIT – The objective has not changed for many iterations**

This is an emergency measure for the rare occasions when the solution procedure appears to be *cycling*. Suppose that a zero step is taken for several consecutive iterations, with a basis change occurring each time. It is theoretically possible for the set of basic variables to become the same as they were one or more iterations earlier. The same sequence of iterations would then occur *ad infinitum*.

**EXIT – The Superbasics Limit is too small**

The problem appears to be more non-linear than anticipated. The current set of basic and superbasic variables have been optimized as much as possible and an increase in the number of superbasics is needed. You can use the option SUPERBASICS LIMIT to increase the limit. See also option HESSIAN DIMENSION.

**EXIT – Constraint and objective function could not be calculated**

The function or gradient could not be evaluated. For example, this can occur when MINOS attempts to take a log or a square root of a negative number, when evaluating the expression $x^y$ with $x \leq 0$, or when evaluating $\exp(x)$ for large $x$ and the result is too large to store. The listing file will contain details about where and why evaluation errors occur. To fix this problem, add bounds so that all functions can be properly evaluated. E.g. if you have an expression $x^y$, add a lower bound $x.LO=0.001$ to your model.

In many cases the algorithm can recover from function evaluation errors, for instance if they happen in the line search while evaluating trial points. The message above appears in cases where the algorithm cannot recover, and requires a reliable function or gradient evaluation.

**EXIT – Function evaluation error limit**
The limit of allowed function evaluation errors $\text{DOMLIM}$ has been exceeded.

Function evaluation errors occur when MINOS attempts to evaluate the objective and/or constraints at points where these functions or their derivatives are not defined or where overflows occur. Some examples are given above. The listing file contains details about these errors.

The quick and dirty way to solve this is to increase the GAMS $\text{DOMLIM}$ setting, but in general it is better to add bounds. E.g. if you have an expression $x^y$, then add a bound $x.LO=0.001$ to your model.

EXIT – The current point can not be improved

The line search failed. This can happen if the model is very nonlinear or if the functions are nonsmooth (using a $\text{DNLP}$ model type).

If the model is non-smooth, consider a smooth approximation. It may be useful to check the scaling of the model and think more carefully about choosing a good starting point. Sometimes it can help to restart the model with full scaling turned on:

```gams
option nlp=minos;
solve m minimizing z using nlp; // this one gives "current point cannot be improved"
file fopt /minos.opt/; // write option file
putclose fopt "scale all variables"/
m.optfile=1;
solve m minimizing z using nlp; // solve with "scale all variables"
```

EXIT – Numerical error in trying to satisfy the linear constraints (or the linearized constraints)
The basis is very ill-conditioned.

This is often a scaling problem. Try the full scaling option $\text{scale all variables}$ or, better yet, rescale the model in GAMS via the $\text{.scale}$ suffix or by choosing more appropriate units for variables and RHS values.

EXIT – Not enough storage to solve the model

The amount of workspace allocated for MINOS to solve the model is insufficient. Consider increasing the GAMS option $\text{workfactor}$ to increase the workspace allocated for MINOS to use. The listing file and log file (screen) will contain information about the current workspace allocation. Increasing the workfactor by 50% is a reasonable strategy.

EXIT – Systems error

This is a catch all return for other serious problems. Check the listing file for more messages. If needed rerun the model with $\text{OPTION SYSOUT=ON;}$.

5.27 MOSEK

MOSEK ApS, C/O Symbion Science Park, Fruebjergvej 3, Box 16, 2100 Copenhagen Ø, Denmark
5.27 MOSEK

5.27.1 Introduction

MOSEK is a software package for the solution of linear, mixed-integer linear, quadratic, mixed-integer quadratic, quadratically constraint, conic, and semidefinite mathematical optimization problems. MOSEK is particularly well suited for solving large-scale linear, convex quadratically constraint, and conic programs using an extremely efficient interior point algorithm.

These problem classes can be solved using an appropriate optimizer built into MOSEK. All the optimizers available in MOSEK are built for the solution of large-scale sparse problems. Current optimizers include:

- Interior-point optimizers for continuous and conic problems
- Simplex optimizer for linear problems
- Branch-and-cut optimizer for mixed-integer linear, quadratic, and conic problems

5.27.1.1 Licensing

Licensing of GAMS/MOSEK is similar to other GAMS solvers. MOSEK is licensed in three different ways:

- **GAMS/MOSEK:**
  All model types.

- **GAMS/MOSEK Solver Link:**
  Users must have a separate, licensed MOSEK system. For users who wish to use MOSEK within GAMS and also in other environments.

- **GAMS/OsiMosek:**
  Finally, a bare-bone interface to the LP and MIP solver of Mosek is available under the name OSIMOSEK. It comes free of charge with any GAMS system.

For information regarding MOSEK standalone or interfacing MOSEK with other applications contact sales@mosek.com.

5.27.1.2 Solving Problems in Parallel

MOSEK can exploit multiple CPUs (or a CPU with multiple cores) to solve an optimization problem when using the interior-point or the mixed-integer optimizers.

This implies that whenever the MOSEK interior-point optimizer should solve an optimization problem, then it will try to divide the work so each CPU gets a share of the work. The user decides how many CPUs MOSEK should exploit. Unfortunately, it is not always easy to divide the work. Also some of the coordination work must occur in sequential. Therefore, the speed-up obtained when using multiple CPUs is highly problem dependent. However, as a rule of thumb, if the problem solves very quickly, i.e., in less than 60 seconds, then there is no advantage in using the parallel option.

The parameter `MSK_IPAR_NUM_THREADS` sets the number of threads (and therefore the number of CPU's) that the optimizer will use.
5.27.1.3 Infeasible/Unbounded Models

5.27.1.3.1 Farkas Certificates MOSEK determines if either the primal or the dual problem is infeasible by means of a Farkas certificate. In such a case MOSEK returns a certificate indicating primal or dual infeasibility.

The primal infeasibility certificate indicates a primal infeasible model. For a minimization problem

\[
\begin{align*}
\text{minimize} & \quad \langle c, x \rangle \\
\text{subject to} & \quad Ax = b, \\
& \quad x \geq 0,
\end{align*}
\]

the primal infeasibility certificate is the solution \( y \) satisfying \( A'y \leq 0 \) and \( \langle b, y \rangle > 0 \).

A primal infeasibility certificate is reported in the marginal records of the variables and equations. As no primal solution is available in this case, the level values for variables and equations and the objective function value are set to 0 (setting them to NA would be more appropriate, but GAMS does not support this well). At the moment, primal infeasibility certificate are not available for conic programs.

Since GAMS reports all model statuses in the primal space, the notion of dual infeasibility does not exist and GAMS reports a status of unboundedness, which assumes that the primal problem is feasible. Although GAMS reports the primal as unbounded, there is the possibility that both the primal and dual problem are infeasible. To check if this is the case, the user can set appropriate lower and upper bounds on the objective variable, using the \((\text{variable}).\text{LO}\) and \((\text{variable}).\text{UP}\) suffixes and resolve.

The dual infeasibility certificate is reported in the level values for the variables. As no dual solution exists, the marginal values for both variables and equations are set to NA.

For more details on primal and dual infeasibility certificates see the MOSEK Modeling Cookbook.

5.27.1.3.2 Infeasibility Report MOSEK has some facilities for diagnosing the cause of a primal or dual infeasibility. They can be turned on using the parameter setting \texttt{MSK_IPAR_INFEAS_REPORT.AUTO}. This causes MOSEK to print a report about an infeasible subset of the constraints, when an infeasibility is encountered. Moreover, the parameter \texttt{MSK_IPAR_INFEAS_REPORT.LEVEL} controls the amount of information presented in the infeasibility report. We will use the \texttt{TRANSPORT} example from the GAMS Model Library with increased demand \((b(j) \leftarrow 1.6b(j))\) to make the model infeasible. MOSEK produces the following infeasibility report:

**MOSEK PRIMAL INFEASIBILITY REPORT.**

Problem status: The problem is primal infeasible

The following constraints are involved in the primal infeasibility.

<table>
<thead>
<tr>
<th>Index</th>
<th>Name</th>
<th>Lower bound</th>
<th>Upper bound</th>
<th>Dual lower</th>
<th>Dual upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>supply(seattle)</td>
<td>none</td>
<td>3.500000e+002</td>
<td>0.000000e+000</td>
<td>1.000000e+000</td>
</tr>
<tr>
<td>2</td>
<td>supply(san-diego)</td>
<td>none</td>

</tr>
<tr>
<td>5</td>
<td>demand(topeka)</td>
<td>4.400000e+002</td>
<td>none</td>
<td>1.000000e+000</td>
<td>0.000000e+000</td>
</tr>
</tbody>
</table>

The following bound constraints are involved in the infeasibility.

<table>
<thead>
<tr>
<th>Index</th>
<th>Name</th>
<th>Lower bound</th>
<th>Upper bound</th>
<th>Dual lower</th>
<th>Dual upper</th>
</tr>
</thead>
</table>

The report indicates which constraints and bounds are causing the infeasibility. In this case, the constraints causing infeasibility are \texttt{supply} and \texttt{demand}. The values in the columns \texttt{Dual lower} and \texttt{Dual upper} are also useful, because if the dual lower value is different from zero for a constraint, then it implies that the lower bound on the constraint is important for the infeasibility. Similarly, if the dual upper value is different from zero on a constraint, then this implies the upper bound on the constraint is important for infeasibility.
5.27 MOSEK

5.27.1.4 Conic Programming

MOSEK is well suited for solving generalized linear programs involving certain conic constraints.

For an overview of quadratic conic programming and how these conic constraints are implemented in GAMS, see the Section Conic Programming in the GAMS User’s Guide. Note, that for Mosek no variable can appear in more than one conic constraint.

Additionally, the primal power cone, defined as

\[ x_0^\alpha x_1^{1-\alpha} \geq \sqrt{n \sum_{i=2}^{n} x_i^2}, \quad x_0, x_1 \geq 0, \]

with \( \alpha \in (0, 1) \), and the primal exponential cone, defined as

\[ x_0 \geq x_1 \exp(x_2/x_1), \quad x_0, x_1 \geq 0, \]

are available.

Since GAMS does not offer capabilities to directly restrict a variable to one of these cones, the GAMS/MOSEK link tries to detect the above algebra from a general nonlinear equation. For example, the following GAMS code should work with MOSEK:

Set i / 0*10 /;
Variable x(i);
Equations e1, e2;
Scalar alpha;
e1.. x('0')**alpha * x('1')**(1-alpha) =G= sqrt(sum(i$(ord(i)>2), sqr(x(i))));
e2.. x('0') =G= x('1') * exp(x('2') / x('1'));
x.lo('0') = 0;
x.lo('1') = 0;

See also testlib models powercone1, powercone2, and expcone1.

5.27.2 Solver Options

MOSEK works like other GAMS solvers, and many options can be set in the GAMS model (see GAMS Options). The most relevant GAMS options are reslim, nodlim, iterlim (iteration limit for simplex and interior point algorithms), optca, optcr, and optfile. A description of all available GAMS options can be found in GAMS Options and Solver related options.

We remark that MOSEK contains many complex solver options, many of which require a deep understanding of the algorithms used. For information on how to use a GAMS/Mosek options file, see The Solver Option File. For example, an option file

\[
\begin{align*}
&\text{MSK_IPAR_INTPNT_MAX_ITERATIONS} & 20 \\
&\text{MSK_IPAR_INTPNT_SCALING} & \text{MSK_SCALING_NONE}
\end{align*}
\]

limits the number of interior-point iterations to 20 and disables scaling.

In the following, we summarize the MOSEK options that are available through the GAMS/MOSEK interface. For details, see Detailed Descriptions of MOSEK Options.

5.27.2.1 General
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_DPAR_OPTIMIZER_MAX_TIME</td>
<td>Maximum amount of time the optimizer is allowed to spend on the optimization.</td>
<td>GAMS ResLim</td>
</tr>
<tr>
<td>MSK_DPAR_SEMIDEFINITE_TOL_APPROX</td>
<td>Tolerance to define a matrix to be positive semidefinite.</td>
<td>1e-10</td>
</tr>
<tr>
<td>MSK_IPAR_AUTO_SORT_A_BEFORE_OPT</td>
<td>Controls whether the elements in each column of the coefficient matrix are sorted before an optimization is performed.</td>
<td>MSK_OFF</td>
</tr>
<tr>
<td>MSK_IPAR_NUM_THREADS</td>
<td>Controls the number of threads employed by the optimizer.</td>
<td>GAMS Threads</td>
</tr>
<tr>
<td>MSK_IPAR_OPTIMIZER</td>
<td>The parameter controls which optimizer is used to optimize the task.</td>
<td>MSK_OPTIMIZER_FREE</td>
</tr>
<tr>
<td>MSK_IPAR_TIMING_LEVEL</td>
<td>Controls the amount of timing performed inside MOSEK.</td>
<td>1</td>
</tr>
<tr>
<td>MSK_SPAR_PARAM_READ_FILE_NAME</td>
<td>Modifications to the parameter database is read from this file.</td>
<td></td>
</tr>
</tbody>
</table>

### Problem Data

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_DPAR_CHECK_CONVEXITY_REL_TOL</td>
<td>This parameter controls when the full convexity check declares a problem to be non-convex.</td>
<td>1e-10</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_SYM_MAT_TOL</td>
<td>Absolute zero tolerance for elements in symmetric matrices.</td>
<td>1e-12</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_SYM_MAT_TOL_HUGE</td>
<td>An element in a symmetric matrix which is larger than this value in absolute size causes an error.</td>
<td>1e+20</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_SYM_MAT_TOL_LARGE</td>
<td>An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed.</td>
<td>1e+10</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_TOL_AIJ_HUGE</td>
<td>An element in the constraint matrix which is larger than this value in absolute size causes an error.</td>
<td>1e+20</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_TOL_AIJ_LARGE</td>
<td>An element in the constraint matrix which is larger than this value in absolute size causes a warning message.</td>
<td>1e+10</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_TOL_BOUND_INF</td>
<td>Any bound which in absolute value is greater than this parameter is considered infinite.</td>
<td>1e+16</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_TOL_BOUND_WRN</td>
<td>If a bound value is larger than this value in absolute size, then a warning message is issued.</td>
<td>1e+08</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_TOL_CJ_LARGE</td>
<td>A coefficient in the objective function which is larger than this value in absolute terms causes a warning message.</td>
<td>1e+08</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_TOL_C_HUGE</td>
<td>A coefficient in the objective function which is larger than the value in absolute terms is considered to be huge and generates an error.</td>
<td>1e+16</td>
</tr>
</tbody>
</table>
## 5.27 MOSEK

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_DPAR_DATA_TOL_QIJ</td>
<td>Absolute zero tolerance for coefficients of quadratic terms.</td>
<td>1e-16</td>
</tr>
<tr>
<td>MSK_DPAR_DATA_TOL_X</td>
<td>Zero tolerance for constraints and variables i.e. if the distance between the lower and upper bound is less than this value, then the lower and upper bound is considered identical.</td>
<td>1e-08</td>
</tr>
<tr>
<td>MSK_DPAR_LOWER_OBJ_CUT</td>
<td>Lower objective limit.</td>
<td>-1e+30</td>
</tr>
<tr>
<td>MSK_DPAR_LOWER_OBJ_CUT_FINE_TRIH</td>
<td>Lower objective limit threshold.</td>
<td>-5e+29</td>
</tr>
<tr>
<td>MSK_DPAR_QCQO_REFORMULATE_REL_DROP_TOL</td>
<td>This parameter determines when columns are dropped in incomplete Cholesky factorization during reformulation of quadratic problems.</td>
<td>1e-15</td>
</tr>
<tr>
<td>MSK_DPAR_UPPER_OBJ_CUT</td>
<td>Upper objective limit.</td>
<td>1e+30</td>
</tr>
<tr>
<td>MSK_DPAR_UPPER_OBJ_CUT_FINE_TRIH</td>
<td>Upper objective limit threshold.</td>
<td>5e+29</td>
</tr>
<tr>
<td>MSK_IPAR_CHECK_CONVEXITY</td>
<td>Specify the level of convexity check on quadratic problems.</td>
<td>MSK_CHECK_CONVEXITY_FULL</td>
</tr>
<tr>
<td>QEXTRACTALG</td>
<td>Switch to choose extraction algorithm for quadratic equations in GAMS interface.</td>
<td>0</td>
</tr>
<tr>
<td>SDPCHECKVARS</td>
<td>Switch to disable checking that for every entry of a PSD matrix variable also a corresponding GAMS variable is present.</td>
<td>1</td>
</tr>
</tbody>
</table>

### 5.27.2.3 Presolving

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_DPAR_PRESOLVE_TOL_ABS_LINDEP</td>
<td>Absolute tolerance employed by the linear dependency checker.</td>
<td>1e-06</td>
</tr>
<tr>
<td>MSK_DPAR_PRESOLVE_TOL_AIJ</td>
<td>Absolute zero tolerance employed for constraint coefficients in presolve.</td>
<td>1e-12</td>
</tr>
<tr>
<td>MSK_DPAR_PRESOLVE_TOL_REL_LINDEP</td>
<td>Relative tolerance employed by the linear dependency checker.</td>
<td>1e-10</td>
</tr>
<tr>
<td>MSK_DPAR_PRESOLVE_TOL_S</td>
<td>Absolute zero tolerance employed for dual variables in presolve.</td>
<td>1e-08</td>
</tr>
<tr>
<td>MSK_DPAR_PRESOLVE_TOL_X</td>
<td>Absolute zero tolerance employed for primal variables in presolve.</td>
<td>1e-08</td>
</tr>
<tr>
<td>MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL</td>
<td>Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve.</td>
<td>-1</td>
</tr>
<tr>
<td>MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_TRIES</td>
<td>Control the maximum number of times the eliminator is tried.</td>
<td>-1</td>
</tr>
<tr>
<td>MSK_IPAR_PRESOLVE_LINDEP_ABS_WORK_TRI</td>
<td>Controls the linear dependency check, which is potentially computationally expensive.</td>
<td>100</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------------------------------------------------</td>
<td>------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>MSK_IPAR_PRESOLVE_LINDEP_REL_TRH</td>
<td>Controls the linear dependency check, which is potentially computationally expensive.</td>
<td>100</td>
</tr>
<tr>
<td>MSK_IPAR_PRESOLVE_LINDEP_USE</td>
<td>Controls whether the linear constraints are checked for linear dependencies.</td>
<td>MSK_ON</td>
</tr>
<tr>
<td>MSK_IPAR_PRESOLVE_MAX_NUM_PASS</td>
<td>Control the maximum number of times presolve passes over the problem.</td>
<td>-1</td>
</tr>
<tr>
<td>MSK_IPAR_PRESOLVE_MAX_NUM_REDUCTIONS</td>
<td>Controls the maximum number of reductions performed by the presolve.</td>
<td>-1</td>
</tr>
<tr>
<td>MSK_IPAR_PRESOLVE_USE</td>
<td>Controls whether the presolve is applied to a problem before it is optimized.</td>
<td>MSK_PRESOLVE_MODE_FREE</td>
</tr>
</tbody>
</table>

### 5.27.2.4 Simplex Optimizer

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_DPAR_BASIS_REL_TOL_S</td>
<td>Maximum relative dual bound violation allowed in an optimal basic solution.</td>
<td>1e-12</td>
</tr>
<tr>
<td>MSK_DPAR_BASIS_TOL_S</td>
<td>Maximum absolute dual bound violation in an optimal basic solution.</td>
<td>1e-06</td>
</tr>
<tr>
<td>MSK_DPAR_BASIS_TOL_X</td>
<td>Maximum absolute primal bound violation allowed in an optimal basic solution.</td>
<td>1e-06</td>
</tr>
<tr>
<td>MSK_DPAR_SIMPLEX_ABS_TOL_Pivot</td>
<td>Absolute pivot tolerance employed by the simplex optimizers.</td>
<td>1e-07</td>
</tr>
<tr>
<td>MSK_DPAR_SIM_LU_TOL_REL</td>
<td>Relative pivot tolerance for LU factorization in simplex optimizers and basis identification.</td>
<td>0.01</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_BASIS_FACTOR_USE</td>
<td>Controls whether an LU factorization of the basis is used in a hot-start.</td>
<td>MSK_ON</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_DEGEN</td>
<td>Controls how aggressively degeneration is handled.</td>
<td>MSK_SIM_DEGEN_FREE</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_DUAL_CRASH</td>
<td>Controls whether crashing is performed in the dual simplex optimizer.</td>
<td>90</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_DUAL_RESTRICT_SELECTION</td>
<td>Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the dual simplex.</td>
<td>50</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_DUAL_SELECTION</td>
<td>Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer.</td>
<td>MSK_SIM_SELECTION_FREE</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_EXPLOIT_DUPVEC</td>
<td>Controls if the simplex optimizers are allowed to exploit duplicated columns.</td>
<td>MSK_SIM_EXPLOIT_DUPVEC_OFF</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_HOTSTART</td>
<td>Controls the type of hot-start that the simplex optimizer perform.</td>
<td>MSK_SIM_HOTSTART_FREE</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_HOTSTART_LU</td>
<td>Determines if the simplex optimizer should exploit the initial factorization.</td>
<td>MSK_ON</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_MAX_ITERATIONS</td>
<td>Maximum number of iterations that can be used by a simplex optimizer.</td>
<td>GAMS IterLim</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_MAX_NUM_SETBACKS</td>
<td>Controls how many set-backs are allowed within a simplex optimizer.</td>
<td>250</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_NON_SINGULAR</td>
<td>Controls if the simplex optimizer ensures a non-singular basis, if possible.</td>
<td>MSK_ON</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_PRIMAL_CRASH</td>
<td>Controls whether crashing is performed in the primal simplex optimizer.</td>
<td>90</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_PRIMAL_RESTRICT_SELECTION</td>
<td>Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the primal simplex.</td>
<td>50</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_PRIMAL_SELECTION</td>
<td>Controls the choice of the incoming variable, known as the selection strategy, in the primal simplex optimizer.</td>
<td>MSK_SIM_SELECTION_FREE</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_REFORMULATION</td>
<td>Controls if the simplex optimizers are allowed to reformulate the problem.</td>
<td>MSK_SIM_REFORMULATION_OFF</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_SAVE_LU</td>
<td>Controls if the LU factorization stored should be replaced with the LU factorization corresponding to the initial basis.</td>
<td>MSK_OFF</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_SCALING</td>
<td>Controls how much effort is used in scaling the problem before a simplex optimizer is used.</td>
<td>MSK_SCALING_FREE</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_SCALING_METHOD</td>
<td>Controls how the problem is scaled before a simplex optimizer is used.</td>
<td>MSK_SCALING_METHOD_POW2</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_SEED</td>
<td>Sets the random seed used for randomization in the simplex optimizers.</td>
<td>23456</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_SOLVE_Form</td>
<td>Controls whether the primal or the dual problem is solved by the primal-/dual-simplex optimizer.</td>
<td>MSK_SOLVE_FREE</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_STABILITY_PRIORITY</td>
<td>Controls how high priority the numerical stability should be given.</td>
<td>50</td>
</tr>
<tr>
<td>MSK_IPAR_SIM_SWITCH_OPTIMIZER</td>
<td>Controls the simplex behavior.</td>
<td>MSK_OFF</td>
</tr>
</tbody>
</table>

5.27.2.5 Interior Point Optimizer and Basis Identification
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_DPAR_INTPNT_CO_TOL_DFEAS</td>
<td>Dual feasibility tolerance used by the interior-point optimizer for conic problems.</td>

### 5.27.3 The MOSEK Log File

The MOSEK log output gives much useful information about the current solver progress and individual phases.

#### 5.27.3.1 Log Using the Interior Point Optimizer

The following is a MOSEK log output from running the **TRNSPORT** model from the GAMS Model Library:

```
Optimizer started.  
Interior-point optimizer started.  
Presolve started.  
Linear dependency checker started.  
Linear dependency checker terminated. 
Eliminator - tries :  0  time : 0.00 
Lin. dep. - tries : 1  time : 0.00 
Lin. dep. - number : 0  
Presolve terminated. Time: 0.00  
Optimizer - threads : 1  
Optimizer - solved problem : the primal  
Optimizer - Constraints : 5  
Optimizer - Cones : 0  
Optimizer - Scalar variables : 11  conic : 0  
Optimizer - Semi-definite variables: 0  scalarized : 0  
Factor - setup time : 0.00  dense det. time : 0.00  
Factor - ML order time : 0.00  GP order time : 0.00  
Factor - nonzeros before factor : 11  after factor : 12  
Factor - dense dim. : 0  flops : 1.80e+02  
```
The first part gives information about the presolve (if used). The main log follows:

```

Problem status: PRIMAL_AND_DUAL_FEASIBLE
Solution status: OPTIMAL
Primal. obj: 1.5367500000e+02 nrm: 6e+02 Viol. con: 0e+00 var: 0e+00
Dual. obj: 1.5367500000e+02 nrm: 2e-01 Viol. con: 0e+00 var: 5e-11

Return code - 0 [MSK_RES_OK]: No error occurred.

The last section gives details about the model and solver status, primal and dual feasibilities, as well as solver resource times. Furthermore, the log gives information about the basis identification phase. Some of this information is listed in the GAMS solve summary in the model listing (.LST) file as well.

The fields in the main MOSEK log output are:

<table>
<thead>

</tr>
<tr>
<td>TIME</td>
<td>Current elapsed solving time in seconds.</td>
</tr>
</tbody>
</table>

The log then gives information about solving the model with discrete variables fixed in order to determine marginals. Option SOLVEFINAL can be used to disable this step. The fixed problem is solved as a regular LP with warm start information. So the log looks identical to the MOSEK simplex optimizer for linear programs:

Solving fixed problem...

Optimizer started.
Simplex optimizer started.
Presolve started.
Eliminator - tries : 0 time : 0.00
Lin. dep. - tries : 0 time : 0.00

Final Solve: 4.000000 (0 iterations)

Best possible: 0.333333
Absolute gap: 3.666667
Relative gap: 0.916667

5.27.4  Semidefinite Programming with GAMS/MOSEK (experimental)

With Version 7, MOSEK introduced a semidefinite programming (SDP) solver into their portfolio. The following introduction is taken from the Mosel Documentation.
Semidefinite programming is a generalization of quadratic conic programming, allowing the use of matrix variables belonging to the convex cone of positive semidefinite matrices

\[ S^+_r = \{ X \in S_r : z^T X z \geq 0, \ \forall z \in \mathbb{R}^r \}, \]

where \( S_r \) is the set of \( r \times r \) real-valued symmetric matrices. MOSEK can solve semidefinite optimization problems of the form

\[
\begin{align*}
\text{minimize} & \quad \sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \langle A_{ij}, X_j \rangle + c^f \\
\text{subject to} & \quad l^c_i \leq \sum_{j=0}^{n-1} a_{ij} x_j + \sum_{j=0}^{p-1} \langle A_{ij}, X_j \rangle \leq u^c_i, \quad i = 0, \ldots, m-1, \\
& \quad l_j^T \leq x_j \leq u_j^T, \quad j = 0, \ldots, p-1,
\end{align*}
\]

(SDP)

where the problem has \( p \) symmetric positive semidefinite (PSD) variables \( X_j \in S^+_r \) of dimension \( r_j \) with symmetric coefficient matrices \( \overline{C}_j \in S_r \), and \( \overline{A}_{ij} \in S_r \). We use the standard notation for the matrix inner product, i.e., for \( A, B \in \mathbb{R}^{m \times n} \) we have

\[ \langle A, B \rangle := \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} A_{ij} B_{ij}. \]

### 5.27.4.1 Example

An example for a mixed semidefinite and conic quadratic programming problem with a 3-dimensional PSD matrix variable is the following:

\[
\begin{align*}
\text{minimize} & \quad \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix}, X \rangle + x_0 \\
\text{subject to} & \quad \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, X \rangle + x_0 = 1 \\
& \quad \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, X \rangle + x_1 + x_2 = \frac{1}{2} \\
& \quad x_0 \geq \sqrt{x_1^2 + x_2^2} \\
& \quad X \succeq 0
\end{align*}
\]

The GAMS/MOSEK interface offers an experimental interface to MOSEK’s SDP solver. It allows to state SDP’s of the form (SDP) in GAMS language. For instance, the example problem from above can be formulated as follows (sdp01 in the GAMS Test Library):

```plaintext
Set i / 0 * 2 /;
alias(i, ip);
Variables barX(i,i) PSDMATRIX
x(i) simple vars
z objective var;
x.lo('0') = 0;
Parameters barAobj(i,i) coefficients of barX in objective
barAe1(i,i) coefficients of barX in e1
barAe2(i,i) coefficients of barX in e2
;
Table barAobj(i,i)
```

The GAMS/MOSEK interface offers an experimental interface to MOSEK’s SDP solver. It allows to state SDP’s of the form (SDP) in GAMS language. For instance, the example problem from above can be formulated as follows (sdp01 in the GAMS Test Library):

```plaintext
Set i / 0 * 2 /;
alias(i, ip);
Variables barX(i,i) PSDMATRIX
x(i) simple vars
z objective var;
x.lo('0') = 0;
Parameters barAobj(i,i) coefficients of barX in objective
barAe1(i,i) coefficients of barX in e1
barAe2(i,i) coefficients of barX in e2
;
Table barAobj(i,i)
```
We see that the matrix $\bar{X}$ is defined via the 2-dimensional GAMS variable $\text{barX}$. Additionally, the keyword `PSDMATRIX` at the beginning of the descriptive text (!) of the variable is used to indicate that the variables belonging to symbol $\text{barX}$ are to be interpreted as a matrix variable with PSD constraint.

The Model shown above can be solved with MOSEK via the statements

```
option qcp = mosek;
Solve m minimizing z using QCP;
```

As GAMS has no native support for conic programming, the modeltype is specified as QCP.

The solve statement produces the following log output (see also Log Using the Interior Point Optimizer):

```

5.27.4.2 Usage

The general syntax for defining a symmetric matrix or an (indexed) set of symmetric matrices with PSD constraints in GAMS is

Variable X(a,b,c,...,i1,...,ik,i1,...,ik) "PSDMATRIX_k <explanatory text>";

The number $k > 0$ specifies the number of indices that define the row/column dimension of the matrix. Specifying only the term PSDMATRIX is equivalent to PSDMATRIX_1. For a given $k$, the $2k$-last indices are used to index the rows and columns of the matrix. The dimensions $a, b, c, ...$ are optional and can be used to index a set of matrices. In the GAMS/MOSEK output, a number in parenthesis is used to indicate the number of PSD matrices that have been found for one symbol. For example, the code

Set i / a,b /;
Set j / s01 * s42 /;
Variables z, X(j,i,i) PSDMATRIX;
generates the output

Recognizing SDP variables for symbols X (42)

if all matrices $X(j,.,.)$ also occur in a model instantiation.

Note

The current syntax for declaring PSD matrix variables via the explanatory text a variable is a temporary solution that will hopefully be replaced by a GAMS language feature in the future.

Variables that were tagged as belonging to a PSD matrix can only occur in linear constraints. Within these constraints, the coefficient matrix for a PSD matrix needs to be specified in symmetric form. That is, if the parameter matrix barAobj in the example above is equivalently specified as

Table barAobj(i,i)
0 1 2
0 2.0 0.0 0.0
1 2.0 2.0 0.0
2 0.0 2.0 2.0

the GAMS/MOSEK interface will quit with the error message
SDP coefficient matrix not symmetric: defObj_z: 2*barX(1,0) != 0*barX(0,1)

Bounds on entries in a PSD matrix variable can be specified as usual with .lo and .up attributes. These bound constraints are translated into linear constraints by the interface. If different bounds are given to symmetric entries of a PSD matrix variable (X_{i,j} vs. X_{j,i}), the stronger bounds are used, which is equivalent to adding constraints for each of the matrix entries. For nonpositive lower bounds on diagonal entries, no extra constraints are added, as they are implied by the PSD constraint.

5.27.4.3 GAMS variables vs. PSD matrix entries

As GAMS is not aware that a indexed variable will be interpreted as PSD matrix variable, it may not generate variables for all matrix entries when instantiating a model. This is especially critical if the modeler specified bounds on matrix entries that do not appear in any of the model equations, as these bounds would not be visible to the GAMS/MOSEK interface.

As an example, consider the SDP relaxation max\{-⟨W,\tilde{X}⟩\} : X_{i,i} = 1 \forall i, X \succeq 0\} corresponding to the Goemans-Williamson Randomized Approximation Algorithm for MaxCut:

Parameter X(i,i) edge weights;  
Variable X(i,j) PSDMATRIX  
objective var;  
Equation sdpobj;  
sdpobj.. sum((i,j), -W(i,j)*(X(i,j) + X(j,i))) =e= sdpobjvar;  
X.fx(i,i) = 1.0;  
model maxcutsdp / all /;  

As W(i,i)=0, GAMS will not create any variables for X(i,i) when instantiating the model in a solve statement. As a consequence, the constraints X(i,i)=1 will not be visible to GAMS/MOSEK. However, as MOSEK will compute values for the full matrix X, it will also compute values for the diagonal entries of X.

Further, the GAMS/MOSEK interface can pass primal solution values only for those entries of a PSD matrix variable that have a corresponding GAMS variable. This may make a solution matrix appear not to be PSD in GAMS, because not all entries have been passed back.

To be aware of such problems, the GAMS/MOSEK interface checks that it has a GAMS variable available for every entry of a PSD matrix variable. If not, it will report an error like

ERROR: Have 1600 GAMS variables for entries of 400 x 400 PSD Variable X(,), expected 160000 many.

This check can be disabled by setting the option SDPCHECKVARS to 0. Note, that the check is not able to alarm the user in situations where no GAMS variables were created for all entries of a row and corresponding column.

A simple workaround for this issue is to force all variables to be generated when a model is instantiated. This can be done by adding something like eps*sum((i,j),X(i,j)) to one of the equations. Note, that eps is numerically equal to a 0.0 in GAMS, but has the effect that the term sum((i,j),X(i,j)) is passed to the solver with 0.0-coefficient.

5.27.4.4 Dual Values for PSD constraints

The PSD constraint on a matrix variable \tilde{X} is associated with a dual PSD matrix variable \tilde{Y}. As GAMS is not aware of the PSD constraints, it is also not aware of the corresponding dual variables. Thus, there is no native way to pass the duals for the PSD constraints back to GAMS. (Recall, that the marginals for a PSDMATRIX variable X are used to store the dual values associated with the bound constraints on matrix entries.)

To work around this issue, the GAMS/MOSEK interface offers the option SDPSOLUFILE. This option allows to specify the name of a GDX file that stores primal values for all entries of a matrix variable and dual values of the corresponding PSD constraint. For a variable X(i,j), the GDX file stores the primal matrix value for all entries (i,j) (i.e., not just the ones for which GAMS variables were created, therefor offering another workaround for the issue discussed in the previous section) as level values of variable X and the dual matrix for the PSD constraint as marginal values.
5.27.4.5 Infeasible and Unbounded SDPs

The GAMS/Mosek link currently does not pass on certificates for primal or dual infeasibility from Mosek to GAMS if PSD variables are present.

5.27.5 Detailed Descriptions of MOSEK Options

**FIXOPTFILE (string):** Name of option file which is read just before solving the fixed problem.

**MSK_DPAR_ANA_SOL_INFEAS_TOL (real):** If a constraint violates its bound with an amount larger than this value, the constraint name, index and violation will be printed by the solution analyzer.

Default: 1e-06

**MSK_DPAR_BASIS_REL_TOL_S (real):** Maximum relative dual bound violation allowed in an optimal basic solution.

Default: 1e-12

**MSK_DPAR_BASIS_TOL_S (real):** Maximum absolute dual bound violation in an optimal basic solution.

Range: [1e-09, ∞]

Default: 1e-06

**MSK_DPAR_BASIS_TOL_X (real):** Maximum absolute primal bound violation allowed in an optimal basic solution.

Range: [1e-09, ∞]

Default: 1e-06

**MSK_DPAR_CHECK_CONVEXITY_REL_TOL (real):** This parameter controls when the full convexity check declares a problem to be non-convex.

Increasing this tolerance relaxes the criteria for declaring the problem non-convex. A problem is declared non-convex if negative (positive) pivot elements are detected in the Cholesky factor of a matrix which is required to be PSD (NSD). This parameter controls how much this non-negativity requirement may be violated. The matrix $Q$ is considered to not be PSD if the pivot element for column $i$ is less or equal to $-\|Q_{ii}\| \cdot MSK_DPAR_CHECK_CONVEXITY_REL_TOL$.

Default: 1e-10

**MSK_DPAR_DATA_SYM_MAT_TOL (real):** Absolute zero tolerance for elements in symmetric matrices.

If any value in a symmetric matrix is smaller than this parameter in absolute terms MOSEK will treat the values as zero and generate a warning.

Range: [1e-16, 1e-06]

Default: 1e-12
MSK_DPAR_DATA_SYM_MAT_TOL_HUGE (real): An element in a symmetric matrix which is larger than this value in absolute size causes an error. ↔

Default: 1e+20

MSK_DPAR_DATA_SYM_MAT_TOL_LARGE (real): An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed. ↔

Default: 1e+10

MSK_DPAR_DATA_TOL_AIJ_HUGE (real): An element in the constraint matrix which is larger than this value in absolute size causes an error. ↔

Default: 1e+20

MSK_DPAR_DATA_TOL_AIJ_LARGE (real): An element in the constraint matrix which is larger than this value in absolute size causes a warning message. ↔

Default: 1e+10

MSK_DPAR_DATA_TOL_BOUND_INF (real): Any bound which in absolute value is greater than this parameter is considered infinite. ↔

Default: 1e+16

MSK_DPAR_DATA_TOL_BOUND_WRN (real): If a bound value is larger than this value in absolute size, then a warning message is issued. ↔

Default: 1e+08

MSK_DPAR_DATA_TOL_CJ_LARGE (real): A coefficient in the objective function which is larger than this value in absolute terms causes a warning message. ↔

Default: 1e+08

MSK_DPAR_DATA_TOL_C_HUGE (real): A coefficient in the objective function which is larger than the value in absolute terms is considered to be huge and generates an error. ↔

Default: 1e+16

MSK_DPAR_DATA_TOL_QIJ (real): Absolute zero tolerance for coefficients of quadratic terms. ↔

Default: 1e-16

MSK_DPAR_INTPNT_CO_TOL_DFEAS (real): Dual feasibility tolerance used by the interior-point optimizer for conic problems. ↔

Range: [0, 1]

Default: 1e-08

See also: MSK_DPAR_INTPNT_CO_TOL_NEAR_REL.
**MSK_DPAR_INTPNT_CO_TOL_INFEAS** *(real):* Infeasibility tolerance used by the interior-point optimizer for conic problems.  

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: [0, 1]

Default: 1e-12

**MSK_DPAR_INTPNT_CO_TOL_MU_RED** *(real):* Relative complementarity gap tolerance used by the interior-point optimizer for conic problems.  

Range: [0, 1]

Default: 1e-08

**MSK_DPAR_INTPNT_CO_TOL_NEAR_REL** *(real):* Termination tolerance multiplier that is used if no accurate solution can be found.  

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: [1, \(\infty\)]

Default: 1

**MSK_DPAR_INTPNT_CO_TOL_PFEAS** *(real):* Primal feasibility tolerance used by the interior-point optimizer for conic problems.  

Range: [0, 1]

Default: 1e-08

See also: **MSK_DPAR_INTPNT_CO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_CO_TOL_REL_GAP** *(real):* Relative gap termination tolerance used by the interior-point optimizer for conic problems.  

Range: [0, 1]

Default: 1e-08

See also: **MSK_DPAR_INTPNT_CO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_QO_TOL_DFEAS** *(real):* Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.  

Range: [0, 1]

Default: 1e-08

See also: **MSK_DPAR_INTPNT_QO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_QO_TOL_INFEAS** *(real):* Infeasibility tolerance used by the interior-point optimizer for quadratic problems.  

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: \([0, 1]\)
Default: \(1e^{-12}\)

**MSK_DPAR_INTPNT_QO_TOL_MU_RED (real)**: Relative complementarity gap tolerance used by the interior-point optimizer for quadratic problems.

Range: \([0, 1]\)
Default: \(1e^{-08}\)

**MSK_DPAR_INTPNT_QO_TOL_NEAR_REL (real)**: Termination tolerance multiplier that is used if no accurate solution can be found.

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: \([1, \infty]\)
Default: 1

**MSK_DPAR_INTPNT_QO_TOL_PFEAS (real)**: Primal feasibility tolerance used by the interior-point optimizer for quadratic problems.

Range: \([0, 1]\)
Default: \(1e^{-08}\)

See also: **MSK_DPAR_INTPNT_QO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_QO_TOL_REL_GAP (real)**: Relative gap termination tolerance used by the interior-point optimizer for quadratic problems.

Range: \([0, 1]\)
Default: \(1e^{-08}\)

See also: **MSK_DPAR_INTPNT_QO_TOL_NEAR_REL**.

**MSK_DPAR_INTPNT_TOL_DFEAS (real)**: Dual feasibility tolerance used by the interior-point optimizer for linear problems.

Range: \([0, 1]\)
Default: \(1e^{-08}\)

**MSK_DPAR_INTPNT_TOL_DSAFE (real)**: Controls the initial dual starting point used by the interior-point optimizer.

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: \([0.0001, \infty]\)
Default: 1
**MSK_DPAR_INTPNT_TOL_INFEAS** (*real*): Infeasibility tolerance used by the interior-point optimizer for linear problems.  

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: \([0, 1]\)

Default: \(1e^{-10}\)

**MSK_DPAR_INTPNT_TOL_MU_RED** (*real*): Relative complementarity gap tolerance used by the interior-point optimizer for linear problems.

Range: \([0, 1]\)

Default: \(1e^{-16}\)

**MSK_DPAR_INTPNT_TOL_PATH** (*real*): Controls how close the interior-point optimizer follows the central path.

A large value of this parameter means the central path is followed very closely. On numerically unstable problems it may be worthwhile to increase this parameter.

Range: \([0, 0.999]\)

Default: \(1e^{-08}\)

**MSK_DPAR_INTPNT_TOL_PFEAS** (*real*): Primal feasibility tolerance used by the interior-point optimizer for linear problems.

Range: \([0, 1]\)

Default: \(1e^{-08}\)

**MSK_DPAR_INTPNT_TOL_PSAFE** (*real*): Controls the initial primal starting point used by the interior-point optimizer.

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it may be worthwhile to increase this value.

Range: \([0.0001, \infty]\)

Default: 1

**MSK_DPAR_INTPNT_TOL_REL_GAP** (*real*): Relative gap termination tolerance used by the interior-point optimizer for linear problems.

Range: \([1e^{-14}, \infty]\)

Default: \(1e^{-08}\)

**MSK_DPAR_INTPNT_TOL_REL_STEP** (*real*): Relative step size to the boundary for linear and quadratic optimization problems.

Range: \([0.0001, 0.999999]\)

Default: 0.9999

**MSK_DPAR_INTPNT_TOL_STEP_SIZE** (*real*): Step size tolerance.
If the step size falls below the value of this parameter, then the interior-point optimizer assumes it is stalled. In other words the interior-point optimizer does not make any progress and therefore it is better stop.

Range: [0, 1]
Default: 1e-06

**MSK_DPAR_LOWER_OBJ_CUT** *(real)*: Lower objective limit. →

If either a primal or dual feasible solution is found proving that the optimal objective value is outside, the interval \((\text{MSK\_DPAR\_LOWER\_OBJ\_CUT}, \text{MSK\_DPAR\_UPPER\_OBJ\_CUT})\), then MOSEK is terminated.

Range: \([-\infty, \infty]\]
Default: -1e+30

See also: **MSK_DPAR_LOWER_OBJ_CUT\_FINITE\_TRH**.

**MSK_DPAR_LOWER_OBJ_CUT\_FINITE\_TRH** *(real)*: Lower objective limit threshold. →

If the lower objective cut (\(\text{MSK\_DPAR\_LOWER\_OBJ\_CUT}\)) is less than this value, then it is treated as infinity.

Range: \([-\infty, \infty]\]
Default: -5e+29

**MSK_DPAR_MIO_MAX\_TIME** *(real)*: This parameter limits the maximum time spent by the mixed-integer optimizer. →

A negative number means infinity.

Range: \([-\infty, \infty]\]
Default: -1

**MSK_DPAR_MIO_REL\_GAP\_CONST** *(real)*: This value is used to compute the relative gap for the solution to an integer optimization problem. →

Range: \([1e-15, \infty]\]
Default: 1e-10

**MSK_DPAR_MIO_TOL\_ABS\_GAP** *(real)*: Absolute optimality tolerance employed by the mixed-integer optimizer. →

Default: GAMS OptCA

**MSK_DPAR_MIO_TOL\_ABS\_RELAX\_INT** *(real)*: Absolute relaxation tolerance of the integer constraints. →

That means if the fractional part of a discrete variable \(\min(|x| - \lfloor x \rfloor, \lceil x \rceil - |x|)\) is less than the tolerance, then the integer restriction is assumed to be satisfied.

Range: \([1e-09, \infty]\]
Default: 1e-05
MSK_DPAR_MIO_TOL_FEAS (real): Feasibility tolerance for mixed integer solver. 

Range: [1e-09, 0.001]
Default: 1e-06

MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT (real): If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation.

A value of 0.0 means that the value is selected automatically.

Range: [0, 1]
Default: 0

MSK_DPAR_MIO_TOL_REL_GAP (real): Relative optimality tolerance employed by the mixed-integer optimizer.

Default: GAMS OptCR

MSK_DPAR_OPTIMIZER_MAX_TIME (real): Maximum amount of time the optimizer is allowed to spent on the optimization.

A negative number means infinity.

Range: [-∞, ∞]
Default: GAMS ResLim

MSK_DPAR_PRESOLVE_TOL_ABS_LINDEP (real): Absolute tolerance employed by the linear dependency checker.

Default: 1e-06

MSK_DPAR_PRESOLVE_TOL_AIJ (real): Absolute zero tolerance employed for constraint coefficients in presolve.

Range: [1e-15, ∞]
Default: 1e-12

MSK_DPAR_PRESOLVE_TOL_REL_LINDEP (real): Relative tolerance employed by the linear dependency checker.

Default: 1e-10

MSK_DPAR_PRESOLVE_TOL_S (real): Absolute zero tolerance employed for dual variables in presolve.

Default: 1e-08

MSK_DPAR_PRESOLVE_TOL_X (real): Absolute zero tolerance employed for primal variables in presolve.

Default: 1e-08

MSK_DPAR_QCQO_REFORMULATE_REL_DROP_TOL (real): This parameter determines when columns are dropped in incomplete Cholesky factorization during reformulation of quadratic problems.
Default: $1e^{-15}$

**MSK_DPAR_SEMIDEFINITE_TOL_APPROX** (real): Tolerance to define a matrix to be positive semidefinite. ←

Range: $[1e^{-15}, \infty]$  
Default: $1e^{-10}$

**MSK_DPAR_SIMPLEX_ABS_TOL_PIV** (real): Absolute pivot tolerance employed by the simplex optimizers. ←

Range: $[1e^{-12}, \infty]$  
Default: $1e^{-07}$

**MSK_DPAR_SIM_LU_TOL_REL_PIV** (real): Relative pivot tolerance for LU factorization in simplex optimizers and basis identification. ←

A value closer to 1.0 generally improves numerical stability but typically also implies an increase in the computational work.

Range: $[1e^{-06}, 0.999999]$  
Default: 0.01

**MSK_DPAR_UPPER_OBJ_CUT** (real): Upper objective limit. ←

If either a primal or dual feasible solution is found proving that the optimal objective value is outside the interval ($MSK_DPAR_LOWER_OBJ_CUT$, $MSK_DPAR_UPPER_OBJ_CUT$), then MOSEK is terminated.

Range: $[-\infty, \infty]$  
Default: $1e+30$

See also: **MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH**.

**MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH** (real): Upper objective limit threshold. ←

If the upper objective cut $MSK_DPAR_UPPER_OBJ_CUT$ is greater than this value, then it is treated as infinity.

Range: $[-\infty, \infty]$  
Default: $5e+29$

**MSK_IPAR_AUTO_SORT_A_BEFORE_OPT** (string): Controls whether the elements in each column of the coefficient matrix are sorted before an optimization is performed. ←

This is not required but makes the optimization insusceptible to reorderings of variables.

Default: **MSK_OFF**

<table>

<td>Basis identification is performed if the interior-point optimizer terminates without an error.</td>
</tr>
<tr>
<td>MSK_BI_IF_FEASIBLE</td>
<td>Basis identification is not performed if the interior-point optimizer terminates with a problem status saying that the problem is primal or dual infeasible.</td>
</tr>
</tbody>
</table>

See also: MSK_IPAR_BI_CLEAN_OPTIMIZER, MSK_IPAR_BI_IGNORE_MAX_ITER, MSK_IPAR_BI_IGNORE_NUM_ERROR, MSK_IPAR_BI_MAX_ITERATIONS.

MSK_IPAR_INTPNT_DIFF_STEP (string): Controls whether different step sizes are allowed in the primal and dual space. ↔

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>
**MSK_IPAR_INTPNT_MAX_ITERATIONS** (integer): Controls the maximum number of iterations allowed in the interior-point optimizer. ←

Default: GAMS IterLim

**MSK_IPAR_INTPNT_MAX_NUM_COR** (integer): Controls the maximum number of correctors allowed by the multiple corrector procedure. ←

A negative value means that MOSEK is making the choice.

Range: \{-1, ..., \infty\}

Default: -1

**MSK_IPAR_INTPNT_MAX_NUM_REFINEMENT_STEPS** (integer): Maximum number of steps to be used by the iterative refinement of the search direction. ←

A negative value implies that the optimizer chooses the maximum number of iterative refinement steps.

Range: \{-\infty, ..., \infty\}

Default: -1

**MSK_IPAR_INTPNT_MULTI_THREAD** (string): Controls whether the interior-point optimizers can employ multiple threads if available. ←

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_OFF_COL_TRH** (integer): Controls how aggressively offending columns are detected in the Jacobian of the constraint matrix. ←

0 means no detection, 1 means aggressive detection, and higher values mean less aggressive detection.

Default: 40

**MSK_IPAR_INTPNT_ORDER_GP_NUM_SEEDS** (integer): The GP ordering is dependent on a random seed. ←

Therefore, trying several random seeds may lead to a better ordering. This parameter controls the number of random seeds tried. A value of 0 means that MOSEK makes the choice.

Default: 0

**MSK_IPAR_INTPNT_ORDER_METHOD** (string): Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system. ←

Default: MSK_ORDER_METHOD_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ORDER_METHOD_FREE</td>
<td>The ordering method is chosen automatically.</td>
</tr>
</tbody>
</table>
**value** | **meaning**
---|---
MSK_ORDER_METHOD_APPMINLOC | Approximate minimum local fill-in ordering is employed.
MSK_ORDER_METHOD_TRY_GRAPHPAR | Always try the graph partitioning based ordering.
MSK_ORDER_METHOD_FORCE_GRAPHPAR | Always use the graph partitioning based ordering even if it is worse than the approximate minimum local fill ordering.
MSK_ORDER_METHOD_NONE | No ordering is used.

**MSK_IPAR_INTPNT_REGULARIZATION_USE** *(string)*: Controls whether regularization is allowed. ↔

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_SCALING** *(string)*: Controls how the problem is scaled before the interior-point optimizer is used. ↔

Default: MSK_SCALING_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SCALING_FREE</td>
<td>The optimizer chooses the scaling heuristic.</td>
</tr>
<tr>
<td>MSK_SCALING_NONE</td>
<td>No scaling is performed.</td>
</tr>
<tr>
<td>MSK_SCALING_MODERATE</td>
<td>A conservative scaling is performed.</td>
</tr>
<tr>
<td>MSK_SCALING_AGGRESSIVE</td>
<td>A very aggressive scaling is performed.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_SOLVE_FORM** *(string)*: Controls whether the primal or the dual problem is solved. ↔

Default: MSK_SOLVE_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SOLVE_FREE</td>
<td>The optimizer is free to solve either the primal or the dual problem.</td>
</tr>
<tr>
<td>MSK_SOLVE_PRIMAL</td>
<td>The optimizer should solve the primal problem.</td>
</tr>
<tr>
<td>MSK_SOLVE_DUAL</td>
<td>The optimizer should solve the dual problem.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_INTPNT_STARTING_POINT** *(string)*: Starting point used by the interior-point optimizer. ↔

Default: MSK_STARTING_POINT_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_STARTING_POINT_FREE</td>
<td>The starting point is chosen automatically.</td>
</tr>
<tr>
<td>MSK_STARTING_POINT_GUESS</td>
<td>The optimizer guesses a starting point.</td>
</tr>
<tr>
<td>MSK_STARTING_POINT_CONSTANT</td>
<td>The optimizer constructs a starting point by assigning a constant value to all primal and dual variables. This starting point is normally robust.</td>
</tr>
<tr>
<td>value</td>
<td>meaning</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MSK_STARTING_POINT_SATISFY_BOUNDS</td>
<td>The starting point is chosen to satisfy all the simple bounds on nonlinear variables. If this starting point is employed, then more care than usual should be employed when choosing the bounds on the nonlinear variables. In particular very tight bounds should be avoided.</td>
</tr>
</tbody>
</table>

**MSK\_IPAR\_LOG** *(integer)*: Controls the amount of log information. 

The value 0 implies that all log information is suppressed. A higher level implies that more information is logged.

Default: 10

**MSK\_IPAR\_LOG\_BI** *(integer)*: Controls the amount of output printed by the basis identification procedure.

A higher level implies that more information is logged.

Default: 1

**MSK\_IPAR\_LOG\_BI\_FREQ** *(integer)*: Controls logging frequency of the basis identification

Default: 2500

**MSK\_IPAR\_LOG\_CHECK\_CONVEXITY** *(integer)*: Controls logging in convexity check on quadratic problems.

Set to a positive value to turn logging on. If a quadratic coefficient matrix is found to violate the requirement of PSD (NSD) then a list of negative (positive) pivot elements is printed. The absolute value of the pivot elements is also shown.

Default: 0

**MSK\_IPAR\_LOG\_FEAS\_REPAIR** *(integer)*: Controls the amount of output printed when performing feasibility repair.

Default: 1

**MSK\_IPAR\_LOG\_INFEAS\_ANA** *(integer)*: Controls amount of output printed by the infeasibility analyzer procedures.

A higher level implies that more information is logged.

Default: 1

**MSK\_IPAR\_LOG\_INTPNT** *(integer)*: Controls amount of output printed by the interior-point optimizer.

A higher level implies that more information is logged.

Default: 1

**MSK\_IPAR\_LOG\_MIO** *(integer)*: Controls the log level for the mixed-integer optimizer.
A higher level implies that more information is logged.

Default: 4

**MSK_IPAR_LOG_MIO_FREQ** *(integer)*: Controls how frequent the mixed-integer optimizer prints the log line.  
It will print a line every time `MSK_INT_PARMIO_FREQ` relaxations have been solved.

Range: \([-\infty, ..., \infty]\)

Default: 10

**MSK_IPAR_LOG_ORDER** *(integer)*: If turned on, then factor lines are added to the log.

Default: 1

**MSK_IPAR_LOG_PRESOLVE** *(integer)*: Controls amount of output printed by the presolve procedure.

A higher level implies that more information is logged.

Default: 1

**MSK_IPAR_LOG_RESPONSE** *(integer)*: Controls amount of output printed when response codes are reported.

A higher level implies that more information is logged.

Default: 0

**MSK_IPAR_LOG_SIM** *(integer)*: Controls amount of output printed by the simplex optimizer.

A higher level implies that more information is logged.

Default: 4

**MSK_IPAR_LOG_SIM_FREQ** *(integer)*: Controls simplex optimizer logging frequency.

Default: 1000

**MSK_IPAR_LOG_STORAGE** *(integer)*: When turned on, MOSEK prints messages regarding the storage usage and allocation.

Default: 0

**MSK_IPAR_MIO_BRANCH_DIR** *(string)*: Controls whether the mixed-integer optimizer is branching up or down by default.

Default: `MSK_BRANCH_DIR_FREE`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_BRANCH_DIR_FREE</code></td>
<td>The mixed-integer optimizer decides which branch to choose.</td>
</tr>
<tr>
<td><code>MSK_BRANCH_DIR_UP</code></td>
<td>The mixed-integer optimizer always chooses the up branch first.</td>
</tr>
<tr>
<td><code>MSK_BRANCH_DIR_DOWN</code></td>
<td>The mixed-integer optimizer always chooses the down branch first.</td>
</tr>
<tr>
<td><code>MSK_BRANCH_DIR_NEAR</code></td>
<td>Branch in direction nearest to selected fractional variable.</td>
</tr>
<tr>
<td><code>MSK_BRANCH_DIR_FAR</code></td>
<td>Branch in direction farthest from selected fractional variable.</td>
</tr>
<tr>
<td><code>MSK_BRANCH_DIR_ROOT_LP</code></td>
<td>Chose direction based on root lp value of selected variable.</td>
</tr>
</tbody>
</table>
**MSK_IPAR_MIO_CONIC_OUTER_APPROXIMATION** (*string*): If this option is turned on outer approximation is used when solving relaxations of conic problems; otherwise interior point is used.

Default: `MSK_OFF`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_ON</code></td>
<td>Switch the option on.</td>
</tr>
<tr>
<td><code>MSK_OFF</code></td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_CUT_CLIQUE** (*string*): Controls whether clique cuts should be generated.

Default: `MSK_ON`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_ON</code></td>
<td>Switch the option on.</td>
</tr>
<tr>
<td><code>MSK_OFF</code></td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_CUT_CMIR** (*string*): Controls whether mixed integer rounding cuts should be generated.

Default: `MSK_ON`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_ON</code></td>
<td>Switch the option on.</td>
</tr>
<tr>
<td><code>MSK_OFF</code></td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_CUT_GMI** (*string*): Controls whether GMI cuts should be generated.

Default: `MSK_ON`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_ON</code></td>
<td>Switch the option on.</td>
</tr>
<tr>
<td><code>MSK_OFF</code></td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_CUTIMPLIED_BOUND** (*string*): Controls whether implied bound cuts should be generated.

Default: `MSK_OFF`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_ON</code></td>
<td>Switch the option on.</td>
</tr>
<tr>
<td><code>MSK_OFF</code></td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_CUT_KNAPSACK_COVER** (*string*): Controls whether knapsack cover cuts should be generated.

Default: `MSK_OFF`
MSK_IPAR_MIO_CUT_SELECTION_LEVEL (integer): Controls how aggressively generated cuts are selected to be included in the relaxation.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses the level of cut selection.</td>
</tr>
<tr>
<td>0</td>
<td>Generated cuts less likely to be added to the relaxation.</td>
</tr>
<tr>
<td>1</td>
<td>Cuts are more aggressively selected to be included in the relaxation.</td>
</tr>
</tbody>
</table>

MSK_IPAR_MIO_FEASPUMP_LEVEL (string): Controls the way the Feasibility Pump heuristic is employed by the mixed-integer optimizer.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses how the Feasibility Pump is used.</td>
</tr>
<tr>
<td>0</td>
<td>The Feasibility Pump is disabled.</td>
</tr>
<tr>
<td>1</td>
<td>The Feasibility Pump is enabled with an effort to improve solution quality.</td>
</tr>
<tr>
<td>2</td>
<td>The Feasibility Pump is enabled with an effort to reach feasibility early.</td>
</tr>
</tbody>
</table>

MSK_IPAR_MIO_HEURISTIC_LEVEL (integer): Controls the heuristic employed by the mixed-integer optimizer to locate an initial good integer feasible solution.

A value of zero means the heuristic is not used at all. A larger value than 0 means that a gradually more sophisticated heuristic is used which is computationally more expensive. A negative value implies that the optimizer chooses the heuristic. Normally a value around 3 to 5 should be optimal.

Range: {-∞, ..., ∞}

Default: -1

MSK_IPAR_MIO_MAX_NUM_BRANCHES (integer): Maximum number of branches allowed during the branch and bound search.

A negative value means infinite.

Range: {-∞, ..., ∞}

Default: -1

MSK_IPAR_MIO_MAX_NUM_RELAXS (integer): Maximum number of relaxations allowed during the branch and bound search.

A negative value means infinite.

Range: {-∞, ..., ∞}

Default: GAMS NodLim
**MSK_IPAR_MIO_MAX_NUM_ROOT_CUT_rounds** *(integer)*: Maximum number of cut separation rounds at the root node.

Default: 100

**MSK_IPAR_MIO_MAX_NUM_SOLUTIONS** *(integer)*: The mixed-integer optimizer can be terminated after a certain number of different feasible solutions has been located.

If this parameter has the value \( n > 0 \), then the mixed-integer optimizer will be terminated when \( n \) feasible solutions have been located.

Range: \(-\infty, ..., \infty\)

Default: -1

**MSK_IPAR_MIO_NODE_OPTIMIZER** *(string)*: Controls which optimizer is employed at the non-root nodes in the mixed-integer optimizer.

Default: MSK_OPTIMIZER_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_OPTIMIZER_FREE</td>
<td>The optimizer is chosen automatically.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_INTPNT</td>
<td>The interior-point optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_CONIC</td>
<td>The optimizer for problems having conic constraints.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_PRIMAL_SIMPLEX</td>
<td>The primal simplex optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_DUAL_SIMPLEX</td>
<td>The dual simplex optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_FREE_SIMPLEX</td>
<td>One of the simplex optimizers is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_MIXED_INT</td>
<td>The mixed-integer optimizer.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_NODE_SELECTION** *(string)*: Controls the node selection strategy employed by the mixed-integer optimizer.

Default: MSK_MIO_NODE_SELECTION_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_MIO_NODE_SELECTION_FREE</td>
<td>The optimizer decides the node selection strategy.</td>
</tr>
<tr>
<td>MSK_MIO_NODE_SELECTION_FIRST</td>
<td>The optimizer employs a depth first node selection strategy.</td>
</tr>
<tr>
<td>MSK_MIO_NODE_SELECTION_BEST</td>
<td>The optimizer employs a best bound node selection strategy.</td>
</tr>
<tr>
<td>MSK_MIO_NODE_SELECTION_PSEUDO</td>
<td>The optimizer employs selects the node based on a pseudo cost estimate.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE** *(string)*: Enables or disables perspective reformulation in presolve.

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>
**MSK_IPAR_MIO_PROBING_LEVEL** *(integer)*: Controls the amount of probing employed by the mixed-integer optimizer in presolve. 

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses the level of probing employed</td>
</tr>
<tr>
<td>0</td>
<td>Probing is disabled</td>
</tr>
<tr>
<td>1</td>
<td>A low amount of probing is employed</td>
</tr>
<tr>
<td>2</td>
<td>A medium amount of probing is employed</td>
</tr>
<tr>
<td>3</td>
<td>A high amount of probing is employed</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_PROPAGATE_OBJECTIVE_CONSTRAINT** *(string)*: Use objective domain propagation. 

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_RINS_MAX_NODES** *(integer)*: Controls the maximum number of nodes allowed in each call to the RINS heuristic. 

The default value of -1 means that the value is determined automatically. A value of zero turns off the heuristic.

Range: \{-1, ..., ∞\}

Default: -1

**MSK_IPAR_MIO_ROOT_OPTIMIZER** *(string)*: Controls which optimizer is employed at the root node in the mixed-integer optimizer. 

Default: MSK_OPTIMIZER_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_OPTIMIZER_FREE</td>
<td>The optimizer is chosen automatically.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_INTPNT</td>
<td>The interior-point optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_CONIC</td>
<td>The optimizer for problems having conic constraints.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_PRIMAL_SIMPLEX</td>
<td>The primal simplex optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_DUAL_SIMPLEX</td>
<td>The dual simplex optimizer is used.</td>
</tr>
<tr>
<td>MSK_OPTIMIZER_FREE_SIMPLEX</td>
<td>One of the simplex optimizers is used.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL** *(integer)*: Controls whether presolve can be repeated at root node. 

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses whether presolve is repeated.</td>
</tr>
</tbody>
</table>
### MSK_IPAR_MIO_SEED (integer)

Sets the random seed used for randomization in the mixed integer optimizer.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Never repeat presolve.</td>
</tr>
<tr>
<td>1</td>
<td>Always repeat presolve.</td>
</tr>
</tbody>
</table>

Selecting a different seed can change the path the optimizer takes to the optimal solution.

Default: 42

### MSK_IPAR_MIO_VB_DETECTION_LEVEL (integer)

Controls how much effort is put into detecting variable bounds.

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>The optimizer chooses.</td>
</tr>
<tr>
<td>0</td>
<td>No variable bounds are detected.</td>
</tr>
<tr>
<td>1</td>
<td>Only detect variable bounds that are directly represented in the problem.</td>
</tr>
<tr>
<td>2</td>
<td>Detect variable bounds in probing.</td>
</tr>
</tbody>
</table>

Default: -1

### MSK_IPAR_NUM_THREADS (integer)

Controls the number of threads employed by the optimizer.

If set to 0 the number of threads used will be equal to the number of cores detected on the machine. If using the conic optimizer, the value of this parameter set at first optimization remains constant through the lifetime of the process. MOSEK will allocate a thread pool of given size, and changing the parameter value later will have no effect. It will, however, remain possible to demand single-threaded execution by setting MSK_IPAR_INTPNT_MULTI_THREAD. For the mixed-integer optimizer and interior-point linear optimizer there is no such restriction.

Default: GAMS Threads

### MSK_IPAR_OPF_WRITE_HEADER (string)

Write a text header with date and MOSEK version in an OPF file.

Default: MSK_ON

### MSK_IPAR_OPF_WRITE_HINTS (string)

Write a hint section with problem dimensions in the beginning of an OPF file.

Default: MSK_ON
**MSK_IPAR_OPF_WRITE_LINE_LENGTH** (*integer*): Aim to keep lines in OPF files not much longer than this.  

Default: 80

**MSK_IPAR_OPF_WRITE_PARAMETERS** (*string*): Write a parameter section in an OPF file.  

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_PROBLEM** (*string*): Write objective, constraints, bounds etc. to an OPF file.  

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_SOLUTIONS** (*string*): Enable inclusion of solutions in the OPF files.  

Default: MSK_OFF

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_SOL_BAS** (*string*): Whether to include basic solution in OPF files.  

If **MSK_IPAR_OPF_WRITE_SOLUTIONS** is **MSK_ON** and a basic solution is defined, include the basic solution in OPF files.  

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPF_WRITE_SOL_ITG** (*string*): Whether to include integer solution in OPF files.  

If **MSK_IPAR_OPF_WRITE_SOLUTIONS** is **MSK_ON** and an integer solution is defined, write the integer solution to OPF files.  

Default: MSK_ON

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>
**MSK_IPAR_OPF_WRITE_SOL_ITR (string):** Whether to include interior solution in OPF files. ✏️

If `MSK_IPAR_OPF_WRITE_SOLUTIONS` is `MSK_ON` and an interior solution is defined, write the interior solution to OPF files.

Default: `MSK_ON`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_ON</code></td>
<td>Switch the option on.</td>
</tr>
<tr>
<td><code>MSK_OFF</code></td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_OPTIMIZER (string):** The parameter controls which optimizer is used to optimize the task. ✏️

Default: `MSK_OPTIMIZER_FREE`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_OPTIMIZER_FREE</code></td>
<td>The optimizer is chosen automatically.</td>
</tr>
<tr>
<td><code>MSK_OPTIMIZER_INTPNT</code></td>
<td>The interior-point optimizer is used.</td>
</tr>
<tr>
<td><code>MSK_OPTIMIZER_CONIC</code></td>
<td>The optimizer for problems having conic constraints.</td>
</tr>
<tr>
<td><code>MSK_OPTIMIZER_PRIMAL_SIMPLEX</code></td>
<td>The primal simplex optimizer is used.</td>
</tr>
<tr>
<td><code>MSK_OPTIMIZER_DUAL_SIMPLEX</code></td>
<td>The dual simplex optimizer is used.</td>
</tr>
<tr>
<td><code>MSK_OPTIMIZER_FREE_SIMPLEX</code></td>
<td>One of the simplex optimizers is used.</td>
</tr>
<tr>
<td><code>MSK_OPTIMIZER_MIXED_INT</code></td>
<td>The mixed-integer optimizer</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL (integer):** Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve. ✏️

A negative value means the parameter value is selected automatically.

Range: \{-∞, ..., ∞\}

Default: -1

**MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_NUM_TRIES (integer):** Control the maximum number of times the eliminator is tried. ✏️

A negative value implies MOSEK decides.

Range: \{-∞, ..., ∞\}

Default: -1

**MSK_IPAR_PRESOLVE_LINDEP_ABS_WORK_TRH (integer):** Controls the linear dependency check, which is potentially computationally expensive. ✏️

Range: \{-∞, ..., ∞\}

Default: 100

**MSK_IPAR_PRESOLVE_LINDEP_REL_WORK_TRH (integer):** Controls the linear dependency check, which is potentially computationally expensive. ✏️

Range: \{-∞, ..., ∞\}

Default: 100

**MSK_IPAR_PRESOLVE_LINDEP_USE (string):** Controls whether the linear constraints are checked for linear dependencies. ✏️

Default: `MSK_ON`
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PRESOLVE_MAX_NUM_PASS** (*integer*): Control the maximum number of times presolve passes over the problem. 

A negative value implies MOSEK decides.

Range: \(-\infty, ..., \infty\)

Default: \(-1\)

**MSK_IPAR_PRESOLVE_MAX_NUM_REDUCTIONS** (*integer*): Controls the maximum number of reductions performed by the presolve.

The value of the parameter is normally only changed in connection with debugging. A negative value implies that an infinite number of reductions are allowed.

Range: \(-\infty, ..., \infty\)

Default: \(-1\)

**MSK_IPAR_PRESOLVE_USE** (*string*): Controls whether the presolve is applied to a problem before it is optimized.

Default: **MSK_PRESOLVE_MODE_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_PRESOLVE_MODE_OFF</td>
<td>The problem is not presolved before it is optimized.</td>
</tr>
<tr>
<td>MSK_PRESOLVE_MODE_ON</td>
<td>The problem is presolved before it is optimized.</td>
</tr>
<tr>
<td>MSK_PRESOLVE_MODE_FREE</td>
<td>It is decided automatically whether to presolve before the problem is optimized.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_PTF_WRITE_TRANSFORM** (*string*): If enabled, then constraint blocks with identifiable conic slacks are transformed into conic constraints and the slacks are eliminated.

Default: **MSK_ON**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_ON</td>
<td>Switch the option on.</td>
</tr>
<tr>
<td>MSK_OFF</td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_SIM_BASIS_FACTOR_USE** (*string*): Controls whether an LU factorization of the basis is used in a hot-start.

Forcing a refactorization sometimes improves the stability of the simplex optimizers, but in most cases there is a performance penalty.

Default: **MSK_ON**
### MSK_IPAR_SIM_DEGEN (string): Controls how aggressively degeneration is handled.

Default: MSK_SIM_DEGEN_FREE

<table>

### MSK_IPAR_SIM_DUAL_CRASH (integer): Controls whether crashing is performed in the dual simplex optimizer.

In general if a basis consists of more than \((100 \times \text{MSK_IPAR_SIM_DUAL_CRASH})\) percent fixed variables, then a crash will be performed.

Default: 90

### MSK_IPAR_SIM_DUAL_RESTRICT_SELECTION (integer): Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the dual simplex.

The dual simplex optimizer can use a so-called restricted selection/pricing strategy to choose the outgoing variable. Hence, if restricted selection is applied, then the dual simplex optimizer first choose a subset of all the potential outgoing variables. Next, for some time it will choose the outgoing variable only among the subset. From time to time the subset is redefined. A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Range: \(\{0, ..., 100\}\)

Default: 50

### MSK_IPAR_SIM_DUAL_SELECTION (string): Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer.

Default: MSK_SIM_SELECTION_FREE

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SIM_SELECTION_FREE</td>
<td>The optimizer chooses the pricing strategy.</td>

</tbody>
</table>

**MSK_IPAR_SIM_MAX_ITERATIONS** *(integer)*: Maximum number of iterations that can be used by a simplex optimizer.

Default: `GAMS IterLim`

**MSK_IPAR_SIM_MAX_NUM_SETBACKS** *(integer)*: Controls how many set-backs are allowed within a simplex optimizer.

A set-back is an event where the optimizer moves in the wrong direction. This is impossible in theory but may happen due to numerical problems.

Default: 250

**MSK_IPAR_SIM_NON_SINGULAR** *(string)*: Controls if the simplex optimizer ensures a non-singular basis, if possible.

Default: `MSK_ON`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MSK_ON</code></td>
<td>Switch the option on.</td>
</tr>
<tr>
<td><code>MSK_OFF</code></td>
<td>Switch the option off.</td>
</tr>
</tbody>
</table>
**MSK_IPAR_SIM_PRIMAL_CRASH** *(integer)*: Controls whether crashing is performed in the primal simplex optimizer.

In general if a basis consists of more than \((100 \times \text{MSK_IPAR_SIM_PRIMAL_CRASH})\) percent fixed variables, then a crash will be performed.

Default: 90

**MSK_IPAR_SIM_PRIMAL_RESTRICT_SELECTION** *(integer)*: Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the primal simplex.

The primal simplex optimizer can use a so-called restricted selection/pricing strategy to chooses the outgoing variable. Hence, if restricted selection is applied, then the primal simplex optimizer first choose a subset of all the potential incoming variables. Next, for some time it will choose the incoming variable only among the subset. From time to time the subset is redefined. A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Range: \{0, ..., 100\}

Default: 50

**MSK_IPAR_SIM_PRIMAL_SELECTION** *(string)*: Controls the choice of the incoming variable, known as the selection strategy, in the primal simplex optimizer.

Default: **MSK_SIM_SELECTION_FREE**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSK_SIM_SELECTION_FREE</td>
<td>The optimizer chooses the pricing strategy.</td>

<tr>
<td><code>MSK_SOLVE_DUAL</code></td>
<td>The optimizer should solve the dual problem.</td>
</tr>
</tbody>
</table>

**MSK_IPAR_SIM_STABILITY_PRIORITY** *(integer)*: Controls how high priority the numerical stability should be given.  

Range: `{0, ..., 100}`

Default: 50
**MSK_IPAR_SIM_SWITCH_OPTIMIZER** *(string)*: Controls the simplex behavior. 

The simplex optimizer sometimes chooses to solve the dual problem instead of the primal problem. This implies that if you have chosen to use the dual simplex optimizer and the problem is dualized, then it actually makes sense to use the primal simplex optimizer instead. If this parameter is on and the problem is dualized and furthermore the simplex optimizer is chosen to be the primal (dual) one, then it is switched to the dual (primal).

Default: **MSK_OFF**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>MSK_ON</strong></td>
<td>Switch the option on.</td>

### 5.27.6 Setting up a GAMS/MOSEK-Link license

To use the GAMS/MOSEK solver with a GAMS/MOSEK-Link license you have save a MOSEK standalone license and point to the MOSEK license file via environment variable `MOSEKLM_LICENSE_FILE`.  

---
5.28 NLPEC

5.28.1 Introduction

The GAMS/NLPEC solver, developed jointly by Michael Ferris of UW-Madison and GAMS Development, solves MPEC and MCP models via reformulation of the complementarity constraints. The resulting sequence of NLP models are parameterized by a scalar $\mu$ and solved by existing NLP solvers. The resulting solutions are used to recover an MPEC or MCP solution.

GAMS/NLPEC serves a number of purposes. In many cases, it is an effective tool for solving MPEC models, the first such tool available within GAMS. It also serves as a way to experiment with the many reformulation strategies proposed for solving MPEC and MCP models. Without something like NLPEC (and a library of models to test with) a comprehensive and thorough test and comparison of the various reformulation strategies would not be possible. To better serve these purposes, NLPEC has an open architecture. The model reformulations are written out as GAMS source for solution via an NLP solver, so it is possible to view this source and modify it if desired.

A brief note about notation is in order. The GAMS keyword positive is used to indicate nonnegative variables. The same holds for nonpositive variables and the GAMS keyword negative.

5.28.2 Usage

GAMS/NLPEC can solve models of two types: MPEC and MCP. If you did not specify NLPEC as the default MPEC or MCP solver, use the following statement in your GAMS model before the solve statement:

```gams
option MPEC=nlpec; { or MCP }
```

You can also make NLPEC the default solver via the command line:

```bash
gams nash MPEC=nlpec MCP=nlpec
```

You can use NLPEC with its default strategy and formulation, but most users will want to use an options file (Section Options) after reading about the different types of reformulations possible (Section Reformulation). In addition, an understanding of the architecture of NLPEC (Section Open Architecture) will be helpful in understanding how GAMS options are treated. Although NLPEC doesn't use the GAMS options workspace, workfactor, optcr, optca, reslim, iterlim, and domlim directly, it passes these options on in the reformulated model so they are available to the NLP subsolver.

5.28.3 Reformulation

In this section we describe the different ways that the NLPEC solver can reformulate an MPEC as an NLP. The description also applies to MCP models: just consider MCP to be an MPEC with a constant objective. The choice of reformulation, and the subsidiary choices each reformulation entails, are controlled by the options described in the section on Setting the Reformulation Options and referenced throughout this section.

The original MPEC model is given as:

$$\min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m} f(x, y)$$
subject to the constraints

\[ g(x, y) \leq 0 \]  \hspace{1cm} (2)

and

\[ y \text{ solves } MCP(h(x, \cdot), \mathbf{B}). \]  \hspace{1cm} (3)

In most of the reformulations, the objective function (1) is included in the reformulated model without change. In some cases, it may be augmented with a penalty function. The variables \( x \) are typically called upper level variables (because they are associated with the upper level optimization problem) whereas the variables \( y \) are sometimes termed lower level variables.

The constraints (2) are standard nonlinear programming constraints specified in GAMS in the standard fashion. In particular, these constraints may be less than inequalities as shown above, or equalities or greater than inequalities. The constraints will be unaltered by all our reformulations. These constraints may involve both \( x \) and \( y \), or just \( x \) or just \( y \), or may not be present at all in the problem.

The constraints of interest are the equilibrium constraints (3), where (3) signifies that \( y \in \mathbb{R}^m \) is a solution to the mixed complementarity problem (MCP) defined by the function \( h(x, \cdot) \) and the box \( \mathbf{B} \) containing (possibly infinite) simple bounds on the variables \( y \). A point \( y \) with \( a_i \leq y_i \leq b_i \) solves (3) if for each \( i \) at least one of the following holds:

\[ h_i(x, y) = 0 \]
\[ h_i(x, y) \geq 0, \quad y_i = a_i; \]
\[ h_i(x, y) \leq 0, \quad y_i = b_i. \]  \hspace{1cm} (4)

As a special case of (4), consider the case where \( a = 0 \) and \( b = +\infty \). Since \( y_i \) can never be \( +\infty \) at a solution, (4) simplifies to the nonlinear complementarity problem (NCP):

\[ 0 \leq h_i(x, y), 0 \leq y_i \text{ and } y_i h_i(x, y) = 0, \quad i = 1, \ldots, m \]  \hspace{1cm} (5)

namely that \( h \) and \( y \) are nonnegative vectors with \( h \) perpendicular to \( y \). This motivates our shorthand for (4), the "perp to" symbol \( \perp \):

\[ h_i(x, y) \perp y_i \in [a_i, b_i] \]  \hspace{1cm} (6)

The different ways to force (6) to hold using (smooth) NLP constraints are the basis of the NLPEC solver.

We introduce a simple example now that we will use throughout this document for expositional purposes:

\[ \min_{x_1, x_2, y_1, y_2} \quad x_1 + x_2 \]
\[ \text{subject to} \quad x_1 \leq 0, \quad x_2 \leq 0, \quad y_1 - y_2 + 1 \leq x_1 \perp y_1 \geq 0 \]
\[ x_2 + y_2 \perp y_2 \in [-1, 1] \]

This problem has the unique solution \( x_1 = 0, x_2 = -1, y_1 = 0, y_2 = 1 \). Note that \( f(x, y) = x_1 + x_2 \) and \( g(x, y) = x_1^2 + x_2^2 - 1 \) are the objective function and the standard nonlinear programming constraints for this problem. The function \( h(x, y) \) is given by:

\[ h(x, y) = \begin{bmatrix} x_1 - y_1 + y_2 - 1 \\ x_2 + y_2 \end{bmatrix} \]

and

\[ a = \begin{bmatrix} 0 \\ -1 \end{bmatrix}, \quad b = \begin{bmatrix} \infty \\ 1 \end{bmatrix}. \]

This example is written very succinctly in GAMS notation as:
5.28 NLPEC

\$TITLE simple mpec example

variable f, x1, x2, y1, y2;
positive variable y1;
y2.lo = -1;
y2.up = 1;
equations cost, g, h1, h2;
cost.. f =E= x1 + x2;
g.. sarr(x1) + sarr(x2) =L= 1;
h1.. x1 =G= y1 - y2 + 1;
h2.. x2 + y2 =N= 0;
model example / cost, g, h1.y1, h2.y2 /;
solve example using mpec min f;

Note that the equation cost is used to define f, the constraint g defines the function g, and h is defined by h1 and h2. The complementarity constraints utilize the standard GAMS convention of specifying the orthogonality relationship between h and y in the model statement. The interpretation of the "." relies on the bounds a and b that are specified using positive, negative, or lo and up keywords in GAMS.

Note that since h2 really specifies a function h2 and not a constraint h2(x,y) = 0, we use the GAMS syntax =N= to ensure this is clear here. Since the relationships satisfied by h1 and h2 are determined by the bounds, =G= could also be replaced by =N= in h1.

In describing the various reformulations for (6), it is convenient to partition the y variables into free F, lower bounded L, upper bounded U and doubly bounded B variables respectively, that is:

B := \{ y = (y_F, y_L, y_U, y_B) : a_L ≤ y_L, y_U ≤ b_U, a_B ≤ y_B ≤ b_B \}.

We will assume (without loss of generality) that a_B < b_B. If a_i = b_i then (6) holds trivially for the index i and we can remove the constraint h_i and its corresponding (fixed) variable y_i from the model. The complementarity condition for variables in y_i ∈ F is simply the equality h_i(x,y) = 0 so these equality constraints are moved directly into the NLP constraints g of the original model as equalities. Thus, NLPEC needs only to treat the singly-bounded variables in L and U and the doubly-bounded variables in B. In the above example, L = \{1\}, U = \{\} and B = \{2\}.

5.28.3.1 Product reformulations

Product reformulations all involve products of y_i with h_i, or products of y_i with some auxiliary or slack variables that are set equal to h_i. The underlying point is that the constraints (3) are entirely equivalent to the following system of equalities and inequalities:

\begin{align*}
  w_L &= h_L(x,y), \quad a_L \leq y_L, \quad w_L \geq 0 \quad \text{and} \quad (y_L - a_L)^T w_L = 0 \\
  v_U &= -h_U(x,y), \quad y_U \leq b_U, \quad v_U \geq 0 \quad \text{and} \quad (b_U - y_U)^T v_U = 0 \\
  w_B - v_B &= h_B(x,y), \quad a_B \leq y_B \leq b_B, \quad w_B \geq 0, \quad v_B \geq 0 \\
  (y_B - a_B)^T w_B &= 0, \quad (b_B - y_B)^T v_B = 0.
\end{align*}

Note that each inner product is a summation of products of nonnegative terms: a slack variable and the difference between a variable and its bound. In each of these products, either the slack variable or its complement must be zero in order to have a solution. Complementarity is forced by the multiplication of these two terms. The above reformulation is specified using option reftype mult.

There are a number of variations on this theme, all of which can be specified via an options file. All of the inner products could be put into the same equation, left as in (7) above, or broken out into individual products (one for each i ∈ L ∪ U, two for each i ∈ B). For example, the complementarity constraints
associated with lower bounded variables involve nonnegativity of \( w_L, y_L \geq a_L \) and either of the following alternatives:

\[
(y_L - a_L)^T w_L = \sum_{i \in L} (y_i - a_i) w_i = 0
\]

or

\[
(y_i - a_i) w_i = 0, \quad i = 1, \ldots, m
\]

These different levels of aggregation are chosen using option aggregate none|partial|full.

Since all of the inner products in (7) involve nonnegative terms, we can set the inner products equal to zero or set them \( \leq 0 \) without changing the feasible set. To choose one or the other, use the option constraint equality|inequality.

As a concrete example, consider the option file

```
reftype mult
aggregate none
constraint inequality
```

applied to the simple example given above. Such an option file generates the nonlinear programming model:

\[
\begin{align*}
\text{min} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, \quad w_1 \geq 0, \quad y_1 \geq 0 \\
& \quad w_1 y_1 \leq \mu \\
& \quad w_2 - v_2 = x_2 + y_2, \quad w_2, v_2 \geq 0, \quad y_2 \in [-1, 1] \\
& \quad (y_2 + 1) w_2 \leq \mu, \quad (1 - y_2) v_2 \leq \mu
\end{align*}
\]

By default, a single model is generated with the value \( \mu \) set to 0. There are many examples (e.g. interior point codes, many LP and NLP packages, published results on reformulation approaches to MPEC) that illustrate the value of starting with a "nearly-complementary" solution and pushing the complementarity gap down to zero. For this reason, the inner products in (7) above are always set equal to (or \( \leq \)) a scalar \( \mu \) instead of zero. By default \( \mu \) is zero, but options exist to start \( \mu \) at a positive value (e.g. InitMu 1e-2), to decrease it by a constant factor in a series of looped solves (e.g. NumSolves 4, UpdateFac 0.1), and to solve one last time with a final value for \( \mu \) (e.g. FinalMu 0). If the following lines are added to the option file

```
initmu 1.0 
num solves 4
```

then five consecutive solves of the nonlinear program (8) are performed, the first one using \( \mu = 1 \) and each subsequent solve dividing \( \mu \) by 10 (and starting the NLP solver at the solution of the previous model in this sequence).

As a final example, we use a combination of these options to generate a sequence of nonlinear programs whose solutions attempt to trace out the "central path" favored by interior point and barrier algorithms:

```
reftype mult
constraint equality
initmu 1.0
num solves 4
updatefac 0.1
finalmu 1e-6
```

produces 6 nonlinear programs of the form

\[
\begin{align*}
\text{min} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, \quad w_1 \geq 0, \quad y_1 \geq 0 \\
& \quad w_1 y_1 = \mu \\
& \quad w_2 - v_2 = x_2 + y_2, \quad w_2, v_2 \geq 0, \quad y_2 \in [-1, 1] \\
& \quad (y_2 + 1) w_2 = \mu, \quad (y_2 - 1) v_2 = \mu
\end{align*}
\]

for values of \( \mu = 1, 0.1, 0.01, 0.001, 0.0001 \) and \( 1e-6 \).
5.28.3.1.1 Slacks and doubly bounded variables  Slack variables can be used to reduce the number of times a complex nonlinear expression appears in the nonlinear programming model, as was carried out in (7). For a simpler illustrative example the NCP constraints (5) are equivalent to the constraints:

\[ w_i = h_i(x, y), 0 \leq w_i, 0 \leq y_i, \text{ and } y_i w_i = 0, \quad i = 1, \ldots, m \]

This reformulation has an additional equality constraint, and additional variables \( w \), but the expression \( h_i \) only appears once. There are cases when this formulation will be preferable, and the simple option `slack none` controls the use of the \( w \) variables.

When there are doubly bounded variables present, these two slack options work slightly differently. For the `positive` case, the reformulation introduces two nonnegative variables \( w_i \) and \( v_i \) that take on the positive and negative parts of \( h_i \) at the solution as shown in (7). Since this is the default value of the option `slack`, the example (8) shows what ensues to both singly and doubly bounded variables under this setting.

For the case `slack none`, Scholtes proposed a way to use a multiplication to force complementarity that requires no slack variables:

\[ h_i \perp a_i \leq y_i \leq b_i \iff a_i \leq y_i \leq b_i, (y_i - a_i)h_i \leq \mu, (y_i - b_i)h_i \leq \mu \]  \hspace{1cm} (9)

Note that unlike the inner products in Section Reformulation, we can expect that one of the inequalities in (9) is unlikely to be binding at a solution (i.e. when \( h_i \) is nonzero). Therefore, we cannot use an equality in this reformulation, and furthermore the products must not be aggregated. Thus, if you use this option, the reformulation automatically enforces the additional options `constraint inequality` and `aggregate none` on the doubly bounded variables, even if the user specifies a conflicting option. Thus the option file

\texttt{reftype mult slack none}

results in the model

\[
\begin{align*}
\min_{x_1, x_2, y_1, y_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad x_1 - y_1 + y_2 - 1 \geq 0, y_1 \geq 0 \\
& \quad (x_1 - y_1 + y_2 - 1)y_1 = \mu \\
& \quad y_2 \in [-1, 1], (y_2 + 1)(x_2 + y_2) \leq \mu, (y_2 - 1)(x_2 + y_2) \leq \mu
\end{align*}
\]

Note that the complementarity constraint associated with \( y_1 \) is an equality (the default) while the constraints associated with \( y_2 \) are inequalities for the reasons outlined above.

In the case of doubly bounded variables, a third option is available for the slack variables, namely `slack one`. In this case, only one slack is introduced, and this slack removes the need to write the function \( h_i \) twice in the reformulated model as follows:

\[ h_i(x, y) \perp a_i \leq y_i \leq b_i \iff a_i \leq y_i \leq b_i, w_i = h_i(x, y), (y_i - a_i)w_i \leq \mu, (y_i - b_i)w_i \leq \mu \]

Note that the slack variable \( w \) that is introduced is a free variable. It is not known before solving the problem whether \( w_i \) will be positive or negative at the solution.

We take this opportunity to introduce a simple extension to our option mechanism, namely the ability to set the options for singly and doubly bounded variables differently. For example, the option file

\texttt{reftype mult slack positive one}
sets the option **slack positive** for the singly bounded variables and the option **slack one** for the doubly bounded variables resulting in the model

\[
\begin{align*}
\min & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\
& \quad w_1 y_1 = \mu_1 \\
& \quad w_2 = x_2 + y_2, y_2 \in [-1,1], (y_2 + 1)w_2 \leq \mu_2, (y_2 - 1)w_2 \leq \mu_2
\end{align*}
\]

Additional options such as

- **initmu** 1.0 3.0
- **numsolves** 2
- **updatefac** 0.1 0.2

allow the values of \( \mu \) for the singly and doubly bounded variables to be controlled separately. In this case \( \mu_1 \) takes on values of 1, 0.1 and 0.01, while \( \mu_2 \) takes on values 3.0, 0.6 and 0.12 in each of the three nonlinear programming models generated.

### 5.28.3.2 NCP functions

An NCP-function is a function \( \phi(r, s) \) with the following property:

\[
\phi(r, s) = 0 \iff r \geq 0, s \geq 0, rs = 0
\]

Clearly, finding a zero of an NCP-function solves a complementarity problem in \((r, s)\). We can replace the inner products of nonnegative vectors in (7) with a vector of NCP functions whose arguments are complementary pairs, e.g. \((y_i - a_i, w_i)\) becomes \(\phi(y_i - a_i, w_i) = 0\), \(i \in \mathcal{L}\) and arrive at another way to treat the complementarity conditions. Note that an NCP function forces both nonnegativity and complementarity, so constraints to explicitly force nonnegativity are not required, though they can be included.

Examples of NCP functions include the min function, \(\min(r, s)\), and the Fischer-Burmeister function

\[
\phi(r, s) = \sqrt{r^2 + s^2} - r - s
\]

There is no requirement that an NCP function be nonnegative everywhere (it may be strictly negative at some points), so there is little point in setting the option **constraint**; it will automatically take on the value **constraint equality**. NCP functions cannot be aggregated, so the **aggregate** option will always be set to **none**.

Since the arguments to the NCP functions are going to be nonnegative at solution, we cannot use the functions \(h_i\) directly in the case of doubly-bounded variables. We must use slacks \(w - v = h_i\) to separate \(h_i\) into its positive and negative parts (but see Section **Doubly bounded variables** below). The slacks can be **positive** or **free**, since the NCP function will force positivity at solution. For the singly-bounded variables, slacks are optional, and can also be **positive** or **free**.

Both of the NCP functions mentioned above suffer from being non-differentiable at the origin (and at points where \(r = s\) for the min function). Various smoothed NCP-functions have been proposed that are differentiable. These smooth functions are parameterized by \(\mu\), and approach the true NCP-function as the smoothing parameter approaches zero. For example, the Fischer-Burmeister function includes a perturbation \(\mu\) that guarantees differentiability:

\[
\phi_{FB}(r, s) := \sqrt{r^2 + s^2} + 2\mu - (r + s).
\]  

(10)

You can choose these particular NCP functions using option **RefType min|FB|fFB**. The difference between the last two is that **RefType FB** writes out GAMS code to compute the function \(\phi_{FB}\), while **RefType fFB** makes use of the GAMS intrinsic function \(\text{NCPF}B(r, s, \mu)\) that computes \(\phi_{FB}\) internally. In general, using the GAMS intrinsic function should work better since the intrinsic can guard against overflow, scale the arguments before computing the function, and use alternative formulas that give more accurate results for certain input ranges.

As an example, the option file
reftype fFB
slack free
initmu 1e-2

generates the reformulation

\[
\begin{align*}
\min_{x_1,x_2,y_1,y_2,w_1,w_2,v_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1 \\
& \quad \phi_{FB}(w_1,y_1,\mu) = 0 \\
& \quad w_2 - v_2 = x_2 + y_2 \\
& \quad \phi_{FB}(y_2 + 1, w_2, \mu) = 0, \quad \phi_{FB}(1 - y_2, v_2, \mu) = 0
\end{align*}
\]

with a value of \( \mu = 0.01 \). Following a path of solutions for decreasing values of \( \mu \) is possible using the options discussed above.

Each of the two arguments to the NCP function will be nonnegative at solution, but for each argument we have the option of including a nonnegativity constraint explicitly as well. This results in the 4 values for the option NCPBounds none|all|function|variable. When no slacks are present, this option controls whether to bound the function \( h_i \) as well as including it in the NCP function, e.g. \( h_i \geq 0, \phi(h_i, y_i - a_i) = 0 \). When slacks are present, we require that the slack setting be consistent with the bound setting for the function argument to the NCP function, where NCPBounds none|variable is consistent with free slack variables and NCPBounds all|function is consistent with positive slack variables.

Thus, the option file

reftype min
slack positive
NCPBounds function

generates the reformulation

\[
\begin{align*}
\min_{x_1,x_2,y_1,y_2,w_1,w_2,v_2} & \quad x_1 + x_2 \\
\text{subject to} & \quad x_1^2 + x_2^2 \leq 1 \\
& \quad w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0 \\
& \quad \min(w_1,y_1) = \mu \\
& \quad w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0 \\
& \quad \min(y_2 + 1, w_2) = \mu, \min(1 - y_2, v_2) = \mu
\end{align*}
\]

The NCPBounds function option means that the variable argument to the NCP function (in this case \( y \)) does not have its bounds explicitly enforced. It should be noted that this nonlinear program has nondifferentiable constraints for every value of \( \mu \). For this reason, the model is constructed as a dnlp model (instead of an nlp model) in GAMS.

A smoothed version of the min function was proposed by Chen & Mangasarian:

\[
\phi_{CM}(r,s) := r - \mu \log(1 + \exp((r - s)/\mu)).
\] (11)

This function is not symmetric in its two arguments, so \( \phi_{CM}(r,s) \neq \phi_{CM}(s,r) \). For this reason, we distinguish between the two cases. Unlike the Fischer-Burmeister function \( \phi_{FB} \), \( \phi_{CM} \) is not defined in the limit (i.e. for \( \mu = 0 \)) if you use GAMS code to compute it. However, the GAMS intrinsic NCPCM(r,s,mu) handles this limit case internally. The option RefType CMxf|CMfx|fCMxf|fCMfx chooses a reformulation based on the function \( \phi_{CM} \). Again, the last two choices use the GAMS intrinsic function.
5.28.3.2.1 Doubly bounded variables Like the mult reformulation (7), reformulations using NCP functions are appropriate as long as we split the function $h_i$ matching a doubly-bounded variable into its positive and negative parts $w_i = v_i = h_i$. To avoid this, Billups has proposed using a composition of NCP functions to treat the doubly-bounded case:

$$h_i \perp a_i \leq y_i \leq b_i \iff \phi_{FB}(y_i - a_i, \phi_{FB}(b_i - y_i, -h_i)) = 0 \quad (12)$$

Use option RefType | fBill to choose such a reformulation for the doubly-bounded variables. The first option value writes out the function in explicit GAMS code, while the second writes it out using the GAMS intrinsic function NCPFB.

5.28.3.3 Penalty functions

All of the reformulations discussed so far have reformulated the complementarity conditions as constraints. It is also possible to treat these by moving them into the objective function with a penalty parameter $1/\mu$: as $\mu$ goes to zero, the relative weight placed on complementarity increases. Ignoring the NLP constraints, we can rewrite the original MPEC problem as

$$\min_{x \in \mathbb{R}^n, y \in \mathbb{R}^m} f(x, y) + \frac{1}{\mu} (y_L - a_L)^T w_L + (b_L - y_L)^T v_L + (y_B - a_B)^T w_B + (b_B - y_B)^T v_B$$

subject to the constraints

$$w_L = h_L(x, y), \quad a_L \leq y_L, \quad w_L \geq 0$$
$$v_L = -h_L(x, y), \quad y_L \leq b_L, \quad v_L \geq 0$$
$$w_B - v_B = h_B(x, y), \quad a_B \leq y_B \leq b_B, \quad w_B \geq 0, \quad v_B \geq 0 \quad (14)$$

Choose this treatment using option RefType penalty. The options aggregate and constraint are ignored, since the inner products here are all aggregated and there are no relevant constraints. It is possible to do a similar reformulation without using slacks, so the options slack none | positive can be used in conjunction with this reformulation type.

The following option file shows the use of the penalty reformulation, but also indicates how to use a different reformulation for the singly and doubly bounded variables:

```
reftype penalty mult
slack none *
initmu 1.0
numsolve 2
updatefac 0.1 0.2
```

The "*" value allows the slack option to take on its existing value, in this case positive. Applied to our simple example given above, such an option file generates the nonlinear programming model:

$$\min_{x_1, x_2, y_1, y_2, w_2, v_2} \quad x_1 + x_2 + \frac{1}{\mu_1} y_1 (x_1 - y_1 + y_2 - 1)$$
subject to

$$x_1^2 + x_2^2 \leq 1$$
$$x_1 - y_1 + y_2 - 1 \geq 0, \quad y_1 \geq 0$$
$$w_2 - v_2 = x_2 + y_2, \quad w_2, v_2 \geq 0, \quad y_2 \in [-1, 1]$$
$$(y_2 + 1)w_2 \leq \mu_2, \quad (1 - y_2)v_2 \leq \mu_2$$

The penalty parameter $\mu_1$ is controlled separately from the doubly bounded constraint parameter $\mu_2$. For consistency with other options, the penalty parameter in the objective is $1/\mu$ meaning that as $\mu_1$ tends to zero, the penalty increases. The option initmu has only one value, so both the singly and doubly bounded $\mu$ values are initialized to 1. In the above example, three solves are performed with $\mu_1 = 1, 0.1$ and $0.01$ and $\mu_2 = 1, 0.2$ and $0.04$.  

---

2146 Solver Manuals
5.28.3.4 Testing for complementarity

In some cases a solution to the reformulated model may not satisfy the complementarity constraints of the original MPEC, e.g. if a large penalty parameter is used in the reformulation. It can also happen that the solution tolerances used in the NLP solver allow solutions with small error in the NLP model but large error in the original MPEC. For example if \( x = f(x) = .001 \) then the NLP constraint \( xf(x) = 0 \) may satisfy the NLP feasibility tolerance but it's not so easy to claim that either \( x \) or \( f(x) \) is zero. The NLPEC solver includes a check that the proposed solution does in fact satisfy the complementarity constraints. The complementarity gap is computed using the definition common to all GAMS MCP solvers in computing the \( \text{objval} \) model attribute for an MCP model. The tolerance used for this complementarity gap can be adjusted using the \texttt{testtol} option.

5.28.4 Options

For details on how to create and use an option file, see the introductory chapter on solver usage.

For most GAMS solvers, the use of an options file is discouraged, at least for those unfamiliar with the solver. For NLPEC, however, we expect that most users will want to use an options file from the very beginning. NLPEC is as much a tool for experimentation as it is a solver, and as such use of the options file is encouraged.

Option values can take many different types (e.g. strings, integers, or reals). Perhaps the most important option to remember is one with no value at all: the \texttt{help} option. \texttt{Help} prints a list of the available options, along with their possible values and some helpful text. The options file is read sequentially, so in case an option value is set twice, the latter value takes precedence. However, any consistency checks performed on the options values (e.g. \texttt{RefType fBill} cannot be used with \texttt{aggregate full}) are made after the entire options file is read in, so the order in which different options appear is not important, provided the options are not specified twice.

5.28.4.1 Setting the Reformulation Options

While NLPEC has many options, there is a small set of five options that, taken together, serve to define the type of reformulation used. Listed in order of importance (highest priority items first), these reformulation options are the \texttt{RefType}, \texttt{slack}, \texttt{constraint}, \texttt{aggregate} and \texttt{NCPBounds} options. In some cases, setting the highest-priority option \texttt{RefType} is enough to completely define a reformulation (e.g. \texttt{RefType penalty} in the case of doubly-bounded variables). In most cases though, the lower-priority options play a role in defining or modifying a reformulation. It's useful to consider the reformulation options in priority order when creating option files to define reformulations.

Some of the combinations of the reformulation options don't make sense. For example, the use of an NCP function to force complementarity between its two input arguments requires a separate function for each complementary pair, so setting both \texttt{RefType min} and \texttt{aggregate full} is inconsistent. NLPEC implements consistency checks on the reformulation options using the priority order: Given a consistent setting of the higher priority options, the next-highest priority option is checked and, if necessary, reset to be consistent with the items of higher priority. The end result is a set of consistent options that will result in a working reformulation. NLPEC prints out the pre- and post-checked sets of reformulation options, as well as warning messages about changes made. In case you want to use an option that NLPEC doesn't think is consistent, you can use the \texttt{NoCheck} option: this suppresses the consistency checks.

Each of the reformulation options in the table below takes two values - one for the singly-bounded variables in \( L \cup U \) and another for the doubly-bounded variables in \( B \). If one option value appears, it sets both option values. When setting both option values, use an asterisk "\*" to indicate no change. So for example, an option file

\[
\text{RefType fCMxf} \\
\text{RefType * fBill}
\]

first sets the \texttt{RefType} to \texttt{fCMxf} for all variable types, and then resets the \texttt{RefType} to \texttt{fBill} for doubly-bounded variables.
### 5.28.4.2 Reformulation Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>

5.28.4.4 The Outdated equreform Option

In the early versions of NLPEC the only way to set the reform type was via the equreform option. Each valid equreform value represented a preselected combination of the options from Section Setting the Reformulation Options. This made it difficult to experiment with combinations not preselected, so the options in Section Setting the Reformulation Options were added. Be default, the equreform option has value 0 and is not used. To get the old behavior, set equreform to a positive value - this will force the options in Section Setting the Reformulation Options to be ignored. The general options in Section General Options are used no matter how the reformulation type is selected - via RefType or equreform.

Table 1: Values for `equreform` option.

### 5.28.5 Open Architecture

In this section we describe the architecture of the NLPEC solver, i.e. the way the solver is put together. This should be useful to anybody using NLPEC for experiments or to those wanting to know the details of how NLPEC works.

The foundation for the NLPEC solver is the software library (also used in the GAMS/CONVERT solver) that allows us to write out a scalar GAMS model that is mathematically equivalent to the original, or
to write out selected pieces of such a model. Using this software, NLPEC creates a GAMS NLP model using one of the reformulation strategies from Section Reformulation. This model may contain many new variables and/or equations, but it will surely contain the (non)linear expressions defining the original model as well. Once the scalar model has been created, NLPEC calls GAMS to solve this model, using the current NLP solver. The option parmFile can be used to pass on additional options to this GAMS job. After the model has solved, NLPEC reads the NLP solution, extracts the MPEC solution from it, and passes this MPEC solution back to GAMS as it terminates.

There are a number of advantages to this architecture. First, its openness makes it easy to see exactly what reformulation is being done. The intermediate scalar GAMS NLP model can be made available after the run by either saving the scratch directory (i.e. run with keep=1) or using the dotGams option to select an alternate file name. This intermediate model contains all the details of the reformulation. It can be used for debugging in case things didn’t work out as expected. It is also possible to modify this file to do some quick and dirty experiments with similar reformulation strategies. Another advantage is the variety of NLP solvers that can be plugged in to solve the reformulated model. There is no need to program (and debug) an interface to an NLP package to run experiments with an NLP solver - the existing GAMS link is all that is needed. It is also easy to experiment with non-default solver options that may be more appropriate for reformulated MPEC models or for a particular choice of reformulation.

5.29 Octeract Engine

Octeract Engine is a deterministic solver to find globally optimal solutions for mixed-integer nonlinear programs (MINLPs). Distinguishing highlights of Octeract are its powerful and flexible symbolic reformulation engine and its parallelism capabilities. For more detailed information, we refer to the Octeract Knowledge Base.

5.29.1 Usage

The following statement can be used inside your GAMS program to specify that Octeract should be used:

Option SOLVER = OCTERACT;

The above statement should appear before the Solve statement. If Octeract was specified as the default solver during GAMS installation, the above statement is not necessary.

GAMS/Octeract by default uses CPLEX to solve LP/MIP problems, if licensed, and CLP/CBC otherwise. By setting options LP_SOLVER or MILP_SOLVER, other solvers can be selected:

- If a license for GAMS/CPLEX, GAMS/OsiCPLEX, GAMS/CPLEX-link is available, then CPLEX can be used.
- If a Gurobi license is installed on the machine, then Gurobi can be used.
- If a FICO Xpress license is installed on the machine, then Xpress can be used. A GAMS/XPRESS license is currently not sufficient.
5.29.1.1 Specification of Octeract Options

GAMS/OCTERACT supports the GAMS parameters reslim, iterlim, nodlim, workspace, optcr, and threads. The interpretation of threads differs from its original meaning in the sense that also on systems with hyperthreading enabled only the number of actual processor cores is taken into account. Further, GAMS/OCTERACT is limited to the use of at most 16 cores and distributed parallelization is not available.

Options can be specified by a solver options file. A small example for an octeract.opt file is:

```
LP_SOLVER HIGHS
MILP_SOLVER HIGHS
STARTING_POINT_IPOPT VARIABLE_MID_POINT
```

It causes Octeract to use HiGHS to solve LP or MIP problems and to use a different starting point strategy for calls of Ipopt.

5.29.2 List of Octeract Options

In the following, we give a detailed list of all Octeract options.

5.29.2.1 Octeract Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPLY_CB</td>
<td>This enables or disables constraint probing for domain reduction.</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>BIG_COEFF_TOLERANCE</td>
<td>Sets the maximum acceptable absolute value of a coefficient in the lower bounding problem. If a coefficient is greater than this number, the solver will use other, less effective methods instead of solving the lower bounding linear problem (LP).</td>
<td>1e+09</td>
</tr>
<tr>
<td></td>
<td>Range: [0, ∞]</td>
<td></td>
</tr>
<tr>
<td>BIG_GAP_TOLERANCE</td>
<td>This option states that if the difference between a node’s upper bound and the parent’s lower bound is smaller than BIG_GAP_TOLERANCE, then solve the relaxation.</td>
<td>1e+60</td>
</tr>
<tr>
<td></td>
<td>Range: [0, ∞]</td>
<td></td>
</tr>
<tr>
<td>BINARY_REFORMULATION_PROCEDURE</td>
<td>If REFORMULATE_BINARIES is enabled, this option determines which method to use in the reformulation of binary variables.</td>
<td>Quadratic_Concave_Constraint</td>
</tr>
<tr>
<td></td>
<td>Range: Quadratic_Concave_Constraint, Quadratic_Equality_Constraint, Exponential_Reformulation, Continuous_Relaxation.</td>
<td></td>

<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>BOUND_VIOLATION_TOLERANCE</td>
<td>Bound violation tolerance is used to confirm whether solutions returned by third-party solvers are indeed feasible, within that tolerance. Relaxing this tolerance can help in problems where finding a feasible solution is difficult, or where the global solution is eliminated due to slight constraint violations. Range: [0, 1]</td>
<td>1e-08</td>
</tr>
<tr>
<td>BQCQP_REFORMULATION_METHOD</td>
<td>Type of reformulation used for BQCQP's. The default option is SSLINEARBQCQP which linearises the BQCQP following Sherali and Smith, “An improved linearization strategy for zero-one quadratic programming problems”, 2007. The CONVEXIFY option tries to convexify the problem in a similar way as the convexification for BQP's. See also the Octeract docu. Range: SSLINEARBQCQP, CONVEXIFY</td>
<td>SSLINEARBQCQP</td>
</tr>
<tr>
<td>BQP_REFORMULATION_METHOD</td>
<td>The BQP_REFORMULATION_METHOD option allows the user to select the reformulation method applied to Binary Quadratic Problems during the solving process. See also the Octeract docu. Range: AUTOMATIC, LINEAR, QUADRATIC, SSLINEAR</td>
<td>AUTOMATIC</td>
</tr>
<tr>
<td>BQP_SPARSITY_TOLERANCE</td>
<td>The maximal sparsity for a Binary Quadratic Problem (BQP) to be reformulated as a linear problem. Range: [0, 1]</td>
<td>0.8</td>
</tr>
<tr>
<td>BRANCHING_STRATEGY</td>
<td>The heuristic for selecting the variable to branch in the branch and bound method when solving a problem. See also the Octeract docu. Range: AUTOMATIC, MOST_VIOLATED_TERM, HYBRID_INTEGER_LEAST_REduced_AXIS, MAX_SEPArATION_DISTANCE, STRONG_BRANCHING</td>
<td>AUTOMATIC</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>

<tr>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>CALCULATE_LB_LARGE_COEFS</td>
<td>If this option is enabled, the Engine will remove constraints with large coefficients when solving a relaxation to find the lower bound of a problem.</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>CBC_LB_MAX_NODES</td>
<td>This sets the maximum number of nodes to explore by CBC when it is used to solve a relaxation to find the lower bound of the problem.</td>
<td>1000</td>
</tr>
<tr>
<td></td>
<td>Range: {0, ..., 2000000000}</td>
<td></td>
</tr>
<tr>
<td>CBC_PRESOLVE</td>
<td>This enables or disables the CBC presolver.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_VIOLATION_TOLERANCE</td>
<td>This tolerance determines the acceptable constraint violation when applying domain reduction techniques. Relaxing this tolerance can help in problems where finding a feasible solution is difficult, or where the global solution is eliminated due to slight constraint violations.</td>
<td>1e-06</td>
</tr>
<tr>
<td></td>
<td>Range: [0, 1]</td>
<td></td>
</tr>
<tr>
<td>CONVERGENCE_TOLERANCE</td>
<td>This sets a tolerance to determine whether the algorithm has converged to global optimality. Note that this is used as both absolute and a relative gap tolerance. See also the Oysteract docu.</td>
<td>GAMS optcr</td>
</tr>
<tr>
<td></td>
<td>Range: [0, ∞]</td>
<td></td>
</tr>
<tr>
<td>CP_MAX_ITERATIONS</td>
<td>This option sets the limit for the number of iterations performed by Constraint Propagation (CP). See also the Oysteract docu.</td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>Range: {0, ..., ∞}</td>
<td></td>
</tr>
<tr>
<td>CP_NUMBER_COMPARISON_TOLERANCE</td>
<td>This is the tolerance for comparison of two values within the Constraint Propagation (CP) algorithm, used in particular for the purpose of updating bounds with tighter ones. See also the Oysteract docu.</td>
<td>1e-06</td>
</tr>
<tr>
<td></td>
<td>Range: [0, 1]</td>

<tr>
<td>HEUR_SAP</td>
<td>This option enables or disables the Shift and Propagate (SAP) heuristic. Range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>HEUR_ZERO</td>
<td>This option enables or disables the Zero heuristic. Range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>INFINITY</td>
<td>This sets the default bound for unbounded variables. Global optimisation requires all variables to be bounded before the solving process begins. If you do not provide bounds for a variable, its bounds will be automatically set to ±INFINITY. The default value is quite conservative - reducing this number can greatly improve performance. Range: [0, ∞]</td>
<td>1e+07</td>
</tr>
<tr>
<td>INTEGER_REFORMULATION_VAR_RANGE_LIMIT</td>
<td>This option sets the maximum bound difference for integer variables in IQP and IQCQP, for which integer reformulation is to be applied. This is necessary to avoid creating huge problems with poor accuracy and numerical issues. Range: {0, ..., 100000}</td>
<td>5000</td>
</tr>
<tr>
<td>INTEGRALITY_VIOLATION_TOLERANCE</td>
<td>Integrality violation tolerance is the acceptable violation before the solver determines that a variable is no longer an integer. Relaxing this tolerance can prevent integer solutions from being fathomed due to small constraint violations. Range: [0, 1]</td>
<td>0.001</td>
</tr>
<tr>
<td>IPOPT_INITIAL_VALUE</td>
<td>When STARTING_POINT_IPOPT is set to CUSTOM_CONSTANT_VALUE, IPOPT_INITIAL_VALUE determines the value of the initialisation of the primal variables given to IPOPT. See also the Octeract docu. Range: real</td>
<td>1</td>
</tr>
<tr>
<td>IS_PURGE_CUTS_ENABLED</td>
<td>The option allows flagging for purging cuts. This is for cut management purposes. Range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>LLB_TOLERANCE</td>
<td>This tolerance is used to compare solutions of upper bounding problems and lower bounding problems. These two numbers are typically results of two separate local optimisation problems, potentially using two different third-party solvers. Range: $[0, \infty]$</td>
<td>0.001</td>
</tr>
<tr>
<td>LP_SOLVER</td>
<td>This sets the solver which will be used to solve Linear Programming (LP) problems. Range: IPOPT, OSICLP, OSICBC, CPLEX, GUROBI, XPRESS, HIGHS</td>
<td>OSICLP</td>
</tr>
<tr>
<td>MAX_CB_DEPTH</td>
<td>This sets the maximum depth in the branching tree at which constraint probing should be adding additional constraints. If this is set to 0, depth is unlimited. Range: ${0, \ldots, \infty}$</td>
<td>1</td>
</tr>
<tr>
<td>MAX_SOLVER_ITERATIONS</td>
<td>This sets the maximum number of solver iterations in serial mode (this option is ignored in parallel mode). Range: ${1, \ldots, \infty}$</td>
<td>GAMS iterlim</td>
</tr>
<tr>
<td>MAX_SOLVER_MEMORY</td>
<td>This option sets the memory limit allowed during the solving process, i.e. if the memory used exceeds this limit the solving process is terminated. Range: ${0, \ldots, \infty}$</td>
<td>GAMS workspace</td>
</tr>
<tr>
<td>MAX_SOLVER_TIME</td>
<td>This sets a timeout for the solver in seconds (elapsed real time). Range: $[1, \infty]$</td>
<td>GAMS reslim</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>MILP_LB_TIMEOUT</td>
<td>This option sets the timeout (in seconds) for the MIP solver that it is used to solve MILP lower bounding problems at every node of the branch-and-bound tree (e.g., relaxations of MINLPs). The suggestion to change this option is usually triggered when the MILP problems often time out. In this case, you have two options: (i) increase the timeout, or (ii) decrease the timeout. A larger timeout could result in some/all MILP problems being solved to global optimality, which can produce superior bounds. If those problems are really hard to solve, it is often practical to reduce the timeout to 1. Doing so effectively means that we don’t waste too much computing time on sub-problems that can not be solved quickly, and redirect that time to the engine's own branch-and-bound. Range: $[1, \infty]$</td>
<td>5</td>
</tr>
<tr>
<td>MILP_SOLVER</td>
<td>This sets the solver which will be used to solve Mixed-integer Linear Programming (MILP) problems. Range: OSICBC, CPLEX, GUROBI, XPRESS, HIGHS</td>
<td>OSICBC</td>
</tr>
<tr>
<td>MIP_SOLVER</td>
<td>Umbrella option to use the specified MIP solver to solve all types of sub-problems it supports. If set to OSICBC/HIGHS, it will overwrite LP_SOLVER and MILP_SOLVER. If set to CPLEX, it will override LP_SOLVER, MILP_SOLVER, QP_SOLVER, and QCQP_SOLVER. Range: CPLEX, OSICBC, HIGHS</td>
<td>CPLEX if licensed, otherwise OSICBC</td>
</tr>
<tr>
<td>NUM_CORES</td>
<td>This sets the number of cores to be used by the Engine to solve the problem. Range: ${-\infty, \ldots, 16}$</td>
<td>GAMS threads</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>NUMBER_COMPARISON_TOLERANCE</td>
<td>This tolerance is used to determine whether two floating point numbers are the same. Its use in the solver is context sensitive, as outward rounding is always used to ensure that solutions are not incorrectly eliminated. Range: [0, 1]</td>
<td>1e-06</td>
</tr>
<tr>
<td>OBBT_MAX_DEPTH</td>
<td>This sets the maximum depth in the branching tree at which Optimisation Based Bounds Tightening (OBBT) should be applied. See also the Octeract docu. Range: (1, \ldots, \infty)</td>
<td>(\infty)</td>

5.30 ODHCPLEX

5.30.1 Introduction

GAMS/ODHCPLEX is a solver from Optimization Direct Inc. that implements a set of heuristic methods (named ODHeuristics) for finding feasible solutions to Mixed Integer Programming (MIP and MIQCP) models that uses IBM CPLEX as its underlying solver engine. It is designed for large-scale models which a MIP solver would find intractable: either by it being unable to find feasible solutions at all or; more usually, by being unable to find feasible solutions of adequate quality in the time available to its user.

It is intended for users who are familiar with MIP modelling and have some knowledge of using the GAMS/CPLEX solver. GAMS/ODHCPLEX does not demand expert specialism in this field.

ODHCPLEX can be used in two ways: it is implemented as a stand-alone ODHeuristic engine, which can be used on its own (ODHeuristicMethod=STANDALONE); and also within the CPLEX optimizer, within which it can supply and receive solutions from the main CPLEX caller (ODHeuristicMethod=ODH-CPLEX (default)) thereby accelerating optimization compared with GAMS/CPLEX run on its own.

The ODHeuristic engine has a heuristic method for finding an initial feasible solution that it designed to complement, those of CPLEX. Since its main algorithmic procedure works by improving an incumbent feasible solution, getting an initial one is important and may consume a significant part of its total runtime. When used on its own (i.e. ODHeuristicMethod=STANDALONE), users should experiment to discover whether ODHeuristics' or CPLEX's initial feasible solution methods work best, but within ODH-CPLEX (i.e. ODHeuristicMethod=ODH-CPLEX) both methods are run in parallel and the winner is chosen automatically.

ODHeuristics' principal algorithm works by solving a sequence of sub-models. An innovative aspect of this process is its ability to use the model's symbolic structure to achieve the sub-model decomposition. It does this by analyzing the symbolic names that the user gives to the decision variables and careful specification of how this should be done this is worthwhile. ODHCPLEX can work without this analysis, but it usually takes about twice as much runtime.

## 5.29.2.2 Link Options
5.30.2 Specifying Model Structure

The ODHeuristic method needs to break the model down into sub-models. It can do this in one of three ways:

1. Automatically using its decomposition heuristic;

2. Using information specified by the user in the IndexKey parameter;

3. By simply assigning each variable to a different block (or key); or

4. By using the dot option notation with the option .key.

By default, the program will use information specified by the IndexKey parameter if it is set and its automatic decomposition heuristic otherwise. This may be overridden by the Decomposition parameter. If it is set to 0 (zero), option 3 above is selected. If it is set to 1, its automatic decomposition method is used, and if it is set to 2, option 4 above is selected.

Whilst the automatic decomposition method often works well, there may be an advantage to specifying decomposition through the IndexKey parameter. After performing the decomposition in whatever way, the program analyses the decomposition and displays statistics showing the maximum and minimum number of variables in each key or block and showing a percentage score to the decomposition as a whole. A typical display is of the form:

Variables/key 205.58 (+/-304.79), max/min variables/key 933(32) / 60(113).
There are 227 keys (4149 keys were dropped) with 46872 values.
Decomposition score 13.66%, graph score 2074/3135232.

Other things (such as the distribution of variables in keys and the number of keys) being equal, the smaller the percentage decomposition score, the better the decomposition is and the more effective the program will be.

5.30.2.1 Using the IndexKey parameter

The program needs to associate sets of variables with distinct values of a single index. The user can specify this association with a pattern to which some or all of the variables conform. The pattern is in standard C scanf format (see, for example, Kernighan and Ritchie’s 2nd edition of The C Programming Language, section B1.3 Formatted Input). Currently allowable index values must be non-negative integers, so the pattern must include d. For example, if we have variables x whose first index names starts with a number of letters then an underscore followed by a numeric index value (like x(firstone_1), x(another_1), x(firstone_2), x(another_2), ...) the pattern

\[ x(%*[\text{a-z}]_%d) \]

associates those variables whose name ends in _1 with index value 1, those whose name ends in _2 with index value 2 and so on. The pattern is called an index key referred to by the program as the option parameter IndexKey, for example

\[ \text{IndexKey}=%*[\text{xy}(t_%d) \]
It may, however, be desirable to consider variables whose names are, say, \( x(t_2) \) and \( y(t_2) \), to belong to different index values, i.e. to belong to different groups. One way of doing this is to identify them with separate index keys. These can be supplied to \texttt{IndexKey} as two fields separated by a semi-colon, for example

\[
\text{IndexKey}=x(t_{\%d});y(t_{\%d})
\]

Up to 10 fields can be specified in this way.

On the other hand, it may be desirable to consider such variables as having the same index key and their nomenclature may not permit their identification by a single key field. For example, suppose there are variables \( john(t_1), john(t_2), \ldots, jane(t_1), jane(t_2), \ldots \) and \( johnny(t_1), johnny(t_2), \ldots \) and we want to associate \( john(t_x) \) and \( jane(t_x) \) as belonging to key value \( x \), but want to ignore \( johnny(t_x) \).

Two key fields can be used to do this by

\[
\text{INDEXKEY}=john(t_{\%d});jane(t_{\%d})
\]

By default \( john(t_2) \) and \( jane(t_2) \) would not share the same index value, but if the option parameter \texttt{KeyType}, is set to 1, the heuristic will group them together so as to share the same index.

If \texttt{IndexKey} is not specified, the program uses a default decomposition.

The program divides the model up into parts associated with different values of the \texttt{IndexKey} (if specified), using an integer interval divisor. Initially this is a number not less than 2 and it is increased as the search progresses. When no improved solution is found after a number, \texttt{MaxRepeat}, of attempts with the maximum interval divisor, \texttt{MaxInterDiv}, the program terminates. Default values are provided for \texttt{MaxRepeat} and \texttt{MaxInterDiv}, so these do not have to be specified by the user.

### 5.30.3 Heuristic Parameters

There are a number of other parameters which control the behaviour of the heuristic program. These may be left at their default values or specified on the GAMS/ODHCPLEX option file. In addition, many GAMS/CPLEX options can be supplied in the GAMS/ODHCPLEX option file to tweak the CPLEX behavior, see tables below. Note however that - although they can be technically set - these GAMS/CPLEX options may not have any influence on a GAMS/ODHCPLEX solve. For detailed descriptions of the GAMS/CPLEX options, see Detailed Descriptions of CPLEX Options.

Parameter names and their meanings are summarized in the table below.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

</tbody>
</table>
### 5.30.4 Parallel execution using multiple threads

Both ODHHeuristicMethods STANDALONE and ODH-CPLEX can use multiple simultaneous threads. ODH-CPLEX must use separate threads for the main CPLEX solve and for the ODHeuristics engine. The STANDALONE just uses the ODHeuristics engine which may use multiple simultaneous threads. Thus the processing capability of multi-core hardware can be exploited effectively.

GAMS/ODHCPLEX will ignore the GAMS threads parameter and use its own default. The default ODHeuristic method (i.e. ODH-CPLEX) requires multiple threads to work and with the GAMS threads default of 1 this will not work.

Whilst there are good defaults for allocating available threads, it may be worthwhile to give some attention to the allocation of threads between the main CPLEX solver and the ODHeuristics engine for ODH-CPLEX and STANDALONE.

If the option ODHThreads is set to \( n \), \( n \) threads are allocated in total, otherwise the total number of threads allocated for both ODH-CPLEX and STANDALONE is set to the number of physical processors available on the computer. If the ODHThreads option is set to a number greater than the number of available processors, multiple threads will have to share the same processor, which may severely degrade performance.

In general, the more threads allocated to the main CPLEX solver, the faster it will run, and similarly, the more allocated to the ODHeuristics engine, the faster it will run. The best balance depends on the model being solved and whether it is intended to run to optimality or to an optimality gap of (say) 0.05 or 0.1. If the GAMS/Cplex Threads is not set, ODH-CPLEX defaults to allocating a quarter of the threads to the ODHeuristics engine and the remainder to the main CPLEX solve. Otherwise it allocates the specified number of threads to the main CPLEX solver and the remainder to the ODHeuristics engine.

Within the ODHeuristics engine, the principal heuristic algorithm can run in parallel on multiple threads. Each algorithmic thread uses CPLEX to solve sub-models and each such instance of CPLEX can itself run on multiple threads. So some attention needs to be given to the allocation of threads between them. If SUB_CPX_THREADS is not set, the CPLEX solver will use one thread for each available logical processor to solve the sub-models. This means that only one thread will be available for the solution improvement heuristic. If the option SUB_CPX_THREADS is set, then by default the heuristic engine sets its number of algorithmic threads to

\[
\text{number_of_available_processors} / \text{SUB_CPX_THREADS}
\]

where number_of_available_processors is: the number of logical processors for STANDALONE; and for ODH-CPLEX it is this number less those allocated to the main CPLEX solver.

Many Intel and compatible processors support hyperthreading (where this is enabled on the computer and operating system) and if so there will be two logical processors for every physical core. Using them can severely degrade performance, so if they are enabled it is often a good idea to set ODHThreads to the number of physical processors. Note that on machines with a large number of processors (cores), the principal bottleneck for large scale optimization is usually memory access. In practice it is often better to
use only about half of the available cores on (say) a 24 core Intel Xeon system. This is model dependent and some experimentation is worthwhile.

Although the operating system's scheduler usually allocates threads to logical processors so that they run on separate physical cores where possible, it will have more threads to manage than those of the heuristic or CPLEX and so will change this allocation as the heuristic and CPLEX run so as to balance its workload effectively. There is a performance penalty to doing this from the perspective of the heuristic run time. For the ODHeuristics STANDALONE, this can be avoided by locking the heuristic threads to specific processors by setting the heuristic option parameter ProcessorLock to 1. It is not supported for ODH-CPLEX. Under Windows, beware that the threads need to be locked at an above normal priority so this may have a negative impact on other programs concurrently running on the machine.

5.30.5 Determinism

Many users require that repeated runs of their applications under the same conditions give the same results, albeit in slightly variable times. The heuristic runs in this way by default. However, there is a performance penalty that has to be paid for synchronizing the threads. On average, performance can be considerably improved performance at the expense of non-repeatable execution by setting the heuristic option parameter Deterministic to 0. This is often preferred by users with particularly large and difficult models.

5.30.6 Detailed Descriptions of ODHCLPEX Options

advind (integer): advanced basis use

   Default: 1

aggecutlim (integer): aggregation limit for cut generation

   Default: 3

aggfill (integer): aggregator fill parameter

   Default: 10

aggind (integer): aggregator on/off

   Default: -1

auxrootthreads (integer): number of threads for auxiliary tasks at the root node

   Default: 0

baralg (integer): algorithm selection

   Default: 0

barcolnz (integer): dense column handling

   Default: 0

barcrossoalg (integer): barrier crossover method

   Default: 0
**5.30 ODHCPLEX**

`bardisplay` *(integer)*: progress display level

- Default: 1

`barepcomp` *(real)*: convergence tolerance

- Default: $1.0 \times 10^{-8}$

`bargrowth` *(real)*: unbounded face detection

- Default: $1.0 \times 10^{12}$

`baritlim` *(integer)*: iteration limit

- Default: 2147483647

`barmaxcor` *(integer)*: maximum correction limit

- Default: $-1$

`barobjrng` *(real)*: maximum objective function

- Default: $1.0 \times 10^{20}$

`barorder` *(integer)*: row ordering algorithm selection

- Default: 0

`barqcpepcomp` *(real)*: convergence tolerance for the barrier optimizer for QCPs

- Default: $1.0 \times 10^{-7}$

`barstartalg` *(integer)*: barrier starting point algorithm

- Default: 1

`bbinterval` *(integer)*: best bound interval

- Default: 7

`bendersfeascuttol` *(real)*: Tolerance for whether a feasibility cut has been violated in Benders decomposition

- Default: $1.0 \times 10^{-6}$

`bendersoptcuttol` *(real)*: Tolerance for optimality cuts in Benders decomposition

- Default: $1.0 \times 10^{-6}$

`bendersstrategy` *(integer)*: Benders decomposition algorithm as a strategy

- Default: 0

`bndstrenind` *(integer)*: bound strengthening

- Default: $-1$

`bqpcuts` *(integer)*: boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality
Default: 0

**brdir** (integer): set branching direction
Default: 0

**bttol** (real): backtracking limit
Default: 1.0

**calcqcpduals** (integer): calculate the dual values of a quadratically constrained problem
Default: 1

**cliques** (integer): clique cut generation
Default: 0

**clocktype** (integer): clock type for computation time
Default: 2

**clonelog** (integer): enable clone logs
Default: 0

**coeredind** (integer): coefficient reduction on/off
Default: -1

**conflictalg** (integer): algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model
Default: 0

**conflictdisplay** (integer): decides how much information CPLEX reports when the conflict refiner is working
Default: 1

**covers** (integer): cover cut generation
Default: 0

**cpumask** (string): switch and mask to bind threads to processors (Linux only)
Default: auto

**cpxpresolve** (integer): Applies CPLEX presolve to full model
Default: 0

<table>
<thead>
<tr>

5.30 ODHCPLEX

**craind (integer):** crash strategy (used to obtain starting basis) →

Default: 1

**cutlo (real):** lower cutoff for tree search →

Default: \(-1.0e+75\)

**cutoff (real):** GMO cutoff →

Default: 0.0

**cutpass (integer):** maximum number of cutting plane passes →

Default: 0

**cuts (string):** default cut generation →

Default: 0

**cutsfactor (real):** cut limit →

Default: \(-1.0\)

**cutup (real):** upper cutoff for tree search →

Default: \(1.0e+75\)

**datacheck (integer):** controls data consistency checking and modeling assistance →

Default: 0

**decompdensity (real):** Matrix density above which automatic decomposition assigns each variable to a separate key →

Default: 0.3

**decomposition (integer):** Model decomposition method. →

Default: \(-1\)

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>0</td>
<td>Assign each variable to a separate key</td>
</tr>
<tr>
<td>1</td>
<td>Use automatic decomposition method</td>
</tr>
<tr>
<td>2</td>
<td>Use decomposition based on dot option .key</td>
</tr>
</tbody>
</table>

**depind (integer):** dependency checker on/off →

Default: \(-1\)

**deterministic (boolean):** Specifies whether the solution improvement heuristic is run in deterministic or opportunistic (i.e. non-deterministic) mode →

Default: 1
<p>| | |</p>
<table>
<thead>

**dettilim** *(real)*: deterministic time limit

Default: $1.0e+75$

**disjcuts** *(integer)*: disjunctive cuts generation

Default: 0

**divetype** *(integer)*: MIP dive strategy

Default: 0

**divflt** *(real)*: solution pool range filter coefficients

Default: 0

**divfltol** *(real)*: lower bound on diversity

Default: `mindouble`

**divfltup** *(real)*: upper bound on diversity

Default: `maxdouble`

**divisor** *(integer)*: Initial divisor for sub models

Initial sub model size is model size times 1 over Divisor. Ignored if `InterDiv` is set.

Default: `automatic`

**domlim** *(integer)*: domain violation number

Default: 0

**dprind** *(integer)*: dual simplex pricing

Default: 0

**dynamicrows** *(integer)*: switch for dynamic management of rows

Default: $-1$

**dynamicssearch** *(integer)*: Search strategy for CPLEX caller and sub-model solves

Default: $-1$
**eachcutlim (integer):** sets a limit for each type of cut

Default: 2100000000

**epagap (real):** absolute stopping tolerance

Synonym: optca

Default: $1.0 \times 10^{-6}$

**epgap (real):** relative stopping tolerance

Synonym: optcr

Default: $1.0 \times 10^{-4}$

**epint (real):** integrality tolerance

Default: $1.0 \times 10^{-5}$

**eplin (real):** degree of tolerance used in linearization

Default: 0.001

**epmrk (real):** Markowitz pivot tolerance

Default: 0.01

**epopt (real):** optimality tolerance

Default: $1.0 \times 10^{-6}$

**epper (real):** perturbation constant

Default: $1.0 \times 10^{-6}$

**eprelax (real):** relaxation for feasOpt

Default: $1.0 \times 10^{-6}$

**eprhs (real):** feasibility tolerance

Default: $1.0 \times 10^{-6}$

**extracplexlog (boolean):** Write addition CPLEX output to log

Default: 0

<table>

</table>

firstfeas effort (integer): Effort limit on first feasible heuristic

If the option value is positive the exact value is used as the level of effort. If the value is negative no more than the absolute value of the option is used as the level of effort. The larger the effort level, the more effort is expended before giving up.
Default: -500

firstfeas shift (integer): First feasible heuristic variable shifting in found solutions

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not shift</td>
</tr>
<tr>
<td>1</td>
<td>Moderate shifting</td>
</tr>
<tr>
<td>2</td>
<td>Aggressive shifting</td>
</tr>
</tbody>
</table>

fixoptfile (string): name of option file which is read just before solving the fixed problem

flowcovers (integer): flow cover cut generation
Default: 0

flowpaths (integer): flow path cut generation
Default: 0
**folding (integer):** LP folding will be attempted during the preprocessing phase

Default: -1

**fpheur (integer):** feasibility pump heuristic

Default: 0

**fraccand (integer):** candidate limit for generating Gomory fractional cuts

Default: 200

**fraccuts (integer):** Gomory fractional cut generation

Default: 0

**fracpass (integer):** maximum number of passes for generating Gomory fractional cuts

Default: 0

**freegamsmodel (boolean):** preserves memory by dumping the GAMS model instance representation temporarily to disk

Default: 0

**globalbounds (integer):** Use of global bounds from CPLEX caller

Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Never use</td>
</tr>
<tr>
<td>2</td>
<td>Always use</td>
</tr>
<tr>
<td>1-4</td>
<td>Intensity of use</td>
</tr>
</tbody>
</table>

**gubcovers (integer):** GUB cover cut generation

Default: 0

**heurfreq (integer):** heuristic frequency

Default: 0

**heuristicEffort (real):** the effort that CPLEX spends on heuristics during a MIP solve

Default: 1.0

**implbd (integer):** implied bound cut generation

Default: 0

**indexkey (string):** Pattern used to match variable names for grouping into sub-models discussed above

**indicoptstrict (boolean):** abort in case of an error in indicator constraint in solver option file

Default: 1

**integeronly (integer):** Variables to include in INDEXKEY

Default: -1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>0</td>
<td>All variables</td>
</tr>
<tr>
<td>1</td>
<td>Only non-continuous variables</td>
</tr>
</tbody>
</table>

**integertol** *(real)*: Integrality tolerance for variable values

Default: $1e^{-5}$

**interdiv** *(integer)*: Initial divisor value

Default: 4

**intsollim** *(integer)*: maximum number of integer solutions

Default: 2147483647

**itlim** *(integer)*: iteration limit

Synonym: iterlim

Default: 2147483647

**.key** *(integer)*: Variable block or key number

Default: 0

**keytype** *(boolean)*: Treatment of multiple INDEXKEYs

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Considered separately e.g. INDEXKEY=x₂;y₂ means x₂ and y₂ belong to separate groups</td>
</tr>
<tr>
<td>1</td>
<td>Considered together e.g. INDEXKEY=x₂;y₂ means x₂ and y₂ belong to the same group</td>
</tr>
</tbody>
</table>

**.lazy** *(boolean)*: Lazy constraints activation

Default: 0

**lazyconstraints** *(boolean)*: Indicator to use lazy constraints

Default: 0

**lbheur** *(boolean)*: local branching heuristic

Default: 0

**liftprojcuts** *(integer)*: lift-and-project cuts

Default: 0

**localimplied** *(integer)*: generation of locally valid implied bound cuts
lpmethod (integer): algorithm to be used for LP problems

Default: 0

maxbacktrack (integer): The maximum number of backtracks permitted in sub-model solves

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>0</td>
<td>Infinite</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Use this value if a better solution is available</td>
</tr>
</tbody>
</table>

maxbound (real): The largest (smallest) non infinite bound value ODH will accept for upper (lower) bounds

If this value is positive, bounds exceeding MAXBOUND are reduced to MAXBOUND; if this value is negative, bounds exceeding -MAXBOUND are ignored.

Default: 1e+9

maxinfrepeat (integer): Maximum divisor value when solution is infeasible

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatically determined</td>
</tr>
<tr>

</tbody>
</table>

maxinterdiv (integer): Maximum divisor value

Default: 0

maxrepeat (integer): Maximum number of sub-model repeat solves for each divisor value

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatically determined</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Use this value</td>
</tr>
</tbody>
</table>

mcfcuts (integer): multi-commodity flow cut generation

Default: 0

memoryemphasis (boolean): reduces use of memory

Default: 0

mipdisplay (integer): progress display level
Default: 2

**mipemphasis** *(integer)*: MIP solution tactics

Default: 0

**mipinterval** *(integer)*: progress display interval

Default: 0

**mipkappastats** *(integer)*: MIP kappa computation

Default: 0

**mipordind** *(boolean)*: priority list on/off

Synonym: prioropt

Default: 1

**mipordtype** *(integer)*: priority order generation

Default: 0

**mipsearch** *(integer)*: search strategy for mixed integer programs

Default: 0

**mipstart** *(integer)*: use mip starting values

Default: 0

**miqcpstrat** *(integer)*: MIQCP relaxation choice

Default: 0

**mircuts** *(integer)*: mixed integer rounding cut generation

Default: 0

**mpslongnum** *(boolean)*: MPS file format precision of numeric output

Default: 1

**multimipstart** *(string)*: use multiple mipstarts provided via gdx files

**multobjdisplay** *(integer)*: level of display during multiobjective optimization

Default: 1

**names** *(boolean)*: load GAMS names into Cplex

Default: 1

**netdisplay** *(integer)*: network display level

Default: 2

**netepopt** *(real)*: optimality tolerance for the network simplex method

Default: 1.0e-06

**neteprhs** *(real)*: feasibility tolerance for the network simplex method

Default: 1.0e-06

**netfind** *(integer)*: attempt network extraction

Default: 2

**netitlim** *(integer)*: iteration limit for network simplex

Default: 2147483647

**netppriind** *(integer)*: network simplex pricing

Default: 0

**newcallback** *(integer)*: CPLEX call-back type used

Default: 1
### nodecuts (integer)

Decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree

- Default: 0

### nodefileind (integer)

Node storage file indicator

- Default: 1

### nodelim (integer)

Maximum number of nodes to solve

- Synonym: nodlim
- Default: 2147483647

### nodesel (integer)

Node selection strategy

- Default: 1

### numericalemphasis (boolean)

Emphasizes precision in numerically unstable or difficult problems

- Default: 0

### objdif (real)

Overrides GAMS Cheat parameter

- Synonym: cheat
- Default: 0.0

### objllim (real)

Objective function lower limit

- Default: -1.0e+75

### objtarget (real)

Target objective value

- ODHeuristics terminates when this value is reached. Defaults to -infinity for minimization or +infinity for maximization models.
- Default: 0

### objulim (real)

Objective function upper limit

- Default: 1.0e+75

### odheuristicmethod (string)

ODHeuristic method section

- Default: ODH-CPLEX
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

<tr>
<td>&gt;0</td>
<td>Use the specified number of threads</td>
</tr>
</tbody>
</table>

**odhtimelimit (real):** Elapsed time limit in seconds

Synonym: reslim

Default: GAMS ResLim

**optimalitytarget (integer):** type of optimality that Cplex targets

Default: 0

**parallelmode (integer):** parallel optimization mode

Default: 0

**paramdisplay (boolean):** display the nondefault parameters before optimization

Default: 1

**penalty (real):** The objective function coefficient value for penalties

The objective function coefficient value for the penalties introduced to deal with infeasibilities in the solution improvement heuristic. It is set by default when required and if not specified.

Default: -1

**penperturb (real):** Perturbation tolerance for penalties coefficients
Default: 0

perind (boolean): force initial perturbation ←

Default: 0

perlim (integer): number of stalled iterations before perturbation ←

Default: 0

phase12 (boolean): Specifies whether to use a phaseI/phaseII method to remove infeasibilities ←

Default: 1
### value  |  meaning
---|---
0  |  Use composite objective method
1  |  Use phaseI/phaseII method

**polishafterdettim** *(real)*: deterministic time before starting to polish a feasible solution

Default: \(1.0 \times 10^{75}\)

**polishafterepagap** *(real)*: absolute MIP gap before starting to polish a feasible solution

Default: 0.0

**polishafterepgap** *(real)*: relative MIP gap before starting to polish a solution

Default: 0.0

**polishafterintsol** *(integer)*: MIP integer solutions to find before starting to polish a feasible solution

Default: 2147483647

**polishafternode** *(integer)*: nodes to process before starting to polish a feasible solution

Default: 2147483647

**polishaftertime** *(real)*: time before starting to polish a feasible solution

Default: \(1.0 \times 10^{75}\)

**populatelim** *(integer)*: limit of solutions generated for the solution pool by populate method

Default: 20

**ppriind** *(integer)*: primal simplex pricing

Default: 0

**predual** *(integer)*: give dual problem to the optimizer

Default: 0

**preind** *(boolean)*: turn presolver on/off

Default: 1

**prelinear** *(boolean)*: linear reduction indicator

Default: 1

**prepass** *(integer)*: number of presolve applications to perform

Default: -1

**prereform** *(integer)*: set presolve reformulations

Default: 3

**preslvnd** *(integer)*: node presolve selector
5.30 ODHCPLEX

Default: 0

**pricelim (integer):** pricing candidate list

Default: 0

**printoptions (boolean):** list values of all options to GAMS listing file

Default: 0

**probe (integer):** perform probing before solving a MIP

Default: 0

**probedettime (real):** deterministic time spent probing

Default: 1.0e+75

**probetime (real):** time spent probing

Default: 1.0e+75

**processorlock (boolean):** Thread allocation

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not lock threads to processors</td>
</tr>
<tr>
<td>1</td>
<td>Lock threads to processors</td>

</tbody>
</table>

**qextractalg (integer):** quadratic extraction algorithm in GAMS interface

Default: 0

**qpmakepsdind (boolean):** adjust MIQP formulation to make the quadratic matrix positive-semi-definite

Default: 1

**qpmethod (integer):** algorithm to be used for QP problems

Default: 0

**qtolin (integer):** linearization of the quadratic terms in the objective function of a QP or MIQP model

Default: -1

**quality (boolean):** write solution quality statistics

Default: 0

**quickfirstsolve (boolean):** Accelerate initial CPLEX solve

Default: 0
**randomseed** (*integer*): sets the random seed differently for diversity of solutions  

Default: 202009243

**readflt** (*string*): reads Cplex solution pool filter file  

**record** (*boolean*): Records invocations of Callable Library routines  

Default: 0

**recurse** (*integer*): Recurse using heuristic to solve sub-models when a feasible solution has been obtained  

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not recurse</td>
</tr>
<tr>
<td>1</td>
<td>Recurse thread 0 only</td>

<td>Use automatic decomposition method</td>
</tr>
</tbody>
</table>

**recurseiterlim** (*integer*): Recursed heuristic iteration limit for sub-solves  

Default: 40

**recurselog** (*boolean*): Write thread log files for recursed sub-solves  

Default: 0

**recurseminiterlim** (*integer*): Recursed heuristic minimum iterations before a solution is found in sub-solves  

Default: 0

**recursesoliterlim** (*integer*): Recursed heuristic sub-solves quit after these iterations if a solution is found  

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

relobjdif (real): relative cheat parameter ←
   Default: 0.0

repairtries (integer): try to repair infeasible MIP start ←
   Default: 0

repeatpresolve (integer): reapply presolve at root after preprocessing ←
   Default: -1

rerun (string): rerun problem if presolve infeasible or unbounded ←
   Default: yes

rinsheur (integer): relaxation induced neighborhood search frequency ←
Default: 0

**rltcuts (integer):** Reformulation Linearization Technique (RLT) cuts

Default: 0

**scaind (integer):** matrix scaling on/off

Default: 0

**seed (integer):** Initial random number seed

Default: 1234

**siftalg (integer):** sifting subproblem algorithm

Default: 0

**siftdisplay (integer):** sifting display level

Default: 1

**sifting (boolean):** switch for sifting from simplex optimization

Default: 1

**siftitlim (integer):** limit on sifting iterations

Default: 2147483647

**simdisplay (integer):** simplex display level

Default: 1

**singlim (integer):** limit on singularity repairs

Default: 10

**solnpool (string):** solution pool file name

**solnpoolagap (real):** absolute tolerance for the solutions in the solution pool

Default: 1.0e+75

**solnpoolcapacity (integer):** limits of solutions kept in the solution pool

Default: 2100000000

**solnpoolgap (real):** relative tolerance for the solutions in the solution pool

Default: 1.0e+75

**solnpoolintensity (integer):** solution pool intensity for ability to produce multiple solutions

Default: 0

**solnpoolmerge (string):** solution pool file name for merged solutions
solnpoolnumsym \(\text{(integer)}\): maximum number of variable symbols when writing merged solutions

Default: 10

solnpoolprefix \(\text{(string)}\): file name prefix for GDX solution files

Default: soin

solnpoolreplace \(\text{(integer)}\): strategy for replacing a solution in the solution pool

Default: 0

solutiontype \(\text{(integer)}\): type of solution (basic or non basic) for an LP or QP

Default: 0

solvefinal \(\text{(boolean)}\): switch to solve the problem with fixed discrete variables

Default: 1

sos1reform \(\text{(integer)}\): automatic logarithmic reformulation of special ordered sets of type 1 (SOS1)

Default: 0

sos2reform \(\text{(integer)}\): automatic logarithmic reformulation of special ordered sets of type 2 (SOS2)

Default: 0

startalg \(\text{(integer)}\): MIP starting algorithm

Default: 0

strategy \(\text{(integer)}\): ODH-Cplex Strategy

The aggressive setting attempt to make more progress with each sub-model solve at the cost of more expensive sub solves. Amongst other changes, it sets InterDiv, MaxInterDiv and MaxRepeat if they are not explicitly set by the user.

Default: 1

<table>

<tbody>
<tr>
<td>0</td>
<td>Synchronize with multiple CPLEX threads</td>
</tr>
<tr>
<td>1</td>
<td>Only synchronize with CPLEX thread 0</td>
</tr>
</tbody>
</table>

### tilim (real)
overrides the GAMS ResLim option

Default: 1.0e+75

### trelim (real)
maximum space in memory for tree

Default: 1.0e+75

### tryint (real)
GMO tryint

Default: 0.0

### tuningdettlim (real)
tuning deterministic time limit per model or suite

Default: 1.0e+75

### tuningdisplay (integer)
level of information reported by the tuning tool

Default: 1

### tuningmeasure (integer)
measure for evaluating progress for a suite of models

Default: 1

### tuningrepeat (integer)
number of times tuning is to be repeated on perturbed versions

Default: 1

### tuningtilim (real)
tuning time limit per model or suite

Default: 1.0e+75

### usebasis (boolean)
GMO usebasis

Default: 0

### variableclean (integer)
Clean variable values from sub-models

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No cleaning</td>
</tr>
<tr>
<td>1</td>
<td>Quick cleaning and allow feasible uncleaned solutions if unable to clean</td>
</tr>
<tr>
<td>2</td>
<td>Quick cleaning and disallow uncleaned solutions</td>
</tr>
<tr>
<td>3</td>
<td>Thorough cleaning</td>
</tr>
</tbody>
</table>

varsel (integer): variable selection strategy at each node

Default: 0

warninglimit (integer): determines how many times warnings of a specific type (datacheck=2) will be displayed

Default: 10

workdir (string): directory for working files

Default: .

workeralgorithm (integer): set method for optimizing benders subproblems

Default: 0

workmem (real): memory available for working storage

Default: 2048.0

writeannotation (string): produce a Cplex annotation file

writebas (string): produce a Cplex basis file

writeflt (string): produce a Cplex solution pool filter file

writelp (string): produce a Cplex LP file

writemps (string): produce a Cplex MPS file

writemst (string): produce a Cplex mst file

writeord (string): produce a Cplex ord file

writeparam (string): produce a Cplex parameter file with all active options

writepre (string): produce a Cplex LP/MPS/SAV file of the presolved problem

writeprob (string): produce a Cplex problem file and inferrrs the type from the extension

writesav (string): produce a Cplex binary problem file

zerohalfcuts (integer): zero-half cuts

Default: 0

zerotol (real): Zero tolerance for variable values

Default: 1e-9
5.31 OSICPLEX, OSIGUROBI, OSIMOSEK, OSIXPRESS

The "bare bone" solver links GAMS/OSICPLEX, GAMS/OSIGUROBI, GAMS/OSIMOSEK, and GAMS/OSIXPRESS allow users to solve their GAMS models with a standalone license of CPLEX, GUROBI, MOSEK, or XPRESS. The links use the COIN-OR Open Solver Interface (OSI) to communicate with these solvers. The OSICPLEX link has been written primarily by Tobias Achterberg, the OSIGUROBI link has been written primarily by Stefan Vigerske, the OSIMOSEK link has been written primarily by Bo Jensen, and the OSIXPRESS link has been written primarily by John Doe. Matthew Saltzman is the COIN-OR project leader for OSI.

For more information we refer to the OSI web site.

The OSI links support linear equations and continuous, binary, and integer variables. The following list provides a brief overview on features available with GAMS/Solver and GAMS/Solver-Link licenses that are not available with the bare bone OSI solver links:

- Nonlinear model types such as QCP, MIQCP, NLP and MINLP
- Variable types SemiInt, SemiCont, SOS1 and SOS2
- certain GAMS/Solver options have no OSI counterpart (see e.g. the Comparison of GAMS/CPLEX and GAMS/OSICPLEX options)

5.31.1 Usage

The following statement can be used inside your GAMS program to specify using OSIGUROBI

Option LP = OSIGUROBI; { or MIP or RMIP }

Similar statements apply to OSICPLEX, OSIMOSEK, and OSIXPRESS.

The above statement should appear before the Solve statement.

The links support the general GAMS options reslim (time limit), iterlim (iteration limit), nodlim (node limit), optca (absolute gap tolerance), optcr (relative gap tolerance), cheat (cutoff decrement, only Xpress), and threads. An option file in the format required by the solver can be provided via the GAMS optfile option. See Section Option files for details.

If a MIP is solved via one of the OSI links, only primal solution values are reported by default. To receive also the dual values for the LP that is obtained from the MIP by fixing all discrete variables, the GAMS option integer1 must be set to a nonzero value. Note that this may lead to solving another LP after the MIP solve has finished.

Setting the GAMS option integer2 to a nonzero value makes variable and equation names available to the solver. This option may be useful for debugging purposes.

Setting the GAMS option integer3 to a nonzero value leads to writing the model instance to a file in LP or MPS format before starting the solution process (integer3=1 writes an MPS file, integer3=2 writes an LP files, integer3=4 writes a native MPS file; sum these values to write several files). The name of the MPS file is chosen to be the name of the GAMS model file with the extension .gms replaced by .mps. This option may be useful for debugging purposes.

For OSICPLEX, OSIGUROBI, and OSIXPRESS, setting the GAMS option integer4 to a nonzero value leads to passing the variable level values (.l suffix) to the MIP solver as initial solution. This is analog to mipstart option of the full CPLEX and GUROBI links and the loadmipsol option of the full XPRESS link.
5.31.1 Option files

5.31.1.1 OSICPLEX Options  In an OSICPLEX option file, each line lists one option setting, where the option name and value are separated by space.

Example:

```
CPX_PARAM_MIPEMPHASIS 2
CPX_PARAM_HEURFREQ 42
CPX_PARAM_MIPDISPLAY 4
```

Note that GAMS/OSICPLEX will not process a GAMS/CPLEX option file. Instead, native CPLEX options (CPX...) have to be provided through an OSICPLEX option file (e.g. osicplex.opt) that follows the very strict syntax of a CPLEX parameter file. There is a trick to convert GAMS/CPLEX options into native CPLEX options: Create a regular GAMS/CPLEX option file cplex.opt with the options you would like to set for GAMS/OSICPLEX and add the option writeparam osicplex.opt. For example

```
* Cplex.opt
varsele 3 ! set variable selection to strong branching
writeparam osicplex.opt
```

Run this on any demo sized MIP problem (e.g. [MAGIC] from the GAMS Model Library) using GAMS/CPLEX. After the run you will find a file that looks as follows and can be supplied to GAMS/OSICPLEX to set the variable selection to strong branching (native CPLEX option CPXPARAM_MIP_Strategy_VariableSelect 3):

```
CPLEX Parameter File Version 12.10.0.0
CPXPARAM_Advance 0
CPXPARAM_Threads 1
CPXPARAM_Parallel 1

This includes some CPLEX options that have been set by the GAMS/CPLEX link and you might want to remove from this file.

Note that several GAMS/CPLEX options have no GAMS/OSICPLEX counterpart:

- **solnpool** (Solution Pool)
- **feasopt**
- **iis**
- **objrng, rhsrng** (Sensitivity Analysis)
- **indic** (Indicator constraints)
- **tuning** (Automatic Option Tuning)
- BCH Facility Options
- **quality** (Statistics of Solution)
- **writeXXX** (create some Cplex specific output files, e.g. XXX=sav)
- **tryInt**
- **interactive**
- **fixoptfile**
- **miptrace**
5.31 OSICPLEX, OSIGUROBI, OSIMOSEK, OSIXPRESS

5.31.1.1.2 OSIGUROBI Options  In an OSIGUROBI option file, each line lists one option setting, where the option name and value are separated by space.

Example:

Cuts 2
Heuristics 0.1

5.31.1.1.3 OSIMOSEK Options  An OSIMOSEK option file begins with the line BEGIN MOSEK and terminates with END MOSEK. Comments are introduced with an '%', empty lines are ignored. Each other line starts with a MOSEK parameter value, followed by space, and a value for that parameter.

Example:

BEGIN MOSEK
% disable probing and solve the root node by the interior point solver
MSK_IPAR_MIO_PRESOLVE_PROBING MSK_OFF
MSK_IPAR_MIO_ROOT_OPTIMIZER MSK_OPTIMIZER_INTPNT
END MOSEK

5.31.1.1.4 OSIXPRESS Options  In an OSIXPRESS option file, each line lists one option setting, where the option name and value are separated by an equal sign.

Example:

MIPLOG = 3
HEURFREQ = 2

5.31.1.2 Setup

5.31.1.2.1 OSICPLEX Setup  The setup for GAMS/OSICPLEX is identical to the GAMS/CPLEX-Link setup but to use the bare-bone interface GAMS/OSICPLEX, you do not need a GAMS/CPLEX-Link license but instead you have to request a free of charge GAMS/OSICPLEX license from sales@gams.com.

5.31.1.2.2 OSIGUROBI Setup  The setup for GAMS/OSIGUROBI is identical to the GAMS/Gurobi-Link setup but to use the bare-bone interface GAMS/OSIGUROBI, you do not need a GAMS/GUROBI-Link license.

5.31.1.2.3 OSIMOSEK Setup  The setup for GAMS/OSIMOSEK is identical to the GAMS/MOSEK-Link setup but to use the bare-bone interface GAMS/OSIMOSEK, you do not need a GAMS/MOSEK-Link license.

5.31.1.2.4 OSIXPRESS Setup  The setup for GAMS/OSIXPRESS is identical to the GAMS/XPRESS-Link setup but to use the bare-bone interface GAMS/OSIXPRESS, you do not need a GAMS/XPRESS-Link license.
5.32 PATHNLP

5.32.1 Introduction

This document describes the GAMS/PATHNLP solver for non-linear programs and the options unique to this solver.

PATHNLP solves an NLP by internally constructing the Karush-Kuhn-Tucker (KKT) system of first-order optimality conditions associated with the NLP and solving this system using the PATH solver for complementarity problems. The solution to the original NLP is extracted from the KKT solution and returned to GAMS. All of this takes place automatically - no special syntax or user reformulation is required.

Typically, PATHNLP works very well for convex models. It also has a comparative advantage on models whose solution via reduced gradient methods results in a large number of superbasic variables, since the PATH solver won't construct a dense reduced Hessian in the space of the superbasic variables as reduced gradient solvers do. For nonconvex models, however, PATHNLP is not as robust as the reduced gradient methods.

The theory relating NLP to their KKT systems is well-known: assuming differentiability without convexity, and assuming a constraint qualification holds, then a solution to the NLP must also be a solution to the KKT system. If we also assume convexity, then a solution to the KKT system is also a solution to the NLP - no further constraint qualification is required.

In case PATH fails to find a solution to the KKT system for the NLP, a phase I / phase II method is used in which the phase I objective is simply the feasibility error and the original objective is ignored. If a feasible point is found in phase I then phase II, an attempt to solve the KKT system for the NLP using the current feasible point, is entered.

PATHNLP is installed automatically with your GAMS system. With a demo or community license, it will solve small models only). If your GAMS license includes PATH, this size restriction is removed.

5.32.2 Usage

If you have installed the system and configured PATHNLP as the default NLP solver, all NLP models without a specific solver option will be solved with PATHNLP. If you installed another solver as the default, you can explicitly request that a particular model be solved using PATHNLP by inserting the statement

\texttt{option NLP = pathnlp;}

somewhere before the solve statement. Similar comments hold for the other model types (LP, RMINLP, QCP, etc.) PATHNLP can handle.

The standard GAMS model options iterlim and reslim can be used to control PATHNLP. A description of these options can be found in the GAMS Options section of the chapter on basic solver usage. In general this is enough to use PATHNLP effectively. In some cases, however, you may want to use some of the PATH or PATHNLP options to gain further performance improvements or for other reasons. The rules for using an option file are described in the chapter on basic solver usage. The options used to control PATH can also be used to control PATHNLP. There are also some options unique to PATHNLP.

5.32.3 Options

The tables that follow describe the options unique to PATHNLP as well as the options shared with the PATH solver for MCP models.

5.32.3.1 General options

### 5.33 PATH

**Author**

Michael C. Ferris  
Todd S. Munson

### 5.33.1 Complementarity

A fundamental problem of mathematics is to find a solution to a square system of nonlinear equations. Two generalizations of nonlinear equations have been developed, a constrained nonlinear system which incorporates bounds on the variables, and the complementarity problem (MCP). This document is primarily concerned with the complementarity problem.

The PATH solver for MCP models is a Newton-based solver that combines a number of the most effective variations, extensions, and enhancements of this powerful technique. See PATH vs MILES for a comparison with MILES. Algorithmic details can also be found in papers and technical reports by Dirkse, Ferris, and Munson on [Ferris' Home Page](#).
The complementarity problem adds a combinatorial twist to the classic square system of nonlinear equations, thus enabling a broader range of situations to be modeled. In its simplest form, the combinatorial problem is to choose from 2n inequalities a subset of n that will be satisfied as equations. These problems arise in a variety of disciplines including engineering and economics [60] where we might want to compute Wardropian and Walrasian equilibria, and optimization where we can model the first order optimality conditions for nonlinear programs [102] [114]. Other examples, such as bimatrix games [117] and options pricing [97], abound.

Our development of complementarity is done by example. We begin by looking at the optimality conditions for a transportation problem and some extensions leading to the nonlinear complementarity problem. We then discuss a Walrasian equilibrium model and use it to motivate the more general mixed complementarity problem. We conclude this chapter with information on solving the models using the PATH solver and interpreting the results.

### 5.33.1.1 Transportation Problem

The transportation model is a linear program where demand for a single commodity must be satisfied by suppliers at minimal transportation cost. The underlying transportation network is given as a set $\mathcal{A}$ of arcs, where $(i, j) \in \mathcal{A}$ means that there is a route from supplier $i$ to demand center $j$. The problem variables are the quantities $x_{i,j}$ shipped over each arc $(i, j) \in \mathcal{A}$. The linear program can be written mathematically as

$$
\begin{align*}
&\min_{x \geq 0} \sum_{(i,j) \in \mathcal{A}} c_{i,j} x_{i,j} \\
&\text{subject to} \quad \sum_{j : (i,j) \in \mathcal{A}} x_{i,j} \leq s_i, \forall i \\
&\quad \sum_{i : (i,j) \in \mathcal{A}} x_{i,j} \geq d_j, \forall j.
\end{align*}
$$

(1)

where $c_{i,j}$ is the unit shipment cost on the arc $(i, j)$, $s_i$ is the available supply at $i$, and $d_j$ is the demand at $j$.

The derivation of the optimality conditions for this linear program begins by associating with each constraint a multiplier, alternatively termed a dual variable or shadow price. These multipliers represent the marginal price on changes to the corresponding constraint. We label the prices on the supply constraint $p^s$ and those on the demand constraint $p^d$. Intuitively, for each supply node $i$

$$0 \leq p^s_i, \quad s_i \geq \sum_{j : (i,j) \in \mathcal{A}} x_{i,j},$$

Consider the case when $s_i > \sum_{j : (i,j) \in \mathcal{A}} x_{i,j}$, that is there is excess supply at $i$. Then, in a competitive marketplace, no rational person is willing to pay for more supply at node $i$; it is already over-supplied. Therefore, $p^s_i = 0$. Alternatively, when $s_i = \sum_{j : (i,j) \in \mathcal{A}} x_{i,j}$, that is node $i$ clears, we might be willing to pay for additional supply of the good. Therefore, $p^s_i \geq 0$. We write these two conditions succinctly as:

$$0 \leq p^s_i \quad \perp \quad s_i \geq \sum_{j : (i,j) \in \mathcal{A}} x_{i,j}, \quad \forall i$$

where the $\perp$ notation is understood to mean that at least one of the adjacent inequalities must be satisfied as an equality. For example, either $0 = p^s_i$, the first case, or $s_i = \sum_{j : (i,j) \in \mathcal{A}} x_{i,j}$, the second case.

Similarly, at each node $j$, the demand must be satisfied in any feasible solution, that is

$$\sum_{i : (i,j) \in \mathcal{A}} x_{i,j} \geq d_j.$$

Furthermore, the model assumes all prices are nonnegative, $0 \leq p^d_j$. If there is too much of the commodity supplied, $\sum_{i : (i,j) \in \mathcal{A}} x_{i,j} > d_j$, then, in a competitive marketplace, the price $p^d_j$ will be driven down to 0. Summing these relationships gives the following complementarity condition:

$$0 \leq p^d_j \quad \perp \quad \sum_{i : (i,j) \in \mathcal{A}} x_{i,j} \geq d_j, \quad \forall j.$$

The supply price at $i$ plus the transportation cost $c_{i,j}$ from $i$ to $j$ must exceed the market price at $j$. That is, $p^s_i + c_{i,j} \geq p^d_j$. Otherwise, in a competitive marketplace, another producer will replicate supplier.
increasing the supply of the good in question which drives down the market price. This chain would repeat until the inequality is satisfied. Furthermore, if the cost of delivery strictly exceeds the market price, that is 
\[ p^s_i + c_{i,j} > p^d_j, \] 
then nothing is shipped from \( i \) to \( j \) because doing so would incur a loss and \( x_{i,j} = 0 \). Therefore,

\[ 0 \leq x_{i,j} \perp p^s_i + c_{i,j} \geq p^d_j, \quad \forall (i,j) \in A. \]

We combine the three conditions into a single problem,

\[ \begin{align*}
0 & \leq p^s_i \perp s_i \geq \sum_{j:(i,j) \in A} x_{i,j}, \quad \forall i \\
0 & \leq p^d_j \perp \sum_{i:(i,j) \in A} x_{i,j} \geq d_j, \quad \forall j \\
0 & \leq x_{i,j} \perp p^s_i + c_{i,j} \geq p^d_j, \quad \forall (i,j) \in A.
\end{align*} \tag{2} \]

This model defines a linear complementarity problem that is easily recognized as the complementary slackness conditions \[37\] of the linear program (1). For linear programs the complementary slackness conditions are both necessary and sufficient for \( x \) to be an optimal solution of the problem (1). Furthermore, the conditions (2) are also the necessary and sufficient optimality conditions for a related problem in the variables \((p^s, p^d)\)

\[
\begin{array}{ll}
\max_{p^s, p^d \geq 0} & \sum_j d_j p^d_j - \sum_i s_i p^s_i \\
\text{subject to} & c_{i,j} \geq p^d_j - p^s_i, \quad \forall (i,j) \in A
\end{array}
\]
termed the dual linear program (hence the nomenclature "dual variables").

Looking at (2) a bit more closely we can gain further insight into complementarity problems. A solution of (2) tells us the arcs used to transport goods. A priori we do not need to specify which arcs to use, the solution itself indicates them. This property represents the key contribution of a complementarity problem over a system of equations. If we know what arcs to send flow down, we can just solve a simple system of linear equations. However, the key to the modeling power of complementarity is that it chooses which of the inequalities in (2) to satisfy as equations. In economics we can use this property to generate a model with different regimes and let the solution determine which ones are active. A regime shift could, for example, be a back stop technology like windmills that become profitable if a \( CO_2 \) tax is increased.

5.33.1.1.1 GAMS Code  The GAMS code for the complementarity version of the transportation problem is given in Figure 1; the actual data for the model is assumed to be given in the file transmcp.dat. Note that the model written corresponds very closely to (2). In GAMS, the \( \perp \) sign is replaced in the model statement with a ".". It is precisely at this point that the pairing of variables and equations shown in (2) occurs in the GAMS code. For example, the function defined by \emph{rational} is complementary to the variable \( x \). To inform a solver of the bounds, the standard GAMS statements on the variables can be used, namely (for a declared variable \( z(i) \)):

\[
z \text{.lo(i)} = 0;
\]
or alternatively

\[
\text{positive variable } z;
\]

Further information on the GAMS syntax can be found in [155]. Note that \emph{GAMS} requires the modeler to write \( F(z) \) \( \geq 0 \) whenever the complementary variable is lower bounded, and does not allow the alternative form \( 0 = l = F(z) \).

solve transport using mcp;

5.33.1.1.2 Extension: Model Generalization

While many interior point methods for linear programming exploit this complementarity framework (so-called primal-dual methods [205]), the real power of this modeling format is the new problem instances it enables a modeler to create. We now show some examples of how to extend the simple model (2) to investigate other issues and facets of the problem at hand.

Demand in the model of Figure 1 is independent of the prices \( p \). Since the prices \( p \) are variables in the complementarity problem (2), we can easily replace the constant demand \( d \) with a function \( d(p) \) in the complementarity setting. Clearly, any algebraic function of \( p \) that can be expressed in GAMS can now be added to the model given in Figure 1. For example, a linear demand function could be expressed using

\[
\sum_{i:(i,j)\in A} x_{i,j} \geq d_j(1 - p^d_j), \forall j.
\]

Note that the demand is rather strange if \( p^d_j \) exceeds 1. Other more reasonable examples for \( d(p) \) are easily derived from Cobb-Douglas or CES utilities. For those examples, the resulting complementarity problem becomes nonlinear in the variables \( p \). Details of complementarity for more general transportation models can be found in [48], [62].

Another feature that can be added to this model are tariffs or taxes. In the case where a tax is applied at the supply point, the third general inequality in (2) is replaced by

\[
p^t_i(1 + t_i) + c_{i,j} \geq p^d_j, \forall (i,j) \in A.
\]

The taxes can be made endogenous to the model, details are found in [155].

The key point is that with either of the above modifications, the complementarity problem is not just the optimality conditions of a linear program. In many cases, there is no optimization problem corresponding to the complementarity conditions.
5.33.1.1.3 Nonlinear Complementarity Problem  We now abstract from the particular example to describe more carefully the complementarity problem in its mathematical form. All the above examples can be cast as nonlinear complementarity problems (NCPs) defined as follows:

\[(\text{NCP})\] Given a function \(F : \mathbb{R}^n \to \mathbb{R}^n\), find \(z \in \mathbb{R}^n\) such that

\[0 \leq z \perp F(z) \geq 0.\]

Recall that the \(\perp\) sign signifies that one of the inequalities is satisfied as an equality, so that componentwise, \(z_i F_i(z) = 0\). We frequently refer to this property as \(z_i\) is complementary to \(F_i\). A special case of the NCP that has received much attention is when \(F\) is a linear function, the linear complementarity problem [40].

5.33.1.2 Walrasian Equilibrium

A Walrasian equilibrium can also be formulated as a complementarity problem (see [132]). In this case, we want to find a price \(p \in \mathbb{R}^m\) and an activity level \(y \in \mathbb{R}^n\) such that

\[
0 \leq y \perp L(p) := -A^T p \geq 0 \\
0 \leq p \perp S(p, y) := b + Ay - d(p) \geq 0
\]

(3)

where \(S(p, y)\) represents the excess supply function and \(L(p)\) represents the loss function. Complementarity allows us to choose the activities \(y_j\) to run (i.e. only those that do not make a loss). The second set of inequalities state that the price of a commodity can only be positive if there is no excess supply. These conditions indeed correspond to the standard exposition of Walras’ law which states that supply equals demand if we assume all prices \(p\) will be positive at a solution. Formulations of equilibria as systems of equations do not allow the model to choose the activities present, but typically make an a priori assumption on this matter.

5.33.1.2.1 GAMS Code  A GAMS implementation of (3) is given in Figure 2. Many large scale models of this nature have been developed. An interested modeler could, for example, see how a large scale complementarity problem was used to quantify the effects of the Uruguay round of talks [95].

Figure 2: Walrasian equilibrium as an NCP, walras1.gms

$include walras.dat

positive variables p(i), y(j);
 equations S(i, L(j);
 S(i).. b(i) + sum(j, A(i,j)*y(j)) - c(i)*sum(k, g(k)*p(k)) / p(i) / =g= 0;
 L(j).. -sum(i, p(i)*A(i,j)) =g= 0;
 model walras / S.p, L.y /
 solve walras using mcp;
5.33.1.2.2 Extension: Intermediate Variables In many modeling situations, a key tool for clarification is the use of intermediate variables. As an example, the modeler may wish to define a variable corresponding to the demand function \( d(p) \) in the Walrasian equilibrium (3). The syntax for carrying this out is shown in Figure 3 where we use the variables \( d \) to store the demand function referred to in the excess supply equation. The model \texttt{walras} now contains a mixture of equations and complementarity constraints. Since constructs of this type are prevalent in many practical models, the GAMS syntax allows such formulations.

**Figure 3:** Walrasian equilibrium as an MCP, \texttt{walras2.gms}

```gams
$include walras.dat

positive variables p(i), y(j);
variables d(i);
equations S(i), L(j), demand(i);

demand(i).. 
    d(i) =e= c(i)*sum(k, g(k)*p(k)) / p(i) ;
S(i).. b(i) + sum(j, A(i,j)*y(j)) - d(i) =g= 0 ;
L(j).. -sum(i, p(i)*A(i,j)) =g= 0 ;

model walras / demand.d, S.p, L.y /;
solve walras using mcp;
```

Note that positive variables are paired with inequalities, while free variables are paired with equations. A crucial point misunderstood by many modelers (new and experienced alike) is that the bounds on the variable determine the relationships satisfied by the function \( F \). Thus in Figure 3, \( d \) is a free variable and therefore its paired equation \texttt{demand} is an equality. Similarly, since \( p \) is nonnegative, its paired relationship \texttt{S} is a (greater-than) inequality. See the MCP definition below for details.

A simplification is allowed to the model statement in Figure 3. It is not required to match free variables explicitly to equations; we only require that there are the same number of free columns (i.e. single variables) as unmatched rows (i.e. single equations). Thus, in the example of Figure 3, the model statement could be replaced by

```gams
model walras / demand, S.p, L.y /;
```

This extension allows existing GAMS models consisting of a square system of nonlinear equations to be easily recast as a complementarity problem - the model statement is unchanged. GAMS generates a list of all variables appearing in the equations found in the model statement, performs explicitly defined pairings and then checks that the number of remaining equality rows equals the number of remaining free columns. However, if an explicit match is given, the PATH solver can frequently exploit the information for better solution. Note that all variables that are not free and all inequalities must be explicitly matched.

5.33.1.2.3 Mixed Complementarity Problem A mixed complementarity problem (MCP) is specified by three pieces of data, namely the lower bounds \( \ell \), the upper bounds \( u \) and the function \( F \).

\[ \text{(MCP)} \text{ Given lower bounds } \ell \in \{ \mathbb{R} \cup \{-\infty\}\}^n, \text{ upper bounds } u \in \{ \mathbb{R} \cup \{\infty\}\}^n \text{ and a function } F : \mathbb{R}^n \to \mathbb{R}^n, \text{ find } z \in \mathbb{R}^n \text{ such that precisely one of the following holds for each } i \in \{1, \ldots, n\}: \]

\[
F_i(z) = 0 \quad \text{and} \quad \ell_i \leq z_i \leq u_i \\
F_i(z) > 0 \quad \text{and} \quad z_i = \ell_i \\
F_i(z) < 0 \quad \text{and} \quad z_i = u_i.
\]
These relationships define a general MCP (sometimes termed a rectangular variational inequality [94]). We will write these conditions compactly as

\[ \ell \leq x \leq u \perp F(x). \]

As the MCP model type as defined above is the one used in GAMS, there are some consequences of the definition worth emphasizing here. Firstly, the bounds on the variable determine the relationships satisfied by the function \( F \): the constraint type (e.g. \( =G=, =L= \)) chosen plays no role in defining the problem. This being the case, it is acceptable (and perhaps advisable!) to use an \( =N= \) in the definition of all equations used in complementarity models to highlight the dependence on the variable bounds in defining the MCP. This is not required, however. The constraint types \( =G=, =L= \) and \( =E= \) are also allowed. If the variable bounds are inconsistent with the constraint type chosen, GAMS will either reject the model (e.g. an \( =L= \) row matched with a lower-bounded variable) or silently and temporarily ignore the issue (e.g. an \( =E= \) row matched with a lower-bounded variable). In the latter case, if equality does not hold at solution (allowable if the variable is at lower bound) the is marked in the listing file with a redef.

Secondly, note the contrast between complementarity conditions like \( g(z) \leq 0, z \geq 0 \) and a complementarity problem like \( F(x) \perp 0 \leq x \leq \infty \). The former requires a trivial transformation in order to fit into the MCP framework: \(-g(z) \perp 0 \leq z \leq \infty \). This simple issue is a frequent source of problems and worth looking out for.

The nonlinear complementarity problem of Nonlinear Complementarity Problem is a special case of the MCP. For example, to formulate an NCP in the GAMS/MCP format we set

\[ z.\text{lo}(I) = 0; \]

or declare

positive variable z;

Another special case is a square system of nonlinear equations

(NE) Given a function \( F : \mathbb{R}^n \rightarrow \mathbb{R}^n \) find \( z \in \mathbb{R}^n \) such that

\[ F(z) = 0. \]

In order to formulate this in the GAMS/MCP format we just declare

free variable z;

In both the above cases, we must not modify the lower and upper bounds on the variables later (unless we wish to drastically change the problem under consideration).

An advantage of the extended formulation described above is the pairing between "fixed" variables (ones with equal upper and lower bounds) and a component of \( F \). If a variable \( z_i \) is fixed, then \( F_i(z) \) is unrestricted since precisely one of the three conditions in the MCP definition automatically holds when \( z_i = \ell_i = u_i \). Thus if a variable is fixed in a GAMS model, the paired equation is completely dropped from the model. This convenient modeling trick can be used to remove particular constraints from a model at generation time. As an example, in economics, fixing a level of production will remove the zero-profit condition for that activity.

Simple bounds on the variables are a convenient modeling tool that translates into efficient mathematical programming tools. For example, specialized codes exist for the bound constrained optimization problem

\[ \min f(x) \text{ subject to } \ell \leq x \leq u. \]
The first order optimality conditions for this problem class are precisely MCP(∇f(x), [ℓ, u]). We can easily see this condition in a one dimensional setting. If we are at an unconstrained stationary point, then ∇f(x) = 0. Otherwise, if x is at its lower bound, then the function must be increasing as x increases, so ∇f(x) ≥ 0. Conversely, if x is at its upper bound, then the function must be increasing as x decreases, so that ∇f(x) ≤ 0. The MCP allows such problems to be easily and efficiently processed.

Upper bounds can be used to extend the utility of existing models. For example, in Figure 3 it may be necessary to have an upper bound on the activity level y. In this case, we simply add an upper bound to y in the model statement, and we can replace the loss equation with the following definition:

\[
y_{\text{up}}(j) = 10;
L(j) . \sum(i, p(i)A(i,j)) =e= 0 ;
\]

Here, for bounded variables, we do not know beforehand if the constraint will be satisfied as an equation, less-than inequality or greater-than inequality, since this determination depends on the values of the solution variables. However, let us interpret the relationships that the above change generates. If y_j = 0, the loss function can be positive since we are not producing in the jth sector. If y_j is strictly between its bounds, then the loss function must be zero by the definition of complementarity; this is the competitive assumption. Finally, if y_j is at its upper bound, then the loss function can be negative. Of course, if the market does not allow free entry, some firms may operate at a profit (negative loss). For more examples of problems, the interested reader is referred to [45], [59], [60].

### 5.33.1.3 Solution

We will assume that a file named transmcp.gms has been created using the GAMS syntax which defines an MCP model transport as developed in Transportation Problem. The modeler has a choice of the complementarity solver to use. We are going to further assume that the modeler wants to use PATH.

There are two ways to ensure that PATH is used as opposed to any other GAMS/MCP solver. These are as follows:

1. Add the following line to the transmcp.gms file prior to the solve statement

   ```
   option mcp = path;
   PATH will then be used instead of the default solver provided.
   ```

2. Choose PATH as the default solver for MCP (via the IDE on Windows or elsewhere by rerunning gamsinst from the GAMS system directory).

To solve the problem, the modeler executes the command:

```
gams transmcp
```

where transmcp can be replaced by any filename containing a GAMS model. Many other command line options for GAMS exist; the reader is referred to List of Command Line Parameters for further details.

At this stage, control is handed over to the solver which creates a log providing information on what the solver is doing as time elapses. See Section PATH for details about the log file. After the solver terminates, a listing file is generated containing the solution to the problem. We now describe the listing file output specifically related to complementarity problems.
5.33.1.3.1 Listing File  The listing file is the standard GAMS mechanism for reporting model results. This file contains information regarding the compilation process, the form of the generated equations in the model, and a report from the solver regarding the solution process.

We now detail the last part of this output, an example of which is given in Figure 4. We use "..." to indicate where we have omitted continuing similar output.

**** REPORT SUMMARY :
0 NONOPT
0 INFEASIBLE
0 UNBOUNDED
0 REDEFINED
0 ERRORS
```

After a summary line indicating the model name and type and the solver name, the listing file shows a solver status and a model status. Table 1 and Table 2 display the relevant codes that are returned under different circumstances. A modeler can access these codes within the transmcp.gms file using transport.solvestat and transport.modelstat respectively.

**Table 1:** Solver Status Codes
After this, a listing of the time and iterations used is given, along with a count on the number of evaluation errors encountered. If the number of evaluation errors is greater than zero, further information can typically be found later in the listing file, prefaced by "****". Information provided by the solver is then displayed.

Next comes the solution listing, starting with each of the equations in the model. For each equation passed to the solver, four columns are reported, namely the lower bound, level, upper bound and marginal. GAMS moves all parts of a constraint involving variables to the left hand side, and accumulates the constants on the right hand side. The lower and upper bounds correspond to the constants that GAMS generates. For equations, these should be equal, whereas for inequalities one of them should be infinite. The level value of the equation (an evaluation of the left hand side of the constraint at the current point) should be between these bounds, otherwise the solution is infeasible and the equation is marked as follows:

```
seattle .chicago -0.153 -2.000 +INF 300.000 INFES
```

The marginal column in the equation contains the value of the variable that was matched with this equation.

For the variable listing, the lower, level and upper columns indicate the lower and upper bounds on the variables and the solution value. The level value returned by PATH will always be between these bounds. The marginal column contains the value of the slack on the equation that was paired with this variable. If a variable appears in one of the constraints in the model statement but is not explicitly paired to a constraint, the slack reported here contains the internally matched constraint slack. The definition of this slack is the minimum of equ.l - equ.lower and equ.l - equ.upper, where equ is the paired equation.

Finally, a summary report is given that indicates how many errors were found. Figure 4 is nicely-solved case; when the model has infeasibilities, these can be found by searching for the string "INFES" as described above.

### 5.3.3.1.3.2 Redefined Equations

Unfortunately, this is not the end of the story. Some equations may have the following form:

```
LOWER   LEVEL   UPPER   MARGINAL
new-york 325.000 350.000 325.000 0.225 REDEF
```
This should be construed as a warning from GAMS, as opposed to an error. In principle, the \texttt{REDEF} should only occur if the paired variable to the constraint has a finite lower and/or upper bound and the variable is at one of those bounds. In this case, at the solution of the complementarity problem the sense of the constraint (e.g. $\neq E=\neq$) may not be satisfied. This occurs when GAMS constraints are used to define the function $F$. The bounds on each component of the function $F$ are derived from the bounds on the matching variable component, and these bounds may be inconsistent with those implied by the constraint type used. GAMS warns the user via the \texttt{REDEF} label when the solution found leads to a violated "constraint". To avoid \texttt{REDEF} warnings the $=N=$ can be used to define all complementarity functions.

\textit{Note that a \texttt{REDEF} is not an error, just a warning. The solver has solved the complementarity problem specified.} GAMS gives this report to ensure that the modeler understands that the complementarity problem derives the relationships on the equations from the variable bounds, not from the equation definition.

\subsection{Pitfalls}

As indicated above, the ordering of an equation is important in the specification of an MCP. Since the data of the MCP is the function $F$ and the bounds $\ell$ and $u$, it is important for the modeler to pass the solver the function $F$ and not $-F$.

For example, if we have the optimization problem,

$$
\min_{x \in [0, 2]} (x - 1)^2
$$

then the first order optimality conditions are

$$
0 \leq x \leq 2 \quad \perp \quad 2(x - 1)
$$

which has a unique solution, $x = 1$. Figure 5 provides correct GAMS code for this problem.

\textbf{Figure 5:} First order conditions as an MCP, \texttt{first.gms}

\begin{verbatim}
variables x;
equations d_f;
x.lo = 0;
x.up = 2;
d_f.. 2*(x - 1) =e= 0;
model first / d_f.x /;
solve first using mcp;
\end{verbatim}

However, if we accidentally write the valid equation

$$
d_f.. 0 =e= 2*(x - 1);
$$

the problem given to the solver is

$$
0 \leq x \leq 2 \quad \perp \quad -2(x - 1)
$$

which has three solutions, $x = 0$, $x = 1$, and $x = 2$. This problem is in fact the stationary conditions for the nonconvex quadratic problem,

$$
\max_{x \in [0, 2]} (x - 1)^2,
$$
not the problem we intended to solve.

Continuing with the example, when \( x \) is a free variable, we might conclude that the ordering of the equation is irrelevant because we always have the equation, \( 2(x - 1) = 0 \), which does not change under multiplication by \(-1\). In most cases, the ordering of equations (which are complementary to free variables) does not make a difference since the equation is internally "substituted out" of the model. In particular, for defining equations, such as that presented in Figure 3, the choice appears to be arbitrary.

However, in difficult (singular or near singular) cases, the substitution cannot be performed, and instead a perturbation is applied to \( F \), in the hope of "(strongly) convexifying" the problem. If the perturbation happens to be in the wrong direction because \( F \) was specified incorrectly, the perturbation actually makes the problem less convex, and hence less likely to solve. Note that determining which of the above orderings of the equations makes most sense is typically tricky. One rule of thumb is to check whether if you replace the "\( =e= \)” by "\( =g= \)” , and then increase "\( x \)” , is the inequality intuitively more likely to be satisfied. If so, you probably have it the right way round, if not, reorder.

Furthermore, underlying model convexity is important. For example, if we have the linear program

\[
\begin{align*}
\min_x & \quad c^T x \\
\text{subject to} & \quad Ax = b, \ x \geq 0 
\end{align*}
\]

we can write the first order optimality conditions as either

\[
0 \leq x \perp -A^T \mu + c \\
\mu \text{ free} \perp Ax - b
\]

or, equivalently,

\[
0 \leq x \perp -A^T \mu + c \\
\mu \text{ free} \perp b - Ax
\]

because we have an equation. The former is a linear complementarity problem with a positive semidefinite matrix, while the latter is almost certainly indefinite. Also, if we need to perturb the problem because of numerical problems, the former system will become positive definite, while the later becomes highly nonconvex and unlikely to solve. The rule of thumb here is to consider what happens when the dual multiplier \( \mu \) is made non-negative in the KKT system. In the former system, the constraint becomes \( Ax \geq b \), which is consistent with a minimization and a positive multiplier. In the latter system, we get \( Ax \leq b \), which is backwards.

Finally, users are strongly encouraged to match equations and free variables when the matching makes sense for their application. Structure and convexity can be destroyed if it is left to the solver to perform the matching. For example, in the above example, we could lose the positive semidefinite matrix with an arbitrary matching of the free variables.

### 5.33.2 PATH

Newton’s method, perhaps the most famous solution technique, has been extensively used in practice to solve square systems of nonlinear equations. The basic idea is to construct a local approximation of the nonlinear equations around a given point, \( x^k \), solve the approximation to find the Newton point, \( x^N \), update the iterate, \( x^{k+1} = x^N \), and repeat until we find a solution to the nonlinear system. This method works extremely well close to a solution, but can fail to make progress when started far from a solution. To guarantee progress is made, a line search between \( x^k \) and \( x^N \) is used to enforce sufficient decrease on an appropriately defined merit function. Typically, \( \frac{1}{2} \| F(x) \|^2 \) is used.

PATH uses a generalization of this method on a nonsmooth reformulation of the complementarity problem. To construct the Newton direction, we use the normal map [151] representation

\[
F(\pi(x)) + x - \pi(x)
\]
associated with the MCP, where \( \pi(x) \) represents the projection of \( x \) onto \( \ell, u \) in the Euclidean norm. We note that if \( x \) is a zero of the normal map, then \( \pi(x) \) solves the MCP. At each iteration, a linearization of the normal map, a linear complementarity problem, is solved using a pivotal code related to Lemke's method.

Versions of PATH prior to 4.x are based entirely on this formulation using the residual of the normal map

\[ \| F(\pi(x)) + x - \pi(x) \| \]

as a merit function. However, the residual of the normal map is not differentiable, meaning that if a subproblem is not solvable then a "steepest descent" step on this function cannot be taken. PATH 4.x considers an alternative nonsmooth system \[ \Phi(x) = 0, \] where \( \Phi(x) = \phi(x_i, F(x_i)) \) and \( \phi(a,b) := \sqrt{a^2 + b^2} - a - b \). The merit function, \( \| \Phi(x) \|^2 \), in this case is differentiable, and is used for globalization purposes. When the subproblem solver fails, a projected gradient direction for this merit function is searched. It is shown in [61] that this provides descent and a new feasible point to continue PATH, and convergence to stationary points and/or solutions of the MCP is provided under appropriate conditions.

The remainder of this chapter details the interpretation of output from PATH and ways to modify the behavior of the code. To this end, we will assume that the modeler has created a file named \texttt{transmcp.gms} which defines an MCP model \texttt{transport} as described in Section Transportation Problem and is using PATH 4.x to solve it. See Section Solution for information on changing the solver.

### 5.33.2.1 Log File

We will now describe the behavior of the PATH algorithm in terms of the output typically produced. An example of the log for a particular run is given in Figure 6.

--- Restarting execution

The first few lines on this log file are printed by GAMS during its compilation and generation phases. The model is then passed off to PATH at the stage where the "Executing PATH" line is written out. After some basic memory allocation and problem checking, the PATH solver checks if the modeler required an option file to be read. In the example this is not the case. If PATH is directed to read an option file (see PATH Options below), then the following output is generated after the PATH banner.

Reading options file PATH.OPT
> output_linear_model yes;
Options: Read: Line 2 invalid: hi_there;
Read of options file complete.

If the option reader encounters an invalid option (as above), it reports this but carries on executing the algorithm. Following this, the algorithm starts working on the problem.
5.33.2.1.1 Diagnostic Information  Some diagnostic information is initially generated by the solver at the starting point. Included is information about the initial point and function evaluation. The log file here tells the value of the largest element of the starting point and the variable where it occurs. Similarly, the maximum function value is displayed along with the row producing it. The maximum element in the gradient is also presented with the equation and variable where it is located.

The second block provides more information about the Jacobian at the starting point. This information can be used to help scale the model. See Section Advanced Topics for complete details.

5.33.2.1.2 Crash Log  The first phase of the code is a crash procedure attempting to quickly determine which of the inequalities should be active. This procedure is documented fully in [47], and an example of the Crash Log can be seen in Figure 6. The first column of the crash log is just a label indicating the current iteration number, the second gives an indication of how many function evaluations have been performed so far. Note that precisely one Jacobian (gradient) evaluation is performed per crash iteration. The number of changes to the active set between iterations of the crash procedure is shown under the "diff" column. The crash procedure terminates if this becomes small. Each iteration of this procedure involves a factorization of a matrix whose size is shown in the next column. The residual is a measure of how far the current iterate is from satisfying the complementarity conditions (MCP); it is zero at a solution. See Merit Functions for further information. The column "step" corresponds to the steplength taken in this iteration - ideally this should be 1. If the factorization fails, then the matrix is perturbed by an identity matrix scaled by the value indicated in the "prox" column. The "label" column indicates which row in the model is furthest away from satisfying the conditions (MCP). Typically, relatively few crash iterations are performed. Section PATH Options gives mechanisms to affect the behavior of these steps.

5.33.2.1.3 Major Iteration Log  After the crash is completed, the main algorithm starts as indicated by the "Major Iteration Log" flag (see Figure 7). The columns that have the same labels as in the crash log have precisely the same meaning described above. However, there are some new columns that we now explain. Each major iteration attempts to solve a linear mixed complementarity problem using a pivotal method that is a generalization of Lemke's method [117]. The number of pivots performed per major iteration is given in the "minor" column.

The "grad" column gives the cumulative number of Jacobian evaluations used; typically one evaluation is performed per iteration. The "inorm" column gives the value of the error in satisfying the equation indicated in the "label" column.

At each iteration of the algorithm, several different step types can be taken, due to the use of nonmonotone searches [46], [56] which are used to improve robustness. In order to help the PATH user, we have added two code letters indicating the return code from the linear solver and the step type to the log file. Table 3 explains the return codes for the linear solver and Table 4 explains the meaning of each step type. The ideal output in this column is "SO"; "SD" and "SB" also indicate reasonable progress. Codes different from these are not catastrophic, but typically indicate the solver is having difficulties due to numerical issues or nonconvexities in the model.

Table 3: Linear Solver Codes

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>A cycle was detected.</td>
</tr>
<tr>
<td>E</td>
<td>An error occurred in the linear solve.</td>
</tr>
<tr>
<td>I</td>
<td>The minor iteration limit was reached.</td>
</tr>
<tr>
<td>N</td>
<td>The basis became singular.</td>
</tr>
<tr>
<td>R</td>
<td>An unbounded ray was encountered.</td>
</tr>
<tr>
<td>S</td>
<td>The linear subproblem was solved.</td>
</tr>
<tr>
<td>T</td>
<td>Failed to remain within tolerance after factorization was performed.</td>
</tr>
</tbody>
</table>
### Table 4: Step Type Codes

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>A Backtracking search was performed from the current iterate to the Newton point in order to obtain sufficient decrease in the merit function.</td>
</tr>
<tr>
<td>D</td>
<td>The step was accepted because the Distance between the current iterate and the Newton point was small.</td>
</tr>
<tr>
<td>G</td>
<td>A gradient step was performed.</td>
</tr>
<tr>
<td>I</td>
<td>Initial information concerning the problem is displayed.</td>
</tr>
<tr>
<td>M</td>
<td>The step was accepted because the Merit function value is smaller than the nonmonotone reference value.</td>
</tr>
<tr>
<td>O</td>
<td>A step that satisfies both the distance and merit function tests.</td>
</tr>
<tr>
<td>R</td>
<td>A Restart was carried out.</td>
</tr>
<tr>
<td>W</td>
<td>A Watchdog step was performed in which we returned to the last point encountered with a better merit function value than the nonmonotone reference value (M, O, or B step), regenerated the Newton point, and performed a backtracking search.</td>
</tr>
</tbody>
</table>

#### 5.33.2.1.4 Minor Iteration Log

If more than 500 pivots are performed, a minor log is output that gives more details of the status of these pivots. A listing from transmcp model follows, where we have set the `output_minor_iteration_frequency` option to 1.

```plaintext
Minor Iteration Log
minor t z w v art ckpts enter leave
1 4.2538e-01 8 2 0 0 0 t[ 0] z[ 11]
2 9.0823e-01 8 2 0 0 0 w[ 10]
3 1.0000e+00 9 2 0 0 0 z[ 10] t[ 0]
```

t is a parameter that goes from zero to 1 for normal starts in the pivotal code. When the parameter reaches 1, we are at a solution to the subproblem. The t column gives the current value for this parameter. The next columns report the current number of problem variables z and slacks corresponding to variables at lower bound w and at upper bound v. Artificial variables are also noted in the minor log, see [57] for further details. Checkpoints are times where the basis matrix is refactorized. The number of checkpoints is indicated in the ckpts column. Finally, the minor iteration log displays the entering and leaving variables during the pivot sequence.

#### 5.33.2.1.5 Restart Log

The PATH code attempts to fully utilize the resources provided by the modeler to solve the problem. Versions of PATH after 3.0 have been much more aggressive in determining that a stationary point of the residual function has been encountered. When it is determined that no progress is being made, the problem is restarted from the initial point supplied in the GAMS file with a different set of options. These restarts give the flexibility to change the algorithm in the hopes that the modified algorithm leads to a solution. The ordering and nature of the restarts were determined by empirical evidence based upon tests performed on real-world problems.

The exact options set during the restart are given in the restart log, part of which is reproduced below.

```plaintext
Restart Log
proximal_perturbation 0
crash_method none
crash_perturb yes
nms_initial_reference_factor 2
proximal_perturbation 1.0000e-01
```

If a particular problem solves under a restart, a modeler can circumvent the wasted computation by setting the appropriate options as shown in the log. Note that sometimes an option is repeated in this log. In this case, it is the last option that is used.
5.33.2.1.6 Solution Log  A solution report is now given by the algorithm for the point returned. The first component is an evaluation of several different merit functions. Next, a display of some statistics concerning the final point is given. This report can be used detect problems with the model and solution as detailed in Section Advanced Topics.

At the end of the log file, summary information regarding the algorithm's performance is given. The string "** EXIT - solution found". is an indication that PATH solved the problem. Any other EXIT string indicates a termination at a point that may not be a solution. These strings give an indication of what modelstat and solvestat will be returned to GAMS. After this, the "Restarting execution" flag indicates that GAMS has been restarted and is processing the results passed back by PATH.

5.33.2.2 Status File

If for some reason the PATH solver exits without writing a solution, or the sysout flag is turned on, the status file generated by the PATH solver will be reported in the listing file. The status file is similar to the log file, but provides more detailed information. The modeler is typically not interested in this output.

5.33.2.3 User Interrupts

A user interrupt can be effected by typing Ctrl-C. We only check for interrupts every major iteration. If a more immediate response is wanted, repeatedly typing Ctrl-C will eventually kill the job. The number needed is controlled by the interrupt_limit option. In this latter case, when a kill is performed, no solution is written and an execution error will be generated in GAMS.

5.33.2.4 Preprocessing

The purpose of a preprocessor is to reduce the size and complexity of a model to achieve improved performance by the main algorithm. Another benefit of the analysis performed is the detection of some provably unsolvable problems. A comprehensive preprocessor has been incorporated into PATHC as developed in [58].

The preprocessor reports its finding with some additional output to the log file. This output occurs before the initial point statistics. An example of the preprocessing on the forcebsm model is presented below.

    Zero:  0 Single:    112 Double:    0 Forced:    0
    Preprocessed size: 72

The preprocessor looks for special polyhedral structure and eliminates variables using this structure. These are indicated with the above line of text. Other special structure is also detected and reported.

On exit from the algorithm, we must generate a solution for the original problem. This is done during the postsolve. Following the postsolve, the residual using the original model is reported.

    Postsolved residual: 1.0518e-10

This number should be approximately the same as the final residual reported on the presolved model.
5.33.2.4.1 Constrained Nonlinear System  Modelers typically add bounds to their variables when attempting to solve nonlinear problems in order to restrict the domain of interest. For example, many square nonlinear systems are formulated as

\[ F(z) = 0, \ \ell \leq z \leq u, \]

where typically, the bounds on \( z \) are inactive at the solution. This is not an MCP, but is an example of a "constrained nonlinear system" (CNS). It is important to note the distinction between MCP and CNS. The MCP uses the bounds to infer relationships on the function \( F \). If a finite bound is active at a solution, the corresponding component of \( F \) is only constrained to be nonnegative or nonpositive in the MCP, whereas in CNS it must be zero. Thus there may be many solutions of MCP that do not satisfy \( F(z) = 0 \). Only if \( z^* \) is a solution of MCP with \( \ell < z^* < u \) is it guaranteed that \( F(z^*) = 0 \).

Internally, PATHC reformulates a constrained nonlinear system of equations to an equivalent complementarity problem. The reformulation adds variables, \( y \), with the resulting problem written as:

\[ \ell \leq x \leq u \quad \perp -y \quad y \text{ free} \quad \perp F(x). \]

This is the MCP model passed on to the PATH solver.

5.33.3 PATH Options

The default options of PATH should be sufficient for most models. If desired, PATH-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

We give a list of the available PATH options along with their defaults and meaning below. Note that only the first three characters of every word are significant.

5.33.3.1 General options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>chen_lambda</td>
<td>lambda parameter for Chen-Chen-Kanzow residual</td>
<td>0.8</td>

</table>
GAMS controls the total number of pivots allowed via the `iterlim` option. If more pivots are needed for a particular model then either of the following lines should be added to the `transmcp.gms` file before the `solve` statement:

```plaintext
option iterlim = 2000;
transport.iterlim = 2000;
```

Problems with a singular basis matrix can be overcome by using the `proximal_perturbation` option [26], and linearly dependent columns can be output with the `output_factorization_singularity` option. For more information on singularities, we refer the reader to Section Advanced Topics.

As a special case, PATH can emulate Lemke’s method [39], [117] for LCP with the following options:

```plaintext
crash_method none
crash_perturb no
major_iteration_limit 1
lemke_start first
nms no
```

If instead, PATH is to imitate the Successive Linear Complementarity method (SLCP, often called the Josephy Newton method) [101], [132], [131] for MCP with an Armijo style linesearch on the normal map residual, then the options to use are:

```plaintext
crash_method none
crash_perturb no
lemke_start always
nms_initial_reference_factor 1
nms_memory size 1
nms_mstep_frequency 1
nms_searchtype line
merit_function normal
```

Note that `nms_memory size 1` and `nms_initial_reference_factor 1` turn off the nonmonotone linesearch, while `nms_mstep_frequency 1` turns off watchdogging [35]. `nms_searchtype line` forces PATH to search the line segment between the initial point and the solution to the linear model, while `merit_function normal` tell PATH to use the normal map for calculating the residual.

### 5.33.4 Advanced Topics

This chapter discusses some of the difficulties encountered when dealing with complementarity problems. We start off with a very formal definition of a complementarity problem (similar to the one given previously) which is used in later sections on merit functions and ill-defined, poorly-scaled, and singular models.

#### 5.33.4.1 Formal Definition of MCP

The mixed complementarity problem is defined by a function, $F : D \to \mathbb{R}^n$ where $D \subseteq \mathbb{R}^n$ is the domain of $F$, and possibly infinite lower and upper bounds, $\ell$ and $u$. Let $C := \{ x \in \mathbb{R}^n \mid \ell \leq x \leq u \}$, a Cartesian product of closed (possibly infinite) intervals. The problem is given as

$$MCP : \text{find } x \in C \cap D \text{ s.t. } \langle F(x), y - x \rangle \geq 0, \forall y \in C.$$

This formulation is a special case of the variational inequality problem defined by $F$ and a (nonempty, closed, convex) set $C$. Special choices of $\ell$ and $u$ lead to the familiar cases of a system of nonlinear equations

$$F(x) = 0$$

(generated by $\ell \equiv -\infty, u \equiv +\infty$) and the nonlinear complementarity problem

$$0 \leq x \perp F(x) \geq 0$$

(generated using $\ell \equiv 0, u \equiv +\infty$).
5.3.4.2 Algorithmic Features

We now describe some of the features of the PATH algorithm and the options affecting each.

5.3.4.2.1 Merit Functions

A solver for complementarity problems typically employs a merit function to indicate the closeness of the current iterate to the solution set. The merit function is zero at a solution to the original problem and strictly positive otherwise. Numerically, an algorithm terminates when the merit function is approximately equal to zero, thus possibly introducing spurious "solutions".

The modeler needs to be able to determine with some reasonable degree of accuracy whether the algorithm terminated at solution or if it simply obtained a point satisfying the desired tolerances that is not close to the solution set. For complementarity problems, we can provide several indicators with different characteristics to help make such a determination. If one of the indicators is not close to zero, then there is some evidence that the algorithm has not found a solution. We note that if all of the indicators are close to zero, we are reasonably sure we have found a solution. However, the modeler has the final responsibility to evaluate the "solution" and check that it makes sense for their application.

For the NCP, a standard merit function is
\[
\|(-x)_+, (-F(x))_+, [(x_i)_+(F_i(x))_+]\|
\]
with the first two terms measuring the infeasibility of the current point and the last term indicating the complementarity error. In this expression, we use \((-\cdot)_+)\) to represent the Euclidean projection of \(x\) onto the nonnegative orthant, that is \((-x)_+ = \max(x, 0)\). For the more general MCP, we can define a similar function:
\[
\left\| x - \pi(x), \left( \frac{x_i - \ell_i}{\|\ell_i\| + 1} \right)_+ (F_i(x))_+ \right\|
\]
where \(\pi(x)\) represents the Euclidean projection of \(x\) onto \(C\). We can see that if we have an NCP, the function is exactly the one previously given and for nonlinear systems of equations, this becomes \(\|F(x)\|\).

There are several reformulations of the MCP as a system of nonlinear (nonsmooth) equations for which the corresponding residual is a natural merit function. Some of these are as follows:

- **Generalized Minimum Map:** \(x - \pi(x - F(x))\)
- **Normal Map:** \(F(\pi(y)) + y - \pi(y)\)
- **Fischer Function:** \(\Phi(x)\), where \(\Phi_i(x) := \phi(x_i, F_i(x))\) with
  \[
  \phi(a, b) := \sqrt{a^2 + b^2} - a - b.
  \]
  Note that \(\phi(a, b) = 0\) if and only if \(0 \leq a \perp b \geq 0\). A straightforward extension of \(\Phi\) to the MCP format is given for example in [61].

In the context of nonlinear complementarity problems the generalized minimum map corresponds to the classic minimum map \(\min(x, F(x))\). Furthermore, for NCPs the minimum map and the Fischer function are both local error bounds and were shown to be equivalent in [185]. Figure 10 in the subsequent section plots all of these merit functions for the ill-defined example discussed therein and highlights the differences between them.

The squared norm of \(\Phi\), namely \(\Psi(x) := \frac{1}{2} \sum \phi(x_i, F_i)^2\), is continuously differentiable on \(\mathbb{R}^n\) provided \(F\) itself is. Therefore, the first order optimality conditions for the unconstrained minimization of \(\Psi(x)\), namely \(\nabla \Psi(x) = 0\) give another indication as to whether the point under consideration is a solution of MCP.

The merit functions and the information PATH provides at the solution can be useful for diagnostic purposes. By default, PATH 4.x returns the best point with respect to the merit function because this iterate likely provides better information to the modeler. As detailed in Section PATH Options, the default merit function in PATH 4.x is the Fischer function. To change this behavior the `merit_function` option can be used.
5.33.4.2.2 Crashing Method  The crashing technique [47] is used to quickly identify an active set from the user-supplied starting point. At this time, a proximal perturbation scheme [24], [25] is used to overcome problems with a singular basis matrix. The proximal perturbation is introduced in the crash method, when the matrix factored is determined to be singular. The value of the perturbation is based on the current merit function value.

Even if the crash method is turned off, for example via the option crash_method none, perturbation can be added. This is determined by factoring the matrix that crash would have initially formed. This behavior is extremely useful for introducing a perturbation for singular models. It can be turned off by issuing the option crash_perturb no.

5.33.4.2.3 Nonmontone Searches  The first line of defense against convergence to stationary points is the use of a nonmonotone linesearch [90], [91], [56]. In this case we define a reference value, \( R^k \), and we use this value to test for sufficient decrease:

\[
\Psi(x^k + t_k d^k) \leq R^k + t_k \nabla \Psi(x^k)^T d^k.
\]

Depending upon the choice of the reference value, this allows the merit function to increase from one iteration to the next. This strategy can not only improve convergence, but can also avoid local minimizers by allowing such increases.

We now need to detail our choice of the reference value. We begin by letting \( \{M_1, \ldots, M_m\} \) be a finite set of values initialized to \( \kappa \Psi(x^0) \), where \( \kappa \) is used to determine the initial set of acceptable merit function values.

The value of \( \kappa \) defaults to 1 in the code and can be modified with the nms_initial_reference_factor option; \( \kappa = 1 \) indicates that we are not going to allow the merit function to increase beyond its initial value.

Having defined the values of \( \{M_1, \ldots, M_m\} \) (where the code by default uses \( m = 10 \)), we can now calculate a reference value. We must be careful when we allow gradient steps in the code. Assuming that \( d^k \) is the Newton direction, we define \( i_0 = \arg\max M_i \) and \( R^k = M_{i_0} \). After the nonmonotone linesearch rule above finds \( t_k \), we update the memory so that \( M_{i_0} = \Psi(x^k + t_k d^k) \), i.e. we remove an element from the memory having the largest merit function value.

When we decide to use a gradient step, it is beneficial to let \( x^k = x^{\text{best}} \) where \( x^{\text{best}} \) is the point with the absolute best merit function value encountered so far. We then recalculate \( d^k = -\nabla \Psi(x^k) \) using the best point and let \( R^k = \Psi(x^k) \). That is to say that we force decrease from the best iterate found whenever a gradient step is performed. After a successful step we set \( M_i = \Psi(x^k + t_k d^k) \) for all \( i \in [1, \ldots, m] \). This prevents future iterates from returning to the same problem area.

A watchdog strategy [35] is also available for use in the code. The method employed allows steps to be accepted when they are "close" to the current iterate. Nonmonotonic decrease is enforced every \( m \) iterations, where \( m \) is set by the nms_mstep_frequency option.

5.33.4.2.4 Linear Complementarity Problems  PATH solves a linear complementarity problem at each major iteration. Let \( M \in \mathbb{R}^{n \times n}, q \in \mathbb{R}^n, \) and \( B = [l, u] \) be given. \((z, w, v)\) solves the linear mixed complementarity problem defined by \( M, q, \) and \( B \) if and only if it satisfies the following constrained system of equations:

\[
Mz - w + v + q = 0 \tag{4}
\]

\[
w^T(z - l) = 0 \tag{5}
\]

\[
v^T(u - z) = 0 \tag{6}
\]
where $x + \infty = \infty$ for all $x \in \mathbb{R}$ and $0 \cdot \infty = 0$ by convention. A triple, $(\hat{z}, \hat{w}, \hat{v})$, satisfying equations (4) - (6) is called a complementary triple.

The objective of the linear model solver is to construct a path from a given complementary triple $(\hat{z}, \hat{w}, \hat{v})$ to a solution $(\bar{z}, \bar{w}, \bar{v})$. The algorithm used to solve the linear problem is identical to that given in [44]; however, artificial variables are incorporated into the model. The augmented system is then:

$$Mz - w + v + Da + \frac{(1 - t)}{s}(sr) + q = 0 \quad (8)$$

$$w^T(z - l) = 0 \quad (9)$$

$$v^T(u - z) = 0 \quad (10)$$

$$z \in \mathbb{B}, w \in \mathbb{R}_+^n, v \in \mathbb{R}_+^n, a \equiv 0, t \in [0, 1] \quad (11)$$

where $r$ is the residual, $t$ is the path parameter, and $a$ is a vector of artificial variables. The residual is scaled by $s$ to improve numerical stability.

The addition of artificial variables enables us to construct an initial invertible basis consistent with the given starting point even under rank deficiency. The procedure consists of two parts: constructing an initial guess as to the basis and then recovering from rank deficiency to obtain an invertible basis. The crash technique gives a good approximation to the active set. The first phase of the algorithm uses this information to construct a basis by partitioning the variables into three sets:

1. $W = \{ i \in \{1, \ldots, n\} \mid \hat{z}_i = l_i \text{ and } \hat{w}_i > 0 \}$
2. $V = \{ i \in \{1, \ldots, n\} \mid \hat{z}_i = u_i \text{ and } \hat{v}_i > 0 \}$
3. $Z = \{1, \ldots, n\} \setminus W \cup V$

Since $(\hat{z}, \hat{w}, \hat{v})$ is a complementary triple, $Z \cap W \cap V = \emptyset$ and $Z \cup W \cup V = \{1, \ldots, n\}$. Using the above guess, we can recover an invertible basis consistent with the starting point by defining $D$ appropriately. The technique relies upon the factorization to indicate the linearly dependent rows and columns of the basis matrix. Some of the variables may be nonbasic, but not at their bounds. For such variables, the corresponding artificial will be basic.

We use a modified version of EXPAND [83] to perform the ratio test. Variables are prioritized as follows:

1. $t$ leaving at its upper bound.
2. Any artificial variable.
3. Any $z$, $w$, or $v$ variable.

If a choice as to the leaving variable can be made while maintaining numerical stability and sparsity, we choose the variable with the highest priority (lowest number above).

When an artificial variable leaves the basis and a $z$-type variable enters, we have the choice of either increasing or decreasing that entering variable because it is nonbasic but not at a bound. The determination is made such that $t$ increases and stability is preserved.

If the code is forced to use a ray start at each iteration (lemke_start always), then the code carries out Lemke’s method, which is known [39] not to cycle. However, by default, we use a regular start to
guarantee that the generated path emanates from the current iterate. Under appropriate conditions, this
guarantees a decrease in the nonlinear residual. However, it is then possible for the pivot sequence in the
linear model to cycle. To prevent this undesirable outcome, we attempt to detect the formation of a cycle
with the heuristic that if a variable enters the basis more than a given number of times, we are cycling.
The number of times the variable has entered is reset whenever \( t \) increases beyond its previous maximum
or an artificial variable leaves the basis. If cycling is detected, we terminate the linear solver at the largest
value of \( t \) and return this point.

Another heuristic is added when the linear code terminates on a ray. The returned point in this case is
not the base of the ray. We move a slight distance up the ray and return this new point. If we fail to solve
the linear subproblem five times in a row, a Lemke ray start will be performed in an attempt to solve the
linear subproblem. Computational experience has shown this to be an effective heuristic and generally
results in solving the linear model. Using a Lemke ray start is not the default mode, since typically many
more pivots are required.

For times when a Lemke start is actually used in the code, an advanced ray can be used. We basically
choose the ”closest” extreme point of the polytope and choose a ray in the interior of the normal cone at
this point. This helps to reduce the number of pivots required. However, this can fail when the basis
pertaining to the cell is not invertible. We then revert to the Lemke start.

Since the EXPAND pivot rules are used, some of the variables may be nonbasic, but slightly infeasible,
as the solution. Whenever the linear code finishes, the nonbasic variables are put at their bounds and
the basic variables are recomputed using the current factorization. This procedure helps to find the best
possible solution to the linear system.

The resulting linear solver as modified above is robust and has the desired property that we start from
\((\hat{z}, \hat{w}, \hat{v})\) and construct a path to a solution.

5.33.4.2.5 Other Features Some other heuristics are incorporated into the code. During the first
iteration, if the linear solver fails to find a Newton point, a Lemke start is used. Furthermore, under
repeated failures during the linear solve, a Lemke start will be attempted. A gradient step can also be
used when we fail repeatedly.

The proximal perturbation is reduced at each major iteration. However, when numerical difficulties are
encountered, it will be increased to a fraction of the current merit function value. These are determined
when the linear solver returns a Reset or Singular status.

Spacer steps are taken every major iteration, in which the iterate is chosen to be the best point for the
normal map. The corresponding basis passed into the Lemke code is also updated.

Scaling is done based on the diagonal of the matrix passed into the linear solver.

We finally note, that if the merit function fails to show sufficient decrease over the last 100 iterates, a
restart will be performed, as this indicates we are close to a stationary point.

5.33.4.3 Difficult Models

5.33.4.3.1 Ill-Defined Models A problem can be ill-defined for several different reasons. We
concentrate on the following particular cases. We will call \( F \) well-defined at \( \bar{x} \in C \) if \( \bar{x} \in D \) and ill-
defined at \( \bar{x} \) otherwise. Furthermore, we define \( F \) to be well-defined near \( \bar{x} \in C \) if there exists an open
neighborhood of \( \bar{x}, \mathcal{N}(\bar{x}) \), such that \( C \cap \mathcal{N}(\bar{x}) \subseteq D \). By saying the function is well-defined near \( \bar{x} \), we are
simply stating that \( F \) is defined for all \( x \in C \) sufficiently close to \( \bar{x} \). A function not well-defined near \( \bar{x} \) is
termned ill-defined near \( \bar{x} \).

We will say that \( F \) has a well-defined Jacobian at \( \bar{x} \in C \) if there exists an open neighborhood of \( \bar{x}, \mathcal{N}(\bar{x}) \), such that \( \mathcal{N}(\bar{x}) \subseteq D \) and \( F \) is continuously differentiable on \( \mathcal{N}(\bar{x}) \). Otherwise the function has
an ill-defined Jacobian at $\bar{x}$. We note that a well-defined Jacobian at $\bar{x}$ implies that the MCP has a well-defined function near $\bar{x}$, but the converse is not true.

PATH uses both function and Jacobian information in its attempt to solve the MCP. Therefore, both of these definitions are relevant. We discuss cases where the function and Jacobian are ill-defined in the next two subsections. We illustrate uses for the merit function information and final point statistics within the context of these problems.

**Function Undefined** We begin with a one-dimensional problem for which $F$ is ill-defined at $x = 0$ as follows:

$$0 \leq x \perp \frac{1}{x} \geq 0.$$

Here $x$ must be strictly positive because $\frac{1}{x}$ is undefined at $x = 0$. This condition implies that $F(x)$ must be equal to zero. Since $F(x)$ is strictly positive for all $x$ strictly positive, this problem has no solution.

We are able to perform this analysis because the dimension of the problem is small. Preprocessing linear problems can be done by the solver in an attempt to detect obviously inconsistent problems, reduce problem size, and identify active components at the solution. Similar processing can be done for nonlinear models, but the analysis becomes more difficult to perform. Currently, PATH only checks the consistency of the bounds and removes fixed variables and the corresponding complementary equations from the model.

A modeler would likely not know a priori that a problem has no solution and would thus attempt to formulate and solve it. GAMS code for the model above is provided in Figure 8. We must specify an initial value for $x$ in the code. If we were to not provide one, GAMS would use $x = 0$ as the default value, notice that $F$ is undefined at the initial point, and terminate before giving the problem to PATH. The error message indicates that the function $\frac{1}{x}$ is ill-defined at $x = 0$, but does not imply that the corresponding MCP problem has no solution.

**Figure 8:** GAMS Code for Ill-Defined Function

```gams
positive variable x;
equations F;
F.. 1 / x =g= 0;
model simple / F.x /;
x.l = 1e-6;
solve simple using mcp;
```

After setting the starting point, GAMS generates the model, and PATH proceeds to "solve" it. A portion of the output relating statistics about the solution is given in Figure 9. PATH uses the Fischer Function indicator as its termination criteria by default, but evaluates all of the merit functions given in Section Merit Functions at the final point. The Normal Map merit function, and to a lesser extent, the complementarity error, indicate that the "solution" found does not necessarily solve the MCP.

To indicate the difference between the merit functions, Figure 10 plots them all for this simple example. We note that as \( x \) approaches positive infinity, numerically, we are at a solution to the problem with respect to all of the merit functions except for the complementarity error, which remains equal to one. As \( x \) approaches zero, the merit functions diverge, also indicating that \( x = 0 \) is not a solution.

The natural residual and Fischer function tend toward 0 as \( x \downarrow 0 \). From these measures, we might think \( x = 0 \) is the solution. However, as previously remarked \( F \) is ill-defined at \( x = 0 \). \( F \) and \( \nabla F \) become very large, indicating that the function (and Jacobian) might not be well-defined. We might be tempted to conclude that if one of the merit function indicators is not close to zero, then we have not found a solution. This conclusion is not always warranted. When one of the indicators is non-zero, we have reservations about the solution, but we cannot eliminate the possibility that we are actually close to a solution. If we slightly perturb the original problem to

\[
0 \leq x \perp \frac{1}{x + \epsilon} \geq 0
\]

for a fixed \( \epsilon > 0 \), the function is well-defined over \( C = \mathbb{R}_+^n \) and has a unique solution at \( x = 0 \). In this case, by starting at \( x > 0 \) and sufficiently small, all of the merit functions, with the exception of the Normal Map, indicate that we have solved the problem as is shown by the output in Figure 11 for \( \epsilon = 1 \times 10^{-6} \) and \( x = 1 \times 10^{-20} \).

**Figure 11: PATH Output for Well-Defined Function**

---

**FINAL STATISTICS**

- Inf-Norm of Complementarity . . 1.0000e-14 eqn: (G)
- Inf-Norm of Normal Map . . . . 1.0000e+06 eqn: (G)
- Inf-Norm of Minimum Map . . . . 1.0000e-20 eqn: (G)
- Inf-Norm of Fischer Function . . 1.0000e-20 eqn: (G)
- Inf-Norm of Grad Fischer Fcn . . 1.0000e-20 eqn: (G)
In this case, the Normal Map is quite large and we might think that the function and Jacobian are undefined. When only the normal map is non-zero, we may have just mis-identified the optimal basis. By setting the merit function normal option, we can resolve the problem, identify the correct basis, and solve the problem with all indicators being close to zero. This example illustrates the point that all of these tests are not infallible. The modeler still needs to do some detective work to determine if they have found a solution or if the algorithm is converging to a point where the function is ill-defined.

**Jacobian Undefined** Since PATH uses a Newton-like method to solve the problem, it also needs the Jacobian of $F$ to be well-defined. One model for which the function is well-defined over $C$, but for which the Jacobian is undefined at the solution is: $0 \leq x^\perp - \sqrt{x} \geq 0$. This model has a unique solution at $x = 0$.

Using PATH and starting from the point $x = 1 \times 10^{-14}$, PATH generates the output given in Figure 12.

**Figure 12:** PATH Output for Ill-Defined Jacobian

---

We can see that the gradient of the Fischer Function is nonzero and the Jacobian is beginning to become large. These conditions indicate that the Jacobian is undefined at the solution. It is therefore important for a modeler to inspect the given output to guard against such problems.

If we start from $x = 0$, PATH correctly informs us that we are at the solution. The large value reported for the Jacobian is an indication that the Jacobian is undefined.

### 5.33.4.3.2 Poorly Scaled Models

Well-defined problems can still have various numerical problems that impede the algorithm's convergence. One particular problem is a badly scaled Jacobian. In such cases, we can obtain a poor "Newton" direction because of numerical problems introduced in the linear algebra performed. This problem can also lead the code to a point from which it cannot recover.

The final model given to the solver should be scaled such that we avoid numerical difficulties in the linear algebra. The output provided by PATH can be used to iteratively refine the model so that we eventually end up with a well-scaled problem. We note that we only calculate our scaling statistics at the starting point provided. For nonlinear problems these statistics may not be indicative of the overall scaling of the model. Model specific knowledge is very important when we have a nonlinear problem because it can be used to appropriately scale the model to achieve a desired result.

We look at the titan.gms model in MCPLIB, that has some scaling problems. The relevant output from PATH for the original code is given in Figure 13.

**Figure 13:** PATH Output - Poorly Scaled Model
INITIAL POINT STATISTICS

Maximum of X. . . . . . . . . . . 4.1279e+06 var: (w.29)
Maximum of F. . . . . . . . . . . 2.2516e+00 eqn: (a1.33)
Maximum of Grad F . . . . . . . . 6.7753e+06 eqn: (a1.29)

INITIAL JACOBIAN NORM STATISTICS

Maximum Row Norm. . . . . . . . . 9.4504e+06 eqn: (a2.29)
Minimum Row Norm. . . . . . . . . 2.7680e-03 eqn: (g.10)
Maximum Column Norm . . . . . . . 9.4504e+06 var: (x1.29)
Minimum Column Norm . . . . . . . 1.3840e-03 var: (w.10)

The maximum row norm is defined as
\[ \max_{1 \leq i \leq n} \sum_{1 \leq j \leq n} |(\nabla F(x))_{ij}| \]
and the minimum row norm is
\[ \min_{1 \leq i \leq n} \sum_{1 \leq j \leq n} |(\nabla F(x))_{ij}| . \]

Similar definitions are used for the column norm. The norm numbers for this particular example are not extremely large, but we can nevertheless improve the scaling. We first decided to reduce the magnitude of the a1 block of equations as indicated by PATH. Using the GAMS modeling language, we can scale particular equations and variables using the .scale attribute. To turn the scaling on for the model we use the .scaleopt model attribute. After scaling the a1 block, we re-ran PATH and found an additional block of equations that also needed scaling, a2. We also scaled some of the variables, g and w. The code added to the model follows:

```gams
  titan.scaleopt = 1;
  a1.scale(i) = 1000;
  a2.scale(i) = 1000;
  g.scale(i) = 1/1000;
  w.scale(i) = 100000;
```

By scaling these equation and variable blocks, we have improved the model scaling. The statistics for the manually scaled model are given in Figure 14.

Figure 14: PATH Output - Well-Scaled Model

INITIAL POINT STATISTICS

Maximum of X. . . . . . . . . . . 1.0750e+03 var: (x1.49)
Maximum of F. . . . . . . . . . . 3.9829e-01 eqn: (g.10)
Maximum of Grad F . . . . . . . . 6.7753e+06 eqn: (a1.29)

INITIAL JACOBIAN NORM STATISTICS

Maximum Row Norm. . . . . . . . . 9.4524e+06 eqn: (a2.29)
Minimum Row Norm. . . . . . . . . 2.7680e-03 eqn: (g.10)
Maximum Column Norm . . . . . . . 9.4904e+03 var: (x2.29)
Minimum Column Norm . . . . . . . 1.3840e-01 var: (w.10)

For this particular problem PATH cannot solve the unscaled model, while it can find a solution to the scaled model. Using the scaling features of the GAMS language and the information provided by PATH we are able to remove some of the problem’s difficulty and obtain better performance from PATH.

It is possible to get even more information on initial point scaling by inspecting the GAMS listing file. The equation row listing gives the values of all the entries of the Jacobian at the starting point. The row norms generated by PATH give good pointers for starting to use the row listing.

Not all of the numerical problems are directly attributable to poorly scaled models. Problems for which the Jacobian of the active constraints is singular or nearly singular can also cause numerical difficulty as illustrated next.
5.33.4.3.3 **Singular Models**  Assuming that the problem is well-defined and properly scaled, we can still have a Jacobian for which the active constraints are singular or nearly singular (i.e. it is ill-conditioned). When problems are singular or nearly singular, we are also likely to have numerical problems. As a result the "Newton" direction obtained from the linear problem solver can be very bad. In PATH, we can use proximal perturbation or add artificial variables to attempt to remove the singularity problems from the model. However, it is most often beneficial for solver robustness to remove singularities if possible.

The easiest problems to detect are those for which the Jacobian has zero rows and columns. A simple problem for which we have zero rows and columns is:

\[-2 \leq x \leq 2 \quad \perp \quad -x^2 + 1.\]

Note that the Jacobian, \(-2x\), is non-singular at all three solutions, but singular at the point \(x = 0\). Output from PATH on this model starting at \(x = 0\) is given in Figure 15.

**Figure 15:** PATH Output - Zero Rows and Columns

```
INITIAL POINT STATISTICS
Zero column of order . . . . . . 0.0000e+00 var: (X)
Zero row of order . . . . . . . 0.0000e+00 eqn: (F)
Total zero columns . . . . . . . 1
Total zero rows . . . . . . . . . 1
Maximum of F . . . . . . . . . . 1.0000e+00 eqn: (F)
Maximum of Grad F . . . . . . . 0.0000e+00 eqn: (F)
                      var: (X)
```

We display in the code the variables and equations for which the row/column in the Jacobian is close to zero. These situations are problematic and for nonlinear problems likely stem from the modeler providing an inappropriate starting point or fixing some variables resulting in some equations becoming constant. We note that the solver may perform well in the presence of zero rows and/or columns, but the modeler should make sure that these are what was intended.

Singularities in the model can also be detected by the linear solver. This in itself is a hard problem and prone to error. For matrices which are poorly scaled, we can incorrectly identify "linearly dependent" rows because of numerical problems. Setting `output_factorization_singularities yes` in an options file will inform the user which equations the linear solver thinks are linearly dependent. Typically, singularity does not cause a lot of problems and the algorithm can handle the situation appropriately. However, an excessive number of singularities are cause for concern. A further indication of possible singularities at the solution is a lack of quadratic convergence to the solution.

5.33.5 **Case Study: Von Thunen Land Model**

We now turn our attention towards using the diagnostic information provided by PATH to improve an actual model. The Von Thunen land model is a problem recognized in the mathematical programming literature for its computational difficulty. We attempt to understand more carefully the facets of the problem that make it difficult to solve. This will enable us to outline and identify these problems and furthermore to extend the model to a more realistic and computationally more tractable form.
5.33.5.1 Classical Model

The problem is cast in the Arrow-Debreu framework as an equilibrium problem. The basic model is a closed economy consisting of three economic agents, a landowner, a worker and a porter. There is a central market, around which concentric regions of land are located. Since the produced goods have to be delivered to the market, this is an example of a spatial price equilibrium. The key variables of the model are the prices of commodities, land, labour and transport. Given these prices, it is assumed that the agents demand certain amounts of the commodities, which are supplied so as to maximize profit in each sector. Walras’ law is then a consequence of the assumed competitive paradigm, namely that supply will equal demand in the equilibrium state.

We now describe the problems that the consumers and the producers face. We first look at consumption and derive a demand function for each of the consumer agents in the economy. Each of these agents has a utility function, that they wish to maximize subject to their budgetary constraints. As is typical in such problems, the utility function is assumed to be Cobb-Douglas:

\[ u_a(d) = \prod_c d_c^{\alpha_{c,a}} \quad \alpha_{c,a} \geq 0, \sum_c \alpha_{c,a} = 1, \]

where the \( \alpha_{c,a} \) are given parameters dependent only on the agent. For each agent \( a \), the variables \( d_c \) represent quantities of the desired commodities \( c \). In the Von Thunen model, the goods are wheat, rice, corn and barley. The agent’s endowments determine their budgetary constraint as follows. Given current market prices, an agent’s wealth is the value of the initial endowment of goods at those prices. The agent’s problem is therefore

\[ \max u_a(d) \text{ subject to } (p, d) \leq (p, e_a), d \geq 0, \]

where \( e_a \) is the endowment bundle for agent \( a \). A closed form solution, corresponding to demand from agent \( a \) for commodity \( c \) is thus

\[ d_{c,a}(p) := \frac{\alpha_{c,a}[p, e_a]}{p_c}. \]

Note that this assumes the prices of the commodities \( p_c \) are positive.

The supply side of the economy is similar. The worker earns a wage \( w_L \) for his labour input. The land is distributed around the market in rings with a rental rate \( w_r \) associated with each ring \( r \) of land. The area of land \( a_r \) in each ring is an increasing function of \( r \). The model assumes that labour and land are substitutable via a constant elasticities of substitution (CES) function.

Consider the production \( x_{c,r} \) of commodity \( c \) in region \( r \). In order to maximize profit (or minimize costs), the labour \( y_L \) and land use \( y_r \) solve

\[ \min w_L y_L + w_r y_r \text{ subject to } \phi_c y_c^{\beta_c} y_r^{1-\beta_c} \geq x_{c,r}, \quad y_L, y_r \geq 0, \]

(12)

where \( \phi_c \) is a given cost function scale parameter, and \( \beta_c \in [0, 1] \) is the share parameter. The technology constraint is precisely the CES function allowing a suitable mix of labour and land use. Again, a closed form solution can be calculated. For example, the demand for labour in order to produce \( x_{c,r} \) of commodity \( c \) in region \( r \) is given by

\[ x_{c,r} \left( \frac{w_L}{\phi_c} \right)^{\beta_c} \left( \frac{w_r}{1-\beta_c} \right)^{1-\beta_c}. \]

Considering all such demands, this clearly assumes the prices of inputs \( w_L, w_r \) are positive. A key point to note is that input commodity (factor) demands to produce \( x_{c,r} \) can be determined by first solving (12) for unit demand \( x_{c,r} \equiv 1 \) and then multiplying these factor demands by the actual amount desired. Let \( \bar{y}_L \) and \( \bar{y}_r \) denote the optimal solutions of (12) with \( x_{c,r} \equiv 1 \). Using this fact, the unit production cost \( \gamma_{c,r} \) for commodity \( c \) in region \( r \) can be calculated as follows:
\( \gamma_{c,r} = w_L y_L + w_r y_r \)
\( \gamma_{c,r} = w_L \left( \frac{w_L}{\phi_c w_L} \right)^{\beta_c} \left( \frac{w_r}{1 - \beta_c} \right)^{1 - \beta_c} \)
\( \gamma_{c,r} = \frac{1}{\phi_c} \left( \frac{w_L}{\beta_c} \right)^{\beta_c} \left( \frac{w_r}{1 - \beta_c} \right)^{1 - \beta_c} \).

Transportation is provided by a porter, earning a wage \( w_p \). If we denote the unit cost for transportation of commodity \( c \) by \( t_c \), then unit transportation cost to market is
\( T_{c,r}(w_p) := t_c d_r w_p \),
where \( d_r \) is the distance of region \( r \) to the market. Spatial price equilibrium arises from the consideration:
\( 0 \leq x_{c,r} \perp \gamma_{c,r}(w_L, w_r) + T_{c,r}(w_p) \geq p_c \).
This is intuitively clear; it states that commodity \( c \) will be produced in region \( r \) only if the combined cost of production and transportation equals the market price.

The above derivations assumed that the producers and consumers acted as price takers. Walras’ law is now invoked to determine the prices so that markets clear. The resulting complementarity problem is:
\( \gamma_{c,r} = \frac{1}{\phi_c} \left( \frac{w_L}{\beta_c} \right)^{\beta_c} \left( \frac{w_r}{1 - \beta_c} \right)^{1 - \beta_c} \) (13)
\( 0 \leq x_{c,r} \perp \gamma_{c,r} + T_{c,r}(w_p) \geq p_c \) (14)
\( 0 \leq w_L \perp \epsilon_L \geq \sum_{r,c} x_{c,r} \frac{\beta_c \gamma_{c,r}}{w_L} \) (15)
\( 0 \leq w_r \perp \epsilon_r \geq \sum_{c} x_{c,r} (1 - \beta_c) \gamma_{c,r} \) (16)
\( 0 \leq w_p \perp \epsilon_p \geq \sum_{r,c} t_c d_r x_{c,r} \) (17)
\( 0 \leq p_c \perp \sum_{r,c} x_{c,r} \geq \frac{\alpha_c P \epsilon_p w_p + \alpha_c L \epsilon_L w_L + \alpha_c O \sum_r w_r a_r}{p_c} \) (18)

Note that in (15), (16) and (17), the amounts of labour, land and transport are bounded from above, and hence the prices on these inputs are determined as multipliers (or shadow prices) on the corresponding constraints. The final relationship (18) in the above complementarity problem corresponds to market clearance; prices are nonnegative and can only be positive if supply equals demand. (Some modelers multiply the last inequality throughout by \( p_c \). This removes problems where \( p_c \) becomes zero, but can also introduce spurious solutions.)

The Arrow-Debreu theory guarantees that the problem is homogeneous in prices; \( (x, \lambda w, \lambda p) \) is also a solution whenever \( (x, w, p) \) solves the above. Typically this singularity in the model is removed by fixing a numeraire, that is fixing a price (for example \( w_L = 1 \)) and dropping the corresponding complementary relationship.
Unfortunately, in this formulation even after fixing a numeraire, some of the variables $p$ and $w$ may go to zero, resulting in an ill-defined problem. In the case of the Von Thunen land model, the rental price of land $w_r$ decreases as the distance to market increases, and for remote rings of land, it becomes zero. A standard modeling fix is to put artificial lower bounds on these variables. Even with this fix, the problem typically remains very hard to solve. More importantly, the homogeneity property of the prices used above to fix a numeraire no longer holds, and the corresponding complementary relationship (which was dropped from the problem) may fail to be satisfied. It therefore matters which numeraire is fixed, and many modelers run into difficulty since in many cases the solution found by a solver is invalid for the originally posed model.

In order to test our diagnostic information, we implemented a version of the above model in GAMS. The model corresponds closely to the MCPLIB model pgvon105.gms except we added more regions to make the problem even more difficult. The model file has been documented more fully, and the data rounded to improve clarity.

Our first trial was to solve the model without fixing a numeraire. In this case, PATH 4.x failed to find a solution. At the starting point, the indicators described in Section Ill-Defined Models are reasonable, and there are no zero rows/columns in the Jacobian. At the best point found, all indicators are still reasonable. However, the listing file indicates a large number of division by zero problems occurring in (16). We also note that a nonzero proximal perturbation is used in the first iteration of the crash method. This is an indication of singularities. We therefore added an option to output factorization singularities, and singularities appeared in the first iteration. At this point, we decided to fix a numeraire to see if this alleviated the problem.

We chose to fix the labour wage rate to 1. After increasing the iterations allowed to 100,000, PATH 4.x solved the problem. The statistics at the solution are cause for concern. In particular, the gradient of the Fischer function is 7 orders of magnitude larger than all the other residuals. Furthermore, the Jacobian is very large at the solution point. Looking further in the listing file, a large number of division by zero problems occur in (16).

To track down the problem further, we added an artificial lower bound on the variables $w_r$ of $10^{-5}$, that would not be active at the aforementioned solution. Resolving gave the same “solution”, but resulted in the domain errors disappearing.

Although the problem is solved, there is concern on two fronts. Firstly, the gradient of the Fischer function should go to zero at the solution. Secondly, if a modeler happens to make the artificial lower bounds on the variables a bit larger, then they become active at the solution, and hence the constraint that has been dropped by fixing the price of labour at 1 is violated at this point. Of course, the algorithm is unable to detect this problem, since it is not part of the model that is passed to it, and the corresponding output looks satisfactory.

We are therefore led to the conclusion that the model as postulated is ill-defined. The remainder of this section outlines two possible modeling techniques to overcome the difficulties with ill-defined problems of this type.

### 5.33.5.2 Intervention Pricing

The principal difficulty is the fact that the rental prices on land go to zero as proximity to the market decreases, and become zero for sufficiently remote rings. Such a property is unlikely to hold in a practical setting. Typically, a landowner has a minimum rental price (for example, land in fallow increases in value). As outlined above, a fixed lower bound on the rental price violates the well-established homogeneity property. A suggestion postulated by Professor Thomas Rutherford is to allow the landowner to intervene and “purchase-back” his land whenever the rental cost gets smaller than a certain fraction of the labour wage.

The new model adds a (homogeneous in price) constraint

$$0 \leq i_r \perp w_r \geq 0.0001 \ast w_L$$
and modifies (16) and (18) as follows:

\[
0 \leq w_r \top a_r - i_r \geq \sum_c x_{c,r}(1 - \beta_c)\gamma_{c,r} \frac{w_r}{w_L}
\]

\[
0 \leq p_c \top \sum_r x_{c,r} \geq \frac{\alpha_{c,P}PePw_p + \alpha_{c,L}eLw_L + \alpha_{c,O} \sum_r w_r (a_r - i_r)}{p_c}.
\]

Given the intervention purchase, we can now add a lower bound on \(w_r\) to avoid division by zero errors. In our model we chose \(10^{-5}\) since this will never be active at the solution and therefore will not affect the positive homogeneity. After this reformulation, PATH 4.x solves the problem. Furthermore, the gradient of the Fischer function, although slightly larger than the other residuals, is quite small, and can be made even smaller by reducing the convergence tolerance of PATH. Inspecting the listing file, the only difficulties mentioned are division by zero errors in the market clearance condition (19), that can be avoided a posteriori by imposing an artificial (inactive) lower bound on these prices. We chose not to do this however.

### 5.33.5.3 Nested Production and Maintenance

Another observation that can be used to overcome the land price going to zero is the fact that land typically requires some maintenance labour input to keep it usable for crop growth. Traditionally, in economics, this is carried out by providing a nested CES function as technology input to the model. The idea is that commodity \(c\) in region \(r\) is made from labour and an intermediate good, which is "maintained land". Essentially, the following production problem replaces (12):

\[
\begin{align*}
\min_{y_M, y_L, y_r, g} & \quad w_L(y_M + y_L) + w_r y_r \\
\text{subject to} & \quad y_r \geq (1 - \beta_c - \epsilon)g \\
& \quad y_M \geq \epsilon g \\
& \quad \phi_c y_L^{\beta_c} g^{-\beta_c} \geq 1, \\
& \quad y_M, y_L, y_r, g \geq 0.
\end{align*}
\]

Note that the variable \(y_M\) represents "maintenance labour" and \(g\) represents the amount of "maintained land" produced, an intermediate good. The process of generating maintained land uses a Leontief production function, namely

\[
\min(\lambda_r y_r, \lambda_M y_M) \geq g.
\]

Here \(\lambda_M = \frac{1}{2}, \epsilon\) small, corresponds to small amounts of maintenance labour, while \(\lambda_r = \frac{1}{1 - \beta_c - \epsilon}\) is chosen to calibrate the model correctly. A simple calculus exercise then generates appropriate demand and cost expressions. The resulting complementarity problem comprises (14), (17), (18) and

\[
\begin{align*}
\gamma_{c,r} &= \frac{w_r}{w_L} \left( \frac{w_L (1 - \beta_c - \epsilon)}{1 - \beta_c} \right)^{1-\beta_c} \\
0 &\leq w_L \top e_L \geq \sum_{r,c} x_{c,r} \gamma_{c,r} \left( \beta_c \frac{w_L}{w_L + w_r (1 - \beta_c - \epsilon)} + \epsilon (1 - \beta_c) \right) \\
0 &\leq w_r \top a_r \geq \sum_c x_{c,r} \gamma_{c,r} \left( \frac{1 - \beta_c}{w_L + w_r (1 - \beta_c - \epsilon)} \right)
\end{align*}
\]

After making the appropriate modifications to the model file, PATH 4.x solved the problem on defaults without any difficulties. All indicators showed the problem and solution found to be well-posed.
5.34 quadMINOS

For LP (and RMIP) models that cause difficulty for the standard solvers, quadMINOS provides considerably greater reliability and accuracy than MINOS by using quadruple-precision floating-point arithmetic. Although it is slower by a factor of 20 or 30 for cold-start runs, you can use standard MINOS or another LP solver first and let them do their best. Warm-starts with quadMINOS may give greatly improved solutions at moderate cost.

To take advantage of quadMINOS, the main requirement is to set a few runtime options to non-default values in order to request higher accuracy. For example, it is reasonable to set

```
  Feasibility tolerance 1e-15
  Optimality tolerance 1e-15
```

because IEEE Quad floating-point has nearly 34 digits of precision. For an example of using Double and Quad MINOS together, see [DQQ] in the GAMS model library.

Note

GAMS/quadMINOS can only solve LPs and RMIPs at the moment because GAMS does not provide function evaluations in quad-precision.

The documentation of MINOS also refers to quadMINOS.

5.35 SBB

5.35.1 Introduction

SBB is a GAMS solver for Mixed Integer Nonlinear Programming (MINLP) models. It is based on a combination of the standard Branch and Bound (B&B) method known from Mixed Integer Linear Programming and some of the standard NLP solvers already supported by GAMS. SBB can use all GAMS NLP solvers as subsolvers but it works best with NLP solvers that can utilize a near optimal point as a starting point like Conopt, Minos, and Snopt.

SBB supports all types of discrete variables supported by GAMS, including Binary, Integer, Semicont, Semiint, Sos1, and Sos2.

5.35.2 The Branch and Bound Algorithm

The Relaxed Mixed Integer Nonlinear Programming (RMINLP) model is initially solved using the starting point provided by the modeler. SBB will stop immediately if the RMINLP model is unbounded or infeasible, or if it fails (see option `infeasseq` and `failseq` below for an exception). If all discrete variables in the RMINLP model are integer, SBB will return this solution as the optimal integer solution. Otherwise, the current solution is stored and the Branch and Bound procedure will start.

During the Branch and Bound process, the feasible region for the discrete variables is subdivided, and bounds on discrete variables are tightened to new integer values to cut off the current non-integer solutions. Each time a bound is tightened, a new, tighter NLP submodel is solved starting from the optimal solution to the previous looser submodel. The objective function values from the NLP submodel is assumed to be lower bounds on the objective in the restricted feasible space (assuming minimization), even though the local optimum found by the NLP solver may not be a global optimum. If the NLP solver returns a Locally Infeasible status for a submodel, it is usually assumed that there is no feasible solution to the submodel, even though the infeasibility only has been determined locally (see option `infeasseq` below for an exception). If the model is convex, these assumptions will be satisfied and SBB will provide correct bounds. If the model is not convex, the objective bounds may not be correct and better solutions may exist in other, unexplored parts of the search space.
5.35.3 SBB with Pseudo Costs

Over the last decades quite a number of search strategies have been successfully introduced for mixed integer linear programming (for details see e.g. J.T. Linderoth and M.W.P. Savelsbergh. A Computational Study of Search Strategies for Mixed Integer Programming, INFORMS Journal on Computing, 11(2), 1999). Pseudo costs are key elements of sophisticated search strategies. Using pseudo costs, we can estimate the degradation of the objective function if we move a fractional variable to a close integer value. Naturally, the variable selection can be based on pseudo costs (see SBB option varsel). Node selection can also make use of pseudo cost: If we can estimate the change of the objective for moving one fractional variable to the closed integer value, we can then aggregate this change for all fractional variables, to estimate the objective of the best integer solution reachable from a particular node (see SBB option nodesel).

Unfortunately, the computation of pseudo cost can be a substantial part of the overall computation. Models with a large number of fractional variables in the root node are not good candidates for search strategies which require pseudo costs (varsel 3, nodesel 3,5,6). The impact (positive or negative) of using pseudo cost depends significantly on the particular model. At this stage, general statements are difficult to make.

Selecting pseudo cost related search strategies (varsel 3, nodesel 3,5,6) may use computation time which sometimes does not pay off. However, we encourage the user to try these options for difficult models which require a large number of branch-and-bound nodes to solve.

5.35.4 The SBB Options

SBB works like other GAMS solvers, and many options can be set in the GAMS model. The most relevant GAMS options are IterLim, ResLim, NodLim, OptCA, OptCR, OptfFile, Cheat, and CutOff. A description of all available GAMS options can be found in the GAMS User's Guide Solver related options. GAMS options PriorOpt and TryInt are also accepted by SBB.

SBB uses the var.prior information to select the fractional variable with the smallest priority during the variable selection process. SBB uses the TryInt information to set the branching direction in the B&B algorithm. At the beginning, SBB looks at the levels of the discrete variables provided by the user and if Abs(Round(x.l)-x.l) < m.TryInt, SBB will branch on that variable in the direction of Round(x.l). For example, x.l=0.9 and m.TryInt=0.2. We have Abs(Round(0.9)-0.9)=0.1 < 0.2, so when SBB decides to branch on this variable (because it is fractional, lets say with value 0.5), the node explored next will have the additional constraint x ≥ 1 (the node with x ≤ 0 will be explored later). If everything goes well (there is the chance that we end up in a different local optima in the subsolves for non-convex problems), SBB should reproduce a preset incumbent solution in a couple of nodes.

If you specify <modelname>.OptFile = 1; before the Solve statement in your GAMS model, SBB will then look for and read an option file with the name sbb.opt (see The Solver Option File for general use of solver option files). Unless explicitly specified in the SBB option file, the NLP subsolvers will not read an option file. The syntax for the SBB option file is

```
optname value
```

with one option on each line.

For example,

```
rootsolver conopt.1
subsolver snopt
loginterval 10
```

The first two lines determine the NLP subsolvers for the Branch and Bound procedure. CONOPT with the option file conopt.opt will be used for solving the root node. SNOPT with no option file will be used for the remaining nodes. The last option determines the frequency for log line printing. Every 10th node, and each node with a new integer solution, causes a log line to be printed. The following options are implemented:
<table>

</table>
acceptnonopt (boolean): accepts feasible solution from subsolver

If this option is set to 1 and the subsolver terminates with solver status Terminated by Solver and model status Intermediate Nonoptimal SBB takes this as a good solution and keeps on going. In default mode such a return is treated as a subsolver failure and the failseq is consulted.

Default: 0

avgresmult (integer): average resource multiplicator

Similar to subres, this option allows the user to control the time limit spend in a node. SBB keeps track of how much time is spent in the nodes, and builds an average over time. This average multiplied by the factor avgresmult is set as a time limit for solving a node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure: the node is ignored or the solvers in the failseq are called. The default multiplier avgresmult is 5. Setting avgresmult to 0 will disable the automatic time limit feature. A multiplier is not very useful for very small node solution times; therefore, independent of each node, SBB grants the solver at least 5 seconds to solve the node. The competing option subres overwrites the automatically generated resource limit.

Default: 5

dfsstay (integer): keeps DFS node selection after solution has been found

If the node selection is a B*/DFS mix, SBB switches frequently to DFS node selection mode. It switches back into B* node selection mode, if no subnodes were created (new int, pruned, infeasible, fail). It can be advantageous to search the neighborhood of the last node also in a DFS manner. Setting dfsstay to n instructs SBB to stay in DFS mode for another n nodes.

Default: 0

epint (real): integer feasibility tolerance

The integer infeasibility tolerance.

Range: [1e-9, 1]

Default: 1.0e-5

failseq (string): solver sequence for failed nodes

solver1[.n1] solver2[.n2] ... where solver1 is the name of a GAMS NLP solver to be used if the default solver fails, i.e., if it was not stopped by an iteration, resource, or domain limit and does not return a locally optimal or locally infeasible solution. n1 is the value of optfile passed to the alternative NLP solver. If .n1 is left blank it is interpreted as zero. Similarly, solver2 is the name of a GAMS NLP solver that is used if solver1 fails, and n2 is the value of optfile passed to the second NLP solver. If you have a difficult model where solver failures are not unlikely, you may add more solver.n pairs. You can use the same solver several times with different options files. failseq conopt conopt.2 conopt.3 means to try CONOPT with no options file. If this approach also fails, try CONOPT with options file conopt.op2, and if it again fails, try CONOPT with options file conopt.op3. If all solver and options file combinations fail the node will be labeled ignored and the node will not be explored further. The default is to try only one solver (the rootsolver or subsolver) and to ignore nodes with a solver failure.

infeasseq (string): solver sequence for infeasible nodes
level solver1[,n1] solver2[,n2] ... The purpose of infeasseq is to avoid cutting parts of the search tree that appear to be infeasible but really are feasible. If the NLP solver labels a node Locally Infeasible and the model is not convex a feasible solution may actually exist. If SBB is high in the search tree it can be very drastic to prune the node immediately. SBB is therefore directed to try the solver/option combinations in the list as long as the depth in the search tree is less than the integer value level. If the list is exhausted without finding a feasible solution, the node is assumed to be infeasible. The default is to trust that Locally Infeasible nodes are indeed infeasible and to remove them from further consideration.

intsol {integer}: maximum number of integer solutions ➞

Maximum number of integer solutions. If this number is exceeded, SBB will terminate and return the best solution found so far.

Default: 2100000000

loginterval {integer}: progress display interval ➞

The interval (number of nodes) for which log lines are written.

Default: 1

loglevel {integer}: level of solver display ➞

The level of log output.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>

</tr>
<tr>
<td>2</td>
<td>print best estimate</td>
</tr>
</tbody>
</table>

**rootsolver (string):** solver for the root node

`solver[,n]` Solver is the name of the GAMS NLP solver that should be used in the root node, and `n` is the integer corresponding to optfile for the root node. If `n` is missing, the optfile treated as zero i.e. the NLP solver will not look for an options file. This SBB option can be used to overwrite the default that uses the NLP solver specified with an `Option NLP = solver;` statement or the default GAMS solver for NLP.

Default: GAMS NLP solver

**solvelink (integer):** Solvelink for GAMS NLP solver

Default: 5

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tr>
</tbody>
</table>

**subiter (integer):** iteration limit for the subsolve

The default for `subiter` passed on through `iterlim`. Similar to `subres` but sets the iteration limit for solving a node in the B&B tree.

Default: GAMS iterlim
subres (real): resource limit for the subsolve

The default for subres passed on through reslim. Sets the time limit in seconds for solving a node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure and the node is ignored, or the solvers in the failseq are called.

Default: GAMS reslim

subsolver (string): solver for the subproblems

solver[n] Similar to rootsolver but applied to the subnodes.

Default: GAMS NLP solver

usercallparmfile (string): Command-line parameter include file used in GAMS command-line calls triggered by BCH

usergdxname (string): the name of the GDX file exported from the solver with the solution at the node

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchout.gdx

usergdxnameinc (string): the name of the GDX file exported from the solver with the incumbent solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: bchout_i.gdx

userheurcall (string): the GAMS command line to call the heuristic

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userheurfirst (integer): calls the cut generator for the first n nodes

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

userheurfreq (integer): determines the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

userheurinterval (integer): determines the interval when to apply the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 100

userheurmult (integer): determines the multiplier for the frequency of the cut generator model calls

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 2

userheurnewint (boolean): calls the heuristic if the solver found a new integer feasible solution

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 0

userheurobjfirst (integer): Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 50

varsel (integer): variable selection strategy at each node

Variable selection scheme.

Default: 0
5.35.5 The SBB Log File

The SBB Log file (usually directed to the screen) can be controlled with the loginterval and loglevel options in SBB. It will by default first show the iteration output from the NLP solver that solves the root node. This is followed by output from SBB describing the search tree. An example of this search tree output follows:

<table>
<thead>
<tr>
<th>Node</th>

The fields in the log are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node</td>
<td>The number of the current node. The root node is node 0.</td>
</tr>
<tr>
<td>Act</td>
<td>The number of active nodes defined as the number of subnodes that have not yet been solved.</td>
</tr>
<tr>
<td>Lev</td>
<td>The level in the search tree, i.e., the number of branches needed to reach this node.</td>
</tr>
<tr>
<td>Objective</td>
<td>The objective function value for the node. A numerical value indicates that the node was solved and the objective was good enough for the node to not be ignored. &quot;pruned&quot; indicates that the objective value was worse than the best integer value, &quot;infeasible&quot; indicates that the node was Infeasible or Locally Infeasible, and &quot;ignored&quot; indicates that the node could not be solved (see under failseq above).</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IInf</td>
<td>The number of integer infeasibilities, i.e. the number of variables that are supposed to be binary or integer that do not satisfy the integrality requirement. Semi continuous variables and SOS variables may also contribute to IInf.</td>
</tr>
<tr>
<td>Best Int</td>
<td>The value of the best integer solution found so far. A dash (-) indicates that an integer solution has not yet been found. A star (*) in column one indicates that the node is integer and that the solution is better than the best yet found.</td>
</tr>
<tr>
<td>Best Bound</td>
<td>The minimum value of &quot;Objective&quot; for the subnodes that have not been solved yet (maximum for maximization models). For convex models, Best Bound will increase monotonically. For nonconvex models, Best Bound may decrease, indicating that the Objective value for a node was not a valid lower bound for that node.</td>
</tr>
<tr>
<td>Gap</td>
<td>The relative gap between the Best Integer solution and the Best Bound.</td>
</tr>
</tbody>
</table>

The remaining part of the Log file displays various solution statistics similar to those provided by the MIP solvers. This information can also be found in the Solver Status area of the GAMS listing file.

The following Log file shows cases where the NLP solver fails to solve a subnode. The text "ignored" in the Objective field shows the failure, and the values in parenthesis following the Gap field are the Solve and Model status returned by the NLP solver:

```
Root node solved locally optimal.
Node Act. Lev. Objective IInf Best Int. Best Bound Gap (2 secs)
0   0   0    6046.0186   12   -    6046.0186   -
1   1   1    infeasible    -    -    6046.0186   -
2   0   1    6042.0995   10   -    6042.0995   -
3   1   2    ignored    -    -    6042.0995   - (4,6)
4   0   2    5804.5856   8    -    5804.5856   -
5   1   3    ignored    -    -    5804.5856   - (4,7)
```

The next Log file shows the effect of the `infeasseq` and `failseq` options on the model above. CONOPT with options file `conopt.opt` (the default solver and options file pair for this model) considers the first subnode to be locally infeasible. CONOPT, MINOS, and SNOPT, all with no options file, are therefore tried in sequence. In this case, they all declare the node infeasible and it is considered to be infeasible.

In node 3, CONOPT with option file fails but CONOPT without option file finds a Locally Optimal solution, and this solution is then used for further search. The SBB option file for the following run would be:

```
rootsolver conopt.1
subsolver conopt.1
failseq conopt
infeasseq 100 conopt minos snopt
```

The log looks as follows:

```
Root node solved locally optimal.
Node Act. Lev. Objective IInf Best Int. Best Bound Gap (2 secs)
0   0   0    6046.0186   12   -    6046.0186   -
conopt.1 reports locally infeasible
Executing conopt
conopt reports locally infeasible
Executing minos
minos reports locally infeasible
```
Executing snopt
1 1 1 infeasible - - 6046.0186 -
2 0 1 6042.0995 10 - 6042.0995 -
conopt.1 failed. 4 TERMINATED BY SOLVER, 7 FEASIBLE SOLUTION
Executing conopt
3 1 2 4790.2373 8 - 6042.0995 -
4 2 3 4481.4156 6 - 6042.0995 -
conopt.1 reports locally infeasible
Executing conopt
conopt reports locally infeasible
Executing minos
minos failed. 4 TERMINATED BY SOLVER, 6 INTERMEDIATE INFEASIBLE
Executing snopt
5 3 4 infeasible - - 6042.0995 -
6 2 4 4480.3778 4 - 6042.0995 -

The Log file shows a solver statistic at the end, summarizing how many times an NLP was executed and how often it failed:

NLP Solver Statistics
Total Number of NLP solves : 45
Total Number of NLP failures: 13
Details: conopt minos snopt
# execs 34 3 8
# failures 4 3 6

The solutions found by the NLP solver to the subproblems in the Branch and Bound may not be the global optima. Therefore, the objective can improve even though we restrict the problem by tightening some bounds. These jumps of the objective in the wrong direction which might also have an impact on the best bound/possible are reported in a separate statistic:

Non convex model!
# jumps in best bound : 2
Maximum jump in best bound : 20.626587 in node 13
# jumps to better objective : 2
Maximum jump in objective : 20.626587 in node 13

5.35.6 Comparison of SBB and other MINLP Solvers

GAMS offers a variety of MINLP solvers including local and global MINLP solver. They implement different algorithms and it is usually unclear which solver performs best. Here we give a brief comparison between SBB and the well known solver DICOPT.

DICOPT is based on the outer approximation method. Initially, the RMINLP model is solved just as in SBB. The model is then linearized around this point and a linear MIP model is solved. The discrete variables are then fixed at the optimal values from the MIP model, and the resulting NLP model is solved. If the NLP model is feasible, we have an integer feasible solution.

The model is linearized again and a new MIP model with both the old and new linearized constraints is solved. The discrete variables are again fixed at the optimal values, and a new NLP model is solved.

The process stops when the MIP model becomes infeasible, when the NLP solution becomes worse, or, in some cases, when bounds derived from the MIP model indicate that it is safe to stop.
5.36 SCIP

DICOPT is based on the assumption that MIP models can be solved efficiently while NLP models can be expensive and difficult to solve. The MIP models try to approximate the NLP model over a large area and solve it using much cheaper linear technology. Ideally, only a few NLPs must be solved.

DICOPT can experience difficulties solving models, if many or all the NLP submodels are infeasible. DICOPT can also have problems if the linearizations used for the MIP model create ill-conditioned models. The MIP models may become very difficult to solve, and the results from the MIP models may be poor as initial values for the NLP models. The linearized constraint used by DICOPT may also exclude certain areas of the feasible space from consideration.

SBB uses different assumptions and works very differently. Most of the work in SBB involves solving NLP models. Since the NLP submodels differ only in one or a few bounds, the assumption is that the NLP models can be solved quickly using a good restart procedure. Since the NLP models differ very little and good initial values are available, the solution process will be fairly reliable compared to the solution process in DICOPT, where initial values of good quality seldom are available. Because search space is reduced based on very different grounds than in DICOPT, other solutions may therefore be explored.

Overall, DICOPT should perform better on models that have a significant and difficult combinatorial part, while SBB may perform better on models that have fewer discrete variables but more difficult nonlinearities (and possibly also on models that are fairly non convex).

5.36 SCIP

SCIP (Solving Constraint Integer Programs) is a framework for Constraint Integer Programming oriented towards the needs of Mathematical Programming experts who want to have total control of the solution process and access detailed information down to the guts of the solver. SCIP can also be used as a pure MIP or MINLP solver or as a framework for branch-cut-and-price. Within GAMS, the MIP and MINLP solving facilities of SCIP are available.

For more detailed information, we refer to [4] [1] [2] [21] [20] [74] [127] [88] [89] [75] [22] [192] [191] [204] and the SCIP web site.

GAMS/SCIP uses CPLEX, if licensed, and otherwise SOPLEX [206] as LP solver, the COIN-OR Interior Point Optimizer IPOPT [197] as nonlinear solver, and CppAD to compute derivatives of nonlinear functions.

SCIP supports continuous, binary, integer, semi-continuous, semi-integer variables, indicator constraints, special ordered sets, and branching priorities for discrete variables.

5.36.1 Usage

The following statement can be used inside your GAMS program to specify using SCIP

Option MIP = SCIP; \{ or QCP or NLP or MIQCP or MINLP or ... \}

The above statement should appear before the Solve statement. If SCIP was specified as the default solver during GAMS installation, the above statement is not necessary.
5.36.1.1 Specification of SCIP Options

GAMS/SCIP supports the GAMS parameters `reslim`, `iterlim`, `nodlim`, `optca`, `optcr`, and `workspace`. Further, the option `threads` can be used to control the number of threads used in the MILP presolver, the linear algebra routines of IPOPT, and for solving LPs if CPLEX' barrier solver is used.

Options can be specified by a SCIP options file. A SCIP options file consists of one option or comment per line. A pound sign (`#`) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (`=`) and any amount of white space (blanks or tabs). Further, string values have to be enclosed in quotation marks.

A small example for a scip.opt file is:

```
propagating/probing/maxprerounds = 0
separating/maxrounds = 0
separating/maxroundsroot = 0
```

It causes GAMS/SCIP to disable probing during presolve and to turn off all cut generators.

5.36.1.2 Specification of Indicators

Indicators are a modeling tool to specify that certain equations in a model must only be satisfied if certain binary variables take a specified value. Indicators are not supported by the GAMS language, but can be passed to SCIP via a separate file, see Indicator Constraints for more details on its syntax. The name of that file is specified via the option `gams/indicatorfile` in a SCIP option file. Currently, indicators can only be used for linear equations.

5.36.2 Special Features

5.36.2.1 SCIP interactive shell

The interactive shell in SCIP is a powerful tool that allows the user to display various information (e.g., branching statistics, presolved model), load emphasis settings, interrupt a solve to change parameters or trigger a restart, write the model in various file formats, start SCIP's solution counter, and many more things.

When setting the option `gams/interactive` to a nonempty string, the GAMS/SCIP interface opens the interactive shell of SCIP after having load the GAMS problem and parameters and passes the value of the `gams/interactive` parameter to the SCIP interactive shell.

By default, SCIP behaves as if `gams/interactive` has been set to "optimize write gamssol quit", that is, SCIP is requested to solve the problem, then to pass the solution back to GAMS, and to quit.

An example use of the SCIP interactive shell feature via GAMS is to add the following line to your SCIP options file:

```
gams/interactive = "write prob orig.lp presolve write transprob presol.mps opt write gamssol quit"
```

This instructs SCIP to write the original problem to the file `orig.lp` in LP format, to presolve the instance, to write the presolved problem to the file `presolved.mps` in MPS format, to solve the instance, to write the solution out to GAMS, and to finish.

By omitting the `quit` command, SCIP's interactive shell remains open and awaits user input. The command `help` prints a list of available commands. Note, that on Windows, GAMS need to be called with the option `interactivesolver` enabled to allow user input for the solver process.

A tutorial on using the SCIP shell is available at https://www.scipopt.org/doc/html/SHELL.php.
5.36.2.2 Emphasis Settings

SCIP includes various emphasis settings, which are predefined values for a set of SCIP parameters. Such predefined settings are available for setting the effort that SCIP should spend for, e.g., presolving, separation, or heuristics.

The emphasis settings are not available as single parameters, but can be set via SCIPs interactive shell. E.g., writing `set heuristics emphasis` in the shell displays the available emphasis settings for heuristics (`aggressive, fast, off`) and expects the user to input which setting to use. Further, general emphasis settings are available in the `set emphasis` menu, some of them giving predefined settings similar to the CPLEX option `mipemphasis`.

Via the `gams/interactive` option, c.f. Section SCIP interactive shell, emphasis settings can be activated via a SCIP options file. For example, adding the option

```
gams/interactive = "set emphasis feasibility set loadgams optimize write gamssol quit"
```

instructs SCIP to load the emphasis setting `feasibility` prior to optimizing the model and passing the solution back to GAMS. Note, that setting one of the emphasis settings `feasibility, hardlp, and optimality` resets all previously set parameters to their default values, which includes the ones that are set by the GAMS/SCIP interface or which were loaded from a SCIP options file. Therefore, the command `set loadgams` has been used above to restore these parameter settings.

The following emphasis settings are available in SCIP:

<table>
<thead>
<tr>
<th>shell command</th>
<th>purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>set emphasis easycip</td>
<td>use for easy problems</td>
</tr>
<tr>
<td>set emphasis feasibility</td>
<td>emphasize finding a feasible solution</td>
</tr>
<tr>
<td>set emphasis hardlp</td>
<td>use for problems with a hard LP</td>
</tr>
<tr>
<td>set emphasis optimality</td>
<td>emphasize proving optimality</td>
</tr>
<tr>
<td>set emphasis numerics</td>
<td>increase numerical stability</td>
</tr>
<tr>
<td>set heuristic emphasis</td>
<td>use primal heuristics aggressively</td>
</tr>
<tr>
<td>set presolving emphasis</td>
<td>use only fast presolving steps</td>
</tr>
<tr>
<td>set presolving emphasis</td>
<td>disable all primal heuristics</td>
</tr>
<tr>
<td>set separating emphasis</td>
<td>use cutting plane separators aggressively</td>
</tr>
<tr>
<td>set separate emphasis</td>
<td>use only fast cutting plane separators</td>
</tr>
<tr>
<td>set separate emphasis</td>
<td>disable all cutting plane separators</td>
</tr>
</tbody>
</table>

5.36.2.3 Starting point

Using the `completesol` heuristic, SCIP can try to find a feasible solution based on values given by the user for all or some of the variables. The values need to be specified as variable levels in the GAMS model. The heuristic solves a copy of the problem where variables for which values have been provided are restricted to be close to that value. When an integral value is specified for a binary or integer variable, the variable is fixed to that value. See also Section 2.3.2 in [127] for a more detailed description of the heuristic.

For which variables the level values are passed from GAMS to SCIP is controlled by the parameter `gams/mipstart`. The parameter values have the following meaning:
• 0: do not pass any variable values to SCIP, the heuristic will not run
• 1: pass values for all binary and integer variables to SCIP and let SCIP try to find a feasible solution in its neighborhood by using the completesol heuristic
• 2 (default): pass values for all variables to SCIP and let SCIP check feasibility of the given solution, the heuristic will not run
• 3: pass values for all variables to SCIP and let SCIP try to find a feasible solution in the neighborhood by using the completesol heuristic
• 4: pass values for all binary and integer variables to SCIP which fractionality is at most the value of GAMS option `tryint` (thus, with default `tryint=0`, only for variables with integral values, the value is passed to SCIP) and let SCIP try to find a feasible solution in the neighborhood by using the completesol heuristic

Note, that the completesol heuristic will not run if there are too many variables with unknown values. This behavior can be adjusted by setting parameter `heuristics/completesol/maxunknownrate`.

5.36.2.4 Decomposition Information

SCIP potentially can make use of a user-provided problem decomposition, e.g., in primal heuristics PADM or GINS. Note, that SCIP’s Benders Decomposition is not available with GAMS at the moment. A GAMS user can inform SCIP about such a decomposition by using the .stage variable suffix.

In an attempt to following the same convention on interpreting the .stage variable suffix as the GAMS/CPLEX link, variables which .stage suffix is set to an integral value greater than 0 are assigned to a block with this number. Variables which .stage suffix is set to a fractional value or a value smaller than 1 are assigned to no block.

Note, that the default value for the .stage suffix is 1. Therefore, GAMS/SCIP only passes decomposition information to SCIP if at least one variable has its .stage suffix set to a value different than 1. Moreover, in order to receive the .stage values, `scaleOpt` and `priorOpt` must be left at their default of 0.

5.36.2.5 Solution Pool

When SCIP solves a problem, it may find several solutions, whereof only the best one is available to the GAMS user via the variable level values in the GAMS model. If the option `gams/dumpsolutions` is specified, then all alternative solutions found by SCIP are written into GDX files and an index file with the name given by the this option is written. If the option `gams/dumpsolutionsmerged` is specified, then all alternative solutions found by SCIP are written into a single GDX file, which name is given by the this option.

The GAMS testlib model `dumpsol` shows an example use for this option.

5.36.2.6 Solving process tracing

The option `gams/solvetrace/file` can be used to specify the name of a file where information about the progress of the branch-and-bound tree search in SCIP is stored. The file is created and updated during the solution process, so it may also be used to monitor the progress of SCIP while it still solves the model.

New entries are written periodically, depending on how many nodes have been processed or how much time has been elapsed since the last entry was written. Each entry contains information on the current primal and dual bound.
5.36.2.7 Notes on solving MINLPs

SCIP includes capabilities to handle nonlinear functions that are specified via algebraic expressions. Therefore, neither external/extrinsic functions nor all GAMS mathematical functions are supported.

Nonconvex MINLPs are solved via a spatial branch-and-bound algorithm using linear relaxations. The tightness of this relaxation depends heavily on the variable bounds, thus tight bounds for the nonlinear variables are crucial for SCIP.

Convex MINLPs are much easier to solve for SCIP, provided it recognizes the convexity of the model. The convexity check implemented in SCIP may not give a conclusive answer in all cases. However, setting the option constraints/nonlinear/assumeconvex to TRUE can be used to tell SCIP that it should assume all nonlinear constraints to be of convex type. This may help to improve solving times for convex MINLPs considerably in some cases. However, it can also deteriorate performance as it prevents the use of certain extended formulations.

Another feature that can be especially useful for convex MINLPs is to enable the generation of cuts in feasible solutions, since these supporting hyperplanes can be strong. At the moment, this is only enabled for purely continuous nonlinear programs (QCPs and NLPs), but can be adjusted by parameter constraints/nonlinear/linearizeheursol. In this connection, it may also be beneficial to set separating/poolfreq to 1.

5.36.3 Components

In the following, we list components that are available in SCIP together with some common properties. Many of these properties can be modified with corresponding parameters.

5.36.3.1 Branching Rules

<table>

5.36.4 List of SCIP Options

SCIP supports a large set of options. In the following, we give a detailed list of all SCIP options.

5.36.4.1 gams

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>gams/dumpsolutions</td>
<td>name of solutions index gdx file for writing all alternate solutions</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/dumpsolutionsmerged</td>
<td>name of gdx file for writing all alternate solutions into a single file</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/indicatorfile</td>
<td>name of GAMS options file that contains definitions on indicators</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/interactive</td>
<td>command to be issued to the SCIP shell instead of issuing a solve command</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/mipstart</td>
<td>how to handle initial variable levels, see also section Starting point</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>Range: {0, ..., 4}</td>
<td></td>
</tr>
</tbody>
</table>

5.36.4.2 gams/solvtrace

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>gams/solvtrace/file</td>
<td>name of file where to write branch-and-bound trace information too</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Range: string</td>
<td></td>
</tr>
<tr>
<td>gams/solvtrace/nodefreq</td>
<td>frequency in number of nodes when to write branch-and-bound trace information, 0 to disable</td>
<td>100</td>
</tr>
<tr>
<td></td>
<td>Range: {0, ..., \infty}</td>
<td></td>
</tr>
<tr>
<td>gams/solvtrace/timefreq</td>
<td>frequency in seconds when to write branch-and-bound trace information, 0.0 to disable</td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>Range: [0, \infty]</td>
<td></td>
</tr>
</tbody>
</table>

5.36.4.3 branching

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/clamp</td>
<td>minimal relative distance of branching point to bounds when branching on a continuous variable</td>
<td>0.2</td>
</tr>
<tr>
<td></td>
<td>Range: [0, 0.5]</td>
<td></td>
</tr>
<tr>
<td>branching/delaypscostupdate</td>
<td>should updating pseudo costs for continuous variables be delayed to the time after separation?</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/divingpscost</td>
<td>should pseudo costs be updated also in diving and probing mode?</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
</tbody>
</table>
### Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/lpgainnormalize</td>
<td>strategy for normalization of LP gain when updating pseudocosts of continuous variables (divide by movement of (l^p) value, reduction in (d')omain width, or reduction in (s')ibling) range: (d, l, s)</td>
<td>s</td>
</tr>
<tr>
<td>branching/midpull</td>
<td>fraction by which to move branching point of a continuous variable towards the middle of the domain; a value of 1.0 leads to branching always in the middle of the domain range: [0, 1]</td>
<td>0.75</td>
</tr>
<tr>
<td>branching/midpullreldomtrig</td>
<td>multiply midpull by relative domain width if the latter is below this value range: [0, 1]</td>
<td>0.5</td>
</tr>
<tr>
<td>branching/preferbinary</td>
<td>should branching on binary variables be preferred? range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>branching/checksol</td>
<td>should LP solutions during strong branching with propagation be checked for feasibility? range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>branching/firstsbchild</td>
<td>child node to be regarded first during strong branching (only with propagation): 'u'p child, 'd'own child, 'h'istory-based, or 'a'utomatic range: a, d, u, h</td>
<td>a</td>
</tr>
<tr>
<td>branching/forceallchildren</td>
<td>should all strong branching children be regarded even if one is detected to be infeasible? (only with propagation) range: boolean</td>
<td>0</td>
</tr>
<tr>
<td>branching/roundsbsol</td>
<td>should LP solutions during strong branching with propagation be rounded? (only when checksbsol=True) range: boolean</td>
<td>1</td>
</tr>
<tr>
<td>branching/scorefac</td>
<td>branching score factor to weigh downward and upward gain prediction in sum score function range: [0, 1]</td>
<td>0.167</td>
</tr>
<tr>
<td>branching/scorefunc</td>
<td>branching score function (‘s’um, ‘p’roduct, ‘q’uotient) range: s, p, q</td>
<td>p</td>
</tr>
<tr>
<td>branching/sumadjustscore</td>
<td>score adjustment near zero by adding epsilon (TRUE) or using maximum (FALSE) range: boolean</td>
<td>0</td>
</tr>
</tbody>
</table>
### 5.36.4.5 branching/cloud

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/cloud/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>branching/cloud/maxdepth</td>
<td>maximal depth level, up to which branching rule <code>&lt;cloud&gt;</code> should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>branching/cloud/maxdepthunion</td>
<td>maximum depth for the union</td>
<td>65000</td>
</tr>
<tr>
<td>branching/cloud/maxpoints</td>
<td>maximum number of points for the cloud (-1 means no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>branching/cloud/insuccessrate</td>
<td>minimum success rate for the cloud</td>
<td>0</td>
</tr>
<tr>
<td>branching/cloud/insuccessunion</td>
<td>minimum success rate for the union</td>
<td>0</td>
</tr>
<tr>
<td>branching/cloud/onlyF2</td>
<td>should only F2 be used?</td>
<td>0</td>
</tr>
<tr>
<td>branching/cloud/priority</td>
<td>priority of branching rule <code>&lt;cloud&gt;</code></td>
<td>0</td>
</tr>
<tr>
<td>branching/cloud/usecloud</td>
<td>should a cloud of points be used?</td>
<td>1</td>
</tr>
<tr>
<td>branching/cloud/useunion</td>
<td>should the union of candidates be used?</td>
<td>0</td>
</tr>
</tbody>
</table>

### 5.36.4.6 branching/distribution

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/distribution/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>branching/distribution/maxdepth</td>
<td>maximal depth level, up to which branching rule <code>&lt;distribution&gt;</code> should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>branching/distribution/priority</td>
<td>priority of branching rule <code>&lt;distribution&gt;</code></td>
<td>0</td>
</tr>
<tr>
<td>Options for expert users</td>
<td></td>
<td></td>
</tr>
<tr>
<td>branching/distribution/onlyactivecolumns</td>
<td>should only rows which are active at the current node be considered?</td>
<td>0</td>
</tr>
<tr>
<td>branching/distribution/scoreparam</td>
<td>the score;largest 'd'ifference, 'l'owest cumulative probability,'h'ighest c.p., 'v'otes lowest c.p., votes highest c.p.('w')</td>
<td>v</td>
</tr>
</tbody>
</table>
### 5.36.4.7 branching/fullstrong

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/fullstrong/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td>branching/fullstrong/maxdepth</td>
<td>maximal depth level, up to which branching rule <code>&lt;fullstrong&gt;</code> should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td>branching/fullstrong/priority</td>
<td>priority of branching rule <code>&lt;fullstrong&gt;</code></td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Options for expert users</td>
<td></td>
</tr>
<tr>
<td>branching/fullstrong/forcestrongbranch</td>
<td>should strong branching be applied even if there is just a single candidate?</td>
<td>0</td>
</tr>
<tr>
<td>branching/fullstrong/maxproprounds</td>
<td>maximum number of propagation rounds to be performed during strong branching before solving the LP (-1: no limit, -2: parameter settings)</td>
<td>-2</td>
</tr>
<tr>
<td>branching/fullstrong/probingbounds</td>
<td>should valid bounds be identified in a probing-like fashion during strong branching (only with propagation)?</td>
<td>1</td>
</tr>
<tr>
<td>branching/fullstrong/reevalage</td>
<td>number of intermediate LPs solved to trigger reevaluation of strong branching value for a variable that was already evaluated at the current node</td>
<td>10</td>
</tr>
</tbody>
</table>

### 5.36.4.8 branching/inference

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>branching/inference/conflictprio</td>
<td>priority value for using conflict weights in lex. order</td>
<td>1</td>
</tr>
<tr>
<td>branching/inference/cutoffprio</td>
<td>priority value for using cutoff weights in lex. order</td>
<td>1</td>
</tr>
<tr>
<td>branching/inference/maxbounddist</td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
</tbody>
</table>
### Option Description Default

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>branching/inference/maxdepth</strong></td>
<td>maximal depth level, up to which branching rule <code>&lt;inference&gt;</code> should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td><strong>branching/inference/priority</strong></td>
<td>priority of branching rule <code>&lt;inference&gt;</code></td>
<td>1000</td>
</tr>
<tr>
<td><strong>branching/inference/useweightedsum</strong></td>
<td>should a weighted sum of inference, conflict and cutoff weights be used?</td>
<td>1</td>
</tr>
</tbody>
</table>

**Options for expert users**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>branching/inference/conflictweight</strong></td>
<td>weight in score calculations for conflict score</td>
<td>1000</td>
</tr>
<tr>
<td><strong>branching/inference/cutoffweight</strong></td>
<td>weight in score calculations for cutoff score</td>
<td>1</td>
</tr>
<tr>
<td><strong>branching/inference/fractionals</strong></td>
<td>should branching on LP solution be restricted to the fractional variables?</td>
<td>1</td>
</tr>
<tr>
<td><strong>branching/inference/inferenceweight</strong></td>
<td>weight in score calculations for inference score</td>
<td>1</td>
</tr>
<tr>
<td><strong>branching/inference/reliablescore</strong></td>
<td>weight in score calculations for conflict score</td>
<td>0.001</td>
</tr>
</tbody>
</table>

#### 5.36.4.9 branching/leastinf

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>branching/leastinf/maxbounddist</strong></td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td><strong>branching/leastinf/maxdepth</strong></td>
<td>maximal depth level, up to which branching rule <code>&lt;leastinf&gt;</code> should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td><strong>branching/leastinf/priority</strong></td>
<td>priority of branching rule <code>&lt;leastinf&gt;</code></td>
<td>50</td>
</tr>
</tbody>
</table>

#### 5.36.4.10 branching/lookahead

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>branching/lookahead/maxbounddist</strong></td>
<td>maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes)</td>
<td>1</td>
</tr>
<tr>
<td><strong>branching/lookahead/maxdepth</strong></td>
<td>maximal depth level, up to which branching rule <code>&lt;lookahead&gt;</code> should be used (-1 for no limit)</td>
<td>-1</td>
</tr>
<tr>
<td><strong>branching/lookahead/priority</strong></td>
<td>priority of branching rule <code>&lt;lookahead&gt;</code></td>
<td>0</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>branching/lookahead/abbreviated</td>
<td>toggles the abbreviated LAB.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/abbrevpseudo</td>
<td>if abbreviated: Use pseudo costs to estimate the score of a candidate.</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/addbinconsrow</td>
<td>should binary constraints be added as rows to the base LP? (0: no, 1: separate, 2: as initial rows)</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: {0, ..., 2}</td>
<td></td>
</tr>

<td>branching/lookahead/addclique</td>
<td>add binary constraints with two variables found at the root node also as a clique</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/addnonviocons</td>
<td>should binary constraints, that are not violated by the base LP, be collected and added?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/applychildbounds</td>
<td>should bounds known for child nodes be applied?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/deeperscoringfunction</td>
<td>scoring function to be used at deeper levels</td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>Range: d, f, s, w, l, c, r, x</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/enforcemaxdomreds</td>
<td>should the maximum number of domain reductions maxviolateddomreds be enforced?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/filterbymaxgain</td>
<td>should lookahead branching only be applied if the max gain in level 1 is not uniquely that of the best candidate?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>
<tr>
<td>branching/lookahead/level2avgscore</td>
<td>should the average score be used for uninitialized scores in level 2?</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Range: boolean</td>
<td></td>
</tr>

<td>maximum number of propagation rounds to perform at each temporary node (-1: unlimited, 0: SCIP default)</td>
<td>0</td>
</tr>
<tr>
<td>branching/lookahead/mergedomainreductions</td>
<td>should domain reductions of feasible siblings should be merged?</td>
<td>0</td>
</tr>
<tr>
<td>branching/lookahead/minweight</td>
<td>if scoringfunction is 's', this value is used to weight the min of the gains of two child problems in the convex combination</td>
<td>0.8</td>
</tr>
<tr>
<td>branching/lookahead/onlyviol domreds</td>
<td>should only domain reductions that violate the LP solution be applied?</td>
<td>0</td>
</tr>
<tr>
<td>branching/lookahead/prefersimplebounds</td>
<td>should domain reductions only be applied if there are simple bound changes?</td>
<td>0</td>
</tr>
<tr>
<td>branching/lookahead/propagate</td>
<td>should domain propagation be executed before each temporary node is solved?</td>
<td>1</td>
</tr>
<tr>
<td>branching/lookahead/recursiondepth</td>
<td>the max depth of LAB.</td>
<td>2</td>
</tr>
<tr>
<td>branching/lookahead/reevalage</td>
<td>max number of LPs solved after which a previous prob branching results are recalculated</td>
<td>10</td>
</tr>
<tr>
<td>branching/lookahead/reevalagefsb</td>
<td>max number of LPs solved after which a previous FSB scoring results are recalculated</td>
<td>10</td>
</tr>
<tr>
<td>branching/lookahead/reusebasis</td>
<td>if abbreviated: Should the information gathered to obtain the best candidates be reused?</td>
<td>1</td>
</tr>
<tr>
<td>branching/lookahead/scoringfunction</td>
<td>scoring function to be used at the base level</td>
<td>a</td>
</tr>
<tr>
<td>branching/lookahead/scoringscoringfunction</td>
<td>scoring function to be used during FSB scoring</td>
<td>d</td>
</tr>
<tr>
<td>branching/lookahead/storeunviolatedsol</td>
<td>if only non violating constraints are added, should the branching decision be stored till the next call?</td>
<td>1</td>
</tr>
<tr>
<td>branching/lookahead/updatebranchingresults</td>
<td>should branching results (and scores) be updated w.r.t. proven dual bounds?</td>

</table>
### Option Description Default

#### propagating/probing/maxprerounds
- maximal number of presolving rounds the propagator participates in
- (-1: no limit)
- Range: \([-1, \ldots, \infty]\)
- \(-1\)

#### propagating/probing/maxruns
- maximal number of runs, probing participates in
- (-1: no limit)
- Range: \([-1, \ldots, \infty]\)
- \(1\)

### Options for expert users

#### propagating/probing/delay
- should propagator be delayed, if other propagators found reductions?
- Range: boolean
- \(1\)

#### propagating/probing/maxdepth
- maximal depth until propagation is executed
- (-1: no limit)
- Range: \([-1, \ldots, \infty]\)
- \(-1\)

#### propagating/probing/maxfixings
- maximal number of fixings found, until probing is interrupted
- (0: don't interrupt)
- Range: \([0, \ldots, \infty]\)
- \(25\)

#### propagating/probing/maxnumuseless
- maximal number of probings without fixings, until probing is aborted
- (0: don't abort)
- Range: \([0, \ldots, \infty]\)
- \(0\)

#### propagating/probing/maxsumuseless
- maximal number of successive probings without fixings, bound changes, and implications, until probing is aborted
- Range: \([0, \ldots, \infty]\)
- \(50\)

#### propagating/probing/maxtotaluseless
- maximal number of successive probings without fixings, until probing is aborted
- Range: \([0, \ldots, \infty]\)
- \(1000\)

#### propagating/probing/presolpriority
- presolving priority of propagator
- \(<\text{probing}>\)
- Range: \([-536870912, \ldots, 536870911]\)
- \(-100000\)

#### propagating/probing/presoltiming
- timing mask of the presolving method of propagator
- \(<\text{probing}>\)
- (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL)
- Range: \([2, \ldots, 60]\)
- \(16\)

#### propagating/probing/priority
- priority of propagator
- \(<\text{probing}>\)
- Range: \([-536870912, \ldots, 536870911]\)
- \(-100000\)

#### propagating/probing/proprounds
- maximal number of propagation rounds in probing subproblems
- (-1: no limit, 0: auto)
- Range: \([-1, \ldots, \infty]\)
- \(-1\)

#### propagating/probing/timingmask
- timing when propagator should be called
- (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)
- Range: \([1, \ldots, 15]\)
- \(4\)

---

#### Date

23 Jan 2019

#### 5.37.1 Introduction

This document describes the GAMS/SELKIE solver for equilibrium models. This is a research code, so you should set your expectations accordingly. It doesn't come with extensive documentation or a history of continuous development and improvement. To learn more about the algorithms SELKIE implements and related topics, see Y. Kim's Ph.D. thesis or home page.
5.37.2 Usage

To explicitly request that a model be solved with SELKIE, insert the statement

```
option EMP = selkie;
```

somewhere before the solve statement in the GAMS source. If SELKIE has been selected as the default EMP solver (e.g. by including `EMP=selkie` in the command line arguments of the GAMS run) the above statement is not necessary.

SELKIE-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

An example of a valid SELKIE option file is:

```
* lines starting with a star are comments
diagonalization_method jacobi
parallel_jacobi yes
output_group_log yes
```

5.37.3 Options

<table>
<thead>
<tr>
<th>Option</th>

5.38 SHOT

SHOT (Supporting Hyperplane Optimization Toolkit) is a deterministic solver for mixed-integer nonlinear programming problems (MINLPs).

Originally, SHOT was intended for convex MINLP problems only, but now also has functionality to solve nonconvex MINLP problems as a heuristic method without providing any guarantees of global optimality. SHOT can solve certain nonconvex problem types to global optimality as well.

SHOT has mainly been developed by Andreas Lundell (Åbo Akademi University, Finland) and Jan Kronqvist (Imperial College London, UK). For more details, see [126] [122] [112] [113] [121].

SHOT supports GAMS equations that use the following intrinsic functions: abs, cos, cvPower, div, exp, log, log10, log2, pi, power, rPower, sin, sqr, sqrt, vcPower.

5.38.1 Algorithm

SHOT is based on iteratively creating a tighter polyhedral approximation of the nonlinear feasible set by generating supporting hyperplanes or cutting planes. These linearized problems are then solved with a mixed-integer linear programming (MIP) solver. GAMS/SHOT uses CPLEX, if a GAMS/CPLEX license is available, and otherwise CBC. Users with a license from Gurobi can also select Gurobi as MIP solver. If CPLEX or Gurobi is used, the subproblems can also include quadratic and bilinear nonlinearities directly.

The solution to the outer approximation problem provides a dual bound (i.e., a lower bound when solving a minimization problem) to the optimal value of the original problem if it is convex. If the problem is nonconvex, convergence to the global optimal solution cannot be guaranteed (but might be achieved for certain classes of problems, cf. [122]).

To get a primal bound (i.e., an upper bound when solving a minimization problem) on the optimal value, SHOT utilizes the following heuristics:

- Solving nonlinear programming (NLP) problems where the integer variables have been fixed to valid values. This is done by calling an NLP solver, which is either Ipopt, one of the GAMS NLP solvers, or SHOT itself.
5.38 SHOT

- By checking solutions from the MIP solver's solution pool for points that fulfill also the nonlinear constraints in the original MINLP problem.
- By performing root searches.

When a termination criterion like a tolerance on the relative or absolute objective gap or a time limit is fulfilled, SHOT terminates and returns the current primal solution to GAMS. If the original problem is convex and SHOT could close the objective gap, then this is a global optimal solution to the problem. If it is nonconvex, then there is normally no guarantee that such a solution can be found. However, SHOT will always, in addition to a primal solution, return a valid dual bound on the solution in model attribute objest, unless Model.Convexity.AssumeConvex has been enabled.

5.38.2 Usage

The following statement can be used inside your GAMS program to specify using SHOT

```gams
Option MINLP = SHOT; { or MIQCP }
```
