1 GAMS Documentation Center 1
  1.1 Model Libraries .................................................. 1
  1.2 Further Help .................................................... 2

2 Preface 3
  2.1 Timeline for documentation released with GAMS software ............... 4

3 Release Notes 7
  3.1 Release Types .................................................. 7
  3.2 Release History .................................................. 7
  3.3 40 Distribution .................................................. 12
    3.3.1 40.1.0 Major release (August 01, 2022) .............. 12
  3.4 39 Distribution .................................................. 20
    3.4.1 39.1.0 Major release (May 03, 2022) .............. 20
    3.4.2 39.1.1 Maintenance release (May 18, 2022) ...... 31
    3.4.3 39.2.0 Minor release (June 02, 2022) ............ 32
    3.4.4 39.2.1 Maintenance release (June 21, 2022) ...... 33
    3.4.5 39.3.0 Minor release (July 07, 2022) ............ 34
  3.5 38 Distribution .................................................. 35
    3.5.1 38.1.0 Major release (January 31, 2022) .......... 35
    3.5.2 38.2.0 Minor release (February 17, 2022) ....... 47
    3.5.3 38.2.1 Maintenance release (February 19, 2022) .. 49
    3.5.4 38.3.0 Minor release (April 05, 2022) ......... 50
  3.6 37 Distribution .................................................. 53
    3.6.1 37.1.0 Major release (November 11, 2021) .......... 53
  3.7 36 Distribution .................................................. 60
    3.7.1 36.1.0 Major release (August 02, 2021) .......... 60
    3.7.2 36.2.0 Minor release (September 03, 2021) ...... 71
  3.8 35 Distribution .................................................. 73
    3.8.1 35.1.0 Major release (April 29, 2021) ........... 73
    3.8.2 35.2.0 Minor release (June 02, 2021) ........... 90
  3.9 34 Distribution .................................................. 92
    3.9.1 34.1.0 Major release (January 29, 2021) .......... 92
    3.9.2 34.2.0 Minor release (February 05, 2021) ...... 104
    3.9.3 34.3.0 Minor release (February 25, 2021) ...... 105
  3.10 33 Distribution .................................................. 107
    3.10.1 33.1.0 Major release (November 01, 2020) ...... 107
    3.10.2 33.2.0 Minor release (December 01, 2020) ...... 116
  3.11 32 Distribution .................................................. 117
    3.11.1 32.1.0 Major release (July 31, 2020) ........... 117
    3.11.2 32.2.0 Minor release (August 26, 2020) ...... 124
  3.12 31 Distribution .................................................. 126
    3.12.1 31.1.0 Major release (May 01, 2020) ........... 126
    3.12.2 31.1.1 Maintenance release (May 16, 2020) ..... 138
    3.12.3 31.2.0 Minor release (June 19, 2020) ........ 139
  3.13 30 Distribution .................................................. 140
4 User's Guide

4.1 Installation and Licensing .................................................. 295
4.2 Tutorials and Examples ....................................................... 295
4.3 GAMS Language and Environment ......................................... 296
4.4 Glossary ............................................................................ 297
4.5 Supported Platforms ........................................................... 298
4.6 Installation Notes for Mac OS X ............................................. 299
  4.6.1 Installation using the PKG installer (GAMS40.1.0.pkg) .......... 299
  4.6.2 Uninstall PKG installation ............................................... 301
  4.6.3 Installation using the self-extracting archive (osx_x64_64.sfx.exe) .. 301
4.7 Installation Notes for Unix ..................................................... 305
  4.7.1 Installation .................................................................. 305
  4.7.2 Access to GAMS ............................................................ 306
4.8 Installation Notes for Windows ............................................... 307
  4.8.1 Installation .................................................................. 307
  4.8.2 Visual C++ Redistributable Dependency ............................ 309
  4.8.3 Command Line Use of GAMS .......................................... 309
  4.8.4 Warning from Microsoft SmartScreen Filter ....................... 309
4.9 Standard Locations ............................................................... 310
  4.9.1 Standard Locations on Mac OS X ...................................... 310
  4.9.2 Standard Locations on Unix ............................................. 311
  4.9.3 Standard Locations on Windows ....................................... 312
4.10 Licensing ........................................................................... 313
  4.10.1 General Information ..................................................... 313
  4.10.2 GAMS Community License ............................................ 313
  4.10.3 GAMS Licenses ............................................................ 313
  4.10.4 Installing or updating a license file .................................. 314
  4.10.5 License Problems ......................................................... 314
  4.10.6 Warnings .................................................................. 315
  4.10.7 The GAMS/BASE Module ............................................. 316
  4.10.8 Additional Limits for the Demo and Community License ...... 317
4.11 A GAMS Tutorial by Richard E. Rosenthal ............................... 318
  4.11.1 Introduction .................................................................. 318
  4.11.2 Structure of a GAMS Model ............................................ 320
  4.11.3 Sets ............................................................................ 322
  4.11.4 Data ........................................................................... 323
  4.11.5 Variables ..................................................................... 325
  4.11.6 Equations .................................................................... 326
  4.11.7 Objective Function ...................................................... 329
  4.11.8 Model and Solve Statements .......................................... 329
  4.11.9 Display Statements ...................................................... 330
  4.11.10 The .lo, .l, .up, .m Database ......................................... 330

### Contents

1. **4.34 The Option Statement**
   - 4.34.1 Introduction ......................................................... 695
   - 4.34.2 List of Options .................................................... 697

2. **4.35 System Attributes**
   - 4.35.1 Introduction ......................................................... 709
   - 4.35.2 System Suffixes ..................................................... 709
   - 4.35.3 System Data ........................................................ 713
   - 4.35.4 Access to Hidden Functions ...................................... 715

3. **4.36 The Grid and Multi-Threading Solve Facility**
   - 4.36.1 Introduction ......................................................... 715
   - 4.36.2 The Grid Facility: Basic Concepts ................................. 716
   - 4.36.3 The Grid Facility: A First Example ................................ 716
   - 4.36.4 Advanced Use of Grid Features .................................... 719
   - 4.36.5 Summary of Grid Features ......................................... 721
   - 4.36.6 The Grid Facility: Architecture and Customization .......... 724
   - 4.36.7 Multi-Threading ..................................................... 726

4. **4.37 Special Features for Mathematical Programs**
   - 4.37.1 Introduction ......................................................... 727
   - 4.37.2 Special Mixed Integer Programming (MIP) Features ............. 727
   - 4.37.3 Model Scaling - The Scale Option ................................ 735
   - 4.37.4 Conic Programming in GAMS ....................................... 738
   - 4.37.5 Indicator Constraints ............................................... 742

5. **4.38 GAMS Output**
   - 4.38.1 Introduction ......................................................... 746
   - 4.38.2 An Illustrative Model .............................................. 746
   - 4.38.3 Compilation Output ................................................ 747
   - 4.38.4 Execution Output .................................................. 754
   - 4.38.5 Model Generation Output .......................................... 754
   - 4.38.6 The Solution Report ............................................... 758
   - 4.38.7 Post-Solution Output .............................................. 764
   - 4.38.8 Error Reporting .................................................... 765
   - 4.38.9 Customizing the Output File ..................................... 769

6. **4.39 GAMS Log**
   - 4.39.1 Introduction ......................................................... 772
   - 4.39.2 Header ............................................................. 772
   - 4.39.3 Compilation Log .................................................... 773
   - 4.39.4 Execution Output .................................................. 773

7. **4.40 The GAMS Call and Command Line Parameters**
   - 4.40.1 The Generic GAMS Call ............................................ 775
   - 4.40.2 Double Dash Parameters, Compile-Time Variables and Environment Variables ......................................................... 784
   - 4.40.3 Compile-Time Constants .......................................... 789
   - 4.40.4 GAMS Compile Time and Execution Time Phase ................. 791
   - 4.40.5 List of Command Line Parameters ................................ 792
   - 4.40.6 Detailed Descriptions of All Options ........................... 797
   - 4.40.7 Executing an External Program ................................ 870

8. **4.41 Dollar Control Options**
   - 4.41.1 Introduction ......................................................... 871
   - 4.41.2 List of Dollar Control Options ................................... 872
   - 4.41.3 Detailed Description of Dollar Control Options ................ 878
   - 4.41.4 Conditional Compilation ........................................... 969
   - 4.41.5 Macros in GAMS ..................................................... 977
   - 4.41.6 Compressing and Decompressing Files ............................ 982
   - 4.41.7 Encrypting Files .................................................... 984

9. **4.42 The Put Writing Facility**
   - 4.42.1 Introduction ......................................................... 988
   - 4.42.2 The Syntax ........................................................ 988

- 7.1 Reference Manuals
- 7.2 Tutorials
- 7.3 Examples
- 7.4 Release Notes
- 7.5 Supported Platforms

### 7.6 Expert-Level APIs

- 7.6.1 Supported Platforms
- 7.6.2 GAMS Transfer Matlab

### 7.7 C++ API

- 7.7.1 GAMS Transfer R

### 7.8 Tutorial

- 7.8.1 Getting Started
- 7.8.2 Important Classes of the API
- 7.8.3 How to use API

### 7.9 Tutorial

- 7.9.1 Getting Started
- 7.9.2 Important Classes of the API
- 7.9.3 How to use API
- 7.9.4 How to use the pre configured example projects

### 7.10 Tutorial

- 7.10.1 Getting started
- 7.10.2 Important Classes of the API
- 7.10.3 How to use API

### 7.11 Tutorial

- 7.11.1 Getting started
- 7.11.2 Important Classes of the API
- 7.11.3 How to use the API

### 7.12 Tutorial

- 7.12.1 Getting started
- 7.12.2 Important Classes of the API
- 7.12.3 How to use the API

### 7.13 Release Notes

- 7.13.1 39.1.0
- 7.13.2 35.1.0
- 7.13.3 32.1.0
- 7.13.4 31.1.0
- 7.13.5 30.1.0
- 7.13.6 29.1.0
- 7.13.7 28.1.0
- 7.13.8 27.1.0
- 7.13.9 26.1.0
- 7.13.10 25.1.0
- 7.13.11 24.1.0
- 7.13.12 23.1.0
- 7.13.13 22.1.0
- 7.13.14 21.1.0

GAMS Documentation Center

The GAMS Documentation Center provides you with the technical information on getting started, using and maintaining our GAMS (General Algebraic Modeling System) products.

- Preface
- Release Notes - 40.1.0 Major release (August 01, 2022)
- User’s Guide
  - Installation and Licensing - Guides on installing GAMS for various platforms and using a GAMS license
  - Tutorials and Examples - Step-by-step guides including a number of examples
  - GAMS Language and Environment - Guide through components of GAMS Language and the environment for executing a GAMS model
- Solver Manuals - Manuals of solvers available in the distribution
- Tools Manuals - Manuals of tools available in the distribution
- Application Programming Interfaces - Manuals of Application Programming Interfaces
- Glossary - An alphabetical list of GAMS terms.
- Bibliography

1.1 Model Libraries

From the early stages of the development of GAMS we have collected models to be used in libraries of examples. Many of these are standard textbook examples and can be used in classes on problem formulation or to illustrate points about GAMS. Others are models that have been used in policy or sector analysis and are interesting for both the methods and the data they use. These model libraries are included with all GAMS systems and are also available online.

The following model libraries are available:

- **GAMS Model Library** - includes GAMS models representing interesting and sometimes classic problems, ranged from production and shipment by firms, investment planning, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and many more.
• **GAMS Test Library** - includes GAMS models developed for testing and quality control, both for the GAMS base module and the many solvers distributed with the GAMS system.

• **GAMS Data Library** - includes GAMS models demonstrating various utilities to interface GAMS with other tools and applications such as spreadsheets and database interface.

• **GAMS EMP Library** - includes GAMS Extended Mathematical Programming (EMP) models that illustrate and test the capabilities of GAMS/EMP.

• **GAMS API Library** - includes GAMS Models used as scripts to compile and execute application programs in various programming languages interfacing to GAMS.

• **FIN Library** - includes GAMS practical financial optimization models described in the book *Practical Financial Optimization: Decision Making for Financial Engineers* by Consiglio, Nielsen and Zenios,

• **NOA Library** - includes GAMS nonlinear optimization applications models based on the book *Nonlinear Optimization Applications Using the GAMS Technology* by Neculai Andrei.

• **PSOPT Library** - includes GAMS optimization models based on the book *Power System Optimization Modelling in GAMS* by by Alireza Soroudi.

See [Accessing Model Libraries](#) on how to access a GAMS model from the model libraries.

For large parts of the documentation, references to models from the model libraries are enclosed in square parenthesis (for example, *[TRNSPORT]*).

### 1.2 Further Help

If you have a further question which is not answered by the documentation above, you can get further help from our [GAMS-FAQ](#) which contains materials collected from various support activities or post your question to [GAMS World Forum](#). You can also sign up to our [Newsletters](#) to get the latest information from GAMS. There is also [GAMS Lessons](#), a YouTube Video Channel providing you with some tutorials on how to use our system.

There are a number of contributed documentations that have been contributed by GAMS users as well as presentations, books, posters, and advertisements contributed by people working with GAMS. The McCarl GAMS User Guide are available in various formats (PDF and HTML) and can also be found in the GAMS distribution under mccarl/ subdirectory with an incremental installer (ZIP) available for download.

You can also visit our upcoming courses and workshops or contact one of solution specialists who have wide experience in GAMS modeling.

If you experience a problem using GAMS please contact our [Technical Support](#). If you have a confidential model that you cannot share as is, please read the information on conversion of models before submitting your models to our technical support.
Chapter 2

Preface

The GAMS documentation has changed considerably since it was first released in 1988: in format, in scope and content, and in how it is distributed and accessed. At the same time, it maintains many elements of the original style: part tutorial, part user’s guide, and part reference manual. We describe here the evolution of the GAMS documentation and related topics.

The first published GAMS documentation is the book *GAMS: A User’s Guide* (aka the “red book”) by Brooke, Kendrick, and Meeraus, published in 1988 by The Scientific Press. Copies were sold in bookstores and included a chapter on the model library (100 models at that time), a much-appreciated and well-used index, appendices describing the solvers available (MINOS and ZOOM), and a 5.25 inch floppy disk containing a student version of "PC-GAMS version 2.05". This was followed up in 1992 with *GAMS: A User’s Guide, Release 2.25* (aka the "blue book") by a different publisher (Boyd & Fraser), a soft cover, and no floppy disk: by this time the software was available directly from GAMS. The final section of installation notes in the red book was replaced in the blue book by notes on the new features in GAMS 2.25, but the content was otherwise unchanged.

As the pace of development increased, it became clear that we needed a new documentation scheme, one that would allow us to update the document continuously as language features, models and model libraries, solvers, and tools/utilities were added to or updated in the system. Consequently, we converted the existing documentation to MS Word, expanded, updated, and edited it as appropriate, and sent it to the copy shop to be printed. This was a group effort spearheaded by Ramesh Raman, whose name was included as an author in the User’s Guide first included (along with a CD) in shipments of our 18.0 release in Feb 1999. The solver manuals in this release were collected from various sources (with varying styles, content, and organization) and put into a separate binder. A further push was required to unify this solver documentation (using LaTeX) to use a common style and organization: this unified Solver Manual was included with the 21.0 release of May 2003. In addition to hard-copy, all of these documents were included as PDF in the GAMS system and freely available via the Web. Thus, the shift away from published documentation to manuals produced in-house went hand-in-hand with a shift from printed documents to viewing and searching PDF documents.
During this time Bruce McCarl had been regularly teaching GAMS courses: basic and advanced, targeting a general audience but with a distinct flavor of agricultural economics. As part of this he developed course material to use in his classes, and he was in a good position to notice that the GAMS User Guide was not keeping up with all the updates to the software. With some encouragement from GAMS, Bruce started the ambitious project of creating a new GAMS User’s Guide, one that would be more complete, more to his taste with an increase in tutorial flavor, and designed to take full advantage of being a Web document: linked, cross-referenced, searchable, and indexed. The end result was the McCarl Guide that emerged as a PDF based on a Word document in 2002. This was redone in the more convenient CHM format with the 22.1 release of Mar 2006 and renamed as the Expanded GAMS Guide (McCarl) in release 22.3 of Nov 2006. We also kept the original GAMS User’s Guide, by this time as PDF generated from LaTeX source. With its improved content, organization, and navigability, Bruce's new guide was a boon to all GAMS users, not just those taking his courses. We owe a debt of gratitude to Bruce for this and many other contributions.

The Expanded GAMS Guide (McCarl) was never intended to be printed and was not shipped as hard-copy with GAMS. In 2013, GAMS stopped making physical shipments altogether and moved to an online order-fulfillment system. For those who still wanted printed documentation, the documents were also made available via Amazon’s CreateSpace, but most users browsed the documents online or as part of an installed GAMS system, often via the GAMS IDE, so the need for printable documents was small and growing smaller.

Having two user's guides was counter-intuitive or confusing for some users, especially when the content for some topics was different, missing, or even contradictory. The additional effort required to maintain two documents became more noticeable, especially since the Expanded User Guide (McCarl) was implemented using a Windows-only product that did not lend itself to version control via SVN or git. When we documented our object-oriented APIs in Feb 2013, we used the opportunity to experiment with a doxygen-based authoring process that uses text files as source, is platform-independent, and produces output in multiple formats. The results were good, and in 2015 we hired a consultant, Martha Loewe, to research what it would take to convert all of the GAMS documentation to use the doxygen-based process and to set up a framework for this. We eventually committed fully to this process and produced a unified set of documentation as of release 24.9 in Aug 2017. This involved reorganizing things somewhat to better fit a linked document, merging the two user guides into one (while trying to maintain the best qualities of each), adding links throughout, and submitting everything to review and editing by internal subject matter experts so the content is accurate, updated, and complete. The end result is something we believe is an improvement over its predecessors, but it is also something we are committed to maintaining and improving. The current system allows and encourages immediate updates by the whole GAMS team and has helped foster a culture and attitude where this takes place.

Chapter 3

Release Notes

3.1 Release Types

**Major releases** contain substantial changes to the GAMS system. The License Check date is set to the release date of the major release.

**Minor releases** are mainly issued to provide bug fixes, performance improvements, and maintenance releases of solver libraries. Additionally, they can provide a few new features that do not change existing behavior. The License Check Date remains the same as for the prior major release. This means that any license file that worked with the prior major release will also work with this minor release.

**Maintenance releases** do not provide any new features. They are issued to provide bug fixes, performance improvements, and maintenance releases of solver libraries. The License Check Date remains the same as for the prior major release. This means that any license file that worked with the prior major release will also work with this maintenance release.

3.2 Release History

- 40 Distribution  (distribution start page)
  - 40.1.0 Major release (August 01, 2022)

- 39 Distribution  (distribution start page)
  - 39.1.0 Major release (May 03, 2022)
  - 39.1.1 Maintenance release (May 18, 2022)
  - 39.2.0 Minor release (June 02, 2022)
  - 39.2.1 Maintenance release (June 21, 2022)
  - 39.3.0 Minor release (July 07, 2022)

- 38 Distribution  (distribution start page)
  - 38.1.0 Major release (January 31, 2022)
  - 38.2.0 Minor release (February 17, 2022)
  - 38.2.1 Maintenance release (February 19, 2022)
  - 38.3.0 Minor release (April 05, 2022)

- 37 Distribution  (distribution start page)
- 37.1.0 Major release (November 11, 2021)

- **36 Distribution** (distribution start page)
  - 36.1.0 Major release (August 02, 2021)
  - 36.2.0 Minor release (September 03, 2021)

- **35 Distribution** (distribution start page)
  - 35.1.0 Major release (April 29, 2021)
  - 35.2.0 Minor release (June 02, 2021)

- **34 Distribution** (distribution start page)
  - 34.1.0 Major release (January 29, 2021)
  - 34.2.0 Minor release (February 05, 2021)
  - 34.3.0 Minor release (February 25, 2021)

- **33 Distribution** (distribution start page)
  - 33.1.0 Major release (November 01, 2020)
  - 33.2.0 Minor release (December 01, 2020)

- **32 Distribution** (distribution start page)
  - 32.1.0 Major release (July 31, 2020)
  - 32.2.0 Minor release (August 26, 2020)

- **31 Distribution** (distribution start page)
  - 31.1.0 Major release (May 01, 2020)
  - 31.1.1 Maintenance release (May 16, 2020)
  - 31.2.0 Minor release (June 19, 2020)

- **30 Distribution** (distribution start page)
  - 30.1.0 Major release (January 10, 2020)
  - 30.2.0 Minor release (February 07, 2020)
  - 30.3.0 Minor release (March 06, 2020)

- **29 Distribution** (distribution start page)
  - 29.1.0 Major release (November 15, 2019)

- **28 Distribution** (distribution start page)
  - 28.1.0 Major release (August 02, 2019)
  - 28.2.0 Minor release (August 19, 2019)

- **27 Distribution** (distribution start page)
  - 27.1.0 Major release (April 24, 2019)
  - 27.2.0 Minor release (May 23, 2019)
  - 27.3.0 Minor release (July 04, 2019)

- **26 Distribution** (distribution start page)
  - 26.1.0 Major release (February 02, 2019)

- **25.1 Distribution** (distribution start page)
  - 25.1.1 Major release (May 19, 2018)
  - 25.1.2 Minor release (August 01, 2018)
3.2 Release History

- 25.1.3 Minor release (October 30, 2018)

**25.0 Distribution**
- 25.0.1 Major release (January 17, 2018)
- 25.0.2 Maintenance release (January 31, 2018)
- 25.0.3 Minor release (March 21, 2018)

**24.9 Distribution**
- 24.9.1 Major release (August 30, 2017)
- 24.9.2 Minor release (November 14, 2017)

**24.8 Distribution**
- 24.8.1 Major release (December 21, 2016)
- 24.8.2 Maintenance release (January 03, 2017)
- 24.8.3 Minor release (January 28, 2017)
- 24.8.4 Minor release (April 10, 2017)
- 24.8.5 Maintenance release (May 10, 2017)

**24.7 Distribution**
- 24.7.1 Major release (March 14, 2016)
- 24.7.2 Minor release (July 07, 2016)
- 24.7.3 Maintenance release (July 11, 2016)
- 24.7.4 Minor release (September 19, 2016)

**24.6 Distribution**
- 24.6.1 Major release (January 18, 2016)

**24.5 Distribution**
- 24.5.1 Major release (September 23, 2015)
- 24.5.2 Maintenance release (September 29, 2015)
- 24.5.3 Maintenance release (October 01, 2015)
- 24.5.4 Maintenance release (October 15, 2015)
- 24.5.5 Maintenance release (November 25, 2015)
- 24.5.6 Maintenance release (November 27, 2015)

**24.4 Distribution**
- 24.4.1 Major release (December 20, 2014)
- 24.4.2 Minor release (March 15, 2015)
- 24.4.3 Maintenance release (April 02, 2015)
- 24.4.4 Maintenance release (May 12, 2015)
- 24.4.5 Maintenance release (May 26, 2015)
- 24.4.6 Minor release (June 26, 2015)

**24.3 Distribution**
- 24.3.1 Major release (July 31, 2014)
- 24.3.2 Minor release (August 29, 2014)
- 24.3.3 Minor release (September 19, 2014)

**24.2 Distribution**
– 24.2.1 Major release (December 09, 2013)
– 24.2.2 Maintenance release (March 04, 2014)
– 24.2.3 Maintenance release (May 22, 2014)

• 24.1 Distribution
  – 24.1.1 Major release (May 30, 2013)
  – 24.1.2 Maintenance release (June 16, 2013)
  – 24.1.3 Maintenance release (July 26, 2013)

• 24.0 Distribution
  – 24.0.1 Major release (December 24, 2012)
  – 24.0.2 Maintenance release (February 14, 2013)

• 23.9 Distribution
  – 23.9.1 Major release (July 04, 2012)
  – 23.9.2 Maintenance release (August 29, 2012)
  – 23.9.3 Maintenance release (September 26, 2012)
  – 23.9.4 Maintenance release (October 20, 2012)
  – 23.9.5 Maintenance release (November 09, 2012)

• 23.8 Distribution
  – 23.8.1 Major release (March 17, 2012)
  – 23.8.2 Maintenance release (April 05, 2012)

• 23.7 Distribution
  – 23.7.1 Major release (July 14, 2011)
  – 23.7.2 Maintenance release (July 22, 2011)
  – 23.7.3 Maintenance release (August 23, 2011)

• 23.6 Distribution
  – 23.6.2 Major release (December 13, 2010)
  – 23.6.3 Maintenance release (February 15, 2011)
  – 23.6.4 Maintenance release (April 01, 2011)
  – 23.6.5 Maintenance release (April 08, 2011)

• 23.5 Distribution
  – 23.5.1 Major release (July 05, 2010)
  – 23.5.2 Maintenance release (August 18, 2010)

• 23.4 Distribution
  – 23.4.1 Major release (May 21, 2010)
  – 23.4.3 Maintenance release (May 24, 2010)

• 23.3 Distribution
  – 23.3.1 Major release (November 01, 2009)
  – 23.3.2 Maintenance release (November 18, 2009)
  – 23.3.3 Maintenance release (December 17, 2009)

• 23.2 Distribution
  – 23.2.1 Minor release (August 14, 2009)
• 23.1 Distribution
  – 23.1.1 Major release (July 13, 2009)
  – 23.1.2 Maintenance release (July 23, 2009)
• 23.0 Distribution
  – 23.0.2 Major release (February 14, 2009)
• 22.9 Distribution
  – 22.9.2 Major release (December 01, 2008)
• 22.8 Distribution
  – 22.8.1 Major release (August 01, 2008)
• 22.7 Distribution
  – 22.7.1 Major release (May 01, 2008)
  – 22.7.2 Maintenance release (May 13, 2008)
• 22.6 Major release (December 24, 2007)
• 22.5 Major release (June 01, 2007)
• 22.4 Major release (February 12, 2007)
• 22.3 Major release (November 27, 2006)
• 22.2 Minor release (April 21, 2006)
• 22.1 Major release (March 15, 2006)
• 22.0 Major release (August 01, 2005)
• 21.7 Major release (April 01, 2005)
• 21.6 Minor release (January 26, 2005)
• 21.5 Minor release (November 11, 2004)
• 21.4 Major release (September 06, 2004)
• 21.3 Major release (January 19, 2004)
• 21.2 Maintenance release (September 03, 2003)
• 21.1 Maintenance release (June 02, 2003)
• 21.0 Major release (May 15, 2003)
• 20.7 Maintenance release (June 14, 2002)
• 20.6 Major release (May 25, 2002)
• 20.5 Maintenance release (January 28, 2002)
• 20.4 Maintenance release (January 21, 2002)
• 20.3 Major release (December 24, 2001)
• 20.2 Maintenance release (November 22, 2001)
• 20.1 Major release (October 31, 2001)
3.3 40 Distribution

3.3.1 40.1.0 Major release (August 01, 2022)

3.3.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Daniel Dias, and Scott McDonald.

3.3.1.2 GAMS System

3.3.1.2.1 GAMS

- Added two new indexed operators sAnd and sOr.
- The file containing the collection of legacy default values has been renamed from gams31config.yaml to gamsLegacyConfig.yaml, as legacy behavior is not entirely identical to GAMS 31.
- Changed default of command line parameter digit to off. As a result, extremely large or small constants in the GAMS source will not result in compilation errors but rather in special values (e.g. 1e300 becomes UNDF, 1e-300 becomes EPS). The old default digit=on has been added to gamsLegacyConfig.yaml.
- Changed default of model attribute tolProj to 0. This means that GAMS no longer by default modifies solution values returned by the solver that are close to variable bounds or equation sides.
- Throw a compilation error consistently, when one tries to load data into an Alias. In the past, this was just ignored in some cases. It appears that when writing to an alias in embedded code an exception is made and GAMS implicitly imports into a set, not an alias. Details about this subtlety can be found in the embedded code chapter.
- Made command line parameter IDCProtect available as runtime option as well (the runtime option gets initialized by the command line parameter).
- Do not allow to load a symbol implicitly from $offEmbeddedCode under $onExternalInput, when it was not declared as external input symbol (the same check was so far done for explicit loading only).
- Changed the interaction of external input and $gdxIn to allow the continued use of a $gdxIn file over multiple external input sections. So, the following code works now, but threw an error in the past:

```plaintext
$onExternalInput
$gdxIn transport.gdx
Set i(*) canning plants ;
$load i
$offExternalInput

* Do something but not opening another GDX file

$onExternalInput
Set j(*) markets ;
$load j
$offExternalInput
```
• Changed the behavior when encountering a symbol with unknown dimension with an execution time load or embedded code statement. In the past, this resulted in an error, now the dimension of that symbol is set to 0 (or 1, if it is a set) implicitly. As a result, the following code runs without error now:

```bash
$call gams transport gdx=default
Variable z;
execute_load 'transport.gdx', z;
display z.l;
```

• Also changed the behavior when encountering a symbol with unknown dimension with a compile time embedded code statement. In the past, this resulted in an error, now the dimension of that symbol is set to the dimension defined in the embedded code block.

• Make sure that we do not change the loop control index by implicit loading from endEmbeddedCode (the same check was so far done for explicit loading only).

• Added an explicit error check to ensure that the command line parameter restartNamed is used together with the command line parameter restart only.

• Changed the put utility facility to ignore the extra double quotes added when the print control is set to 4, 5, or 6. In the past that lead to an error since the commands were not recognized when they are quoted.

• We plan to remove language elements to access some commercial and licensing information with the next major release:
  – System suffixes: components, clipCodes, clipComponentMap, componentSolverMap, gamsLicenses, gamsLicenseTypes, lice1, lice2, licenseEvalN, licenseDateEvalS, licenseDateMaintN, licenseDateMaintS, licenseDateS, licenseDateSysN, licenseDateSysS, licenseDaysEval, licenseDaysMaint, licenseDC, licenseEval, licenseID, licenseInstitution, licenseLevel, licenseLevelText, licenseLicensee, licenseMudText, licensePlatform, licensePlatformText, licenseStatus, licenseStatusText, licenseType, licenseVendor, and vendors.
  – Predefined sets componentEDate, componentMDate, and componentLicenseOptions.
  – Many of these are used in the GAMS Model Library model licememo, which we also plan to remove.

• Fixed that exceeding the internal limit of 2.1 billion instructions did not raise an error.

• Fixed a rare problem which stopped GAMS from terminating if a solver invoked in an asynchronous thread did not return.

• Fixed an error causing missing domain information, when implicit sets are used while creating a dump file.

### 3.3.1.2.2 GMSPython

• Added the packages sqlalchemy and greenlet to GMSPython. On Windows, also added the packages sqlalchemy-access, pyodbc, and pywintypes.

### 3.3.1.2.3 Connect

• Domain information is copied into the Connect database when using agents GAMSReader and GDXReader. Agent GDXWriter exports the domain information to the GDX file.
• Added attribute `duplicateRecords` to `GAMSWriter` and `GDXWriter` to control the way to deal with duplicate records in a Connect container symbol when writing to GAMS or GDX. Note that both agents currently deal with duplicate records in a case sensitive way.

• Added new `DomainWriter` agent to modify domain information of Connect symbols.

• Added new `PandasSQLReader` and `PandasSQLWriter` agents to read from and write to SQL databases.

• Updated `Projection` agent:
  – Changed boolean attribute `dropText` to a string attribute `text`.
  – Added boolean attribute `asParameter` to turn variables into parameters with an extra index to store the suffixes.
  – Allow a list of symbol names for attribute `name` to combine multiple scalar symbols into a single one-dimensional symbol.

• Symbol names in Connect are now case sensitive by default. So casing in the YAML file is important and needs to match e.g. when reading from GDX or GAMS (which use case in-sensitive symbol name lookup) or across agents. There is now a global attribute `caseSensitiveLookup` in agent `Options` to control the case-(in)sensitive symbol lookup.

• Added new attribute `debug` in agent `Options` to provide traceback information in case of an exception.

• Dropped support for writing variables and equations with `CSVWriter` and `PandasExcelWriter`. Variables and equations can be turned into parameters using the `Projection` agent.

• Added attribute `trace` to `GAMSReader`, `GAMSWriter`, `GDXReader`, and `GDXWriter`.

• Fixed bug where `PandasExcelWriter` failed when writing no data.

### 3.3.1.2.4 Embedded Python Code Facility

• Allow to specify source code encoding by providing a comment of format `# coding=<encoding name>` as first line in an embedded Python code section.

• If `gams_.debug` is set to an integer greater than 0 a traceback is printed to `stdout` in case of an exception.

### 3.3.1.2.5 Installer

• For Windows, updated the text in the file association dialog to make clear that the GAMS IDE is deprecated.

### 3.3.1.3 Solvers

#### 3.3.1.3.1 BARON

• New libraries 22.7.23.
  – Improved presolve.

#### 3.3.1.3.2 Bonmin and BonminH

• As announced, the solvers Bonmin and BonminH have been removed. For the time being, libraries of GAMS/Bonmin are available at the [COIN-OR GAMSlinks project](https://www.coin-or.org/GAMSlinks). Note, that GAMS does not test or offer support for these libraries.
3.3.1.3.3 CBC, SCIP, SHOT

- New libraries Cbc 2.10.8, Cgl 0.60.0, Clp 1.17.7, Osi 0.108.7, CoinUtils 2.11.6, nauty 2.7r3.

3.3.1.3.4 CONVERT

- Export prettier formulas (x for \(x^{*1}\), power(x,1), vcpower(x,1) or rpower(x,1)).

3.3.1.3.5 COPT

- New libraries 5.0.2.
  - Added possibility to compute feasible relaxation for infeasible problem. New options FeasRelax and FeasRelaxMode to enable this feature and set relaxation mode, respectively. New dot option .feaspref to specify preferences on relaxation of variable bounds and linear constraint sides.
  - Added options MipStartMode and MipStartNodeLimit to adjust handling of complete and partial MIP starts.
  - Added option ReqFarkasRay.
  - Option crossover has been made available.
- Changed handling of MIP starting point:
  - GAMS/COPT will pass on a partial instead of a full MIP start also if MipStartMode = 2 is selected.
  - When setting the value for a discrete variable in a partial MIP start (tryint > 0), it will be rounded to an integer value.
- For an unbounded LP, a primal ray is now returned in the variables level values and UNBND markers are set in the solution listing.
- For an infeasible LP, a Farkas proof is now returned in the equations marginal values and INFES markers are set in the solution listing.

3.3.1.3.6 GLOMIQO

- As announced, dropped GLOMIQO. The use of ANTIGONE is equivalent.

3.3.1.3.7 GUROBI

- New libraries 9.5.2.
  - Changed aggregate option type from bool to int. Allowed values are 0 (off), 1 (moderate) and 2 (aggressive).
- Added support of certain nonlinear constraints: max, min, smax, smin, and, or, sand, sor, abs, exp, **, log, log2, log10, sin, cos, tan, edist, poly. To make these accessible, Gurobi can now be used for model types (D)NLP and (R)MINLP as well, but equations need to follow a special form.
- Added option multimipstart: Use multiple (partial) mipstarts provided via GDX files.
3.3.1.3.8 HiGHS

- New LP/MIP solver HiGHS 1.2.2 developed by the Edinburgh Research Group in Optimization. HiGHS is included in the GAMS base system for users with an academic GAMS license. Users with a commercial GAMS license need to contact sales@gams.com to enable the use of HiGHS.

3.3.1.3.9 Ipopt

  - Added options ma27_print_level, ma57_print_level, and mumps_print_level.
  - Fixed that variable names for variable bounds in detailed log output were wrong for problems with fixed variables.
- New libraries Mumps 5.5.0.

3.3.1.3.10 KNITRO

- New libraries 13.1.0.
  - Significant performance improvements when using the BFGS/LBFGS Hessian approximation.
  - New options:
    * findiff_estnoise: Estimate of the noise in the model when using finite-difference.
    * bar_mpec_heuristic: Enable heuristic approach when solving MPEC models with the barrier algorithm.
    * mip_heuristic_misqp: Enable the MIP MISQP heuristic.
    * mip_restart: Enable the MIP restart procedure.
    * conic_numthreads: Number of threads to use for operations in the conic algorithm.

3.3.1.3.11 LGO

- As announced, dropped LGO.

3.3.1.3.12 MPSGE

- Increased the internal MAXFUN limit (from 10000 to 50000) on the number of components (inputs, outputs, taxes, etc.) in any MPSGE row.
- Print info about the size of the largest MPSGE function (i.e. the one with the most input/output/tax/etc coefficients) to the sysout file.

3.3.1.3.13 MSNLP

- As announced, dropped MSNLP.
3.3.1.3.14 Octeract

- The GAMS/Octeract link has been rewritten.
  - Temporary files are now removed, unless GAMS option keep is enabled.
  - Octeract is now also available for solvelink=5 and solvelink=6.
  - Octeract options are now documented and Octeract option files can be created via the GAMS Studio options editor.
  - The default for MAX_SOLVER_ITERATIONS is now set to GAMS iterlim.
  - The default for MAX_SOLVER_MEMORY is now set to GAMS workspace.
  - New option nllinear.
- New libraries 4.4.1.

3.3.1.3.15 SCIP

- Added support for logical functions bool_and, bool_eqv, bool_imp, bool_not, bool_or, bool_xor. Only constants, binary variable, and logical functions are allowed as arguments for these operators. The GAMS/SCIP link introduces additional variables and constraints of types and, or, and xor to handle these functions.
- New libraries SCIP 8.0 (504f5f2749).
  - Improved and extended cut selection statistics.

3.3.1.3.16 XPRESS

- New libraries 40.01.01.
  - MIP performance improvements:
    * Improved separation of Mixed Integer Rounding (MIR) cuts in the tree.
    * Improved selection of cutting planes based on orthogonality measures.
    * Some subMIP heuristics at the root node now solve the subMIPs using multiple threads.
    * More advanced MIP presolve operations.
  - Improved crash heuristic for dual simplex.
  - Improved parallel performance of the crossover algorithm.
  - Improved sparse matrix-vector multiplication selection method in dual crossover.
  - New option numericalEmphasis: specify emphasis to place on numerical stability over solving time.
  - Changed default of treeCutSelect to -1.
  - Changed default of treeCutSelect_mirRowAggregation to 1.
- Support mipCleanup also for nonlinear models.

3.3.1.4 Tools

3.3.1.4.1 GAMS IDE

- Added a startup message to announce the drop of the classic GAMS IDE.
3.3.1.4.2 GAMS Studio

- New version 1.11.1.
  - New feature: Allow to open a directory to add all files in that directory to a project.
  - New feature: Added HTML format when copying text to clipboard.
  - GDX Viewer improvements:
    * Saves/restore state (e.g. filters, sorting, ...) when data has to be reloaded from file.
    * Added invert selection for column filter and for the attribute selection.
    * Fixed that auto resize of columns was not triggered for 1-dimensional symbols when the table view has been selected as default view.
  - Added zoom for editors/viewers with proportional fonts (GDX Viewer and Option Editor).
  - Added editor to edit efi files for GAMS Engine.
  - Improved and unified filter line edits for tables and trees to support regular expressions and exact matches.
  - Stability improvements, bug fixes, and minor enhancements, e.g.:
    * Moved result files from a GAMS Engine run to the working directory.
    * Added link to MIRO output that opens the directory in the file explorer.
    * Improved trimming behavior of search results.
    * Adjusted wording in search results table header.
    * Fixed focus and auto-fill when re-triggering search dialog while it is already open.
    * Fixed "All Files" filter not showing files without extension on Linux and macOS.
    * Fixed error in restoring selection of MIRO deployment dialog.

3.3.1.4.3 GDX2ACCESS

- We will remove the tool gdx2access in a future GAMS release. GAMS Connect agent PandasSQLWriter should be used instead.

3.3.1.4.4 GDX2SQLITE

- We will remove the tool gdx2sqlite together with the tool sqlite3 in a future GAMS release. GAMS Connect agent PandasSQLWriter should be used instead.

3.3.1.4.5 GDXVIEWER

- For the interactive mode added a startup message to announce the drop of the GDXVIEWER.

3.3.1.4.6 MDB2GMS

- We will remove the tool mdb2gms in a future GAMS release. GAMS Connect agent PandasSQLReader should be used instead.
3.3.1.4.7 MPS2GMS

- Fixed that non-continuous variables in cones (CSECTION) were missing in =c= equations in written GAMS file.
- Polished written GAMS file, in particular eliminate use of $batinclude$.
- Quadratic cones (CSECTION) are now reformulated into quadratic equations. New option CEQUATIONS can be used to enable previous behavior of writing =c= equations.
- Input files that were compressed with gzip (.gz) can now be handled.
- Added support for input in LP format.
- Updated MPS reader to HiGHS 892691737.

3.3.1.4.8 SQL2GMS

- We will remove the tool sql2gms in a future GAMS release. GAMS Connect agent PandasSQLReader should be used instead.

3.3.1.5 APIs

3.3.1.5.1 GAMS Transfer Python

- Modified behavior of registering UELs: Previously, GAMS Transfer generated UELs from data in record order (i.e., all UELs from the first data row are registered, then all UELs from the next row are registered, etc.). GAMS Transfer now registers UELs columnwise (i.e., all UELs from the first domain column are registered, then all UELs from the next domain column are registered, etc.). This behavior change will impact symbols written over "*" or with relaxed domains.
- New Symbol methods hasDuplicateRecords, countDuplicateRecords, findDuplicateRecords, and dropDuplicateRecords to help debug and resolve errors with duplicate records.
- New Container methods hasDuplicateRecords, countDuplicateRecords, and dropDuplicateRecords to help find symbols that contain duplicate records that cause the Symbol to be invalid.
- New Symbol methods hasDomainViolations, countDomainViolations, and dropDomainViolations to help debug and resolve errors with domain violations.
- New Container methods hasDomainViolations, countDomainViolations, and dropDomainViolations to help debug and resolve errors with domain violations.
- Fixed that the column headings of the records DataFrame were not updated when a domain set/alias was renamed or the .domain attribute of a symbol was updated directly.
- Fixed read of equation with unknown subtype (recast as =E/=eq).

3.3.1.5.2 GAMS Transfer R

- New API GAMS Transfer R to exchange data between GAMS and R.

3.3.1.5.3 Python

- As announced, dropped support for Python 3.6.
3.3.1.6 Model Libraries

3.3.1.6.1 GAMS Data Library

- Added `connect04.gms` : Simple Connect Example for SQL.

3.3.1.6.2 GAMS Test Library

- Added `load15.gms` : Test consistent compile time error checking when loading symbols.
- Added `gurobi07.gms` : GUROBI test suite - nonlinear constraints to general constraints.
- Added `load16.gms` : Test implicit dimension setting when loading a symbol.
- Added `gamsxcppmex.gms` : Test calling and validating new C++ compiler against legacy Delphi compiler.
- Added `gdxdiff2.gms` : Test GDXDIFFs fdonly option.
- Added `capdsqr.gms` : Test Connect agent PandasSqlReader.
- Added `capdsqwl.gms` : Test Connect agents PandasSqlWriter.
- Added `cadomainw.gms` : Test Connect agent DomainWriter.

3.4 39 Distribution

3.4.1 39.1.0 Major release (May 03, 2022)

3.4.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Wolfgang Britz, Rob Davies, Torbjoern Jansson, Bruce McCarl, and Yihe Zhuo.

3.4.1.2 GAMS System

3.4.1.2.1 GAMS

- Added basic model statistics (range of absolute non-zero values for the bounds, right hand sides and matrix coefficients) to the output file, and log.
- Added model attributes to access the values of the basic model statistics also programmatically: `rngBndMax`, `rngBndMin`, `rngMatMax`, `rngMatMin`, `rngRhsMax`, `rngRhsMin`.
- Added new command line parameter `multi` to initialize the state of `$on/offMuli` and `$on/offMultiR`.
- Extended the syntax of `$[on][off]Echo[V]$, `$[on][off]Put[V]$, `$[on][off]EmbeddedCode[V]`, and `$[end][pause]EmbeddedCode[V]` with an optional suffix to allow nested use. Note that this might trigger an error for code that was OK before. In the following example, the suffix at `$onEcho` was ignored in the past. Now, this will result in an error, since there is no `$offEcho` with matching suffix:
In embedded code Python, the Python interpreter stays alive even when the embedded code section ends with \texttt{$\text{offEmbeddedCode}$} and \texttt{endEmbeddedCode}. So one has access to Python objects across embedded Python code sections. Nevertheless, the \texttt{gams} object gets newly initialized (with the exception of \texttt{continueEmbeddedCode}). Hence old references to \texttt{gams} or derived objects, e.g. \texttt{sym = gams.get("sym")} still exist in Python but the connected external resources are no longer available. Accessing these objects results in a crash as demonstrated in the following example:

\begin{verbatim}
Set s1 / i1*i3 /, s2 / j1*j3 /;
parameter p1(s1, s2);
$onEmbeddedCode Python:
s1 = gams.get('s1')
s2 = gams.get('s2')
$offEmbeddedCode

$onEmbeddedCode Python:
p1 = [(i, j, 3.14) for i,j in zip(s1, s2) ]
gams.set('p1', p1)
$offEmbeddedCode
\end{verbatim}

In the second embedded Python code section the object references \texttt{s1} and \texttt{s2} use unavailable external resources, and the code in the section will crash GAMS. There is no need to use \texttt{gams} or derived objects from previous embedded code sections, since one can always use the current \texttt{gams} object. For legacy code that makes use of this unintended feature, we allow the use of the deprecated (and hidden) command line option \texttt{freeEmbeddedPython=0} for some time to get the old behavior. If you find yourself in need to set this option, you need to rework your embedded Python code section to prevent use of previous \texttt{gams} and derived objects. The option \texttt{freeEmbeddedPython} will (as announced) eventually be removed.

- Added new command line parameter and option \texttt{ECImplicitLoad}, as well as related dollar control options \texttt{$\text{on/offECImplicitLoad}$}.
- Added new command line parameters \texttt{ConnectIn} and \texttt{ConnectOut} to instruct GAMS to pass the Connect YAML files provided by these option to the Connect framework at the beginning of a GAMS job (\texttt{ConnectIn}) and at the end (\texttt{ConnectOut}) of the GAMS job.
- Added new \texttt{put utility} command \texttt{ECArguments} to extend the embedded code \texttt{arguments} with a dynamic text.
- Added explicit range checking for some \texttt{Put File Attributes}. In the past, unexpected values for some attributes (e.g. \texttt{file.nr = 8;}) could have led to unwanted output. Now, unacceptable values get projected to the nearest acceptable value.
- Updated use of decimals (\texttt{file.nd}) value in floating-point put output. Previously, the decimals value was treated as a specification, with putfile error messages resulting if the output contained fewer decimals. We treat the decimals value as a limit now: it’s not an error if fewer digits are shown because of the width limit or for other reasons.
- Removed the GDX file \texttt{gmspfmap.gdx} that contained some partial mapping of files to components from the system directory.
- There was a hidden option \texttt{work}. This cannot be used anymore. The command line parameter or model attribute \texttt{workSpace} should be used instead.
- Allow \texttt{holdFixed=1} for EMP, but not EMPSP models. The partly reverts the change of \texttt{holdFixed} for EMP models from GAMS 38.
- Fixed a bug where the command line parameters \texttt{holdFixed}, \texttt{nodLim}, \texttt{workFactor} and \texttt{workSpace} took precedence over the related model attributes.
• Fixed an error with constant evaluation in data statements for scalar symbols in a parameter statement.

• Fixed output of very large negative numbers (e.g. -DBL_MAX) to trace files.

• Fixed minor rounding and display issues with double-precision numbers. This is relevant to values displayed in the listing file, put files, and less commonly in the GAMS log. Ties are now resolved using the round-to-even rule instead of round-towards-zero. This new tie-breaking rule is consistent with the display routines in C++, Python, Julia, and R. For example:

  – with option decimals=5, scalar p / 9999998.4/ was displayed as 1.00000E+7 – now as 9.999998E+6
  – with option dispwidth=9, decimals=5, scalar p / -8.123441235/ was displayed as -8.123E+1 – now as -8.1234412
  – very small values (1e-250 or less) were displayed as 0 but are now displayed using E-format in the usual way
  – displaying 1.5 or 2.5 with zero decimals both now show 2, while previously 1.5 would display as 1
  – similarly, 1.75 with decimals=1 now displays as 1.8 instead of 1.7 as it did previously

3.4.1.2.2 Connect

• We have added the Connect framework to the distribution. Connect gives unified and platform independent access to data exchange with different formats (e.g., CSV and Excel). The instructions how to access the various data sources are given in YAML syntax. Connect is available as a standalone command line utility (gamsconnect), via the GAMS command line parameters ConnectIn and ConnectOut, and via embedded Connect code. The Connect framework is currently in beta status.

3.4.1.2.3 Embedded Code

• Allow implicit loading of symbols in embedded code. In the past the embedded code had to "set" a symbol and the symbol has to be explicitly imported on the $off/end/pauseEmbeddedCode line. This is no longer necessary. By default, a symbol that has been "set" by the embedded code will be imported into GAMS. The behavior with respect to this implicit loading is controlled by the command line parameter ECImplicitLoad and the dollar control options $on/offECImplicitLoad.

3.4.1.2.4 Embedded Connect Code Facility

• We added the new embedded code engine Connect. The embedded Connect code gives access to the Connect framework. The YAML formatted "code" can be utilized to import and export data with GAMS during compile and execution time.

3.4.1.2.5 Embedded Python Code Facility

• The Python version of GMSPython has been updated to 3.8.13.
• Added the packages cerberus and pyyaml-include to GMSPython.
• Removed decoration (---) from log messages printed using gams.printLog() and fixed a bug that prevented long messages from being displayed correctly.
3.4.1.2.6 Extrinsic Function libraries

- As announced the extrinsic function library parcclib has been dropped.
- The mutex library mtxclib, hidden in the system since 24.6, has now been documented and modified. With this version a mutex first has to be created via the function Create before it can be used (e.g. locked).

3.4.1.2.7 Windows Installer

- The installer no longer creates a Desktop icon for the GAMS IDE by default.
- Fixed bug that prevented command line parameter /desktopIcons=no from having an effect.

3.4.1.3 Solvers

3.4.1.3.1 CONOPT

- New libraries 3.17M.
  - Fixed issue with incorrect infeasibility reporting for infeasible CNS models or models with infinite post-triangular variables.
- New libraries 4.27.
  - Improved preprocessor on models with very small coefficients and models with constant nonlinear Jacobian elements.
  - Improved detection of post-triangular parts in CNS models.
  - Improved speed of analyzing the numerical stability and density of definitional constraints.
  - Improved numerical stability of creating and testing the initial basis.
  - Added options:
    * Flg_TraceCNS: Flag for tracing a CNS solution.
    * Trace_MinStep: Minimum step between reinversions when using TraceCNS.

3.4.1.3.2 COPT

- New libraries 4.0.5.
  - Improved performance for LP and MIP solving.
  - Added support for convex quadratic equations in continuous problems (model types QCP and RMIQCP). Currently, marginals are not provided if quadratic constraints are present.
  - Added option to find an Irreducible Inconsistent Subsystem (IIS) for an infeasible LP or MIP. New options iis to enable the IIS finder and IISMethod to specify IIS finder method.
  - New parameter BarOrder to specify ordering algorithm in Barrier solver.
  - For GAMS/COPT-Link users: If no COPT license is available, COPT can still be used for non-commercial use and LPs with at most 10000 variables and 10000 constraints and for MIPs/QCPs with at most 2000 variables and 2000 constraints.
3.4.1.3.3 CPLEX

- New libraries 22.1.0.
  - New options:
    * lowerobjstop: in a minimization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value lower than or equal to the specified value.
    * upperobjstop: in a maximization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value greater than or equal to the specified value.
  - Removed CPLEX Remote Object Server and Distributed MIP.
  - Removed options `computeserver`, `polishtime`, `rampuptimelimit`, `rampupduration` and `rampuptimelimit`.
- New option `exactkappa`: Report exact condition number in quality report. Note: Previously, the exact condition number has always been reported. Now, default is to not do it due to possibly high computation times.
- Add previously hidden options:
  - `iafile`: secondary option file to be read in interactive mode triggered by `iatriggerfile`.
  - `iatriggerfile`: file that triggers the reading of a secondary option file in interactive mode.
  - `iatriggerertime`: time interval in seconds the link looks for the trigger file in interactive mode.
  - `ltol`: basis identification primal tolerance.
  - `mtol`: basis identification dual tolerance.
  - `readparams`: read CPLEX parameter file.

3.4.1.3.4 DE

- Introduced an experimental and hidden option `pipsStages` to annotate the resulting deterministic equivalent with PIPS-IPM++ conforming block information.

3.4.1.3.5 EMPSP

- For EMPSP models feasible empty rows will no longer be sent to the solver.

3.4.1.3.6 GLOMIQO

- We plan to drop GLOMIQO with the next major release. The ANTIGONE solver (a superset of GLOMIQO) remains in the system.

3.4.1.3.7 GUSS/ScenarioSolver

- GUSS/ScenarioSolver allows now to manually scale model instances via the `.scale` variable and equation suffix together with model attribute `scaleOpt=1`.

3.4.1.3.8 Ipopt

3.4.1.3.9 KNITRO

- Added support for models with more than $2^{31}$ entries in the coefficients matrix.
- Changed handling of initial levels and marginals, see initvalues0 and initvalues.
- Only scale the model instance if scaleOpt is set to 1.
- Added options:
  - initvalues0: enable use of initial guess for levels and marginals (first solve).
  - initvalues: enable use of initial guess for levels and marginals (subsequent solve).

3.4.1.3.10 LGO

- We plan to drop LGO with the next major release.

3.4.1.3.11 Lindo/LindoGlobal

3.4.1.3.12 MOSEK

- New libraries 9.3.20.
- For GAMS/MOSEK and GAMS/OsiMosek, a separate MOSEK license is now required also for academic GAMS licenses that include a GAMS/MOSEK link license but no full GAMS/MOSEK license.

3.4.1.3.13 MSNLP

- We plan to drop MSNLP with the next major release.

3.4.1.3.14 Octeract

- New libraries 4.3.1.
  - Fixed that GAMS options were ignored when a solver options file was specified.

3.4.1.3.15 ODHCPLEX

- New libraries 6.11.

3.4.1.3.16 SCIP Optimization Suite

- New libraries PaPILO 2.0 (60ab076).
- New libraries SoPlex 6.0 (f084e555).
- New libraries SCIP 8.0 (899dc92dda).
3.4.1.3.17 XA

- We plan to drop XA with the next major release.

3.4.1.3.18 XPRESS

- New libraries 39.01.06.

3.4.1.4 Tools

3.4.1.4.1 GAMS Studio

- New version 1.10.1.
  - New feature: Added pin view: The main edit area can be split vertically or horizontally to show a second editor.
    - Ctrl + Left Click on a tab creates a vertical split.
    - Ctrl + Shift + Left Click on a tab creates a horizontal split.
  - Added new search scope: Folder (aka Find in Files).
    - This allows users to search a directory on disk without having to load the whole directory in Studio first.
  - Some rework of the "Search and Replace" dialog:
    - Added file exclusion pattern input field and functionality.
    - Added info about number of files searched to search dialog.
    - Changed default position of search dialog to top right.
    - Search now respects open file behavior settings when jumping to results in unopened files.
    - Fixed crash in search when current editor has no file associated.
    - Fixed search not being interruptible when searching many small files.
  - Added GDX Viewer tab to the settings dialog.
  - Added new setting to specify the default symbol view of the GDX Viewer.
  - User model libraries have been moved to the first tab of the Model Library Explorer.
  - Stability improvements, bug fixes, and minor enhancements, e.g.:
    - Configuration editor now displays gamsconfig.yaml file only.
    - Added search related group to project explorer when files were found that were unknown to Studio.
    - Added automatic deactivation of search selection when leaving "Selection" search scope.
    - Added feedback for empty search term, invalid regex, and invalid path in search dialog.
    - Added completer handling for $offEcho.
    - Changed behavior of completer: Allow all keywords after opening a paired dollar control option (DCO) and showing closing DCOs first.
    - Ensure unique project name and keep log name in sync with project name.
    - Fixed crash in ModelLibrary dialog on Ctrl-rightClick on entry.
    - Fixed white table headers in dark mode.
    - Fixed code completer activation issues.
    - Fixed broken syntax in data statements with division.
### 3.4.1.4.2 MPS2GMS

- The tool has been reimplemented and now uses the readers of the HiGHS solver.
- If the MPS file appears to be in fixed form (row or character names with spaces and at most 8 characters), then parsing in fixed form is attempted.
- GDX and GMS files are now also written if no GDX and GMS filenames are provided explicitly.
- Dropped support for writing an MPS file.
- Dropped support for OBJNAME section.
- Sections SOS and SETS are now assumed to follow the format used by CPLEX, GUROBI, and FICO XPRESS.
- Dropped parameters NAME, N, RHS, RANGES, BOUNDS, MPSOut, Trace.
- Added parameter COLUMNINTVARSAREBINARY to specify how to handle integer variables that appear first in COLUMNS section.
- Quadratic coefficient matrices are no longer written in symmetric form. Zero coefficients (eps) that were written to GDX in certain situations are now omitted.
- See also the MPS2GMS documentation.

### 3.4.1.5 APIs

#### 3.4.1.5.1 GAMS Transfer Matlab

- New version 0.2.0:
  - Improved documentation.
  - Added "equals" method to Container and Symbol classes to compare containers or symbols, respectively.
  - Added "copy" method to Symbol classes to copy symbols to another container.
  - Added support to read symbols directly from Container (not just ConstContainer).

#### 3.4.1.5.2 GAMS Transfer Python

- GAMS Transfer will now accept any mixed-case string representations of special values for undef, na, and eps (i.e., Undef or UnDef are now valid).
- Performance enhancements associated with reading/writing GAMS special values.
- Performance enhancement in .removeSymbols(): isValid check flag is no longer reset for all symbols in the Container if removing a Parameter, Variable or Equation.
- Fixed bug when replacing string special values in a dataframe whose index was not uniformly spaced.
- Fixed bug when testing scalar values with .isUndef.

#### 3.4.1.5.3 GMD

- Special value -0.0 for EPS is now properly recognized.
- gmdCopySymbol allows to copy parameter, variable, and equation symbols into a set symbol.
- Added gmdGetUserSpecialValues to access special values GMD currently accepts.
3.4.1.5.4 GMO

- Added properties `gmoHessNZ64`, `gmoHessMaxNZ64`, and `gmoHessLagNZ64` and functions `gmoHessStruct64` and `gmoHessValue64` to get Hessian element counts as 64-bit integer.

- Added properties `gmoQN64` and `gmoQNL64`: all properties returning 32-bit Jacobian nonzero counts now have 64-bit counterparts.

- Fixed a memory leak in the Hessian evaluation: the leak occurred during speculative Hessian evaluations, i.e., evaluations with a tight memory limit intended to see how memory-intensive Hessian evaluation is and if Hessians should be used by the solver.

3.4.1.5.5 High-level APIs

- `GamsModelInstance.solve()` falls back to a warm start in case a hot start fails.

- Added read property for `GAMSSet.SetType` (.NET, Python) and `GAMSSet.getSetType` (Java) to distinguish multi and singleton sets.

- New optional argument `setType=SetType.multi` in `GAMSDatabase.AddSet()` (.NET), `GamsDatabase.add_set()` and `GamsDatabase.add_set_dc()` (Python), and `GAMSDatabase.addSet` (Java) to set type of set.

- Fixed defined enumerated value for options `FDOpt` and `DumpOpt` in Java interface.

3.4.1.6 Model Libraries

3.4.1.6.1 GAMS Model Library

- Dropped `deploy`.

- Dropped `dplytst`.

- Updated `cta.gms`: Controlled Tabular Adjustments.

- Updated `dicegrid.gms`: MIP Decomposition and Parallel Grid Submission - DICE Example.

- Updated `herves.gms`: Herves (Transposable Element) Activity Calculations.

- Updated `qmeanvar.gms`: Financial Optimization: Risk Management using MIQCP.

- Updated `sddp.gms`: Multi-stage Stochastic Water Reservoir Model solved with SDDP.

- Updated `siders.gms`: ERS Data Manipulations with SED.

- Updated `tsp5.gms`: TSP solution with Miller et al subtour elimination.

- Added `asyncincbi.gms`: Asynchronous processing of incumbents reported by GAMS/CPLEX.

- Added `springchain.gms`: Equilibrium of System with Piecewise Linear Springs.

- Added `trussm.gms`: Truss Topology Design with Multiple Loads.
3.4.1.6.2 GAMS Data Library

- Added `gtmvn.gms`: Demonstrate the use of numpy.multivariate_normal on stock return data using Transfer.
- Added `connect01.gms`: Complex Connect Example with Spreadsheets.
- Added `connect02.gms`: Complex Connect Example with CSV Files.
- Added `connect03.gms`: Simple Connect Example with CSV Files.

3.4.1.6.3 GAMS Test Library

- Updated `embpy04.gms`: Test continuation of embedded code blocks to remove tests related to freeEmbeddedPython.
- Updated `mtxlib.gms`: Test basics of the mutex library to reflect changes in extrinsic function mutex library.
- Dropped `parlib01` and corresponding library `[lib]parcclib64` and source `parsource.zip`.
- Dropped `pfmaptst`.
- Added `embmihws.gms`: ModelInstance hot/warmstart switch.
- Added `convert17.gms`: CONVERT test suite - check stage and scale export in dumpgdx.
- Added `caproject.gms`: Test Connect agent Projection.
- Added `cagamsrw.gms`: Test Connect agent GAMSReader/Writer.
- Added `cagdxrw.gms`: Test Connect agent GDXReader/Writer.
- Added `capdxlsrw.gms`: Test Connect agents PandasExcelReader and PandasExcelWriter.
- Added `carxr.gms`: Test Connect agent RawExcelReader.
- Added `capcode.gms`: Test Connect agent PythonCode.
- Added `cacsww.gms`: Test Connect agent CSVWriter.
- Added `embpy12.gms`: Test implicit/explicit loading in Embedded Code.
- Added `cacsrvr.gms`: Test Connect agent CSVReader.
- Added `capdxlsr.gms`: Test Connect agent PandasExcelReader.
- Added `embpy13.gms`: Test implicit/explicit loading in Embedded Code (execution time).
- Added `connectsub.gms`: Test substitution for Connect.
- Added `nestblock01.gms`: Test the use of nested blocks.
3.4.1.6.4 FIN Library

- Use Connect instead of Windows-only gdxxrw to allow running the models on all platforms.
- Updated CreditImmunization: Factor Immunization model for corporate bonds.
- Updated MeanVar: Mean-variance efficient portfolios.
- Updated MeanVarShort: Mean-variance model allowing short sales.
- Updated PutCall: Put/Call efficient frontier model.
- Updated ReadData: Reads excel files and converts them to gdx format.
- Updated SelectiveHedging: Scenario Optimization for selective hedging.
- Updated ThreeStageSPDA: A three stage stochastic programming model for SPDA.

3.4.1.6.5 PSOPT Library

- Use Connect instead of Windows-only gdxxrw to allow running the models on all platforms.
- Updated DED: Dynamic Economic Load Dispatch.
- Updated DED-PB: Price based Dynamic Economic Load Dispatch.
- Updated DED-wind: Dynamic Economic Load Dispatch considering Wind generation.
- Updated DEDESS: Cost based Dynamic Economic Dispatch integrated with Energy Storage.
- Updated DEDESSwind: Cost based Dynamic Economic Dispatch integrated with Energy Storage and Wind.
- Updated ESSDCOPFwind: DC-OPF integrated with Energy Storage and Wind.
- Updated MultiperiodACOPF24bus: Multi-period AC-OPF for IEEE 24-bus network considering wind and load shedding.
- Updated MultiperiodDCOPF24bus: Multi-period DC-OPF for IEEE 24-bus network considering wind and load shedding.
- Updated PBUC: Price based Unit commitment.
- Updated RampSenDED: Ramp rate sensitivity analysis for Dynamic Economic Load Dispatch.

### 3.4.2 39.1.1 Maintenance release (May 18, 2022)

#### 3.4.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz and Arne Schulz.

#### 3.4.2.2 Solvers

##### 3.4.2.2.1 CPLEX

- Fixed `mipkappastats` report in case of relaxed or fixed solve after MIP solve (enabled by `rerun = no` and `solvefinal = yes`, respectively).

##### 3.4.2.2.2 KNITRO

- Fixed incorrect detection as an infeasible model when it actually was feasible (happened if KNITRO terminated due to small relative change in objective).
3.4.2.3 Tools

3.4.2.3.1 GAMSCONNECT

- Fixed problem with gamsconnect command line tool not working properly when environment variables PYTHONPATH or PYTHONHOME were set.

3.4.2.3.2 GAMS Studio

- New version 1.10.2 with some bug fixes, stability improvements, and minor enhancements, e.g.:
  - Made sure the correct file gets the focus on Studio start-up.
  - Fixed crash on closing a tab when project settings are active.
  - Fixed closing behavior of search dialog on Windows when using X button.

3.4.2.3.3 GDXDIFF

- Fixed wrong differences of parameters with option fldOnly.

3.4.2.3.4 MODEL2TEX

- Fixed problem with model2tex not working properly when environment variables PYTHONPATH or PYTHONHOME were set.

3.4.3 39.2.0 Minor release (June 02, 2022)

3.4.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Dominic Lencz.

3.4.3.2 GAMS System

3.4.3.2.1 GAMS

- Fixed potential wrong dump file with implicit sets.

3.4.3.2.2 Connect

- Fixed a problem in GAMSWriter agent that registered unused labels with GAMS.

3.4.3.2.3 Embedded Python Code Facility

- Fixed a problem with ignoring gams.ws.my_eps.
3.4.3.3 Solvers

3.4.3.3.1 CONOPT

- New libraries 4.28.

3.4.3.4 Tools

3.4.3.4.1 GAMS Studio

- New version 1.10.4 with some bug fixes, and minor enhancements, namely:
  - Added support for optional suffixes for $\text{[on][off][Echo][S][V]}$, $\text{[on][off][Put][S][V]}$, $\text{[on][off][EmbeddedCode][S][V]}$, and $\text{[end][pause][EmbeddedCode][S][V]}$.
  - Fixed GAMS Engine not adding files in subdirectories from $\ast .efi$ file.
  - Fixed problem receiving results from Engine when there is an execution error.

3.4.3.5 APIs

3.4.3.5.1 GAMS Transfer Matlab

- New version 0.2.1:
  - Fixed read of variable with unknown subtype (recast as free).
  - Fixed check of variable type on variable creation.
  - Fixed $\text{isEps}$, $\text{isNA}$, and $\text{isUndef}$ of $\text{SpecialValues}$ for sparse matrix input.
  - Fixed default values of external, conic, and boolean equations.

3.4.3.5.2 GAMS Transfer Python

- Fixed read of variable with unknown subtype (recast as free).
- Fixed default values of equation subtypes ($\text{eq}$, $\text{geq}$, $\text{leq}$, $\text{cone}$, $\text{external}$, and $\text{boolean}$).

3.4.3.5.3 GMD

- Fixed a problem with aliases to the universe.

3.4.4 39.2.1 Maintenance release (June 21, 2022)

3.4.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz and Erwin Kalvelagen.
3.4.4.2 GAMS System

3.4.4.2.1 GAMS

- Report correct number in Solve Summary if iteration count exceeds \texttt{maxInt}.
- Added missing entry for empty scalar equations to the tree view of the output file.

3.4.4.2.2 Connect

- Fixed a problem with \texttt{indexSubstitutions} in \texttt{CSVReader} agent where labels in the last index column were not substituted when reading a set without text columns.

3.4.4.3 Solvers

3.4.4.3.1 CPLEX

- Fixed crash after singular basis error.
- Fixed overflow in node and iteration counts.

3.4.4.3.2 SHOT

- New libraries 1.1 (c9bc78df).

3.4.5 39.3.0 Minor release (July 07, 2022)

3.4.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Bruce McCarl and Tom Rutherford.

3.4.5.2 GAMS System

3.4.5.2.1 GAMS

- Fixed a problem that limited the number of characters written to a single line in the log using \texttt{put files} to 255.

3.4.5.3 Solvers

3.4.5.3.1 SCIP Optimization Suite

- New libraries SCIP 8.0 (95d63636d5).
- New libraries PaPILO 2.1.0.
3.4.5.3.2 SHOT

- New libraries 1.1 (033622c6).

3.4.5.4 Tools

3.4.5.4.1 GAMS Studio

- New version 1.10.5 with some bug fixes, and minor enhancements, for example:
  - Fixed Studio ignoring setting to open in current project when opening a file from Explorer.
  - Fixed search not reacting to changes in project file list.
  - Fixed search not always adding new files to correct search group.
  - Fixed potential crash when closing Studio while search dialog is open.
  - Fixed opening of empty editor when using search results to open a deleted file.
  - Added automatic update of results list when still open from last search.

3.4.5.5 APIs

3.4.5.5.1 GMO

- Fixed a crash caused by memory corruption in the Hessian evaluation: the crash occurred while cleaning up after speculative Hessian evaluations that exceed a user-specified memory limit.

3.5 38 Distribution

3.5.1 38.1.0 Major release (January 31, 2022)

3.5.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Albert Brouwer, Arne Drud, Daniel Jungen, Scott McDonald, Tom Rutherford, Seyed Amin Sedgh, and Wenjin Zhou.

3.5.1.2 Platforms

- As announced, dropped support for Mac OS X 10.14 (Mojave).
- Added support for Mac OS X 12 (Monterey).
3.5.1.3 GAMS System

3.5.1.3.1 GAMS

- Added new command line parameter `dumpOptGDX` to load the data needed in `dumpOpt` files from GDX instead of data statements.
- Added new command line parameter `ReferenceLineNo` to control the line numbers written to a reference file.
- We plan to drop the command line parameter `freeEmbeddedPython` with the next major release.
- Extended the Solve Summary written with asyncSolLst=1 to include information about controlling loop indices during job submission, name of the solver called, source line number of the solve statement, resource and iteration limit.
- Make handling of execution errors during model generation (e.g. division by zero in an equation) more consistent across different settings for the `solveLink` option. In the past, the error count was set to 0 automatically when returning from a solve with `solveLink=0` only (which is equivalent to setting `execError=0` after the solve statement). This is not done anymore.
- Write additional information about execution errors during model generation (e.g. division by zero error) to the lst file, e.g., the equation name and index causing the problem.
- Improve recognition of `/` as path delimiter on Windows.
- Pause automated time dependent log update while executing embedded code sections.
- Check for certain byte order marks (BOMs) in GAMS input files. Files with UTF8 BOM can be processed now, other BOMs generate a compilation error.
- Added support for (mixed-integer) quadratic models whose Q matrices contain more than $2^{31} = 2,147,483,648$ nonzeros in their upper triangle. At this time, only the solver links for CPLEX and ODHCPLEX are capable of handling such large model instances.
- Changed system suffix `isAlfaBeta` to `isAlphaBeta`.
- Fixed a problem for EMP models with `holdFixed` model attribute.
- Fixed a problem where IDCGenerateGDXInput, IDCGenerateGDXOutput, IDCGDXOutput, and IDCGenerateGDX did not write a GDX file if the execution was stopped with `abort[.noError]`.

3.5.1.3.2 Extended Mathematical Programming (EMP)

- Stochastic EMP: Changed the `stage` behavior so that it creates an explicit error when a stage gets assigned twice for the symbol. In the past, this caused erratic behavior.

3.5.1.3.3 Embedded Python Code Facility

- The Python version of GMSPython has been updated to 3.8.12.

3.5.1.3.4 Extrinsic Function libraries

- With the next distribution we will drop the extrinsic function library `parcclib`. 
3.5.1.4 Solvers

3.5.1.4.1 BARON

- New libraries 22.1.16.
  - new presolve implementation with novel presolve techniques for linear and nonlinear optimization problems improves performance for many problem classes
  - more classes of SOCPs are now recognized
  - new lift-and-project implementation that extends the previous RLT implementations to generic NLPs and MINLPs and leads to substantial reduction of duality gaps for difficult problems
  - improved tree management, including restarts of branch-and-bound search
  - improved branching routines for the identification of most important branching variables
  - dynamic LP algorithm selection strategy improves robustness for numerically difficult problems by automatically choosing between CPLEX (if licensed) and CLP/CBC and possibly switching during the search, see also option LPSol
  - improved control on the effect of floating point round-off errors
  - faster hashing routines
  - the embedded FilterSD algorithm is now off by default
  - better integration with GAMS NLP subsolvers
  - improvements to CBC and IPOPT interfaces
  - update the Xpress interface to work with FICO XPRESS 39
- Fixed reporting of proven irreducible infeasible sets ("IIS" instead of "(I)IS").

3.5.1.4.2 CONOPT

- New libraries 4.25.
  - General improvements in the construction of the initial basis and in the startup of the optimization process, especially for very large models.
  - Many small improvements and corrections of errors found by users.

3.5.1.4.3 CONVERT

- The symbol $\mathbf{w}$ in DumpGDX is now stored sparse.
- Changed option default of GDXHessian and GDXQuadratic to 0.

3.5.1.4.4 COPT

- For GAMS demo and community licenses, model size limitations as for other solvers apply. For an unlimited GAMS/COPT or GAMS/COPT-Link license, contact sales@gams.com.

3.5.1.4.5 CPLEX

- Fix appending userjobid to userincbicall, usergdxin, and usergdxnameinc in BCH calls.
- Fixed computing dual multiplier at cone top (QCP models).
3.5.1.4.6 DICOPT

- Fixed that non-default stage information was setup in sub-MIPs when prioropt=0.

3.5.1.4.7 KNITRO

- New libraries 13.0.
  - Introduces an updated, parallel, branch-and-bound solver for mixed-integer optimization. This updated solver is able to exploit parallelism and uses improved heuristics to solve mixed-integer problems much faster than before.
  - Offers new initial point strategies for non-convex quadratic programs (QPs) and quadratically constrained quadratic programs (QCQPs). These new initial point strategies improve the likelihood of finding the global solution, and can be used in conjunction with the Knitro multi-start procedure to search for global or better local solutions for non-convex QP and QCQP models.
  - Offers significant robustness and speed improvements on difficult nonlinear optimization problems.
  - Offers improved performance when using the SQP and MISQP algorithms on larger models.
  - Added options:
    * `ncvx_qcp(init)`: Specifies the initialization strategy used for non-convex QPs and QCQPs.
    * `mip_cutoff`: This value specifies the objective cutoff value for MIP.
    * `mip_heuristic_lns`: Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics.
    * `mip_liftproj`: Specifies rules for adding lift and project cuts.
    * `mip_multistart`: Use to enable MIP multi-start at the branch-and-bound level.
    * `mip_numthreads`: Specify the number of threads to use for MIP branch and bound.
  - Renamed options (old option names still available as synonyms but deprecated):
    * `bar_pencons` to `bar_penaltycons`.
    * `bar_penrule` to `bar_penaltyrule`.
    * `mip_integral_gap_abs` to `mip_opt_gap_abs`.
    * `mip_integral_gap_rel` to `mip_opt_gap_rel`.
    * `par_mnumthreads` to `ms_numthreads`.
    * `par_blasnumthreads` to `blas_numthreads`.
    * `par_lsnumthreads` to `linsolver_numthreads`.
    * `tuner_maxtimecpu` to `tuner_maxtime_cpu`.
    * `tuner_maxtimereal` to `tuner_maxtime_real`.
  - Added option values:
    * `blasoption`: 3.
    * `mip_heuristic_diving`: bits 1 - 4.
  - Changed option defaults:
    * `restarts`: -1 (auto).
    * `mip_strong_candlim`: 128.
- Fixed possible error of incorrect Jacobian for QCP models.

3.5.1.4.8 Lindo/LindoGlobal

- New libraries 13.0.319.
3.5.1.4.9 LocalSolver

- As announced, dropped LocalSolver and LocalSolver70.

3.5.1.4.10 MOSEK

- New libraries 9.3.11.
  - Added support for LPs and MIPs with more than $2^{31}$ entries in the coefficients matrix.

3.5.1.4.11 Octeract

- New libraries 4.1.0.
  - Reduced memory requirement and improved performance.

3.5.1.4.12 ODHCPLEX

- New libraries 6.0.8.
  - Added support of solution pool export via solnpool and solnpoolmerge.

3.5.1.4.13 SCIP Optimization Suite

- New libraries PaPILO 2.0.0.
  - Added dual postsolve functionality for LPs.
  - Immediate application of a presolvers reductions if run sequentially.
  - Improvements in performance and functionality of many presolvers.
  - For more details, see [22] and the PaPILO CHANGELOG.
  - Updated TBB to version 2021.5.0.

- New libraries SoPlex 6.0.0.
  - PaPILO can now be enabled as presolver by setting int:simplifier to the new value 2.
  - SoPlex can now be interrupted by Ctrl+C/SIGINT.
  - Changed default for option int:simplifier from 1 to new value 3. The value 1 now means ”auto”.
  - New option real:simplifier_modifyrowfac.
  - For more details, see [22] and the SoPlex CHANGELOG.

- New libraries SCIP 8.0.0.
  - Symmetry handling:
    - New symmetry handling inequalities based on the Schreier Sims table, which are able to handle symmetries of arbitrary kinds of variables.
    - The symmetry code can now heuristically search for orbitopes that do not completely handle a symmetry component and add certain Schreier Sims cuts to such components.
    - In-tree restarts due to tree size estimation have been made compatible with orbital fixing.
    - Improved performance of upgrades to packing/partitioning orbitopes, symresack cover separation, and propagation for orbisack and symresack.
* Symmetry handling has been extended to detect also symmetries between variables that also appear in nonlinear constraints.

- Cutting planes:
  * New separator **mixing** to generate mixing cuts.
  * New separator **rlt** to compute cuts via the reformulation-linearization technique (RLT).
  * New separator **minor** to compute cuts from 2x2 minors of a violated semidefiniteness constraint that is implied by the extended formulation for bilinear products.
  * New separator **interminor** to compute intersection cuts from 2x2 (not only principle) minors of a violated rank-one constraint that is implied by the extended formulation for bilinear products (currently disabled by default).
  * Separator "aggregation" now uses the objective cutoff row as base row and separates lifted cover cuts based on newer lifting function of Letchford and Souli (2019).
  * Separators "strongcg" and "gomory" now share the same computed basis.

- Primal Heuristics:
  * New construction heuristic **DPS** which additionally needs a user-provided decomposition and splits the problem into several sub-SCIPs according to this decomposition. The sub-SCIPs are solved and updated repeatedly until a feasible solution of the original problem is found.
  * PADM can now reoptimize found solution with original objective function.
  * The RENS neighborhood in the heuristic ALNS now fixes fractional variables if necessary for reaching its target fixing rate.
  * Revised and improved heuristic subNLP, in particular choice of NLP iteration limit and starting condition and reuse of subSCIP.

- The handling of algebraic expressions and nonlinear constraints has been rewritten:
  * Support for trigonometric functions sine and cosine and for the entropy function has been added.
  * Improved recognition of common subexpressions, in particular square and bilinear terms.
  * All type of nonlinear constraints, including quadratic and second-order-cones, are now handled by the constraint handler for nonlinear constraints. The specialized constraint handlers have been removed. However, methods that work on a particular nonlinear structure are now implemented via nonlinear handlers (nlhldr).
  * Added nonlinear handler for quadratic, bilinear, convex, concave, and quotient expressions, second-order cone constraints, and perspective tightening for expressions in semi-continuous variables.
  * As before, an extended formulation for nonlinear constraints is constructed. However, this formulation is now handled implicitly and used to construct the LP relaxation only, while the original formulation is used to check feasibility, propagate variable domains, etc. This difference should drastically improved the likelihood that a solution that satisfies the nonlinear constraints in the presolved problem is also feasible for the original problem.
  * Products in nonlinear constraints are no longer disaggregated for the extended formulation.
  * Improved analysis on which nonlinear variables in nonlinear constraints can be increased or decreased without harming feasibility by taking monotonicity into account.
  * Improved linearization of (sums of) products of binary variables, e.g., clique information is now taken into account.
  * When a variable appears in only one concave less-or-equal constraint, it will be fixed to one of its bounds in more cases now.
  * New branching rule for variables in nonlinear constraints that scores candidates based on constraint violation, variable type, and pseudo-costs simultaneously. Variables that are added for the extended formulation of a nonlinear constraint are no longer branched on by default.
  * New strategies to deal with weak estimators for nonlinear functions and small violations of nonlinear constraints.
  * Improved under/overestimation of multidimensional vertex-polyhedral (e.g., multilinear or concave) functions by use of scaling and keeping the cut-generating LP around.
* Added tables to print statistics of nonlinear constraint handler, nonlinear handlers, and handlers for all supported functions.

- Revised and improved interfaces to Ipopt and CppAD, e.g.:
  * Optimization of taped expressions and sparse Hessian evaluation of CppAD are used now.
  * Added table to print statistics on NLP solvers.

- The interfaces to Gurobi and Mosek are thread-safe now.

- Parameters removed:
  * `gams/resolvenlp`
  * `constraints/abspower/*`, `constraints/bivariate/*`, `constraints/quadratic/*`, `constraints/soc/*`
  * `constraints/nonlinear/cutmaxrange`, `constraints/nonlinear/lifeasheasft`, `constraints/nonlinear/reformulate`, `constraints/nonlinear/sepanlpmintcnt`, `constraints/nonlinear/enfocutsremovable`, `constraints/nonlinear/maxexpansionexponent`, `constraints/nonlinear/upgrade/abspower`, `constraints/nonlinear/upgrade/and`, `constraints/nonlinear/upgrade/bivariate`, `constraints/nonlinear/upgrade/quadratic`
  * `constraints/orbitope/usedynamicprop`
  * `heuristics/multistart/nlpminimpr`
  * `heuristics/subnlp/iteroffset`, `heuristics/subnlp/iterquotient`, `heuristics/subnlp/nlpiterlim`, `heuristics/subnlp/nlptimelim`, `heuristics/subnlp/runalways`, `heuristics/subnlp/minimprove`, `heuristics/subnlp/nlpoptfile`, `heuristics/subnlp/resolverfromscratch`, `heuristics/subnlp/resolverfromscratch`
  * `propagating/symmetry/disabledofrestart`
  * `separating/convexproj/nlptimelim`, `separating/gauge/nlptimelim`, `separating/strongcg/dynamiccuts`, `separating/strongcg/maxronds`, `separating/strongcg/maxrondsroot`, `separating/strongcg/maxsepcuts`, `separating/strongcg/maxsepcutsroot`

- Parameters added:
  * `branching/inference/conflictprio`, `branching/inference/cutoffprio`
  * `cuteselection/hybrid/*`
  * `decomposition/disablereplicators`
  * `expr/log/minzerodistance`, `expr/pow/minzerodistance`
  * `heuristics/alns/nodesquotmin`, `heuristics/alns/initializingrc`, `heuristics/alns/maxcallssamesol`
  * `heuristics/dps/*`
  * `heuristics/padm/reoptimize`
  * `heuristics/subnlp/expectedfeas`, `heuristics/subnlp/feasolstol`, `heuristics/subnlp/iterinit`, `heuristics/subnlp/nimitsolves`, `heuristics/subnlp/nodesfactor`, `heuristics/subnlp/nodesoffset`, `heuristics/subnlp/presolveemphasis`, `heuristics/subnlp/setctol`, `heuristics/subnlp/successrateexp`, `heuristics/subnlp/opttol`,
  * `misc/avoidmemout`
  * `nlhdlr/bilinear/*`, `nlhdlr/concave/*`, `nlhdlr/convex/*`, `nlhdlr/default/*`, `nlhdlr/perspective/*`, `nlhdlr/quadratic/*`, `nlhdlr/quotient/*`, `nlhdlr/soc/*`
  * `nlpi/ipopt/*`
  * `presolving/mlp/probfilename`
  * `propagating/obbt/createincons`,

---

**3.5 38 Distribution**

---
* separating/maxcoefficientfractionfacsrowprepr, separating/filtercutpoolrel

* timing/nlpieval

- Parameters changed:
  * default of constraints/nonlinear/maxproprounds changed from 1 to 10
  * default of display/nexternbranchcands/active changed from 2 to 1 also for nonlinear instances
  * default of display/nfrac/active changed from 2 to 1 also if discrete variables are present
  * default of heuristics/dualval/priority changed from 0 to -10
  * default of heuristics/lface/priority changed from -1104000 to -1104010
  * default of heuristics/mutation/priority changed from -1103000 to -1103010
  * default of heuristics/ulpdiving/priority changed from -1003000 to -1003010
  * default of heuristics/repair/priority changed from 0 to -20
  * default of heuristics/simplerounding/priority from 0 to -30
  * default of heuristics/subnlp/forbidfixings from 1 to 0
  * default of heuristics/subnlp/itermin changed from 300 to 20
  * default of SCIPheuristics/subnlp/priority heuristics/subnlp/priority changed from -2000000 to -2000010
  * default of heuristics/trivialnegation/priority changed from 40000 to 39990
  * default of heuristics/trustregion/priority changed from -1102000 to -1102010
  * default of heuristics/trysol/priority changed from -3000000 to -3000010
  * default of misc/usesymmetry changed from 3 to 7 and range changed from \{0,...,3\} to \{0,...,7\}
  * default of presolving/qpkktref/maxrounds changed from -1 to 0
  * default of propagating/obbt/onlynonconvexvargs changed from 0 to 1
  * default of propagating/symmetry/addsymresacks changed from 1 to 0
  * type of propagating/symmetry/recompute restart changed from boolean to int with range \{0,...,2\}
  * default of separating/strongcg/maxbounddist changed from 1 to 0
  * default of separating/strongcg/priority changed from -2000 to -100000
  * replaced separating/minortho by cutselection/hybrid/minortho, replaced separating/minorthoroot by cutselection/hybrid/minorthoroot, replaced separating/dircutoffdistfacs by cutselection/hybrid/dircutoffdistweight, replaced separating/efficacyfacs by cutselection/hybrid/efficacyweight, replaced separating/intsupportfacs by cutselection/hybrid/intsupportfacs, replaced separating/objparallelfacs by cutselection/hybrid/objparallelweight

- For more details, see [22] and the SCIP release notes.

- Added support for GAMS functions \( \text{sin}, \text{cos}, \text{and entropy} \) for GAMS/SCIP.
- Since SCIP has dropped support for \( \text{min}, \text{and max} \), the GAMS/SCIP link reformulates GAMS functions \( \text{min} \) and \( \text{max} \) by use of \( \text{abs} \) now.
- Removed the feature that ran Ipopt from a returned solution that is recognized by SCIP to be not feasible in the original (non-presolved) nonlinear problem in order to obtain a feasible solution.
3.5.1.4.14 SHOT

- New libraries 1.1 (e225a002).

3.5.1.4.15 XPRESS

- New libraries 39.01.03.
  - Improved MIP performance:
    * The Optimizer now uses an ML module to decide whether to use in-tree cutting. See autoCutting.
    * Improved separation of Mixed Integer Rounding (MIR) cuts.
    * Improved cut activation and deactivation strategies.
    * Improved application of strong branching during the tree search.
    * More information carried through a MIP restart.
  - Improved crossover performance after a Barrier solve through automatic objective perturbation. See barObjPerturb.
  - Improved Barrier performance for large problems on CPUs that support AVX2 (requires setting cpuPlatform to -2).
  - New options:
    * autoCutting: Automatically decide whether to generate cutting planes at local nodes in the tree.
    * barObjPerturb: Defines how the barrier perturbs the objective.
    * ioTimeout: Maximum number of seconds to wait for an I/O operation before it is cancelled.
    * maxStallTime: Maximum time in seconds that the Optimizer will continue to search for improving solution after finding a new incumbent.
    * preCliqueStrategy: Determines how much effort to spend on clique covers in presolve.
    * siftPresolveOps: Determines the presolve operations for solving the subproblems during the sifting algorithm.
  - Changed option default of xslp.mipDefaultAlgorithm: 1.

- Added option fixoptfile: name of option file which is read just before solving the fixed problem.
- Changed default value of option mipAddCutoff and mipRelCutoff to 0.
- Fixed unnecessary solve of fixed MIP (see mipCleanup) when solving a linear program as MIP.

3.5.1.5 Tools

3.5.1.5.1 BIB2GMS

- As announced, dropped the tool bib2gms.

3.5.1.5.2 CSV2GDX

- Check for certain byte order marks (BOMs) in input files. Files with UTF8 BOM can be processed now, other BOMs generate an explicit error.
3.5.1.5.3 GAMS Studio

- New version 1.9.4.
  - Added Project Options editor.
  - Added possibility to create an empty project.
  - Adjusted loading from a model library to add files to active project working directory if "Open in existing project" is checked.
  - Added selection of user instances on GAMS Engine SaaS.
  - Added selection of namespaces on GAMS Engine Server.
  - Stability improvements, bug fixes, and minor enhancements, e.g.:
    * Expanded MIRO installation location on Mac OS X ifAppBundle has been selected.
    * Adjusted check if the MIRO data contract is available before the MIRO app is deployed.
    * Changed mouse wheel behavior in tab bars:
      - Mouse Wheel Up/Down: moves active tab
      - Ctrl + Mouse Wheel Up/Down: changes active tab
    * Added touch pad support for tab bars.
    * Added highlight in LST file for current section header of LXI viewer.
    * Changed behavior of search in selection: the search selection is now only set once until the user resets it.
    * Changed "Clear" button to remove search selection on first click when present.
    * Fixed non-overridden recurrence of immediate options on command line parameters.
    * Fixed jump behavior of search when using "This File" and navigating different files.
    * Fixed Find Next broken for results across multiple files.
    * Fixed crash on showing "Project Options" for a project without a runnable gms file.
    * Fixed search not updating cache when document has changed.
    * Fixed Clear Selection button not working as intended, when search scope was set to anything but "Selection".
    * Fixed random crash in Search and Replace dialog.
    * Fixed that checks for file type did not ignore casing (gms, Gms, GMS are all valid).
    * Fixed that the default file filter in search dialog expected files to include a '.' character on non-windows platforms.
    * Fixed file filter in search dialog not being ignored for scopes "This File" and "Selection".
    * Fixed search jump behavior when current file is excluded by file filter.
    * Fixed completer and syntax help activation for user defined GAMS source files.

3.5.1.5.4 GDXDIFF

- Reduce size of output GDX file in case of input files without differences.
- Added new option ignoreOrder.

3.5.1.5.5 GDXMRW

- We mark GDXMRW as deprecated and may remove it in a future release. Please use GAMS Transfer Matlab instead. If you encounter issues with the transition to GAMS Transfer Matlab or if you have any feature requests for GAMS Transfer Matlab, do not hesitate to contact us through support.
3.5.1.6.6 **HEXDUMP**

- As announced, dropped the tool `hexdump`.

3.5.1.6 **APIs**

3.5.1.6.1 **C++ high-level API**

- Removed conversion of mapped network drives to UNC paths.
- Fixed addition of GAMS system directory to `PATH` on Windows.

3.5.1.6.2 **GAMS Transfer Matlab**

- New read-only `ConstContainer` (high reading performance).
- `Container` now supports to read from a `ConstContainer` in addition to a GDX file.
- New argument types in `Container::listVariables` and `Container::listEquations` to filter by variable or equation type, respectively.
- `Container::listSets` does not include aliases in the returned list anymore. However, it is still possible to include aliases in `Container::describeSets`.
- New argument `records` in `Container::read` to toggle reading records in addition to symbol meta data.

3.5.1.6.3 **GAMS Transfer Python**

- GAMS Transfer now works with Embedded Python Code.
- New read-only `Container` type called `ConstContainer` (high reading performance).
- New argument types for methods `listVariables()` and `listEquations()` to filter by variable or equation type, respectively.
- The method `listSets()` does not include aliases in the returned list anymore.
- The `Container.read()` argument `values` has been renamed to `records`.
- Fixed bug in `SpecialValues.isNegInf()` that did not properly detect scalar `-inf`.
- Fixed error handling when invalid records are set directly with `.records`.

3.5.1.6.4 **GDX**

- Internal adjustment to detection of special values when writing to GDX. The updated GDX behavior will allow better differentiation between distinct double-precision values that the user wants mapped to distinct special values. For example, -0.0 is no longer confused with +0.0, and different IEEE NaN values can map to different GAMS special values.
3.5.1.6.5 GMO

- Added routines `gmoGetRowQNZOne64`, `gmoMaxQNZ64`, and `gmoObjQMatNZ64` to get element counts as 64-bit integer.
- Adjust routines `gmoGetRowQNZOne`, `gmoMaxQNZ`, and `gmoObjQMatNZ` to return -1 if the element count is too large for a 32-bit integer.
- Added routines `gmoLNZEx` and `gmoLNZEx64` to get the exact count of linear nonzeros in the Jacobian matrix, and adjusted the description of `gmoLNZ` and `gmoLNZ64` to make clear that these are legacy routines returning an overestimate of this count, especially when `gmoUseQ` is true.
- Fix gradient intervals for functions involving `power(x,i)` for `i >= 4` and even.

3.5.1.6.6 High-level APIs

- The `GAMSDatabase` GDX export method now writes `regular` instead of just `relaxed` domain information if available.

3.5.1.6.7 PAL

- Added function `palIsAlpha`. `palIsAlfa` has been deprecated.

3.5.1.6.8 Python

- Added support for Python 3.10.
- We plan to drop support for Python 3.6 in a future GAMS release.

3.5.1.7 Model Libraries

3.5.1.7.1 GAMS Data Library  New model:

- `GMSPythonLib.gms` : `GMSPYTHONLIB` compatibility check (142)

3.5.1.7.2 GAMS Test Library  New models:

- `dumpopt2.gms` : Test `dumpOpt` with `dumpOptGDX`
- `encoding01.gms` : Test processing of source files with BOM

### 3.5.2 38.2.0 Minor release (February 17, 2022)

#### 3.5.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Gwendal Nivanen.
3.5.2.2 GAMS System

3.5.2.2.1 GAMS

- Fixed an incorrect evaluation of intrinsic functions (and their derivatives) having a variable number of arguments (e.g. $edist$ or $poly$). This error did not occur in all cases: it depended on a missing or incorrect initialization in the calling environment.
- Fixed a problem in the extrinsic function declaration which required <$\text{FuncName}$> to be case sensitive.

3.5.2.3 Solvers

3.5.2.3.1 BARON

- New libraries 22.2.3.

3.5.2.3.2 CONOPT

  - Removed option "Flg_Crash_Basis".
  - Changed default of option $\text{Lim_Start_Degen}$ from 10 to 100.

3.5.2.3.3 CONVERT

- Fix missing semi-colon at end of comment in lingo output.
- Fix unary minus in lingo output.

3.5.2.3.4 COPT

- Added option $\text{readparams}$ to instruct COPT to read an additional parameters file.

3.5.2.3.5 CPLEX

- Fix solution pool export: Previously the solution pool was only exported if CPLEX terminated successfully with a solution. Now, the solution pool GDX is exported independent of the CPLEX termination status, but may contain no solution. $\text{solnpoolpoprepeat}$ and $\text{solnpoolpopdel}$ still don't have any effect if CPLEX terminated unsuccessfully.

3.5.2.3.6 GAMSCHK

- Add a missing initialization for the case where no subsolver is called. Without this initialization, incorrect output would occur.
3.5.2.3.7 Ipopt

- New libraries 3.14.5.
  - Fixed that marginals were always zero if Ipopt stopped due to reaching a timelimit.

3.5.2.3.8 XPRESS

- New libraries 39.01.04.

3.5.2.4 APIs

3.5.2.4.1 High-level APIs

- Fixed a problem with `GAMSModelInstance.Instantiate` complaining about a missing dictionary file. This happened when a (default) solver for the model type of the instance is active which does not use a dictionary.

3.5.2.4.2 GAMS Transfer Python

- Added new property `shape` to `Parameter`, `Variable`, and `Equation` to report the corresponding matrix shape if `toDense` or `toSparseCoo` are called.
- Fixed bug with array generation (1D symbols): `toDense` will now generate a `(n,)` array instead of `(1,n)”; harmonized this behavior with `toSparseCoo`.
- Fixed behavior: when `toDense` is called on a scalar symbol an array of shape `(,)` will be returned instead of a `float`.
- Fixed behavior: when `toSparseCoo` is called on a scalar symbol a sparse `coo_matrix` of shape `(1,1)` will be returned instead of a `float`.
- Better handling of numeric domain information within `setRecords` methods: numeric entries are now converted to `str` and generate categories from the `str` equivalents.

3.5.2.4.3 GMO

- The default for the property `gmoHessInclQRows` was accidentally changed to `false` with GAMS 35.1.0. With this release, it has been changed back to its original setting of `true`. That is, also if `useQ` is set, the Hessian will include information on quadratic equations by default again.

3.5.3 38.2.1 Maintenance release (February 19, 2022)

3.5.3.1 Solvers

3.5.3.1.1 CONOPT

- Fixed warning about unknown option name “FLG.CRASH.BASIS” (introduced with GAMS 38.2.0).
3.5.3.1.2 Convert

- Fixed error when exporting CNS models with ampl, jump, lingo and pyomo.

3.5.3.1.3 Octeract

- Avoid that an ObjEst of $\pm 1.797693134E308$ is reported as 1797693134 in GAMS tracefile.

3.5.4 38.3.0 Minor release (April 05, 2022)

3.5.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Daniel Dias, Antti Lehtila, Scott MacDonald, Evangelos Panos, Richard Waltz and Eric Williams.

3.5.4.2 GAMS System

3.5.4.2.1 GAMS

- Fixed wrong numbers about infeasibilities (e.g., in the report summary) when bounds with value EPS are involved.
- Fixed potential unwanted domain violation error when implicit set definition is used while $\$onMulti is active to allow a redefinition of symbol data.
- Fixed potential error when loading data filtered from embedded code.

3.5.4.3 Solvers

3.5.4.3.1 BARON

- New libraries 22.3.21.

3.5.4.3.2 CONVERT

- Fixed export of variable attribute stage for discrete variables when using option DumpGDX.
- Fixed that coefficients in QCMATRIX section were wrong. They had only half its value.
- Fixed missing asterisk for bilinear terms in CplexLP format.

3.5.4.3.3 COPT

- Fixed that indicators from solver options file were ignored.
3.5.4.3.4 CPLEX

- Fixed bug with registering an advanced basis.
- Fixed CPLEX solution status `CPX_STATNUMBEST`. This status is mapped to GAMS model status `feasible`.
- Fixed interactive mode (when no trigger file is set).

3.5.4.3.5 GUROBI

- New libraries 9.5.1.

3.5.4.3.6 IPOPT

- Fixed that names for vector entries corresponding to inequality equations (as shown with `print_level ≥ 8`) could be incorrect due to a wrong mapping of indices.

3.5.4.3.7 KNITRO

- Fixed unnecessary calls to Knitro evaluation callbacks for linear or quadratic constraints.

3.5.4.3.8 Mosek

- New libraries 9.3.18.

3.5.4.3.9 Octeract

- New libraries 4.2.0.
  - Improved performance, in particular for problems with quadratic structures.
  - CPLEX is now automatically chosen as subsolver, if licensed.

3.5.4.3.10 SCIP Optimization Suite

- New libraries SCIP 8.0 (189beea30).
  - Clique lifting for setpartitioning/packing/covering constraints is now only disabled if it has been applied.
- New libraries PaPILO 2.0 (g166dea4).

3.5.4.3.11 XPRESS

- New libraries 39.01.05.
- Changed option default of `xslp_iterLimit`: -1 (auto).
3.5.4.4 Tools

3.5.4.4.1 MODEL2TEX

- Fixed a crash that occurred when `SameAs` was used in equations.

3.5.4.4.2 MPS2GMS

- Fixed that variables in SOS of type 2 were written as SOS of type 1 to GDX file.
- Fixed that upper bounds of 100 for (semi)integer variables were lost.
- Fixed that Σ-rows that did not specify objective functions were not omitted in parameter p (equation right-hand sides).
- Fixed that nonzero coefficients with absolute value at most 1e-20 were lost.
- Fixed that C-rows had arbitrary right-hand side value in GDX file (though this value was not accessed from the GAMS model).
- Fixed that an objective constant (nonzero RHS for objective row in MPS file) was lost.
- Fixed that off-diagonal elements in QUADOBJ and QSECTION sections were not handled correctly.

3.5.4.4.3 GAMS Studio

- New version 1.9.6 with various bug fixes, stability improvements, and minor enhancements, e.g.:
  - Added Page-up/-down keys to extend block edit selection.
  - Added separator line on Windows in horizontal headers of tables and tree views.
  - Remote jobs now can be kept active on Studio exit.
  - Fixed crash in GDX Viewer related to reading a file containing negative UELs.
  - Fixed empty log file when using `logOption=2`.
  - Fixed search not properly counting search results across multiple files.
  - Fixed "Replace All" preview wrongfully including read-only files.
  - Fixed "Search" not always jumping to a result outside current file.
  - Fixed NEOS freezing when the GMS file is not located in the working directory.

3.5.4.5 APIs

3.5.4.5.1 GAMS Transfer Python

- Fixed memory leak associated with `gams2numpy`. 
### 3.6 37 Distribution

#### 3.6.1 37.1.0 Major release (November 11, 2021)

**Acknowledgments**

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Boyan Atanasov, Edna Johanna Molina Bacca, Abhijit Bora, Wolfgang Britz, Bruno Charlier, Hancheng Dai, Rob Davies, Ricardo M. Pinto de Lima, Bruce McCarl, Scott McDonald, Guillaume Nimal, Gwendal Nivanen, Zack Pecenak, Tom Rutherford, Nick Sahinidis, Shima Sasanpour, and Denys Yemshanov.

#### Platforms

- We will drop support for Mac OS X 10.14 (Mojave) with the next major release.

#### GAMS System

**GAMS**

- Added new intrinsic function logit.
- Added new conditional expression onState to check the state of certain dollar control options. An example can be seen here.
- Added command line parameter and option EpsToZero as well as dollar control options $onEpsToZero and $offEpsToZero to allow writing EPS values as zero to GDX.
- Made command line parameters holdFixedAsync, sys15, sys16, sys17, sys18, and sys19 available in option statements as well.
- Avoid warnings if $abort or $call.checkErrorLevel are used within a $ifThen ... $else statement.
- Allow space in limited domain declaration like this: Model transport / all, x (ij) /;
- In the past, GAMS threw an execution error, when execute unload failed because of an invalid file name given. Now, it tries to write to a file with a generic file name first (like it was always done with put files as well).
- Added a new command line parameter and option maxGenericFiles to specify the number of tries to write to a generic file as mentioned above.
- Extended the influence of $offInclude to suppress the include file summary and the creation of an expanded include file as well.
- Added support for (mixed-integer) linear models that generate more than $2^{31} = 2,147,483,648$ nonzeros. At this time, only the solver links for CPLEX, GUROBI, and XPRESS are capable of handling such large model instances. The number of rows and columns is still limited to $2^{31}$.
- Removed a limitation for the model attribute handle that did not allow to set a value which is anything but a Grid handle (specifically, a multi threading handle was rejected before).
- Throw an explicit execution error, if a solver that comes without executable gets called with the Grid Facility (at the moment, this affects DECIS only).
- Fixed calling a solver with the Grid Facility that is not located in the GAMS system directory.
- Fixed alignment of `dmpSym` and `dmpUserSym` output in case of long symbol names.
- Fixed handling of paths with spaces in `gamsconfig.yaml` for items `scriptName` and `executableName` in section `solverConfig`.
- `$Call`, `$execute`, and its variants allow now spaces in the path of the script/program to be called if properly quoted.
- Fixed a zero digit `display` bug, where 0 was shown as 0.0.
- Fixed wrong matrix error detections for discrete variables and right hand side of `external equations` in certain cases.
- Fixed that the GAMS execution system corrupted control or status information in the CPUs SSE registers on Linux when using `$IfE`, `$IfThenE`, and related.

### 3.6.1.3.2 Embedded Python Code Facility

- Print the Python script line number in case an exception is raised.
- Register alias symbols in `gams.db`.
- Provide domain information for symbols via `gams.db[Sym].domains` and `gams.db[Sym].domains_as_strings`.
- Fix a problem in `pyEmbMI` for double bounded but not fixed variables.
- The Python version of GMSPython has been updated to 3.8.11.
- Removed package `schema` and its dependency `contextlib2` from GMSPython.

### 3.6.1.3.3 Extended Mathematical Programming (EMP)

- Added new stochastic EMP keyword `stageDefault` to change the default stage of symbols not assigned to a stage explicitly.
- Changed the `stage` behavior so that it does not count as a terminating error if it is used with a symbol missing in the model.

### 3.6.1.3.4 Windows Installer

- Associate `.gsp` (GAMS Studio project) files with GAMS Studio.

### 3.6.1.4 Solvers

#### 3.6.1.4.1 ANTIGONE, IPOPT, SHOT, SCIP

- Updated Intel MKL to version 2021.2.0 on Windows.

#### 3.6.1.4.2 CONVERT

- Fix default behavior if reading option file fails.
3.6.1.4.3 CPLEX

- Fixed duplicate CPLEX output in GUSS cold starts with GUSS logoption 2.
- Fixed unwanted consideration of some GAMS command line options in tuning.
- Fixed possible ignorance of an interrupt signal (Ctrl+C).
- Disabling CPLEX solution pool on default (when solnpool and solnpoolmerge are not set).
- Fixed invocation of solution pool export in case of CPLEX termination code 104: solution limit reached.
- Fixed possible crash when using mipstopexpr.

3.6.1.4.4 GUROBI

- New libraries 9.5.0.
  - Added norm constraints to general constraint type, see genconstrtype.
  - New option memlimit: Memory limit.
  - New option worklimit: Work limit.
  - New option lpwarmstart: Warm start usage in simplex.
  - New option nlpheur: Controls the NLP heuristic for non-convex quadratic models.
  - New option presos1encoding: Controls SOS1 reformulation.
  - New option presos2encoding: Controls SOS2 reformulation.
  - New option tunemetric: Metric to aggregate results into a single measure.
  - New option tunetargetmipgap: A target gap to be reached.
  - New option tunetargettime: A target runtime in seconds to be reached.
  - New option liftprojectcuts: Lift-and-project cut generation.
  - Changed default option value of TuneTrials: 0 (auto).
  - Changed default option value of CrossoverBasis: -1 (auto). The option type changed from boolean to integer.

3.6.1.4.5 GUSS

- Fixed detection of update requests with symbols that are not present in the generated model.
- Fixed incorrect behavior of option SolveEmpty (not only empty but all scenarios were skipped after threshold reached).

3.6.1.4.6 KNITRO

- Added support for MCP model type.

3.6.1.4.7 Lindo/LindoGlobal

- New libraries 13.0.309.
- Added support for function logit.
3.6.1.4.8  LocalSolver

- New libraries 10.5 (20211014).

3.6.1.4.9  Mosek

- New libraries 9.3.7.

3.6.1.4.10  Octeract

- Added new global MINLP solver Octeract 3.5.0 (https://octeract.com/).
- Octeract can be used for model types QCP, RMIQP, MIQP, NLP, DNLP, RMINLP, and MINLP and is available for Linux and Windows systems.
- For GAMS demo and community licenses, model size limitations similar to other global solvers apply. For an unlimited GAMS/Octeract license, contact sales@gams.com.

3.6.1.4.11  SCIP

- New libraries 7.0 (b2afa5403b).

3.6.1.4.12  SHOT

- New libraries 1.1.0 (11fda1ec).
  - Default value for option Subsolver.Gurobi.NumericFocus changed from 2 to 1.

3.6.1.4.13  SOPLEX

- New libraries 5.0 (ad7592b9).

3.6.1.4.14  XPRESS

- New libraries 38.01.05.

3.6.1.5  Tools

3.6.1.5.1  BIB2GMS

- We will remove the tool bib2gms in a future GAMS release.
3.6.1.5.2 FINDTHISGAMS

- Support for registry keys for .gsp (GAMS Studio project) file association has been added.

3.6.1.5.3 GAMS Studio

- New version 1.8.2.
  - New feature: Added tooltips to source code for keywords and Dollar Control Options (can be deactivated in the settings dialog).
  - Rework of the Project Explorer:
    * Changed naming from "group" to "project".
    * Files now appear in folders relative to the working directory of the assigned project.
    * Added import and export of projects.
    * The projects context menu "Project options" allows to change the name and working directory of the project.
    * Added individual working directories for each project.
    * Added dialog to set the base directory on project import.
  - Highlight remotely executed log (NEOS or GAMS Engine).
  - Removed obsolete MIRO Hypercube mode.
  - Replace TAB characters by the proper amount of spaces when pasting text.
  - Set default TAB size to 8.
  - Allow to use GAMS Engine on a HTTP server when the local SSL is not present.
  - Skipped log duplicate in the NEOS log.
  - Added new search scope Selection which allows users to search inside a text selection.
  - Added zoom for lxi tree view when zooming in lst files.
  - Stability improvements and minor bug fixes, e.g.:
    * Fixed NEOS and GAMS Engine being inactive due to an SSL detection issue.
    * Fixed links to model in NEOS log.
    * Fixed crash when editing long lines ending in an error mark.
    * Fixed highlighting of wrong results in Search Result View.
    * Fixed broken syntax highlighting of execute_*.
    * Fixed completer not opening or staying open unwanted.

3.6.1.5.4 GDX2HAR/HAR2GDX

- We will remove the tools gdx2har and har2gdx in a future GAMS release. The tools can be accessed from the CoPS web site.

3.6.1.5.5 HEXDUMP

- We will remove the tool hexdump in a future GAMS release. A similar functionality is available on Unix systems via the od utility with parameters od -A x -t xiz -v. On Windows od is distributed as part of the POSIX utilities.
3.6.1.5.6  SCENRED

- We will remove the tool SCENRED in a future GAMS release. The tool SCENRED2 should be used instead.

3.6.1.6  APIs

3.6.1.6.1  C++ high-level API

- Fixed GAMSOption::setOutput parameter being ignored in GAMSJob::run().

3.6.1.6.2  gams2numpy

- The binaries are now build with numpy 1.20.3 instead of numpy 1.19.5 for Python 3.7, 3.8, and 3.9.

3.6.1.6.3  GAMS Transfer

- New APIs GAMS Transfer Matlab and GAMS Transfer for Python to exchange data between GAMS and Matlab and Python, respectively.

3.6.1.6.4  GMD

- Allow to add symbols via gmdAddSymbol and gmdAddSymbolX of type alias (GMS_DT_ALIAS).
- Added function gmdFindSymbolWithAlias that provides the actual alias symbol rather than the aliased set in case the requested symbol is an alias.
- Added function gmdGetSymbolByNumber that provides the symbol based on the GMD_NUMBER which includes the alias symbols.
- Added information key GMD_NR_SYMBOLS_WITH_ALIAS for function gmdInfo to retrieve the number of symbols including alias symbols.

3.6.1.6.5  GMO

- Adjusted routine gmoGetMatrixCol to fail if called where quadratic structure is explicitly detected/handled (i.e. useQ is set). This routine was not intended to be used in this case.
- Added routines gmoNZ64, gmoNLNZ64, and gmoLNZ64 to get non-zero counts as 64-bit integer.
- Fixed routine gmoDirtySetRowFNLinstr: it was not computing the number of stored NL instructions correctly.

3.6.1.6.6  PAL

- Added routines palLicenseSolverCheckSizes64 and palLicenseCheck64 for solvers that use 64-bit integers for non-zero counts.
3.6.1.6.7 Python high-level API

- Fixed a problem with property `domains` of a symbol in case the domain list consists of a `GamsSet` and string elements.

3.6.1.7 Model Libraries

3.6.1.7.1 GAMS Model Library

- MS Access and Excel files have been updated to the MS Office 2007 format, i.e., files with the `xls` extension were changed to `xlsx` or `xlsm` files, files with the `mdb` extension were changed to `accdb` files.
- The structured bibliographic information has been removed. As a consequence, the `Author` column in the table of models (documentation and Studio/IDE) has been removed as well as the `Reference` section for the individual model page (web). The bibliographic references remain part of the model source.

New Models:

- `rcpsp.gms`: Resource-Constrained Project Scheduling Problem (429)

3.6.1.7.2 GAMS Test Library New models:

- `asyncfix02.gms`: Test asynchronous solves with `holdFixedAsync` setting
- `genfile01.gms`: Test generic file names
- `offinc01.gms`: Test dollar control option `$offInclude`
- `embpy11.gms`: Test proper domain info in Embedded Code
- `dco01.gms`: Test default state and switching state for dollar control options
- `epstozero1.gms`: Test writing `eps` as zero to GDX
- `fnlogit.gms`: Test correctness of `logit` intrinsic
- `empsp01.gms`: Test EMPSP keyword `stageDefault`
- `gurobi06.gms`: GUROBI test suite - general constraints norm

### 3.7 36 Distribution

#### 3.7.1 36.1.0 Major release (August 02, 2021)

#### 3.7.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Ricardo Manuel Pinto de Lima, Bruce McCarl, Scott
3.7.1.2 GAMS System

- The End User License Agreement (eula.pdf in the GAMS system directory) has been updated to version 08/2021.

3.7.1.2.1 GAMS

- Improved performance of model generation for certain equations where the index order of the equations caused an out of order index reference of variables like in this example:

\[ ejk(j,k).. \sum(i, x(i,j,k)) =e= 42; \]

Added new command line parameter sys19 to deactivate this performance optimization.

- Added new function platformCode and new compile time constants to be used with it.

- Added information about available CPU sockets, cores, and threads to the log.

- Improve error message for invalid values of the .scale attribute.

- Allow to read environment variables and command line parameters at execution time in put context.

- Added Put_Utility commands setEnv and dropEnv to allow environment variable modification at execution time.

- Added Python function gams.get_env to EmbeddedCode Python to access modified environment variables after Python module os has been initialized.

- Fixed a problem causing an unexpected error when beginning execution time embedded code as first statement after starting from a restart file.

- Fixed a potential warning using execution time embedded code after starting from a restart file which was created with action=c.

3.7.1.2.2 Windows Installer

- Windows installer is now built with Inno Setup 6.

- Command line parameter /allUsers=yes\|no has been deprecated and will be removed in a future GAMS release. Use the new parameter /installAllUsers=yes\|no instead.

- New command line flags /allUsers and /currentUser can be used to explicitly control if the installation is performed in administrative or non-administrative installation mode.

3.7.1.2.3 GMSPython

- The Python version has been updated to 3.8.10.

3.7.1.3 Solvers

3.7.1.3.1 Bonmin

- We plan to drop Bonmin and BonminH with one of the next major releases.
### 3.7.1.3.2 CONVERT

- Added support for quadratic constraints in formats CplexLP, CplexMPS, and FixedMPS.
- Added option `SkipNRows`.
- Added option `QExtractAlg`.
- Fixed writing `eps` for zero marginals of non-basic variables or equations in format Gams.

### 3.7.1.3.3 CPLEX

- Added the following options:
  - `multobjoptfiles`: List of option files used for individual solves within multi-objective optimization.
  - `usercut`: User cut activation.
  - `usercutpool`: Indicator to use user cuts.
  - `qextractalg`: quadratic extraction algorithm in GAMS interface.
- Fixed handling of special values (incl. missing zero values) in `multimipstart`.
- Fixed update of Jacobian elements within GUSS scenarios.
- Fixed setting `gubcovers` via `cuts`.

### 3.7.1.3.4 GUROBI

- Added option `qextractalg`: quadratic extraction algorithm in GAMS interface.

### 3.7.1.3.5 GUSS

- Added support of option `savepoint` for scenario solves.

### 3.7.1.3.6 Ipopt and IpoptH

  - Attention
    - Value `pardiso` of option `linear_solver` to choose Pardiso from Intel MKL has been renamed to `pardisomkl`. Renamed `pardiso_*` options to `pardisomkl_*`.
    - Added value `pardiso` for option `linear_solver` to choose to use Pardiso from the Pardiso Solver Project. This solver is not included in the GAMS distribution. A user needs to provide a Pardiso library. Added option `pardisolib` to specify name and path of Pardiso library. Added `pardiso_*` options.
    - Added option `hslib` to specify name and path of HSL library to be loaded at runtime (for users of GAMS/Ipopt or users that want to use HSL_MA77).
    - Changed default of `honor_original_bounds` to `no`. In addition, Ipopt now ensures that, in addition to option `bound_relax_factor`, variable bounds are relaxed by at most `constr_viol_tol`. The Ipopt log now shows the violation of variable bounds in the solution.
- Fixed that marginals for fixed variables were not computed if `fixed_variable_treatment` is set to `make_parameter` (the default). Added value `make_parameter_nodual` for this option to disable calculation of marginals for fixed variables (which can cost an extra evaluation of the Jacobian).
- Added options `max_wall_time`, `print_options_mode`, `print_advanced_options`, and `timing_statistics`.
- Ipopt should now be threadsafe also when used with MUMPS as linear solver (a mutex ensures that only one thread executes MUMPS at a time).
- For more information, including bugfixes, see the Ipopt 3.14.0 release notes.

- Changed default of `constr_viol_tol` to 1e-6.
- GAMS ResLim now sets the default for Ipopt option `max_wall_time` instead of `max_cpu_time`.
- If GAMS ScaleOpt is set, i.e., the model has been scaled manually, then the default of option `nlp_scaling_method` is set to `none`.
- The interface has been extended to warmstart Ipopt if a modified model instance is solved, e.g., in the context of GUSS. For the warmstart, previously initialized Ipopt data structures are reused if possible and option `warm_start_init_point` is enabled, see also Warmstarting IPOPT.
- Enabled `solveLink=6` capability for Ipopt and IpoptH.
- Update of HSL routines (IpoptH only):
  - MA57 3.11.0.
  - HSL_MC68 3.3.1.
  - HSL_MA86 1.6.0.
  - HSL_MA97 2.6.0.
- Update of MUMPS to version 5.4.0.
- Changed default of `mumps_pivot_order` from 5 to 7.

### 3.7.1.3.7 JAMS

- Updated behavior and logging for models with `equ.var` matches in the model statement. If the trivial (aka empty or default) model transformation is specified in the EMP info file, nothing changes: the matches are used as before. In contrast, if a nontrivial or nonempty transformation is specified, the matches are ignored when creating the reformulated model and a message to this effect is sent to the log.

### 3.7.1.3.8 KNITRO

- New libraries 12.4.
  - Improved performance on mixed-integer nonlinear problems (MINLP).
  - Improved performance when using the limited-memory quasi-Newton Hessian approximation.
  - Added option `lin_solver_max_iter`: Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro.
  - Added option `bfgs_scaling`: Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation.
  - Added option `bar_lin_sys_storage`: Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps.
  - Added option `mip_cutting_plane`: Specifies when to apply the cutting plane procedure.
  - Added option `mip_heuristic_diving`: Specifies whether or not to enable the MIP diving heuristic.
- Added option `mip_heuristic_feaspump`: Specifies whether or not to enable the MIP feasibility pump heuristic.
- Added option `mip_heuristic_mpec`: Specifies whether or not to enable the MIP MPEC heuristic.
- Added option `mip_heuristic_strategy`: Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point.
- Deprecated option `mip_heuristic`: Use `mip_heuristic_strategy` instead.

- Added option `qextractalg`: quadratic extraction algorithm in GAMS interface.

3.7.1.3.9 Lindo/LindoGlobal

- New libraries 13.0.291.

3.7.1.3.10 LocalSolver

- New libraries 10.5 (20210624).

3.7.1.3.11 MOSEK

- Added option `QEXTRACTALG`.
- New libraries 9.2.47.

3.7.1.3.12 ODHCPLEX

- New libraries 6.0.4.

3.7.1.3.13 PATH

- New libraries 5.0.04 (maintenance release) include capability to further limit preprocessor output by specifying `output.preprocess.level -1`.

3.7.1.3.14 SCIP

- New libraries 7.0 (d012dac064).
- Updated Ipopt to Ipopt 3.14.1, see also above.
3.7.1.3.15 SHOT

- New libraries 1.1 (c898dd84).
  - SHOT can now call itself to solve fixed NLP problems. Activated with new value 2 for option `Primal.FixedInteger.Solver`. For nonconvex problems it is still recommended to use an external NLP solver.
  - Added also options `Subsolver.SHOt.UseHyperplanes.Fraction`, `Subsolver.SHOt.UseHyperplanes.Use`, `Subsolver.SHOt.UseFBBT`.
  - Added support for semi-continuous and semi-integer variables.
  - Added support for special ordered sets.
  - Improved support for generating supporting hyperplanes for the entire nonlinear feasible set instead of the feasible sets for the individual constraint functions. Activated with new option `Dual.ESH.Rootsearch.UseMaxFunction`.
  - Improved support for passing nonconvex quadratic functions directly to the MIP solver (if supported).
  - Added option `ModelingSystem.GAMS.QExtractAlg`.
  - Added option `Output.GAMS.AlternateSolutionsFile`.
  - Added option `Dual.HyperplaneCuts.SaveHyperplanePoints`.
  - Added option `Dual.MIP.InfeasibilityRepair.Use`.
  - Added option `Dual.ReductionCut.Use`.
  - Changed default of option `Subsolver.Cbc.Scaling` from 0 to 4.
  - Changed default of option `Subsolver.Cplex.NumericalEmphasis` from 0 to 1.
  - Changed default of option `Subsolver.Gurobi.PoolSolution` from 1 to 10.
  - Changed default of option `Model.BoundTightening.FeasibilityBased.TimeLimit` from 5 to 2.
  - Changed default of option `Termination.DualStagnation.IterationLimit` from 50 to \( \infty \).
  - Changed meaning of values 1 and 2 for option `Model.Reformulation.Bilinear.IntegerFormulation`.

- Updated Ipopt to Ipopt 3.14.1, see also above.

3.7.1.3.16 XPRESS

- New libraries 38.01.03.
  - Xpress Optimizer Release Notes:
    * Improved MIP performance.
    * It is now possible to activate a special heuristic solve mode for MIPs, which emphasizes finding new solutions.
    * Improved sifting algorithm when used with Barrier.
    * Improved numerical stability of the Barrier algorithm.
  - Xpress Nonlinear Release Notes:
Significant MINLP performance improvements due to improved nonlinear presolver.

Improved performance on instances with very large separable nonlinear expressions due to improved automatic differentiation.

Multistart now uses the nonlinear primal integral for tie breaking.

- Added options:
  - barPerturb: In numerically challenging cases it is often advantageous to apply perturbations on the KKT system to improve its numerical properties.
  - barRefIter: After terminating the barrier algorithm, further refinement steps can be performed.
  - clamping: Allows for the adjustment of returned solution values such that they are always within bounds.
  - clamping_dual: Adjust primal slack values to always be within constraint bounds.
  - clamping_primal: Adjust primal solution to always be within primal bounds.
  - clamping_rdj: Adjust reduced costs to always be within dual bounds implied by the primal solution.
  - clamping_slacks: Adjust dual solution to always be within the dual bounds implied by the slacks.
  - genConsAbsTransformation: Specifies the reformulation method for absolute value general constraints at the beginning of the search.
  - heurEmphasis: Specifies an emphasis for the search w.r.t. primal heuristics and other procedures that affect the speed of convergence of the primal-dual gap.
  - inputTol: Tolerance on input values elements.
  - mipComponents: Determines whether disconnected components in a MIP should be solved as separate MIPs.
  - mipConcurrentNodes: Sets the node limit for when a winning solve is selected when concurrent MIP solves are enabled.
  - mipConcurrentSolves: Selects the number of concurrent solves to start for a MIP.
  - mipRestartFactor: Fine tune initial conditions to trigger an in-tree restart.
  - mipRestartGapThreshold: Initial gap threshold to delay in-tree restart.
  - netStallLimit: Limit the number of degenerate pivots of the network simplex algorithm, before switching to either primal or dual simplex.
  - nodeProbingEffort: Adjusts the overall level of node probing.
  - outputControls: Toggles the printing of all control settings at the beginning of the search.
  - ppFactor: Partial pricing candidate list sizing parameter.
  - preFolding: Determines if a folding procedure should be used to aggregate continuous columns in an equitable partition.
  - sifoPasses: Determines how quickly we allow to grow the worker problems during the sifting algorithm.
  - sifoSwitch: Determines which algorithm to use for solving the subproblems during sifting.
  - xslp_presolveOps_noLinear: Avoid performing linear reductions at the NLP level.
  - xslp_presolveOps_noSimplifier: Avoid simplifying nonlinear expressions.

- Added option values:
  - deterministic: 2.
  - mipRestart: 2.

- Changed option defaults:
  - mipPresolve: -257 to -1.
  - mipPresolve_symmetryReductions: 0 to 1.

- Deprecated options:
  - xslp_matrixTol. Use matrixTol instead.

- Removed options:
• Added option `algAfterNetwork`: Algorithm to be used for the clean up step after the network simplex solver.

• Added option `qextractalg`: quadratic extraction algorithm in GAMS interface.

• Removed options that were marked deprecated in GAMS 35.

3.7.1.4 Tools

3.7.1.4.1 Cholesky, Eigenvalue, Eigenvector, Invert

• We will remove the tools `cholesky`, `eigenvalue`, `eigenvector`, `invert` in a future GAMS release. Similar functionality has been added via `$libInclude linalg {cholesky,eigenvalue,eigenvector,invert}`. See the header of the file in `<sysdir>\inclib\linalg.gms` for details.

3.7.1.4.2 GAMS Studio

• New version 1.7.2.
  
  – Dropped support for Ubuntu 16.04 LTS and openSUSE Leap 15.2 because the updated AppImage now requires glibc 2.27. Dropped support for Debian 9.
  
  
  – Improved visual distinction between current and other groups in Project Explorer.
  
  – Added a warning message before printing large files.
  
  – Added a list of solvers for each model type to be selected in Extended Parameter Editor and Configuration Editor.
  
  – Added shortcut `Alt+I` (Mac OS X: `Option+I`) to fold blocks of dollar control options.
  
  – Added setting to automatically collapse dollar control option blocks when opening a file (default: off).
  
  – Changed shortcuts to show/hide Extended Parameter Editor
    
    * Windows/Linux: From `Ctrl-Alt-3` to `Shift+Ctrl+3`.
    * Mac OS X: From `Shift-Command-3` to `Control-Option-3`.
  
  – Improvements for syntax highlighter and code completer, e.g.:
    
    * Added support for system attributes and compile-time constants.
    * Added support of quoted elements in syntax highlighter.
    * Disabled code completer for certain code blocks like `$onEmbeddedCode` or `$onPut`.
  
  – Improvements for remote execution support, e.g.:
    
    * Added support for GAMS Engine server with self-signed certificate (`https`).
    * Added support for GAMS Engine server with `http` protocol.
    * Added option to remember login credentials for GAMS Engine in Settings.
    * Renamed "MIRO" Settings page to "Remote" to better reflect new content.
* Improved GAMS Engine dialog.
* Added file type EFI to send additional files to a GAMS Engine server.

- Stability improvements and minor bug fixes, e.g.:
  * Fixed duplicate file entries in the Project Explorer when having two references with different case to a single file
  * Fixed Studio title bar appearing outside of screen in some cases.
  * Fixed wrong content of "File" tab in Reference File Viewer.
  * Fixed missing check of some data locations for GAMS license file.
  * Fixed ESC key not behaving like close button in Settings dialog.
  * Fixed crash when reopening a closed log tab.
  * Fixed that MIRO menu entries were not enabled when MIRO was automatically discovered.
  * Fixed that theme could be broken in Settings dialog when using cancel button.

### 3.7.1.4.3 GDXRank, GDXRename

- We will remove the tools gdxrank and gdxrename in a future GAMS release. Similar functionality has been added via $libInclude gdxservice \{gdxrank,gdxservice\}. See the header of the file in <sysdir>\inclib\gdxservice.gms for details.
- The $libInclude rank functionality now uses $libInclude gdxservice gdxrank to sort a one dimensional parameter instead of the gdxrank tool.

### 3.7.1.4.4 MCFilter

- We will remove the tool mcfilter in a future GAMS release. In case you depend on this tool, this discussion at GAMS World Forum gives an alternative.

### 3.7.1.4.5 MSAppAvail, Shellexecute, XLISTalk

- We will remove the tools msappavail, shelleexecute, xlistalk in a future GAMS release. Similar functionality has been added via $libInclude win32 \{msappavail,shelleexecute,xlistalk\}. See the header of the file in <sysdir>\inclib\win32.gms for details.

### 3.7.1.5 APIs

- As announced we removed all Delphi variants but the dcp version (i.e. gdxdcpdef.pas) and all Fortran variants but the f9 version (i.e. gdxf9def.f90) of the low-level APIs.

#### 3.7.1.5.1 CFG

- The function cfgAlgAllowsModifyProblem now reports correctly for all solvers if they provide the xyzModifyProblem functionality instead of a only for a fixed (and incorrect) list of solvers.
3.7.1.5.2 C++ high-level API

- Removed dependency on Qt. Now requiring C++17.
- As announced we dropped support for Microsoft Visual Studio 2015.
- As announced, the Clang compiled version of libgamscpp.dylib does not work on Mac OS X 10.14 or older anymore. It has been moved to the subfolder apifiles/C++/lib/Clang/. The new libgamscpp.dylib in apifiles/C++/lib/ is compiled with GCC.

3.7.1.5.3 gams_engine

- Updated for GAMS Engine version 21.06.09 and now using OpenAPI Generator version 5.1.1.

3.7.1.5.4 gams2numpy

- New optional parameter merge in gams2numpy.gmdFillSymbolStr that allows duplicate records in the numpy array as well as writing to non-empty symbols.
- New optional parameter relaxedType in gams2numpy.gmdFillSymbol(Str|Raw), and gams2numpy.gdxWriteSymbol(Str|Raw) that allows to automatically convert the columns of the numpy array into the required data types if possible.
- Fixed a bug that prevented error messages from being shown on Linux and further improved error handling.

3.7.1.5.5 GAMSX

- As announced, we have dropped the GAMSX API with this release. The example xp_example2 for various languages has been adjusted to call the GAMS executable instead of the gamsxRunExecDLL GAMS API function.

3.7.1.5.6 GEV

- The gmoptr argument in function gevGetCurrentSolver is deprecated and not used anymore. It will be removed from this function in some future release. Moreover, the function should only be used in solver link library functions xyzReadyAPI or xyzCallSolver.
- Add GEV option SavePoint to query the savePoint option.

3.7.1.5.7 GMO

- Added option qExtractAlg to control the technique used to extract quadratic structure from GAMS models. This structure extraction happens automatically for any QCP model type (e.g. QCP, MIQCP) and the current default choice ThreePass (= 1) is almost always the best one. But there some cases where DoubleForward (= 2) performs much better.
3.7.1.5.8 Solverlink library interface

- The API of a solver link library has changed. This will only affect users that install additional solvers or build and maintain own solver link libraries. The older version of the API is deprecated and will be removed in a future GAMS release. Moreover, COIN-OR project GAMSlinks provides a template to work with both new and old APIs.

3.7.1.6 Model Libraries

3.7.1.6.1 GAMS API Library

- Updated models CPPex2, CSex2, Cex2, Fex2, Jex1, Jex2, PBuildXPLLevelAPI, and VBex2 to adjust for the removal of the GAMSX API.
- Updated model Pgams_engine to be compatible with the latest gams_engine API.

3.7.1.6.2 GAMS Data Library

- Many models have been adjusted to use the library include win32 to compensate for the future drop of the utilities msappavail and shellexecute.
- Updated models CHP, CHP2, Portfolio, Samurai, SpawnGAMSEExcel, Sudoku, and transxls. The corresponding Excel files have been changed from format .xls to .xlsm. Moreover, the VBA code has been adjusted to work without the dropped GAMSX API. The registry key to find the GAMS system directory has been updated.
- Model Samurai2 has been dropped since it became a duplicate of model Samurai after the removal of the GAMSX API.
- Model LeastSquares has been updated to use $libInclude linalg OLS for solving the linear regression problem. The model also works now with more descriptive data set (diabetes data).

3.7.1.6.3 GAMS Test Library  New models:

- platform01.gms : Test platform function
- qcp12.gms : Test different GMO Q extraction algorithms
- asyncfix01.gms : Test asynchronous solves with holdFixed
- savep2.gms : Test savepoint with async solves
- convert16.gms : CONVERT test suite - Basic test of convert output for quadratic model
- embpy09.gms : Test Embedded Code after restart
- scenso18.gms : Check if solver with modify problem use hotstart in GUSS
- gdxrename1.gms : Simple gdxrename test
- gdxrename2.gms : Tests some gdxrename stuff
- scenso9.gms : Test option savepoint in GUSS
- embpy10.gms : Test Embedded Code for Environment Variables
- etsuf01.gms : Test Execution Time Suffixes
- emp33.gms : JAMS: matches from model statement may be ignored

Models trilib01, trilib02, trilib03, parlib01, cpplib00:

- Removed jinja2 from associated source archive. It is now required to have the Python package jinja2 installed to run the ql.py script.
### 3.7.1.7 Solver/Platform availability matrix

### 3.7.2 36.2.0 Minor release (September 03, 2021)

#### 3.7.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Daniel Dias, Andreas Lundell, Bruce McCarl, and Tom Rutherford.

#### 3.7.2.2 GAMS System

##### 3.7.2.2.1 GAMS
• Added new command line parameter `holdFixedAsync` to allow the use of `holdFixed` for models solved asynchronously. Activating this option can lead to inconsistent solutions being reported.

• Fixed a potential crash introduced with GAMS 36.1.0 related to the improved performance of model generation.

3.7.2.3 Solvers

3.7.2.3.1 CONVERT

• Fixed MCP mapping for DumpGDX.

3.7.2.3.2 GAMSCHK

• Fix default solve behavior: if no GCK file is specified, no subsolver should be called as no solution is wanted.

3.7.2.3.3 GUSS

• Fixed options `OptfileInit` and `Optfile` being ignored.
• Added fallback to cold start in case of hot start failure.

3.7.2.3.4 IPOPT

• New libraries 3.14.3.
• Updated MUMPS to version 5.4.1.

3.7.2.3.5 MOSEK

• New libraries 9.3.4.

3.7.2.3.6 SHOT

• New libraries 1.1 (9a8893e7).

3.7.2.4 Tools

3.7.2.4.1 GAMS Studio

• New version 1.7.3 with various bug fixes, stability improvements, and minor enhancements, e.g.:
  – Allow to duplicate multiple lines at once.
  – Added navigation and selection by word using `ctrl+left/right` in LOG-Viewer.
  – Fixed highlighting issue when a symbol declaration ends with a space.
  – Fixed horizontal scroll in LST viewer when cursor is out of view.
  – Fixed that searching backwards in modified document was not working.
  – Fixed "Replace" ignoring case sensitivity option.
3.8 35 Distribution

3.8.1 35.1.0 Major release (April 29, 2021)

3.8.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Matthew Adams, Jürgen Apfelbeck, Wolfgang Britz, Yacine Gaoua, Carolin Kellenbrink, Masoud Javadi, Bruce McCarl, Scott McDonald, Will Raymond, Tom Rutherford, Sebastian Spieker, and Kirk A. Yost.

3.8.1.2 Platforms

- macOS 11 (on Intel CPUs) has been added to the list of supported Mac OS X versions.

3.8.1.3 GAMS System

3.8.1.3.1 GAMS

- Added new dollar control options $gdxLoad and $gdxUnload to load and unload symbols from and to GDX files in a single instruction at compile time.
- Print an extra log line for echo dollar control options $echo, $echoN, and $onEcho, which write to an external file. When running GAMS from one of the GAMS IDEs, this log line can be clicked to open the file created.
- Extended the report generated by dmpSym and dmpUserSym to include another column reporting a memory estimate for each set, parameter, variable, and equation.
- Removed the columns DIM-OK, ACCESS, SPECVAL, EXTERN, TABLE, DOMAIN, and LAGLEAD from the report generated by dmpUserSym. This information is very technical and mostly of internal interest. These columns are still available with dmpSym.
- The status of Multi-Threading for the Grid and Multi-Threading Solve Facility has been changed from beta to released and fully supported.
- Fixed that the stars option was ignored for some messages in the output file.
- Fixed a problem that causes default records in the data statement or when loaded from GDX (see $load) being ignored with implicit set definition. So with

```
Set i;
Parameter p(i<) / i0 0, i1 1, i2 2 /;
```

only i1 and i2 made it into i. Now, i0 is added as well.
- Fixed a problem, where $onDotL and $onDotScale were ignored in put statements.
- Fixed a problem, where $onDelim was applied incorrectly to display and option statements.
- Fixed a problem, where $onSymXRef and $onUElXRef were ignored when there were too many references.
- Fixed and extended the behavior of $eval: If a GAMS function was hidden by a user defined symbol, $eval ignored the latter. This has been changed. Now, the GAMS function needs to be prefixed with system. to be accessed in this case. An example for this behavior is given here.
- Fixed a potential problem when doing a filtered load of symbols with domain violations through EmbeddedCode.
- Fixed an unwanted compilation error that happened if $onExternalInput or $onExternalOutput were used on the same line and after $if.
- Fixed a problem where dumpOpt in combination with $onVerbatim skipped a leading substitution character in an $ifThen block.
3.8.1.4 Solvers

3.8.1.4.1 AlphaECP

- New version 2.11.01.
  - New options:
    - ECPtoltype: AlphaECP termination criterion.
    - MIPoptcltype: Strategy to increase MIPoptclim.
    - MIoptimaliter: MIP is solved to optimality with this frequency.
    - TOLoptcr: Relative termination tolerance for MINLP.
  - Minor bugfixes.
  - For more information, see the release paper.

3.8.1.4.2 ANTIGONE, IPOPT, SHOT, SCIP

- Updated Intel MKL to version 2021.2.0 on Linux and Mac OS X.

3.8.1.4.3 BARON

- The NLP solver selected with option extNLPSolver is used in case NLPSol is set to -1 or 6 (and AllowExternal is 1). In the previous releases Conopt was used with NLPSol value -1.

3.8.1.4.4 BONMIN

- Fixed an issue where a problem with SOS constraints was rejected due to falsely detected negative variable bounds.

3.8.1.4.5 CONOPT

- New libraries for CONOPT3: 3.17K
  - Fixed perturbations of the Jacobian for external equations where 2nd order derivatives are not available.
- Fixed an issue resulting in insufficient CONOPT3 memory.
- Fixed an issue with multi-threading in CONOPT 4.

3.8.1.4.6 CPLEX

- New libraries 20.1.0.1.
- Added option usercallparmfile: Command-line parameter include file used in GAMS command-line calls triggered by BCH.
- Fixed incorrect reporting of infeasible solutions of the unrelaxed model in feasopt mode.
- Fixed incorrect variable matching for options objnreltol and objnabstol.
- Fixed parsing of individual objective functions for multiobjective optimization (any ordering of equation definitions is allowed now).
3.8.1.4.7 GAMSCHK

- Fix problem with handling of row/column patterns introduced in GAMS 34.3.

3.8.1.4.8 GUROBI

- New libraries 9.1.2.
- Added possibility to write a single GDX file with the solution pool (see solnpooldump).
- Added the following options:
  - solnpooldump: Enable merged solution pool GDX.
  - solnpooldumpnumsym: Number of variable symbols in merged solution pool GDX.
  - solnpooldumpprefix: Prefix for variable symbols in merged solution pool GDX.
  - miptrace: Filename of MIP trace file (formerly hidden and undocumented).
  - miptraceon: Node interval when a trace record is written (formerly hidden and undocumented).
  - miptraceoff: Time interval when a trace record is written (formerly hidden and undocumented).
- Fixed incorrectly processed (hidden) options isvname and appname.

3.8.1.4.9 GUSS/Scenario Solver

- Measure time internally rather then relying on solvers' reported resUsd to determine the overall running time.

3.8.1.4.10 KNITRO

- New GAMS/Knitro link using the KN interface.
- Enabled the possibility to use solverlink = 5 on Linux (other platforms were already enabled).
- Added support of variable and equation scaling.
- Added options:
  - names: Enable to pass variable and equation names to Knitro.
  - blasoptionlib: Specifies a dynamic library name that contains object code for BLAS/LAPACK functions.
  - bndrange: Specifies max limits on the magnitude of constraint and variable bounds.
  - cg_pmem: Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner.
  - cg_precond: Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms.
  - cg_stoptol: Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves.
  - convex: Declare the problem as convex by setting to 1 or non-convex by setting to 0.
  - cpuplatform: Specify the target instruction set architecture.
  - initpenalty: Specifies the initial penalty parameter used in the Knitro merit functions.
- **linesearch**: Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate.

- **newpoint**: Specifies additional action to take after every iteration in a solve of a continuous problem.

- **presolve_level**: Set the level of presolve operations to enable through the Knitro presolver.

- **presolve_initpt**: Control whether the Knitro presolver can shift a user-supplied initial point.

- **presolve_passes**: Set a maximum limit on the number of passes through the Knitro presolve operations.

- **presolveop_tighten**: Determine whether or not to enable the Knitro presolve operation to tighten variable bounds.

- **restarts**: Specifies whether or not to enable automatic restarts in Knitro.

- **restarts_maxit**: When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart.

- **strat_warm_start**: Specifies whether or not to invoke a warm-start strategy.

- **findiff_reltol**: Specifies the relative stepsize used for finite-difference gradients.

- **findiff_terminate**: Specifies the termination criteria when using finite-difference gradients.

- **infeasitol_iters**: The optimization process will terminate if the relative change in the feasibility error is less than infeasitol for infeasitol_iters consecutive infeasible iterations.

- **xtol_iters**: The optimization process will terminate if the relative change in all components of the solution point estimate is less than xtol for xtol_iters.

- **bar_conic_enable**: Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm).

- **bar_initpi_MPEC**: Specifies the initial value for the MPEC penalty parameter $\pi$ used when solving problems with complementarity constraints using the barrier algorithms.

- **bar_linsys**: Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps.

- **bar_maxcorrectors**: Specifies the maximum number of corrector steps allowed for primal-dual steps.

- **bar_slackboundpush**: Specifies the amount by which the barrier slack variables are initially pushed inside the bounds.

- **bar_switchobj**: Indicates which objective function to use when the barrier algorithms switch to a pure feasibility phase.

- **act_Lpfeastol**: Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms.

- **act_Lppenalty**: Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms.

- **act_Lppresolve**: Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms.

- **act_parametric**: Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms.

- **act_qppenalty**: Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm.

- **mip_clique**: Specifies rules for adding clique cuts.

- **mip_cutfactor**: This value specifies a limit on the number of cuts added to a node subproblem.

- **mip_heuristic_terminate**: Specifies the condition for terminating the MIP heuristic.

- **mip_intvar_strategy**: Specifies how to handle integer variables.

- **mip_mir**: Specifies rules for adding mixed integer rounding cuts.

- **mip_selectdir**: Specifies the MIP node selection direction rule (for tiebreakers) for choosing the next node in the branch and bound tree.
3.8 35 Distribution

- **mip_zerohalf**: Specifies rules for adding zero-half cuts.
- **ma_outsub**: Enable writing algorithm output to files for the multi-algorithm (algorithm=5) procedure.
- **ms_num_to_save**: Specifies the number of distinct feasible points to save in a file named `knitro_mspoints`.
- **ms_outsub**: Enable writing algorithm output to files for the parallel multistart procedure.
- **ms_savetol**: Specifies the tolerance for deciding if two feasible points are distinct.
- **par_mnumthreads**: Specify the number of threads to use for multistart (when `ms_enable = 1`).
- **out_csvinfo**: Controls whether or not to generates a file `knitro.solve`.
- **out_csvname**: Use to specify a custom csv filename when using `out_csvinfo`.
- **out_hints**: Specifies whether to print diagnostic hints (e.g. about user option settings) after solving.
- **outappend**: Specifies whether output should be started in a new file, or appended to existing files.
- **outdir**: Specifies a single directory as the location to write all output files.
- **outmode**: Specifies where to direct the output from Knitro.
- **outname**: Use to specify a custom filename when output is written to a file using `outmode`.

- Added values to the following options:
  - **blasoption**: 2 (dynamic)
  - **bar_pencons**: -1 (auto), 3 (equalities)
  - **hessopt**: 7 (gauss_newton)
  - **honorbnds**: -1 (auto)
  - **ma_terminate**: 3
  - **mip_knapsack**: 3 (all)
  - **mip_outlevel**: 2 (iterstime), 3 (root)
  - **mip_rootalg**: 4 (sqp), 5 (multi)
  - **scale**: 2 (user_none), 3 (internal)

- Updated the following options to KNITRO defaults:
  - **fstopval**: maxdouble
  - **honorbnds**: -1 (auto)
  - **par_blasnumthreads**: 0
  - **par_ismnumthreads**: 0
  - **xtol**: 1e-12
  - **bar_pencons**: -1 (auto)
  - **bar_switchrule**: -1 (auto)
  - **mip_maxnodes**: 0
  - **mip_maxsolves**: 0
  - **mip_rounding**: -1 (auto)

- Deprecated options:
  - **bar_maxbacktrack**: Use `linesearch_maxtrials` instead.
  - **maxcgit**: Use `cg_maxit` instead.
  - **pivot**: Use `linsolver_pivottol` instead.

- Removed formerly deprecated options:
  - **maxcrossit**
• Removed unused option `reform`.
• Fixed an issue with options not being forwarded to Knitro.

3.8.1.4.11 Lindo/LindoGlobal

• New libraries 13.0.262:
  • LP Solver Improvements:
    * With new enhancements made to the simplex solvers, the average performance on large instances where the number of variables is several times larger than the number of constraints has increased by several folds compared to the previous version.
    * Improved performance on LP’s when using multiple cores with concurrent execution of Primal, Dual, and Barrier.
  • MIP (Mixed Integer Program) Solver:
    * Improved selection of defaults for cuts and heuristics.
  • Global Solver Improvements:
    * Highly improved ability to recognize convexity of various composite functions, especially involving logarithms and sums, which can give a performance improvement of one order-of-magnitude in these cases.
    * Performance improvement for convex-concave type functions.
    * Enhanced capabilities for converting nonlinear functions to linear forms.
    * Substantial performance improvement for non-convex quadratic models.

3.8.1.4.12 LocalSolver

• New libraries 10.0 (20210330).
• We plan to drop LocalSolver and LocalSolver70 by the end of 2021.

3.8.1.4.13 MOSEK

• New libraries 9.2.41.

3.8.1.4.14 MPSGE

• Increased the internal MAXFUN limit (from 5000 to 10000) on the number of components (inputs, outputs, taxes, etc.) in any MPSGE row.

3.8.1.4.15 ODHCPLEX

• New libraries 5.34.
3.8.1.4.16 SBB

- Added option `usercallparmfile`: Command-line parameter include file used in GAMS command-line calls triggered by BCH.

3.8.1.4.17 SCIP

- New libraries 7.0 (c53330372e).

3.8.1.4.18 SNOPT

- New libraries 7.7.7 and new GAMS/SNOPT link.
- Changed option value to SNOPT default for the following options:
  - Linesearch Tolerance: 0.9
  - LI Singularity Tolerance: 3.2e-11
- Removed the following parameters:
  - Start Objective Check
  - Start Constraint Check
  - Stop Objective Check
  - Stop Constraint Check
  - Derivative Level

3.8.1.4.19 XPRESS

- Added support for choosing a different algorithm than primal simplex for solving the fixed MIP (see `mipCleanup`). The algorithm can be chosen with `defaultAlg` and `lpFlags`.
- Deprecated the following options:
  - `algorithm`: Use `defaultAlg` or `lpFlags` instead.
  - `extraPresolve`
  - `lpThreads`
- Added the following options:
  - `algAfterCrossover`: Algorithm to be used for the final clean up step after the crossover.
  - `autoPerturb`: Simplex: Indicates whether automatic perturbation is performed.
  - `autoScaling`: Whether the Optimizer should automatically select between different scaling algorithms.
  - `backtrackTie`: Branch and Bound: Specifies how to break ties when selecting the next node to work on when a full backtrack is performed.
  - `barCores`: If set to a positive integer it determines the number of physical CPU cores assumed to be present in the system by the barrier algorithm.
  - `barFailIterLimit`: Newton barrier: Maximum number of consecutive iterations that fail to improve the solution in the barrier algorithm.
  - `barFreeScale`: Defines how the barrier algorithm scales free variables.
  - `barGapTarget`: Newton barrier: Target tolerance for the relative duality gap.
- **barKernel**: Newton barrier: Defines how centrality is weighted in the barrier algorithm.
- **barObjScale**: Defines how the barrier scales the objective.
- **barOrderThreads**: If set to a positive integer it determines the number of concurrent threads for the sparse matrix ordering algorithm in the Newton barrier method.
- **barPresolveOps**: Controls the Newton barrier specific presolve operations.
- **barRegularize**: Determines how the barrier algorithm applies regularization on the KKT system.
- **barRhsScale**: Defines how the barrier scales the right hand side.
- **branchChoice**: Once a global entity has been selected for branching, this control determines which of the branches is solved first.
- **branchDisj**: Branch and Bound: Determines whether the optimizer should attempt to branch on general split disjunctions during the branch and bound search.
- **branchStructural**: Branch and Bound: Determines whether the optimizer should search for special structure in the problem to branch on during the branch and bound search.
- **cacheSize**: Newton barrier: L2 or L3 (see notes) cache size in kB (kilobytes) of the CPU.
- **choleskyAlg**: Newton barrier: Type of Cholesky factorization used.
- **choleskyTol**: Newton barrier: Tolerance for pivot elements in the Cholesky decomposition of the normal equations coefficient matrix, computed at each iteration of the barrier algorithm.
- **conflictCuts**: Branch and Bound: Specifies how cautious or aggressive the optimizer should be when searching for and applying conflict cuts.
- **coresPerCpu**: Used to override the detected value of the number of cores on a CPU.
- **cpuTime**: How time should be measured when timings are reported in the log and when checking against time limits.
- **crossoverAccuracyTol**: Newton barrier: Determines how crossover adjusts the default relative pivot tolerance.
- **crossoverIterLimit**: Newton barrier: Maximum number of iterations that will be performed in the crossover procedure before the optimization process terminates.
- **crossoverOps**: Newton barrier: Bit vector for adjusting the behavior of the crossover procedure.
- **cutFactor**: Limit on the number of cuts and cut coefficients the optimizer is allowed to add to the matrix during global search.
- **cutSelect**: Bit vector providing detailed control of the cuts created for the root node of a global solve.
- **dualGradient**: Simplex: Dual simplex pricing method.
- **dualize**: Whether presolve should form the dual of the problem.
- **dualizeOps**: Bit-vector control for adjusting the behavior when a problem is dualized.
- **dualPerturb**: Factor by which the problem will be perturbed prior to optimization by dual simplex.
- **dualStrategy**: Bit-vector control specifies the dual simplex strategy.
- **elimFillin**: Amount of fill-in allowed when performing an elimination in presolve.
- **elimTol**: Markowitz tolerance for the elimination phase of the presolve.
- **feasibilityPump**: Branch and Bound: Decides if the Feasibility Pump heuristic should be run at the top node.
- **feasTolPerturb**: Determines how much a feasible primal basic solution is allowed to be perturbed when performing basis changes.
- **feasTolTarget**: Target feasibility tolerance for the solution refiner.
- **forceParallelDual**: Dual simplex: Specifies whether the dual simplex solver should always use the parallel simplex algorithm.
- **genConsDualReductions**: Parameter specifies whether dual reductions should be applied to reduce the number of columns and rows added when transforming general constraints to MIP structs.
- **heurBeforeLp**: Branch and Bound: Determines whether primal heuristics should be run before the initial LP relaxation has been solved.

- **heurDiveIterLimit**: Branch and Bound: Simplex iteration limit for reoptimizing during the diving heuristic.

- **heurDiveRandomize**: Level of randomization to apply in the diving heuristic.

- **heurDiveSoftRounding**: Enables a more cautious strategy for the diving heuristic.

- **heurDiveSpeedUp**: Branch and Bound: Changes the emphasis of the diving heuristic from solution quality to diving speed.

- **heurDiveStrategy**: Branch and Bound: Chooses the strategy for the diving heuristic.

- **heurForceSpecialObj**: Branch and Bound: Whether local search heuristics without objective or with an auxiliary objective should always be used, despite the automatic selection of the Optimizer.

- **heurFreq**: Branch and Bound: Frequency at which heuristics are used in the tree search.

- **heurSearchEffort**: Adjusts the overall level of the local search heuristics.

- **heurSearchFreq**: Branch and Bound: How often the local search heuristic should be run in the tree.

- **heurSearchRootCutFreq**: How frequently to run the local search heuristic during root cutting.

- **heurSearchRootSelect**: Bit vector control for selecting which local search heuristics to apply on the root node of a global solve.

- **heurSearchTreeSelect**: Bit vector control for selecting which local search heuristics to apply during the tree search of a global solve.

- **heurStrategy**: Branch and Bound: Heuristic strategy.

- **historyCosts**: Branch and Bound: How to update the pseudo cost for a global entity when a strong branch or a regular branch is applied.

- **indLinBigM**: Indicator constraints can be internally converted to regular rows (i.e. linearized) using a BigM coefficient whenever the BigM coefficient is smaller or equal to this value.

- **indPreLinBigM**: During presolve, indicator constraints can be internally replaced with regular rows (i.e. linearized) using a BigM coefficient whenever the BigM coefficient is smaller or equal to this value.

- **l1Cache**: Newton barrier: L1 cache size in kB (kilo bytes) of the CPU.

- **lnpBest**: Number of infeasible global entities to create lift-and-project cuts for during each round of Gomory cuts at the top node (see gomCuts).

- **lnpIterLimit**: Number of iterations to perform in improving each lift-and-project cut.

- **localChoice**: Controls when to perform a local backtrack between the two child nodes during a dive in the branch and bound tree.

- **lpFlags**: Bit-vector control which defines the algorithm for solving an LP problem or the initial LP relaxation of a MIP problem.

- **lpFolding**: Simplex and barrier: Whether to fold an LP problem before solving it.

- **lpLogDelay**: Time interval between two LP log lines.

- **lpLogStyle**: Simplex: Style of the simplex log.

- **lpRefineIterLimit**: Simplex iteration limit the solution refiner can spend.

- **markowitzTol**: Markowitz tolerance used for the factorization of the basis matrix.

- **maxCutTime**: Maximum amount of time allowed for generation of cutting planes and reoptimization.

- **maxImpliedBound**: Presolve: When tighter bounds are calculated during MIP preprocessing, only bounds whose absolute value are smaller than maxImpliedBound will be applied to the problem.

- **maxLocalBacktrack**: Branch-and-Bound: How far back up the current dive path the optimizer is allowed to look for a local backtrack candidate node.
- **maxMemoryHard**: Sets the maximum amount of memory in megabytes the optimizer should allocate.
- **maxMemorySoft**: When resourceStrategy is enabled, this control sets the maximum amount of memory in megabytes the optimizer targets to allocate.
- **maxMipTasks**: Branch-and-Bound: The maximum number of tasks to run in parallel during a MIP solve.
- **maxScaleFactor**: Determines the maximum scaling factor that can be applied during scaling.
- **maxTime**: Maximum time in seconds that the Optimizer will run before it terminates, including the problem setup time and solution time.
- **mipDualReductions**: Branch and Bound: Limits operations that can reduce the MIP solution space.
- **mipFracReduce**: Branch and Bound: Specifies how often the optimizer should run a heuristic to reduce the number of fractional integer variables in the node LP solutions.
- **mipKappaFreq**: Branch and Bound: Specifies how frequently the basis condition number (also known as kappa) should be calculated during the branch-and-bound search.
- **mipRampUp**: Controls the strategy used by the parallel MIP solver during the ramp-up phase of a branch-and-bound tree search.
- **mipRefineIterLimit**: Defines an effort limit expressed as simplex iterations for the MIP solution refiner.
- **mipRestart**: Branch and Bound: Controls strategy for in-tree restarts.
- **mipToltarget**: Target mipTol value used by the automatic MIP solution refiner as defined by refineOps.
- **miqcpAlg**: Determines which algorithm is to be used to solve mixed integer quadratically constrained and mixed integer second order cone problems.
- **xslp_mipAlgorithm**: Bitmap describing the MISLP algorithms to be used.
- **xslp_mipFixStepBounds**: Bitmap describing the step-bound fixing strategy during MISLP.
- **xslp_mipRelaxStepBounds**: Bitmap describing the step-bound relaxation strategy during MISLP.
- **netCuts**: Determines the addition of multi-commodity network cuts to a problem.
- **objScaleFactor**: Custom global objective scaling factor, expressed as a power of 2.
- **optimalityTolTarget**: Target optimality tolerance for the solution refiner.
- **outputLog**: Controls the level of output produced by the Optimizer during optimization.
- **outputTol**: Zero tolerance on print values.
- **preAnalyticCenter**: Determines whether analytic centers should be computed and used for variable fixing and the generation of alternative reduced costs.
- **preBasisRed**: Determines whether a lattice basis reduction algorithm should be attempted as part of presolve.
- **preBndRedCone**: Determines whether second order cone constraints should be used for inferring bound reductions on variables when solving a MIP.
- **preBndRedQuad**: Determines whether convex quadratic constraints should be used for inferring bound reductions on variables when solving a MIP.
- **preCoeffElim**: Presolve: Specifies whether the optimizer should attempt to recombine constraints in order to reduce the number of non zero coefficients when presolving a mixed integer problem.
- **preComponents**: Determines whether small independent components should be detected and solved as individual subproblems during root node processing.
- **preComponentsEffort**: Presolve: Adjusts the overall effort for the independent component presolver.
- **preConeDecomp**: Presolve: Decompose regular and rotated cones with more than two elements and apply Outer Approximation on the resulting components.
- **preConvertSeparable**: Presolve: Reformulate problem with non-diagonal quadratic objective and/or constraints as diagonal quadratic or second-order conic constraints.

- **preDomCol**: Presolve: Determines the level of dominated column removal reductions to perform when presolving a mixed integer problem.

- **preDomRow**: Presolve: Determines the level of dominated row removal reductions to perform when presolving a problem.

- **preDupRow**: Presolve: Determines the type of duplicate rows to look for and eliminate when presolving a problem.

- **preElimQuad**: Presolve: Allows for elimination of quadratic variables via doubleton rows.

- **preImplications**: Presolve: Determines whether to use implication structures to remove redundant rows.

- **preLinDep**: Presolve: Determines whether to check for and remove linearly dependent equality constraints when presolving a problem.

- **preObjCutDetect**: Presolve: Determines whether to check for constraints that are parallel or near parallel to a linear objective function, and which can safely be removed.

- **presolveMaxGrow**: Limit on how much the number of non-zero coefficients is allowed to grow during presolve, specified as a ratio of the number of non-zero coefficients in the original problem.

- **presolveOps**: Specifies the operations which are performed during the presolve.

- **presolvePasses**: Number of reduction rounds to be performed in presolve.

- **primalPerturb**: Factor by which the problem will be perturbed prior to optimization by primal simplex.

- **primalUnshift**: Determines whether primal is allowed to call dual to unshift.

- **qcCuts**: Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for the root node, when solving a mixed integer quadratically constrained or mixed integer second order conic problem with outer approximation.

- **qcRootAlg**: Determines which algorithm is to be used to solve the root of a mixed integer quadratically constrained or mixed integer second order cone problem, when outer approximation is used.

- **qSimplexOps**: Controls the behavior of the quadratic simplex solvers.

- **quadraticUnshift**: Determines whether an extra solution purification step is called after a solution found by the quadratic simplex (either primal or dual).

- **randomSeed**: Sets the initial seed to use for the pseudo-random number generator in the Optimizer.

- **refineOps**: Specifies when the solution refiner should be executed to reduce solution infeasibilities.

- **relaxTreeMemoryLimit**: When the memory used by the branch and bound search tree exceeds the target specified by the `treeMemoryLimit` control, the optimizer will try to reduce this by writing nodes to the global file.

- **repairIndefInitEq**: Controls if the optimizer should make indefinite quadratic matrices positive definite when it is possible.

- **resourceStrategy**: Controls whether the optimizer is allowed to make nondeterministic decisions if memory is running low in an effort to preserve memory and finish the solve.

- **rootPresolve**: Determines if presolving should be performed on the problem after the global search has finished with root cutting and heuristics.

- **sbBest**: Number of infeasible global entities to initialize pseudo costs on each node.

- **sbEffort**: Adjusts the overall amount of effort when using strong branching to select an infeasible global entity to branch on.

- **sbEstimate**: Branch and Bound: How to calculate pseudo costs from the local node when selecting an infeasible global entity to branch on.
- **sbIterLimit**: Number of dual iterations to perform in strong branching for each entity.
- **sifting**: Determines whether to enable sifting algorithm with the dual simplex method.
- **xslp_algorithm**: Bitmap describing the SLP algorithm(s) to be used.
- **xslp_analyze**: Bitmap activating additional options supporting model / solution path analysis.
- **xslp_augmentation**: Bitmap describing the SLP augmentation method(s) to be used.
- **xslp_barStartOps**: Controls behaviour when the barrier is used to solve the linearizations.
- **xslp_convergenceOps**: Bitmap describing which convergence tests should be carried out.
- **xslp_filter**: Bitmap for controlling solution updates.
- **xslp_presolveOps**: Bitmap indicating the SLP presolve actions to be taken.
- **xslp_zeroCriterion**: Bitmap determining the behavior of the placeholder deletion procedure.
- **sosRefTol**: Minimum relative gap between the ordering values of elements in a special ordered set.
- **treeCompression**: When writing nodes to the global file, the optimizer can try to use data-compression techniques to reduce the size of the global file on disk.
- **treeCutSelect**: Bit vector providing detailed control of the cuts created during the tree search of a global solve.
- **treeMemoryLimit**: Soft limit, in megabytes, for the amount of memory to use in storing the branch and bound search tree.
- **treeMemorySavingTarget**: When the memory used by the branch-and-bound search tree exceeds the limit specified by the treeMemoryLimit control, the optimizer will try to save memory by writing lower-rated sections of the tree to the global file.
- **treeQCCuts**: Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for nodes other than the root node, when solving a mixed integer quadratically constrained or mixed integer second order conic problem with outer approximation.

- Added options to conveniently set bits of XPRESS bitmap options:
  - New bits of **refineOps**:
    - refineOps_lpOptimal
    - refineOps_mipSolution
    - refineOps_mipNodeLp
    - refineOps_lpPresolve
    - refineOps_iterativeRefiner
    - refineOps_refinerPrecision
    - refineOps_refinerUsePrimal
    - refineOps_refinerUseDual
    - refineOps_mipFixGlobals
    - refineOps_mipFixGlobalsTarget
  - New bits of **mipPresolve**:
    - mipPresolve_reducedCostFixing
    - mipPresolve_logicPreprocessing
    - mipPresolve_allowChangeBounds
    - mipPresolve_dualReductions
    - mipPresolve_globalCoeffTightening
    - mipPresolve_objBasedReductions
    - mipPresolve_allowTreeRestart
    - mipPresolve_symmetryReductions
  - New bits of **presolveOps**:
    - presolveOps_singletonColRemoval
    - presolveOps_singletonRowRemoval
* presolveOps_forcingRowRemoval
* presolveOps_dualReductions
* presolveOps_redundantRowRemoval
* presolveOps_duplicateColRemoval
* presolveOps_duplicateRowRemoval
* presolveOps_strongDualReductions
* presolveOps_variableEliminations
* presolveOps_noIpReductions
* presolveOps_noGlobalDomainChange
* presolveOps_noAdvIpReductions
* presolveOps_linDependRowRemoval
* presolveOps_noIntVarEliminations
* presolveOps_noIntVarAndSosDetect

- New bits of scaling:
  * scaling_rowScaling
  * scaling_colScaling
  * scaling_rowScalingAgain
  * scaling_maximum
  * scaling_curtisReid
  * scaling_byMaxElemNotGeoMean
  * scaling_bigM
  * scaling_simplexObjScaling
  * scaling_ignoreQuadRowPart
  * scaling_beforePresolve
  * scaling_noScalingRowsUp
  * scaling_noScalingColsDown
  * scaling_disableGlobalObjScaling
  * scaling_rhsScaling
  * scaling_noAggressiveQScaling
  * scaling_slackScaling

- New bits of lpFlags:
  * lpFlags_dual
  * lpFlags_primal
  * lpFlags_barrier
  * lpFlags_network

- New bits of cutSelect:
  * cutSelect_clique
  * cutSelect_mir
  * cutSelect_cover
  * cutSelect_mirRowAggregation
  * cutSelect_flowpath
  * cutSelect_implication
  * cutSelect_liftAndProject
  * cutSelect_disableCutRows
  * cutSelect отделCover
  * cutSelect_zeroHalf
  * cutSelect_indicator

- New bits of treeCutSelect:
  * treeCutSelect_clique
  * treeCutSelect_mir
• Renamed the following options to match the original XPRESS options names. Old option names currently serve as alias, but are deprecated and will be removed in an upcoming release:
  - `treePresolveKeepBasis` to `treePresolve_keepBasis`.
  - `slpKnitroOptFile` to `knitroOptFile`.
  - All XPRESS Nonlinear (SLP) options, e.g., `slpSolver` to `xslp_solver`.

• Fixed default values of single bit options for XPRESS bitmap options with negative default values.

3.8.1.5 Tools

3.8.1.5.1 GAMS Studio

• New version 1.6.1.
  - New feature: Static Code Completion which can be activated by pressing `Ctrl + Space`.
  - New feature: Allow to move multiple lines up and down using `Ctrl + Shift + Arrow`.
  - New feature: Allow to close view tabs using the middle mouse button.
  - Added instant update of tab size in editor when changing corresponding setting.
  - Added word under cursor as default search entry when no text selection is present.
  - Allow to move block selections using the arrow keys.
  - Added `*.inc` as common extension for GAMS files.
  - Added user defined extensions for GAMS files.
  - Added automatic reloading of files that appear in the GAMS log.
  - Added setting for user defined extensions for files to be automatically reloaded.
  - Added auto-reload button to file-changed dialog.
  - Added Studio Documentation entry in Help menu.
  - Added setting to change default open file behavior (new group or current group) and adjusted menu entry for alternative file opening behavior.
  - Hotkey `F1` jumps to the corresponding documentation entry for Project Explorer, Process Logs, GDX Diff Dialog, and Search Widget.
  - Improved GDX Viewer, e.g.:
    * Added facility to access domains and filters in Table View.
    * Show original index position of domains in both list view and table view.
    * Improved automatic column widths.
  - Stability improvements and minor bug fixes, e.g.:
    * Fixed crash when LST file is missing (e.g. because of setting `output=NUL`).
    * Fixed "Reset View" not resetting splitter in the LST/LXI-Viewer.
    * Fixed crash related to comment shortcut in solver option editor when pressing it multiple times.
* Fixed wrong sort order after resetting GDX Viewer.
* Fixed GAMS engine not appending /api to the URL on Mac OS X when clicking OK directly after editing the URL.
* Fixed `eolCom` not working in some dollar control option lines (like `$include`).
* Fixed jump to next search result if the result is in a different file and the current one has no results.
* Fixed jump to search result occasionally not working.
* Fixed Find Next/Prev behavior for `.opt` files.

### 3.8.1.5.2 GDXDUMP

- Added a new line at the end of the file, which was missing if the option `noHeader` is set.

### 3.8.1.5.3 GDXMERGE

- Added command line option `strict`. When set to `true`, `gdxmerge` will terminate with an error in case input files cannot be found or the output file already exists.

### 3.8.1.5.4 GDXXRW

- Fixed a potential missing initialization if `incRC` is set for symbols with either `cDim` or `rDim` equal 0.

### 3.8.1.6 APIs

#### 3.8.1.6.1 CFG

- With the next major release the last argument `opt: pointer` of function `cfgAlgReadyAPI` will be dropped.

#### 3.8.1.6.2 DCT

- Functions `dctLoadWithHandle`, `dctSymDomIdx`, `dctDomNameCount`, and `dctDomName` have been deprecated and will be removed in the near future.

#### 3.8.1.6.3 gams2numpy

- Improved error handling.
- New optional parameter `domains` for `gdxWriteSymbolStr` and `gdxWriteSymbolRaw` that can be used to specify the domains of the symbol. Parameter needs to be a list of strings.
3.8.1.6.4 GMO

- Updated to better handle cases where quadratic structure is explicitly detected (i.e. useQ is set) and some but not all of the nonlinear equations are quadratic. Several new functions have been added. In addition, some existing functions have been renamed - the new names are more descriptive and/or more consistent with new and existing function names. The old names are still available as deprecated synonyms - we expect to remove these synonyms in the near future and potentially without warning.

  - Updated API version to 20 - compatible with some older API versions.
  - New read-only properties:
    * gmoObjLNZ: Number of linear nonzeros in objective gradient.
    * gmoObjNLNZEx: Number of GMOORDER_NL nonzeros in objective gradient.
    * gmoObjjQNZeX: Number of GMOORDER_Q nonzeros in objective gradient.
    * gmoObjCVecNZ: Number of nonzeros in c vector of objective (-1 if Q information not used).
    * gmoObjConstEx: Objective constant - this is independent of useQ.
    * gmoObjQConst: Constant in solvers quadratic objective.

  - New functions:
    * gmoGetObjCVec: Get c vector of quadratic objective.
    * gmoGetObjSparseEx: Get information for gradient of objective function (sparse).
    * gmoGetRowStatEx: Get Jacobian row nonzero counts: total and by GMOORDER_XX.
    * gmoGetRowCVecNZOne: Number of nonzeros in c vector of row si (-1 if Q information not used).
    * gmoGetRhsOneEx: Get individual equation RHS - independent of useQ.
    * gmoGetRowSparseEx: Get info for one row of Jacobian (sparse).
    * gmoGetRowCVec: Get c vector of the quadratic form for one row.
    * gmoGetRowQConst: Get the constant of the quadratic form for one row.

  - New read-write properties:
    * gmoHessInclQRows: if useQ is true, this boolean property toggles the inclusion of GMOORDER_Q rows in the Hessian.

  Attention

    The default was originally true but has accidentally been changed to false with this release (35.1.0). That is, if useQ is set, then the Hessian does not include entries from quadratic equations anymore. The default is changed back to true in GAMS 38.2.0.

  - Renamed properties/functions:
    * gmoObjQNZ → gmoObjQMatNZ: Number of nonzeros in lower triangle of Q matrix of objective (-1 if useQ is false).
    * gmoGetObjQ → gmoGetObjQMat: Get lower triangle of Q matrix of objective.
    * gmoGetRowQ → gmoGetRowQMat: Get lower triangle of Q matrix of one row.

3.8.1.6.5 High-Level APIs

- We might drop support for macOS 10.14 for the C++ API with the next major release.
- Fixed an issue with an updater symbol that tries to update a non-existing symbol in the model instance. This used to make the solve method of GAMSModelInstance fail, but now just increases the no-match count.
- Fixed GAMSOptions.Output (.NET), GAMSOptions.setOutput (Java), and GamsOptions.output (Python) parameter being ignored in GAMSJob::Run().
3.8.1.6.6 Low-Level APIs

- For the next major releases, some clean-up of the distributed APIs is planned. In particular, it is planned to remove all Delphi variants but the dcp version (i.e. gdxcpdef.pas) and all Fortran variants but the f9 version (i.e. gdxf9def.f90). Please contact us, if that causes any trouble for your operation.

3.8.1.6.7 PAL

- Added functions palDataDirs and palConfigDirs to retrieve standard locations searched by GAMS.

3.8.1.7 Model Libraries

3.8.1.7.1 GAMS Model Library

- nurses.gms: A Nurse Scheduling Problem (428)

3.8.1.7.2 GAMS Test Library New models:

- gdxmerg3.gms: Test strict mode
- unload15.gms: Test $gdxUnload
- load13.gms: Test $gdxLoad
- conopt02.gms: CONOPT test suite - multi-thread test
- implset2.gms: Test for Implicit Set Definition with default records
- prevwork1.gms: PreviousWork Test
- decla3.gms: Test correct loading after multi declaration of domain set
- delim5.gms: Limited scope for $onDelim
- load14.gms: Test loading of GDX file with bad UELs
- eval08.gms: Test $eval with hidden functions
- embpy07.gms: Test no_match_limit for model instance
- embpy08.gms: Test filtered load from Embedded Code

### 3.8.2 35.2.0 Minor release (June 02, 2021)

#### 3.8.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Johannes Hedtrich, Bruce McCarl, Evangelos Panos, Thomas Rutherford, and Kirk A. Yost.
3.8.2.2 GAMS System

3.8.2.2.1 GAMS

- Allow to write point files with asynchronous solves as well.
- Moved the log line pointing to a reference file from the end of the compilation phase to the end of the run, to make it easier to recognize.
- Automatically deactivate holdFixed if a model is solved asynchronously, since this could lead to inconsistent solutions otherwise. Note that this can make a square model non-square as in cns01. Also note, that this could require some adjustment to models which actually relied on the fact, that models solved like this did not update the solution for fixed variables. Such a change was done for the model jacobi.
- Fixed a problem where the file path specified with $gdxIn or $gdxLoad was ignored when inputDir was applied.
- Fixed a potentially broken work file written with previousWork.
- Fixed the default for command line parameter empty. It should be on but was off.
- Fixed the dollar control options $setComps, $setNames, and $splitOption: They should generate scoped compile-time variable but generated local ones.
- Fixed potentially wrongly reported bounds for models solved with solveLink=6.
- Fixed missing info about objective variable with solveLink = 3 and asyncSolLst = 1.

3.8.2.2.2 EMP

- Fixed handling of the empty UEL in the EMP info file

3.8.2.2.3 GMSPython

- Removed package tqdm.

3.8.2.3 Solvers

3.8.2.3.1 AlphaECP

- New library with some minor bug fixes.

3.8.2.3.2 CONVERT

- Fixed exporting of variable scale attribute in DumpGDX format.

3.8.2.3.3 CPLEX

- Fixed incorrect model status for feasible models after time out in multi-objective optimization.
3.8.2.3.4 KNITRO

- Fixed incorrect model status for KNITRO return code "All nodes have been explored. Integer feasible point found." (KN_RC_MIP_EXH_FEAS).

3.8.2.4 Tools

3.8.2.4.1 GAMS Studio

- New version 1.6.2. with various bug fixes, stability improvements and minor enhancements, e.g.:
  - Fixed issues with enumerated parameters in extended parameter editor.
  - Fixed issues with "set", "option", and "table" in code-completer.
  - Fixed code-completer opening in non-code files.
  - Fixed "Open in current group" not being used for "User Model Library" and "New file".

3.8.2.5 APIs

3.8.2.5.1 Python

- Fixed a bug in the GDX expert-level API that required gdxSymbolGetDomain to be called in a read context (e.g. after gdxDataReadStrStart).
- Fixed a bug in gams2numpy functions gdxReadSymbolStr and gdxReadSymbolRaw that altered the case of the symName argument.

3.8.2.5.2 DCT

- Fixed broken function dctSymDomNames for symbols that have the universe as part of their domain. This caused a crash in sensitivity analysis of CPLEX and Gurobi for models with such variable or equation symbols.

3.8.2.6 Model Libraries

3.8.2.6.1 GAMS Model Library

- Changed jacobi.gms : Asynchronous Jacobi Methods to work with the changed holdFixed behavior with asynchronous solves, mentioned above.

3.9 34 Distribution

3.9.1 34.1.0 Major release (January 29, 2021)

3.9.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Wolfgang Britz, Michael Ferris, Erwin Kalvelagen, Antti Lehtila, Bruce McCarl, Scott McDonald, Cornelius Rüther, Shima Sasanpour, Kaushik Sinha, Elizabeth Wong, and Qi Yuan.
3.9.1.2 Platforms

- The minimal required GLIBC version of the distribution for GNU/Linux is now 2.17.
- Mac OS X 10.13 (High Sierra) is no longer supported.

3.9.1.3 GAMS System

3.9.1.3.1 GAMS

- Improved performance of *dense* operations with out-of-order index positions, as in the following code snippet, where the assignment to \( d_1 \) was significantly slower than the one to \( d_2 \) in the past:

  \[
  d_1(j,i) = \sum ij(i,j), \exp(pij(i,j)))
  \]

  \[
  d_2(j,i) = \sum ij(i,j), \abs(pij(i,j)))
  \]

- Added new debugging option `dmpUserSym`, to print all symbols defined by the user.
- Added new variants `$showFiles`, `$showMacros`, and `$showVariables` of `$show` for shorter reports.
- Print an extra log line for compile time GDX operations `$gdxIn` and `$gdxOut`. When running GAMS from one of the GAMS IDEs, these log line can be clicked to open the file referenced.
- Add anchors to the log that can be clicked when running GAMS from one of the GAMS IDEs for each mention of an input/include file.
- Added extra info to the log in case of an unmatched `$ifThen` and its variants, that can be clicked when a GAMS IDE is used to jump to the initial dollar control option.
- Added more details about the problem to the log in case of an error analyzing the solve statement.
- Added new variants for the command line parameter `fileCase` which allow to use upper or lower case for referenced filenames only and not for the path to the files.
- Fixed a bug where certain checks for errors in the model structure were skipped, if upper and lower bound of a variable are the same. While the selected solver would already have rejected the problem most likely, now GAMS generates an execution error also if lower and upper bounds are the same and
  - the bounds of discrete variables do not have integer values,
  - the lower and upper bounds of binary variables are not equal to 0 or 1, or,
  - the lower bounds of semiCont/semiInt variables are smaller than 0.
- Altered the behavior of `execute.checkErrorLevel`, `putUtility exec.checkErrorLevel`, and `putUtility shell.checkErrorLevel` so the execution would stop right away also within a Flow Control structure, like a `loop`, if an error is encountered. In the past, it would just stop after executing the flow control structure completely.
- Changed the behavior for unloading symbols with `$unload`. In previous versions the writing of the symbols happened while the compiler processed the `$unload` instructions. With this version forward the writing of the symbols and data to GDX is delayed until the GDX file is about to be closed. This has several advantages, e.g. writing of aliases and full domain information, but it can result in different content of the GDX file in some corner cases. Please check for details in the documentation.
- Avoid export of predefined symbols diag and sameAs to GDX. When all symbols should be exported, these are skipped. When they are tried to be exported explicitly, there will be a compilation error.
- Allow to use `Put Utility save` to write a save file of the current state of execution inside loops and other flow control structures as well.
- Fixed a wrongly raised compilation error which could happen when an implicit set definition was used with a `table statement` without data.
- Fixed a problem where `dumpOpt` in combination with `$onVerbatim` skipped parts of an `$ifThen` block.
3.9.1.3.2 GMSPython

- Added the packages `pyexcelerate`, `pyyaml`, `xlsxwriter`, and their dependencies.

3.9.1.4 Solvers

3.9.1.4.1 AMPL

- As announced, dropped the meta-solver AMPL.

3.9.1.4.2 BARON

  - Improved interface to IPOPT for local search.
  - Changed default for option LPSol to new value -1, which makes BARON use CPLEX for LP or MIP relaxations, if licensed, and CLP/CBC otherwise.
  - Further performance improvements and bugfixes.
- Added option BarName to specify name of file into which to write problem in BARON format.

3.9.1.4.3 BDMLP

- As announced, dropped the solver BDMLP.

3.9.1.4.4 BENCH

- As announced, dropped the tool BENCH.

3.9.1.4.5 CONOPT

- New library 4.22.
  - Some improvements for models with external equations.
3.9.1.4.6 CONVERT

- The two solver links CONVERT and CONVERTD were merged under the name CONVERT. Features that were formerly available in only one of the two solver links are now all usable with the new CONVERT link (except for the dropped features, see below). CONVERTD is an alias for CONVERT now.

- JuMP format:
  - Added constraint names.
  - Using `@NLconstraint` and `@NLobjective` instead of `add_NL_constraint` and `set_NL_objective`, respectively.
  - Changed default of option JuMP to `jump.jl`.

- Pyomo format:
  - Fix export of SOS1 and SOS2 variable types.
  - Changed default of option Pyomo to `pyomo.py`.

- DumpGDX format (formerly Hessian or Jacobian):
  - The current behaviour of disabling variable and equation names or UELs when setting the option to "NOVENAMES.gdx" or "NOUELS.gdx" has no special effect anymore. Use GDXNames and GDXUELs instead.

- New options:
  - Width
  - DumpGDX (replaces options Hessian and Jacobian)
  - GDXNames (instead of setting the former options Hessian or Jacobian to "NOVENAMES.gdx")
  - GDXUELs (instead of setting the former options Hessian or Jacobian to "NOUELS.gdx")
  - GDXHessian (enables hessian information for DumpGDX)
  - GDXQuadratic (enables quadratic information for DumpGDX)

- Options PermuteEqus and PermuteVars are now available for all target languages.

- Removed the following formats:
  - AlphaECP
  - AmplNLC
  - Analyze
  - AnalyzeS
  - Baron (GAMS/Baron link provides the option BarName to export this format)
  - Lgo
  - LindoMPI (GAMS/Lindo link provides the option WRITEMPI to export this format)
  - LocalSolver (GAMS/Localsolver link provides the option writelsp to export this format)
  - LSPSol
  - Memo
  - Minopt
  - SFS
  - ViennaDag

- Removed the following experimental formats:
  - AmplNLCG
  - CHull
- CppAD
- Lago
- NLP2MCPE
- PDCO
- Qmaker (use DumpGDX with GDXQuadratic enabled instead)
- UnitBC

- The following formats are deprecated and may be removed in an upcoming release:
  - Hessian (use DumpGDX with GDXHessian enabled instead)
  - Jacobian (use DumpGDX instead)

- The following options don't have any effect anymore and will be removed in an upcoming release:
  - ConeReform
  - IntervalEvalDebug
  - Match
  - Terminate

3.9.1.4.7 CPLEX

- New libraries 20.1.0.
  - Conflict Analysis (iis) now supports SOS variables and indicator constraints.
  - Added options:
    - * prereform*: allows to set presolve reformulations
    - * conflictalg*: algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model
    - * nodedcuts*: allows to decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree
    - * sos1reform*: automatic logarithmic reformulation of special ordered sets of type 1 (SOS1)
    - * sos2reform*: automatic logarithmic reformulation of special ordered sets of type 2 (SOS2)
    - * Value 5 to mipemphasis*: finding high quality feasible solutions as early as possible
  - Deprecated options:
    - * prelinear*: Use prereform instead
  - Deprecated features (will be removed in a future CPLEX release):
    - Remote Object functionality.
    - Distributed parallel optimization of mixed integer programming models (MIP).

- Fixed error messages for CPLEX error 5002 (CPXERR_Q_NOT_POS_DEF).
- Fixed an error that caused a crash for special option file input.
- Fixed an error that wrote additional quotes in GDX files of ranging and column generation information.
- Fixed miptrace timing info.
3.9.1.4.8 Gurobi

- New libraries 9.1.1.
- Added the following options:
  - SolFiles: location to store intermediate solution files
  - DualReductions: disables dual reductions in presolve
  - ProjImpliedCuts: projected implied bound cut generation
  - PSDCuts: PSD cut generation
  - FeasRelaxBigM: Big-M value for feasibility relaxations
- Added possible option values for the following options:
  - MinRelNodes: -1 (automatic)
  - NodeMethod: -1 (automatic)
  - PumpPasses: -1 (automatic)
  - StartNodeLimit: -3 (shut off)
  - ZeroObjNodes: -1 (automatic)
  - AggFill: -1 (automatic)
  - PreSparsify: -1 (automatic)
  - TuneResults: -1 (best results)
  - IISMethod: 2 (ignores bound constraints)
  - IISMethod: 3 (IIS the LP relaxation)
  - Method: 5 (both primal and dual simplex)
- Set option value to GUROBI default for the following options:
  - scaleflag: -1
  - Cutoff: maxdouble
  - ImproveStartGap: 0
  - MinRelNodes: -1
  - NodeMethod: -1
  - PartitionPlace: 15
  - PumpPasses: -1
  - ZeroObjNodes: -1
  - AggFill: -1
  - PreSOS2BigM: -1
  - PreSparsify: -1
  - TuneResults: -1
  - TuneTrials: 3
- Removed the following options:
  - premiqpmethod
  - workerport
- Options for how to access the Gurobi compute server, cluster manager, or Instant Cloud can all be set through the Gurobi license file. Therefore, the following link options have been removed:
  - computeserver
  - csrgroup
- cspassword
- csport
- cspriority
- csrouter
- cstimeoutfrac
- cstlsinsecure
- icsecretkey
- icpool
- icpriority
- instantcloud

- Fixed issue of missing logfile output for logoption = 4.
- Fixed an error that wrote additional quotes in GDX files of ranging information.

3.9.1.4.9 Ipopt

- Updated MUMPS to version 5.3.5.

3.9.1.4.10 KESTREL

- The environment variable NEOS_EMAIL can now be used to provide an e-mail address when submitting a job to NEOS.
- Fixed unintentional reading from option file.

3.9.1.4.11 KNITRO

- New libraries 12.3.0.
  - Improvements in performance, memory usage, numerical stability, and overall stability.

3.9.1.4.12 LINGO

- As announced, dropped the meta-solver LINGO.
3.9.1.4.13 **LS** As announced, dropped the tool LS.

One possibility to adapt existing GAMS code is to use the Python function `numpy.linalg.lstsq` via the GAMS embedded code facility.

For example, the GAMS code

```gams
Set i;
Parameter x(i), y(i);
Variables b0, b1, sse;
Equations sumsq, fit(i);
sumsq.. sse =n= 0;
fit(i).. y(i) =e= b0 + b1*x(i);
option lp = ls;
model leastsq /fit,sumsq/;
solve leastsq using lp minimizing sse;
```

to compute a linear regression for \((x,y)\) can be replaced by

```gams
Set i;
Parameter x(i), y(i);
Scalars b0, b1, sse;
embeddedCode Python:
  import numpy as np
  x = np.array(gams.get('x', keyFormat=KeyFormat.SKIP))
  y = np.array(gams.get('y', keyFormat=KeyFormat.SKIP))
  A = np.vstack([np.ones(len(x)), x,]).T
  res = np.linalg.lstsq(A, y, rcond=None)
  gams.set('b0', [res[0][0]])
  gams.set('b1', [res[0][1]])
  gams.set('sse', [res[1][0]])
endEmbeddedCode
```

For a more detailed example, see the new `LeastSquares.gms` model from the GAMS Data Library.

3.9.1.4.14 **Mosek**

- New libraries 9.2.35.

3.9.1.4.15 **MPECDUMP**

- As announced, dropped the tool MPECDUMP.

3.9.1.4.16 **NLPEC**

- Set the (hidden) GAMS option `relPath` to 1 for the execution of the scalar GAMS model. This fixes a problem when running NLPEC under KESTREL on NEOS.
3.9.1.4.17  ODHCPLEX

- New libraries 5.31.
- Fixed missing output of final CPLEX solve for fixed model.
- Fixed possible values of option `odhpresolve` to 1 and 2.

3.9.1.4.18  PYOMO

- As announced, dropped the meta-solver PYOMO.

3.9.1.4.19  SCIP

- New libraries 7.0 (9a11615b47).

3.9.1.4.20  SoPlex

- New libraries 5.0.2.

3.9.1.4.21  XPRESS

- Non-convex QCPs don't have to be solved as NLP anymore, but are solved by XPRESS Nonlinear if a XPRESS-NLP or XPRESS-MINLP license is used (XPRESS-MINLP for MIQCPs).
- Fixed an issue that prevented the use of XPRESS Knitro with a XPRESS link license.
- Fixed a bug that prevented to solve (MI)QCP models with an XPRESS-MIP license.

3.9.1.5  Tools

3.9.1.5.1  CSV2GDX

- Report the line/field records to the log that lead to `UNDF` conversion for trace level 1 or bigger.
3.9.1.5.2 GAMS Studio

- New version 1.5.2.
  - New feature: Allow to edit and store custom color themes in the settings dialog.
  - New feature: Allow to define custom sections in the code, that can be folded using $onFold / $offFold.
  - Improved MIRO deploy dialog.
  - Added e-mail field for NEOS submissions in NEOS dialog. This can also be initialized from environment variable `NEOS_EMAIL` (which can be set permanently in gamsconfig.yaml).
  - Changed "Autosave on Run" setting to save ALL modified files, not just files of the current group.
  - Changed default light theme comment color to grey for better distinction from declarations.
  - Disabled GAMS syntax highlighting between $onPut/$offPut and $onEcho/$offEcho.
  - Added "select entry" on clicking timestamp in log.
  - Pressing `Enter` in the LXI tree scrolls to the corresponding position in the LST view.
  - Adjusted list of files in Reference File Viewer to be sorted by order in which they have been used.
  - Stability improvements and minor bug fixes, e.g.:
    - Fixed rare problem with undetected external file changes.
    - Fixed broken include file links in combination with end of line comments.
    - Fixed missing request for new search cache after switching file.
    - Fixed rare crash related to LOG output.
    - Fixed endlessly recurring message box for invalid GDX file.
    - Fixed missing update of parameter history for a file assigned to more than one group.
    - Fixed search results not being highlighted in `.log` files.
    - Fixed search performance problem after reset search parameters.
    - Fixed behavior of ESC key when current widget has a selection.
    - Fixed syntax highlighting of `table` statements not detecting row headers.
    - Fixed print dialog shortcut not working directly after Studio launch.

3.9.1.5.3 GDX2VEDA

- Increase the maximum length of symbol names in the Veda definition file from 31 to 63.

3.9.1.5.4 GDXDUMP

- When using the option noData, empty symbols were still written with a data statement. Now empty symbols are also loaded from GDX.

3.9.1.5.5 GDXMRW

- Switch from C to C++ as the compiler for these utilities.
- An unordered_map container is now used to address a performance issue with rgdx and filtered reads.
3.9.1.6 APIs

3.9.1.6.1 C++

- We plan to drop support for Microsoft Visual Studio 2015 for the C++ API with the next major release.

3.9.1.6.2 Python

- Added support for Python 3.9.
- gams2numpy:
  - New functions `gdxGetUelList` and `gmdGetUelList` allow to retrieve the list of UELs.
  - `gdxReadSymbolRaw` and `gmdReadSymbolRaw` do not return the list of UELs anymore.
  - `gdxReadSymbolStr` and `gmdReadSymbolStr` have a new optional input parameter `uelList`.
  - Fixed a bug that prevented loading of required shared objects in certain cases.

3.9.1.6.3 Matlab

- New GAMS Matlab API
  - The API is distributed as package GAMS located in `apifiles/Matlab/api`.
  - Examples can be found in `apifiles/Matlab/examples`.

3.9.1.6.4 GMO

- Fixed the functions `gmoGetObjSparse`, `gmoGetRowSparse`, `gmoGetColSparse`, `gmoHessLoad`, `gmoHessLagStruct`, and `gmoHessLagVal`: they now work properly when `forceLinear` is set, e.g., when using GUSS.

3.9.1.7 Model Libraries

3.9.1.7.1 GAMS API Library

- Changed the following examples to use the MONO compiler `mcs` instead of `dmcs` on Unix:
  - `CSBenders.gms`: Test object oriented C# API using a (multi-threaded) Benders Decomposition Algorithm
  - `CSCalcInverse.gms`: Test expert level C# API to read and write indexed GDX
  - `CSCutstock.gms`: Test object oriented C# API using a cutting stock example
  - `CSex1.gms`: Test expert level C# API to read and write GDX
  - `CSex2.gms`: Test expert level C# API to read and write GDX, set options and execute GAMS
  - `CSWarehouse.gms`: Test object oriented C# API using a warehouse location problem
3.9.1.7.2 GAMS Data Library  New models:

- LeastSquares.gms : Demonstrate the use of numpy.linalg.lstsq on the diabetes test problem using linalg ols (141)

3.9.1.7.3 GAMS Test Library  New models:

- show01.gms : Test $show feature
- dmpsym01.gms : Test dmpSym and dmpUserSym feature
- ide01.gms : Basic test for IDE mode
- cplex08.gms : CPLEX test suite - conflict analysis (841)
- convert13.gms : CONVERT test suite - apply dict to gams format (842)
- convert14.gms : CONVERT test suite - nonlinear expression reformulations (843)
- convert15.gms : CONVERT test suite - support of nonlinear functions (844)
- unload12.gms : Make sure that sameAs and diag cannot be exported to GDX (845)
- unload13.gms : Unload with relaxed and full domain (846)
- unload14.gms : Check that unload happens at GDX file closing time (847)
- dumpopt1.gms : Test verbatim dumpOpt (848)

Removed models:

- LS01 (394)
- LS02 (395)
- LS03 (397)
- LS04 (398)

3.9.1.8 Solver/Platform availability matrix

### 3.9.2 34.2.0 Minor release (February 05, 2021)

#### 3.9.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz and Bruce McCarl.

#### 3.9.2.2 Solvers

##### 3.9.2.2.1 CONOPT

- New libraries 4.23.
  - Improvements for models with external equations, models with very large objective terms, and models with variables that only appear in the objective function.
- Fix parallel function evaluation.

##### 3.9.2.2.2 CONVERT

- Fix variable coefficients in JuMP format.

##### 3.9.2.2.3 CPLEX

- Fixed issue of non-working option `userinebicall`.

3.9.2.2.4 GAMSCHK

- The output formatting for the BLOCKPIC and MATCHIT procedures was adjusted to better handle very small or large values.

3.9.3 34.3.0 Minor release (February 25, 2021)

3.9.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Luis Alberto Herrero Rozas, Robert Howlett, Erwin Kalvelagen, Antti Lehtila, Bruce McCarl, and Shima Sasanpour.

3.9.3.2 GAMS System

3.9.3.2.1 GAMS

- Fixed a problem with embedded Python code and directory names longer than 128 characters.
- Fixed embedded Python code exceptions not handled correctly in case the exception message is empty.
- Fixed a problem where dumpOpt in combination with $onVerbatim produced wrong dollar conditions in an $ifThen block.
- Fixed an abnormal termination issue that occurred on Windows with pathologically-structured large QP models and solvers that use QP structure explicitly.
- Fixed a potentially broken work file written with previousWork. There was a problem introduced with GAMS 34.1 for models written to the work file.
- Fixed wrong behavior of break in certain loops over a set with a single element.

3.9.3.3 Solvers

3.9.3.3.1 CONOPT

- New libraries 4.24:
  - The pre-processor has been updated so it will always return a solution.
- Fixed incorrect reference of row / column in error message.

3.9.3.3.2 CONVERT

- Fixed possibly incorrect sign of objective function in formats with explicit objective function (e.g., Ampl or JuMP).
- Fixed missing objective constant in formats with explicit objective function (e.g., Ampl or JuMP).
- Fixed possibly missing variable / equation in formats GAMS, DictMap and DumpGDX when converting multiple formats at a time.
- Fixed possibly missing parenthesis when dealing with minus zero.
3.9.3.3 GAMSCHK

- An error in the POSTOPT procedure that could lead to a segmentation fault or undefined behavior was fixed.
- The output formatting in the BLOCKLIST procedure was improved.

3.9.3.4 MOSEK

- New libraries 9.2.38.

3.9.3.5 ODHCPLEX

- Fixed issue of possibly incorrect objective bound reported by GAMS.

3.9.3.6 OsiMosek

- Fixed reported dual bound (ObjEst) and model status if solved without having closed the optimality gap.

3.9.3.4 Tools

3.9.3.4.1 GAMS Studio

- New version 1.5.4. with various bug fixes, stability improvements and minor enhancements, e.g.:
  - Added support for ports in GAMS Engine URL.
  - Improved visibility of current word and parentheses highlighting.
  - Fixed wrong color initialization for dark theme.
  - Fixed unwanted cursor jump when searching listing files without results.
  - Fixed MIRO execution issue if model filenames contain spaces.
  - Fixed GDX file reloading while being rewritten.
  - Fixed file links in log not handling relative paths on Windows.

3.9.3.4.2 GDXDUMP

- With option noData the empty symbols are marked with an end of line comment `!!empty`.
- The dollar control options are written in a consistent camel-case style if the output is in GAMS syntax.

3.9.3.4.3 GDXXRW

- Fixed a crash which happened when the rng was defined multiple times for a text by accident.
3.9.3.6  Expert Level APIs

- When introducing `gdxStoreDomainSets` with GAMS 33 the default was accidentally set to 0 (don’t enable use of one dimensional sets as domain sets). This has been corrected with this version. Setting `gdxStoreDomainSets` to 0 is for real experts only, since it can cause inconsistent GDX files when used in combination with `gdxSymbolSetDomain`.

3.9.3.6.1  Matlab

- Fixed Java class attribute access to support Matlab versions down to 2017b.

3.10  33 Distribution

3.10.1  33.1.0 Major release (November 01, 2020)

3.10.1.1  Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Pablo Cachinero, Michael Ferris, and Ben Huebner.

3.10.1.2  Platforms

- We plan to increase the minimal required GLIBC version of the distribution for GNU/Linux to 2.17 with the next major release.
- We plan to drop support for Mac OS X 10.13 (High Sierra) with the next major release.

3.10.1.3  GAMS System

3.10.1.3.1  GAMS

- Allow to set the `.stage` attribute for discrete variables as well. This can be useful for certain solvers like SCIP.
- The status of the Embedded Code Facility has been changed from beta to released and fully supported. The nature of embedded code (especially Python embedded code) prohibits a level of backward compatibility as we guarantee for intrinsic GAMS language features: The Python interpreter together with distributed packages are evolving. Moreover, the GAMS/Python communication (e.g. via `gams.get()`/`set()`) will be subject to necessary modifications.
- Allow multi-line Python strings constructed with triple quotes (""" or """") in embedded Python code without getting additional spaces from the internal extra indentation. For multiple lines of Python code that use the line continuation character \\, extra indentation is not omitted.
- Added new dollar control options `$on/offIDCProtect` to control if symbols which are declared as external input can be changed at execution time.
• Quoted text in a display statement adds now an entry to the navigation pane of the LST Viewer in GAMS Studio as well.

• Print an extra log line when execute_load (or one of its variants) is executed. When running GAMS from one of the GAMS IDEs, this log line can be clicked to open the file loaded. Also the log lines generated for execute_unload[idx] were adjusted for better distinction. So adding these lines to a model

```plaintext
execute_unload  't.gdx', f;
execute_unloadidx 't.gdx', f;
execute_load    't.gdx', f;
```

generates this log:
--- GDX File (execute_unload) C:\t m p\t.gdx
--- GDX File (execute_unloadidx) C:\t m p\t.gdx
--- GDX File (execute_load) C:\t m p\t.gdx

• Fixed a problem using captureModelInstance with solveLink=5/6/7; if captureModelInstance=1 and solveLink=6/7, solveLink will be reset to 3/4 automatically.

• Fixed a problem with file names longer than 128 characters for option IDCGenerateJSON.

3.10.1.3.2 GMSPython

• Added the packages urllib3, certifi, and their dependencies.

3.10.1.4 Solvers

3.10.1.4.1 AMPL, LINGO, MPECDUMP, PYOMO

• We plan to drop the meta-solvers AMPL, LINGO, MPECDUMP, and PYOMO with the next major release. Convert will continue to produce model instances in these formats with the exception of MPECDUMP.

3.10.1.4.2 ANTIGONE, IPOPT, SHOT, SCIP

• Updated Intel MKL to version 2020.2 on Linux and Mac OS X.

3.10.1.4.3 BARON

• New libraries 20.10.16.
  – Performance improvements including faster automatic differentiation, improved probing, improved local search, and improvements in BARON’s cutting plane routines.
  – Changed default of option WantDual to 1. That is, dual values are now provided by default for nonlinear problems, too.
  – CBC updated to 2.10.5.

3.10.1.4.4 BDMLP

• We plan to drop the LP/MIP solver BDMLP with the next major release. Other free alternatives like Cbc outperform BDMLP.
3.10.1.4.5 BENCH

- We plan to drop the meta-solver BENCH with the next major release. Scripting tools provide much better facilities to generate benchmarks.

3.10.1.4.6 CONOPT

- New library 4.21.
  - Added a warning if the unscaled residuals in a feasible model are large due to very large scale factors.
  - Updated the selection of definitional constraints and improved the numerical behavior.
  - Changed tolerances in the derivative debugger related to very large derivatives.
  - Logic for Definition constraints updated:
    * Infeasibilities are handled with a forward push routine and a backward pull routine.
    * The way dense fill-in is removed is updated and the runtime is improved.
  - Changed a tolerance in the Derivative debugger.
  - Fixed an error in one-dimensional search when there are large 2nd derivatives or discontinuous 1st derivatives. Tried to recover a point that did not exist.
  - Fixed an error with model *hda*: there was a conflict between monotonicity and a tolerance.
  - Fixed some occurrences of system errors 12371, 12372, 88120.
  - Fixed a problem with a very small pivot (non-default tolerance) that created an incorrect penalty constraint.
  - Fixed an error that could appear in models with very long constraints.

3.10.1.4.7 Convert and ConvertD

- Added support for semi-integer and semi-continuous variables and complementarity constraints to scalar JuMP output format.
- Added information about discrete variables to the GDX files created by options Hessian and Jacobian for CONVERTD.
- The Hessian and Jacobian option for CONVERTD report the .stage variable and equation attribute in the variable and equations records only. In the past, the .prior and .scale attributes were reported.
- Fixed an error with suppressed complementarity constraints in Pyomo output.
- Fixed handling of semicontinuous variables with lower bound equal upper bound when writing MPS files.

3.10.1.4.8 Couenne

- As announced, the solver Couenne has been removed from the GAMS system. For the time being, libraries of GAMS/Couenne are available at the COIN-OR GAMSlinks project. Note, that GAMS does not test or offer support for these libraries.
3.10.1.4.9 CPLEX

- The two solver links CPLEX and CPLEXD were merged under the name CPLEX. Features that were formerly available in only one of the two solver links are now all usable with the new CPLEX link. Those features include:
  - Formerly only CPLEX:
    * SOS1 and SOS2 sets
    * Branching priorities
    * Indicator constraints
    * Conflict refiner
    * Ranging / sensitivity analysis
    * Solution pool for mixed-integer (quadratic) problems
  - Formerly only CPLEXD:
    * Better handling of quadratic constraints (e.g. providing duals)
    * Hot start capability in GUSS
    * Solving multiple instances of GAMSModelInstance in parallel using GAMS APIs
    * Solvelink=solvelink.AsyncThreads
    * Cplex remote object and distributed MIP
    * Benders decomposition

- New features:
  - Partial MIP starts: allow to only include variable levels to the MIP start that are integer (within the tolerance tryint, see mipstart)
  - Multiple MIP starts provided via GDX (see multimipstart)
  - Lower / upper bound ranging / sensitivity analysis (see bndrng)
  - Lazy constraints (see userlazyconcall or .lazy)
  - Added MIP statistics (e.g. number of nodes, solve time, objective lower and upper bounds) to BCH call via GDX files usergdxnameinc and usergdxname.

- Added options:
  - Added option multimipstart for multiple MIP starts
  - Added option conflictdisplay
  - Added option multobjtolmip: the default value changes the behavior of the multi-objective optimization for continuous models
  - Added option bndrng: lower / upper bound ranging / sensitivity analysis
  - Added option indicoptstrict: handle erroneous indicator constraints
  - Added option userlazyconcall: adding lazy constraints using BCH
  - Added dot option .lazy: select linear constraints as lazy constraints
  - Added option mipstopexpr: custom MIP stopping criterion to terminate during branch-and-bound

- Changed options:
  - Changed behaviour of rngrestart: If the specified file extension is GDX, the ranging results will be exported as GDX instead of GMS.
  - Changed behaviour of miptracenode and miptracetime: option has no effect and MIP trace is appended when the solver reports global progress
  - Changed behaviour of quality: added entries regarding indicator constraints and MIP condition numbers
  - Changed default of randomseed from 0 to 201909284
3.10 Distribution

- Changed default of `tuningtilim` from 10000 to 1e75
- Changed default of `tuningdettilim` from 1e7 to 1e75
- Changed default of `workmem` from 128 to 2048
- Changed name `rtlcuts` to `rltcuts`
- Added documentation for partial MIP starts to `mipstart`

- Updated documentation for multiobjective optimization about CPLEX's two different strategies for continuous and discrete models (see also `multobjtolmip`).

- Fixed an error in BCH user heuristics where a false objective function of the incumbent was reported to CPLEX (in former CPLEXD link).

3.10.1.4.10 GUROBI

- New libraries 9.1.0.
- New option `rngrestart`: Export sensitivity information as GAMS readable format (GMS or GDX).
- New option `mipstopexpr`: Custom MIP stopping criterion to terminate during branch-and-bound.
- New option `norelheurwork`: controls NoRel heuristic.
- New option `norelheurt ime`: controls NoRel heuristic.
- New option `tunecleanup`: Enables a tuning cleanup phase.
- New option `poolgapabs`: Maximum absolute gap for stored solutions.
- New option `integralityfocus`: Indicator for stricter enforcement of integrality constraints.
- New option `value -1 for option .lazy`: Treat as a user cut.
- Removed option `norelheuristic`. A finer control of Gurobi's NoRelHeuristic is done through the newly introduced options `norelheurwork` and `norelheurt ime`.

3.10.1.4.11 IPOPT

- Changed default of option `acceptable_iter` from 15 to 0. This disables a heuristic in Ipopt to stop early with a solution that doesn't satisfy the usual termination tolerances when progress is slow.

3.10.1.4.12 Kestrel

- Fixed a bug that prevented job submission on Linux and Mac OS X due to a missing certificate.

3.10.1.4.13 Lindo/LindoGlobal

- Added the facility to detect irreducible infeasible and unbounded sets (IIS and IUS) and some options to control this.
- Added support for functions `div`, `log2`, `round`, and `trunc`. 
3.10.1.4.14  LocalSolver

- New libraries 9.5 (20200923).

3.10.1.4.15  LS

- We plan to drop the least-square solver LS with the next major release. The Python method `numpy.linalg.lstsq` included in the GAMS distribution can be used within an embedded Python code section to efficiently minimize the sum of squared residuals.

3.10.1.4.16  MOSEK

- New libraries 9.2.28.

3.10.1.4.17  ODHCPLEX

- More features available in the GAMS link:
  - SOS1 and SOS2 sets
  - Branching priorities
  - Indicator constraints
  - Partial MIP starts: allow to only include variable levels to the MIP start that are integer (within the tolerance tryint, see mipstart).
  - Multiple MIP starts provided via GDX (see multimipstart)

3.10.1.4.18  SCIP

- New libraries 7.0 (5b13bda).
- The workaround to assign a non-continuous variable to a block for problem decomposition (use suffix .prior without priorOpt=1) is not necessary anymore (.stage is now available for non-continuous variables). If one runs a model that continues to use this workaround with this version of GAMS, all non-continuous variables will end up in block 1 independent of the .prior value.

3.10.1.4.19  SHOT

- Gurobi is now available as solver for the MIP or MIQCP relaxation on Mac OS X, too.
- Fixed return of final dual bound found by SHOT to GAMS (objEst attribute).

3.10.1.4.20  SolveEngine

- Dropped link to Satalia SolveEngine because Satalia retired SolveEngine Beta and a successor is not yet available.
3.10.1.4.21 SoPlex

- New libraries 5.0 (2afa64b6).

3.10.1.4.22 XPress

- New libraries 8.10.1.
  - Removed option mislpAlgorithmFinalSLP.
  - Removed option mislpAlgorithmNoFinalRounding.
  - Added option mislpCutStrategy.
  - Added option mipstopexpr: Custom MIP stopping criterion to terminate during branch-and-bound.

3.10.1.5 Tools

3.10.1.5.1 GAMS IDE and GAMS Studio

- Fixed that Bonmin and Ipopt solver option files could not be created or edited via the options editor.

3.10.1.5.2 GAMS Studio

- New version 1.4.2.
  - New feature: Remote execution with GAMS Engine.
  - New feature: Allow to open $[bat|lib]include files by context menu, F2 shortcut, or holding Ctrl and click on the filename.
  - Renamed About GAMS dialog to GAMS Licensing dialog to make it more clear, that this allows to install a GAMS license.
  - Improved GAMS license detection during Studio start and in GAMS Licensing dialog; if the content of a license file is in the clipboard when starting Studio, a dialog to install the license is started.
  - Added support for comma separated list as file filter in search dialog.
  - Changed behavior of ”Whole Words” search option: $ is now considered a word boundary.
  - Reworked NEOS integration, e.g.:
    * Allowing to kill submitted active jobs.
    * Moved NEOS control options into dialog.
    * Changed default parameter from forceWork=1 to previousWork=1.
    * Improved handling of network errors.
  - Minor bug fixes and improvements, e.g.:
    * Added dialog for confidentiality and terms of use confirmation before submitting models to NEOS.
    * Added Arrow Up/Down as shortcuts to jump to search results when Results View is focused.
    * Added tooltips to options in search dialog.
    * Syntax coloring improvements.
    * Fixed file codec selection for the model assembly dialog.
    * Fixed and enhanced reloading mechanism of the GDX Viewer.
    * Fix to ensure that lowercase directory names are always used for MIRO directories, e.g. data\myModel instead of data\myModel.
    * Fixed empty history on welcome page when starting Studio with no tabs open.
    * Fixed potential crash if files are modified in the background while a dialog is open.
3.10.1.5.3 MessageReceiverWindow

- Since GAMS does not support any 32bit platform anymore, this tool is compiled for x64 instead of Any CPU now.

3.10.1.5.4 MODEL2TEX

- Deprecated command line parameter -e has been removed.

3.10.1.6 APIs

3.10.1.6.1 .NET

- Since GAMS does not support any 32bit platform anymore, the .Net DLL is compiled for x64 instead of Any CPU now.

3.10.1.6.2 C++

- Adjusted compilation of examples to new handling of critical sections in expert level APIs.
- Adjusted some examples since GAMS/CplexD is now a synonym for GAMS/Cplex.

3.10.1.6.3 Python

- New experimental API gams_magic that enables the use of GAMS in Jupyter notebooks has been added. This release of gams_magic should be considered a beta product and will be subject to changes in the future that may result in compatibility issues.
- New API gams_engine that allows the creation of Python clients for GAMS Engine has been added.

3.10.1.7 Expert Level APIs

- The new files gcmt.c and gcmt.h are now required when compiling/linking C expert level API files (e.g. gdxcc.c/h) to protect critical sections in the interface for multi-threaded applications. On some platforms, this might also require linking against additional libraries, e.g. libpthread on Linux. Adding the define GC_NO_MUTEX when compiling the C expert level API files provides the old behavior.
- Added new call gdxStoreDomainSets to the GDX API to control the use of one-dimensional sets as domain sets. Disabling the storage of domain information for a one-dimensional set when writing to GDX saves memory but prevents the set from being used for domain checking.

3.10.1.8 Model Libraries

3.10.1.8.1 GAMS API Library  New models:

- Pgams_engine.gms : Test gams_engine API (60)
- Pneos.gms : Test submitting GAMS models to NEOS server (61)
### 3.10.1.8.2 GAMS Test Library

**New models:**

- *lindgl05.gms* : Test new functions added to GAMS/Lindo(Global) (828)
- *cplex04.gms* : CPLEX test suite - free gams model test (829)
- *cplex05.gms* : CPLEX test suite - interactive (830)
- *cplex06.gms* : CPLEX test suite - multiobjective (831)
- *cplex07.gms* : CPLEX test suite - bch incumbent checker (832)
- *sens01.gms* : sensitivity / ranging test (833)
- *mipstophexpr1.gms* : mip stop expression test (834)
- *attrib01.gms* : Test attribute setting and preservation in Convert (835)
- *gamsjupyter01.gms* : Test GAMS Jupyter Notebooks (836)
- *cmi01.gms* : Test captureModelInstance option with all solveLink combinations (837)

### 3.10.2 33.2.0 Minor release (December 01, 2020)

#### 3.10.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

#### 3.10.2.2 GAMS System

##### 3.10.2.2.1 GAMS

- Fixed some problems with Implicit set definition:
  - When doing a filtered load from GDX or embeddedCode, the defined set only gets the elements actually loaded but not the ones that were filtered out.
  - Merging to start of existing data (with `$onMulti`) does not lead to out-of-order data anymore.

#### 3.10.2.3 Solvers

##### 3.10.2.3.1 CPLEX

- Fixed issue where option writemst did not produce any output.

##### 3.10.2.3.2 KNITRO

- Add workaround to avoid abnormal termination of Knitro 12.2 libraries on AMD processors.

#### 3.10.2.4 Tools

##### 3.10.2.4.1 GAMS Studio

- New version 1.4.5 with various bug fixes, stability improvements and minor enhancements, e.g.:
  - Added error output to system log if the given MIRO installation location is invalid.
  - Disabled run actions and MIRO menu when active group has no active executable file.
  - Fixed a problem with GAMS parameters being ignored in rare cases.
  - Fixed a potential crash when reloading a large `gms` file while the syntax highlighter was still processing that file.
  - Improved Search and Replace, e.g.:
    * Improved performance of Find Next/Previous.
    * Added possibility to interrupt Find Next/Previous.
    * Fixed a problem which did not allow to jump to search results beyond the 50,000th match of the search term.
    * Fixed handling of wrapped lines in search.
  - Improved MIRO and Engine dialogs, e.g.:
    * Removed standalone MIRO assembly file dialog and added it to a new reworked MIRO deploy dialog instead.
    * Fixed version comparison in GAMS Engine dialog.
3.11 32 Distribution

3.11.1 32.1.0 Major release (July 31, 2020)

3.11.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Youngdae Kim, Michaja Pehl, Thomas Rutherford, and Igor Sheleg.

3.11.1.2 Platforms

- Dropped support for Sparc Solaris and AIX systems.

3.11.1.3 GAMS System

3.11.1.3.1 GAMS

- New default values for some GAMS options:

<table>
<thead>
<tr>
<th>Option</th>
<th>new default</th>
<th>old default</th>
</tr>
</thead>
<tbody>
<tr>
<td>logOption</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>empty</td>
<td>on</td>
<td>off</td>
</tr>
<tr>
<td>errMsg</td>
<td>1</td>
<td>0</td>
</tr>
<tr>

<td>1000</td>
</tr>
<tr>
<td>solveLink</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>iterLim</td>
<td>2147483647</td>
<td>2e9</td>
</tr>
</tbody>
</table>

In order to work with the default values active in GAMS 31, copy the file `gams31config.yaml` (part of the GAMS system directory) into the location searched by GAMS for configuration files (e.g. the GAMS system directory) with the name `gamsconfig.yaml`.

- Extended the impact of command line parameter `etLim`, so that it reduces `resLim` for models solved automatically if that is greater than `etLim - timeElapsed`.

- Added new option `zeroToEps` to allow reading zero values as EPS at execution time.

- Added new options `procTreeMemMonitor` and `procTreeMemTicks` to enable monitoring of a memory high-water mark for the GAMS process and all its children.

- Adjusted behavior of command line parameters `restart`, `restartNamed`, `save`, `saveObfuscate`, `xsave`, and `xsaveObfuscate`: If a file name is given including a file extension, this extension is kept. In the
past it was replaced by a default extension. Also, '?' is not allowed in the file name when writing a save file anymore.

- Extended influence of command line parameter inputDir, so that it also extends the search path for GDX files loaded with $gdxIn.
- Extended the search space for files included via $libInclude, extrinsic function libraries, and external equation libraries: Now, the directories inclib, extrinsic_functions, and external_equations, resp., are checked in all GAMS standard locations before [GAMS System Directory]/inclib, [GAMS System Directory], and [GAMS Working Directory], respectively.
- Renamed the command line parameter execErr to maxExecError to be in sync with the related function maxExecError. The old name is still available as a synonym.
- Added command line parameter previousWork to instruct GAMS to write a workfile using the format of an older GAMS version. This is useful in particular with submission to the NEOS server.
- Adjusted the function values returned by the power functions (e.g. $x^{**}y$). In some cases where $x$ is very small and positive the derivatives may become unbounded but the function values are well-behaved and can still be computed precisely and without overflow.
- Fixed a problem on Linux when the XGD_CONFIG_DIRS or XGD_DATA_DIRS variables have more than 7 directory entries.

3.11.1.3.2 GMSPython

- Added the packages pandas, numpy, openpyxl, schema, tqdm and their dependencies.

3.11.1.3.3 Mac OS X Installer

- New way to install GAMS on Mac OS X using a PKG installer, see the installation notes.

3.11.1.3.4 Windows Installer

- Added a checkbox for enabling/disabling the creation of a start menu entry to the Select Start Menu Folder Wizard page. The default state of the checkbox is inherited from previous installations.
- Command line argument /noIcons can be used in order to check the Don’t create a Start Menu folder checkbox on the Select Start Menu Folder page.
- New command line argument /desktopIcons=yes|no (default:yes) can be used in order to turn on/off the creation of Desktop icons.
- The installer now writes all registry entries either to HKEY_CURRENT_USER\Software\Classes (current user) or HKEY_LOCAL_MACHINE\Software\Classes (all users).
- Show warning in case the system GAMSDIR environment variable is updated, but a user GAMSDIR environment variable exists and not vice versa.
- Always notify the operating system about changed environment variables.
- Changed the default installation location from C:\GAMS\win64\XX.Y to C:\GAMS\XX (e.g. C:\GAMS\32).
- Desktop shortcut names have been changed to GAMS IDE 32 and GAMS Studio 32.
- Start menu entry reads GAMS XX (e.g. GAMS 32) instead of GAMS XX.Y (win32/win64).
- Fixed a bug that prevented file associations (.gdx and .gms files) from working properly in certain cases.
3.11.1.4 Solvers

3.11.1.4.1 Bonmin, CBC, Couenne, LocalSolver, Osi links, SHOT, SoPlex

- Fixed that a setting of GAMS option `iterlim` to 2000000000 (the previous default) was not passed on to the solver.

3.11.1.4.2 CONOPT

- Added Conopt4 to the thread-safe solvers. It now can be used with `solveLink=6`.

3.11.1.4.3 CONVERT

- New output format: JuMP scalar model.

3.11.1.4.4 GUROBI

- Fixed a bug introduced with 31.1.0 and only partly fixed in 31.1.1 where the `GRB_LICENSE_FILE` environment variable was incorrectly dropped.

3.11.1.4.5 Ipopt

- Updated Mumps to 5.3.3.

3.11.1.4.6 KESTREL

- Kestrel interface source code has been ported from Python 2 to Python 3.
- Also on Windows, the source code of the link is now distributed instead of a binary.
- The GAMS distributed Python interpreter (`GMSPython`) is used for running the Kestrel client.

3.11.1.4.7 KNITRO

- New libraries 12.2.2.
  - Knitro 12 adds many improvements to the Knitro mixed-integer (MIP/MINLP) branch-and-cut solver. Several new cuts controlled by Knitro user options have been introduced including mixed-integer rounding cuts, zero-half cuts and clique cuts. In addition, improvements were made to the knapsack cuts implementation.
  - Knitro 12 offers several enhancements to the Knitro presolver. The presolver has been extended to allow multiple passes through the presolve operations. There are new presolve operations for variables in complementarity constraints and to tighten variable bounds.
  - Knitro 12 offers efficiency and storage/memory improvements in the callable library C API - the one used in the GAMS link!
  - Knitro 12.2 enables default parallelism when using multi-start or multi-algorithm features.
  - Knitro 12.2 offers several performance speed-ups:
    * on very large models with the default (i.e. interior-point) algorithm: potentially dramatic
    * when using the limited-memory BFGS Hessian option
    * in the SQP algorithm
  - A number of minor bug fixes and performance improvements are included in this release: rare segmentation fault with knapsack cuts fixed, bug in convexity detection fixed, poor/slow choice of algorithm for LP sub-problems fixed, poor/slow presolve issue on MIP models fixed.
3.11.1.4.8 LocalSolver

- New libraries 9.5 (20200701).
- Setting iterlim to the maximal possible value (2147483647) will not change the default iteration limit of LocalSolver anymore, see also the documentation.

3.11.1.4.9 Mosek

3.11.1.4.10 ODHCPLEX

- New libraries 5.2.2.
- New options integerTol, subOrder, subPresolve, zeroTol, penPerturb, and threadZeroSync have been added. The options newCallback and variableClean allow for more option values.
- New handling of solutions that are not quite integer but within the integer feasibility tolerance of CPLEX but become infeasible if one rounds the integer variables. ODHCPLEX used to reject such solutions (while in CPLEX (and other MIP solvers) such solutions are considered acceptable for the user).

3.11.1.4.11 SoPlex

- Setting iterlim to the maximal possible value (2147483647) will not change the iteration limit of SoPlex anymore, so that SoPlex will run without a limit.

3.11.1.4.12 XPRESS

- New libraries 8.8.5.
- New solver: XPRESS SLP and XPRESS Knitro for nonlinear (mixed-integer) programming.
  - XPRESS SLP is a sequential linear programming (SLP) solver and XPRESS Knitro equals Knitro, but the problem is passed through the XPRESS nonlinear presolve.
  - Both can solve convex MINLP to global optimality and act as a heuristic method for general nonconvex problems.
  - XPRESS SLP offers a multistart to run different configurations in parallel or to start with multiple initial guesses.
  - If both XPRESS SLP and XPRESS Knitro are licensed, XPRESS can choose the nonlinear solver automatically based on instance attributes.
  - For more information about the XPRESS SLP algorithm, see FICO Xpress Optimization Help (Nonlinear Reference Manual).
  - XPRESS SLP and XPRESS Knitro are available on all supported platforms.
  - XPRESS SLP requires a license for continuous nonlinear models or for mixed-integer nonlinear models.
  - XPRESS Knitro requires a GAMS/Knitro license in addition to the XPRESS license for (mixed-integer) nonlinear models.
3.11.5 Tools

3.11.5.1 CHK4UPD

- If the components of the checked license have different expiration dates, the validity of the license always refers to the base component now. In the past, the component with the oldest expiration date was used.

3.11.5.2 FINDTHISGAMS

- Support for registry key changes of the Windows installer has been added.
- New command line parameters list, delete, write, and ide. See the documentation for detailed information.

3.11.5.3 GAMS Studio

- New version 1.3.3.
  - New feature: Code Folding
    * Shortcut Alt+L switches folding state of the current block.
    * Shortcut Alt+0 folds and Shift+Alt+0 unfolds all foldable blocks.
    * Code folding is possible for pairs of parentheses that span multiple lines or Dollar Control Options that come in pairs.
  - New feature: Remote execution on NEOS Server for Optimization
    * Models can be executed remotely via the menu GAMS -> Run NEOS or the execute button located in the toolbar.
    * Note: Usually it takes some time before the GAMS version at NEOS gets updated. During that time one might get an error because of an incompatible workfile version. This can be avoided by setting the command line parameter previousWork to 1.
  - New feature: Navigation History
    * Mouse button 4/5 or Alt+Left/Right on Windows/Linux and Ctrl+[/] on Mac OS X can now be used to jump back to a previous text cursor positions or forward again. This is helpful to quickly navigate between different locations in files that one is currently working with.
  - New feature: Distraction Free Mode
    * Distraction Free Mode quickly turns off everything except for the editor window for better focus on modeling work. This is especially useful for small screens. When leaving Distraction Free Mode all Studio widgets will be put back where they were. To switch to and from Distraction Free Mode go to the Menu > View > Distraction Free Mode, or press Ctrl+Alt+Enter on Windows and Linux, or Cmd+Option+Enter on Mac OS X.
  - New feature: Print support for text files (gms, txt, lst, dmp, ...). This is accessible with the shortcut Ctrl+P or in the menu File -> Print.
  - Added automatic switch to first non-empty tab when searching the Model Library Explorer. The old tab selection is restored if that tab contains results again.
  - Added header labels to copy actions in GDX Viewer table view. Two additional entries that allow to copy without the labels are available via the context menu.
  - Added dmp extension to list of executable file types.
  - Added Shift+Option+Up/Down hotkey to start block-edit on Mac OS X.
  - Changed terminal to native Mac OS X Terminal on Mac OS X.
Stability improvements and minor bug fixes, e.g.:

- Fixed syntax highlighter not recognizing "+" and "+" in "Model" statement.
- Fixed missing LXI pane for files containing more than one dot.
- Fixed group name for gms files containing more than one dot in the name.
- Fixed rare random crash when opening the MIRO Model Assembly File dialog.
- Fixed some icons not following selected theme.
- Fixed line wrapping behavior not following settings.
- Fixed that bookmarks in help view were not being saved permanently.
- Fixed crash on reading LXI files containing empty lines.
- Fixed some issues with the license file detection and info in the "About GAMS" dialog.
- Fixed missing reload if a opened GDX file gets recreated.

3.11.1.5.4 MODEL2TEX

- Source code of model2tex has been ported to Python 3 and does not support Python 2 anymore.
- Distribute source code instead of binary on Windows. model2tex.exe has been replaced by model2tex.cmd.
- The GAMS distributed Python interpreter (GMSPython) is used for executing model2tex.
- Command line parameter -e has been deprecated and will be removed in the future.

3.11.1.6 APIs

- Automatically finding a GAMS installation from the Windows registry has been changed according to the changes to the Windows installer ([HKEY_CURRENT_USER\HKEY_LOCAL_MACHINE]\Software\Classes\gams.location).
- The performance of the Object-oriented APIs (in particular the class GAMSDatabase) has been improved.

3.11.1.6.1 .NET

- Change to GAMSWorkspace.AddCheckpoint: The checkpointName is now determined automatically as well when given as string.Empty, not only when set to null or being omitted.

3.11.1.6.2 Python

- As announced, dropped support for Python 2. The Object-oriented API as well as the expert-level APIs can be used with Python 3.6, Python 3.7, and Python 3.8.
- An experimental object oriented data interface called gamstransfer has been added. This interface is built on the expert-level Python APIs and simplifies the work of reading and writing GDX files. The underlying data structure is built on structured numpy arrays; this structure allows data to be easily converted directly to Pandas DataFrames (or other native Python data types). This release of gamstransfer should be considered a beta product and will be subject to changes in the future that may result in compatibility issues.
- New experimental API gams2numpy for communicating data between GAMS and numpy arrays has been added. This release of gams2numpy should be considered a beta product and will be subject to changes in the future that may result in compatibility issues.
3.11.1.7 Model Libraries

3.11.1.7.1 GAMS Model Library  New models:

- scenmerge.gms : Combining scenario results in a directory tree with gdxmerge (427)

3.11.1.7.2 GAMS Test Library  New models:

- zerotoeeps1.gms : Test data loading with $onEps and option zeroToEps (821)
- idir01.gms : Test including files from different locations (822)
- mrw02.gms : Test MessageReceiverWindow.exe from Python (823)
- memmon1.gms : Test procTreeMemMonitor=1 behavior (824)
- gams2numpy01.gms : Test gams2numpy Python API string mode (826)
- gams2numpy02.gms : Test gams2numpy Python API raw mode (827)

3.11.1.7.3 GAMS API Library  New models:

- Pgamstransfer.gms : Test gamstransfer API (58)
- Pgams2numpy.gms : Test gams2numpy API (59)

3.11.2 32.2.0 Minor release (August 26, 2020)

3.11.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Charles Chan, Ricardo Lima, Sandro Konrad Luh, Ami Reznik, Tom Rutherford, and Berk Uzundere.

3.11.2.2 GAMS System

3.11.2.2.1 GAMS

- Introduced new values 3 and 4 for option savePoint that allow to save the point file in the scratch directory.
- Fixed a bug which in rare cases caused GAMS to write files exceeding 80,000 characters per line (and thus the maximum line length GAMS can handle) when the command line parameter dumpopt was set.
- Fixed a bug in restart files that incorrectly stored the location of the GAMS configuration file (gmscmpXX.txt).
- Fixed a bug that is related to providing the GAMS configuration file (gmscmpXX.txt) explicitly via command line parameter subSys.
- Fixed reporting of compilation errors in encrypted input files.
- Fixed the count of discrete variables in the model statistics in case any discrete variable was fixed.

3.11.2.2.2 Windows Installer

- Fixed a bug that prevented registry entries from being removed correctly during uninstallation.
3.11.2.3 Solvers

3.11.2.3.1 Gurobi

- New libraries 9.0.3.

3.11.2.3.2 Lindo/LindoGlobal

- New libraries 12.0.208.
  - Fixed a rare problem with stochastic problems.

3.11.2.3.3 Mosek

- New libraries 9.2.18.

3.11.2.3.4 SCIP

- New libraries 7.0 (80549b8905).
- PaPILO updated to 1.0 (d0e5444cd).

3.11.2.3.5 SoPlex

- New libraries 5.0 (3623dbc0).

3.11.2.4 Tools

3.11.2.4.1 GAMS Studio

- New version 1.3.4.
  - Minor bug fixes, e.g.:
    * Show community license type in the solver matrix.
    * Fixed missing tab browser button when Studio starts in maximized or full-screen mode.
    * Fixed insertion of auto-closing characters in unwanted situations (e.g. beginning of a word).

3.11.2.4.2 GDX2VEDA

- Fixed a bug which in rare cases crashed the tool for large data sets on Windows.

3.11.2.5 Model Libraries

3.11.2.5.1 GAMS Test Library

- Updated models:
  * savep1.gms: execute_loadpoint: save point - clear - loadpoint - reoptimize (65)
3.12 31 Distribution

3.12.1 31.1.0 Major release (May 01, 2020)

3.12.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Christoph Böhringer, Wolfgang Britz, Andreas Lundell, Scott McDonald, Victor Nechifor, Renger van Nieuwkoop, A. Omidi, Christoph Pahmeyer, Soummya Roy, Thomas Rutherford, Alireza Soroudi, Tim Varelmann, and Elizabeth Wong.

3.12.1.2 Platforms

- As announced, dropped support for 32-bit MS Windows.

3.12.1.3 GAMS System

3.12.1.3.1 GAMS

- Extended the syntax of the model statement to allow to restrict the domain of variables used in the model at one spot.
- Added dollar control options $on/offSuffixDLVars and command line parameter SuffixDLVars to control whether it is allowed to use suffixes on variables with limited domains in a model.
- Added new command line parameters to initialize the state of certain dollar control options: Digit, Empty, EolCom, Filtered, InlineCom, Listing.
- Extended the behavior of the command line parameter checkErrorLevel, so that it also initializes the state of the dollar control option $on/offCheckErrorLevel.
- Extended the behavior of the command line parameter strictSingleton, so that it also initializes the state of the dollar control option $on/offStrictSingleton.
- Added new command line parameters to set the default values for certain put file attributes: PutND, PutNR, PutPS, PutPW.
- Removed the limit on the number of significant digits allowed in floating-point values in GAMS source.

Historically, GAMS has run on widely different platforms where even the floating-point arithmetic varied. To ensure the precision specified in the GAMS input didn't exceed what could be stored and computed with as GAMS ran, we limited the amount of precision (i.e. the number of digits used for numbers in the GAMS source) that could be specified. This limit could be relaxed by using the $offDigit control.

Modern computers all support IEEE double-precision arithmetic. It's a well-accepted and familiar standard, and the new behavior - to convert the decimal value in the GAMS source into the nearest double-precision value, regardless of the number of digits specified - is what is generally expected. There is a limit (currently 40) on the number of digits treated as significant: digits beyond this point are quietly treated as zero.

For "nice" values (i.e. those with fewer than 17 digits of precision and exponents of limited size, like 3.14159 or 2.5032e10) there is no difference in the old and new behavior. But for values specified with 17 or more digits of precision or having exponents of large size, the double-precision values can vary slightly between the old and new systems. The new values are the correct ones.

The new command line parameter sys18 has been added in case any users require the old behavior.
• New options `encryptKey` and `decryptKey` to encrypt and decrypt source based on a key rather than a target license. This allows developers to create encrypted input files that can be executed with any GAMS license and the right key.

• GAMS will search standard locations for the license file `gamslice.txt` including the GAMS system directory. The standard locations for your operating system are described in the installation notes. You can also continue to use the `license` command line parameter to point to a specific license file.

• GAMS can now use a configuration file `gamsconfig.yaml` to specify default values for command line parameters and environment variables: see details in GAMS Configuration in YAML Format. This can be used to implement user-specific default option settings that are shared between different GAMS versions. In the future, we also expect to use this capability to support the setting of options and defaults that support backward compatibility; this will become important as we change GAMS defaults in significant ways to modernize the user experience in the light of current computing environments and user expectations.

• Added system suffixes `%system.licenseFileName%`, `%system.userConfigDir%`, and `%system.userDataDir%`.

• Embedded Python Code Facility:
  - Embedded Python code can be used with Python 3.6, 3.7, and 3.8. GMSPython is used for embedded code by default on the core platforms.
  - The GAMS command line parameter `pySetup` has been deprecated. The environment variable `GMSPYTHONLIB` that needs to point to the Python library (e.g. `python38.dll` on Windows) determines the Python installation to be used in embedded Python code.
  - The `gams.set` method to write data back to GAMS has a new argument `mapKeys` that allows to pass a callable to remap the elements of the key.

• Removed GAMS return code 116 ("Could not find GMSPython").

• Fixed the `card` operator for scalar symbols, so that it always returns 1 when the symbol has data. In the past it might have been wrong for symbols that had no data in the declaration, but just from an assignment.

• Fixed issues where GAMS would crash on exceptionally large models (more than 268 million rows or columns) with certain non-default options selected.

• Fixed a problem which allowed multiple declarations of the same equation or variable when `$offMulti` was active.

• Fixed some 3-argument intrinsic functions whose third argument was optional (e.g. `ncpVUSin`) - these were not taking the default value for the third argument correctly into account when called with two arguments.

• Fixed a bug which caused wrong execution of `$onPut` and `embeddedCode` after Programming Flow Controls that were not terminated with a semicolon.

• Fixed a bug which caused variable and equation records fixed at 0 to be dumped incorrectly with `dumpOpt`.

• Fixed incomplete warning when writing a non-default status of `$on/offEmpty` to a save file.

• `execMode` did not prevent the execution of `scriptExit`. This has been fixed.

3.12.1.3.2 GMSPython

• GMSPython has been upgraded from Python 3.6 to Python 3.8 and comes without Python package installer `pip`.

• Added the package `ply`. 
3.12.1.3.3 Libinclude

- The libinclude file `rank.gms`, which is based on the `gdxrank` tool, got a complete overhaul. The temporary GDX files resides now in the scratch directory, so multiple GAMS models using `rank.gms` can coexist in the same working directory. Moreover, the percentile calculation works with sort values that may include +inf/-inf. Some checks have been added that result in execution errors in case the operation was not successful, e.g. if `gdxrank` failed to sort.
- Fixed a bug in `pyEmbMI.gms` that prevented string options from being set properly.

3.12.1.3.4 Documentation

- Improved the layout. The new layout provides a more responsive view on a smaller screen.

3.12.1.3.5 Windows Installer

- Default installation mode has been changed from `All Users` to `Current User`. This can be changed on the Advanced Options page or by providing `/allUsers=yes` when running the installer from a command prompt.
- The default application used for associating GAMS (.gms) and GDX (.gdx) files has been changed from the GAMS IDE to GAMS Studio.
- New command line argument `/allUsers=yes|no` (default: no) can be used in order to install for `All Users` instead of `Current User`.
- New command line argument `/noLicense=yes|no` (default: no) can be used in order to prevent any GAMS license from being written.
- New GAMS License page:
  - Allows to select a GAMS license to be used. The installer tries to find GAMS licenses in different locations and automatically selects a license to be used with the following precedence:
    * Clipboard
    * C:\Users\username\Documents\GAMS
    * Previous GAMS installation found from the registry (User)
    * Previous GAMS installation found from the registry (System)
  - A license file is written to C:\Users\username\Documents\GAMS when installing for Current User (default). Installing for All Users or checking Write License to System Directory will write the license to the system directory instead.

3.12.1.4 Solvers

3.12.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2020.0 on Windows.

3.12.1.4.2 BARON

  - Improved local search strategies.
  - Increased effectiveness of cut pool manager.
  - Improved relaxations for MIQPs.
  - Added new LP subsolver based on HSL’s LA04.
3.12.1.4.3 CBC

- GAMS/CBC did not use the default value for all parameters as documented and as used in the CBC standalone program. This has been fixed. To restore some of the previous behavior, the following parameter setting can be used:

```plaintext
nodeStrategy hybrid
preprocess off
cuts off
cliqueCuts off
flowCoverCuts off
gomoryCuts off
knapackCuts off
mirCuts off
twoMirCuts off
probingCuts off
zeroHalfCuts off
heuristics 0
feaspump off
greedyHeuristic off
roundingHeuristic off
```

3.12.1.4.4 CONOPT

- New libraries 3.13L.
  - Added new facilities to print the variables changed by the pre-processor. See options prprec, rtpprec, and rtprel.

- New libraries 4.19.
  - Some errors related to the duals and basic/nonbasic flags for some definitional constraints and forcing constraints have been corrected.
  - The two tolerances Tol_IFixed and Tol_DFixed for when a variables is fixed have been unified into a single tolerance, Tol_Fixed.
  - The routine for detecting definitional constraints has been simplified and some options from previous versions are no longer used (Flg_DC_Uinique, Lim_DFVars, and Tol_Def_Ini) and Tol_Def_Mult has a new default value.

3.12.1.4.5 CONVERT

- Added support for option HeaderTimeStamp, which was added for ConvertD before, in Convert.

3.12.1.4.6 COUENNE

- We plan to drop Couenne with one of the next major releases.

3.12.1.4.7 CPLEX

- Fixed incorrect display of selection of LPMethod when rerunning without presolve for infeasible model.
- Fixed incorrect selection of LPMethod when rerunning without presolve for infeasible model in CplexD.
3.12.1.4.8 GUROBI

- New libraries 9.0.2.
- If GAMS/Gurobi is licensed, the setting of the environment variable `GRB_LICENSE_FILE` is ignored. The setting of this environment variable interfered with the GAMS/Gurobi licensing.

3.12.1.4.9 IPOPT

- New libraries 3.13.2.
  - MA28 can no longer be loaded at run-time from a user-provided HSL library. Removed option 'ma28_pivot'.
  - The default of option `ma77_order` has changed from 'amd' to 'metis'.
  - The default of option `ma97_print_level` has changed from 0 to -1.
  - The default of option `mumps_pivot_order` has been changed from 7 to 5 to work around a bug in MUMPS.
- Updated MUMPS to version 5.3.1. MUMPS has been build with OpenMP support enabled.
- Updated METIS (used by HSL codes and MUMPS) to version 5.1.0.

3.12.1.4.10 KESTREL

- Fixed a problem with the control file version that prevented Kestrel from being used in GAMS 30.

3.12.1.4.11 Lindo/LindoGlobal

- Increased the number of allowed nonlinear nonzeros in the global solver from 30 to 50 when operating under a demo license.

3.12.1.4.12 LocalSolver

- New libraries 9.5 (20200409).
  - Performance improvements on mixed-variable models like unit commitment or network design problems.
  - Performance improvements on routing and scheduling problems like CVRPTW or jobshop scheduling problems.
  - Better and faster lower bounds for nonlinear problems as well as for combinatorial problems like TSP.
- New parameter `verbosity`.
- Fixed handling of semi-integer variables.

3.12.1.4.13 MOSEK

- New libraries 9.2.4.
- Avoid MOSEK error 1243 on general nonlinear models.
3.12.1.4.14 SCIP

- New libraries 7.0.0 (0bc4dc9c65).
  - The symmetry code has been completely restructured and modularity has been increased.
  - It is now possible to use orbitopes (i.e., polyhedral symmetry handling techniques) and
    orbital fixing on the same instance.
  - Branching decisions can now take symmetry information into account by filtering
    first variables from orbits (new parameter `branching/relpscost/filtercandssym`) and
    transferring pseudo cost information to variables in orbit (new parameter
    `branching/relpscost/transsympscost`).
  - Improved performance of orbital fixing and orbitope propagation.
  - Branching decisions can now take symmetry information into account by filter-
    ing first variables from orbits (new parameter `branching/relpscost/filtercandssym`) and
    transferring pseudo cost information to variables in orbit (new parameter
    `branching/relpscost/transsympscost`).
  - Improved detection of packing/partitioning orbitopes.
  - New possible value 3 for `misc/usesymmetry` and changed default from 2 to 3.
  - Renamed parameter `propagating/orbitalfixing/enableafterrestart` to `propagating/symmetry/recomputeafterrestart`
    which decides whether to recomputate symmetries after a restart or not.
  - Changed default of `constraints/orbite/propfreq` from 5 to 1.
  - Changed default of `constraints/orbite/separafreq` from 5 to -1.
  - Removed parameters `constraints/orbisack/checkalwaysfeas`, `constraints/orbitope/checkalwaysfeas`, `constraints/symresack/checkalwaysfeas`.
  - Removed parameters `constraints/orbisack/checkalwaysfeas`, `constraints/orbitope/checkalwaysfeas`.
  - Removed parameters `propagating/orbitalfixing/symcomptiming`, `propagating/orbitalfixing/performpresolving`, and `propagating/orbitalfixing/recomputerestart`.
  - New parameter `constraints/orbite/usedynamicprop` to enable propagation of or-
    bitope constraints by reordering the rows based on the branching strategy.
  - New parameter `constraints/symresack/checkmonotonicity` to enable upgrade to pack-
    ing/partitioning symresacks even if the underlying permutation is not monotone.

- Presolve:
  - The presolve library PaPIL0 (Parallel Presolve for Integer and Linear Optimization) 1.0
    has been integrated as additional presolver for mixed-integer linear programs.
  - Expressions of form $|x|^p x$ in a nonlinear constraint are now sometimes recognized and
    handled by abspower constraints.
  - Some more quadratic constraints are now recognized as second-order cone constraints.
  - New presolver dualsparsify that tries to combine variables to cancel nonzero coefficients in
    the constraint matrix of a MIP.
  - Improved performance of tworowbnd presolver. New parameters added. Changed default of
    `presolving/tworowbnd/priority` from -500000 to -2000.
  - Extended presolver duallinear by the ability to perform convex combinations of continuous
    variables to calculate better bounds for the dual variables. New parameters added.
  - Huge clique tables are now avoided by restricting the number of nonzero entries relative to
    the number of nonzeros in the problem. New parameter `presolving/clqtablefac`.
  - New parameter `constraints/linear/extractcliques` to turn clique extraction off.
  - Improved presolver "domcol" to not require a complete representation of all constraints in
    the matrix.
  - Enabling aggressive presolving now activates all available presolving plugins, and decreases
    parameter `presolving/restartfac` correctly with respect to default.
* New parameter constraints/linear/maxdualmultaggr and constraints/linear/maxmultaggr to limit the maximum coefficient dynamism of an equation on which multiaggregation is performed. Smaller values make multiaggregations numerically more stable.

* Changed default of constraints/quadratic/empathy4and from 0 to 2. This leads to stronger but larger reformulations for products of binary variables.

− Primal heuristics:
  * New Large Neighborhood Search heuristic "Trust region", available as both a standalone heuristic and a neighborhood inside of Adaptive Large Neighborhood Search.
  * New heuristic Adaptive Diving, which registers all publicly available dive sets from other diving heuristics, learns online which divesets reach the best score, and executes them more frequently.
  * New penalty alternating direction heuristic PADM that splits the problem into several sub-SCIPs according to a user-provided decomposition (see below). The sub-SCIPs are solved on an alternating basis until a feasible solution of the original problem is found.
  * The GINS heuristic can make use of a user-provided decomposition (see below) by selecting a block of variables that maximizes the potential, and randomly selecting a start variable for the neighborhood and/or by selecting an interval of consecutive blocks as neighborhood, until fixing rate is reached. In this case, no variable is randomly selected. Several new parameters added for the use of a decomposition in GINS.
  * The LP face heuristic now wastes less time if it decides not to run.
  * Improved performance of Adaptive Large Neighborhood Search heuristic on merely continuous problems.
  * All primal heuristics that use sub-SCIPs are now disabled within the heuristics fast emphasis setting.
  * Replaced parameter heuristics/localbranching/useuct by heuristics/useuctsubscip, which affects all LNS heuristics.
  * New parameters heuristics/shiftandpropagate/minfixingratelp and heuristics/locks/minfixingratelp to stop the heuristics after propagating integer fixings if no sufficient fixing of the all variables (including continuous) could be achieved.
  * Changed default value of heuristics/coefdiving/freq from 10 to -1.
  * Changed default value of heuristics/conflictdiving/freq from -1 to 10.
  * Changed default value of heuristics/conflictdiving/lockweight from 1.0 to 0.75.
  * Changed default value of heuristics/rins/nodes from 0.1 to 0.3 (due to other code changes, this should not affect default behavior).
  * New value 1 available for heuristics/gins/potential to allow computation based on local LP solution.
  * The display column for memory usage ("mem") now shows the creator name for every new incumbent solution. The heuristic display characters now represents the type of the heuristic (diving, Large Neighborhood Search, propagation, etc.). Changed default of display/width from 139 to 143.

− Branching:
  * New rule vanillafullstrong, mostly for scientific purpose.
  * Improved branching point selection when branching on nonlinear variables. Instead of using exactly the LP solution, a point closer to the middle of the variables domain is chosen. Added parameters branching/midpull and branching/midpullreldomtrig.
  * Many updates to parameters of lookahead branching rule.
  * New parameter branching/relpscost/degeneracyaware to switch degeneracy-aware hybrid branching, which adjusts weights of different scores in relpscost (hybrid) branching rule based on degeneracy information and skips strong branching for very high degeneracy rates.

− Separation:
  * Improvements in cut presolving and cgmip separator.
  * New parameter separating/cgmip/genprimalsols that allows to generate initial primal solutions from Gomory cuts.
* Changed default of `separating/rapidlearning/freq` from -1 to 5. Various new parameters for `rapidlearning`.
* Changed default of `separating/efficacyfac` from 1.0 to 0.6.

- Approximations on the search tree completion and estimates on the tree size have been added.
  * The approximate search tree completion is shown in a new display column.
  * The tree size estimate is used to trigger a restart if, after a reasonable initialization, the estimated size of the remaining tree is large.
  * New parameter group `branching/treemodel` to specify the tree model.

- SCIP can now store user decompositions. A GAMS user can specify one decomposition via the `.stage` variable suffix. Statistics regarding the decomposition are printed to the log before presolving (if `display/statistics` is enabled) and after presolving. New parameter `decomposition/maxgraphedge`.

- Extended the dual proof analysis for infeasible LPs to consider also locally valid rows (new parameter `conflict/uselocalrows`).

- If a reference value is given, the primal-reference and reference-dual integrals are calculated automatically and printed within the SCIP statistics.

- Emphasis settings for numerically challenging instances have been added. They increase numerical stability of (mostly) presolving operations such as (multi-)aggregations at the cost of performance.

- Renamed parameters `misc/allowdualreds` and `misc/allowobjprop` to `misc/allowstrongdualreds` and `misc/allowweakdualreds`, respectively.

- Replaced parameter `numerics/lpfeastol` by `numerics/lpfeastolfactor` to specify which factor should be applied to the SCIP feasibility tolerance to initialize the primal feasibility tolerance of the LP solver.

- New parameter `lp/minmarkowitz` to set the Markowitz stability threshold. High values sacrifice performance for stability.

- Changed default of `propagating/redcost/useimplics` from TRUE to FALSE.

- See also the full release notes and the release paper.

- Symmetry detection and handling is now available on Windows, too.

- Updated Ipopt to 3.13, see above.

- Removed value `soplex2` for option `lp/solver`. `soplex` is now the default if no CPLEX license is available.

### 3.12.1.4.15 SHOT

- New solver by Andreas Lundell (Åbo Akademi University, Finland) and Jan Kronqvist (Imperial College London, UK).

- SHOT is a deterministic solver for mixed-integer nonlinear programming problems (MINLPs). It can solve convex and some nonconvex MINLP problems to global optimality. For other nonconvex problems, SHOT acts as a heuristic method, i.e., without providing guarantees of global optimality. For more information, see the GAMS/SHOT solver manual, the SHOT website, and the publications [126] [122].

- SHOT 1.0.0 (527f1a11) is available for Linux, Mac OS X (≥ 10.13), and Windows. It can be used with a GAMS base system license.
3.12.1.4.16  SoPlex

- New libraries 5.0.0 (6535a3c8).
  - Improvements in memory management.
  - The number of violations is now shown in the log.
- GAMS/SoPlex is now available for multithreaded solves.

3.12.1.4.17  XPRESS

- New libraries v8.8.3 (aka Optimizer 35.01.04). It has been a longer-than-usual time since the previous library update, so the list of updates and improvements enhancing performance, stability, and correctness is extensive and not reproduced here. For details, visit and search the FICO Community page.

3.12.1.5  Tools

3.12.1.5.1  GAMS IDE and GDXVIEWER

- As mentioned above, we switched the default application to be associated with GAMS files on Windows from the GAMS IDE to GAMS Studio with this release. The classic GAMS IDE has been shipped with the GAMS system for the last 20 years and is still the workhorse for many GAMS programmers. However, it does not provide all the features we see in modern development environments.
  Both the GAMS IDE and GDXVIEWER rely on a rather old software stack, which is hard to maintain with current operating systems and will become even harder over time. So we plan to drop the GAMS IDE and GDXVIEWER with an upcoming major release.

3.12.1.5.2  GAMS Studio

- New version 1.1.0.
  - Stability improvements.
  - Introduced new settings format.
  - Attention
    This required a reset of all settings. They are saved now in JSON format. As a consequence, Studio 1.0.0 cannot use settings that were written by Studio versions prior to 1.0.0 and vice versa.
  - Changed the default file encoding to UTF-8 for all platforms (this mostly affects Windows, there should be no change for other platforms).
  - Added option to change the default text encoding to Edit -> Encoding -> Select encodings.
  - Introduced Dark Theme for Windows and Linux as well (can be changed through Settings -> Editor).
  - Added editor for GAMS Configuration and menu entry for default GAMS Configuration file.
  - Added option to change display format of numerical values in GDX Viewer.
  - Changed location of default workspace and model library.
3.12.31 Distribution

- Changed location where gamslice.txt is put when created using the ”About GAMS” dialog to the new standard locations searched by GAMS (see installation notes for details).
- Improved shortcut layout:
  * Reintroduced ”Open Terminal” shortcut as Ctrl+T.
  * Introduced shortcut for ”Run MIRO base mode”: F8.
  * Introduced shortcut for ”Run MIRO hypercube mode”: Shift + F8.
  * Introduced shortcut for ”Run MIRO configuration mode”: Shift + F7.
  * Changed shortcut for focus ”Project Explorer” to Ctrl + 1.
  * Changed shortcut for focus ”Editor” to Ctrl + 2.
  * Changed shortcut for focus ”Parameter Editor” to Ctrl + 3.
  * Changed shortcut to extend and collapse ”Parameter Editor” to Ctrl + Alt + 3
  * Changed shortcut for focus ”Tab Browser” to Ctrl + 4.
  * Changed shortcut for focus ”Process Log” to Ctrl + 5.
  * Changed shortcut of duplicate line to Ctrl+D.
  * Changed shortcut of ”Toggle Comment” in ”Parameter Editor” to Ctrl + *
  * Changed shortcut of action ”Go to matching parentheses” to: Ctrl + B
  * Changed shortcut of action ”Select to matching parentheses” to: Ctrl + Shift + B
  * Fixed shortcut on Mac OS X: block edit mode is now CMD+Shift+Arrow Key.

3.12.1.5.3 GDXMERGE

- Fixed a problem when merging a GDX file with name .gdx.

3.12.1.5.4 GDXXRW

- Added new option dSetText to control the reading of explanatory text for set elements of domain sets.

3.12.1.6 Object Oriented APIs

- Option pySetup has been removed from the class GAMSOptions.
- Removed GAMS return code 116 (”Could not find GMSPython”) from the enumerate type representing the GAMS return code.
- Fixed a memory leak with GAMSModelInstance.solve.

3.12.1.6.1 C++

- As announced, dropped support for Microsoft Visual Studio 2013.

3.12.1.6.2 Python

- GAMS Python API is now distributed in source code under the MIT open source license.
- To access the GAMS API, the Python interpreter needs to find files in <GAMS Systemdirectory>/apifiles/Python/ and <GAMS Systemdirectory>/apifiles/Python/gams, where XY corresponds to the Python version X.Y, e.g. 3.7. The GMSPython installation is already set up to find all required files. The documentation section Let Python find the GAMS Python files gives details on how to use an external Python system with GAMS.
- There is a different directory structure in <GAMS Systemdirectory>/apifiles/Python. The content of the api directory has been moved to different places:
  - api_27 for the binary Python 2.7 API files,
  - src for the files required to build the expert-level API files from source,
  - gams for source files of the GAMS Python API plus a few extra Python source files for working with indexed EMP syntax, e.g. emppython1, and
  - thirdparty for the Python package ply for processing of indexed EMP syntax.
3.12.1.7 Expert Level APIs

- We plan to remove the GAMSX API with one of the next major releases.
- Added `palSetSystemName` to setup a generic auditline in PAL. Increased PAL API version to 3.

3.12.1.8 Model Libraries

3.12.1.8.1 GAMS API Library

- All Python examples have been reworked. Tests are performed also with the Python installation in `GMSPython`.
- New model `PBuildXPLevelAPI.gms`: Test building the expert-level APIs (57).

3.12.1.8.2 GAMS Data Library

New models:
- `rank01.gms`: Rank a vector, and display the data in sorted order (135)
- `rank02.gms`: Generate percentiles for a random vector (136)
- `rank03.gms`: Use `GDXRANK` to report multisectoral Monte Carlo results (137)
- `rank04.gms`: Repeated computation of percentiles within a loop (138)
- `rank05.gms`: Percentile ranking of household expenditure data with heterogenous household size (139)
- `GMSPythonCheck.gms`: Consistency check for `GMSPython` (140)

3.12.1.8.3 GAMS Model Library

- Updated model `encrypt.gms`: Input file encryption demo (318)
- New model: `waterld.gms`: Design of a Water Distribution Network with Limited Domain of Variables (426)

3.12.1.8.4 GAMS Test Library

New models:
- `gdxxrw15.gms`: GDXXRW - Testing option `dSetText` (810)
- `card03.gms`: Test card operator for scalar symbols (811)
- `limdom01.gms`: Test limited domains for variables in model (812)
- `limdom02.gms`: Test performance of limited domains for variables in model (813)
- `limdom03.gms`: Test the syntax of the model statement for limited domains for variables (814)
- `limdom04.gms`: Advanced test for limited domains for variables in model (815)
- `fnncpf3.gms`: Test correctness of `ncpf` intrinsic (816)
- `fnncpvupow2.gms`: Test correctness of `NCPVUpow` intrinsic (817)
- `fnncpvusin2.gms`: Test correctness of `NCPVUsin` intrinsic (818)
- `loop10.gms`: Test relaxed punctuation for control structures (819)
- `dirs01.gms`: Test search and processing of `gamslice.txt` and `gamsconfig.yaml` in user space (820)
### 3.12.1.8.5 PSOPT Model Library

- Updated model: *MultiperiodDCOPF24bus*: Multi-period DC-OPF for IEEE 24-bus network considering wind and load shedding

3.12.2 31.1.1 Maintenance release (May 16, 2020)

3.12.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jan Abrell, Michael Ferris, Nick Sahinidis, and Karlo Šepetanc.

3.12.2.2 GAMS System

3.12.2.2.1 GAMS

- Fixed a bug where loading an empty universe from a GDX file caused an error.
- Fixed a bug in gamsinst that is used by the IDE to display available solvers.
- GAMS continues to search directories for the license and configuration file even if the construction of some directory names fails due to the absence of some environment variables, e.g. HOME.

3.12.2.2.2 GAMS Data Exchange (GDX)

- Fixed a bug where domain violations in higher dimensions might have been undetected when writing symbols to GDX.

3.12.2.3 Solvers

3.12.2.3.1 GUROBI

- Fixed a bug introduced with 31.1.0 where the GRB_LICENSE_FILE environment variable was incorrectly dropped.

3.12.2.3.2 MOSEK

- New libraries 9.2.7.

3.12.2.4 Tools

3.12.2.4.1 GAMS Studio

- New version 1.1.1.
  - Added command line parameter editor warnings for missing values.
  - Fixed problem with command line parameters not being updated when changing group.
  - Fixed behavior of Ctrl - End shortcut in process log and lst file view.
  - Fixed settings export not working when file already exists.
  - Fixed numpad not working when running Studio from an AppImage on Linux.
  - Fixed Shift+Arrow Key not working when running Studio from an AppImage on Linux.
3.12.2.5 Object Oriented APIs

- Fixed a bug in the Python API when exporting options (GAMSOptions.export()) that contain defines.

3.12.2.6 Model Libraries

3.12.2.6.1 GAMS Test Library

- Updated model dirs01.gms: Test search and processing of gamslice.txt and gamsconfig.yaml in user space (820)

3.12.3 31.2.0 Minor release (June 19, 2020)

3.12.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Salvador Doménech Martínez, and Kaushik Sinha.

3.12.3.2 GAMS System

3.12.3.2.1 GAMS

- The demo/community license limit of indexed external in- and output symbols for the GAMS/MIRO connector has been increased from 5 to 10. There is no limit on scalar external in- and output symbols. Starting with this version, one dimensional singleton sets are also not limited.

- Extend the influence of the command line parameter multiPass, so that it also ignores errors about unknown dimension with empty data statements when set to 2.

- Added three new put utility commands incMsg, incLog, and incMsgLog to include the content of a file into the log or listing file.

- Fixed a crash for CNS models which get solved asynchronously while asyncSolLst is set to 1.

3.12.3.3 Solvers

3.12.3.3.1 Gurobi

- Added option dumpBCSol to write incumbent solutions to GDX point files while Gurobi optimizes.

3.12.3.3.2 LocalSolver

- New libraries 9.5 (20200429).

3.12.3.3.3 Mosek

- New libraries 9.2.10.
3.12.3.3.4 SCIP

- New library 7.0 (01ae80d797).
- Fixed default setting for option misc/usesymmetry on Windows (was still set to 0, but should be 3).

3.12.3.3.5 SHOT

- New library 1.0.1.

3.12.3.4 Tools

3.12.3.4.1 GAMS Studio

- New version 1.1.2.
  - Performance improvements.
  - Stability improvements and minor bug fixes, e.g.,
    - Fixed crash when reopening a tab of a file that was removed from Project Explorer.
    - Fixed behavior of hotkeys to jump to beginning and end of line and page up/down.
    - Fixed Goto dialog jumping to beginning of file when entering invalid values.
    - Fixed shortcuts to focus Project Explorer and Editor not working when undocked.
    - Fixed that sizes of dock-widgets were not stored in FullScreen or Maximized window.

3.12.3.5 Object Oriented APIs

3.12.3.5.1 .NET

- Fixed a problem with reading labels which contain non-ASCII characters through GAMSSymbolRecord.Keys.

3.12.3.6 Expert Level APIs

3.12.3.6.1 C#

- Fixed a problem with reading arrays of strings which contain non-ASCII characters through different APIs.

3.13 30 Distribution

3.13.1 30.1.0 Major release (January 10, 2020)

3.13.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Todd Munson, Suguru Otani, Nick Sahinidis, and Dimitri Tomanos.
3.13.1.2 Platforms

- As announced, dropped support for Windows 7. The minimal required Windows version is now 8.1.
- Moved platform 32-bit MS Windows to peripheral platforms. We will completely drop support for 32-bit MS Windows with GAMS 31 (which was originally announced for GAMS 30).

3.13.1.3 Licensing and Demo Limits

- The GAMS demo limits have been increased. GAMS will generate linear (LP, RMIP, MIP) models up to 2000 constraints and 2000 variables and up to 1000 constraints and 1000 variables for all other model types. No other limits apply (e.g. non-zeros or discrete variables). Some solvers (e.g., the global solvers ANTIGONE, BARON, and LindoGlobal) might enforce additional restrictions.
- GAMS provides a free community license for users on request. This community license allows generating even larger models: up to 5000 constraint and variables for linear and 2500 constraints and variables for other model types. These free licenses are for demonstration and evaluation but not for commercial and production work, see the GAMS End User License Agreement.
- Starting with this release, GAMS requires a valid license even for the free demo system. Free demo licenses (time-limited for 12 months) can be generated at the download page. The free demo and community licenses require also a recent version (not older than 18 months) of GAMS to run. Please check the license documentation for details.
- GAMS Beta versions will stop working 90 days after their release. This is to prevent accidental use of beta software.

3.13.1.4 GAMS System

3.13.1.4.1 GAMS

- Added system suffix MACAddress, which contains the MAC address of the first network adapter.
- Allow to declare more than one parameter as table on a single line.
- Added new dollar control options $[on][off]Filtered: These control how GAMS loads data from GDX with $load, $loadR, and $loadM as well as from $offEmbeddedCode.
- Added new dollar control options $loadFiltered, $loadFilteredM, and $loadFilteredR to load data from GDX in filtered mode explicitly.
- Added new dollar control options $[on][off]ExternalInput to load data implicitly from an external source and $[on][off]ExternalOutput to save data implicitly to an external target.
- Added new command line parameters IDCGDXInput, IDCGDXOutput, IDCGenerateGDX, IDCGenerateGDXInput, IDCGenerateGDXOutput, IDCGenerateJSON, and IDCJSON.
- Embedded Python Code:
  - Changed the optional boolean argument domCheck to an enumerated option DomainCheckType in the gams.set method in embedded code. This might break existing code. Even if the domCheck argument was not used, the default behavior at execution time changes. In previous versions the content was domain checked, now it is read filtered.
  - The argument mergeType was documented incorrectly. With type MergeType.DEFAULT (or no argument given) GAMS merged the content, in contrast to what the documentation said (here replace was mentioned).
- Terminate with a proper error message if lines in the EMP info file exceed the maximum line length of 1020 characters.
- Fixed a problem where the order of a semicolon and certain dollar control options changed the behavior of the compiler.
3.13.1.4.2 Installer

- In addition to ..gms files, the Windows installer also associates .gdx files with either the GAMS IDE or GAMS Studio.

3.13.1.5 Solvers

3.13.1.5.1 BARON

  - Performance improvements for large-scale and mixed-integer quadratic problems.
  - Improvements in interface to IPOPT.

3.13.1.5.2 CBC

- New libraries.

3.13.1.5.3 CONOPT

- New library 4.16 with bug fixes.
  - Improvement in the transition from Phase 0 to Phase 1 and in the one-dimensional search close to optimality.

3.13.1.5.4 CPLEX

- New libraries 12.10.0.0.
- New options epLin and heuristicEffort.

3.13.1.5.5 GUROBI

- New libraries 9.0.0.
  - Gurobi 9 comes with a new bilinear solver, which allows to solve non-convex quadratic programming problems. The new parameter nonConvex needs to be set.
  - New general constraint types have been added to model functions like log, exp, sin, cos, and tan. New options funcPieces, funcPieceError, funcPieceRatio, funcPieceLength, and funcMaxVal have been added to control the piece-wise-linear discretization. The dot options doFuncPieces, doFuncPieceError, doFuncPieceRatio, and doFuncPieceLength allow control on an individual constraint basis.
- New parameters for new cutting planes: BQPCuts, relaxLiftCuts, and RLTcuts.
  - Fixed a problem when reporting the primal solution only.
  - Report the dual bound for continuous non-convex QP and QCP problems.
3.13.1.5.6 JAMS/LogMIP

- New option `userPFFile` to provide additional GAMS command line parameters for the GAMS run of the reformulated model.

3.13.1.5.7 LocalSolver

- New libraries 9.0 (20191219).

3.13.1.5.8 MOSEK

- New libraries 9.1.9.

3.13.1.5.9 ODHCPLEX

- New libraries 4.3.2 with bug fixes and performance improvements.

3.13.1.5.10 PATH

- New library 5.0.01 with bug fixes.
  - Fix seg fault when using the hidden option `output_hidden_options`.

3.13.1.5.11 SCIP

- New libraries 6.0 (90a56e0b).
  - Default for option `heuristics/rins/nodesquot` changed from 0.1 to 0.3.

3.13.1.6 Tools

3.13.1.6.1 GAMS Studio

- New version 0.14.1.
  - Stability improvements.
  - Added GDX Diff dialog to compare two GDX files. It can be opened by choosing `Tools > GDX Diff` from the menu or through the context menu off a GDX file in the Project Explorer.
  - Allow to open OS specific terminal in current working directory (`Tools > Terminal`) or in working directory of a specific group (using the context menu in the Project Explorer)
    * Note: This feature does not work on all Linux distributions, e.g., Ubuntu, yet.
  - Added basic integration of GAMS MIRO.
    * Note: This requires a separate installation of the GAMS MIRO package.
  - Improved GDX Viewer layout to optimize used screen space.
  - Adjusted layout of Reference File Viewer.
  - Added clear button to filter input field in GDX Viewer and Reference File Viewer.
3.13.1.7 Object Oriented APIs

3.13.1.7.1 C++

- We plan to drop support for Microsoft Visual Studio 2013 and maybe also 2015 with the next major release.

3.13.1.7.2 Python

- Added support for Python 3.8.
- As announced, dropped support for Python 3.4.

3.13.1.8 Expert Level APIs

- Added support for Python 3.8.
- As announced, dropped support for Python 3.4.

3.13.1.9 Model Libraries

3.13.1.9.1 GAMS Data Library  New models:

- pickstock.gms: Stock selection problem with MIRO (133)
- transport.gms: Classical transportation problem with MIRO (134)

3.13.1.9.2 GAMS Test Library  New models:

- embpy05.gms: Test merge/replace when loading data from embedded code (804)
- embpy06.gms: Test domain check/filtered when loading data from embedded code (805)
- load12.gms: Tests filtered load (806)
- idc01.gms: Implicit Data Contract Test (807)
- gurobi05.gms: GUROBI test suite - general constraints sin/cos (808)
- studio01.gms: Test Studio Startup (809)

3.13.2 30.2.0 Minor release (February 07, 2020)

3.13.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Iswar Radhakrishnan, Simon Scolan, and Kirk Yost.

3.13.2.2 GAMS System

3.13.2.2.1 GAMS

- Fixed a problem when writing implicit data contract in JSON format (IDCGenerateJSON) with symbols that use a set more than once in its domain.
- Fixed a potential wrong domain violation error for symbols declared under $onExternalInput.
- Fixed gamsinst and the IDE to give better messages in case a license file is absent.
- GAMS incorrectly removed indexed semi-integer and semi-continuous variables that have been fixed at a level other than zero with holdFixed set to 1. This has been fixed.
- GAMS also removes scalar semi-integer and semi-continuous variables now, when they have been fixed at zero with holdFixed set to 1.
- Fixed an issue where protected symbols could be changed using certain option statements.
- Added new command line parameter IDCProtect to control assignment behavior of external input symbols at execution time: 0 allows assignment, 1 (default) protects external input symbols from being changed.
- Adjusted reading of GAMS command-line arguments on non-Windows platforms to allow for empty arguments and arguments with preceding and trailing blanks. Windows users will not be affected by this change, nor will users who do not use quotes to protect arguments. But these invocations will now work differently on Unix, and will give the same result as on Windows:
  - `gams main.gms --myPrefix "" user1 " four blanks here "`
  - `$call gams subjob.gms --cityA Tokyo --cityB ""`

3.13.2.3 Solvers

3.13.2.3.1 CONOPT

- New library 4.17 with bug fixes.
  - Fixed a problem where small infeasibilities were not correctly reported back to GAMS.
3.13.2.3.2 DICOPT

- Fixed a possible crash during exit when having used Ipopt as NLP solver.

3.13.2.3.3 GUROBI

- New libraries 9.0.1.
- Fixed a problem with tuning of lp/mps files. In contrast to the documentation, the tuning suite contained the model generated by GAMS when providing a list of models in lp/mps files to tune.
- Made value 3 available for Gurobi option `scaleFlag`, available since Gurobi 7.5.

3.13.2.3.4 MOSEK

- New libraries 9.1.11.

3.13.2.3.5 PATH

- New library 5.0.02.
  - Fix to two preprocessor issues: wrong solutions were being returned.

3.13.2.4 Tools

3.13.2.4.1 GAMS Studio

- New version 0.14.3.
  - Stability improvements.
  - New icon design.
  - Added filter facility for value columns in GDX Viewer.

3.13.3 30.3.0 Minor release (March 06, 2020)

3.13.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Andres J. Calderon, Antti Lehtila, Grégoire Pichenot, and Karlo Šepetanc.
3.13.3.2 GAMS System

3.13.3.2.1 GAMS

- Allow to create a secure work file on any platform for any target license platform.
- Fixed a bug which could have caused wrong domain violation errors with $\text{offEmbeddedCode}$.
- Symbols set in embedded Python code via the GAMS Python object oriented API (i.e. \texttt{gams.db[sym]}) were imported with \texttt{MergeType} ”replace” and \texttt{DomainCheckType} ”filtered”. This has been adjusted to both \texttt{MergeType} and \texttt{DomainCheckType} set to ”default”.
- Fixed a problem which was introduced with GAMS 30.1: The default for $\text{on}_\text{Filtered}$ should always be $\text{on}_\text{Filtered}$. This was not the case when restarting from an old work file.

3.13.3.3 Solvers

3.13.3.3.1 Antigone, Bonmin, Cbc, Couenne, Ipopt, SCIP

- The number of threads as specified by option \texttt{threads} was disregarded. This has been fixed.

3.13.3.3.2 CONOPT

- New library 4.18 with bug fixes.
- The degeneracy-breaking logic has been improved for numerically difficult models and the interaction between defined variables and initialized variables has been improved.

3.13.3.3.3 JAMS/LogMIP

- The maximum length of the directory name plus file name that GAMS can execute is 255. JAMS and LogMIP stopped working earlier. This has been fixed.

3.13.3.3.4 LocalSolver

- Added missing \texttt{lskeygen} tool for Linux system.

3.13.3.3.5 MOSEK

3.13.3.4 Tools

3.13.3.4.1 GAMS Studio

- New version 0.14.4.
  - Stability improvements.
  - Introduced Dark Mode support for macOS.
3.14 29 Distribution

3.14.1 29.1.0 Major release (November 15, 2019)

3.14.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, David Bernal Neira, Erwin Kalvelagen, and Scolan Simon.

3.14.1.2 Platforms

- As announced, dropped support for Mac OS X 10.12 (Sierra).
- After more than 20 years we plan to drop support for 32-bit MS Windows with the next major release. Some components, e.g., GAMS IDE and gdxxrw, will remain 32-bit executables in the 64-bit MS Windows GAMS distribution.
- We plan to drop support for MS Windows 7 with the next major release.

3.14.1.3 GAMS System

3.14.1.3.1 GAMS

- Extended the GAMS log to print out the Double Dash Parameters set in addition to the non-default Command Line Parameters.
- Added dollar control option $setDDList.Cont to allow to define a list of double dash parameters to be checked over multiple lines.
- Added new ways to execute external programs which implicitly check the errorLevel returned and raise a compilation or execution error if it is not zero, namely $call.checkErrorLevel, $hiddencall.checkErrorLevel, exec.execute.checkErrorLevel, put_utility exec.checkErrorLevel and put_utility shell.checkErrorLevel. This behavior can also be triggered without using the checkErrLevel suffix by setting $onCheckErrorLevel and checkErrorLevel, respectively.
- Added command line option captureModelInstance to capture all model instances generated and solved by a solve statement during a GAMS run.
- Allow to declare a parameter as table without entering data.
- Added new Dollar Control Options eval.Set, evalGlobal.Set, and evalLocal.Set to define a compile-time variable based on the content of a GAMS set.
- Removed limit of 10,000 columns in table declaration.
- Changed trace record fields of quadratic model types from historic to today's names (QP --> QCP, QMIP --> MIQCP, RQMIP --> RMIQCP).
- The gams.exe and gamskeep.exe programs on 64-bit Windows are now native 64-bit executables. Because of some technical requirements related to the Interrupt functionality, the IDE invokes GAMS via the new 32-bit program gams32.exe.
- Fixed wrong return string for %gams.action%.
- Fixed a problem with interval evaluation for Extrinsic Functions.
- Fixed a problem with GAMS parameter scriptExit when running from the object-oriented APIs, GAMS Studio, or GAMS IDE.
- Fixed a problem with trace record field ETSolve which reported NA always.
- Fixed a problem with potentially wrong explanatory text when implicit sets are loaded using $load.
3.14.1.3.2 Installer

- The DMG installer for Mac OS X has been reorganized and is now notarized, so that it should work on Mac OS X 10.15.
- The selfextracting archive for Mac OS X is now a 64-bit application.

3.14.1.4 Solvers

3.14.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2019.5 on Linux and Mac OS X.
- Updated Intel MKL libraries to version 2018.4 on Windows 64-bit again.

3.14.1.4.2 CBC

- New libraries.

3.14.1.4.3 CONOPT

- New library 4.15 with bug fixes.
- Option DF Method has been replaced by the options Tol_Def_Mult and Tol_Def_Init.

3.14.1.4.4 Convert

- Fixed a bug that caused a crash with option nlp2mcp selected.

3.14.1.4.5 DICOPT

- Fixed so called "integer cuts" when both binary and integer variables are present. DICOPT generated two integer cuts in this case, one that excluded the current values of binary variables and another one that excluded the current values of integer values. Now a single combined cut is generated, which allows that the values of the binary variables can repeat if the values of the integer values change and vice versa.
- Setting option weight to a value larger $10^{20}$ now disables the augmented penalty relaxation, that is, linearizations of nonlinear equations are added as hard constraints to the MIP relaxation instead of soft constraints.
- Enabling option convex now changes the default for option weight to maxdouble.

3.14.1.4.6 Examiner

- Added option objvarAutoAdjust to adjust objective variable to make objective equation feasible for models that allow objective reformulation.
3.14.1.4.7 Lindo/LindoGlobal

- New libraries 12.0.169.
- Added support for function `signPower`.

3.14.1.4.8 LocalSolver

- New libraries 9.0 (20191004) for Linux, Mac OS X, and 64-bit Windows.
  - Performance improvements on packing, routing, and scheduling problems as well as on nonlinear continuous problems.

3.14.1.4.9 LGO

- Fixed a bug in the computation of the best feasible solution - an uninitialized variable was used.

3.14.1.4.10 MOSEK

- New libraries 9.1.1.
- Correct rejection of problems with non-quadratic nonlinear objective function when constraints are linear.

3.14.1.4.11 SoPlex

- New libraries 4.0 (083219e0).

3.14.1.4.12 SCIP

- New libraries 6.0 (a15f6c41).

3.14.1.5 Tools

3.14.1.5.1 GAMS Studio

- New version 0.13.2
  - Stability and performance improvements.
  - Allow to adjust the numerical precision in the GDX Viewer.
  - Added dialog to create/update license file (pops up when a license is in the user's clipboard and "About GAMS" is opened).
  - Added full screen mode (shortcut on Windows and Linux: ALT+Return, shortcut on Mac OS X: META+CMD+F).
  - Added auto-resizing of columns when opening the Reference File Viewer.
  - Reworked process log to better handle long and fast output.
  - Improved behavior of F1 (Help) Key: Studio now opens widget specific help if available.
  - Renamed "Output View" to "Process Log".
- Added a tutorial about the usage of GAMS Studio to the documentation.
- As announced, dropped Studio for 32-bit Windows.
3.14.1.6 Object Oriented APIs

3.14.1.6.1 Python

- Added support for Python 3.7 on Windows 64-bit, Linux, and Mac OS X.
- We plan to drop support for Python 3.4 with the next major release.
- Support for Python 2.7 officially stops January 1, 2020. We plan to drop support for Python 2.7 with some future release. If you rely heavily on the availability and support of the GAMS API for Python 2.7 please contact support@gams.com to discuss your options.

3.14.1.6.2 Java

- Increase the minimum version requirement of the Java Runtime Environment to Java SE 8.
- The remove operation GAMSDatabaseIterator.remove is no longer supported. The method now throws an instance of java.lang.UnsupportedOperationException and performs no other actions. (To remove all records of the current iterating symbol, use the method GAMSSymbol.clear instead.)
- Fixed the behavior of the remove operation GAMSSymbolIterator.remove. The method now removes all records of the last GAMSSymbol element returned by an instance of GAMSSymbolIterator and can be called only once per call to GAMSSymbolIterator.next. The behavior of an iterator is unspecified if the underlying collection is modified while iterating.

3.14.1.7 Expert Level APIs

- Added support for Python 3.7 on Windows 64-bit, Linux, and Mac OS X.
- We plan to drop support for Python 3.4 with the next major release.
- We plan to drop support for Python 2.7 with some future release.

3.14.1.8 Model Libraries

3.14.1.8.1 GAMS Model Library

- Added inscribedsquare.gms: Inscribed Square Problem.

3.14.1.8.2 GAMS Test Library

- Extrinsic function test models: Upgraded query-library generation code ql.py to Python 3. The default for property "description" has been changed to be an empty string.

3.15 28 Distribution

3.15.1 28.1.0 Major release (August 02, 2019)

3.15.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Johan Löfberg, Hans Mittelmann, and José Luis Vilar Zanón.

3.15.1.2 Platforms

- We plan to drop support for Mac OS X 10.12 (Sierra) with the next GAMS major release.

3.15.1.3 GAMS System

3.15.1.3.1 GAMS

- Added new dollar control option $\text{scratchFileName}$.
- Fixed a bug which caused a problem when unloading a multi-dimensional Alias at compile-time.

3.15.1.3.2 Documentation

- Improved ranking of results in offline search by minimizing the effect of the length of a document on the importance of a search term in that document.
- When searching the index, only relevant results are shown for subcategories as well.
- The full-text search now shows also results for a search in the index.

3.15.1.4 Solvers

3.15.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Downgraded Intel MKL libraries to version 2018.3 on Windows 64-bit.

3.15.1.4.2 ANTIGONE

- The timelimit is now applied to the wallclock time and wallclock time is reported in the log and back to GAMS.
3.15.1.4.3 BARON

- New libraries 19.7.13.
  - New relaxations and branching rules for nonconvex mixed-integer quadratic programs, leading to significant speedups for this class of problems.
  - Increased robustness in various range reduction routines.
  - Increased solvability of large-scale problems by BARON’s cut generators.
  - Enhanced convexity recognition routines.
  - Updated to IPOPT 3.12.13 and CBC 2.10.1.
- Fixed passing constant equations to BARON.

3.15.1.4.4 CBC

- Revised solver options.
  - Updated the documentation and possible values for many options, bringing them closer to the original Cbc option names and values.
  - The following options changed their type from boolean to string: crossover, cutoffConstraint, combineSolutions, Dins, DivingRandom, DivingCoefficient, DivingFractional, DivingGuided, DivingLineSearch, DivingPseudoCost, DivingVectorLength, feasPump, naiveHeuristics, pivotAndFix, randomizedRounding, Rens, Rins, roundingHeuristic, proximitySearch, presolve
  - For options dualPivot, primalPivot, and scaling value "auto" has been renamed to "automatic".
  - For option costStrategy, values "binaryfirst" and "binarylast" have been renamed to "01first" and "01last", respectively.
  - The following options have been added: factorization, denseThreshold, smallFactorization, sparseFactor, biasLU, psi, substitution, primalWeight, autoScale, bscale, gamma, KKT, expensiveStrong, OrbitalBranching, infeasibilityWeight, fixOnDj, sosPrioritize, cutLength, lagomoryCuts, latwomirCuts, hOptions, combine2Solutions, diveSolves, feasPump_artcost, feasPump_trachab, feasPump_cutoff, feasPump_increment, dwHeuristic, pivotAndComplement, VndVariableNeighborhoodSearch

3.15.1.4.5 CONOPT

- CONOPT3 accepts models with empty rows. The GAMS/CONOPT3 link sets the hidden option LSAZRW to true.

3.15.1.4.6 Convert

- Replaced the OSiL writer. The new writer supports more GAMS intrinsic functions and produces slightly smaller OSiL files with more compact expression trees.

3.15.1.4.7 IPOPT

- Fixed handling of Ipopt's feasible-point-found status.
3.15.1.4.8 LocalSolver

- Added option logfreq.

3.15.1.4.9 MOSEK

- New libraries 9.0.98.
  - Introduced the power and exponential cones, see also Conic Programming.
  - As announced, the optimizer for general convex nonlinear problems has been removed. Thus, solving a NLP, DNLP, MINLP, or RMINLP for which a conic reformulation is not recognized will now result in a missing capability solver status with GAMS/Mosek.
  - Improved presolve for particular conic problems.
  - Tighten the stopping criteria when solving conic optimization problems: Changed default of MSK_DPAR_INTPNT_CO_TOL_INFEAS from 1e-10 to 1e-12, of MSK_DPAR_INTPNT_CO_TOL_REL_GAP from 1e-7 to 1e-8, and of MSK_DPAR_INTPNT_QO_TOL_INFEAS from 1e-10 to 1e-12. However, note that one can let Mosek relax feasibility and optimality tolerances if it cannot make sufficient progress, see MSK_DPAR_INTPNT_CO_TOL_NEAR_REL and MSK_DPAR_INTPNT_QO_TOL_NEAR_REL.
  - Changed scaling of interior-point optimizer so better accuracy is obtained in some cases.
  - Introduced an outer approximation method for solving conic mixed integer optimization problems. This can be enabled with the parameter MSK_IPAR_MIO_CONIC OUTER APPROXIMATION.
  - Much improved performance on recent AMD CPUs. For linear algebra, the BLIS library is employed when run on AMD CPUs.
  - Better performance on CPUs that support AVX-512 instructions.
  - Removed parameters: MSK_DPAR_DATA_TOL_AIJ, MSK_DPAR_INTPNT_NL_*
  - Further new parameters: MSK_IPAR_PRESOLVE_MAX_NUM_PASS, MSK_IPAR_PRESOLVE_MAX_NUM_PREP, MSK_IPAR_SIM_SEED, MSK_IPAR_INTPNT_ORDER_GP_NUM_SEEDS, MSK_IPAR_MIO_MAX_NUM_ROOT, MSK_IPAR_MIO_PROPAGATE_OBJECTIVE_CONSTRAINT, MSK_IPAR_MIO_SEED, MSK_IPAR_MIO_FEASPUMP_LEVEL, MSK_IPAR_WRITE_COMPRESSION, MSK_IPAR_OPF_WRITE_LP, MSK_IPAR_PTF_WRITE_TRANSFORM
  - Changed default of MSK_DPAR_MIO_TOL_ABS_GAP from 0 to value of GAMS option OptCA (was used for MSK_DPAR_MIO_NEAR_TOL_ABS_GAP before) and of MSK_DPAR_MIO_TOL_REL_GAP from 0 to value of GAMS option OptCR (was used for MSK_DPAR_MIO_NEAR_TOL_REL_GAP before).

- Fixed handling of Mosek certificates for primal and dual infeasibility, see Infeasible/Unbounded Models.

3.15.1.4.10 SCIP

- New libraries 6.0 (f79421d).
3.15.1.5 Tools

3.15.1.5.1 GAMS Studio

- New version 0.12.3.
  - Stability and performance improvements.
  - Added GAMS Solver Option Editor to view and edit a solver-specific option file.
  - Renamed Option Editor to Parameter Editor to better distinguish solver options and GAMS parameters.
  - Added menu entry GAMS -> Delete scratch directories to delete all scratch directories in current working directory. A similar dialog will also be triggered if GAMS returns 110 (“Too many scratch directories”).
  - Added file associations and icons for .gms and .gdx files on Mac OS X.
  - Changed shortcut to focus Main widget from Ctrl+H to CTRL+E (there was a collision on Mac OS X).
  - Improved keyboard navigation between files and widgets.
- We plan to drop Studio for 32 bit Windows with the next major release.

3.15.1.6 APIs

- As announced, dropped support for Python 2.6.
- We plan to increase the minimum version requirement of the Java Runtime Environment to Java SE 8 with the next major release.

3.15.1.7 Model Libraries

3.15.1.7.1 GAMS Model Library

- Changed model sigma in immun to minimize standard-deviation instead of variance.
- Added missing nonnegativity requirement on variables in model wall.

3.15.2 28.2.0 Minor release (August 19, 2019)

3.15.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Nayee Chowdhury, Salvador Doménech Martínez, Michael Ferris, Antti Lehtila, Evangelos Panos, Jochen Uhrich, and Alexey Ziuzin.
3.15.2.2 GAMS System

3.15.2.2.1 GAMS

- Setting $\text{onMultiR}$ allows the redefinition of macros as well now.
- Fixed a problem finding the Python interpreter, that comes with GAMS, in certain cases.
- Fixed a bug in the model generation, which could have caused a crash or wrong results in some cases.

3.15.2.3 Solvers

3.15.2.3.1 CPLEXD

- Corrected reporting of solution for (MI)QCP problems when using feasopt.
- CplexD now reports the objective of the feasible relaxation in the solution summary when using feasopt.

3.15.2.4 Tools

3.15.2.4.1 GAMS Studio

- New version 0.12.4
  - Stability and performance improvements.
  - Improved robustness of glb file parser (see User Libraries).
  - Added "What's new" menu entry to show latest changes of Studio.

3.15.2.5 Object Oriented APIs

- Fixed a problem, where GAMSDatabase.Export triggered an exception because of domain violations, even if only relaxed domains were used.

3.15.2.5.1 Java

- Added new method GAMSSymbolRecord.dispose for on-demand release of external resources hold by non-java library.

3.16 27 Distribution

3.16.1 27.1.0 Major release (April 24, 2019)

3.16.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Arne Drud, Jan-Erik Justkowiak, Renger van Nieuwkoop, and Manuel Wetzel.
3.16.1.2 Platforms

- As announced, support for Mac OS X 10.11 (El Capitan) has been dropped.
- As announced, support for Windows Vista has been dropped.

3.16.1.3 GAMS System

3.16.1.3.1 GAMS

- **Embedded Python Code:**
  - Allow Implicit Set Definition (or: Domain Defining Symbol Declarations) now for symbols loaded from embedded code as well.
  - Changed the default behavior of $offEmbeddedCode and endEmbeddedCode: Previously, internal resources got freed and with the next start of an embedded Python code section, the Python environment had to be reinitialized. This is not the case anymore. Also, the interpreter stays "alive" now, which allows to access Python symbols defined in one embedded code block in a following block. The old behavior could still be activated by setting the new command line parameter freeEmbeddedPython to 1.
  - Changed the optional boolean argument merge to an enumerated option mergeType in the gams.set method in embedded code. This might break existing code. Even if the merge argument was not used, the default behavior at compile time changes. In previous versions the content of an already defined symbol was quietly replaced while GAMS now triggers a compilation error 194 Symbol redefined.
  - Fixed a bug in embedded code when setting pySetup to 0. Additional steps are required on Linux and Mac OS X to use an alternative Python installation. Details can be found in section Porting to a Different Version of Python.
  - A GAMSDatabase created in embedded code via gams.ws.add_database(source_database = gams.db) had all the symbols but no data. This has been fixed.
  - gams.db.export(file_name) in embedded code resulted in an error for scalar symbols without data. This has been fixed.
  - Fixed a problem with embeddedCode/continueEmbeddedCode after an assignment that was not finished with a ; like in this example:
    ```plaintext
    Set i /1*3/;
    Parameter xl(i);
    xl(i) = uniform(0.5,1)
    embeddedCode Python:
    print(list(gams.get('xl')))
    endEmbeddedCode
    Display xl;
    ```
    This leads to an error now. In the past, the assignment in line 3 was executed after the embeddedCode block leading to unexpected results.

- Extended the GAMS log to print out the non-default Command Line Parameters.

- Improved performance of execute/unload when option gdxUELs is set to full.

- Improve performance of model generation when multi-dimensional variables are used, where the controlling set for dimension n>1 is big, e.g.:

  ```plaintext
  Set tiny /1*2/, huge /1*100000/ ;
  Variable x(i,j); Equation e;
  ...
  e.. sum((tiny,huge), x(tiny,huge)) =e= 42;
  ```
• Fixed a potential crash when more than 250 million labels are used in one model.
• Fixed a bug with Implicit Set Definition: When used with $onMulti to merge data into a non-empty set, it could have happened that an element was added twice in some cases.
• Fixed a bug causing a broken dump file if $onVerbatim and $ifThen was used with DumpOpt.

3.16.1.3.2 Documentation
• Added documentation for the put utility keyword assignText (which has been in the system since 24.6).

3.16.1.3.3 GDX library
• Improve the behavior of GDX when handling large data sets (e.g. writing a set with 210 million elements, each having its own lengthy set text). Performance is better - less memory and less time are required. The limits on the amount of data that can be handled have been extended somewhat, and when these limits are reached this is handled more gracefully than previously - with a helpful message instead of a segmentation fault or erroneous results.
• Introduce consistent handling of the empty string vis-a-vis set text for UELs. This is only relevant for user applications that use the low-level GDX API in an unsupported way.
  − Previously the proper usage was to avoid adding the empty string to the list of set text strings. Applications that broke this rule would produce a GDX file with an abnormal internal structure. This structure may lead to jumbled set text.
  − With the updated GDX, it is not necessary to avoid adding an empty string to the set text list.
  − Applications holding to previous proper usage (i.e. those that avoid adding the empty string to the list of set text strings) will produce good GDX files regardless of GAMS version, and these files will behave as expected regardless of the GAMS version in which they are used.

3.16.1.4 Solvers
3.16.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP
• Updated Intel MKL libraries to version 2019.3 on Linux and Mac OS X and to 2018.4 on Windows 64-bit.

3.16.1.4.2 BARON
• New libraries 19.3.24.
  − Improved automatic differentiator that is up to two orders of magnitude faster for large-scale problems.
  − Improved data structures and cut pool manager to reduce memory footprint and time requirements for large-scale problems.
  − Improvements in various components, including parallel threads and BARON's IPOPT interface for Mac OS X.
  − New tree management algorithms.
  − Improved range reduction and probing algorithms.
  − Using Intel MKL for faster BLAS and LAPACK routines.
  − Ipopt now uses METIS for linear system partitioning.
  − New option FirstLoc to terminate BARON as soon as a local optimum is found.
• New option ClockType to determine whether wall-clock or CPU time should be reported back to GAMS.
3.16.1.4.3 BDMLP and SBB

- The definition of SOS1 and SOS2 variables has changed. BDMLP and SBB used to count the number of elements in a set that are off the lower bound. BDMLP and SBB were the only two solvers in the GAMS solver portfolio with this definition. All other solvers counted elements that are off zero. The definition of SOS1 and SOS2 variables in BDMLP and SBB has been changed to the off zero definition to make their behavior more consistent with other GAMS solvers.

3.16.1.4.4 CBC

- New libraries 2.10.
  - Improved handling of SOS, starting point, and symmetries.
  - Improved performance of primal heuristics regarding the handling of implicit integer variables.
  - Mini-B&B is now disabled when solving with multiple threads.
  - Changed default value for zero half cuts parameter from off to ifmove.

3.16.1.4.5 CONOPT 4

- New library 4.11 with improvements in reliability and efficiency for large and difficult models.
- New option Tol_Opt_LinF: Optimality tolerance when infeasible in Linear Feasibility Model.

3.16.1.4.6 CPLEX/CPLEXD

- New libraries 12.9.0.
  - New options: CPLEXfolding, CPLEXwriteprob (CplexD only), CPLEXwarninglimit.
  - New hierarchical multi-objective optimization (CplexD only): CPLEXmultobj, CPLEXmultobjmethod, CPLEXobjnabstol, CPLEXobjnreltol.
  - The symmetry breaking parameter CPLEXsymmetry now applies only to MIP models. Use the new CPLEXfolding parameter for LP models.

3.16.1.4.7 GUROBI

- New libraries 8.1.1.

3.16.1.4.8 JAMS

- Experimental indexed EMP syntax has been updated: It can now take all the equilibrium related keywords (max, min, vi, qvi, dualvar, visol, and implicit) and shared constraints and variables.

3.16.1.4.9 LocalSolver

- New libraries 8.5 (20190130).
  - Strong lower bounds based on nonlinear relaxation techniques coupled with innovative branch-and-bound heuristics.
3.16.1.4.10 Mosek

- New libraries 8.1.0.80.

3.16.1.4.11 ODHCPLEX

- New libraries 4.23.

3.16.1.4.12 OQNLP

- As announced, OQNLP has been dropped.

3.16.1.5 Tools

3.16.1.5.1 CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.
- New library 6.2.0 on Mac OS X.

3.16.1.5.2 GAMS Studio

- New version 0.11.1.
  - Stability and performance improvements.
  - Introduced a toolbar to replace the "Execution and Option Parameter Editor".
  - Editor
    * Improved the syntax highlighting.
    * Allow to open huge read-only (lst) files without significant memory requirement.
    * Added bookmark support.
    * Added Ctrl+Up/Ctrl+Down as shortcut for line wise scrolling without moving the text cursor.
    * Added Ctrl+Home/Ctrl+End as shortcut for page wise scrolling without moving the text cursor.
    * Added warning pop-up when trying to open a >50 Mb file in edit mode.
  - Various
    * Added Ctrl+Alt+L to extend/collapse the extended option editor
  - Forced light application theme on Mac OS X to circumvent problems using the Dark Mode of Mac OS X Mojave.

3.16.1.5.3 GDXDUMP

- New command line option setText to show the list of set text stored in a GDX file.
- Option symbols now lists the cardinality of a symbol in the column Records.
3.16.1.5.4 GDXXRW

- Fixed exit behavior if there were some duplicate records found when reading a symbol but less than specified by `maxDupeErrors`. If there are no other errors the exit code is 0 now (it was 16 in the past).

3.16.1.5.5 GMSZIP/GMSUNZIP

- Replaced the 32bit binaries `gmszip` and `gmsunzip` by more recent 64bit versions on Mac OS X.

3.16.1.5.6 MPS2GMS

- Turn some errors that can be safely ignored when reading an MPS file into warnings.

3.16.1.6 Object Oriented APIs

3.16.1.6.1 Python

- Fixed a bug with default variable levels being 1.0 instead of 0.0.

3.16.1.7 Model Libraries

3.16.1.7.1 GAMS Data Library

- `GDX2ACCESSExample1.gms` : Dumping the Contents of `transport.gdx` (125)
- `GDX2ACCESSExample2.gms` : Writing Explanatory Text to Database (126)
- `GDX2ACCESSExample3.gms` : Dumping a large Table to Database (127)
- `GDX2ACCESSExample4.gms` : Special Value Mapping (128)
- `GDX2ACCESSExample5.gms` : Renaming Fields (129)

3.16.1.7.2 GAMS Test Library

- `sosmiqcp01.gms` : SOS1 and SOS2 behavior - MIQCP (794)
- `sosmip01.gms` : SOS1 and SOS2 behavior - MIP (795)
- `sosminlp01.gms` : SOS1 and SOS2 behavior - MINLP (796)

3.16.1.8 Solver/Platform availability

3.16.2 27.2.0 Minor release (May 23, 2019)

3.16.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Michael Burkhhardt, and Karlo Šepetanc.

3.16.2.2 GAMS System

3.16.2.2.1 GAMS

- Fix problem with missing entries for scalar variables and equations in the index file for the GAMS Output in certain cases.

3.16.2.3 Solvers

3.16.2.3.1 CONOPT

- New library 3.17J.
- New library 4.12.

3.16.2.3.2 Lindo/LindoGlobal

- New libraries 12.0.157.

3.16.2.3.3 LOCALSOLVER

- New libraries 8.5 (20190430).

3.16.2.3.4 NLPEC

- Added new option parmFile to allow to point to additional options for the GAMS run of the scalar model produced by NLPEC.

3.16.2.3.5 ODHCPLEX

3.16.2.3.6 OSIXPRESS

- Fixed use of standalone Xpress license.
3.16 27 Distribution

3.16.2.4 Tools

3.16.2.4.1 GAMS Studio

- New version 0.11.2.
  - Stability and performance improvements.
  - GDX Viewer
    * Added Drag and Drop feature in GDX Table View

3.16.2.5 Object Oriented APIs

3.16.2.5.1 Python

- Fixed a memory leak in the Python 3 version of the API.
- We plan to drop support for Python 2.6 with the next major release.

3.16.2.6 Expert Level APIs

- Fixed a memory leak in the Python 3 version of the APIs.
- We plan to drop support for Python 2.6 with the next major release.

3.16.3 27.3.0 Minor release (July 04, 2019)

3.16.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Erwin Kalvelagen, Wolfgang Kuehn, Bruce McCarl, and Michael Winkler.

3.16.3.2 GAMS System

- Fixed a bug that resulted in undercounting the number of physical and logical processors on Windows systems with more than 64 logical processors. GAMS/Base and many solvers use this count, e.g. when setting threads to 0 or -1.

3.16.3.2.1 GAMS

- Allow domain projection with $load also if the source symbol is a variable or equation.
- Fixed the cause for an unwanted compilation error with embeddedCode in certain situations.
- Unified behavior of the profile option: In the past, the Profile Summary was always written, when the profiling was activated from the command line, but was sometimes omitted when set as an option. Now, the summary gets always written. It does not matter anymore, where profiling was activated.
3.16.3.2.2 Documentation

- Added a Preface that reflects the history of the GAMS documentation. In particular it points out
  the importance of external contributors, in particular Bruce McCarl.

3.16.3.3 Solvers

3.16.3.3.1 BARON

- Fixed load of Xpress library on Linux.

3.16.3.3.2 CBC

- New libraries.

3.16.3.3.3 CONOPT

- New library 3.17K.
- Bug fix in library 4.12.

3.16.3.3.4 GAMSCHK

- Fixed error in postopt report. Previously, the report for the column occurring last in the listing file
  would be omitted, and all its entries would appear in the report for the preceding column.
- Fixed crash that occurred in some cases.
- The above problems occurred in GAMS 26 and previous. A fix was introduced with GAMS 27, but
  this fix went too far and introduced new problems. With this version, the fix to 27.1 is reverted and
  a more moderate fix is used instead.

3.16.3.3.5 LocalSolver

- Fixed missing solver log.

3.16.3.3.6 Mosek

- New libraries 8.1.0.81.
- Fixed ignoring option solvefinal.

3.16.3.3.7 SCIP

- New libraries 6.0.2.
3.16.3.3.8 SoPlex

- New libraries 4.0.2.

3.16.3.4 Tools

3.16.3.4.1 GAMS Studio

- New version 0.11.5
  - Stability and performance improvements.
  - Added buttons to toolbar to show/hide Project Explorer, Output-, and Help widget.
  - Added shortcut Ctrl+H to focus Main widget.
  - Added shortcut Ctrl+Shift+G to focus Output widget.
  - Added shortcut Esc to close several widgets.
  - GDX Viewer:
    * Columns in the data view are now resized to the minimum width necessary to see all the data automatically.
    * Added shortcut to auto-resize all columns in the data view after the width was changed by hand (Ctrl+R).
  - Search:
    * Added shortcut Ctrl+Enter for "Search All".
    * Added ability to replace in more than one file at a time.
    * Find Next/Previous now respects all search options and will jump to the next file if there are also matches.

3.16.3.5 Object Oriented APIs

3.16.3.5.1 Python

- Fixed a bug in GamsJob.interrupt() that caused an OverflowError on 64 bit platforms.

3.17 26 Distribution

3.17.1 26.1.0 Major release (February 02, 2019)

3.17.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Stefano Alva, Adam Christensen, Hanna Donau, Stephen Frank, Anastasis Giannousakis, Jan-Erik Justkowiak, David Laudy, Andreas Lundell, Thomas Maindl, Nils Mattus, Scott McDonald, Noah Rhodes, Tom Rutherford, and Anna Straubinger.
3.17.1.2 Versioning

From this release on, we use a new interpretation on the GAMS version number scheme XX.Y.Z. XX alone now indicates the GAMS distribution number (was XX.Y before). Y is used to distinguish between beta, major, and minor releases of the XX distribution. Z is used to distinguish different maintenance releases. That is, we now use

- XX.0.Z for beta versions,
- XX.1.0 for the major release of distribution XX,
- XX.Y.0, Y > 1, for minor releases,
- XX.Y.Z, Y ≥ 1, Z > 0, for maintenance releases.

See Release Types regarding the meaning or what constitutes a major, minor, or maintenance release. As before, we increase the required license date for major releases only.

Further, we changed the default installation directory of the GAMS system from using only the distribution number to also include the minor version number. Thus, as before, GAMS is now installed into directory names which contain the XX.Y part of the GAMS version number.

3.17.1.3 Platforms

- We plan to drop support for Mac OS X 10.11 (El Capitan) with the next major release.
- We plan to drop support for Windows Vista with the next major release.
- Fixed problem using solvers with Fortran dependencies on a Mac OS X 10.11 system.

3.17.1.4 GAMS System

3.17.1.4.1 GAMS

- Changed behavior of $compress, $decompress, and $encrypt: source and target cannot be identical anymore; this could have lead to unreliable behavior in the past.
- Extended the influence of $onMulti: This affects the model statement as well now.
- Added new dollar control option $onMultiR, which is similar to $onMulti but replaces existing data instead of merging into it.
- Added put_utility keyword solver to select a solver for a given or all possible model types by name at execution time.
- Extended the syntax to allow Implicit Set Definition (or: Domain Defining Symbol Declarations). Here is a small example showing how this can be used:

```plaintext
Set
   i 'canning plants'
   j 'markets';

Table d(i<,j<) 'distance in thousands of miles'
          new-york chicago topeka
seattle    2.5    1.7    1.8
san-diego  2.5    1.8    1.4;

Display i,j;
```
And this is the result of the `Display` statement:

```plaintext
---- 10 SET i canning plants
    seattle , san-diego

---- 10 SET j markets
    new-york , chicago , topeka
```

- Updated the base module and components as necessary to allow for spaces in names of any files and directory used by GAMS, including the system directory, the working directory, the scratch directory, the process directory, and remove any checks warning about and preventing this. While the Windows system had already allowed spaces in previous versions, this change updates the other platforms to behave similarly.

- Changed the reading of command-line arguments on non-Windows platforms! This should only affect how arguments with spaces in them are passed on to GAMS. Previously, such arguments needed extra quoting or protection on non-Windows platforms. With this update, the extra protection is no longer needed: the same quoting of space-containing arguments can be used on all platforms. For example, with GAMS 25.1 and previous, two pairs of quotes were required on non-Windows platforms to protect spaces in an argument:

  ```plaintext
gams xx.gms --MY_GDX '"outer space"'
```

while now only one pair of quotes is needed on all platforms:

```plaintext
gams xx.gms --MY_GDX "outer space"
```

- Increased the number of labels, which can be handled by GAMS from 200 million to \(\sim 2.1\) billion and let GAMS terminate with the meaningful error message, if that limit is reached.

- Windows only: Fixed a bug which treated a path (e.g. to an input file or used as `inputDir`) as relative path, if it starts with `\/`. Example: When running `cd C:\tmp & gams.exe /data/myModel.gms`, GAMS tried to load the file `C:\tmp\data\myModel.gms` in the past. Now, it loads `C:\data\myModel.gms`.

- Fixed some problems with option `asyncSolLst`.

- Fixed a bug which could have caused GAMS to accept duplicate entries in a data statement, when they came in unsorted order.

- Fixed the dollar control option `$onUpper` (it did not do anything before).

### 3.17.1.4.2 GMSPython

- Updated `pip` to work with recent Mac OS X versions.

### 3.17.1.5 Solvers

#### 3.17.1.5.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Fixed an MKL error when running any of these solvers after CPLEX with `solvelink=5` in the same GAMS run on Linux.

- Updated Intel MKL libraries to version 2019.0 on Linux and to version 2018.3 on Windows 64-bit.
3.17.1.5.2 BARON

- New libraries 18.11.12 for 64-bit platforms.
  - New cutting planes for convex-transformable functions.
  - New cutting planes for polynomial optimization problems.
  - More robust treatment of cutting planes.
  - Improved optimality-based range reduction mechanisms.
  - CBC can now use multiple threads on Windows, too.
- We plan to drop BARON for Windows 32-bit with some future release.
- The solver time reported back to GAMS (resource usage) is now the wall clock time instead of the CPU time.

3.17.1.5.3 Bonmin, CBC, Couenne, Ipopt

- New libraries.

3.17.1.5.4 CONOPT 4

- New library 4.09 with many reliability improvements and a fix for wrong non-opt markers.

3.17.1.5.5 CPLEX

- Ctrl-C (or Interrupt) was broken for GAMS/CplexD. This has been fixed.
- Improved performance of retrieving the solution for a QCP with many quadratic rows.

3.17.1.5.6 Gurobi

- The solver time reported back to GAMS (resource usage) is now the wall clock time instead of the CPU time on Unix.
- Allow quadratic rows with =E= and let Gurobi deal with potential errors. Gurobi can sometimes substitute quadratic terms defined by =E= rows. The check of quadratic row to be either =L= or =G= in the GAMS/Gurobi link prevented this.

3.17.1.5.7 KESTREL

- Added support for MPSGE models.

3.17.1.5.8 Knitro

- New libraries 11.1.1 (11.0.1 for 32-bit Windows) containing several bug fixes and performance improvements, including:
  - improved performance on convex quadratic models,
  - improved generation of knapsack cuts, resulting in faster performance on some MINLP models,
  - improved performance when using the SQP algorithm,
  - new values for option linSolver to choose parallel factorization routines MA97 and MA86.
- Artelys has announced that Knitro 11.0 was the last Knitro release to support 32-bit Windows. We will be dropping GAMS/Knitro for 32-bit Windows in the near future.
3.17.1.5.9  **Lindo/LindoGlobal**

- New libraries 12.0.90.
  - LP Solver Improvements:
    - With new enhancements made to the simplex solvers, the average performance on large instances has increased by 18% for the primal simplex and 15% for the dual simplex compared to the previous version.
    - Improved performance on LP’s when using multiple cores with concurrent execution of Primal, Dual, and Barrier.
  - Quadratic and Nonlinear Solver Improvements:
    - Much faster handling of large quadratic matrices, e.g., 1000 x 1000.
  - Global Solver Improvements:
    - Improved handling of discontinuous functions, e.g., MOD(x,k), ROUND(x).

3.17.1.5.10  **LocalSolver**

- New libraries 8.0 (20181106).
  - Performance improvements on routing & scheduling problems, especially Pickup & Delivery problems.
  - Learning algorithms inside LocalSolver, which allow to automatically and dynamically tune up the search process for each solved instance, were improved. This leads to improved performances, especially for short resolution times (minutes).

3.17.1.5.11  **Mosek**

- New libraries 8.1.0.72.

3.17.1.5.12  **ODHCPLEX**

- New libraries 4.09 for Linux with many reliability improvements.
- New libraries 4.13 for Windows 64-bit with many reliability improvements and addressing dynamic loading in concurrent threads and processes.
- Updated options: *DynamicSearch*, *FirstFeas*, and *Strategy*

3.17.1.5.13  **OQNLP**

- We plan to drop OQNLP with the next major release.
3.17.1.5.14 PATH

- New libraries 5.0.00.
  - Fixed crash in Lemke's method that could happen for models with extremely poor scaling.
  - New capability to use alternate basis-handling packages via dynamic loading of shared libraries. Two alternate packages are currently supported:
    - BLU-LUSOL: Block LU updating using the LUSOL routines. The shared library required for this is included in the distribution.
    - UMFPACK: Tim Davis’ multifrontal LU factorization package. The shared library required for this is not included in the GAMS distribution, but can be downloaded from the SuiteSparse site. N.B.: We have verified UMFPACK on Linux, Mac OS X, and Windows using UMFPACK v5.7.7 from SuiteSparse 5.3.0.

3.17.1.5.15 SCIP

- New libraries 6.0.1.
  - Primal Heuristics
    * new diving heuristic farkasdiving that dives into the direction of the pseudosolution and tries to construct Farkas-proofs
    * new diving heuristic conflictdiving that considers locks from conflict constraints
    * performance improvements for Adaptive Large Neighborhood Search
      - changed default of parameter heuristics/alns/adjustminimprove from 1 to 0
      - changed default of parameter heuristics/alns/alpha from 0.2 to 0.0016
      - new parameter heuristics/alns/adjusttargetnodes
      - changed default of parameter heuristics/alns/eps from 0.5 to 0.468584
      - changed default of parameter heuristics/alns/gamma from 0.2 to 0.0704146
      - changed default of parameter heuristics/alns/minimprovehigh from 0.1 to 0.01
      - changed default of parameter heuristics/alns/minimprovevelow from 0.0001 to 0.01
      - removed parameter heuristics/alns/stallnodefactor
      - changed default of parameter heuristics/alns/startminimprove from 0.05 to 0.01
      - changed default of parameter heuristics/alns/targetnodefactor from 1.5 to 1.05
      - new parameter heuristics/alns/unfixtol
      - changed default of parameter heuristics/alns/crossover/minfixingrate from 0.4 to 0.3
      - changed default of parameter heuristics/alns/dins/maxfixingrate from 0.5 to 0.9
      - changed default of parameter heuristics/alns/dins/minfixingrate from 0.1 to 0.3
      - changed default of parameter heuristics/alns/localbranching/minfixingrate from 0 to 0.3
      - changed default of parameter heuristics/alns/mutation/minfixingrate from 0.4 to 0.3
      - changed default of parameter heuristics/alns/proximity/minfixingrate from 0 to 0.3
      - changed default of parameter heuristics/alns/rens/maxfixingrate from 0.7 to 0.9
      - changed default of parameter heuristics/alns/rins/maxfixingrate from 0.6 to 0.9
      - changed default of parameter heuristics/alns/rins/minfixingrate from 0.2 to 0.3
      - changed default of parameter heuristics/alns/zeroobjective/minfixingrate from 0 to 0.3
  - New branching rule lookahead that evaluates potential child and grandchild nodes to determine a branching decision
  - LP Solver Interface
    * lp/checkstability is now properly implemented for use with SoPlex
    * new parameter lp/alwaysgetduals
3.17.26 Distribution

- new parameter lp/checkfarkas
  - Separation (cutting planes)
    - cuts generated from certain quadratic constraints with convex feasible region are now global
    - new parameter separating/dircutoffdistfac
    - new parameter separating/efficacyfac
    - removed parameter separating/maxincrounds
    - new parameter separating/zerohalf/dircutoffdistweight
    - new parameter separating/zerohalf/efficacyweight
    - changed default of parameter separating/zerohalf/goodscore from 0.9 to 1
    - new parameter separating/zerohalf/goodmaxparall
    - new parameter separating/zerohalf/initseed
    - new parameter separating/zerohalf/maxparall
    - new parameter separating/zerohalf/objparalweight
  - Symmetry Handling
    - restructured timing of symmetry computation to allow to add symmetry handling components within presolving
    - changed default of parameter constraints/symresack/ppsymresack from 0 to 1
    - new parameter presolving/symbreak/addconsstming
    - changed default of parameter presolving/symbreak/detectorbitopes from 1 to 0
    - removed parameter "presolving/symmetry/computepresolved"
    - new parameter propagating/orbitalfixing/enabledafterrestarts
    - new parameter propagating/orbitalfixing/performpresolving
    - changed default of parameter propagating/orbitalfixing/presolpriority from 0 to -1000000
    - changed default of parameter propagating/orbitalfixing/presoltimeing from 28 to 16
    - new parameter propagating/orbitalfixing/symcomptiming
    - improved bound tightening for some quadratic equations
    - new parameter display/relevantstats
    - new parameter misc/scaleobj
    - removed implfree presolver
    - See also the full release notes and the release paper.

3.17.1.5.16 SELKIE  The SELKIE solver - new to GAMS with this release - is an EMP solver that implements decomposition methods for multi-agent equilibrium and related models.

3.17.1.5.17 SoPlex

- New libraries 4.0.1.
  - new simplifier step to perform variable aggregation for equations with two variables
  - new parameter bool:ensureray to re-solve the original problem in case of infeasibility/unboundedness to get a valid proof/ray
  - See also the full release notes and the release paper.
3.17.1.5.18 Xpress

• New libraries 33.01.10.
  – local symmetry re-detection in MIP tree search
  – improved branching for highly symmetric MIPs
  – new or improved cuts, degeneracy handling, crossover, preprocessing
  – FICO does not release patches for all platforms with each patch release, so some platforms lag behind the most-used ones.

3.17.1.6 Tools

3.17.1.6.1 CSDP

• See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.

3.17.1.6.2 CSV2GDX

• Extended recognition of special values:
  – N/A is recognized as NA,
  – TRUE is recognized as 1,
  – FALSE, NONE and NULL are recognized as 0.

• Added new option text to specify the column to get explanatory text from when reading a set.

• Changed handling of bad UELs: Reading a bad UEL (e.g. a UEL exceeding the maximum length) causes an error now. The old behavior can be enabled again using the new option acceptBadUels.

3.17.1.6.3 GAMS Studio

• New version 0.10.3
  – Stability and performance improvements.
  – Added a new section Comparing GAMS Studio and GAMSIDE to the documentation.
  – Added a Reference File Viewer to navigate the source code of GAMS models via a reference file, especially when multiple files are involved. A reference file contains all symbol references of GAMS models and is created using the reference parameter when running the model.
  – Added a Tab Browser to list and search through all open files. It is accessible with a button next to the main tab bar or via the shortcut Ctrl+K.
  – GDV Viewer :
    * Added a first, basic version of a Table View : The new button ”Table View” switches the view to a table based representation. The button is only enabled for multidimensional symbols and puts the last dimension into the header of the table. Drag and drop of items is not yet supported but will be in the future.
    * Added option to hide specific value columns for variables and equations.
    * Added support for the use of different encodings using the ”Edit->Encoding” menu. The default encoding for a GDX file generated in Studio by running a GMS file with automatic GDX creation (F10) is the one used by the GMS file.
  – Editor
* Added smart typing: Automatic insertion of closing character for brackets and quotes.
* Added ability to select text and press either a opening bracket or quote to surround text with these symbols.
* Improved backspace behavior, if auto indentation is active.

- Output Widget
  * Added info, warning, and error messages to GAMS Studio system log.
  * GAMS log files are now written to disk (can be disabled in settings).
  * Added "clear log" context menu entry.

- Project Explorer
  * Studio automatically adds all files specified through GAMS parameters (.gdx, .ref, .lst) to the Project Explorer.
  * Allow to rename Project Explorer groups.
  * Groups are closed if they are empty.
  * If a group is closed the associated GAMS process will be stopped.
  * Added drag and drop of files between groups.
  * Added shortcut to focus Project Explorer (Ctrl+J) and allow to navigate using arrow keys to select a file.
  * Added "Select all", "Expand all" and "Collapse all" to the context menu.
  * Added shortcut to select all files (Ctrl+A).

- Various
  * Added context menu for tabs (offering different close actions).
  * Added animation for groups with running GAMS processes.
  * Studio comes to foreground when double clicking a Studio-associated file.
  * The "About GAMS" dialog contains many important information like used GAMS version, system directory, or license information. It features a "Copy System Information" button which copies all of these information to easily attach them to a support request. The dialog has a second tab which gives an overview about solvers, their license status, and what kinds of capabilities they have.
  * "File -> New..." dialog starts with a default for a new file name.
  * "File -> Open..." (or drag'n'drop) of one file now focuses that file if it is already present in the Project Explorer.
  * New entry "File -> Open... in new group" to force creation of new group (even if the is already present in the Project Explorer).
  * "File -> Open..." (or drag'n'drop) of multiple files puts all files opened at once into a single group instead of individuals.
  * Added shortcut to focus command line parameter edit field (Ctrl+L).
  * Added Ctrl+F as close shortcut for search dialog.
  * Changed shortcut to open Settings dialog to F7.

Note
This version of GAMS Studio does not support the Dark Mode of MacOS Mojave. Please disable this mode to use GAMS Studio.

3.17.1.6.4 GDXDUMP

- New options for writing out special values: NAOut, UndfOut, PINfOut, MINfOut, and ZeroOut.
- Fixed broken generated GAMS code, if UelTable option was used, but there were no UELs.
- Lower and upper bounds of equations are dumped always now (even if their values are the default). This fixes a potential problem, that the equation type is unknown for the generated GAMS code.
- When writing CSV files the element text of set elements could not be written. Now with enabled option CSVSetText the element text of a set element is written as the last column in the CSV file.
3.17.1.6.5 GDXXRW

- Fixed a bug which could have caused a crash when reading merged cells from Excel using the GDXXRW options useRC and cMerge=1.

3.17.1.6.6 MODEL2TEX

- The new script `model2tex.sh` sets the required dependencies for the model2tex tool on Linux and Mac OS X. Using this script is the recommended way for using model2tex. Calling the Python script directly is not recommended anymore since the used Python interpreter would need to be configured manually. `model2tex.sh` uses the Python interpreter that comes with the GAMS distribution.

3.17.1.7 Object Oriented APIs

3.17.1.7.1 Python

- The `setup.py` script now installs the idx expert-level API.

3.17.1.8 Model Libraries

3.17.1.8.1 GAMS Data Library  New models added:

- `csv2gdx2.gms` : CSV2GDX Example 2 - Reading CSV Files with CSV2GDX (111)
- `csv2gdx3.gms` : CSV2GDX Example 3 - Reading Semicolon separated Data (112)
- `csv2gdx4.gms` : CSV2GDX Example 4 - Dealing with missing Labels and Duplicates (113)
- `csv2gdx5.gms` : CSV2GDX Example 5 - Reading more than one Parameter from a single Input File (114)
- `csv2gdx6.gms` : CSV2GDX Example 6 - Reading economic Data from the World Bank Data Catalog (115)
- `csv2gdx7.gms` : CSV2GDX Example 7 - Reading special Values with CSV2GDX (116)
- `csv2gdx8.gms` : CSV2GDX Example 8 - Reading an compressed encrypted Input File (117)
- `csv2gdx9.gms` : CSV2GDX Example 9 - Reading Options from an external File (118)
- `GDXXRWExample17.gms` : Reading several Scalars from Spreadsheet (119)
- `GDXXRWExample18.gms` : Reading Sets from Spreadsheet (120)
- `GDXXRWExample19.gms` : Writing Parameter to Spreadsheet including Zero Values (121)
- `GDXXRWExample20.gms` : Reading empty Cells with colMerge and reading merged Excel Ranges with cMerge (122)
- `GDXXRWExample21.gms` : Skipping empty Rows or Columns and Ignoring Rows or Columns (123)
- `GDXDUMPExample1.gms` : GDXDUMP - Adding double Quotes to an user defined Header when writing to CSV (124)
3.17.1.8.2 GAMS EMP Library  New model added:

- `emppython1.gms`: Three Simple EMP Models with Indexed EMP Syntax and Python Parser (104)

3.17.1.8.3 GAMS Test Library  New models added:

- `csv2gdx7.gms`: CSV2GDX - Checking the Error Messages for incorrect Parameter Input (752)
- `csv2gdx8.gms`: CSV2GDX - Testing the `valueDim` Option (753)
- `csv2gdx9.gms`: CSV2GDX - Testing the Field Separator Tab (754)
- `csv2gdx10.gms`: CSV2GDX - Testing the Field Separator Semicolon (755)
- `csv2gdx11.gms`: CSV2GDX - Testing the Field Separator Comma (756)
- `selkie01.gms`: SELKIE test suite (757)
- `selkie02.gms`: SELKIE test suite (758)
- `selkie03.gms`: SELKIE test suite (759)
- `selkie04.gms`: SELKIE test suite (760)
- `selkie05.gms`: SELKIE test suite (761)
- `selkie06.gms`: SELKIE test suite (762)
- `selkie07.gms`: SELKIE test suite (763)
- `selkie08.gms`: SELKIE test suite (764)
- `selkie09.gms`: SELKIE test suite (765)
- `selkie10.gms`: SELKIE test suite (766)
- `selkie11.gms`: SELKIE test suite (767)
- `selkie12.gms`: SELKIE test suite: sub-diagonalization (768)
- `selkie13.gms`: SELKIE test suite: dualvar (769)
- `selkie14.gms`: SELKIE test suite: isolated implicit variable (770)
- `selkie15.gms`: SELKIE test suite: proximal perturbation (771)
- `selkie16.gms`: SELKIE test suite: obj variable setting (772)
- `selkie17.gms`: SELKIE test suite: obj variable setting (773)
- `selkie18.gms`: SELKIE test suite: obj variable not free (774)
- `selkie19.gms`: SELKIE test suite: equation marginal values (775)
- `put12.gms`: Testing `put` utility solver (776)
- `gdxxrw8.gms`: GDXXRW - Testing the Option intAsText (777)
- `gdxxrw9.gms`: GDXXRW - Testing the Option checkDate (778)
- `gdxxrw10.gms`: GDXXRW - Testing cMerge when reading Sets with the values Option (779)
- `gdxxrw11.gms`: GDXXRW - Reading and writing special Values (780)
- gdxrwl2.gms: GDXXRW - Testing the skipEmpty and cMerge Option
- gdxrwl3.gms: GDXXRW - Testing the values Option when reading or writing Set Elements
- gdxrwl4.gms: GDXXRW - Testing different Excel Range Specifications
- gdxdump2.gms: GDXDUMP - Testing the dumping Functionality on several GDX Files
- gdxdump3.gms: GDXDUMP - Dumping special Values of a Parameter from GDX
- gdxdump4.gms: GDXDUMP - Dumping special Values of Variable-Subfields from GDX
- onmulti8.gms: Test for $onMultiR
- implset1.gms: Test for Implicit Set Definition
- emppy1.gms: Test an equilibrium model using emp python
- emppy2.gms: Formulate the simplevi.gms example using emp python
- emppy3.gms: Test a combination of optimization and vi agents using emp python
- miqcp04.gms: Test behavior for integer infeasible model
- duplic01.gms: Detecting duplicate entries in unsorted data

### 3.18 25.1 Distribution

#### 3.18.1 25.1.1 Major release (May 19, 2018)

#### 3.18.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Eden Huang, Katja Buhrkal Jensen, Jan-Erik Justkowiak, Erwin Kalvelagen, Marko Loparic, Bruce McCarl, Scott McDonald, Edmund Moshammer, Andres Ramos, Tom Rutherford, Wilfredo Sifuentes, and Tapio Westerlund.

#### 3.18.1.2 Platforms

- On Windows, some solvers in the GAMS distribution as well as GAMS Studio have dependencies on certain MS Visual C++ runtime libraries. Most of them are included in the GAMS distribution or are present on most Windows systems. However, we are aware that in rare cases, some libraries are missing. In such situations, we advise to run the appropriate installer for these libraries:
  - On a 32-bit GAMS version, execute `[GAMS system]\apifiles\C++\lib\vs2013\vcredist_x86.exe`, followed by `[GAMS system]\apifiles\C++\lib\vs2015\vcredist_x86.exe`.
  - On a 64-bit GAMS version, execute `[GAMS system]\apifiles\C++\lib\vs2017\vcredist_x64.exe`.

32.01 29.01
3.18.1.3 GAMS System

3.18.1.3.1 GAMS

- New conditional expressions to be used in conditional compilation, namely `gdxDimension`, `gdxEquType`, `gdxParType`, `gdxSetType`, `gdxSymExist`, `gdxVarType`, and `uelExist`. Details about these can be found [here](#).

- New command line option `LstTitleLeftAligned`: Write title of LST file left aligned.

- New command line option `ShowOSMemory`: Show the memory usage reported by the operating system (either resident set size or virtual set size) instead of the internal counting.

- GAMS throws now a compilation error if an unexpected suffix at a symbol is encountered in an option statement involving identifiers. In the past such suffixes were ignored, which could have given the impression that they were actually doing something. So, all the `.dim1` suffixes in the following example will create an error now:

```plaintext
Set i(*)
   j(*)
   ij(*,*) / i1.j1, i1.j2, i2.j1, i2.j2 /

Option i < ij.dim1;
Option i <= ij.dim1;

Set k / k1*k6 /;
Parameter ii(*) / i1 4, i2 5, i3 6 /
   iii(k,*)

Option iii > ii.dim1;
Option shuffle = ii.dim1;
```

- The details of the expansion of multi-line macros were changed with this release. In the past, trailing white space in the macro definition was always removed. Now, in multi-line macros, the white space before the continuation character `\` is preserved. This example demonstrates the difference:

```plaintext
$macro xAndY(x,y) x and \
   y
scalar x /1/;
if(xAndY(1,x), display 'true');
```

In the past, this caused a compilation error, since the macro was expanded to `if(1 and y, display 'true');` ("and" and "y" were concatenated to "andy"). Now that the white space after "and" is preserved, this does not cause a problem anymore.

- The statement `Alias (k,k);` for an unknown symbol `k` causes a compilation error now.

- In rare cases, embedded code recognized indented Python code incorrectly. This has been fixed.

- New property `gams.debug` for controlling debug information of the Object-oriented API in embedded code sections.

- Fixed a problem related to SSL support in `GMSPython` that prevented certain tools (e.g. pip) from working on Linux and Mac OS X.

- Models of type MCP can now be solved with modifiable parameters in the GUSS framework and as OO-API `GAMSModelInstance`. 
3.18.1.4 Solvers

3.18.1.4.1 BARON

- New libraries 18.5.8.
  - Updated to Ipopt 3.12.8 and CBC 2.9.9.
  - Replaced Ipopt's linear solver MUMPS by MA57 from HSL, a collection of Fortran codes for large-scale scientific computation. Thus, when using IPOPT as NLP solver, BARON may now be more robust and a little faster, especially for problems without integer variables.
  - New bounds reduction strategies based on optimality conditions can reduce the size of the branch-and-bound tree.
  - Rewrote core memory management routines for speed increase and memory reduction.
  - On some problems, BARON currently provides incorrect marginal values. This problem will be fixed in the near future.

- The use of Ipopt in BARON on MacOS X is no longer disabled by default.

- There will be no future updates of BARON for Windows 32-bit.

3.18.1.4.2 Bonmin(H), CBC, Couenne

- Wall-clock time is now always used to apply a timelimit to Branch-and-Bound. The nww option clocktype can be used to switch back to CPU time.

3.18.1.4.3 CONOPT

- New libraries 4.05 for CONOPT 4.
  - Improvements for multi-threading.

- New libraries for CONOPT 3.

- Fixed problems with redundancy in preprocessor and an issue related to system error 2024.

3.18.1.4.4 ConvertD

- Added options PermuteVars and PermuteEqus to permute the declaration of variables and equations, respectively, in scalar GAMS output.

- Tweaked printing of variable bounds and activity levels in scalar GAMS output.

- Fixed handling of infinite upper bounds for integer variables in scalar GAMS output: A line that sets GAMS option intvarup to 0 is now added to the output.

3.18.1.4.5 Couenne

- New libraries.
3.18.1.4.6 DICOPT

- Improvements to Feasibility Pump:
  - Fixed handling of nonlinear objective function when maximizing.
  - Fixed update of cutoff decrement after a solution with objective value very close to zero has been found.
  - Fixed translation of NLP projection problem optimal value to norm of associated projection. Changed default for option `fpprojzerotol` from 1e-6 to 1e-4.
  - Added creation of cuts derived from solution of NLP projection problem. Use option `fpprojcuts` to disable.
  - Added option `fpintegercuts` to disable integer cuts or enable them for mixed-binary problems only. The latter is the new default.
  - Added option `fp_mipgap` to specify an optimality tolerance (relative gap limit) for the MIP projection problem.
  - The `stall limit` is now only applied after a first solution has been found. Changed default for option `fpiterlimit` to 20.

3.18.1.4.7 GUROBI

- New libraries 8.0.
  - As announced for GAMS 24.9, Gurobi 8 is no longer supported for Windows 32-bit. We continue to ship Gurobi 7.5 for this platform.
- New partition heuristic based on user annotation via the new `dot` option `.partition` and enabled with new option `PartitionPlace`.
- Completely new interface to Gurobi's Remote Services (i.e. compute server, distributed algorithm, and instant cloud). For details see Compute Server and the following sections.

3.18.1.4.8 JAMS

- Added capability to handle QVI models.
- The options controlling the reformulation strategy for shared variables in multi-agent EMP models have changed: see ImplVarModel for details.

3.18.1.4.9 LocalSolver

- New libraries 7.5 (20180405).
- To use LocalSolver 7.5, a machine-specific LocalSolver license is now required on Linux, too. See the solver manual on how to obtain such a license. Alternatively, it is still possible to use LocalSolver 7.0 by choosing LOCALSOLVER70 instead of LOCALSOLVER as solver.

3.18.1.4.10 Mosek

- New libraries 8.1.0.53.
3.18.1.4.11 ODHCPLEX

- A new solver GAMS/ODHCPLEX from Optimization Direct Inc. has been added to the GAMS solver portfolio.
- The solver implements a set of heuristic methods (named ODHeuristics) for finding feasible solutions to Mixed Integer Programming (MIP and MIQCP) models and uses IBM CPLEX as its underlying solver engine.
- The heuristics decomposition method works in an automatic fashion or can be guided by user specified selections.
- Users will need a GAMS/CPLEX or GAMS/Cplex link license for this solver to work. Commercial users will also need a GAMS/ODHCPLEX license.
- Currently, the solver is available for Windows 64-bit only.

3.18.1.4.12 SCIP

- New libraries 5.0 (09c736f).
  - changed default for parameter constraints/quadratic/gaugecuts from 1 to 0
  - changed default for parameter heuristics/completesol/freq from 1 to 0
  - changed default for parameter separating/cmir/freq from -1 to 10
  - changed default for parameter separating/cmir/freq from 1 to 0
  - changed default for parameter separating/flowcover/freq from -1 to 10
  - changed default for parameter separating/flowcover/freq from 1 to 0

3.18.1.4.13 Xpress

- New libraries 32.01.10 containing several minor bug fixes and performance improvements.

3.18.1.5 Tools

3.18.1.5.1 GAMS Studio

- This release contains the first preview version of GAMS Studio - a completely new integrated development environment for GAMS. GAMS Studio is still in a very early stage of development, but we believe it is already mature enough to be a productive tool. GAMS Studio is available for Linux, Mac OS X, and Windows only.
- GAMS Studio combines many (but not all) features of the classic GAMS IDE with some new elements:
  - a code editor to write GAMS models (including basic syntax coloring, block edit mode, etc.),
  - execution of GAMS models,
  - an output panel that presents the progressing GAMS log,
  - a listing viewer (including a tree view to navigate through the file) to inspect the listing file,
  - an interactive option editor to set GAMS parameters,
  - a GDX viewer that shows the table of content and data of GDX files and offers useful details like sorting and filtering of data,
– a project explorer helps to manage different projects in one session, and
– an integrated help system to make it easier to find additional information, e.g., by pressing F1
  while the cursor is on a GAMS keyword in the code editor.

• We encourage our users to weigh in, help prioritize GAMS Studio's future development directions,
  or provide any other feedback. If you find problems, miss features, or have comments, please send a
  note to studio@gams.com.

• It is also possible to contribute directly or build on top of GAMS Studio, since the source code is
  available on GitHub (https://github.com/GAMS-dev/studio) under the GNU GPL license (see

• We plan to provide updates for GAMS Studio frequently in the near future, also separate from new
  releases of the GAMS distribution. To facilitate the update process, Studio includes an interactive
  check (requiring an Internet connection) for the availability of newer versions. This "Check for
  Update" button can be found below the menu "Help".

• A short overview about GAMS Studio can be found in the YouTube channel GAMS Lessons.

  Note

  – New options to define the association for GAMS files (.gms) have been added to the
    installer for GAMS on Windows. For now, the GAMS IDE is still the default choice, but
    this may change for future releases.
  – On Linux, Studio is installed in the form of an AppImage as part of the GAMS system
    directory.
  – On Mac OS X, Studio is part of the DMG installer only. It is installed as an additional
    application in the Applications directory next to the GAMS Terminal application and is
    available through the Launchpad. GAMS files (.gms) are associated with GAMS Studio.

  Attention

  – In rare cases, GAMS Studio crashes when the Open or Save dialog gets opened. This is
    mostly related to third party software, e.g. older versions of "Dell Backup and Recovery".
    It is recommend to update, switch off or uninstall the software.
  – We are aware of some performance issues at this stage of development. So while things
    work well, for example, with the models from our model libraries, you might experience
    some delay when working with huge files, e.g., while searching or when the log is processed
    for very long output.

3.18.1.5.2 XLSDump

• Sometimes, Excel Spreadsheets contain links to pictures, which cannot be found. This situation
  caused an error in XLSDump in previous versions. Now, such an error is ignored.

3.18.1.6 Object Oriented APIs

• New implementation of GAMSJob.Interrupt() on Linux and Mac OS X that removes dependency
to the command line tool pstree.

3.18.1.6.1 C++

• Added support for Microsoft Visual Studio 2015 on Windows 32-bit.
3.18.1.6.2 Java

- Changed the naming scheme of a temporary working directory to be created from `yyyyMMddHHmmss` to the prefixed `gams` (defined by `GAMSGlobals.workingDirectoryPrefix`), in case no working directory has been specified.

- Fixed the behavior when a GAMSDatabase is added with a name that already exists. A GAMSException will be raised now (see `GAMSWorkspace.addDatabase(String databaseName)` and `GAMSWorkspace.addDatabaseFromGDX(String gdxFileName, String databaseName)`).

- Calls on `GAMSWorkspace.finalize` and `GAMSSymbolIterator.finalize` are no longer available, because calling a finalizer method can arbitrarily delay the reclamation of object instances and potentially create unpredictable outcome. Whenever the object is no longer needed it is recommended to explicitly dispose the object rather than to rely on the Java garbage collector to do the job. See `GAMSDatabase.dispose`, `GAMSModelInstance.dispose`, and `GAMSOptions.dispose`.

3.18.1.7 Expert Level APIs

- All Java native interfaces to `expert-level APIs` are now included in `\[Path/To/GAMS]/apifiles/Java/api/GAMSJavaAPI.jar`.

3.18.1.7.1 GMO

- The constant `MAXEVALTHREADS` (i.e. the number of parallel threads supported for function and derivative evaluations in the solver interface library GMO) has been increased from 16 to 64. This effectively increases the same limit in the CONOPT4 solver.

3.18.1.8 Model Libraries

3.18.1.8.1 PSOPTLIB - Power System Optimization Modelling in GAMS

- This new library by Alireza Soroudi has been added to the GAMS system. This is a collection of the models based on the book *Power System Optimization Modelling in GAMS* by Alireza Soroudi. The library contains a selection of 32 models from various areas of power system optimization expressed in GAMS. Book and library describe how the General Algebraic Modeling System (GAMS) can be used to solve various power system operation and planning optimization problems. The book is the first of its kind to provide readers with a comprehensive reference that includes the solution codes for basic/advanced power system optimization problems in GAMS, a computationally efficient tool for analyzing optimization problems in power and energy systems. The book covers theoretical background as well as the application examples and test case studies. It is a suitable reference for dedicated and general audiences including power system professionals as well as researchers and developers from the energy sector and electrical power engineering community and will be helpful to undergraduate and graduate students.

- You can retrieve the individual models through the IDE and Studio model library browser, via the command line utility `psoptlib` or through calls in the Object Oriented APIs.

3.18.1.8.2 GAMS EMP Library

- `simpleqvi1.gms` : Simple Quasi-Variational Inequality (101)
- `simpleqvi2.gms` : Simple Quasi-Variational Inequality (102)
- `simpequil3.gms` : Simple Generalized Nash Equilibrium Problem (103)
3.18.1.8.3 GAMS Model Library

- guss2dim.gms: Two dimensional scenario GUSS Example (423)
- obstacle.gms: An Obstacle Problem (424)
- csched: Added two more formulations for a related problem. Contributed by Tapio Westerlund.

### 3.18.2 25.1.2 Minor release (August 01, 2018)

#### 3.18.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Shaoyan Guo, Eden Huang, David Laudy, Evangelos Panos, Wilfredo Sifuentes and Larissa de Vries.

#### 3.18.2.2 Platforms

- Fixed problem using solvers with Fortran dependencies on a Mac OS X 10.11 system.

#### 3.18.2.3 GAMS System

##### 3.18.2.3.1 GAMS

- Fixed a bug which caused an unexpected error when using the + operator in a model statement with the following symbol being a model itself, like this:

```
variable x;
equation e1, e2;
e1.. x =L= 5;
e2.. x =G= 3;
model m2 /e2/;
model m /e1+m2/;
solve m min x use lp;
```

#### 3.18.2.4 Solvers

##### 3.18.2.4.1 BARON

- Fixed translation of branching priority values when specified in BARON options file and GAMS option PriorOpt not enabled.
- Specifying maxdouble as branching priority in a BARON options file now behaves as if specifying inf as branching priority in a GAMS model.
3.18.2.4.2 BONMIN

- The default for option `number_cpx_threads` is now initialized according to the value of the GAMS option `threads`.

3.18.2.4.3 CONOPT

- New libraries 3.17I for CONOPT 3.
- New libraries 4.06 for CONOPT 4.

3.18.2.4.4 GUSS

- Models with variable parameters and model attribute `holdFixed=1` could not be solved with 25.1.1. In this release the `holdFixed` option is automatically turned off.

3.18.2.4.5 Ipopt

- New libraries.
  - Fixed problems in handling of time limit (reslim).

3.18.2.4.6 LocalSolver

- New libraries 7.5 (20180601).

3.18.2.4.7 ODHCPLEX

- New libraries 3.4.3.
- ODHCPLEX is now available for Linux, too.

3.18.2.4.8 SoPlex

- New libraries 3.1 (b0e0048).

3.18.2.4.9 SCIP

- New libraries 5.0 (1d9c207).

3.18.2.5 Tools

3.18.2.5.1 MODEL2TEX

- Backslashes in the explanatory text of symbols are replaced automatically with `\textbackslash`. 
3.18 25.1 Distribution

3.18.2.5.2 GAMS Studio

- New version 0.9.2
  - Stability improvements
  - Allow only one instance of Studio to run at the same time (when file association for Studio is active, a double click on a gms file will open that file in a running Studio instance and does not open a new Studio)
  - Added startup parameter \texttt{--gams-dir} to specify a non-default GAMS system folder to be used
  - Added shortcuts for Interrupt and Stop (F12 and Shift+F12)
  - Restructured the File -> Encoding menu
  - About dialog: added button to copy product information to clipboard
  - GDX Viewer: added facility to search for symbols
  - Option Editor: allow to use F1 to open help
  - Project Explorer:
    - "Add Existing Files" allows to add multiple files at once
    - Added context menu entry to open the log for a group-node
  
  \textbf{Note}
  - When migrating from an older version of GAMS Studio, one might have an empty project explorer and no recent files listed. This is expected behavior because of a bug fix within the GAMS Studio settings file.

3.18.2.6 Object Oriented APIs

3.18.2.6.1 Python

- Fixed a bug that prevented the setup.py file to be called with parameter \texttt{--noCheck} for turning off the version check.
- The setup.py script can be used from an arbitrary location. It is not required anymore to switch to the files location before installing.

3.18.3 25.1.3 Minor release (October 30, 2018)

3.18.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.18.3.2 GAMS System

3.18.3.2.1 GAMS

- Fixed a bug which caused the \texttt{sysIdent} property not being set correctly after a solve statement.
- Fixed a bug which could have caused a problem with \texttt{execute_load} being called after \texttt{endEmbeddedCode} in a loop.
3.18.3.3 Solvers

3.18.3.3.1 ANTIGONE

- If interrupting ANTIGONE (using Ctrl+C, for example), the final trydual NLP solve does no longer stop immediately in the first iteration.

3.18.3.3.2 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2018.4 on Mac OS X.

3.18.3.3.3 CONVERTD

- When using options Jacobian or Hessian, new symbols iobj, objConst, and objJacVal are written to the GDX file. If the model can be reformulated with a true objection function, the symbol iobj contains the label of the objective defining equation, while the symbols objConst and objJacVal constain the objective constant and the coefficient of the objective variable. If the model cannot be reformulated with a true objective, iobj will be empty and objConst and objJacVal will be 0.

3.18.3.3.4 GUROBI

- New libraries 8.1.0.
- Option GUROBi preqlinearize allows the value of 2 (Force Linearization and get compact relaxation).

3.18.3.3.5 JAMS

- Added some experimental indexed EMP syntax. See example model emppython1.gms: Three Simple EMP Models with Indexed EMP Syntax and Python Parser.

3.18.3.3.6 Lindo/LindoGlobal

- New libraries 11.0.338.

3.18.3.3.7 MOSEK

- New libraries 8.1.0.64.

3.18.3.4 Tools

3.18.3.4.1 CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.
3.18.3.5 Object Oriented APIs

3.18.3.5.1 Python

- The UpdateAction Primal and Dual in a GamsModifier were not recognized and triggered an exception. This has been fixed.

3.18.3.6 Model Libraries

3.18.3.6.1 GAMS EMP Library

- emppython1.gms: Three Simple EMP Models with Indexed EMP Syntax and Python Parser (104)

3.19 25.0 Distribution

3.19.1 25.0.1 Major release (January 17, 2018)

3.19.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Jeff Dischler, Michael Ferris, Dhruv Gupta, Erwin Kalvelagen, Florian Landis, Andre Lemelin, Erfan Mohagheghi, Anthony Paul, and Nathan Sudermann-Merx.

3.19.1.2 Platforms

- Due to the discontinuation of Cplex on Windows 32bit (with Cplex 12.7 in 2016) we are faced with potentially phasing out/dropping solvers depending on Cplex on Windows 32bit with the next major release. The most likely candidate for this is ANTIGONE. These solvers will still be available for 64-bit Windows and other supported platforms. Other solver vendors (e.g. Gurobi and FICO-Xpress) have also announced the discontinuation of their product on the Windows 32bit platform. If you rely heavily on the availability and support of the Windows 32bit platform please contact support@gams.com to discuss your options.

- As announced, dropped support for x86-64 Solaris.

- As announced, increased the minimal required MacOS X version to 10.11.

- As announced, increased the minimal required GLIBC version on Linux to 2.12.
3.19.1.3 GAMS System

3.19.1.3.1 GAMS

- Extended the $offEmbeddedCode facility to allow the use of a "projection operator":
  $offEmbeddedCode {symbol[[<]=]embSymbol[.dimX]]}
  More information can be found here.
- Added support for the Object-oriented GAMS Python API in the Embedded Code Facility for Python. The method gams.set() accepts instances of type GamsParameter, GamsSet, etc. as data. Instances of GamsWorkspace and GamsDatabase can be retrieved using the properties gams.ws and gams.db. The property gams.wsWorkingDir can be used to specify the working directory of the created GamsWorkspace.
- Added $libinclude pyEmbMI to conveniently work with Python OO-API GamsModelInstance from embedded code. See embmiex1.gms: Simple Embedded Code ModelInstance example.
- Fixed a problem in embedded code when reading an empty scalar symbol.
- Fixed a problem when solving a model with solveLink 5, 6, or 7 with communicating scales without scaleOpt active.
- The EPS value in the Embedded Code Facility for Python has been changed to 4.94066E-324. This is the same value that is used for EPS in the Object-oriented Python API.
- New Put Utility save: Writes a save file of the current state of execution.
- Improvement for the Put Utility Statement: It is no longer required to define a file and activate it, just to use a put utility.
- New command line option fileStemApFromEnv: Append a string read from an environment variable to the fileStem.
- Change to command line option fileStem: Create an immediate error when the value contains a "\" or "/" character to avoid problems later on.
- Fixed a bug with execute unload, which could have caused a set to be exported mistakenly as alias to a different set, if symbol renaming was used.
- Fixed a bug which prevented to open more than 65,000 put files.
- Solves with scaleOpt=1 using GUSS or instantiations of OO-API GAMSModelInstances resulted in some circumstances in the report of scaled solutions or other erroneous behavior. Hence GAMS will now reset the modelname.scaleOpt attribute to NA before such a solve or GAMSModelInstance generation. As a consequence, models solved via GUSS or as a GAMSModelInstance in the OO-APIs will not be scaled by GAMS.
- Solving MCP models with scaleOpt=1 using the solvers AMPL or PYOMO creates an execution error now. In the past this lead to wrong results potentially.

3.19.1.4 Solvers

3.19.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2018.0 for Linux and Mac OS X and to version 2018.1 on Windows 64-bit.

3.19.1.4.2 CBC

- New libraries.
3.19.1.4.3 CONOPT

- New libraries 3.17G (Conopt3).
- New libraries 4.04 (Conopt4).
  - Fixed a system error 65666.

3.19.1.4.4 Couenne

- New libraries.
  - Bugfixes and tuning for fixed point bound tightening.
- If Couenne does not find a feasible solution, but the initial point is feasible, then the initial point is now reported back to GAMS.

3.19.1.4.5 CONVERT

- If the filename provided for the Jacobian or Hessian option contains the string novenames ConvertD will not export the original equation and variable names as set text to elements of sets i and j. Having the original equation and variable names can make the GDX file significantly larger and slow to write and read.
- Fixed a problem when trying to write scaled MCP models.

3.19.1.4.6 CPLEX

- New libraries 12.8.0.
- New parameters
  - SubMIPScale: Parameter to scale the problem matrix when CPLEX solves a subMIP during MIP optimization
  - SubMIPStartAlg: Starting algorithm for subMIP of a MIP
  - SubMIPSubAlg: Algorithm for subproblems of a subMIP of a MIP
  - DynamicRows: Switch for dynamic management of rows
  - Sifting: Switch for sifting from simplex optimization
- In CplexD allow the BendersPartition to be set via the .stage variable suffix together with option BendersPartitionInStage.

3.19.1.4.7 Gurobi

- Fixed a problem for model with SOS variables but no constraints.

3.19.1.4.8 KESTREL

- New options neos_username and neos_user_password can be used in the option file in order to submit authenticated jobs using a NEOS user account.
3.19.1.4.9  LocalSolver

- New libraries 7.5 (20171117) for Mac OS X and Windows.
  - Preprocessing entirely rewritten: size reduction by a factor up to 10 on some huge instances.
  - Combinatorial models based on booleans and integers: performance improvement and increased ability to prove optimality.
  - Continuous linear and nonlinear models: performance improvement through the integration of state-of-the-art algorithms.
- Note, that to use LocalSolver 7.5, a machine-specific LocalSolver license is now required. See the solver manual on how to obtain such a license. Alternatively, it is still possible to use LocalSolver 7.0 by choosing LOCALSOLVER70 instead of LOCALSOLVER as solver.

3.19.1.4.10  Mosek

- New libraries 8.1.0.34.

3.19.1.4.11  SBB

- Fixed a bug introduced in 24.8 that prevents the infeasSeq option to work.

3.19.1.4.12  SCIP

- New libraries 5.0 (2b35b18).
  - SCIP can now automatically detect and exploit symmetries in MIPs (Linux and Mac OS X only)
    * added parameter misc/usesymmetry to determine which symmetry handling should be used
    * added parameter groups presolving/symmetry, presolving/symbreak, constraints/symresack,
      constraints/orisack, constraints/orbitope
  - Presolving
    * new presolver sparsify that tries to cancel nonzero coefficients in linear constraints by adding multiples of linear equalities
    * disabled reformulation of products of a binary variable with a linear term that does not solely involve binary variables
      · added parameter constraints/quadratic/binreformbinaryonly to disable reformulation of products of binary and non-binary variables
    * revised disaggregation of quadratic constraints: the number of created constraints can now be controlled and the disaggregated constraints are scaled in order to increase numerical accuracy
      · replaced constraints/quadratic/disaggregate by constraints/quadratic/maxdisaggrsize to bound the total number of created constraints when disaggregating a quadratic constraint
      · added parameter constraints/quadratic/disaggmergemethod to change the strategy of how to merge independent blocks of quadratic constraints
  - Primal Heuristics
    * new primal heuristic ALNS that orchestrates eight different LNS heuristics adaptively using algorithms for the multi-armed bandit problem
* new primal heuristic MPEC that solves a MPEC reformulation of a mixed-binary nonlinear problem by regularized NLP reformulations
* improved the clique and variable bound pre-root heuristics, which are now often able to fix many more variables
  - removed parameters heuristics/clique/\{multiplier,initseed\}
  - replaced parameter heuristics/\{clique,vbounds\}/minfixingrate by heuristics/clique/minintfixingrate, heuristics/vbounds/minintfixingrate, heuristics/clique/minmipfixingrate, and heuristics/vbounds/minmipfixingrate, which check the fixing rate before LP solving and after sub-MIP presolve
  - added parameters heuristics/clique/maxbacktracks and heuristics/vbounds/maxbacktracks to limit the number of backtracks in the fix-and-propagate phase
  - added parameters heuristics/clique/uselockfixings and heuristics/vbounds/uselockfixings to enable fixing of additional variables based on variable locks
  - added parameters heuristics/vbounds/feasvariant and heuristics/vbounds/tightenvariant to specify the fixing variants used by the vbounds heuristic
  - changed default for parameters heuristics/clique/freq and heuristics/vbounds/freq from -1 to 0
  - changed default for parameter heuristics/clique/priority from -1000500 to 5000
  - changed default for parameter heuristics/vbounds/priority from -1100600 to 2501
* added parameters heuristics/completesol/beforepresol, heuristics/completesol/maxlpiter, and heuristics/completesol/maxcontvars
* changed default for parameter heuristics/indicator/oneopt from 1 to 0
* changed default for parameter heuristics/locks/minfixingrate from 0.25 to 0.65
* changed default for parameter heuristics/locks/priority from 2000 to 3000

- Separation (cutting planes)
  * utilizing linear inequalities (computed in the OBBT propagator) to compute stronger linearizations for bilinear terms
    - added parameters constraints/quadratic/usebilinameqbranch, constraints/quadratic/minscorebilinterms, and constraints/quadratic/bilinameqmaxseparounds
    - added parameter constraints/quadratic/mincurvcollectbilinterms to change the minimal curvature of constraints to be considered when returning bilinear terms to other plugins
    - added parameters propagating/obbt/itlimitfactorbilin, propagating/obbt/minnonconvexity, and propagating/obbt/createbilinameqs
  * improved cut post-processing (apply coefficient tightening, enforce maximal dynamism), selection, and management
    - added parameters separating/maxlocalbounddist, separating/maxcoefratio, and separating/intsupportfac
    - removed parameter separating/orthofac
    - changed default for parameter separating/cutagelimit from 100 to 80
    - changed default for parameter separating/minefficacy from 0.05 to 0.0001
    - changed default for parameter separating/minefficacyroot from 0.001 to 0.0001
    - changed defaults for parameters separating/minortho and separating/minorthoroot from 0.5 to 0.9
    - changed default for parameter separating/objparalfac from 0.0001 to 0.1
    - changed default for parameter separating/poolfreq from 0 to 10
  * MIP cutting planes are now separated within the tree search, too
    - parameter separating/maxstallrounds only applies to nodes in the tree (not the root node, anymore); use the new parameter separating/maxstallroundsroot for the root node
    - added parameters separating/\*/expbackoff to all separators, which increases the frequency exponentially over the depth in the tree
    - added parameter separating/maxincrounds
• changed default for parameter `separating/maxstallrounds` from 5 to 1
• changed default for parameter `separating/maxrounds` from 5 to -1
• changed default for parameter `separating/maxroundsrootsubrun` from 1 to -1
• changed default for parameter `separating/gomory/delayedcuts` from 1 to 0
• changed default for parameter `separating/gomory/freq` from 0 to 10
• changed default for parameter `separating/gomory/maxbounddist` from 0 to 1
• changed default for parameter `separating/impliedbounds/freq` from 0 to 10
• changed default for parameter `separating/impliedbounds/maxbounddist` from 0 to 1
• changed default for parameter `separating/strongcg/freq` from 0 to 10
• changed default for parameter `separating/strongcg/maxbounddist` from 0 to 1
• changed default for parameter `separating/zerohalf/freq` from -1 to 4
• changed default for parameter `separating/zerohalf/maxbounddist` from 0 to 1

* new implementation of zerohalf separator
  • added parameters `separating/zerohalf/badscore`, `separating/zerohalf/densityoffset`, `separating/zerohalf/goodscore`, `separating/zerohalf/maxcutcands`, `separating/zerohalf/maxrowdensity`, `separating/zerohalf/maxslack`, `separating/zerohalf/maxslackroot`, and `separating/zerohalf/minviol`
  • removed parameters `separating/zerohalf/delayedcuts`, `separating/zerohalf/ignoreprevzhcuts`, `separating/zerohalf/maxcutcands`, `separating/zerohalf/maxcutfound`, `separating/zerohalf/maxcutfoundroot`, `separating/zerohalf/maxdepth`, `separating/zerohalf/maxncalls`, `separating/zerohalf/maxtestdelta`, `separating/zerohalf/onlyorigrows`, `separating/zerohalf/relaxcontvars`, `separating/zerohalf/scalefraccoeffs`, `separating/zerohalf/trynegscaling`, `separating/zerohalf/usezhcutpool`, `separating/zerohalf/preprocessing/*`, and `separating/zerohalf/separating/*`
  • changed default for parameter `separating/zerohalf/maxroundsroot` from 10 to 20
  • changed default for parameter `separating/zerohalf/maxsepacuts` from 50 to 20
  • changed default for parameter `separating/zerohalf/maxsepacutsroot` from 500 to 100

* faster implementation of CMIR cut generation heuristic
  • moved many parameters for flowcover and cmir separators to new parameter group `separating/aggregation`
  • changed default for parameters `separating/cmir/freq` and `separating/flowcover/freq` from 0 to -1
  • changed default for parameters `separating/cmir/maxbounddist` and `separating/flowcover/maxbounddist` from 0 to 1
  • changed default for parameter `separating/cmir/priority` from -3000 to -100000
  • changed default for parameter `separating/flowcover/priority` from -4000 to -100000

* additional parameter changes
  • removed parameter `separating/feastolfac`
  • removed parameter `separating/cgmip/allowlocal`
  • removed parameters `separating/\{gomory,strongcg\}/maxweightrange`
  • changed default for parameter `separating/gomory/makeintegral` from 1 to 0
  • changed default for parameter `separating/gomory/maxrank` from 3 to -1
  • changed default for parameter `separating/gomory/sidetypebasis` from 0 to 1
  • added parameter `constraints/indicator/maxsepanonviolated` to stop separation after separation of non violated cuts
  • removed parameters `constraints/\{abspower,bivariate,quadratic,nonlinear\}/mincutefficacysepa`, `constraints/\{abspower,bivariate,quadratic,nonlinear\}/mincutefficacynofac`, and `constraints/soc/minefficacy`

– Propagation
  • use disjoint set to reduce peak memory usage and time to compute clique table connectedness information
  • added analysis of the clique table which identifies possible aggregations via the search for strongly connected components and may detect infeasible assignments on the way
• added parameter propagating/vbounds/minnewcliques to specify the minimum number of new cliques to trigger another clique table analysis
• added parameters propagating/vbounds/maxcliquesmedium and propagating/vbounds/maxcliquesexhaustive to limit the number of cliques relative to the number of binary variable for performing clique table analysis
• changed default for parameter propagating/vbounds/presolpriority from 0 to -90000
• changed default for parameter propagating/vbounds/presoltiming from 28 to 24
  * extended conflict analysis by analyzing dual solutions of boundexceeding LPs and improved dual ray analysis
  • removed parameters conflict/usemir and conflict/prefermir
  • added parameter conflict/sepaaltproofs
  • added parameter conflict/prefinfproof to determine whether to prefer infeasibility proof to boundexceeding proof
  • changed default for parameter conflict/useboundlp to 'b'
  • changed default for parameter conflict/maxvarsfac from 0.1 to 0.15
  • changed default for parameter conflict/maxvarsfac from 30 to 0
  – LP Relaxation
    * use LP solution polishing during probing and diving mode to activate it during many primal heuristics; remains disabled during strong branching and OBBT
    • only effective if using SoPlex as LP solver
    • added value 3 for parameter lp/solutionpolishing to enable LP polishing only during probing and diving mode
    * added parameter lp/refactorinterval to change the refactorization interval of the LP solver
  – removed parameters constraints/\{abspower,bivariate,nonlinear,quadratic,soc\}/scaling
  – added parameter groups table/* to control statistic output
  – See also the full release notes, the changelog, and the release paper.
• Fixed a problem when solving a model with solveLink 6 or 7 with scaleOpt active.

3.19.1.4.13 SolveEngine

• The GAMS time limit (reslim) is now passed to SolveEngine. Added solver option hardtimelimit to specify a time limit that is enforced on the GAMS side.

3.19.1.4.14 SoPlex

• New libraries 3.1.0 (876e6e8).
  – New scaling method that combines geometric and equilibrium scaling. Use new value 6 for option int:scaler to activate this.
  – See also the release paper.

3.19.1.4.15 Xpress

• New libraries 32.01.05.

3.19.1.5 Tools

3.19.1.5.1 CDSP

• See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.
3.19.1.5.2 GDXXRW

- Sometimes, Excel is not ready (e.g. because some data needs to be refreshed, when a worksheet is opened), when a read request is sent by GDXXRW. This could cause an exception. With this release we changed the behavior of GDXXRW to wait a second and resend the request in this case. This basically mimics the behavior of setting RWait to 1000 in case of the mentioned exception.

3.19.1.6 Object Oriented APIs

3.19.1.6.1 C++

- Changed the compiler from GCC to Clang on Mac OS X.
- API binaries have been moved to apifiles/C++/lib. On Windows, there are further subdirectories for different compiler versions.
- Update of Visual Studio solutions for the examples on Windows. Three different solutions reflecting the supported versions of Microsoft Visual Studio are available (e.g. examples-vs2013.sln, examples-vs2015.sln, examples-vs2017.sln).
- The GAMS C++ API tutorial has been reworked. Information about building the C++ API examples via cmake, qmake, and Microsoft Visual Studio has been added.
- New example TransportGDX that shows how to import and export GDX files. A description has been added to the tutorial.

3.19.1.6.2 .NET

- Changes for GAMSSymbol and GAMSSymbolRecord: Both classes got the IEqualable<> Interface. As a result the behavior of the Equals function as well as the == and != operators were modified. For both classes Equals and == returns now true, if the internal data reference is the same. Here is an example:

```
GAMSVariable x1 = db.GetVariable("x");
GAMSVariable x2 = db.GetVariable("x");
if (x1 == x2)
    Console.WriteLine("x1 == x2");
else
    Console.WriteLine("x1 != x2");

if (x1.Equals(x2))
    Console.WriteLine("x1 equals x2");
else
    Console.WriteLine("x1 does not equal x2");
```

In previous versions we got this output:

```
x1 != x2
x1 does not equal x2
```

Now we get:

```
x1 == x2
x1 equals x2
```
- New example TransportGDX that shows how to import and export GDX files.
3.19.1.6.3 Java

- The minimum version requirement of the Java Runtime Environment for using the GAMS Java API is now Java SE 7.
- New `TransportGDX` example to demonstrate how to import and export GDX files.
- Removed method `GAMSSymbol.compact`, deprecated since 24.8.1 (December 2016).
- Changed equivalence behavior of `GAMSSymbol` and `GAMSSymbolRecord` objects. As a result, two symbol objects with the same internal reference are now equivalent, similar to symbol record objects:
  - Two symbols are equivalent if and only if they have the same internal reference.
  - Two symbol records are equivalent if and only if they have the same internal reference.

The behavior of operator `==` remains unchanged. The following example illustrates the new equivalence behavior:

```java
GAMSVariable x1 = db.getVariable("x");
GAMSVariable x2 = db.getVariable("x");
GAMSVariable x3 = x1;
assertTrue(x1.equals(x2)); // true, previously false
assertFalse(x1 == x2); // false, previously false
assertTrue(x1.equals(x3)); // true, previously true
assertTrue(x1 == x3); // true, previously true
```

3.19.1.6.4 Python

- Added implementation of `__eq__()` and `__ne__()` to classes `GamsSymbol` and `GamsSymbolRecord` and its derived classes. As a result the behavior of the operators `==` and `!=` has changed. `==` now returns `True`, if the internal data reference is the same. The behavior of `is` remains unchanged. The following example illustrates the change:

```python
x1 = db["x"]
x2 = db["x"]
print(x1 == x2) # now: True, before: False
print(x1 is x2) # now: False, before: False
```

- New example `transport_gdx.py` that shows how to import and export GDX files. A description has been added to the tutorial.

3.19.1.7 Expert Level APIs

- As announced, the expert-level C++ API files were removed from the distribution. Users should switch to the expert-level C API files. The object-oriented C++ API introduced in the last major release could also be a good alternative for replacement if the user C++ code exchanges data and runs a GAMS model.

  The expert-level Java API files now ensure the load of jni libraries in the similar order as those employed by the Object Oriented Java API: first load from `java.library.path`, if neither specified nor found then from the directory where the API classes are located.

3.19.1.7.1 GDX

- Do not allow empty filename as argument for `gdxOpenAppend`, `gdxOpenRead`, `gdxOpenWrite`, and `gdxOpenWriteEx`. This will create an error right away now.
3.19.1.8 Model Libraries

3.19.1.8.1 GAMS Model Library

- embmiex1.gms: Simple Embedded Code ModelInstance example (417)
- spbenders1.gms: Stochastic Benders - Sequential GAMS Loop (418)
- spbenders2.gms: Stochastic Benders - Async Subsolve GAMS Loop (419)
- spbenders3.gms: Stochastic Benders - Sequential GamsModelInstance (420)
- spbenders4.gms: Stochastic Benders - Parallel MPI (421)
- spbenders5.gms: Stochastic Benders - Parallel MPI with GAMSModelInstance (422)

- Most models in the GAMS Model library have been refurbished to reflect a common syntax style and features introduced since the model was added.
- prime: Make use of the break statement for a little nicer and faster formulation.

3.19.1.8.2 GAMS Test Library

- scensol7.gms: Test GUSS Option ReportLastScen (737)
- emp27.gms: Test LOGMIP/EMP on x.fx=0 handling (738)
- empppy03.gms: Test projection operator when loading data from embedded code (739)
- qcp11.gms: Test dual solution of SOCP (740)
- put11.gms: Put Utility without file handle (741)

### 3.19.2 25.0.2 Maintenance release (January 31, 2018)

#### 3.19.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Tom Rutherford.

#### 3.19.2.2 GAMS System

##### 3.19.2.2.1 GAMS

- Bugfix: `$/offEmbeddedCode` does not ignore `$/onUNDF` anymore.
- Bugfix: Special values (NA, EPS, INF, ...) are correctly communicated from embedded code back to GAMS.
- Bugfix: Took care about a problem, which caused an unexpected execution error for certain uses of `Put_Utility`.
- Fixed a bug in GMSPython on Mac OS X which prevented the Python interpreter from working. This problem occurred with the DMG installer only.

3.19.2.3 Solvers

3.19.2.3.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- On Linux, removed the MKL libraries that were optimized to certain x86 instruction sets (AVX, etc.) as this resulted in errors when running ANTIGONE or SCIP, probably due to library conflicts.

3.19.2.3.2 CPLEX

- Option Tuning can be repeated in a GAMS/Cplex option file to provide a larger number of model instances for tuning. Before this change the number was restricted by the maximum line length of an option line (256 characters).

3.19.2.3.3 LocalSolver

- New libraries 7.5 (20180119) for Mac OS X and Windows.

3.19.2.4 Tools

3.19.2.4.1 CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.

3.19.2.4.2 CSV2GDX

- Bugfix: Reading sets (no Value or Values option) with the option AutoRow works again.

3.19.3 25.0.3 Minor release (March 21, 2018)

3.19.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Dominik Bongartz, Wolfgang Britz, Erwin Kalvelagen, Maria Kannavou, Hans Mittelmann, Christoph Pahmeyer, Gilles Scouvart, and Hermann Westerholt.

3.19.3.2 GAMS System

3.19.3.2.1 GAMS

- Bugfix for Put Utility: If a put_utility statement was used as the first statement to mark a file as active (so no statement like put fx; was used before) and following put or put_utility statements did not mention this file explicitly, then the file association got lost.

- Bugfix: Avoid a crash when one of the following attributes was used on an empty Singleton Set: .len, .uel, .val (an execution error is generated instead now)

- Bugfix for command line option fileStemApFromEnv: In the past, if the input file was defined including a file extension, the value of this option was extended to the extension and not to the file stem as intended. This is fixed now.

- Bugfix for $if exist File on Windows: In the past, if a file was specified as <Drive>:/<File>, e.g., C:/t.txt (note the forward slash '/') after the colon(':'), this always returned false, even if the file exists. That has been fixed now.
3.19.3.3 Solvers

3.19.3.3.1 BARON

- Fixed use of .EquClass option.

3.19.3.3.2 BONMIN(H), CBC, Couenne

- Branch-and-bound now checks wallclock-time, if running with multiple threads.

3.19.3.3.3 CONOPT4

- New libraries 4.05.
  - Improved the selection of post-triangular variables when there are multiple candidates.

3.19.3.3.4 CPLEX

- Bugfix: If the Cplex conflict refiner (triggered by option iis) could not identify a conflict the behavior was erratic. This has been fixed.
- Bugfix: Value 6 for option MIPStart was documented but got rejected. This has been fixed.

3.19.3.3.5 DICOPT

- Fixed setup of NLP projection problem in feasibility pump.
- Fixed stopping criterion when using stop on crossover: DICOPT was stopping as soon as the relative gap between the objective value of the best known solution and the bound provided by the MIP relaxation was below 0.001, thus might have declared suboptimal solutions as optimal. With this release, DICOPT will use the value of GAMS option optcr as optimality tolerance. Note, that the default for this option is 0.1 (!).

3.19.3.3.6 Ipopt(H)

- New libraries.

3.19.3.3.7 MOSEK

- No update, but be aware that Mosk announced to drop the convex nonlinear optimizer in their next major release (Mosek 9). Thus, in a future GAMS release, GAMS/Mosek will not accept models with model types NLP or DNLP anymore. Note, that linear or quadratic problems (LP, MIP, (MI)QCP) are not affected.
3.19.3.3.8 SCIP

- New libraries 5.0.1 (227c4c7).
  - New option `presolving/symmetry/displaynorbitvars`.

3.19.3.3.9 SoPlex

- New libraries 3.1.1 (ab921a5).

3.19.3.4 Tools

3.19.3.4.1 MODEL2TEX

- Added support for singleton sets.
- Fixed a dependency bug on Mac OS X which prevented `model2tex` from working.
- Fixed a bug regarding SOS variables.
- Fixed a bug regarding domain jumps.
- Added support for Python 3 on Linux and Mac OS X.

3.20 24.9 Distribution

3.20.1 24.9.1 Major release (August 30, 2017)

3.20.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jan Abrell, Etienne Ayotte-Sauvé, Wolfgang Britz, Florian Habermacher, Florian Häberlein, Maximilian Held, Ignacio Herrero, Hanspeter Höschle, Erwin Kalvelagen, Toni Lastusilta, John Ross, Tom Rutherford, and Linus Schrage.

3.20.1.2 Platforms

- The set of supported platforms has not changed, but we've divided it into the core platforms (Windows 32-bit, Windows 64-bit, Linux, and Mac OS X) and the peripheral platforms (AIX, x86-64 Solaris, and Sparc64 Solaris). See Supported Platforms for more details. Please note, however, that we are not changing the content or behavior of GAMS based on this division: GAMS models will continue to work in the same cross-platform way for both core and peripheral platforms.
- We will drop support for x86-64 Solaris with GAMS 25.0.
- We may increase the minimal required GLIBC version on Linux to 2.12 with GAMS 25.0.
- We may increase the minimal required MacOS X version to 10.11 with GAMS 25.0.
3.20.1.3 GAMS System

3.20.1.3.1 GAMS

- New feature, the Embedded Code Facility: This extends the connectivity of GAMS to other programming languages. It allows the use of Python code during compile and execution time. GAMS symbols are shared with the external code, so no communication via disk is necessary. The embedded code feature is available on Linux, MacOS X, and Windows. For these platforms, a Python 3.6 installation is included with the GAMS distribution. If the user wants to work with a different Python 3.6, installed separately, for models with embedded code the new command line option `pySetup` needs to be set to 0.

  **Note**
  This feature is currently in beta status. Any feedback to support@gams.com is appreciated.

- New command line option `procDirPath`: Specifies the directory where the process directory should be created.

- New compile time constants to set the model attribute `solPrint`:
  - 0 = `%solPrint.Off%
  - 1 = `%solPrint.On%
  - 2 = `%solPrint.Silent%

- New compile time constants to set the model attribute `solveOpt`:
  - 0 = `%solveOpt.Replace%
  - 1 = `%solveOpt.Merge%
  - 2 = `%solveOpt.Clear%

- Allow new string synonyms to set the integer values of the following command line options:
  - `solPrint`: Off (=0); On (=1); Silent (=2)
  - `sysOut`: Off (=0); On (=1);

- Fixed a bug where the following dollar control options did not get written to the dump file when the command line parameter `dumpOpt` was used. Sometimes this caused an error in the generated file.
  - `$[on|off]DotScale`
  - `$[on|off]Embedded`
  - `$[on|off]Expand`
  - `$[on|off]Local`
  - `$[on|off]Macro`
  - `$[on|off]Margin`
  - `$[on|off]Order`
  - `$[on|off]StrictSingleton`
  - `$[on|off]UNDF`

- Fixed an error which caused the loss of equation information when using the Grid facility in certain cases. This could have caused problems when a hot start should be performed.

- A parameter error is now created if the key of a 'double dash' GAMS parameter exceeds 63 characters (in the past, the key was truncated silently in this case).

- Fixed a crash which happened if the .tl suffix was used on an empty Singleton Set in a put statement.

- Fixed a bug which could have caused a crash if nested loops where used in a particular combination.

- Fixed a bug with `$onPut ... $offPut` in a for and repeat structure: When `$onPut` was the first statement inside one of these programming flow control features, it was executed just once and not repeatedly.
3.20.1.3.2 Special Functions

- Several of the more exotic GAMS intrinsic functions (aka "special functions") were re-implemented to address some bug reports and to pass a more rigorous set of tests. The updated functions include the loggamma, gamma, logbeta, beta, and binomial functions. In general, the updated functions offer improved precision and a more consistent behavior in exceptional cases (e.g. overflows, singularities, and domain violations) compared to the previous versions. In addition, the gamma and beta functions are now classified as smooth (NLP) instead of nonsmooth (DNLP) and the domains of the beta and binomial functions have been changed.

3.20.1.3.3 Documentation

- The contents of GAMS User's Guide and the McCarl (Expanded) User's Guide have been merged, revised, and reorganized as User's Guide as well as A GAMS Tutorial by Richard E. Rosenthal. Also other parts of the documentation has been reorganized and are now more closely integrated.
- The McCarl GAMS User Guide (CHM and PDF) can now be found in the mccarl/ subdirectory in the distribution.
- The PDFs containing the solver manuals and the GAMS User's Guide have been replaced by a single PDF containing large parts of the current documentation. However, the main format for the documentation is HTML.

3.20.1.4 Solvers

3.20.1.4.1 BARON

- New libraries 17.8.7.
  - New range reduction techniques and relaxations for quadratic constraints.
  - New heuristics for finding feasible solutions of integer programs.
  - Improvements in interfaces to local NLP solvers, including the use of second-order derivatives.
  - FilterSQP added to the list of local solvers. New option AllowFilterSQP and added new possible value 14 for option NLPSol.
  - Bugfixes.

3.20.1.4.2 CBC

- New libraries.
  - Fixed some problems with the handling of SOS type 2 in presolve.
- Added option dumpsolutionsmerged to write all found alternate solutions into a single GDX file.

3.20.1.4.3 Conopt

- New libraries 3.17E and 4.03.
  - Fixed a serious error in Conopt4 for exactly threads=8. Moreover, improved multi-threading performance.
  - Major revisions to Conopt4 for reliability and performance.
- The option Rtzern is now user settable for Conopt3.
3.20.1.4.4 CONVERT

- The GAMS equation and variable scale values (suffix .scale) will be communicated to CONVERT independent of the ScaleOpt model attribute.

3.20.1.4.5 CPLEX

- Added option workerAlgorithm to select the method for optimizing Benders subproblems.
- Added option writeAnnotation to create Cplex annotation file.
- The header of MIP/solve trace files contains now the option number and the name of the model.

3.20.1.4.6 DECIS

- DecisC, DecisM, and the EMP-SP solver Decis are now available for MacOS X.

3.20.1.4.7 GAMSCHK

- The procedures that generate output in the listing file are summarized at the end of the GAMSCHK execution. If you use the IDE, these summary lines are clickable and locate the cursor to the corresponding subsection in the IDE. Moreover, the procedures are also entered in the listing file index after the Solution Report.
- The lower bound for options LevelFilt and MargFilt has been reset from 1 to -5.

3.20.1.4.8 GUROBI

- New libraries 7.5.1.
  - Fewer constraint violations in MIQP solutions: Gurobi has tightened the internal tolerances for MIQP models to reduce the number of cases where the solution exhibits small constraint violations.
- New parameter startNodeLimit provides additional control over how much is performed to complete a partial MIP start.
- Gurobi 7.5 will be the last Gurobi release that supports 32-bit Windows. You should plan to migrate your applications to 64-bit Windows in the future.
- The header of MIP/solve trace files contain now the active option number and the name of the model.

3.20.1.4.9 GUSS/Scenario Solver

- Fixed a problem when initializing variables bounds to 0 (updateType=0) that have scenario update parameters for lower and upper bounds.
3.20.1.4.10 Lindo/LindoGlobal

- New libraries 11.0
  - LP Solver Improvements:
    * With new enhancements made to the simplex solvers, the average performance on large instances has increased by 20% for the primal simplex and 15% for the dual simplex compared to the previous version.
  - MIP Solver Improvements:
    * New symmetry detection capabilities to reduce overall branch-bound effort. This may dramatically reduce the time needed to prove optimality on some models with integer variables.
    * Perspective and soft-clique cuts effective on difficult MIQP and models with assignment constraints.
  - Global Solver Improvements:
    * Improved stability and robustness through several enhancements to quadratic recognition and range reduction.
  - Nonlinear Solver Improvements:
    * New major release of the nonlinear solver.
    * Improved preprocessor.
    * Use of interval function and derivative computations.
    * Advanced scaling leading to improved solution quality.

3.20.1.4.11 LocalSolver

- New libraries 7.0 (20170728).
  - Reinforcement of mixed-integer linear programming (LP & MIP) techniques for combinatorial optimization.
  - Reinforcement of nonlinear programming techniques (NLP) for numerical optimization.

3.20.1.4.12 MINOS/QUADMINOS

- New libraries 5.6 (dated July 2016).
  - Improved handling of singularities and empty cols in pivoting code.
  - Further bug fixes and improvements.
- Fix improper handling of scaled CNS models.
- Fix handling of logging frequency.
- QUADMINOS, the quadruple-precision version of MINOS, has been available in previous releases (since 24.4). This release includes the library model [DQQ], an example of how to use MINOS and QUADMINOS together to compute greatly improved solutions at moderate cost.

3.20.1.4.13 MOSEK

- New libraries 8.1.0.23.
  - Performance of the presolve has been improved slightly.
  - Multi-thread performance of the conic optimizer has been improved for certain large models.
  - Changed scaling for quadratic and quadratically constraint optimization problems.
  - Bugfixes.
3.20.1.4.14 MPSGE

- The MPSGE $sysInclude mpsgeset allows now for an optional argument -mt=0 or 1 after the model name. The default value for the argument mt can be controlled via the double dash option --MPSGEMT=0 or 1. If the mt option is set to 1 the MODEL.GEN file is created in the GAMS scratch directory. Hence the $include before the solve needs to read $include "%gams.scrdir%MODEL.GEN". This allows to run multiple MPSGE jobs with the same model in the same working directory. The default of this option is 0. The model hansmge demonstrates the use.

3.20.1.4.15 SBB

- The header of MIP/solve trace files contains now the option number and the name of the model.

3.20.1.4.16 SCIP

- New libraries 4.0 (9d3c1b1).
  - Improved conflict analysis through central conflict pool and dual ray analysis for primal infeasible LPs.
  - New solution polishing to improve integrality of LP solutions when using SoPlex as LP solver.
  - Added adaptive solving behavior of SCIP based on solving phases and heuristic transitions.
  - Revised pseudo random number generation and introduced central random seed for all plugins.
  - Randomized tie-breaking in different parts of the code to reduce performance variability.
  - New primal heuristics GINS, LP face, Complete Sol, Locks, Repair, and Multistart.
  - The 1-opt heuristic is now iterated as long as new incumbents are found.
  - Improved tuning of heuristic timings.
  - Reduced memory usage of primal heuristics that use problem copies.
  - New presolving steps that disaggregate SOC constraints, reformulate QP's by adding KKT conditions, and treat variables appearing only in a single quadratic constraint with proper square coefficients.
  - New separators for gauge cuts, convex projection cuts, and perspective cuts for indicator constraints.
  - Improved knapsack approximation algorithms, greedy knapsack solution for the flow cover separation, clique partitioning, and clique separation.
  - New propagator for OBBDT on convex NLP relaxation.
  - Tuned propagation methods of several constraint handlers and propagation timings.
  - Improved and extended stuffing for linear constraints.
  - Changed handling of coupling constraints for indicator constraints.
  - See also the full release notes, the changelog, and the release paper.
  - Changed parameters:
    * presolving/components/* moved to constraints/components/*
    * conflict/deptscorefac renamed to conflict/graph/deptscorefac
    * misc/permutationseed renamed to randomization/permutationseed
    * misc/permuteconss renamed to randomization/permuteconss
    * misc/permutevars renamed to randomization/permutevars
    * branching/random/seed: default changed from 0 to 41
    * constraints/indicator/sepcouplingcuts: default changed from 0 to 1
    * constraints/SOS1/perfimplanalysis: default changed from 1 to 0
    * heuristics/ofins/freq: default changed from -1 to 0
212 Release Notes

* heuristics/reoptsls/freq: default changed from -1 to 0
* heuristics/trivialnegation/freq: default changed from -1 to 0
* heuristics/clique/initseed: default changed from 0 to 61
* lp/solver: default changed from soplex to soplex2, if CPLEX is not licensed
* presolving/abortfac: default changed from 0.001 to 0.0008
* separating/clique/cliquedensity: default changed from 0.05 to 0
* conflict/usesb: default changed from 0 to 1

- Added option gams/dumpsolutionsmerged to write all found alternate solutions into a single GDX file.
- Changed default for timing/clocktype to wallclock time.
- Initial variable levels can now be passed as partial solution to SCIP. To control the various possibilities, the type of option gams/mipstart has changed from bool to integer. See also subsection Starting point in the GAMS/SCIP solver manual.

3.20.1.4.17 SolveEngine

- New solver SolveEngine to solve LP and MIP problems remotely via the Satalia SolveEngine. The SolveEngine aggregates different solution algorithms for optimization problems and automatically selects an algorithm that seems to suite best for a given model instance.
- GAMS/SolveEngine comes free of charge with any licensed GAMS system. Users must have an API key for the Satalia SolveEngine to submit jobs.

3.20.1.4.18 SoPlex

- New libraries 3.0 (c32c55a).
  - Added a new scaling implementation Least squares (Curtis-Reid scaling).
  - Added persistent scaling to keep scaled LP for multiple reoptimizations.
  - Added an experimental version of a decomposition based approach to avoid degeneracy in the dual simplex method. This feature is activated by setting the parameter bool:decompositiondualsimplex to true, which sets the basis representation to 'row' and the algorithm to 'dual'.
  - New parameter bool:computedegen to enable computation of the degeneracy of the basis in each iteration.
  - New parameter int:printcondition to enable printing the condition number of the basis during solve.
  - Automatically use the row representation for problems with more than 20% more constraints than variables.
  - Changed default for parameter int:factor_update_max from 200 to new value 0.
  - See also the full release notes and the release paper.
- Changed default type of timer to wallclock time.
3.20.1.4.19 XPRESS

- New libraries: Optimizer 31.01.09 (aka XPRESS 8.3). There are many improvements and additions:
  - The parallel MIP code has been completely rewritten to improve performance and scalability.
    * Reduced overhead for small, easy MIPs.
    * Reduced the memory usage for very large MIPs, especially those that are significantly reduced during the initial preprocessing.
    * Heuristics can now be run in parallel with cutting in deterministic mode. Previously, heuristics would only be run in parallel after cutting.
    * Improved implementation of zero-half cutting.
    * Aggregated Mixed Integer Rounding cuts have been improved for network-type problems.
  - New presolve reductions, strengthenings and reformulations for convex quadratic problems.
  - Improved performance and numerical stability of crossover.
  - Code support for AVX2 in the barrier solver: use option cpuPlatform to select the target instruction set.
  - Crossover after a barrier solve is now multi-threaded: see option crossoverThreads for details.
- The header of MIP/solve trace files contains now the option number and the name of the model.

3.20.1.5 Tools

3.20.1.5.1 CSV2GDX

- New option ValueDim: Indicate if an extra dimension for values is added even if there is just one value column. This is ignored, if there is no value column.

3.20.1.5.2 GDXDUMP

- Fixed a problem with writing a scalar variable or equation in CSV format with all fields.

3.20.1.5.3 GDXMERGE

- Improved feedback about problems when processing input files.

3.20.1.6 Object Oriented APIs

- Fixed a bug regarding SymbolUpdateType.Zero that prevented records from being updated in GAMSModelInstance.Solve().

3.20.1.6.1 C++

- This release contains a beta version of the object-oriented C++ API that can be used to control GAMS from within C++11 and later. It allows the seamless integration of GAMS into C++ applications by providing appropriate classes for the interaction with GAMS. The GAMSDatabase class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the GAMSJob class and by using the GAMSModelInstance class a sequence of closely related model instances can be solved in an efficient way.
- The API is available in the distributions for Linux, MacOS X, and Windows.
- Furthermore, the C++ API is published under MIT license and is hosted at the GAMS GitHub organization.
- To use this API please check the GAMS API documentation.
3.20.1.6.2 .NET

- New functions `GAMSWorkspace.AddJobFromApiLib`, `GAMSWorkspace.AddJobFromNoaLib` to create `GAMSJob` from models from the GAMS API Library and the Nonlinear Optimization Applications Library.

3.20.1.6.3 Python

- New functions `GamsWorkspace.add_job_from_apilib`, `GamsWorkspace.add_job_from_noalib` to create `GamsJob` from models from the GAMS API Library and the Nonlinear Optimization Applications Library.
- Added a version check for the setup.py scripts to avoid unintentional installation of wrong versions.

3.20.1.7 Expert Level APIs

- With GAMS 25.0, the expert-level C++ API files will be removed from the distribution. Users should switch to the expert-level C API files. The object-oriented C++ API introduced in this release could also be a good alternative for replacement if the user C++ code exchanges data and runs a GAMS model.

3.20.1.7.1 GAMS Modeling Object

- Changed the function `gmoGetModelTypeTxt`: Added argument for model type number instead of using the model type of the stored model.

3.20.1.8 Model Libraries

3.20.1.8.1 GAMS Data Library

- `embeddedSort.gms`: Sorting of numerical data using the embedded code facility (108)
- `embeddedSplit.gms`: Splitting of labels using the embedded code facility (109)
- `embeddedMultiInstance.gms`: Handling multiple instances of the embedded code facility at once (110)

3.20.1.8.2 GAMS Model Library

- `dqq.gms`: Warm-starting quad-precision MINOS (414)
- `cbenders.gms`: Cplex Benders for a Simple Facility Location Problem (415)
- `robustlp.gms`: Robust linear programming as an SOCP (416)
3.20.1.8.3 GAMS Test Library

- mpsge14.gms: MPSGE sync test: .GEN/integer1/nnsoves (713)
- fn_sincosinvr.gms: Test sin/cos func/grad interval evals (714)
- procdir1.gms: Test correct behavior of procDir, scrDir and procDirPath (715)
- empbp06.gms: Bilevel model with phantom vars owned by leader (716)
- fnsl.exp.gms: Test correctness of slexp intrinsic (717)
- fn.slexp2.gms: Test correctness of slexp intrinsic (718)
- fn.sqexp.gms: Test correctness of sqexp intrinsic (719)
- fn.sqexp2.gms: Test correctness of sqexp intrinsic (720)
- fn.slog10.gms: Test correctness of slog10 intrinsic (721)
- fn.slog102.gms: Test correctness of slog10 intrinsic (722)
- fn.sqlog10.gms: Test correctness of sqlog10 intrinsic (723)
- fn.sqlog102.gms: Test correctness of sqlog10 intrinsic (724)
- fn.srec.gms: Test correctness of srec intrinsic (725)
- fn.srec2.gms: Test correctness of srec intrinsic (726)
- fn.sqrec.gms: Test correctness of sqrec intrinsic (727)
- fn.sqrec2.gms: Test correctness of sqrec intrinsic (728)
- fn.loggamma.gms: Test correctness of loggamma intrinsic (729)
- fn.binomial.gms: Test correctness of binomial intrinsic (730)
- breakcont2.gms: Advanced test for break and continue statements (731)
- fn.logbeta.gms: Test correctness of logbeta intrinsic (732)
- fn.beta.gms: Test correctness of beta intrinsic (733)
- ssuffix.gms: List of all System Suffixes (734)
- embpy01.gms: Test for embedded code facility (735)
- embpy02.gms: Test for embedded code facility (736)

### 3.20.2 24.9.2 Minor release (November 14, 2017)

#### 3.20.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Paul Buckland, William N. Caballero, Xin Fang, Christophe Gouel, Fabricio Porras-Ortiz, Shigeru Tsubakitani, and Haoshui Yu.
3.20.2.2 GAMS System

3.20.2.2.1 GAMS

- Added prefixing of PYTHONPATH with the site-packages directory of the GAMS Python 3.6 installation in GMSPython.
- Added support for Python sets in the Embedded Python Code method gams.set().
- Speed up detection/extraction of quadratic terms for QCP models.
- Do not allow the use of Embedded Code if execMode is set to 2 or higher.

3.20.2.2.2 Installer

- Removed the execution of a Python script during the Windows installation process that patches the path of certain Python programs in GMSPython\Scripts.

3.20.2.3 Solvers

3.20.2.3.1 BARON

- New libraries 17.10.16.
- Due to a problem with the Ipopt interface in BARON on Mac OS X, the use of Ipopt in BARON is currently disabled on Mac OS X.
- GAMS can now pass a term like \((-\text{negativeConstant})^\text{negativeIntegerVariable}\) to BARON.

Note

By default, GAMS correctly rejects such a formulation, though. To work around this, MaxExecError needs to be set to a positive number and the option sys12 needs to be set to 1. Here is an example, how this could be used:

```plaintext
scalar a /-2/;
integer variable x;
x.lo = -3;
x.up = 3;

variable z;
equation e;
e.. z =e=a**x;
model m /e/;
x.l=1;
MaxExecError = 10;
option sys12 = 1;
solve m min z use minlp;
```

3.20.2.3.2 CPLEX

- Removed any limits on the number of Threads in a GAMS/CPLEX option file. Previously, the maximum for option Threads was 128.
3.20.2.3.3 CONOPT

- New libraries 3.17F.
  - Fixed an infinite loop when using option LMMXSF.

3.20.2.3.4 CONVERT

- Fix for variables with negative lower and infinite upper bound in LINGO output. The LINGO output has been changed to always use the @Bnd keyword to write variable bounds.

3.20.2.3.5 GUROBI

- New libraries 7.5.2.

3.20.2.3.6 GUSS/Scenario Solver

- Added the GUSS option ReportLastScen. If this is set to 1 the solution of the last scenario will be reported back to GAMS rather than solution of the base case. This is particularly useful when GUSS is used to implement a homotopy approach where the shock to a parameter is sliced in several small shocks and hence the last scenario represents the solution to the shocked system.

3.20.2.3.7 Lindo/LindoGlobal

- New libraries 11.0.300.

3.20.2.3.8 LogMIP

- Fixed improper handling of variables fixed at zero that occurred if they were used in nonlinear equations in a disjunction reformulated via the convex hull.

3.20.2.3.9 Mosek

- New libraries 8.1.0.31.
- Fixed dual solution for conic quadratic problems.

3.20.2.3.10 SCIP

- New libraries 4.0 (#22b4564).

3.20.2.3.11 SoPlex

- New libraries 3.0 (#3bfa247).
3.20.2.4 Object Oriented APIs

3.20.2.4.1 C++

- Added a try/catch block around the code that uses the classes from the GAMS C++ OO-API in all examples. Without this, the exceptions thrown by the methods of the GAMS classes will not be reported and harmless exceptions, like a compilation or execution error in the GAMSJob.run method result in application crashes.

3.20.2.4.2 Python

- Fixed a bug in the setup script that prevented files from being installed in the correct location in certain cases.

3.21 24.8 Distribution

3.21.1 24.8.1 Major release (December 21, 2016)

3.21.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Etienne Ayotte-Sauvé, Wolfgang Britz, Göran Bylund, Wietse Dol, Gregory Dourbois, Katja Jensen, Josef Kallrath, Toni Lastusilta, Renger van Nieuwkoop, and Tom Rutherford.

3.21.1.2 Platforms

- On Linux, the minimal required GLIBC version is now 2.7.
- On MacOS X, for some solvers (ANTIGONE, BARON, CPLEX, COIN-OR, SOPLEX, SCIP) the minimal required Mac OS X version is now 10.10. We will drop support for older Mac OS X versions for the complete GAMS system with the next major release.
- A generic license (with platform code GEN) is now limited to the platforms Windows, Linux, and Mac OS X. If you have a generic license and need a license for one of the other platforms (e.g. AIX), please contact sales or support to receive an additional license file for that platform free of charge.

3.21.1.3 GAMS System

3.21.1.3.1 GAMS

- The statements Break and Continue were added to allow more control over the execution of control structures (loop/while/repeat/for):
  - Break [n];: Terminate the n inner most control structures (n is optional, if it is omitted, it is set to 1).
  - Continue;: Jump to the end of the inner most control structure.
• Extend the report summary of the solution report to print the number of variables and equations where the level was projected to one of the bounds (compare model attribute tolProj), if that number is greater than 0.

• The model attribute tolProj to project levels to bounds is no longer ignored when the GAMS Grid Facility (SolveLink = 3 or 4) is used.

• New command line option fileStem: Sets the file stem for output files which use the input file name as stem by default, see fileStem for more details.

• New option MCPRHoldfx (can be set using the option statement, a command line parameter, or model attribute):
  – Prints list of rows that are perpendicular to variables removed due to the holdfixed setting if set to 1.

• New option AsyncSollst (can be set using the option statement, or a command line parameter):
  – If set to 1, GAMS prints a solution listing to the lst file also when an asynchronous solve (see The Grid and Multi-Threading Solve Facility) is used.
  – The default value is 0.

• New variant for the SolveLink option and model attribute: 7 (compile time constant %solveLink.Threads Simulate%) - The problem is passed to the solver in core without use of temporary files, GAMS waits for the solver to come back but uses same submission process as 6 (see Multi-threading Submission Testing)

• New function numCores (available at both compile and execution time): Returns the number of logical cores in the system.

• Allow macro expansion in the domain list of a symbol declaration.

• New dollar control splitOption that splits a string representing a option/value pair into option name and option value.

• Fixed a problem with the optional maxWait parameter of the function readyCollect.

• Fixed potential error in file created by dumpOpt, if there were symbols loaded from GDX.

• Fixed an error which could lead to wrong results when assigning to a symbol while the symbol’s alias was used on the right hand side of the assignment.

• Fixed an error which could lead to a crash if a phantom set element was used to control an assignment inside a loop.

• Fixed a problem with unscaling solutions for MCP models that resulted in incorrect dual values for scaled MCPs. For an example, compare the new test library model mcp11 when run with 24.8 and with something previous.

3.21.1.3.2 Documentation

• The offline documentation now provides search and keyword indexing functionalities in addition to navigating the documentation.

• The Microsoft Compiled HTML help file gams.chm is no longer available.

• The table of contents for browsing the GAMS model libraries is now available offline in HTML format.
3.21.1.4 Solvers

3.21.1.4.1 BARON

3.21.1.4.2 CPLEX

- New libraries 12.7.0.0.
- Support for the platform MS Windows 32 bit, Solaris i86pc, and Solaris SPARC 64bit has been dropped by IBM for Cplex 12.7. The GAMS system for these platforms contains Cplex 12.6.3.
- Cplex 12.7 implements Benders Algorithm. This is available in CplexD only.
- The IIS option triggers now the conflict refiner. The IIS function in Cplex 12.7 has been replaced by the conflict refiner. The IIS option now also works on infeasible models with model status Infeasible No Solution as well as on problems with discrete variables.
- New parameters
  - BendersFeasCutTol: Tolerance for whether a feasibility cut has been violated in Benders decomposition
  - BendersOptCutTol: Tolerance for optimality cuts in Benders decomposition
  - BendersStrategy: Benders decomposition algorithm as a strategy
  - DataCheck: Data consistency checking and modeling assistance
  - RLTcuts: Reformulation Linearization Technique (RLT) cuts
- Modified parameters:
  - MipStart: A value of 6 accepts the (partial) MipStart without any checks

3.21.1.4.3 CONOPT

- This distribution includes the first official release of the CONOPT4 solver. The chapter in the solver manual has an interesting subsection on when you should use CONOPT4 for all existing CONOPT users.
- The current solver alias CONOPT still points to the CONOPT3 solver. This might change in the next, or next but one major release. We invite you to share your experience with this new version of CONOPT via support (support@gams.com) with us.

3.21.1.4.4 ConvertD

- Write proper scale and prior information for equations and variables with option Jacobian.

3.21.1.4.5 DICOPT

- An implementation of a Feasibility Pump primal heuristic (for convex MINLP) has been added to DICOPT. This heuristic can be run before the actual DICOPT algorithm. Outer approximation cuts from the MIP subproblem of the Feasibility Pump are transferred to initialize the MIP outer approximation of the main DICOPT algorithm. Option feaspump can be used to enable the Feasibility Pump and various other options are available to tune the feasibility pump.
- Option convex has been added to indicate the presence of convex MINLP. If this option is set, the defaults for various other options are modified.
3.21.1.4.6 GUROBI

- New libraries 7.0.1.
- Explore alternative solutions via the Solution Pool.
- New parameters
  - BestObjStop: Objective value to stop optimization
  - BestBdStop: Objective bound to stop optimization
  - InfProofCuts: Infeasibility proof cut generation
  - StrongCGCuts: Strong-CG cut generation
  - DegenMoves: Degenerate simplex moves
  - TuneCriterion: Tuning criterion
  - SolNPool: Activate export of alternative solution
  - PoolSolutions, PoolSearchMode, and PoolGap to control generation of alternative solutions
- Gurobi 7 supports general constraints. With the help of the dot-option .GenConstrType the user can classify a constraint to be of type Max, Min, Abs, And, and Or.
- Gurobi 7 supports indicator constraints.
- Gurobi 7 supports multi objective hierarchical optimization. Details can be found in the GAMS/Gurobi manual, in subsection Multiple Objectives.

3.21.1.4.7 JAMS

- New option ZipDebug=xxx.zip to specify that, in the event of abnormal termination or behavior, a zip file of debugging info be created.
- New reformulation options to handle shared or duplicated equations and variables in equilibrium models.

3.21.1.4.8 Knitro

- New libraries 10.2.0.
  - Significant speed and robustness improvements when using BFGS (hessopt=2) or L-BFGS (hessopt=6) Hessian approximations with the default Knitro interior-point method.
  - General performance improvement on mixed-integer models.
  - Minor bug fixes.
  - New mixed-integer SQP (MISQP) algorithm for nonlinear mixed-integer models (mip_method=3). This new algorithm is intended for small, potentially non-convex models with possibly expensive function evaluations. It can be used even when integer variables are not relaxable (i.e. functions can only be evaluated with integer variables at integer points) by setting mip_relaxable=0, and can be used with parallel multistart.
  - New option mip_nodealg to control algorithm used at B&B nodes: overrides the generic algorithm option.
- The Knitro Tuner is now available from the GAMS/Knitro link.
3.21.1.4.9 Lindo/LindoGlobal

- New libraries 10.0.131.
  - LP Solver Improvements:
    * With new enhancements made to the simplex solvers, the average performance on large instances has increased by 35% for the primal simplex and by 20% for the dual simplex compared to the previous version.
  - MIP Solver Improvements:
    * New heuristic algorithms help to find significantly better solutions for many models with knapsack constraints and block structures.
    * New MIP preprocessing level devoted to tightening variable bounds for some nonlinear models.
  - Stochastic Solver Improvements:
    * Improved cut management for Nested Benders Decomposition Method leading to speed improvements over 60% for large linear multistage SP instances.
    * Better handling of multistage SP models which do not have full-recourse.
  - Global Solver Improvements:
    * Incorporates bound tightening process to the linearization procedure and improve solvability of linearized model.

3.21.1.4.10 LocalSolver

- New libraries 6.5 (20160729).
  - For near-linear (discrete or continuous) problems, new moves have been introduced based on linear programming and mixed-integer linear programming techniques. These moves allow to intensify the search on near-linear models by exploring optimally larger neighborhoods.
- Added possibility for "Hierarchical Optimization of Multiple Objective Functions".
- Removed option origlog. GAMS/LocalSolver will now always print the original LocalSolver log.
- Fixed level values of aggregated variables in solution.

3.21.1.4.11 Mosek

- New libraries 8.0.0.48 (Mosek release notes)
  - Presolve performance has been improved.
  - The eliminator in the presolve has been reimplemented, is usually faster, and requires much less memory.
  - Presolve has been improved on conic quadratic problems.
  - The numerical stability of conic optimizer has been improved significantly, particularly for semidefinite optimization problems.
  - The scaling routine for the conic optimizer is more aggressive.
  - Quadratic and quadratically constrained problems are now internally converted to conic form and are solved using the conic optimizer. Nevertheless full primal and dual information to the original problems is available.
  - A dualizer for conic quadratic problems is now available. By default it dualize the problems before optimizing if deemed worthwhile. The dualization is transparent to the user and can be turned off.
The conic optimizer linear algebra is now parallelized using Cilk Plus and scales better when the number of threads is increased for large problems. Moreover, for smallish problems using too many threads does not hurt performance.

The computational efficiency graph partitioning based ordering method in the interior-point optimizer has been improved.

It is now possible to force the interior-point optimizer to run in the calling thread.

Only one mixed integer optimizer is available now, which corresponds to the mixed integer conic optimizer that was introduced with version 7.

The primal network simplex optimizer has been removed. It is suggested to use the dual simplex optimizer instead.

The primal-dual simplex optimizer has been removed. It is suggested to use the dual simplex optimizer instead.

The concurrent optimizer has been removed. It is suggested to use the interior-point optimizer instead.

The following GAMS/Mosek options have been removed:

- MSK_IPAR_ANA_SOL_BASIS
- MSK_IPAR_ANA_SOL_PRINT_VIOLATED
- MSK_IPAR_CONCURRENT_NUM_OPTIMIZERS
- MSK_IPAR_CONCURRENT_PRIORITY_DUAL_SIMPLEX
- MSK_IPAR_CONCURRENT_PRIORITY_FREE_SIMPLEX
- MSK_IPAR_CONCURRENT_PRIORITY_INTPNT
- MSK_IPAR_CONCURRENT_PRIORITY_PRIMAL_SIMPLEX
- MSK_DPAR_FEASREPAIR_TOL
- MSK_IPAR_FEASREPAIR_OPTIMIZE
- MSK_IPAR_INTPNT_FACTOR_DEBUG_LVL
- MSK_IPAR_INTPNT_FACTOR_METHOD
- MSK_IPAR_LOG_CONCURRENT
- MSK_IPAR_LOG_NONCONVEX
- MSK_IPAR_LOG_PARAM
- MSK_IPAR_LOG_SENSITIVITY
- MSK_IPAR_LOG_SENSITIVITY_OPT
- MSK_IPAR_MAX_NUM_WARNINGS
- MSK_IPAR_MIO_CONT_SOL
- MSK_IPAR_MIO_CUT_CG
- MSK_IPAR_MIO_CUT_LEVEL_ROOT
- MSK_IPAR_MIO_CUT_LEVEL_TREE
- MSK_IPAR_MIO_FEASPUMP_LEVEL
- MSK_DPAR_MIO_HEURISTIC_TIME
- MSK_IPAR_MIO_HOTSTART
- MSK_IPAR_MIO_KEEP_BASIS
- MSK_IPAR_MIO_LOCAL_BRANCH_NUMBER
- MSK_DPAR_MIO_MAX_TIME_APRX_OPT
- MSK_IPAR_MIO_PRESOLVE_AGGREGATE
- MSK_IPAR_MIO_PRESOLVE_PROBING
- MSK_IPAR_MIO_PRESOLVE_USE
- MSK_DPAR_MIO_REL_ADD_CUT_LIMITED
- MSK_IPAR_MIO_STRONG_BRANCH
- MSK_DPAR_MIO_TOL_MAX_CUT_FRAC_RHS
- MSK_DPAR_MIO_TOL_MIN_CUT_FRAC_RHS
- MSK_DPAR_MIO_TOL_REL_RELAX_INT
The following GAMS/Mosek options have been added:

- `MSK_DPAR_DATA_SYM_MAT_TOL`: Absolute zero tolerance for elements in symmetric matrices.
- `MSK_DPAR_DATA_SYM_MAT_TOL_HUGE`: An element in a symmetric matrix which is larger than this value in absolute size causes an error.
- `MSK_DPAR_DATA_SYM_MAT_TOL_LARGE`: An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed.
- `MSK_DPAR_INTPNT_QO_TOL_DFEAS`: Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
- `MSK_DPAR_INTPNT_QO_TOL_INFEAS`: Controls when the conic interior-point optimizer declares the model primal or dual infeasible.
- `MSK_DPAR_INTPNT_QO_TOL_MU_RED`: Relative complementarity gap feasibility tolerance used when interior-point optimizer is applied to a quadratic optimization problem.
- `MSK_DPAR_INTPNT_QO_TOL_NEAR_REL`: Termination tolerance multiplier that is used if no accurate solution can be found.
- `MSK_DPAR_INTPNT_QO_TOL_PFEAS`: Primal feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
- `MSK_DPAR_INTPNT_QO_TOL_REL_GAP`: Relative gap termination tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
- `MSK_IPAR_INTPNT_MULTI_THREAD`: Controls whether the interior-point optimizers can employ multiple threads if available.
- `MSK_IPAR_MIO_CUT_CLIQUE`: Controls whether clique cuts should be generated.
- `MSK_IPAR_MIO_CUT_GMI`: Controls whether GMI cuts should be generated.
- `MSK_IPAR_MIO_CUTIMPLIED_BOUND`: Controls whether implied bound cuts should be generated.
- `MSK_IPAR_MIO_CUT_KNAPSACK_COVER`: Controls whether knapsack cover cuts should be generated.
- `MSK_IPAR_MIO_CUT_SELECTION_LEVEL`: Controls how aggressively generated cuts are selected to be included in the relaxation.
- `MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE`: Enables or disables perspective reformulation in presolve.
- `MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL`: Controls whether presolve can be repeated at root node.
- `MSK_IPAR_MIO_VB_DETECTION_LEVEL`: Controls how much effort is put into detecting variable bounds.
- `MSK_IPAR_OPF_WRITE_HEADER`: Write a text header with date and MOSEK version in an OPF file.
* **MSK_IPAR_OPF_WRITE_HINTS**: Write a hint subsection with problem dimensions in the beginning of an OPF file.
* **MSK_IPAR_OPF_WRITE_PROBLEM**: Write objective, constraints, bounds etc.
* **MSK_IPAR_OPF_WRITE_SOL_BAS**: Whether to include basic solution in OPF files.
* **MSK_IPAR_OPF_WRITE_SOL_ITG**: Whether to include integer solution in OPF files.
* **MSK_IPAR_OPF_WRITE_SOL_ITR**: Whether to include interior solution in OPF files.
* **MSK_IPAR_OPF_WRITE_SOLUTIONS**: Enable inclusion of solutions in the OPF files.
* **MSK_DPAR_SEMIDEFINITE_TOL_APPROX**: Tolerance to define a matrix to be positive semidefinite.
* **MSK_IPAR_WRITE_DATA_PARAM**: If this option is turned on the parameter settings are written to the data file as parameters.
* **MSK_IPAR_WRITE_LP_FULL_OBJ**: Write all variables, including the ones with 0-coefficients, in the objective.
* **MSK_IPAR_WRITE_MPS_FORMAT**: Controls in which format the MPS is written.
* **MSK_IPAR_WRITE_TASK_INC_SOL**: Controls whether the solutions are stored in the task file too.
* **MSK_SPAR_WRITE_LP_GEN_VAR_NAME**: Sometimes when an LP file is written additional variables must be inserted.

- For the following options, the default value has changed:
  * **MSK_DPAR_MIO_TOL_FEAS** from 1e-7 to 1e-6
  * **MSK_IPAR_LOG_MIO_FREQ** from 1000 to 10
  * **MSK_IPAR_WRITE_PRECISION** from 8 to 15

- Fixed selection of optimizer for "fixed solve" of a mixed-integer conic problem.

### 3.21.1.4.12 Pyomo

- Fixed compatibility issues with different versions of Pyomo.

### 3.21.1.4.13 SCIP

- New libraries 3.2 (#0d4fc08).
- Changed the default LP solver to SoPlex also for the case where a CPLEX license is available, due to problems when using CPLEX 12.7.0.0 as LP solver in SCIP.

### 3.21.1.4.14 SoPlex

- The GAMS/SoPlex interface has been rewritten and does not use the OsiSpx layer anymore. The solver OSISOPLEX is now an alias for the solver SoPlex.
- SoPlex parameter files can now be used.
- SoPlex can now be warmstarted when only the model instance data changes (e.g., via GUSS).
- New libraries 2.2 (df190de).
3.21.1.5 Tools

3.21.1.5.1 CSV2GDX

- Improved error reporting.

3.21.1.5.2 GDXDUMP

- New command line option `CSVAllFields` to get all fields (level, marginal, lower, upper, and scale) when writing a variable or equation symbol in CSV format.

3.21.1.5.3 MODEL2TEX

- Increased the page width of the txt file generated by the GAMS command line option `docfile` to 32767 (max. value).
- Changed the default encoding to `latin` and added a new command line parameter that allows to change the encoding (`-e=ENCODING`)
- Changed the default format of the symbol tables.
- The JSON style file contains a new property called `columnSetting` that allows to adjust the columns.
- Avoid some unnecessary parentheses in sum and product operators.
- Minor change in the equations subsection that removes several warnings.
- Several minor bug fixes.

3.21.1.5.4 GDXXRW

- Fixed a problem when writing a symbol with option merge or clear to a range with `CDim=0` or `RDim=0`.

3.21.1.5.5 GMSZIP/GMSUNZIP

- New versions of Info-ZIP’s tools `zip` (version 3.1c02) and `unzip` (version 6.00). The executable names have been prefixed with ”gms” for clear identification.

3.21.1.6 Object Oriented APIs

- New option `GAMSOptions.ErrorLog`: Maximal number of error message lines written to the log for each error.

3.21.1.6.1 .NET

- New examples that demonstrate the use of the API in a graphical environment: TransportGUI, CutstockGUI, FarmGUI.
- Distribute compiled GUI examples in directory `<GAMSDir>\apifiles\GUIexamples` on Windows.
- `GAMSWorkspace.AddJobFromFile`: Throw an exception if a given file does not exist.
3.21.1.6.2 Python

- The option `GamsOptions.errorlog` has been renamed to `GamsOptions.errorlog` in order to indicate it as public.

3.21.1.7 Model Libraries

3.21.1.7.1 GAMS API Library

- `PInterrupt.gms`: Test GamsJob interrupt mechanism in object oriented Python API (54)
- `CSInterrupt.gms`: Test GamsJob interrupt mechanism in object oriented .Net API (55)

3.21.1.7.2 GAMS Model Library

- `asyncloop.gms`: Transportation Problem with async loop body execution (411)
- `trnsindic.gms`: Fixed Charge Transportation Problem with Indicator Constraints (412)
- `timesteps.gms`: Accessing previous (or next) time steps in an equation fast (413)
- Modified models:
  - Make use of the new `break` statement to formulate the following models a little nicer: `tsp1`, `tsp4`, `cutstock`, `awktsp`, `sddp`, `sipres`, `allbases`, `qfilter`
  - `tgridmix`: The logic of submission and collection has been reworked so that the scenario sets do not have to be one dimensional and ordered (contributed by Tom Rutherford).
  - `asyncjobs`: The logic for putting out the log line in time intervals was flawed and has been corrected.

3.21.1.7.3 GAMS Test Library

- `emp17.gms`: Simple test of one optimizing agent (693)
- `breakcont1.gms`: Test break and continue statements (694)
- `lindgl04.gms`: Test non-convex quadartic program with Lindo(Global) (695)
- `mcp11.gms`: Test marginals for a scaled MCP problem (696)
- `csv2gdx1.gms`: Test csv2gdx on input containing spaces (697)
- `gdxxrw7.gms`: Test merge and clear option for special data layout (698)
- `scale02.gms`: Test that an MCP with scales is rejected when appropriate (699)
- `emp18.gms`: Test JAMS/EMP on implicit variable handling (700)
- `emp19.gms`: Test JAMS/EMP on implicit variable handling (701)
- `emp20.gms`: Test JAMS/EMP on implicit variable handling (702)
- `emp21.gms`: Test JAMS/EMP on implicit variable handling (703)
- `emp22.gms`: Test JAMS/EMP on implicit variable handling (704)
3.21 24.8 Distribution

- emp23.gms: Test JAMS/EMP on implicit variable handling (705)
- emp24.gms: Test JAMS/EMP on implicit variable handling (706)
- emp25.gms: Test JAMS/EMP on implicit variable handling (707)
- emp26.gms: Test JAMS/EMP on implicit variable handling (708)
- gurobi02.gms: GUROBI test suite - general constraints max,min,abs (709)
- gurobi03.gms: GUROBI test suite - general constraints and,or (710)
- slx01.gms: run tests for different solvelink values (711)
- gurobi04.gms: GUROBI test suite - multi objective (712)

3.21.2 24.8.2 Maintenance release (January 03, 2017)

3.21.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Evangelos Panos.

3.21.2.2 GAMS System

3.21.2.2.1 GAMS

- Change for command line parameter MultiPass: If it is set to 2, all errors from \$gdxIn are ignored now
- Fixed a bug which caused wrong results in some assignments which use symbols that were used out-of-order in previous assignments.

3.21.2.3 Solvers

3.21.2.3.1 SCIP

- Added a workaround that allows for using CPLEX 12.7.0.0 as LP solver in SCIP again. For the moment, the default is still to use SoPlex.

3.21.3 24.8.3 Minor release (January 28, 2017)

3.21.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Mohammad R. Hesamzadeh, and Katja Jensen.

3.21.3.2 GAMS System

3.21.3.2.1 GAMS

- Fixed potentially wrong values for model attribute etSolver for cases where the command line option solveLink was set to 1, 2 or 5.
3.21.3.3 Solvers

3.21.3.3.1 BARON

- New libraries 17.1.2.
  - More robust links with COIN-OR solvers and a better link with FICO Xpress.
  - Some new RLT cuts are included in relaxations.

3.21.3.3.2 DE

- Create a capability error if DE is called to solve a model of type EMP without stochastic information.

3.21.3.3.3 DECIS

- Create a capability error if DECIS is called to solve a model of type EMP without stochastic information.

3.21.3.3.4 Examiner2

- Fix behavior when the subsolver returns a model status like 19 Infeasible - No Solution. The model status can be passed unchanged back to GAMS in such a case.

3.21.3.3.5 Kestrel

- Adjusted the default URL to https using port 3333.
- Fixed a bug that prevented to specify the protocol in the neos_server parameter in an option file. The complete format of the parameter is now protocol://host:port.

3.21.3.3.6 LINDO

- Create a capability error if LINDO is called to solve a model of type EMP without stochastic information.

3.21.3.3.7 MOSEK

- New libraries 8.0.0.53.

3.21.3.3.8 SCIP

- Changed the default LP solver back to CPLEX, if available (see also 24.8.1 and 24.8.2 release notes).
3.21.3.4 Tools

3.21.3.4.1 GDXDUMP

- Fixed wrong output in case of nested quotes in symbol text.

3.21.3.5 Model Libraries

3.21.3.5.1 GAMS Model Library

- linearne: Minor fix to model formulation (contributed by Mohammad R. Hesamzadeh).

3.21.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Ivan Leung, Tara Rengarajan, and Sajjad Shafiei.

3.21.4.2 GAMS System

3.21.4.2.1 GAMS

- Fixed an issue which caused unnecessary memory consumption if many indexed symbols with explicit labels were used.

3.21.4.3 Solvers

3.21.4.3.1 BARON

- New libraries 17.4.1.
  - Bug fixes and an enhanced convexity detector.

3.21.4.3.2 CPLEX

- New libraries 12.7.1.0.
  - Note that with this update the log generated by Cplex changed in a way that the Cplex options set (either by the user or by GAMS defaults) are displayed. This is intentional and no sign of a problem. So one could see something like this in the log when running GAMS/Cplex:

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPXPARAM_Simplex_Limits_Iterations</td>
<td>2000000000</td>
</tr>
<tr>
<td>CPXPARAM_TimeLimit</td>
<td>1000</td>
</tr>
<tr>
<td>CPXPARAM_Threads</td>
<td>1</td>
</tr>
</tbody>
</table>
3.21.4.3.3 DICOPT

- Fixed serious bug in feasibility pump implementation.

3.21.4.3.4 Examiner, Examiner2

- The list of checks to perform for solved models was set incorrectly when the trace option was used.

3.21.4.3.5 GUROBI

- New libraries Gurobi 7.0.2.
- Added options MultiObjMethod and MultiObjPre.
- Fixed a problem that lead to wrong error messages when setting the ObjNAbsTol and ObjNRelTol parameters.
- Fixed a problem that reported back the wrong alternative solution.

3.21.4.3.6 JAMS

- Fix problem with bilevel models having variables owned by the leader but not appearing in the leader objective or constraints.

3.21.4.3.7 Lindo/LindoGlobal

- New libraries 10.0.179.

3.21.4.3.8 MOSEK

- New libraries 8.0.0.60.

3.21.4.3.9 NLPEC

- Fix problem handling empty constraints (e.g. \( \text{eps} x = \text{G} = 0 \)) that appear in MPEC models. Note that such models can easily be produced by JAMS/EMP.

3.21.4.4 Object Oriented APIs

3.21.4.4.1 Python

- Added support for Python 3.6.
- Fixed a bug in `GamsJob.run()` that prevented the underlying GAMS model from terminating, if executables spawned by GAMS generate log output that is not captured.
3.21.5 24.8.5 Maintenance release (May 10, 2017)

3.21.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Ana Carolina, Gary Goldstein, Erwin Kalvelagen, Amit Kamdia, Toni Lastusilta, Antti Lehtila, Bruce McCarl, and Hans Kristian Ringkjob.

3.21.5.2 Platforms

- The AIX system is now build on AIX 7.1.

3.21.5.3 GAMS System

3.21.5.3.1 GAMS

- Fixed a bug which could cause a crash in particular assignments involving singleton sets or explicit labels. This was introduced with GAMS 24.8.4.
- Fixed problems with the break statement:
  - There was a potential crash if break was used in a "sparse loop", e.g., \texttt{loop(j$x(j), ...).}
  - If break was used in a loop with more than one index, e.g., \texttt{loop((i,j), ...)}, that loop was treated as multiple loops for the break statement, one for each index. Now it is treated as just one loop as intended.
  - Fixed a problem where a loop was not correctly recognized as a loop if it runs over just one fixed element, e.g., \texttt{loop(i('i2'), ...)}.

3.21.5.4 Solvers

3.21.5.4.1 BARON

- Initialize BARON option Threads with value of GAMS option Threads, if the latter is at least 1.

3.21.5.4.2 CBC

- New libraries.
  - Fixed a bug in presolve that caused problems with fixed discrete variables.

3.21.5.4.3 GUROBI

- Suboptimal solutions were not reported back to GAMS. This has been fixed.

3.21.5.4.4 Lindo/LindoGlobal

- New libraries 10.0.182.
3.21.5.4.5 MOSEK

- New libraries 8.0.0.69.

3.22 24.7 Distribution

3.22.1 24.7.1 Major release (March 14, 2016)

3.22.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Alex Dowling, Johannes Hedtrich, Austin Milt, and Salvador Pineda.

3.22.1.2 GAMS System

3.22.1.2.1 GAMS

- Be more strict when the syntax $\texttt{LOAD par=var.L}$ is used: This creates an error now, if \texttt{par} is not a parameter (if \texttt{par} was a variable before, the complete variable \texttt{var} was loaded as if the suffix was omitted).
- GAMS Grid Facility (\texttt{SolveLink = 3 or 4})
  - Fixed a bug for the model attribute \texttt{objval}: This could have been wrong when the objective variable was scaled.
  - Fixed a bug for the marginals: These could have been wrong when the objective variable was scaled.
- Solving in parallel threads (\texttt{SolveLink = 6})
  - Allow to solve scaled models (model attribute \texttt{scaleOpt} is set to 1) as well (this generated an execution error before).

3.22.1.3 Solvers

3.22.1.3.1 BARON

- New libraries 16.3.4.
  - Faster LP interfaces.
  - Additional checks on solution reliability of LP and NLP subsolvers.
  - New automatic differentiation routines.
  - Improved handling of memory-intensive problems.
  - Enhanced presolving for continuous and integer programs.
  - New primal heuristic for integer programs.
  - New facilities for solving constraint (non)linear systems (CNS).
3.22.1.3.2 CBC

- New libraries.

3.22.1.3.3 ConvertID

- The GDX file created with option Jacobian contains now a set ANl that indicates the non-linear Jacobian elements.

3.22.1.3.4 CPLEX

- For an unbounded model Cplex did not mark the unbounded variables correctly. This has been fixed.

3.22.1.3.5 GUROBI

- Gurobi Optimization, Inc. has decided to end the current arrangement that allows us to offer GAMS/Gurobi integrated licenses. GAMS will continue to offer the latest version of Gurobi but users will need to get a Gurobi license from Gurobi Optimization, Inc. plus a GAMS/Gurobi link license from GAMS or use the free OsiGurobi link. This includes evaluation and demo licenses. For existing GAMS/Gurobi customers the following transition arrangements have been negotiated. The GAMS/Gurobi integrated license will continue to work as long as the license stays under maintenance. Academic GAMS/Gurobi customers will not be able to renew maintenance on their GAMS/Gurobi integrated license, their license will be changed into a GAMS/Gurobi link license. Academic users can get free Gurobi licenses from www.gurobi.com. In the past, academic GAMS/Gurobi link or GAMS/OsiGurobi licenses did not require a Gurobi license installed. This has changed with this release.
  - New libraries 6.5.1
  - The option PreSOS1BigM and PreSOS2BigM were incorrectly classified as integer options. They have been reclassified as real option.

3.22.1.3.6 IPOPTH

- Fixed a memory access issue in the linear solver HSL MA86 in case of very large models.

3.22.1.3.7 LocalSolver

- New libraries 6.0 (20160308).

3.22.1.3.8 MOSEK

- New libraries 7.1.0.49.
3.22.1.3.9 SBB

- Fixed a problem with option UserHeurCall. This option required that all discrete variables were declared first in the model. This is not necessary anymore.

3.22.1.3.10 SCIP

- New libraries 3.2 (#f69c505).
  - The timing mask for parameters constraints/.../presoltiming, presolving/.../timing, and propagating/.../presoltiming changed from 2/4/8 for fast/medium/exhaustive to 4/8/16.
  - Parameter constraints/SOS1/updateconflpresol has been renamed to constraints/SOS1/perfimplanalysis.
  - [Detailed Changelog](#).

3.22.1.3.11 SOPLEX

- New libraries 2.2 (#12d3858).

3.22.1.4 Tools

3.22.1.4.1 GAMS IDE

- Fixed a bug which caused an error when opening the FINLIB (Practical Financial Optimization Models).

3.22.1.4.2 MODEL2TEX

- Fixed a bug regarding negative variables.
- Fixed a bug regarding subscripts of symbol names with underscores.
- Fixed a bug that prevented alternative names from being replaced in Ord constructs.
- New parameter -o (-OUTPUT) that allows to specify an alternative output file.
- Use UTF8 encoding.
- The columns of the symbol table have a fixed (equal) width.
- The original name of a symbol that is changed using the JSON style file is displayed in the symbol table.
- The JSON style file is alphabetically sorted by keys.

3.22.1.5 Object Oriented APIs

- Fixed a bug with the property GAMSOptions.Defines (.NET), GAMSOptions.defines (Java), and GamsOptions.defines (Python): When too many entries were added, all of them were ignored.
3.22.1.5.1 Python

- Fixed a memory leak in GamsDatabase.

3.22.1.6 Model Libraries

3.22.1.6.1 GAMS Test Library

- scale01.gms : Test results of scaled model (692)

3.22.2 24.7.2 Minor release (July 07, 2016)

3.22.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Peter Alexander, Daniel Balistrieri, Paul Buckland, Denis Hess, Eden Huang, Josef Kallrath, Sherman Robinson, Tom Rutherford, Jhih-Shyang Shih, and Loic Ventre.

3.22.2.2 Platforms

- With the next major release, the minimal glibc version requirement for the GAMS distribution on Linux will be increased to 2.7.

3.22.2.3 GAMS System

3.22.2.3.1 GAMS

- Improved the performance for assignments from one large symbol to itself inside a loop, when only one element gets changed, e.g.:
  \[
  \text{loop}((j,cty,yrs,sim), \ldots; \text{par}(j,cty,'Total',yrs,sim) = \text{sum}(lnd, \text{par}(j,cty,lnd,yrs,sim)));
  \]
- Fixed a performance issue which caused very long model generation time for large scalar models.

3.22.2.4 Solvers

3.22.2.4.1 BARON

- New libraries 16.5.16.
  - Added option WantDual to indicate whether BARON should make a final call to an NLP solver to try to compute duals if an inexpensive method of calculating them failed.
- CompIIS option did not print IIS into listing file. This has been fixed.

3.22.2.4.2 CBC

- New libraries.
3.22.2.4.3 CPLEX

- New libraries 12.6.3.0.2.
- A memory leak in Cplex has been fixed that showed up in combination with the OO-API GAMSMo-
  dleInstance class.
- Fixed a problem with CplexD option FreeGamsModel.
- Fixed a problem with MipStart in combination with SemiInt or SemiCont variables with lower
  bound 0.

3.22.2.4.4 GUROBI

- New libraries 6.5.2.

3.22.2.4.5 JAMS

- Fix handling of objectives in optimizing agents of equilibrium systems in cases where the objective
  coefficient was not 1 or -1, and in the equation level returned for the objective row(s).

3.22.2.4.6 LocalSolver

- New libraries 6.0 (20160625).

3.22.2.4.7 Mosek

- New libraries 7.1.0.52.

3.22.2.4.8 OsiMosek

- Fixed handling of gap tolerances and node limit of MIP solves.

3.22.2.4.9 SBB

- Fixed a problem with models that have domain violations in the root NLP.
- Clearly identify text written to the listing file as output from the root solver.

3.22.2.4.10 SCIP

- New libraries 3.2 (#e99d344).

3.22.2.4.11 SoPlex

- New libraries 2.2 (#3c5e86f).
3.22.2.4.12  PATH

- Fixed a problem with bogus report of empty rows/cols when benchmarking a model, i.e. solving with iterlim=0.

3.22.2.4.13  XPRESS

- Several minor bug fixes that affect correctness and performance in some uncommon cases.

3.22.2.5  Tools

- Increase maximum available memory for GDXVIEWER, MDB2GMS, SQL2GMS, XLS2GMS, GDX2HAR, and HAR2GDX to 3GB.

3.22.2.5.1  CSV2GDX

- Fixed a problem with labels with trailing blanks. Labels with trailing blanks potentially resulted in a broken GDX file.
- Introduced the symbolic constant \texttt{LastCol} for the \texttt{Values} parameter.
- Report duplicate keys.

3.22.2.5.2  GDXXRW

- Fixed a problem with unnecessary memory consumption when writing with option clear or merge.
- Symbols and text were not written in sequence as instructed. This has been fixed.
- Added command line parameter \texttt{ReCalc} that by default prevents frequent recalculations in Excel while writing to the spreadsheet.

3.22.2.6  Object Oriented APIs

- Fixed a bug which did not clear a pending Ctrl-C event, so that it might have been applied to a following \texttt{GAMSModelinstance.Solve} by accident.
- Fixed a problem, that caused a crash instead of a \texttt{GAMSException} in some rare cases.

3.22.2.6.1  Python

- Fixed a minor bug regarding the names of GamsJob listing files.

3.22.2.7  Model Libraries

- Some URLs in various models have been updated.
3.22.3 24.7.3 Maintenance release (July 11, 2016)

3.22.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Josef Kallrath, and Toni Lastusilta.

3.22.3.2 Tools

3.22.3.2.1 CSV2GDX

- Fixed a bug which caused an error when reading sets from a csv file.

3.22.3.2.2 MODEL2TEX

- Fixed a bug regarding wrongly generated equations in the generated LaTeX file.

3.22.4 24.7.4 Minor release (September 19, 2016)

3.22.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Manuel Alvarez, Felix Färber, Ricardo Manuel Pinto de Lima, and Tara Rengarajan.

3.22.4.2 GAMS System

3.22.4.2.1 GAMS

- Fixed a problem when using extrinsic function libraries using API version 1.
- Extend possible range of \( n \) in \texttt{fact(n)} at compile time. It was limited to 20 in the past. Now it can be up to 166 (as in assignments at execution time).

3.22.4.2.2 Installer

- New default group name (\texttt{GAMS xx.x (xx bit)}) for the start menu on Windows 10.

3.22.4.3 Solvers

3.22.4.3.1 BARON

  - Small performance improvements and robustification of LP solver interfaces and bugfixes.
  - The starting point is now utilized before invoking projection and other initialization strategies.
  - The option \texttt{DeltaTerm} is now recognized again.
3.22.4.3.2 Couenne

- New libraries.

3.22.4.3.3 CPLEXD

- The option MipStart accepts now values other than 0 and 1. The value describes the effort level Cplex uses to determine a MipStart from the starting variable levels. The value 2 is interesting because it just checks for feasibility of the MipStart. In this case the level of all variables, not only the discrete ones, are passed on to Cplex.

3.22.4.3.4 DE

- DE crashed if multiple joint variables were present in one stage. This has been fixed.

3.22.4.3.5 Lindo/LindoGlobal

- New libraries 9.0.293.

3.22.4.3.6 Mosek

- New libraries 7.1.0.55.

3.22.4.3.7 SCIP

- New libraries 3.1 (#6b9196f).

3.22.4.3.8 SoPlex

- New libraries 2.2 (#074950a).

3.22.4.4 Tools

3.22.4.4.1 CSV2GDX

- Fixed a bug which lead to a rejection of unquoted labels with spaces. This bug was introduced in 24.7.2.

3.22.4.4.2 GDXXRW

- Fixed a bug which caused an error message when reading a sheet with a non-empty range that contained no data.
3.22.4.5 Object Oriented APIs

- `GAMSModelInstance.Instantiate`: Skip creation of GDX file, which was unreachable from within the APIs anyway.

3.22.4.5.1 Python

- Added support for Python 3.4 on Mac OS X.
- Fixed a problem with Exceptions in `GamsWorkspace`.

3.23 24.6 Distribution

3.23.1 24.6.1 Major release (January 18, 2016)

3.23.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Etienne Ayotte-Sauvé, Michael Ferris, Per Ivar Helgesen, Erwin Kalvelagen, Martha Loewe, Geoff Moore, and Renger van Nieuwkoop.

3.23.1.2 Platforms

- The minimal supported Mac OS X version has been increased to 10.9 (Mavericks). COIN-OR solvers, Gurobi, SCIP, and SoPlex now require a system with at least Mac OS X 10.9. The GAMS base system, tools, and other solvers are still working on Mac OS X 10.7 and 10.8, but may stop working in a future release without extra announcement.
- The installer for Wine on Linux has been dropped.

3.23.1.3 GAMS System

3.23.1.3.1 GAMS

- Increased controlled set nesting limit from 120 to 300.
- New option `SHUFFLE`.
- New option for command line parameter `MultiPass`:
  - 0: standard compilation
  - 1: check-out compilation
  - 2: as 1 and in addition skip `$call` and ignore errors because of missing files with `$include` (NEW)
- Allow to load variable and equation attributes into a parameter at compile time, e.g. `$LOAD par=var.L` (par being a parameter and var a variable)
Solving in parallel threads (beta feature)

A new variant for the SolveLink option and model attribute has been added. If SolveLink is set to 6 (compile time constant \%solveLink.Async Threads\%), GAMS does not wait for the solver to return and does not collect the result when a solve statement is executed. Instead, the model is generated and then passed to the solver in a separate thread while GAMS continues the execution. This way, multiple models can be solved in parallel and the results can be collected later.

This is similar to the Grid Facility (SolveLink = \%solveLink.Async Grid\%=3) with the difference, that the solver does not operate in its own process space but in a separate thread, which allows efficient in-memory communication between GAMS and the solver (like it is done with SolveLink = \%solveLink.Load Library\%=5). After the solve statement, one can store a handle of the model instance (using the model attribute mymodel.handle) and use the same functions that are used for the Grid Facility to collect the solution and deal with the model instance: HandleCollect(handle), HandleStatus(handle), and HandleDelete(handle).

The new function ReadyCollect(handleParameter [, maxWait]) can be used to wait until a model is ready to be collected. It can be used for both SolveLink = \%solveLink.Async Threads\% and SolveLink = \%solveLink.Async Grid\%. The arguments and return codes are:

- **Arguments**
  - handleParameter: parameter holding handles of model instances to wait for
  - maxWait: maximum time to wait (+INF if omitted)

- **Return Codes**
  - 0: (one of) the requested job(s) is ready
  - 1: no active job to wait for
  - 2: no handle provided
  - 3: invalid handle
  - 4: user specified time-out when using a SolveLink = \%solveLink.Async Threads\% handle
  - 5: user specified time-out when using a SolveLink = \%solveLink.Async Grid\% handle
  - 8: unknown error (should not happen)

The new option threadsAsync (available on the command line and with the option statement) sets the maximum number of threads that should be used for the asynchronous solves. If a negative number is set, this specifies how many of the available processors on the host machine should not be used. The default setting is -1.

Currently, the following solvers can be used with SolveLink = \%solveLink.Async Threads\%:

- CONOPT
- CPLEXD
- GUROBI
- MOSEK
- OSICPLEX
- OSIGUROBI
- SCIP

If another solver is selected, SolveLink = \%solveLink.Async Grid\% will be used instead (which is noted in the log).

An example of how this new feature can be used, can be seen in the GAMS Model Library model tgridmix.

### 3.23.1.3.2 Stochastic Programming with EMP

- Fixed a bug which caused wrong expected values for parametric distribution using the RandVar keyword.
3.23.1.4 Solvers

3.23.1.4.1 ANTIGONE

- New libraries.

3.23.1.4.2 BARON

- The handling of branching priorities in a GAMS/BARON options file has changed. Priorities should now always be given in the GAMS convention.

3.23.1.4.3 Convert

- GAMS branching priorities are now converted to BARON branching priorities when writing a BARON input file.

3.23.1.4.4 CPLEX

- New libraries 12.6.3.
- Cplex and CplexD now report the deterministic time spend (in ticks not in seconds) in the model attribute $\text{ETAlg}$.
- IBM's Cplex cloud offering "DOcloud" can be accessed via the Kestrel solver.

3.23.1.4.5 DICOPT

- New option $\text{usexinit}$ instructs DICOPT to start the NLP sub-solves from the user supplied input point.

3.23.1.4.6 GUROBI

- New libraries 6.5.
- New option $\text{PreMIQCPForm}$ that determines the format of the presolved version of an MIQCP model.
- New option $\text{WorkerPort}$ specifies a non-default port number for the distributed worker machines.
- New option $\text{VarHint}$. The variable hints communicated through $\text{level}$ and $\text{tryint}$ will affect the heuristics that Gurobi uses to find feasible solutions, and the branching decisions that Gurobi makes to explore the MIP search tree.
- GAMS/Gurobi supports solving models in the Gurobi Instant Cloud.
- Fixed a problem with option $\text{IIS}$ for models with SOS variables.

3.23.1.4.7 IPOPT

- MKL Pardiso is now available as linear solver on Mac OS X, too.
3.23.1.4.8 KESTREL

- The Kestrel client provides experimental access to IBM's DOcloud offering.

3.23.1.4.9 PATH

- Minor fix for zero tolerance in the basis reset routine of the Lemke method.

3.23.1.4.10 Sulum

- Sulum will be dropped from the distribution with GAMS 24.8.

3.23.1.4.11 XPRESS

- Updated Optimizer libraries for Windows and Linux: 28.01.05 → 28.01.10.
- Several minor bug fixes that affect correctness and performance in some corner cases.

3.23.1.5 Tools

3.23.1.5.1 ASK

- New feature SelectDirectory.

3.23.1.5.2 GAMS IDE

- Sorting by symbol name is no longer case sensitive.
- GDX viewer can now show numbers with full precision.
- The option editor no longer shows the dot options.
- Fixed a bug where the cursor was not shown after double-clicking on a red line.

3.23.1.5.3 GDX2SQLITE

- New version 0.7.
  - Added option varchar to export character columns as VARCHAR(255) instead of TEXT.
  - Better names of columns when option small is used.
  - Adding timing info.

3.23.1.5.4 GDXMERGE

- Protect against very large symbols causing memory errors.
- Added option EXCLUDE to exclude symbols from being merged.
3.23.1.5.5 GDXXRW

- An empty range is no longer an error.

3.23.1.5.6 SQL2GMS

- In the old version double quotes were removed when reading a command file. In this version we keep double quotes to be able to escape SQL names (table names, column names). E.g. we now can handle non-standard names by double quoting them in a query. Depending on the database you can do:

  \[ q = \text{select "Some COLUMN" from "This Table"} \]

  Note that some databases (such as SQL Server) use [ ] for this goal.

  In the special case where you write:

  \[ q = \text{"select c from t"} \]

  the surrounding double quotes are removed before passing the query on to the database.

3.23.1.5.7 MODEL2TEX

- If an identifier is changed using the specifications in the JSON style file, underscores are no longer changed from "_" to "\_". This makes it possible to use subscripts when replacing an identifier.

3.23.1.6 Object Oriented APIs

3.23.1.6.1 Java

- Fixed a bug in `GAMSModelInstance.copyModelInstance` method when duplicating scratch directory.

3.23.1.6.2 Python

- New example `transport8a.py`.

3.23.1.7 Model Libraries

3.23.1.7.1 GAMS EMP Library

- `nbcontindep`: use sampling for continuous distributions if another solver than Lindo is selected
- `nbcontjoint`: use sampling for continuous distributions if another solver than Lindo is selected
- `nbsimple`: use discrete distribution
3.23.1.7.2 GAMS Test Library

- shuffle1.gms: Test for option shuffle (690)
- sl601.gms: Check correct behavior when using solveLink=6 (691)

3.24 24.5 Distribution

3.24.1 24.5.1 Major release (September 23, 2015)

3.24.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Guillaume Erbs, Michael Ferris, Mahbube Habibian, Josef Kallrath, Jean Mercenier, Stan Peter, Ingmar Schlecht, and Mark Thissen.

3.24.1.2 Platforms

- Support for Windows XP has been dropped completely with this release (as announced).

3.24.1.3 GAMS System

3.24.1.3.1 GAMS

- New model attributes
  - maxInfes: Maximum of infeasibilities
  - meanInfes: Arithmetic mean of infeasibilities
- New option solver. This simplifies the selection of the (default) solver for multiple model types.
  - The command line option solver=abc initializes the default solver for the model types solver abc is capable of to abc. This initialization is done before the default solvers of individual model types are set via command line options. So a command line with lp=conopt solver=bdmlp will first set BDMLP as the default solver for model types LP, RMIP, and MIP (these are the model types BDMLP can handle) and then reset Conopt as the default solver for LP. The order of these parameters on the command line has no impact (i.e. lp=conopt solver=bdmlp behaves identically to solver=bdmlp lp=conopt). If multiple occurrences of option solver appear, the last one sets the option as it is with other options, including LP, MIP, ...
  - The solver for multiple model types can be set via the option solver=abc; in the GAMS model source code. This sets the solver for model types abc can handle to abc. With the option solver=abc; the order among other solver setting options is significant. For example, option lp=conopt, solver=bdmlp; will first set the solver for LP to Conopt and in the next step to BDMLP because BDMLP is capable of handling model type LP. Setting solver twice can also make sense: option solver=conopt, solver=cbc; will result into setting the solver for model types CNS, DNLP, NLP, QCP, RMIQCP, and RMINLP to Conopt and the solver for model types LP, RMIP, and MIP to CBC.
- When using $LOADDC the reporting of domain errors has been improved.
- This release features several improvements of the execution system. The following lists some (extreme) examples:
– Improved performance when indices of accessed symbol are in "wrong" order, e.g.:

```gams
$if not set size $set size 10000
set v / v1*v%size% /
set e / e1*e%size% /;
alias(v,w);
set evw(e,v,w) /#e:#v:#w/;
vw(v,w) = sum(e, evw(e,v,w));
vw(v,w) = sum(e, evw(e,v,w));
The final assignment can be done in less than 1% of the time required by GAMS 24.4.
```

– Improved performance when assigning to non-empty symbols when the assignment is driven by their domain, e.g.:

```gams
$if not set size $set size 5000
set i / i1*i%size% /; alias (i,j);
parameter a(i,j), b(i,j);
a(i,j)$uniform(0,1)<0.95 = 1;
b(i,j) = not a(i,j);
a(i,j) = b(i,j);
The final assignment can be done in just \(~5\%\) of the time required by GAMS 24.4.
```

– Improved performance when executing certain combinations of mappings, e.g.:

```gams
$if not set size1 $set size1 8000
$if not set size2 $set size2 24
$if not set size3 $set size3 200000
set hi / 1*%size1% /
set ti / 1*%size2% /
set h / h1*h%size1% /
set t / t1*t%size2% /
hmapx(h,hi) / #h:#hi /
tmapx(t,ti) / #t:#ti /;
parameter xi(hi,ti), x1(h,t);
x1(h,t) = sum((hmapx(h,hi),tmapx(t,ti)), xi(hi,ti));
The final assignment can be done in just \(~2\%\) of the time required by GAMS 24.4.
```

– Improved performance when "searching" a lot in a large symbol, e.g.:

```gams
$if not set size1 $set size1 50
$if not set size2 $set size2 200000
$if not set size3 $set size3 150000
set f / f1*f%size1%/;
set j / j1*j%size2%/;
set l / l1*l%size3%/;
fjmap(f,l)=$uniform(0,1)<0.25;
parameter jpar(j,l) /#j:#l 10/
jpar(f,j) = sum(l$flmap(f,l), jpar(j,l));
The final assignment can be done in just \(~10\%\) of the time required by GAMS 24.4.
```

### 3.24.1.3.2 Documentation

- The complete GAMS technical documentation (release and installation notes, user's guides, solver and tools manuals, API reference manuals) is now available in HTML format with a unified table of contents. The documentation is available in the following forms:
  
  - The [online GAMS documentation](https://www.gams.com/) provides search and keyword indexing functionalities in addition to navigating the GAMS documentation.
3.24.1.3.3 Installer

- New way to install GAMS on Mac OS X using a DMG file.

3.24.1.4 Solvers

3.24.1.4.1 ANTIGONE

- Added option conopt_optfile to set name of options file to be used for CONOPT calls in ANTIGONE.

3.24.1.4.2 BARON

- New also available for Mac OS X.
- New libraries 15.9.22.
- New NLP solver for local search: FilterSD.
- Options:
  - New option Threads: Number of cores used for solution of MIP subproblems.
  - New option IISOrder: Order in which constraints are considered in the search for an IIS.
  - Options ConTol and IntTol removed. Tolerances are now set by AbsConFeasTol, RelConFeasTol, AbsIntFeasTol, and RelIntFeasTol.
  - Options MultMSize, MultRel, NLPDoLin, MipGap, MipNodes, MipRel, NoutIterMip, BilRel, Cvxbt, CvxInitOA, CvxRel, MipCuts, and RLTRel: Algorithmic features that have been parameterized are now handle in an automatic way.
- The time limit is enforced based on CPU time for single-threaded jobs and based on wall-clock time for multi-threaded jobs.
- Simplified the screen output (eliminated some details and simplified time to a real number in seconds).
- Updated CBC to 2.9.5.
- Updated Ipopt to 3.12.3.

3.24.1.4.3 CBC

- New libraries 2.9.
  - Introduced specialized branching methods for dealing with "big Ms".
  - Introduction of conflict cuts (off by default, enable with option conflictcuts).
  - Introduced new methods for dealing with symmetry.
3.24.1.4.4 Conopt

- New libraries 3.17A.
  - Corrected problem with options Ls2ndi and Lmusdf.
  - Systems errors related to very tight memory (984) and the inversion routine (2027) have been removed.
  - Three new options have been added to allow the modeler to see the order of the pre-triangular and post-triangular part of the model and the definitional equations:
    * PRPRET: Flag for printing the pre-triangular part of the model.
    * PRDEF: Flag for printing the defined variables and their defining constraints.
    * PRPOST: Flag for printing the post-triangular part of the model.

3.24.1.4.5 Couenne

- New libraries 0.5 (major update).
- Better handling of function signpower(x,k) for positive integer k ≤ 10.
- The default values for the following options have changed:
  - cont_var_priority from 2000 to 99.
  - int_var_priority from 1000 to 98.
  - feas_pump_milpmethod from -1 to 0.
  - feas_pump_poolcomp from 0 to 4.
  - output_level from 0 to 4.

3.24.1.4.6 CPLEX

- New option FreeGamsModel. This option preserves memory by dumping the GAMS model instance representation temporarily to disk. This option is available in CplexD only.

3.24.1.4.7 GUROBI

- New libraries 6.0.5 (technical release).
- New option FreeGamsModel. This option preserves memory by dumping the GAMS model instance representation temporarily to disk.

3.24.1.4.8 GUSS/ScenarioSolver

- The set of GUSS model attributes (Set ma "GUSS Model Attributes" / System.GUSSModelAttributes /;) has changed:
  - The attribute NumNOpt has been removed.
  - The attributes MaxInfes and MeanInfes have been added.

3.24.1.4.9 IPOPT

- New libraries 3.12 (minor changes).
3.24.1.4.10 JAMS

- **SubSolver** option fixed: it was sometimes ignored.

3.24.1.4.11 Kestrel

- The option file can be omitted. In this case, the Kestrel call is done with default settings.

3.24.1.4.12 Lindo/LindoGlobal

- Dropped Lindo/LindoGlobal libraries for Intel Solaris as announced previously.
- New libraries 9.0.225.

3.24.1.4.13 LocalSolver

- New libraries 5.5.
  - Improved accuracy and performance on numerical or mixed-variable optimization problems.

3.24.1.4.14 MINOS

- Adjusted default upper bound on the superbasics limit from 500 to 5000 and consider the number of nonlinear constraint variables, not just the nonlinear objective variables, when computing the superbasics limit: memory is plentiful and cheap.
- Fixed case of memory corruption that resulted when using an initial point containing very many superbasic variables. If the initial point contains more than 5000 superbasics, limit the Hessian dimension to 5000 even though the superbasic limit is larger.

3.24.1.4.15 MOSEK

- New libraries 7.1.0.33.
- The GAMS option `iterlim` now sets the iteration limit for both simplex and interior point algorithms.
- More MOSEK options are now available in GAMS/Mosek:
  - `MSK_IPAR_MIO_CUT_CG`: Controls whether CG (Chvatal-Gomory) cuts should be generated.
  - `MSK_IPAR_MIO_CUT_CMIR`: Controls whether mixed integer rounding cuts should be generated.
  - `MSK_IPAR_MIO_PROBING_LEVEL`: Controls the amount of probing employed by the mixed-integer optimizer in presolve.
  - `MSK_IPAR_MIO_RINS_MAX_NODES`: Controls the maximum number of nodes allowed in each call to the RINS heuristic.
  - `MSK_DPAR_MIO_TOL_MAX_CUT_FRAC_RHS`: Maximum value of fractional part of right hand side to generate CMIR and CG cuts for.
  - `MSK_DPAR_MIO_TOL_MIN_CUT_FRAC_RHS`: Minimum value of fractional part of right hand side to generate CMIR and CG cuts for.
  - `MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT`: If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation.
3.24.1.4.16 OS

- Now a hidden solver. Will be dropped from the distribution at some time (without further notice).

3.24.1.4.17 PATH

- New libraries 4.07.03.
- Adjusted to use wall-clock time on all platforms.
- Time limit checked more frequently, e.g. at each pivot.
- The presolve has been extended to find more reductions.
- Minor bug fixes.

3.24.1.4.18 SCIP

- New libraries 3.2 #c9c4375 (major update):
  - Presolving levels FAST, MEDIUM, and EXHAUSTIVE are now used to better coordinate the various presolvers.
  - Generalized upgrade from (SOC-representable) quadratic constraints to SOC constraints.
  - New primal heuristics “distribution diving”, “indicator”, and “bound”, improved clique and variable bound heuristics, and adjusted diving heuristics to solve fewer LPs.
  - New branching rules ”distribution”, ”multaggr”, and a new rule for SOS1 constraints.
  - New reliability notions and improved treatment of nonlinearities in hybrid reliability pseudo cost branching.
  - New separator ”eccuts” for generating edge-concave cuts for quadratic constraints and improved separation for convex quadratic constraints.
  - Decreased total memory usage by using more buffer data structures.
  - Improved propagation and separation for SOS of type 1 by using information from a conflict graph.
  - See also the full release notes, the change log, and the technical report.
- The following options were removed or replaced:
  - constraints/.../delaypresol and constraints/.../timemask replaced by constraints/.../presoltiming and constraints/.../proptiming.
  - presolving/domcol/singcolstuffing replaced by presolving/stuffing/....
  - presolving/.../delay replaced by presolving/.../timing.
  - propagating/.../presoldelay replaced by propagating/.../presoltiming.
  - propagating/obbt/maxlookahead removed.
- For the following options, the default value changed:
  - constraints/SOS1/sepaq frec from 0 to 10.
  - ”heuristics/clique/minfixingrate” from 0.5 to 0.25.
  - ”heuristics/vbounds/minfixingrate” from 0.5 to 0.25.
  - heuristics/actconsdiving/maxdiveavgquotnosol from 0 to 1.
- heuristics//actconsdiving/maxdiveubquotnosol from 0.1 to 1.
- heuristics/dins/nwaitingnodes from 0 to 200.
- lp/rowrepswitch from -1 to 1.2.
- presolving/abortfac from 0.0001 to 0.001.
- presolving/restartfac from 0.05 to 0.025.
- presolving/immrestartfac from 0.2 to 0.1.
- presolving/dualinfer/priority from 20010000 to -200.
- propagating/obbt/itlimitfactor from 5 to 10.

3.24.1.4.19 SoPlex

- New libraries 2.2.0 (major update).

3.24.1.4.20 SULUM

- New libraries 4.3.892.
  - Several bug fixes in both the MIP solver and the LP solver.
  - Improved numeric stability, degeneracy handling, and perturbation scheme in LP optimizer.
  - Added a new combined pricing scheme to the dual simplex optimizer.
  - Improved presolve and restart in MIP optimizer.

3.24.1.4.21 XPRESS

- New libraries for XPRESS v7.9: Optimizer 28.01.05.
  - Significantly improved linear algebra routines for the simplex solvers improving efficiency of a wide range of problems.
  - Improvement heuristics called more often.
  - The MIP log now provides information which heuristic finds a solution.
  - Improved linear dependency checker for large problems.
  - Improved scaling, including scaling of big-M type rows and of the Curtis-Reid scaling option.
  - Improved inference-learning from infeasible subproblem during the MIP search.
  - Improved presolver for quadratic instances.
  - Improved handling of Special Ordered Sets.
  - Improved propagation of conflict cuts.

3.24.1.5 Tools

3.24.1.5.1 GAMS IDE

- In the model library browser the IDE may provide hints about the content of the column when hovering over the headers.
- Option to specify file extensions for files that will be reloaded without a confirmation dialog.
3.24.1.5.2 GDXDIFF

- When renaming the temporary file to `gdxdiff.gdx` fails, issue a ViewClose command in case the file is open in the GAMSIDE and try to rename again.
- If no difference was found, issue a message in the log indicating this.
- Add a set with two elements with explanatory text of the two files compared.

3.24.1.5.3 GDXMERGE

- When a filename cannot be used as a UEL, use a generated name instead.

3.24.1.5.4 GDXXRW

- New options Ignor erows and IgnoreColumns to ignore a set of rows or columns for a symbol. Rows can be specified as `IgnoreRows=1,4:5` and columns `IgnoreColumns=A,D:F` or `IgnoreColumns=1,4:6`.

3.24.1.5.5 MODEL2TEX

- The beta version of this tool allows the automatic generation of LaTeX code that documents a given GAMS model.

3.24.1.5.6 MPSGE

- The documentation of MPSGE has moved again. It can now be found in the User’s Guide.

3.24.1.6 Object Oriented APIs

- New examples `SpecialValues` and `Clad` (Java: `specialvalues/SpecialValues.java, clad/Clad.java`; Python: `special_values.py, clad.py`).
- New functions to retrieve models from the GAMS API Library and the Nonlinear Optimization Applications Library:
  - Java: `GAMSWorkspace.addJobFromApiLib` and `GAMSWorkspace.addJobFromNoaLib`.
  - Python: `GamsWorkspace.apilib` and `GamsWorkspace.noalib`.

3.24.1.6.1 Python

- Added support for Python 3.4 (Windows and Linux only). The examples have been changed to be compatible with all supported Python versions.
3.24.1.7 Model Libraries

3.24.1.7.1 NOALIB - Nonlinear Optimization Applications Using the GAMS Technology

- This new library by Neculai Andrei has been added to the GAMS system. This is a collection of the models based on the book *Nonlinear Optimization Applications Using the GAMS Technology* by Neculai Andrei. The library contains a wide spectrum of nonlinear optimization applications expressed in GAMS. The book and library emphasize the local solutions of the large-scale, complex, continuous nonlinear optimization applications, and the abundant examples in GAMS are highlighted by those involving ODEs, PDEs, and optimal control. The collection of these examples will be useful for software developers and testers.

- You can retrieve the individual models through the IDE model library browser or via the command line utility `noalib`.

3.24.1.7.2 GAMS API Library

- CSSpecialValues.gms: Test handling of Special Values in object oriented C# API
- PSpecialValues.gms: Test handling of Special Values in object oriented Python API
- JSpecialValues.gms: Test handling of Special Values in object oriented Java API
- CSNUnit.gms: Compiles and runs NUnit tests for object oriented C# API
- CSClad.gms: Test changing solver options while running using the interrupt method
- PClad.gms: Test changing solver options while running using the interrupt method
- JClad.gms: Test changing solver options while running using the interrupt method

3.24.1.7.3 GAMS Data Library

- `invert1`: Pass `gams.sysdir%` to R script to make linkage between GAMS and R explicit.
- `gdxmrw_tr3`: Canonical form LP created in Matlab and solved via `gams()` Mex-function.
- `gdxmrw_tr4`: Better example of `gams()` usage.
- `gdxmrw_tr5`: Better example of `gams()` usage.

3.24.1.7.4 GAMS EMP Library

- `transecs`: Fix formulation as embedded complementarity system and provide equivalent alternative as single-agent equilibrium system.
- `farmnbd.gms`: The Farmer's Problem - Stochastic with NBD
3.24.1.7.5  GAMS Model Library

- In the IDE the GAMS Model Library browser has now a Lic column indicating the license requirement of a model. The letters D and G indicate that the model does not require a license. Models with G can even be solved by a global solver without a license (the demo limit for global solvers is 10 variables and 10 equations). A letter L indicates that a license is required.
  - tgridmix: Fix the logic for sleeping. Only do that if no more jobs to be scheduled or all cores are busy.

3.24.1.7.6  GAMS Test Library

- asynntrp: Make this model work under Unix that have the pstree utility available.
- call6.gms: Call GAMS in a folder containing a %
- cmexc01.gms: Trigger unexpected cmexRC error
- rs02.gms: Solving Three-dimensional Noughts and Crosses using Cplex and Gurobi distributed MIP
- single04.gms: Check handling of singleton sets assigned and referenced in a loop
- model2tex1.gms: Test that model2tex produces a tex file
- exmcp6.gms: External Equation - Example MCP 6
- scensol6.gms: Test execute_loadhandle for GUSS/GRID
- idxperm1.gms: Check correct behavior when permuting indices in model generation
- idxperm2.gms: Check correct behavior when permuting indices in loop etc

3.24.2 24.5.2 Maintenance release (September 29, 2015)

3.24.2.1  Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Kevin Doran and Renger van Nieuwkoop.

3.24.2.2  GAMS System

3.24.2.2.1  GAMS

- Fixed a bug which caused a crash for certain assignments, in particular it had to be an assignment to a symbol that was also referenced on the RHS, with permuted indices and we actually set some of the records to zero which were non-zero before.

3.24.2.3  Object Oriented APIs

3.24.2.3.1  .NET

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. (This is for Mono only.)
3.24.2.3.2 Python

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. The property `GamsWorkspace.system_directory` now always returns the canonical path with all symbolic links resolved.

3.24.2.4 Model Libraries

3.24.2.4.1 GAMS Test Library

- `idxperm3.gms`: Check correct behavior when permuting indices of symbol used on LHS and RHS (686)

3.24.3 24.5.3 Maintenance release (October 01, 2015)

3.24.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz.

3.24.3.2 GAMS System

3.24.3.2.1 GAMS

- Fixed a bug which caused wrong results in some cases of out-of-order assignments

3.24.4 24.5.4 Maintenance release (October 15, 2015)

3.24.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Per Ivar Helgesen and Jan Imhof.

3.24.4.2 GAMS System

3.24.4.2.1 GAMS

- Fixed a bug which caused wrong results in some cases of out-of-order assignments, in particular it had to be an assignment using the same controlling set more than once in one symbol, e.g. `p(1, j, 1)`.
- Fixed a bug when handling suffixes (e.g. `.val`) of Singleton Sets in Equations.

3.24.4.3 Object Oriented APIs

3.24.4.3.1 .NET

- Fixed a bug with the property `GAMSOptions.IDir`.
3.24.4.4 Model Libraries

3.24.4.4.1 GAMS Test Library

- single05.gms: Check correctness of set attributes for singleton sets (687)
- idxperm4.gms: Check correct behavior when permuting indices of symbol using same controlling set multiple times (688)

3.24.5 Maintenance release (November 25, 2015)

3.24.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Albrecht, Stefan Kemnitz, Martha Loewe, Thomas Maindl, Bruce McCarl, and Andres Ramos.

3.24.5.2 GAMS System

3.24.5.2.1 GAMS

- GAMS now always reports the upper bound that is sent to the solver in the column listing and solution report. Hence, with IntVarUp=1 GAMS prints the value of 100 for integer and semiint variables that are at default bound value +INF.
- Fixed a bug which could cause a crash when referencing attributes of equations (e.g. marginals) after a model was solved with a non-default solveLink setting and there was no solution returned.

3.24.5.2.2 Stochastic Programming with EMP

- Fixed a bug which caused wrong sample sizes if the sample keyword was used more than once and with different sample sizes.

3.24.5.3 Solvers

3.24.5.3.1 Cbc

- New libraries.

3.24.5.3.2 CplexD

- Fixed a problem with the computeserver option. The value for the computeserver option is limited to 255 characters. In order to specify a longer list of workers, one can now use multiple lines with the computeserver option.
3.24.5.3.3 Ipopt

- New libraries.

3.24.5.3.4 LocalSolver

- New libraries 5.5 (20151028).

3.24.5.3.5 Mosek

- New libraries 7.1.0.41.

3.24.5.3.6 SCIP

- New libraries 3.2 (#e9a5ca7).
  - Removed options constraints/SOS1/bipbranch, constraints/SOS1/neighbranch, and constraints/SOS1/sos1branch.

3.24.5.3.7 SoPlex

- New libraries 2.2 (#f17b9e7).

3.24.5.4 Tools

3.24.5.4.1 put_toexcel, put_tohtml

- Fixed a problem with put_toexcel and put_tohtml.

3.24.6 24.5.6 Maintenance release (November 27, 2015)

3.24.6.1 Solvers

3.24.6.1.1 COUENNE

- New libraries.

3.24.6.1.2 IPOPT, BONMIN, SCIP

- Fixed issue that Ipopt and Bonmin always read ipopt.opt, despite of the optfile setting in GAMS.
3.25 24.4 Distribution

3.25.1 24.4.1 Major release (December 20, 2014)

3.25.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Erwin Kalvelagen, Jeff Linderoth, and Erkka Rinne.

3.25.1.2 GAMS System

3.25.1.2.1 GAMS

- Fixed a bug causing a potential crash when solving an EMP model having an open file handle without an external file name at the same time.
- The execMode setting is not ignored by put utility anymore.
- Added gbin/md5sum.exe to Windows distribution. This utility allows users to verify the file integrity of newly downloaded GAMS installation files.
- The gbin_new directory will be removed with the next distribution.

3.25.1.2.2 Installer

- Windows installer removes the GAMS entry in the current user hive of the registry, if GAMS is installed for all users. Previously, the hive for the current user remained unchanged in this situation.

3.25.1.2.3 Extrinsic Function libraries

- The new extrinsic function library parcclib was added to the system. This library demonstrates how to access the GAMS parameter file and use it's information through the GAMS Option Object. Further information can be found in the GAMS User's Guide, Appendix J.
- Allow up to 20 arguments (used to be 10).
- Support for extrinsic function libraries that do not provide gradient and/or Hessian values. GAMS uses finite differences (same method as for .gradn and .hessn) to approximate the derivatives, even inside a solver. The example function library trilib now implements function Sine without any derivatives and leaves their calculation to GAMS.
- New GAMS options have been introduced to parameterize the numerical derivative calculations. While these are most important for extrinsic functions, they also apply to the .gradn/.hessn calculations of intrinsic functions.
  - FDDelta: step size in the numeric gradient and Hessian calculation. For single argument functions, GAMS evaluates the function at f(x-d) and f(x+d) for the numerical gradient. If function values are used for the numerical Hessian, GAMS evaluates at f(x-2d), f(x), and f(x+2d). For multi argument functions, the same is done for the components of the input argument vector. The default for FDDelta is 1e-5. This option can be set from the command line, in an option statement, and as a model attribute.
  - Note: In previous releases it was possible to set the step size for .gradn/.hessn using the option Real1. This does not work anymore.
3.25 24.4 Distribution 261

- **FDOpt**: The option value packs two option in the different digits: $ij$. The $i$ digit indicates if scaling of the step size ($\text{FDDelta}$) by the value of the input argument should be turned off. If $i=0$ (scaling on) the following step size is used: $\max(1,|x|)\times\text{FDDelta}$. The $j$ digit is mostly for testing, but has one setting that might be relevant when the extrinsic function provides gradient but no Hessian values. The numerical derivatives routine in this case uses the gradient calculation from the extrinsic function to approximate the Hessian. If the gradient is expensive to calculate compared to a function evaluation, it could be beneficial to use multiple function values to approximate the Hessian. In this case set the $j$ digit to 1. Here are all possible values for this option:
  * 0: All derivatives analytically if available, for numerical Hessian use gradient values, scale delta
  * 1: All derivatives analytically if available, for numerical Hessian use function values, scale delta
  * 2: Gradient analytically, force Hessian numerically using gradient values, scale delta (testing only)
  * 3: Gradient analytically, force Hessian numerically using function values, scale delta (testing only)
  * 4: Force gradient and Hessian numerically, scale delta (testing only)
  * 10: Same as 0, but no scale of delta
  * 11: Same as 1, but no scale of delta
  * 12: Same as 2, but no scale of delta (testing only)
  * 13: Same as 3, but no scale of delta (testing only)
  * 14: Same as 4, but no scale of delta (testing only)
- **Note**: In previous releases it was possible to deactivate the scaling for `.gradn/.hessn` using the option `Integer1`. This does not work anymore.

- Renamed and better documented the `EXTRFUNC_ERROR` enum to `EXTRFUNC_EVALERROR` in the C header `extrfunc.h`. The old values are deprecated and will be removed in a future release.

### 3.25.1.2.4 Documentation

- The manuals of all solver and several tools are now available in HTML format. A PDF that contains all solver manuals is still available (`docs/solvers/allsolvers.pdf`).

### 3.25.1.3 Solvers

#### 3.25.1.3.1 AlphaECP

- Alpha-ECP v2.10.06.
  - Added support for solver trace file, i.e. new option `solvetrace`.

#### 3.25.1.3.2 ANTIGONE, GloMIQO

- Now also available for Mac OS X.

#### 3.25.1.3.3 BARON

- New libraries 14.4.0.
  - Added reliability branching for integer variables.
  - Bug fixes in CBC interface and IIS module.
  - Improved performance of problem reading and reformulation.
  - Updated Ipopt to version 3.11.9.
3.25.1.3.4 BENCH

- Removed option `cumulative`. This option makes no sense anymore since all solvers are spawned asynchronously and all get the same limits.

3.25.1.3.5 CBC

- Fixed a race-condition in log output when using multiple threads.
- New libraries.

3.25.1.3.6 Couenne

- New libraries.

3.25.1.3.7 CONOPT

- New libraries 3.16D.
  - Tolerance adjustments that make sense if NaN appears in intermediate calculations.

3.25.1.3.8 CPLEX

- Don't rerun primal simplex in cases where there is already an infeasibility status.
- New libraries 12.6.1.
- New parameters:
  - `qtolin` controls the linearization of the quadratic terms in the objective function of a QP or MIQP model
  - `localimplied` controls the generation of locally valid implied bound cuts

3.25.1.3.9 DICOPT

- Added support for `=N=` rows.

3.25.1.3.10 GUROBI

- New libraries 6.0.0.
- Fixed problem in tuning. Previous version did not write out link options in the tuned option file.
- Gurobi 6.0 supports a distributed MIP algorithm (option `DistributedMIPJobs`). This requires the Gurobi Compute Server to be licensed.
- Explicit lazy constraint: Users can use the "dot" option `.lazy` to mark constraints as lazy. Possible values are 0, 1, 2, and 3. See option `.lazy` for details.
- Option `ConcurrentMIPJobs` has been renamed to `ConcurrentJobs`. The distributed concurrent optimizer now also handles LP models.
- Option `ScaleFlag` allows now value 2 which enables aggressive scaling.
- New parameters:
  - `DistributedMIPJobs` controls the number of workers of the distributed MIP algorithm
  - `.lazy` marks constraints as lazy constraints
  - `LazyConstraints` controls the use of lazy constraints
3.25.1.3.11 Knitro

- New libraries 9.1.0.
  - Overall speed and robustness improvements on NLP and MINLP models.
  - New algorithm choice introduced: active-set SQP.
  - Optional barrier solution refinement procedure: option bar_refinement = NO/yes.
  - Deterministic parallel multi-start: option ms_deterministic = no/YES.
- Dropped Knitro for Solaris on Intel CPUs (as announced).

3.25.1.3.12 LocalSolver

- Added the hybrid mathematical programming solver LocalSolver 5.0 (Beta) from Innovation 24 to the GAMS solvers portfolio.
- LocalSolver can be applied to large-scale, mixed-variable, non-convex optimization problems (GAMS model types MIP, (MI)QCP, (MI/D)NLP). It combines local search techniques, constraint propagation and inference techniques, linear and mixed-integer programming techniques, and nonlinear programming techniques in a unique hybrid neighborhood search approach to find high-quality feasible solutions. Hence, LocalSolver offers an alternative for problems where conventional branch-and-bound and/or outer-approximation based solution methods do not provide satisfactory results.
- It is suggested to set the GAMS options for iteration or timelimit (iterlim, reslim) appropriately to limit the effort that LocalSolver spends on the problem.

3.25.1.3.13 Lindo/LindoGlobal

- We will drop Lindo/LindoGlobal libraries for Intel Solaris with the next major release (24.5).
- New libraries 9.0.142 for Linux, Mac OS X, and Windows:
  - Support for semi-continuous variables.
  - Simplex LP algorithm implementation has been improved for speed and robustness. The performance improvements compared to previous version are 90% for primal simplex and 45% for the dual simplex.
  - Knapsack related cuts improvements. Significantly faster solve times on models with certain knapsack-like constraints.
  - Improved default node selection rules improves performance on most MIPs.
  - New branching variable rule options: maximum coefficients and neighborhood branching. Can reduce number of branches on certain MIPs.
  - Perspective reformulation capability gives improved performance on quadratic portfolio models with semi-continuous variables, e.g. min-buy quantities.
  - Improved default settings for NLPs gives 5% average speed improvement.
  - New preprocessing for LP/MIP significantly reduces coefficient density of certain dense matrices.

3.25.1.3.14 Mosek

- New libraries 7.1.0.12.
  - Improved performance of the mixed-integer conic optimizer.
3.25.1.3.15 MSNLP/OQNLP

- These solvers now use Conopt as their default solver if Conopt is licensed. Otherwise they will use lsgrg as before.

3.25.1.3.16 OS

- We plan to drop the OS solver with GAMS 24.5. The capability of convert to write OSiL files will be kept.

3.25.1.3.17 SCIP

- New libraries 3.1 #020e055.

3.25.1.3.18 SoPlex

- New libraries 2.0 #d67b17b.

3.25.1.3.19 Sulum

- New libraries 4.0.665.
  - Improvements in presolve, leading to more reductions.
  - General improvements in obtaining a feasible solution faster, especially with focus on the root node to obtain a good bound. Rewrite and improvements of feasibility pump, objective diving.
  - The simplex algorithm is now exchanging more information with the branch and cut method. Improvement of SINS heuristic (finding a better basis after the node solve).
  - Added a MIP root restart feature based on reductions.
  - Cutting planes generation was both improved and extended.
  - Changed default for option `mipmaxrestarts` from 5 to 1.

3.25.1.3.20 XPRESS

- New libraries for XPRESS v7.8: Optimizer 27.01.02.
  - Automatic solution refinement for LP and MIP models.
  - Improved deterministic concurrent LP.

3.25.1.4 Tools

3.25.1.4.1 GAMSIDE

- Added option to suppress trailing zeroes in GDX viewer.
- Improved ability to open files from the Windows Shell.
- Cutoff for number of lines to be syntax colored or not.
- When saving a file, the Undo buffer is no longer cleared.
3.25.1.4.2 GDXDUMP

- Text quoted with a single quote did not have a separator when writing SymbolAsSet.
- Added option SymbolAsSetDI.
- Avoid string overflow when quoting text.
- Added more types for sets and equations.

3.25.1.4.3 GDXXRW

- Added option values=All which is the new default when CDim=0 or RDim=0.

3.25.1.4.4 GDXVIEWER

- Added ACCDB format as an output option for MSAccess.

3.25.1.4.5 GDX2SQLite, Scenred, Scenred2

- These tools are now also available for AIX.
- Moved documentation of Scenred and Scenred2 from docs/solvers to docs/tools.

3.25.1.4.6 IDECMDS

- Allow a pattern to be specified to close files.

3.25.1.4.7 MPS2GMS

- The mps2gms tool now produces proper generic GAMS source for models with quadratic terms.
- Bug fix for MPS files written by Cplex that contain SOS constraints.

3.25.1.4.8 MPSGE

- Moved manual to "docs/tools".

3.25.1.5 Expert Level APIs

- There are new API files for the "Indexed GDX" (IDX) library in $GAMS Dir$/apifiles$/Language$/api:
  - The indexed GDX library can be used to read and write indexed GDX files.
  - Each symbol in such a GDX file must be a parameter.
  - Each parameter must have a domain consisting of a UELs which forms an integer sequence starting at 1.
  - This way the data is provided in a format convenient to store in arrays in the target language.
  - In GAMS such a file can be read using $LoadIDX$ during compilation.
  - In GAMS such a file can be written using $execute_unloadIDX$ during execution.
  - The new example $GAMS Dir$/apifiles$/CSharp$ $xp_CalcInverseIDX$ makes use of this API, this example is also used in the APIlib model $CSCalcInverse$. 
3.25.1.5.1 Python

- Fixed a bug regarding lists of strings in Python 3 (e.g. `gdxDataWriteStr()`).

3.25.1.6 Object Oriented APIs

- We changed the handling of GAMS Aliases in the object oriented APIs:
  - If we ask for the number of GAMSSymbols in a GAMSDatabase, the Aliases will be excluded.
  - If we iterate over all GAMSSymbols in a GAMSDatabase, Aliases will be skipped.
  - If we ask explicitly for an Alias in a GAMSDatabase (`GAMSDatabase.GetSet("a")` with `a` being an Alias) we will get a reference to the GAMSSet referenced by the Alias, not the Alias itself.
  - Note: Aliases can appear in a GAMSDatabase only, if it was initialized by a GDX file containing an Alias.
  - The new examples `Alias` demonstrate this new behavior for the different OO API languages.

3.25.1.6.1 Python

- Fixed a bug in `GamsDatabase.merge_record` that prevented the function from creating a record if none was found.

3.25.1.7 Model Libraries

3.25.1.7.1 GAMS API Library

This is a new collection of GAMS models. It can be accessed in the GAMS IDE at Model Libraries -> GAMS API Library or through the command line tool `apilib`. The models in this collection can be used as scripts to compile and execute the example applications using the GAMS object oriented APIs as well as the expert level APIs, which can be found in `<GAMS Dir>/apifiles`.

- `apiutil.gms`: Generates the API Model Library files (01)
- `testapi.gms`: API Quality Assurance Test (02)
- `Cex1.gms`: Test expert level C API to read and write GDX (03)
- `CSex1.gms`: Test expert level C# API to read and write GDX (04)
- `CPPex1.gms`: Test expert level C API to read and write GDX in C++ (05)
- `DCex1.gms`: Test expert level Delphi (function) API to read and write GDX (06)
- `DOex1.gms`: Test expert level Delphi (object) API to read and write GDX (07)
- `DPex1.gms`: Test expert level Delphi (pure) API to read and write GDX (08)
- `Fex1.gms`: Test expert level Fortran API to read and write GDX (09)
- `Jex1.gms`: Test expert level Java API to read and write GDX (10)
- `Pex1.gms`: Test expert level Python API to read and write GDX (11)
- `VBex1.gms`: Test expert level VB.Net API to read and write GDX (12)
- `Cex2.gms`: Test expert level C API to read and write GDX, set options and execute GAMS (13)
• CSex2.gms: Test expert level C# API to read and write GDX, set options and execute GAMS (14)
• CPPex2.gms: Test expert level C API to read and write GDX, set options, and execute GAMS in C++ (15)
• DOex2.gms: Test expert level Delphi (object) API to read and write GDX, set options and execute GAMS (16)
• Fex2.gms: Test expert level Fortran API to read and write GDX, set options and execute GAMS (17)
• Jex2.gms: Test expert level Java API to read and write GDX, set options and execute GAMS (18)
• Pex2.gms: Test expert level Python API to read and write GDX, set options and execute GAMS (19)
• VBex2.gms: Test expert level VB.Net API to read and write GDX, set options and execute GAMS (20)
• CStrseq.gms: Test object oriented C# API running a sequence of examples based on a transport model (21)
• CPPtrseq.gms: Test object oriented C++ API running a sequence of examples based on a transport model (22)
• Jtrseq.gms: Test object oriented Java API running a sequence of examples based on a transport model (23)
• Ptrseq.gms: Test object oriented Python API running a sequence of examples based on a transport model (24)
• VBtrseq.gms: Test object oriented VB.Net API running a sequence of examples based on a transport model (25)
• CSBenders.gms: Test object oriented C# API using a (multi-threaded) Benders Decomposition Algorithm (26)
• JBenders.gms: Test object oriented Java API using a (multi-threaded) Benders Decomposition Algorithm (27)
• PBenders.gms: Test object oriented Python API using a (multi-threaded) Benders Decomposition Algorithm (28)
• CSCutstock.gms: Test object oriented C# API using a cutting stock example (29)
• JCutstock.gms: Test object oriented Java API using a cutting stock example (30)
• PCutstock.gms: Test object oriented Python API using a cutting stock example (31)
• CSDomainChecking.gms: Test object oriented C# API for domain checks (32)
• JDomainCheck.gms: Test object oriented Java API for domain checks (33)
• PDomainChecking.gms: Test object oriented Python API for domain checks (34)
• JInterrupt.gms: Test object oriented Java API for interrupting running GAMS jobs (35)
• CSTsp.gms: Test object oriented C# API using a Traveling Salesman Problem (36)
• JTsp.gms: Test object oriented Java API using a Traveling Salesman Problem (37)
• PTsp.gms: Test object oriented Python API using a Traveling Salesman Problem (38)
• CSWarehouse.gms: Test object oriented C# API using a warehouse location problem (39)
• JWarehouse.gms : Test object oriented Java API using a warehouse location problem (40)
• PWarehouse.gms : Test object oriented Python API using a warehouse location problem (41)
• CSAlias.gms : Test handling of Aliases in object oriented C# API (42)
• JAlias.gms : Test handling of Aliases in object oriented Java API (43)
• PAlias.gms : Test handling of Aliases in object oriented Python API (44)
• apihtm.gms : Generates HTM apilib library files (45)
• CSCalcInverse.gms : Test expert level C# API to read and write indexed GDX (46)

3.25.1.7.2 GAMS Data Library

• Note: Opening an Excel file (.xls) in protected view may work improperly due to Microsoft issue 2745652. Fix: Enable editing of the Excel file and reopen the file.
• gdxmrw_qp1_starter.gms : Portfolio Analysis with Matlab and GAMS (91)
• gdxmrw_qp2_starter.gms : Portfolio Analysis with Matlab and GAMS (92)
• gdxmrw_tr1.gms : Transport LP with non-indexed GDX data interface (93)
• gdxmrw_tr2.gms : Transport LP with indexed GDX data interface (94)
• gdxmrw_qp3.gms : QP solver M-file using GAMS and GDXMRW (95)
• gdxmrw_autoopen.gms : Tests that gdxrxw calls the auto_open macro facility (96)
• gdxmrw_qp4.gms : Calling GAMS model from Matlab (97)
• gdxmrw_intro01_init.gms : Introduction to data transfer between Matlab and GAMS (98)
• gdxmrw_intro02_init.gms : Introduction to calling GAMS from Matlab (99)
• gdxmrw_irgdx01_init.gms : Reading data from a indexed GDX file with IRGDX (100)
• gdxmrw_iwgdx01_init.gms : Writing data into a indexed GDX file with IWGDX (101)
• gdxmrw_rgdx01_init.gms : Reading data from a GDX file into a structure with RGDX (102)
• gdxmrw_wgdx01_init.gms : Writing structured data into a GDX file with WGDX (103)
• gdxmrw_ext01_init.gms : Extended use of GDXMRW (104)

3.25.1.7.3 GAMS Model Library

• Modified models
  – tsp1 and tsp4 now use Singleton Sets
  – flowchan had incorrect boundary conditions
  – licememo: give a full solver/model type matrix independent of the actual license
• partssupply.gms : Parts Supply Problem (404) (contains ps2f,s .. ps5_s,mn, which are still available, as submodels)
• qfilter.gms : Audio filter design using quad-precision MINOS (405)
• derivtst.gms : How to test derivatives of functions (406)
• carseq.gms : Car Sequencing (407)
• pmedian.gms : P-Median problem (408)
• sgolfer.gms : Social Golfer Problem (409)
3.25.1.7.4 GAMS Test Library

- Modified Models
  - trilib01, trilib02, and trilib03: Compare numeric gradient and Hessian values in the models. Function Sine in the library does not provide derivatives anymore. Lower the tolerances for acceptance due to numerical derivatives of function Sine

- indic04.gms : Test of indicator constraints with explicit labels (663)
- parlib01.gms : Test extrinsic functions in parcclib (667)
- convert10.gms : CONVERT test suite - check interval evaluator in Convert (668)
- convert11.gms : CONVERT test suite - check interval evaluator in Convert (669)
- convert12.gms : CONVERT test suite - check interval evaluator in Convert (670)
- lazy01.gms : Test lazy constraints (671)
- mps2gms1.gms : Test mps2gms (672)
- execmode01.gms : Test execmode behavior (673)

3.25.2 24.4.2 Minor release (March 15, 2015)

3.25.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Sergey Kuznetsov, Ricardo M. De Lima, and Corey Noone.

3.25.2.2 GAMS System

3.25.2.2.1 GAMS

- Fixed potential problem when running on Windows in a workDir containing a %.
- Fixed problem with EMP solves with solvelink=Solvelink.AsyncGrid%.
- Fixed problem with GUSS/Grid when using execute_loadhandle instead of handlecollect.

3.25.2.3 Solvers

3.25.2.3.1 ANTIGONE

- New libraries.

3.25.2.3.2 CONOPT

- Introduced new boolean option PreTri2Log that send message from Conopt's pre-triangular analyzer that go to the listing file also to the GAMS log. The option requires the generation of the model dictionary, so mymodel.DictFile=1; has to be added before the Solve statement.
3.25.2.3.3 CONVERT

- Convert and ConvertD: Fix for writing scalar MCP models that contained fixed variables removed by \texttt{holdfixed=1}.
- ConvertD: Add support for external equations in scalar GAMS models.
- ConvertD: Propagate EPS to scalar GAMS models.

3.25.2.3.4 Couenne

- New libraries.

3.25.2.3.5 Examiner2

- Support added for custom trace files.

3.25.2.3.6 GUROBI

- New libraries 6.0.2.

3.25.2.3.7 Lindo/LindoGlobal

- New libraries 9.0.157 for Linux, Mac OS X, and Windows.

3.25.2.3.8 LocalSolver

- New libraries 5.0 (20150119).

3.25.2.3.9 Mosek

- New libraries 7.1.0.24.

3.25.2.3.10 SCIP

- New libraries 3.1 \#67d713c.
- Fixed overwriting of solvetrace file by final NLP resolving.

3.25.2.3.11 SoPlex

- New libraries 2.0 \#8381aa4.
3.25.2.4 Tools

3.25.2.4.1 GDXMRW

- gdxInfo: fix output of domains in symbol declaration
- gdxInfo: handle aliases properly

3.25.2.5 Object Oriented APIs

- Fixed overwriting of the default value for the integer1 option when running with GAMSModelInstance, which lead to unexpected solver behavior.
- Fixed potential problem with GAMSModelInstance used with BARON.

3.25.2.5.1 .NET

- New property GAMSSymbol.DomainsAsStrings: Domains of Symbol, each element is a string, if the domain is an alias in GAMS, this call will return the name of the Alias, not the name of the aliased Set.

3.25.2.5.2 Java

- Changed naming scheme of GDX output scratch file to sequence number.

3.25.2.5.3 Python

- Fixed a bug in the constructor of all subclasses of GamsSymbol that occurred when the explanatory text was omitted.
- New property GamsSymbol.domains_as_strings: Domains of Symbol, each element is a string. If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set.

3.25.2.6 Expert Level APIs

3.25.2.6.1 GMO

- Fixes to gmoGetRowJacInfoOne and gmoGetColJacInfoOne: In case of an empty row/column, now return -1 in colidx/rowidx if index base is 0.

3.25.2.7 Model Libraries

3.25.2.7.1 GAMS Model Library

- dyncge.gms: A Recursive-Dynamic Standard CGE Model (410)
272 Release Notes

3.25.3 24.4.3 Maintenance release (April 02, 2015)

3.25.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Guillaume Erbs and Emiliano Traversi.

3.25.3.2 Solvers

3.25.3.2.1 Examiner2

- Fixed incapability to continue on a trace file that already has trace records in it.

3.25.3.2.2 LocalSolver

- Corrected computation of values for free variables that appeared (linearly) in one equation only.

3.25.3.3 Tools

3.25.3.3.1 GDXXRW

- In 24.4.2 we quietly introduced a new way to determine the content of a sheet. This resulted in a bug for empty sheets and sheets that have been saved with an active filter. This has been fixed.

3.25.4 24.4.4 Maintenance release (May 12, 2015)

3.25.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Thomas Counsell, Michael Ferris, Jean Mercenier, and Loïc Ventre.

3.25.4.2 Solvers

3.25.4.2.1 Gurobi

- New libraries 6.0.4.
- The new libraries do not work on Windows XP anymore. As the library for COIN-OR solvers, SCIP, and SoPlex link to the Gurobi library, these solvers also do not work on Windows XP anymore.

3.25.4.2.2 Ipopt

- New libraries for Linux and Mac OS X.
  - Fixed an issue in the MA97 interface that lead to convergence problems.
3.25.4.2.3 Minos

- Consider the number of nonlinear constraint variables, not just the nonlinear objective variables, when computing the superbasics limit: memory is plentiful and cheap.
- Fixed case of memory corruption that resulted when using an initial point containing very many superbasic variables. If the initial point contains more than 500 superbasics, limit the Hessian dimension to 500 even though the superbasic limit is larger.

3.25.4.2.4 Mosek

- New libraries 7.1.0.30.

3.25.4.2.5 Xpress

- New libraries Optimizer 27.01.08 (was 27.01.02 before).

3.25.4.3 Tools

3.25.4.3.1 GDXDUMP

- Fixed a problem when writing a scalar or scalar variable/equation in format CSV.

3.25.4.4 Object Oriented APIs

- Fixed a potential problem with GAMSModelinstance and certain OS culture settings.

3.25.4.5 Model Libraries

3.25.4.5.1 GAMS EMP Library

- transecs: Fixed formulation as embedded complementarity system and provide equivalent alternative as single-agent equilibrium system.

3.25.5 24.4.5 Maintenance release (May 26, 2015)

3.25.5.1 Solvers

3.25.5.1.1 COIN-OR solvers, SCIP, SoPlex

- On Windows 32bit, OsiGurobi was split off into a separate library, so that other COIN-OR solvers (e.g., Bonmin, Cbc, Couenne, Ipopt) and SCIP and SoPlex do not require the Gurobi 6.0.4 library anymore. Thus, for this release, only Gurobi and OsiGurobi do not run on Windows XP anymore (see 24.4.4 notes on Gurobi).
3.25.6 24.4.6 Minor release (June 26, 2015)

3.25.6.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Erwin Kalvelagen, Rich Roberts, and Jens Schulz.

3.25.6.2 Solvers

3.25.6.2.1 CONOPT

- New libraries 3.16F.
- New option LMUSD for handling definitional equations.
- New option RVFILL for memory allocation when memory is tight.
- Changed a sorting procedure in the preprocessor. Models with some very dense rows and many pre-triangular variables can experience a significant speedup for the preprocessor.

3.25.6.2.2 CPLEX

- New libraries 12.6.2.0.
- Option changes:
  - The popular option value -1 for BarCrossAlg to turn off the crossover after a run with barrier has been deprecated. The new way to turn off crossover is to set the new option SolutionType to 2.
  - The option SolutionTarget has been renamed to OptimalityTarget.
  - The option CutsFactor has a new default (-1).
- New options:
  - BQPcuts: Boolean Quadric Polytope cuts for solving nonconvex QP or MIQP to global optimality.
  - CPUMask: Switch and mask to bind threads to processors. Binding threads to processors/cores helps to reduce variability in running time when using multiple threads.
  - SolutionType: Type of solution (basic or non basic) for an LP or QP. Set this option to 2 to prevent crossover after barrier.

3.25.6.2.3 MOSEK

- New libraries 7.1.0.31.

3.25.6.3 Tools

3.25.6.3.1 GAMSIDE

- Added .ref for reference file to the files open dialog.
- Left arrow in the first character position now moves to the end of the previous line.
3.26.3.2 GDXXRW

- Restore the old behavior when reading a set with Values=Strings; all elements will be included, not only the ones with a string.
  - Option Values=String and All are now deprecated and results in a warning; replaced with Dense.
  - New options Values=Dense or Sparse.

3.26.3.3 XLSTalk

- Allow for up to 9 parameters for macro call.

3.26 24.3 Distribution

3.26.1 24.3.1 Major release (July 31, 2014)

3.26.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Michael Bond, Sebastian Bothor, Jared Erickson, Michael Ferris, Josef Kallrath, Bastian Niebel, Matt Preston, and Tom Rutherford.

3.26.1.2 Platforms

- The Linux 32bit and Solaris 32bit distributions have been dropped (as announced).
- Support for Windows XP may be dropped with some future GAMS version. As several of our solver vendors have already dropped support for Windows XP, some components of a GAMS system may cease to work under Windows XP in the future. If you notice that a 64bit GAMS system is not working on your Windows XP 64bit machine, please let us know.

3.26.1.3 GAMS System

3.26.1.3.1 GAMS

- Introduced new keyword Singleton Set: A Singleton Set in GAMS is a special Set that has at most one element (zero elements are allowed as well). Singleton Sets can be especially useful in assignment statements since they don’t need to be controlled by a controlling index nor an indexed operator, e.g.:

```gams
Set s / s1*s3 /;
Singleton Set single(s) / s2 /;
Parameter p(s);
Scalar x;

p(s) = ord(s);
```

```gams
x = p(single);
```
NOTE: Assigning membership to Singleton Sets is different than to usual sets. Since Singleton Sets can never have more than one element, any assignment to a Singleton Set first clears or empties the set, so no explicit clear is necessary. This is illustrated in the following example:

```
Set       i  Static Set    / a, b, c / 
          ii(i) Dynamic Set / b /;
Singleton Set   si(i) Dynamic Singleton Set / b /;
ii('c') = yes;
si('c') = yes;
Display ii, si;
```

Here is the output from the display statement in the listing file:

```
---- 8 SET ii Dynamic Set 
b, c
---- 8 SET si Dynamic Singleton Set 
c
```

More information can be found in the GAMS Users Guide.

- The behavior of assignments to Singleton Sets can be influenced by the new option strictSingleton [0/1]: This option affects the behavior of a membership assignment to a Singleton Set. With strictSingleton = 0 GAMS does not complain about an assignment with more than one element on the right hand side but takes the first one. With strictSingleton = 1 (default), such an assignment raises an error. This option be set via an option statement and via a command line option.

- Similarly, data statements for Singleton Sets can be influenced by the new dollar control options $onStrictSingleton/$offStrictSingleton: With $offStrictSingleton GAMS does not complain about a data statement for a Singleton Set that has more than one element but takes the first one. With $onStrictSingleton (default), such an assignment raises an error.

- Introduced so-called obfuscated save files, which are save files where symbol and UEL names have been obfuscated. The new options saveobfuscate (so) and xsaveobfuscate (xso) can be used to generate uncompressed and compressed, respectively, obfuscated save files. Additionally, a new option restartNamed (rn) has been added which can be used to bring back the original names when restarting from an obfuscated save file. The intended use is the following.

- Compile (only) a GAMS model into a named and an obfuscated save file:
  
  `$call gams transport a=c s=0named saveobfuscate=0anon`

- Move the obfuscated save file to a non-secure machine and execute it there:
  
  `$echo * Empty > empty.gms`
  `$call gams empty r=0anon s=1anon`

- Bring the new (still obfuscated) save file with the results back to the safe machine and do a continued compilation with reporting and export. The continued compilation restarts from the obfuscated save file with all the results, etc., but gets a second save file with proper names through option restartNamed:

  `$call gams unload 'supply', supply.m; > unload.gms`

In this execution, everything is taken from the obfuscated restart file, except for the symbol and UEL names and the listing file title and subtitle, which are taken from the file specified via restartNamed.

- Allow to load the universe of labels from a GDX file into a set at run-time:
execute_load 'someFile', someSet=*

Note, that only labels known to the GAMS program will be loaded.

• Fixed a bug that caused wrong results when evaluating \texttt{prod} (or \texttt{smin/smax}) over an empty set inside \texttt{sum} like in the following example:

\begin{verbatim}
sets r / 1 /
s       / 1, 2 /
rs(r,s)  / 1.1 /
subrs(r,s) / 1.2 /;
scalar z1;
z1 = sum(rs, prod(subrs(rs), 2));
display z1;
\end{verbatim}

• Fixed a bug in calling error logging routine for extrinsic functions from within solvers.

3.26.1.3.2 Function libraries

• The extrinsic function library \texttt{cppcclib} has been expanded to include functions for the PDF and CDF of the trivariate normal distribution. Additionally, documentation for \texttt{cppcclib} has been added to Appendix J of the GAMS User's Guide and the relevant testlib models \texttt{cpplib00 thrucpplib05} have been added or updated.

3.26.1.4 Solvers

3.26.1.4.1 ANTIGONE, Bonmin, Cbc, Couenne, SCIP, Sulum

• Solvetrace files now include the GAMS input name (usually GAMS model name with \texttt{.gms} extension stripped) in the header line.

3.26.1.4.2 BARON

• New libraries 14.0.2
  – Significant advances in the handling of integer programs. In addition to several classes of integer cutting planes, calls to MIP solvers and hybrid LP/MIP/NLP relaxations for MINLPs have been added.
  – Complete rewrite of the interfaces to LP solvers.
  – Improvements in probing routines.
  – More robust checks for the validity of the solution of LP/NLP subsolvers.
  – Introduced interfaces to COIN-OR/OSI and CBC 2.8.9.
  – Increased numerical robustness for numerically challenging problems.
  – New range reduction techniques.
  – Systematic treatment of infeasible problems. With the \texttt{CompIIS} option, which by default is 0, the computation of an Irreducible Inconsistent Set (IIS) can be requested. Five different algorithms are available, with corresponding values of \texttt{CompIIS} equal to 1, ..., 5. Algorithm 1 is a fast heuristic, while algorithms 2 through 5 are more time consuming exact algorithms. If an IIS is found, it is reported in the GAMS listing file. BARON does not consider bounds on binary variables to be part of the IIS. For general integers, the option \texttt{IISint} can be be used to signal that general integers should be considered as potential members of the IIS, i.e, integrality constraints are questioned.
  • Fixed handling of BARON termination status when activating \texttt{DeltaTerm} option.
3.26.1.4.3 BONMIN

- Dropped MIP capability (use CBC instead).

3.26.1.4.4 CONOPT

- New libraries 3.16B.
  - The new option `Lsusdf` was added. If turned on (the default) CONOPT's preprocessor will look for definitional constraints which are constraints of the form $x = f(y)$ where the bounds on $x$ are wider than the range of the function $f$, given the bounds on $y$. CONOPT will search for and select a maximal set of independent definitional constraints. The dependent variable in a definitional constraints will be selected for the initial basis and CONOPT will try to use the definition to initialize $x$. There are two other options associated with this procedure: If `Lsusdf` is enabled (default), then only unique definitional constraints are selected. If it is disabled, then option `Lfusdf` specifies a limit (default 2) on the number of candidates a definitional constraint can have.
  - The option `Lsflsh` – flush the buffer, has now been implemented and is automatically turned on if there is a systems error.
  - The lower bound on option `Rtipvr` changed from 1.e-3 to 1.e-10.

3.26.1.4.5 Convert

- The AMPL writer supports special ordered sets, semicontinuous variables, and semiinteger variables now.
- Row names in `.lp` and `.mps` files now start with 'e' instead of 'c', so they match the names written by the `dict` option.

3.26.1.4.6 CPLEX

- New libraries 12.6.0.1.

3.26.1.4.7 CPLEX, SCIP, XPRESS

- Fixed handling of indicator constraints when specified with explicit labels.

3.26.1.4.8 DE

- New option `VaBigM` to control the Big M for a Value at Risk reformulation.
3.26.1.4.9 EMPSP

- New keywords \texttt{VaRUp} (=\texttt{VaR}) and \texttt{VaRLo}: These keywords can be used to optimize the Value at Risk for a certain confidence level. The syntax is similar to the one from \texttt{cVaRUp} (=\texttt{cVaR}) and \texttt{cVaRLo}:

\begin{verbatim}
VaR [rv var] scalar
\end{verbatim}

More information can be found here.

- Changed the order of the parameters for the triangular distribution from

\begin{verbatim}
randvar <name> triangular <low> <high> <mid>
\end{verbatim}

to

\begin{verbatim}
randvar <name> triangular <low> <mid> <high>
\end{verbatim}

3.26.1.4.10 Examiner2

- Fixed a bug in processing special ordered sets.

3.26.1.4.11 GUSS/Scenario Solver

- GUSS/Scenario solver can now be combined with the GAMS Grid Facility (see example \texttt{GUSSGRID} in the GAMS Model Library).

- New option \texttt{RestartType} to determines restart point for the scenarios:
  - 0: Restart from last solution (default)
  - 1: Restart from solution of base case
  - 2: Restart from input point

- New option \texttt{SolveEmpty} (default 0) to limit the number of empty scenarios (no scenario data) that are being solved. When the limit is reached, further empty scenarios will be skipped. Skipped scenarios will be reported to the log and listing file.

3.26.1.4.12 Ipopt

- New libraries.

3.26.1.4.13 Knitro

- As Ziena Optimization has dropped support for Knitro on Solaris (x86) a while ago, we plan to drop GAMS/Knitro on Solaris with the next release.

3.26.1.4.14 Lindo/LindoGlobal

- New libraries 8.0.550.

- LindoGlobal is no longer available for Sparc Solaris (as announced).
3.26.1.4.15 Mosek

- New libraries 7.0.0.121 (Linux, Mac OS X) and 7.0.0.123 (Windows).

3.26.1.4.16 OQNLP

- OQNLP is no longer available for Linux (as announced).

3.26.1.4.17 OS

- GAMS to OSiL conversion now creates more compact instances, especially for quadratic equations and long sums or products in general nonlinear expressions.

3.26.1.4.18 SCIP

- New libraries 3.1 #695c979.
  - Added new primal heuristics "random rounding", "proximity", and "dual value", new branching rule "cloud branching", and new node selectors "breadthfirst" and "uct".
  - Added support for strong branching with domain propagation in full strong and reliability pseudo cost branching.
  - Improved numerical stability (now taking the rank of cuts into account; more checks on LP solution; disabled scaling in feasibility check of nonlinear constraints).
  - Many improvements in presolving.
  - Strong branching LP solutions are now checked for feasibility.
  - Changed or removed parameters:
    - branching/relpscost/maxlookahead: default changed from 9 to 8.
    - branching/relpscost/maxreliable: default changed from 8 to 5.
    - constraints/bivariate/scaling: default changed from TRUE to 'o' (type changed to character).
    - constraints/quadratic/scaling: default changed from TRUE to 'o' (type changed to character).
    - constraints/soc/scaling: default changed from TRUE to 'o' (type changed to character).
    - constraints/varbound/maxlpcoef: default changed from 1E6 to 1E9.
    - heuristics/crossover/minnodes: default changed from 500 to 50.
    - heuristics/dins/minnodes: default changed from 500 to 50.
    - heuristics/feaspump/objfactor: default changed from 1 to 0.1.
    - heuristics/rens/minnodes: default changed from 500 to 50.
    - heuristics/rins/freq: default changed from -1 to 25.
    - heuristics/rins/freqofs: default changed from 5 to 0.
    - heuristics/rins/minfixingrate: default changed from 0 to 0.3.
    - heuristics/rins/minnodes: default changed from 500 to 50.
    - heuristics/shiftandpropagate/sortkey: default changed from 'u' to 'v'.
    - lp/checkfeas: replaced by new parameters lp/checkdualfeas and lp/checkprimfeas.
    - numerics/dualfeastol: default changed from 1E-6 to 1E-7.
    - presolving/dualfix/*: replaced by propagating/dualfix/*
    - propagating/pseudoobj/presoldelay: default changed from TRUE to FALSE.
    - propagating/pseudoobj/timingmask: default changed from 5 to 7.
    - propagating/redcost/timingmask: default changed from 2 to 6.
    - separating/cgmip/objweightsize: renamed to separating/cgmip/objweightsize and default changed from FALSE to TRUE.
    - separating/minefficacyroot: default changed from 0.01 to 0.001.
    - separating/closecuts/relintnormtype: removed
3.26.1.4.19 SoPlex

- New libraries 2.0.0.

3.26.1.4.20 XPRESS

- New libraries 26.01.08.

3.26.1.5 Tools

3.26.1.5.1 GDX2SQLITE

- GDX2SQLITE is a new tool to dump the complete contents of a GAMS GDX file into a SQLite database file.

3.26.1.5.2 GDXDUMP

- New option SymbolsAsSet to write the symbol table for a set as data.

3.26.1.5.3 GDXMRW

- New utilities irgdx and iwgdx for exchanging indexed GDX data with Matlab.

3.26.1.5.4 GDXRENAME

- New utility to rename the same unique elements in a GDX file using a mapping given by a second GDX file.

3.26.1.5.5 GDXXRW

- New option to allow the use of R1C1 notation to specify a cell or a range.
- Reading a set using the option Values=string now skips empty cells.

3.26.1.6 Expert Level APIs

3.26.1.6.1 GMO

- Removed previously deprecated function gmoDirtyExtractDefVar.
- Added a number of functions to access information from an EMP info file, to compute the optimality gap, to access extrinsic function libraries, and to get the name of the GAMS input file.
3.26.1.7 Object Oriented APIs

- New example transport14.
- New method `GAMSSymbolRecord.Key(int index)` (Java: `GAMSSymbolRecord.getKey`, Python: `GamsSymbolRecord.key(int index)`) to retrieve the key of `GAMSSymbolRecord` (Python: `GamsSymbolRecord`) for a given positional index.
- `GAMSSymbol.CopySymbol` now works for the universe of a `GAMSDatabase` (`GAMSDatabase.GetSet("*")`). When copying into the Universe, a merge will be performed.
- Real domains are now registered when exporting a `GAMSDatabase` to GDX (so far, only relaxed domains were registered).
- `GAMSJob.Run` (Python: `GamsJob.run`) now creates `OutDB` (Python: `out_db`) also if it raises a `GAMSExceptionExecution`.
- `GamsModelInstance.Solve` (Java/Python: `GamsModelInstance.solve`) now also works for solvers which require a subsolver, e.g., DICOPT.

3.26.1.7.1 .NET

- Fixed default value for `systemDirectory` argument in `GAMSWorkspace` constructor when using MONO: If no value is given, first the `PATH` and then the (DY)LD_LIBRARY_PATH is checked for a valid GAMS system directory.

3.26.1.7.2 Java

- It is no longer necessary to specify `-Djava.library.path` when running a program. If `java.library.path` is specified, the shared libraries will be loaded from `java.library.path`. Otherwise, the shared libraries will be loaded from the class path that contains `GAMSJavaAPI.jar`.
- It is no longer necessary to set up environment variables (`PATH`, (DY)LD_LIBRARY_PATH) before running a program to find the GAMS system directory, as it can now be specified during run time.
- In the `GAMSWorkspace` default constructor, the default setting for finding the GAMS system directory from environment variables in the following order (depends on the target platform) are applied:
  - Windows: first from `PATH` environment variable. If not found, then from the Windows registry `gams.location`,
  - Mac OS X: first from `PATH` environment variable. If not found, then from `DYLD_LIBRARY_PATH`,
  - other Unix: from `PATH` environment variable. If not found, then from `LD_LIBRARY_PATH`.
- In the non-default `GAMSWorkspace` constructor, the following rules are applied:
  - In case a user specifies a system directory, the API will verify the directory and will not search for GAMS system directory from an environment variable, even when the directory is invalid.
  - In case the specified system directory is `null` or a user does not specify a system directory, the API will apply the default setting from above.
- A memory leak in `GAMSDatabaseIterator` has been closed.
- Issues when using a non-standard locale (`LANG` environment variable) have been fixed.
- All deprecated classes and methods since 24.1 have been removed.
3.26.1.7.3 Python

- New behavior on determining a system directory automatically when a workspace is created.
  - Linux: If no system directory is specified in the GamsWorkspace constructor, check PATH first. If no system directory was found, check LD_LIBRARY_PATH.
  - Mac OS X: If no system directory is specified in the GamsWorkspace constructor, check PATH first. If no system directory was found, check DYLD_LIBRARY_PATH.
  - Windows: If no system directory is specified in the GamsWorkspace constructor, check the Windows registry.

3.26.1.8 Model Libraries

3.26.1.8.1 GAMS Data Library

- MakeQL: Moved querylibrary generator into trisource.zip, which comes with Test Library models trilib01, trilib02, trilib03, and trilib04. Removed MakeQL model.
- invert1.gms: Matrix inversion via R (89)
- invert2.gms: Matrix inversion via Matlab (90)

3.26.1.8.2 GAMS Model Library

- clad.gms: Computation of Fairs extramarital affairs model estimates (397)
- gussex1.gms: Simple GUSS example (398)
- gussrisk.gms: Simple investment example with varying weight for risk using GUSS (399)
- gussgrid.gms: Simple GUSS Grid example (400)
- circpack.gms: Pack circles in the smallest possible rectangle (401)
- tablelayout.gms: Configuring text layout in table cells to minimize table height (402)
- asyncjobs.gms: Execute asynchronously several GAMS jobs and collect the fastest (403)

3.26.1.8.3 GAMS Test Library

- trilib01: Reworked triclib.c source code. Rewrote querylibrary generator.
- single01.gms: Check handling of singleton sets (639)
- execerr1.gms: Test for execerr option (640)
- single02.gms: Check assignment to singleton sets (641)
- scensol4.gms: Basic GUSS Test (642)
- gdxmrw06.gms: run a battery of GDXMRW tests (643)
- single03.gms: Check singleton sets in put statement (644)
• unload11.gms : Check that GAMS does not crash when writing to non-existing folder (645)
• refact00.gms : Check that GAMS produces expected workfile with option sys14=1 (646)
• refact01.gms : Refactor suite test 1 (647)
• scenempty.gms : Empty scenario GUSS Test (648)
• obfusc01.gms : Test use if obfuscated workfile (649)
• load11.gms : Load UEL Table (650)
• gussskip.gms : Simple GUSS example with skipped scenario (651)
• refact02.gms : Refactor suite test 2 (653)
• cpplib03.gms : Test extrinsic functions in cppcclib (654)
• cpplib04.gms : Test extrinsic functions in cppcclib (655)
• cpplib05.gms : Test extrinsic functions in cppcclib (656)
• cpplib00.gms : Test build of CPP library (657)
• syschk2.gms : Test impact of sys10 setting (658)
• scensol5.gms : Test handling of scenario dictionary sets with more than 50 entries (659)
• call5.gms : Check that gams works with COMSPEC unset (660)
• idxoper1.gms : Test indexed operations (661)
• gdxsqlite1.gms : Test basic functionality of GDX2SQLITE tool (662)

3.26.2 24.3.2 Minor release (August 29, 2014)

3.26.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Alvaro Lorca Galvez, Scott McDonald, Tom Rutherford, Nick Sahinidis, and Uwe Schneider.

3.26.2.2 GAMS System

3.26.2.2.1 GAMS

• Allow empty scalar data statements:

    $onempty
    scalar xyz / /;

3.26.2.2.2 Extrinsic Function libraries

• Pass on parameter file name via LibInit call.
3.26.2.3 Solvers

3.26.2.3.1 BARON

- New libraries 14.0.3.

3.26.2.3.2 CBC

- New libraries.

3.26.2.3.3 CONOPT

- New libraries 3.16C.
  - Added checks for internal intermediate results being NaN (Not A Number). If this happens, CONOPT will stop and return a message about it. The solver status will return 4 "Terminated by Solver" and model status 6 or 7, "Intermediate Infeasible" or "Intermediate Feasible."

3.26.2.3.4 CONVERT

- Fixed bug in interval evaluations for functions and gradients.
- The interval evaluations are now triggered by their own option (e.g. `intervalEval=yes`) instead of being part of every Jacobian or Hessian dump.

3.26.2.3.5 Cplex

- Some Cplex tuning parameters had no or the wrong effect. This has been fixed.
- The BCH usercutcall was not called in case of new constrains only for true cuts (see e.g. GAMS Model library model bchtsp). This has been fixed.

3.26.2.3.6 Examiner2

- Fixed error in processing options file.
- Fixed error in trace file generation.

3.26.2.3.7 Ipopt

- New libraries.

3.26.2.3.8 Mosek

- New libraries 7.0.0.126.
  - Fixed an issue with using the Mosek extended license for MIP solving on Mac OS X.
3.26.2.3.9 Osi links

- Fixed writing MPS files with row and column names.

3.26.2.3.10 SCIP

- New libraries 3.1 #322574a
  - Changed default of option heuristics/proximity/minimprove from 0.25 to 0.02.
  - Changed default of option heuristics/proximity/usefinallp from TRUE to FALSE.

3.26.2.3.11 XPRESS

- New libraries 26.01.14 for Linux and Windows.

3.26.2.4 Tools

3.26.2.4.1 GDXDUMP

- When generating $GDXIN filename, the filename now includes the full path of the GDX input file.

3.26.2.4.2 GDXXRW

- In the previous release, we changed the behavior that when reading with Values=String, the empty cells no longer created an entry. Because reading with this option was the default for the cases with RDim=0 or CDim=0, we changed this default to Values=NoData in order not to break existing code.

3.26.2.4.3 Shellexecute

- Fixed error causing problems during parameter processing.

3.26.2.5 Expert Level APIs

- Delphi: Distinguish between 32 bit and 64 bit compiler.
3.26.2.6 Object Oriented APIs

- Make more GAMS options available through the GAMSOptions class:
  - GAMSOptions.AppendExpand: Expand file append option
  - GAMSOptions.AppendOut: Output file append option
  - GAMSOptions.DumpOpt: Writes preprocessed input to the file input.dmp
  - GAMSOptions.DumpParms: GAMS parameter logging
  - GAMSOptions.ErrMsg: Placing of compilation error messages
  - GAMSOptions.Expand: Expanded (include) input file name
  - GAMSOptions.FErr: Alternative error message file
  - GAMSOptions.JobTrace: Job trace string to be written to the trace file at the end of a Gams job
  - GAMSOptions.LimCol: Maximum number of columns listed in one variable block
  - GAMSOptions.LimRow: Maximum number of rows listed in one equation block
  - GAMSOptions.LogLine: Amount of line tracing to the log file
  - GAMSOptions.On115: Generate errors for unknown unique element in an equation
  - GAMSOptions.Output: Output file
  - GAMSOptions.PageContr: Output file page control option
  - GAMSOptions.PageSize: Output file page size (=0 no paging)
  - GAMSOptions.PageWidth: Output file page width
  - GAMSOptions.Reference: Symbol reference file
  - GAMSOptions.ScriptExit: Program or script to be executed at the end of a GAMS run
  - GAMSOptions.Suppress: Compiler listing option
  - GAMSOptions.Symbol: Symbol table file
  - GAMSOptions.TraceLevel: Solvestate threshold used in conjunction with a=GT

3.26.2.7 Model Libraries

3.26.2.7.1 GAMS Data Library

- Fixed some errors in some Matlab examples.

3.26.3 24.3.3 Minor release (September 19, 2014)

3.26.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Henrik Dahl.

3.26.3.2 Solvers

3.26.3.2.1 ANTIGONE, Bonmin, CBC, Couenne, Ipopt, SCIP

- Fixed issue loading MKL libraries on Linux machines with AVX2 instruction set.
3.26.3.3  Tools

3.26.3.3.1  ASK, GDXVIEWER, SQL2GMS, XLS2GMS

- Fixed problem with character set used for error messages.

3.26.3.3.2  GDXXRW

- Fixed error when reading special values from Excel.

3.26.3.3.3  MDB2GMS, SQL2GMS

- Fixed problem when using comma as decimal separator.

3.26.3.4  Object Oriented APIs

3.26.3.4.1  Java

- Fixed a location of listing file when creating a job from (full-path) file without giving a job name.
3.27 24.2 Distribution

3.27.1 24.2.1 Major release (December 09, 2013)

3.27.2 24.2.2 Maintenance release (March 04, 2014)

3.27.3 24.2.3 Maintenance release (May 22, 2014)

3.28 24.1 Distribution

3.28.1 24.1.1 Major release (May 30, 2013)

3.28.2 24.1.2 Maintenance release (June 16, 2013)

3.28.3 24.1.3 Maintenance release (July 26, 2013)

3.29 24.0 Distribution

3.29.1 24.0.1 Major release (December 24, 2012)

3.29.2 24.0.2 Maintenance release (February 14, 2013)

3.30 23.9 Distribution

3.30.1 23.9.1 Major release (July 04, 2012)

3.30.2 23.9.2 Maintenance release (August 29, 2012)

3.30.3 23.9.3 Maintenance release (September 26, 2012)

3.30.4 23.9.4 Maintenance release (October 20, 2012)

3.30.5 23.9.5 Maintenance release (November 09, 2012)

3.31 23.8 Distribution

3.31.1 23.8.1 Major release (March 17, 2012)

3.31.2 23.8.2 Maintenance release (April 05, 2012)

- Bugfix for models with $=X=$ rows and MCP (i.e. MPSGE)
- GloMIQO resets $\text{OptCR}=0$ properly to $1e-9$ and accepts now Ctrl-C on Windows
- Knitro handles MINLP failures better
- XPRESS handles $=E=$ quadratic constraints better now
- Changed position of Library Form in GAMSIDE (avoid hang in corner to corner screen setup)
- Model Trnsxc11 added to GAMS Data Library
- Model ps5_a_sp added to GAMS Model Library
3.32 23.7 Distribution

3.32.1 23.7.1 Major release (July 14, 2011)

3.32.2 23.7.2 Maintenance release (July 22, 2011)

- Alphaecp: Alphaecp v2.04.02
- Conopt3: Fixed a system error 2003
- Dicopt: Fixed a bug for accidentally determined crossovers
- Inclib: updated put_reorderit.gms from Bruce McCarl
- Cbc: Disabled preprocessing in case of semicont/semiint variables, it seems buggy
- Cplex: Does no longer require finite bounds on semicont variables
- Gamsinst: Fix problem with blanks in sysdir and IDE error when not having a license

3.32.3 23.7.3 Maintenance release (August 23, 2011)

- alphaecp: fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
- apifiles:
  - get rid of warnings in cc interface,
  - fix problem with compilation of fat binaries on Darwin in cc interface
  - fix error in gdxSymbolGetDomain in Python interface
  - fix errors with constant definitions in C# interface
  - add constant definitions and additional constructor (which gets a handle) in Java interfaces
- conopt3: Version 3.15A maintenance release
- cplex:
  - fix for interrupt (Ctrl-C) when running with solvelink=5
  - fix memory leak
- dicopt:
  - fix reporting of objest in case of a crossover
  - fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
- gamscmex: fix bug related to the internal organization of non-linear code, affects two-argument functions in rare cases
- gamside:
  - close chart files too when changing system directory
  - GAMS project file name independent of casing
- gdxdump: suppress on/off empty when writing single symbol
- gdxmrw: was missing on 64bit Linux
- grid: fix potential problem with scaling
• kestrel: added Xpress support
• minos fix: for interrupt (Ctrl-C)
• sbb: fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
• snopt fix: for interrupt (Ctrl-C)
• xpress: update global search to use callbacks called during root node processing and improve scheme to stop XPRESS when gap is achieved or on user interrupt

3.33 23.6 Distribution

3.33.1 23.6.2 Major release (December 13, 2010)

3.33.2 23.6.3 Maintenance release (February 15, 2011)

• Cmex: Fix for variable level projection
• Bonmin: Several fixes for outer-approximation based algorithms
• Cplex: New version 12.2.0.2
• Gurobi: New version 4.0.1
• Knitro: Documentation update
• Scip: New version 2.0.1
• Xpress: Fix for crash on 64 bit Solaris
• McCarl Guide: Updates for 23.6
• Gdxxrw: Includes system error message when we cannot start Excel
• Gdxmrw: Minor bugfixes

3.33.3 23.6.4 Maintenance release (April 01, 2011)

• CMEX: Maximal nested includes were raised to 40
• Mosek: New Version6 Rev 105
• Lindoglobal: New Version 6.1.1.553
• Conopt: New Version 3.14W
• Xpress: Memory leak fix
• Coin: Solver fixes
• JAMS: Updates for disjunctions
• GDXXRW: Fixes
• GDXMRW: Updates
• McCarl and GDXUtils: Documentation updates
• Model Libraries: Updates
3.33.4 23.6.5 Maintenance release (April 08, 2011)

- CMEX: Bug fix related to situations with very large number of labels in connection with a restart with continued compilation

3.34 23.5 Distribution

3.34.1 23.5.1 Major release (July 05, 2010)

3.34.2 23.5.2 Maintenance release (August 18, 2010)

- AlphaECP: Fix for crash running under IDE
- API: Updated Python and Java APIs and examples
- Baron: Fixed issue with output formatting under Linux
- Baron: Memory leak when using BARON with external NLP solver
- Gdxmerge: Do not use path when checking for merged.gdx
- Gurobi: Fixed typo for option displayinterval
- McCarl Guide: Updates for 23.5
- Mosek 6 rev 85 libraries
- MPS2GMS: Removed mps2gms debug message
- Snopt: Fix for wrong return code (local,global)
- Xlsdump utility added

3.35 23.4 Distribution

3.35.1 23.4.1 Major release (May 21, 2010)

3.35.2 23.4.3 Maintenance release (May 24, 2010)

3.36 23.3 Distribution

3.36.1 23.3.1 Major release (November 01, 2009)

3.36.2 23.3.2 Maintenance release (November 18, 2009)

- Gurobi 2.0.1 library with bug fixes
- MOSEK 6 rev 53 library with bug fixes
- Updated CoinOS library with bug fixes
- Solver optfile bug fix in GAMSCHK
- Synchronized tolproj (1e-8) option for solvelink=3
### 3.37.3 23.3.3 Maintenance release (December 17, 2009)
- MOSEK 6 rev 55 library with bug fixes
- 32bit HAR utilities available in 64bit Windows System
- Slow solution reporting in GAMS/Gurobi and other solvers fixed

### 3.37 23.2 Distribution

### 3.37.1 23.2.1 Minor release (August 14, 2009)

### 3.38 23.1 Distribution

### 3.38.1 23.1.1 Major release (July 13, 2009)

### 3.38.2 23.1.2 Maintenance release (July 23, 2009)
- MPSGE: MPSGE ignored the \texttt{m.workspace} and \texttt{m.workfactor} settings
- GAMSCHK: Fixed a problem with the layout of the reports in some models

### 3.39 23.0 Distribution

### 3.39.1 23.0.2 Major release (February 14, 2009)

### 3.40 22.9 Distribution

### 3.40.1 22.9.2 Major release (December 01, 2008)

### 3.41 22.8 Distribution

### 3.41.1 22.8.1 Major release (August 01, 2008)

### 3.42 22.7 Distribution

### 3.42.1 22.7.1 Major release (May 01, 2008)

### 3.42.2 22.7.2 Maintenance release (May 13, 2008)
- DICOPT/ALPHAEC/LOGMIP/LOGBOA: Fixed Cplex scaling bug
- GAMS/CPLEX: Small cosmetic Cplex bug fix. We got "CPLEX Error 3003: Not a mixed-integer problem." In case we cannot solve the fixed problem. This was due to some query calls about nodes and iteration.
- GAMSIDE: Fixed a bug that could cause an out of memory error when moving a row or column to the plane index in the gdx data viewer
- GAMS/DEA: Avoid writing zeros to GDX files
- GAMS/LGOLIB: Fixed a memory leak
- Minor documentation updates
- Note: AIX and Mac OS X PPC were not updated.
3.43 22.6 Major release (December 24, 2007)
3.44 22.5 Major release (June 01, 2007)
3.45 22.4 Major release (February 12, 2007)
3.46 22.3 Major release (November 27, 2006)
3.47 22.2 Minor release (April 21, 2006)
3.48 22.1 Major release (March 15, 2006)
3.49 22.0 Major release (August 01, 2005)
3.50 21.7 Major release (April 01, 2005)
3.51 21.6 Minor release (January 26, 2005)
3.52 21.5 Minor release (November 11, 2004)
3.53 21.4 Major release (September 06, 2004)
3.54 21.3 Major release (January 19, 2004)
3.55 21.2 Maintenance release (September 03, 2003)
3.56 21.1 Maintenance release (June 02, 2003)
3.57 21.0 Major release (May 15, 2003)
3.58 20.7 Maintenance release (June 14, 2002)
3.59 20.6 Major release (May 25, 2002)
3.60 20.5 Maintenance release (January 28, 2002)
3.61 20.4 Maintenance release (January 21, 2002)
3.62 20.3 Major release (December 24, 2001)
3.63 20.2 Maintenance release (November 22, 2001)
3.64 20.1 Major release (October 31, 2001)
Chapter 4

User's Guide

This documentation guides GAMS users through several topics in the GAMS system.

4.1 Installation and Licensing

This part leads step by step through the installation process on three main platforms and describes the GAMS licensing system:

- Supported Platforms
- Installation Notes for Mac OS X
- Installation Notes for Unix
- Installation Notes for Windows
- Standard Locations
- Licensing

4.2 Tutorials and Examples

This part describes step by step through several selected tutorials and a small number of examples.

- A GAMS Tutorial by Richard E. Rosenthal
- Quick Start Tutorial
- Good Coding Practices
- Fixing Compilation Errors
- Finding and Fixing Execution Errors and Performance Problems
- Comparative Analyses with GAMS
- Good NLP Formulations
- Data Exchange with Other Applications
4.3 GAMS Language and Environment

This part introduces the components of the GAMS language in an ordered way, interspersed with detailed examples that are often drawn from the model library.

- Introduction - an introduction to the GAMS User’s Guide.
- GAMS Programs - The structure of the GAMS language and its components
- Set Definition - The declaration and initialization of sets, subsets, and domain checking.
- Dynamic Sets - The membership assignment, the usage of dollar controls, and set operations.
- Sets as Sequences: Ordered Sets - Special features used to deal with a set as if it were a sequence.
- Data Manipulations with Parameters - The declaration and assignment of GAMS parameters.
- Data Entry: Parameters, Scalars and Tables - Three basic forms of GAMS data types: Parameters, Scalars and Tables.
- Variables - The declaration and attributes of GAMS variables.
- Equations - The definition and declaration of GAMS equations.
- Model and Solve Statements - The specification of a GAMS model and how to solve it.
- Conditional Expressions, Assignments and Equations - The conditional assignments, expressions and equations in GAMS.
- The Display Statement - The syntax, control, and label order in display.
- Programming Flow Control Features - The GAMS programming flow control features: loop, if-elseif, while, and for statements.
- The Option Statement - The list and detailed description of options.
- System Attributes - The system attributes
- The Grid and Multi-Threading Solve Facility - The basic concepts and Grid Features.
- Special Features for Mathematical Programs - Special features in GAMS that do not translate across solvers, or are specific to certain model types.
The following discusses the execution of GAMS, the use of special features, and other miscellaneous topics.

- **GAMS Output** - The control of GAMS compilation output, execution output, output produced by a solve statement, and error reporting.
- **GAMS Log**
- **The GAMS Call and Command Line Parameters** - The list and detailed description of GAMS command line parameters.
- **Dollar Control Options** - The list and detailed description of dollar control options.
- **The Put Writing Facility** - The put writing facility of the GAMS language.
- **Solver Usage** - Controlling solvers.
- **The Save and Restart Feature** - The GAMS save and restart feature and the work file.
- **Embedded Code Facility** - The Embedded Code Facility (e.g. how to embed Python code into GAMS).
- **GAMS Connect** - The GAMS Connect Framework.
- **Extrinsic Functions** - The extrinsic function library and comparison with external equations.
- **External Equations** - A facility for connecting code written in different programming languages to equations and variables in a GAMS model.
- **GAMS Return Codes** - The structure of error codes, the return codes of the GAMS compiler and execution system, and the driver return codes.
- **GAMS Data eXchange (GDX)** - GAMS Data eXchange (GDX) facilities and utilities for Binary Data Exchange.
- **Extended Mathematical Programming (EMP)** - Extended Mathematical Programming (EMP).
- **Accessing Model Libraries** - Introduction of GAMS Model Library.
- **Mathematical Programming System for General Equilibrium analysis (MPSGE)** - A mathematical programming system for general equilibrium analysis which operates as a subsystem within GAMS.
  - Introduction to MPSGE
  - MPSGE Models in GAMS
  - Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE
  - Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae
  - A Library of Small Examples for Self-Study
  - Linking Implan Social Accounts to MPSGE
  - The MPSGE guide is also available as PDF

### 4.4 Glossary

An alphabetical list of GAMS terms is available in the **Glossary**.
4.5 Supported Platforms

GAMS divides the set of supported platforms into so-called core platforms and peripheral platforms to recognize and better describe how the two sets of platforms have evolved. The user communities for core platforms are large, active, and well-identified, but not so for the peripheral platforms. For the core platforms, GAMS will continue to make each new release of GAMS directly available for download, while the peripheral platforms will be available by request only. Finally, changes in the availability of core platforms will be announced well in advance of the event, while changes to support for peripheral platforms may occur with little or no notice.

The core platforms are the following:
Note

Compared to most of the GAMS system, GAMS Studio has some additional system requirements which are detailed here.

There are currently no peripheral platforms.

While the GAMS execution system itself is available on all supported platforms, for certain solvers, tools, and APIs, different availabilities can apply. For details, see

- Supported Platforms for Solvers
- Supported Platforms for Tools
- Supported Platforms for High-level APIs
- Supported Platforms for Low-level APIs

### 4.6 Installation Notes for Mac OS X

To install GAMS, please follow the steps below as closely as possible. We advise you to read this entire document before beginning the installation procedure. Furthermore, we recommend to use the PKG installer for Mac OS X because it includes the GAMS Studio and it integrates GAMS into Mac OS X, e.g. it is possible to open the GAMS Studio via the Launchpad.

Two installation procedures are available for GAMS on Mac OS X:

- Installation using the PKG installer (GAMS40.1.0.pkg)
- Installation using the self-extracting archive (osx_x64.sfx.exe)

### 4.6.1 Installation using the PKG installer (GAMS40.1.0.pkg)

1. Obtain the GAMS PKG file, which is available from [http://www.gams.com/download](http://www.gams.com/download).
2. Double click the package and follow the instructions. By clicking on Customise in the tab Installation Type you can decide to add GAMS to the PATH as well as to reject the installation of GAMS Studio. Note that adding GAMS to the PATH is done by modifying your shell profile file (~/.zprofile, ~/.bash_profile etc.). A backup of your old profile is saved (~/.zprofile.gamsbackup, ~/.bash_profile.gamsbackup etc.).
3. In order to test the GAMS installation with GAMS Studio open the Launchpad and click the GAMS Studio 40 icon to open the application. Alternatively, go to Applications and open the GAMS Studio 40 application.
4. Install your license via the corresponding GAMS Studio dialog. The license file is nowadays sent via email, with instructions. You can also request a demo license from http://www.gams.com/download.

Optionally, you can create the license file 'gamslice.txt' in a directory that GAMS searches to find a license. GAMS searches a couple of system wide and user specific standard locations for a license file.

5. Open the Model Library Explorer and open the TRANSPORT model (sequence number 001). Run the model and check the contents of the process log, which should be similar to the Terminal output listed in the next bullet point.

6. In order to test the GAMS installation without using GAMS Studio open a Terminal window. Execute the following commands to see if everything works as expected:

```
gamslib trnsport
gams trnsport
```

The output should be similar to this:

```
--- Job trnsport Start 06/26/14 11:24:56 24.3.1 r46409 DEX-DEG Mac x86_64/Darwin
GAMS 24.3.1  Copyright (C) 1987-2014 GAMS Development. All rights reserved

4.6.2 Uninstall PKG installation

To uninstall a GAMS installation that was installed using the PKG installer, run the following command from the terminal: `sudo bash /Library/Frameworks/GAMS.framework/Versions/40/Resources/uninstall.sh`. Additionally, you can remove GAMS from the PATH in your shell profile file (e.g., `~/.zprofile`, `~/.bash_profile`) if GAMS was added to the PATH during installation.

4.6.3 Installation using the self-extracting archive (osx_x64_64_sfx.exe)

1. Obtain the GAMS distribution file, which is available from [http://www.gams.com/download](http://www.gams.com/download), in one large self-extracting zip archive with a `sfx.exe` file extension, e.g., `osx_x64_64_sfx.exe`. Check that it has the execute permission set. If you are not sure how to do this, just type in the command `chmod 755 osx_x64_64_sfx.exe`.

Attention

The common way to install GAMS on a Mac is the PKG installer. When one tries to run the sfx installer (e.g. for unattended installation) under macOS 10.15 (Catalina) or newer, the installer and several related files will be tagged with the `com.apple.quarantine` flag. There are different solutions to this problem:

- The flag can be removed by the following command:
  ```bash
  xattr -rd com.apple.quarantine osx_x64_64_sfx.exe
  ```
- Instead of downloading the sfx installer through the browser, use a command line tool such as curl (note that by downloading the software, you agree to the License Agreement). The download link may need to be adjusted, depending on the distribution that should be downloaded.
  ```bash
  curl https://d37drm4t2jghv5.cloudfront.net/distributions/29.1.0/macosx/osx_x64_64_sfx.exe
  ```

2. Choose a location where you want to create the GAMS system directory (the GAMS system directory is the directory where the GAMS system files should reside). At this location the GAMS installer will create a subdirectory with a name that indicates the distribution of GAMS you are installing. For example, if you are installing the 24.3 distribution in `/Applications/GAMS`, the installer will create the GAMS system directory `/Applications/GAMS/gams24.3.osx_x64_64_sfx`. If the directory where you want to install GAMS is not below your home directory, you may need to have root privileges on the machine.

3. Create the directory that should contain the GAMS system directory, for instance `/Applications/GAMS`. Change to this directory (`cd /Applications/GAMS`). Make sure `pwd` returns the name of this directory correctly.

4. Run the distribution file, either from its current location or after transferring it to the directory that should contain the GAMS system directory. By executing the distribution file, the GAMS distribution should be extracted. For example, if you downloaded the distribution file into your home directory, you might execute the following commands:

   ```bash
   mkdir /Applications/GAMS
   cd /Applications/GAMS
   ~/osx_x64_64_sfx.exe
   ```

5. Create the license file `gamslicetxt` in a directory GAMS searches to find a license. The license file is nowadays sent via email, with instructions. You can also request a demo license from [http://www.gams.com/download](http://www.gams.com/download).
Attention

Do not store the gamslice.txt in the GAMS system directory. This invalidates the code signature and cause Gatekeeper to reject the bundle!

GAMS searches a couple of system wide and user specific locations for a license file. For Mac OS X these locations include /Library/Application Support/GAMS and /Users/username/Library/Application Support/GAMS. The locations can vary due to different system configuration. One can get an ordered list of data directories GAMS searches for gamslice.txt by running the program ./gamsinst -listdirs from the GAMS system directory. Even though this list might contain locations in the system directory, e.g. /Applications/GAMS31.1 we strongly discourage to place gamslice.txt here.

6. Change to the GAMS system directory and run the program ./gamsinst. It will prompt you for default solvers to be used for each class of models. If possible, choose solvers you have licensed since unlicensed solvers will only run in demonstration mode. These solver defaults can be changed or overridden by:
   a. rerunning ./gamsinst and resetting the default values
   b. setting a command line default, e.g., gams transport lp=soplex
   c. an option statement in the GAMS model, e.g: option lp=soplex;

7. Add the GAMS system directory to your path (see below).

8. To test the installation, log in as a normal user and run a few models from your home directory, but not the GAMS system directory:

   LP: transport (objective value: 153.675)
   NLP: chenery (objective value: 1058.9)
   MIP: bid (optimal solution: 15210109.512)
   MINLP: procsel (optimal solution: 1.9231)
   MCP: scarfmc (no objective function)
   MPSGE: scarfmg (no objective function)

9. If you move the GAMS system to another directory, remember to rerun ./gamsinst. It is also good practice to rerun ./gamsinst when you change your license file if this has changed the set of licensed solvers.

4.6.3.1 Access to GAMS

To run GAMS you must be able to execute the GAMS programs located in the GAMS system directory. There are several ways to do this. Remember that the GAMS system directory in the examples below may not correspond to the directory where you have installed your GAMS system.

1. If you are using the C shell (csh) and its variants you can modify your .cshrc file by adding the second of the two lines given below:

   set path = (/your/previous/path/setting )
   set path = ( $path /Applications/GAMS/gams24.3_osx_x64_64_sfx ) # new

2. Those of you using the Bourne (sh) or Korn (ksh) shells and their variants can modify their .profile file by adding the second of the three lines below:

   PATH=/your/previous/path/setting
   PATH=$PATH:/Applications/GAMS/gams24.3_osx_x64_64_sfx # new
   export PATH

   If the .profile file does not exist yet, it needs to be created. You should log out and log in again after you have made any changes to your path.
3. You may prefer to use an alias for the names of the programs instead of modifying the path as described above. C shell users can use the following commands on the command line or in their .cshrc file:

```
alias gams /Applications/GAMS/gams24.3_osx_x64_64_sfx/gams
alias gamslib /Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib
```

The correct Bourne or Korn shell syntax (either command line or .profile) is:

```
alias gams=/Applications/GAMS/gams24.3_osx_x64_64_sfx/gams
alias gamslib=/Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib
```

Again, you should log out and log in order to put the alias settings in .cshrc or .profile into effect.

4. Casual users can always type the absolute path names of the GAMS programs, e.g.:

```
/Applications/GAMS/gams24.3_osx_x64_64_sfx/gams trnsport
```

### 4.6.3.2 Example

The following shows the log of a session, where a user downloads a GAMS 24.3.1 system and installs it under Applications/GAMS/gams24.3_osx_x64_64_sfx. It is assumed that a GAMS license file has been stored as /Users/doe/gamslice.txt.

```
doe@mac:/Users/doe$ curl -L -k -O \\nhttp://d37drm4t2jghv5.cloudfront.net/distributions/24.3.1/macosx/osx_x64_64_sfx.exe
% Total  % Received  % Xferd  Average Speed   Time   Time  Time     Current
     100  148M  100  148M    0     0  4374k --:--:-- --:--:--  5906k

doe@mac:/Users/doe$ chmod 755 osx_x64_64_sfx.exe

doe@mac:/Users/doe$ cd /Applications/GAMS

doe@mac:/Applications/GAMS$ ~/osx_x64_64_sfx.exe
    creating: gams24.3_osx_x64_64_sfx/
    inflating: gams24.3_osx_x64_64_sfx/sp2full.m
    inflating: gams24.3_osx_x64_64_sfx/optpathnlp.def
    inflating: gams24.3_osx_x64_64_sfx/MessageReceiverWindow.exe
    inflating: gams24.3_osx_x64_64_sfx/datalib

</tbody>
</table>

We are now prepared to set read and execute permissions on the GAMS system files. If you are not sure which option to choose, we recommend option 3.
You can set read (and execute) permission for:
1. user only.
2. user and group.
3. user, group, and world.
Enter your choice now

3

The files "gams", "gamslib", etc., are now executable.
You can run these commands in a number of ways:
1. Call them using an absolute path (i.e. /Applications/GAMS/gams24.3_osx_x64_64_sfx/gams).
2. Create your own aliases for them.
3. Add the GAMS system directory "/Applications/GAMS/gams24.3_osx_x64_64_sfx" to your path.
Method 3. is recommended.
4.7 Installation Notes for Unix

4.7.1 Installation

To install GAMS, please follow the steps below as closely as possible. We advise you to read this entire document before beginning the installation procedure. Additionally, a video on how to install GAMS on Linux is available at https://www.youtube.com/watch?v=Mx_tYI3wyP4.

1. Obtain the GAMS distribution file, which is available from http://www.gams.com/latest, in one large self-extracting zip archive with a _sfx.exe file extension, e.g., linux_x64_64_sfx.exe on a Linux 64bit system. Check that it has the execute permission set. If you are not sure how to do this, just type in the command, e.g., chmod 755 linux_x64_64_sfx.exe.
2. Choose a location where you want to create the GAMS system directory (the GAMS system directory is the directory where the GAMS system files should reside). At this location the GAMS installer will create a subdirectory with a name that indicates the distribution of GAMS you are installing. For example, if you are installing the 24.3 distribution in /opt/gams, the installer will create the GAMS system directory /opt/gams/gams24.3_linux_x64_64.sfx. If the directory where you want to install GAMS is not below your home directory, you may need to have root privileges on the machine.

3. Create the directory that should contain the GAMS system directory, for instance /opt/gams. Change to this directory (cd /opt/gams). Make sure pwd returns the name of this directory correctly.

4. Run the distribution file, either from its current location or after transferring it to the directory that should contain the GAMS system directory. By executing the distribution file, the GAMS distribution should be extracted. For example, if you downloaded the distribution file into your home directory, you might execute the following commands:

```
mkdir /opt/gams
cd /opt/gams
~/linux_x64_64_sfx.exe
```

5. Create the license file gamslice.txt in a directory GAMS searches to find a license or use the corresponding GAMS Studio dialog. The license file is nowadays sent via email, with instructions. You can also request a demo license from http://www.gams.com/download. GAMS searches a couple of system wide and user specific standard locations for a license file.

6. Change to the GAMS system directory and run the program ./gamsinst. It will prompt you for default solvers to be used for each class of models. If possible, choose solvers you have licensed since unlicensed solvers will only run in demonstration mode. These solver defaults can be changed or overridden by:
   a. rerunning ./gamsinst and resetting the default values
   b. setting a command line default, e.g., gams trnsport lp=soplex
   c. an option statement in the GAMS model, e.g: option lp=soplex;

7. Add the GAMS system directory to your path (see below).

8. To test the installation, log in as a normal user and run a few models from your home directory, but not the GAMS system directory:

```
LP: trnsport (objective value: 153.675)
NLP: chenery (objective value: 1058.9)
MIP: bid (optimal solution: 15210109.512)
MINLP: procsel (optimal solution: 1.9231)
MCP: scarfmcp (no objective function)
MPSGE: scarfmge (no objective function)
```

9. If you move the GAMS system to another directory, remember to rerun ./gamsinst. It is also good practice to rerun ./gamsinst when you change your license file if this has changed the set of licensed solvers.

### 4.7.2 Access to GAMS

To run GAMS you must be able to execute the GAMS programs located in the GAMS system directory. There are several ways to do this. Remember that the GAMS system directory in the examples below may not correspond to the directory where you have installed your GAMS system.

1. If you are using the C shell (csh) and its variants you can modify your .cshrc file by adding the line
4.8 Installation Notes for Windows

4.8.1 Installation

1. Run windows_x64_64.exe (Windows 64bit): This file is available from https://www.gams.com/latest. Please note that the installation may require administrative privileges on your machine.

You have two options to run the installer: In default or advanced mode. In the default mode, the installer will prompt you for the name of the directory in which to install GAMS. We call this directory the **GAMS directory**. You may accept the default choice or pick another directory. Please remember: if you want to install two different versions of GAMS, they must be in separate directories.

If you choose to use the advanced mode, the installer will also ask you for a name of a start menu folder, if GAMS should be installed for all users, if the **GAMS directory** should be added to the **PATH** environment variable and which desktop icons should be created.

The **GAMS License** page allows to select a GAMS license. The installer tries to find GAMS licenses in different locations and automatically selects a license to be used with the following precedence:

- Clipboard
- C:\Users\username\Documents\GAMS
- Previous GAMS installation found from the registry (User)
- Previous GAMS installation found from the registry (System)
In addition it is possible to browse for a license file (gamslice.txt) or to skip all license related actions (No License) and install one after the installation process. Note that the use of GAMS requires a license. A free demo license can be requested at https://www.gams.com/download. A license file is written to C:|Users\username\Documents\GAMS when installing for Current User (default). Installing for All Users or checking Write License to System Directory will write the license to the GAMS system directory instead.

For automating the installation of GAMS, it is possible to provide the command line parameters /SP=  /SILENT. This will install GAMS in a non-interactive manner using default settings. Note that depending on the security settings, the User Account Control asking for permission might still be active. The following command line parameters are available to further customize the non-interactive installation:

- /installAllUsers=yes|no (default:no): Can be used in order to install for All Users instead of Current User.
- /noLicense=yes|no (default:no): Can be used in order to prevent any GAMS license from being written.
- /noIcons can be used in order to check the Don't create a Start Menu folder checkbox on the Select Start Menu Folder page.
- /desktopIcons=yes|no (default:undef) can be used in order to turn on/off the creation of Desktop icons. The default (undef) is to create a desktop icon for GAMS Studio but not for GAMS IDE.
- /allUsers: Perform installation in administrative install mode.
- /currentUser: Perform installation in non administrative install mode. If specified, /installAllUsers=yes has no effect.

Attention

Under Windows 10 the Windows Installer package may not update system environment variables (see Microsoft Forum). To work around this issue, log off of Windows after the installation, and then log on again.

Note

The installer can be run unattended with the switches /SILENT or /VERYSILENT and might require some post installation task (like copying the license file to an appropriate location). This unattended mode also skips execution of some code in the installer that can cause failures on exotically configured systems.

2. During the installation of GAMS, the setup process helps in setting up the license to be used with GAMS. In case no license has been selected during this process it is required to set this up manually. The license file is nowadays sent via email, with instructions. You can also request a demo license from https://www.gams.com/download. If you don't have a license file yet, choose No license when asked for the GAMS license options. You can install a license later by either manually creating the license file gamslice.txt in a directory GAMS searches to find a license or use the corresponding GAMS Studio dialog.

GAMS searches a couple of system wide and user specific standard locations for a license file.

3. Choose the default solvers: Run GAMS Studio by double clicking studio.exe from the GAMS system subdirectory Studio. To view or edit the default solvers, open the GAMS Configuration Editor in Studio. You can also skip this and thus accept the existing defaults if you wish, but most users want to select new default solvers for each model type.

4. Run a few models to test the GAMS system: The Model Library Explorer allows you to pick some models from the GAMS model library easily. After selecting one, press F9 to run it, and view the solution. To test your installation, run the following models from the GAMS model library:

LP: transport (objective value: 153.675)
NLP: chenery (objective value: 1058.9)
4.8 Installation Notes for Windows

MIP: bid (optimal solution: 15210109.512)
MINLP: procsel (optimal solution: 1.9231)
MCP: scarfmcp (no objective function)
MPSGE: scarfmge (no objective function)

4.8.2 Visual C++ Redistributable Dependency

- Some solvers in the system as well as GAMS Studio have dependencies on certain Visual C++ libraries. These are present on most Windows systems but are missing on some. If you get a complaint about missing libraries on startup of GAMS Studio or when solving a model, please run the installer vcredist_x64.exe for these libraries, which can be found in the GAMS installation folder in directory \[GAMS system\]\apifiles\C++\lib\vs2017.

4.8.3 Command Line Use of GAMS

Users wishing to use GAMS from the command line (aka the console mode) may want to perform the following steps. These steps are not necessary to run GAMS via Studio.

1. We recommend to add the GAMS directory to your environment path in order to avoid having to type in an absolute path name each time you run GAMS. Run the installer in advanced mode and mark the check-box **Add GAMS directory to PATH environment variable**.

2. Run the program **gamsinst**: gamsinst is a command line program used to configure GAMS. It prompts the user for default solvers to be used for each model type. If possible, choose solvers you have licensed, since unlicensed solvers will only run in demonstration mode. The solver defaults can be changed by:
   a. rerunning gamsinst and resetting the default values
   b. setting a command line default, e.g. **gams trnsport lp=soplex**
   c. by an option statement in the GAMS model, e.g: **option lp=soplex;**

   The system wide solver defaults are shared by the command line and GAMS Studio, so you can also choose to set these defaults using GAMS Studio.

4.8.4 Warning from Microsoft SmartScreen Filter

The SmartScreen is a feature that is used in several Microsoft products, including the Internet Explorer, Microsoft Edge, as well as in Windows 8 and newer versions of Windows. It is supposed to help to protect your computer against unwanted software. It uses a reputation-based system to rate files downloaded from the internet. That means that a file gets a better reputation when it gets download more often. As a result you might get a warning like this, especially for GAMS distributions that were recently released:

clicking on “More info” will display an option to continue the installation process.
4.9 Standard Locations

GAMS looks for specific files in some system-wide and user-specific locations which are independent of the GAMS installation. This allows the user to store these files in one place without the need to adjust anything when moving from one GAMS version to another. These folders are referred to as standard locations and are split into two groups: configuration directories and data directories. Here are some examples of files, which will be found in the data directories (or subfolders of these):

- The GAMS license file
- LibInclude files
- External Equation libraries
- Extrinsic Function libraries

The GAMS configuration file is expected in one of the configuration directories.

The exact location depends on the operating system used and user specific settings. Running gamsinst -listdirs on the command line shows the folders searched explicitly.

4.9.1 Standard Locations on Mac OS X

4.9.1.1 Configuration Directories

These folders get searched on Mac OS X (in the listed order):

- The GAMS system directory
- The subfolder GAMS in $HOME/Library/Preferences ($HOME usually contains the user's home directory)

Here is an example output of gamsinst -listdirs:

Config directories (searched for e.g. gamsconfig.yaml):
/Users/JaneDoe/GAMS32
/Users/JaneDoe/Library/Preferences/GAMS
4.9.1.2 Data Directories

These folders get searched on Mac OS X (in the listed order):

- The subfolder GAMS in $HOME/Library/Application Support ($HOME usually contains the user's home directory)
- The subfolder GAMS in /Library/Application Support
- The subfolder Resources next to the GAMS system directory
- The GAMS system directory

Here is an example output of `gamsinst -listdirs`:

```
Data directories (searched for e.g. gamslice.txt):
/Users/JaneDoe/Library/Application Support/GAMS
/Library/Application Support/GAMS
/Users/JaneDoe/Resources
/Users/JaneDoe/GAMS32
```

4.9.2 Standard Locations on Unix

4.9.2.1 Configuration Directories

On Unix the environment variables XDG_CONFIG_HOME and XDG_CONFIG_DIRS (see XDG Base Directory Specification) influence the search directories. These folders get searched on Unix (in the listed order):

- The GAMS system directory
- The subfolder GAMS of folders from $XDG_CONFIG_DIRS or the subfolder GAMS in /etc/xdg
- The folder $XDG_CONFIG_HOME or the subfolder GAMS in $HOME/.config ($HOME usually contains the user's home directory)

Here is an example output of `gamsinst -listdirs`:

```
Config directories (searched for e.g. gamsconfig.yaml):
/home/JohnDoe/GAMS32
/etc/xdg/GAMS
/home/JohnDoe/.config/GAMS
```

4.9.2.2 Data Directories

On Unix the environment variables XDG_DATA_HOME and XDG_DATA_DIRS (see XDG Base Directory Specification) influences the search directories. These folders get searched on Unix (in the listed order):

- The folder $XDG_DATA_HOME or the subfolder GAMS in $HOME/.local/share ($HOME usually contains the user's home directory)
- The subfolder GAMS of folders from $XDG_DATA_DIRS or the subfolder GAMS in /usr/local/share and the subfolder GAMS in /usr/share
- The GAMS system directory

Here is an example output of `gamsinst -listdirs`:

```
Data directories (searched for e.g. gamslice.txt):
/home/JohnDoe/.local/share/GAMS
/usr/local/share/GAMS
/usr/share/GAMS
/home/JohnDoe/GAMS32
```
4.9.3 Standard Locations on Windows

4.9.3.1 Configuration Directories

These folders get searched on Windows (in the listed order):

- The GAMS system directory
- The subfolder GAMS in C:\ProgramData
- The subfolder GAMS in AppData\Local in the User's directory
- The subfolder GAMS in Documents in the User's directory

Here is an example output of `gamsinst -listdirs`:

Config directories (searched for e.g. gamsconfig.yaml):

```
C:\GAMS\32
C:\ProgramData\GAMS
C:\(Users\JohnDoe\AppData\Local\GAMS
C:\(Users\JohnDoe\Documents\GAMS
```

4.9.3.2 Data Directories

These folders get searched on Windows (in the listed order):

- The subfolder GAMS in Documents in the User's directory
- The subfolder GAMS in AppData\Roaming in the User's directory
- The subfolder GAMS in C:\ProgramData
- The subfolder data in the GAMS system directory
- The subfolder data\GAMS in the GAMS system directory
- The GAMS system directory

Here is an example output of `gamsinst -listdirs`:

Data directories (searched for e.g. gamslice.txt):

```
C:\(Users\JohnDoe\Documents\GAMS
C:\(Users\JohnDoe\AppData\Roaming\GAMS
C:\ProgramData\GAMS
C:\GAMS\32\data
C:\GAMS\32\data\GAMS
C:\GAMS\32
```

Note: When running as a service, the "User's directory" mentioned above is not C:\Users\UserName but resolves to something like C:\Windows\system32\config\systemprofile. So the above output could look like this:

```
Data directories (searched for e.g. gamslice.txt):

C:\Windows\system32\config\systemprofile\Documents\GAMS
C:\Windows\system32\config\systemprofile\AppData\Roaming\GAMS
C:\ProgramData\GAMS
C:\GAMS\32\data
C:\GAMS\32\data\GAMS
C:\GAMS\32
```
4.10 Licensing

4.10.1 General Information

The GAMS system and all connected solvers can be downloaded from the GAMS website at https://www.gams.com/download. The use of the software is governed by the GAMS End User License Agreement, which is available on our website and can also be found in the GAMS System directory (eula.pdf). Without a valid GAMS license the system will not run and produces the following output:

*** No license specified and no gamslice.txt found in standard locations.

You can request a free demo license at https://www.gams.com/download. The demo license lets you generate and solve linear models (LP, RMIP, and MIP) that do not exceed 2000 variables and 2000 constraints. For all other model types the model cannot be larger than 1000 variables and 1000 constraints. Some solvers might enforce additional limits for the demo license. The demo license of MIRO connector allows up to 10 indexed input and output symbols.

GAMS will terminate with an error message, if it hits one of the limits above:

*** Status: Terminated due to a licensing error
*** Inspect listing file for more information

The demo license is time-limited for 12 months and on expiration you need to request a new license. Moreover, a valid free demo license requires a recent GAMS version (not older than 18 months).

4.10.2 GAMS Community License

Users can request a free community license from community@gams.com. The community license lets you generate and solve linear models (LP, MIP, and RMIP) that do not exceed 5000 variables and 5000 constraints. For all other model types the model cannot be larger than 2500 variables and 2500 constraints. Restrictions you experience with the demo license, i.e. additional limits enforced by some solvers, time-limitation of 12 months, and a recent GAMS system also apply to the community license. The free demo and community license cannot be combined with a professional license. These free demo and community licenses are for demonstration and evaluation but not for commercial and production work.

4.10.3 GAMS Licenses

GAMS licenses beyond the free demo and community license require a license for the GAMS Base Module and for most of the GAMS/Solvers and the GAMS/Solver-Links:

- The GAMS Base Module includes the GAMS Language Compiler, GAMS-APIs, many utilities, some solvers without size restrictions, and most solvers in “demo” mode with a model size limitation. See details below.
- A GAMS/Solver connects the GAMS Base module to a particular solver and includes a license for this solver to be used through GAMS. It is not necessary to install additional software. A GAMS/Solver-Link connects the GAMS Base Module to a particular solver, but does not include a license for the solver. It may be necessary to install additional software before the solver can be used.

We distinguish between academic and commercial licenses. Academic licenses can only be used for teaching and research at degree granting institutions. Moreover, we distinguish between time-limited and perpetual licenses. For perpetual licenses the first year of maintenance, support and updates is included in the initial purchase of the software. Maintained licenses qualify for free updates, adding components, platform-switching without additional charge, and multi-copy discounts on the same platform. After the first year maintenance can be extended by paying a fee. Licenses are typically limited to a single computer platform type (e.g. Windows or Linux), but there are also licenses available, which will work on all major platform supported by GAMS. Free academic licenses are available for certain solvers. Please visit the GAMS website for further information about the pricing of an appropriate license.
4.10.4 Installing or updating a license file

A GAMS license file is an ASCII file of six lines, which was sent to you via e-mail. Please copy all six lines into a file gamslice.txt and place this into a location searched by GAMS. Details can be found in the installation notes of the specific operating system:

- GAMS Installation Notes for Windows
- GAMS Installation Notes for Mac OS X
- GAMS Installation Notes for Unix

Before installing a new GAMS version, please check whether it will work with your current GAMS license. The utility CHK4UPD can be used to see if a newer GAMS version is available and what the newest version is that can be used with a given license. This is done by running CHK4UPD without arguments or by giving the name of a local license file. CHK4UPD is also available through GAMS Studio and can be accessed through: Help -> Check for Update. Below is a sample output for a license, which is still under maintenance:

D:\>chk4upd
*** Processing GAMS system directory C:\gams\win64\24.8
*** Reading license file C:\ProgramData\GAMS\gamslice.txt
*** Your system is up to date
D:\>

If your license is no longer under maintenance, you will receive a message like the one below:

*** Processing GAMS system directory C:\GAMS\win64\23.9
*** Reading license file C:\ProgramData\GAMS\gamslice.txt
*** Your license is 1276 days too old to run with the most recent system
*** The version of your GAMS system is 23.9.5
*** The last GAMS version you can use is 24.1.3
*** Please request the download of an older version from sales@gams.com
*** For ordering an update to use the most recent version (24.8.5)
*** please contact your distributor

4.10.5 License Problems

Errors or warnings triggered by a problem with the GAMS license file (gamslice.txt) are reported both in the log file and in the lst file. Below are some typical error and warning messages and instructions how to overcome them.

4.10.5.1 No License File present

Without a license file GAMS will not work. If you have received a license file (gamslice.txt), follow the instruction from the previous section. Do not try to rename it or to modify the contents of the license file. Without a license GAMS will give you an error message like the one below:

*** No license specified and no gamslice.txt found in standard locations.
4.10.5.2 License File Invalid or Corrupted

Running GAMS with an invalid license will give you an error message like the one below:

*** License File validation failed

Do not try to modify your license file, any change will break it. If the original license file is no longer available, please contact sales@gams.com and ask for a copy of your license file. Please attach the license file you are currently using. This error also pops up, if you are using a license file, which was issued for a different platform.

4.10.5.3 License File expired

If are trying to run an old license file with a newer GAMS distribution, you may get an error message stating:

*** License file too old for this version of GAMS.
*** Maintenance expired 2840 days ago.
*** More than 60 days since expiration, sorry...
*** Run an older GAMS system or renew the license

Replace that GAMS system with the one you got together with your license file (use the CHK4UPD utility mentioned above to find out the latest version you can use with the current license; old systems are available on request from sales@gams.com) or update your license to the current version.

4.10.5.4 No License (for a particular Solver) found

If one of the solvers you are trying to use (or is selected as the default solver) is not included in your license file and the size of the model exceed the limits of the free demo or community version, you will get an error stating:

*** No license found
*** To update your license, please contact your distributor.

Check whether the default solvers for a particular problem class are included in the license. Please note that some of the solvers call other solvers as a sub-solver, e.g.:

- GAMS/DICOPT requires an NLP and a MIP solver
- GAMS/SBB requires an NLP solver
- MPSGE: If GAMS/PATH is not included in your license, please select GAMS/MILES, which is included in the base system as the default solver for MCP problems.

4.10.6 Warnings

4.10.6.1 License file too old for this version of GAMS

The complete message is:

*** License file too old for this version of GAMS.
*** Maintenance expired xx days ago.

If GAMS continues working, you can ignore this warning. However, any forthcoming GAMS distribution will most likely not work, but downgrade to the limits of the free demo system.
4.10.6.2 License File has expired xx days ago

This warning (without further error messages) indicates that the time limited license (e.g. an evaluation license) will stop working soon.

4.10.7 The GAMS/BASE Module

The GAMS/BASE module includes:

- **Language Compiler and Execution System**
- **GAMS IDE** *(Integrated Development Environment) (Windows only)*
  - Project Management
  - Editor, Syntax coloring, Spell checking
  - Launching and monitoring of (multiple) GAMS processes
  - Listing file / Tree view / Syntax-error navigation
  - Solver selection / option selection
  - GDX Viewer: Data cube and export (e.g. to MS Excel), charting facilities

- **GAMS Studio** *(platform independent, Beta version)*
  - Editor, Syntax coloring
  - Launching and monitoring of (multiple) GAMS processes
  - Listing file / Tree view / Syntax-error navigation
  - GDX Viewer

- **GAMS Free Solvers and Links**
  - Open Source (COIN-OR): CBC, Ipopt, SHOT
  - CONVERT, JAMS and LOGMIP, NLPEC
  - MILES
  - EXAMINER, GAMSCHK
  - Academic licenses only: ODHeuristic (requires a GAMS/CPLEX or GAMS/CPLEX-Link license), SCIP, Soplex
  - OSI Solver Links
  - GAMS/KESTREL for using the NEOS Server with a local GAMS system

- **Most other solvers in limited versions for demonstration and evaluation, but no commercial use:** 2000 constraints and variables for linear models, and 1000 constraints and variables for other model types. For licensed academic users the size limits are increased: 5000 constraints and variables for linear models, and 2500 constraints and variables for other model types. The solvers might enforce additional limits.

- **EMP** *(Extended Mathematical Programming Framework)*

- **Posix Utilities**
  - Academic licenses only: MIRO Connector for using external input and output symbols.

- **GDX** *(GAMSData eXchange) and related GDX Utilities*
  - Binary data exchange between application, GAMS, and the solver (fast, saves disk space, tailored for large sparse matrices, platform independent, direct GDX interfaces, API support for high-level programming languages)
4.10 Licensing

- **GDX Utilities:** GDX Viewer, GDXRANK, GDX2HAR, HAR2GDX, GDXMERGE, GDXDUMP, GDXCOPY, GDXDIFF, MDB2GMS, GDXMRW, GDXRW, GDXXRW, GDX2XLS, XLSDump, INVERT, CHOLESKY, EIGENVALUE, EIGENVECTOR

- **Various other tools**

- **GAMS APIs**
  - **Expert-Level GAMS APIs**
    - GAMS
    - GDX
    - Option
    - Supported Languages: C, C++, C#, Delphi, Fortran, Java, Python, VBA, VB.Net
  - **Object-Oriented GAMS APIs**
    - Supported Languages: C++, C#, Java, Python, VB.Net

- **Documentation**

- **Model Libraries**

### 4.10.8 Additional Limits for the Demo and Community License

The model size limits enforced by GAMS are:

- 2000 variables and 2000 constraints for linear (LP, RMIP, and MIP) models with a demo license
- 1000 variables and 1000 constraints for all other model types with a demo license
- 5000 variables and 5000 constraints for linear (LP, RMIP, and MIP) models with a community license
- 2500 variables and 2500 constraints for all other model types with a community license

In addition to the GAMS model size limits, the solvers might impose stricter limits when running with a demo or community license. We use $m$ for the number constraints, $n$ for the number variables, $nd$ for the number of discrete variables, $nz$ for the number nonzeros, and $nlnz$ for the number nonlinear nonzeros:

- **Antigone, Baron, LindoGlobal, and Octeract** require $m \leq 50$, $n \leq 50$, and $nlnz \leq 50$ with a demo license.
- **Antigone, Baron, LindoGlobal, and Octeract** require $m \leq 300$, $n \leq 300$, and $nlnz \leq 100$ with a community license.
- **Cplex and ODHCPLEX** require $m \leq 2000$ and $n \leq 2000$ with a *pro-bono* community license.
- **Decis and Knitro** require $m \leq 300$, $n \leq 300$, $nd \leq 50$, $nz \leq 2000$, and $nlnz \leq 1000$ with a demo and community license.
- **Xpress** requires $m + n \leq 5000$ with a community license.
- In addition **Gurobi** requires a license file from the vendor to operate.
4.11 A GAMS Tutorial by Richard E. Rosenthal

4.11.1 Introduction

Richard E. Rosenthal of the Naval Postgraduate School in Monterey, California wrote a detailed example of the use of GAMS for formulating, solving, and analyzing a small and simple optimization problem. The example is a quick overview of GAMS and its main features. Many references are made to other parts of the documentation, but they are only to tell you where to look for more details; the material here can be read profitably without reference to the rest of the documentation.

The example is an instance of the transportation problem of linear programming, which has historically served as a 'laboratory animal' in the development of optimization technology. [See, for example, Dantzig (1963)\(^1\).] It is a good choice for illustrating the power of algebraic modeling languages like GAMS because the transportation problem, no matter how large the instance at hand, possesses a simple, exploitable algebraic structure. You will see that almost all of the statements in the GAMS input file we are about to present would remain unchanged if a much larger transportation problem were considered.

In the familiar transportation problem, we are given the supplies at several plants and the demands at several markets for a single commodity, and we are given the unit costs of shipping the commodity from plants to markets. The economic question is: how much shipment should there be between each plant and each market so as to minimize total transport cost?

The algebraic representation of this problem is usually presented in a format similar to the following.

Indices:

\[ i = \text{plants} \]
\[ j = \text{markets} \]

Given Data:

\[ a_i = \text{supply of commodity of plant } i \text{ (in cases)} \]
\[ b_j = \text{demand for commodity at market } j \]
\[ c_{ij} = \text{cost per unit shipment between plant } i \text{ and market } j \]

Decision Variables:

\[ x_{ij} = \text{amount of commodity to ship from plant } i \text{ to market } j \]

where \( x_{ij} \geq 0 \), for all \( i, j \)

Constraints:

- Observe supply limit at plant \( i \): \( \sum_j x_{ij} \leq a_i \) for all \( i \) (cases)
- Satisfy demand at market \( j \): \( \sum_i x_{ij} \geq b_j \) for all \( j \) (cases)

Objective Function: Minimize \( \sum_i \sum_j c_{ij} x_{ij} \) (\$K)

---

Note that this simple example reveals some modeling practices that we regard as good habits in general and that are consistent with the design of GAMS. First, all the entities of the model are identified (and grouped) by type. Second, the ordering of entities is chosen so that no symbol is referred to before it is defined. Third, the units of all entities are specified, and, fourth, the units are chosen to a scale such that the numerical values to be encountered by the optimizer have relatively small absolute orders of magnitude. (The symbol $\$K$ here means thousands of dollars.)

The names of the types of entities may differ among modelers. For example, economists use the terms *exogenous variable* and *endogenous variable* for *given data* and *decision variable*, respectively. In GAMS, the terminology adopted is as follows: indices are called *sets*, given data are called *parameters*, decision variables are called *variables*, and constraints and the objective function are called *equations*.

The GAMS representation of the transportation problem closely resembles the algebraic representation above. The most important difference, however, is that the GAMS version can be read and processed by a computer.

**Table 1**: Data for the transportation problem (adapted from Dantzig, 1963) illustrates Shipping Distances from Plants to Markets (1000 miles) as well as Market Demands and Plant Supplies.

<table>
<thead>
<tr>
<th>Plants ↓</th>
<th>New York</th>
<th>Chicago</th>
<th>Topeka</th>
<th>Markets ←</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
<td>350</td>
</tr>
<tr>
<td>San Diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
<td>600</td>
</tr>
</tbody>
</table>

Demands →
<table>
<thead>
<tr>
<th>Supplies ↑</th>
</tr>
</thead>
<tbody>
<tr>
<td>325</td>
</tr>
<tr>
<td>300</td>
</tr>
<tr>
<td>275</td>
</tr>
</tbody>
</table>

As an instance of the transportation problem, suppose there are two canning plants and three markets, with the data given in table Table 1. Shipping distances are in thousands of miles, and shipping costs are assumed to be $90.00 per case per thousand miles. The GAMS representation of this problem is as follows:

```
$title a transportation model
Sets
   i     canning plants / seattle, san-diego /
   j     markets       / new-york, chicago, topeka / ;
Parameters
   a(i) capacity of plant i in cases
       / seattle  350
       san-diego 600 /
   b(j) demand at market j in cases
       / new-york 325
       chicago 300
       topeka 275 /
Table d(i,j) distance in thousands of miles
   seattle     new-york | chicago | topeka
   san-diego   2.5       | 1.7     | 1.8
   2.5         | 1.8     | 1.4 ;
Scalar f freight in dollars per case per thousand miles /90/ ;
Parameter c(i,j) transport cost in thousands of dollars per case ;
   c(i,j) = f * d(i,j) / 1000 ;
Variables
```
\( x(i,j) \) shipment quantities in cases
\( z \) total transportation costs in thousands of dollars;

Positive Variable \( x \);

Equations

\begin{align*}
\text{cost} & \quad \text{define objective function} \\
\text{supply}(i) & \quad \text{observe supply limit at plant } i \\
\text{demand}(j) & \quad \text{satisfy demand at market } j;
\end{align*}

\begin{align*}
\text{cost} & \quad z = \text{e}= \sum((i,j), c(i,j) \times x(i,j)) ; \\
\text{supply}(i) & \quad \sum(j, x(i,j)) = \text{l} = a(i) ; \\
\text{demand}(j) & \quad \sum(i, x(i,j)) = \text{g} = b(j) ;
\end{align*}

Model transport /all/ ;

Solve transport using lp minimizing z ;

Display x.l, x.m ;

If you submit a file containing the statements above as input to GAMS, the transportation model will be formulated and solved. Details vary on how to invoke GAMS on different of computers, but the simplest ('no frills') way to call GAMS is to enter the word GAMS followed by the input file's name. You will see a number of terse lines describing the progress GAMS is making, including the name of the file onto which the output is being written. When GAMS has finished, examine this file, and if all has gone well the optimal shipments will be displayed at the bottom as follows.

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>50.000</td>
<td>300.000</td>
<td></td>
</tr>
<tr>
<td>san-diego</td>
<td>275.000</td>
<td>275.000</td>
<td></td>
</tr>
</tbody>
</table>

You will also receive the marginal costs (simplex multipliers) below.

<table>
<thead>
<tr>
<th></th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>0.036</td>
<td></td>
</tr>
<tr>
<td>san-diego</td>
<td>0.009</td>
<td></td>
</tr>
</tbody>
</table>

These results indicate, for example, that it is optimal to send nothing from Seattle to Topeka, but if you insist on sending one case it will add $0.036 \times 1000 = 36.00$ to the optimal cost.

4.11.2 Structure of a GAMS Model

For the remainder of the tutorial, we will discuss the basic components of a GAMS model, with reference to the example above. The basic components are listed in table Table 2.

\textbf{Table 2:} The basic components of a GAMS model
There are optional input components, such as edit checks for bad data and requests for customized reports of results. Other optional advanced features include saving and restoring old models, and creating multiple models in a single run, but this tutorial will discuss only the basic components.

Before treating the individual components, we give a few general remarks.

1. A GAMS model is a collection of statements in the GAMS Language. The only rule governing the ordering of statements is that an entity of the model cannot be referenced before it is declared to exist.

2. GAMS statements may be laid out typographically in almost any style that is appealing to the user. Multiple lines per statement, embedded blank lines, and multiple statements per line are allowed. You will get a good idea of what is allowed from the examples in this tutorial, but precise rules of the road are given in the next Chapter.

3. When you are a beginning GAMS user, you should terminate every statement with a semicolon, as in our examples. The GAMS compiler does not distinguish between upper-and lowercase letters, so you are free to use either.

4. Documentation is crucial to the usefulness of mathematical models. It is more useful (and most likely to be accurate) if it is embedded within the model itself rather than written up separately. There are at least two ways to insert documentation within a GAMS model. First, any line that starts with an asterisk in column 1 is disregarded as a comment line by the GAMS compiler. Second, perhaps more important, documentary text can be inserted within specific GAMS statements.

5. As you can see from the list of input components above, the creation of GAMS entities involves two steps: a declaration and an assignment or definition. *Declaration* means declaring the existence of something and giving it a name. *Assignment or definition* means giving something a specific value or form. In the case of equations, you must make the declaration and definition in separate GAMS statements. For all other GAMS entities, however, you have the option of making declarations and assignments in the same statement or separately.

6. The names given to the entities of the model must start with a letter and can be followed by up to 62 more letters or digits.
4.11.3 Sets

Sets are the basic building blocks of a GAMS model, corresponding exactly to the indices in the algebraic representations of models. The Transportation example above contains just one Set statement:

```gams
Sets
   i canning plants / seattle, san-diego /;
   j markets / new-york, chicago, topeka /;
```

The effect of this statement is probably self-evident. We declared two sets and gave them the names `i` and `j`. We also assigned members to the sets as follows:

```gams
i = {Seattle, San Diego}
```

```gams
j = {New York, Chicago, Topeka}.
```

You should note the typographical differences between the GAMS format and the usual mathematical format for listing the elements of a set. GAMS uses slashes `/` rather than curly braces `{}' to delineate the set simply because not all computer keyboards have keys for curly braces. Note also that multiword names like 'New York' have to be quoted ((e.g. 'New York' or "New York") or you must use hyphens instead of blanks (e.g. New-York').

The words after the set names in the `sets` statement above are called text. Text is optional. It is there only for internal documentation, serving no formal purpose in the model. The GAMS compiler makes no attempt to interpret the text, but it saves the text and 'parrots' it back to you at various times for your convenience.

It was not necessary to combine the creation of sets `i` and `j` in one statement. We could have put them into separate statements as follows:

```gams
Set i canning plants / seattle, san-diego /;
Set j markets / new-york, chicago, topeka /;
```

The placement of blank spaces and lines (as well as the choice of upper- or lowercase) is up to you. Each GAMS user tends to develop individual stylistic conventions. (The use of the singular `set` is also up to you. Using `set` in a statement that makes a single declaration and `sets` in one that makes several is good English, but GAMS treats the singular and plural synonymously.)

A convenient feature to use when you are assigning members to a set is the asterisk. It applies to cases when the elements follow a sequence. For example, the following are valid set statements in GAMS.

```gams
Set t time periods /1991*2000/;
Set m machines /mach1*mach24/;
```

Here the effect is to assign

```gams
m = {mach 1, mach 2,......, mach 24 }.
```

Note that set elements are stored as character strings, so the elements of `t` are not numbers.

Another convenient feature is the alias statement, which is used to give another name to a previously declared set. In the following example:

```gams
Alias (t,tp);
```

the name `tp` is like a `t' in mathematical notation. It is useful in models that are concerned with the interactions of elements within the same set.

The sets `i`, `j`, `t`, and `m` in the statements above are examples of static sets, i.e., they are assigned their members directly by the user and do not change. GAMS has several capabilities for creating dynamic sets, which acquire their members through the execution of set-theoretic and logical operations. Dynamic sets are discussed in chapter `Dynamic Sets`. Another valuable advanced feature is multidimensional sets, which are discussed in section `Multi-Dimensional Sets`. 
4.11.4 Data

The GAMS model of the transportation problem demonstrates three of the different formats that are allowable for entering data. The three formats are:

- Lists
- Tables
- Direct assignments

The next three subsections will discuss each of these formats in turn.

4.11.4.1 Data Entry by Lists

The first format is illustrated by the first Parameters statement of the example, which is repeated below.

Parameters

a(i) capacity of plant i in cases
    / seattle 350
    san-diego 600 /

b(j) demand at market j in cases
    / new-york 325
    chicago 300
    topeka 275 / ;

This statement has several effects. Again, they may be self-evident, but it is worthwhile to analyze them in detail. The statement declares the existence of two parameters, gives them the names $a$ and $b$, and declares their domains to be $i$ and $j$, respectively. (A domain is the set, or tuple of sets, over which a parameter, variable, or equation is defined.) The statement also gives documentary text for each parameter and assigns values of $a(i)$ and $b(j)$ for each element of $i$ and $j$. It is perfectly acceptable to break this one statement into two, if you prefer, as follows.

Parameters a(i) capacity of plant i in cases
    / seattle 350
    san-diego 600 / ;

Parameters b(j) demand at market j in cases
    / new-york 325
    chicago 300
    topeka 275 / ;

Here are some points to remember when using the list format.

1. The list of domain elements and their respective parameter values can be laid out in almost any way you like. The only rules are that the entire list must be enclosed in slashes and that the element-value pairs must be separated by commas or entered on separate lines.
2. There is no semicolon separating the element-value list from the name, domain, and text that precede it. This is because the same statement is being used for declaration and assignment when you use the list format. (An element-value list by itself is not interpretable by GAMS and will result in an error message.)

3. The GAMS compiler has an unusual feature called domain checking, which verifies that each domain element in the list is in fact a member of the appropriate set. For example, if you were to spell 'Seattle' correctly in the statement declaring Set i but misspell it as 'Seatle' in a subsequent element-value list, the GAMS compiler would give you an error message that the element 'Seatle' does not belong to the set i.

4. Zero is the default value for all parameters. Therefore, you only need to include the nonzero entries in the element-value list, and these can be entered in any order.

5. A scalar is regarded as a parameter that has no domain. It can be declared and assigned with a Scalar statement containing a degenerate list of only one value, as in the following statement from the transportation model:

Scalar f freight in dollars per case per thousand miles /90/;

If the domain of a parameter has two or more dimensions, it can still have its values entered by the list format. This is very useful for entering arrays that are sparse (having few non-zeros) and super-sparse (having few distinct non-zeros).

4.11.4.2 Data Entry by Tables

Optimization practitioners have noticed for some time that many of the input data for a large model are derived from relatively small tables of numbers. Thus, it is very useful to have the table format for data entry. An example of a two-dimensional table (or matrix) is provided in the transportation model:

Table d(i,j) distance in thousands of miles

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

The effect of this statement is to declare the parameter d and to specify its domain as the set of ordered pairs in the Cartesian product of i and j. The values of d are also given in this statement under the appropriate heading. If there are blank entries in the table, they are interpreted as zeroes.

As in the list format, GAMS will perform domain checking to make sure that the row and column names of the table are members of the appropriate sets. Formats for entering tables with more columns than you can fit on one line and for entering tables with more than two dimensions are given in Chapter Data Entry: Parameters, Scalars and Tables.

4.11.4.3 Data Entry by Direct Assignment

The direct assignment method of data entry differs from the list and table methods in that it divides the tasks of parameter declaration and parameter assignment between separate statements. The transportation model contains the following example of this method:

Parameter c(i,j) transport cost in thousands of dollars per case ;

\[ c(i,j) = f \times d(i,j) / 1000 ; \]
It is important to emphasize the presence of the semicolon at the end of the first line. Without it, the GAMS compiler would attempt to interpret both lines as parts of the same statement. (GAMS would fail to discern a valid interpretation, so it would send you an error message.)

The effects of the first statement above are to declare the parameter \( c \), to specify the domain \((i,j)\), and to provide some documentary text. The second statement assigns to \( c(i,j) \) the product of the values of the parameters \( f \) and \( d(i,j) \). Naturally, this is legal in GAMS only if you have already assigned values to \( f \) and \( d(i,j) \) in previous statements.

The direct assignment above applies to all \((i,j)\) pairs in the domain of \( c \). If you wish to make assignments for specific elements in the domain, you enclose the element names in quotes. For example,

\[
c('Seattle','New-York') = 0.40;
\]

is a valid GAMS assignment statement.

The same parameter can be assigned a value more than once. Each assignment statement takes effect immediately and overrides any previous values. (In contrast, the same parameter may not be declared more than once. This is a GAMS error check to keep you from accidentally using the same name for two different things.)

The right-hand side of an assignment statement can contain a great variety of mathematical expressions and built-in functions. If you are familiar with a scientific programming language such as C, you will have no trouble in becoming comfortable writing assignment statements in GAMS. (Notice, however, that GAMS has some efficiencies not shared by C. For example, we were able to assign \( c(i,j) \) values for all \((i,j)\) pairs without constructing 'loops'.)

The GAMS standard operations and supplied functions are given later. Here are some examples of valid assignments. In all cases, assume the left-hand-side parameter has already been declared and the right-hand-side parameters have already been assigned values in previous statements.

\[
\begin{align*}
\text{csquared} &= \text{sqr}(c); \\
\text{e} &= m*\text{csquared}; \\
\text{w} &= 1/\text{lamda}; \\
\text{eqo}(i) &= \text{sqrt}(2*\text{demand}(i)\*\text{ordcost}(i)/\text{holdcost}(i)); \\
\text{t}(i) &= \min(p(i), q(i)/r(i), \log(s(i))); \\
\text{euclidean}(i,j) &= \text{qrt}(\text{sqr}(\text{xi}(i) - \text{xi}(j) + \text{sqr}(\text{x2}(i) - \text{x2}(j)))); \\
\text{present}(j) &= \text{future}(j)*\exp(-\text{interest}\*\text{time}(j));
\end{align*}
\]

The summation and product operators to be introduced later can also be used in direct assignments.

### 4.11.5 Variables

The decision variables (or endogenous variables) of a GAMS-expressed model must be declared with a `Variables` statement. Each variable is given a name, a domain if appropriate, and (optionally) text. The transportation model contains the following example of a `Variables` statement.

Variables

\[
\begin{align*}
\text{x}(i,j) & \quad \text{shipment quantities in cases} \\
\text{z} & \quad \text{total transportation costs in thousands of dollars}
\end{align*}
\]

This statement results in the declaration of a shipment variable for each \((i,j)\) pair. (You will see in chapter Equations, how GAMS can handle the typical real-world situation in which only a subset of the \((i,j)\) pairs is allowable for shipment.)

The \( z \) variable is declared without a domain because it is a scalar quantity. Every GAMS optimization model must contain one such variable to serve as the quantity to be minimized or maximized.

Once declared, every variable must be assigned a type. A selection of permissible types are given in table Table 3. For a full list, see section Variable Types.

**Table 3:** Permissible variable types
<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Allowed Range of Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>free (default)</td>
<td>$-\infty$ to $+\infty$</td>
</tr>
<tr>
<td>positive</td>
<td>0 to $+\infty$</td>
</tr>
<tr>
<td>negative</td>
<td>$-\infty$ to 0</td>
</tr>
<tr>
<td>binary</td>
<td>0 or 1</td>
</tr>
<tr>
<td>integer</td>
<td>0, 1, ..., 100 (default)</td>
</tr>
</tbody>
</table>

The variable that serves as the quantity to be optimized must be a scalar and must be of the free type. In our transportation example, $z$ is kept free by default, but $x(i,j)$ is constrained to non-negativity by the following statement.

Positive variable $x$ ;

Note that the domain of $x$ should not be repeated in the type assignment. All entries in the domain automatically have the same variable type.

Section The .lo, .l, .up, .m Database describes how to assign lower bounds, upper bounds, and initial values to variables.

4.11.6 Equations

The power of algebraic modeling languages like GAMS is most apparent in the creation of the equations and inequalities that comprise the model under construction. This is because whenever a group of equations or inequalities has the same algebraic structure, all the members of the group are created simultaneously, not individually.

4.11.6.1 Equation Declaration

Equations must be declared and defined in separate statements. The format of the declaration is the same as for other GAMS entities. First comes the keyword, Equations in this case, followed by the name, domain and text of one or more groups of equations or inequalities being declared. Our transportation model contains the following equation declaration:

Equations
cost define objective function
supply(i) observe supply limit at plant i
demand(j) satisfy demand at market j ;

Keep in mind that the word Equation has a broad meaning in GAMS. It encompasses both equality and inequality relationships, and a GAMS equation with a single name can refer to one or several of these relationships. For example, cost has no domain so it is a single equation, but supply refers to a set of inequalities defined over the domain $i$. 

4.11.6.2 GAMS Summation (and Product) Notation

Before going into equation definition we describe the summation notation in GAMS. Remember that
GAMS is designed for standard keyboards and line-by-line input readers, so it is not possible (nor would
it be convenient for the user) to employ the standard mathematical notation for summations.

The summation notation in GAMS can be used for simple and complex expressions. The format is
based on the idea of always thinking of a summation as an operator with two arguments: \( \text{Sum(}
\text{index of summation, summand}) \) A comma separates the two arguments, and if the first argument
requires a comma then it should be in parentheses. The second argument can be any mathematical expression
including another summation.

As a simple example, the transportation problem contains the expression

\[ \text{Sum}(j, x(i,j)) \]

that is equivalent to \( \sum_j x_{ij} \).

A slightly more complex summation is used in the following example:

\[ \text{Sum}((i,j), c(i,j)*x(i,j)) \]

that is equivalent to \( \sum_i \sum_j c_{ij}x_{ij} \).

The last expression could also have been written as a nested summation as follows:

\[ \text{Sum}(i, \text{Sum}(j, c(i,j)*x(i,j))) \]

In section Conditional Indexed Operations, we describe how to use the dollar operator to impose restric-
tions on the summation operator so that only the elements of \( i \) and \( j \) that satisfy specified conditions are
included in the summation.

Products are defined in GAMS using exactly the same format as summations, replacing \( \text{Sum} \) by \( \text{Prod} \). For
example,

\[ \text{prod}(j, x(i, j)) \]

is equivalent to: \( \Pi_j x_{ij} \).

Summation and product operators may be used in direct assignment statements for parameters. For
example,

\[ \text{scalar totsupply total supply over all plants;} \]
\[ \text{totsupply} = \text{sum}(i, a(i)); \]
4.11.6.3 Equation Definition

Equation definitions are the most complex statements in GAMS in terms of their variety. The components of an equation definition are, in order:

1. The name of the equation being defined
2. The domain
3. Domain restriction condition (optional)
4. The symbol ' .. '
5. Left-hand side expression
6. Relational operator: =l=, =e=, =g= or others. For a complete list, see Table Equation Types.
7. Right-hand side expression

The transportation example contains three of these statements.

```
cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;
supply(i) .. sum(j, x(i,j)) =l= a(i) ;
demand(j) .. sum(i, x(i,j)) =g= b(j) ;
```

Here are some points to remember.

- The power to create multiple equations with a single GAMS statement is controlled by the domain. For example, the definition for the demand constraint will result in the creation of one constraint for each element of the domain j, as shown in the following excerpt from the GAMS output.

```
demand(new-york)..x(seattle,new-york) + x(san-diego,new-york)=g=325 ;
```  
```
demand(chicago).. x(seattle,chicago) + x(san-diego,chicago) =g=300 ;
```  
```
demand(topeka).x(seattle,topeka) + x(san-diego,topeka) =g=275 ;
```

- The key idea here is that the definition of the demand constraints is exactly the same whether we are solving the toy-sized example above or a 20,000-node real-world problem. In either case, the user enters just one generic equation algebraically, and GAMS creates the specific equations that are appropriate for the model instance at hand. (Using some other optimization packages, something like the extract above would be part of the input, not the output.)

- In many real-world problems, some of the members of an equation domain need to be omitted or differentiated from the pattern of the others because of an exception of some kind. GAMS can readily accommodate this loss of structure using a powerful feature known as the dollar or 'such-that' operator, which is not illustrated here. The domain restriction feature can be absolutely essential for keeping the size of a real-world model within the range of solvability.

- The relational operators have the following meanings:
  
  - =l=  less than or equal to
  - =g=  greater than or equal to
  - =e=  equal to

- It is important to understand the difference between the symbols '=' and '=e='. The '=' symbol is used only in direct assignments, and the '=e=' symbol is used only in equation definitions. These two contexts are very different. A direct assignment gives a desired value to a parameter before the solver is called. An equation definition also describes a desired relationship, but it cannot be satisfied until after the solver is called. It follows that equation definitions must contain variables and direct assignments must not.
4.11 A GAMS Tutorial by Richard E. Rosenthal

- Variables can appear on the left or right-hand side of an equation or both. The same variable can appear in an equation more than once. The GAMS processor will automatically convert the equation to its equivalent standard form (variables on the left, no duplicate appearances) before calling the solver.

- An equation definition may appear anywhere in the GAMS input, provided the equation and all variables and parameters to which it refers were previously declared. (Note that it is permissible for a parameter appearing in the equation to be assigned or reassigned a value after the definition. This is useful when doing multiple model runs with one GAMS input.) The equations need not be defined in the same order in which they were declared.

4.11.7 Objective Function

This is just a reminder that GAMS has no explicit entity called the objective function. To specify the function to be optimized, you must create a variable, which is free (unconstrained in sign) and scalar-valued (has no domain) and which appears in an equation definition that equates it to the objective function.

4.11.8 Model and Solve Statements

The word model has a very precise meaning in GAMS. It is simply a collection of equations. Like other GAMS entities, it must be given a name in a declaration. The format of the declaration is the keyword model followed by the name of the model, followed by a list of equation names enclosed in slashes. If all previously defined equations are to be included, you can enter \texttt{/all/} in place of the explicit list. In our example, there is one model statement:

\begin{verbatim}
model transport /all/ ;
\end{verbatim}

This statement may seem superfluous, but it is useful to advanced users who may create several models in one GAMS run. If we were to use the explicit list rather than the shortcut \texttt{/all/}, the statement would be written as

\begin{verbatim}
model transport / cost, supply, demand / ;
\end{verbatim}

The domains are omitted from the list since they are not part of the equation name. The list option is used when only a subset of the existing equations comprises a specific model (or sub-model) being generated.

Once a model has been declared and assigned equations, we are ready to call the solver. This is done with a \texttt{solve} statement, which in our example is written as

\begin{verbatim}
solve transport using lp minimizing z ;
\end{verbatim}

The format of the solve statement is as follows:

1. The key word solve
2. The name of the model to be solved
3. The key word using
4. An available solution procedure. A complete list is given below. For further details, see section Classification of Models.
<table>
<thead>
<tr>
<th>Solution</th>

</tbody>
</table>

5. The keyword 'minimizing' or 'maximizing'

6. The name of the variable to be optimized

### 4.11.9 Display Statements

The `solve` statement will cause several things to happen when executed. The specific instance of interest of the model will be generated, the appropriate data structures for inputting this problem to the solver will be created, the solver will be invoked, and the output from the solver will be printed to a file. To get the optimal values of the primal and/or dual variables, we can look at the solver output, or, if we wish, we can request a display of these results from GAMS. Our example contains the following statement:

```gams
display x.l, x.m ;
```

that calls for a printout of the final levels, `x.l`, and marginal (or reduced costs), `x.m`, of the shipment variables, `x(i,j)`. GAMS will automatically format this printout in to dimensional tables with appropriate headings.

### 4.11.10 The .lo, .l, .up, .m Database

GAMS was designed with a small database system in which records are maintained for the variables and equations. The most important fields in each record are:

- `.lo` lower bound
- `.l` level or primal value
- `.up` upper bound
- `.m` marginal or dual value

The format for referencing these quantities is the variable or equation's name followed by the field's name, followed (if necessary) by the domain (or an element of the domain).

GAMS allows the user complete read-and write-access to the database. This may not seem remarkable to you now, but it can become a greatly appreciated feature in advanced use. Some examples of use of the database follow.
4.11.10.1 Assignment of Variable Bounds and/or Initial Values

The lower and upper bounds of a variable are set automatically according to the variable's type (free, positive, negative, binary, or integer), but these bounds can be overwritten by the GAMS user. Some examples follow.

\[
\begin{align*}
x.\text{up}(i,j) &= \text{capacity}(i,j) ; \\
x.\text{lo}(i,j) &= 10.0 ; \\
x.\text{up}(\text{seattle},\text{new-york}) &= 1.2*\text{capacity}(\text{seattle},\text{new-york}) ;
\end{align*}
\]

It is assumed in the first and third examples that \( \text{capacity}(i,j) \) is a parameter that was previously declared and assigned values. These statements must appear after the variable declaration and before the \texttt{Solve} statement. All the mathematical expressions available for direct assignments are usable on the right-hand side.

In nonlinear programming it is very important for the modeler to help the solver by specifying as narrow a range as possible between lower and upper bound. It is also very helpful to specify an initial solution from which the solver can start searching for the optimum. For example, in a constrained inventory model, the variables are \( \text{quantity}(i) \), and it is known that the optimal solution to the unconstrained version of the problem is a parameter called \( \text{eoq}(i) \). As a guess for the optimum of the constrained problem we enter

\[
\text{quantity.l}(i) = 0.5*\text{eoq}(i) ;
\]

(The default initial level is zero unless zero is not within the bounded range, in which case it is the bound closest to zero.)

It is important to understand that the \texttt{.lo} and \texttt{.up} fields are entirely under the control of the GAMS user. The \texttt{.l} and \texttt{.m} fields, in contrast, can be initialized by the user but are then controlled by the solver.

4.11.10.2 Transformation and Display of Optimal Values

(This section may be skipped on first reading if desired.)

After the optimizer is called via the \texttt{solve} statement, the values it computes for the primal and dual variables are placed in the database in the \texttt{.l} and \texttt{.m} fields. We can then read these results and transform and display them with GAMS statements.

For example, in the transportation problem, suppose we wish to know the percentage of each market's demand that is filled by each plant. After the solve statement, we would enter

\[
\begin{align*}
\text{parameter pctx(i,j) perc of market j's demand filled by plant i;} \\
pctx(i,j) &= 100.0*x.l(i,j)/b(j) ; \\
\text{display pctx ;}
\end{align*}
\]

Appending these commands to the original transportation problem input results in the following output:

\[
\begin{array}{llll}
pctx & \text{percent of market j's demand filled by plant I} \\
\text{new-york} & \text{chicago} & \text{topeka} \\
\text{seattle} & 15.385 & 100.000 \\
\text{san-diego} & 84.615 & 100.000
\end{array}
\]
For an example involving marginal, we briefly consider the *ratio constraints* that commonly appear in blending and refining problems. These linear programming models are concerned with determining the optimal amount of each of several available raw materials to put into each of several desired finished products. Let \( y(i,j) \) be the variable for the number of tons of raw material \( i \) put into finished product \( j \). Suppose the *ratio constraint* is that no product can consist of more than 25 percent of one ingredient, that is,

\[
y(i,j)/q(j) = l= 0.25 ;
\]

for all \( i, j \). To keep the model linear, the constraint is written as

\[
\text{ratio}(i,j) .. y(i,j) - 0.25*q(j) = l= 0.0 ;
\]

rather than explicitly as a ratio.

The problem here is that \( \text{ratio}.m(i,j) \), the marginal value associated with the linear form of the constraint, has no intrinsic meaning. At optimality, it tells us by at most how much we can benefit from relaxing the linear constraint to

\[
y(i,j) - 0.25*q(j) = l= 1.0 ;
\]

Unfortunately, this relaxed constraint has no realistic significance. The constraint we are interested in relaxing (or tightening) is the nonlinear form of the ratio constraint. For example, we would like to know the marginal benefit arising from changing the ratio constraint to

\[
y(i,j)/q(j) = l= 0.26 ;
\]

We can in fact obtain the desired marginals by entering the following transformation on the undesired marginals:

```plaintext
parameter amr(i,j) appropriate marginal for ratio constraint ;
amr(i,j) = ratio.m(i,j)*0.01*q.l(j) ;
display amr ;
```

Notice that the assignment statement for \( \text{amr} \) accesses both \( .m \) and \( .l \) records from the database. The idea behind the transformation is to notice that

\[
y(i,j)/q(j) = l= 0.26 ;
\]

is equivalent to

\[
y(i,j) - 0.25*q(j) = l= 0.01*q(j) ;
\]
4.11.11 GAMS Output

The default output of a GAMS run is extensive and informative. For a complete discussion, see chapter GAMS Output. This tutorial discusses output partially as follows:

- Echo Print
- Reference Maps
- Status Reports
- Error Messages
- Model Statistics
- Solution Reports

A great deal of unnecessary anxiety has been caused by textbooks and users' manuals that give the reader the false impression that flawless use of advanced software should be easy for anyone with a positive pulse rate. GAMS is designed with the understanding that even the most experienced users will make errors. GAMS attempts to catch the errors as soon as possible and to minimize their consequences.

4.11.11.1 Echo Prints

Whether or not errors prevent your optimization problem from being solved, the first section of output from a GAMS run is an echo, or copy, of your input file. For the sake of future reference, GAMS puts line numbers on the left-hand side of the echo. For our transportation example, which luckily contained no errors, the echo print is as follows:

```plaintext
2 Sets
3    i   canning plants       / seattle, san-diego /
4    j   markets             / new-york, chicago, topeka /
5
6 Parameters
7
8    a(i)  capacity of plant i in cases
9        /  seattle  350
10       san-diego  600 /
11
12    b(j)  demand at market j in cases
13        /  new-york  325
14       chicago  300
15       topeka   275 /
16
17 Table d(i,j)  distance in thousands of miles
18    new-york  chicago  topeka
19    seattle  2.5    1.7    1.8
20    san-diego  2.5    1.8    1.4 ;
21
22 Scalar f  freight in dollars per case per thousand miles /90/ ;
23
24 Parameter c(i,j)  transport cost in thousands of dollars per case ;
25
26    c(i,j) = f * d(i,j) / 1000 ;
27
28 Variables
```
29 \( x(i,j) \) shipment quantities in cases
30 \( z \) total transportation costs in thousands of dollars ;
31
32 Positive Variable \( x \) ;
33
34 Equations
35 \( \text{cost} \) define objective function
36 \( \text{supply}(i) \) observe supply limit at plant \( i \)
37 \( \text{demand}(j) \) satisfy demand at market \( j \) ;
38
39 \( \text{cost} .. \quad z =e= \sum(i,j), c(i,j)\times x(i,j) ; \)
40
41 \( \text{supply}(i) .. \quad \sum(j, x(i,j)) =l= a(i) ; \)
42
43 \( \text{demand}(j) .. \quad \sum(i, x(i,j)) =g= b(j) ; \)
44
45 Model transport /all/ ;
46
47 Solve transport using lp minimizing \( z \) ;
48
49 Display \( x.l, \) \( x.m \) ;
50

The reason this echo print starts with line number 2 rather than line number 1 is because the input file contains a dollar-print-control statement. This type of instruction controls the output printing, but since it has nothing to do with defining the optimization model, it is omitted from the echo. The dollar print controls must start in column 1.

\$title a transportation model

The \$title statement causes the subsequent text to be printed at the top of each page of output. Other available instructions are given in chapter Dollar Control Options.

4.11.11.2 Error Messages

When the GAMS compiler encounters an error in the input file, it inserts a coded error message inside the echo print on the line immediately following the scene of the offense. These messages always start with **** and contain a '$' directly below the point at which the compiler thinks the error occurred. The $ is followed by a numerical error code, which is explained after the echo print. Several examples follow.

Example 1: Entering the statement

\[ \text{set \ q quarterly time periods / spring, sos1, fall, wtr / ;} \]

results in the echo

\[ \text{1 \ set \ q quarterly time periods / spring, sos1, fall, wtr / ; } \quad **** \]

In this case, the GAMS compiler indicates that something is wrong with the set element sum. At the bottom of the echo print, we see the interpretation of error code 160:

Error Message
160 Unique element expected....
The problem is that sos1 is a reserved word, which cannot be used as identifiers in general. The complete list of reserved words is shown in this chapter. Thus our set element must have a unique name like 'summer'. This is a common beginner's error.

**Example 2:** Another common error is the omission of a semicolon preceding a direct assignment or equation definition. In our transportation example, suppose we omit the semicolon prior to the assignment of \( c(i,j) \), as follows.

```plaintext
Parameter c(i,j) transport cost in 1000s of dollars per case
c(i,j) = f * d(i,j) / 1000 ;
```

Here is the resulting output.

```
16 Parameter c(i,j) transport cost in 1000s of dollars per case
17 c(i,j) = f * d(i,j)/1000
**** $97 $195,96,409
Error Message
96 Blank needed between identifier and text
(-or- illegal character in identifier)
(-or- check for missing ';' on previous line)
97 Explanatory text can not start with '$', '=', or '..'
(-or- check for missing ';' on previous line)
195 Symbol redefined with a different type
409 Unrecognizable item - skip to find a new statement
looking for a ';' or a key word to get started again
```

It is not uncommon for one little offense like our missing semicolon to generate five intimidating error messages. The lesson here is: concentrate on fixing the first error and ignore the other! The first error detected (in line 17), code 97, indicate that GAMS thinks the symbols in line 17 are a continuation of the documentary text at the end of line 16 rather than a direct assignment as we intended. The error message also appropriately advises us to check the preceding line for a missing semicolon.

Unfortunately, you cannot always expect error messages to be so accurate in their advice. The compiler cannot read your mind. It will at times fail to comprehend your intentions, so learn to detect the causes of errors by picking up the clues that abound in the GAMS output. For example, the missing semicolon could have been detected by looking up the c entry in the cross-reference list (to be explained in the next section) and noticing that it was never assigned.

<table>
<thead>
<tr>
<th>SYMBOL</th>
<th>TYPE</th>
<th>REFERENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>PARAM</td>
<td>declared</td>
</tr>
</tbody>
</table>

**Example 3:** Many errors are caused merely by spelling mistakes and are caught before they can be damaging. For example, with 'Seattle' spelled in the table differently from the way it was introduced in the set declaration, we get the following error message.

```
4 sets
5   i canning plants /seattle, san-diego /
6   j markets /new-york, chicago, topeka /
7
8 table d(i,j) distance in thousand of miles
9   new-york  chicago  topeka
10   seattle  2.5    1.7    1.8
11   san-diego 2.5    1.8    1.4
**** $170
Error Message
170 Domain violation for element
```
Example 4: Similarly, if we mistakenly enter dem(j) instead of b(j) as the right-hand side of the demand constraint, the result is

45  demand(j) ..  sum(i, x(i,j) ) =g=  dem(j) ;

****
   Error Message
  140  Unknown symbol

Example 5: The next example is a mathematical error, which is sometimes committed by novice modelers and which GAMS is adept at catching. The following is mathematically inconsistent and, hence, is not an interpretable statement.

For all $i$, $\sum_{j} x_{ij} = 100$

There are two errors in this equation, both having to do with the control of indices. Index $i$ is over-controlled and index $j$ is under-controlled.

You should see that index $i$ is getting conflicting orders. By appearing in the quantifier 'for all $i$', it is supposed to remain fixed for each instance of the equation. Yet, by appearing as an index of summation, it is supposed to vary. It can't do both. On the other hand, index $j$ is not controlled in any way, so we have no way of knowing which of its possible values to use.

If we enter this meaningless equation into GAMS, both errors are correctly diagnosed.

   meaningless(i) ..  sum(i, x(i,j)) =e=  100 ;

****
   Error Messages
  125  Set is under control already [This refers to set $i$.]
  149  Uncontrolled set entered as constant [This refers to set $j$.]

More information about error reporting is given in section Error Reporting. Comprehensive error detection and well-designed error messages are a big help in getting models implemented quickly and correctly.

4.11.11.3 Reference Maps

The next section of output, which is the last if errors have been detected, is a pair of reference maps that contain summaries and analyses of the input file for the purposes of debugging and documentation.

The first reference map is a cross-reference map such as one finds in most modern compilers. It is an alphabetical, cross-referenced list of all the entities (sets, parameters, variables, and equations) of the model. The list shows the type of each entity and a coded reference for each appearance of the entity in the input. The cross-reference map for our transportation example is as follows (we do not display all tables). To turn the cross-reference map on, please add the line

$onSymXRef

at the beginning of your model right after the $title statement.
For example, the cross-reference list tells us that the symbol \( a \) is a parameter that was declared in line 9, defined (assigned value) in line 10, and referenced in line 42. The symbol \( i \) has a more complicated entry in the cross-reference list. It is shown to be a set that was declared and defined in line 4. It is referenced once in lines 9, 18, 25, 27, 30, 37, 44 and referenced twice in lines 40 and 44. Set \( i \) is also used as a controlling index in a summation, equation definition or direct parameter assignment in lines 27, 40, 42 and 44.

For the GAMS novice, the detailed analysis of the cross-reference list may not be important. Perhaps the most likely benefit he or she will get from the reference maps will be the discovery of an unwanted entity that mistakenly entered the model owing to a punctuation or syntax error.

The second part of the reference map is a list of model entities grouped by type and listed with their associated documentary text. For example, this list is as follows.

**SETS**

\( i \)   canning plants  
\( j \)   markets

**PARAMETERS**

\( a \)   capacity of plant \( i \) in cases  
\( b \)   demand at market \( j \) in cases  
\( c \)   transport cost in thousands of dollars per case  
\( d \)   distance in thousands of miles  
\( f \)   freight in dollars per case per thousand miles

**VARIABLES**

\( x \)   shipment quantities in cases  
\( z \)   total transportation costs in thousands of dollars

**EQUATIONS**

\( \text{cost} \)   define objective function  
\( \text{demand} \)   satisfy demand at market \( j \)  
\( \text{supply} \)   observe supply limit at plant \( i \)

**MODELS**

\( \text{transport} \)
4.11.11.4 Equation Listings

Once you succeed in building an input file devoid of compilation errors, GAMS is able to generate a model. The question remains, and only you can answer it, does GAMS generate the model you intended?

The equation listing is probably the best device for studying this extremely important question. A product of the solve command, the equation listing shows the specific instance of the model that is created when the current values of the sets and parameters are plugged into the general algebraic form of the model. For example, the generic demand constraint given in the input file for the transportation model is

\[
\text{demand}(j) \ldots \sum(i, x(i,j)) \geq b(j) ;
\]

while the equation listing of specific constraints is

\[
\begin{align*}
\text{--------demand} & \quad =g= \quad \text{satisfy demand at market j} \\
\text{demand(new-york)} & \quad x(\text{seattle, new-york}) + x(\text{san-diego, new-york}) \geq 325 ; \\
\text{demand(chicago)} & \quad x(\text{seattle, chicago}) + x(\text{san-diego, chicago}) \geq 300 ; \\
\text{demand(topeka)} & \quad x(\text{seattle, topeka}) + x(\text{san-diego, topeka}) \geq 275 ;
\end{align*}
\]

The default output is a maximum of three specific equations for each generic equation. To change the default, insert an input statement prior to the solve statement:

\[\text{option limrow = r ;}\]

where \(r\) is the desired number.

The default output also contains a section called the column listing, analogous to the equation listing, which shows the coefficients of three specific variables for each generic variable. This listing would be particularly useful for verifying a GAMS model that was previously implemented in MPS format. To change the default number of specific column printouts per generic variable, the above command can be extended:

\[\text{option limrow = r, limcol = c ;}\]

where \(c\) is the desired number of columns. (Setting \text{limrow} and \text{limcol} to 0 is a good way to reduce the size of your lst file after your model has been debugged.) In nonlinear models, the GAMS equation listing shows first-order Taylor approximations of the nonlinear equations. The approximations are taken at the starting values of the variables.

4.11.11.5 Model Statistics

The last section of output that GAMS produces before invoking the solver is a group of statistics about the model's size, as shown below for the transportation example.

\begin{center}
\text{MODEL STATISTICS}
\end{center}

\begin{tabular}{|l|c|c|}
\hline
\text{BLOCKS OF EQUATIONS} & 3 & \text{SINGLE EQUATIONS} & 6 \\
\text{BLOCKS OF VARIABLES} & 2 & \text{SINGLE VARIABLES} & 7 \\
\text{NON ZERO ELEMENTS} & 19 & & \\
\hline
\end{tabular}

The \text{BLOCK} counts refer to the number of generic equations and variables. The \text{SINGLE} counts refer to individual rows and columns in the specific model instance being generated. For nonlinear models, some other statistics are given to describe the degree of non-linearity in the problem.
### 4.11.11.6 Status Reports

After the solver executes, GAMS prints out a brief *Solve Summary* whose two most important entries are SOLVER STATUS and the MODEL STATUS. For our transportation problem the solve summary is as follows:

```
SOLVE SUMMARY
MODEL TRANSPORT OBJECTIVE z
TYPE LP DIRECTION MINIMIZE
SOLVER CPLEX FROM LINE 49

**** SOLVER STATUS 1 Normal Completion
**** MODEL STATUS 1 Optimal
**** OBJECTIVE VALUE 153.6750
```

The status reports are preceded by the same `****` string as an error message, so you should probably develop the habit of searching for all occurrences of this string whenever you look at an output file for the first time. The desired solver status is 1 NORMAL COMPLETION, but there are other possibilities, documented in section The Solve Summary, which relate to various types of errors and mishaps.

There are eleven possible model statuses, including the usual linear programming termination states (1 Optimal, 3 Unbounded, 4 Infeasible), and others relating to nonlinear and integer programming. In nonlinear programming, the status to look for is 2 Locally Optimal. The most the software can guarantee for nonlinear programming is a local optimum. The user is responsible for analyzing the convexity of the problem to determine whether local optimality is sufficient for global optimality. In integer programming, the status to look for is 8 Integer Solution. This means that a feasible integer solution has been found. More detail follows as to whether the solution meets the relative and absolute optimality tolerances that the user specifies.

### 4.11.11.7 Solution Reports

If the solver status and model status are acceptable, then you will be interested in examining the results of the optimization. The results are first presented in as standard mathematical programming output format, with the added feature that rows and columns are grouped and labeled according to names that are appropriate for the specific model just solved. In this format, there is a line of printout for each row and column giving the lower limit, level, upper limit, and marginal. Generic equation block and the column output group the row output by generic variable block. Set element names are embedded in the output for easy reading. In the transportation example, the solver outputs for `supply(i)`, `demand(j)`, and `x(i,j)` are as follows:

```
---- EQU supply observe supply limit at plant i
    LOWER  LEVEL  UPPER  MARGINAL
seattle  -INF  350.000  350.000  EPS
san-diego -INF  550.000  600.000  .

---- EQU demand satisfy demand at market j
    LOWER  LEVEL  UPPER  MARGINAL
```
The single dots '.' in the output represent zeroes. The entry EPS, which stands for epsilon, mean very small but nonzero. In this case, EPS indicates degeneracy. (The slack variable for the Seattle supply constraint is in the basis at zero level. The marginal is marked with EPS rather than zero to facilitate restarting the optimizer from the old basis.)

If the solvers results contain either infeasibilities or marginal costs of the wrong sign, then the offending entries are marked with INFES or NOPT, respectively. If the problem terminates unbounded, then the rows and columns corresponding to extreme rays are marked UNBND.

At the end of the solvers solution report is a very important report summary, which gives a tally of the total number of non-optimal, infeasible, and unbounded rows and columns. For our example, the report summary shows all zero tallies as desired.

**** REPORT SUMMARY : 0 NONOPT 0 INFEASIBLE 0 UNBOUNDED

After the solver's report is written, control is returned from the solver back to GAMS. All the levels and marginals obtained by the solver are entered into the GAMS database in the .l and .m fields. These values can then be transformed and displayed in any desired report. As noted earlier, the user merely lists the quantities to be displayed, and GAMS automatically formats and labels an appropriate array. For example, the input statement.

display x.l, x.m ;

results in the following output.

---- 50 VARIABLE x.L shipment quantities in cases

new-york  325.000  325.000  +INF  0.225
chicago   300.000  300.000  +INF  0.153
topeka    275.000  275.000  +INF  0.126

---- VAR x shipment quantities in cases

 LOWER   LEVEL   UPPER   MARGINAL

seattle .new-york  .  50.000  +INF  .
seattle .chicago   .  300.000 +INF  .
seattle .topeka    .   .  +INF  0.036
san-diego .new-york .  275.000 +INF  .
san-diego .chicago  .   .  +INF  0.009
san-diego .topeka  .  275.000  +INF  .

As seen in reference maps, equation listings, solution reports, and optional displays, GAMS saves the documentary text and 'parrots' it back throughout the output to help keep the model well documented.
4.11.12 Summary

This tutorial has demonstrated several of the design features of GAMS that enable you to build practical optimization models quickly and effectively. The following discussion summarizes the advantages of using an algebraic modeling language such as GAMS versus a matrix generator or conversational solver.

- By using an algebra-based notation, you can describe an optimization model to a computer nearly as easily as you can describe it to another mathematically trained person.

- Because an algebraic description of a problem has generality, most of the statements in a GAMS model are reusable when new instances of the same or related problems arise. This is especially important in environments where models are constantly changing.

- You save time and reduce generation errors by creating whole sets of closely related constraints in one statement.

- You can save time and reduce input errors by providing formulae for calculating the data rather than entering them explicitly.

- The model is self-documenting. Since the tasks of model development and model documentation can be done simultaneously, the modeler is much more likely to be conscientious about keeping the documentation accurate and up to date.

- The output of GAMS is easy to read and use. The solution report from the solver is automatically reformatted so that related equations and variables are grouped together and appropriately labeled. Also, the display command allows you to modify and tabulate results very easily.

- If you are teaching or learning modeling, you can benefit from the insistence of the GAMS compiler that every equation be mathematically consistent. Even if you are an experienced modeler, the hundreds of ways in which errors are detected should greatly reduce development time.

- By using the dollar operator and other advanced features not covered in this tutorial, one can efficiently implement large-scale models. Specific applications of the dollar operator include:

  1. It can enforce logical restrictions on the allowable combinations of indices for the variables and equations to be included in the model. You can thereby screen out unnecessary rows and columns and keep the size of the problem within the range of solvability.

  2. It can be used to build complex summations and products, which can then be used in equations or customized reports.

  3. It can be used for issuing warning messages or for terminating prematurely conditioned upon context-specific data edits.

4.12 Quick Start Tutorial

GAMS (the General Algebraic Modeling System) is a high-level modeling system for mathematical programming problems. This tutorial is aimed at modelers who are new to GAMS and are looking for a quick introduction to the core features of GAMS. Note that the text contains many links to the GAMS User's Guide for further exploration. Observe that this tutorial is adapted from the Quick Start Tutorial from Bruce McCarl. Another introductory text is the tutorial A GAMS Tutorial by Richard E. Rosenthal.
4.12.1 Three Basic Models

Most modelers who are interested in GAMS have one (or more) of the following backgrounds:

- They wish to solve constrained optimization problems with objective functions.
- They are looking for a system to solve general equilibrium problems that arise in various areas of economics.
- They wish to solve nonlinear systems of equations that arise in engineering.

GAMS is well equipped to model and solve all three types of problems. We will start by introducing examples for all three areas and the discussions that will follow will refer to these three basic examples.

4.12.1.1 First Example: Solving a Linear Programming Problem (LP)

The simplest constrained optimization problem is an LP. Assume we wish to solve the following LP that represents a simple farm model where profit is maximized:

\[
\begin{align*}
\text{max} & \quad 109X_{\text{corn}} + 90X_{\text{wheat}} + 115X_{\text{cotton}} \\
\text{s.t.} & \quad X_{\text{corn}} + X_{\text{wheat}} + X_{\text{cotton}} \leq 100 \quad \text{(land)} \\
& \quad 6X_{\text{corn}} + 4X_{\text{wheat}} + 8X_{\text{cotton}} \leq 500 \quad \text{(labor)} \\
& \quad X_{\text{corn}} \geq 0 \quad \text{(nonnegativity)} \\
& \quad X_{\text{wheat}} \geq 0 \quad \text{(nonnegativity)} \\
& \quad X_{\text{cotton}} \geq 0 \quad \text{(nonnegativity)}
\end{align*}
\]

Note that there are three decision variables: \(X_{\text{corn}}\) denotes the land assigned to growing corn, \(X_{\text{wheat}}\) is the land assigned to growing wheat and \(X_{\text{cotton}}\) represents the land where cotton is grown. In the first line the total profit is expressed as a function of the land allotted to the three crops, the multipliers represent the expected profit per acre depending of the type of crop. The first inequality imposes a limit on the available land, the second inequality imposes a limit on the available labor and the final three lines restrict the decision variables to nonnegative values.

This problem may be expressed in GAMS as follows:

```gams
Positive Variables Xcorn, Xwheat, Xcotton;
Variables Z;
Equations obj, land, labor;
obj.. Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
land.. Xcorn + Xwheat + Xcotton =l= 100;
labor.. 6 * Xcorn + 4 * Xwheat + 8 * Xcotton =l= 500;
Model farmproblem / obj, land, labor /;
solve farmproblem using LP maximizing Z;
```

We will analyze this formulation and discuss every part of it after introducing the other two basic examples.
4.12 Quick Start Tutorial

4.12.1.2 Second Example: Solving for an Economic Equilibrium

The simplest general equilibrium model is the single good, single market problem. Assume we wish to solve the following equilibrium problem:

Demand Price: \[ P \geq P_d = 6 - 0.3Q_d \]

Supply Price: \[ P \leq P_s = 1 + 0.2Q_s \]

Quantity Equilibrium: \[ Q_s \geq Q_d \]

Nonnegativity: \[ P \geq 0 \]
\[ Q_s \geq 0 \]
\[ Q_d \geq 0 \]

Here \( P \) is the market clearing price, \( P_d \) is the demand curve, \( Q_d \) denotes the quantity demanded, \( P_s \) the supply curve and \( Q_s \) the quantity supplied. Note that this is a problem in 3 equations and 3 variables. The variables are \( P, Q_d, \) and \( Q_s \). Note that \( P_d \) and \( P_s \) are not variables, since they can be computed from the equality relations.

Usually all equality constraints are used for such a set up. However, we will use a more general setup, because it relaxes some assumptions and more accurately depicts a model ready to be implemented in GAMS. In particular, we permit the case where the supply curve price intercept may be above the demand curve price intercept and thus the market may clear with a nonzero price but a zero quantity. In addition, we allow the market price to be above the demand curve price and below the supply curve price. We also impose some additional conditions based on Walras’ Law to ensure a proper solution in such cases.

\[ Q_d(P - P_d) = 0 \text{ or } Q_d(P_d - (6 - 0.3Q_d)) = 0 \]
\[ Q_s(P - P_s) = 0 \text{ or } Q_s(P_s - (1 + 0.2Q_s)) = 0 \]
\[ P(Q_s - Q_d) = 0 \]

Here the quantity demanded is nonzero only if the market clearing price equals the demand curve price, the quantity supplied is nonzero only if the market clearing price equals the supply curve price and the market clearing price is only nonzero if \( Q_s = Q_d \).

The simplest GAMS formulation is given below. Note that we needed to rearrange the equation \( \text{Psupply} \) in order to achieve a greater than inequality, thus we accomodated the requirements of the solver PATH.

Positive Variables \( P, Q_d, Q_s \);

Equations \( \text{Pdemand, Psupply, Equilibrium;} \)
\( \text{Pdemand.} \quad P \implies g = 6 - 0.3\text{Qd;} \)
\( \text{Psupply.} \quad (1 + 0.2\text{Qs}) \implies g = P; \)
\( \text{Equilibrium..} \quad Q_s \implies g = Q_d; \)

Model problem / \text{Pdemand.Qd, Psupply.Qs, Equilibrium.P} /;

solve problem using MCP;

We will analyze this formulation and discuss every component of it after introducing the third example.
4.12.1.3 Third Example: Solving a Nonlinear Equation System

Engineers often wish to solve a nonlinear system of equations. Examples include chemical equilibria or problems in the context of oil refining. Many other such problems of this type exist. The problem that follows is adapted from the paper Wall, T W, Greening, D, and Woolsey , R E D, “Solving Complex Chemical Equilibria Using a Geometric-Programming Based Technique” Operations Research 34, 3 (1987).

\[ ba \ast so4 = 1 \]
\[ baoh / ba / oh = 4.8 \]
\[ hso4 / so4 / h = 0.98 \]
\[ h \ast oh = 1 \]
\[ ba + 1e-7*baoh = so4 + 1e-5*hso4 \]
\[ 2 \ast ba + 1e-7*baoh + 1e-2*h = 2 \ast so4 + 1e-5*hso4 + 1e-2*oh \]

Note that this is a nonlinear system of equations with the variables \( ba, so4, baoh, oh, hso4 \) and \( h \). The following formulation in GAMS is from the model [WALL] in the GAMS model library.

Variables \( ba, so4, baoh, oh, hso4, h \);

Equations \( r1, r2, r3, r4, b1, b2 \);

\[ r1.. \quad ba \ast so4 =e= 1 \]
\[ r2.. \quad baoh / ba / oh =e= 4.8 \]
\[ r3.. \quad hso4 / so4 / h =e= 0.98 \]
\[ r4.. \quad h \ast oh =e= 1 \]
\[ b1.. \quad ba + 1e-7*baoh =e= so4 + 1e-5*hso4 \]
\[ b2.. \quad 2 \ast ba + 1e-7*baoh + 1e-2*h =e= 2 \ast so4 + 1e-5*hso4 + 1e-2*oh \]

Model wall / all / ;

ba.l=1; so4.l=1; baoh.l=1; oh.l=1; hso4.l=1; h.l=1;
solve wall using nlp minimizing ba;

4.12.2 Components of the Example Models

Now that we have our three basic models in place, we will analyze them and identify and discuss their components, including variables, equations, model definitions, solve statements and starting points.

4.12.2.1 Variables in the Example Models

Variables in GAMS have to be declared as variables with a variable statement. The variable statements in the examples above are repeated below:

- First example:
4.12 Quick Start Tutorial

Positive Variables  Xcorn, Xwheat, Xcotton;
Variables  Z;

• Second example:
Positive Variables  P, Qd , Qs;

• Third example:
Variables  ba, so4, baoh, oh, hso4, h ;

Note that variable(s) is a keyword in GAMS. Positive is another keyword, it serves as a modifier to the keyword variable and has the effect that the variables that follow may take only nonnegative values. Variables that are declared with the keyword variable without a modifier are unrestricted in sign. For more details on variable declarations and variable types, see sections Variable Declarations and Variable Types respectively.

Observe that GAMS is not case sensitive and allows a line feed to be used instead of a comma. Thus, the following three variable declarations are all valid and have the same effect:

POSITIVE VARIABLES  Xcorn, Xwheat, Xcotton;
Positive Variables  xcorn, xwheat, xcotton;
positive variables  Xcorn Xwheat , Xcotton;

In the GAMS formulation of the first example, we have introduced the variable Z in addition to the three variables that featured in the mathematical formulation. Note that GAMS requires the optimization model

Maximize \( cx \)

to have the following form:

Maximize \( z \)

\[ z = cx \]

Here \( z \) is a variable, also called objective variable. Observe that it is the objective variable that is maximized, not the function \( cx \). The name of the objective variable may be chosen freely by the user, like any other variable name. The objective variable is a free variable, which means that it has no bounds. Hence, it each optimization problem there must always be at least one free variable.

Given the requirement of an objective variable in an optimization problem, we need to declare a new free variable and introduce an equation for it. In our first example we declared \( Z \) as a free variable, then we declared and specified the equation \( \text{obj} \) setting \( Z \) equal to the objective function expression and we instructed the solver to maximize \( Z \). The relevant lines of code from the first example follow:

Variables  Z;
Equation  \( \text{obj} \), \( \text{land} \), \( \text{labor} \);
obj..  \( Z =e= 109 \times Xcorn + 90 \times Xwheat + 115 \times Xcotton; \)
solve farmproblem using LP maximizing Z;

Note
In some optimization problems users do not need to introduce a new variable to serve as an objective variable, but a free variable that already features in the model may be used. For example, in the second example above, \( ba \) is a free variable that is used as objective variable, since the model type NLP requires an objective variable. We will discuss this further below.
4.12.2.2 Equations in the Example Models

Each equation in a model must first be declared with an equation declaration statement and then defined with an equation definition statement. We repeat the respective statement from the three examples below:

- First example:
  
  Equations obj, land, labor;
  
  obj.. Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
  land.. Xcorn + Xwheat + Xcotton =l= 100;
  labor.. 6 * Xcorn + 4 * Xwheat + 8 * Xcotton =l= 500;

- Second example:
  
  Equations Pdemand, Psupply, Equilibrium;
  
  Pdemand.. P =g= 6 - 0.3*Qd;
  Psupply.. ( 1 + 0.2*Qs) =g= P;
  Equilibrium.. Qs =g= Qd;

- Third example:
  
  Equations r1, r2, r3, r4, b1, b2;
  
  r1.. ba * so4 =e= 1 ;
  r2.. baoh / ba / oh =e= 4.8 ;
  r3.. hso4 / so4 / h =e= .98 ;
  r4.. h * oh =e= 1 ;
  b1.. ba + 1e-7*baoh =e= so4 + 1e-5*hso4 ;
  b2.. 2 * ba + 1e-7*baoh + 1e-2*h =e= 2 * so4 + 1e-5*hso4 + 1e-2*oh ;

Note that the equation declaration statement begins with the keyword Equation(s). Its main purpose is to name the equation(s). For further details on equation declarations, see section Declaring Equations.

The algebraic structure of the equation is specified in the equation definition statement, where the name of the equation is followed by two dots .. and the algebra. The relation between the left-hand side and right-hand side is specified by special symbols indicating the equation type. The most common symbols are =e= for equality, =l= for a less than or equal to relation and =g= for a greater than or equal to relation. An overview of all GAMS equation types is given in Table Equation Types. For more information on equation definitions, see sections Defining Equations and Conditional Equations.

4.12.2.3 Model Definitions in the Example Models

Once all structural elements of a model have been defined and specified, a model statement is used to define the model that will be solved. The model statement form the three examples follow:

- First example:
  
  Model farmproblem / obj, land, labor /;

- Second example:
  
  Model problem / Pdemand.Qd, Psupply.Qs, Equilibrium.P /;
• Third example:

Model wall / all / ;

Note that a model statement always starts with the keyword model. It is followed by the name of the model which users may choose freely and a list of the equations that are part of the model. Observe that the list of equations in the first example contains all equations that were declared and defined. However, this need not be the case. It is possible to declare and define an equation and then not use it in a model. For example, users could define several models that contain different subsets of equations. If all equations that were previously declared and defined enter the model, the keyword all may be used as a shortcut, like in the third example.

Attention

Only equations that have been declared may be listed in a model statement. All equations in a model must have been defined before the model can be solved.

Note that equilibrium problems like the second example are solved as Mixed Complementarity Problems (MCPs). MCPs require a special variant of the model statement where not only the equations are listed, but also their complementarity relationships. The complementarity relationship between an equation and its associated variable is marked with a dot ".". Hence, in the second example, the equation demand is perpendicular to the variable Qd, the equation supply is perpendicular to the variable Qs and the equation Equilibrium is perpendicular to the variable P.

In the three model statements above the name of the model was immediately followed by the list of the equations included in the model. Observe that an optional explanatory text may be inserted after the name of the model.

4.12.2.4 Solve Statements in the Example Models

After the model has been defined it remains to be solved, i.e. to find a solution for the variables. The solve statement directs GAMS to use a solver to optimize the model or solve the system of equations. The solve statements of the three examples follow:

• First example:

    solve farmproblem using LP maximizing Z;

• Second example:

    solve problem using MCP;

• Third example:

    solve wall using nlp minimizing ba;

Note that a solve statement always begins with the keyword solve followed by the name of the model, as previously specified with a model statement, the keyword using and the type of the model. We have an LP (linear programming problem) in the first example, an MCP (mixed complementarity problem) in the second example and an NLP (nonlinear programming program) in the third example. A complete list of GAMS model types is given in section Classification of Models. After the model type the direction of the optimization is given: either maximizing as in the first example or minimizing as in the third example. In the final position is the name of the objective variable that is to be optimized.
MCPs and systems of equations of the model type Constrained Nonlinear System (CNS) do not have objective variables. Therefore their solve statements end with the model type.

Observe that the system of nonlinear equations in the second example was expressed as an NLP that requires an objective function and a related objective variable. Actually this is an older practice in GAMS as the GAMS model type CNS was added after this example was initially formulated. Hence, we could alternatively use the following solve statement:

```gams
solve wall using cns;
```

However, note that the model type CNS can only be solved by select solvers and cannot incorporate integer variables. A formulation as an optimization problem relaxes these restrictions, thus allowing the use of the model type MINLP and all NLP solvers. If the model type NLP or one of its variants is chosen, one of the variables must be selected as objective variable to be optimized. Observe that which variable is chosen may not really have any effect since a feasible solution requires all of the simultaneous equations to be solved. Thus, while in the third example the variable `ba` is maximized, there is no inherent interest in attaining its maximum - it is just convenient.

### 4.12.2.5 Starting Points

In the third example we have the following line before the solve statement:

```gams
ba.l=1; so4.l=1; baoh.l=1; oh.l=1; hso4.l=1; h.l=1;
```

Note that this line provides starting points for the variables in the model. The suffix `.l` appended to a variable name denotes the level value of that variable. If a level value of a variable is specified before the solve statement, this value will act as a starting point for the search algorithms. The level value of a variable is one example of a variable attribute. Other examples include lower and upper bounds which may be set with the suffixes `.lo` and `.up`. For more information on variable attributes, see section Variable Attributes. For guidance on how to choose good starting points, see the tutorial Good NLP Formulations. Specifying starting points may be important for avoiding numerical problems in the model solution. For more on this topic, see the tutorial Finding and Fixing Execution Errors and Performance Problems.

Observe that the statements above are the first examples of assignment statements in this tutorial. Assignment statements play a crucial role in GAMS, they are introduced in section The Assignment Statement.

### 4.12.3 Running a GAMS Job

The model formulation of a GAMS model is saved in a text file with the extension `.gms`, say `myfile.gms`. Then the file is submitted to GAMS. GAMS will execute the instructions in the `.gms` file, with the result that calculations are done, solvers are used and an output file with the solution results is created. The output file is also called the listing file. By default, the name listing file of the input file `myfile.gms` will be `myfile.lst`.

There are two ways to submit a job to GAMS: via the command line and via the GAMS IDE.
4.12 Quick Start Tutorial

4.12.3.1 Running GAMS on the Command Line

The model formulation of a GAMS model is saved in a text file with the extension .gms, say myfile.gms. This file may be run with GAMS using the following call:

> gams myfile

Note the extension .gms may be omitted. This basic GAMS call may be extended with arguments that are called command line parameters. The following example serves as illustration:

> gams transport pw=80 ps=9999 s=mysave

Note that there are three command line parameters: the first will set the page width to 80, the second will set the page length to 9999 and the third will have the effect that a work file named mysave is saved. GAMS offers many command line parameters, they are introduced and discussed in detail in chapter The GAMS Call and Command Line Parameters.

4.12.3.2 Running GAMS with the IDE

The GAMS Integrated Development Environment is a graphical user interface for Windows that facilitates editing, development, debugging GAMS models and running GAMS jobs.

4.12.4 Examining The Output

The output of a GAMS run is saved in the output or listing file. The listing file may contain many parts. Some parts may be suppressed by the modeler, other parts are suppressed by default and need to be activated. For an introduction and detailed discussion, see chapter GAMS Output.

In this section we will review the output that is generated by running the three example models.

4.12.4.1 The Echo Print

The listing file always begins with the echo print. The echo print is a copy of the input file with added line numbers. For example, the echo print of the first example is given below:

1 Positive Variables Xcorn, Xwheat, Xcotton;
2 Variables Z;
3
4 Equations obj, land, labor;
5
6 obj.. Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
7 land.. Xcorn + Xwheat + Xcotton =l= 100;
8 labor.. 6 * Xcorn + 4 * Xwheat + 8 * Xcotton =l= 500;
9
10 Model farmproblem / obj, land, labor /;
11
12 solve farmproblem using LP maximizing Z;

Note that the echo print of the other two examples follows the same principles. Note further, that the echo print serves as an important reference guide since GAMS reports the line numbers of any errors that were detected and of solve and display statements.

Observe that usually the code of even experienced GAMS modelers will contain compilation errors. They are marked in the echo print. For more information on compilation error and how to resolve them, see section Compilation Errors and the tutorial Fixing Compilation Errors.
4.12.4.2 Model Generation Output

Once GAMS has successfully compiled the input file and any numerical computations in assignments have been performed, the solve statements will be executed. The first step is generating a computer readable version of the equations in the problem that will be passed on to an appropriate solver system. During the model generation phase GAMS creates the following output:

- A listing of the equations of the model.
- A listing of the variables of the model.
- A summary of the model structure.
- If errors were detected during model generation they will be reported as well.

4.12.4.2.1 The Equation Listing  The equation listing is the first part of the output generated by a solve statement. By default, the first three equations in every block are listed. The equation listing of the first two equations of each of the three examples are given below:

- **First example:**
  
  Equation Listing  SOLVE farmproblem Using LP From line 12
  
  ---- obj  =E=
  
  obj.. - 109*Xcorn - 90*Xwheat - 115*Xcotton + Z =E= 0 ; (LHS = 0)
  
  ---- land  =L=
  
  land.. Xcorn + Xwheat + Xcotton =L= 100 ; (LHS = 0)

- **Second example:**
  
  Equation Listing  SOLVE problem Using MCP From line 10
  
  ---- Pdemand  =G=
  
  Pdemand.. P + 0.3*Qd =G= 6 ; (LHS = 0, INFES = 6 ****)
  
  ---- Psupply  =G=
  
  Psupply.. - P + 0.2*Qs =G= -1 ; (LHS = 0)

- **Third example:**
  
  Equation Listing  SOLVE wall Using NLP From line 16
  
  ---- r1  =E=
  
  r1.. (1)*ba + (1)*so4 =E= 1 ; (LHS = 1)
  
  ---- r2  =E=
  
  r2.. - (1)*ba + (1)*baoh - (1)*oh =E= 4.8 ; (LHS = 1, INFES = 3.8 ****)
4.12 Quick Start Tutorial

Note that the equation listing is a representation of the algebraic structure of the linear terms in the equation and a local representation containing the first derivatives of the nonlinear terms. The nonlinear terms are automatically placed in parentheses to indicate a local approximation. For further details, see section The Equation Listing in chapter GAMS Output.

4.12.4.2.2 The Column Listing  The column or variable listing contains a list of the individual coefficients sorted by column rather than by row (like in the equation listing). By default, the first three entries for each variable are shown, along with their lower bound \( .lo \), upper bound \( .up \) and current level values \( .l \). The column listing of the first two variables for each of the three examples are given below.

- **First example:**
  
  Column Listing  
  
  SOLVE farmproblem Using LP From line 12

  ---- Xcorn

  Xcorn
  
  (.LO, .L, .UP, .M = 0, 0, +INF, 0)
  
  -109  
  1  land
  6  labor

  ---- Xwheat

  Xwheat
  
  (.LO, .L, .UP, .M = 0, 0, +INF, 0)
  
  -90  
  1  land
  4  labor

- **Second example:**

  Column Listing  
  
  SOLVE problem Using MCP From line 10

  ---- P

  P
  
  (.LO, .L, .UP, .M = 0, 0, +INF, 0)
  
  1  Pdemand
  -1  Psupply

  ---- Qd

  Qd
  
  (.LO, .L, .UP, .M = 0, 0, +INF, 0)
  
  0.3  Pdemand
  -1  Equilibrium

- **Third example:**

  Column Listing  
  
  SOLVE wall Using NLP From line 16
4.12.4.2.3 Model Statistics  The final information generated while a model is being prepared for solution, is the statistics block. Its most obvious use is to provide details on the size and nonlinearity of the model. The model statistics of the third example follow.

MODEL STATISTICS

<table>
<thead>
<tr>
<th>BLOCKS OF EQUATIONS</th>
<th>6</th>
<th>SINGLE EQUATIONS</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCKS OF VARIABLES</td>
<td>6</td>
<td>SINGLE VARIABLES</td>
<td>6</td>
</tr>
<tr>
<td>NON ZERO ELEMENTS</td>
<td>20</td>
<td>NON LINEAR N-Z</td>
<td>10</td>
</tr>
<tr>
<td>DERIVATIVE POOL</td>
<td>20</td>
<td>CONSTANT POOL</td>
<td>16</td>
</tr>
<tr>
<td>CODE LENGTH</td>
<td>22</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For more information on model statistics, see section The Model Statistics in chapter GAMS Output.

4.12.4.3 The Solution Report

The final major component of the listing file is the solution output. It consists of a summary, some solver-specific output and a report of the solutions for equations and variables.

4.12.4.3.1 The Solve Summary  The solve summary is very important since it contains an overview of key information of the solution. The solve summary of the third example is given below.

SOLVE SUMMARY

<table>
<thead>
<tr>
<th>MODEL</th>
<th>wall</th>
<th>OBJECTIVE</th>
<th>ba</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE</td>
<td>NLP</td>
<td>DIRECTION</td>
<td>MINIMIZE</td>
</tr>
<tr>
<td>SOLVER</td>
<td>CONOPT</td>
<td>FROM LINE</td>
<td>16</td>
</tr>
</tbody>
</table>

**** SOLVER STATUS  1 Normal Completion
**** MODEL STATUS   2 Locally Optimal
**** OBJECTIVE VALUE 1.0000

RESOURCE USAGE, LIMIT  0.034  1000.000
ITERATION COUNT, LIMIT 7 2000000000
EVALUATION ERRORS 0 0

For details on the solve summary including possible values for SOLVER STATUS and MODEL STATUS, see section The Solve Summary in chapter GAMS Output.
4.12.4.3.2 The Solver Report  The next part of the listing file is the solver report. It contains solver specific output. The respective output of the third example follows:

CONOPT 3 24.7.3 r58181 Released Jul 11, 2016 DEG x86 64bit/MacOS X

C O N O P T 3 version 3.17A
Copyright (C) ARKI Consulting and Development A/S
Bagsvaerdvej 246 A
DK-2880 Bagsvaerd, Denmark

Pre-triangular equations: 0
Post-triangular equations: 0

** Optimal solution. There are no superbasic variables.

For more on solver reports, see section Solver Report in chapter GAMS Output.

4.12.4.3.3 The Solution Listing  The solution listing is a row-by-row then column-by-column listing of the solutions returned to GAMS by the solver program. Each individual equation and variable is listed including their level and marginal values and their lower and upper bounds. The solution listing of the first example follows:

<table>
<thead>
<tr>
<th>LOWER</th>
<th>LEVEL</th>
<th>UPPER</th>
<th>MARGINAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
<td>EQU obj</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>----</td>
<td>EQU land</td>
<td>-INF</td>
<td>100.0000</td>
</tr>
<tr>
<td>----</td>
<td>EQU labor</td>
<td>-INF</td>
<td>500.0000</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>LOWER</th>
<th>LEVEL</th>
<th>UPPER</th>
<th>MARGINAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
<td>VAR Xcorn</td>
<td>.</td>
<td>50.0000</td>
</tr>
<tr>
<td>----</td>
<td>VAR Xwheat</td>
<td>.</td>
<td>50.0000</td>
</tr>
<tr>
<td>----</td>
<td>VAR Xcotton</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>----</td>
<td>VAR Z</td>
<td>-INF</td>
<td>9950.0000</td>
</tr>
</tbody>
</table>

Note that single dots '.' represent zeros. The extended range arithmetic symbols \(-\text{INF}\) and \(+\text{INF}\) denote minus and plus infinity respectively. \(\text{EPS}\) is another extended range arithmetic symbol that often appears in solution listings. In this context, it is used to indicate basis status in the degenerate case. For example, a basic variable is indicated by a zero (single dot) marginal, while a non-basic variable whose marginal is (nearly) zero is indicated by a marginal of \(\text{EPS}\). For further details, see section The Solution Listing in chapter GAMS Output.

4.12.5 Exploiting the Algebraic Structure

GAMS was deliberately designed to make it easy to express algebraic relationships. Thus it provides notation for indexed operations like sums. Assume that \(z\) is defined as the sum over \(x_i\) where \(i = \{1, 2, 3\}:\n
\[
z = \sum_{i=1}^{3} x_i = x_1 + x_2 + x_3
\]

This can be expressed in GAMS in the following way:
Here \( i \) is a set with three elements, \( z \) is a scalar or variable and \( x(i) \) is a parameter or variable defined over the set \( i \). Note that the keyword \texttt{sum} automatically cycles through all elements of the set \( i \).

Indexed operations like \texttt{sum} may be used in the algebraic specification of equations or in the context of assignments where the value of identifiers are computed. In the following two sections we will introduce revised versions of the first two examples, where we illustrate how using \texttt{sum} simplifies the code and enables more general formulations.

### 4.12.5.1 Revised First Example

Recall that the first example is the following LP:

\[
\begin{align*}
\text{max } & \quad 109X_{\text{corn}} + 90X_{\text{wheat}} + 115X_{\text{cotton}} \\
\text{s.t. } & \quad X_{\text{corn}} + X_{\text{wheat}} + X_{\text{cotton}} \leq 100 \quad \text{(land)} \\
& \quad 6X_{\text{corn}} + 4X_{\text{wheat}} + 8X_{\text{cotton}} \leq 500 \quad \text{(labor)} \\
& \quad X_{\text{corn}} \geq 0 \quad \text{(nonnegativity)} \\
& \quad X_{\text{wheat}} \geq 0 \quad \text{(nonnegativity)} \\
& \quad X_{\text{cotton}} \geq 0 \quad \text{(nonnegativity)}
\end{align*}
\]

Note that this is a special case of the general resource allocation problem that can be written as follows:

\[
\begin{align*}
\text{max } & \quad \sum_j c_j X_j \\
\text{s.t. } & \quad \sum_j a_{ij} X_j \leq b_i \quad \text{for all } i \\
& \quad X_j \geq 0 \quad \text{for all } j,
\end{align*}
\]

where

- \( j = \{\text{corn, wheat, cotton}\} \)
- \( i = \{\text{land, labor}\} \)
- \( X_j = \{X_{\text{corn}}, X_{\text{wheat}}, X_{\text{cotton}}\} \)
- \( c_j = \{109, 90, 115\} \)
- \( a_{ij} = \begin{pmatrix} 1 & 1 & 1 \\ 6 & 4 & 8 \end{pmatrix} \)
- \( b_i = \{100, 500\} \).

This model may be formulated in GAMS in the following way:

```gams
Set j / corn, wheat, cotton / i / land, labor /;
Parameter c(j) / corn 109, wheat 90, cotton 115 / b(i) / land 100, labor 500 /;
Table a(i,j)
    corn wheat cotton
land    1      1      1
labor   6      4      8
```

Positive Variables \( x(j) \);
Variables \( \text{profit} \);

Equations
\[
\text{objective} \\
\text{constraint}(i) \\
\]
\[
\text{objective}.. \quad \text{profit} = e = \sum(j, (c(j)) \times x(j)) \\
\text{constraint}(i) .. \quad \sum(j, a(i,j) \times x(j)) = l = b(i) \\
\]

Model resalloc /all/;
solve resalloc using LP maximizing profit;

We will discuss the components of this model in section Components of the Revised Example Models below.

4.12.5.2 Revised Second Example

Recall that the second example is an economic equilibrium model with a single commodity:

- **Demand Price:** \( P \geq P_d = 6 - 0.3Q_d \)
- **Supply Price:** \( P \leq P_s = 1 + 0.2Q_s \)
- **Quantity Equilibrium:** \( Q_s \geq Q_d \)
- **Nonnegativity:** \( P \geq 0 \), \( Q_s \geq 0 \), \( Q_d \geq 0 \)

A more general formulation of this model accommodates multiple commodities. Consider the following formulation where \( c \) denotes the commodities:

- **Demand Price for** \( c \): \( P_c \geq P_{d_c} = I_{d_c} - \sum_{c} S_{d_c, cc} Q_{d cc} \) for all \( c \)
- **Supply Price for** \( c \): \( P \leq P_{s_c} = I_{s_c} + \sum_{c} S_{s_c, cc} Q_{s cc} \) for all \( c \)
- **Quantity Equil. for** \( c \): \( Q_{s c} \geq Q_{d c} \) for all \( c \)
- **Nonnegativity:** \( P_c \geq 0 \) for all \( c \), \( Q_{s c} \geq 0 \) for all \( c \), \( Q_{d c} \geq 0 \) for all \( c \),

where

- \( P_c \) is the price of commodity \( c \),
- \( Q_{d c} \) is the quantity demanded of commodity \( c \),
- \( P_{d c} \) is the price from the inverse demand curve for commodity \( c \),
- \( Q_{s c} \) is the quantity supplied of commodity \( c \),
- \( P_{s c} \) is the price from the inverse supply curve for commodity \( c \),
- \( cc \) is an alternative notation for the commodities and is equivalent to \( c \),
- \( I_{d c} \) is the inverse demand curve intercept for \( c \),
- \( S_{d c, cc} \) is the slope of the inverse demand curve. It is used to model the effect of buying one unit of commodity \( cc \) on the demand price of commodity \( c \). When \( c = cc \) it is an own commodity effect and when \( c \neq cc \) it is a cross commodity effect.
• $I_{S_c}$ is the inverse supply curve intercept for $c$,

• $S_{sc,cc}$ is the slope of the inverse supply curve. It is used to model the effect of supplying one unit of commodity $cc$ on the supply price of commodity $c$. When $c = cc$ it is an own commodity effect and when $c \neq cc$ it is a cross commodity effect.

This model may be formulated in GAMS in the following way:

```gams
Set commodities / corn, wheat /;
Set curvetype / supply, demand/;
Table intercepts(curvetype,commodities)
  corn   wheat
   demand  4    8
   supply  1    2;
Table slopes(curvetype,commodities,commodities)
  corn   wheat
   demand.corn -.3  -.1
   demand.wheat -.07 -.4
   supply.corn  .5   .1
   supply.wheat  .1  .3;
Positive Variables P(commodities)
             Qd(commodities)
             Qs(commodities);
Equations PDemand(commodities)
              PSupply(commodities)
              Equilibrium(commodities);
Alias (cc,commodities);
Pdemand(commodities)..
  P(commodities) =g= intercepts("demand",commodities)
                   + sum(cc,slopes("demand",commodities,cc)*Qd(cc));
Psupply(commodities)..
  intercepts("supply",commodities)
       + sum(cc,slopes("supply",commodities,cc)* Qs(cc)) =g= P(commodities);
Equilibrium(commodities)..
  Qs(commodities) =g= Qd(commodities);
Model problem / Pdemand.Qd, Psupply.Qs,Equilibrium.P /;
solve problem using MCP;
```

### 4.12.6 Components of the Revised Example Models

The revised example models have several new features including sets, specific data entry, and variables and equations that are defined over sets. In addition, if the models are run, modelers will notice some differences in the output. In this section we will discuss these new language features and the differences in the output they entail.
4.12 Quick Start Tutorial

4.12.6.1 Sets in the Revised Examples

In the revised examples we used the subscripts i, j, commodities and cc. In GAMS, subscripts are sets. They have to be defined before they may be used as subscripts. Sets are defined with set statements. Consider the set statement from the first revised example:

```
Set  j  / corn, wheat, cotton /
     i  / land, labor /;
```

Note that the statement begins with the keyword set followed by the name of the set and a list of the elements of the set. Note further, that more than one set may be defined with one set statement. In addition, an optional explanatory text may be inserted after the name of the set and also after each set element. For more details on set definitions, see chapter Set Definition.

Observe that the following line appears in the revised second example:

```
Alias (cc,commodities);
```

This is an alias statement that introduces a new alternative name for a set that was defined earlier. In our example, the set commodities was defined in the first line of the code and cc is the alias, the alternative name for the set commodities. Note that more than one alias may be defined in an alias statement. For further information on aliases, see section The Alias Statement: Multiple Names for a Set.

Note that in our example the alias facilitates to consider both the effects of own and cross commodity quantity on the demand and supply price for an item.

4.12.6.2 Data Entry in the Revised Examples

GAMS provides three formats for data entry: scalars, parameters and tables. Usually scalars are defined with a scalar statement, data vectors are defined with a parameter statement and matrices are defined with a table statement.

Note that we used parameter and table statements in the revised examples. In this section we will discuss parameter and table statements. For details on scalar statements, see section Scalars.

Parameters

The parameter format is used to enter items defined over sets. Generally, the parameter format is used for data items that are one-dimensional (vectors), but multi-dimensional data may be entered with a parameter statement as well. Consider the parameter statement from the first revised example:

```
Parameter  c(j) / corn 109, wheat 90, cotton 115 /
         b(i) / land 100, labor 500 /;
```

Note that the statement begins with the keyword parameter followed by the name of the parameter and the set over which the parameter is defined, the index or domain. Then a list follows where a numerical value is assigned to each member of the index set. Note that the referenced elements must have been defined to be members of the respective set. By default, elements of the domain that are not listed in the parameter statement are assigned the value of zero. Note that more than one parameter may be defined with one parameter statement. For further details on parameter statements, see section Parameters.

Tables

The table format is used to enter data that are dependent on two or more sets. Consider the following two table statements from the revised examples:
Table \( a(i,j) \) crop data
\[
\begin{array}{ccc}
\text{corn} & \text{wheat} & \text{cotton} \\
\text{land} & 1 & 1 & 1 \\
\text{labor} & 6 & 4 & 8 \\
\end{array}
\]

Table intercepts(curvetype,commodities)
\[
\begin{array}{cc}
\text{corn} & \text{wheat} \\
\text{demand} & 4 & 8 \\
\text{supply} & 1 & 2 \\
\end{array}
\]

Note that the statement begins with the keyword `table` followed by the name of the table and the sets over which the table is defined. The next line serves as header for the columns of the table, the elements of the set in the second index position are listed here. The elements of the set in the first index position are the headers of the rows. Thus the elements of the two index positions span a grid where numerical values may be entered. Like in the parameter format, the referenced set elements must have been defined to be members of the respective set.

Note
Alignment is crucial in table statements. The numerical entries must be placed in one and only one column of the table.

By default, elements of the domain that are not listed in the table statement are assigned the value of zero. Note that only one table may be defined with a table statement. For further details on table statements, see section `Tables`. Observe that data may also be entered with assignment statements. For more information, see section `Data Entry by Assignment`.

### 4.12.6.3 Indexed Variables and Equations in the Revised Examples

When the algebraic structure of a problem is exploited in modeling, variables and equations are often defined over one or more sets, they are **indexed**. For example, in the first revised example we have the following lines:

Positive Variable \( x(j) \);
Equations constraint(i);

Note that here the variable \( x \) is defined over the set \( j \) and the equation \( \text{constraint} \) is indexed over the set \( i \). Similarly, in the second revised example we have the following variable and equation statements:

Positive Variables \( P(\text{commodities}) \)
\[
\begin{array}{c}
\text{Qd(\text{commodities})} \\
\text{Qs(\text{commodities})} \\
\end{array}
\]
Equations \( \text{PDemand(\text{commodities})} \)
\[
\begin{array}{c}
\text{PSupply(\text{commodities})} \\
\text{Equilibrium(\text{commodities})} \\
\end{array}
\]

Observe that here all positive variables and all equations are indexed over the set \( \text{commodities} \). Such definitions indicate that the variables and equations are potentially defined for every element of the defining set. Thus, for example, a variable \( P \) could exist for each and every element of the set \( \text{commodities} \). However, how many of these potential cases are activated is determined by the respective equation definition statement(s) where the variable \( P \) is used. For further details on indexed variables and equations, see chapter `Variables` and section `Indexed Equations` respectively.

Next, we will discuss the equation definition statements. The respective lines from the first revised example follow:
4.12 Quick Start Tutorial

```
objective.. profit =e= sum(j, (c(j))*x(j));
constraint(i).. sum(j, a(i,j) *x(j)) =l= b(i);
```

Note that the equation `constraint` is indexed over the set `i` and there are no restrictions specified in the equation definition statement. Thus, GAMS will generate a separate equation for every element of the set `i` in the model generation phase.

The same logic applies to the indexed equations of the second revised example whose definition statements are repeated below:

```
Pdemand(commodities)..
P(commodities) =g= intercepts("demand",commodities) + sum(cc,slopes("demand",commodities,cc)*Qd(cc));
Psupply(commodities)..
intercepts("supply",commodities) + sum(cc,slopes("supply",commodities,cc)*Qs(cc)) =g= P(commodities);
Equilibrium(commodities)..
Qs(commodities) =g= Qd(commodities);
```

Observe that equations may be defined over only a part of their domain. This restriction is usually achieved with dollar conditions. For details see section Conditional Equations.

4.12.6.4 Differences in the Output

If variables and equations are defined over sets, some parts of the listing file will look different. In particular, there are some changes in the equation listing, the variable listing and the solution listing.

Revised Models: The Equation Listing

Note that indexed variables are given with their indices in the equation listing. In addition, the specific equations generated for each element of the domain are listed under the name of an indexed equation. To illustrate, we present the equation listing of the first revised example below:

```
---- objective =E=
objective.. - 109*x(corn) - 90*x(wheat) - 115*x(cotton) + profit =E= 0 ; (LHS = 0)

---- constraint =L=
constraint(land).. x(corn) + x(wheat) + x(cotton) =L= 100 ; (LHS = 0)
constraint(labor).. 6*x(corn) + 4*x(wheat) + 8*x(cotton) =L= 500 ; (LHS = 0)
```

Revised Models: The Column Listing

Similar to indexed equations in the equation listing, each instance of a variable is listed under the name of an indexed variable in the variable listing. The respective output of the first revised model follows.
Revised Models: The Solution Listing

In the solution listing of the revised models there is a separate line for each element of the index set. The respective output of the first revised model is given below:

--- EQU constraint

<table>
<thead>
<tr>
<th>LOWER</th>
<th>LEVEL</th>
<th>UPPER</th>
<th>MARGINAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>land</td>
<td>-INF</td>
<td>100.0000</td>
<td>100.0000</td>
</tr>
<tr>
<td>labor</td>
<td>-INF</td>
<td>500.0000</td>
<td>500.0000</td>
</tr>
</tbody>
</table>

--- VAR x

<table>
<thead>
<tr>
<th>LOWER</th>
<th>LEVEL</th>
<th>UPPER</th>
<th>MARGINAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>corn</td>
<td>.</td>
<td>50.0000</td>
<td>+INF</td>
</tr>
<tr>
<td>wheat</td>
<td>.</td>

4.12.7 Documenting the GAMS Code

We have now covered the essential GAMS features. However, any good code includes documentation, otherwise it might be useless if it is revisited after a longer time. GAMS offers three ways to document the code: comments, explanatory texts and naming.

Comments

There are several ways to add comments in GAMS. The most common are single line comments and block comments. Single line comments may be inserted on any line by placing an asterisk * in the first column position. The text that follows the asterisk will be completely ignored by the GAMS compiler and may contain any content including GAMS keywords. Note that several successive lines may be single line comments. Block comments are marked with the dollar control option $ontext at the beginning of the comment block and the dollar control option $offtext at the end of the comment. Block comments usually
span several lines, but they may also contain just one line on the one hand and whole sections of the code on the other hand.

In addition, users may freely enter blank lines to set off certain sections of the code and generally enhance readability. For further details on comments, see section Comments.

**Explanatory Text**

Declarations of sets, parameters, variables and equations may include an optional descriptive text that follows the name of the identifier. In addition, the elements of sets may be accompanied by a text. This text is more than a comment: it is retained by GAMS and is displayed whenever results are written for the respective identifier in the output file. Note that the explanatory text may be quoted or unquoted and single or double quotes may be used, but they must match. An example is given below. For further details, see section Text.

**Naming**

Apart from avoiding reserved words, names for identifiers in GAMS may be freely chosen. Some modelers, particularly if they have a background in mathematics, prefer short names like $x(i)$. Other modelers strongly prefer longer descriptive names that makes it easier for them to recall what quantities are denoted. In this case naming is regarded as part of the documentation. GAMS accommodates both styles and modelers may choose which style works best for them. If short names are used, we recommend to generously use descriptive texts and comments for documentation.

To illustrate the virtues of comments, blank lines, explanatory text and long names we will repeat the code of the revised LP from above and then offer an alternative, documented formulation.

```gams
Set       j     / corn, wheat, cotton /    
          i     / land, labor /;
Parameter c(j)  / corn 109, wheat 90, cotton 115 /    
        b(i)  / land 100, labor 500 /;
Table     a(i,j) corn wheat cotton     
 land    1     1     1    
 labor   6     4     8    ;
Positive Variables x(j); Variables profit;
Equations objective constraint(i) ;
objective.. profit =e= sum(j, (c(j))*x(j));
constraint(i).. sum(j, a(i,j) *x(j)) =l=  b(i);
Model resalloc /all/;
solve resalloc using LP maximizing profit;

The documented version with longer names follows:

$ontext
well formatted algebraic version of the first example model
$offtext
Set   products  'Items produced by farm'
```
Parameter netreturns(products) 'Net returns per unit produced'
  / corn 109, wheat 90, cotton 115 /
endowments(resources) 'Amount of each resource available'
  / land 100, labor 500 /

Table resourceusage(resources,products) 'Resource usage per unit produced'
corn wheat cotton
  land  1  1  1
  labor  6  4  8 ;

Positive Variables production(products) 'Number of units produced';
Variables profit 'Total sum of net returns';

Equations profitAcct 'Profit accounting equation'
  available(resources) 'Resource availability limit';

$ontext
  Specify definition of profit
$offtext
profitAcct..
  profit =e= sum(products, netreturns(products)*production(products));

$ontext
  Limit available resources
  Fix at exogenous levels
$offtext
available(resources)..
  sum(products,
    resourceusage(resources,products) *production(products))
=l= endowments(resources);

Model resalloc /all/;
solve resalloc using LP maximizing profit;

4.12.8 Guidelines on Ordering GAMS Statements and Formatting GAMS Programs

A GAMS program is a collection of GAMS statements. In this section we will offer some general guidelines on ordering GAMS statements and formatting GAMS programs.

- GAMS is case insensitive. This applies to GAMS keywords as well as to user-defined names. For example, the keyword VARIABLE is identical to Variable and variable and the user-defined name mincost is identical to minCost and minCOST. However, note that the spelling in the output file is determined by the spelling in the first occurrence of an identifier or label.
Individual GAMS statements may be formatted in almost any style. Multiple lines may be used for a statement, blank lines may be embedded and any number of spaces or tabs may be inserted. In addition, several statements may be placed on one line. Note that they have to be separated by semicolons ;.

We recommend that every GAMS statement is terminated with a semicolon ;. However, note that semicolons are not mandatory if the next word is a GAMS keyword.

Identifiers like sets, parameters, scalars, tables, acronyms, variables, equations, models and files must first be declared and defined before they may be used in the code. An identifier is named in a declaration statement and specific values are assigned to it when it is defined. Often identifiers are defined at the same time they are declared. Note that for equations the declaration and definition statements are always distinct.

The names for identifiers and labels and the explanatory text must follow certain rules. See chapter GAMS Programs and the tutorial Good Coding Practices for more information.

Statements must be ordered such that identifiers are declared before they are used. If identifiers are used on the right-hand side of an assignment statement, they must also have been defined. If they are used in an equation and the equation is included in a model, then they must be assigned data before a solve statement for the respective model. Note that compilation errors will be triggered if this order is not followed.

4.12.9 Adding Complexity

There are several GAMS features that are widely used and serve to add subtlety and complexity to models. They include exception handling through conditionals, displaying data in the output file and report writing where the information from the optimal solution is used to create reports that meet the needs of modelers and their clients.

4.12.9.1 Conditionals

Assignments are often valid only for certain cases and sometimes equations should reasonably be restricted to a subset of the domain over which they were defined. It is easy to model such assignments and equations in GAMS with conditionals. Conditional expressions in GAMS are introduced and discussed in detail in chapter Conditional Expressions, Assignments and Equations. In this section we will only give a quick overview to demonstrate the capabilities of conditionals in GAMS.

Note that the dollar condition is at the heart of conditionals in GAMS. The general form of a conditional expression is as follows:

\[
\text{term \$ logical\_condition}
\]

This translates to: "Do something with 'term' only if the logical condition is true." Observe that term may be a number, a set, a parameter, a variable or an equation. The dollar operator \$ is a GAMS speciality and one of the most powerful features of GAMS. The logical condition may take many different forms, see section Logical Conditions for details.

The following examples illustrate how conditionals in GAMS may be used.

Conditional Assignments

Consider the following example:
$x \ (y > 0) = 10;

Note that $x$ is assigned the value of ten only if the scalar $y$ is greater than zero, otherwise no assignment is made and $x$ keeps its previous value. For more information, see section Conditional Assignments.

**Conditional Indexed Operations**

Consider the following example:

$$z = \text{sum}[i \ (y(i) \neq 0), x(i)];$$

Note that the term $x(i)$ will only be included in the sum if $y(i)$ is nonzero. For further information, see section Conditional Indexed Operations.

**Conditionals in the Domain of Definition of Equations**

Consider the following equation definition statements:

$$\text{Eq1} \ (qq > 0) \ldots \ x\var =e= 3;$$
$$\text{Eq2} \ (\text{sum}(i, q(i)) > 0) \ldots \ y\var =l= 4;$$
$$\text{Eq3}(i) \ (a(i) > 0) \ldots \ ivar(i) =g= -a(i);$$

Note that in each equation the domain of definition is restricted to those cases where the logical condition evaluates to TRUE. For further details, see section Dollar Control over the Domain of Definition.

**Conditionals in the Algebraic Formulation of Equations**

Our last example illustrates how a dollar condition may be used in the body of an equation:

$$\text{Eq4} \ldots \ x\var + y\var \ (qq > 0) =e= 3;$$

Note that the term $y\var$ is included in the equation only if $qq$ is greater than zero, otherwise $y\var$ is treated as if it were zero. For more information, see section Dollar Operators within the Algebra of Equations.

### 4.12.9.2 Displaying Data

In GAMS, the display statement is a quick way to write data into the output file. For example, assume we add the following statement after the solve statement in the revised and documented version of the farm linear programming model above:

`display profit.l, production.l;`

Recall that profit and production are variables. The suffix .l indicates that we wish to display the variable attribute level. The following output will be generated in the listing file:

```
---- 47 VARIABLE profit.L = 9950.000 Total sum of net returns
---- 47 VARIABLE production.L Number of units produced
    corn 50.000, wheat 50.000
```

Observe that the name of the variable, the explanatory text and the respective numerical values are given. In addition to data like parameters, sets, variable attributes, equation attributes and model attributes, quoted text may be displayed. Note that numerical entries that equal zero will not be displayed. For a more detailed introduction, see chapter The Display Statement.
4.12.9.3 Report Writing

In many cases modelers wish to summarize the most important results of the solution in a table for a quick overview. GAMS allows post-solution computations where information from the solution may be used to assign values to new parameters that are then displayed. The information from the solution most often used for report writing includes the level values of variables and equations and the marginal values of equations (also called dual values or shadow prices). Note that variable and equation attributes are accessed as follows:

\[ \text{var_name.sfx} \]
\[ \text{eqn_name.sfx} \]

Here \text{var_name} and \text{eqn_name} is the name of the variable and equation in GAMS respectively. The attribute is denoted by .sfx, where sfx may be l for level and m for marginal. Note that the suffix sfx may take other values as well. For details see sections Variable Attributes and Equation Attributes.

Observe that the numerical values of the levels and marginals of variables and equations are generally undefined until a solve statement is executed. After GAMS has retrieved the solution from the solver, the respective values from the solution are assigned to the attributes. These values remain unchanged until the next solve, where they are replaced with the values from the most recent solution.

In the remainder of this section we will present two examples to illustrate report writing. Assume we add the following report writing sequence after the solve statement to the revised and documented version of the farm linear programming model above:

```
Set item / Total, "Use by", Marginal /;
Set qitem / Available, Corn, Wheat, Cotton, Value /;
Parameter Thisreport(resources,item,qitem) 'Report on resources';
Thisreport(resources,"Total","Available") = endowments(resources);
Thisreport(resources,"Use by",qitem) =
    sum(products$sameas(products,qitem),
        resourceusage(resources,products) * production.l(products));
Thisreport(resources,"Marginal","Value") =
    available.m(resources);

option thisreport:2:1:2;
display thisreport;
```

Note that both, equation marginals (available.m(resources)) and variable levels (production.l(products)) are included in the calculations. The function sameas in the logical condition above returns the value TRUE if the element of the set products is equivalent to the element of the set qitem and FALSE otherwise. Thus this condition ensures that the third index of the parameter Thisreport is identical to the element of the set products in the sum. Observe that with the option statement in the penultimate line the appearance of the display is customized. For details see section Local Display Control. The following report will be generated by the display statement:

```
---- 61 PARAMETER Thisreport Report on resources

<table>
<thead>
<tr>
<th></th>
<th>Total</th>
<th>Use by</th>
<th>Use by</th>
<th>Marginal</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Available</td>
<td>corn</td>
<td>wheat</td>
<td>Value</td>
</tr>
<tr>
<td>land</td>
<td>100.00</td>
<td>50.00</td>
<td>50.00</td>
<td>52.00</td>
</tr>
<tr>
<td>labor</td>
<td>500.00</td>
<td>300.00</td>
<td>200.00</td>
<td>9.50</td>
</tr>
</tbody>
</table>
```
Similarly, we could add the following report writing sequence to the revised version of the equilibrium model above:

```plaintext
Set qitem / Demand, Supply, "Market Clearing" /;
Set item / Quantity, Price /;

Parameter myreport(qitem,item,commodities);
myreport("Demand","Quantity",commodities) = Qd.l(commodities);
myreport("Supply","Quantity",commodities) = Qs.l(commodities);
myreport("Market Clearing","Price",commodities) = P.l(commodities);

display myreport;
```

Note that in the new parameter the level values for supply and demand as well as the market clearing price are saved. The resulting report follows:

```
---- 39 PARAMETER myreport

<table>
<thead>
<tr>
<th></th>
<th>Corn</th>
<th>Wheat</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supply</td>
<td>Quantity</td>
<td>1.711</td>
</tr>
<tr>
<td>Demand</td>
<td>Quantity</td>
<td>1.711</td>
</tr>
<tr>
<td>Market Clearing</td>
<td>Price</td>
<td>2.671</td>
</tr>
</tbody>
</table>
```

For more on report writing, see chapters The Display Statement and The Put Writing Facility.

### 4.12.10 Advantages of Algebraic Modeling in General

We will conclude this tutorial with a discussion of the advantages of using algebraic modeling in general.

Algebraic modeling languages like GAMS facilitate model formulations in general algebraic terms, that are very concise and readable. Language elements that are essential include sets that may serve as indices, algebraic expressions, indexed operations, powerful sparse index and data handling variables and constraints with user-defined names. Model formulations are largely independent of the data and exact application contexts. Such formulations may be easily transferred to different contexts, data may be added without the need to reformulate the model and the model may be extended to reflect additional complexity.

However, GAMS algebraic requirements and the summation notation are difficult for some users. Some modelers will always prefer the exact problem context, not an abstract general formulation. This may lead to a strategy most modelers use: Start with a small concrete formulations that capture the essence of the problem and support the development of more general GAMS models.

#### 4.12.10.1 One Model - Different Contexts

In the linear programming problem above we modeled profit maximizing in a farm. This model may easily be transferred to another context as follows:
Set products 'Items produced'
   / Chairs, Tables, Dressers /
resources 'Resources limiting production'
   / RawWood, Labor, WarehouseSpace /

Parameter Netreturns(products) 'Net returns per unit produced'
   / Chairs 19, Tables 50, Dressers 75 /
Endowments(resources) 'Amount of each resource available'
   / RawWood 700, Labor 1000, WarehouseSpace 240 /

Table Resourceusage(resources,products) 'Resource usage per unit produced'
  Chairs Tables Dressers
  RawWood  8   20  32
  Labor    12  32  45
  WarehouseSpace  4   12  10

Positive Variables Production(products) 'Number of units produced';
Variables Profit 'Total sum of net returns';

Equations ProfitAcct 'Profit accounting equation'
   Available(resources) 'Resource availability limit';

ProfitAcct..
   Profit =e= sum(products, netreturns(products) * production(products)) ;
Available(resources).. 
   sum(products, resourceusage(resources,products) * production(products)) 
   =l= endowments(resources);

Model resalloc /all/;
solve resalloc using LP maximizing Profit;

Note that in this model we have chairs, tables and dressers instead of corn, wheat and cotton and raw wood, labor and warehouse space instead of land and labor, but the algebraic structure of the model is the same. Thus we still have sets for products and resources, parameters for net returns per unit produced and available resources, a table for resource usage per unit produced and exactly the same variables and equations, the same model and solve statement. Hence, if the algebraic structure for a type of problem is built, it may be used in another context of the same problem type with just minor modifications in the data.

4.12.10.2 Adding More Data

It is easy to add more data to a model. For example, we could add two new products and two new resources to the carpenter model above in the following way:

Set products 'Items produced'
   / Chairs, Tables, Dressers, HeadBoards, Cabinets /
resources 'Resources limiting production'
   / RawWood, Labor, WarehouseSpace, Hardware, ShopTime /

Parameter Netreturns(products) 'Net returns per unit produced'
   / Chairs 19, Tables 50, Dressers 75, HeadBoards 28, Cabinets 25 /
Endowments(resources) 'Amount of each resource available'
User's Guide

/ RawWood 700, Labor 1000, WarehouseSpace 240, Hardware 100, Shoptime 600 /

Table Resourceusage(resources,products) 'Resource usage per unit produced'

<table>
<thead>
<tr>
<th>Chairs</th>
<th>Tables</th>
<th>Dressers</th>
<th>HeadBoards</th>
<th>Cabinets</th>
</tr>
</thead>
<tbody>
<tr>
<td>RawWood</td>
<td>8</td>
<td>20</td>
<td>32</td>
<td>22</td>
</tr>
<tr>
<td>Labor</td>
<td>12</td>
<td>32</td>
<td>45</td>
<td>12</td>
</tr>
<tr>
<td>WarehouseSpace</td>
<td>4</td>
<td>12</td>
<td>10</td>
<td>3</td>
</tr>
<tr>
<td>Hardware</td>
<td>1</td>
<td>1</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>Shoptime</td>
<td>6</td>
<td>8</td>
<td>30</td>
<td>5</td>
</tr>
</tbody>
</table>

Positive Variables Production(products) 'Number of units produced';
Variables Profit 'Total sum of net returns';

Equations ProfitAcct 'Profit accounting equation'
Available(resources) 'Resource availability limit';

ProfitAcct..
Profit =e= sum(products, netreturns(products) * production(products)) ;

Available(resources)..
sum(products, resourceusage(resources,products) * production(products)) =l= endowments(resources);

Model resalloc /all/;
solve resalloc using LP maximizing Profit;

Observe that the elements HeadBoards and Cabinets were added to the set Products and the elements Hardware and ShopTime were added to the set Resources. In addition, the data in the two parameters and the table was updated to reflect these new labels. However, the model structure remained unchanged. Thus, GAMS models may easily be extended from smaller to larger data sets. Note that this feature may be exploited for model development. Users may develop a model with a small data set and test and debug it. Afterwards, they may move to the full problem data set without having to alter the algebraic structure of the model. For more details on this strategy, see section Small to Large: Aid in Development and Debugging.

4.12.10.3 Extending the Model

Assume we wish to make a model more complex by adding new features. For example, we could extend the carpenter model above to reflect the possibility of renting or hiring additional resources subject to a maximum limit. Consider the following code:

Set products 'Items produced'
    / Chairs, Tables, Dressers /
resources 'Resources limiting production'
    / RawWood, Labor, WarehouseSpace/
hireterms 'Resource hiring terms'
    / Cost, Maxavailable /;

Parameter Netreturns(products) 'Net returns per unit produced'
    / Chairs 19, Tables 50, Dressers 75 /
Endowments(resources) 'Amount of each resource available'
    / RawWood 700, Labor 1000, WarehouseSpace 240 /;
Table Resourceusage(resources,products) 'Resource usage per unit produced'

<table>
<thead>
<tr>
<th>Chairs</th>
<th>Tables</th>
<th>Dressers</th>
</tr>
</thead>
<tbody>
<tr>
<td>RawWood</td>
<td>8</td>
<td>20</td>
</tr>
<tr>
<td>Labor</td>
<td>12</td>
<td>32</td>
</tr>
<tr>
<td>WarehouseSpace</td>
<td>4</td>
<td>12</td>
</tr>
</tbody>
</table>

Table Hiredata(resources,hireterms) 'Resource hiring data'

<table>
<thead>
<tr>
<th>Cost</th>
<th>Maxavailable</th>
</tr>
</thead>
<tbody>
<tr>
<td>RawWood</td>
<td>3</td>
</tr>
<tr>
<td>Labor</td>
<td>12</td>
</tr>
<tr>
<td>WarehouseSpace</td>
<td>4</td>
</tr>
</tbody>
</table>

Positive Variables Production(products) 'Number of units produced'

Variables HireResource(resources) 'Resources hired';

Variables Profit 'Total sum of net returns';

Equations ProfitAcct 'Profit accounting equation'

Available(resources) 'Resource availability limit'

Hirelimit(resources) 'Resource hiring limit';

ProfitAcct.. Profit
  =e= sum(products, Netreturns(products) * Production(products))
  - sum(resources, Hiredata(resources,"cost") * HireResource(resources));

Available(resources)..
  sum(products,
    Resourceusage(resources,products) * Production(products))
=1= Endowments(resources) + HireResource(resources);

Hirelimit(resources)..
  HireResource(resources) =l= Hiredata(resources,"Maxavailable");

Model resalloc /all/;

solve resalloc using LP maximizing Profit;

Observe that we introduced the set hireterms, the table Hiredata, the positive variable HireResource and the equation Hirelimit. In addition, we included new terms in the equations Profit and Available to reflect that through hiring the resources are increased, but hiring comes with a cost diminishing the profit. Thus the algebraic structure of the earlier model could be used as the core for this model that has additional features.

Note that this method may also be exploited for model development. Users may adapt models from other studies customizing them for the problem at hand and thus speeding up the development process. In addition to adapting models from related earlier studies that were done by the modeler or his group, model development may be jumpstarted by adapting models from the extensive GAMS Model Library.

4.13 Good Coding Practices

The GAMS language is quite flexible regarding the syntax and format of the code it accepts, offering users considerable latitude in how they organize and format their GAMS code. Most modelers develop their own style as they gain experience with the GAMS system. This tutorial reflects the coding preferences of Bruce A. McCarl (currently professor of Agricultural Economics at Texas A&M University). Note that Bruce has extensive experience with GAMS, both as a modeler and an educator, and many GAMS users
know, use, and benefit from his work. The goal of this tutorial is not to present a rigid set of rules to follow arbitrarily, but rather to help users develop their own coding preferences and style. The larger goal is to build self-documenting models that are easy to read and understand, to edit, and to debug: both for the developer working in the present, and for a larger group of colleagues and consultants working with the model over a span of months or years.

We will cover the following topics:

- Using Longer Names and Descriptive Text
- Including Comments
- Choosing Raw Data Instead Of Computed Data
- Avoiding the Universal Set in the Context of Data Input
- Defining Sets and Subsets Wisely
- Structuring and Formatting Files to Improve Readability
- Other Suggestions

4.13.1 Using Longer Names and Descriptive Text

The readability of GAMS code may be significantly improved by using longer self-explanatory names for identifiers (e.g. names of sets, parameters, variables, etc). Consider the following lines of code from the production and inventory model [ROBERT]:

Sets p 'products' / low, medium, high /
    r 'raw materials' / scrap, new /
    tt 'long horizon' / 1*4 /
    t(tt) 'short horizon' / 1*3 /;

Table a(r,p) input 'coefficients'

<table>
<thead>
<tr>
<th></th>
<th>low</th>
<th>medium</th>
<th>high</th>
</tr>
</thead>
<tbody>
<tr>
<td>scrap</td>
<td>5</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>new</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

Table c(p,t) 'expected profits'

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>low</td>
<td>25</td>
<td>20</td>
<td>10</td>
</tr>
<tr>
<td>medium</td>
<td>50</td>
<td>50</td>
<td>50</td>
</tr>
<tr>
<td>high</td>
<td>75</td>
<td>80</td>
<td>100</td>
</tr>
</tbody>
</table>

Variables x(p,tt) 'production and sales'
    s(r,tt) 'opening stocks'
    profit;

Positive variables x, s;

Equations cc(t) 'capacity constraint'
    sb(r,tt) 'stock balance'
    pd 'profit definition' ;

cc(t).. sum(p, x(p,t)) =l= m;
sb(r,tt+1) =e= s(r,tt) - sum(p, a(r,p)*x(p,tt));

pd.. profit =e= sum(t, sum(p, c(p,t)*x(p,t))
  - sum(r, misc("storage-c",r)*s(r,t)))
  + sum(r, misc("res-value",r)*s(r,"4"));

s.up(r,"1") = misc("max-stock",r);

These lines may be reformatted in the following way (see (good.gms)):

Sets process /low 'uses a low amount of new materials',
    medium 'uses a medium amount of new materials',
    high 'uses a high amount of new materials'/
rawmaterial /scrap, new/
Quarters /spring, summer, fall, winter/
quarter(Quarters) /spring, summer, fall/
Table usage(rawmaterial,process) 'input coefficients'
    low    medium  high
scrap  5        3       1
new    1        2       3
Table expectprof(process,quarters) 'expected profits'
    spring summer fall
low     25       20      10
medium  50       50      50
high    75       80      100;
Variables production(process,Quarters) 'production and sales'
    openstock(rawmaterial,Quarters) 'opening stocks'
    profit;
Positive variables production, openstock;
Equations capacity(quarter) 'capacity constraint'
    stockbalan(rawmaterial,Quarters) 'stock balance'
    profitacct 'profit definition';

capacity(quarter)..
    sum(process, production(process,quarter)) =l= mxcapacity;
stockbalan(rawmaterial,Quarters+1)..
    openstock(rawmaterial,Quarters+1) =e=
    openstock(rawmaterial,Quarters)
    - sum(process, usage(rawmaterial,process)
        *production(process,Quarters));
profitacct.. profit =e=
    sum(quarter,
        sum(process, expectprof(process,quarter)
            *production(process,quarter))
    - sum(rawmaterial, miscdata("store-cost",rawmaterial)*
        openstock(rawmaterial,quarter)))
    + sum(rawmaterial, miscdata("endinv-value",rawmaterial)
        *openstock(rawmaterial,"winter"));
openstock.up(rawmateral,"spring") = miscdata("max-stock",rawmateral);

Note that the two formulations are equivalent in their effect, but in the second formulation longer, more descriptive names were used for the sets, tables, variables and equations. In addition, longer names were used for the set elements and in the definition of the set process the set elements have additional explanatory text. Observe that the second formulation is easier to understand. This will be particularly useful if and when the code is revisited in 5 years' time.

Note
- Recall that GAMS allows long names for identifiers and labels (set elements). Users may exploit this feature to introduce long descriptive names. However, note that names for labels that are longer than 10 characters do not work well in multi-column displays. See the paragraph on customizing display width for details.
- Use explanatory text for identifiers to indicate units, sources, descriptions, etc. It's not that hard to do and it pays dividends later.
- Similarly, use explanatory text for set elements as appropriate.

For example, the descriptive text in the in the second line in the following code snippet is much more informative than the text in the first line:

Parameter vehsales(r) 'regional vehicle sales';
Parameter vehsales(r) 'regional vehicle sales ($ millions/yr)';

Note that the descriptive text will be displayed whenever the respective identifier is displayed. Hence, including units in the text will save time if results will have to be interpreted later.

4.13.2 Including Comments on Procedures and the Nature and Sources of Data

We recommend that the documentation of the code offers answers to the following questions:

- What are the units of the variables and parameters?
- Where did the data come from?
- What are the characteristics of the data such as units and year of applicability?
- Why was a constraint set up in the way it is implemented?

In addition, it is often helpful to add comments that describe assumptions, the intent of equation terms, data sources, including document name, page number, table number, year of applicability, units, URL etc.

Consider the following example where various forms of comments are illustrated:
4.13 Good Coding Practices

* this is a one line comment that could describe data

$ontext
My data could be described in this multi-line comment
This is the second line
$offtext

* The following dollar control option activates end-of-line comments
* and redefines the symbol for end-of-line comments

$eolCom #
x = sum(i, z(i)) ; # this is an end-of-line comment

* The following dollar control option activates in-line comments
* and redefines the symbols for in-line comments

$inLineCom (* *)
x = sum(i, z(i)) ; (* this is an in-line comment *) r = sum(i, z(i)) ;

For more information on comments in GAMS, see section Comments.

4.13.3 Choosing Raw Data Instead Of Computed Data

Modelers often have a choice how they enter data: they could either use raw data and transform it to the extent needed inside GAMS or process data externally and enter the final results into GAMS. The second choice may be attractive if the raw data is available in a spreadsheet where it can be manipulated before it is introduced to GAMS. However, over time spreadsheets and other data manipulation programs change or get lost and often these programs are not documented well. Therefore, we recommend to enter data into GAMS in a form that is as close as possible to the actual collected data and then manipulate the data with GAMS to obtain the desired form. This will make it much easier to update models later or to work out implicit assumptions.

4.13.4 Avoiding the Universal Set in the Context of Data Input

While GAMS permits using the universal set * as an index in a parameter or table statement, in most cases it is not advisable to do so. Consider the following example from the production and inventory model [ROBERT]:

Sets r 'raw materials' / scrap, new /;
Table misc(*,r) 'other data'
  scrap new
  max-stock 400 275
  storage-c .5 2
  res-value 15 25;

pd.. profit =e= sum(t, sum(p, c(p,t)*x(p,t))
  - sum(r, misc("storage-c",r)*s(r,t)))
  + sum(r, misc("res-value",r)*s(r,"4"));

Note that the definition of the table misc indicates that any entry in the first index position is allowed. There is no domain checking. Consequently, if the label res-value is misspelled as res-val in the equation pd, GAMS will compile and execute the program without signaling an error, but instead of the expected values (i.e. misc(r,"res-value")), the values of misc(r,"res-val") will be used in the equation. These zero values will lead to faulty results, and the modeler will not be alerted to this fact. To ensure that the results of a GAMS run are reliable and trustworthy, we strongly recommend to use domain checking by introducing a new set for the labels in the first index position of the table misc:
Sets  
   r   'raw materials'
    / scrap, new /
  miscitem 'misc input items'
    / max-stock, storage-c, res-value /;

Table  misc(miscitem,r) 'other data'

<table>
<thead>
<tr>
<th></th>
<th>scrap</th>
<th>new</th>
</tr>
</thead>
<tbody>
<tr>
<td>max-stock</td>
<td>400</td>
<td>275</td>
</tr>
<tr>
<td>storage-c</td>
<td>.5</td>
<td>2</td>
</tr>
<tr>
<td>res-value</td>
<td>15</td>
<td>25</td>
</tr>
</tbody>
</table>

Observe that the new set miscitem contains exactly the labels that appear in the rows of the table misc. Hence the set miscitem may be used in the first index position of the definition of misc without loss of generality, but with the benefit of domain checking.

### 4.13.5 Defining Sets and Subsets Wisely

Generally, the elements of a set have a feature in common or they are similar in some way. In this section we will give some guidance on how to partition the labels in the data into sets. In addition, we will discuss in which contexts it is useful to introduce subsets. For an introduction to sets in GAMS, see chapter Set Definition.

For example, suppose we have three grades of oil and three processes to crack it. The question arises whether we should introduce one set with nine elements or two sets with three elements and a two-dimensional set. We recommend the second alternative.

In another example, we consider a budget for farm spending: we have annual (i.e. cumulative yearly) spending for fertilizer and for seed and also monthly spending for labor and for water. There are 26 decisions or items in the budget. We could introduce a set with 26 elements or we could use the following formulation:

```gams
Sets resources / fertilizer, seed, labor, water /
   periods  / jan, feb, mar, apr, may, jun, jul, aug, sep, oct, nov, dec, annual /
   use(resources,periods)
    / (fertilizer,seed).annual
       (labor,water)  .(jan,feb,mar,apr,may,jun,jul,aug,sep,oct,nov,dec) /;
```

We recommend the formulation above and to err on the side of being more extensive or exact with set definitions.

Occasionally it is necessary to group some labels into one set for a certain purpose and then single out some of them for another purpose. Subsets facilitate modeling such a case. For example, a set of all cities in a model may be needed to enter distances and compute related transportation costs. In addition, a subset can be used to specify the cities that are hubs for some activity, since some equations should be restricted to these hubs.
4.13.6 Structuring and Formatting Files to Improve Readability

In this section we will offer some guidelines on structuring and formatting the GAMS code to make it easy to read.

There are several ways to structure the GAMS code. Two styles are outlined in section Organization of GAMS Programs. The following recommendation to enter the sections of the code in a fixed order is an extended version of the first style:

1. Set definitions for sets that are data related
2. Parameter, scalar and table definitions, possibly intermixed with calculations
3. Variable definitions
4. Equation declarations
5. Equation definitions (algebraic specification of equations)
6. Model and solve statement(s)
7. Definitions of sets and parameters for report writing
8. Calculations for report writing
9. Display statement(s) for reports

Note that the code will be easiest to navigate if each section of the code contains only one type of statements. For example, interspersing set definitions with parameter definitions will make the code unnecessarily difficult to read.

In addition to following a fixed structure, it is also essential to properly format the code. Of course, formatting is in many respects a matter of taste. The following list offers some ideas:

- Align the names of identifiers and descriptive text, as demonstrated in the examples in this tutorial and in the GAMS User's Guide in general.
- Use spacing and indents.
- Use blank lines to highlight something and to mark sections of the code.
- Ensure that variables and all their index positions are on one line in equation definitions.
- Indent in indexed operations like sums and programming flow control structures like loops and if statements to delineate terms. The structure of a long and complex statement may be revealed through careful indentation and thoughtful placement of closing parentheses.

We will demonstrate the effect of proper formatting with the following two examples. The first example contains valid GAMS code, but is deliberately poorly formatted:

```gams
Sets    products 'available production process' / low 'uses low new materials'
         medium 'uses medium new materials', high 'uses high new materials'
         rawmaterial 'source of raw materials' / scrap, new /
         Quarters 'long horizon' / spring, summer, fall, winter /
         quarter(Quarters) 'short horizon' / spring, summer, fall /
 Variables production(products,Quarters) 'production and sales'
         openstock(rawmaterial,Quarters) 'opening stocks', profit
 Positive variables production, openstock;
 Equations capacity(quarter) 'capacity constraint',
     stockbalan(rawmaterial,Quarters) 'stock balance',
     profitacct profit definition ;
 profitacct.. profit =e= sum(quarter, sum(products, expectprof(
     products,quarter) *production(products,quarter))-
     sum(rawmaterial,miscdata("store-cost",rawmaterial)*openstock(rawmaterial,
     ,quarter)))+ sum(rawmaterial, miscdata("endinv-value",rawmaterial) *openstock(rawmaterial,"winter"))
```

The second example is well formatted:

```gams
Sets    products 'available production process' / low 'uses low new materials'
         medium 'uses medium new materials', high 'uses high new materials'
         rawmaterial 'source of raw materials' / scrap, new /
         Quarters 'long horizon' / spring, summer, fall, winter /
         quarter(Quarters) 'short horizon' / spring, summer, fall /
 Variables production(products,Quarters) 'production and sales'
         openstock(rawmaterial,Quarters) 'opening stocks', profit
 Positive variables production, openstock;
 Equations capacity(quarter) 'capacity constraint',
     stockbalan(rawmaterial,Quarters) 'stock balance',
     profitacct profit definition ;
 profitacct.. profit =e= sum(quarter, sum(products, expectprof(
     products,quarter) *production(products,quarter))-
     sum(rawmaterial,miscdata("store-cost",rawmaterial)*openstock(rawmaterial,
     ,quarter)))+ sum(rawmaterial, miscdata("endinv-value",rawmaterial) *openstock(rawmaterial,"winter")))
```
The second example contains the same code as the first example, but is carefully formatted:

Sets products 'available production process'
   / low 'uses a low amount of new materials',
   medium 'uses a medium amount of new materials',
   high 'uses a high amount of new materials'/
rawmateral 'source of raw materials' / scrap, new /
Quarters 'long horizon' / spring, summer, fall, winter /
quarter(Quarters) 'short horizon' / spring, summer, fall /
;

Variables production(products,Quarters) 'production and sales'
   openstock(rawmateral,Quarters) 'opening stocks'
   profit ;

Positive Variables production, openstock ;

Equations capacity(quarter) 'capacity constraint'
   stockbalan(rawmateral,Quarters) 'stock balance'
   profitacct 'profit definition' ;

profitacct..
   profit =e= 
   sum(quarter,
      sum(products, expectprof(products,quarter)
         *production(products,quarter)
      )
      - sum(rawmateral, miscdata("store-cost",rawmateral)*
         openstock(rawmateral,quarter)
      )
   )
   + sum(rawmateral, miscdata("endinv-value",rawmateral)
      *openstock(rawmateral,"winter")
   )
   ;

Observe that inserting blank lines, aligning the names of identifiers and descriptive text, and indenting and formatting closing parentheses in the sums makes the code much easier to read and understand (both now and in the future) and is well worth adopting as standard practice when writing GAMS code.

4.13.7 Other Suggestions

We will complete this tutorial by offering some other useful suggestions that may help modelers develop their own conventions.

Even though GAMS is case insensitive, it is advisable to establish some convention on the use of upper and lower case letters. For example, Paul N. Leiby (currently at Oak Ridge National Laboratory) uses lower case for texts and comments, and upper case for GAMS reserved words and variable and parameter names. The casing used when an identifier or label is first encountered in a GAMS program is the casing stored by GAMS and used in subsequent outputs like the listing file or a GDX file. Any casing can be used (so nowhere is equivalent to nowhere) but the casing stored is determined by first use.

A similar situation holds for label quoting: the type of quotes stored (if any) are determined by first use.

Note that the dollar control option $onSymList will cause a list of all identifier names to be displayed in the compilation output of the output file. This list may be used to review the spelling and casing of the identifiers as they will appear in output files. Similarly, the dollar control option $onUELList will cause
an ordered list of all labels to be displayed in the compilation output of the output file. This is useful for checking both the case and order of the labels used in the GAMS program. For more on issues related to label ordering, see section Ordered and Unordered Sets.

To keep track of the data types of identifier names, some modelers always start set names with $s$-, names of parameters with $d$-, variables names with $v$- and equation names with $e$-.

Some experienced GAMS users always surround explanatory text with quotes: this makes the text stand out, prevents it from being interpreted as a label or identifier, and allows special characters like $\$, - and & to be used.

If a file is used by several modelers and is updated occasionally, a file modification log at the top of the file will be in order. It should contain the following information: the modification date, version number, modification(s) made and who made the modification. For example, a set called \texttt{version} may be used to keep track of the dates the input files were modified:

\begin{verbatim}
Set version(*,*,*,*);
   ...
version("my_file","May","19","2016") = yes;
version("my_include_file","Sep","30","2016") = yes;
   ...
display version;
\end{verbatim}

Note that the display statement will generate a display of all elements of the set \texttt{version}, each indicating on which day a component of the model was modified.

### 4.14 Fixing Compilation Errors

As detailed in chapter GAMS Output, the execution of a GAMS program passes through several stages, where the compilation is the first stage. Often when a program is run for the first time, it cannot be solved successfully because of compilation errors. This can be very frustrating, especially for new users. In this tutorial we will explain the causes of the most common compilation errors and offer some advice on how to fix them. For an introduction to compilation errors, see section Compilation Errors. In addition, the tutorial A GAMS Tutorial by Richard E. Rosenthal offers some detailed material on this topic.

Note

Frequently, many compilation errors in the latter part of the code are actually consequential errors that will disappear as soon as the compilation errors in the beginning have been resolved. Therefore we recommend to start with fixing the first few errors and to run the program again. More often than not, many subsequent compilation errors will have vanished.

#### 4.14.1 Preliminary Remarks

Before we will turn to an overview of the most common errors, examples that illustrate them and advice how to resolve them, we will provide some basic information on compilation errors and error messages.
4.14.1.1 Finding Compilation Errors

Compilation errors are marked with four asterisks (****) in the compilation output of the GAMS listing file (also called output file or lst file, since it has the extension .lst), hence it is easy to detect lines where compilation errors occurred by inspection.

Note

Compilation error messages also appear in the LOG file. And, if the GAMS IDE is used, a double-click at an error message in the LOG will navigate directly to the problematic code in the source file.

Consider the following simple example:

Set c "crops" / barley, wheat, soy, wheat, rice /

If this set statement appears in a program, the resulting compilation output will contain the following lines:

1 Set c "crops" / barley, wheat, soy, wheat, rice /
   **** $172

Error Messages

172 Element is redefined

Note that in the echo print of the input file a line starting with **** is inserted and the dollar sign $ followed by a number appears on this line. This indicates that a compilation error - in this case error 172 - was discovered in the line above. In addition, a list of all errors with explanatory error messages is given at the end of the echo print.

In our example, the error refers to wheat and the error message addresses the cause of the error: the respective element is redefined. Thus we check the other elements of the set and quickly realize that wheat appears a second time. If we delete the second instance of wheat and run the code again, this line will not cause any errors anymore. Note that many compilation errors are as easy to fix as demonstrated here.

4.14.1.2 Repositioning Compilation Error Messages

By default, the error messages are listed at the end of the echo print. GAMS allows to customize this position with the command line parameter ErrMsg: the value of 1 for ErrMsg will move the error messages directly beneath the line where the respective error is marked and the value of 2 will suppress the error messages in the lst file completely. Note that the default is 0.

Consider the following simple example.

Set a / a1 * a7 /
Set b(a) / a7 * a9 /
Parameter p(k) / i3 47 /

The resulting compilation output will contain the following lines:
4.14 Fixing Compilation Errors

1 Set a / a1 * a7 /;
2 Set b(a) / a7 * a9 /;
**** $170
3 Parameter p(k) / i3 47 /;
**** $120
...

Error Messages

120 Unknown identifier entered as set
170 Domain violation for element

Next, we run the same code with the following call:

> gams test ErrMsg=1

The resulting compilation output follows.

1 Set a / a1 * a7 /;
2 Set b(a) / a7 * a9 /;
**** $170
**** 170 Domain violation for element
3 Parameter p(k) / i3 47 /;
**** $120
**** 120 Unknown identifier entered as set

Observe that the error messages are now placed on the line after the error is marked. This can be especially useful if the program contains many lines of code.

Note

Users may change the system level defaults by entering the line ErrMsg=1 in the file.gmsprmnt.txt on Windows, or.gmsprmun.txt on Unix machines as in the following example:

******************************************************************************
* GAMS 2.50 Default Parameterfile for Windows NT                      *
* Gams Development Corp.                                              *
* Date : 20 Mar, 1998                                                 *
******************************************************************************
* entries required by CMEX, put in by gams.exe:                       *
* SYSDIR                                                             *
* SCRDIR                                                             *
* SCRIPTNEXT                                                         *
* INPUT                                                              *
errmsg=1

4.14.2 Resolving Common Compilation Errors

There are hundreds of compilation errors in GAMS, but some of them are particularly frequent. In the table below we present these common errors, with a brief description of the possible cause and a link to a subsection below where examples and more details are given. We recommend that users also read the error messages, since they often contain additional hints.
<table>
<thead>
<tr>
<th>GAMS Error</th>

4.14.2.1 Error A: Misplaced Semicolons

Maybe the most common error for new users is related to semicolons. Consider the following example adapted from the well-known transportation model [TRNSPORT]:

Sets i "canning plants" / Seattle, San-Diego / ;
   j "markets" / New-York, Chicago, Topeka / ;

The resulting compilation output will contain the following lines:

```
20  Sets i  canning plants  / Seattle, San-Diego / ;
21   j  markets  / New-York, Chicago, Topeka / ;
****  $140  $36
...
```

Error Messages

36 '=' or '..' or ':=' or '$=' operator expected
   rest of statement ignored
140 Unknown symbol

What went wrong? GAMS statements like the set statement in our example have to terminate with a semicolon, unless the next line of code begins with a reserved word. Now, set statements may extend over several lines and define several sets. In our example, the set statement extends over two lines and two sets are declared. However, there is a semicolon at the end of the first line, therefore GAMS assumes that the set statement ends there. The symbol j at the beginning of the next line has not been declared yet and it is not a GAMS keyword, thus it is marked as Unknown symbol. Note that error 36 is a consequential error that will disappear as soon as the first error has been resolved.

How do we fix this? There are two ways: either we could drop the semicolon at the end of the first line and thus indicate that the set statement continues to the second line or we could insert the keyword Set at the start of the second line and thus introduce a new set statement. These two alternatives are illustrated below:

Sets i "canning plants" / Seattle, San-Diego / ;
   j "markets" / New-York, Chicago, Topeka / ;

or

Sets i "canning plants" / Seattle, San-Diego / ;
Set j "markets" / New-York, Chicago, Topeka / ;

Note

- In general, GAMS statements have to be terminated with a semicolon. The semicolon may be omitted if the next line starts with a GAMS keyword.
- Even if it is not required, it is good practice to always end a statement with a semicolon.
4.14.2.2 Error B: Missing Semicolons

Consider the following example adapted from the well-known transportation model [TRNSPORT]:

Equations
  cost       "define objective function"
  supply(i)  "observe supply limit at plant i"
  demand(j)  "satisfy demand at market j"

  cost ..   z =e=  sum((i,j), c(i,j)*x(i,j)) ;

The resulting compilation output will contain the following lines:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>52</td>
<td>Equations</td>
</tr>
<tr>
<td>53</td>
<td>cost define objective function</td>
</tr>
<tr>
<td>54</td>
<td>supply(i) observe supply limit at plant i</td>
</tr>
<tr>
<td>55</td>
<td>demand(j) satisfy demand at market j</td>
</tr>
<tr>
<td>56</td>
<td></td>
</tr>
<tr>
<td>57</td>
<td>cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;</td>
</tr>
</tbody>
</table>

**** $97 $195,96,195,96 $195,96
...

Error Messages

96 Blank needed between identifier and text
(-or- illegal character in identifier)
(-or- check for missing ';' on previous line)

97 Explanatory text can not start with '$', '=' or '..'
(-or- check for missing ';' on previous line)

What went wrong? GAMS statements like the equation declaration in our example have to terminate with a semicolon, unless the next line of code begins with a GAMS keyword. In our example, we omitted the semicolon at the end of the equation declaration statement and started a new statement after a blank line.

How do we fix this? We simply add a semicolon after the last explanatory text at the end of the equation declaration statement.

Note

A missing semicolon is often associated with error 96 or 97.

4.14.2.3 Error C: Spelling Mistakes

This error occurs if sets, set elements, parameters, etc. are referenced with a different name than the name they were declared with. Note that differences in capitalization are not considered spelling mistakes since GAMS is case insensitive.

Consider the following example adapted from the well-known transportation model [TRNSPORT]:

---
Sets i "canning plants" / Seattle, San-Diego /  
   j "markets" / New-York, Chicago, Topeka / ;

Parameters a(i) "capacity of plant i in cases"  
   / Seatle 350  
       san-diego 600 / ;

Equations  
  cost "define objective function"  
  supply(i) "observe supply limit at plant i"  
  demand(j) "satisfy demand at market j" ;

cst .. z =e= sum((i,j), c(i,j)*x(i,j)) ;

The resulting compilation output will contain the following lines:

20 Sets i canning plants / Seattle, San-Diego /  
21   j markets / New-York, Chicago, Topeka / ;
22
23 Parameters a(i) capacity of plant i in cases  
24  / Seatle 350  
**** $170  
25 san-diego 600 / ;
...
49 Equations  
50 cost define objective function  
51 supply(i) observe supply limit at plant i  
52 demand(j) satisfy demand at market j ;
53
54 cst .. z =e= sum((i,j), c(i,j)*x(i,j)) ;
**** $140  
...
Error Messages

140 Unknown symbol
...
170 Domain violation for element

What went wrong? Note that in line 24 the set element Seattle was referenced as Seatle. GAMS does not recognize this symbol as an element of the set i and thus marks this with error 170: Domain violation. GAMS catches this error since it automatically performs domain checking. The typo in line 54, where the equation cost is referenced as cst, is marked with error 140 (Unknown symbol), since cst was not declared before.

Note

Set name misspellings are associated with error 120, set element misspellings with 170 and other misspellings with 140.

Fixing errors like these is as easy as fixing typos.
4.14.2.4 Error D: Missing Set Elements

Sometimes users forget to include an element in a set statement, but reference it later. Consider the following simple example:

```
Set       c "crops"       / barley, wheat, soy /;
Parameter d(c) "demand in metric tons" / rice 3, barley 1, wheat 4, soy 2 /;
```

The resulting compilation output will contain the following lines:

```
1 Set       c "crops"       / barley, wheat, soy /;
2 Parameter d(c) "demand in metric tons" / rice 3, barley 1, wheat 4, soy 2 /;
**** $170
...
Error Messages

170 Domain violation for element
```

What went wrong? Note that the symbol *rice* was not defined as an element of the set *c*, thus GAMS does not recognize it and marks it with error 170: *Domain violation*. GAMS catches this error since it automatically performs *domain checking*.

Note

If symbols are not defined as set elements, but are referenced as if they belong to the set later, error 170 will occur.

This is easy to fix: we just add the missing element(s) to the elements of the respective set.

4.14.2.5 Error E: Problems with Indices

Recall that variables, sets, parameters and equation may be defined over one or more indices. If the identifiers are referenced later in the program, the indices must appear exactly in the order that was specified in the respective definition statement. Consider the following example adapted from the well-known transportation model [TRNSPORT]:

```
Sets i "canning plants" / seattle, san-diego /
     j "markets"       / new-york, chicago, topeka / ;
Table d(i,j) "distance in thousands of miles"
        new-york  chicago  topeka
seattle   2.5      1.7      1.8
san-diego  2.5      1.8      1.4   ;
Scalar f "freight in dollars per case per thousand miles" /90/ ;
Parameter c(i,j) "transport cost in thousands of dollars per case";
c(i,j,j) = f * d(j,i) / 1000 ;
```

The resulting compilation output will contain the following lines:
4.14 Fixing Compilation Errors

Parameter \( c(i,j) \) transport cost in thousands of dollars per case;
\[ c(i,j,j) = f \times d(j,i) / 1000; \]

Error Messages

148 Dimension different - The symbol is referenced with more/less indices as declared
171 Domain violation for set

What went wrong? Note that the parameter \( c \) was declared over two indices, but in the assignment statement in line 41 it is referenced with three indices. Such a mistake is marked with error 148. Note further, that the indices of \( d \) are referenced in the wrong order, which is marked with error 171.

Note

If an identifier is referenced with more or less indices as declared, then the error 148 will be triggered.
If the indices are in the wrong order, the error 171 will be triggered.

This is easy to fix: we just check the declaration or definition statement(s) and adjust the reference.

Observe that the domain error 171 is also triggered if an identifier is referenced with index say \( i \), but was defined over say \( j \). However, there will be no domain error if \( i \) is a subset of \( j \) or \( i \) and \( j \) reference the same set since they are aliases.

4.14.2.6 Error F: Summing over Sets that are Already Indexed

Consider the following equation definition that is adapted from the well-known transportation model [TRNSPORT]:

\[
supply(i) .. \sum((i,j), x(i,j)) =l= a(i); \]

The resulting compilation output will contain the following lines:

59 \[ supply(i) .. \sum((i,j), x(i,j)) =l= a(i); \]

Error Messages

125 Set is under control already

What went wrong? Note that the equation is indexed over the set \( i \), therefore the indexed operation \( \sum \) in the body of the equation may not be controlled by the index \( i \) again.

Note

Summing over sets that are already indexed will trigger error 125.

How do we fix this? We need to carefully check the indexed operation and drop the surplus index. In other cases the controlling index may have to be dropped from the equation name. Note that an error like this is often indicative of a lack of clarity in thinking.
4.14.2.7 Error G: Uncontrolled Sets

Consider the following equation definition that is adapted from the well-known transportation model [TRNSPORT]:

\[
\text{demand .. } \sum(i, x(i,j)) \geq b(j) \ ;
\]

The resulting compilation output will contain the following lines:

```
61 demand .. sum(i, x(i,j)) =g= b(j) ;
**** $149 $149
...
```

Error Messages

149 Uncontrolled set entered as constant

What went wrong? Note that the variable \(x\) is indexed over the sets \(i\) and \(j\), but, while \(i\) is the index of the indexed operation \(\text{sum}\), \(j\) is "free": it does neither appear as index of the equation nor as controlling index in \(\text{sum}\). Therefore it was entered as if it were a constant. Note further, that \(j\) is also used as an index on the right-hand side of the equation without being controlled.

Note

Error 149 marks instances when an index is not controlled in the context of an equation or an indexed operation like \(\text{sum}\) or \(\text{prod}\).

How do we fix this? We have to think what we actually want to model. In this case we need to enter \(j\) as a controlling index for the equation. But it would also be possible to add it as a controlling index for \(\text{sum}\) (but not both!). In the latter case there would still be the error on the right-hand side which needed to be taken care of with another indexed operation, e.g., \(\text{sum}\) again. Both approaches would remove the compilation error, but one has to think about what actually should be modeled to decide which is the right fix here.

4.14.2.8 Error H: Mismatched Parentheses

Consider the following two equations adapted from the model [CHENERY]:

\[
\text{mb}(i) \cdot x(i) = g = y(i) + \sum(j, aio(i,j) \cdot x(j)) + (e(i) - m(i)) \cdot t(i) ;
\]

...  
\[
\text{dvv}(i) \cdot (\text{sig}(i) < 0) \cdot \text{v}(i) = e = (\pi \cdot (1 - \text{del}(i)) / \text{del}(i)) \cdot (-\rho(i) / (1 + \rho(i))) ;
\]

The resulting compilation output will contain the following lines:

```
137 mb(i) .. x(i) =e= y(i) + sum(j, aio(i,j)*x(j)) + ( e(i) - m(i) )*$t(i) ;
**** $408,409
...
155 dvv(i)$(sig(i) <> 0).. vv(i) =e= (pi*(1-del(i))/del(i))**(-rho(i)/(1+rho(i))) ;
**** $8
...
```

Error Messages

8 ')' expected
...
408 Too many ),] or }
409 Unrecognizable item - skip to find a new statement looking for a ';' or a key word to get started again
What went wrong? Note that in the first equation we have one surplus closing parenthesis, this is marked with error 408. The error marked with 409 is a consequential error, it will disappear once the first error has been fixed. In the second equation, one closing parenthesis is missing resulting in error 8.

Attention

Opening and closing parentheses ( ), square brackets [ ] and braces (curly brackets) { } must match.

Note

Surplus closing parentheses, bracketes and braces are marked with error 408 and missing closing parenthesis, brackets and braces are marked with error 8. Missing opening parentheses, brackets and braces may result in GAMS marking surplus closing parentheses, brackets and braces; surplus opening parentheses, brackets and braces may result in GAMS marking missing closing parentheses, brackets and braces.

While fixing errors like these entails carefully counting opening and closing parentheses, there are strategies that help to prevent mismatching parentheses errors. Many text editors (like the GAMS IDE) offer a feature that identifies matching parentheses and will issue a warning if there is a mismatch. We recommend to use this feature. Further, we recommend to also use the alternatives to parentheses: square brackets and braces. They are especially useful if there are several opening parentheses since it is easier to determine by inspection if each has a matching closing symbol.

4.14.2.9 Error I: Mistakes Relating to Equations

Recall that each declared equation must be defined if it is to be used in a model statement. If the equation definition is missing, GAMS will mark an error beneath the solve statement that refers to a model which references the respective undefined equation. Consider the following example adapted from the well-known transportation model [TRNSPORT]:

Equations

\begin{align*}
\text{cost} & \quad \text{"define objective function"} \\
\text{supply}(i) & \quad \text{"observe supply limit at plant i"} \\
\text{demand}(j) & \quad \text{"satisfy demand at market j"} \\
\end{align*}

\begin{align*}
\text{cost} .. & \quad z =e= \sum((i,j), c(i,j)*x(i,j)) \\
\text{supply}(i) .. & \quad \sum(j, x(i,j)) =l= a(i) \\
\end{align*}

Model transport /all/ \\
solve transport using lp minimizing z \\

The resulting compilation output will contain the following lines:

60 Model transport /all/ \\
61 solve transport using lp minimizing z \\
**** $71,256 \\
**** The following LP errors were detected in model transport: \\
**** 71 demand is an undefined equation \\
... \\
Error Messages

71 The symbol shown has been declared as an equation, but no
  Symbolic equation (..) was found. hint - look for commas in the
  Documentation text for the equations. use quotes around the
  Text or eliminate the commas.
256 Error(s) in analyzing solve statement. More detail appears
  Below the solve statement above
What went wrong? Note that the equation demand was declared and included in the model transport, but it was not defined. GAMS detects that the equation definition is missing when it compiles the solve statement that relates to the model transport. Therefore the error 71 appears only there. The error 256 is a consequential error, it will disappear once the missing equation definition has been added (before the solve statement).

Note

Error 71 marks a missing equation definition. The message associated with this error is a nice example of an error message that is very descriptive and offers advice on how to fix the error.

Apart from forgetting to define a declared equation and forgetting to terminate the equation definition statement with a semicolon (see above), two other mistakes relating to equations are frequent: omitting the syntax element .. after the name of the equation and not properly defining the equation type in the equation definition statement. The following simple example adapted from the portfolio analysis model [ALAN] illustrates these mistakes:

\[
\begin{align*}
\text{fsum} \sum(i, x(i)) & =e= 1.0; \\
\text{dmean..} \sum(i, \text{mean}(i)*x(i)) & = \text{target};
\end{align*}
\]

The resulting compilation output will contain the following lines:

\[
\begin{align*}
45 & \text{fsum } \sum(i, x(i)) & =e= 1.0; \\
**** & $36 \\
46 & \text{dmean.. } \sum(i, \text{mean}(i)*x(i)) & = \text{target}; \\
**** & $37 \\
...
\end{align*}
\]

```
 Error Messages
36 '=' or '..' or ':=' or '$=' operator expected
   rest of statement ignored
37 '='=l=' or '='e=' or '='g=' operator expected
```

What went wrong? Note that in the first equation the two dots .. are missing, which is marked with error 36, and in the second equation the equation type is not properly specified, which leads to error 37.

4.14.2.10 Error J: Issues with Nonlinear Expressions

The compilation error messages 51 to 60 refer to issues with nonlinear expressions involving variables in equations. For example, nonlinear expressions in an LP model will cause errors of this sort. So will discontinuous functions with endogenous arguments in an NLP model. For information on endogenous arguments in functions, see section Functions in Equation Definitions. For an overview of GAMS model types, see section Classification of Models.

Consider the following simple artificial example:

```
Variables x, y, z;
Equations eq1, eq2;

eq1.. x**2 - y =e= z ;
eq2.. min(x,y) =l= 20 ;

Model silly / all /;
solve silly using lp maximizing z ;
```
The resulting compilation output will contain the following lines:

```
7  Model silly / all /;
8  solve silly using lp maximizing z;
**** $54,51,256
**** The following LP errors were detected in model silly:
**** 54 equation eq1.. VAR operands for **
**** 51 equation eq2.. the function MIN is called with non-constant arguments
```

**Error Messages**

51 Endogenous function argument(s) not allowed in linear models
54 Endogenous operands for ** not allowed in linear models
256 Error(s) in analyzing solve statement. More detail appears
Below the solve statement above

Note that error 54 marks the nonlinear expression $x^2$ in a linear model and error 51 refers to the discontinuous function $\min$ that may be used with variables only in models of the type DNLP. The error 256 is a consequence of the two previous errors.

### 4.14.2.11 Error K: Using Undefined Data

Referencing data items that were not declared with a scalar, parameter or table statement will cause error 140: GAMS will indicate that the respective symbol is unknown. More often data items are declared, but not defined, i.e. they are not initialized with values.

Consider the following example adapted from the well-known transportation model [TRNSPORT]. Assume that the scalar $f$ is declared, but has no numerical value. The resulting compilation output will contain the following lines:

```
40  Scalar f freight in dollars per case per thousand miles;
41
42  Parameter c(i,j) transport cost in thousands of dollars per case;
43
44   c(i,j) = f * d(i,j) / 1000;
**** $141
...
61  Model transport /all/;
62  solve transport using lp minimizing z;
**** $257
63
64  display x.l, x.m;
**** $141
...
```

**Error Messages**

141 Symbol declared but no values have been assigned. Check for missing data definition, assignment, data loading or implicit assignment via a solve statement.
A wild shot: You may have spurious commas in the explanatory text of a declaration. Check symbol reference list.
257 Solve statement not checked because of previous errors
What went wrong? Note that the scalar $f$ was declared, but there was no value assigned to it. Thus, when it is referenced in the calculation in line 44, the "empty" scalar causes error 141. Error 257 is a consequential error and leads to the second error 141. This error occurs in the context of variable attributes in the display statement. Recall that variable attributes are data associated with variables. As the solve statement could not be checked, the level and marginal values of the variable $x$ are not defined and hence error 141 follows.

Note

Error 141 marks places where data items, that have not been defined, are referenced in computations in the context of assignment statements. It also marks places where undefined variable (or equation) attributes are referenced.

In addition, undefined data items may be referenced in the context of equation definitions. Suppose we declare the parameter $c$ in model [TRANSPORT], but forget the corresponding assignment statement. Then the compilation output will contain the following lines:

57    cost ..      z =e=  sum((i,j), c(i,j)* x(i,j)) ;
...  
62    solve transport using lp minimizing z ;
**** $66,256
**** The following LP errors were detected in model transport:
**** 66 equation cost.. symbol "c" has no values assigned
...

Error Messages

66 The symbol shown has not been defined or assigned
A wild shot: You may have spurious commas in the explanatory text of a declaration. Check symbol reference list.
256 Error(s) in analyzing solve statement. More detail appears
Below the solve statement above

Note that the missing data in the body of the equation cost is marked with error 66 and the following error is a consequential error which will disappear once 66 has been fixed.

Note

Referencing undefined data items in the body of an equation causes error 66.

4.14.2.12 Error L: Referencing Set Elements Without Quotes

Recall that if set elements are referenced, they need to appear in single or double quotes. Omitting the quotes may cause different errors depending on the context. The following example is adapted from the well-known transportation model [TRANSPORT]. Suppose we start by defining the two sets and the two parameters and then add the following statements:

Scalar s;
s = a(seattle);

The resulting compilation output will contain the following lines:
4.14 Fixing Compilation Errors

37  Scalar s;
38  s = a(seattle);
**** $120,340,149,171
...
Error Messages

120  Unknown identifier entered as set
149  Uncontrolled set entered as constant
171  Domain violation for set
340  A label/element with the same name exist. You may have forgotten
to quote a label/element reference. For example,
set i / a,b,c /; parameter x(i); x('a') = 10;

What went wrong? On the right-hand side of the assignment statement we have a reference with missing quotes. Note that this creates four (!) errors:

- 120 - GAMS expects a controlling set and Seattle is not recognized and therefore considered an unknown identifier.
- 340 - Then GAMS realizes that actually there is a label called Seattle in the program and helpfully offers a hint: You may have forgotten to quote a label/element reference.
- 149 - See section Error G: Uncontrolled Sets above.
- 171 - See section Error E: Problems with Indices above.

This is a nice example for one mistake triggering several errors that may look daunting. However, fixing them is as easy as adding single or double quotes.

4.14.2.13 Error M: Missing Declaration Statements

Recall that sets, parameters, variables and equations have to be declared before they may be used in definition or assignment statements. Suppose the equation demand in the well-known transportation model [TRNSPORT] was defined but not declared. Then the compilation output would contain the following lines:

59  demand(j) .. sum(i, x(i,j)) =g= b(j) ;
**** $140
...
Error Messages

140  Unknown symbol

Note that as demand was not declared, GAMS does not recognize it and therefore marks it with error 140: Unknown symbol.

Note

If error 140 is reported, the respective declaration statement is probably missing. However, the underlying cause may also be a simple typo.
4.14.2.14 Error N: Using the Same Name for Different Identifiers

Recall that each GAMS identifier must have a unique name. If the same name is used more than once, an error will be triggered. Consider the following modification of the transportation model [TRNSPORT]:

Parameters  capacity(i)  "capacity of plant i in cases"
            / Seattle 350, San-Diego 600 /
            demand(j)  "demand at market j in cases"
            / New-York 325, Chicago 300, Topeka 275 /;

Equations  cost "define objective function"
           supply(i) "observe supply limit at plant i"
           demand(j) "satisfy demand at market j" ;

The resulting compilation output will contain the following lines:

47 Equations
48   cost define objective function
49   supply(i) observe supply limit at plant i
50   demand(j) satisfy demand at market j ;

**** $195
...

Error Messages

195 Symbol redefined with a different type

What went wrong? Note that demand was first declared as a parameter and later as an equation. GAMS will mark this repeated use of the same name with error 195.

4.14.2.15 Error O: Using ORD with an Unordered Set

Recall that the operation ord is only defined for ordered sets. If ord is used with an unordered set, error 198 will be triggered.

Consider the following example:

Set   a  "a couple of the elements" / r2, r3 /;
Set   b  "more elements" / r1*r4 /
Scalar c  "counter" / 0 /;

loop( b $ (ord(b) > 3),
     c = c + 1 );
display c;

The resulting compilation output will contain the following lines:
Error Messages

198 Set used in 'ord' or lag is not ordered.
    Hint: Some of the elements of the set were used before this
    was initialized and the order was different from the order used
    in this set. Try to initialize the set earlier.
    $offOrder allows lag operations on dynamic sets, reset with
    $onOrder

What went wrong? Two elements of the set \( b \) featured already in set \( a \) that was defined before set \( b \). Therefore the order of the elements in set \( b \) is as follows:

\[ r2 \quad r3 \quad r1 \quad r4 \]

Obviously, this set is not ordered and hence GAMS marks error 198 when the operator \( \text{ord} \) is applied to it.

How do we fix this? In this case it is easy: we just define the set \( b \) before set \( a \) and \( b \) will be an ordered set.

Consider one last example:

```
Set a "all elements" / r1*r10 /;
Set b "elements in different order" / r3, r1, r4, r7 /;
Scalar c "counter" / 0 /;
```

```
loop( b $ (ord(b) > 3),
    c = c + 1 );
display c;
```

The resulting compilation output will contain the following lines:

```
5 loop( b $ (ord(b) > 3),
   **** $198
6 c = c + 1 );
```

What went wrong? Note that even though all elements in set \( b \) are also elements of set \( a \), they are not specified in the same order. Therefore the set \( b \) is unordered. For more details, see section Ordered and Unordered Sets.

4.15 Finding and Fixing Execution Errors and Performance Problems

This tutorial is structured in four main parts: we will discuss how to find and resolve errors that are detected during execution of a GAMS model, we will give some guidance for model development and debugging and we will present techniques to increase efficiency by reducing GAMS execution time and memory use.
4.15.1 Resolving Execution Errors

Recall that GAMS passes through a program file several times in the process of generating and solving a model. Errors may occur in each phase. In this section we will give some guidance on how to resolve errors that occur during execution, so after compilation. For advice on resolving compilation errors, see the tutorial Fixing Compilation Errors. For more information on the process of generating and solving a model in GAMS, see the introduction to chapter GAMS Output.

At execution, several things could go wrong and cause an error. We will look at these potential error sources separately in this section. First we look at arithmetic errors and exceeded internal limits during data manipulation, we will continue with problems during model generation and model solution. At the end, we will briefly discuss how execution errors may be managed with the function execError.

4.15.1.1 Arithmetic Errors

GAMS execution errors may be caused by illegal arithmetic operations like a negative argument for log, division by zero and exponentiation where the base is a negative number. The following simple example serves as illustration:

```
Set   s   / s1*s5 / ;
Parameter p(s) "data to be exponentiated"
           d(s) "divisors"
           r(s) "result";
p   = 1;
p("s2") = -1;
d   = 1;
d("s3") = 0;
r   = p(s)**2.1 / d(s)
display r;
```

The first sign that something in the execution went wrong is the following flag in the log output:

```
*** Status: Execution error(s)
```

The resulting execution output will contain the following lines:

```
Execution
**** Exec Error at line 10: rPower: FUNC DOMAIN: x**y, x < 0
**** Exec Error at line 10: division by zero (0)
---- 11 PARAMETER r result
s1 1.000, s2 UNDF, s3 UNDF, s4 1.000, s5 1.000
```

Observe that the execution output begins with two error messages that can be easily found since they are marked with four asterisks ****. The error messages are very informative: they indicate the line where the errors occurred and provide details about the nature of the errors. Further, the output generated by the display statement shows that the errors occurred when the values for r("s2") and r("s3") were computed. Inspecting the assignment statement for these two values, we realize that in the first instance
the base for the exponentiation is -1, which obviously is a negative number and hence is not allowed in this operation. In the second instance, the problem is that we divide by $d("s3")$ which equals zero.

In this example, the errors are easily resolved with data revisions. In general, we recommend to use conditional assignments to prevent errors like these.

Note that in the example above the error messages indicated exactly where the problem was and it was easy to find the cause of the error. However, this is not always the case. In particular, if the problem is within a multi-dimensional item the user will need more patience. Usually it helps to display the results of the problematic operation and look for faulty entries. In addition, displaying the input data to the respective operation will help to investigate the numerical properties of the data that was entered in the computation. Often more displays will be needed to trace faulty input data through the program. Eventually this will lead the user to understand why the data has taken on the specific numerical values it has.

4.15.1.2 Exceeding GAMS Limits

By default, GAMS stops the solve of a model after 1e10 seconds (wall clock time) or 2e9 iterations. These limits may be adjusted with the options reslim and iterlim respectively. Note that both options are also available as command line parameters and model attributes. In addition, the workspace may be limited with the command line parameters WorkFactor and Workspace. Note that these options are also available as model attributes. If any of these limits are exceeded, the execution of the solve statement will be interrupted.

For example, we could add the following option statement somewhere before the solve statement in the production model [CHENERY]:

```plaintext
option iterlim = 20;
```

Note that this statement reduces the iteration limit to just 20. The log output will contain the following lines:

```
** Feasible solution. Value of objective = 1033.34069261
** The iteration limit has been reached.
--- Restarting execution
--- chenery.gms(228) 2 Mb
--- Reading solution for model chenrad
*** Status: Normal completion
--- Job chenery.gms Stop 11/21/16 16:52:43 elapsed 0:00:00.106
```

Also the solve summary in the listing file notes the interrupt:

```
SOLVE SUMMARY
MODEL       chenrad       OBJECTIVE       td
TYPE        NLP            DIRECTION       MAXIMIZE
SOLVER      CONOPT         FROM LINE       228

**** SOLVER STATUS  2 Iteration Interrupt
**** MODEL STATUS   7 Feasible Solution
**** OBJECTIVE VALUE 1058.9199
RESOURCE USAGE, LIMIT 0.078 1000.000
ITERATION COUNT, LIMIT 20 20
EVALUATION ERRORS 0 0
```
Observe that the solver status **Iteration Interrupt** indicates that the execution terminated because the iteration limit has been reached resulting in a feasible solution, but not the optimal solution. The line **ITERATION COUNT, LIMIT ...** reports that 20 iterations were performed and that 20 was also the limit for the number of iterations. Setting `iterlim` to a larger value will resolve this issue.

Similarly, allocating too little work space will cause the solver to terminate with no solution. For example, restricting the work space for the nonlinear test model [MHW4D] to just 0.1 MB and running it with the solver MINOS will produce the following lines in the log output:

```
Work space requested by solver -- 0.77 Mb
Work space requested by user -- 0.10 Mb
Work space allocated -- 0.10 Mb

EXIT - Not enough storage to solve the model.
    Request at least 0.19 Mbytes.
```

The **solve summary** in the listing file will contain the following information:

```
SOLVE SUMMARY

MODEL wright
TYPE NLP
SOLVER MINOS

**** SOLVER STATUS 9 Setup Failure
**** MODEL STATUS 13 Error No Solution
```

Note that increasing the work space to at least the minimum amount requested by the solver will resolve this issue.

When dealing with large nonlinear expressions defined over a very large domain, one can face the following error.

```
*** Status: Terminated due to limits in NLCodeAdd
*** Cannot handle more than 2147483647 instruction in NL code
*** Inspect listing file for more information
```

The first thing to check in this case is correctness of the model i.e., if you are not generating anything more than necessary. If this is not the case and the model is indeed large, a generic advise is to introduce intermediate variables to get a smaller code size per block of equations. One can also consider partitioning the domains so that one can have more number of smaller blocks.
4.15.1.3 Resolving Model Generation Errors

Further execution errors may be detected when GAMS is generating the model before passing it to the solver. These errors may be arithmetic errors in the body of equations or errors in the structure of the model that cause the model to be inherently infeasible.

Consider the following simple example with arithmetic errors in the body of the equations. They are similar to the errors in the assignment in the example in section Arithmetic Errors above.

```
Set s / s1*s5 / ;
Parameter p(s) "data to be exponentiated"
    d(s) "divisors"
    m(s) "multipliers";
p(s) = 1;
p("s2") = -1;
d(s) = 1;
d("s3") = 0;
m(s) = 1;
m("s4") = 0;
Positive variable x(s);
Variable z;
Equations obj "objective function"
    xlim;
    obj.. z =e= sum(s,p(s)**2.2*x(s));
    xlim(s).. m(s) / d(s)*x(s) =e= 1;
Model mymodel / all /;
solve mymodel using lp maximizing z;
```

If we run this model, the log output will contain the following lines:

```
*** SOLVE aborted
--- Executing CPLEX: elapsed 0:00:00.006
--- test.gms(23) 4 Mb 3 Errors
*** Status: Execution error(s)
--- Job test.gms Stop 11/21/16 19:10:12 elapsed 0:00:00.006
```

Observe that the solve was aborted since there are 3 execution errors. The equation listing in the listing file will contain further details about these execution errors:

```
Equation Listing  SOLVE mymodel Using LP From line 23

**** Exec Error at line 19: rPower: FUNC DOMAIN: x**y, x < 0
---- obj =E= objective function
obj.. - x(s1) + UNDF*x(s2) - x(s3) - x(s4) - x(s5) + z =E= UNDF ; (LHS = UNDF)

**** Exec Error at line 20: division by zero (0)
**** Exec Error at line 20: Equation infeasible due to rhs value
```
Note that there is an arithmetic error relating to exponentiation in the first equation and an arithmetic error and an infeasibility in the second equation.

In our example, it was easy to detect the execution errors and their cause. However, an error in a multi-dimensional equation block may be much more difficult to find. Note that by default, only the first three entries in each equation block are shown in the equation listing. We recommend to use the option limrow to get a full listing, as this is the easiest way to inspect execution errors in the body of equations.

4.15.1.4 Resolving Solve Errors

In the solution phase, an external solver program processes the model and creates output with details about the solution process. Solve errors may be either function evaluation errors or presolve errors.

4.15.1.4.1 Resolving Function Evaluation Errors

Some solve statements require the evaluation of nonlinear functions and the computation of derivatives. Since these calculations are not carried out by GAMS but by other subsystems not under the direct control of GAMS, errors associated with these calculations are reported in the solution report.

Function evaluation errors are numerical errors like those discussed in section Arithmetic Errors above. Other examples include square roots of negative variables and squaring a negative term, say $x$, using the syntax $x^{2}$.

Attention

Squaring a negative term, say $x$, using the syntax $x^{2}$ will cause an error. However, the alternatives $\text{sqr}(x)$ and $x\times x$ will work (see here for an explanation).

Note that by default the solver subsystems will interrupt the solution process if arithmetic errors are encountered. Users may wish to permit a certain number of arithmetic errors and have reported error warnings instead. The option domlim facilitates this modification. Note that the default value for domlim is zero.

The best way to avoid evaluating functions outside their domain of definition is to specify reasonable variable bounds. However, there are cases when bounds are not enough. Consider the following simple example:

```
Set i / i1*i5 /;
Variables x(i), z;
Equations r1, r2(i);

r1.. z =e= log(sum(i, x(i)));
r2(i).. x(i) =l= 10;
x.lo(i) = 0;
x.l(i) = 5;

Model takelog / all /;
solve takelog using nlp minimizing z;
```
If we try to solve this little program with the solver MINOS, the log output will contain the following line:

EXIT - Function evaluation error limit exceeded.

The solution report in the listing file will have more detailed information:

```
SOLVE SUMMARY
MODEL takelog OBJECTIVE z
TYPE NLP DIRECTION MINIMIZE
SOLVER MINOS FROM LINE 12

**** SOLVER STATUS 5 Evaluation Interrupt
**** MODEL STATUS 7 Feasible Solution
**** OBJECTIVE VALUE 0.0000

RESOURCE USAGE, LIMIT 0.183 1000.000
ITERATION COUNT, LIMIT 0 2000000000
EVALUATION ERRORS 2 0

... EXIT - Function evaluation error limit exceeded.

**** ERRORS/WARNINGS IN EQUATION r1
 2 error(s): log: FUNC DOMAIN: x < 0 (RETURNED 0)

... **** REPORT SUMMARY : 1 NONOPT ( NOPT)
0 INFEASIBLE
0 UNBOUNDED
1 ERRORS ( ****)
```

Note that the solver status has a value of 5 (Evaluation Interrupt), which means that the solver has been interrupted as more evaluation errors have been encountered than specified with the option domlim. In our case domlim equals its default value zero, thus one error is enough to cause the interruption. The equation in which the evaluation error occurred and the type of error is reported a few lines later. In our example, the equation r1 is problematic, since we take the logarithm of the expression \( \sum(i, x(i)) \), an expression which may become zero.

Note that in models such as this each individual variable \( x(i) \) should be allowed to become zero, but the sum should not. This may be achieved by introducing an intermediate variable, say \( xsum \), adding a lower bound greater than zero for it and using this variable as the argument for the function \( \log \):

```
Variable xsum;
xsum.lo = 0.0001;

Equations defxsum, r1;
defxsum ..     xsum =e=  \sum(i, x(i));
r1..          z =e= \log(xsum);
```
For more information on intermediate variables, see section *Avoiding Expressions in Nonlinear Functions* in the tutorial *Good NLP Formulations*.

Observe that solvers report the type of arithmetic problem encountered and the problematic equation, but do not identify the particular offending variable or the labels in the index of an equation that cause the error. If the cause is not obvious, users will have to investigate the numerical properties of the variables, labels and parameters in the body of the respective equation. This may involve the following:

- Displaying the input data items to the nonlinear terms in the respective equation.
- Searching the solution for equations that are infeasible (INFES) and variables that are nonoptimal (NOPT) in order to see where problems are present and which variables were being manipulated at the end of the run.
- Investigating variables and equations whose level values are zero, negative or very large at the end of the run.
- Deactivating part of the code to narrow down the problem as discussed in section *Isolating Terms in Slow Statements* below.

Resolving function evaluation errors will usually entail the following techniques:

- Adding lower bounds to variables to keep them above zero.
- Adding upper bounds to variables to prevent them from getting too large.
- Reformulating the model, for example, introducing intermediate variables.
- Providing better starting points that direct the solver search to a more relevant region. See section *Specifying Initial Values* in tutorial *Good NLP Formulations* for details.
- Fixing faulty input data.

### 4.15.1.4.2 Presolve Errors

Some solvers use a pre-processing step where the program is presolved to make the main solution process faster. During this step model errors could already be discovered, as in the following example:

```plaintext
Variables    z;
Integer Variables y1,y2;
Equations    r1,r2,r3,r4;
    r1..  z=e=y1+y2;
    r2..  y1=g=0.10;
    r3..  y2=g=0.10;
    r4..  y1+y2=l=1;
Model badpresol /all/;
solve badpresol using mip maximizing z;
```

For this problem, Cplex detects in the presolve already, that there is no feasible integer solution. This is reported in the log:
Row 'r4' infeasible, all entries at implied bounds.
Presolve time = 0.00 sec. (0.00 ticks)

... 

CPLEX Error 1217: No solution exists.
Problem is integer infeasible.

Here, Cplex makes it clear, where we have a problem: Row r4 is infeasible, because all entries are at their
"implied bounds". Lets look at r2 and r3 to see what this means: These equations set a lower bound
of 0.1 for y1 and y2. Since both variables are defined as Integer Variables, they get an implicit lower
bound of 1. Given that, equation r4 must be infeasible.

4.15.1.4.3 Solver Specific Limits  Many solvers have internal limits that may be exceeded and may
cause the listing file to report an execution error. These errors may be resolved by using either GAMS
options or solver specific options to increase the respective limits. Usually, the listing file will contain
information about which options to use. Note that the solver manuals distributed with GAMS list the
options that may be specified for each solver. For example, to relax the MINOS major iteration limit, the
user may create a file named minos.opt with the following line:

Major iterations 1000

More about solver option files can be found in section The Solver Options File.

4.15.1.5 Managing Execution Errors with the Function execError

The function execError facilitates implementing procedures that manage execution errors. Consider the
following example, which is an extension of the example in section Arithmetic Errors above.

Set s / s1*s5 / ;
Parameter p(s) "data to be exponentiated"
   d(s) "divisors"
   r(s) "result";

   p(s) = 1;
p("s2") = -1;
d(s) = 1;
d("s3") = 0;
r(s) = p(s)**2.1 / d(s)
display r;

*cause z to be undefined
Scalar z;
z = 1/0;

if(execError > 0,
   r(s)$(r(s) = z) = 0;);
display r;

Observe that we introduced a new scalar z that is deliberately undefined. In the if statement that follows, we
use the function execError in the logical condition and the undefined scalar in the conditional assignment.
The if statement has the effect that undefined entries are removed from the array of the parameter r, as
illustrated in the following lines of the execution output:
Execution

**** Exec Error at line 10: rPower: FUNC DOMAIN: x**y, x < 0
**** Exec Error at line 10: division by zero (0)

----   11 PARAMETER r result
s1  1.000,  s2 UNDF,  s3 UNDF,  s4  1.000,  s5  1.000

**** Exec Error at line 16: division by zero (0)

----  20 PARAMETER r result
s1  1.000,  s4  1.000,  s5  1.000

In addition, the function execError may be used to reset the count of the number of execution errors. Typically, it is reset to zero so that GAMS will terminate with the status message Normal completion. For example, we could add the following line at the end of the code in the example above:

execError = 0;

Note

Setting execError = 0; will not only result in a normal completion in the example above. A solve statement will not be executed if there were execution errors before by default. Setting execError = 0; before the solve statement, will allow to execute it again.

Setting execError = 0; results also in a notification in the log:

*****************************************************
*** Errors have been cleared ***
*****************************************************
*** Status: Normal completion

4.15.2 Small to Large: Aid in Development and Debugging

Many GAMS users are overly impressed with how easily GAMS handles large models. Modelers often feel such a facility means they should always work on the full model. The result is often a large, sometimes extremely large, model in the early stages of model development. Debugging such large formulations is not easy.

The algebraic modeling style employed in GAMS is inherently expandable. This offers interesting possibilities in terms of the strategy that may be employed for model development and debugging which are discussed herein.
4.15 Finding and Fixing Execution Errors and Performance Problems

4.15.2.1 An Illustrative Example

The set based algebraic modeling style implemented in GAMS is by its very nature easy to expand. It is easy to use the same model formulation on differently sized data sets. We will illustrate this based on the transportation model [TRNSPORT]. Note that we included some post-solution calculations at the end.

* Data section
Sets i "canning plants" / Seattle, San-Diego /
   j "markets" / New-York, Chicago, Topeka / ;

Parameters a(i) "capacity of plant i in cases"
   / Seattle 350, San-Diego 600 /
   b(j) "demand at market j in cases"
   / New-York 325, Chicago 300, Topeka 275 / ;

Table d(i,j) "distance in thousands of miles"
    New-York   Chicago  Topeka
Seattle     2.5      1.7     1.8
San-Diego   2.5      1.8     1.4

Scalar f "freight in dollars per case per thousand miles" / 90 / ;

Parameter c(i,j) "transport cost in thousands of dollars per case"
   c(i,j) = f * d(i,j) / 1000 ;

* Model Section
Positive Variable x(i,j) "shipment quantities in cases"
Variable z "total transportation costs in thousands of dollars"

Equations cost "define objective function"
   supply(i) "observe supply limit at plant i"
   demand(j) "satisfy demand at market j"

   cost .. z =e= sum((i,j), c(i,j) * x(i,j)) ;
   supply(i) .. sum(j, x(i,j)) =l= a(i) ;
   demand(j) .. sum(i, x(i,j)) =g= b(j) ;

Model transport /all/ ;
solve transport using lp minimizing z ;

Parameter m(*,*) "commodity movement";
   m(i,j) = x.l(i,j);
   m("total",j) = sum(i, x.l(i,j));
   m(i,"total") = sum(j, x.l(i,j));
   m("total","total") = sum(j, m("total",j));
option decimals = 0;
display m;

This model may be easily extended by adding more data:

* Data section
Sets i "canning plants" / Seattle, San-Diego, Baltimore, Dallas /
   j "markets" / New-York, Chicago, Topeka, Boston, Miami /;
Parameters  

a(i) "capacity of plant i in cases"
/ Seattle 350, San-Diego 600, Baltimore 450, Dallas 750 /

b(j) "demand at market j in cases"
/ New-York 325, Chicago 300, Topeka 275, Boston 330, Miami 290 /;

Table  
d(i,j) "distance in thousands of miles"

<table>
<thead>
<tr>
<th></th>
<th>New-York</th>
<th>Chicago</th>
<th>Topeka</th>
<th>Boston</th>
<th>Miami</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
<td>3.1</td>
<td>3.3</td>
</tr>
<tr>
<td>San-Diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
<td>3.0</td>
<td>2.7</td>
</tr>
<tr>
<td>Baltimore</td>
<td>0.2</td>
<td>0.7</td>
<td>1.8</td>
<td>0.4</td>
<td>1.1</td>
</tr>
<tr>
<td>Dallas</td>
<td>1.5</td>
<td>0.9</td>
<td>0.5</td>
<td>1.8</td>
<td>1.3</td>
</tr>
</tbody>
</table>

Scalar f "freight in dollars per case per thousand miles" /90/;

Parameter  
c(i,j) "transport cost in thousands of dollars per case";
c(i,j) = f * d(i,j) / 1000;

* Model Section

Positive Variable  
x(i,j) "shipment quantities in cases";

Variable  
z "total transportation costs in thousands of dollars";

Equations  
cost "define objective function"
supply(i) "observe supply limit at plant i"
demand(j) "satisfy demand at market j";

cost ..  
z =e=  
  sum((i,j), c(i,j) * x(i,j)) ;
supply(i) ..  
  sum(j, x(i,j)) =l=  
  a(i) ;
demand(j) ..  
  sum(i, x(i,j)) =g=  
  b(j) ;

Model transport /all/;
solve transport using lp minimizing z;

Parameter  
m(*,*) "commodity movement";
m(i,j) = x.l(i,j);
m("total",j) = sum(i, x.l(i,j));
m(i,"total") = sum(j, x.l(i,j));
m("total","total") = sum(j, m("total",j));
option decimals = 0;
display m;

Observe that the two sets (i and j) were enlarged, the capacity (a) and demand (b) data were expanded to cover the new plant and market entries and the distance table (d) was adjusted accordingly. However, the data calculation, equations, model definition, model solution and report writing sections are identical in the two models.

4.15.2.2 Motivation and Step by Step Guide

As we have demonstrated in the example above, GAMS allows the model structure, calculations and report writing to be developed and implemented using a small data set, that may be easily expanded to larger data sets. Thus, we strongly recommend to start with a representative purposefully small data set and enlarge it to its full size once the work of model development, testing and debugging has been done. In short: work from small to large.

The larger the model the longer it takes to compile it, generate the model, execute and solve it. Generally, time expands exponentially. Working with a large model from the start will often lead to frustration even when the user is trying to find some relatively small data problems.
If a model that has already been completed needs some modification, it will be tempting to use the large data set instead of developing the modifications on a small data set. We strongly advise to use a small data set in this case, as experience shows that this way a considerable amount of time may be saved.

We recommend to follow these steps in model development:

1. Set up a small data set representing the full model with all structural features, set names, parameters etc.
2. Implement all data calculations, model features and report writing calculations.
3. Test the results of step 2 thoroughly.
4. Save the small model. Then implement a larger version with the full data set. Create separate files for data, calculation, model definition and report writing to maintain size independence. Use include files or the save and restart feature.
5. Test the larger model. Use the modeling techniques discussed below to facilitate your work.
6. Keep the small model current. As additional structural features are added to the large model, use it to test them. See section Introducing Strategical Subsets below for an easy way to maintain a small model.

4.15.2.3 Modeling Techniques

If users follow the steps for model development outlined in section Motivation and Step by Step Guide above, they will notice that it will not always be possible to model every needed feature with the small model. It is important to carefully choose the small data set so that it has all features of the larger data set. However, occasionally the peculiarities and interrelationships of the full data set cannot be reproduced in the small data set. In this section we will introduce some modeling techniques for finding problems that arise only when the full data set is used. They include saving and restarting to isolate the problem area, strategically introducing subsets and data reduction.

4.15.2.3.1 Isolating Problem Areas through Saving and Restarting

Suppose we have a model with a large data set that takes several hours to run and we wish to add some lines of code in a relatively small segment. The best way to do this is by isolating the relevant part. Isolating the part we wish to modify makes it possible to do tests and repairs without having to input data, do initial calculations and solve the whole model with each run. We recommend to use save and restart files.

For example, in chapter The Save and Restart Feature we demonstrate how to split the transportation model [TRNSPORT] in three parts: the file tranmodel.gms contains the data and the model, the file transolve.gms contains the solve statement and the file tranreport.gms contains a display statement. To run the whole model we use the following sequence, saving and restarting from the saved file:

```gams
> gams tranmodel s=s1
> gams transolve r=s1  s=s2
> gams tranreport r=s2
```

Assume we want a more elaborate report than just the display of some level values. As the file tranreport.gms contains the code relevant for reporting, we will modify only this file. Then we will test the result by running only this file, restarting from s2, without having to solve the whole model repeatedly.
4.15.2.3.2 Introducing Strategical Subsets  When full data sets are used in debugging or development, it is often helpful to narrow the focus on a few items in a set by introducing subsets. The following example is a modified version of the extended transportation model from section An Illustrative Example above.

* Data section

Sets i "canning plants" / Seattle, San-Diego, Baltimore, Dallas /
  j "markets" / New-York, Chicago, Topeka, Boston, Miami / ;

Sets plants(i) "a reduced set of canning plants"
  / Seattle, San-Diego /
  markets(j) "a reduced set of demand markets"
  / New-York, Chicago, Topeka / ;

*plants(i) = yes; markets(j) = yes;

Parameters a(i) "capacity of plant i in cases"
  / Seattle 350, San-Diego 600, Baltimore 450, Dallas 750 /
  b(j) "demand at market j in cases"
  / New-York 325, Chicago 300, Topeka 275, Boston 330, Miami 290 /;

Table d(i,j) "distance in thousands of miles"

<table>
<thead>
<tr>
<th></th>
<th>New-York</th>
<th>Chicago</th>
<th>Topeka</th>
<th>Boston</th>
<th>Miami</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
<td>3.1</td>
<td>3.3</td>
</tr>
<tr>
<td>San-Diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
<td>3.0</td>
<td>2.7</td>
</tr>
<tr>
<td>Baltimore</td>
<td>0.2</td>
<td>0.7</td>
<td>1.8</td>
<td>0.4</td>
<td>1.1</td>
</tr>
<tr>
<td>Dallas</td>
<td>1.5</td>
<td>0.9</td>
<td>0.5</td>
<td>1.8</td>
<td>1.3</td>
</tr>
</tbody>
</table>

Scalar f "freight in dollars per case per thousand miles" /90/ ;

Parameter c(i,j) "transport cost in thousands of dollars per case"
  c(plants,markets) = f * d(plants,markets) / 1000 ;

* Model section

Positive Variable x(i,j) "shipment quantities in cases";
Variable z "total transportation costs in thousands of dollars";

Equations cost "define objective function"
  supply(i) "observe supply limit at plant i"
  demand(j) "satisfy demand at market j";

  cost .. z =e= sum((plants,markets), c(plants,markets) * x(plants,markets)) ;
  supply(plants) .. sum(markets, x(plants,markets)) =l= a(plants) ;
  demand(markets) .. sum(plants, x(plants,markets)) =g= b(markets) ;

Model transport /all/ ;
solve transport using lp minimizing z ;

Observe that we introduced the subsets plants and markets that contain only some of the elements of their supersets i and j. Note that all tables, parameters and variables are defined with the supersets, the equations are declared over the supersets, but defined over the subsets and the calculation of the parameter c is also restricted to the subsets. Hence the model is restricted to the elements of the subsets. However, it is easy to change the restricted model back to the full model by removing the asterisks indicating a comment line:
plants(i) = yes; markets(j) = yes;

Observe that the sets plants and markets are now dynamic sets. Note that this assignment could be inserted anywhere in the code. Thus, introducing strategic subsets may be combined with isolating problem areas, as detailed in section Isolating Problem Areas through Saving and Restarting above.

Introducing strategic subsets has proven to be an effective way of maintaining a small data set with little effort. Users only have to choose elements that are representative for model development and debugging from the full sets.

4.15.2.3.3 Reducing Data  Recall that GAMS skips cases where data items equal zero. Thus a large model may be reduced by temporarily removing data from data sets by simply setting items to zero. Consider the following example:

```gams
Sets o 'origin' / o1*o100 / d 'destination' / d1*d100 /;
Parameter dist(o,d) 'distance';
dist(o,d) = 120 + 50*ord(d) - 0.5*ord(o);
Sets so(o) 'small set of origins for testing' / o4, o47, o91 / sd(d) 'small set of destinations' / d3, d44, d99 /;
dist(o,d) $ (not (so(o) and sd(d))) = 0;
Parameter cost(o,d) 'transportation cost';
cost(o,d) $ dist(o,d) = 3 + 2*dist(o,d);
display cost, dist;
```

Note that we introduced strategic subsets and used them in the logical condition of a conditional assignment to set almost all entries of the parameter dist to zero. Note further, that the assignment for the parameter cost is conditioned on nonzero entries for the distance. Now, if the model were conditioned on nonzero transportation costs, the size of the whole model would be greatly reduced.

4.15.3 Increasing Efficiency: Reducing GAMS Execution Time

GAMS can take a long time for computations and model generation. There are some signs which indicate that it may be possible to reduce the execution time, e.g., an execution time that is unexpectedly long in general or a long execution of a single line, which could be seen, if the log shows the same line number for a long time.

In this section we will discuss how to find the causes for slow program execution and how to eliminate the main causes for slow execution.

4.15.3.1 Finding the Causes for Slow Program Execution

The best strategy for discovering the causes for slow execution is a combination of the techniques discussed in section Small to Large: Aid in Development and Debugging above and the techniques that we will introduce in this section, including generating an execution profile and isolating terms in slow statements. We will also touch briefly on observing the log file and we will point out why this is not the first choice.
4.15.3.1.1 Generating an Execution Profile  The quickest way to find GAMS statements that take particularly long to execute, is generating an execution profile in the output file. The execution profile contains the individual and cumulative time required to execute the sections of the GAMS model as well as information on memory use. An execution profile is generated when the option profile is assigned a value larger than zero (zero is the default). This can be done either by setting a command line parameter or by using the option statement. We will show an example of an execution profile below. For more information on execution profiles, further examples and details on the values the option profile may take, see the detailed description here.

Consider the following example:

```gams
option profile = 1;
option limrow = 0; option limcol = 0;
option solprint = off;

Sets    a / 1*22 /, b / 1*22 /, c / 1*20 /,
        d / 1*20 /, e / 1*22 /;

Parameters x(e,d,c,b,a), y, z(a,b,c,d,e);
x(e,d,c,b,a) = 10;
z(a,b,c,d,e) = x(e,d,c,b,a);
y = sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a));

Variable obj;
Positive Variable var(e,b,a);

Equations objeq, r(b,c,d), q(a,b,c);

objeq.. obj =e= sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a) * var(e,b,a));
r(b,c,d).. sum((a,e), var(e,b,a)) =l= sum((a,e), x(e,d,c,b,a)*z(a,b,c,d,e));
q(a,b,c).. sum((d,e), var(e,b,a)/x(e,d,c,b,a)*z(a,b,c,d,e)) =l= 20;

Model slow /all/;
solve slow maximizing obj using lp;

Parameter sumofvar;
sumofvar = sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a)*var.l(e,b,a));
display sumofvar;
```

The listing file will contain an execution profile like this (spread over the file):

```plaintext
---- 9 Assignment x  0.374  0.374 SECS  109 MB 4259200
---- 10 Assignment z  2.231  2.605 SECS  286 MB 4259200
---- 11 Assignment y  2.324  4.929 SECS  286 MB 0
---- 23 Solve Init slow 0.000  4.961 SECS  287 MB
---- 18 Equation objeq  3.510  8.471 SECS  287 MB 1
---- 19 Equation r  3.088 11.559 SECS  464 MB 8800
---- 20 Equation q  5.741 17.300 SECS  470 MB 9680
---- 23 Solve Fini slow 0.780 18.080 SECS 470 MB
---- 26 Assignment sumofvar 2.620  2.652 SECS  287 MB 0
---- 27 Display 0.032  2.684 SECS  287 MB
---- 27 GAMS Fini  0.000  0.000 SECS  287 MB
```
The first column shows the line number in the input file of the GAMS statement that is executed. The second column reports the type of statement. For an overview of all GAMS statements, see section Classification of GAMS Statements. The next two columns give the individual time needed to execute the respective statement and the cumulative time spent so far. The memory use follows and finally, the number of assignments generated in the respective line is shown.

In addition, there is a Profile Summary at the end of the lst file showing the most expensive statements:

--- Profile Summary (19 records processed)---

<table>
<thead>
<tr>

| 0.359| 0.470GB| GAMS Fini|}

This shows that the execution of the statements in line numbers 20, 18, 19, 26, 11 and 10 are the most expensive ones (in this order). One reason is an inconsistent order when sets are referenced; we will discuss this topic in section Ordering Indices Consistently below.

Note that the execution profile may contain many lines that are not informative since the execution times reported are negligible. These lines may be suppressed by using the the option profileTol to specify the minimum execution time (in seconds) that is to be included. Observe that the option profileTol is available as command line parameter and option statement.

Note further, that the command line parameter profileFile facilitates writing the profiling information to a separate file (instead of the listing file).

### 4.15.3.1.2 Isolating Terms in Slow Statements

In some cases the execution profile shows that the cause for a long execution time is connected with a very long statement. For example, the objective function in some models and some report calculations may take hundreds of lines of code and can contain many terms that are added. If such a long statement is problematic in terms of execution time, it will be necessary to deactivate parts of the code and run the program repeatedly to find the precise lines that are at the root of the problem. This can be done by using comments.

### 4.15.3.1.3 Observing the Log File

Some modelers choose to examine the log file or watch the screen during execution to find the causes for slow program execution. However, we advise against this approach for the following reasons:

- Statements that are executed slowly are easily missed and often statements are misidentified. In addition, screen watchers may be distracted and will have to repeat the process.
- GAMS line reporting can be misleading if flow control statements like if statements and loop statements are executed. For example, individual calculations in a loop are not reported to the screen. A user watching the screen would notice that the loop takes a lot of time, but there is no indication which statement within the loop is problematic. This applies to all GAMS control structures.

Therefore we recommend to use the option profile as the main tool for finding the causes for slow program execution. For details, see section Generating an Execution Profile above. In addition, see the techniques outlined in section Advice for Repairing Puzzling Nonworking Code below.
4.15.3.2 Eliminating the Main Causes for Slow Program Execution

The main reasons for a slow program execution include an inconsistent index order when sets are referenced and taking irrelevant cases into consideration. In this section we will give some guidance on how to eliminate these causes, and also point to problems due to the scaling of a model which could cause an unnecessarily long execution time for the solver.

4.15.3.2.1 Ordering Indices Consistently

GAMS employs a sparse matrix data storage scheme. For example, consider the parameter \( p(a,b,c) \). Assume that the set \( a \) has \( k \) elements, the set \( b \) has \( n \) elements and \( c \) has \( m \) elements. Then the entries for \( p \) are stored in the following order:

\[
\begin{align*}
  a_1 b_1 c_1 \\
  a_1 b_1 c_2 \\
  \vdots \\
  a_1 b_1 c_m \\
  a_1 b_2 c_1 \\
  \vdots \\
  a_1 b_2 c_m \\
  \vdots \\
  a_1 b_n c_m \\
  a_2 b_1 c_1 \\
  \vdots \\
  a_k b_n c_m
\end{align*}
\]

Note that it is a systematic order where the last entry varies the fastest and the first the slowest. Observe that GAMS will withdraw entries from memory fastest if they are referenced in an order consistent with the storage order. Thus, in the following example, the first assignment statement will be processed faster than the second assignment statement.

\[
x(a,b,c) = p(a,b,c); \\
y(b,c,a) = p(a,b,c);
\]

Note

GAMS will execute a program fastest if the sets are always referenced in the same order in definitions, assignments and equations.

The example that follows illustrates this principle. First we will solve a program where the indices appear in an arbitrary order and we will record the output generated by setting the option profile to 1. Then we will reformulate the program so that the indices will always appear in an alphabetical order and solve it again, recording the profile output. In the final step, we will compare the execution times of the two runs. We will use the example introduced above.

Note

That the indices in the parameters and equations appear in a random order. Here is the profile from the six most expensive statements again:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td><strong>Assignment</strong> z</td>
<td>2.231</td>
<td>2.605 SECS</td>
</tr>
<tr>
<td>11</td>
<td><strong>Assignment</strong> y</td>
<td>2.324</td>
<td>4.929 SECS</td>
</tr>
<tr>
<td>18</td>
<td><strong>Equation</strong> objeq</td>
<td>3.510</td>
<td>8.471 SECS</td>
</tr>

<td>17.300 SECS</td>
</tr>
<tr>
<td>26</td>
<td><strong>Assignment</strong> sumofvar</td>
<td>2.620</td>
<td>2.652 SECS</td>
</tr>
</tbody>
</table>
In the next step we reformulate the program such that the indices always appear in the same order. For example, we define the parameter $x$ as $x(a,b,c,d,e)$ instead of $x(e,d,c,b,a)$. Here is the complete rewritten model:

```plaintext
option profile = 1;
option limrow = 0; option limcol = 0;
option solprint = off;

Sets a / 1*22 /, b / 1*22 /, c / 1*20 /, d / 1*20 /, e / 1*22 /;

Parameters x(a,b,c,d,e), y, z(a,b,c,d,e);

x(a,b,c,d,e) = 10;
z(a,b,c,d,e) = x(a,b,c,d,e);
y = sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e));

Variable obj;
Positive Variable var(a,b,e);

Equations objeq, r(b,c,d), q(a,b,c);

objeq..   obj =e= sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e) * var(a,b,e));
r(b,c,d).. sum((a,e), var(a,b,e)) =l= sum((a,e), x(a,b,c,d,e)*z(a,b,c,d,e));
q(a,b,c).. sum((d,e), var(a,b,e)/x(a,b,c,d,e)*z(a,b,c,d,e)) =l= 20;

Model slow /all/;
solve slow maximizing obj using lp;

Parameter sumofvar;
sumofvar = sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e)*var.l(a,b,e));
display sumofvar;
```

After running the modified program, the profile for expensive statements looks like this:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th>SECS</th>
<th>MB</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Assignment z</td>
<td>0.593</td>
<td>0.983</td>
<td>215</td>
<td>4259200</td>
</tr>
<tr>
<td>11</td>
<td>Assignment y</td>
<td>0.671</td>
<td>1.654</td>
<td>215</td>
<td>0</td>
</tr>
<tr>
<td>18</td>
<td>Equation objeq</td>
<td>1.778</td>
<td>3.432</td>
<td>215</td>
<td>1</td>
</tr>
<tr>
<td>19</td>
<td>Equation r</td>
<td>2.215</td>
<td>5.647</td>
<td>392</td>
<td>8800</td>
</tr>
<tr>
<td>20</td>
<td>Equation q</td>
<td>1.763</td>
<td>7.410</td>
<td>398</td>
<td>9680</td>
</tr>
<tr>
<td>26</td>
<td>Assignment sumofvar</td>
<td>0.952</td>
<td>0.983</td>
<td>216</td>
<td>0</td>
</tr>
</tbody>
</table>

Observe that executing for example the assignment to $z$ took just 0.593 seconds compared to 2.231 seconds in the first run. Substantial percentage reductions were achieved in all time consuming cases by consistently referencing the sets in the same order.

### 4.15.3.2.2 Replace loops with assignments

The following statement assigns a constant value to a parameter.

```plaintext
loop((i,j,k),p(i,j,k)=2;)
```

The following assignment is preferred instead.

```plaintext
p(i,j,k)=2;
```
4.15.3.2.3 Restricting Assignments and Equations to Relevant Cases

4.15.3.2.3.1 Assignments
Assume that we have a set of cities with different production capacities and demands for various products. We want to know the maximum transportation cost (which depends on the distance, the amount shipped and a fixed factor) from each city to all others. This cost can be calculated in the following way:

Sets c "cities" / c1*c800 /  
  p "products" / p1*p10 /;  
Alias (c,cc);

Parameter capacity(c,p) "Production capacity for product p in city c"  
  demand(c,p) "Demand for product p in city c"  
  distance(c,cc) "Distance between two cities";

*Generate some sparse, random data
  capacity(c,p)$(uniform(0,1)<0.05) = uniformInt(150,250);  
  demand(c,p)$(uniform(0,1)<0.025) = uniformInt(50,150);  
  distance(c,cc)$(not sameas(c,cc)) = uniformInt(10,800);

Parameter maxCost(c,cc) "Maximum transportation costs between two cities";
  
  maxCost(c,cc) = sum(p, min(capacity(c,p), demand(cc,p))*distance(c,cc)*90);

The performance profile will tell us something like this:

--- 16 Assignment maxCost 0.265 0.436 SECS 19 MB 8756

Since we know, that the parameter \texttt{maxCost} will be zero for a pair of cities if there is no product with production capacity in the first city and demand in the second one, we could reduce the execution time for the last assignment:

Sets c "cities" / c1*c800 /  
  p "products" / p1*p10 /;  
Alias (c,cc);

Parameter capacity(c,p) "Production capacity for product p in city c"  
  demand(c,p) "Demand for product p in city c"  
  distance(c,cc) "Distance between two cities";

*Generate some sparse, random data
  capacity(c,p)$(uniform(0,1)<0.05) = uniformInt(50,150);  
  demand(c,p)$(uniform(0,1)<0.025) = uniformInt(50,150);  
  distance(c,cc)$(not sameas(c,cc)) = uniformInt(10,800);

Parameter maxCost(c,cc) "Maximum transportation costs between two cities";
  
  maxCost(c,cc)$sum(p, capacity(c,p)*demand(cc,p))  
    = sum(p, min(capacity(c,p), demand(cc,p))*distance(c,cc)*90);

So we did not do the calculation of \texttt{maxCost} if we knew before, that it must be zero anyway. This results in a reduced runtime:

--- 17 Assignment maxCost 0.031 0.187 SECS 19 MB 8756
Note

To restrict computations in assignment to the relevant cases, we recommend using dollar conditions and filtering sets. These concepts are introduced and discussed in detail in chapter Conditional Expressions, Assignments and Equations.

For more examples, see sections Conditional Assignments and Conditional Indexed Operations.

4.15.3.2.3.2 Variables and Equations

Like assignments, variables and equations need to be restricted to relevant cases to avoid unnecessary inefficiencies. Dollar conditions and filtering sets may be used over the domain of definition as well as in the body of an equation.

Let's extend the assignment example from the previous paragraph and use the generated data in a transportation model:

```plaintext
Sets
c "cities" / c1*c800 /
p "products" / p1*p10 /;
Alias (c,cc);
Parameter capacity(c,p) "Production capacity for product p in city c"
  demand(c,p) "Demand for product p in city c"
distance(c,cc) "Distance between two cities";
*Generate some sparse, random data
capacity(c,p)$(uniform(0,1)<0.05) = uniformInt(150,250);
demand(c,p)$(uniform(0,1)<0.025) = uniformInt(50,150);
distance(c,cc)$(not sameas(c,cc)) = uniformInt(10,800);
Parameter shipCost(c,cc) "Transportation costs between two cities per case"
  maxCost(c,cc) "Maximum transportation costs between two cities"
  = distance(c,cc)*90;
  maxCost(c,cc)$sum(p, capacity(c,p)*demand(cc,p))
  = sum(p, min(capacity(c,p), demand(cc,p))*shipCost(c,cc));
Variables
  x(c,cc,p) "shipment quantities in cases"
  z "total transportation costs in thousands of dollars";
Positive Variable x;
Equations
cost "define objective function"
supply(c,p) "observe supply limit at plant i"
dem(cc,p) "satisfy demand at market j";
cost.. z =e= sum((c,cc,p), shipCost(c,cc)*x(c,cc,p)) ;
supply(c,p).. sum(cc, x(c,cc,p)) =l= capacity(c,p) ;
dem(cc,p).. sum(c, x(c,cc,p)) =g= demand(cc,p) ;
Model transport /all/ ;
Solve transport using lp minimizing z ;
```

The Profile Summary tells us, that the equations are rather expensive to generate and also the reading of the solution takes some time because of the size of the model:
However, as in the previous example, we know, that a product \( p \) won’t be shipped from city \( c \) to city \( cc \) if there is either no production capacity in the first city or no demand in the second one. So we could reduce the size of our model by not generating variables and equations from which we know, that they are irrelevant for the solution. Here is a improved formulations of the equations:

\[
\begin{align*}
\text{cost}.. & \quad z = \sum((c,cc,p)$(capacity(c,p)*demand(cc,p)),\ shipCost(c,cc)*x(c,cc,p)) \\
\text{supply(c,p)$capacity(c,p)}.. & \quad \sum(cc$demand(cc,p), \ x(c,cc,p)) = l= capacity(c,p) \\
\text{dem(cc,p)$demand(cc,p)..} & \quad \sum(c$capacity(c,p), \ x(c,cc,p)) = g= demand(cc,p)
\end{align*}
\]

This decreases the size of the model and thus the execution time to generate the model and load the solution significantly:

---- Profile Summary (18 records processed)
  0.031  0.035GB  33 Equation  cost (1)  
  0.031  0.034GB  39 Solve Read transport  
  0.016  0.035GB  34 Equation  supply (380)  

Note that the equation \text{dem} does not even show up in the summary anymore since its generation was done quickly.

For more details on conditions in equations, see section Conditional Equations.

4.15.3.2.4 Keep the model well scaled  Model solutions within GAMS frequently require manipulation of large matrices and many computations. The heart of most solvers includes many numerical procedures such as a sparse matrix inverter and sets of convergence and infeasibility tolerances. Numerical problems often arise within such procedures. Poorly scaled models can cause excessive time to be taken in solving or can cause the solver to fail. GAMS can assist the user to formulate a well scaled model. Details about this can be found in the sections Model Scaling - The Scale Option and Scaling Variables and Equations.

4.15.3.3 Other Approaches

In addition to the techniques discussed in section Eliminating the Main Causes for Slow Program Execution above, the following approaches may help to reduce the time needed for program execution:

- Trying another appropriate solver.
- Reformulating the model. This may yield particularly good results, if the model is reformulated in such a way that another model type is used, that is easier to solve or for which more advanced solver technology is available.
- Using starting points for NLP models, as discussed in section Specifying Initial Values.
- Trading memory for time.
We conclude the discussion of this topic with an example that demonstrates how memory may be traded for time. If an extensive calculation is repeated many times in a model, it may be possible to restructure the code so that the calculation is performed only once, then the result is saved and accessed later. Consider the following equation:

\[
\text{obj. } z = e = \text{sum}[(i,j,k,l), \ a(i,j,k,l) * \text{sum}(m, u(m,i))];
\]

The execution time may be substantially reduced by defining a new parameter, say \( p \), for the second sum and using this parameter in the equation:

\[
\text{Parameter } p(i);
\]

\[
p(i) = \text{sum}(m, u(m,i));
\]

\[
\ldots
\]

\[
\text{obj. } z = e = \text{sum}[(i,j,k,l), \ a(i,j,k,l) * p(i)];
\]

There is only one caveat: Users need to carefully consider whether the input data, here \( u(m,i) \), is modified between the assignment for the new parameter \( p \) and the equation where \( p \) is used. If \( u \) is updated, then the assignment statement needs to be repeated, otherwise the data that enters the equation will not be current.

### 4.15.4 Increasing Efficiency: Reducing Memory Use

Besides slow program execution, excessive memory use may be of concern for modelers. In this section we will present some approaches on how to find the causes for extraordinary memory use and give some advice on eliminating the main causes for it.

#### 4.15.4.1 Finding the Causes for Excessive Memory Use

The main techniques for finding the causes for excessive memory use are the same as those for finding the causes for slow program execution. We discussed these techniques in section Finding the Causes for Slow Program Execution above.

In addition, the option \texttt{dmpUserSym} is useful in this context. GAMS will report the number of records stored for each symbol at the point in the program where the option \texttt{dmpUserSym} is inserted together with some rough memory estimate.

Consider the following example:

\[
\text{Sets i /1*5 /, j /1*5 /, k /1*5 /, l /1*5 /, m /1*5 /, n /1*5 /, o /1*5 /;}
\]

\[
\text{Parameters y(i,j,k,l,m,n,o)}
\]

\[
q(i,j,k);
\]

\[
\text{Variables x(i,j,k,l,m,n,o)}
\]

\[
f(i,j,k)
\]

\[
\text{obj;}
\]

\[
y(i,j,k,l,m,n,o) = 10;
\]

\[
q(i,j,k) = 10;
\]

\[
x.up(i,j,k,l,m,n,o) = 10;
\]

\[
x.scale(i,j,k,l,m,n,o) = 1000;
\]

\[
\text{Equations z(i,j,k,l,m,n,o)}
\]

\[
\text{Equation z;}
\]

\[
\text{z(i,j,k,l,m,n,o) = e = sum[(i,j,k,l), a(i,j,k,l) * p(i)];}
\]

\[
\text{...}
\]

\[
\text{obj.. z =e= sum[(i,j,k,l), a(i,j,k,l)*p(i)];}
\]
res(i,j,k)
ob;

ob.. obj =e= sum((i,j,k,l,m,n,o), x(i,j,k,l,m,n,o));
z(i,j,k,l,m,n,o).. x(i,j,k,l,m,n,o) =l= 8;
res(i,j,k).. f(i,j,k) =l= 7;

Model memory /all/;
option dmpUserSym;
solve memory maximizing obj using lp;

Note that an option statement with dmpUserSym was added before the solve statement. It generates the following memory dump that is included in the execution output of the listing file:

SYMBOL TABLE DUMP (USER SYMBOLS ONLY), NR ENTRIES = 16
ENTRY   ID   TYPE   DIM   LENGTH   MEMORYEST   DEFINED   ASSIGNED   DATAKNOWN
135    i    SET    1    5      0 MB    TRUE    FALSE    TRUE
136    j    SET    1    5      0 MB    TRUE    FALSE    TRUE
137    k    SET    1    5      0 MB    TRUE    FALSE    TRUE
138    l    SET    1    5      0 MB    TRUE    FALSE    TRUE
139    m    SET    1    5      0 MB    TRUE    FALSE    TRUE
140    n    SET    1    5      0 MB    TRUE    FALSE    TRUE
141    o    SET    1    5      0 MB    TRUE    FALSE    TRUE
142    y    PARAM  7    78125  3 MB   FALSE    TRUE    FALSE
143    q    PARAM  3    125   0 MB   FALSE    TRUE    FALSE
144    x    VAR    7    78125  5 MB   FALSE    TRUE    FALSE
145    f    VAR    3    0      0 MB   FALSE    TRUE    FALSE
146    obj   VAR    0    0      0 MB   FALSE    TRUE    FALSE
147    z    EQU    7    0      0 MB   FALSE    TRUE    FALSE
148    res   EQU    3    0      0 MB   FALSE    TRUE    FALSE
149    ob    EQU    0    0      0 MB   FALSE    TRUE    FALSE
150    memory MODEL  0    3    TRUE    TRUE    TRUE

END OF SYMBOL TABLE DUMP

The column ID contains the names of the symbols, the column TYPE gives the data type of the respective entry, the column DIM reports the number of indices and the column LENGTH gives the number of records that is related to memory use, which is estimated in the column MEMORYEST. Note that the other columns are not relevant for this discussion.

Observe that the rows with high counts in column LENGTH indicate symbols within the GAMS program which have large numbers of internal records that must be stored. This is associated with corresponding memory requirements. Note also that not all length counts are of equal significance. In particular, variables and equations use more memory per element than parameters, since they have bounds, levels, marginals and scales that are associated with them. Parameters use more memory per element than sets, since sets may need just one indicator for yes or no. However, the explanatory text for set elements might increase the memory requirements for set elements.

Nevertheless, users may use this report to identify items with many records and verify that all of them are actually needed. For more details, see section Eliminating the Main Causes for Excessive Memory Use below.

4.15.4.2 Eliminating the Main Causes for Excessive Memory Use

As detailed in section Eliminating the Main Causes for Slow Program Execution above, the main causes for a slow program execution include an inconsistent index order when sets are referenced and taking irrelevant cases into consideration. These programming habits also tend to cause excessive memory use. In this section we will give some advice on avoiding memory traps and show how the memory may be cleared of data that is no longer needed.
4.15 Finding and Fixing Execution Errors and Performance Problems

4.15.4.2.1 Avoiding Memory Traps  Users may inadvertently use a lot of memory if they import data from a database with long explanatory text for sets or set elements. In addition, setting variable attributes for scaling or bounds may be problematic. Consider the following example:

\[
\begin{align*}
\text{x.scale}(i,j,k,l,m) &= 100; \\
\text{x.lo}(i,j,k,l,m) &= 10; \\
\text{x.up}(i,j,k,l,m) &= 77;
\end{align*}
\]

These assignments will probably set many more values than are relevant for a particular problem. Therefore we recommend to carefully consider which label combinations are actually necessary and to restrict the assignments to these cases by the use of dollar conditions or filtering sets. For more information, see section Conditional Assignments.

4.15.4.2.2 Clearing Memory of Unneeded Data  Sometimes a lot of memory space is used for data that is needed at some point, but not later. Consider the following simple example:

\[
\begin{align*}
\text{set } i &\ /1*1000/ \\
&\ j\ /1*1000/; \\
\text{parameter}\& \text{ distance}(i,j) \\
&\ \text{cost}(i,j); \\
\text{distance}(i,j) &= 100+\text{ord}(i)+\text{ord}(j); \\
\text{cost}(i,j) &= 4+8*\text{dist}(i,j);
\end{align*}
\]

Assume that the parameter distance is used only here, but nowhere else in the program. Therefore users may wish to free the memory space occupied by the data connected with distance. The option clear may be used to achieve this:

\[
\text{option clear = distance;}
\]

This will reset all entries in the matrix associated with distance to zero.

Alternatively, an identifier that is no longer needed could be reset to its default value(s) with an assignment statement. In the example above, we could write:

\[
\text{distance}(i,j) = 0;
\]

This statement will have the same effect as the option statement. The advantage of the option statements is that they offer a more compact alternative that is particularly useful if equations or variables are to be cleared and multiple equation attributes or variable attributes are affected.

Note that the dollar control options $clear and $kill may also be used to free memory. These are compile time directives, which have a similar effect on the memory consumption but have different side effects: while $clear will reset the values to their defaults, $kill will completely remove the identifier from the program. Hence an identifier that was ”killed” may be used later in another declaration and definition statement. For example, the following code snippet is legal:

\[
\text{Set i /1, 2 ,3/;}
\text{$kill i}$
\text{Set i /a, b, c/;}
\]

With $clear instead of $kill this would cause a compilation error.
4.15.4.3 Setting Memory Limits with HEAPLIMIT

In a server environment and in other cases (e.g. to avoid the use of virtual memory) the amount of memory a GAMS run is allowed to use may have to be limited. The command line parameter heapLimit serves this purpose: the amount of memory for GAMS compilation and execution is limited to a specified number (in MB). If the data storage exceeds this limit, the job will be terminated with return code 10, out of memory. In addition, the function heapLimit may be used to interrogate the current limit and to reset it.

Note that limiting memory use for solver execution is not possible from within the GAMS program. However, some solvers like the NLP solver CONOPT have their own heapLimit option which ensures that the solver will not use more dynamic memory than specified.

4.15.4.4 Advice for Repairing Puzzling Nonworking Code

Assume a GAMS run was terminated and we cannot get a profile output (e.g. because GAMS ran out of memory and crashes). A memory overrun error causes the operating system buffer handling procedures to generally lose the last few lines of profile information when the job malfunctioned. How do we find the problem in this case?

We recommend to use the techniques outlined in section Modeling Techniques above. In addition, successively deactivating code in search for the last GAMS statement that worked will help in most cases. This can be done by using comments. If at some point the run terminates properly, the user will slowly activate parts of the last statements that were deactivated until the code performance will get worse again. By iteratively activating and deactivating terms, the precise problematic terms may be found. The save and restart feature could also be used to save the results until a certain statement and then to execute only the statements that are suspected to be problematic.

4.16 Comparative Analyses with GAMS

Once a model is completed, it is almost always used to investigate alternative scenarios where the analyst compares the results of various scenario assumptions. In this tutorial we will show how such comparative analyses (also called sensitivity analyses) are done with GAMS. We will first demonstrate an easy approach, where we will manually change input parameters, use repeated solves and generate reports. In a second step, we will introduce another approach, where a loop structure will be used to automatically cycle through the scenarios. We recommend to read the sections on the manual approach first, since the sections on the automated approach build on code blocks developed in the early sections.

4.16.1 Manual Approach

Suppose we wish to do a comparative analysis by altering some input data in a model. We will use as an example the farm profit-maximizing model farmcomp.gms. The following vector of prices for primary commodities is a part of the input data:

Parameter price(primary) 'prices for products in USD'
   / corn 2.20, soybeans 5.00, beef 0.50 /;
We will use these data as a base case and compare it with two alternative scenarios: in the first scenario we will change the price of beef to $0.70 and in the second scenario we will change the price of corn to $2.70.

The GAMS file farmrep.gms is related to our example model. It contains only calculations for report writing and may be included with the dollar control option $include. It will generate a report based on the solution of the last solve that was executed in the GAMS program farmcomp.gms. The report consists of several tables. We will focus on the table Farm Summary that is associated with the parameter summary. The relevant code is given below:

Set alli 'allitems'
/ corn, soybeans, beef, cattle,
   water, cropland, pastureland,
   fertilizer, seed, othercost, veterinary, supplement,
   "April labor", "May labor", "summer labor", "Sept labor", "Oct labor",
   cattlefeed, total /;

Set measures 'output measures'
/ "Net Income", "Land Use", "Dry Cropping", "Irr Cropping",
 "Livestock", "Resource Value", "Product Value" /;

Parameter summary(alli,measures) 'Farm Summary';

Note that the table for the parameter summary will contain rows for the commodities which are elements of the set alli and columns for all elements of the set measures.

We will use a third GAMS file, mancomp.gms, for our comparative analysis. The code of this third GAMS file follows:

$include farmcomp.gms
display price;
$include farmrep.gms
price("beef") = 0.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms
price("corn") = 2.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms

Note that this code first solves the original model that also contains the set definitions for the report, displays the initial prices and generates a report. In a second step the price for beef is changed to $0.70, the modified model is solved, the prices for the first alternative scenario are displayed and a report is generated. In a third step the price for corn is changed to $2.70, the model is solved again, the prices for the second alternative scenario are displayed and a third report is generated. Note that in the second alternative scenario (the third solve) the beef price is $0.70, since it was not reset to base levels after the second run.

There will be three tables associated with the parameter summary in the listing file, one for each solve. The first table reports the results associated with the base case:
### 279 PARAMETER summary Farm Summary

<table>
<thead>
<tr>
<th>Net Income</th>
<th>Land use</th>
<th>Dry Cropp$^*$</th>
<th>Irr Cropp$^*$</th>
<th>Livestock Resource $^*$</th>
<th>Product V$^*$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Corn</td>
<td>20.00</td>
<td>200.00</td>
<td></td>
<td></td>
<td>2.20</td>
</tr>
<tr>
<td>Soybeans</td>
<td>480.00</td>
<td></td>
<td></td>
<td></td>
<td>5.00</td>
</tr>
<tr>
<td>Beef cattle</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>0.50</td>
</tr>
<tr>
<td>Water</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>615.79</td>
</tr>
<tr>
<td>Cropland</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>16.83</td>
</tr>
<tr>
<td>Pastureland</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>128.49</td>
</tr>
<tr>
<td>April Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>84.26</td>
</tr>
<tr>
<td>May Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>32.34</td>
</tr>
<tr>
<td>Oct Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>27.01</td>
</tr>
<tr>
<td>Cattlefeed</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>11.50</td>
</tr>
<tr>
<td>Total</td>
<td>162685.05</td>
<td>500.00</td>
<td>200.00</td>
<td></td>
<td>4.71</td>
</tr>
</tbody>
</table>

The second table reports the results from the first alternative scenario where the price for beef was changed to $0.70:

### 351 PARAMETER summary Farm Summary

<table>
<thead>
<tr>
<th>Net Income</th>
<th>Land use</th>
<th>Dry Cropp$^*$</th>
<th>Irr Cropp$^*$</th>
<th>Livestock Resource $^*$</th>
<th>Product V$^*$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Corn</td>
<td>22.84</td>
<td>160.85</td>
<td></td>
<td></td>
<td>2.34</td>
</tr>
<tr>
<td>Soybeans</td>
<td>489.86</td>
<td></td>
<td></td>
<td></td>
<td>5.00</td>
</tr>
<tr>
<td>Beef cattle</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>0.70</td>
</tr>
<tr>
<td>Cropland</td>
<td>673.55</td>
<td></td>
<td></td>
<td></td>
<td>866.67</td>
</tr>
<tr>
<td>Pastureland</td>
<td>130.00</td>
<td></td>
<td></td>
<td></td>
<td>1456.90</td>
</tr>
<tr>
<td>April Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>82.29</td>
</tr>
<tr>
<td>May Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>80.53</td>
</tr>
<tr>
<td>Sept Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>53.57</td>
</tr>
<tr>
<td>Oct Labor</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>46.21</td>
</tr>
<tr>
<td>Cattlefeed</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>4.89</td>
</tr>
<tr>
<td>Total</td>
<td>373686.10</td>
<td>512.70</td>
<td>160.85</td>
<td></td>
<td>4.89</td>
</tr>
</tbody>
</table>

And the third table reports the results from the second alternative scenario where the price for corn was changed to $2.70 and the price for beef stayed at $0.70:

### 423 PARAMETER summary Farm Summary

<table>
<thead>
<tr>
<th>Net Income</th>

<tr>
<td>Total</td>
<td>375839.30</td>
<td>442.22</td>
<td>200.00</td>
<td></td>
<td>5.36</td>
</tr>
</tbody>
</table>
This quick way to do a comparative analysis has the following drawbacks:

- The relevant output is spread over more than 140 lines.
- There is no cross-scenario report.
- The price of beef in the second alternative scenario is problematic, since it was not automatically reset to the original base price.
- The handling of solves and report writing is repetitive.

The first two issues will be addressed in section Writing Cross-Scenario Reports, a solution for the third issue will be given in section Resetting Data to Base Levels and an alternative approach that will resolve the last issue is presented in section An Automated Approach - Avoiding Repeated Work.

4.16.1.1 Writing Cross-Scenario Reports

We will generate a cross-scenario report by introducing two new sets and a new parameter in a revised version of the third GAMS file, `mancombp.gms`:

```gams
Set scenarios / base, beefp, beefcorn /;
Set ordr / "Scenario Setup", "Scenario Results"/;
Parameter savsumm(ordr,*,alli,scenarios) 'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,alli,"base") = summary(alli,measures);
```

Note that the set `scenarios` contains the base case and the two alternative scenarios and the set `ordr` introduces places to save the assumptions and results of the different runs. The new parameter `savsumm` is similar to the parameter `summary` introduced above, but it has two additional dimensions. Observe that the first assignment copies the current setup of the price vector and the second assignment copies the results that are stored in the parameter `summary`.

The full code follows:

```gams
$include farmcomp.gms
$include farmrep.gms
Set ordr / "Scenario Setup", "Scenario Results" /;
Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*,alli,scenarios) 'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,alli,"base") = summary(alli,measures);

price("beef") = 0.70;
solve farm using LP maximizing netincome;
display price ;
$include farmrep.gms
savsumm("Scenario Setup","price",primary,"beefp") = price(primary);
savsumm("Scenario Results",measures,alli,"beefp") = summary(alli,measures);

price("corn") = 2.70;
display price ;
solve farm using LP maximizing netincome;
$include Farmrep.gms
savsumm("Scenario setup","price",primary,"beefcorn") = price(primary);
savsumm("Scenario Results",measures,alli,"beefcorn") = summary(alli,measures);

option savsumm:2:3:1;
display savsumm;
```
Observe that the last index in the assignments for `savsumm` is "base" after the first solve, "beefp" after the second solve and "beefcorn" after the third solve. Note that option statement in the penultimate line of the code customizes the output generated by the display statement that follows. For details see section Local Display Control. The listing file will contain the following output:

```
----- 436 PARAMETER savsumm Comparative Farm Summary

<table>
<thead>
<tr>
<th>Scenario Setup .price .Corn</th>
<th>base</th>
<th>beefp</th>
<th>beefcorn</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scenario Setup .price .Soybeans</td>
<td>5.00</td>
<td>5.00</td>
<td>5.00</td>
</tr>
<tr>
<td>Scenario Setup .price .Beef</td>
<td>0.50</td>
<td>0.70</td>
<td>0.70</td>
</tr>
<tr>
<td>Scenario Results.Net Income .Total</td>
<td>162685.05</td>
<td>373686.10</td>
<td>375839.30</td>
</tr>
<tr>

<td>489.86</td>
<td>410.24</td>
</tr>
<tr>
<td>Scenario Results.Dry Cropping .Total</td>
<td>500.00</td>
<td>512.70</td>
<td>442.22</td>
</tr>
<tr>
<td>Scenario Results.Irr Cropping .Corn</td>
<td>200.00</td>
<td>160.85</td>
<td>200.00</td>
</tr>
<tr>
<td>Scenario Results.Irr Cropping .Total</td>
<td>200.00</td>
<td>160.85</td>
<td>200.00</td>
</tr>
<tr>
<td>Scenario Results.Livestock .cattle</td>
<td>615.79</td>
<td>866.67</td>
<td>866.67</td>
</tr>
<tr>
<td>Scenario Results.Resource Value.Cropland</td>
<td>128.49</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Scenario Results.Resource Value.Pastureland</td>
<td>84.26</td>
<td>1456.90</td>
<td>1316.09</td>
</tr>
<tr>
<td>Scenario Results.Resource Value.April Labor</td>
<td>32.34</td>
<td>82.29</td>
<td>61.39</td>
</tr>
<tr>
<td>Scenario Results.Resource Value.May Labor</td>
<td>27.01</td>
<td>80.53</td>
<td>61.72</td>
</tr>
<tr>
<td>Scenario Results.Resource Value.Sept Labor</td>
<td>32.34</td>
<td>82.29</td>
<td>61.39</td>
</tr>
<tr>
<td>Scenario Results.Resource Value.Oct Labor</td>
<td>11.50</td>
<td>46.21</td>
<td>87.21</td>
</tr>
<tr>
<td>Scenario Results.Product Value .Corn</td>
<td>2.20</td>
<td>2.34</td>
<td>2.70</td>
</tr>
<tr>
<td>Scenario Results.Product Value .Soybeans</td>
<td>5.00</td>
<td>5.00</td>
<td>5.00</td>
</tr>
<tr>
<td>Scenario Results.Product Value .Beef</td>
<td>0.50</td>
<td>0.70</td>
<td>0.70</td>
</tr>
<tr>
<td>Scenario Results.Product Value .Cattlefeed</td>
<td>4.71</td>
<td>4.89</td>
<td>5.36</td>
</tr>
</tbody>
</table>
```

In this cross-scenario report all output is in one table and it is easy to compare the base case with the two alternative scenarios.

We could also add percentage change calculations by introducing a further parameter, `savsummp`:

```
Parameter savsummp(ordr,*,alli,scenarios) 'Comparative Farm Summary (percent chg)';

savsummp(ordr,measures,alli,scenarios)$savsummp(ordr,measures,alli,"base") =
  round{ [savsummp(ordr,measures,alli,scenarios) - savsummp(ordr,measures,alli,"base")]*100 /
  savsummp(ordr,measures,alli,"base"),1 }

savsummp(ordr,measures,alli,scenarios)$[(savsummp(ordr,measures,alli,"base") = 0) and (savsummp(ordr,measures,alli,scenarios) <> 0)] = na;

option savsummp:1:3:1;
display savsummp;
```

Note that both assignment statements are conditional assignments. The first assignment computes percentage changes rounded to one decimal place and the second assignment sets the percentage change to NA if the value in the base case is zero. The output generated by the display statement follows:
4.16 Comparative Analyses with GAMS

4.16.1.2 Resetting Data to Base Levels

In the example above the price for beef was changed to $0.70 for the first alternative scenario and it stayed at $0.70 in the second alternative scenario, since we did not reset it manually to the base level. However, in most cases users find it preferable to reset all data to base levels before a new scenario is run. This may be done by saving the base level data in a new parameter, say `saveprice`, and then resetting the data to base levels before each scenario. In the following final version of the third GAMS file, `mancompc.gms`, the levels of the commodity prices are reset before each new run:

```gams
$include farmcomp.gms
$include farmrep.gms

Parameter saveprice(alli) 'saved prices';
saveprice(alli) = price(alli);

Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*,alli,scenarios) 'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,alli,"base") = summary(alli,measures);

price(alli) = saveprice(alli);
price("beef") = 0.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms
savsumm("Scenario setup","price",primary,"beefp") = price(primary);
savsumm("Scenario Results",measures,alli,"beefp") = summary(alli,measures);

price(alli) = saveprice(alli);
price("corn") = 2.70;
display price;
solve farm using LP maximizing netincome;
$include farmrep.gms
savsumm("Scenario setup","price",primary,"beefcorn") = price(primary);
savsumm("Scenario Results",measures,alli,"beefcorn") = summary(alli,measures);

option savsumm:2:3:1;
display savsumm;
```

---

### PARAMETER savsummp Comparative Farm Summary (percent chg)

| Scenario Results.Irr Cropping .Corn | -19.6 |
| Scenario Results.Irr Cropping .Total | -19.6 |
| Scenario Results.Livestock .cattle | 40.7  |
| Scenario Results.Resource Value.Water | -100.0 |
| Scenario Results.Resource Value.Cropland | -100.0 |
| Scenario Results.Resource Value.Pastureland | 1629.0 |
| Scenario Results.Resource Value.April Labor | 154.4 |
| Scenario Results.Resource Value.May Labor | 198.1 |
| Scenario Results.Resource Value.Sept Labor | NA |
| Scenario Results.Resource Value.Oct Labor | 301.8 |
| Scenario Results.Product Value .Corn | 6.4  |
| Scenario Results.Product Value .Beef | 40.0  |
| Scenario Results.Product Value .Cattlefeed | 3.9  |
In this section we demonstrated how to do a comparative analysis manually, including a cross-scenario report and resetting the data before each new scenario is run. However, there is still a lot of repetition in how the solves and reports are handled. This issue will be addressed in the next section.

4.16.2 An Automated Approach - Avoiding Repeated Work

The basic structure of a comparative analysis that avoids repetitive instructions for solves and report writing is outlined in the Figure below. Note that the first three boxes represent preparatory steps that are the usual parts of a GAMS program: the initial data is set up, the model is defined and solved. The comparative model analysis begins with the box labeled "Step 1". In Step 1 names for the scenarios are introduced and the scenario data is defined. In Step 2 the base data that will be changed during the scenario runs are saved in a new parameter. We will use this parameter later to restore the data to their base levels before each new scenario run. Starting with Step 3 we enter a loop, where the looping set is the set of scenarios introduced in Step 1. As usual, the statements in the loop are executed for each scenario to be analyzed. The first statement restores the data to their base levels (Step 3). Thus we will always start with the same data. In Step 4 the data and the model is updated for the current scenario and in Step 5 the model solved. In Step 6 a report for the individual scenarios is generated. In Step 7 parameters for cross-scenario comparative reports are saved. In Step 8 we check if more scenarios are to be solved and if this is the case, we return to repeat Steps 3-8 until all scenarios are completed. Finally, we display a comparative report that presents the information saved across scenarios.
This flow chart is implemented in the file `compare.gms` that is given below. Note that it is based on the farm profit-maximizing example discussed in section Manual Approach above. All sets and parameters were introduced in the sections above, only the table `scenprice` in the implementation of Step 1 is new.

*Step 1 - Setup scenarios
Set ordr / "Scenario Setup", "Scenario Results" /;
Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*,alli,scenarios) 'Comparative Farm Summary';
Table scenprice(primary,scenarios) 'price changes by scenario'
   base   beefp   beefcorn
   corn   2.70
   soybeans
   beef   0.70

*Step 2 - Save data
Parameter savprice(primary) 'save primary commodity prices';
savprice(primary) = price(primary);
Step 3 - Reset data to base level
loop(scenarios,
  price(primary) = savprice(primary);
)

Step 4 - Change data to levels needed in scenario
  price(primary)$scenprice(primary,scenarios) = scenprice(primary,scenarios);
  display price;

Step 5 - Solve model
  solve farm using LP maximizing netincome;

Step 6 - Single scenario report writing
  $include farmrep.gms

Step 7 - Cross-scenario report writing
  savsumm("Scenario Setup","price",primary,scenarios) = price(primary);
  savsumm("Scenario Results",measures,alli,scenarios) = summary(alli,measures);

Step 8 - End of loop
);

Step 9 - Compute and display final results
option savsumm:2:3:1;
  display savsumm;

Note that the main feature that facilitates this automatic approach is a loop statement. Loop statements are introduced and discussed in section The Loop Statement. Note further, that in Step 4 we used a conditional assignment to restrict the change of data to those primary commodities that have nonzero entries for the respective scenario in parameter scenprice. For details on conditional assignments, see section Conditional Assignments.

4.16.2.1 Adding A Scenario

Given the implementation of an automated comparative analysis above, it is easy to add a new scenario. Only two small modifications are needed: a name for the new scenario has to be added to the set scenarios and the respective data has to be added to the table scenprice. Both changes are in Step 1. The lines of the respective code are given below:

Set scenarios / base, beefp, beefcorn, new/;
Table scenprice(primary,scenarios) 'price alterations by scenario'
  base  beefp  beefcorn  new
  corn  2.70
  soybeans  4.32  0.70

Note that we added a third alternative scenario called new, where the price of soybeans is changed to $4.32. Note further, that the remainder of the code is not changed. Once the new scenario is added to the set scenarios and the respective data is specified in the table, it will enter the loop and thus all the statements in the loop will be executed for the new scenario.

Observe that the new scenario above was similar to the other scenarios: the price for a primary commodity was modified. However, in some cases new scenarios require that other data, like resources, are changed. For example, assume that in a new scenario the landtype "cropland" is increased by 30%. Note that the available resources were defined in the parameter available(alli), where available("cropland") equals 700. To accommodate this new scenario we will add the following lines of code to Steps 1 to 4:
4.16 Comparative Analyses with GAMS

*Step 1 - Setup scenarios
Set scenarios / base, beefp, beefcorn, new /;
Table scenavailable(alli,scenarios) 'resource alterations by scenario'
  base   beefp  beefcorn  new
  cropland  1.3;

*Step 2 - Save data
Parameter saveavailable (alli) 'save available resources';
saveavailable (alli) = available (alli);

*Step 3 - Reset data to base level
loop(scenarios,
  available (alli) = saveavailable (alli);
)

*Step 4 - Change data to levels needed in scenario
available(alli)$scenavailable(alli,scenarios) =
  available(alli)*scenavailable(alli,scenarios);
display price, available;

Note that in Step 1 we added a new table, scenavailable, to specify the resource alternations by scenario. Observe that the values of scenavailable will be used as multipliers in Step 4. In Step 2 we introduced the parameter saveavailable, that will play a similar role for the available resources like the parameter savprice does for the prices of the primary commodities: the base levels are saved in this parameter and we will use it to restore the values of available to their base levels before each new scenario run. This is implemented with the new assignment in Step 3. In Step 4 the data levels of the parameter available are modified as required for the current scenario using a conditional assignment. Note the similarities to the assignment for updating the values of price in Step 4 above. Steps 5 to 9 remain unchanged. Thus we achieved an automated comparative analysis with an additional scenario where another parameter is modified by adding just a few lines of code. The full code is given in the GAMS file compareother.gms.

4.16.2.2 Changing the Structure of a Model

Many studies require modifications of the structure of a model. In GAMS, context-sensitive model structures may be implemented with dollar conditions. Dollar conditions may be used to control equations as well as specific terms.

To illustrate, we will extend the profi-maximizing farm model from the previous sections to include a conditional constraint that limits the number of cattle. This constraint will be only active if a scalar that varies with the scenarios is nonzero. Consider the lines of code that follow. Note that the set animals is a subset of the set alli, the elements of the set livemanage denote various ways of managing crops and animals, and liveprod is a positive variable for livestock production.

$include farmcomp.gms
$include farmrep.gms

Scalar cowlim 'activates cowlimit constraint' /1/;
Equation cowlimit 'conditional equation on cow limits';
cowlimit$cowlim.. sum((animals,livemanage), liveprod(animals,livemanage)) =l= 100;
Model farmcowlim /all/;

Set ordr / "Scenario setup", "Scenario Results" /;
Set scenarios / base, cowlim /;
Parameter savprice(primary) 'save primary commodity prices';
savprice(primary) = price(primary);
Parameter cowlims(scenarios) 'cowlimit by scenario'
loop(scenarios,
    cowlim = cowlims(scenarios);
    solve farmcowlim using LP maximizing netincome;
);

Note that in the loop the value of the scalar cowlim is updated before each scenario is run. Note further, that this value determines whether the new equation cowlimit will be active or not. The complete code is given in the GAMS file comparemod.gms.

### 4.16.3 Ranging analysis

Some users are interested in getting ranging output in the form of LP cost and right hand side ranging results. Unfortunately, the base version of GAMS does not yield such information. The user wishing such information has two alternatives. First, one may cause the model to be repeatedly solved under a set of values for the key parameter using the procedures discussed above, but this is cumbersome if a lot of parameters are involved. Second, one can use solver dependent features of GAMS that can be retrieved into a GAMS parameter. Please refer to the solver manuals (e.g. for GAMS/CPLEX: Sensitivity Analysis) for further information how to use them.

### 4.17 Good NLP Formulations

In this tutorial we offer some advice and guidance on how to set up or formulate an NLP model so that a solver will be able compute a good solution and do so quickly, reliably, and predictably. Much of this applies to other model classes allowing nonlinear functions, but for ease and simplicity of exposition we focus on the NLP case here.

A good formulation for an NLP model typically involves several things, including specifying sensible initial values, setting variable bounds, and scaling variables and equations. Other factors to consider are techniques for blocking degenerate cycling and the potential benefits of avoiding expressions in nonlinear functions. Finally we look at reformulations and approximations for discontinuous functions like \(\text{abs}\), \(\text{max}\) and \(\text{min}\) in section Reformulating DNLP Models.

#### 4.17.1 Specifying Initial Values

The variable levels and equation marginals in GAMS are typically passed to a solver to be used as the initial point. The initial values specified are especially important for NLP models for several reasons:

- Non-convex models may have multiple local solutions. Local NLP solvers search for a local solution and return it when it is found. An initial point in the neighborhood of a desired solution is more likely to return that solution.
- Initial values that (almost) satisfy many of the constraints reduce the work involved in finding a first feasible solution.
- Initial values that are close to a local optimum reduce the work required to find that local optimum, therefore reducing solution time.
- The progress of the optimization algorithm is based on good directional information, i.e on good derivatives. The derivatives in a nonlinear model depend on the current point, so an improved initial point can improve solver performance.
4.17 Good NLP Formulations

Variable levels and equation marginals are specified by setting the variable attribute .L and the equation attribute .m before solution. This is often done with assignments that occur before the solve statement, e.g.:

\[
\text{domPrice}.L(i,\text{region},t) = \text{domPrice0}(i,\text{region},t);
\]
\[
\text{flowLim}.m(\text{arcs}) = 1;
\]

Note

The default value for the variable levels and equation marginals is 0.

The variable bounds also play a role in determining the initial point passed to the NLP solver. When a solve occurs, the levels for all variables in the model are first projected onto the set defined by the variable bounds. Thus, setting a variable's lower bound to a positive value ensures that the initial value of this variable will never be zero. This is very useful, since in many cases zero is an unsuitable initial value for nonlinear variables. For example, based on the product term \(x \cdot y\), an initial value of zero for \(x\) will lead to an initial derivative value of zero wrt \(y\), so it will appear as if the function does not depend on \(y\). Variables at zero can also cause numerical difficulties with logarithms, real powers, or divisions. These difficulties occur not just at zero but also for very small values (i.e. values very close to zero) as well.

We recommend to specify as many sensible initial values for the nonlinear variables as possible. It may be desirable to initialize all variables to 1 or to the scale factor if the GAMS scaling option is used. A better alternative is to first select reasonable values for some variables that are known from context or experience to be important and then to use some of the equations of the model to compute the values for other variables. For example, consider the following equation, where \(\text{pm}, \text{pwm}\) and \(\text{er}\) are variables and \(\text{tm}\) is a parameter:

\[
\text{pmDef}(i) \ldots \text{pm}(i) = \text{pwm}(i) \cdot \text{er} \cdot (1 + \text{tm}(i));
\]

The following assignment statements use the equation to derive consistent initial values for the variable \(\text{pm}\) from sensible initial values for the variables \(\text{pwm}\) and \(\text{er}\):

\[
\text{pwm}.L(i) = 1;
\]
\[
\text{er}.L = 1;
\]
\[
\text{pm}.L(i) = \text{pwm}.L(i) \cdot \text{er}.L \cdot (1 + \text{tm}(i));
\]

It would be a mistake to assign only to \(\text{pwm}\) and \(\text{er}\) and assume that the solver will choose to adjust the variable \(\text{pm}\) to make the equation feasible: it could choose to adjust \(\text{pwm}\) or \(\text{er}\) instead. With all the assignments above made, we can be assured that the equation \text{pmDef} will be satisfied at the initial point.

Setting the initial point by loading a prior solution that has been saved via the savepoint mechanism is also an effective strategy that is very easy to implement.
4.17.2 Setting Variable Bounds

Lower and upper bounds on variables are set by assigning values to the variable attributes .lo and .up in the following way:

```plaintext
price.lo(i,region,t) = 1e-4;
flow.up(arcs) = arcCap(arcs);
```

Lower and upper bounds on variables in nonlinear models serve multiple purposes. Some bounds represent constraints based on the reality that is being modeled. For example, a certain production level must be non-negative or an arc in a network has a flow capacity of at most ten. These bounds are called *model bounds*. Other bounds help the algorithm by preventing it from moving far away from any optimal solution and/or into regions with singularities in the nonlinear functions or unreasonably large function or derivative values. These bounds are called *algorithmic bounds*. Solver performance can be improved and execution errors (see domLim and domUsd) avoided when algorithmic bounds on variables are introduced.

Model bounds are determined by the reality being modeled and do not cause any problems. However, algorithmic bounds must be carefully chosen by the modeler. We recommend to pay particular attention if a variable is the argument in \( \log(x) \), \( \log_{10}(x) \) or \( \exp(x) \) and if a variable occurs in the denominator of a division. If \( \log(x) \) or \( \log_{10}(x) \) appears in a model, where \( x \) is a variable, we recommend a lower bound of \( 1.e-3 \) for \( x \) since \( \log(x) \) gets very small as \( x \) approaches zero and is undefined for negative values of \( x \). In addition, the first derivative gets very large as \( x \) approaches zero. If \( \exp(x) \) features in a model, where \( x \) is a variable, we recommend an upper bound between 20 and 25 for \( x \). If a variable \( x \) appears in the denominator, we recommend a lower bound of \( 1.e-2 \) for \( x \), since \( 1/x \) is extremely nonlinear for small arguments. Small values for variables used with negative exponents are also not desirable. Solver performance can be improved and execution errors avoided when one introduces algorithmic bounds on variables.

Note that lower and upper bounds facilitate finding a feasible solution as most solvers will honor bounds at all times, but inequalities are not necessarily satisfied at intermediate points. A further advantage of variable bounds compared to inequalities is improved presolve performance: NLP solver preprocessors will typically incur little or no computational overhead due to variable bounds.

4.17.3 Avoiding Expressions in Nonlinear Functions

It is often useful to avoid nonlinear functions of expressions (e.g. a division by the sum of many variables). Instead, an *intermediate* variable can be used for the expression. This applies in particular if the expressions depend on many variables. Consider the following example:

```plaintext
variable x(i), y;
equation ydef;
ydef.. y =e= 1 / sum(i, x(i));
```

This example could be reformulated via the intermediate variable \( x_{sum} \) and its defining equation \( x_{sumdef} \) in the following way:

```plaintext
variable x(i), y, xsum;
equation xsumdef, ydef;
xsumdef.. xsum =e= sum(i, x(i));
ydef .. y =e= 1/xsum;
xsum.lo = 1.e-2;
```

In the equation \( ydef \), the intermediate variable \( x_{sum} \) appears in the denominator instead of the original summation. This allows us to impose a lower bound on the variable \( x_{sum} \) to avoid dividing by zero. Of course, the model will contain more rows and columns if intermediate variables are introduced, but this increase in size is offset by a decrease in complexity and, in many cases, by an increase in sparsity as well.
4.17.4 Scaling Variables and Equations

Recall that nonlinear programming algorithms use the derivatives of the objective function and the constraints to find good search directions and they use function values to determine if constraints are satisfied or not. The relative size of the derivatives and the function values is influenced by the units of measurement that are used for the variables and constraints, and will have an effect on the performance of the solver and the result computed. Therefore, a proper, consistent scaling of the model is important to the success of the solution algorithm and the quality of the answer returned.

For example, assume that two goods are equally costly: both cost $1 per kg. However, the first is specified in grams and the second in metric tons, so that their coefficients in the cost function will be vastly different: $1000 per gram and 0.001 per ton respectively. If cost is measured in $1000 units, then the coefficients will be 1 and 1.e-6 respectively. This discrepancy in size may cause the algorithm to ignore the variable with the smaller coefficient, since the coefficient is comparable to some of the zero tolerances. To avoid such problems, the units of measurements need to be carefully chosen, that is, variables and constraints need to be properly scaled.

We recommend scaling with the following goals in mind:

- Solution level values of variables should fall into a range around 1, e.g. from 0.01 to 100.
- The magnitude of the nonzero constraint marginals at solution should fall into a range around 1, e.g. from 0.01 to 100.
- The magnitude of the derivatives of the nonlinear terms (i.e. the Jacobian elements) should fall into a range around 1, e.g. from 0.01 to 100, both at the initial point and at the solution.
- The constants in the equations should have absolute values around 1, e.g. from 0.01 to 100.

Well-scaled variables are measured in appropriate units. In most cases users should select the unit of measurement for the variables such that their expected value is around unity. Of course, there will always be some variation. For example, if \( x(i) \) is the production at location \( i \), one could select the same unit of measurement for all components of \( x \), say, a value around the average capacity.

In well-scaled equations the individual terms are measured in appropriate units. After choosing units for the variables users should choose the unit of measurement for the equations such that the expected values of the individual terms are around 1. For example, if these rules are followed, material balance equations will usually have coefficients of 1 and -1.

Usually well-scaled variables and equations result in well-scaled derivatives. To check whether the derivatives are well-scaled, we recommend running the model with a positive value for the option limrow and inspecting the coefficients in the equation listing of the GAMS list file.

For more about scaling in GAMS, see section Model Scaling - The Scale Option. Note that while many solvers have internal scaling procedures, a better result can generally be achieved by a judicious choice of units by the model developer.

4.17.5 Blocking Degenerate Cycling

Most commercial linear programming solvers use a perturbation technique to avoid degenerate cycling during the solution process: they temporarily add small numbers to the right-hand sides of equations. In general, NLP solvers do not have such an internal feature. Sometimes the success and performance of an NLP solver can be enhanced by a manual perturbation formulation.

In particular, if users observe that the NLP solution process has a large number of iterations where the solver does not make significant progress in altering the objective function value, we recommend to modify
the equations in the model by replacing the value of zero on the right-hand side with a small number. This may accelerate the solution process. Assume that we have the following equation:

\[ f(x) \leq 0 \]

This could be reformulated as:

\[ f(x) \leq \delta \ast 0.001 \]

Here we set \( \delta \) to 1 if we wish to keep the addition and to zero otherwise. The value of 0.001 is just an example and needs to be adjusted based on the model context. The number should be chosen such that it does not introduce significant distortions into the problem solution. Such an addition quite frequently reduces solution time by helping the solver avoid degenerate cycling. If it is done correctly, the resulting model solution is not qualitatively different from the original model solution. Users may also first solve the model with \( \delta = 1 \) and subsequently with \( \delta = 0 \) to get rid of the effects of the small numbers.

We recommend that user avoid using the same number but instead use some systematically varying number or a random number. The technique of adding a small number on the right-hand side may also be used in problems where many equations have the same nonzero value on the right-hand side.

### 4.17.6 Reformulating DNLP Models

Nonlinear models in GAMS belong to one of the following two classes: smooth and discontinuous. Typically, all functions with endogenous arguments contained in the model are smooth functions (i.e. functions with continuous derivatives) like \( \text{sin}, \text{exp} \) and \( \text{log} \). These models can be solved using NLP. If any of the endogenous functions in the model are not smooth (i.e. are discontinuous), the model cannot be solved as an NLP: the DNLP model type must be used instead. Examples of non-smooth functions include \( \text{ceil} \) and \( \text{sign} \), where the function itself is not continuous, and \( \text{max}, \text{min}, \) and \( \text{abs} \), where the derivatives are not continuous. Typically, NLP solvers are designed to work with continuous derivatives, and much of the convergence theory behind them assumes this continuity. Discontinuous functions or derivatives may cause numerical problems, poor performance, spurious (i.e. wrong) solutions, and other issues, so they should be used with special care and only if necessary.

N.B.: to avoid a proliferation of model types, nonlinear programming is the only model type split into smooth (NLP) and nonsmooth (DNLP) variants. All other model types allowing nonlinear functions (e.g. MINLP, MCP, CNS) include both smooth and nonsmooth functions. This is not because nonsmooth functions are less problematic in these contexts. It simply became too unwieldy to maintain this distinction across all types of nonlinear models.

A powerful and effective way to model discontinuous functions is with binary variables, which results in a model of type MINLP. The model [ABSMIP] demonstrates this formulation technique for the functions \( \text{abs}, \text{min}, \text{max} \) and \( \text{sign} \). Alternatively, reformulations or approximations may be used to model discontinuous functions such that the resulting model is of type NLP. Here we offer some guidance on how to reformulate or approximate the discontinuous functions \( \text{abs}, \text{max} \) and \( \text{min} \) using only smooth functions and continuous variables and thus transform a DNLP model into an NLP. This transformation is generally more reliable than solving the original as a DNLP.

Note that some of the reformulations suggested below enlarge the feasible space. They rely on the objective function to choose a solution that is contained in the original feasible space, i.e. where the relationship defined by the nonsmooth function holds. If the objective cannot be relied on to do this, it is also possible to use one of the smooth approximations for the nonsmooth functions defined below.
4.17.6.1 Reformulating and Approximating the Function ABS

The function \(\text{abs}(x)\) returns the absolute value of the argument \(x\). If we are minimizing an absolute value, then we can split this value into its positive and negative parts (both represented by positive variables) and minimize the sum of these variables. This formulation enlarges the feasible region but the optimal solution will be the one where the sum of the positive and negative parts is equal to the absolute value.

\[
\begin{align*}
\text{variables} & \quad x, y, z; \\
\text{equations} & \quad \text{obj '1-norm'} \\
& \quad f; \\
& \quad \text{obj.. abs}(x) + \text{abs}(y) =E= z; \\
& \quad f \quad \text{sqr}(x-3) + \text{sqr}(y+5) =L= 1; \\
\text{model nonsmooth / obj, f /}; \\
\text{solve nonsmooth using dnlp min z;} \\
\text{positive variables} & \quad \text{xPlus, xMinus, yPlus, yMinus;} \\
\text{equations} & \quad \text{obj2 'smooth version of 1-norm'} \\
& \quad \text{xDef} \\
& \quad \text{yDef} \\
& \quad \text{obj2.. xPlus + xMinus + yPlus + yMinus =E= z;} \\
& \quad \text{xDef.. x =E= xPlus - xMinus;} \\
& \quad \text{yDef.. y =E= yPlus - yMinus;} \\
\text{model smooth / obj2, xDef, yDef, f /}; \\
\text{solve smooth using nlp min z;}
\end{align*}
\]

Note that the discontinuity in the derivative of the function \(\text{abs}\) has been converted into lower bounds on the new variables \(x\text{Plus, x}\text{Minus, etc: these bounds are handled routinely by any NLP solver. Note too that the feasible space is larger than before. For example, many pairs x}\text{Plus and x}\text{Minus satisfy our equation x =E= x}\text{Plus - x}\text{Minus. However, our objective ensures that one of x}\text{Plus and x}\text{Minus will be zero at the solution so that the sum of x}\text{Plus and x}\text{Minus will be the absolute value of x.}

In case the objective function does not contain a term that tries to minimize the absolute value, a smooth approximation can be used instead of the reformulation described above. This approximation should be close to the absolute value and also have smooth derivatives. Such an approximation for \(\text{abs}(f(x))\) is:

\[
\sqrt{\text{sqr}(f(x)) + \text{sqr}(\text{delta})}
\]

Here \(\text{delta}\) is a small scalar. The value of \(\text{delta}\) controls the accuracy of the approximation and the curvature around \(f(x)=0\). The approximation error is largest when \(f(x)=0\) and decreases as \(f(x)\) gets farther from zero. A value for \(\text{delta}\) ranging between 1.e-3 and 1.e-4 should be appropriate in most cases. Users could also use a larger value in an initial optimization, reduce it and solve the model again. If \(\text{delta}\) is reduced below 1.e-4, then large second order terms might lead to slow convergence or even prevent convergence. An example of this approximation used for the previous example is below:

\[
\$\text{macro MYABS(t,d)} \quad [\sqrt{\text{sqr}(t)+\text{sqr}(d)}]\n\]

\[
\text{equation obj3;}
\text{obj3.. MYABS(x,1e-4) + MYABS(y,1e-4) =E= z;} \\
\text{model approx / obj3, f /}; \\
\text{solve approx using nlp min z;}
\]
Note the use of the macro facility to encapsulate the smooth reformulation. As mentioned above, this approximation has its largest error where \( f(x) = 0 \). If it is important to get accurate values at this point, then we recommend the following alternative approximation:

\[
\sqrt{\left(f(x) + \delta\right)^2 + \left(f(x) + \delta\right)^2} - \delta
\]

Note that the only difference is the subtraction of the constant term \( \delta \). In this case, the error will equal zero at \( f(x) = 0 \) and it will increase to \(-\delta\) as \( f(x) \) moves away from zero.

### 4.17.6.2 Reformulating and Approximating the Function MAX

The function \( \text{max}(x_1, x_2, x_3, \ldots) \) returns the maximum value of the arguments, where the number of the arguments may vary. Typically, the equation

\[
t \geq \text{max}(f(x), g(y))
\]

is replaced by two inequalities:

\[
t \geq f(x) \\
t \geq g(y)
\]

Here \( x, y \) and \( t \) are variables and \( f(x) \) and \( g(y) \) are some functions depending \( x \) and \( y \) respectively. Provided the objective function has some term that tries to minimize \( t \), one of the constraints will become binding at solution and \( t \) will equal the maximum of the two terms. The extension to more than two arguments in the function \( \text{max} \) should be obvious. A simple example follows:

```plaintext
variables  
x / LO 0, L 0.2, UP [pi/2] /  
xm 'max[sin(x),cos(x)]'  
z 'objective var'  
;
equation oDef;  
oDef.. x / 100 + max[sin(x),cos(x)] =E= z;  

model nonsmooth / oDef /;  
solve nonsmooth using dnlp min z;  

equations oDef2, sinBnd, cosBnd;  
oDef2.. x / 100 + mx =E= z;  
sinBnd.. mx =G= sin(x);  
cosBnd.. mx =G= cos(x);  

model smooth / oDef2, sinBnd, cosBnd /;  
solve smooth using nlp min z;  

In case the objective function does not force the max-term to be minimized, a smooth approximation for \( \text{max}(f(x), g(y)) \) can be used, as in the following example code:

\[
\left[\frac{f(x) + g(y) + \sqrt{(f(x)-g(y))^2 + \delta^2}}{2}\right]
\]

\[
\left[\frac{f(x) + g(y) + \sqrt{(f(x)-g(y))^2 + \delta^2}}{2}\right]
\]
4.18 Data Exchange with Other Applications

```plaintext
$macro MYMAX(t1,t2,d) [0.5 * [t1 + t2 + sqrt(sqr(t1-t2) + sqr(d))] ]
equation oDef3;
oDef3.. x / 100 + MYMAX(sin(x),cos(x),1e-4) =E= z;
model approx / oDef3 /;
solve approx using nlp min z;
```

Here $delta$ is a small scalar, preferably ranging from 1.e-2 to 1.e-4. The approximation error takes its maximum of $delta/2$ when $f(x)=g(y)$ and decreases as one moves away from this point. To shift the error away from the point of discontinuity, the following approximation can be used:

$$\frac{[f(x) + g(y) + \sqrt{sqr(f(x)-g(y)) + sqr(delta))} - delta]}{2}$$

### 4.17.6.3 Reformulating and Approximating the Function MIN

The reformulation of and approximation to the $\min$ function is similar to the $\max$ case above and will not be repeated in full here. Briefly,

$$t =e= \min(f(x),g(y))$$

is replaced by:

$$t =l= f(x)$$
$$t =l= g(y)$$

and is effective as long as the objective maximizes $t$. If not, this smooth approximation for $\min(f(x),g(y))$ can be used:

$$\frac{[f(x) + g(y) - \sqrt{sqr(f(x)-g(y)) + sqr(delta))}]}{2}$$

4.18.1 Data Exchange with Text Files

This tutorial describes some ways on how to exchange data between GAMS and text files (usually in ASCII format).

4.18.1.1 Reading Text Files During Compilation

GAMS can read arbitrary text files during compile time by inserting them into the compiler input stream. The file content is then assumed to be GAMS code. Thus, including a text file within a data statement (see also Data Entry: Parameters, Scalars and Tables) allows for an easy way to include data from a text file, as long as the syntax in the text file can be understood by the GAMS compiler. This way, model specification and data input can be separated into different files.

The $include compile-time command is used to instruct the GAMS compiler to include the context of a different file at the current position of the input stream. As a result, the GAMS code behaves as if the $include statement has been replaced by the content of the file to be included. This can be very handy when including data from a separate text file. For instance, when data for a table is actually coming from another environment, one could replace the TABLE statement by an include statement. A GAMS table is in fact very well suited for a human being to be read or written, but it is rather awkward for programs to generate (e.g., the numbers have to be approximately below the corresponding headers). Therefore, often parameters are used and long series of assignment statements are generated. For instance, consider the following fragment from model [TRNSPORT]:

Table d(i,j) 'distance in thousands of miles'
    new-york      chicago    topeka
seattle       2.5         1.7     1.8
san-diego     2.5         1.8     1.4 ;

When the data for this table is coming from a program it is more convenient to say in the main program:

Parameter d(i,j) 'distance in thousands of miles';
$include data.inc
display d;

and to have the include file data.inc contain the machine generated statements:

d("seattle","new-york") = 2.5;
d("san-diego","new-york") = 2.5;
d("seattle","chicago") = 1.7;
d("san-diego","chicago") = 1.8;
d("seattle","topeka") = 1.8;
d("san-diego","topeka") = 1.4;

In fact, GAMS can deal quite comfortably with a large number of such assignment statements.

Note, that since the included file is considered as part of the GAMS input stream, it is also echoed in the listing file. When including large text files with data statements, echoing these files in the listing file can be undesired. To suppress echoing to the listing file, the $include statement can be surrounded by $offlisting and $onlisting instructions:
parameter d(i,j) 'distance in thousands of miles';
$offlisting
$include data.inc
$onlisting
display d;

In the listing file, line numbers are skipped where the $offlisting is in effect.

In some cases it may be more convenient to use the initialization syntax of parameters. That is, the main GAMS file could contain the fragment:

parameter d(i,j) 'distance in thousands of miles' /
$include data2.inc
/;
display d;

and the data file contains the following records:

seattle .new-york 2.5
san-diego.new-york 2.5
seattle .chicago 1.7
san-diego.chicago 1.8
seattle .topeka 1.8
san-diego.topeka 1.4

This approach is preferable for large data sets as it is more efficient for GAMS.

Note

Tables and parameters are handled exactly the same way by GAMS internally. The only difference is in the specification of data.

When using a table statement, data can also be specified in CSV (Comma-separated values) format if the $ondelim command has been issued. This format can, for instance, be generated by spreadsheet programs.

As example, consider again the following fragment from model [TRNSPORT]:

Table d(i,j) 'distance in thousands of miles'

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

A file data.csv that specifies the data of this table in CSV format would have the content

,new-york,chicago,topeka
seattle,2.5,1.7,1.8
san-diego,2.5,1.8,1.4

Notice the empty first element in the first line, which corresponds to the top-left blank in the above table.

This file can now be included directly into GAMS by using the $ondelim and $offdelim commands:

Table d(i,j) 'distance in thousands of miles'
$ondelim
$include data.csv
$offdelim
;
Attention

The $ondelim command only enables the use of commas as a separation symbol. The use of a different separation character is not supported by GAMS. This can become an issue if, for example, a CSV file has been generated with a language setting where commas are used as decimal point and semicolons are used for separating entries in the CSV file. In such a situation, data.csv would have the content

, new-york; chicago; topeka
seattle; 2,5; 1,7; 1,8
san-diego; 2,5; 1,8; 1,4

Therefore, such text files need to be preprocessed before read into GAMS. The following code uses the POSIX tool tr to (simultaneously) replace commas by dots and semicolons by commas:

$call "tr ,; ., < data.csv > data2.csv"
Table d(i,j) 'distance in thousands of miles';
$ondelim
$include data2.csv
$offdelim

CSV files can also be used to input higher dimensional data into GAMS. For instance, consider the 3 dimensional table yieldtl from model [TURKEY]:

Table yieldtl(l,cl,ty) 'livestock yield time series (kg per head)'

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>sheep.meat</td>
<td>10.60</td>
<td>11.42</td>
<td>10.60</td>
<td>9.38</td>
<td>8.97</td>
<td>6.93</td>
</tr>
<tr>
<td>sheep.milk</td>
<td>23.7</td>
<td>24.1</td>
<td>24.2</td>
<td>24.0</td>
<td>23.9</td>
<td></td>
</tr>
<tr>
<td>sheep.wool</td>
<td>1.3</td>
<td>1.3</td>
<td>1.3</td>
<td>1.3</td>
<td>1.3</td>
<td>1.3</td>
</tr>
<tr>
<td>sheep.hide</td>
<td>0.5</td>
<td>0.6</td>
<td>0.6</td>
<td>0.5</td>
<td>0.6</td>
<td>0.4</td>
</tr>
<tr>
<td>goat.milk</td>
<td>37.7</td>
<td>38.1</td>
<td>38.2</td>
<td>38.3</td>
<td>37.8</td>
<td></td>
</tr>
<tr>
<td>goat.wool</td>
<td>0.6</td>
<td>0.6</td>
<td>0.6</td>
<td>0.6</td>
<td>0.6</td>
<td>0.6</td>
</tr>
<tr>
<td>goat.hide</td>
<td>0.2</td>
<td>0.3</td>
<td>0.3</td>
<td>0.3</td>
<td>0.2</td>
<td>0.3</td>
</tr>
<tr>
<td>angora.milk</td>
<td>1.77</td>
<td>1.77</td>
<td>2.66</td>
<td>2.21</td>
<td>1.77</td>
<td>1.77</td>
</tr>
<tr>
<td>angora.wool</td>
<td>1.6</td>
<td>1.6</td>
<td>1.6</td>
<td>1.6</td>
<td>1.6</td>
<td>1.4</td>
</tr>
<tr>
<td>angora.hide</td>
<td>0.1</td>
<td>0.1</td>
<td>0.1</td>
<td>0.1</td>
<td>0.1</td>
<td>0.1</td>
</tr>
<tr>
<td>cattle.milk</td>
<td>210.0</td>
<td>208.1</td>
<td>219.8</td>
<td>213.8</td>
<td>214.8</td>
<td>217.5</td>
</tr>
<tr>
<td>cattle.hide</td>
<td>3.3</td>
<td>3.4</td>
<td>2.9</td>
<td>3.0</td>
<td>2.6</td>
<td>3.3</td>
</tr>
<tr>
<td>buffalo.meat</td>
<td>43.73</td>
<td>45.42</td>
<td>40.61</td>
<td>37.21</td>
<td>32.20</td>
<td>32.68</td>
</tr>
<tr>
<td>buffalo.milk</td>
<td>267.1</td>
<td>269.2</td>
<td>263.8</td>
<td>219.6</td>
<td>275.5</td>

<tr>
<td>poultry.meat</td>
<td>2.24</td>
<td>2.24</td>
<td>2.24</td>
<td>2.24</td>
<td>2.24</td>
<td>2.24</td>
</tr>
<tr>
<td>poultry.egg</td>
<td>62.4</td>
<td>62.2</td>
<td>64.2</td>
<td>78.3</td>
<td>76.4</td>
<td>73.3</td>
</tr>
</tbody>
</table>

When the data for this parameter is prepared by another application (such as a relational database), it may be more convenient to write it out in a comma-separated value form, e.g., a file data.csv could have the content

"sheep","meat","1974",10.60
"sheep","meat","1975",11.42
"sheep","meat","1976",10.60
Including such formatted data into a GAMS model is possible by using $ondelim for Parameter Data for Higher Dimensions. Thus, the GAMS code would be

```gams
Parameter yieldtl(l,cl,ty) 'livestock yield time series (kg per head)'
/ $ondelim
$include data.csv
$offdelim
/;
```

### 4.18.1.2 Writing Text During Compilation

The commands $echo, $onecho, and $offecho send text to named files during compilation. $echo sends one line and is invoked using the syntax:

```
$echo 'text to be sent' > externalfile
```

or

```
$echo 'text to be sent' >> externalfile
```

The use of "">

```
$onecho > externalfile
line 1 of text to be sent
line 2 of text to be sent
...
lst line of text to be sent
$offecho
```

A typical example for the usage of these commands is the generation of a solver options file.

Additionally, the $log command can be used to send messages to the log file during compilation.
4.18.1.3 Writing Text Files During Execution

The put writing facility allows customized text output. This is a fairly complex but powerful and flexible report writing facility.

Assume that the following GAMS code is added to the end of model [TRNSPORT]. It instructs GAMS to write the model and the solve status together with levels of the decision variables to a file results.txt:

File results / results.txt /;
put results;
put "Model status", transport.modelstat /;
put "Solver status", transport.solvestat /;
put "Objective", z.l /;
put "Shipments" /;
loop((i,j),
    put i.tl, j.tl, x.l(i,j) /);
putclose;

First, a file object results is declared by using the File statement. The data of the file statement specifies the name of the file (results.txt). Next, line put results; instructs GAMS that for the following put statements, the file results should be used. In the following, the model status and the solve status are written, together with some descriptive text. These model attributes are set by a solve statement. The character '/' instructs GAMS to add a linebreak (newline character) to the results file. The next thing to write out are some variable values. Here, first the level value of variable z is written, followed by a loop that writes for each element of sets i and j the name of the elements (accessed via the .tl attribute) and the level value of x(i,j). Finally, the putclose; statement instructs GAMS to close the current file. This will ensure that possibly cached data is flushed to the file.

The output will look like:

Model status 1.00
Solver status 1.00
Objective 153.67
Shipments
    seattle  new-york  50.00
    seattle  chicago   300.00
    seattle  topeka    0.00
    san-diego new-york 275.00
    san-diego chicago  0.00
    san-diego topeka  275.00

This form can be hard to read by other applications, e.g., because some space characters are to be considered as separators, while others are really part of a string (e.g. "Model status"). However, by using the print control option .pc of the put writing facility, comma-separated value files can be written. That is, by adding the line results.pc = 5;; i.e.,

File results / results.txt /;
    results.pc = 5;
put results;
put "Model status", transport.modelstat /;
put "Solver status", transport.solvestat /;
put "Objective", z.l /;
put "Shipments" /;
loop((i,j),
    put i.tl, j.tl, x.l(i,j) /);
putclose;
4.18 Data Exchange with Other Applications

one obtains the following output:

"Model status",1.00
"Solver status",1.00
"Objective",153.67
"Shipments"
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00

If several parameters of the same dimension should be written to a file in a customized format, the put statements can become rather repetitive. For example, the level and marginal values of variable \(x\) and the parameters \(c\) and \(d\) from model [TRNSPORT] should be written. This can be coded easily as:

```plaintext
file results / results.txt /;
results.pc = 5;
put results;
loop((i,j), put "distance", i.tl, j.tl, d(i,j) / );
loop((i,j), put "cost", i.tl, j.tl, c(i,j) / );
loop((i,j), put "levels", i.tl, j.tl, x.l(i,j) / );
loop((i,j), put "marginals", i.tl, j.tl, x.m(i,j) /);
putclose;
```

A separation of the code that writes the data (loop and put statements) from the data that is written (descriptive text, set names, etc.) can be achieved by using $batinclude. This command works similar to the $include statement (see also Section Reading Text Files During Compilation above), but allows for additional arguments (separated by blanks). While including the file, markers %1, %2, etc., are replaced by the value of the 1st, 2nd, etc., argument.

By using $batinclude, the above example could be simplified to

```plaintext
file results / results.txt /;
results.pc = 5;
put results;
$batinclude put.inc distance i j d
$batinclude put.inc cost i j c
$batinclude put.inc level i j x.l
$batinclude put.inc marginal i j x.m
putclose;
```

where the file put.inc contain the actual loop and put statements:

```plaintext
loop((%2,%3), put "%1", %2.tl, %3.tl, %4(%2,%3) / );
```

Finally, the The Put_Utility Statement is referred, which is loosely connected to the put statement and allows the dynamic generation of file names, etc.
4.18.2 Data Exchange with Microsoft Excel

This tutorial gives an overview on how to exchange data between GAMS and Microsoft Excel.

GAMS can communicate with Microsoft Excel via GDX (GAMS Data Exchange) files. In order to write data from GAMS and to Excel, selected GAMS data can be written into a GDX file and then to an Excel file: GAMS -> GDX -> Excel. Similarly selected Excel data can be written to a GDX file and then read into GAMS: Excel -> GDX -> GAMS.

Some of GAMS/Excel data exchange tools that provide functionality to exchange data between GAMS and Excel are also discussed in the section Data Exchange Tools. The data exchange between GAMS and a CSV (Comma-separated values) file format and GAMS is covered in Data Exchange with Text Files.

4.18.2.1 From GAMS to Excel

Consider the following modification of the [TRNSPORT] model from the gams model library.

Sets
i 'canning plants' / seattle, san-diego /
j 'markets' / new-york, chicago, topeka / ;

Parameters
a(i) 'capacity of plant i in cases'
  / seattle 350
  san-diego 600 /
b(j) 'demand at market j in cases'
  / new-york 325
  chicago 300
  topeka 275 /

Table d(i,j) 'distance in thousands of miles'
  new-york 2.5 1.7 1.8
  san-diego 2.5 1.8 1.4 ;

Scalar f 'freight in dollars per case per thousand miles' /90/ ;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f * d(i,j) / 1000 ;

Variables
x(i,j) 'shipment quantities in cases'
z 'total transportation costs in thousands of dollars' ;

Positive Variable x ;

Equations
cost 'define objective function'
supply(i) 'observe supply limit at plant i'
demand(j) 'satisfy demand at market j'
cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;
4.18 Data Exchange with Other Applications

supply(i) .. sum(j, x(i,j)) =l= a(i) ;
demand(j) .. sum(i, x(i,j)) =g= b(j) ;
Model transport /all/ ;
Solve transport using lp minimizing z ;
Display x.l, x.m ;

*=== Export to Excel using GDX utilities
*=== First unload to GDX file (occurs during execution phase)
execute_unload "results.gdx" x.L x.M
*=== Now write to variable levels to Excel file from GDX
*=== Since we do not specify a sheet, data is placed in first sheet
execute 'gdxxrw.exe results.gdx o=results.xlsx var=x.L'
*=== Write marginals to a different sheet with a specific range
execute 'gdxxrw.exe results.gdx o=results.xlsx var=x.M rng=NewSheet!f1:i4'

After the solve statement, the data (x.L and x.M) from variable x can be written into a GDX file during the execution time using the command executeUnload:

execute_unload "results.gdx" x.L x.M

The executeunload command above is executed during the actual execution phase to create a GDX file called results.gdx. The solution x and the marginals of x in the GDX file can be written to the Excel file results.xlsx using GDXXRW tool:

execute 'gdxxrw.exe results.gdx var=x.L'
execute 'gdxxrw.exe results.gdx var=x.M rng=NewSheet!f1:i4'

For the first call for x.L, there is no range specified and the data is written in cell A1 and beyond in the first available sheet. For the second call for marginals x.M, data will be written to cells F1:I4 in the sheet named NewSheet.

Note that GAMS can also write data into a GDX file during compile time. It is also possible to convert data stored in a GDX file into an Excel file spreadsheets using GDX2XLS tool and to write GAMS data to standard output formatted as a GAMS program with data statements using GDXDUMP tool.

4.18.2.2 From Excel to GAMS

Consider the following modification of the [TRNSPORT] model from the gams model library and the file results.xlsx file created from the previous example.

Sets
i 'canning plants’ / seattle, san-diego /
j 'markets’ / new-york, chicago, topeka / ;

Parameters
a(i) 'capacity of plant i in cases'
   / seattle 350
   san-diego 600 /

b(j) 'demand at market j in cases'
   / new-york 325
   chicago 300
   topeka 275 / ;

Table d(i,j) 'distance in thousands of miles'

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
<td>1.4</td>
</tr>
</tbody>
</table>

Scalar f 'freight in dollars per case per thousand miles' /90/ ;

Parameter c(i,j) 'transport cost in thousands of dollars per case' ;

\[ c(i,j) = \frac{f \times d(i,j)}{1000} ; \]

Variables
x(i,j) 'shipment quantities in cases'
z 'total transportation costs in thousands of dollars' ;

Positive Variable x ;

Equations
cost 'define objective function'
supply(i) 'observe supply limit at plant i'
demand(j) 'satisfy demand at market j' ;

\[ \text{cost} \quad z = \text{sum}(i,j, c(i,j) \times x(i,j)) ; \]

\[ \text{supply}(i) \quad \text{sum}(j, x(i,j)) = a(i) ; \]

\[ \text{demand}(j) \quad \text{sum}(i, x(i,j)) = b(j) ; \]

Model transport /all/ ;

==== Import from Excel using GDX utilities

==== First unload to GDX file (occurs during compilation phase)
$call gdxxrw.exe results.xlsx par=Level rng=sheet1!A1:D3

==== Now import data from GDX
Parameter Level(i,j);
$gdxin results.gdx
$load Level
$gdxin

==== Fix variables to values from Excel file
\[ x.FX(i,j) = Level(i,j) ; \]
display Level, x.L;

Solve transport using lp minimizing z ;
Display x.l, x.m;

The data in the Excel file can be loaded into a GDX file using the \$call command and GDXXRW tool:

\$call gdxrw.exe results.xlsx par=Level rng=A1:D3

The command \$call above executes a program called GDXXRW during compile time. The GDXXRW reads data from the range A1:D3 in results.xlsx into a GAMS parameter called Level in the GDX file results.gdx. As an output GDX file is not specified when calling GDXXRW, the output file will be derived from the input file by changing the file extension of the input file and removing any path information.

To import data from a GDX file into a parameter, the parameter must be defined over appropriate sets before read. The data from a GDX file can be read during the compile time using the commands \$gdxin and \$load:

Parameter Level(i,j);
\$gdxin results.gdx
\$load Level
\$gdxin

The first command \$gdxin specifies the name of the GDX file results.gdx to be read. The command \$load reads parameter Level from the GDX file. The second command \$gdxin closed the GDX file.

GAMS can read from a GDX file either during compile time or during execution time. See Example 4 - Reading a GDX File when reading data with domain information and Example 5 - Reading a GDX File when reading from a GDX file during execution time.

Note that it is also possible to write all worksheets of an Excel workbook into a GDX file using XLSDUMP tool.

4.18.2.3 Data Exchange Tools

There are a number of tools that provide functionality to exchange data between GAMS and an Excel file. This section discusses some of the data exchange tools with some examples. The complete list of the tools can be found at GAMS/Excel Data Exchange tools.

4.18.2.3.1 GDXXRW  GDXXRW is a tool to read and write Excel spreadsheet data. GDXXRW can read multiple ranges in a spreadsheet and write the data to a 'GDX' file, or read from a 'GDX' file, and write the data to different ranges in a spreadsheet.

How to use GDXXRW to exchange data between GAMS and Excel is covered in the section From GAMS to Excel and the section From Excel to GAMS. More details on usage and examples of GDXXRW tool is covered in GDXXRW.
XLS2GMS is a simple utility that allows you to extract data from an Excel spreadsheet and convert it into a GAMS include file. XLS2GMS can be run interactively or in batch mode.

Consider the Excel data from the following spreadsheet:

The data can be imported from the Excel file into a GAMS include file by calling XLS2GMS tool and inserted an include file as parameter data elements using the command $include:

```gams
set ssi /
   'new york', 'washington dc', 'los angeles', 'san francisco'
/;
parameter ssdata(ssi) /
$call =d:\util\xls2gms I="c:\my documents\test2.xlsx" B O=d:\tmp\x.inc
$include d:\tmp\x.inc
$display ssdata;
```

Notice the B parameter, which is needed as there are embedded blanks in the labels.

Sometimes a translation between the labels used in the model and the ones used in the is needed. One way to do this is to use a mapping set in GAMS. Suppose the rest of the model is defined in terms of the set I which is defined as:

```gams
set i / ny, dc, la, sf/;
```

To map a parameter data defined over this set, the following simple GAMS fragment can be used:
set map(i,ssi) mapping set / 
  ny.'new york'
  dc.'washington dc'
  la.'los angeles'
  sf.'san francisco'
/;
display map;

parameter data(i);
data(i) = sum(map(i,ssi), ssdata(ssi));
display data;

4.18.2.3 SQL2GMS In some cases it is convenient to consider tabular data in an Excel spreadsheet as a database table and to import it via GDX file using the SQL2GMS tool.

Consider the following spreadsheet:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>year</td>
<td>loc</td>
<td>prod</td>
<td>sales</td>
<td>profit</td>
</tr>
<tr>
<td>2</td>
<td>1997</td>
<td>la</td>
<td>hardware</td>
<td>80</td>
<td>5</td>
</tr>
<tr>
<td>3</td>
<td>1997</td>
<td>la</td>
<td>software</td>
<td>60</td>
<td>10</td>
</tr>
<tr>
<td>4</td>
<td>1997</td>
<td>nyc</td>
<td>hardware</td>
<td>100</td>
<td>15</td>
</tr>
<tr>
<td>5</td>
<td>1997</td>
<td>nyc</td>
<td>software</td>
<td>130</td>
<td>25</td>
</tr>
<tr>
<td>6</td>
<td>1997</td>
<td>sfö</td>
<td>hardware</td>
<td>50</td>
<td>9</td>
</tr>
<tr>
<td>7</td>
<td>1997</td>
<td>sfö</td>
<td>software</td>
<td>60</td>
<td>6</td>
</tr>
<tr>
<td>8</td>
<td>1997</td>
<td>was</td>
<td>hardware</td>
<td>80</td>
<td>7</td>
</tr>
<tr>
<td>9</td>
<td>1997</td>
<td>was</td>
<td>software</td>
<td>90</td>
<td>8</td>
</tr>
<tr>
<td>10</td>
<td>1998</td>
<td>la</td>
<td>hardware</td>
<td>88</td>
<td>5,25</td>
</tr>
<tr>
<td>11</td>
<td>1998</td>
<td>la</td>
<td>software</td>
<td>66</td>
<td>10,5</td>
</tr>
<tr>
<td>12</td>
<td>1998</td>
<td>nyc</td>
<td>hardware</td>
<td>110</td>
<td>15,75</td>
</tr>
<tr>
<td>13</td>
<td>1998</td>
<td>nyc</td>
<td>software</td>
<td>143</td>
<td>26,25</td>
</tr>
<tr>
<td>14</td>
<td>1998</td>
<td>sfö</td>
<td>hardware</td>
<td>55</td>
<td>9,45</td>
</tr>
<tr>
<td>15</td>
<td>1998</td>
<td>sfö</td>
<td>software</td>
<td>66</td>
<td>6,3</td>
</tr>
<tr>
<td>16</td>
<td>1998</td>
<td>was</td>
<td>hardware</td>
<td>88</td>
<td>7,35</td>
</tr>
<tr>
<td>17</td>
<td>1998</td>
<td>was</td>
<td>software</td>
<td>99</td>
<td>8,4</td>
</tr>
</tbody>
</table>

This table can be read using an SQL query:

```sql
SELECT year,loc,prod,'sales',sales FROM [profitdata$] 
  UNION SELECT year,loc,prod,'profit',profit FROM [profitdata$]
```

The table name is equal to the sheet name(profitdata). We can pass the query to the Excel ODBC driver using the tool SQL2GMS tool as follows:
set y 'years' /1997,1998/;
set c 'city' /la,nyc,sfo,was/;
set p 'product' /hardware,software/;
set k 'key' /sales,profit/;

$onecho > excelcmd.txt
c=DRIVER=Microsoft Excel Driver (*.xls, *.xlsx, *.xlsm, *.xlsb);dbq=%system.fp%profit.xlsx;
q=SELECT year,loc,prod,'sales',sales FROM [profitdata$] \ 
  UNION SELECT year,loc,prod,'profit',profit FROM [profitdata$]
x=fromexcel.gdx
$offecho
$call =sql2gms @excelcmd.txt
parameter d(y,c,p,k) ;
$gdxin excel.gdx
$load d=p
display d;

and the DISPLAY results will be:

--- 21 PARAMETER d FROM SQL2GMS

INDEX 1 = 1997

<table>
<thead>
<tr>
<th></th>
<th>sales</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>la</td>
<td>hardware 80.000</td>
<td>5.000</td>
</tr>
<tr>
<td>la</td>
<td>software 60.000</td>
<td>10.000</td>
</tr>
<tr>
<td>nyc</td>
<td>hardware 100.000</td>
<td>15.000</td>
</tr>
<tr>
<td>nyc</td>
<td>software 130.000</td>
<td>25.000</td>
</tr>
<tr>
<td>sfo</td>
<td>hardware 50.000</td>
<td>9.000</td>
</tr>
<tr>
<td>sfo</td>
<td>software 60.000</td>
<td>6.000</td>
</tr>
<tr>
<td>was</td>
<td>hardware 80.000</td>
<td>7.000</td>
</tr>
<tr>
<td>was</td>
<td>software 90.000</td>
<td>8.000</td>
</tr>
</tbody>
</table>

INDEX 1 = 1998

<table>
<thead>
<tr>
<th></th>
<th>sales</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>la</td>
<td>hardware 88.000</td>
<td>5.250</td>
</tr>
<tr>
<td>la</td>
<td>software 66.000</td>
<td>10.500</td>
</tr>
<tr>
<td>nyc</td>
<td>hardware 110.000</td>
<td>15.750</td>

<tr>
<td>was</td>
<td>hardware 88.000</td>
<td>7.350</td>
</tr>
<tr>
<td>was</td>
<td>software 99.000</td>
<td>8.400</td>
</tr>
</tbody>
</table>

4.18.2.3.4 **GDXVIEWER**  
GDXVIEWER is a tool to view and convert data contained in GDX files. It can also export to csv, xlsx, xml-files and pivot tables. The usage and examples are covered in GDXVIEWER.

4.18.2.3.5 **GDX2XLS**  
GDX2XLS tool to convert the contents of a GDX file into an Excel file or an xml-file. The usage and examples are covered in GDX2XLS.
4.18.3  Data Exchange with Databases

This tutorial provides a guidance on how to exchange data between GAMS and various Database Management System.

4.18.3.1  Data Exchange with DB2

DB2 is one of IBM's relational database management systems.

4.18.3.1.1  Import from DB2  

DB2 has an EXPORT command that can be used to generate comma delimited files. An example of a DB2 session illustrating this is shown below:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Type</th>
<th>Type name</th>
<th>Length</th>
<th>Scale</th>
<th>Nulls</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCA</td>
<td>SYIBM</td>
<td>VARCHAR</td>
<td>10</td>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>LOCB</td>
<td>SYIBM</td>
<td>VARCHAR</td>
<td>10</td>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>DISTANCE</td>
<td>SYIBM</td>
<td>DOUBLE</td>
<td>8</td>
<td>0</td>
<td>Yes</td>
</tr>
</tbody>
</table>

3 record(s) selected.

<table>
<thead>
<tr>
<th>LOCA</th>
<th>LOCB</th>
<th>DISTANCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>new-york</td>
<td>+2.500000000000000E+000</td>
</tr>
<tr>
<td>seattle</td>
<td>chicago</td>
<td>+1.700000000000000E+000</td>
</tr>
<tr>
<td>seattle</td>
<td>topeka</td>
<td>+1.800000000000000E+000</td>
</tr>
<tr>
<td>san-diego</td>
<td>new-york</td>
<td>+2.500000000000000E+000</td>
</tr>
<tr>
<td>san-diego</td>
<td>chicago</td>
<td>+1.800000000000000E+000</td>
</tr>
<tr>
<td>san-diego</td>
<td>topeka</td>
<td>+1.400000000000000E+000</td>
</tr>
</tbody>
</table>

6 record(s) selected.

Number of rows exported: 6
The resulting data file `export.txt` will look like:

```
"seattle","new-york",+2.50000000000000E+000
"seattle","chicago",+1.70000000000000E+000
"seattle","topeka",+1.80000000000000E+000
"san-diego","new-york",+2.50000000000000E+000
"san-diego","chicago",+1.80000000000000E+000
"san-diego","topeka",+1.40000000000000E+000
```

This file can be read into GAMS using `$include`:

```gams
parameter d(i,j) 'distance in thousands of miles' /
   $ondelim
   $include export.txt
   $offdelim
;/
display d;
```

### 4.18.3.1.2 Export to DB2

DB2 has an `IMPORT` command that can read delimited files. As an example consider the file generated by GAMS `PUT` statements:

```
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

A transcript of a DB2 session to read this file, is given below:

```
------------------------------------- Command Entered -------------------------------------
create table results(loca varchar(10) not null,
                       locb varchar(10) not null,
                       shipment double not null) ;
-------------------------------------------------------------------------------------------
DB20000I The SQL command completed successfully.

------------------------------------- Command Entered -------------------------------------
import from c:\tmp\import.txt of del insert into results ;
-------------------------------------------------------------------------------------------
SQL3109N The utility is beginning to load data from file "c:\tmp\import.txt".
SQL3110N The utility has completed processing. "6" rows were read from the input file.
SQL3221W ...Begin COMMIT WORK. Input Record Count = "6".
SQL3222W ...COMMIT of any database changes was successful.
SQL3149N "6" rows were processed from the input file. "6" rows were successfully inserted into the table. "0" rows were rejected.
```
4.18 Data Exchange with Other Applications

Number of rows read = 6
Number of rows skipped = 0
Number of rows inserted = 6
Number of rows updated = 0
Number of rows rejected = 0
Number of rows committed = 6

For very large data sets it is advised to use the LOAD command:

------------------------------------- Command Entered -------------------------------------
load from c:\tmp\import.txt of del insert into results ;
-------------------------------------------------------------------------------------------

SQL3501W  The table space(s) in which the table resides will not be placed in 
backup pending state since forward recovery is disabled for the database.

SQL3109N  The utility is beginning to load data from file "c:\tmp\import.txt".

SQL3500W  The utility is beginning the "LOAD" phase at time "03-20-2000
18:11:50.213782".

SQL3519W  Begin Load Consistency Point. Input record count = "0".

SQL3520W  Load Consistency Point was successful.

SQL3110N  The utility has completed processing. "6" rows were read from the 
input file.

SQL3519W  Begin Load Consistency Point. Input record count = "6".

SQL3520W  Load Consistency Point was successful.

SQL3515W  The utility has finished the "LOAD" phase at time "03-20-2000
18:11:50.337092".

Number of rows read = 6
Number of rows skipped = 0
Number of rows loaded = 6
Number of rows rejected = 0
Number of rows deleted = 0
Number of rows committed = 6

For smaller data sets one can also generate a series of INSERT statements using the PUT facility.

4.18.3.2 Data Exchange with MS Access

Microsoft Office Access, previously known as Microsoft Access, is a relational database management 
system from Microsoft. It is a member of the Microsoft Office system.

4.18.3.2.1 Import from MS Access

MDB2GMS  MDB2GMS is a tool to convert data from an Microsoft Access database 
into GAMS readable format. The source is an MS Access database file (*.mdb or *.accdb) and the target 
is a GAMS Include File or a GAMS GDX File. MDB2GMS is part of the GAMS Data eXchange Tools, 
see documentation for more information.
4.18.3.2.1.2 SQL2GMS  SQL2GMS is a tool to convert data from an SQL database into GAMS readable format. The source is any data source accessible through Microsoft's Data Access components including ADO, ODBC and OLEDB. The target is a GAMS Include File or a GAMS GDX File. SQL2GMS is part of the GAMS Data eXchange Tools, see documentation for more information.

4.18.3.2.1.3 CSV Files  Microsoft Access can export tables into comma delimited text files using its Save As/Export menu. Suppose we have the following table:

<table>
<thead>
<tr>
<th>loca</th>
<th>locb</th>
<th>distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>new-york</td>
<td>2.5</td>
</tr>
<tr>
<td>seattle</td>
<td>chicago</td>
<td>1.7</td>
</tr>
<tr>
<td>seattle</td>
<td>topeka</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>new-york</td>
<td>2.5</td>
</tr>
<tr>
<td>san-diego</td>
<td>chicago</td>
<td>1.8</td>
</tr>
<tr>
<td>san-diego</td>
<td>topeka</td>
<td>1.4</td>
</tr>
</tbody>
</table>

After choosing Save As/Export and selecting Text Files we get the following window:
Just using the default settings, we get the following file:

"seattle","new-york",2.50
"seattle","chicago",1.70
"seattle","topeka",1.80
"san-diego","new-york",2.50
"san-diego","chicago",1.80
"san-diego","topeka",1.40

which can be handled in GAMS by $ondelim/$offdelim and $include:

```gams
parameter d(i,j) 'distance in thousands of miles' / $ondelim
   $include dist.txt
   $offdelim /;
display d;
```

### 4.18.3.2.1.4 Import Dates from Access

GAMS dates are one day off when importing from MS Access. Suppose we have an MS Access table with one single date column:

```plaintext
datefield
--------
3/12/2007
3/13/2007 10:00:00 AM
3/14/2007 8:30:00 PM
```
The date data above can be imported into GAMS using $call and MDB2GMS tool as follows:

```
$call =mdb2gms I="%system.fp%Sample.accdb" Q="select datefield,Cdbl(datefield) from datetable" O=x.inc

parameter p(*) /
  $include x.inc
/
display p;
alias(*,i);
parameter q(*,+);
loop(i$p(i),
  q(i,'year') = gyear(p(i));
  q(i,'month') = gmonth(p(i));
  q(i,'day') = gday(p(i));
  q(i,'hour') = ghour(p(i));
  q(i,'minute') = gminute(p(i));
);
display q;
```

Note that the Cdbl() function converts the date to a floating point number (double precision). The generated include file looks like:

```
* -----------------------------------------------------
* MDB2GMS Version 2.8, January 2007
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* DAO version: 3.6
* Jet version: 4.0
* Database: D:\mdb2gms\examples\Sample.accdb
* Query: select datefield,Cdbl(datefield) from datetable
* -----------------------------------------------------
'
3/12/2007 39153
3/13/2007 10:00:00 AM 39154.4166666667
3/14/2007 8:30:00 PM 39155.8541666667
* -----------------------------------------------------
```

which looks o.k. However, when we look at the GAMS results in the listing file we see:

```
---- 28 PARAMETER p
3/12/2007 39153.000, 3/13/2007 10:00:00 AM 39154.417, 3/14/2007 8:30:00 PM 39155.854
```

```
---- 39 PARAMETER q

          | year | month | day  | hour | minute |
----------|------|-------|------|------|--------|
3/12/2007 | 2007 | 3.000 | 13.000 |
3/13/2007 | 2007 | 3.000 | 14.000 | 10.000 |
3/14/2007 | 2007 | 3.000 | 15.000 | 20.000 | 30.000 |
```

Clearly the dates are off by one day: see the column day. We can fix this problem in different places, e.g. in the query or in the GAMS model by subtracting 1.0 from an imported date. This problem occurs not only in MS Access but also with other software packages.

4.18.3.2.2 Export to MS Access
4.18 Data Exchange with Other Applications

4.18.3.2.2.1 GDX2ACCESS  
GDX2ACCESS is a tool to dump the whole contents of a GDX file to a new MS Access file (.mdb or .accdb file). GDX2ACCESS is part of the GAMS Data eXchange Tools, see documentation for more information.

4.18.3.2.2.2 GDXVIEWER  
Access tables in MS Access files can be directly generated by the GDXVIEWER tool. The GDXVIEWER tool uses OLE automation to export data to an MS Access database. This means that MS Access needs to be installed for the Access Export facility to work. GDXVIEWER is part of the GAMS Data eXchange Tools, see documentation for more information.

4.18.3.2.2.3 VBScript  
VBScript is a scripting tool that can be used to talk to COM objects. In this case we use it to tell Access to import a CSV file.

```
$ontext
Import a table into MS Access using VBscript
$offtext
$if exist new.accdb $call del new.accdb
set i /i1*i10/;
alias (i,j);
parameter p(i,j);
p(i,j) = uniform(-100,100);
display p;
file f /data.csv/;
f.pc=5;
put f,'i','j','p'/;
loop((i,j),
   put i.tl, j.tl, p(i,j):12:8/
);
putclose;
execute "=cscript access.vbs";

$onecho > access.vbs
'this is a VBscript script
Wscript.Echo "Running script: access.vbs"
DbLangGeneral = ";:LANGID=0x0409;CP=1252;COUNTRY=0"
strSQL = "SELECT * INTO mytable FROM [Text;HDR=Yes;Database=%system.fp%;FMT=Delimited].[data#csv]"
Wscript.Echo "Query : " & strSQL
Set oJet = CreateObject("DAO.DBEngine.36")
Wscript.Echo "Jet version : " & oJet.version
Set oDB = oJet.createDatabase("new.accdb",DbLangGeneral)
Wscript.Echo "Created : " & oDB.name
oDB.Execute strSQL
Set TableDef = oDB.TableDefs("mytable")
Wscript.Echo "Rows inserted in mytable : " & TableDef.RecordCount
oDB.Close
Wscript.Echo "Done"
$offecho
```

The CSV file contains a header row with the names of the fields:

```
"i","j","p"
"i1","i1",-65.65057360
"i1","i2",68.65334160
"i1","i3",10.07507120
"i1","i4",-39.77241920
"i1","i5",-41.55757660
....
```
The text driver specification `HDR=Yes` makes sure the first row in the CSV file is treated specially. The log will look like:

```
U:\temp>gams vbaccess.gms
--- Job vbaccess.gms Start 01/28/08 16:57:37
GAMS Rev 149 Copyright (C) 1987-2007 GAMS Development. All rights reserved
...
--- Starting compilation
--- vbaccess.gms(4) 2 Mb
--- call del new.accdb
--- vbaccess.gms(38) 3 Mb
--- Starting execution: elapsed 0:00:00.109
--- vbaccess.gms(18) 4 Mb
Microsoft (R) Windows Script Host Version 5.6
Copyright (C) Microsoft Corporation 1996-2001. All rights reserved.
...
Running script: access.vbs
Query : SELECT * INTO mytable FROM [Text;HDR=Yes;Database=U:\temp\;FMT=Delimited ].[data#csv]
Jet version : 3.6
Created : U:\temp\new.accdb
Rows inserted in mytable : 100
Done
--- Putfile f U:\temp\data.csv
*** Status: Normal completion
--- Job vbaccess.gms Stop 01/28/08 16:57:38 elapsed 0:00:00.609
U:\temp>
```

Please note that although the `$onecho/$offecho` is at the bottom of the GAMS file, the file `access.vbs` is created at compile time. I.e. before the executable statements like `PUT`, `EXECUTE` are executed.

### 4.18.3.2.2.4 JScript

The same script using `JScript` is similar to the one with VScript. We only price the script itself.

```jscript
$ontext
Import a table into MS Access using JScript
$offtext
$if exist new.accdb $call del new.accdb

set i /i1*i10/;
alias (i,j);
parameter p(i,j);

p(i,j) = uniform(-100,100);
display p;

file f /data.csv/;
f.pc=5;
put f,'i','j','p'/;
loop((i,j),
    put i.tl, j.tl, p(i,j):12:8/
);
putclose;

execute "=cscript access.js";
```
4.18 Data Exchange with Other Applications

```javascript
$onecho > access.js
// this is a JScript script
WScript.Echo("Running script: access.js");

dbLangGeneral = ";LANGID=0x0409;CP=1252;COUNTRY=0";
strSQL = "SELECT * INTO mytable FROM [Text;HDR=Yes;Database=.;FMT=Delimited].[data#csv]";
WScript.Echo("Query : ", strSQL);

oJet = new ActiveXObject("DAO.DBEngine.36");
WScript.Echo("Jet version : ", oJet.version);

oDB = oJet.createDatabase("new.accdb", dbLangGeneral);
WScript.Echo("Created : ", oDB.name);

oDB.Execute(strSQL);
TableDef = oDB.TableDefs("mytable");
WScript.Echo("Rows inserted in mytable : ", TableDef.RecordCount);

oDB.Close();
WScript.Echo("Done");
$offecho
```

4.18.3.2.2.5 Combining GDX2ACCESS and VBscript

Data in a GDX file do not contain domain information. I.e. a parameter c(i,j) is really stored as c(*,*)
As a result GDX2ACCESS will invent field names like dim1, dim2, Value. In some cases this may not be convenient, e.g. when more descriptive field names are required. We will show how a small script in VBscript can handle this task. The script will rename the fields dim1, dim2, Value in table c to i, j, and transportcost.

```vbscript
$call "gamslib 1"
$include transport.gms
* export to gdx file.
* The domains i,j are lost: gdx only stores c(*,*)
execute_unload "c.gdx",c;
* move to access database
* column names are dim1,dim2
* execute "+gdx2access c.gdx"
* rename columns
* execute "+cscript access.vbs"

$onecho > access.vbs
' this is a VBscript script
WScript.Echo "Running script: access.vbs"

' Office 2000 DAO version
' Change to local situation.
Set oDAO = CreateObject("DAO.DBEngine.36")
script.Echo "DAO version : " & oDAO.version

Set oDB = oDAO.openDatabase("%system.fp%\c.accdb")
WScript.Echo "Opened : " & oDB.name
```

The above VBscript fragment needs to be adapted according to the DAO version available on the client machine. This can be implemented in a more robust fashion by letting MS Access find the DAO engine:

```
' this is a VBscript script
WScript.Echo "Running script: access.vbs"
set oa = CreateObject("Access.Application")
set oDAO = oa.DBEngine
Wscript.Echo "DAO Version: " & oDAO.version
Set oDB = oDAO.openDatabase("%system.fp%c.accdb")
Wscript.Echo "Opened : " & oDB.name
Set oTable = oDB.TableDefs.Item("c")
Wscript.Echo "Table : " & oTable.name
' rename fields
oTable.Fields.Item("dim1").name = "i"
oTable.Fields.Item("dim2").name = "j"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"
oDB.Close
Wscript.Echo "Done"
```

Please note that the macro `%system.fp%` is replaced by GAMS by the working directory (this is the project directory when running GAMS from the IDE).

### 4.18.3.3 Data Exchange with MySQL

MySQL is a multi-threaded, multi-user SQL database management system.

#### 4.18.3.3.1 Import from MySQL

MySQL can write the results of a `SELECT` statement to a file as follows:
mysql> select * from dist;
+-------------------+----------+----------+
| loca              | locb     | distance |
+-------------------+----------+----------+
| seattle           | new-york | 50       |
| seattle           | chicago  | 300      |
| seattle           | topeka   | 0        |
| san-diego         | new-york | 275      |
| san-diego         | chicago  | 0        |
| san-diego         | topeka   | 275      |
+-------------------+----------+----------+
6 rows in set (0.01 sec)

mysql> select * from dist into outfile '/tmp/data.csv'
   -> fields terminated by ','
   -> optionally enclosed by '"'
   -> lines terminated by '\n';
Query OK, 6 rows affected (0.00 sec)

The resulting CSV file looks like:

"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275

which can be read by GAMS directly. This approach can be automated as follows:

[erwin@localhost erwin]$ cat myscript
use test
select * from dist into outfile '/tmp/data.csv'
   fields terminated by ','
   optionally enclosed by '"'
   lines terminated by '\n';
[erwin@localhost erwin]$ cat x.gms
set i /seattle, san-diego/;
set j /new-york, chicago, topeka/;
$call 'mysql -u root < myscript'
parameter dist(i,j) /
$ondelim
$include /tmp/data.csv
$offdelim
/
display dist;
[erwin@localhost erwin]$ gams x
GAMS Rev 132 Copyright (C) 1987-2002 GAMS Development. All rights reserved
Licensee: GAMS Development Corporation, Washington, DC  G871201:0000XX-XXX
Free Demo, 202-342-0180, sales@gams.com, www.gams.com  DC9999
--- Starting compilation
--- x.gms(5) 1 Mb
--- call mysql -u root < myscript
--- .data.csv(6) 1 Mb
--- x.gms(15) 1 Mb
The listing file shows that the table is read correctly:

```gams
set i /seattle, san-diego/
set j /new-york, chicago, topeka/;
parameter dist(i,j) /
   INCLUDE /tmp/data.csv
   "seattle","new-york",50
   "seattle","chicago",300
   "seattle","topeka",0
   "san-diego","new-york",275
   "san-diego","chicago",0
   "san-diego","topeka",275
   /;
display dist;
```

SEQ GLOBAL TYPE PARENT LOCAL FILENAME
1 1 INPUT 0 0 /home/erwin/x.gms
2 5 CALL 1 5 mysql -u root < myscript
3 8 INCLUDE 1 8 ./tmp/data.csv

**** 18 PARAMETER dist

<table>
<thead>
<tr>
<th>SEQ</th>
<th>GLOBAL</th>
<th>TYPE</th>
<th>PARENT</th>
<th>LOCAL</th>
<th>FILENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>INPUT</td>
<td>0</td>
<td>0</td>
<td>/home/erwin/x.gms</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>CALL</td>
<td>1</td>
<td>5</td>
<td>mysql -u root &lt; myscript</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
<td>INCLUDE</td>
<td>1</td>
<td>8</td>
<td>./tmp/data.csv</td>
</tr>
</tbody>
</table>

Instead of maintaining the MySQL script in a separate file, it can also be written by GAMS using `$onecho/$offecho` and a statement like:

```gams
$onecho > myscript
use test
select * from dist into outfile '/tmp/data.csv'
   fields terminated by ','
   optionally enclosed by "",
   lines terminated by '
';
$offecho
```

This will write the script at compile time.
4.18.3.3.2 Export to MySQL  GAMS can export data to MySQL by creating a script containing a series of SQL INSERT statements, as shown in section Oracle CSV Import.

It is noted that MySQL does have a REPLACE statement which is a useful blend of an INSERT and UPDATE statement: update a row if it already exists, otherwise insert it. This is not standard SQL however, so it can cause problems when moving to another database.

For larger result sets it may be better to use the LOAD DATA INFILE command. This command can read directly ASCII text files such as comma delimited CSV files.

Consider again the data file created by the PUT statement:

"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00

The following transcript shows how to import this into MySQL:

mysql> create table dist(loca varchar(10), locb varchar(10), distance double precision);
Query OK, 0 rows affected (0.00 sec)

mysql> show tables;
+----------------+
| Tables_in_test |
+----------------+
| dist |
+----------------+
1 row in set (0.00 sec)

mysql> describe dist;
+----------+-------------+------+-----+---------+-------+
| Field    | Type        | Null | Key | Default | Extra |
+----------+-------------+------+-----+---------+-------+
| loca     | varchar(10) | YES  |     | NULL    |       |
| locb     | varchar(10) | YES  |     | NULL    |       |
| distance | double      | YES  |     | NULL    |       |
+----------+-------------+------+-----+---------+-------+
3 rows in set (0.00 sec)

mysql> load data infile '/tmp/data.txt' into table dist
-> fields terminated by ',',
-> optionally enclosed by '"',
-> lines terminated by '\n';
Query OK, 6 rows affected (0.00 sec)
Records: 6 Deleted: 0 Skipped: 0 Warnings: 0

mysql> select * from dist;
+-----------+----------+----------+
| loca      | locb     | distance |
+-----------+----------+----------+
| seattle   | new-york | 50       |
| seattle   | chicago  | 300      |
| seattle   | topeka   | 0        |
| san-diego | new-york | 275      |
Note that we used no keys in our table definition. In practice it is of course highly recommended to define proper keys.

4.18.3.4 Data Exchange with Oracle

The Oracle Database (commonly referred to as Oracle RDBMS or simply as Oracle) is a relational database management system (RDBMS) software product released by Oracle Corporation.

4.18.3.4.1 Import from Oracle

4.18.3.4.1.1 SQL*Plus To export an Oracle table a simple solution is to write an SQL*Plus script. E.g. if our table looks like:

```sql
SQL> describe dist;
Name Null? Type
----------------------------------- -------- ------------------------
LOCA NOT NULL VARCHAR2(10)
LOCB NOT NULL VARCHAR2(10)
DISTANCE NUMBER

SQL> select * from dist;
LOCA LOCB DISTANCE
---------- ---------- ---------
seattle new-york 2.5
topeka new-york 2.5
seattle chicago 1.7
topeka chicago 1.8
seattle topeka 1.4
san-diego new-york 2.5
san-diego chicago 1.8
san-diego topeka 1.4
6 rows selected.
```

then the following script will export this table:

```sql
set pagesize 0
set pause off
set heading off
spool data
select loca||','||locb||','||distance from dist;
spool off
```

The resulting data file "data.lst" will look like:
4.18 Data Exchange with Other Applications

seattle,new-york,2.5
seattle,chicago,1.7
seattle,topeka,1.8
san-diego,new-york,2.5
san-diego,chicago,1.8
san-diego,topeka,1.4

This almost looks like our data initialization syntax for parameters:

SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4

The only differences are in the delimiters that are being used. These differences are easily digested by GAMS once it is in ondelim mode. I.e. the following syntax can be used to read the data.lst file:

```gams
parameter d(i,j) 'distance in thousands of miles' /
$ondelim
$include data.lst
$offdelim
/;
```

display d;

4.18.3.4.1.2 SQL2GMS An alternative way to import data from Oracle is to use the tool SQL2GMS which can talk to any database with an ADO or ODBC interface.

4.18.3.4.1.3 Import dates from Oracle databases and converting them to GAMS dates For most softwares it is easy to generate dates that GAMS can import and understand. The most common issue is that GAMS is one day off compared to Excel, Delphi, Access, ODBC etc. Oracle is somewhat more involved. First it is useful to have the date/time exported as a Julian date. This can be done with the following stored procedure:

```sql
-- julian representation of a date/time
-- Erwin Kalvelagen, feb 2007
create or replace function to_julian(d IN TIMESTAMP)
return number
is
begin
return to_number(to_char(d,'J')) + to_number(to_char(d,'SSSSS'))/86400;
end;
```

This function can be used to export dates as simple floating point numbers. In GAMS we need just a simple adjustment by adding a constant 'datediff' defined by:

```gams
scalar
    refdategams "march 16, 2006, 00:00"
    refdateoracle "march 16, 2006, 00:00" /2453811/
    datediff "difference between GAMS and Oracle date"
;
refdategams = jdate(2006,3,16);
datediff = refdategams-refdateoracle;
```

This trick has been applied in a complex scheduling application where dates are important data types that must be exchanged between the application logic and database tier and the optimization engine.
4.18.3.4.2 Export to Oracle

4.18.3.4.2.1 Oracle CSV Import  A familiar way of moving data into Oracle is to generate standard SQL INSERT statements. The PUT facility is flexible enough to handle this. For instance the following code:

```gams
file results /results.sql/;
results lw=0;
results nw=0;
put results;
loop((i,j),
    put "insert into result (loca, locb, shipment) ";
    put "values ("',i.tl,"','",j.tl,"','",x.l(i,j)),";"
);
putclose;
```

will generate these SQL statements:

```
insert into result (loca, locb, shipment) values ('seattle','new-york',50.00);
insert into result (loca, locb, shipment) values ('seattle','chicago',300.00);
insert into result (loca, locb, shipment) values ('seattle','topeka',0.00);
insert into result (loca, locb, shipment) values ('san-diego','new-york',275.00);
insert into result (loca, locb, shipment) values ('san-diego','chicago',0.00);
insert into result (loca, locb, shipment) values ('san-diego','topeka',275.00);
```

The .lw and .nw attributes for the put file indicate that no extra spaces around the labels and the numeric values are needed. These field width attributes have a default value of 12 which would cause the values to look like:

```
'seattle', 'new-york', 50.00
```

If the amount of data is large the utility SQL*Loader can be used to import comma delimited input. I.e. the GAMS code:

```gams
file results /results.txt/;
results pc=5;
put results;
loop((i,j),
    put i.tl, j.tl, x.l(i,j)/
);
putclose;
```

produces a file results.txt:

```
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

The following SQL*Loader control file will read this file:

```
LOAD DATA
INFILE results.txt
INTO TABLE result
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
(loca,locb,shipment)
```
4.18 Data Exchange with Other Applications

4.18.3.4.2.2 GDX to Oracle Database tables in an SQL RDBMS can be directly generated by the GDXVIEWER tool. The GDXVIEWER can use three methods to export to Oracle and other RDBMSs:

1. The direct ADO/ODBC link can create a new table and populate it.
2. The SQL INSERT script generator can create a script with a number of INSERT statements.
3. The SQL UPDATE script generator can create a script with a number of UPDATE statements.

4.18.3.5 Data Exchange with SQL Server

4.18.3.5.1 Import from SQL Server Microsoft SQL Server is Microsoft's flagship database. It comes in different flavors, including SQL Server, MSDE and SQL Server Express.

4.18.3.5.1.1 Using SQL2GMS A good way to import SQL server data into GAMS is using the SQL2GMS tool. Below is an example of its use:

```gams
$set commandfile commands.txt
$onecho > %commandfile%
C=provider=sqlolodb;data source=athlon\SQLExpress;Initial catalog=test;user id=sa;password=password
O=C:\WINNT\gamsdir\xx.inc
Q=SELECT * FROM x
$offecho
$call =sql2gms %commandfile%
parameter p(i,j) /
$include "C:\WINNT\gamsdir\xx.inc"
/;
display p;
```

4.18.3.5.1.2 Using the BCP utility and CSV files To export SQL Server data to CSV files we can use the BCP utility.

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>bcp test..results out x.csv -S athlon\sqlexpress -c -U sa -P password -t
Starting copy...
6 rows copied.
Network packet size (bytes): 4096
Clock Time (ms.) Total : 10 Average : (600.00 rows per sec.)
```

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type x.csv
```
seattle,new-york,50.0
seattle,chicago,300.0
seattle,topeka,0.0
san-diego,new-york,275.0
san-diego,chicago,0.0
san-diego,topeka,275.0
```

It is somewhat more difficult to create a proper CSV file. A format specification file can help here. For an example see the next section on Data Exchange with Sybase. Other tools to export files include DTS (Data Transformation Services) and linked ODBC data sources.
Finally we can program directly an interface between SQL server tables and GAMS GDX files. A small example in C# can look like:

```csharp
# Example C# code for interfacing SQL server tables with GAMS GDX files

```
4.18 Data Exchange with Other Applications

C:\Program Files\Microsoft SQL Server\90\Tools\binn>bcp test..x in c:\winnt\gamsdir\results.csv \
-S athlon\sqlexpress -c -U sa -P password -t,

Starting copy...

6 rows copied.
Network packet size (bytes): 4096
Clock Time (ms.) Total : 10 Average : (600.00 rows per sec.)

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test
2> select * from x;
3> go

<table>
<thead>
<tr>
<th>loca</th>
<th>locb</th>
<th>shipment</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>new-york</td>
<td>50</td>
</tr>
<tr>
<td>seattle</td>
<td>chicago</td>
<td>300</td>
</tr>
<tr>
<td>seattle</td>
<td>topeka</td>
<td>0</td>
</tr>
<tr>
<td>san-diego</td>
<td>new-york</td>
<td>275</td>
</tr>
<tr>
<td>san-diego</td>
<td>chicago</td>
<td>0</td>
</tr>
<tr>
<td>san-diego</td>
<td>topeka</td>
<td>275</td>
</tr>
</tbody>
</table>

(6 rows affected)
1> quit

Unfortunately, dealing with quoted strings is not straightforward with this tool (an example using a format file is shown in the next section on Data Exchange with Sybase). The same thing holds for BULK INSERT, which can read:

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
seattle,new-york,50.00
seattle,chicago,300.00
seattle,topeka,0.00
san-diego,new-york,275.00
san-diego,chicago,0.00
san-diego,topeka,275.00

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test
2> create table x(loca varchar(10), locb varchar(10), shipment float)
3> go

<table>
<thead>
<tr>
<th>loca</th>
<th>locb</th>
<th>shipment</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>new-york</td>
<td>50</td>
</tr>
<tr>
<td>seattle</td>
<td>chicago</td>
<td>300</td>
</tr>
<tr>
<td>seattle</td>
<td>topeka</td>
<td>0</td>
</tr>
<tr>
<td>san-diego</td>
<td>new-york</td>
<td>275</td>
</tr>
<tr>
<td>san-diego</td>
<td>chicago</td>
<td>0</td>
</tr>
<tr>
<td>san-diego</td>
<td>topeka</td>
<td>275</td>
</tr>
</tbody>
</table>

(6 rows affected)
1> select * from x
2> go
4.18.3.5.2.2 Export using the ODBC Text Driver  A slower but flexible way to load CSV files is to use a linked server through the ODBC Text Driver. First create an ODBC DSN using the Text Driver. This can be done through the ODBC Data Source Administrator Data Sources (ODBC) Then we can use the system procedure SP_AddLinkedServer.

---

C:\Program Files\Microsoft SQL Server\90\Tools\binn\ type c:\winnt\gamsdir\results.csv
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00

C:\Program Files\Microsoft SQL Server\90\Tools\binn\ type transport.sql
--
-- test database
--
use test

-- create table in SQL server
--
cREATE TABLE results (loca VARCHAR(10), locb VARCHAR(10), ship FLOAT)
GO

-- Create a linked server
--
EXEC sp_addlinkedserver txtsrv,'Jet 4.0','Microsoft.Jet.OLEDB.4.0','c:\winnt\gamsdir',NULL,'Text'
GO

-- copy data from text file c:\winnt\gamsdir\results.csv
--
INSERT INTO results(loca,locb,ship)
SELECT * FROM txtsrv...results#csv
GO

-- check if all arrived
--
SELECT * FROM results
GO

-- release linked server
--
EXEC sp_dropserver txtsrv
GO

--
-- clean up
--
drop table results

go

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\sqlexpress
1> :r transport.sql
Changed database context to 'test'.

(6 rows affected)
loca locb ship
---------- ---------- ------------------------
seattle new-york 50
seattle chicago 300
seattle topeka 0
san-diego new-york 275
san-diego chicago 0
san-diego topeka 275

(6 rows affected)
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>

A slightly different approach is the following:

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\sqlexpress
1> create table t(loca varchar(10), locb varchar(10), ship float)
2> go
1> insert into t
2> select * from
3> OpenRowSet('Microsoft.Jet.OLEDB.4.0',
4> 'Text;Database=c:\winnt\gamsdir\;HDR=NO',
5> 'select * from results.csv')
6> go

(6 rows affected)
1> select * from t
2> go
loca locb ship
---------- ---------- ------------------------
seattle new-york 50
seattle chicago 300
seattle topeka 0
san-diego new-york 275
san-diego chicago 0
san-diego topeka 275

(6 rows affected)
1> drop table t
2> go
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>

This can be automated from GAMS as follows:
file results /results.csv/;
results.pc=5;
put results;
loop((i,j),
    put i.tl, j.tl, x.l(i,j)/
);
putclose;

file sqlinsert /insert.sql/;
put sqlinsert;
put "use test"/;
put "insert into t select * from OpenRowSet('Microsoft.Jet.OLEDB.4.0',"
      "'Text;Database=c:\winnt\gamsdir\;HDR=NO','select * from results.csv')"/;
putclose;
execute '="C:\Progra~1\Microsoft SQL Server\90\Tools\binn\sqlcmd" -S athlon\SQLExpress -i insert.sql';

4.18.3.5.2.3 Export using the GDXVIEWER When using GDXVIEWER to export data to MS SQL server it is noted that MSSQL Server does not accept the default SQL type double for double precision numbers. You will need to set this setting to float or double precision.

When we export variable x from the transport model, we see:

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test
2> go
Changed database context to 'test'.
1> select * from x
2> go
<table>
<thead>
<tr>
<th>dim1</th>
<th>dim2</th>
<th>level</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>new-york</td>
<td>50</td>
</tr>
<tr>
<td>seattle</td>
<td>chicago</td>
<td>300</td>
</tr>
<tr>
<td>seattle</td>
<td>topeka</td>
<td>0</td>
</tr>
<tr>
<td>san-diego</td>
<td>new-york</td>
<td>275</td>
</tr>
<tr>
<td>san-diego</td>
<td>chicago</td>
<td>0</td>
</tr>
<tr>
<td>san-diego</td>
<td>topeka</td>
<td>275</td>
</tr>
</tbody>
</table>
(6 rows affected)
1> quit
C:\Program Files\Microsoft SQL Server\90\Tools\binn>

4.18.3.6 Data Exchange with SQLite

See GDX2SQLITE for more information.

4.18.3.7 Data Exchange with Sybase

4.18.3.7.1 Import from Sybase
4.18.3.7.1 Import using the bcp utility

Sybase is largely the same as SQL Server. For exporting ASCII files from a Sybase table, the utility (Using the BCP utility and CSV files) can be used.

An example of use of this utility is shown below:

```
[erwin@fedora sybase]$ isql -U sa -S LOCALHOST -D testdb -P sybase -J iso_1
1> select * from results
go
loca  locb  shipment
---------- ---------- -------------------
seattle  new-york  50.000000
seattle  chicago  300.000000
seattle  topeka  0.000000
san-diego  new-york  275.000000
san-diego  chicago  0.000000
san-diego  topeka  275.000000
(6 rows affected)
1> quit
[erwin@fedora sybase]$ cat bcp.fmt
10.0
4
1 SYBCHAR 0 0 "\n" 1 loca
2 SYBCHAR 0 10 "","" 1 loca
3 SYBCHAR 0 10 "," 2 locb
4 SYBCHAR 0 17 
"n" 3 shipment
[erwin@fedora sybase]$ bcp testdb..results out res.txt -S LOCALHOST -U sa -P sybase -J iso_1 -f bcp.fmt
Starting copy...
6 rows copied.
Clock Time (ms.): total = 1  Avg = 0 (6000.00 rows per sec.)
[erwin@fedora sybase]$ cat res.txt
"seattle","new-york",50.0
"seattle","chicago",300.0
"seattle","topeka",0.0
"san-diego","new-york",275.0
"san-diego","chicago",0.0
"san-diego","topeka",275.0
[erwin@fedora sybase]$ 
```

Note: the first column in the format file is a dummy (it has length 0). This is in order to write the leading quote, as bcp only allows for termination symbols.

This can be automated using the following GAMS code:

```gams
sets
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /

$onecho > bcp.fmt
10.0
4
1 SYBCHAR 0 0 "\n" 1 loca
2 SYBCHAR 0 10 "","" 1 loca
```
4.18.3.7.1.2 Import using the SQL2GMS utility  The SQL2GMS tool uses ADO or ActiveX Data Objects to extract data from relational databases. It can connect to almost any database from any vendor as it supports standards like ODBC. See documentation for more information.

4.18.3.7.1.3 Import using a 'SQL2GMS' VBS script  The following GAMS code will generate and execute a script written in VBScript. It mimics the behavior of SQL2GMS.EXE and can be used for debugging or the script can be passed on to the IT support people in case there are problems with accessing the database.

```gams
$ontext
  This script mimics SQL2GMS.
  Erwin Kalvelagen
  November 2006
$offtext

$onecho > sql2gms.vbs
,
  ' parameters
  t1 = 3  ' connection timeout
t2 = 0  ' command timeout
c = "Provider=MSDASQL;Driver={SQL Server};Server=DUOLAP\SQLEXPRESS;Database=testdata;Uid=gams;Pwd=gams;"  ' connection string
q = "select * from data"  ' query
o = "output.inc"  ' the output file to be generated
b = false  ' whether to quote indices (e.g. because of embedded blanks)
,

4.19 Executing GAMS from other Environments

4.19.1 Some General Comments

Nowadays the object-oriented APIs are the most efficient and elegant way to interact with the GAMS system. They allow the effective communication of data, and do parameterized runs of GAMS. This whole chapter describes a much more basic interaction of GAMS through calling the GAMS executable from different environments. This still can be useful, e.g. if no object-oriented API is available for the particular target language (e.g. VBA).

While the principle of calling the GAMS executable holds for all operating systems, this chapter often focuses on the Windows platform.

One of the interesting problems one faces when spawning GAMS.EXE in a Windows environment is multi-threading. If one does not take precautions, a call to Shell (VB function) or CreateProcess (Win32 API function) causes GAMS to run asynchronously: the function will return while GAMS is still running. In order to read the results one would need to wait until the GAMS job has finished. The machinery for this requires some Windows trickery, and for Visual Basic version 6 and Delphi version 4 we have implemented some small examples that illustrate how this can be done.

Another issue that needs to be addressed is that GAMS needs a place to put its scratch files. By default this is the current directory, a concept that is not always clear in a windowing environment. A good way of dealing with this is to set both the current drive and the current directory before running the GAMS job. It should be noted that GAMS needs write permission there. In the examples we use the Windows TEMP directory for this, but in a real application you may want to use a designated directory. The Windows TEMP directory is found by calling the API function GetTempPath.

4.19.1.1 The GAMS architecture

GAMS itself is a console mode application. In fact it is not a single program, but a driver program (GAMS.EXE on Windows, otherwise GAMS) that executes in turn the GAMS language compiler (GAMSCMEX) or one of the solvers. For a model with a single solve statement, GAMS.EXE will first call GAMSCMEX to compile the GAMS model. Then GAMSCMEX will start executing the internal code that was generated by the compiler. As soon as it hits the instructions belonging to a SOLVE statement it will generate model instance, and GAMSCMEX will exit. Then GAMS.EXE will spawn a solver capable of solving the model. As soon as the solver is finished, GAMS.EXE will execute GAMSCMEX again so it can read the solution and can continue with executing instructions.
4.19.2 Spawning GAMS from VBA

Visual Basic for Applications (VBA) is a programming language that is built into most Microsoft Office applications, e.g. Excel and Access. A VBA program may include modules, which can be imported from files, i.e. in the VBA editor you can choose menu “File”→“Import File”. The GAMS distribution includes some VBA modules, which can be found from:

\[ \text{<GAMS System Directory>\apifiles\VBA\api, e.g. "C:\GAMS\win64\24.5\apifiles\VBA\api"} \]

Attention

- In order to avoid issues, it's recommended to use the latest version of the modules, i.e. the modules found in the latest GAMS release.

For example, the following modules can be found:

- gamsglobals.bas: Global constants that are used in other modules
- gdxvba.bas: GAMS Data Exchange Object
- idxvba.bas: GAMS IDX Object
- optvba.bas: GAMS Option Object

For more information, see Expert-Level APIs. VBA programs that use the API can be found from:

\[ \text{<GAMS System Directory>\apifiles\VBA, e.g. "C:\GAMS\win64\24.5\apifiles\VBA"} \]

The models can also be retrieved via GAMSIDE -> Model Libraries -> GAMS Data Utilities Models.

4.19.2.1 Spawning GAMS from Excel

Calling GAMS out of Excel requires some more work than just Data Exchange with Microsoft Excel. The application calling GAMS out of Excel has to:

1. Locate the GAMS system directory and adjust the system path accordingly.
2. Copy the GAMS model into a temporary directory (by default the temporary directory of Windows)
3. Extract the model data from the spreadsheet into a GAMS readable format (gdx)
4. Execute GAMS (solve the model, write the solution back to gdx file)
5. Import the model results back from the gdx files into the spreadsheet
6. Update the spreadsheet (graphics, tables)

Using Visual Basic for Applications (VBA) this can be implemented with a few lines of code:

```vba
Sub solve()
    Dim WorkDir As String
    WorkDir = TempDir()
    Call ClearSolution
    If (Not AddGAMSPath()) Then ' needed to find gdxdclib64.dll and gams.exe
        Exit Sub
    End If
    Call ExportGDXFile(WorkDir)
    Call WriteGAMSModel(WorkDir & "portfolio.gms")
    Call RunGAMS(WorkDir & "portfolio.gms", WorkDir)
    Call ReadListing(WorkDir & "portfolio.lst")
    Call ImportGDXFile(WorkDir)
End Sub
```

For further details, please inspect the VBA part of the examples below.
4.19.2.2 A Simple Example

This very simple example shows how GAMS can be invoked from an Excel spreadsheet. The "example spreadsheet" has a button, which will cause GAMS to run the trnsport.gms model stored in c:/tmp. There is no data exchange.

A more complete application will write an include file for a GAMS model, and will import a comma delimited file with results when the run is finished. An example of such a complete application is described in http://www.gams.com/mccarl/excelgams.pdf.

4.19.2.3 Sudoku Example

This "spreadsheet" is a complete example that uses GDX files to exchange information solves a 25x25 Sudoku problem using CPLEX. You will need a GAMS/CPLEX license to be able to run the spreadsheet. The MIP model solves very easily: the solution is found in the presolve phase.

Note: This spreadsheet requires distribution 22.6 or younger to work properly. If you are using an older distribution, please download "this one".

4.19.2.3.1 Problem

4.19.2.3.2 Solution

4.19.2.4 Efficient frontier example

This "example" (screen shot below) solves a series of NLPs to create an efficient frontier of a portfolio optimization problem.

Note: This spreadsheet requires distribution 22.6 or younger to work properly. If you are using an older distribution, please download "this one".

4.19.3 Spawning GAMS from C

The example below shows an absolute minimal version of calling GAMS from a C program:

```c
#include <stdio.h>

int main(int argc, char** argv)
{
    system("gams trnsport lo=2");
    return 0;
}
```

As can be seen the GAMS executable gams.exe is called via a simple invocation of system(). The extra command line parameter lo=2 indicates that the log file is not written to the screen (this is the default) but to a file model.log.

If we want to generate some data from the application program (e.g. parameter DEMAND), we can use an include file which is written by the application. Of the way back results can be read from a PUT file. The GAMS file can now look like:
Sets
i canning plants / seattle, san-diego /
j markets / new-york, chicago, topeka /

Parameters
a(i) capacity of plant i in cases
/ seattle 350
   san-diego 600 /
b(j) demand at market j in cases
$/include demand.inc /
$include demand.inc /

Table d(i,j) distance in thousands of miles
new-york | chicago | topeka  
seattle   | 2.5     | 1.7     | 1.8
san-diego | 2.5     | 1.8     | 1.4

Scalar f freight in dollars per case per thousand miles /90/ ;

Parameter c(i,j) transport cost in thousands of dollars per case ;
c(i,j) = f * d(i,j) / 1000 ;

Variables
x(i,j) shipment quantities in cases
z total transportation costs in thousands of dollars ;

Positive Variable x ;

Equations
cost define objective function
supply(i) observe supply limit at plant i
demand(j) satisfy demand at market j ;
cost .. z =e= sum((i,j), c(i,j)*x(i,j)) ;
supply(i) .. sum(j, x(i,j)) =l= a(i) ;
demand(j) .. sum(i, x(i,j)) =g= b(j) ;

Model transport /all/ ;
Solve transport using lp minimizing z ;

Display x.l, x.m ;

file fout /results.txt/;
put fout;
loop((i,j),
   put x.l(i,j):17:5/;
);
putclose;

The corresponding C program could look like:

```
//
// example of running a GAMS model
```
4.19 Executing GAMS from other Environments

4.19.4 Spawning GAMS from Visual Basic

This example shows how GAMS can be invoked from a VB program.

When executed a simple window appears where a GAMS model can be specified and possible other command line options. The [GAMS] button will execute the model.

When the Normal display is used, a console window will be opened. This console window will be closed automatically at the end of the run if the Close process window on completion check box is checked. Minimized does not show a window, but in the taskbar an icon will appear. If the job takes a long time, the user can click on this icon to make the console window visible. The Hidden option prevents any GAMS associated window or icon to appear.

Note: it is required for this program to work, that the GAMS system directory is in the path. If this is not the case, an error code of -1 is returned.

The main program is attached below, the full source for this example is "available for download".

```vb
Attribute VB_Name = "vBGams"
Option Explicit
' ------------------------------
' Module Name: VBGams
' File: gams.bas
' Version: 1.1
',
', ' Functions:
' VB_Gams32 - sets up process directory, parameter file, and console, and manages
```
4.19.5 Spawning GAMS from Delphi

This is a Delphi 4 application that has similar features as the Visual Basic application described in the previous paragraph.

Note: it is required for this program to work, that the GAMS system directory is in the path. If this is not the case, an error code of -1 is returned. The main code is attached below, the full source and the executable for this example are "available for download".
unit main;

4.19 Executing GAMS from other Environments

4.19.6 Spawning GAMS from Visual C++

In "this example" we call GAMS from a simple Visual C++ application.

The additional concern is here that we want to intercept the GAMS screen output so it can be written to a multi-line edit control. For more information about the used technique see the Microsoft publication: HOWTO: Spawn Console Processes with Redirected Standard Handles (Q190351) in the Microsoft Knowledge Base.

4.19.7 Spawning GAMS from C#

Below is a simple example:

```csharp
using System.Diagnostics;

void RunGamsModel()
{
    Process p = new Process();
    p.StartInfo.FileName = gamsexe;
    p.StartInfo.Arguments = "\" + modelname + \" LO=0 --runid=\" + runid;
    p.Start();
    p.WaitForExit();
}
```

The command line formed here is `gams modelname LO=0 --runid=xxx`. The option `LO` (logoption) will disable writing a log, and the option `--runid` passes a parameter to the GAMS model (inside the model you can access this through `%runid%`).

4.19.8 Spawning GAMS from Java

Java has a class `Runtime` that implements spawning of processes using the `Exec()` method. This is quite trivial to use in applications, but in applets the default security settings don't allow this operation (in general). The problem can be solved by loading the applet from a local drive or by using a signed applet. Similarly if the Java classes are loaded from inside a database, this operation may require additional privileges. For an example see the previous section, where GAMS is called from Oracle using a Java Stored Procedure. The relevant code may look like:

```java
import java.io.File;

class RunGAMS {
    public static void main(String[] args) {
        System.out.println("Start");
        String[] cmdArray = new String[5];
        cmdArray[0] = "<PATH/TO/GAMS>" + File.separator + "gams";
        cmdArray[1] = "<PATH>" + File.separator + "transport.gms";
        cmdArray[2] = "WDIR=<PATH>" + File.separator + "TMP";
        cmdArray[3] = "SCRDIR=<PATH>" + File.separator + "TMP";
        cmdArray[4] = "LO=2";
        try {
            Process p = Runtime.getRuntime().exec(cmdArray);
            p.waitFor();
        } catch (java.io.IOException e) {
            System.err.println(">>>>" + e.getMessage());
            e.printStackTrace();
        } catch (InterruptedException e) {
            System.err.println(">>>>" + e.getMessage());
            e.printStackTrace();
        }
        System.out.println("Done");
    }
}
```
Below another example, which avoids problems, if the model has a long screen log (the buffer gets filled and locks the execution), which could happen if GAMS does not write the log to the file like above. This example is based on suggestion made by Edson Valle.

```java
import java.io.File;
import java.io.BufferedReader;
import java.io.InputStreamReader;
class RunGAMS {
    public static void main(String[] args) {
        System.out.println("Start");
        String[] cmdArray = new String[5];
        cmdArray[0] = "<PATH/TO/GAMS>" + File.separator + "gams.exe";
        cmdArray[1] = "" + File.separator + "transport.gms";
        cmdArray[2] = "" + File.separator + "tmp";
        cmdArray[3] = "LO=3";
        try {
            Process p = Runtime.getRuntime().exec(cmdArray);
            BufferedReader stdInput = new BufferedReader(new InputStreamReader(p.getInputStream()));
            String s = null;
            while((s=stdInput.readLine()) !=null){
                System.out.println(s);
            }
            p.waitFor();
        } catch (java.io.IOException e ) {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        } catch (InterruptedException e ) {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        }
        System.out.println("Done");
    }
}
```

For an example of GAMS usage from a Java based server environment see Alexander Sokolov, Information environment and architecture of decision support system for nutrient reduction in the Baltic Sea, Department of Systems Ecology, Stockholm University.

### 4.19.9 Spawning GAMS from a Web Server

Running GAMS remotely using a Web based thin-client architecture requires that GAMS is executed directly or indirectly from the Web server or HTTP server. A simple way of doing this is via a CGI process. Common Gateway Interface (CGI) programs can be written in many languages such as C, Perl or Delphi. CGI is relatively slow, as for each interaction, even the most simple one, a process needs to be started. Alternatives exist in the form of CGI extensions such as FastCGI or using DLLs or shared libraries. A basic algorithm for a CGI script could be:

- Create a unique directory, and CD to that directory.
- Get information from user forms and save it as GAMS readable files.
- Run GAMS making sure it does not write the log to the screen (i.e. use the option LO=2 (log to a file) or LO=3 (log to stdout)).
- Let the model write solution info to text files using the PUT statement.
- Read solution, and create formatted HTML to send back to the user.
- Remove temp files and directory.
Complications arise when there is a need to show graphics (files need to be stored somewhere and discarded after a while), when jobs take a long time to finish (you will need to add a facility where the user can pick up results at a later moment) or when the server resources can be exhausted (e.g. because of a large number of simultaneous users or because of large models).

An important complicating issue in the above list are jobs that take more time to finish: web servers like to respond to the user within a short time, and time out errors will occur if a job takes a long time. The solution is to use a queue based approach. An actual implementation available is the NEO Server — there is also a GAMS interface to NEOs: KESTREL - Remote Solver Execution on NEO Servers.

### 4.19.10 Spawning GAMS from PHP

A minimal example

**index.html**

```html
<html>
<body>
<form action="calling_gams.php" method="post">
    Solve transport with f = <select name="f">
        <option>70</option>
        <option>80</option>
        <option>90</option>
        <option>100</option>
    </select>
    <input type="submit" value="call GAMS"/>
</form>
</body>
</html>
```

**calling_gams.php**

```php
<?php
$f = $_POST['f'];
//some model data
$modelfile = 'transport_php.gms';
$city = array('new-york', 'chicago', 'topeka');
$demand = array(325.0, 300.0, 275.0);
//write demand.inc
$fh = fopen('./demand.inc', 'w+');
for($i=0; $i<count($city); $i++){
    fwrite($fh, $city[$i]." ".round($demand[$i], 0)."n");
}
fclose($fh);
//write f.inc
$fh = fopen('./f.inc', 'w+');
fwrite($fh, $f);
fclose($fh);
//call gams
system('./path/to/gams/gams ' . $modelfile . ' lo=2');
//read solutions
$fh = fopen('./results.txt', 'r');
echo "<p>result of \'.$modelfile.' (f='.$f.') :</p>";</b></p>
while (!feof($fh)){
    $line = fgets($fh);
    echo '<p>'.$line.' </p> ;
}
fclose($fh);
?>
```

**transport_php.gms**

Sets

```
Sets
i  canning plants / seattle, san-diego /
j  markets / new-york, chicago, topeka /;
```

Parameters

```
Parameters
a(i)  capacity of plant i in cases
/  seattle 350
    san-diego 600 /
```
4.20 Using GAMS Studio

This tutorial on using GAMS Studio was written initially by and is distributed by courtesy of Bruce A.
McCarrl. Bruce has extensive experience with GAMS, both as a modeler and an educator, and many

2Specialist in Applied Optimization, Distinguished Professor of Agricultural Economics, Texas A&M University, Principal, McCarl and Associates, mccarl[at]tamu.edu, brucemccarl[at]gmail.com, http://agecon2.tamu.edu/people/faculty/
GAMS users know, use, and benefit from his work. This tutorial presents a guided tour to the usage of GAMS Studio and on some items it reflects Bruce’s personal view and preferences.

4.20.1 What Is It?

*A multi platform (not only PCs with Windows) graphical interface to run GAMS*

GAMS uses two phases.

1. **Text edit**
   First, one uses a text editor and creates a file which contains GAMS instructions.

2. **File submission**
   Second, one submits that file to GAMS which executes those instructions causing calculations to be done, solvers to be used and a solution file of the execution results to be created.

Approaches to use GAMS.

1. More batch oriented traditional method use a text editor set up the model then use **DOS (or UNIX)** command line instructions to find errors in and run the model.

2. GAMS STUDIO or GAMS IDE alternatives. Graphical interfaces to create, debug, text edit and run GAMS files.

Summary of steps to using

1. Install GAMS and STUDIO on your computer

2. Open STUDIO through the icon

3. Open or create a file by going to the file selection in the upper left corner.

4. Prepare the file so you think it is ready for execution

5. Run the file with GAMS by clicking the run button or pressing F9

6. Open and navigate around the output
4.20.2 Installation

Install GAMS and STUDIO

GAMS STUDIO is automatically installed when GAMS is installed and you get the choice of whether to use STUDIO or the IDE as primary editor. To install do the following steps:

1. Download the GAMS installation file from www.gams.com under Resources and Download.

2. Start the installation.

Installer should place an icon on the desktop yielding

4.20.3 Using STUDIO after Installation

During the install you will find
Which allows you to choose which graphical interface to use as the default. For now choose STUDIO.

Open STUDIO through the icon

Open the File menu choice. Select a file.
Note, the file location determines where all generated files are placed (to place files elsewhere use the save as dialogue) and where GAMS looks for files when executing. I recommend that you make sure your file is in a place where you want it also making sure that place contains all associated files ie this is the file storage directory for this endeavor.

Fix defaults and suppress cursor driven object highlighting. When first opening Studio go to settings and I would make sure check marks are as follows especially the checked ones in the red boxes and the unchecked green one.
Here selecting the **Process Log** and possibly the **Explorer** are of interest.
The Explorer will open automatically when a file is opened and the Process Log will open when a solve is done. I usually hide the Explorer and sometimes want to get rid of the Process window.

4.20.3.1 Getting Started

4.20.3.1.1 Create or open an existing GMS file  Several cases are possible

1. Create a new file (covered later)

2. Open an existing file – at first this will be in

then you see something like
3. Open the GAMS model library explorer under the GAMS tab or press F6 (this is the simplest for first time users and the one we will use)

Select a model like transport.gms
It will be automatically saved in the last directory you used or in the STUDIO default Workspace directory.

4.20.3.1.2 Prepare file for execution When using model library `transpgms` should now appear as part of your STUDIO screen.

The STUDIO contains a full-featured editor. Go through the file and change what you want.

You can also customize the appearance somewhat through the settings choice under the File menu.
There you can change font size (under editor), tabs, default file location (called workspace) and some other features on how GAMS runs. For now leave it alone.

4.20.3.1.3 Make sure right file is executed

Unlike a lot of other programs, STUDIO does not necessarily execute the file you have been working on rather executing what it calls the "main" file.

In particular, if you activate the explorer view then the main file is the one marked with a **green triangle** as below. If the triangle is not marking the file to be run you need to right click on that file and then choose **Set as main file**. In turn the triangle will move.
4.20.3.1.4 Run GAMS by clicking the run button

The **Process Log** window (green) will then appear which logs the steps executed in running the model. The **LST file** (red) and the **navigation window** (magenta) also appear. Note to save space I would close the Explorer window and drag the **Process Log** window (green) to the bottom or the right hand side. The process window on the bottom is illustrated here and it is on the right side on the following picture.
4.20 Using GAMS Studio

Here it is after reconfiguring by dragging the Process Log up and to the right then resizing and repositioning.

Now use the process window (green) to navigate the LST file or open created files. By double clicking on lines in that window you access the LST file at particular locations or open created files. What and where you access is determined by the color of the line you click on.
### Color of Line and Function and Destination When Double Clicked

<table>
<thead>
<tr>
<th>Color of Line</th>
<th>Function and Destination When Double Clicked</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blue line</td>
<td>Opens LST file and jumps to corresponding place.</td>
</tr>
<tr>
<td>Non-bolded black line</td>
<td>Control click on this takes you to LST file. Double click on error message takes you to spot in LST file.</td>
</tr>
<tr>
<td>Red line</td>
<td>Marks errors encountered. Cursor is positioned at first red line. When clicked on cursor jumps to Source (GMS) file location of error. Control click takes you to error location in LST file. Error description text is in execution process log and in LST file. You can use a little red icon in source to jump to error message in LST file or a green arrow in the LST to go to error location in source.</td>
</tr>
<tr>
<td>Green line</td>
<td>Causes studio to open a file that was created during the run like a GDX, PUT or REF file.</td>
</tr>
</tbody>
</table>

---

**4.20.3.1.5 Navigate with process window**  
After double-clicking on any non-red line, or if we used the automatically open list file option our main editing window is augmented by the **LST file** (green) (see the magenta tabs)
4.20 Using GAMS Studio

We can navigate as we would with an editor or word processor, as we are automatically in STUDIO text editor.

Sometimes I want to get the process window and explorer out of the way. I can do this through the view window and also through the icons (red) on the right side of the top bar.

Clicking on these opens and closes the explorer and the process window.

4.20.3.1.6 Navigate with LXI window

<table>
<thead>
<tr>
<th>Navig. Line</th>
<th>Function and Destination When Clicked.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compilation</td>
<td>Jumps to top of echo print in LST file</td>
</tr>
<tr>
<td>Error Mess.</td>
<td>Jumps to list of error messages when errors present</td>
</tr>
<tr>
<td>Navig. Line</td>
<td>Function and Destination When Clicked.</td>
</tr>
<tr>
<td>-------------</td>
<td>----------------------------------------</td>
</tr>
<tr>
<td>Equat. listing</td>
<td>Jumps to list of equation contents</td>
</tr>
<tr>
<td>Equation</td>
<td>Expandable allowing jump list of equation contents</td>
</tr>
<tr>
<td>Variab. listing</td>
<td>Jumps to list of variable</td>
</tr>
<tr>
<td>Variable</td>
<td>Expandable allowing jump to list of variable contents</td>
</tr>
<tr>
<td>Model stat.</td>
<td>Jumps to model statistics part of LST file</td>
</tr>
<tr>
<td>Solut.Report</td>
<td>Jumps to model summary solution report</td>
</tr>
<tr>
<td>SolEQU</td>
<td>Expandable allowing jump solution for each equation</td>
</tr>
<tr>
<td>SolVAR</td>
<td>Expandable allowing jump to solution for variable</td>
</tr>
<tr>
<td>Execution</td>
<td>Jumps to beginning of post solve execution</td>
</tr>
<tr>
<td>Display</td>
<td>Jump to displays of specific parameters and other items</td>
</tr>
</tbody>
</table>

### 4.20.3.2 Working with your own files

Now you are ready to work with your own files. You may already have a file or you may need to create one.

**Creating a new file - Two principal ways**

1. Open an existing file through the library or from a location on your hard disk. Then use the `save as` dialogue from the `file` menu to change its name. Now modify contents to what you want. You may cut and paste as in other Windows programs.

2. Open the `file` menu and use the `new` option. You will then be prompted for a name (I called it mine) with the extension `.gms` and then have a `blank screen` (green) into which you may type GAMS instructions.

Save that file wherever you want and reopen it that will become the new default directory (this only occurs upon an open not a save as) and any subsequent non library opens, simple includes or saves will go there. Imports from the library go to the default workspace.
4.20.4 The Welcome and Explorer Windows

As you have worked with STUDIO you will find it shows a Welcome (magenta) window (unless you told it not to in settings), that remembers previous files plus gives access to documentation.

There as of now you get links to files recently used, and links to some documentation.

Also on the left hand side is an Explorer (green) window that shows recent files and allows you to open by double clicking. This remains whether you are in the welcome page or editing files unless it is not checked in the View dialogue.

4.20.5 Fixing Compilation Errors

No one is perfect, errors always occur. The STUDIO can help you in finding and fixing those errors.

Let’s look at an example with a small typo to illustrate (note: source vs. sorce). A run yields the windows below where the right part is the process window (green) positioned to show the first error and the center is the lst file (magenta) positioned to show the first error.
The red lines in the process window mark errors with error messages just below. To see where the errors occurred click on the very first red line which opens the source file or look at the LST file where the marking $ appears.

A click on the red line takes you to the place in the source where the error was made. The tip here is always start at the top of the process file when doing this.

A double click on a black line takes you to the error location in the LST file.

Also in the source file window note the small red circle that appears on the line with the error. Clicking on that transfers you to the LST file where the error message appears.

And there a small gray circle with an arrow in it that when clicked on will transfer you back to the source file.
4.20.6  Ways to find and/or replace text strings

For finding you can use the search menu under the Edit tab or control F

Subsequently you get
Which allows both search and replace. As of now this opens with the last option you used and may start with initially with an all files setting.

After the search you find

Where all occurrences of the search term in the current file are highlighted in yellow and to the right there is a list of all files that contain that search term (green) in all of the directories corresponding to files opened in the explorer.

The search dialogue is straight forward with arrow keys to jump to next (F3 also works for forward and shift F3 for backward) and the all files can be manipulated as shown (in yellow).

### 4.20.7 Matching Parentheses

The STUDIO provides you with a way of checking on how the parentheses match up in your GAMS code. This involves positioning your cursor just before an open parentheses or just after a close (Just after also works if there are not multiple parentheses). In either case the corresponding close or open is highlighted in green. Additionally positioning the cursor right before the beginning parentheses and tapping Ctrl + b will lead you to the matching ending parentheses whether it be 1, 100, or 1000+ lines away and vice versa.
When the expression in parentheses carries on the several lines the marking is in multiple lines and Ctrl + b will transfer position back and forth.

This feature will also match up { } or [ ] with a red marking if the types don’t match.

### 4.20.8 Moving Blocks

The STUDIO allows one to move text blocks through standard Cut and Paste Operations in two fashions.

1. One can identify a continuous block of text with the mouse or the keyboard (the latter involves putting the cursor at a beginning point then hold the shift key down and use the arrow keys).

2. One can identify a **column block of text** (blue) with the mouse or the keyboard (these involve holding **alt and shift down** then moving the mouse or the cursor with the arrow keys).

<table>
<thead>
<tr>
<th>Table</th>
<th>d(i,j) 'distance in thousands of miles'</th>
</tr>
</thead>
<tbody>
<tr>
<td>new-york</td>
<td>chicago</td>
</tr>
<tr>
<td>seattle</td>
<td>2.5</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.5</td>
</tr>
</tbody>
</table>

In turn copy, cut, and paste can be done with the Edit menu or with control c, x and v respectively as in normal windows. Control insert also pastes.

Also if one types with a column block highlighted than the character goes in all rows of the block and replaces what was there before.
4.20.9 Syntax Coloring

A feature in the STUDIO is syntax coloring. The STUDIO recognizes a subset of the GAMS syntax and reflects this in the display colors. Note in the display below that commands, explanatory text and set elements are differentially colored.

```
Parameter
  a(i) 'capacity of plant i in cases'
    / seattle 350
    / san-diego 600 /
  b(j) 'demand at market j in cases'
    / new-york 325
    / chicago 300
    / topeka 275 /;
Table d(i,j) 'distance in thousands of miles'
  new-york  chicago  topeka
  seattle    2.5    1.7    1.8
  san-diego  2.5    1.8    1.4;
Scalar f 'freight in dollars per case per thousand miles' / 90 /;
Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;
Variable
  x(i,j) 'shipment quantities in cases'
  z    'total transportation costs in thousands of dollars';
Positive Variable x;
Equation
  cost    'define objective function'
  supply(i) 'observe supply limit at plant i'
  demand(j) 'satisfy demand at market j';
  cost..  z =e= sum((i,j), c(i,j)*x(i,j));
```

For now unlike in the IDE one cannot alter these syntax colors.
4.20.10 Showing where a symbol appears

Studio has a feature that identifies where a symbol is used. Taking the library file *agreste.gms* and positioning the cursor over a symbol like c (blue) then double clicking places a (gray) highlight over all visible instances of that symbol.

```
$Title Model Definition

Variable
  xcrop(p,z) 'cropping activities' (ha),
  xliver(z)  'livestock activity defined on feed techniques' (head),
  xlive     'livestock production' (head),
  lswitch(s) 'land downgrading' (ha),
  xprod(s)  'crop production' (ton),
  cons(dr)  'on-farm consumption' (ton),
  sales(s)  'crop sales' (ton),
  flab(tm)  'family labor' (man-days),
  tlab(tm)  'temporary labor' (man-days),
  plab      'permanent labor' (workers),
  rationr  'livestock ration requirements' (cr),
  pdev(ty)  'positive price deviations' (cr),
  ndev(ty)  'negative price deviations' (cr),
  yfarm     'farm income' (cr),
  revenue   'from crop and livestock sales' (cr),
  cropcost  'accounting: cropping activities cost' (cr),
  labcost   'accounting: labor costs - including family' (cr),
  vetcost   'accounting: veterinary services cost' (cr);

Positive Variable xcrop, xliver, lswitch, sales, cons, flab, tlab, plab,

Equation
  landb(s) 'land balance',
  lbal    'livestock balance',
  rliv    'livestock ration requirements definition',
  mbalc(s) 'material balance: crops',
  dprod(s) 'crop production definition',
  cond    'on farm consumption definition',
  labc(tm) 'labor supply-demand relation',
  ddev(ty) 'crop price deviation definition';
```

4.20.11 Accessing Documentation Via the Help

To access GAMS documentation choose help or F1
And if you choose documentation you get access through a window in lower right corner as shown. Therein you can navigate, search, and look at the index. Also if you get on the documentation page and go to the bottom you find the McCarl guide.

If your cursor is on a reserved word in the source file and you press F1 an index opens to all treatments of that word although in some strange places.

There is a document that explains features in the STUDIO and a YouTube video that can be accessed through the welcome page or in the general GAMS documentation under Tools.
4.20.12 Making GDX files

STUDIO can create and show GDX files. To create in STUDIO use the GAMS tab and choose a GDX creating choice. Alternatively use one of the other ways in the language as we will discuss elsewhere.

To browse a GDX file open it with the file open dialogue or click on green lines for ones created during a run in the process window and then for the transport example:

Here in the left-hand panel one gets an alphabetical listing of the items in the GDX file and their characteristics. Then clicking on a left-hand panel item leads to the item contents being revealed in the right hand panel. As of now you can reorder columns and filter values then in table mode can move things in rows into columns and vice versa.
4.20.13 Examining GDX files

When you have opened a GDX file and selected an item then you get a window like that on the previous page.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Name</th>
<th>Type</th>
<th>Dim</th>
<th>Records</th>
<th>Text</th>
<th>i</th>
<th>j</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>a</td>
<td>Parameter</td>
<td>1</td>
<td>2</td>
<td>capacity of plan</td>
<td>seattle</td>
<td>new-york</td>
<td>2.5</td>
</tr>
<tr>
<td>4</td>
<td>b</td>
<td>Parameter</td>
<td>1</td>
<td>3</td>
<td>demand at mar</td>
<td>seattle</td>
<td>chicago</td>
<td>1.7</td>
</tr>
<tr>
<td>7</td>
<td>c</td>

<td>Parameter</td>
<td>2</td>
<td>6</td>
<td>distance in thou</td>
<td>san-diego</td>
<td>topeka</td>
<td>1.4</td>
</tr>
</tbody>
</table>

If in the right-hand panel you dragged \textbf{i to the right of value} (brown below) you get

Also by \textbf{clicking on the header} you \textbf{cause the array to be sorted with a ^ marking the sort order} and by \textbf{clicking on}
you can establish a filter (green above and brown below) and choose what elements to display (blue below).
4.20.14 A difficulty you will have

When using and teaching both the IDE and STUDIO, I find that file locations sometimes gives me fits. I have a rule of thumb to avoid problems, but you will most likely inadvertently not follow it.

When working with a model with multiple files make sure they are located in the same directory location.

You do not have to follow this rule but deviations are the same as asking for trouble. When you are actively working on a file that you have opened from a directory then STUDIO will look for files in the directory where active file is located.

Also when you run a file which contains includes GAMS will look in the directory where the active file is located.

4.20.15 Command Line Parameters

Experienced DOS or UNIX based GAMS users are used to having command line parameters associated with their GAMS execution commands. In STUDIO a command line parameter entry box (magenta) is available just to the right of the execute button. The parameters are associated with a file and STUDIO will remember these whenever the file is opened.
This is particularly useful for save, restart, limrow, limcol, pw and rf parameters as once they are defined they are associated with every subsequent use of the file.

As of now there is no way to provide command line parameters for use in every run (like a wide page width) as there was in the IDE.

GAMS provides assistance with command line parameters through the command line parameter editor. To activate it check the symbol at the far right (red) up top. Then part of the screen becomes as below. In the left hand part existing command line parameters (purple) in use (magenta) are listed along with their values. On the right all possible command line parameters are listed with definitions (green) and a search dialogue is provided (blue).
The search dialogue looks for text in any of the fields, thus typing in \texttt{wid} brings up page width as does \texttt{pw} and \texttt{maxi} brings up those with maximum in the description.

Note pressing F1 while the cursor is on a command line entry opens help to a place with a detailed description of that parameter.

### 4.20.16 Solver Option Files

STUDIO allows you to edit or create a solver option file. When using the solver \texttt{Conopt} you create \texttt{conopt.opt} or with \texttt{Cplex} use \texttt{cplex.opt} (or \texttt{.opt} or \texttt{.10} or \texttt{.11}) and more generally \texttt{solvername.opt}. Specifying such a file allows you to manipulate the way the solver works on the model. For example, you can alter scaling, tolerances, iteration limits, solver algorithm, and branch and bound strategy along with many other things.

Now in Studio the option file editor is accessed by either

- Right clicking on the \texttt{group name} (red) for a group where you want an option file then choosing \texttt{add new solver option file} (blue) and picking the \texttt{appropriate solver name} (magenta)

- Creating a file like \texttt{baron.opt} then when you bring that up in the editor the option file editor appears. In the editor you see \texttt{options in use} (blue), \texttt{possibilities and definitions} (red)

### 4.20.17 Using Libraries

STUDIO allows one to access libraries under the GAMS menu item and choosing the \texttt{Model Library Explorer} (purple).
4.20 Using GAMS Studio

In turn this opens a screen which identifies names of the libraries in tabs with a count of included files and, for the tab selected, the library contents. Furthermore across the top are tabs that when clicked on cause sorts. The picture below came after I clicked on the tab name with the model library active.

Users can define their own libraries. They have to define what’s called a GLB file and the formatting creation of this is discussed in my newsletter in the second issue: [https://www.gams.com/mccarl/newsletter/news2.htm](https://www.gams.com/mccarl/newsletter/news2.htm).

4.20.18 Using reference files - Listing and Unraveling Data items

GAMS has a command line parameter to create reference files (aka. .ref files) called reference (short: rf). These files give information on where things are defined and used.

Why? GAMS Modelers sometimes have to deal with complex implementations that

- Use include statements to incorporate numerous files.
- Have been developed by others.
- Have a complex structure with definitions and uses of items widely spread in a file or files.
- Contain items that are defined but never used.
- Were developed some time ago but are not extensively documented.
When faced with such cases one often asks

- Are there items defined in the program that are not used and if so what are they and where are they?
- In what files is an item defined, declared and used?

To resolve these questions some years ago I wrote a Fortran program called GAMSMAP but never made it widely available. Subsequently it was included into the GAMSIDE and then STUDIO.

When a `.ref` file is opened it creates a window as follows

![Example of GAMSMAP output](image)

The **column on the left** (red) gives tags that can be clicked on and the key ones are

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Symbols</td>
<td>a list of items that are declared and a count of them</td>
</tr>
<tr>
<td>Set</td>
<td>a list of the sets that exist in the program and a count</td>
</tr>
<tr>
<td>Variable</td>
<td>a list of the variables in the program and a count</td>
</tr>
<tr>
<td>Parameter</td>
<td>a list of the parameters (items defined in scalar, parameter or table statements) and a count.</td>
</tr>
<tr>
<td>Equation</td>
<td>a list of the equations in the program and the names of files in which they appear</td>
</tr>
<tr>
<td>Model</td>
<td>a list of the models that exist in the program and the names of files in which they appear</td>
</tr>
<tr>
<td>Unused</td>
<td>a list of items that are declared or that are not used anywhere in the model</td>
</tr>
<tr>
<td>File used</td>
<td>a list of the files included into the model</td>
</tr>
</tbody>
</table>

### 4.20.18.1 All Symbols Tab

The all symbols tab causes the output to appear as follows:
4.20 Using GAMS Studio

This shows all symbols used. The columns give

- the symbol name (Name),
- its type (Type),
- its dimension (Dim),
- the sets over which it is dimensioned (Domain)
- the explanatory text used in its declaration (Text).

Things can be sorted by clicking on the column headings.

One can search for symbols using the box at the bottom

4.20.18.2 Sets, Parameters etc. Tabs

The display contains 5 lines that when activated give information for sets, parameters etc. The resultant display lists all items falling in a class (for all things that are sets or parameters etc.) and information on their characteristics and use. Specifically one gets output as follows (for the sets in this case)
In this output once clicked on the entries tell the names of the files in which certain things happen relative to the identified items. The categories of things include the file name, line and column where items are declared, defined and used as discussed below.

Clicking on a line takes you to the file and place where the item appears.

Clicking on a column name causes it to be sorted.

After clicking on an item one gets

Entries in location columns identify files where items are

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Declared</td>
<td>places where the named item is declared in a Set, Parameter, Table, Scalar, Variable, Equation, Acronym, File or Model command. This will be the first appearance.</td>
</tr>
<tr>
<td>Defined</td>
<td>places set elements or data are explicitly entered. For equations this tells where the .. specification begins.</td>
</tr>
<tr>
<td>Assigned</td>
<td>places where items appear on left hand side of an assignment statement</td>
</tr>
<tr>
<td>Implicitly-Assigned</td>
<td>places where an equation or variable has data put into it by the results of a solve statement.</td>
</tr>
<tr>
<td>Controlled</td>
<td>places where set is used in controlling a sum or defining an equation</td>
</tr>
<tr>
<td>Ref</td>
<td>places where item is on left hand side of assignment statement or in a model equation</td>
</tr>
</tbody>
</table>
Clicking on lines here opens the subject file in the specific place.

### 4.20.18.3 File used Tab

The file used tab causes the output to appear as follows:

![File Location](image)

This gives the names of the files included in the program with their full path references.

### 4.20.18.4 Unused Tab

The unused tab identifies items that are declared (in set parameter etc. statements) but are never used on the right hand side of an assignment (=) statement or in a model equation:

![Unused Tab](image)

which shows the same information as in the All Symbols tab except when an item is clicked on one gets information on the files where it is declared.
4.20.18.5 Steps to use the Reference File Viewer

The Reference File Viewer will only work after a particular “reference file” has been created by a GAMS run. The file is generated by adding the `rf` option to the command line call entering a command in the command line box of Studio as follows (a=c cause compilation only)

Once the file has been run with the `rf` option the logfile is augmented with the (green) line identifying the `.ref` file name as below

Double clicking on this opens the Reference File Viewer window.

The run of GAMS with the `rf` option places the name of the `.ref` file in green in the GAMS log file and double clicking on that line causes the Reference File Viewer to be opened.

Several notes about the run

- The `rf=` command specifies the name of the file the Reference File Viewer will use. Generally, the Reference File Viewer expects it to have the extension `.ref`.
- The `.ref` file only covers the program components in a run and does not include any information from restart files. In general it is best to explicitly use all the files in one program without use of save and restart.
- It is often useful to just generate the reference file without any execution on behalf of the GAMS program. This is done by including the `a=c` option on the command line or in the command parameter IDE box.
4.20 Using GAMS Studio

4.20.19 Editing Solver Option Files

Sometimes it is desirable to change solver specific options. This includes modifying things like branch and bound strategy, degree of scaling, barrier versus simplex solution approach, solution tolerances etc. The specific options allowed are described in the solver manuals. In addition Studio contains a solver option file editor that presents a solver specific menu of all possible options, default values and ones that have been altered. This is activated by either

- Opening or saving a file with solvername.opt (Like MINOS.opt)
- Right clicking on a group file name (red) in the Studio Explorer then selecting add new solver option file (blue) and subsequently selecting one of the many available solver names (magenta and only a few shown). This will create a file you then need to save.

Once it opens the general format of the solve option editor is as follows. Note the specific content depends on the solver chosen and in this case I use GAMSCHK.
Here in the right part we see a list of all possible options (magenta) for this solver with boxes checked for those that are in the option file. A brief description of default values (blue), entry type (red), if relevant allowable settings (yellow) and a one sentence description of the option (green). In the left part we see the current entries (purple) in the option file and their settings (purple).

Subsequently when this file is opened or its tab activated then this solver option editor appears.

Note, pressing F1 while on an option opens help to a place with a detailed description of that option.

4.20.20 When is it Not Worth Using?

There are costs and benefits of these approaches.

The STUDIO is much easier for simple models and can run across platforms.

The DOS/command line approach is generally better for models in customized environments.

A development strategy for more complex implementations

1. Use the STUDIO to get it right
2. Debug components of large models using save and restart
3. Then use script files or DOS/UNIX with batch files such as
   - GAMS mymodel -lo 0 -s ./t/save1
   - call myprogram.exe
   - GAMS moremod -lo 0 -r ./t/save1

4.20.21 What does it not do?

A number of IDE features are currently missing. Just to inventory (note the last three are pretty unimportant to me.)

- Ability to save output from the reference files
- Ability to change the file associations when clicking on them in Windows Explorer (you get more than I like at the moment and sometimes I want more)
- Project files (mixed blessing)
- Text file differencing (can use other programs)
- Spell checking

4.20.22 What does it not do so well?

Here are also some difficulties with it as of today

- Washed out colors – on my machine the syntax and error coloring is not very prominent.
- Excessive library choices and no way to put the ones you have no interest in somewhere out of the way. Plus any user defined libraries are at the end and there is no way to reorder.
4.21 Introduction

4.21.1 Summary

Today, algebraic modeling languages are widely accepted as the best way to represent and solve mathematical programming problems. Their main distinguishing features are the use of relational algebra and the ability to provide partial derivatives on multidimensional, very large and sparse structures. In this chapter we will briefly describe some of the origins of GAMS and provide background information that shaped early design decisions.

4.21.2 The Origins of GAMS

The initial Research and Development of GAMS was funded by the International Bank for Reconstruction and Development, usually referred to as The World Bank. Since 1987, further Research and Development has been funded by GAMS Development Corporation. GAMS was developed in close cooperation of mathematical economists who were and still are an important group of GAMS users. The synergy between economics, computer science and operations research was the most important success factor in the development of the system. Mathematical Programming and economics theory are closely intertwined. The Nobel Prize in Economics awarded to Leonid Kantorovich and Tjalling Koopmans in 1975 for their “contribution to the theory of optimal allocation of resources” was really a prize in mathematical programming. Other Nobel laureates like Kenneth Arrow in 1972, Wassily Leontief in 1973, and Harry Markowitz in 1990 are well known names in math programming. Another early example of this synergy is the use of LP in refining operations, which was started by Alan Manne, an economist, with his book on Scheduling of Petroleum Refinery Operations in 1956.

The origins of linear programming algorithms all go back to George Dantzig’s early work in the 1940s and 1950s. Computing technology and algorithmic theory had developed at a rapid pace. Thirty years later, we could solve problems of practical size and complexity that allowed us to test of the economic theory on real life problems. The research agenda at the World Bank in the 1970s and 1980s created the perfect environment to bring different disciplines together to apply mathematical programming to research and operational questions in Economic Development.

4.21.3 Background and Motivation

From the very beginning, the driving force behind the development of the General Algebraic Modeling System (GAMS) has been the users of mathematical programming who believed in optimization as a the powerful and elegant framework for solving real life problems in the sciences and engineering. At the same time, these users were frustrated with the high cost, skill requirements, and overall low reliability of applying optimization tools. Most of our initiatives and support for new development came from the worlds of economics, finance, and chemical engineering. These disciplines find it natural to view and understand the world and its behavior as a mathematical program.

GAMS’s impetus for development arose out of the frustrating experiences of a large economic modeling group at the World Bank. In hindsight, one may call it a historical accident that in the 1970s mathematical economists and statisticians were assembled to address problems of development. They used the best techniques available at the time to solve multisectoral economy-wide models and large simulation and optimization models in agriculture, steel, fertilizer, power, water use, and other sectors. Although the group produced impressive research, initial successes were difficult to reproduce outside their well functioning research environment. The existing techniques to construct, manipulate, and solve such models required several manual, time-consuming, and error-prone translations into the different, problem-specific representations required by each solution method. During seminar presentations, modelers had to defend the existing versions of their models, sometimes quite irrationally, because the time and money needed to make proposed changes were prohibitive. Their models just could not be moved to other environments.
because special programming knowledge was needed, and data formats and solution methods were not portable.

The idea of an algebraic approach to represent, manipulate, and solve large-scale mathematical models fused old and new paradigms into a consistent and computationally tractable system. Using matrix generators (see appendix GAMS versus Fortran Matrix Generators) for linear programs taught us the importance of naming rows and columns in a consistent manner. The connection to the emerging relational data model became evident. Painful experience using traditional programming languages to manage those name spaces naturally lead one to think in terms of sets and tuples, and this led to the relational data model. Combining multidimensional algebraic notation with the relational data model was the obvious answer. Compiler writing techniques were by now widespread, and languages like GAMS could be implemented relatively quickly. However, translating this rigorous mathematical representation into the algorithm specific format required the computation of partial derivatives on very large systems. In the 1970s, TRW developed a system called PROSE that took the ideas of chemical engineers to compute point derivatives that were exact derivatives at a given point, and to embed them in a consistent, Fortran-style calculus modeling language. The resulting system allowed the user to use automatically generated exact first and second order derivatives. This was a pioneering system and an important demonstration of a concept. However, in our opinion PROSE had a number of shortcomings: it could not handle large systems, problem representation was tied to an array-type data structure that required address calculations, and the system did not provide access to state-of-the-art solution methods. From linear programming, we learned that exploitation of sparsity was the key to solve large problems. Thus, the final piece of the puzzle was the use of sparse data structures.

With all pieces in place, all we had to do was adopt the techniques to fit into one consistent framework and make it work for large problems.

4.21.4 Design Goals and Changing Focus

The original and still valid goal is to improve the model builder’s productivity, reduce costs, and improve reliability and overall credibility of the modeling process. To achieve this, we established the following key principles to guide the GAMS development:

- The problem representation is independent of the solution method.
- The data representation follows the relational data model.
- The problem and data representations are independent of computing platforms.
- The problem and data representations are independent of user interfaces.
- Optimization methods will fail, and systems have to be designed to be fail-safe.

Another way to express these principles is to think in terms of layers of representations and capabilities that have clearly defined interfaces and functions. The oldest and most basic layer is the solver layer or implementation of a specific algorithm. Above the solver is the model layer, expressed in an algebraic modeling language. The modeling layer translates the mathematical representation into a computational structure required by a specific solution method and provides various services such as function and derivative evaluations and error recovery. Above the modeling layer is the application or domain layer, which is highly context sensitive and has knowledge about the problem to be solved and the kind of user interacting with the system.

The representation of the model in GAMS is in a form that can be easily read by humans and by machines. This means that the GAMS program itself is the documentation of the model, and that the separate description required in the past (which was a burden to maintain, and which was seldom up-to-date) is no longer needed. Moreover, the design of GAMS incorporates the following features that specifically address the user's documentation needs:
• A GAMS model representation is concise, and makes full use of the elegance of the mathematical representation.

• All data transformations are specified concisely and algebraically. This means that all data can be entered in their most elemental form and that all transformations made in constructing the model and in reporting are available for inspection.

• Explanatory text can be made part of the definition of all symbols and is reproduced whenever associated values are displayed.

• All information needed to understand the model is in one document.

Of course some discipline is needed to take full advantage of these design features, but the aim is to make models more accessible, more understandable, more verifiable, and hence more credible.

It is instructive to put the development of modeling systems into some historic perspective and see how the focus and technical constraints have changed in the last 30 years. We can observe three major phases that shift the emphasis from computational issues to modeling issues and finally the application or the real problems. Each phase defined one of the main system layers discussed above. The dominant constraints in the first phase were the computational limits of our algorithms. Problem representation had to abide by algorithmic convenience, centralized expert groups managed large, expensive and long lasting projects and end users were effectively left out. The second phase has the model in focus. Applications are limited by modeling skill, project groups are much smaller and decentralized, the computational cost are low and the users are involved in the design of the application. Applications are designed to be independent of computing platforms and frequently operate in a client-server environment.

We believe that we are entering a third phase which has the application as its focus and the optimization model is just one of many analytic tools that help making better decisions. The users are often completely unaware of any optimization model or use a mental model that is different from the actual model to solved by optimization techniques. User interfaces are build with off-the-shelf components and frequently change to adjust to evolving environments and new computing technologies. As with databases, modeling components have a much longer life than user interfaces. We have observed cases where the model has remained basically unchanged over many years, whereas the computing environments and user interfaces have changed several times. The solvers used to solve the models have changed, the computing platforms have changed, the user interfaces have changed and the overall performance of the model has changed without any change in the model representation.

4.22 GAMS Programs

4.22.1 Introduction

This chapter provides a look at the structure of the GAMS language and its components. It should be emphasized again that GAMS is a programming language, and that programs must be written in the language to use it. A GAMS program is contained in a disk file, which is usually constructed with a text editor of choice (e.g. the GAMS IDE). When GAMS is ’run’, the file containing the program (the input file) is submitted to be processed. After this processing has finished, the results, which are in the output file(s), can be inspected. By default the GAMS log appears on the screen while GAMS runs, keeping the user informed about progress and error detection. It is the responsibility of the user to inspect the output file(s) carefully to see the results and to diagnose any errors.
4.22.2 The Structure of GAMS Programs

GAMS programs consist of one or more statements (sentences) that define data structures, initial values, data modifications, and symbolic relationships (equations). While there is no fixed order in which statements have to be arranged, the order in which data modifications are carried out is important. Symbols must be declared as to type before they are used, and must have values assigned before they can be referenced in assignment statements. Each statement is followed by a semicolon except the last statement, where a semicolon is optional.

Note

The semicolon at the end of a statement can be omitted if a new GAMS keyword follows. However, to improve readability of the code, it is recommended to use the semicolon at the end of a statement anyway.

4.22.2.1 Format of GAMS Input

GAMS input is free format. A statement may be placed anywhere on a line, multiple statements may appear on a line, or a statement may be continued over any number of lines as follows:

```
statement;
statement;
statement; statement; statement;
the words that you are now reading is an example of a very long statement which is stretched over two lines;
```

Blanks and end-of-lines may generally be used freely between individual symbols or words. GAMS is not case sensitive. This means that lower and upper case letters may be mixed freely but are treated identically. Up to 80,000 characters may be placed on a line and completely blank lines may be inserted for easier reading.

Not all lines are a part of the GAMS language. Two special symbols, the asterisk ‘∗’ and the dollar symbol ‘$’ may be used in the first position on a line to indicate a non-language input line. An asterisk in column one means that the line will not be processed, but treated as a comment. For more on comments, see section Comments. A dollar symbol in the first position indicates that compiler options or directives are contained in the rest of the line (see chapter Dollar Control Options for more information).

For example, multiple files may be used as input through the use of the $include facility. In short, the statement

```
$include file1
```

inserts the contents of the specified file (file1 in this case) at the location of the call. A more complex versions of this is the option $batinclude. Both options are introduced and discussed in details in chapter Dollar Control Options.
4.22.2 Classification of GAMS Statements

Each statement in GAMS is classified into one of two groups:

1. Declaration and definition statements.
2. Execution statements.

A declaration statement describes the class of a symbol. Often initial values are provided in a declaration, then it may be called a definition. The specification of symbolic relationships for an equation is a definition. The declaration and definition statements are:

- acronym
- alias
- equation declaration
- equation definition
- file
- function
- model
- parameter
- scalar
- set
- table
- variable

Execution statements are instructions to carry out actions such as data transformation, model solution, and report generation. The execution statements are:

- abort
- assignment
- break
- continue
- display
- execute
- for
- if
- loop
- option
- put
- put_utility
Note
While an assignment is an execution statement, it also defines the symbol on the left hand side of the assignment.

Although there is great freedom about the order in which statements may be placed in a GAMS program, certain arrangements are commonly used. The two most common are discussed next.

4.22.2.3 Organization of GAMS Programs

One common style of organizing GAMS statements places the data first, followed by the model and the solution statements.

Style 1:

*Data:*

Set declarations and definitions

Parameter declarations and definitions

Assignments

Displays

*Model:*

Variable declarations

Equation declarations

Equation definitions

Model definition(s)

*Solution:*

Solve(s)

Displays
In this style of organization, the sets are placed first. Then the data is specified with parameter, scalar, and table statements. Next, the model is defined with the variable declarations, equation declarations, equation definitions and one or more model statements. Finally, the model is / models are solved and the results are displayed. One can refer to the model transport as an example for this style.

A second style emphasizes the model by placing it before the data. This is a particularly useful order when the model is to be solved repeatedly with different data sets.

**Style 2:**

*Model:*

- Set declarations
- Parameter declarations
- Variable declarations
- Equation declaration
- Equation definition
- Model definition

*Data:*

- Set definitions
- Parameter definitions
- Assignments
- Displays

*Solution:*

- Solve
- Displays

Here, there is a separation between declaration and definition. For example, sets and parameters may be declared first with the following statements:

```
Set c "crops" ;
Parameter yield(c) "crop yield" ;
```

Later they may be defined with the statements:

```
Set c / wheat, clover, beans / ;
Parameter yield(c) / wheat 1.5
                     clover 6.5
                     beans 1.0 / ;
```

The first statement declares that the identifier c is a set and the later statement defines the elements in this set. Similarly, in the second statement yield is declared to be a parameter and later the corresponding data is given.

**Note**

Sets and parameters that are used in equations must be declared before the equations are specified. However, they may be defined after the equation specifications but before the specific equation is used in a solve statement. This gives GAMS programs substantial organizational flexibility.
4.22.3 Data Types and Definitions

Each symbol or identifier has exactly one of the following basic GAMS data types:

- acronyms
- equations
- files
- functions
- models
- parameters
- sets
- variables

Note
- Scalars and tables are not separate data types but convenient input formats for the data type parameter. For details see the overview Parameters, Scalars and Tables.
- GAMS uses shorthand symbols for each data type in the output. For details see the overview GAMS Data Types and their Shorthand Symbols.

Declarations have common characteristics. The following example has a typical structure:

Parameter a(i,j) "input-output matrix" ;

The structure is:
Keyword for data type - identifier (with index list) - explanatory text ;.

Note that the index list (or domain list) and the explanatory text are always optional characteristics. However, we recommend to specify the index list if the data type is defined over a domain; the advantages of this practice are outlined in section Domain Checking.

Note
Variables, sets, parameters and equations may be declared and defined over one or more indices or dimensions. Currently the maximum number of dimensions for all these data types is 20.

It is also recommend to add an explanatory text for reasons of clarity. For more on explanatory texts, see section Text below. Other examples for declarations follow:

Set time "time periods" ;
Model turkey "turkish fertilizer model" ;
Variables x,y,z ;

Observe that in the last example a number of identifiers (separated by commas) is declared in one statement.
4.22 GAMS Programs

4.22.4 Language Items

Before proceeding with more language details, a few basic symbols need to be defined and the rules for recognizing and writing them in GAMS established. These basic symbols are often called lexical elements and form the building blocks of the language. They are:

- characters
- comments
- delimiters
- identifiers (idents)
- labels
- numbers
- reserved words and tokens
- text

Each of these items is discussed in detail in the following subsections.

Attention

As noted previously, GAMS is not case sensitive, so we may use any mix of lower and upper case.

4.22.4.1 Characters

A few characters are not allowed in a GAMS program, because they are illegal or ambiguous on some machines. Generally, all unprintable and control characters are illegal. The only place where any character is legal, is in an `$ontext-$offtext` block as illustrated in section Block Comments below. For completeness, the full set of legal characters are listed in Table 1. Note that most of the uncommon punctuation characters are not part of the language, but they may be used freely in the context of explanatory texts, comments, and labels (if quoted). Similarly, special language specific characters (e.g. ä, ß, à, é, ç, ì, ñ) may also be used freely in explanatory texts, comments, and labels (if quoted).

Table 1: Legal Characters

<table>
<thead>
<tr>
<th>Legal Characters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A to Z</td>
<td>alphabet</td>
</tr>
<tr>
<td>a to z</td>
<td>alphabet</td>
</tr>
<tr>
<td>0 to 9</td>
<td>numerals</td>
</tr>
<tr>
<td>+</td>
<td>plus</td>
</tr>
<tr>
<td>-</td>
<td>minus</td>
</tr>
<tr>
<td>=</td>
<td>equals</td>
</tr>
<tr>
<td>&lt;</td>
<td>less than</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
</tr>
<tr>
<td>( )</td>
<td>parenthesis</td>
</tr>
<tr>
<td>[ ]</td>
<td>square brackets</td>
</tr>
<tr>
<td>{ }</td>
<td>braces</td>
</tr>
<tr>
<td>’</td>
<td>single quote</td>
</tr>
<tr>
<td>“</td>
<td>double quote</td>
</tr>
</tbody>
</table>
### Legal Characters

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\</td>
<td>back slash</td>
</tr>
<tr>
<td>/</td>
<td>slash</td>
</tr>
<tr>
<td>,</td>
<td>comma</td>
</tr>
<tr>
<td>:</td>
<td>colon</td>
</tr>
<tr>
<td>;</td>
<td>semicolon</td>
</tr>
<tr>
<td>.</td>
<td>dot</td>
</tr>
<tr>
<td>?</td>
<td>question mark</td>
</tr>
<tr>
<td>!</td>
<td>exclamation mark</td>
</tr>
<tr>
<td></td>
<td>space</td>
</tr>
<tr>
<td>-</td>
<td>underscore</td>
</tr>
<tr>
<td>&amp;</td>
<td>ampersand</td>
</tr>
<tr>
<td>^</td>
<td>circumflex</td>
</tr>
<tr>
<td>#</td>
<td>pound sign</td>
</tr>
<tr>
<td>*</td>
<td>asterisk</td>
</tr>
<tr>
<td>%</td>
<td>percent</td>
</tr>
<tr>
<td>@</td>
<td>at</td>
</tr>
<tr>
<td>$</td>
<td>dollar</td>
</tr>
</tbody>
</table>

**Note**

Not every character listed above is allowed to be used in every place (for example, identifiers have certain limitations).

---

### 4.22.4.2 Reserved Words

GAMS, like other programming languages such as C and Java, uses reserved words (often also called keywords) that have predefined meanings. Users are in general not permitted to use these for their own definitions, neither as identifiers nor labels. The complete list of reserved words is given below. In addition, a small number of symbols constructed from non-alphanumeric characters have a meaning in GAMS.

**Note**

While it is not allowed to use reserved words as identifiers and labels in general, it is still possible (put not recommended) in certain cases which are explained in more detail further below.

- abort
- acronym[s]
- alias
- all
- and
- binary
- break
- card
- continue
- diag
• display
• do*
• else
• elseif
• endfor*
• endif*
• endloop*
• endwhile*
• eps
• equation[s]
• execute
• execute_load
• execute_loaddc
• execute_loadhandle
• execute_loadpoint
• execute_unload
• execute_unloaddi
• execute_unloadidx
• file[s]
• for
• free
• function[s]
• if
• inf
• integer
• logic
• loop
• model[s]
• na
• negative
• nonnegative
• no
• not
• option[s]
• or
• ord
• parameter[s]
• positive
• procedure[s] (deprecated)
• prod
• put
• put_utility/put_utilities
• putclear
• putclose
• putfmcl
• puthd
• putheader
• putpage
• puttitle
• puttl
• repeat
• sameas
• sand
• scalar[s]
• semicont
• semiint
• set[s]
• singleton
• smax
• smin
• solve
• sor
• sos1
• sos2
• sum
• system
• table[s]
• then*
• undf
• until
• variable[s]
• while
• xor
• yes
Attention

Some of the keywords above can actually be used as an identifier (e.g. `sameas`). But if they get used as identifier, their built-in meaning as part of the GAMS language can not be accessed anymore.

Note

The words marked with * in the list above are no reserved words by default. However, they get a special meaning if the dollar control option `$onEnd` is set.

The following list shows words which have a special meaning in GAMS (e.g. they are part of the solve statement), but can be used as identifiers anyway:

- eq
- eqv
- ge
- gt
- imp
- le
- lt
- maximizing
- minimizing
- ne
- scenario
- using

The reserved non-alphanumeric symbols are:

- ..
- =l=
- =g=
- =e=
- =n=
- =x=
- =c=
- =b=
- --
- ++
- **
- ->
- <=>
4.22.4.3 Identifiers

Identifiers are the names given to sets, parameters, variables, models, etc. GAMS requires an identifier to start with a letter followed by more letters or digits. The length of an identifier is currently limited to 63 characters. Identifiers may only contain alphanumeric characters (letters or numbers) or underscores (_). Examples of legal identifiers are:

a   a15   revenue   x0051

Note that the following identifiers are incorrect:

15   $casg   milk&meat

Attention

A name used for one data type cannot be reused for another.

4.22.4.4 Labels

Labels are set elements. They may be up to 63 characters long and may be used in quoted or unquoted form.

The unquoted form is simpler to use but places restrictions on characters allowed, in that any unquoted label must start with a letter or digit and can only be followed by letters, digits, underscores (_) or the sign characters + and -. Examples of valid unquoted labels are:

Phos-Acid   1986   1952-53   A
September   H2SO4   Line-1

Quotes can be used to delimit labels. Quoted labels may begin with and include any legal character. Either single or double quotes may be used but the closing quote has to match the opening quote. A label quoted with double quotes may contain a single quote (and vice versa). Most experienced users avoid quoted labels because they can be tedious to enter and confusing to read. There are a couple of special circumstances though. If we want to make a label stand out, we could put asterisks in it and indent it. A more subtle example is that GAMS keywords may be used as labels if they are quoted. So labels like parameter, put or while may be used if they are quoted. Some examples of quoted labels follow:

'   *TOTAL*   'MATCH'   '10%-INCR'   '12' / FOOT'   "line 1"

Note

- Labels do not have any numerical value. The label '1986' does not have the numerical value 1986 and the label '01' is different from the label '1'. One can access the numerical value of a label with the Set Attributes .val attribute.
- Leading blanks in a label are significant and preserved while trailing blanks are trimmed. So 'label1' is different from 'label1', but 'label2' is identical to 'label2'.

To summarize, set names are identifiers and set elements are labels. An overview of the rules for constructing identifiers and labels is given in the following table.
Identifiers and set elements may also be associated with a line of descriptive text. This text is more than a comment: it is retained by GAMS and is displayed whenever results are written for the identifier.

Text may be quoted or unquoted. Quoted text may contain any character except the quote character used. Single or double quotes may be used but they must match. Text has to fit on one line and cannot exceed 255 characters in length. Text used in unquoted form must follow a number of mild restrictions. Unquoted text cannot start with a reserved word, ‘..’ or ‘=’ and must not include semicolons ‘;’ , commas ‘,’ or slashes ‘/’. End of lines terminate a text. These restrictions are a direct consequence of the GAMS syntax and are usually followed naturally by the user. Some examples are:

```
this is text
final product shipment (tpy)
"quoted text containing otherwise illegal characters ; /,"
'use single quotes to put a "double" quote in text'
```

4.22.4.6 Numbers

Numeric values are entered in a style similar to that used in other computer languages

Attention

- Blanks cannot be used in a number: GAMS treats a blank as a separator.
- The common distinction between real and integer data types does not exist in GAMS. If a number is used without a decimal point it is still stored as a real number.

In addition, GAMS uses an extended range arithmetic that contains special symbols for infinity (INF), negative infinity (-INF), undefined (UNDF), epsilon (EPS), and not available (NA). The user cannot enter UNDF; it is only produced by an operation that does not have a proper result, such as division by zero. All the other special symbols may be entered and used as if they were ordinary numbers. For more details, see section Extended Range Arithmetic.

The following example shows various legal ways of entering numbers:

```
0       156.70    -135    .095     1.
2e10    2e+10     15.e+10  .314e5   +1.7
0.0     .0        0.      INF      -INF
EPS     NA
```

The letter e denotes the well-known scientific notation allowing convenient representation of very large or small numbers. For example,

```
1e-5 = 1 * 10^{-(5)} = 0.00001;
3.56e6 = 3.56 * 10^6 = 3,560,000;
```
Note

- GAMS uses a smaller range of numbers than many computers are able to handle. This has been done to ensure that GAMS programs will behave in the same way on a wide variety of machines, including personal computers. GAMS will create an error if a number with an absolute value greater or equal to \(1.0e+300\) is used.

- A number may be entered with up to 16 significant digits. The dollar control option \$offDigit can be used to control the behavior if this number is exceeded.

4.22.4.7 Delimiters

As mentioned before, statements are separated by a semicolon ‘;’. However, if the next statement begins with a reserved word (often called keyword in succeeding chapters), then GAMS does not require that the semicolon is used.

The characters comma ‘,’ and slash ‘/’ are used as delimiters in data lists, to be introduced later. The comma terminates a data element (as does an end-of-line) and the slash terminates a data list.

4.22.4.8 Comments

A comment is an explanatory text that is not processed or retained by the computer. There are several ways to include comments in a GAMS program.

4.22.4.8.1 Blank Lines  The user may freely enter blank lines to set off certain sections and enhance readability. For example, in transport there are blank lines between the different parameters:

```plaintext
Sets
   i "canning plants" / seattle, san-diego /
   j "markets" / new-york, chicago, topeka /;

Parameters
   a(i) "capacity of plant i in cases"
       / seattle 350
       san-diego 600 /
   b(j) "demand at market j in cases"
       / new-york 325
       chicago 300
       topeka 275 /;
```

4.22.4.8.2 Single Line Comments  Users may insert a single line comment on any line by placing an asterisk ‘*’ in column 1. The text that follows the asterisk is the comment and may contain GAMS reserved words, messages or any other content. It is completely ignored by the GAMS compiler. Note that several successive lines may be single line comments as in the example below.

The default asterisk ‘*’ may be replaced by other symbols. GAMS provides the dollar control option \$comment to customize the comment character (for more on dollar control options, see chapter Dollar Control Options). The new comment character cannot be used in column 1 as before, since now it has a special meaning. The change of comment character should be used with great care. An example can be seen here:
*normal comment
*next line is a deactivated GAMS statement
* x=sum(I,z(i));
$comment !
!comment with new character
$comment *
*now we are back to how it should be

In the fourth line, the new comment character ! replaces the GAMS default * as the comment delimiter. Note that single line comments appear in the echo print of the GAMS output as numbered lines. For details see section The Echo Print of the Input File.

4.22.4.8.3 Block Comments For longer comments special 'block' delimiters may be used that cause GAMS to ignore an entire section of the program. The dollar control option $ontext marks the beginning of the comment block and the option $offtext marks the end. Note that the $ symbol must be in the first character position. The example below illustrates the use of the block comment and also contains some useful information. For more on dollar control options, see chapter Dollar Control Options.

$ontext
Following a $ontext directive in column 1 all lines are ignored by GAMS but printed on the output file until the matching $offtext is encountered, also in column 1. This facility is often used to logically remove parts of programs that are not used every time, such as statements producing voluminous reports. Every $ontext must have a matching $offtext in the same file
$offtext

Note that block comments appear in the echo print without line numbers. For details see section The Echo Print of the Input File.

4.22.4.8.4 End-of-Line Comments Comments may also be placed at the end of a line that contains GAMS code. The dollar control option $onEolCom activates end-of-line comments. The default symbol to indicate that the comment begins is a double exclamation mark !!. This symbol may be reset with the option $eolCom followed by the desired symbol which may be one character or a two-character sequence. The following example serves as illustration. For more on dollar control options, see chapter Dollar Control Options.

Scalar x /0/;
$onEolCom
x=x+1;  !! eol comment
x = x  !! eol comment in line of GAMS statement, where the GAMS statement continues to the next line +1;
$eolCom &&
x=x+1;  && eol comment with new symbol

Note that the option to add end-of-line comments may be deactivated with the dollar control option $offEolCom. End-of-line comments appear in the echo print on the appropriate lines. For details see section The Echo Print of the Input File.
4.22.4.8.5  In-Line Comments Comments may also appear in a line of GAMS code. The dollar control option $onInLine activates in-line comments. By default, the in-line comment symbols are set to the two character pairs '/*' and '*/', where '/*' indicates that the in-line comment begins and '*/' indicates that the in-line comment ends. The comment may span lines till the end-of-comment characters are encountered. The in-line comment symbols may be reset with the option $inLineCom followed by the desired pair of characters. The following example serves as illustration. For more on dollar control options, see chapter Dollar Control Options.

Scalar x /0/;
$onInLine
x=x /* in-line comment*/ +1;
$offInLine
x=x /* in-line comment in line that continues to next line */ +1;
$onLineCom /& &/
x=x /& in-line comment with new character &/ +1;

Note that the option to add in-line comments may be deactivated with the dollar control option $offInLine. In-line comments appear in the echo print on the appropriate lines. For details see section The Echo Print of the Input File. Note that in-line comments may be allowed to be nested using the dollar control option $onNestCom.

4.22.4.8.6  Outside Margin Comments GAMS provides the facility to define margins. The active code is within the margins, everything outside the set margins is ignored by the compiler and treated as comment. The dollar control option $onMargin activates margin marking and $offMargin deactivates it. The option $minCol is used to specify the first column, where GAMS code that is to be compiled may appear. Similarly, the option $maxCol is used to specify the last column for GAMS code. The following example shows how this works. For more on dollar control options, see chapter Dollar Control Options.

$context

1 2 3 4 5 6
12345678901234567890123456789012345678901234567890
$offtext

$onMargin minCol 20 maxCol 45
Now I have turned on the margin marking. Set i plant /US, UK/
Scalar x / 3.145 / Define some parameters.
Parameter a, b;

$offMargin

The text before column 20 and after column 45 is treated as a comment. Note that the full content of the lines is copied to the echo print, including everything outside the margins. For details see section The Echo Print of the Input File.

4.22.4.8.7  Hidden Comments Finally, GAMS also allows hidden comments, that are not copied to the echo print of the GAMS output file. These comments contain information that is only relevant for the person manipulating the file. They are single line comments starting with the dollar control option $hidden. An example follows. For more on dollar control options, see chapter Dollar Control Options.

$hidden a comment I do not want in LST file
set a /a1,a2/;
set b /a2,c2/;
set c /a3,d3/;
This completes the discussion of the components of the GAMS language. Many unfamiliar terms used in this chapter are further explained in the Glossary.

4.23 Set Definition

4.23.1 Introduction

Sets are fundamental building blocks in any GAMS model. They allow the model to be succinctly stated and easily read. In this chapter we will introduce how sets are declared and initialized. More advanced set concepts, such as assignments to sets, and lag and lead operations are covered in the chapters Dynamic Sets and Sets as Sequences. The topics discussed in this chapter will be enough to provide a good start on most models. We will introduce simple sets, subsets, multi-dimensional sets, singleton sets and the universal set. The chapter will be concluded by a topic on domain checking, a very important feature of GAMS, and a section about Domain Defining Symbol Declarations.

4.23.2 Simple Sets

Using common mathematical notation, a set \( S \) that contains the elements \( a \), \( b \) and \( c \) is written as:

\[
S = \{a, b, c\}
\]

Using GAMS notation, the same set is defined in the following way:

```gams
set S / a, b, c /;
```

The set statement begins with the keyword `set`, \( S \) is the name of the set, and its members are \( a \), \( b \), and \( c \). They are labels, but are often referred to as elements or members.

4.23.2.1 Defining a Simple Set: The Syntax

In general, the syntax for simple sets in GAMS is as follows:

```gams
set [s] set_name ["text"] [/element [text] {,element [text]} /]
   {,set_name ["text"] [/element [text] {,element [text]} /] } ;
```

`Set [s]` is the keyword that indicates that this is a set statement. `Set_name` is the internal name of the set in GAMS, it is an identifier. The optional explanatory text may be used to describe the set or a specific set element for future reference and to ease readability. The list of set elements is delimited by forward slashes. `Element` is the name of the set element(s). Note that each element in a set must be separated from other elements by a comma or by an end-of-line, and each element is separated from any associated text by a blank.

Consider the following example from the Egyptian fertilizer model [FERTS], where the set of fertilizer nutrients could be written as
The order in which the set members are listed is usually not important. However, if the members represent, for example, time periods, then it may be useful to refer to the next or previous member. There are special operations to do this, and they are discussed in chapter Sets as Sequences: Ordered Sets. For now, it is enough to remember that the order in which set elements are specified is not relevant, unless and until some operation implying order is used. At that time, the rules change, and the set becomes what we will later call an ordered set.

Note

- The data statement, i.e. specification of set elements in forward slashes can be omitted. In such cases a set is declared without being defined.
- More than one set may be declared and defined in one set statement. Examples are given in subsection Declaring Multiple Sets below.

### 4.23.2.2 Illustrative Examples

Consider the following example based on the model [SHALE]:

```plaintext
Set cf "final products" / syncrude "refined crude (mil bbls)"
     lpg  "liquefied petroleum gas (million bbls)"
     ammonia "ammonia (mil tons)"
     coke  "coke (mil tons)"
     sulfur "sulfur (mil tons)" /;
```

The set statement is introduced with the keyword `set`, the name of the set is `cf` and the explanatory text "final products" describes the set. The set has five elements with explanatory texts that contain details of the units of measurement.

Usually sets are declared and defined once and then referenced in the model. There are two exceptions: the dollar control option `onMulti` allows adding more elements later, and dynamic sets. For details on dynamic sets, see chapter Dynamic Sets. The following code sightly varies the previous example to demonstrate the option `$onMulti`:

```plaintext
Set cf "final products" / syncrude "refined crude (mil bbls)"
     lpg  "liquefied petroleum gas (million bbls)"
     ammonia "ammonia (mil tons)" /
$onmulti
Set cf "more final products" / coke  "coke (mil tons)"
     sulfur "sulfur (mil tons)" /;
```

After `$onmulti` additional elements are added to the set `cf`. Note that without the dollar control option `$onMulti` that would generate an error as per default a symbol can have at most one data statement.
4.23 Set Definition

4.23.2.3 Sequences as Set Elements

The asterisk ‘∗’ plays a special role in set definitions. It is used to relieve the tedium of typing a sequence of elements for a set, and to make intent clearer. For example, in a simulation model there might be ten annual time periods from 1991 to 2000. Instead of typing ten years, the elements of this set can be written as:

Set t "time" / 1991 * 2000 /;

This means that the set includes the ten elements 1991, 1992, ..., 2000. GAMS builds up these label lists by looking at the differences between the two labels. If the only characters that differ are digits, with the number L formed by these digits in the left and R in the right, then a label is constructed for every integer in the sequence L to R. Any non-numeric differences or other inconsistencies cause errors.

The following example illustrates the most general form of the 'asterisked' definition:

Set g1 / a1bc * a20bc /;

Note that this is not the same as:

Set g2 / a01bc * a20bc /;

Both sets have 20 members, but they have only 11 members in common.

Lists in decreasing order are also possible:

Set y "years in decreasing order" / 2000 * 1991 /;

As a last example, the following set definitions are both illegal because they are not consistent with the rule given above for making lists:

Set illegal1 / a1x1 * a9x9 /;
Set illegal2 / a1 * b9 /;

4.23.2.4 Declaring Multiple Sets

The keyword set does not need to be used for each set, rather only at the beginning of a group of sets. It is often convenient to put a group of set declarations (and definitions) together at the beginning of the program. When this is done the set keyword needs only be used once. Those who prefer to intermingle set declarations with other statements, have to use a new set statement for each additional group of sets. Note that the keywords set and sets are equivalent. The following example below shows how two sets can be declared together. Note that the semicolon is used only after the last set is declared.

Sets s "Sectors" / manuf, agri, services, government /;
Sets r "Regions" / north, eastcoast, midwest, sunbelt /;
4.23.2.5 Using Previously Defined Sets in Set Definitions

The following notation allows previously defined sets to be used in a new set definition:

Set i / i1 * i4 /
   j / j6 * j9 /
   k / #i, set.j /;

The set k contains all elements of the sets i and j. Note that the hash sign '#' followed by a set name is a shorthand for referring to all the elements in a set. The notation set.set.name works identically and is just a different way to refer to all elements in a previously defined set.

4.23.3 The Alias Statement: Multiple Names for a Set

Sometimes it is necessary to have more than one name for the same set. In input-output models for example, each commodity may be used in the production of all other commodities and it is necessary to have two names for the set of commodities to specify the problem without ambiguity. In the general equilibrium model [ORANI], the set of commodities c is written as

Set c "Commodities" / food, clothing /;

A second name for the set c is established with either of the following statements:

Alias (c, cp) ;
Alias (cp, c) ;

Here cp is the new set name that can be used instead of the original set name c.

Note
The newly introduced set name may be used as an alternative name for the original set; the associated set will always contain the same elements as the original set.

With the alias statement more than one new name may be introduced for the original set:

Alias (c,cp, cpp, cppp);

Here cp, cpp, ccppp are all new names for the original set c.
4.23 Set Definition

Note

The order of the set names in the alias statement does not matter. The only restriction is that exactly one of the sets in the statement must be defined earlier. All the other sets are introduced by the alias statement.

Typical examples for the usage of aliases are problems where transportation costs between members of one set have to be modeled. The following code snippet is adapted from the Andean fertilizer model [ANDEAN]:

```gams
Set i "plant locations" / palmasola, pto-suarez, potosi, baranquill, cartagena /;
Alias(i,ip);
Table tran(i,i) "transport cost for interplant shipments (us$ per ton)"
     palmasola pto-suarez potosi baranquill
pto-suarez 87.22
potosi   31.25 55.97
baranquill 89.80 114.56 70.68
cartagena 89.80 114.56 70.68  5.00
;
Parameter mui(i,ip) "transport cost: interplant shipments (us$ per ton)";
mui(i,ip) = (tran(i,ip) + tran(ip,i));
```

The alias statement introduces `ip` as another name for the set `i`. The `table tran` is two-dimensional and both indices are the set `i`. The data for the transport cost between the plants is given in this table; note that the transport costs are given only for one direction here, i.e. the costs from `pto-suarez` to `palmasola` are explicitly specified in the table while the costs in the opposite direction are not given at all. The parameter `mui` is also two-dimensional and both indices refer to the set `i`, but this time the alias `ip` is used in the second position. The parameter `mui` is defined with the assignment statement in the next line: `mui` contains the transport costs from one plant location to the other, in both directions. Note that if `mui` were defined without the alias, then all its entries would have been zero. For other examples where aliases are used, see sections The Universal Set and Finding Sets from Data below.

4.23.4 Subsets

It is often necessary to define sets whose members must all be members of some larger set. The syntax is:

```gams
set set_ident1(set_ident2) ;
```

Here `set` is the keyword indicating that this is a set statement, and `set_ident1` is a subset of the larger set `set_ident2`. The larger set is also called superset.

For instance, we may wish to define the sectors in an economic model following the style in [CHENERY].

```gams
Set i "all sectors" / light-ind, food+agr, heavy-ind, services /
t(i) "traded sectors" / light-ind, food+agr, heavy-ind /
nt "non-traded sectors" / services /;
```

Some types of economic activity, for example exporting and importing, may be logically restricted to a subset of all sectors. In order to model the trade balance we need to know which sectors are traded, and one obvious way is to list them explicitly, as in the definition of the set `t` above. The specification `t(i)` means that each member of the set `t` must also be a member of the set `i`. GAMS will enforce this relationship, which is called domain checking. Obviously, the order of declaration and definition is important: the membership of `i` must be known before `t` is defined, otherwise checking cannot be done.
Note

All elements of the subset must also be elements of the superset.

It is legal but unwise to define a subset without reference to the larger set, as is done above for the set nt. In this case domain checking cannot be performed: if services were misspelled no error would be marked, but the model may give incorrect results. Hence, it is recommended to use domain checking whenever possible. It catches errors and allows to write models that are conceptually cleaner because logical relationships are made explicit.

An alternative way to define elements of a subset is with assignments:

Set i "all sectors" / light-ind, food+agr, heavy-ind, services /
   t(i) "traded sectors" / light-ind, heavy-ind /;
t('food+agr') = yes;

In the last line the element food+agr of the set i is assigned to the subset t. Assignments may also be used to remove an element from a subset:

t('light-ind') = no;

Note that yes and no are reserved words in GAMS. Note further that if a subset is assigned to, it then becomes a dynamic set. For more on assignments in GAMS in general, see section The Assignment Statement.

Attention

A subset can be used as a domain in the declaration of other sets, variables, parameters and in equations as long as it is no dynamic set.

This completes the discussion of sets in which the elements are simple. This is sufficient for many GAMS applications. However, there are a variety of problems for which it is useful to have sets that are defined in terms of two or more other sets.

4.23.5 Multi-Dimensional Sets

It is often necessary to provide mappings between elements of different sets. For this purpose, GAMS allows the use of multi-dimensional sets. For the current maximum number of permitted dimensions, see Dimensions. The next two subsections explain how to express one-to-one and many-to-many mappings between sets.

4.23.5.1 One-to-one Mapping

Consider a set whose elements are pairs: \( A = \{ (b, d), (a, c), (c, e) \} \). In this set there are three elements and each element consists of a pair of letters. This kind of set is useful in many types of modeling. For example, in the world aluminum model \([\text{ALUM}]\) a port has to be associated with a nearby mining region

Set i "mining regions" / china, ghana, ee+ussr, s-leone /
n "ports" / accra, freetown, leningrad, shanghai /
in(i,n) "mines to ports map" / china .shanghai
   ghana .accra
   ee+ussr.leningrad
   s-leone.freetown /;

Here i is the set of mining regions, n is the set of ports and in is a two dimensional set that associates each port with a mining region. The dot between china and shanghai is used to create one such pair. Blanks may be used freely around the dot for readability. The set in has four elements, and each element consists of a region-port pair. The notation \((i,n)\) after the set name in indicates that the first member of each pair must be a member of the set i of mining regions, and that the second must be in the set n of ports. GAMS will domain check the set elements to ensure that all members belong to the appropriate sets.
4.23 Set Definition

4.23.5.2 Many-to-Many Mapping

A many-to-many mapping is needed in certain cases. Consider the following sets:

Set  i / a, b / 
    j / c, d, e / 
    ij1(i,j) / a..c, a..d / 
    ij2(i,j) / a..c, b..c / 
    ij3(i,j) / a..c, b..c, a..d, b..d /;

Here the set \( ij1 \) presents a one-to-many mapping where one element of the set \( i \) maps onto many elements of the set \( j \). The set \( ij2 \) represents a many-to-one mapping where many elements of the set \( i \) map onto one element of the set \( j \). The set \( ij3 \) is the most general case: a many-to-many mapping where many elements of the set \( i \) map to many elements of the set \( j \).

These sets may be written compactly as:

Set  i / a, b / 
    j / c, d, e / 
    ij1(i,j) / a.(c,d) / 
    ij2(i,j) / (a,b).c / 
    ij3(i,j) / (a,b).(c,d) /;

The parenthesis provides a list of elements that is expanded when creating pairs. Note that the dot ‘.’, if used like above, acts as product operator and supports building the Cartesian product of sets.

Attention

When complex sets like this are created, it is important to check that the desired set has been obtained. The checking can for example be done be done by using a display statement.

GAMS provides more notation to define multi-dimensional sets in a succinct way. As introduced above the hash sign ‘#’ followed by a set name is a shorthand for referring to all the elements in a set. The matching operator ‘::’ may be used to map ordered sets. This operator is similar to the product operator ‘.’. However, in this case elements are matched pairwise by mapping elements with the same order number. The examples below demonstrate these concepts.

Set  i / a, b / 
    j / c, d, e / 
    ij4a(i,j) / a.#j / 
    ij4b(i,j) / a.c, a.d, a.e / 
    ij5a(i,j) / #i.#j / 
    ij5b(i,j) / a.c, a.d, a.e, b..c, b..d, b..e / 
    ij6a(i,j) / #i:#j / 
    ij6b(i,j) / a.c, b..d /;

Note that set names that differ only by the last letter denote identical sets. For example, set \( ij4a \) is identical to set \( ij4b \). Observe that set \( i \) has two elements and set \( j \) has three elements, where \( e \) is the element with the highest order. Set \( ij6a \) is an ordered mapping of all elements of set \( i \) to all elements of set \( j \). However, since there is a mismatch in the number of elements, element \( e \) is not mapped to.

These concepts may be generalized to sets with higher dimensions. Mathematically, these are called 3-tuples, 4-tuples, or more generally, \( n \)-tuples. Some examples for the compact representation of sets of \( n \)-tuples using combinations of dots, parentheses, and commas are shown in Table 1.
A powerful and very compact way to define multi-dimensional sets is with a special option that takes an identifier as value and carries out identifier operations like index matching using the matching operator ':'. The following example illustrates the method.

```plaintext
Set i / i1*i4 /
j / j1*j5 /
k / k1,k2 /
h / h1*h3 /;
Set b(i,j,k), c(i,j,k,h);
Option b(i:j,k), c(b:h);
display b, c;
```

The set \( b \) is a three-dimensional set, the option statement specifies which permutations of the elements of \( i, j, \) and \( k \) are elements of \( b \). The matching operator ': ' is between \( i \) and \( j \), so we must first match the elements of the sets \( i \) and \( j \). That gives us the the first two positions. For the third position we cycle through all elements of the set \( k \). This results in the following elements for the set \( b \):

\[
i1.j1.k1, i1.j1,k2, i2.j2.k1, \ldots , i4.j4.k2
\]

The set \( c \) is a four-dimensional set. Note that the first three dimensions are identical to the domain of the set \( b \). The option statement specifies that in the first three positions we will have elements of the set \( b \) and and these are matched with the elements of the set \( h \) which are in the fourth position. Now, the set \( h \) has only three elements, so only the first three elements of the set \( b \) are matched with the members of the set \( h \). This results in the following set:

\[
i1.j1.k1.h1, i1.j1.k2.h2, i2.j2.k1.h3
\]

As recommended above, it is important to always check whether the multi-dimensional sets generated with compact statement like these are indeed the sets that were intended.

For more sophisticated examples of how to use the matching operator within an option statement please see section Index Matching .
### 4.23.5.3 The Table Format for Multi-Dimensional Sets

An alternative way to declare multi-dimensional sets is with tables. We show by example how tables may be used in the context of set definitions:

Set origins / Berlin, Paris /
  destinations / London, Chicago, Budapest /
  linked_1(origins,destinations) "cities linked by railways"
  / Berlin.London, Berlin.Budapest, 

Set Table linked_2(origins,destinations)

<table>
<thead>
<tr>
<th></th>
<th>London</th>
<th>Chicago</th>
<th>Budapest</th>
</tr>
</thead>
<tbody>
<tr>
<td>Berlin</td>
<td>yes</td>
<td>no</td>
<td>yes</td>
</tr>
<tr>
<td>Paris</td>
<td>yes</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The set linked_1 is a two-dimensional set that is defined with the dot notation introduced above. The set linked_2 is the same set defined using the table notation: the keyword set is followed by the keyword table and the name of the set with its domain. The table itself consists of the elements of the first index in the first column, the elements of the second index in the first row, and the data in the grid positions. Note that the keyword yes indicates that a label combination is part of the two-dimensional set and the keyword no or a blank indicates that the label combination is not contained in the new set. Please see section Tables for detailed requirements for inputting data in the table format.

Alternatively, the multi-dimensional set may be declared first without any elements, and the elements are added later in a separate table statement:

Set origins / Berlin, Paris /
  destinations / London, Chicago, Budapest /
  linked_2(origins,destinations) "cities linked by railways";

Table linked_2(origins,destinations)

<table>
<thead>
<tr>
<th></th>
<th>London</th>
<th>Chicago</th>
<th>Budapest</th>
</tr>
</thead>
<tbody>
<tr>
<td>Berlin</td>
<td>yes</td>
<td>no</td>
<td>yes</td>
</tr>
<tr>
<td>Paris</td>
<td>yes</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Instead of the keywords yes and no users may also use numbers to specify membership in the two-dimensional set: nonzero numeric entries mean that a label combination is part of the set and zero or a blank indicates that the label combination is not contained in the set.

### 4.23.5.4 Projection and Aggregation of Sets

In GAMS, projection and aggregation operations on sets can be performed in two different ways: with an option statement and with an assignment. For a detailed discussion, see section Projection and Aggregation of Sets and Parameters.
4.23.6 Singleton Sets

A singleton set in GAMS is a special set that has at most one element (zero elements are allowed as well). Like other sets, singleton sets may have a domain with several dimensions. For the current maximum number of permitted dimensions, see Dimensions. Singleton sets are declared and defined with the keyword singleton that acts as a modifier to the keyword set:

```
Set i / a, b, c /
Singleton Set j / d /
   k(i) / b /
   l(i,i) / b.c /
```

The sets j, k and l are declared as singleton sets, each of them has just one element. The set k is a subset of the set i and the set l is a two-dimensional set.

Note that a data statement for a singleton set with more than one element will create a compilation error:

```
1 Singleton Set s / s1*s3 /;
 **** $844
2 display s;
```

Error Messages

844 Singleton with more than one entry (see $onStrictSingleton)

It also possible to assign an element to a singleton set. In this case the singleton set is automatically cleared of the previous element first. For example, adding the following line to the code above will result in set k containing only element a after execution:

```
k('a') = yes;
```

The dollar control option offStrictSingleton may be used to allow sets that are declared as singleton sets to have more than one element in compile time definitions. However, in this case only the first listed element is a valid element of the set. Note that the value of zero for the command line parameter strictSingleton has the same effect for execution time definitions of singleton sets via assignment statements.

For more on dollar control options, see chapter Dollar Control Options. For more on GAMS command line parameters, see chapter The GAMS Call and Command Line Parameters. For more on compilation errors, see section Compilation Errors.

Singleton sets can be especially useful in assignment statements since they do not need to be controlled by a controlling index or an indexed operator like other sets. Consider the following examples:

```
Set i / a, b, c /
Singleton Set k(i) / b /
   h(i) / a /
Parameter n(i) / a 2, b 3, c 5 /
Scalar z1, z2;

z1 = n(k);
z2 = n(k) + 100*n(h);
```

The singleton sets k and h are both subsets of the set i. The parameter n is defined over the set i. The scalar z1 is assigned a value of the parameter n without naming the respective label explicitly in the assignment. It is already specified in the definition of the singleton set k. The assignment statement for the scalar z2 contains an expression where the singleton sets k and h are referenced without a controlling index or an indexed operation.

Note

Singleton sets cannot be used as domains.
4.23.7 The Universal Set: * as Set Identifier

GAMS provides the universal set denoted by '*' for cases where the user wishes not to specify an index but have only a placeholder for it. The following examples show two ways how the universal set is introduced in a model. We will discuss the advantages and disadvantages of using the universal set later. The first example is from the production and inventory model [ROBERT]:

\begin{verbatim}
Sets r "raw materials" / scrap, new /
Table misc(*,r) "other data"
   scrap new
max-stock   400  275
storage-c   .5   2
res-value   15   25;
\end{verbatim}

A table is an input format for the data type parameter and has at least two dimensions. For details see section Tables. In our example, the first index is the universal set '*' and the second index is the previously defined set r. Since the first index is the universal set any entry whatsoever is allowed in this position. In the second position elements of the set r must appear, they are domain checked, as usual.

The second example illustrates how the universal set is introduced in a model with an alias statement.

\begin{verbatim}
Alias (new_universe,*);
Set k(new_universe) / Chicago /;
\end{verbatim}

The alias statement links the universal set with the set name new_universe. Set k is a subset of the universal set and Chicago is declared to be an element of k. Any item may be added freely to k.

The universal set is particularly useful for generating reports, since it allows the use of any labels without having to define special sets for them. For an example, see section Set Attributes below. For more on report writing, see chapter The Put Writing Facility.

Attention

It is recommended not to use the universal set for data input, since there is no domain checking and thus typos will not be detected and data that the user intends to be in the model might actually not be part of it.

Observe that in GAMS a simple set is always regarded as a subset of the universal set. Thus the set definition

\begin{verbatim}
Set i / i1*i10 /;
\end{verbatim}

is the same as

\begin{verbatim}
Set i(*) / i1*i10 /;
\end{verbatim}

GAMS follows the concept of a domain tree for domains in GAMS. It is assumed that a set and its subset are connected by an arc where the two sets are nodes. Now consider the following one dimensional subsets:

\begin{verbatim}
Set i, ii(i), j(i), jj(j), jjj(jj);
\end{verbatim}

These subsets are connected with arcs to the set i and thus form a domain tree that is rooted in the universe node '*'. This particular domain tree may be represented as follows:

\begin{verbatim}
* - i - ii
   |    
   - j - jj - jjj
\end{verbatim}

Note that with the construct i(jjj) we may access ii iterating through the members of jjj. For an example, see domain tree in the loop statement.

Observe that the universal set is assumed to be ordered and operators for ordered sets such ord, lag and lead may be applied to any sets aliased with the universal set.
4.23.8 Set and Set Element Referencing

Sets or set elements are referenced in many contexts, including assignments, calculations, equation definitions and loops. Usually GAMS statements refer to the whole set or a single set element. In addition, GAMS provides several ways to refer to more than one, but not all elements of a set. In the following subsections we will show by example how this is done. GAMS also has set functions that specifically reference sets and are introduced in the chapter about logical conditions.

4.23.8.1 Referencing the Whole Set

Most commonly whole sets are referenced as in the following examples:

Set i / i1*i100 /;
Parameter k(i);
k(i) = 4;
Scalar z;
z = sum(i, k(i));

The parameter \(k\) is declared over the set \(i\), in the assignment statement in the next line all elements of the set \(i\) are assigned the value 4. The scalar \(z\) is defined to be the sum of all values of the parameter \(k(i)\).

4.23.8.2 Referencing a Single Element

Sometimes it is necessary to refer to specific set elements. This is done by using single or double quotes around the label(s). We may add the following line to the example above:

\[k('i77') = 15;\]

This statement changes the value of \(k('i77')\) to 15, all the other values of \(k\) remain 4.

4.23.8.3 Referencing a Part of a Set

There are multiple ways to restrict the domain to more than one element, e.g. subsets, conditionals and tuples. Suppose we want the parameter \(k\) from the example above to be assigned the value 10 for the first 8 elements of the set \(i\). The following two lines of code illustrate how easily this may be accomplished with a subset:

Set j(i) / i1*i18 /;
k(j) = 10;

First we define the set \(j\) to be a subset of the set \(i\) with exactly the elements we are interested in. Then we assign the new value to the elements of this subset. The other values of the parameter \(k\) remain unchanged. For examples using conditionals and tuples, see sections Restricting the Domain: Conditionals and Restricting the Domain: Tuples respectively.

4.23.9 Set Attributes

A GAMS set element has several numbers attached to it. These values are called attributes; they may be recovered during execution. The attributes are listed in Table 3.
### 4.23 Set Definition

<table>
<thead>
<tr>
<th>Set Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Position</td>
<td>.pos</td>
<td>Element position in the current set (set does not have to be ordered), starting with 1.</td>
</tr>
<tr>
<td>Ord</td>
<td>.ord</td>
<td>Same as .pos but for ordered sets only.</td>
</tr>
<tr>
<td>Offset</td>
<td>.off</td>
<td>Element position in the current set minus 1. So .off = .pos - 1 (set does not have to be ordered).</td>
</tr>
<tr>
<td>Reverse</td>
<td>.rev</td>
<td>Reverse element position in the current set, so the value for the last element is 0, the value for the penultimate is 1, etc. (set does not have to be ordered).</td>
</tr>
<tr>
<td>Unique Element List</td>
<td>.uel</td>
<td>Element position in the unique element list. For details see section Ordered and Unordered Sets</td>
</tr>
<tr>
<td>Length</td>
<td>.len</td>
<td>Length of the set element name (a count of the number of characters).</td>
</tr>
<tr>
<td>Value</td>
<td>.val</td>
<td>If a set element is a number, this attribute gives the value of the number. For extended range arithmetic symbols, the symbols are reproduced. If a set element is a string that is not a number, then this attribute is not defined and trying to use it results in an error.</td>
</tr>
<tr>
<td>First set element</td>
<td>.first</td>
<td>Returns 1 for the first set element, otherwise 0.</td>
</tr>
<tr>
<td>Last set element</td>
<td>.last</td>
<td>Returns 1 for the last set element, otherwise 0.</td>
</tr>
</tbody>
</table>

**Table 3: Set Attributes**

The attributes may be accessed with an assignment statement:

```plaintext
data(set_name) = set_name.attribute ;
```

Here `data` is a parameter, `set_name` is the name of the set and `.attribute` is one of the attributes listed above. The following example serves as illustration:

```plaintext
Set id "example set" / Madison, tea-time, '-inf', '-7', '13.14'/;
Parameter report(id,*) "set attribute values";

report(id,'position') = id.pos ;
report(id,'reverse') = id.rev ;
report(id,'offset') = id.off ;
report(id,'length') = id.len ;
report(id,'first') = id.first;
report(id,'last') = id.last ;

display report;
```

The parameter `report` is declared to have two dimensions with the set `id` in the first position and the universal set in the second position. In the following six statements the values of `report` are defined for six entries of the universal set. Note how the flexibility of the universal set is used here to make reporting easy. The `display statement` generates the output that follows.

```plaintext
---- 11 PARAMETER report set attribute values

<table>
<thead>
<tr>
<th>position</th>
<th>reverse</th>
<th>offset</th>
<th>length</th>
<th>first</th>
<th>last</th>
</tr>
</thead>
<tbody>
<tr>
<td>Madison</td>
<td>1.000</td>
<td>4.000</td>
<td>7.000</td>
<td>1.000</td>
<td></td>
</tr>
<tr>
<td>tea-time</td>
<td>2.000</td>
<td>3.000</td>
<td>1.000</td>
<td>8.000</td>
<td></td>
</tr>
<tr>
<td>-inf</td>
<td>3.000</td>
<td>2.000</td>
<td>2.000</td>
<td>4.000</td>
<td></td>
</tr>
<tr>
<td>-7</td>
<td>4.000</td>
<td>1.000</td>
<td>3.000</td>
<td>2.000</td>
<td></td>
</tr>
<tr>
<td>13.14</td>
<td>5.000</td>
<td>4.000</td>
<td>5.000</td>
<td>1.000</td>
<td></td>
</tr>
</tbody>
</table>
```
4.23.10 Finding Sets from Data

Sometimes it is desirable to find a set from the available data in order to use it later in the model. We will show by example how this may be accomplished using the alias statement, the universal set and conditionals. Suppose we have only the data related to the transportation model [TRNSPORT] and we want to identify the sets. We can tell from the data that there are two sets that we are interested in. First, we define these two sets as aliases of the universal set, which means that no elements are specified:

Alias(sources, places, *);

Then we enter the data that contain an indicator of which set elements are valid entries in the sets to be computed. We use the table format.

<table>
<thead>
<tr>
<th>Table trandata (sources,places) &quot;data from spreadsheet&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Newyork</td>
</tr>
<tr>
<td>Seattle</td>
</tr>
<tr>
<td>Sandiego</td>
</tr>
<tr>
<td>totalneed</td>
</tr>
</tbody>
</table>
| ;

Next we define subsets that we will need in the calculations that follow:

Set source(sources) "sources in spreadsheet data" destination(places) "destination in spreadsheet data";

Now we have everything that we need to do the calculation using the data on hand. In our case, a label qualifies as an element of the set source if it has an entry for totalsupply in the table above, and a label is an element of the set destination if it has an entry for totalneed in the table trandata:

source(sources)$(trandata(sources,"totalsupply")) = yes;
destination(places)$(trandata("totalneed", places )) = yes;

These conditional assignments define the elements of the sets source and destination. From this point on these sets may be used in the model. However, note that the resulting sets are dynamic sets. Hence they cannot be used as domains in declaration statements of other sets, parameters, variables and equations. But they may be referenced and used in equation definitions.

Such computations may for example be useful if the user gets a data table from elsewhere and needs to specify the sets. Alternatively, if the data is available in gdx format, the dollar control option load provides functionality to project sets from data contained in a GDX file.

See also section Implicit Set Definition (or: Domain Defining Symbol Declarations).
4.23.11 Domain Checking

The GAMS compiler performs a check to ensure that each label quoted as a member of a set is indeed an element of the respective set, and each element defined in a subset is in fact a member of the superset. This screening for consistency is called *domain checking*. It is done whenever a domain is referenced, be it in set, variable, parameter or equation declarations and definitions, or in assignments. The following examples serve as illustration.

Set i "all cities" / Lima, Toronto, Wuhan, Shanghai /
    as(i) "Asian cities" / Wuhan, Shanghai, Calcutta /
    am "American cities" / Lima, Toronto /;

The set `as` is declared to be a subset of the set `i`, therefore domain checking will test every label for inconsistencies. It will catch two errors: there is a typo in `Shanghai` and `Calcutta` is not a member of the set `i`, so it cannot legally be a member of a subset.

1 Set i "all cities" / Lima, Toronto, Wuhan, Shanghai /
2    as(i) "Asian cities" / Wuhan, Shanghai, Calcutta /

**** $170 $170
**** 170 Domain violation for element
3 am "American cities" / Lima, Toronto /;

The user can rectify the spelling error, and either delete `Calcutta` from the subset `as` or add it to the superset `i`. The following line will pass domain checking:

Set as(i) "Asian cities" / Wuhan, Shanghai /;

Note that `am` is not declared as a subset of the set `i` even though it apparently should contain cities contained in `i`. Hence, `am` cannot be domain checked and the typo in `Toronto` will go undetected. This has consequences for the next line:

Parameter pam(am) "population in millions" / Lima 8.9, Toronto 5.6 /;

In this parameter definition the domain of the parameter `pam` is the set `am`. GAMS will report an error here, since domain checking does not recognize the label `Toronto`. `Toronto`, as specified in the definition of the set `am` above would be accepted.

A further example for domain checking concerns multi-dimensional domains where the user accidentally switches the positions of the indices:

Parameter h(as,am) / Wuhan.Lima 10, Wuhan.Toronto 12, Shanghai.Lima 7/;
Parameter d(as,am);
  d(as,am) = 5*h(am,as) + 78;

Observe that we assume that the typo in the label `Toronto` has been rectified. The parameter `h` is defined over the domain `(as,am)`. However, in the assignment statement in the last line above, it is referenced with the domain `(am,as)`. This mistake is caught by domain checking and an error is reported.

As we have seen in the definition of the set `am` above, domain checking is not compulsory. If the following statement is entered, GAMS makes no assumptions about `rho` until further information is provided.
set t years / 1988 * 1995 /;
Parameter rho discount rate ;

The modeler may later choose to domain check rho by continuing the definition with the following line:

Parameter rho(t) / 1988 0.07, 1989*1994 0.10, 1995 0.09 /;

Alternatively, the modeler may choose not to domain check the parameter rho, as is shown in the deliberately nonsensical (but legal) statement that follows:

Parameter rho / 1988.January 0.07, strategy-1.cost 44, cat.capacity 99 /;

If a parameter is not domain-checked, the only restriction is that the dimensionality must be constant. Once the number of labels per data item has been established it is frozen; to refer to the parameter differently is an error.

Note

Domain checking is automatic; it is only suppressed in two cases:
1. The index is the universal set or a set aliased to the universal set, see the examples above.
2. The dollar control option $onWarning is used. It has the effect that warnings rather than errors are reported for domain violations.

We urge modelers to use domain checking whenever possible. It catches errors and allows users to write models that are conceptually cleaner because logical relationships are made explicit.

Note that the dollar control option $load is available in several variations to enable domain checking when loading data from a GDX file. For details, see $loadDC, $loadDCM and $loadDCR and chapter GAMS Data eXchange (GDX).

4.23.12 Implicit Set Definition (or: Domain Defining Symbol Declarations)

As seen above, sets can be defined through data statements in the declaration. Alternatively, sets can be defined implicitly through data statements of other symbols which use these sets as domains. This is illustrated in the following example, which is derived from the [TRNSPORT] model:

Set
   i 'canning plants'
   j 'markets';

Table d(i<,j<) 'distance in thousands of miles'
    new-york  chicago  topeka
     seattle    2.5   1.7    1.8
     san-diego  2.5   1.8    1.4;

Display i,j;

Note the < signs in the domain list of the declaration of d (d(i<,j<)). These signal, that the set i will contain all elements which define the first dimension of symbol d and that the set j will contain all elements which define the second dimension of symbol d, respectively. So, this is the output of the Display statement at the end:
This syntax is not limited to the table statement, but can be used with any symbol declaration. Also, one domain set can be defined through multiple symbols using the same domain, when using the dollar control option onMulti:

Set
  food
    fruits(food<) / apple, orange /
  $onMulti
    vegetable(food<) / carrot, cauliflower /
    meat(food<) / beef, pork /;

Display food;

This is the output of the Display statement:

---- 8 SET food
apple , orange , carrot , cauliflower, beef , pork

Note
If the < sign is used to mark a declaration as "domain defining", this attribute is not limited to the data statement following this declaration, but also influences other ways to define data at compile time like the dollar control option load, as shown in the following example:

Set
  i 'canning plants'
  j 'markets';

Parameter d(i<,j<) 'distance in thousands of miles';

$gdxIn data.gdx
$load d

Attention
Only non-zero elements in a symbol will add elements to an implicitly defined set. This is illustrated in the following two examples.

Set
  i 'canning plants'
  j 'markets';

Table d(i<,j<) 'distance in thousands of miles'
  new-york    chicago    topeka
  seattle  2.5        1.8
  san-diego 2.5        1.4;

Display i,j;
Note the empty column for chicago. Since there is no data, chicago will not end up in the set j, which can be seen in the output of the Display statement:

```
---- 10 SET j markets
new-york, topeka
```

Also, an explicit 0 in a data statement does not add elements to an an implicitly defined set (in contrast to an eps). This is shown in the following GAMS code and output:

```
Set
  j 'markets';

Parameter
  b(j) 'demand at market j in cases'
    / new-york 325
    chicago 0
    topeka eps /;

Display j;
```

```
---- 10 SET j markets
new-york, topeka
```

See also section Finding Sets from Data.

4.23.13 Summary

In GAMS, a simple set consists of a set name and the elements of the set. Both the name and the elements may have associated text that explains the name or the elements in more detail. More complex sets have elements that are pairs or even n-tuples. These sets with pairs and n-tuples are ideal for establishing relationships between the elements in different sets. GAMS also uses a domain checking capability to help catch labeling inconsistencies and typographical errors made during the definition of related sets.

The discussion here has been limited to sets whose members are all specified as the set is being declared. For many models this is all the user needs to know about sets. Later we will discuss more complicated concepts, such as sets whose membership changes in different parts of the model (assignment to sets) and other set operations such as unions, complements and intersections.

4.24 Dynamic Sets

4.24.1 Introduction

Sets in general are covered in chapter Set Definition. In this chapter we introduce a special type of sets: dynamic sets. The sets that we discuss in detail in chapter Set Definition have their elements stated at compile time (e.g. enclosed in slashes at the set declaration or when loading a set from gdx via $load) and during execution time the membership is never changed. Therefore they are called static sets. In contrast, the elements of dynamic sets are not fixed, but may be added and removed during execution of the program. Dynamic sets are most often used as controlling indices in assignments or equation definitions and as the conditional set in a dollar-controlled indexed operation. We will first show how assignments are used to change set membership in dynamic sets. Then we will introduce set operations and the last part of this chapter covers dynamic sets in the context of dollar conditions.
4.24 Dynamic Sets

4.24.2 Assigning Membership to Dynamic Sets

Dynamic Sets may be assigned to in a similar way as other data types. There are only two possible values: yes and no. Note that arithmetic operations cannot be performed on sets in the same way as on value typed identifiers (parameters, variables and equations subtypes). However, there are special set operations.

4.24.2.1 The Syntax

Like any other set, a dynamic set has to be declared before it may be used in the model. Often, a dynamic set is declared as subset of a static set. Dynamic sets in GAMS may also be multi-dimensional like static sets. The maximum number of permitted dimensions follows the rules of the basic Data Types and Definitions. For multi-dimensional dynamic sets the index sets can also be specified explicitly at declaration. That way dynamic sets are domain checked. Of course it is also possible to use dynamic sets that are not domain checked. This provides additional power and flexibility but also a lack of intelligibility and danger. Any label is legal as long as such a set's dimension, once established, is preserved.

In general, the syntax for assigning membership to dynamic sets in GAMS is:

\[
\text{set_name(index_list | label) = yes | no ;}
\]

Set name is the internal name of the set in GAMS, index_list refers to the domain of the dynamic set and label is one specific element of the domain. An assignment statement may assign membership to the dynamic set either to the whole domain or to a subset of the domain or to one specific element. Note that, as usual, a label must appear in double or single quotes. Yes and no are keywords in GAMS. They are used to add members to or remove them from the dynamic set. Examples are given in the following subsections.

4.24.2.2 Illustrative Example

Throughout this chapter we will use examples adapted from the database model [ZLOOF] to illustrate the introduced concepts. Here we start with assignments of membership to dynamic sets.

```
Set  item    "all items" / dish, ink, lipstick, pen, pencil, perfume /
    subitem1(item) "first subset of item" / pen, pencil /
    subitem2(item) "second subset of item";

subitem1('ink') = yes ;
subitem1('lipstick') = yes ;
subitem2(item) = yes ;
subitem2('perfume') = no ;
display subitem1, subitem2;
```

Note that the sets subitem1 and subitem2 are declared like any other set. The two sets become dynamic as soon as they are assigned to a few lines later. They are also domain checked: the only members they will ever be able to have must also be members of the set item. The first assignment not only makes the set subitem1 dynamic, it also has the effect that its superset item becomes a static set and from then on its membership is frozen. The first two assignments each add one new element to subitem1. Note that both are also elements of item, as required. The third assignment is an example of the familiar indexed assignment: subitem2 is assigned all the members of item. The last assignment removes the label 'perfume' from the dynamic set subitem2. The output generated by the display statement is shown below:
Note that even though the labels 'pen' and 'pencil' were declared to be members of the set subitem1 before the assignment statements that added the labels 'ink' and 'lipstick' to the set, they appear in the listing above at the end. The reason is that elements are displayed in the internal order, which in this case is the order specified in the declaration of the set item.

Alternatively, the elements of the set subitem2 could be assigned in the following way:

```
subitem2(item) = no;
subitem2(subitem1) = yes;
subitem2('dish') = yes;
```

The first statement removes all elements from the set subitem2. The second statement adds all elements of the set subitem1. Note that this assignment is permitted since the set subitem1 is a proper subset of the set item (which is the domain of subitem2). The third statement adds one additional element.

### 4.24.2.3 Dynamic Sets with Multiple Indices

As mentioned earlier, dynamic sets may be multi-dimensional. The following lines continue the example above and illustrate assignments for multi-dimensional sets.

```
Sets sold(item) "items sold" / pencil, pen /
sup "suppliers" / bic, parker, waterman /
supply(sold, sup) ;

supply('pencil', 'bic') = yes ;
supply('pen', sup) = yes ;
```

Note that supply is a two-dimensional dynamic set. It links sold items with their respective suppliers. Other examples with multi-dimensional dynamic sets are in subsections Dynamic Sets in Conditional Assignments and Conditional Indexed Operations with Dynamic Sets below.

All the mechanisms using asterisks and parenthesized lists that were introduced in section Multi-Dimensional Sets in chapter Set Definition are available for dynamic sets as well.
4.24 Dynamic Sets

4.24.2.4 Equations Defined over the Domain of Dynamic Sets

Generally, dynamic sets are not permitted as domains in declarations of sets, variables, parameters and equations. However, they may be referenced and sometimes it is necessary to define an equation over a dynamic set.

Note

The trick is to declare the equation over the entire domain but define it over the dynamic set.

For example, defining an equation over a dynamic set can be necessary in models that will be solved for arbitrary groupings of regions simultaneously. We assume there are no explicit links between regions, but that we have a number of independent models with a common data definition and common logic. We illustrate with an artificial example, leaving out lots of details.

Set allr "all regions" / N, S, W, E, N-E, S-W /
   r(allr) "region subset for particular solution"
   type "set for various types of data" ;
Scalar price /10/ ;
Parameter revenue(allr);
Table data(allr,type) "all other data ..." ;
Variables activity1(allr) "first activity"
   activity2(allr) "second activity"
   revenue(allr) "revenue" ;
Equations resource1(allr) "first resource constraint ..."
   prodbal1(allr) "first production balance ..." ;
   resource1(r).. activity1(r) =l= data(r,'resource-1');
   prodbal1(r).. activity2(r)*price =e= revenue(r) ;

To repeat the important point: the equation is declared over the set allr, but defined over r, a subset. Note that the variables and data are declared over allr but referenced over r. Then the set r may be assigned arbitrary combinations of elements of the set allr, and the model may be solved any number of times for the chosen groupings of regions.

4.24.2.5 Assigning Membership to Singleton Sets

Singleton sets have only one element. Hence any assignment to a singleton set first clears or empties the set, no explicit action to clear the set is necessary. This is illustrated with the following example:

Set    i   "Static Set"   / a, b, c /
   ii(i) "Dynamic Set"   / b /;
Singleton Set si(i) "Dynamic Singleton Set" / b /;
ii('c') = yes;
si('c') = yes;
display ii, si;

Note that both ii and si are subsets of the set i, but only si is declared as a singleton set. The assignment statements assign to both sets the element 'c'. While 'c' is added to the set ii, it replaces the original element in the singleton set si. The output from the display statement confirms this:
---- 8 SET ii Dynamic Set
b, c

---- 8 SET si Dynamic Singleton Set
c

For more information on singleton sets in GAMS, see section Singleton Sets.

Attention

That an assignment to a singleton set first clears the set always, means that it is even cleared if there would be no change at all for a regular set:

Singleton Set s / 1 /;
s(s)$0 = yes;
display s;

Here is the output from the display statement in the listing file:

---- 3 SET s

( EMPTY )

The assignment behavior can be changed with the option and command line parameter strictSingleton which affects the behavior of a membership assignment to a Singleton Set. With strictSingleton=0 GAMS does not complain about an assignment with more than one element on the right hand side but takes the first one. With strictSingleton=1 (default), such an assignment raises an error. Consider the following example:

Set i "Static Set" / a, b, c /
Singleton Set si(i) "Dynamic Singleton Set";
si(i) = ord(i) > 1;
display si;

By default, the above code will trigger an error as an assignment to a singleton set with more than one element on the right hand side is forbidden:

*** Error at line 3: Multiple assignment to Singleton Set not allowed (see option strictSingleton)

However, with option (or command line parameter) strictSingleton=0 GAMS does not complain about such an assignment with more than one element on the right hand side but takes the first one:

Set i "Static Set" / a, b, c /
Singleton Set si(i) "Dynamic Singleton Set";
option strictSingleton = 0;
si(i) = ord(i) > 1;
display si;

The output from the display statement confirms this:

---- 5 SET si Dynamic Singleton Set
b

4.24.3 Set Operations

GAMS provides symbols for arithmetic set operations that may be used with dynamic sets. An overview of the set operations in GAMS is given in Table 1. Examples and alternative formulations for each operation follow. Note that in the table below the set i is the static superset and the sets j and k are dynamic sets.
4.24 Dynamic Sets

<table>
<thead>
<tr>
<th>Set Operation</th>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set Union</td>
<td>j(i) + k(i)</td>
<td>Returns a subset of ( i ) that contains all the elements of the sets ( j ) and ( k ).</td>
</tr>
<tr>
<td>Set Intersection</td>
<td>j(i) * k(i)</td>
<td>Returns a subset of ( i ) that contains the elements of the set ( j ) that are also elements of the set ( k ).</td>
</tr>
<tr>
<td>Set Complement</td>
<td>not j(i)</td>
<td>Returns a subset of ( i ) that contains all the elements of the set ( i ) that are not elements of the set ( j ).</td>
</tr>
<tr>
<td>Set Difference</td>
<td>j(i) - k(i)</td>
<td>Returns a subset of ( i ) that contains all the elements of the set ( j ) that are not elements of the set ( k ).</td>
</tr>
</tbody>
</table>

**Table 1:** Set Operations with Dynamic Sets

The following examples draw on the database model [ZLOOF] that we introduced above. Recall that the set \( \text{item} \) is the superset of the dynamic sets \( \text{subitem1} \) and \( \text{subitem2} \). We add new dynamic sets for the results of the respective set operations. The following example illustrates that the dynamic set operations are equivalent to the following alternative ways of representation.

Sets \( \text{union1(item)}, \text{intersection1(item)}, \text{complement1(item)}, \text{difference1(item)} \)

\[
\text{union1(item)} = \text{subitem1(item)} + \text{subitem2(item)}; \quad \text{display union1;}
\]

\[
\text{union2(item)} = \text{subitem1(item)}; \quad \text{display union2;}
\]

\[
\text{intersection1(item)} = \text{subitem1(item)} * \text{subitem2(item)}; \quad \text{display intersection1;}
\]

\[
\text{intersection2(item)} = \text{yes$(subitem1(item) and subitem2(item))}$; \quad \text{display intersection2;}
\]

\[
\text{complement1(item)} = \text{not subitem1(item)}; \quad \text{display complement1;}
\]

\[
\text{complement2(item)} = \text{yes; complement2(subitem1) = no}; \quad \text{display complement2;}
\]

\[
\text{difference1(item)} = \text{subitem2(item)} - \text{subitem1(item)}; \quad \text{display difference1;}
\]

\[
\text{difference2(item)} = \text{yes$(subitem2(item))}$; \quad \text{display difference2;}
\]

The display statements will show that the above assignment statements for each operation result in the same dynamic set like using the set operator. Observe that the alternative formulations for the set intersection and set difference involve conditional assignments. Conditional assignments in the context of dynamic sets are discussed in depth in the next section.

**Note**

The indexed operation `sum` may be used for set unions. Similarly, the indexed operation `prod` may be used for set intersections. For examples see section **Conditional Indexed Operations with Dynamic Sets** below.

### 4.24.4 Using Dollar Controls with Dynamic Sets

The remainder of this chapter assumes familiarity with the **dollar condition** that is introduced in chapter **Conditional Expressions, Assignments and Equations**. All the dollar control machinery is available for use with dynamic sets. In fact, the full power of dynamic sets can be exploited using these dollar controls.

Recall that set membership of subsets and dynamic sets may be used as a logical condition; see subsection **Logical Conditions: Set Membership and Set Functions** for details. Set membership may also be a building block in complex logical conditions that are constructed using the logical operators `not`, `and`, `or`, `xor`, `imp` and `eqv`. Moreover, the set operations introduced in the previous section may also be used in logical conditions. Like other dollar conditions, dollar conditions with dynamic sets are used in the context of assignments, indexed operations and equations. We will discuss in detail each of these in the following subsections.

Apart from being part of logical conditions, dynamic sets may be assigned members with conditional assignments. Examples are given in the next subsection.
4.24.4.1 Dynamic Sets in Conditional Assignments

Dynamic sets may be used in two ways in conditional assignments: they may be the item on the left-hand side that is assigned to and they may be part of the logical condition. Below we present examples for both. The examples are again based on the database model [ZLOOF] that we introduced above.

```
Set item "all items" / dish, ink, lipstick, pen, pencil, perfume /
   subitem1(item) "first subset of item" / ink, lipstick, pen, pencil /
   subitem2(item) "second subset of item";
subitem2(item)$subitem1(item) = yes;
display subitem2;
```

The conditional assignment adds the members of dynamic set subitem1 to the dynamic set subitem2. Thus subitem2 will have the following elements:

```
---- 6 SET subitem2  second subset of item
ink , lipstick, pen , pencil
```

Note that instead of using subitem1 in a dollar condition we could also write:

```
subitem2(subitem1) = yes;
```

In the next example of a conditional assignment, a dynamic set features in the logical condition on the right-hand side. The first statement clears the set subitem2 of any previously assigned members and the second statement assigns all members of subitem1 to subitem2. The following conditional assignment will have the same result:

```
subitem2(item) = no;
subitem2(item) = yes$subitem1(item);
```

The logical condition in this assignment is subitem1(item). It is satisfied for all members of the set subitem1. Hence the statement assigns all elements of the domain item that are members of the set subitem1 to the dynamic set subitem2. Note that in this assignment the dollar operator is on the right. In the section Dollar on the Right we show that conditional assignments with the dollar operator on the right-hand side imply an if-then-else structure where the else case is automatically zero. Unlike parameters, dynamic sets cannot be assigned the value of zero, they are assigned the value no instead. Therefore a more explicit formulation of the conditional assignment above would be:

```
subitem2(item) = no;
subitem2(item) = yes$subitem1(item) + no$(not subitem1(item));
```

For more on sets in logical conditions, see section Logical Conditions: Set Membership and Set Functions. For more on conditional assignments, see section Conditional Assignments.
4.24 Dynamic Sets

4.24.4.2 Conditional Indexed Operations with Dynamic Sets

Indexed operations in GAMS are introduced in section Indexed Operations. They may be controlled by dollar conditions as discussed in section Conditional Indexed Operations. The domain of conditional indexed operations is often restricted by a set, called the conditional set. Dynamic sets may be used as conditional sets or they may be assigned to with a statement that features a conditional indexed operation on the right-hand side. We will illustrate both cases with examples.

Suppose we have a set of origins, a set of destinations and a table specifying the flight distance between them:

```gams
Set i "origins" / Chicago, Philadelphia /
    j "destinations" / Vancouver, Bogota, Dublin, Rio, Marrakech / ;
Table d(i,j) "distance (miles)"
    Vancouver  Bogota  Dublin  Rio    Marrakech
Chicago      1777    2691    3709   5202   4352
Philadelphia 2438    2419    3306   4695   3757 ;
```

We wish to find the longest distance that we can travel given that we have a limit of 3500 miles.

```gams
Set can_do(i,j) "connections with less than 3500 miles";
can_do(i,j)$(d(i,j) < 3500) = yes;
display can_do;
Scalar maxd "longest distance possible"
maxd = smax((i,j)$can_do(i,j), d(i,j));
display maxd;
```

The dynamic set `can_do` contains all connections that are less than 3500 miles. The scalar `maxd` is defined by a conditional assignment where the indexed operation `smax` scans all entries of the parameter `d` whose label combinations are members of the set `can_do` and chooses the largest value. The output generated by the `display` statements is shown below:

```
---- 11 SET can_do connections with less than 3500 miles

<table>
<thead>
<tr>
<th></th>
<th>Vancouver</th>
<th>Bogota</th>
<th>Dublin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chicago</td>
<td>YES</td>
<td>YES</td>
<td></td>
</tr>
<tr>
<td>Philly</td>
<td>YES</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>

---- 15 PARAMETER maxd = 3306.000 longest distance possible
```

There is a shorter alternative formulation for this assignment; see subsection Filtering through Dynamic Sets below for details.

Finally, we also wish to know which flight connection is linked to the longest possible distance. Consider the following two lines:

```gams
Singleton set maxc(i,j) "maximum distance connection";
maxc(i,j) = yes$can_do(i,j) and (d(i,j) = maxd);
```

---
The dynamic singleton set is assigned the member of the dynamic set can_do whose distance equals the maximum distance.

The full power of indexed operators becomes apparent with multi-dimensional dynamic sets. As earlier in this chapter, we illustrate with fragments of code adapted from the relational database model [ZLOOF].

Set dep "departments" / cosmetics, hardware, household, stationary, toy /
sup "suppliers" / bic, dupont, parker, revlon /
item "items sold" / dish, ink, lipstick, pen, pencil, perfume /
sales(dep,item) "departments and items sold" /
    cosmetics. (lipstick,perfume)
    hardware. ink
    household. (dish,pen)
    stationary. (dish,ink,pen,pencil)
    toy. (ink,pen,pencil) /
supply(item,sup) "items and suppliers" /
    dish.(bic,dupont), ink.(bic,parker), lipstick.revlon
    pen.(parker,revlon), pencil.(bic,parker), perfume.revlon /
Set g03(dep) "departments selling items supplied by Parker";
g03(dep) = sum(item$supply(item,'parker'), sales(dep,item));
display g03;

The assignment above is used to create the set of departments that sell items supplied by 'parker'. Note that the set g03 is a subset of the set dep. Its members are specified by assignment, hence it is a dynamic set. Note that the assignment is made to a set, therefore the indexed operator sum refers to a set union (and not to an addition as would be the case if the assignment were made to a parameter). The indexed operation is controlled by the two-dimensional set supply with the label 'parker' in the second index position. This logical condition is TRUE for all members of the set supply where the second index is 'parker'. Hence the summation is over all items sold, provided that the supplier is 'parker'. Given the declaration of the set supply, this means 'ink', 'pen' and 'pencil'. The associated departments are thus all departments except for 'cosmetics':

---- 19 SET g03 departments selling items supplied by Parker
    hardware , household , stationary , toy

Now suppose we are interested in the departments that are selling only items supplied by 'parker'. We introduce a new dynamic set g11 and the following assignment adds the desired departments:

Set g11(dep) "departments only selling items supplied by parker";
g11(dep) = prod(sales(dep,item), supply(item,"parker"));
display g11;

Note that the indexed operation prod refers to set intersections in the context of assignments to dynamic sets. From all departments linked with items only those are included where all items sold are supplied by 'parker'. This means that departments that additionally sell items that are not supplied by 'parker' are excluded. Hence, only 'hardware' and 'toy' are added to g11.
4.24.4.3 Conditional Equations with Dynamic Sets

Recall that dollar conditions in the context of equations may restrict the domain of the equation and they may also feature in the algebraic formulation of the equation; see section Conditional Equations for more information. In both instances dynamic sets may be used as part of the logical condition. Dollar conditions with dynamic sets in the algebra of equations are similar to conditional assignments with dynamic sets; see section Dynamic Sets in Conditional Assignments above. The example that follows illustrates the use of a dynamic set to restrict the domain of definition of an equation. In section Equations Defined over the Domain of Dynamic Sets above we had the following equation definition:

\[
\text{prodbal1}(r) \ldots \quad \text{activity2}(r) \cdot \text{price} = \text{e} = \text{revenue}(r) ;
\]

Recall that \( r \) is a dynamic set and a subset of the set \( \text{allr} \). Hence this equation may be rewritten in the following way:

\[
\text{prodbal1}(\text{allr}) \cdot \$ \cdot \text{r(\text{allr})} \ldots \text{activity2(\text{allr})} \cdot \text{price} = \text{e} = \text{revenue(\text{allr})} ;
\]

Note that both formulations achieve the same result: restricting the domain of definition to those elements that belong to the dynamic set \( r \). While in the second formulation the condition is specified explicitly, in the first formulation the domain is *filtered* through the dynamic set \( r \). This is the topic of the next subsection.

4.24.4.4 Filtering through Dynamic Sets

The filtering process is introduced and explained in section Filtering Sets in chapter Conditional Expressions, Assignments and Equations. In certain circumstances it is an alternative to the dollar condition to restrict the domain of equations, sets, variables, parameters and indexed operations. We already saw an example for restricting the domain of definition of an equation in the previous subsection. The next example refers to restricting the domain in an indexed operation. In section Conditional Indexed Operations with Dynamic Sets we had the following assignment:

\[
\text{maxd} = \text{smax}((\text{i}, \text{j}) \cdot \$ \cdot \text{can_do(i), j}), \text{d(i, j)});
\]

Recall that \( \text{maxd} \) is a scalar, \( \text{i} \) and \( \text{j} \) are sets, \( \text{can_do} \) is a dynamic set and \( \text{d} \) is a two-dimensional parameter. Note that the conditional set is the dynamic set \( \text{can_do} \). The assignment may be rewritten in the following way:

\[
\text{maxd} = \text{smax}((\text{can_do(i, j)}), \text{d(i, j)}) ;
\]

Here the indexed operation is filtered through the dynamic set \( \text{can_do} \), a dollar condition is not necessary.
4.25 Sets as Sequences: Ordered Sets

4.25.1 Introduction

Sets are introduced in chapter Set Definition. There we state that in general, sets in GAMS are regarded as an unordered collection of labels. However, in some contexts, say, multi-period planning models, some sets need to be treated as if they were sequences. In this chapter we will establish the notion of ordered sets and we will cover their special features and the associated operations.

Examples where ordered sets are needed include economic models that explicitly represent conditions in different time periods that are linked, location problems where the formulation may require a representation of contiguous areas, as in a grid representation of a city, scheduling problems and programs that model stocks of capital with equations of the form \( \text{stocks at the end of period } n \text{ are equal to stocks at the end of period } n - 1 \text{ plus net gains during period } n \).

Note
Models involving sequences of time periods are often called dynamic models, because they describe how conditions change over time. This use of the word dynamic unfortunately has a different meaning from that used in connection with dynamic sets, but this is unavoidable.

4.25.2 Ordered and Unordered Sets

Certain one-dimensional sets may be treated as if they were a sequence. Those sets need to be ordered and static. A one-dimensional set is ordered if the definition or initialization of the elements in the set corresponds to the order of the labels in the GAMS Entry order.

Note
- The GAMS entry order is the order in which the individual labels first appear in the GAMS program, either explicitly or as a result of using the shorthand asterisk notation.
- For the sake of simplicity, sets that are static and ordered are often just referred to as ordered sets.

GAMS maintains a unique element list where all labels that are used as elements in one or more sets are listed. The order of the elements in any one set is the same as the order of those elements in the unique element list. This means that the order of a set may not be what it appears to be if some of the labels were used in an earlier definition. The internal GAMS order of the labels can be made visible with the dollar control option \$onUELlist. This directive generates a map that is shown in the compilation output of the listing file. For details on the listing file and GAMS output in general, see chapter GAMS Output. A good rule of thumb is that if the user wants a set to be ordered and the labels in the set have not been used already, then they will be ordered.

In the example below we show ordered and unordered sets and the map showing the order. The input is:

\[
\text{$onUELlist}
\]
Note that the label "1987" is the first label seen by GAMS. It appears again as the last label in the initialization list for the set t2. This means that the set t2 is not ordered and any attempt to use t2 in a context implying order, such as the operations introduced later in this chapter, will cause error messages. Observe that the set t3 is ordered, as all the members of t3 have appeared in the GAMS program before, and in the same order that they are listed in the definition of t3.

The unique element listing map below shows the entry order (the important one) and the sorted order, obtained by sorting the labels into dictionary order. The single digits on the left are the sequence numbers of the first label on that line.

<table>
<thead>
<tr>
<th>Entry Order</th>
<th>Sorted Order</th>
</tr>
</thead>
</table>

A set can always be made ordered by moving its declaration closer to the beginning of the program. With these restrictions in mind, we will continue in the next section with the operations that may be used with ordered sets.

**4.25.3 Sorting a Set**

Note that besides the entry order of unique elements there is also a sorted (alphabetical) order. To obtain the sorted order (of an ordered or unordered set) the special predefined two-dimensional set SortedUELs(∗,∗) can be used. Consider the following example where set j is reported in an alphabetically sorted format:

```gams
define set j / c, a, b, 1, 2, 11 /;
define display j;
alias(∗, u);
define file ordered /ordered.txt/;
define loop(SortedUEL(u, j), put ordered j.tl:0 ' ');
putclose ordered;
```

The output generated by the display statement follows:

```
-----          2 SET j
  c,  a,  b,  1,  2,  11
```

Note that, as expected, the display statement shows the elements of set j in the entry order not in alphabetical order. However, the elements are listed in alphabetical order in the file ordered.txt. Note furthermore, that alphabetical sorting leads to an order where e.g. 11 precedes 2.

```
1 11 2 a b c
```

In the example above u is aliased with the Universal Set. For an introduction to writing external files with put, see chapter The Put Writing Facility.
4.25.4 Ord and Card Operators

As stated in section Labels in chapter GAMS Programs, labels in GAMS do not have a numerical value. The examples used were that the label '1986' does not have a numerical value of 1986 and the label '01' is different from the label '1'. This section introduces two operators - ord and card - that return integer values when applied to sets. While the integer values returned do not represent the numerical value of the label, they can be used for the same purpose.

Note

GAMS provides some string manipulation capability by extending the card and ord operators to also work on strings.

4.25.4.1 The Ord Operator

The operator ord returns the relative position of a member in a set.

Attention

By default the operator ord may be used only with one-dimensional sets that are static and ordered.

Some examples show the usage.

Set t "time periods" / 1985*1995 / ;
Parameter val(t) ;
val(t) = ord(t);

Note that as a result of the statements above, the value of val('1985') will be 1, val('1986') will be 2 and so on.

A common use of ord is in setting up vectors that represent quantities growing in some analytically specified way. For example, suppose a country has 56 million people in the base period and the population is growing at the rate of 1.5 percent per year. Then the population in succeeding years can be calculated as follows:

population(t) = 56*(1.015**(ord(t) - 1)) ;

It is often useful to simulate general matrix operations in GAMS. The first index of a two dimensional parameter can conveniently represent the rows, the second the columns and order is necessary. The example below shows how to set the upper triangle of a matrix equal to the row index plus the column index, and the diagonal and lower triangle to zero.

Set i "row and column labels" / x1*x10 /;
alias (i,j);
Parameter a(i,j) "a general square matrix";
a(i,j) $(ord(i) < ord(j)) = ord(i) + ord(j);
Note that in the assignment statement the logical condition \((\text{ord}(i) < \text{ord}(j))\) restricts the assignment to the entries of the upper triangle. For more information on logical conditions and conditional assignments in GAMS, see sections Logical Conditions and Conditional Assignments respectively.

Note that the strict requirement that the set needs to be ordered for the operator \(\text{ord}\) to be used may be relaxed with a dollar control option called \text{offOrder}. Consider the following lines where we revisit the example from the previous section.

\[
\text{\$offOrder}
\]

\[
\]

\[
\]

\[
\text{Parameter p(t2);}\]

\[
\text{p(t2) = \text{ord}(t2);}\]

\[
\text{display p;}
\]

Note that, as we explained above, the set \(t2\) is not ordered. Therefore using \(\text{ord}(t2)\) somewhere in the model will usually cause the program to be terminated with an error message. However, with the dollar control option \text{offOrder} active, the set \(t2\) is treated as if it were ordered and the display statement will generate the following output:

\[
\begin{align*}
\text{---- 6 PARAMETER p} \\
\text{1987 1.000, 1983 2.000, 1984 3.000, 1985 4.000, 1986 5.000}
\end{align*}
\]

While this may be useful in some circumstances, the option comes with a price, since the system will not be able to diagnose odd and incorrect formulations and data sets. The strict requirement that the set needs to be ordered for the \(\text{ord}\) operator can be turned on again via \text{onOrder}.

### 4.25.4.2 The Card Operator

The operator \text{card} returns the number of elements in a set.

Note

The operator \text{card} may be used with any set: static and dynamic sets, ordered and unordered sets.

The following example illustrates its use:

\[
\text{Set \ t "time periods" / 1985*1995 /;}
\]

\[
\text{Scalar s;}
\]

\[
\text{s = \text{card}(t);}\]

\[
\text{Display s;}
\]

Note that \(s\) will be assigned the value 11 since the set \(t\) has 11 elements.

A common use of \text{card} is to specify some condition only for the final period, for example to fix a variable. Consider the following artificial example:

\[
\text{c.fx(t)$(\text{ord}(t) = \text{card}(t)) = \text{demand}(t);}\]

Note that the logical condition \((\text{ord}(t) = \text{card}(t))\) restricts the assignment to the last element of the set \(t\): no assignment is made for other members of \(t\). The advantage of this way of fixing the variable \(c\) is that the membership of \(t\) can be changed safely and this statement will always fix \(c\) for the last element. For more information on logical conditions and conditional assignments in GAMS, see sections Logical Conditions and Conditional Assignments respectively.

### 4.25.5 Lag and Lead Operators

Lag and lead operators are used to relate the \textit{current} member of an ordered set to the \textit{previous} or \textit{next} member of the set. GAMS provides two forms of lag and lead operators (linear and circular), they are summarized in Table 1. Note that in the table below \(t\) is a member of an ordered set and \(n\) is a positive integer.
Table 1: Linear and Circular Lag and Lead Operators

<table>
<thead>
<tr>
<th>Operation</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linear Lag</td>
<td>t - n</td>
<td>Refers to the element of the ordered set whose relative position in the set is ( \text{ord}(t) - n ).</td>
</tr>
<tr>
<td>Linear Lead</td>
<td>t + n</td>
<td>Refers to the element of the ordered set whose relative position in the set is ( \text{ord}(t) + n ).</td>
</tr>
<tr>
<td>Circular Lag</td>
<td>t -- n</td>
<td>Same as ( t - n ), only here the first element of the set is assumed to be preceded by the last element of the set, thus forming a circle of elements.</td>
</tr>
<tr>
<td>Circular Lead</td>
<td>t ++ n</td>
<td>Same as ( t + n ), only here the last element of the set is assumed to be followed by the first element of the set, thus forming a circle of elements.</td>
</tr>
</tbody>
</table>

Note that the only difference between linear and circular lag and lead operators is how endpoints are treated. Linear operators assume that there are no members preceding the first and following the last member of the ordered set. This assumption may result in elements of the set being referenced that actually do not exist. Therefore the user must think carefully about the treatment of endpoints: models with linear lag and lead operators will need special exception handling logic to deal with them. The next two sections will describe how this issue is handled in GAMS in the context in which these operators are typically used: assignments and equations. Linear lag and lead operators are useful for modeling time periods that do not repeat, like a set of years (say 1990 to 1997).

Circular lag and lead operators assume that the first and last members of the set are adjacent, so as to form a circular sequence of members. This means that \( \text{first}--1 \) is a reference to \( \text{last} \) and \( \text{last}++2 \) is the same as \( \text{first}++1 \). All references and assignments are defined. The assumption of circularity is useful for modeling time periods that repeat, such as months of the year or hours in the day. It is quite natural to think of January as the month following December. Agricultural farm budget models and workforce scheduling models are examples of applications where circular leads occur naturally.

Note

- GAMS is able to distinguish the linear lag and lead operators \('-\) and \('+\)' from arithmetic operators by context. To avoid ambiguity, GAMS does not allow to mix lag and lead operators with arithmetic operators. For example, \( i+1+1 \) is not allowed, but writing \( i+(1+1) \) would work.
- Observe that the lag (or lead) value \( n \) does not have to be an explicit constant: it can be an arbitrary expression, provided that it evaluates to an integer. If it does not, error messages will be produced. A negative result causes a switch in sense (from lag to lead, for example).

Note that if lag and lead operators are used with an unordered set, the program will terminate with an error message. The strict requirement that the set be ordered may be relaxed with the dollar control option \$offOrder. If the directive \$offOrder is added, in the lines that follow unordered sets are treated as if they were ordered and therefore lag and lead operators may be used with them. While this may be advantageous in some circumstances, the option comes with a price, since the system will not be able to diagnose odd and incorrect formulations and data sets. The strict requirement that the set needs to be ordered for the use of lag and lead operators can be turned on again via \$onOrder.

The next two subsections will give some illustrative examples on the use of lag and lead operators in assignment statements and in equations respectively.
4.25.5.1 Lags and Leads in Assignments

Lag and lead operators may be used in assignment statements. The use of a lag or lead operator on the right-hand side of an assignment is called a reference, while their use on the left-hand side is called an assignment and involves the definition of a domain of the assignment. The concepts behind reference and assignment are equally valid for the linear and circular forms of the lag and lead operators. However, the importance of the distinction between reference and assignment is not pronounced for circular lag and lead operators, because non-existent elements are not referred to in this case.

Note

A reference to a non-existent element causes the default value zero to be used, whereas an attempt to assign to a non-existent element results in no assignment being made.

We will first illustrate linear lag and lead operators for reference and assignment. Then we will turn to the circular form of the operators.

4.25.5.1.1 Linear Lag and Lead Operators in Assignments - Reference

Consider the following example, where the lag operator is used on the right-hand side of an assignment statement:

Set t "time sequence" / y-1987*y-1991 /;
Parameter a(t), b(t);
a(t) = 1986 + ord(t);
b(t) = -1;
b(t) = a(t-1);
option decimals = 0;
display a, b;

Note that the option statement suppresses the decimal places from the display statement.

---- 7 PARAMETER a
---- 7 PARAMETER b

Note that, as expected, the values for the parameter a are 1987, 1988 up to 1991 corresponding to the labels "y-1987", "y-1988" and so on. Observe that the parameter b is initialized to −1 so that the result of the next assignment can be seen clearly. Note that in the last assignment the lag operator '−' is used on the right-hand side, resulting in the values for b to equal the values for a from the previous period. If there is no previous period, as with the first element, "y-1987", the value zero is assigned, replacing the previous value of −1 (values of zero for parameters are not displayed).
4.25.5.1.2 Linear Lag and Lead Operators in Assignments - Assignment  Consider the following variation of the previous example. Here the lead operator is used on the left-hand side of an assignment statement:

Set t "time sequence" / y-1987*y-1991 / ;
Parameter a(t), c(t) ;
a(t) = 1986 + ord(t) ;
c(t) = -1;
c(t+2) = a(t) ;
option decimals = 0;
display a, c ;

Note that, as before, the option statement suppresses the decimal places from the display statement.

---- 7 PARAMETER a
---- 7 PARAMETER c

The assignment to a is explained in the previous subsection. Note that the parameter c is initialized to -1. The assignment to c involving the lead operator on the left-hand side needs special attention. It is best to spell out step by step how this assignment is made. For each member of t in sequence, find the member of c associated with t+2. If it exists, replace its value with the value of a(t). If not (as with labels "y-1990" and "y-1991") make no assignment. The first member of the set t is "y-1987", therefore the first assignment is made to c("y-1989") which takes the value of a("y-1987"), that is 1987. No assignments at all are made to c("y-1987") and c("y-1988"); these two retain their previous values of -1.

4.25.5.1.3 Circular Lag and Lead Operators in Assignments  The following example illustrates the use of circular lag and lead operators in assignment statements.

Set s "seasons" / spring, summer, autumn, winter /;
Parameter val(s) / spring 10, summer 15, autumn 12, winter 8 /
    lagval(s)
    leadval(s);
lagval(s) = -1 ;
lagval(s) = val(s--2) ;
leadval(s) = -1 ;
leadval(s++1) = val(s) ;
option decimals = 0;
display val, lagval, leadval;

Note that, as before, the option statement suppresses the decimal places from the display statement. The results are shown below.

----- 10 PARAMETER val
spring 10, summer 15, autumn 12, winter 8
----- 10 PARAMETER lagval

---
In the example parameter lagval is used for reference while leadval is used for assignment. Notice that the case of circular lag and lead operators does not refer to any non-existent elements. The difference between reference and assignment is therefore not important. Note that the following two statements from the example above,

\[
\begin{align*}
\text{lagval}(s) & = \text{val}(s--2) ; \\
\text{leadval}(s++1) & = \text{val}(s) ;
\end{align*}
\]

are equivalent to

\[
\begin{align*}
\text{lagval}(s++2) & = \text{val}(s) ; \\
\text{leadval}(s) & = \text{val}(s--1) ;
\end{align*}
\]

The use of reference and assignment have been reversed with no difference in effect.

### 4.25.5.2 Lags and Leads in Equations

The principles established in the previous section follow quite naturally into equation definitions. A lag or lead to the left of the ‘..’ symbol is a modification of the domain of definition of the equation. The linear form may cause one or more individual equations to be suppressed. A lag or lead operation in the body of an equation (to the right of the ‘..’ symbol) is a reference. If the associated label is not defined, the term vanishes.

Note

All lag and lead operands must be **exogenous**. For more information, see section **Functions in Equation Definitions**.

In the next two subsections we will provide examples illustrating the use of the linear form of the lag and lead operators in equations to modify the domain of definition and for reference respectively. In the last subsection we will turn to circular lag and lead operators in equations.

### 4.25.5.2.1 Linear Lag and Lead Operators in Equations - Domain Control

Consider the following simple artificial multi-period example. We specify a complete model and encourage users to solve it and further explore it.
Sets t / t1*t5 / tfirst(t);
Parameter i(t) / #t 1 /;
Scalar k0 / 3.00 /;

tfirst(t) = yes$(ord(t) = 1);

Variables k(t), z;
k.fx(tfirst) = k0;

Equations kk(t), dummy;
dummy.. z =e= 0;
kk(t+1).. k(t+1) =e= k(t) + i(t);

model m /all/;
option limrow = 10;
solve m using lp min z;

Note that the equation \(kk\) is declared over the set \(t\), but it is defined over the domain \((t+1)\). Therefore the first equation that will be generated is the following:

\[
k('t2') =e= k('t1') + i('t1');
\]

Note that the value of the variable \(k('t1')\) is fixed at the value of scalar \(k0\). Observe that for the last element of \(t\), the term \(k(t+1)\) is not defined and therefore the equation will not be generated. If lag or lead operators are used in the domain of definition of an equation, the equation listing can be a useful tool to verify whether the equations that have been generated are those that were intended:

\[
\begin{align*}
kk(t2) &.. - k(t1) + k(t2) =E= 1 ; (LHS = 0, INFES = 1 ****) \\
nk(t3) &.. - k(t2) + k(t3) =E= 1 ; (LHS = 0, INFES = 1 ****) \\
nk(t4) &.. - k(t3) + k(t4) =E= 1 ; (LHS = 0, INFES = 1 ****) \\
nk(t5) &.. - k(t4) + k(t5) =E= 1 ; (LHS = 0, INFES = 1 ****)
\end{align*}
\]

To summarize, the lead operator in the domain of definition has restricted the number of constraints generated so that there are no references to non-existent variables.

For a more realistic model that illustrates the usage of linear lag operators in equations, see for example the optimal economic growth model [RAMSEY].

### 4.25.5.2.2 Linear Lag and Lead Operators in Equations - Reference

In the previous subsection we showed how to write the equation \(kk\) using the lead operator for domain control in combination with fixing the variable \(k(tfirst)\) to \(k0\). An alternative formulation could neglect the fixing of \(k(tfirst)\) and use a lag operator and a dollar condition in the body of the equation while the domain of definition is unrestricted:

\[
kk(t). \ k(t) =e= k(t-1) + i(t-1) + k0$tfirst(t);
\]

Note that for the first element of the set \(t\) the terms \(k(t-1)\) and \(i(t-1)\) are not defined and therefore vanish. Without the conditional term, the resulting equation would be:

\[
k('t1') =e= 0;
\]

However, this would lead to different results as \(k('t1')\) would not be set to the value of \(k0\) anymore. Therefore the conditional expression \(k0$tfirst(t)\) is added. Observe that in this formulation equations are generated for all time periods, no equation is suppressed.

In general, the choice between using lag and lead operators as reference like in the last example or in domain control is often a matter of taste.
In the case of circular lag and lead operators, the difference between their use in domain control and as reference is not important because it does not lead to any equations or terms being suppressed. Consider the following artificial example.

```
Set s "seasons" / spring, summer, autumn, winter /;

Variable produ(s) "amount of goods produced in each season"
      avail(s) "amount of goods available in each season"
      sold(s) "amount of goods sold in each season";

Equation matbal(s);

matbal(s).. avail(s++) =e= avail(s) + produ(s) - sold(s);
```

In this example four individual equations are generated. They are listed below.

```
avail('summer') =e= avail('spring') + produ('spring') - sold('spring');
avail('autumn') =e= avail('summer') + produ('summer') - sold('summer');
avail('winter') =e= avail('autumn') + produ('autumn') - sold('autumn');
avail('spring') =e= avail('winter') + produ('winter') - sold('winter');
```

Note that for the last element of the set s the term avail(s++) is evaluated to avail('spring'). This term is well defined and therefore it does not vanish. Similarly, using the circular lead operator in the domain of definition like in the following line will result in the same four equations being generated as above and no equation being suppressed.

```
matbal(s++).. avail(s++) =e= avail(s) + produ(s) - sold(s);
```

4.25.6 Summary

This chapter introduced the concept of ordered sets. All the features in GAMS that dealt with this issue including the ord and card functions, as well as the linear and circular forms of the lag and lead operators were described in detail.

4.26 Data Manipulations with Parameters

4.26.1 Introduction

In this chapter we explicitly cover only parameter manipulation, including all aspects of data handling. Much of this material is relevant elsewhere (e.g., to sets), but for specifics related to assignment to sets, to conditions, and to assignments within flow control constructs such as the loop statement, see chapters Dynamic Sets, Conditional Expressions, Assignments and Equations and Programming Flow Control Features respectively.

Once initialized, data often requires manipulation in order to bring it into a form most suitable for use in a model or an application. The assignment statement is the way to do this. All the possible components of the assignment statement except conditions are introduced and discussed in this chapter.
4.26.2 The Assignment Statement

The assignment statement is the fundamental data manipulation statement in GAMS. It may be used to define or alter values associated with sets, parameters, variables or equations.

A simple assignment is written in the style associated with many other computer languages. GAMS uses the traditional symbols for addition (+), subtraction (-), multiplication (*) and division (/). We will use them in the examples that follow, and give more details in section Expressions.

4.26.2.1 Scalar Assignments

Consider the following artificial sequence:

```gams
scalar x / 1.5 /;
  x = 1.2;
  x = x + 2;
```

The scalar `x` is initialized to be 1.5. The second statement changes the value to 1.2, and the third changes it to 3.2. The second and third statements are assignments: each replaces the current value of `x` with a new one.

Note that the same symbol can be used on the left and right of the = sign. The new value is not available until the calculation is complete, and the operation gives the expected result.

Note

An assignment cannot start with a reserved word. A semicolon is therefore required as a delimiter before all assignments.

Note that extended range identifiers (e.g. `INF`) and acronyms may also be used in assignment statements. For specific details, see sections Extended Range Arithmetic and Acronym Usage respectively.

4.26.2.2 Indexed Assignments

The GAMS syntax for performing indexed assignments is extremely powerful. This operation offers what may be thought of as simultaneous or parallel assignments and provides a concise way of specifying large amounts of data. Consider the mathematical statement \( DJ_d = 2.75 \cdot DA_d \) for all elements of \( d \). This means that for every member of the set \( d \), a value is assigned to \( DJ \). This can be written in GAMS as follows:

```gams
dj(d) = 2.75*da(d) ;
```

This assignment is known technically as an indexed assignment and set \( d \) as the controlling index or controlling set.
Attention

The index set(s) on the left hand side of an indexed assignment are referred to synonymously as the controlling indices, controlling sets, or controlling domain of the assignment.

The extension to two or more controlling indices should be obvious. There will be an assignment made for each label combination that can be constructed using the indices inside the parentheses. Consider the following example of an assignment to all 100 data elements of the parameter a.

```
sets row / r-1*r-10 /
col / c-1*c-10 /
sro(row) / r-7*r-10 /;
parameters r(row) / r-1*r-7 4, r-8*r-10 5/
c(col) / c-1*c-5 3, c-6*c-10 2/;
parameters a(row,col);
a(row,col) = 13.2 + r(row)*c(col);
The calculation in the last statement is carried out for each of the 100 unique two-label combinations that can be formed from the elements of row and col. An explicit formulation of the first of these assignments follows:

a('r-1','c-1') = 13.2 + r('r-1')*c('c-1');
```

Note that for indexed assignments a copy of the symbols on the right hand side is installed before the assignment is carried out. That means it does not work "in-place" or recursively. Consider the following example where we compute the first ten Fibonacci numbers and store them in parameter f using a loop. The example also illustrates how such a recursive calculation does not work with a parallel assignment statement for parameter g.

```
set i / i1*i10 /
parameter
  f(i) / i1 1 /
g(i) / i1 1 /;
loop(i$(ord(i)>=2),
  f(i) = f(i-2) + f(i-1);
);
g(i)$$(ord(i)>=2) = g(i-2) + g(i-1)
display f,g;
The display statement results in the following output.

---- 9 PARAMETER f
  i1 1.000,   i2 1.000,   i3 2.000,   i4 3.000,   i5 5.000
  i6 8.000,   i7 13.000,  i8 21.000,  i9 34.000, i10 55.000

---- 9 PARAMETER g
  i1 1.000,   i2 1.000,   i3 1.000
```
4.26.2.3 Restricting the Domain in Assignments

Sometimes it is necessary to make assignments over selected elements of a set instead of over the entire domain. There are several ways to accomplish this: using explicit labels, subsets, conditionals and tuples.

4.26.2.3.1 Restricting the Domain: Explicit Labels  The strongest restriction of the domain is assigning a value to just one element. Labels may be used explicitly in the context of assignments to accomplish this. The following example illustrates:

\[ a(’r-7’,’c-4’) = -2.36; \]

This statement assigns a constant value to just one element of the parameter \( a \). All other elements of \( a \) remain unchanged. Labels must be quoted when used in this way.

4.26.2.3.2 Restricting the Domain: Subsets  In general, wherever a set name may occur in an indexed assignment, a subset may be used instead.

Consider the following example:

\[ a(sro,’col-10’) = 2.44 -33*r(sro); \]

Since the set \( sro \) was declared as a subset of the set \( row \), we can use \( sro \) as a controlling index in the assignment above to make the assignment only for the elements of \( sro \).

4.26.2.3.3 Restricting the Domain: Conditionals  Conditional assignments are discussed in detail in section Conditional Assignments in chapter Conditional Expressions, Assignments and Equations. For details on the types of logical conditions, see section Logical Conditions. Here we present a simple example to illustrate:

\[ a(row,col)$[a(row,col) >= 100] = INF; \]

This assignment has the following effect: all elements of the parameter \( a \) whose value was at least 100 are assigned the value INF, while all other elements of \( a \) remain unchanged.

4.26.2.3.4 Restricting the Domain: Tuples  Tuples or multi-dimensional sets are introduced in section Many-to-Many Mapping. In this simple example we show how they may be used to restrict the domain. The example builds on the first example in this section. We repeat the whole code here for clarity.

```
sets row / r-1*r-10 /
col / c-1*c-10 /
sro(row) / r-7*r-10 /
set tuple(row,col) /r-1.c-1, r-1.c-10, r-10.c-1, r-10.c-10/;
parameters r(row) /r-1*r-7 4, r-8*r-10 5/
c(col) /c-1*c-5 3, c-6*c-10 2/;
parameters a(row,col), b(row,row);
a(row,col) = 13.2 + r(row)*c(col); 
a(tuple(row,col)) = 7 + r(row)*c(col); 
a(tuple) = 0.25 * a(tuple); 
```

Note that we have introduced the new set \( tuple \). It is two-dimensional and contains just four elements. As before, the parameter \( a \) is first assigned values for all its 100 elements. We then change some of these values using the set \( tuple \) as domain. The values of the elements of the parameter \( a \) that are not elements of the set \( tuple \) remain unchanged.

For a more elaborate example involving tuples, see section Filtering Sets in Assignments.
4.26 Data Manipulations with Parameters

4.26.2.4 Issues with Controlling Indices

Attention

The number of controlling indices on the left of the = sign should be at least as large as the number of indices on the right. There should be no index on the right-hand side of the assignment that is not present on the left unless it is operated on by an indexed operator. For more on indexed operators, see section Indexed Operations.

Consider the following statement:

\[ a(\text{row},'\text{col-2}') = 22 - c(\text{col}) ; \]

GAMS will flag this statement as an error since \text{col} is an index on the right-hand side of the equation but not on the left.

Note that there would be no error here if \text{col} were a singleton set. Since there is only one element in a singleton set, the intent and behavior is well-defined even when \text{col} is not under control.

Attention

Each set is counted only once to determine the number of controlling indices. If the intent is for a set to appear independently more than once within the controlling domain, the second and subsequent occurrences of the set should be aliases of the original set, so that the number of controlling indices is equal to the number of indices. For details on aliases, see section The Alias Statement: Multiple Names for a Set.

Consider the following statement as an illustration:

\[ b(\text{row},\text{row}) = 7.7 - r(\text{row}) ; \]

This statement has only one controlling index, namely \text{row}. One element (on the diagonal of \text{b}) is assigned for each element of \text{row}, for a total of 10 assigned values. None of the off-diagonal elements of \text{b} will be changed!

If the intent is to assign values to each element of \text{b}, this can be done by introducing an alias \text{rowp} for \text{row} and using this alias in the second index position. There will then be two controlling indices and GAMS will make assignments over all 100 values of the full Cartesian product. The following example illustrates this method:

\[ \text{alias}(\text{row},\text{rowp}) ; \]
\[ b(\text{row},\text{rowp}) = 7.7 - (r(\text{row}) + r(\text{rowp}))/2 ; \]

4.26.3 Expressions

An expression is an arbitrarily complicated specification for a calculation, with parentheses nested as needed for clarity and intent. In this section the discussion of parameter assignments will continue by showing in more detail the expressions that may be used on the right of the = sign. We will cover standard arithmetic operations and indexed operations here, and functions and extended range arithmetic in the next two sections.

4.26.3.1 Standard Arithmetic Operations

The standard arithmetic symbols and operations and their order of precedence are given in Table 1. Note that 1 denotes the highest order of precedence and 3 denotes the lowest order of precedence. Parentheses can be used to override the default precedence order in the usual way. Operators (including exponentiation) on the same level are evaluated from left to right.
Table 1: Standard Arithmetic Operations

Note that the full GAMS operator precedence hierarchy also includes logical operators; it is given in section Mixed Logical Conditions. Note further that the symbols for addition, subtraction and multiplication have a different meaning if they are used in the context of sets. For details see sections Set Operations and Lag and Lead Operators.

Attention

The operation \( x^{**}y \) is equivalent to the function \( rPower(x,y) \) and is calculated internally as \( e^{y \times \log(x)} \). This operation is not defined if \( x \) is negative; an error will result in this case. If the possibility of negative values for \( x \) is to be admitted and the exponent is known to be an integer, then the function \( power(x,n) \) may be used.

Like many GAMS intrinsic functions, the operation \( x^{**}y \) is not defined for all possible input values. When evaluating nonlinear functions and operators GAMS guards against evaluating at or very near singular points and in such cases signals an error or returns an appropriate function value.

Note

As usual, operations within parentheses or brackets are evaluated before other numerical calculations, where the innermost parentheses are resolved first. Any of the pairs ( ), [ ] and { } are allowed.

Consider for example:

\[ x = 5 + 4*3^{**}2; \]

For clarity, this could have been written as follows:

\[ x = 5 + (4*3^{**}2) ; \]

In both cases the result is 41.

Note

It is often better to use parentheses than to rely on the order of precedence of operators, since this prevents errors and clarifies intentions.

Note that expressions may be freely continued over many lines: an end of line is permissible at any point where a blank may be used. Blanks may be used for readability around identifiers, parentheses and operation symbols. Blanks are not allowed within identifiers or numbers, and are significant inside the quotes used to delimit labels.

4.26.3.2 Indexed Operations

In addition to the simple operations in Table 1, GAMS also provides the following six indexed operations.
Table 2: Indexed Operations

These six operations are performed over one or more controlling indices. The syntax in GAMS for these operations is:

\[ \text{indexed_op( (index_list), expression);} \]

Indexed_op is one of the four keywords for indexed operations, index_list is the list of the controlling indices and expression is the expression to be evaluated. If there is only one controlling index, the parentheses around it may be removed. Consider the following simple example adapted from [ANDEAN]:

```
sets i plants / cartagena, callao, moron /
    m product / nitr-acid, sulf-acid, amm-sulf /;
parameter capacity(i,m) capacity in tons per day
    totcap(m) total capacity by process ;

totcap(m) = sum(i, capacity(i,m));
```

The index over which the summation is done, i, is separated from the reserved word `sum` by a left parenthesis and from the data term `capacity(i,m)` by a comma. The set `i` is called the controlling index for this operation. The scope of the control is the pair of parentheses `()` that start immediately after the sum. Note that using normal mathematical representation the last line could be written as: \( \text{totC}_m = \sum_i \text{C}_{im} \).

It is also possible to sum simultaneously over the domain of two or more sets as in the first assignment that follows. The second assignment demonstrates the use of a less trivial expression than an identifier within the indexed operation.

```
count = sum((i,j), a(i,j)) ;
emp = sum(t, l(t)*m(t)) ;
```

The equivalent mathematical forms are:

\[ \text{count} = \sum_i \sum_j A_{ij} \quad \text{and} \quad \text{emp} = \sum_t L_t M_t. \]

Note that the following alternative notation may be used for the first assignment above:
count = sum(i, sum(j, a(i,j)));

In the context of sets the sum operator may be used to compute the number of elements in a set and for projections. For details see section Projection and Aggregation of Sets.

The smin and smax operations are used to find the largest and smallest values over the domain of the index set or sets. The index for the smin and smax operators is specified in the same manner as in the index for the sum operator. In the following example we want to find the largest capacity:

\[ lrgunit = \text{smax}((i,m), \text{capacity}(i,m)) \]

Attention

The indexed operations smin and smax may be used in equation definitions only if the corresponding model is of type DNLP. For more on GAMS model types, see GAMS Model Types.

Note

- In the context of assignment statements, the attributes of variables and equations (e.g. \text{x.up}(i,j)) may be used in indexed operations just as scalars and parameters are used. For more on variable and equations attributes, see sections Variable Attributes and Equation Attributes respectively.
- In the context of equation definitions, scalars, parameters and variables may appear freely in indexed operations. For more on equation definitions, see section Defining Equations.

Sometimes it is necessary to restrict the domain of indexed operations. This may be done with the same techniques as in indexed assignments, see section Restricting the Domain in Assignments for details. See also section Conditional Indexed Operations for more details on conditions in the context of indexed operations.

We now turn to two additional capabilities that are available in GAMS to add power and flexibility to expression calculations: functions and extended range arithmetic.

### 4.26.4 Functions

Functions play an important role in the GAMS language, especially for nonlinear models. Like other programming languages, GAMS provides a number of built-in or intrinsic functions. GAMS is used in an extremely diverse set of application areas and this creates frequent requests for the addition of new and quite sophisticated or specialized functions. There is a trade-off between satisfying these requests and avoiding a complexity not needed by most users. The GAMS Function Library Facility provides the means for managing this trade-off, see subsection Extrinsic Functions below.
4.26.4 Intrinsic Functions

GAMS provides many functions, ranging from commonly used standard functions like exponentiation, logarithms, and trigonometric functions to utility functions for controlling and querying the running GAMS job or process. The complete list of available functions is given in the following tables: Mathematical Functions, String Manipulation Functions, Logical Functions, Time and Calendar Functions, and GAMS Utility and Performance Functions. For details specific to using these functions in equations, see the section on Expressions in Equation Definitions.

Some of the tables that follow contain an endogenous classification column "End. Classif." that specifies in which models the function may legally appear. In order of least to most restrictive, the choices are DNLP, NLP, any, none. See section Classification of Models for details on model types in GAMS. Note well: functions classified as any are only permitted with exogenous (constant) arguments.

Functions are typically used in assignment statements and equations. In these cases, they are only evaluated at execution time. Some functions can also be used at compile time, e.g. to compute the factorial or square root of a scalar. Some of the tables below contain a column "Compile Time" indicating which functions can be used at compile time.

A word on the notation in the tables below: for function arguments, lower case indicates that an endogenous variable is allowed. For details on endogenous variables, see section Functions in Equation Definitions. Upper case function arguments indicate that a constant is required. Arguments in square brackets may be omitted: the default values used in such cases are specified in the function description provided.

4.26.4.1.1 Mathematical Functions Mathematical functions may be used as expressions in assignment statements and in equation definitions. We start with some simple examples to illustrate. A list with all mathematical functions available in GAMS is given in Table 3.

Exp(x)

\[ a = \exp(t); \]
\[ b = \exp(t+2); \]

The GAMS function \( \exp(x) \) returns the exponential \( e^x \) of its argument. The assignments above set \( a = e^t \) and \( b = e^{t+2} \) respectively.

Log(x)

\[ z(j) = \log(y(j)); \]

The GAMS function \( \log(x) \) returns the natural logarithm of its argument. The assignment above evaluates the logarithm once for each element of the controlling domain \( j \).

Max(x1,x2,x3,...)

\[ x = \max(y+2, t, t\cdot t); \]

The function \( \max \) returns the maximum of a set of expressions or terms. In the assignment above, \( x \) will be assigned the maximum of \( y + 2, t, \) and \( t \cdot t \).

Round(x[,DECPL])

The function \( \text{round} \) rounds its argument \( x \) to the specified number \( \text{DECPL} \) of places, where positive values of \( \text{DECPL} \) indicating rounding to the right of the decimal point. If the argument \( \text{DECPL} \) is not specified, it defaults to zero, and the function rounds its argument to the nearest integer value. For example,
In the first assignment \( q \) is rounded to the nearest integer value, while in the second \( q \) is rounded to the number of decimals specified by \( d \). The result of the third assignment is 12.43, while the final assignment results in a value of 520.

\begin{align*}
\frac{1}{x} & \quad \text{if } x \geq S \\
\frac{1}{S} - \frac{x-S}{S^2} + \frac{(x-S)^2}{S^3} & \quad \text{otherwise}
\end{align*}
\] where \( S \geq 10^{-10} \), default \( S = 10^{-10} \). | NLP | no
sqrt(x) | Square root of \( x \), see MathWorld | NLP | yes
tan(x) | Tangent of the argument \( x \), where \( x \) must be in radians, see MathWorld | NLP | yes
tanh(x) | Hyperbolic tangent of \( x \), where \( x \) must be in radians, see MathWorld | NLP | no
trunc(x) | Truncation: returns the integer part of \( x \), truncating towards zero. | DNLP | yes
uniform(LOW,HIGH) | Generates a random number from the uniform distribution between \( LOW \) and \( HIGH \), see MathWorld | none | no
uniformInt(LOW,HIGH) | Generates an integer random number from the discrete uniform distribution whose outcomes are the integers between \( LOW \) and \( HIGH \), inclusive, see MathWorld | none | no
vcPower(x,Y) | Returns \( x^Y \) for \( x \geq 0 \). | NLP | no

### 4.26.4.1.2 String Manipulation Functions
GAMS provides some string manipulation capability by extending the `card` and `ord` functions to work on strings as well as sets. In Table 4 the extended behavior is described. In this context, the functions take strings and places as arguments, and the numeric places argument must be a constant. This behavior only applies to execution-time usage of these functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>card(STRING)</strong></td>
<td>Returns the number of characters in the string.</td>
</tr>
<tr>
<td><strong>ord(STRING[,PLACE])</strong></td>
<td>Returns the ASCII code number of a character in a position in a string. The optional place entry defaults to 1 if omitted and identifies the character position within the string to be examined (1 for the first, 2 for the second, etc.).</td>
</tr>
</tbody>
</table>

There are four types or sources of strings in this context. A string may be a string literal, i.e. a concatenation of letters and blanks as in "drink it" in the example that follows. It may be the symbol text (aka the explanatory text) associated with any symbol. Or it may be the labels or text associated with the elements of a set. The following table gives an overview:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>card(STRING)</strong></td>
<td>Returns the number of characters in the string.</td>
</tr>
<tr>
<td><strong>ord(STRING[,PLACE])</strong></td>
<td>Returns the ASCII code number of a character in a position in a string. The optional place entry defaults to 1 if omitted and identifies the character position within the string to be examined (1 for the first, 2 for the second, etc.).</td>
</tr>
</tbody>
</table>
4.26 Data Manipulations with Parameters

<table>
<thead>
<tr>
<th>Notation</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>characters</td>
<td>A concatenation of characters and blanks: all legal GAMS characters are</td>
<td>The characters must be surrounded by double or single quotes.</td>
</tr>
<tr>
<td></td>
<td>allowed, see section Characters for details.</td>
<td></td>
</tr>
<tr>
<td>symbol_name.ts</td>
<td>The string is the explanatory text associated with a symbol name.</td>
<td>If the explanatory text is missing, the value of card is 0.</td>
</tr>
<tr>
<td>set_name.tl</td>
<td>The string is the label for a set element.</td>
<td>This string type may be used only when set_name is part of the controlling</td>
</tr>
<tr>
<td></td>
<td></td>
<td>domain.</td>
</tr>
<tr>
<td>set_name.te</td>
<td>The string is the explanatory text associated with a set element.</td>
<td>This string type may be used only when set_name is part of the controlling</td>
</tr>
<tr>
<td></td>
<td></td>
<td>domain. If the explanatory text is missing, the value of card is 0.</td>
</tr>
</tbody>
</table>

The string types are illustrated in the following example. Note that the directive in the first line activates the end-of-line comment option, see eolCom.

```
$oneolcom
variable z 'any symbol can have explanatory text';
set teas "teas available to order" / black "English Breakfast", green, peppermint /;
scalar p;
  p = card("drink it"); !! result: p=8
  p = card(z.ts);     !! result: p=36
  p = card(teas.ts);  !! result: p=23
loop{teas,
  p = card(teas.tl)   !! length of set element label from the set "teas" : "teas" is the controlling set
  display "length of set element label", p;
  p = card(teas.te)   !! length of set element explanatory text: "teas" is the controlling set
  display "length of set element explanatory text", p;
};
```

Note that the strings teas.tl and teas.te are used in the context of a loop statement (see section The Loop Statement). This is a typical usage pattern.

4.26.4.1.3 Logical Functions Logical functions may be used as expressions in assignment statements as in the following example.

```
x = ifthen(tt=2, 3, 4+y);
```

Here \( x = 3 \) if \( tt = 2 \), otherwise \( x = 4 + y \).

The logical functions available in GAMS are given in Table 6. Note that logical functions may also be used in conditions and logic equations, see sections Logical Conditions and Logic Equations respectively. Most of the logical functions can also be indicated using the familiar operator notation, e.g. \((x \text{ and } y), (x \geq y), \text{ etc.}\). In such cases, the operator notation is allowed at compile time. The last column in Table 6 indicates if a logical function can be used at compile time (yes) or if only its alternative notation is available (alt). Further, note that the inputs and outputs of these functions are often logical/Boolean values, so GAMS does implicit conversions as necessary. As expected, false becomes 0 and true becomes 1 when converting logical values to numeric, and 0 becomes false and nonzero becomes true when numeric values are converted to logicals. For details on behavior when the inputs are special values, see sections Extended Range Arithmetic and Acronym Usage, but note that EPS, +INF, -INF, and acronyms become true when converted to logicals.

**Table 6: Logical Functions**
<table>
<thead>
<tr>
<th>Function</th>

<td>Returns true iff ( x \neq y )</td>
<td>DNLP</td>
<td>alt</td>
</tr>
</tbody>
</table>

4.26.4.1.4 Time and Calendar Functions GAMS offers several functions that relate to time and dates. The fundamental measurement of time in GAMS is the serial day number beginning with January 1, 1900. This serial day number is a real number whose integer part contains a unique number for each day and whose fractional part contains information about hours, minutes, and seconds. We can think of the serial day number as being a date.time pair. The day information extracted from serial day numbers is based on the Gregorian calendar.

Note

In all functions given in Table 7, serial day 1 is January 1, 1900.

All of the functions in Table 7 can be used at compile time.

Table 7: Time and Calendar Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
</tr>
</thead>
<tbody>
<tr>
<td>gday(SDAY)</td>
<td>Returns Gregorian day from a serial day number date.time.</td>
<td>any</td>
</tr>
<tr>
<td>gdow(SDAY)</td>
<td>Returns Gregorian day of week from a serial day number date.time.</td>
<td>any</td>
</tr>
<tr>
<td>ghour(SDAY)</td>
<td>Returns Gregorian hour of day from a serial day number date.time.</td>
<td>any</td>
</tr>
<tr>
<td>gleap(SDAY)</td>
<td>Returns 1 if the year that corresponds to a serial day number date.time, is a leap year, else returns 0.</td>
<td>any</td>
</tr>
<tr>
<td>gmillisec(SDAY)</td>
<td>Returns Gregorian milli second from a serial day number date.time.</td>
<td>any</td>
</tr>
<tr>
<td>gminute(SDAY)</td>
<td>Returns Gregorian minute of hour from a serial day number date.time.</td>
<td>any</td>
</tr>
<tr>
<td>gmonth(SDAY)</td>
<td>Returns Gregorian month from a serial day number date.time.</td>
<td>any</td>
</tr>
<tr>
<td>gsecond(SDAY)</td>
<td>Returns Gregorian second of minute from a serial day number date.time.</td>
<td>any</td>
</tr>
<tr>
<td>gyear(SDAY)</td>
<td>Returns Gregorian year from a serial day number date.time.</td>
<td>any</td>
</tr>
<tr>
<td>jdate(YEAR,MONTH,DAY)</td>
<td>Returns a serial day number.</td>
<td>any</td>
</tr>
<tr>
<td>jnow</td>
<td>Returns the current time as a serial day number.</td>
<td>none</td>
</tr>
<tr>
<td>jstart</td>
<td>Returns the time of the start of the GAMS job as a serial day number.</td>
<td>none</td>
</tr>
<tr>
<td>jtime(HOUR,MIN,SEC)</td>
<td>Returns fraction of a day that corresponds to hour, minute and second.</td>
<td>any</td>
</tr>
</tbody>
</table>

4.26.4.1.5 GAMS Utility and Performance Functions GAMS provides several functions that may be used to get (and in some cases set) GAMS system information, for example:

```
scalar o;
```
```
o = heapLimit;
heapLimit = 1024;
```

### Table 8: GAMS Utility and Performance Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
<th>Compile Time</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>embeddedHandle</code></td>
<td>Returns the handle for the last embedded code section executed, see section Syntax in chapter Embedded Code Facility for details.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td><code>errorLevel</code></td>
<td>Return code of the most recently used command.</td>
<td>none</td>
<td>yes</td>
</tr>
<tr>
<td><code>execError</code></td>
<td>Get or set the number of execution errors.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td><code>gamsRelease</code></td>
<td>Returns the release number of the running GAMS system, for example 24.7.</td>
<td>none</td>
<td>yes</td>
</tr>
<tr>
<td><code>gamsVersion</code></td>
<td>Returns the version number of the running GAMS system, for example 247.</td>
<td>none</td>
<td>yes</td>
</tr>
<tr>
<td><code>handleCollect</code></td>
<td>Tests if the solve of the model instance identified by the calling argument HANDLE is done: if so, it loads the solution into GAMS. For details, see Table 1 in section Grid Computing.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td><code>handleDelete</code></td>
<td>Deletes the model instance identified by HANDLE. For details, see Table 1 in section Grid Computing.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td><code>handleStatus</code></td>
<td>Tests if the solve of the model instance identified by HANDLE is done: if so, it loads the solution into a GDX file. For details, see Table 1 in section Grid Computing.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td><code>handleSubmit</code></td>
<td>Resubmits the model instance identified by HANDLE for solution. For details, see Table 1 in section Grid Computing.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td><code>heapFree</code></td>
<td>Get the amount of free memory in the heap in MB, i.e. memory allocated to the process and available for future use by GAMS.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td><code>heapLimit</code></td>
<td>Get or set the current heap limit (maximum allowable dynamic memory usage) in Mb.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td><code>heapSize</code></td>
<td>Get the current heap size in Mb.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td><code>jobHandle</code></td>
<td>Returns the process ID (PID) of the last job started.</td>
<td>none</td>
<td>yes</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>End. Classif.</td>
<td>Compile Time</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------------</td>
<td>--------------</td>
</tr>
<tr>
<td>jobKill(PID)</td>
<td>Sends a kill signal to the job with process ID PID. The return value is 1 if this was successful, 0 otherwise.</td>
<td>none</td>
<td>yes</td>
</tr>
<tr>
<td>jobStatus(PID)</td>
<td>Get the status of the job with process ID PID. Possible return values are: 0: error (input is not a valid PID or access is denied) 1: process is still running 2: process is finished with return code which could be accessed by errorlevel 3: process not running anymore or was never running, no return code available</td>
<td>none</td>
<td>yes</td>
</tr>
<tr>
<td>jobTerminate(PID)</td>
<td>Sends an interrupt signal to the job with process ID PID. The return value is 1 if this was successful, 0 otherwise.</td>
<td>none</td>
<td>yes</td>
</tr>
<tr>
<td>licenseLevel</td>
<td>Get an indicator for the type of license: 0: demo license, limited to small models 1: full unlimited developer license 2: run time license, no new variables or equations can be introduced besides those inherited from a work file 3: application license, only works with a specific work file which is locked to the license file 5: community license, limited to somewhat bigger models compared to demo license.</td>
<td>any</td>
<td>no</td>
</tr>
<tr>
<td>licenseStatus</td>
<td>Returns non-zero if a license error has occurred.</td>
<td>any</td>
<td>no</td>
</tr>
<tr>
<td>mapVal(x)</td>
<td>Returns an integer value that indicates what special value (if any) is stored in the input x. Possible results: 0: x is not a special value 4: x is UNDF (undefined) 5: x is NA (not available) 6: x is INF (∞) 7: x is -INF (-∞) 8: x is EPS &gt;8: x is an acronym</td>
<td>any</td>
<td>no</td>
</tr>
<tr>
<td>maxExecError</td>
<td>Get or set the maximum number of execution errors. See also maxExecError.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td>numCores</td>
<td>Get the number of logical CPU cores in the system</td>
<td>any</td>
<td>yes</td>
</tr>
</tbody>
</table>
### 4.26.4.2 Extrinsic Functions

Using the GAMS Function Library Facility, functions may be imported from an external library into a GAMS model. Apart from the import syntax, the imported functions may be used in the same way as intrinsic functions. In particular, they may be used in equation definitions. Some function libraries are included with the standard GAMS software distribution, but GAMS users can also create their own libraries using an open programming interface. The GAMS Test Library instances [TRILIB01], [TRILIB02], [TRILIB03], and [CPPLIB00] are simple examples (in the programming languages C, Delphi, Fortran and C++, respectively) that come with every GAMS system.

For details on using and creating extrinsic function libraries, and on the extrinsic function libraries that are provided with GAMS, see the chapter on Extrinsic Functions.

### 4.26.4.3 Function Suffixes

Up to this point, this section has described and discussed functions without mentioning their derivatives. These derivatives are very important, though: most of the nonlinear solvers integrated with GAMS will require first derivatives to solve models, and many will also use or require second derivatives as well. It is sometimes useful (e.g. when testing an extrinsic function) to evaluate the derivatives of GAMS functions instead of the functions themselves. This can be done via function suffixes.

Function suffixes can specify the evaluation of a gradient (i.e. first derivative), a Hessian (i.e. second derivative), a minimum or maximum value of the function over a given range, or the minimum or maximum value of the gradient over a given range. A full list of function suffixes is given in Table 9. For functions whose arguments are constant, the derivatives are zero, so typically `func` is a mathematical function listed in Table 3 above. Note that function suffixes are not defined for functions without arguments (for example, `pi`), so specifying something like `pi.grad` results in a compilation error.

#### Table 9: Function Suffixes

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>End. Classif.</th>
<th>Compile Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>platformCode</td>
<td>Returns an integer indicating the current platform. Possible return values can be seen here.</td>
<td>any</td>
<td>yes</td>
</tr>
<tr>
<td>readyCollect(HANDLES[,MAXWAIT])</td>
<td>Waits until a model solution is ready to be collected. For details, see Table 1 in section Grid Computing.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td>sleep(SEC)</td>
<td>Pause or sleep execution for SEC seconds.</td>
<td>none</td>
<td>yes</td>
</tr>
<tr>
<td>timeClose</td>
<td>Returns the accumulated closedown time, i.e. the time GAMS uses to save its state to disk prior to a solve.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td>timeComp</td>
<td>Returns the compilation time in seconds.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td>timeElapsed</td>
<td>Returns the elapsed time since the start of a GAMS run in seconds.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td>timeExec</td>
<td>Returns the execution time in seconds.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td>timeStart</td>
<td>Returns the accumulated startup time, i.e. the time GAMS uses to restore its state from disk after a solve.</td>
<td>none</td>
<td>no</td>
</tr>
<tr>
<td>Function Suffix</td>
<td>Description</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>func.value(x)</code></td>
<td>Value of the function <code>func</code> at <code>x</code>, equals <code>func(x)</code>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>func.grad(x)</code></td>
<td>Value of the gradient of the function <code>func</code> at <code>x</code>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>func.gradn(x)</code></td>
<td>Value of the gradient of the function <code>func</code> at <code>x</code>, computed numerically.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>func.hess(x)</code></td>
<td>Value of the Hessian of the function <code>func</code> at <code>x</code>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>func.hessn(x)</code></td>
<td>Value of the Hessian of the function <code>func</code> at <code>x</code>, computed numerically.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>func.low(x1:x2)</code></td>
<td>Lower bound of the function <code>func(x)</code> on the interval <code>[x1,x2]</code>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>func.high(x1:x2)</code></td>
<td>Upper bound of the function <code>func(x)</code> on the interval <code>[x1,x2]</code>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>func.gradL(x1:x2)</code></td>
<td>Lower bound of the gradient of the function <code>func(x)</code> on the interval <code>[x1,x2]</code>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>func.gradH(x1:x2)</code></td>
<td>Upper bound of the gradient of the function <code>func(x)</code> on the interval <code>[x1,x2]</code>.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Consider the following simple example:

```plaintext
scalars g, l, h, gl, gh;

  g = sin.grad(0);
  l = sin.low(pi/3:pi/2);
  h = sin.high(pi/3:pi/2);
  gl = sin.gradL(pi/3:pi/2);
  gh = sin.gradH(pi/3:pi/2);

display g, l, h, gl, gh;
```

For univariate functions like sine or cosine, there is no need to specify a variable index when evaluating derivatives. For multivariate functions, the default is to take partial derivatives w.r.t. the first variable. To specify other variables, the colon syntax in the example below is used.

```plaintext
scalars
  x / 1 /
  ylo / -1 /
  yup / 2 /
  e0, e1, elo, ehi
  e_1, e_2
  e_11, e_22, e_21
;

  e0 = edist(x,ylo);
  e1 = edist(x,yup);
  elo = edist.low (x,ylo:x,yup);
  ehi = edist.high(x,ylo:x,yup);

  e_1 = edist.grad(x,yup);
  * e_1 = edist.grad(1:x,yup); same as above
  e_2 = edist.grad(2:x,yup);

  e_11 = edist.hess(x,yup);
  * e_11 = edist.hess(1:1:x,yup); same as above
  e_22 = edist.hess(2:2:x,yup);
  e_21 = edist.hess(2:1:x,yup);

display x, ylo, yup, e0, e1, elo, ehi, e_1, e_2, e_11, e_22, e_21;
```
For more examples, see model \([\text{FUNCS4}]\) in the GAMS Test Library.

**Note**

- The function suffixes **value**, **grad**, **gradn**, **hess** and **hessn** are also defined for extrinsic functions. When implementing an extrinsic function, be aware that missing derivatives will be computed numerically: see model \([\text{TRILIB01}]\) for an example.

To compute derivatives numerically, GAMS uses finite difference approximations. This computation can be controlled with two options: the **FDOpt** option controls which variant of the finite difference method is used, while the **FDDelta** option controls the step size.

### 4.26.5 Extended Range Arithmetic and Error Handling

GAMS uses an *extended range* arithmetic to handle missing data, the results of undefined operations, infinite values, and zeros that are stored explicitly. The *special values* used in this arithmetic are listed and described in Table 10 below, along with the value of the **mapVal** function that corresponds to these values. We can think of special values as any value for which **mapVal** does not return 0.

<table>
<thead>
<tr>
<th>Special value</th>
<th>Description</th>
<th>mapVal</th>
</tr>
</thead>
<tbody>
<tr>
<td>INF</td>
<td>Plus infinity. Similar to IEEE plus infinity. Behaves in the expected way in computations, so that e.g. min(x,INF) = x unless x is also special.</td>
<td>6</td>
</tr>
<tr>
<td>-INF</td>
<td>Minus infinity. Similar to IEEE minus infinity. Behaves in the expected way in computations, so that e.g. max(x,INF) = x unless x is also special.</td>
<td>7</td>
</tr>
<tr>
<td>NA</td>
<td>Not available - used to indicate missing data. It is a sticky value: e.g. max(x,NA) = NA even for x = INF</td>
<td>5</td>
</tr>
<tr>
<td>UNDF</td>
<td>Undefined - indicates the result of an undefined or illegal operation. Similar to IEEE NaN. A user cannot directly set a value to UNDF unless the dollar control option onUNDF is active. For details, see the chapter on Dollar Control Options.</td>
<td>4</td>
</tr>
<tr>
<td>EPS</td>
<td>A stored zero value. If the dollar control option onEPS is active, zeros in a parameter or table statement are treated as EPS. For details on dollar control options, see chapter Dollar Control Options.</td>
<td>8</td>
</tr>
</tbody>
</table>

**Table 10:** Special Values for Extended Range Arithmetic

**Attention**

Avoid creating or using numbers with very large (1.0e299 or above) or very small (1.0e-299 or below) magnitudes. Large numbers may be treated by GAMS as undefined (UNDF) or other special values, leading to unpredictable and unusable results. Always use INF (or -INF) explicitly for arbitrarily large (or small) numbers.

GAMS has defined the results of all arithmetic operations and all function evaluations that use these special values. The behavior is designed to both maximize utility and minimize surprise, and is illustrated in the library model \([\text{CRAZY}]\). For example: 1+INF evaluates to INF, 1-EPS to 1, NA * 2 to NA, and EPS+INF to UNDF.

The following table shows a selection of results for exponentiation and division for a variety of input parameters including NA and INF.
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a**b</th>
<th>power(a,b)</th>
<th>a/b</th>

<tr>
<td>2</td>
<td>INF</td>
<td>UNDF</td>
<td>UNDF</td>
<td>0</td>
</tr>
</tbody>
</table>

Table 11: Extended Range Arithmetic in Exponentiation and Division

Note that most extended range identifiers may be used in assignment statements, as illustrated below.

\[
a(\text{row},'\text{col}-3') = \text{NA};
\]
\[
a(\text{row},'\text{col}-4') = \text{INF};
\]
\[
a(\text{row},'\text{col}-5') = -\text{INF};
\]

The values most often used in assignments are \text{NA} in incomplete tables and \text{INF} for variable bounds.

The special value \text{EPS} is numerically equal to zero, so when used in the context of numerical comparisons, it behaves as zero. For example, the logical expressions \(x > 0\) and \(x > \text{EPS}\) have the same result. However, \text{EPS} is a stored zero, so setting a parameter to zero (e.g. \(a(\text{row},\text{col})=0\)) results in no values being stored for \(a\), while setting a parameter to \text{EPS} (e.g. \(a(\text{row},\text{col})=\text{EPS}\)) results in the value \text{EPS} being stored for every \((\text{row},\text{col})\) tuple. This is sometimes useful, especially if \(a\) is used later in loops (see Programming Flow Control Features) or dollar conditions (see Conditional Expressions, Assignments and Equations). For example, consider the statement

\[
a(\text{row},\text{col})\$[a(\text{row},\text{col})] = \text{INF} ;
\]

In the case where \(a\) was originally assigned to be zero, the dollar-condition is always false so no infinities are assigned. If \(a\) was originally assigned the value \text{EPS}, the dollar-condition is always true and every tuple in \(a\) will be set to infinity.

When an attempted arithmetic operation is illegal or has undefined results because of the value of arguments (division by zero is the normal example), an error is reported and the result is set to undefined (\text{UNDF}). The error is marked on the output file with a row of four asterisks \(\ast\ast\ast\ast\) making this sequence a good search target in the editor. GAMS will also report the line number of the offending statement and give as much detail as possible about the cause. From there on, the resulting \text{UNDF} is treated as a proper data value and does not trigger additional error messages. For more on error messages, see chapter GAMS Output.

Note

GAMS will not solve a model if an error has been detected, and it will terminate with an error condition.

It is therefore wise to anticipate and avoid operations like division by zero that will cause errors. This is most easily done with the dollar control, and is discussed in section The Dollar Condition.
4.26.6 Predefined Symbols

GAMS offers several predefined symbols including: sameAs, diag, sortedUels, solvers, licenseCodes, solverCapabilities, componentEDate, componentMDate, and ComponentLicenseOptions. With the exception of sameAs, diag, and sortedUels these predefined symbols are for very special (and mostly internal) purposes, but the way they work is identical.

These symbols can be used in a GAMS program without being declared but work in an idiosyncratic way. For example, the complete program

display solvers, sameAs;

compiles and executes without error and produces the following result in the listing file:

---- 1 SET Solvers  Available Solvers
       ( EMPTY )

---- 1 SET SameAs  Set Element Comparison Without Checking
       ( EMPTY )

However, if labels have been declared (in any set) that corresponds to a solver name, then set solvers will contain this label. Consider the following example:

Set titles / Lord, Baron, Duke /;
Set greeks / Euclid, Pythagoras, Antigone /;
display solvers, sameAs;

Note that Antigone and Baron are the names of solvers in GAMS and therefore they will be displayed as a member of the set solvers. Also note that the set sameAs contains the diagonal elements for both sets:

---- 3 SET Solvers  Available Solvers
       Baron, Antigone

---- 3 SET SameAs  Set Element Comparison Without Checking
       Lord Baron Duke Euclid Pythagoras Antigone
       Lord YES
       Baron YES
       Duke YES
       Euclid YES
       Pythagoras YES
       Antigone YES

User defined symbols can have the same name as a predefined symbol. In this case the user symbol hides the predefined symbols as demonstrated in the following example:

Set diag / 1*3 /;
$if setType diag $log diag is a set
$if preType diag $log diag is a predefined type

The log will only contain the line diag is a set. The test $if preType diag fails.

The list of all predefined symbols can be retrieved by declaring and displaying a set using some system data

set pre /system.predefinedSymbols/; display pre; which results in

---- 1 SET pre
       SameAs , Diag , Solvers
       LicenseCodes , SolverCapabilities , SortedUels
       ComponentEDate , ComponentMDate , ComponentLicenseOptions
4.26.7 Summary

GAMS provides powerful facilities for data manipulation with parallel assignment statements, built-in functions and extended range arithmetic.

4.27 Data Entry: Parameters, Scalars and Tables

4.27.1 Introduction

Data handling is of crucial importance in all modeling applications. The quality of the numbers and the intelligence with which they are used is likely to be at least as important as the logic of the model in determining if an application is successful or not. GAMS has been designed to have a complete set of facilities for entering information, manipulating it and reporting on the results. In this chapter we will concentrate on data entry. Chapter Data Manipulations with Parameters introduces and discusses data manipulations. For details on reporting, see chapters GAMS Output, The Display Statement, The Put Writing Facility, and GAMS Data eXchange (GDX).

One very important principle will motivate all our discussions on data:

Note

Data should be entered in its most basic form and each data item should be entered only once.

There are two reasons for adopting this principle. Numbers are almost certain to change, and when they do we want to be able to make the process of changing them as easy and safe as possible. We also want to make our model easy for others to read and understand. Keeping the amount of data as small as possible will certainly help. All the data transformations are shown explicitly in the GAMS representation, which makes it possible to reproduce the results of a study and shows the reader all the assumptions made during data manipulation. Another advantage is that everything needed to run or change the model is included in one program that can easily be moved from place to place or from one machine to another.

This chapter deals with the data type parameter. For other data types, see section Data Types and Definitions. Data for parameters can be entered in three basic formats: scalar, list oriented, or tables of two or more dimensions. For each of these formats, GAMS offers a separate keyword:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scalar</td>
<td>Single (scalar) data entry.</td>
</tr>
<tr>
<td>Parameter</td>
<td>List oriented data, defined over one or more sets.</td>
</tr>
<tr>
<td>Table</td>
<td>Table oriented data, must involve two or more dimensions.</td>
</tr>
</tbody>
</table>

Table 1: Parameters, Scalars and Tables

Note that the term parameter is used in two ways: as data type and as keyword, so one could also see scalars and tables as special formats of parameters. Each of the data input formats will be introduced and discussed in the following sections. At the end of the chapter the special data type acronym is introduced.

Note

• By default, parameters in all input formats may only be initialized once, thereafter data must be modified with assignment statements. This can be changed using the dollar control option $onMulti.
This chapter explains the complete syntax to declare parameters which includes the optional initialization. So, while it is possible to initialize the data at declaration, often the data is read from other sources like databases or spreadsheets. More information about this can be found in the chapter Data Exchange with Other Applications.

4.27.2 Scalars

The scalar statement is used to declare and (optionally) initialize a GAMS parameter of dimensionality zero. This means that there are no associated sets, so there is exactly one number associated with the parameter.

4.27.2.1 The Syntax

In general, the syntax for a scalar declaration in GAMS is as follows:

```
scalar[s] scalar_name [text] [/numerical_value/]
   { scalar_name [text] [/numerical_value/]} ;
```

The keyword `scalar[s]` indicates that this is a scalar statement and `scalar_name` is the internal name of the scalar in GAMS, it is an identifier. The optional explanatory text is used to describe the scalar and the optional numerical_value is assigned to be the value of `scalar_name`. Numerical_value can be given as fixed number or as constant evaluation. Alternatively, the special data type acronym may be used as value. For details on acronyms, see section Acronyms.

Note that more than one scalar may be declared in one scalar statement. The entries have to be separated by commas or by end of line. For advice on explanatory text and how to choose a `scalar_name`, see the tutorial Good Coding Practices.

Note that scalars may be declared but not initialized in the scalar statement. A value can also be assigned later as illustrated in the example that follows.

4.27.2.2 An Illustrative Example

An example of a scalar definition in GAMS is shown below.

```
Scalar
   rho "discount rate" / .15 /
   irr "internal rate of return"
   life "financial lifetime of productive units" / 20 /;
```

The statement above initializes rho and life, but not irr. Later on another scalar statement can be used to initialize irr or an assignment statement could be used to provide the value:

```
irr = 0.07;
```

For more on scalar assignments and parameter assignments in general, see section Data Entry by Assignment.
4.27.3 Parameters

The parameter format is used to enter list oriented data which can be indexed over one or several sets.

4.27.3.1 The Syntax

In general, the syntax for a parameter declaration in GAMS is as follows:

\[
\text{parameter}[s] \text{ param}_\text{name}[(\text{index\_list})] \text{ [text] } / \text{ element } = \text{ numerical\_value} \\
{,\text{element } = \text{ numerical\_value}} / \\
{,\text{param\_name}[(\text{index\_list})] \text{ [text] } / \text{ element } = \text{ numerical\_value} \\
{,\text{element } = \text{ numerical\_value}} /} ;
\]

The keyword parameter[s] indicates that this is a parameter statement and param_name is the internal name of the parameter in GAMS, it is an identifier. A parameter may be defined over one or more sets that may be specified in the index_list. Note that the specification of the index list in the declaration is optional. However, mostly it is advisable to specify it for reasons of clarity and to enable domain checking. For more on domain checking, see section Domain Checking. The optional explanatory text is used to describe the parameter.

Parameter initialization requires a list of data elements, each consisting of a label or label-tuple and a value. Element is an element of the defining set or - if there is more than one defining set - a combination of the elements of the defining sets. The referenced set elements must belong to the set that the parameter is indexed over. Finally, numerical_value is the value assigned to the record defined by the set element or element tuple. It can be given as fixed number or as constant evaluation. Alternatively, the special data type acronym may be entered as value. For details on acronyms, see section Acronyms.

Note

The default value of a parameter is 0.

Slashes must be used at the beginning and end of the list, and commas must be used if several data elements are listed in one line. An equals sign or a blank separates the label tuple from its associated value. A parameter can be defined in a similar syntax to that used for a set. For advice on explanatory text and how to choose a parameter name, see the tutorial Good Coding Practices.

Note

Several parameters may be declared in one parameter statement.

4.27.3.2 Illustrative Examples

The following example illustrates the parameter statement. It is adapted from [MEXSS]. We also show the set definitions because they make the example clearer. For more on sets definitions, see chapter Set Definition.

```
Set i "steel plants" / hylsa monterrey 
    hylsap puebla /

j "markets" / mexico-df, monterrey, guadalaja /;

Parameter
dd(j) "distribution of demand" 
    / mexico-df 55, 
    guadalaja 15 /;
```
The index specification for the parameter `dd` means that there will be a vector of data associated with it, one number corresponding to every member of the set `j`. The numbers are specified along with the declaration in a format very reminiscent of the way we specify sets: in this simple case a label followed by a blank separator and then a value. Any of the legal number entry formats are allowable for the value. For details on number formats in GAMS, see subsection Numbers. The default data value is zero. Since `monterrey` has been left out of the data list, the value associated with `dd('monterrey')` is zero. As with sets, commas are optional at end of line.

We may also list several data elements on a line, separated by commas as in the following example:

```
Parameter
   a(i) / seattle = 350, san-diego = 600 /
   b(i) / seattle 2000, san-diego 4500 /;
```

If a parameter is defined over a set and all elements of the set are assigned the same value, then the following notation may be used as a shortcut:

```
parameter param_name[(set_name)] [text] /(#|set.)set_name numerical_value/;
```

Here `set` is a reserved word and `set_name` is the name of the set as it has been declared in a previous set declaration statement. Instead of `set`, one could also use the `#` sign. The following artificial example illustrates this notation:

```
Set j /j1, j2/;
Parameter hh(j) /set.j 10/
    gg /#j 10/;
```

This resolves in `hh('j1') = hh('j2') = gg('j1') = gg('j2') = 10`.

Note

By default it is not possible to define an empty parameter at declaration. This may be changed using the dollar control option `$onEmpty`, as shown in the following example:

```
Set i / seattle, san-diego /;
$onEmpty
Parameter
   a(i) / /;
```

That initializes `a('seattle')` and `a('san-diego')` to 0. So it is not the same as this:

```
Set i / seattle, san-diego /;
Parameter
   a(i);
```

Here, `a` is declared, but not initialized (so, it is not defined yet) and one would get an error when trying to read it.
4.27.3.3 Parameter Data for Higher Dimensions

A parameter may have several dimensions. For the current maximum number of permitted dimensions, see Dimensions. The list oriented data initialization through the parameter statement can be easily extended to data of higher dimensionality. The label that appears on each line in the one-dimensional case is replaced by a label tuple for higher dimensions. The elements in the $n$-tuple are separated by dots (.) just like in the case of multi-dimensional sets.

The following example illustrates the use of parameter data for higher dimensions:

Parameter

\[
\text{salaries(employee,manager,department)}
\]

\[
/ \text{anderson .murphy .toy} = 6000 \\
\text{hendry .smith .toy} = 9000 \\
\text{hoffman .morgan .cosmetics} = 8000 /;
\]

All the mechanisms using asterisks and parenthesized lists that we introduced in our discussion of sets are available here as well. For details see section Multi-Dimensional Sets. Below is an artificial example, in which a very small fraction of the total data points are initialized. GAMS will mark an error if the same label combination (or label-tuple) appears more than once in a data list.

Set row / row1*row10 /
col / col1*col10 /;
Parameter

\[
a(row, col)
\]

\[
/ (row1,row4) . col2*col7 12 \\
\text{row10} . col10 17 \\
\text{row1*row7} . col10 33 /;
\]

In this example the twelve elements row1.col2 to row1.col7 and row4.col2 to row4.col7 are all initialized at 12, the single element row10.col10 at 17, and the seven elements rows1..col10 to row7.col10 at 33. The other 80 elements (out of a total of 100) remain at their default value, which is 0. This example shows the ability of GAMS to provide a concise initialization or definition for a sparse data structure.

4.27.4 Tables

Tabular data can be declared and initialized in GAMS using a table statement. For two and higher-dimensional parameters this provides an easier and more concise method of data entry than the list based approach, since - at least in smaller tables - each label appears only once.

4.27.4.1 The Syntax

In general, the syntax for a table declaration in GAMS is as follows:

```
table table_name[(index_list)] [text] [EOL
    element { element } EOL
    {element numerical_value { numerical_value} EOL}
} ;
```
The keyword **table** indicates that this is a **table** declaration and **table_name** is the internal name of the table in GAMS, it is an **identifier**. The name of the parameter can be followed by the **index_list**. In the **index_list** the sets are specified over which the table is defined. Note that the specification of the index list in the declaration is optional. However, mostly it is advisable to specify it for reasons of clarity and to enable domain checking. For more on domain checking, see section Domain Checking. The optional **explanatory text** is used to describe the table, followed by EOL which means ”end of line”, a line break. **Element** is an element of one of the driving sets. More details follow below. **Numerical_value** is the value of the entry associated with the corresponding element combination. It can be given as fixed number or as **constant evaluation**. Alternatively, the special data type **acronym** may be used as value. For details on acronyms, see section Acronyms. For advice on explanatory text and how to choose a **table_name**, see the tutorial Good Coding Practices.

**Attention**

By default, the table statement is the only statement in the GAMS language that is not free format. This may be changed using the dollar control option $onDelim.

The following rules apply:

- The relative positions of all entries in a table are significant. This is the only statement where end of line (EOL) has meaning. The character positions of the numeric table entries must overlap the character positions of the column headings.

- The column section has to fit on one line.

- The sequence of values forming a row must be on the same line.

- The element definition of a row can span more than one line.

- A specific column can appear only once in the entire table.

The rules for building simple tables are straightforward. The components of the header line are

```
keyword - identifier - index_list - text
```

Note that the **index_list** and the **text** are optional. Labels are used on the top and the left to map out a rectangular grid that contains the data values. The order of labels is unimportant, but if domain checking has been specified (i.e. the **index_list** has been given in the first line of the table declaration) each label must match one in the associated set. Labels must not be repeated, but can be left out if the corresponding numbers are all zero or not needed. At least one blank must separate all labels and data entries. Blank entries imply that the default value (zero) will be associated with that label combination.

**Note**

- Tables must have at least two dimensions. For the current maximum number of permitted dimensions, see Dimensions.

- The **table** statement can also be terminated with a ; in the first line, so without entering data. In this case the parameter **table_name** would be declared but not initialized.

- In contrast to the **set**, **scalar**, and **parameter** statements, only one identifier may be initialized in a **table** statement, though multiple ones could be declared.
4.27.4.2 An Illustrative Example

In the following example a simple table is presented. It is adapted from [KORPET], the relevant set definitions are also given.

Set i "plants"
   / inchon, ulsan, yosu /
m  "productive units"
   / atmos-dist "atmospheric distillation unit"
   steam-cr "steam cracker"
   aromatics "aromatics unit"
   hydrodeal "hydrodealkylator" /;

Table ka(m,i) "initial cap. of productive units (100 tons per yr)"
    inchon  ulsan  yosu
atmos-dist   3702   12910  9875
steam-cr     517    1207
aromatics    181    148
hydrodeal    180  
;

In this example the row labels are drawn from the set m and those on the column from the set i. Note that the data for each row is aligned under the corresponding column headings. Entries that are not specified are assigned the default value zero.

Note

If there is any uncertainty about which column a number belongs to, GAMS will protest with an error message and mark the ambiguous entry.

Attention

Special care has to be taken, if tabs are used. The GAMS command line option TabIn controls the tab spacing. Note that this spacing might be different form the spacing that the editor is showing, hence the visible alignment might be different from the alignment that GAMS is actually using.

4.27.4.3 Continued Tables

If a table has too many columns to fit nicely on a single line, then the columns that don't fit may be continued on additional lines. We use the same example to illustrate:

Table ka(m,i) "initial cap. of productive units (100 tons per yr)"
    inchon  ulsan
atmos-dist   3702   12910
steam-cr     517
aromatics    181
hydrodeal    180
+yosu
atmos-dist   9875
steam-cr     1207
aromatics    148
;

The crucial item is the plus '+' sign above the row labels and to the left of the column labels in the continued part of the table. The row labels have been duplicated, except that hydrodeal has been left out, since it does not have any associated data. Tables may be continued as many times as necessary.
4.27.4.4 Tables with more than Two Dimensions

Tables may have more than two dimensions. For the current maximum number of permitted dimensions, see Dimensions. As usual, dots are used to separate adjacent labels and may be used in the row or column position. The label on the left of the row corresponds to the first set in the index list, and that on the right of each column header to the last. Obviously, there must be the same number of labels associated with each number in the table, as there are sets in the index list.

The best layout depends on the size of the defining sets and the amount of data. It should provide the most intuitively satisfactory way of organizing and inspecting the data. For most people it is easier to look down a column of numbers than across a row. However, putting extra labels on the row has the advantage of greater density of information.

The following example, adapted from [MARCO], illustrates the use of tables with more than two dimensions.

Set ci "commodities : intermediate" / naphtha "naphtha" dist "distillate" gas-oil "gas-oil" / cr "commodities : crude oils" / mid-c "mid-continent" w-tex "west-texas" / q "attributes of intermediate products" / density, sulfur /;

Table attrib(ci, cr, q) "blending attributes"

<table>
<thead>
<tr>
<th></th>
<th>density</th>
<th>sulfur</th>
</tr>
</thead>
<tbody>
<tr>
<td>naphtha. mid-c</td>
<td>272</td>
<td>.283</td>
</tr>
<tr>
<td>naphtha. w-tex</td>
<td>272</td>
<td>1.48</td>
</tr>
<tr>
<td>dist . mid-c</td>
<td>292</td>
<td>.526</td>
</tr>
<tr>
<td>dist . w-tex</td>
<td>297</td>
<td>2.83</td>
</tr>
<tr>
<td>gas-oil. mid-c</td>
<td>295</td>
<td>.98</td>
</tr>
<tr>
<td>gas-oil. w-tex</td>
<td>303</td>
<td>5.05</td>
</tr>
</tbody>
</table>

The table attrib could also be laid out as shown below:

Table attrib (ci,cr,q) "blending attributes"

<table>
<thead>
<tr>
<th></th>
<th>w-tex.density</th>
<th>mid-c.density</th>
<th>w-tex.sulfur</th>
<th>mid-c.sulfur</th>
</tr>
</thead>
<tbody>
<tr>
<td>naphtha</td>
<td>272</td>
<td>272</td>
<td>1.48</td>
<td>.283</td>
</tr>
<tr>
<td>dist</td>
<td>297</td>
<td>292</td>
<td>2.83</td>
<td>.526</td>
</tr>
<tr>
<td>gas-oil</td>
<td>303</td>
<td>295</td>
<td>5.05</td>
<td>.98</td>
</tr>
</tbody>
</table>

4.27.4.5 Condensing Tables

All the mechanisms using asterisks and parenthesized lists that were introduced in the discussion of sets are available here as well. For details on these mechanisms, see section Multi-Dimensional Sets. The following example shows how repeated columns or rows can be condensed with asterisks and lists in parentheses. The set membership is not shown, but can easily be inferred.
Table upgrade(strat, size, tech)

<table>
<thead>
<tr>
<th>tech</th>
<th>small.tech1</th>
<th>small.tech2</th>
<th>medium.tech1</th>
<th>medium.tech2</th>
</tr>
</thead>
<tbody>
<tr>
<td>strategy-1</td>
<td>.05</td>
<td>.05</td>
<td>.05</td>
<td>.05</td>
</tr>
<tr>
<td>strategy-2</td>
<td>.2</td>
<td>.2</td>
<td>.2</td>
<td>.2</td>
</tr>
<tr>
<td>strategy-3</td>
<td>.2</td>
<td>.2</td>
<td>.2</td>
<td>.2</td>
</tr>
<tr>
<td>strategy-4</td>
<td>.2</td>
<td>.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table upgradex(strat, size, tech) "alternative way of writing table"

<table>
<thead>
<tr>
<th>tech1*tech2</th>
<th>strategy-1.(small,medium)</th>
<th>.05</th>
</tr>
</thead>
<tbody>
<tr>
<td>strategy-2*strategy-3.(small,medium)</td>
<td>.2</td>
<td></td>
</tr>
<tr>
<td>strategy-4.medium</td>
<td>.2;</td>
<td></td>
</tr>
</tbody>
</table>

4.27.4.6 Handling Long Row Labels

It is possible to continue the row labels in a table on a second, or even third line in order to accommodate a reasonable number of columns. The break must come after a dot, and the rest of each line containing an incomplete row label-tuple must be blank.

The following example, adapted from [INDUS], is used to illustrate. This table actually has nine columns and many rows, here we have reproduced just a small part to show continued row label-tuples.

Table yield (c,t,s,w,z) "crop yield (metric tons per acre)"

<table>
<thead>
<tr>
<th>wheat.(bullock, semi-mech).la-plant. (heavy, january)</th>
<th>nwpf</th>
<th>pmw</th>
</tr>
</thead>
<tbody>
<tr>
<td>.385</td>
<td>.338</td>
<td></td>
</tr>
<tr>
<td>wheat.(bullock, semi-mech).la-plant. light</td>
<td>.506</td>
<td>.446</td>
</tr>
<tr>
<td>wheat.(bullock, semi-mech).la-plant. standard</td>
<td>.592</td>
<td>.524</td>
</tr>
<tr>
<td>wheat.(bullock, semi-mech).(qk-harv, standard). (heavy, january)</td>
<td>.439</td>
<td>.387</td>
</tr>
</tbody>
</table>

4.27.5 Constant Evaluation

Instead of fixed numerical values, one can also use constant expressions to assign values to parameters in a data statement. The syntax of constant expressions used in data statements follows the GAMS syntax as described in Data Manipulations with Parameters, but is restricted to scalar values and a subset of the GAMS intrinsic functions, as summarized below:

- Real numbers only
- Evaluation left to right
- Operator precedence:
  - ^ **
  - * /
  - + - binary and unary
  - < <= = <> >= > LE LE EQ NE GE GT
  - NOT
  - AND
  - OR XOR EQV IMP
• See Functions for list of supported functions

When used in a data statement, the constant expressions have to be enclosed in a pair of square brackets [ ] or curly brackets { }. Spaces can be used freely inside those brackets. Here is a little example:

```plaintext
Scalars x "PI half" / [pi/2] / 
e "famous number" / [ exp( 1 ) ] /;
```

```plaintext
Parameter y "demo" / USA.(high,low) [1/3]  
USA.medium {1/4} /;
```

### 4.27.6 Data Entry by Assignment

Data may also be entered using assignment statements. Assignments are introduced and discussed in detail in section The Assignment Statement. This section here is a short outlook and shows how parameters that have already been declared may be assigned values. The general assignment statement has the following form:

```plaintext
parameter_name[(index_list)] = expression;
```

Here `parameter_name` is the name of a parameter that has been declared previously in a scalar, parameter or table statement, `index_list` indicates the controlling indices and may either contain a set or sets, a label or label tuple or a combination of those, and `expression` may be a number, a numerical expression or an acronym. For details on numerical expressions, see section Expressions.

The following examples illustrate how assignments may be used for data entry.

```plaintext
Set j / j1, j2, j3 /;
Scalar a1;
Scalars a2 / 11 /;
Parameter cc(j), bc(j) / j2 22 /;

a1 = 10;
a2 = 5;
cc(j) = bc(j)+10;
cc("j1") = 1;
```

The scalar `a1` is declared but not initialized in the first scalar statement. It is assigned the value of 10 in the first assignment. The scalar `a2` is initialized in the second scalar statement and this value is changed to 5 in the second assignment. Note that the original data is not retained. In the parameter statement the parameter `cc(j)` is declared but not initialized and the parameter `bc(j)` is only initialized for `j2`. This means that `bc('j2') = 22` and `bc('j1') = bc('j3') = 0`, the default value. Now, the third assignment sets the parameter `cc(j)` and assigns to all elements of the set `j` the value of the parameter `bc(j)` plus 10. So we have `cc('j2') = 32` and `cc('j1') = cc('j3') = 10`. Note that in this example the set `j` has only three elements so only 3 assignments are made simultaneously. However, suppose that the number of set elements is large, say 100,000, then to each element a value is assigned with just one assignment statement. Finally, the value of `cc('j1')` is changed to 1.

Observe that in the examples above assignments either refer to one specific set element or to the whole set. It is also possible to make assignments to only a part of the set. The mechanisms for partial set references are discussed in section Restricting the Domain in Assignments. Set elements that are not assigned new values in an assignment with a partial set reference retain their previous values. Recall that these may be the default value, values from the parameter or table statement, or values resulting from previous calculations.
4.27 Data Entry: Parameters, Scalars and Tables

4.27.7 Acronyms

An acronym is a special data type that allows the use of strings as values. Note that acronyms have no numeric values and are treated as character strings only.

4.27.7.1 The Syntax

The declaration for an acronym is similar to a set or parameter declaration. The basic format is as follows:

```
Acronym[s] acronym_name [text] {, acronym_name [text]};
```

The keyword `acronym[s]` indicates that this is an acronym statement and `acronym_name` is the internal name of the acronym in GAMS, it is an identifier. The optional explanatory text is used to describe the acronym. For advice on explanatory text and how to choose an `acronym_name`, see the tutorial Good Coding Practices.

Note that more than one acronym may be declared in one acronym statement. The entries have to be separated by commas or by end of line. A simple example illustrates this:

```
Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
```

4.27.7.2 Acronym Usage

Acronyms may be used as data in scalar, parameter and table statements. An example for acronyms in a parameter statement follows.

```
Set machines / m-1*m-5 /;
Acronym
    Monday, Tuesday, Wednesday, Thursday, Friday;
Parameter
    shutdown(machines)
    / m-1 Tuesday
    m-2 Wednesday
    m-3 Friday
    m-4 Monday
    m-5 Thursday /;
```

Acronyms may also be used in assignments as in the example below. For more on assignments, see section The Assignment Statement.

```
Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
Scalar dayOfWeek;
dayOfWeek = Wednesday;
```

Note that numerical operations like addition or subtraction are not allowed with acronyms. Such operations would be meaningless since acronyms do not have numeric values.

Another context where acronyms may be used is in logical conditions. For more on logical conditions, see chapter Conditional Expressions, Assignments and Equations. This is shown in the following example:
Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
Scalar dayOfWeek
  workHours /6/;
dayOfWeek = Wednesday;
workHours$(dayOfWeek <> Friday) = 8;

Note that only the equality and inequality operators may be used with acronyms. Other operations like addition and division are meaningless since acronyms do not have numeric values.

Acronyms are specific to GAMS and hence difficult to deal with when exchanging data with other systems. Users often replace parameters that contain acronyms with dynamic sets that have an additional index whose values correspond to the acronyms found in the original parameter. The machine shutdown data from above can be represented via a two-dimensional set as follows:

Set machines / m-1*m-5 /;
  weekdays / Monday, Tuesday, Wednesday, Thursday, Friday /
  shutdown(machines,weekdays) / m-1.Tuesday
   m-2.Wednesday
   m-3.Friday
   m-4.Monday
   m-5.Thursday /;

4.27.8 Summary

In this chapter, the declaration and initialization of parameters with the Scalar, Parameter, and Table statement have been discussed. Chapter Data Manipulations with Parameters will describe how this data can be changed with assignment statements.

4.28 Variables

4.28.1 Introduction

This chapter covers the declaration and manipulation of GAMS variables. Many of the concepts covered in the previous chapters are directly applicable here.

A variable is the GAMS name for what are called endogenous variables by economists, columns or activities by linear programming experts, and decision variables by industrial Operations Research practitioners. They are the entities whose values are generally unknown until after a model has been solved. A crucial difference between GAMS variables and columns in traditional mathematical programming terminology is that one GAMS variable is likely to be associated with many columns in the traditional formulation.

4.28.2 Variable Declarations

A GAMS variable, like all other identifiers, must be declared before it may be referenced.
4.28.2.1 The Syntax

The declaration of a variable is similar to a set or parameter declaration, in that domain lists and explanatory text are allowed and recommended, and several variables may be declared in one statement. The syntax is given below.

[var_type] variable[s] var_name [(index_list)] [text] [/var_data/] {, var_name [(index_list)] [text]}

The keyword var_type denotes the optional variable type that is explained in detail in the next subsection. Variable[s] is the keyword that indicates that this is a variable statement. Var name is the internal name of the variable in GAMS, it is an identifier. In the optional index list the set or sets may be specified over which an indexed variable is declared. The optional explanatory text may be used to describe the variable for future reference and to ease readability. Specifying variable data is another optional element in the variable statement. Variable data allows to initialize variable attributes at compile time. For an example and details on variable attributes, see section Variable Attributes.

A typical variable statement adapted from the model [RAMSEY] is shown below for illustration:

Variables
k(t) capital stock (trillion rupees)
c(t) consumption (trillion rupees per year)
i(t) investment (trillion rupees per year)
utility utility measure;

The declaration of k above implies, as usual, that references to k are restricted to the domain of the set t. A model that includes k will probably have several corresponding variables in the associated mathematical programming problem: most likely one for each member of t. In this way, very large models can be constructed using a small number of variables. (It is quite unusual for a model to have as many as 50 distinct variables.) It is still unclear from the declaration whether utility is not domain checked or whether it is a scalar variable, i.e., one without associated sets. Later references will be used to settle the issue. For more details on domain checking, see section Domain Checking.

As the syntax indicates, the explanatory text is optional. However, it is important that variable declarations include explanatory text and that this be as descriptive as possible, since the text is used to annotate the solution output. Note the use of 'per' instead of '/' in the text above: slashes are illegal in all unquoted text.

Note
- Variable names, the contained set element names plus the explanatory text must obey the general rules for language items.
- Variables can be defined over from 0 up to 20 sets
- The sets over which variables are declared indicate that these variables are potentially defined for every element of the defining sets. However the actual definition of variables does not occur until variables appear in an equation definition where the equation needs to be part of a model that in turn occurs in a solve statement.

4.28.2.2 Variable Types

There are nine basic types of variables that may be used in variable statements. These are shown in table Table 1.
<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
<th>Default Bound</th>
<th>Lower Bound</th>
<th>Default Upper Bound</th>
<th>Upper Bound</th>
</tr>
</thead>
<tbody>
<tr>
<td>free (default)</td>
<td>No bounds on variable. Both bounds may be changed from the default values by the user.</td>
<td>-inf</td>
<td></td>
<td>+inf</td>
<td></td>
</tr>
<tr>
<td>positive or nonnegative</td>
<td>No negative values are allowed for variable. The user may change both bounds from the default value.</td>
<td>0</td>
<td></td>
<td>+inf</td>
<td></td>
</tr>
<tr>
<td>negative</td>
<td>No positive values are allowed for variables. The user may change both bounds from the default value.</td>
<td>-inf</td>
<td></td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>binary</td>
<td>Discrete variable that can only take values of 0 or 1. For details see section Types of Discrete Variables. In relaxed Model types the integrality requirement is relaxed.</td>
<td>0</td>
<td></td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>integer</td>
<td>Discrete variable that can only take integer values between the bounds. The user may change both bounds from the default value. The default upper bound inside GAMS is +inf but when the variable is passed on to the solver, the option or command line parameterIntVarUpdecides what upper bound (by default +inf) is passed on to the solver in case GAMS has upper bound +inf. In relaxed Model types the integrality requirement is relaxed.</td>
<td>0</td>
<td></td>
<td>+inf</td>
<td></td>
</tr>
<tr>
<td>sos1</td>
<td>A set of variables, such that at most one variable within a group may have a non-zero value. For details see section Types of Discrete Variables.</td>
<td>0</td>
<td></td>
<td>+inf</td>
<td></td>
</tr>
<tr>
<td>Keyword</td>
<td>Description</td>
<td>Default Lower Bound</td>
<td>Default Upper Bound</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>---------------------</td>
<td>--------------------</td>
<td></td>
<td></td>
</tr>
<tr>
<td>sos2</td>
<td>A set of variables, such that at most two variables within a group may have non-zero values and the two non-zero values are adjacent. For details see section Types of Discrete Variables.</td>
<td>0</td>
<td>+inf</td>
<td></td>
<td></td>
</tr>
<tr>
<td>semicont</td>
<td>Semi-continuous, must be zero or above a given minimum level. For details see section Types of Discrete Variables.</td>
<td>1</td>
<td>+inf</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| semiint | Semi-integer, must be zero or above a given minimum level and integer. For details see section Types of Discrete Variables.  
The default upper bound inside GAMS is +inf but when the variable is passed on to the solver, the option or command line parameter IntVarUp decides what upper bound (by default +inf) is passed on to the solver in case GAMS has upper bound +inf. In relaxed Model types the integrality requirement is relaxed. | 1 | +inf |

**Table 1:** Variable types and default bounds

The default type is **free**, which means that if the type of the variable is not specified, it will not be bounded at all. The most frequently used types are **free** and **positive**. The type **positive variables** is used for variables for which negative values are meaningless, such as capacities, quantities or prices. Note that bounds may be changed using variable attributes and assignment statements, see section **Variable Attributes**.

**Note**

- Every optimization model must contain at least one unrestricted named variable (i.e. one declared with the keywords **Variable** or **Free Variable**). This variable is the objective variable. Even an objective variable can have lower and upper bounds assigned via the .lo and .up variable attribute.

- If a model is unbounded, a frequent cause for the unboundedness is that the modeler forgot to make a variable positive.
4.28.2.3 Styles for Variable Declaration

Two styles are commonly used to declare variable types. The first is to list all variables with domain specifications and explanatory text as a group, and later to group them separately as to type. The example shown below is adapted from [MEXSS]. The default type is free, so phi and phipsi will be free variables in the example below. Note the use of variable names derived from the original mathematical representation.

**Variables**

- \( u(c,i) \) "purchase of domestic materials (mill units per yr)"
- \( v(c,j) \) "imports (mill tpy)"
- \( e(c,i) \) "exports (mill tpy)"
- \( \phi \) "total cost (mill us$)"
- \( \phi \text{ipsi} \) "raw material cost (mill us$)"

Positive Variables \( u, v, e \);

The commas in the list of positive variables are required separators.

**Attention**

It is possible to declare an identifier more than once. However, the second and any subsequent declarations should only add new information that does not contradict what has already been entered.

The second popular way of declaring variables is to list them in groups by type. We rewrite the example above using this second method:

**Free Variables**

- \( \phi \) "total cost (mill us$)"
- \( \phi \text{ipsi} \) "raw material cost (mill us$)"

Positive Variables

- \( u(c,i) \) "purchase of domestic materials (mill units per yr)"
- \( v(c,j) \) "imports (mill tpy)"
- \( e(c,i) \) "exports (mill tpy)"

The choice between the two approaches is best based on clarity.

4.28.3 Variable Attributes

While a GAMS parameter has one number associated with each unique label combination, a variable has several. They represent:

<table>
<thead>
<tr>
<th>Variable Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lower bound</td>
<td>.lo</td>
<td>Lower bound for the variable. Set by the user either explicitly or through default values associated with the variable type.</td>
</tr>
<tr>
<td>Upper bound</td>
<td>.up</td>
<td>Upper bound for the variable. Set by the user either explicitly or through default values associated with the variable type.</td>
</tr>
<tr>
<td>Fixed value</td>
<td>.fx</td>
<td>A fixed value for the variable. If set it results in the upper and lower bounds of the variable to be set to the value of the .fx attribute.</td>
</tr>
</tbody>
</table>
### Variable Attributes

<table>
<thead>
<tr>
<th>Variable Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activity level</td>
<td>.l</td>
<td>Activity level for the variable, also the current value or starting point. This attribute is reset to a new value when a model containing the variable is solved. The activity level is used to construct a basis for the model.</td>
</tr>
<tr>
<td>Marginal</td>
<td>.m</td>
<td>The marginal value (or reduced cost) for the variable. This attribute is reset to a new value when a model containing the variable is solved. The activity level is used to construct a basis for the model.</td>
</tr>
<tr>
<td>Scale factor</td>
<td>.scale</td>
<td>Numerical scaling factor for all coefficients associated with the variable if the model attribute scaleopt is set to 1. For more on scaling, see section Model Scaling - The Scale Option. Only applicable for continuous variables.</td>
</tr>
<tr>
<td>Branching priority</td>
<td>.prior</td>
<td>Branching priority value used in mixed integer programming models if the model attribute prioropt is set to 1. For details see section Setting Priorities for Branching. It can also be used to relax discrete restrictions by setting .prior = +inf regardless of the prioropt setting. Only applicable for discrete variables.</td>
</tr>
<tr>
<td>Stage</td>
<td>.stage</td>
<td>This attribute allows to assign variables to stages in a stochastic program or other block structured model. Thus, among other places, it is used for 2-stage stochastic programs solved with DECIS or the Benders partition in Cplex.</td>
</tr>
</tbody>
</table>

#### Table 2: Variable Attributes

Users distinguish between these values when necessary by appending the suffix to the variable name. Examples are given below.

It is possible to specify initial values for these variable attributes at compile time. This can be done within the variable declaration statement as illustrated in the following example or during execution time as explained in section Assigning Values to Variable Attributes.

**Variable x1(j) my first / j1.up 10 , j1.lo 5, j1.l 7, j1.m 0, j1.scale 20 /;**

The upper bound of the variable x1("j1") is set to 10, the lower bound is set to 5, the starting value for the activity level is set to 7 and the starting value for the marginal is set to 0. The variable is also scaled by the factor 20, which means it is *multiplied* by 20.

Note that it is also possible to use a table structure to assign values to variable attributes. The following example is adapted from model [TRNSPORT].

**Variable Table x(i,j) initial values**

```plaintext
1  m
seattle. new-york 50
seattle. chicago 300
san-diego.new-york 275
san-diego.chicago 0.009;
```

---

**4.28 Variables** 617
Note

- `.fx` and attributes `.lo` and `.up` on the same variable cannot be in a data statement. `.fx` sets both `.lo` and `.up` and hence we would have a double definition of the same attribute. Since attribute `.scale` is applicable for continuous variables and attribute `.prior` for discrete variables, they share the same internal space in a GAMS variable. Some solvers can make use of priorities even for continuous variables (e.g. BARON). Such priorities need to be supplied via a solver option file.

- The attribute `.stage` uses the same internal space as `.scale` and `.prior`. So a model cannot specify scale factor and branching priorities together with stages.

- Fixing a semi-continuous or semi-integer variable to a non-zero value like `x.fx = 4` does not result in a truly fixed variable. The domain of the variable remains `{0,4}`. To really fix a semi-continuous or semi-integer variable, the discrete restriction could be relaxed by setting the branching priority to infinity (`x.prior=inf`).

- For variables in discrete models (such as MIP, MINLP), the `.m` attribute provides the marginals obtained by fixing all the discrete variables and solving the resulting continuous problem (such as LP, NLP). Many solvers allow to enable/disable solving such a fixed problem. When disabled, no marginals will be provided for discrete models.

In addition to the variable attributes introduced above, there are a number of variable attributes that cannot be assigned but may be used in computations. They are given in Table 3.

<table>
<thead>
<tr>
<th>Variable Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>.range</td>
<td>The difference between the lower and upper bounds for a variable. It becomes zero if the lower equals the upper bound, e.g. if the <code>.fx</code> attribute is set.</td>
</tr>
<tr>
<td>Slack upper bound</td>
<td>.slackup</td>
<td>Slack from variable upper bound. This is defined as the greater of two values: zero or the difference between the upper bound and the level value of a variable.</td>
</tr>
<tr>
<td>Slack lower bound</td>
<td>.slacklo</td>
<td>Slack from variable lower bound. This is defined as the greater of two values: zero or the difference between the level value and the lower bound of a variable.</td>
</tr>
<tr>
<td>Slack</td>
<td>.slack</td>
<td>Minimum slack from variable bound. This is defined as the minimum of two values: the slack from the variable lower bound and the slack from the variable upper bound.</td>
</tr>
<tr>
<td>Infeasibility</td>
<td>.infeas</td>
<td>Amount by which a variable is infeasible falling below its lower bound or above its upper bound. This is defined as the smallest of three values: zero, the difference between the lower bound and the level value, the difference between the level value and the upper bound of a variable, i.e. <code>max(0, lower-level, level-upper)</code>.</td>
</tr>
</tbody>
</table>

Table 3: Additional Variable Attributes that Cannot Be Assigned but May Be Used in Computations.

### 4.28.3.1 Bounds on Variables

All default bounds set at declaration time may be changed using assignment statements.

**Attention**

For discrete variable types, the consequences of the type declaration cannot be completely undone (e.g. the `.scale` attribute is not available) but their value domain can be changed to continuous by setting attribute `.prior` to infinity.
Bounds on variables are the responsibility of the user. After variables have been declared, default bounds have already been assigned: for many purposes, especially in linear models, the default bounds are sufficient. In nonlinear models, however, bounds play a far more important role. It may be necessary to provide bounds to prevent undefined operations, such as division by zero. In nonlinear programming it is often necessary to define a 'reasonable' solution space that will assist in efficiently finding a solution.

Attention

The lower bound cannot be greater than the upper bound: if you happen to impose such a condition, GAMS will generate an execution error, namely "**** Matrix error - lower bound > upper bound" when executing a solve statement.

Note that the upper bound on integer and semi-integer variables needs special consideration. The default upper bound is +inf and the option or command line parameter IntVarUp controls what upper bound is sent to the solver. With the current default value (0) of IntVarUp, an upper bound of +inf is sent to the solver. Setting IntVarUp to one will pass 100 as the default upper bound to the solver. The other available values for IntVarUp work like zero, but enable special reports/execution errors in case the solution reports a level value greater than 100 for any integer variable with a default bound of +inf.

4.28.3.2 Fixing Variables

GAMS allows the user to fix variables through the .fx variable suffix. This is almost equivalent to setting the lower bound and upper bound equal to the fixed value. The attribute .fx also resets the activity level .l to the fixed value. When setting .lo and .up the activity level remains unchanged. A solve statement will project the activity level within the active bounds. Fixed variables can subsequently be freed by changing the lower and upper bounds.

4.28.3.3 Activity Levels of Variables

GAMS allows the user to set the activity levels of variables through the .l variable suffix. These activity levels of the variables prior to the solve statement serve as initial value for the solver. This is particularly important for nonlinear programming problems. For discrete models in many cases the solver needs an additional indicator to interpret the activity levels as a feasible integer solution via a solver option (e.g. Cplex' mipstart).

Attention

- GAMS only stores variables with non-default values (similar to storing only non-zero values of parameters). Non-default variables can be accidentally created by using harmlessly looking assignments like
  
x.up(i,j,k,l) = 0;

  Even if the equations only reference such variables over a small subset of \((i,j,k,l)\) this statement creates \(\text{card}(i) \times \text{card}(j) \times \text{card}(k) \times \text{card}(l)\) variable records in the GAMS database. Such fixings of \(x(i,j,k,l)\) to 0 can be avoided by using dynamic sets or dollar conditions in the equation algebra to only reference tuples of \((i,j,k,l)\) for which \(x(i,j,k,l)\) can possible have a non-zero value.

- In order to filter only necessary tuples for an equation the filtering conditions needs to be provided only once when defining the equation (equ(1,j,k)). This is different for variables because they appear in many equations and the filtering condition needs to be potentially repeated many time. Therefore it is good practice and reduces GAMS model generation time if the filtering of the variables is governed by a dynamic set:

  \[
  \text{sum}((i,j)\{\text{ord}(i) \text{ord}(j) \text{cap}(i,j)>0\}, x(i,j))
  \]

  versus

  \[
  \text{set net(i,j); net(i,j) = ord(i)ord(j) cap(i,j)>0;}
  \text{sum(net(i,j), x(i,j))}
  \]
4.28.4 Variables in Display and Assignment Statements

GAMS allows the modeler to use the values associated with the various attributes of each variable in assignment and display statements. The next two subsections explain the use of variables on the left and right-hand sides of assignment statements respectively. Then we will explain the use of variables in display statements.

4.28.4.1 Assigning Values to Variable Attributes

Assignment statements operate on one variable attribute at a time, and require the suffix to specify which attribute is being used. Any index list comes after the suffix.

The following code snippets are from models [MEXSS] and [RAMSEY]. The first example illustrates the use of assignment statements to set upper and lower bounds on variables.

\[
x\.up(c, i, j) = 1000; \quad \text{phi\.lo} = \text{inf};
\]

A very common use is to bound one particular entry individually:

\[
p\.up('pellets', 'ahmsa', 'mexico-df') = 200;
\]

Or to put small lower bounds on a variable identifier used as a divisor in a nonlinear program:

\[
c\.lo(t) = 0.01;
\]

Or to provide initial values for a nonlinear problem:

\[
c\.l(t) = 4*c\.init(t);
\]

Remember that the order is important in assignments, and notice that the two pairs of statements below produce very different results. In the first case, the lower bound for \(c('1985')\) will be 0.01, but in the second, the lower bound is 1.

\[
c\.fx('1985') = 1; \quad c\.lo(t) = 0.01;
c\.lo(t) = 0.01; \quad c\.fx('1985') = 1;
\]

Everything works as described in the previous chapter, including the various mechanisms described there of indexed operations, dollar operations, subset assignments and so on. An example from model LOCATION follows.

\[
\text{ship\.sm\.lo}(sl,m)$\text{(ord(sl) = 1 and ord(m) = 1)} = 1;
\]

The lower bound of the variable \text{ship\.sm}(sl,m) is set to 1 and this assignment is only valid for \text{ship\.sm}('s1','d1'), the realization of the variable where both indices are the first members of their respective sets.
4.28.4.2 Variable Attributes in Assignments

Using variable attributes on the right-hand side of assignment statements is important for a variety of reasons. Two common uses are for generating reports and for generating initial values for some variables based on the values of other variables. For more on variable attributes in report writing, see section Displaying Variable Attributes below and especially chapter The Put Writing Facility.

The following examples adapted from model [CHENERY] illustrate the use of variable attributes on the right-hand side of assignment statements:

* initial values for variables

\[
\begin{align*}
y.l(i) &= 250 ; \quad x.l(i) = 200 ; \\
e.l(t) &= 0 ; \quad m.l(t) = 0 ; \\
g.l(t) &= \text{mew}(t) + \text{xsi}(t) \cdot m.l(t) ; \\
h.l(t) &= \text{gam}(t) - \text{alp}(t) \cdot e.l(t) ; \\
&\ldots
\end{align*}
\]

* generating report after solve

Scalar

\[
\begin{align*}
\text{cva} & \quad "\text{total value added at current prices}" \\
\text{rva} & \quad "\text{real value added}" \\
\text{cli} & \quad "\text{cost of living index}"
\end{align*}
\]

\[
\begin{align*}
\text{cva} &= \sum(i, v.l(i) \cdot x.l(i)) ; \\
\text{cli} &= \sum(i, p.l(i) \cdot \text{ynot}(i)) / \sum(i, \text{ynot}(i)) ; \\
\text{rva} &= \text{cva}/\text{cli} ;
\end{align*}
\]

Display cli, cva, rva ;

As with parameters, a variable must have some non-default data values associated with it before it can be used in a display statement or on the right-hand side of an assignment statement. After a solve statement has been processed or if non-default values have been set with an assignment statement, this condition is satisfied. Solve statements are introduced and discussed in chapter Model and Solve Statements.

Attention

The .fx suffix is mostly just a shorthand for .lo and .up and can therefore only be used only on the left-hand side of an assignment statement.

Note

- In general, the variable level needs to be specified via the attribute .l for assignment statements. However, the dollar control option $on/offDotL allows the implicit use of the attribute .l in assignment statements, thus it facilitates using the same algebra in model definitions and assignment statements. This is especially useful in the context of macros.
4.28.4.3 Displaying Variable Attributes

The display statement is introduced and discussed in detail in chapter The Display Statement. Here we demonstrate how variable attributes are used in display statements.

Since several values are associated with each variable, the user must specify which attribute should be displayed when using variables in display statements. As before, appending the appropriate suffix to the variable name does this and no domain specification may appear. As an example, we show how to display the level of $\phi$ and the level and the marginal values of $v$ from [MEXSS]:

```
display phi.l, v.l, v.m;
```

The output looks similar, except that (of course) the listing shows which of the values is being displayed. Because zeroes, and especially all zero rows or columns, are suppressed, the patterns seen in the level and marginal displays will be quite different, since non-zero marginal values are often associated with activity levels of zero.

Mexico Steel - Small Static (MEXSS,SEQ=15)

```
Execution

---- 203 VARIABLE PHI.L = 538.811 total cost 
      (mill us$)
---- 203 VARIABLE V.L imports 
      (mill tpy) 
      ( ALL 0.000 )
---- 203 VARIABLE V.M imports 
      (mill tpy) 
      mexico-df monterrey guadalaja 
      steel 7.018 18.822 6.606

We should mention here a clarification of our previous discussion of displays. It is actually the default values that are suppressed on display output. For parameters and variable levels and marginals, the default is zero, and so zero entries are not shown. For bounds, however, the defaults can be non-zero. The default value for the upper bound of a positive variable is $+\text{INF}$, and if we would also display $v.\text{up}$ above, for example, we would see:

```
---- 203 VARIABLE V.UP imports 
      (mill tpy) 
      ( ALL $+\text{INF}$ )
```

If any of the bounds have been changed from the default value, then only the entries for the changed elements will be shown. This may sound confusing, but since few users display bounds it has not proved troublesome in practice.

Note

The attribute .range may be used in display statements. It provides a convenient way to check whether a variable is fixed as it lists the 0 values explicate because the default for range (which won’t be displayed) is $+\text{inf}$.
4.28.5 Summary

Remember that wherever a parameter may appear in a display or an assignment statement, a variable may also appear - provided that it is qualified with one of the suffixes. The only places where a variable name may appear without a suffix is in a variable declaration, as has been shown in this chapter, in an equation definition, which is discussed in chapter Equations, or in a $on/offDotL block.

4.29 Equations

4.29.1 Introduction

The keyword equation defines GAMS names that may be used in the model statement. A GAMS equation name is associated with the symbolic algebraic relationships that will be used to generate the constraints in a model. The algebraic relationships are defined by using constants, mathematical operators, functions, sets, parameters and variables. As with variables, one GAMS equation may be defined over a group of sets and in turn map into several individual constraints associated with the elements of those sets. Most of the example code in this chapter is from the model location.

This chapter is organized as follows. First, we introduce how equations are declared and defined, then we discuss expressions in equation definitions, followed by a section on equation attributes. A summary and quick reference conclude the chapter.

4.29.2 Declaring Equations

An equation must be declared before it can be defined and used in a model.

4.29.2.1 The Syntax

The declaration of an equation is similar to a set or parameter declaration. The syntax is given below.

Equation[s] eqn_name [(index_list)] [explanatory text] [/eqn_data/] {, eqn_name [(index_list)] [explanatory text] [/eqn_data/]} ;

Equation[s] is the reserved word that indicates that one or more blocks of equations are about to be declared. A block of equations may initiate one or more individual constraints. Eqn_name is the internal name of the equation, an identifier in GAMS. In the optional index_list the set or sets are specified over which an indexed equation is declared. The optional explanatory text may be used to describe the equation for future reference and to ease readability. Specifying equation data is another optional element in the equation declaration. Equation data allows to initialize equation attributes at compile time. For an example see the next section. For more on equation attributes see section Equation Attributes.

One or more equations may be declared in one equation statement. The equation names have to be separated by commas or by a line break as in the example that follows. The end of the declaration statement is indicated by a semicolon.

Note

It is good practice to end the equation declaration with a semicolon, even though it is not mandatory if the next statement starts with a GAMS keyword.

For advice on choosing equation names and phrasing the explanatory text see chapter Good Modeling Practices.
4.29.2.2 An Illustrative Example

The following example is from the model location. In addition to the equation declarations the relevant set definitions are given.

Sets
    sl 'supply locations' /s1, s2/
    wh 'warehouse locations' /a, b, c/;

Equations
    tcost_eq 'total cost accounting equation'
    supply_eq(sl) 'limit on supply available at supply location'
    capacity_eq(wh) 'warehouse capacity' /a.scale 50, a.l 10, b.m 20/;

The keyword Equations marks the beginning of the equation declaration. Each equation name is optionally followed by its domain (associated set or sets) unless it is a scalar equation. It is possible but not good practice to declare indexed equations without their domains. The name of the first equation is tcost_eq and it is followed by the explanatory text 'total cost accounting equation'. The name of the equation tcost_eq is not followed by any associated sets. Since we follow good practice here we assume that tcost_eq is a scalar equation. Scalar equations do not have any associated sets and will generally produce one equation in the model. For more on scalar equations see subsection Scalar Equations.

The other two equations are indexed equations, they are declared over a set. The equation supply_eq is declared over the set sl and the equation capacity_eq is declared over the set wh. In typical circumstances an indexed equation declaration implies that a block of constraints will be generated. For example, equation supply_eq(sl) implies that two constraints will be generated, one for each element of the set sl. For more on indexed equations see subsection Indexed Equations.

The declaration of the equation capacity_eq specifies some equation attributes. The first entry indicates that the equation capacity_eq('a') is scaled by a factor of 50, which means division of all entries in that equation by 50 upon model passage to the solver. For more on scaling see section Model Scaling - The Scale Option. The second entry sets the initial value of the equation capacity_eq('a') to 10 and b.m means that the initial marginal value of the equation capacity_eq('b') is set to 20. Alternatively, a table structure may be used to specify the values of equation attributes. The following table may replace the notation above.

Equation Table capacity_eq(wh) 'warehouse capacity'
        scale  l  m
    a      50   10  
    b         20 ;

For more on equation attributes see section Equation Attributes.

Note

An equation may be declared over more than one set.

4.29.3 Defining Equations

After declaring equations they have to be defined. The definition of an equation specifies the algebraic structure of the equation in GAMS. The syntax is given first, an illustrative example follows and in the remainder of this section some of the key components of equation definitions are discussed.
4.29.3.1 The Syntax

The syntax for defining an equation is as follows:

```
eqn_name(index_list)[$logical_condition(s)].. expression eqn_type expression ;
```

Eqn_name is the name of the equation as introduced in the equation declaration, that may be followed by an index_list for indexed equations. In the index_list the set or sets are specified over which an indexed equation is defined. These sets are also called domain of definition of the equation. One or more logical conditions are optional. For an example see Indexed Equations. For more on logical conditions in equation definitions see Dollar Control over the Domain of Definition. The two dots '..' are mandatory and indicate the start of the algebra. It is good practice to end the definition of an equation with a semicolon, even though it is not mandatory if the next statement starts with a GAMS keyword.

Attention

An equation must be declared before it is defined.

Expression refers to an algebraic expression which may include variables, parameters, functions, and constants among other items. For details on expressions in GAMS, see section Expressions.

Attention

Only variables that appear at least once with a nonzero coefficient in an equation definition will appear in a model.

Eqn_type refers to the equation type denoted by the symbol between the right-hand side and left-hand side expressions that form the equation. The symbols that are allowed are given in Table 1.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=e=</td>
<td>Equality: right-hand side must equal left-hand side.</td>
</tr>
<tr>
<td>=g=</td>
<td>Greater than: left-hand side must be greater than or equal to right-hand side.</td>
</tr>
<tr>
<td>=l=</td>
<td>Less than: left-hand side must be less than or equal to right-hand side.</td>
</tr>
<tr>
<td>=n=</td>
<td>No relationship implied between left-hand side and right-hand side. This equation type is ideally suited for use in MCP models and in variational inequalities.</td>
</tr>
<tr>
<td>=x=</td>
<td>Equation is defined by external programs. See External Equations.</td>
</tr>
<tr>
<td>=c=</td>
<td>Conic constraint. See Conic Programming in GAMS.</td>
</tr>
<tr>
<td>=b=</td>
<td>Boolean equations. See Logic Equations.</td>
</tr>
</tbody>
</table>

Table 1: Equation Types

Equation definitions may be carried over as many lines of input as needed. Blanks may be inserted to improve readability, and expressions may be arbitrarily complicated.

Note that an equation can only be defined once. By using logical conditions it is possible to control which constraints are generated. In addition, the components of an equation may be modified by changing the data it uses. However, if the logic of the equation needs to be changed then a new equation with a new name has to be declared and defined.
4.29.3.2 An Illustrative Example

Consider the following example adapted from the model [mexss]. The associated variable and equation declarations are also included.

Variables phi, phipsi, philam, phipi, phieps;
Equations obj;
obj.. phi =e= phipsi + philam + phipi - phieps;

The name of the equation being defined is obj and the symbol =e= indicates that this is an equality. Any of the following forms of the equation are mathematically equivalent.

\[
\begin{align*}
\text{obj.. } & \phi + \phi_i + \phi_p - \phi = \phi_i \\
\text{obj.. } & \phi_i - \phi = \phi_p + \phi_i - \phi \\
\text{obj.. } & 0 = \phi + \phi_i - \phi_p - \phi_i + \phi_i - \phi_p \\
\end{align*}
\]

Note

The arrangement of the terms in the equation is a matter of choice, but often a particular one is chosen because it makes the model easier to understand.

4.29.3.3 Scalar Equations

A scalar equation will produce one equation in the associated optimization problem. The equation obj defined above is an example of a scalar equation which contains only scalar variables. Note that scalar equations may contain indexed variables. However, they must occur with an indexed operator such as sum or prod, unless the indexed variables refer to a singleton set (a set with only one element). Consider the following example from the model location. Note that the set wh has three elements.

\[
\text{configure_eq.. } \sum(\text{wh}, \text{build(wh)}) =l= 1;
\]

The variable build is defined over the set wh, it is an indexed variable. It may be used in the scalar equation configure_eq since it occurs in conjunction with the indexed operator sum.

4.29.3.4 Indexed Equations

All the set references in scalar equations are within the scope of indexed operators or they refer to singleton sets; thus many variable, set and parameter references can be included in one equation. In addition, GAMS also allows for equations to be defined over a domain, thereby developing a compact representation for constraints. The index sets to the left of ‘..’ are called the domain of definition of the equation.
4.29 Equations

Note

• Domain checking ensures that the domain over which an equation is defined is the set (or the sets) or a subset of the set (or the sets) over which the equation was declared.

• As a corollary, domain checking also catches the error of the indices being listed in an inconsistent order. For example, declaring an equation as `myequation(s,t)` and then naming it in the definition as `myequation(t,s)` causes an error (unless `s` and `t` are aliases of the same set). For more information, see section Domain Checking.

The following indexed equation with a single index generates a separate constraint for each member of the driving (or controlling) set. It is taken from the model [chenery]. In this example, `t` is a set with three members, `mew` and `xsi` are parameters and `m` and `g` are variables.

```plaintext
dg(t).. g(t) =e= mew(t) + xsi(t)*m(t) ;
```

As the set `t` has three members, three constraints will be generated, one for each member of `t` specifying the dependence of `g` on `m`. The data associated with the parameters `mew` and `xsi` are used to build the individual constraints. This data does not have to be known when the equation is defined, but it has to be populated before a model containing the equation is solved.

The extension to two or more indices on the left of `..` is obvious. There will be one constraint generated for each combination of set elements that can be constructed using the indices inside the parenthesis. Here are two examples from the model [aircraft], a scheduling model.

```plaintext
bd(j,h).. b(j,h) =e= dd(j,h) - y(j,h) ;
yd(j,h).. y(j,h) =l= sum(i, p(i,j)*x(i,j)) ;
```

The domain of definition of both equations is the Cartesian product of `j` and `h`: constraints will be generated for every set element pair that can be constructed from the members of these two sets.

The next example illustrates the use of the optional logical conditions in the definition of equations. It is taken from the production and distribution model [ferts].

```plaintext
CC(m,i)$mpos(m,i).. sum(p$ppos(p,i), b(m,p)*z(p,i)) =l= util*k(m,i) ;
```

`CC` is a capacity constraint defined for elements of the sets `m` and `i`. However, in this case not all cases of `m` exist at each location `i`, and the mapping set `mpos(m,i)` tells the cases where `m` exists at `i` and thus is used to restrict the domain cases for which the constraints are actually generated. The control of the summation over `p` with `ppos(p,i)` is an additional logical condition, and is required because not all processes `p` are possible at all locations `i`.

The equation may alternatively written in the following way:

```plaintext
CC(mpos(m,i)).. sum(ppos(p,i), b(m,p)*z(p,i)) =l= util*k(m,i) ;
```

Instead of defining the equation over the indices `(m,i)` the equation is defined over the set `mpos` that is itself defined over the indices `(m,i)`. A similar logic applies to restricting the summation.

Conditional expressions are introduced and discussed in the section Conditional Expressions, Assignments and Equations. See specifically Dollar Control over the Domain of Definition for logical conditions in equation definitions.
4.29.3.5 Using Labels Explicitly in Equations

Sometimes it can be necessary to refer to specific set elements in equations. This can be done as with parameters - by using quotes or double quotes around the label. Consider the following example from the model location:

\[ \text{sum}(m, \text{ship}_\text{wm}(\text{wh},m)) = \text{build}(\text{wh}) \times \text{data}(\text{wh},"capacity") \; ; \]

4.29.3.6 Logic Equations

Logic equations use Boolean algebra and have to evaluate to TRUE (or 1) to be feasible. The Boolean functions available in GAMS and the default order of precedence of the operators are given in Table 2. Note that 1 denotes the highest order of precedence or the most binding operator and 3 denotes the lowest order of precedence or the least binding operators. As usual, the default order of precedence holds only in the absence of parentheses and operators on the same level are evaluated from left to right.

<table>
<thead>
<tr>
<th>Function</th>
<th>Operator</th>
<th>Alternative Notation</th>
<th>Return Values</th>
<th>Order of precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Negation</td>
<td>not x</td>
<td>bool_not(x)</td>
<td>returns 1 if ( x = 0 ), else returns 0</td>
<td>1</td>
</tr>
<tr>

<td>3</td>
</tr>
<tr>
<td>Material equiv</td>
<td>x eqv y</td>
<td>bool_eqv(x,y)</td>
<td>returns 0 if exactly one argument is 0, else returns 1</td>
<td>3</td>
</tr>
</tbody>
</table>

Table 2: Boolean Functions and Operator Precedence

Note that in the table above \( x \) and \( y \) are binary variables.

There are three ways to declare and define logic equations:

1. The logic equation is declared using the keyword Logic Equation and the definition contains only Boolean algebra symbols.
2. The logic equation is declared like any other equation using the keyword Equation and in the definition the symbol \( =b= \) appears indicating that it is a logic equation.
3. This is a combination of the first two options: the equation is declared with the keyword Logic Equation and defined using the symbol \( =b= \).

The following example demonstrates the first way to declare and define a logic equation. It is adapted from the food manufacturing problem [foodemp]. In this problem the blending of oils is modeled.
Sets
  m        "planning period (month)" / m1*m6 /
p        "raw oils"         / v1*v2, o1*o3 /

Variables
  induse(m,p) "indicator for usage of raw oil per month" ;
  Binary variable induse;

Logic Equation
  deflogic(m) "if some vegetable raw oil is used we also need to use the non-vegetable oil o3" ;
  deflogic(m).. induse(m,'v1') or induse(m,'v2') -> induse(m,'o3');

The variable induse is a binary variable, it can only take the values 0 and 1. The equation ensures that in an optimal solution if either vegetable oil v1 or vegetable oil v2 is blended in a product, then non-vegetable oil o3 is also blended in that product.

An alternative formulation of the equation deflogic using the =b= notation is given below.

  deflogic(m).. induse(m,'v1') or induse(m,'v2') -> induse(m,'o3') =b= 1;

Note that the value of 1 on the right-hand side means that the logic expression on the left-hand side must evaluate to TRUE in a feasible solution. To illustrate further, we could negate the left-hand side expression using the logic operator not and then the right-hand side would have to evaluate to zero or FALSE to yield the same result as above. The respective equation definition follows.

  deflogic(m).. not (induse(m,'v1') or induse(m,'v2') -> induse(m,'o3')) =b= 0;

Note that currently logic equations are allowed only in models of the GAMS model type EMP. For more on GAMS model types see section Classification of Models.

4.29.4 Expressions in Equation Definitions

The arithmetic operators and some of the functions that are described in section Expressions may be used in equation definitions.

Consider the following example adapted from the model [chenery] demonstrating the use of parentheses and exponentiation.

  dem(i) ..   y(i) =e= ynot(i)*(pd*p(i))**thet(i) ;

A list of arithmetic operators is given in subsections Standard Arithmetic Operations and Indexed Operations.
4.29.4.1 Functions in Equation Definitions

All available GAMS functions are listed in the section Functions. Some functions are not allowed at all in equation definitions. They include random distribution functions and are marked with none in the third column of the tables listing all functions.

Attention

Some functions like uniform and normal are not allowed in equation definitions.

The use of the other functions is determined by the type of arguments in the model. There are two types of arguments:

1. **Exogenous arguments:** The arguments are known. Parameters and variable attributes (for example, .l and .m attributes) are used as arguments. The expression is evaluated once when the model is being set up and most mathematical functions as well as time and calendar functions are allowed.

2. **Endogenous arguments:** The arguments are variables and therefore unknown at the time of model setup. The function will be evaluated many times at intermediate points while the model is being solved. Note that the occurrence of any function with endogenous arguments implies that the model is not linear.

Functions that are allowed only with exogenous arguments are marked with any in the tables listing all functions.

There are two types of functions allowing endogenous arguments: smooth functions and discontinuous functions. Smooth functions are continuous functions with continuous derivatives (like sin, exp, log). Discontinuous functions include continuous functions with discontinuous derivatives (like max, min, abs) and discontinuous functions (like ceil, sign). Smooth functions may be used routinely in nonlinear models. However, discontinuous functions may cause numerical problems and should be used only if unavoidable, and only in a special model type called DNLP. For more details on model types see section Classification of Models.

Attention

The best way to model discontinuous functions is with binary variables. The result is a model of the type MINLP. The model [ABSMIP] demonstrates this formulation technique for the functions abs, min, max and sign. See also section Reformulating DNLP Models. We strongly discourage the use of the DNLP model type.

In Table 3 the use of functions in equation definitions is summarized.

<table>
<thead>
<tr>
<th>Functions are allowed ...</th>
<th>Description of Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>not at all</td>
<td>Functions that are marked none in the third column of the tables listing all functions in section Functions.</td>
</tr>
<tr>
<td>only with exogenous arguments</td>
<td>Functions that are marked any in the third column of the tables listing all functions in section Functions.</td>
</tr>
<tr>
<td>with endogenous arguments</td>
<td>Smooth functions. They are marked NLP in the third column of the tables listing all functions in section Functions.</td>
</tr>
<tr>
<td>with endogenous arguments</td>
<td>Discontinuous functions. They are marked DNLP in the third column of the tables listing all functions in section Functions.</td>
</tr>
</tbody>
</table>
4.29 Equations

Table 3: Functions in Equation Definitions

4.29.4.2 Preventing Undefined Operations in Equations

Some operations are not defined at particular values of the arguments. Two examples are division by 0 and the \( \log \)- of 0. While this can easily be identified at model setup for exogenous functions and expressions, it is a lot more difficult when the terms involve variables. The expression may be evaluated many times when the problem is being solved and the undefined result may arise only under certain cases. One way to avoid an expression becoming undefined is adding bounds to the respective variables. Consider the following example from the model [ramsey]:

\[
c_{lo}(t) = 0.01 ;
\]

\[
\text{util . utility} = \text{e= sum(t, beta(t)*log(c(t))) ;}
\]

Specifying a lower bound for \( c(t) \) that is slightly larger than 0 prevents the \( \log \)-function from becoming undefined.

4.29.5 Equation Attributes

Equation attributes may be specified in a similar way as variable attributes. Five values are associated with each unique label combination of every equation. They are denoted by the suffixes \( .l \), \( .m \), \( .lo \), \( .up \) and \( .scale \). A list of the attributes and their description is given in Table 4.

<table>
<thead>
<tr>
<th>Equation Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lower bound</td>
<td>.lo</td>
<td>Negative infinity for ( =l= ) equations. Right hand side value for ( =g=, =e=, ) and ( =b= ) equations. Zero for ( =c= ) equations.</td>
</tr>
<tr>
<td>Upper bound</td>
<td>.up</td>
<td>Positive infinity for ( =g= ) and ( =c= ) equations. Right hand side value for ( =l=, =e=, ) and ( =b= ) equations.</td>
</tr>
<tr>
<td>Equation level</td>
<td>.l</td>
<td>Level of the equation in the current solution, equal to the level of all terms involving variables.</td>
</tr>
<tr>
<td>Marginal</td>
<td>.m</td>
<td>Marginal value for equation. This attribute is reset to a new value when a model containing the equation is solved. The marginal value for an equation is also known as the shadow price for the equation and in general not defined before solution but if present it can help to provide a basis for the model</td>
</tr>
<tr>
<td>Scale factor</td>
<td>.scale</td>
<td>Numerical scaling factor that scales all coefficients in the equation. This is only used when the model attribute ( scaleopt ) is set to 1. For more on scaling, see section ( Model Scaling - The Scale Option. )</td>
</tr>
<tr>
<td>Stage</td>
<td>.stage</td>
<td>This attribute allows to assign equations to stages in a stochastic program or other block structured model. Its current use is limited to 2-stage stochastic programs solved with DECIS.</td>
</tr>
</tbody>
</table>

Table 4: Equation Attributes

Note that all attributes except for \( .scale \) and \( .stage \) contain the attribute values of equations after a solution of the model has been obtained. For some solvers it can be useful to specify marginal values \( .m \) and level values \( .l \) on input to provide starting information. Also note that the marginal value is also known as the \( dual \) or \( shadow price. \) Roughly speaking, the marginal value \( .m \) of an equation is the amount by which the value of the objective variable would change if the equation level were moved one unit.
Equation attributes may be referenced in expressions and can be used to specify starting values (see section Declaring Equations). In addition, they serve for scaling purposes and for reporting after a model was solved. For example, they may be displayed using the display statement. The following example is from the model location.

Model warehouse 'warehouse location model' /all/;
solve warehouse using mip min tcost;
display supply_eq.l;

The display statement generates the following output at the end of the listing file:

---- 108 EQUATION supply_eq.l limit on supply available at supply location

s1 50.000, s2 75.000

The level values of the equation supply_eq are displayed. As expected, there are two level values, one for each member of the set s1 over which the equation supply_eq was defined.

Note

By default, all equation attributes introduced above except for .scale are echoed to the solution report that is part of the listing file.

In addition to the equation attributes introduced above, there are a number of equation attributes that cannot be assigned but may be used in computations. They are given in Table 5.

<table>
<thead>
<tr>
<th>Equation Attribute</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>.range</td>
<td>The difference between the lower and upper bounds of an equation.</td>
</tr>
<tr>
<td>Slack lower bound</td>
<td>.slacklo</td>
<td>Slack from equation lower bound. This is defined as the greater of two values: zero or the difference between the level value and the lower bound of an equation.</td>
</tr>
<tr>
<td>Slack upper bound</td>
<td>.slackup</td>
<td>Slack from equation upper bound. This is defined as the greater of two values: zero or the difference between the upper bound and the level value of an equation.</td>
</tr>
<tr>
<td>Slack</td>
<td>.slack</td>
<td>Minimum slack from equation bound. This is defined as the minimum of two values: the slack from equation lower bound and the slack from equation upper bound.</td>
</tr>
<tr>
<td>Infeasibility</td>
<td>.infeas</td>
<td>Amount by which an equation is infeasible falling below its lower bound or above its upper bound. This is defined as max(0, lower bound - level, level - upper bound).</td>
</tr>
</tbody>
</table>

Table 5: Additional Equation Attributes that Cannot Be Assigned but May Be Used in Computations.

4.29.6 Summary and Quick Reference

In this chapter we have covered the declaration and definition of equations in GAMS, arithmetic operations and functions that may be used in equations and equation attributes. A list summarizing the main points to keep in mind follows.
4.30 Model and Solve Statements

4.30.1 Introduction

This chapter brings together all the concepts discussed in previous chapters by explaining how to specify a model and solve it.

4.30.2 The Model Statement

The model statement is used to collect equations into groups and to label them so that they can be solved. The simplest form of the model statement uses the keyword all: the model consists of all equations declared before the model statement is entered. For most simple applications this is all the user needs to know about the model statement.

- Equations must be declared before they may be defined. [1]
- It is good practice to add an explanatory text to the declaration. [2]
- More than one equation may be declared at once. The equation names have to be separated by commas or by a line break. [3]
- Equations may be declared and defined over sets which are called the domain of definition of the equation. [4]
- One indexed equation may generate many constraints depending on the size of the set(s) over which it is defined. [5]
- Equations may be defined over subsets. The dollar condition may be used to filter the members of a set so that only a subset of the members are considered. [6]
- The set(s) over which an equation is defined must be consistent with the set(s) over which the equation was declared, being the set(s) themselves or a subset of the set(s). [7]
- The arrangement of terms in an equation is up to the other. Variables can appear on both sides of an equation. [8]
- Labels of specific set elements may be used explicitly in equations. [9]
- All arithmetic operations that may be used to evaluate expressions are also allowed in equations. [10]
- Many functions that are defined in GAMS may be used in equations. [11]
- It is good practice to set bounds for variables to avoid undefined operations if equations contain operations that are undefined at certain values. [12]
- Equations have attributes similar to variables (.l, .m, .lo, .up and .scale). [13]
4.30.2.1 The Syntax

In general, the syntax for a model declaration in GAMS is as follows:

```
model[s] model_name [text] [ / (all | eqn_name {, eqn_name}) {, var_name(set_name)} /]
{,model_name [text] [ / (all | eqn_name {, eqn_name}) {, var_name(set_name)} /]} ;
```

The keyword `model[s]` indicates that this is a model statement and `model_name` is the internal name of the model in GAMS, it is an identifier. The optional explanatory text is used to describe the model, `all` is a keyword as introduced above and `eqn_name` is the name of an equation that has been declared prior to the model statement. `Var_name(set_name)` is a couple of previous declared variable and and set to limit the domain of variables in the model. More details about this are described in the following subsection. For advice on explanatory text and how to choose a `model_name`, see the tutorial Good Coding Practices.

Note

Model statements for Mixed Complementarity Problem (MCP) and Mathematical Program with Equilibrium Constraints (MPEC) models require a slightly different notation, since complementarity relationships need to be included. For details see subsections Mixed Complementarity Problem (MCP) and Mathematical Program with Equilibrium Constraints (MPEC).

An example of a model definition in GAMS is shown below.

```
Model transport "a transportation model" / all /;
```

The model is called `transport` and the keyword `all` is a shorthand for all known (declared) equations.

Several models may be declared (and defined) in one model statement. This is useful when experimenting with different ways of writing a model, or if one has different models that draw on the same data. Consider the following example, adapted from [PROLOG], in which different groups of the equations are used in alternative versions of the problem. Three versions are solved: the linear, nonlinear, and 'expenditure' versions. The model statement to define all three is:

```
Model nortonl "linear version" / cb,rc,dfl,bc,obj /
nortonn "nonlinear version" / cb,rc,dfn,bc,obj /
nortone "expenditure version" / cb,rc,dfe,bc,obj /;
```

Here `cb`, `rc`, etc. are the names of the equations. We will describe below how to obtain the solution to each of the three models.

Note

If several models are declared and defined with one model statement, the models have to be separated by commas or linefeeds and a semicolon terminates the entire statement.

If several models are declared then it is possible to use one previously declared model in the declaration of another. The following examples illustrate this:

```
Model one "first model" / tcost_eq, supply_eq, demand_eq /
two "second model that nests first" / one, balance_eq /
three "third model that nests first and second" / two, capacity_eq, configure_eq /;
```
Model one is declared and defined using the general syntax, model two contains all the equations of model one and the equation balance_eq, and model three contains all of model two and the equations capacity_eq and configure_eq.

In addition to nesting models as illustrated above, it is also possible to use the symbols + and - to augment or remove items relative to models that were previously defined. The following examples serve as illustration:

Model four "fourth model: model three minus model one" / three-one /  
  five "fifth model: model three without eqn configure_eq" / three-configure_eq /  
  six "sixth model: model four plus model two" / four+two /;

Model four contains the equations from model three except for those that belong to model one. Model five contains all equations from model three except for equation configure_eq. Model six contains the union of the equations in model four and two. Note that both model names and equation names may be used in association with the symbols + and -.

4.30.2.1.1 Limited domain for variables  As mentioned above, it is possible to limit the domain of variables used in a model in the model statement. This allows to restrict the generation of blocks of variables in a single place instead of using, e.g., dollar conditions at every place where this variable block is used in equations (which might be required for an efficient model generation).

The following examples is based on the basic transportation model [TRNSPORT]. To limit the transportation network in that model to certain links (e.g. because some are blocked because of some reason) one could introduce a subset of the free links and use that with dollar conditions in the equations like this:

* Initialize whole network as free  
Set freeLinks(i,j) Useable links in the network / #i.#j /;

  cost.. z =e= sum((i,j), c(i,j)*x(i,j)$freeLinks(i,j));
  supply(i).. sum(j, x(i,j)$freeLinks(i,j)) =l= a(i);  
  demand(j).. sum(i, x(i,j)$freeLinks(i,j)) =g= b(j);

* Block a particular link  
freetLinks('san-diego','topeka') = no;

Model transport / all /;  
solve transport using lp minimizing z;

Now, instead of adding the dollar condition to each appearance of x in the model, one could simply add a domain restriction for that variable to the model statement directly by specifying a variable and the set that limits its domain. Using this approach, the previous example looks like this:

* Initialize whole network as free  
Set freeLinks(i,j) Useable links in the network / #i.#j /;

  cost.. z =e= sum((i,j), c(i,j)*x(i,j));
  supply(i).. sum(j, x(i,j)) =l= a(i);  
  demand(j).. sum(i, x(i,j)) =g= b(j);

* Block a particular link  
freetLinks('san-diego','topeka') = no;

Model transport / all, x(freeLinks) /;  
solve transport using lp minimizing z;
Note

If one adds the domain restriction to the model statement, internally GAMS inserts a dollar condition to every appearance of the restricted variables in equations of the model. When doing this, the indices are copied as they appear with the variable. So, in the example above, \( x(i,j) \) becomes \( x(i,j)\$freeLinks(i,j) \). In the same way \( x(i-1,j+1) \) becomes \( x(i-1,j+1)\$freeLinks(i-1,j+1) \) and \( x('seattle','chicago') \) becomes \( x('seattle','chicago)\$freeLinks('seattle','chicago') \).

Attention

As a consequence of above's note one could see some unexpected results, like "division by zero errors", if it is not done carefully. For example, the following dummy model, will trigger such an error, since we sum over all \( i \), but some \( x \) were excluded leaving a 0 as divisor:

```plaintext
Set i / i1*i3 /
   sub(i) / i2 /;
Positive Variable x(i);
Variable     z;
Equation     obj;

obj.. z =e= sum(i, 1/x(i));
x.lo(i) = 1;
Model m / obj, x(sub) /;
solve m min z use nlp;
```

4.30.2.2 Classification of Models

Various types of problems can be solved with GAMS. Note that the type of the model must be known before it may be solved. The model types are briefly discussed in this section. GAMS checks that the model is in fact the type the user thinks it is, and issues explanatory error messages if it discovers a mismatch - for instance, that a supposedly linear model contains nonlinear terms. Some problems may be solved in more than one way, and the user has to choose which way to use. For instance, if there are binary or integer variables in the model, it can be solved either as a MIP or as a RMIP.

The model types and their identifiers, which are needed in the a solve statement, are given in Table 1. For details on the solve statement, see section The Solve Statement.

</tbody>
</table>

**Table 1: GAMS Model Types**

**Note**

- The relaxed model types RMIP, RMINLP, RMIQCP, and RMPEC solve the problem as the corresponding model type (e.g. MIP for RMIP) but relax the discrete requirement of the discrete variables. This means that integer and binary variables may assume any values between their bounds. SemiInteger and SemiCont variables may assume any values between 0 and their upper bound. For SOS1 and SOS2 variables the restriction of the number of non-zero values is removed.

- Many "LP" solvers like Cplex offer the functionality of solving convex quadratic models. So the Q matrices in the model need to be positive semidefinite. An extension to this are the
second-order cone programs (SOCP) with either symmetric or rotated cones. See the solver manuals (e.g. on MOSEK) for details.

• Unlike other checks on the model algebra (e.g. existence of discrete variables or general non-linear terms), the GAMS compiler does not enforce a quadratic model to only consist of quadratic and linear terms. This requirement is enforced at runtime for a particular model instance.

4.30.2.2.1 Linear Programming (LP) Mathematically, the Linear Programming (LP) problem looks like:

\[
\begin{align*}
\text{Minimize or maximize} & \quad cx \\
\text{subject to} & \quad Ax \alpha b \\
& \quad L \leq x \leq U,
\end{align*}
\]

where \(x\) is a vector of variables that are continuous real numbers, \(cx\) is the objective function, and \(Ax \alpha b\) represents the set of constraints. Here, \(\alpha\) is an equation operator. For details on the equation types allowed in GAMS, see Equation Types. \(L\) and \(U\) are vectors of lower and upper bounds on the variables.

GAMS supports free (unrestricted) variables, positive variables, and negative variables. Note that users may customize lower and upper bounds, for details see section Bounds on Variables.

For information on LP solvers that can be used through GAMS see the Solver/Model type Matrix.

4.30.2.2 Nonlinear Programming (NLP) Mathematically, the Nonlinear Programming (NLP) problem looks like:

\[
\begin{align*}
\text{Minimize or Maximize} & \quad f(x) \\
\text{subject to} & \quad g(x) \alpha 0 \\
& \quad L \leq x \leq U,
\end{align*}
\]

where \(x\) is a vector of variables that are continuous real numbers, \(f(x)\) is the objective function, and \(g(x) \alpha 0\) represents the set of constraints. For details on the equation types allowed in GAMS, see Equation Types. Note that the functions \(f(x)\) and \(g(x)\) have to be differentiable. \(L\) and \(U\) are vectors of lower and upper bounds on the variables.

For information on NLP solvers that can be used through GAMS see the Solver/Model type Matrix. See also the tutorial Good NLP Formulations.

Note

NLP models may have the nonlinear terms inactive. In this case setting the model attribute TryLinear to 1 causes GAMS to check the model and use the default LP solver if possible. For details on model attributes, see subsection Model Attributes.
4.30.2.2.3 Quadratically Constrained Programs (QCP)  Mathematically, the Quadratically Constrained Programming (QCP) problem looks like:

Maximize or Minimize \( cx + x'Qx \)
subject to \( A_i x + x'R_i x \leq b_i \) for all \( i \)
\( L \leq x \leq U, \)

where \( x \) denotes a vector of variables that are continuous real numbers, \( cx \) is the linear part of the objective function, \( x'Qx \) is the quadratic part of the objective function, \( A_i x \) represents the linear part of the \( i \)th constraint, \( x'R_i x \) its quadratic part and \( b_i \) its right-hand side. For details on the equation types allowed in GAMS, see Equation Types”. Further, \( L \) and \( U \) are vectors of lower and upper bounds on the variables.

Note that a QCP is a special case of the NLP in which all the nonlinearities are required to be quadratic. As such, any QCP model can also be solved as an NLP. However, most "LP" vendors provide routines to solve LP models with a quadratic objective. Some allow quadratic constraints as well. Solving a model using the QCP model type allows these "LP" solvers to be used to solve quadratic models as well as linear ones. Some NLP solvers may also take advantage of the special (quadratic) form when solving QCP models.

Attention

In case a model with quadratic constraints is passed to a QCP solver that only allows a quadratic objective, a capability error will be returned (solver status 6 CAPABILITY PROBLEMS). Some solvers will fail when asked to solve a non-convex quadratic problems as described above.

Note

Using the model attribute TryLinear causes GAMS to see if the problem can be solved as an LP problem. For details on model attributes, see subsection Model Attributes.

For information on QCP solvers that can be used through GAMS see the Solver/Model type Matrix.

4.30.2.2.4 Nonlinear Programming with Discontinuous Derivatives (DNLP)  Mathematically, the Nonlinear Programming with Discontinuous Derivatives (DNLP) problem looks like:

Maximize or Minimize \( f(x) \)
subject to \( g(x) \leq 0 \)
\( L \leq x \leq U, \)

where \( x \) is a vector of variables that are continuous real numbers, \( f(x) \) is the objective function, \( g(x) \leq 0 \) represents the set of constraints, and \( L \) and \( U \) are vectors of lower and upper bounds on the variables. For details on the equation types allowed in GAMS, see Equation Types. Note that this is the same as NLP, except that non-smooth functions, like \( \text{abs}, \min, \max \) may appear in \( f(x) \) and \( g(x) \).

For information on DNLP solvers that can be used through GAMS see the Solver/Model type Matrix.

Attention

- We strongly advise against using the model type DNLP. The best way to model discontinuous functions is with binary variables, which results in a model of the type MINLP. The model [ABSMMIP] demonstrates this formulation technique for the functions \( \text{abs}, \min, \max \) and \( \text{sign} \). See also section Reformulating DNLP Models.
- Solvers may have difficulties when dealing with the discontinuities, since they are really NLP solvers and the optimality conditions and the reliance on derivatives may be problematic. Using a global solver may alleviate this problem.
4.30.2.2.5 Mixed Integer Programming (MIP) Mathematically, the Mixed Integer Linear Programming (MIP) problem looks like:

Maximize or Minimize \[ c_1 t + c_2 u + c_3 v + c_4 w + c_5 x + c_6 y + c_7 z \]
subject to \[ A_1 t + A_2 u + A_3 v + A_4 w + A_5 x + A_6 y + A_7 z \leq b \]
\[ t \in \mathbb{R} \]
\[ u \geq 0 \quad \text{and} \quad u \leq L_2 \quad \text{and} \quad u \in \mathbb{Z} \]
\[ v \in (0, 1) \]
\[ w \in \text{SOS1} \]
\[ x \in \text{SOS2} \]
\[ y = 0 \quad \text{or} \quad L_6 \leq y \]
\[ z = 0 \quad \text{or} \quad L_7 \leq z \quad \text{and} \quad z \in \mathbb{Z}, \]

where

- \( c_1 t + c_2 u + c_3 v + c_4 w + c_5 x + c_6 y + c_7 z \) is the objective function,
- \( A_1 t + A_2 u + A_3 v + A_4 w + A_5 x + A_6 y + A_7 z \leq b \) represents the set of constraints of various equality and inequality forms,
- \( t \) is a vector of variables that are continuous real numbers,
- \( u \) is a vector of variables that can only take integer values smaller than \( L_2 \),
- \( v \) is a vector of binary variables,
- \( w \) is a vector of variables that belong to \( \text{SOS1} \) sets; this means that at most one variable in the set is nonzero,
- \( x \) is a vector of variables that belong to \( \text{SOS2} \) sets; this means that at most two adjacent variables in the set are nonzero,
- \( y \) is a vector of variables that are semi-continuous; they are either zero or larger than \( L_6 \),
- \( z \) is a vector of variables that are semi-integer; they are integer and either zero or larger than \( L_7 \).

For details on the equation types allowed in GAMS, see Equation Types. For more details on MIPs in GAMS, especially the use of \( \text{SOS} \) and \( \text{semi} \) variables, see section Special Mixed Integer Programming (MIP) Features.

For information on MIP solvers that can be used through GAMS see the Solver/Model type Matrix.

Attention

Not all MIP solvers cover all the cases associated with \( \text{SOS} \) and \( \text{semi} \) variables. Please consult the solver manuals for details on capabilities.

4.30.2.2.6 Mixed Integer Nonlinear Programming (MINLP) Mathematically, the Mixed Integer Nonlinear Programming (MINLP) problem looks like:

Maximize or Minimize \[ f(x) + Dy \]
subject to \[ g(x) + Hy \leq 0 \]
\[ L \leq x \leq U \]
\[ y = \{0, 1, 2, \ldots\}, \]

where \( x \) is a vector of variables that are continuous real numbers, \( y \) denotes a vector of variables that can only take integer values, \( f(x) + Dy \) is the objective function, \( g(x) + Hy \leq 0 \) represents the set of constraints, and \( L \) and \( U \) are vectors of lower and upper bounds on the variables. For details on the equation types allowed in GAMS, see Equation Types. Further, \( y = \{0, 1, 2, \ldots\} \) is the integrality restriction on \( y \).

For information on MINLP solvers that can be used through GAMS see the Solver/Model type Matrix.
4.30 Model and Solve Statements

Note

• SOS and semi variables can also be accommodated by some solvers. Please consult the solver manuals for details on capabilities.

• The model attribute TryLinear causes GAMS to examine whether the problem may be solved as a MIP problem. For details on model attributes, see subsection Model Attributes.

4.30.2.2.7 Mixed Integer Quadratically Constrained Programs (MIQCP) A Mixed Integer Quadratically Constrained Program (MIQCP) is a special case of the MINLP in which all the nonlinearities are required to be quadratic. For details see the description of the QCP, a special case of the NLP.

For information on MIQCP solvers that can be used through GAMS, see the Solver/Model type Matrix.

Note

The model attribute TryLinear causes GAMS to examine whether the problem may be solved as a MIP problem. For details on model attributes, see subsection Model Attributes.

4.30.2.2.8 Mixed Complementarity Problem (MCP) Unlike the other model types we have introduced so far, the Mixed Complementarity Problem (MCP) does not have an objective function. An MCP is specified by three pieces of data: a function \( F(z) : \mathbb{R}^n \rightarrow \mathbb{R}^n \), lower bounds \( \ell \in \{ \mathbb{R} \cup \{-\infty\} \}^n \) and upper bounds \( u \in \{ \mathbb{R} \cup \{\infty\} \}^n \). A solution is a vector \( z \in \mathbb{R}^n \) such that for each \( i \in \{1, \ldots, n\} \), one of the following three conditions hold:

\[
\begin{align*}
F_i(z) = 0 & \quad \text{and} \quad \ell_i \leq z_i \leq u_i \quad \text{or} \\
F_i(z) > 0 & \quad \text{and} \quad z_i = \ell_i \quad \text{or} \\
F_i(z) < 0 & \quad \text{and} \quad z_i = u_i.
\end{align*}
\]

This problem can be written compactly as

\[
F(z) \perp L \leq z \leq U,
\]

where the symbol \( \perp \) (which means "perpendicular to", shortened to "perp to") indicates pair-wise complementarity between the function \( F \) and the variable \( z \) and its bounds.

The following special case is an important and illustrative example:

\[
F(z) \perp z \geq 0.
\]

In this example, the unstated but implied upper bound \( u \) is infinity. Since \( z \) is finite, we cannot have \( z_i = u_i \) and the third condition above cannot hold: this implies \( F(z) > 0 \). The remaining two conditions imply pair-wise complementarity between \( z \geq 0 \) and \( F(z) \geq 0 \). This is exactly the Nonlinear Complementarity Problem, often written as

\[
F(z) \geq 0, \quad z \geq 0, \quad \langle F(z), z \rangle = 0.
\]

None of this rules out the degenerate case (i.e. \( F_i(z) \) and \( z_i \) both zero). In practice, these can be difficult models to solve.

Another special case arises when the bounds \( L \) and \( U \) are infinite. In this case, the second and third conditions above cannot hold, so we are left with \( F(z) = 0 \), a square system of nonlinear equations. And finally, we should mention a special case that occurs frequently in practice: if \( \ell_i = u_i \) (i.e. \( z_i \) is fixed) then we have a complementary pair: one of the three conditions will hold as long as \( F_i(z) \) is defined. Essentially, fixing a variable removes or obviates the matching equation. This is often useful when modeling with MCP.

The definition above describes the canonical MCP model as it exists when GAMS passes it to an MCP solver. Some models have exactly this form even in the GAMS code, but usually some processing is done by the GAMS system to arrive at a model in this form. Here we'll describe the steps of this process and illustrate with an example from the model library.
1. The process starts with the list of rows (aka single equations) and columns (aka single variables) that make up the MCP model, and potentially some matching information.

- The usual rules apply: rows are part of the model because their associated equations are included in the model statement, but columns only become part of the model by use: a column enters the model only if it is used in some row of the model. Therefore including a variable symbol as part of a match in the model statement will not influence the set of columns belonging to the model.
- Matches (where they exist) are pointers from rows to columns.
- Technically, the MCP is defined via a function $F$ while a model contains constraints. Given a constraint, we define an associated function as LHS - RHS, so e.g. $F_i \geq 0$ is consistent with a =G= constraint.

2. The explicit matches are processed: each match creates a complementary pair. What remains after the explicit matches are consumed are the unmatched rows and unmatched columns.

- It is an error for any column to be matched to multiple rows, so the row-column matching is one-to-one.
- For each match some consistency checks between the column bounds and the row type are made. For details, see Table 2.
- For example, matching an =N= row with any column is good, matching an =E= row with a free column is good, matching an =E= row with a lower-bounded column is allowed, and matching a =G= row with an upper-bounded column results in an error.

3. Any fixed columns remaining are ignored: these columns can be treated like exogenous variables or parameters.

4. If what remains is a set of =E= rows and an equal number of unbounded columns, these can be matched up in any order and we have a well-defined MCP. If this is not what remains, an error is triggered.

To illustrate how this works, consider the spatial equilibrium model [SPATEQU] with the following model statement:

```
Model P2R3_MCP / dem, sup, in_out.p, dom_trad.x /;
```

1. The model P2R3_MCP includes the rows from equations dem, sup, in_out and exactly the columns used by these rows. Checking the listing file, we see columns for Qd, Qs, x, and p. In addition, the model statement specifies two matches: in_out.p and dom_trad.x. These matches always take the form of an equation.variable pair, with no indices or domains included.

2. In this example, the rows corresponding to the equation in_out match up perfectly with the columns from the variable p: there are no holes in the set of rows or columns because of some dollar conditions in the equation definition. We have a one-to-one match so all the rows of in_out and columns of p are consumed by the match in the model statement. The same holds for the dom_trad.x pair, so what is left are the rows of dem and sup and the columns of Qd and Qs, all of which are unmatched.

3. There are no fixed variables to remove.

4. Since dem and sup are =E= constraints and Qd and Qs are free variables, we can match them in any order without changing the solution set for this model. The counts of these unmatched equality rows and unmatched free variables are equal, so we get a well-defined MCP.

When rows are matched explicitly to columns, some care must be taken to match them consistently. For example, consider a row-column match g.y. The row g can be of several types: =N=, =E=, =G=, or =L=. An =N= row can be matched to any sort of variable: the =N= doesn’t imply any sort of relationship, which works perfectly with our definition of $\perp$ above: the allowed sign or direction of $g$ is determined completely...
by the bounds on the complementary variable $y$. If $g$ is an $=E=$ row, this is consistent with a free variable $y$, but what if $y$ has an active lower bound? By definition we allow $g$ to be positive at solution, but this violates the declaration as an $=E=$ row. Such cases can be handled by marking the row with a *redef*. The total number of redefs for a given model is available via the `NumRedef` model attribute and is shown in the report summary. Note that the set of rows marked depends on the solution: in the example above, if $g$ is zero at solution it will not be marked as a redef, regardless of what the bounds are on $y$. Finally, some combinations are simply not allowed: they will result in a model generation error. The table below lists the outcome for all possible combinations.

**Table 2: MCP Matching**

<table>
<thead>
<tr>
<th>Column Bounds</th>
<th>$=N=$</th>
<th>$=E=$</th>
<th>$=G=$</th>

</tr>
</tbody>
</table>

The definition, process, and rules above have several implications for valid MCP models:

- It is always acceptable to use the $=N=$ notation when defining the equations in an MCP model, provided these equations are matched explicitly. In this case the bounds on $F(z)$ are implied by the bounds on the matching columns, and redefs will never occur.
- Variables that are known to be lower-bounded (no upper bound) will match consistently with $=G=$ equations.
- Variables that are known to be upper-bounded (no lower bound) will match consistently with $=L=$ equations.
- Variables that are known to be unbounded will match consistently with $=E=$ equations.
- Where the bound structure is not known in advance, or both upper and lower bounds exist, a match with an $=N=$ equation will always be consistent. Other equation types will result in errors or redefs.
- The model may initially have fewer rows than columns, as long as the “extra” columns are unmatched fixed columns that ultimately get removed from the MCP passed to the solver.
- Any bounded-but-not-fixed column must be matched explicitly to a row.
- The only rows that may be unmatched are $=E=$ rows.
- It is customary to re-use the constraints of an LP or NLP model when formulating the MCP corresponding to the Karush-Kuhn-Tucker (KKT) conditions. If the original model is a *minimization*, the LP/NLP marginals .m and the variables for these marginals in the MCP will use the same sign convention, and the orientation for the constraints will be consistent between the two models, making re-use easier.

As mentioned above, it is typical to use the same equations in both NLP and MCP models. Sometimes, it is not the original equation that is wanted for the MCP, but rather the reoriented (aka negated or flipped) equation. For example, the flipped version of $x^{++1.5} =L= y$ is $y =G= x^{++1.5}$, while $\text{sqr}(u) - \text{sqr}(v) =E= 5$ becomes $-\text{sqr}(u) + \text{sqr}(v) =E= -5$. Instead of re-implementing the equation in flipped form, the same result can be achieved by prefixing the equation name with a `-` in the model statement. See the [mcp10] model for an example of such usage. When equations are used in flipped form, they are marked with a *redir* in the listing file’s solution listing.

An example of complementarity that should be familiar to many is the relationship between a constraint and its associated dual multiplier: if the constraint is non-binding, its dual multiplier must be zero (i.e. at
bound) while if a dual multiplier is nonzero the associated constraint must be binding. In fact, the KKT or first-order optimality conditions for LP and NLP models can be expressed and solved as an MCP.

These complementarity relationships found in optimization problems are useful in understanding the marginal values assigned to rows and columns in the GAMS solution for MCP. With no objective function, the usual definition for marginal values and their interpretation isn’t useful. Instead, the GAMS MCP convention for the marginal values of columns is to return the slack of the associated row (i.e. its value when interpreted and evaluated as a function). For the marginal values of rows, the level value (not the slack) of the associated column is returned. When we apply this convention to the NCP \( F(z) \geq 0, z \geq 0, \langle F(z), z \rangle = 0 \) we see pairwise complementarity between the levels and marginals returned for each of the rows and columns in the model. This is also the case if we take the KKT conditions of an LP in a suitable standard form: minimization, \( x \geq 0, Ax \geq b \).

MCPs arise in many application areas including applied economics, game theory, structural engineering and chemical engineering. For further details on this class of problems, see http://www.neos-guide.org/content/complementarity-problems.

For information on MCP solvers that can be used through GAMS, see Solver/Model type Matrix.

### 4.30.2.2.9 Constrained Nonlinear System (CNS)

The Constrained Nonlinear System (CNS) is the second GAMS model type that does not have an objective function. Mathematically, a CNS model looks like:

\[
\begin{align*}
\text{Find} \\
\text{subject to}
\end{align*}
\]

\[
x
\]

\[
F(x) = 0
\]

\[
L \leq x \leq U
\]

\[
G(x) \alpha b,
\]

where \( x \) is a set of continuous variables and \( F \) is a set of nonlinear equations of the same dimension as \( x \). This is a key property of this model type: the number of equations equals the number of variables, so we have a square system. The (possibly empty) constraints \( L \leq x \leq U \) are not intended to be binding at the solution, but instead are included to constrain the solution to a particular domain, to avoid regions where \( F(x) \) is undefined, or perhaps just to give the solver a push in the right direction. The (possibly empty) constraints \( G(x) \alpha b \) are intended to serve the same purpose as the variable bounds and are silently converted to equations with bounded slacks.

Note that since there is no objective in a CNS model, there are no marginal values for variables and equations. Any marginal values already stored in the GAMS database will remain untouched. CNS models also make use of some model status values that allow a solver to indicate if the solution is unique (e.g. for a non-singular linear system) or if the linearization is singular at the solution. For singular models (solved or otherwise), the solver can mark one or more dependent rows with a \( \text{depnd} \). The total number of rows so marked for a given model is available via the \( \text{NumDepnd} \) model attribute and is shown in the report summary.

The CNS model is a generalization of a square system of equations \( F(x) = 0 \). Such a system could also be modeled as an NLP with a dummy objective. However, there are a number of advantages to using the CNS model type, including:

- A check by GAMS that the model is really square,
- solution/model diagnostics by the solver (e.g. singular at solution, (locally) unique solution),
- CNS-specific warnings if the side constraints \( L \leq x \leq U \) or \( G(x) \alpha b \) are active at a solution,
- and potential improvement in solution times, by taking better advantage of the model properties.

For information on CNS solvers that can be used through GAMS, see the Solver/Model type Matrix.
4.30.2.2.10 Mathematical Program with Equilibrium Constraints (MPEC) Mathematically, the Mathematical Program with Equilibrium Constraints (MPEC) problem looks like:

\[
\begin{align*}
\text{Maximize or Minimize} & \quad f(x, y) \\
\text{subject to} & \quad g(x, y) \leq 0 \\
& \quad L_x \leq x \leq U_x \\
& \quad F(x, y) \perp L_y \leq y \leq U_y,
\end{align*}
\]

where \( x \) and \( y \) are vectors of continuous real variables. The variables \( x \) are often called the control or upper-level variables, while the variables \( y \) are called the state or lower-level variables. \( f(x, y) \) is the objective function. \( g(x, y) \leq 0 \) represents the set of traditional (i.e., NLP-type) constraints; some solvers may require that these constraints only involve the control variables \( x \). The function \( F(x, y) \) and the bounds \( L_y \) and \( U_y \) define the equilibrium constraints. If \( x \) is fixed, then \( F(x, y) \) and the bounds \( L_y \) and \( U_y \) define an MCP; the discussion of the "perp to" symbol \( \perp \) in that section applies here as well. From this definition, we see that the MPEC model type contains NLP and MCP models as special cases of MPEC.

A simple example of an entire MPEC model is given below.

```gams
variable z, x1, x2, y1, y2;
positive variable y1;
y2.lo = -1;
y2.up = 1;
equations cost, g, h1, h2;
cost.. z =E= x1 + x2;
g.. sqr(x1) + sqr(x2) =L= 1;
h1.. x1 =G= y1 - y2 + 1;
h2.. x2 + y2 =N= 0;
model example / cost, g, h1.y1, h2.y2 /;
solve example using mpec min z;
```

Note that as in the MCP, the complementarity relationships in an MPEC are specified in the model statement via equation-variable pairs: the \( h1.y1 \) specifies that the equation \( h1 \) is perpendicular to the variable \( y1 \) and the \( h2.y2 \) specifies that the equation \( h2 \) is perpendicular to the variable \( y2 \). For details on the solve statement, see section The Solve Statement.

While the MPEC model formulation is very general, it also results in problems that can be very difficult to solve. The state-of-the-art for MPEC solvers is not nearly as advanced as that for other model types. As a result, you should expect the MPEC solvers to be more limited by problem size and/or robustness issues than solvers for other model types.

For information on MPEC solvers that can be used through GAMS, see the Solver/Model type Matrix. For more details on MPECs and solver development, see [http://www.neos-guide.org/content/mathematical-programs-equilibrium-constraints](http://www.neos-guide.org/content/mathematical-programs-equilibrium-constraints).

4.30.2.2.11 Extended Mathematical Programs (EMP) Extended Mathematical Programming (EMP) is an (experimental) framework for automated mathematical programming reformulations. Using EMP, model formulations that GAMS cannot currently handle directly or for which no robust and mature solver technology exists can be automatically and reliably reformulated or transformed into models for which robust and mature solver technology does exist within the GAMS system. For more details, see the chapter on EMP. Currently EMP supports:

- Equilibrium problems including variational inequalities, Nash games, and Multiple Optimization Problems with Equilibrium Constraints (MOPECs).
Hierarchical optimization problems such as bilevel programs.

- Disjunctive programs for modeling discrete choices with binary variables.

- Stochastic programs including two-stage and multi-stage stochastic programs, chance constraints and risk measures such as Variance at Risk (VaR) and Conditional Variance at Risk (CVaR).

Apart from the disjunctive and stochastic programming models mentioned above, EMP models are typically processed (aka solved) via the JAMS solver: this solver does the work of reformulation/transformation, calling GAMS to solve this reformulation, and post-processing the solution that results to bring it back in terms of the original EMP model.

Examples demonstrating how to use the EMP framework and the JAMS and DE solvers are available in the GAMS EMP Library. These solvers require no license of their own to run but can and do call subsolvers that do require a license.

4.30.2.3 Model Attributes

Models have attributes that hold a variety of information, including

- information about the results of a solve performed, a solve statement, the solution of a model,
- information about certain features to be used by GAMS or the solver,
- information passed to GAMS or the solver specifying various settings that are also subject to option statements.

Model attributes are accessed in the following way:

\[
\text{model\_name.attribute}
\]

Here model\_name is the name of the model in GAMS and .attribute is the specific attribute that is to be accessed. Model attributes may be used on the left-hand side and the right-hand side of assignments. Consider the following example:

\[
\begin{align*}
\text{transport.resLim} & = 600; \\
x & = \text{transport.modelStat};
\end{align*}
\]

In the first line the attribute .resLim of the model transport is specified to be 600 (seconds). In the second line the value of the attribute .modelStat of the model transport is assigned to the scalar x. Note that model attributes may also be used in display statements.

Some of the attributes are mainly used before the solve statement to provide information to GAMS or the solver link. Others are set by GAMS or the solver link and hence are mainly used after a solve statement.

Moreover, some of the attributes used before the solve may also be set via an option statement or the command line. Consider the following example:

\[
\text{option ResLim=10;}
\]
This line is an option statement and applies to all models. One can set the model attribute .ResLim to overwrite the global ResLim option. In order to revert the individual .ResLim to the global ResLim option, one needs to set the model attribute to NA. For more on option statements, see chapter The Option Statement.

```plaintext
  gams mymodel ResLim=10
```

This sets the global ResLim option when invoking the gams run (e.g. from the command line). For more on command line parameters, see chapter The GAMS Call and Command Line Parameters.

Note that a model-specific option takes precedence over the global setting specified with an option statement and that a setting via an option statement takes precedence over a setting via the command line parameter.

The complete list of model attributes is given below. Observe that each entry is linked to a detailed description of the respective attribute, including information of whether the attribute is also available as command line parameter or option statement. Note that detailed descriptions of all GAMS command line parameters, options and model attributes are given in section Detailed Descriptions of All Options.

### 4.30.2.3.2 Model Attributes Mainly Used After Solve

### 4.30.3 The Solve Statement

Once a model has been defined using the model statement, the solve statement prompts GAMS to call one of the available solvers for the particular model type. This section introduces and discusses the solve statement in detail. For a list of GAMS model types, see Table 1. For information on how to specify desired solvers, see section Choosing a Solver.

**Note**

It is important to remember that GAMS does *not* solve the problem, but passes the problem definition to one of a number of separate solver programs that are integrated with the GAMS system.

### 4.30.3.1 The Syntax of the Solve Statement

In general, the syntax for a `solve` statement is as follows. Note that there are two alternatives that are equally valid:

```gams
solve model_name using model_type maximizing|minimizing var_name;
solve model_name maximizing|minimizing var_name using model_type ;
```

The keyword `solve` indicates that this is a `solve` statement. `Model_name` is the name of the model as defined by a `model` statement. Note that the `model` statement must be placed before the `solve` statement in the program. The keyword `using` is followed by `model_type`, which is one of the GAMS model types described above, see Table 1. The keywords `maximizing` or `minimizing` indicate the direction of the optimization. `Var_name` is the name of the objective variable that is being optimized. An example of a `solve` statement in GAMS is shown below.

```gams
Solve transport using lp minimizing cost ;
```

`Solve` and `using` are reserved words, `transport` is the name of the model, `lp` is the model type, `minimizing` is the direction of optimization, and `cost` is the objective variable. Note that an objective variable is used instead of an objective row or function.
Attention

The objective variable must be scalar and of type free, and must appear in at least one of the equations in the model.

Recall that some model types (e.g. the Constrained Nonlinear System (CNS) or the Mixed Complementarity Problem (MCP)) do not have an objective variable. So their solve statement syntax is slightly different:

solve model_name using model_type;

As before, solve and using are keywords, model_name is the name of the model as defined by a model statement and model_type is the GAMS model type CNS or MCP. There is no objective variable and consequently no direction of optimization. An example from the spatial equilibrium model [SPATEQU] illustrates this solve statement:

Solve P2R3_MCP using mcp;

P2R3_MCP is the model name, the model type is MCP and as expected, there is no objective variable.

The EMP model type serves many purposes including some experimental ones. The solve statement with model type EMP can be with or without the objective variable and optimization direction. For more information, see chapter Extended Mathematical Programming (EMP).

4.30.3.2 Actions Triggered by the Solve Statement

When GAMS encounters a solve statement during compilation (the syntactic check of the input file) or execution (actual execution of the program), it initiates a number of special actions. The purpose is to prevent waste that would be caused by solving a model that has apparently been incorrectly specified. During compilation the following are verified:

1. All symbolic equations have been defined and the objective variable is used in at least one of the equations.
2. The objective variable is scalar and of type free (even though lower and upper bounds may have been specified)
3. MCP models are checked for appropriate complementarity and squareness.
4. Each equation fits into the specified problem class (linearity for LP, continuous derivatives for NLP, as outlined above).
5. All sets and parameters in the equations have values assigned.
4.30 Model and Solve Statements

Note

GAMS issues explanatory error messages if it discovers that the model is not according to type; for example, the presence of nonlinear terms in a supposedly LP model. For details on error messages, see chapter GAMS Output.

At execution time the solve statement triggers the following sequence of steps:

1. The model is translated into the representation required by the solution system to be used.

2. Debugging and comprehension aids that the user wishes to see are produced and written to the output file (EQUATION LISTING, etc). For customizing options (e.g. LimRow and LimCol), see chapter The Option Statement.

3. GAMS verifies that there are no inconsistent bounds or unacceptable values (for example, NA or UNDF) in the problem.

4. Any errors detected at this stage cause termination with as much explanation as possible, using the GAMS names for the identifiers causing the trouble.

5. GAMS designs a solution strategy based on the possible availability of level values or basis information from a previous solution: all available information is used to provide efficiency and robustness of operation. Any specifications provided by the user (Iteration limits etc.) are incorporated. A solver is chosen which is either the default solver for that problem type, the solver specified on the command line or the solver chosen by an option statement. For details see section Choosing a Solver.

6. GAMS passes control to the solution subsystem and waits while the problem is being solved.

7. GAMS reports on the status of the solution process and loads solution values back into the GAMS database. This causes new values to be assigned to the .l and .m fields for all individual equations and variables in the model. In addition, the post solution model attributes are assigned. The procedure for loading back the data associated with level and marginal values may be customized using the SolveOpt model attribute and option. A row by row and column by column listing of the solution is provided by default. It may be suppressed by the SolPrint model attribute or option. Any apparent difficulty with the solution process will cause explanatory messages to be displayed. Errors caused by forbidden nonlinear operations are reported at this stage.

Note

When the solver does not provide a dual solution (.m), then GAMS does not print the marginal column in the solution listing and set the marginal field in variables and equations to NA.

The outputs from these steps, including any possible error messages, are discussed in detail in chapter GAMS Output.

4.30.4 Programs with Several Solve Statements

Several solve statements can be processed in the same program. The next few subsections discuss various instances where several solve statements may be needed in the same file. If sequences of expensive or difficult models are to be solved, it might be useful to interrupt program execution and continue later. For details on this topic, see chapter The Save and Restart Feature.
4.30.4.1 Several Models

If there are different models then the solves may be sequential, as below. Each of the models in \([\text{PROLOG}]\) consists of a different set of equations, but the data are identical, so the three solves appear in sequence with no intervening assignments:

Solve nortonl using nlp maximizing z;
Solve nortonn using nlp maximizing z;
Solve nortone using nlp maximizing z;

When there is more than one solve statement in the program, GAMS uses as much information as possible from the previous solution to provide a starting point or basis in the search for the next solution.

4.30.4.2 Loop: One Model, Different Data

Multiple solves may also occur as a result of a solve statement within a \(\text{loop}\) statement. Loop statements are introduced and discussed in detail in chapter Programming Flow Control Features; here we show that they may contain a solve statement and thus lead to multiple solves within one model. The example from \([\text{MEANVAR}]\) computes the efficient frontier for return and variance for a portfolio selection problem at equidistance points.

\[
\begin{align*}
\text{loop(p(pp),} & \quad v.fx = v.min + (v.max-v.min)/(\text{card(pp)}+1)\text{*ord(pp);} \\
& \quad \text{Solve var1 maximizing m using nlp;} \\
& \quad xres(1,p) = x.l(i); \\
& \quad xres(\text{mean}',p) = m.l; \\
& \quad xres(\text{var}',p) = v.l; \\
\end{align*}
\]

The set \(p\) is a set of point between the minimum and maximum variance, it is the driving set of the loop. A variance variable \(v\) is fixed at a equidistance points. With each iteration through the loop another variance level is used, the \(\text{NLP}\) model var1 is solved for each iteration and the outputs are stored in the parameter \(xres(*,p)\), to be used later for reporting. As often for reporting purposes, the universal set \(*\) is used.

This example demonstrates how to solve the same model (in terms of variables and equations) multiple times with slightly different data. For such situations the Gather-Update-Solve-Scatter (GUSS) facility improves on the loop implementation by saving generation time and minimizing the communication with the solver. GUSS is activated by the additional keyword \text{scenario} in the solve statement followed by a set name that provides mapping information between parameters in the model and the scenario containers. A GUSS implementation of the loop would look as follows:

\[
\begin{align*}
\text{parameter vfx(p), px(p,i), pm(p);} \\
\text{set dict / p .scenario.''} \\
& \quad v \text{.fixed .vfx} \\
& \quad x \text{.level .px} \\
& \quad m \text{.level .pm /;} \\
& \quad vfx(p(pp)) = v.min + (v.max-v.min)/(\text{card(pp)}+1)\text{*ord(pp);} \\
& \quad \text{Solve var1 maximizing m using nlp scenario dict;} \\
& \quad xres(1,p) = px(p,i); \\
& \quad xres(\text{mean}',p) = pm(p); \\
& \quad xres(\text{var}',p) = vfx(p); \\
\end{align*}
\]
4.30.4.3 Customizing Solution Management: SolveOpt

It is important to consider how GAMS manages solutions if multiple models are solved. By default, GAMS merges subsequent solutions with prior solutions. This is not an issue if all models operate over the same set of variables. However, recursive procedures, different equation inclusions or logical conditions may cause only part of the variables or different variables to appear in the models to be solved. In such a case it might be useful to modify the solution management procedure using the model attribute or option SolveOpt.

4.30.4.4 Sensitivity or Scenario Analysis

Multiple solve statements can be used not only to solve different models, but also to conduct sensitivity tests, or to perform case (or scenario) analyses of models by changing data or bounds and then solving the same model again. While some commercial LP systems allow access to “sensitivity analysis” through GAMS it is possible to be far more general and not restrict the analysis to either solver or model type. This facility is even more useful for studying many scenarios since no commercial solver will provide this information.

An example of sensitivity testing is in the simple oil-refining model [MARCO]. Because of pollution control, one of the key parameters in oil refinery models is an upper bound on the sulfur content of the fuel oil produced by the refinery. In this example, the upper bound on the sulfur content of fuel oil was set to 3.5 percent in the original data for the problem. First, the model is solved with this value. Next, a slightly lower value of 3.4 percent is used and the model is solved again. Finally, the considerably higher value of 5 percent is used and the model is solved for the last time. Key solution values are saved for later reporting after each solve. This is necessary because a following solve replaces any existing values. The key solution values are the activity levels of the process level $z$, a variable that is defined over a set of processes $p$ and a set of crude oils $cr$. The complete sequence is:

```gams
parameter report(*,*,*) "process level report";

qs('upper','fuel-oil','sulfur') = 3.5 ;
Solve oil using lp maximizing phi;
report(cr,p,'base') = z.l(cr,p) ;
report('sulfur','limit','base') = qs('upper','fuel-oil','sulfur');

qs('upper','fuel-oil','sulfur') = 3.4 ;
Solve oil using lp maximizing phi ;
report(cr,p,'one') = z.l(cr,p) ;
report('sulfur','limit','one') = qs ('upper','fuel-oil','sulfur');

qs('upper','fuel-oil','sulfur') = 5.0 ;
Solve oil using lp maximizing phi ;
report(cr,p,'two') = z.l(cr,p) ;
report('sulfur','limit','two') = qs('upper','fuel-oil','sulfur');

Display report ;
```

Note that the parameter report is defined over the universal set or short universe. In general, the universe is useful when generating reports, otherwise it would be necessary to provide special sets containing the labels used in the report. Any mistakes made in spelling labels used only in the report should be immediately apparent, and their effects should be limited to the report. The parameter qs is used to set the upper bound on the sulfur content in the fuel-oil, and the value is retrieved for the report. Note that the display statement in the final line is introduced and discussed in detail in chapter The Display Statement. This example shows not only how simply sensitivity analysis can be done, but also how the associated multi-case reporting can be handled.

The output from the display statement is shown below. Observe that there is no production at all if the permissible sulfur content is lowered. The case attributes have been listed in the row SULFUR.LIMIT. Section Global Display Controls contains more details on how to arrange reports in a variety of ways.
### 4.30.4.5 Iterative Implementation of Non-Standard Algorithms

Another use of multiple solve statements is to permit iterative solution of different blocks of equations, most often using solution values from the first solve as data for the next solve. These decomposition methods are useful for certain classes of problems because the subproblems being solved are smaller, and therefore more tractable. One of the most common examples of such a method is the Dantzig-Wolfe decomposition.

An example of a problem that is solved in this way is a multi-commodity network flow problem in [DANWOLFE].

### 4.30.5 Choosing a Solver

After a model has been checked and prepared as described above, GAMS passes the model to a solver. When the GAMS system is installed default solvers for all model types are specified and these solvers are used if the user doesn’t specify anything else. It is easy to switch to other appropriate solvers provided the user has the corresponding license. There are multiple ways to switch solvers:

1. Using a command line parameter of the following form:
   
   ```
   gams mymodel model_type=solver name
   ```
   
   For example,
   
   ```
   gams mymodel lp=cbc
   ```

2. With an option command of the following form that is placed before the `solve` statement:
   
   ```
   Option model_type=solver_name;
   ```
   
   Here `option` is a keyword, `model_type` is the same model type that is used in the `solve` statement and `solver_name` is the name of one of the available solvers. For example,
   
   ```
   Option LP=cbc, NLP=conopt, MIP=cbc, MINLP=default;
   ```
   
   The `MINLP=default` switches back to the default solver for the MINLP model type.
3. Instead of providing a particular solver for a model type, the option `Solver` can be used to use a given solver for all model types this solver can handle.

    Option Solver=cbc;

4. (Re)running `gamsinst` at any time and altering the choice of default solver as described in the installation notes.

Note

A list of all solvers and current default solvers may be generated in the listing file with `Option SubSystems;`.

### 4.30.6 Making New Solvers Available with GAMS

This short section is to encourage those of you who have a favorite solver not available through GAMS. Linking a solver program with GAMS requires some programming skills and the use of libraries provided by GAMS. There is a collection of open source solver links to GAMS at the COIN-OR project [GAMSLinks](http://www.gams.com/links). The benefits of a link with GAMS to the developer of a solver are several. They include:

- Immediate access to a wide variety of test problems.
- An easy way of making performance comparisons between solvers.
- The guarantee that a user has not somehow provided an illegal input specification.
- Elaborate documentation, particularly of input formats, is not needed.
- Access to the existing community of GAMS users, for marketing or testing.

This completes the discussion of the model and solve statements.

### 4.31 Conditional Expressions, Assignments and Equations

#### 4.31.1 Introduction

This chapter deals with the way in which conditional assignments, expressions and equations are made in GAMS. The index operations already described are very powerful, but it is necessary to allow for exceptions of one sort or another. For example, heavy trucks may not be able to use a particular route because of a weak bridge, or some sectors in an economy may not produce exportable products. Exceptions such as these may easily be modeled with a logical condition combined with the dollar operator `$`, a very powerful feature of GAMS introduced in this chapter.

This chapter is organized as follows: We will introduce the general form of the dollar condition first and then we will focus on the various types of logical conditions. Next, we will discuss how dollar conditions are used to build conditional assignments, conditional indexed operations and conditional equations. We will conclude the chapter by showing that in certain cases conditions may be modeled using filtering sets instead of the dollar operator. Programming flow control features such as the if statement, the loop, the while statement, and the for statement are not covered in this chapter. These can be found in the chapter [Programming Flow Control Features](#).
4.31.2 The Dollar Condition

The dollar operator is one of the most powerful features in GAMS. The general syntax for a conditional expression is:

\[
term \; $ \; \text{logical\_condition}
\]

Here, \textit{term} can be a number, a (indexed) symbol, and also a complex expression. The dollar operator may be read as \textit{under the condition that} the following \textit{logical\_condition} evaluates to \textbf{TRUE} (or is unequal 0).

Consider the following simple condition, where \(a\) and \(b\) are scalars.

\[
\text{if (} b > 1.5 \text{), then } a = 2
\]

This can be written in GAMS using the dollar operator as follows.

\[
a \; $ \; (b > 1.5) \; = \; 2 \;
\]

Note that the \textit{term} is the scalar \(a\) and the \textit{logical\_condition} is the expression \((b > 1.5)\). If the condition is not satisfied, no assignment is made. To make it clear, this conditional assignment may be read as: \textit{‘given that \(b\) is greater than 1.5, \(a\) equals 2’}.

Logical conditions may take various forms, they are introduced in the next section. Conditional expressions may be used in the context of assignments, indexed operations and equations. These topics are covered in later sections of this chapter.

\textbf{Note}

Logical conditions used with the dollar operator cannot contain variables. However, \textit{variable attributes} are allowed.

4.31.3 Logical Conditions

Logical conditions are special expressions that evaluate to a value of either \textbf{TRUE} or \textbf{FALSE}. Logical conditions may be numerical expressions and numerical relations, they may refer to set membership and they may also contain acronyms. In the following subsections this is shown in the context of simple conditional assignments with the dollar operator on the left-hand side (compare section \textit{Dollar on the Left}).

In this section we use many examples to illustrate the concepts that are being introduced. In all these examples \(a\) and \(b\) are scalars, \(s, t, u\) and \(v\) are parameters, and \(i\) and \(j\) are sets.
4.31 Conditional Expressions, Assignments and Equations

4.31.3.1 Logical Conditions: Numerical Expressions

Numerical expressions may serve as logical conditions: a result of zero is treated as the logical value \texttt{FALSE} and a non-zero result is treated as the logical value \texttt{TRUE}. The following example illustrates this point.

\[
\begin{align*}
b &\implies (2\times a - 4) = 7; \\
\end{align*}
\]

Here the numerical expression \((2\times a - 4)\) is the logical condition. The numerical expression is zero if \(a\) equals 2, and non-zero otherwise. Hence the logical value of the expression is \texttt{FALSE} for \(a = 2\) and \texttt{TRUE} for all other values of \(a\). The assignment is only made if the numerical expression evaluates to \texttt{TRUE}, otherwise no assignment is made.

\textbf{Attention}

Values of the \textit{extended range arithmetic} such as \texttt{inf} are also allowed in logical conditions. If the result of a numerical expression used as a logical condition takes any of these values, the logical value is \texttt{TRUE}, even for e.g. \texttt{eps}, which is numerically 0.

Observe that \texttt{functions} are also allowed in logical conditions. If they evaluate to zero, the logical condition is \texttt{FALSE}, otherwise it is \texttt{TRUE}. Consider the following example:

\[
\begin{align*}
b &\implies \cos(a) = 7; \\
\end{align*}
\]

Note that the assignment is only made if the cosine of \(a\) does not equal zero.

4.31.3.2 Logical Conditions: Numerical Relational Operators

Numerical relational operators compare two numerical expressions and return a logical value. For completeness, all numerical relational operators are listed in \textit{Table 1}.

<table>
<thead>
<tr>
<th>Relation</th>
<th>Operator</th>
<th>Alternative Notation</th>
<th>Return Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strictly less than</td>
<td>(x &lt; y)</td>
<td>(x \lt y)</td>
<td>Returns \texttt{TRUE} if (x &lt; y), else returns \texttt{FALSE}.</td>
</tr>
<tr>
<td>Less than or equal to</td>
<td>(x \leq y)</td>
<td>(x \leq y)</td>
<td>Returns \texttt{TRUE} if (x \leq y), else returns \texttt{FALSE}.</td>
</tr>
<tr>
<td>Equal to</td>
<td>(x = y)</td>
<td>(x \ eq\ y)</td>
<td>Returns \texttt{TRUE} if (x = y), else returns \texttt{FALSE}.</td>
</tr>
<tr>
<td>Not equal to</td>
<td>(x \neq y)</td>
<td>(x \ ne\ y)</td>
<td>Returns \texttt{TRUE} if (x \neq y), else returns \texttt{FALSE}.</td>
</tr>
<tr>
<td>Greater than or equal to</td>
<td>(x \geq y)</td>
<td>(x \ ge\ y)</td>
<td>Returns \texttt{TRUE} if (x \geq y), else returns \texttt{FALSE}.</td>
</tr>
<tr>
<td>Strictly greater than</td>
<td>(x &gt; y)</td>
<td>(x \ gt\ y)</td>
<td>Returns \texttt{TRUE} if (x &gt; y), else returns \texttt{FALSE}.</td>
</tr>
</tbody>
</table>

\textbf{Table 1:} Numerical Relational Operators

Consider the following examples.

\[
\begin{align*}
b &\implies (a < 0) = 10; \\
\end{align*}
\]
\[ b \$ (\text{sqr}(a) > a) = 12; \]
\[ a \$ (\text{sum}(i, s(i)) > 0 ) = 7; \]
\[ t(i) \$ (a <> 0) = t(i) + 1; \]

In the first line the logical condition is the relational expression \((a < 0)\). The assignment is only made if this expression is \text{TRUE}, that is, if the scalar \(a\) is negative. The logical condition in the second line is a bit more complex. It evaluates to \text{FALSE} if \(0 \leq a \leq 1\). For all other values of \(a\), it evaluates to \text{TRUE}. So the assignment is made for all values of \(a\), except for those values of \(a\) that are in the closed interval \([0, 1]\). Note that if \(a = -3\), then the logical condition in the first line will be \text{TRUE}, so \(b\) will become 10. In addition, the logical condition in the second line will be \text{TRUE}, so \(b\) will change to 12. The logical condition in the third line evaluates to \text{TRUE} if the sum of all values of the parameter \(a\) is strictly positive. Then \(a\) is assigned the value of 7. The assignment in the last line depends on whether \(a\) is non-zero. If \(a\) is zero no assignment is made, otherwise all entries of the parameter \(t\) are updated.

Note that acronyms may also be used with relational operators to build logical conditions. However, only the equality operator = and inequality operator <> are allowed in the context of acronyms, since they have no numerical values and the other operators would be meaningless. For an example, see section 

\text{Acronym Usage}.

### 4.31.3.3 Logical Conditions: Logical Operators

GAMS offers standard logical operators that may combine two or more logical conditions to build complex logical expressions. For example, if several expressions are required to be \text{TRUE} simultaneously, they may be connected with the operator \text{and}. The logical operators available in GAMS are listed in Table 2 and Table 3. Another way to construct complex logical conditions is by nesting them. For details, see subsection \text{Nested Dollar Conditions} below.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Operator</th>
<th>Alternative Notation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Negation</td>
<td>not (x)</td>
<td></td>
<td>The logical condition (x) has to be \text{FALSE}, in order for the expression to be \text{TRUE}.</td>
</tr>
<tr>
<td>Logical conjunction</td>
<td>(x \text{ and } y)</td>
<td></td>
<td>Two logical conditions are \text{TRUE} simultaneously.</td>
</tr>
<tr>
<td>Logical disjunction</td>
<td>(x \text{ or } y)</td>
<td></td>
<td>At least one of two logical conditions applies.</td>
</tr>
<tr>
<td>Exclusive disjunction</td>
<td>(x \text{ xor } y)</td>
<td></td>
<td>Exactly one of two logical conditions applies.</td>
</tr>
<tr>
<td>Logical implication</td>
<td>(x \text{ imp } y)</td>
<td>(x \rightarrow y)</td>
<td>If the logical condition (x) is \text{TRUE} but at the same time the logical condition (y) is \text{FALSE}, then the whole expression is \text{FALSE}, in all other cases the expression evaluates to \text{TRUE}.</td>
</tr>
<tr>
<td>Logical equivalence</td>
<td>(x \text{ eqv } y)</td>
<td>(x \leftrightarrow y)</td>
<td>Both logical conditions are either \text{TRUE} simultaneously or \text{FALSE} simultaneously for the whole expression to be \text{TRUE}.</td>
</tr>
</tbody>
</table>

\text{Table 2: Logical Operators}

The logical values of these operators are summarized in the following truth table.

<table>
<thead>
<tr>
<th>(x)</th>
<th>(y)</th>
<th>not (x)</th>
<th>(x \text{ and } y)</th>
<th>(x \text{ or } y)</th>
<th>(x \text{ xor } y)</th>

<td>FALSE</td>
<td>FALSE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>TRUE</td>
<td></td>
<td>TRUE</td>
<td>FALSE</td>
<td>TRUE</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

The following somewhat artificial examples serve as illustration.

```plaintext
Set i / i1*i5 /;
Parameter s(i) / i1 3, i2 5, i4 8 /
  t(i) / i1*i4 13 /
  u(i) / i2 1 /
  v(i) / i1 7, i3 2 /

u(i) $ (not s(i)) = v(i);
u(i) $ (s(i) and u(i) and t(i)) = s(i);
u(i) $ (s(i) or v(i) or t(i)) = 4;
```

Note that there are three conditional assignments for the parameter u. In the first assignment the logical condition is (not s(i)). This condition holds for all entries of s that are not specified and therefore zero by default: s(i1) and s(i5). Hence u(i1) and u(i5) are assigned the values of v(i1) and v(i5) respectively. The value of v(i1) is 2 and the value of v(i5) is zero by default. After the first assignment we have u(i2)=1 and u(i3)=2, all other values of u are zero. Note that the logical condition failed for u(i2) and therefore its value remained unchanged. The logical condition in the second assignment is TRUE for those labels of the set i that have non-zero entries in the parameters s, u and t simultaneously. This condition holds only for i2. Therefore u(i2)=s(i2)=5 and all other values of u remain unchanged, resulting in non-zero values only for u(i2) and u(i3). The logical condition in the last assignment evaluates to TRUE for all labels of the set i that have at least one non-zero entry in the parameters s, v and t. This holds for all labels except for i5. Therefore u(i5) stays zero and all other values of u are changed to 4. These examples demonstrate the power of the dollar operator combined with logical operators. Even more complex logical conditions are possible; see subsection Mixed Logical Conditions below for details.

4.31.3.4 Logical Conditions: Set Membership and Set Functions

Apart from numerical and relational expressions, set membership and functions referencing set elements may be used as a logical condition. Consider the following example as illustration for set membership as logical condition.

```plaintext
Set i / i1*i5 /;
Parameter s(i) / i1 3, i2 5, i3 11, i4 8, i5 1 /
  t(i) / i1*i4 13 /
  u(i) / i2 1 /
  v(i) / i1 7, i3 2 /

u(i) $ (not s(i)) = v(i);
```

Note that the set j is a subset of the set i and that the parameter t is declared but not defined. The conditional expression t(i)$ j(i) in the last line restricts the assignment to the members of the subset j since only they satisfy the condition j(i). The values for t(i1) and t(i5) remain unchanged. In this case this means that they are zero (by default). Note that there is an alternative formulation for this type of conditional assignment; for details see subsection Filtering Sets in Assignments below.
Note

Only the membership of subsets and dynamic sets may be used as logical conditions.

The use of set membership as a logical condition is an extremely powerful feature of GAMS, see section Conditional Equations below for more examples.

Logical conditions may contain functions that return particular values depending on the position of elements in sets, the size of sets or the comparison of set elements to each other or text strings. These functions are presented in Table 4.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description and Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sameAs(element1,element2)</code> or <code>sameAs(&quot;text&quot;,element2)</code> or <code>sameAs(element1,&quot;text&quot;)</code></td>
<td>Returns TRUE if <code>element1</code> is identical to <code>element2</code> or <code>element1</code> is identical to <code>text</code>, and FALSE otherwise.</td>
</tr>
<tr>
<td><code>diag(element1,element2)</code> or <code>diag(&quot;text&quot;,element2)</code> or <code>diag(element1,&quot;text&quot;)</code></td>
<td>Same as function <code>sameAs</code>, but returns numerical value 1 for TRUE and 0 for FALSE.</td>
</tr>
<tr>
<td><code>card(set_name)</code></td>
<td>Returns the number of elements in a set. Note that this can also be called with a quoted text and returns the number of characters of that text in that case. For more details, see section The Card Operator.</td>
</tr>
<tr>
<td><code>ord(set_name)</code></td>
<td>Returns the relative position of an element in a set. Note that <code>ord</code> may be used only with one-dimensional, static, ordered sets. For more details, see section The Ord Operator.</td>
</tr>
</tbody>
</table>

Table 4: Functions Referencing Sets

In the following example we have two sets of cities and we want to know how many of them feature in both sets.

```gams
Set i / Beijing, Calcutta, Mumbai, Sydney, Johannesburg, Cairo /;
Set j / Rome, Paris, Boston, Cairo, Munich, Calcutta, Barcelona /;
Scalar b;
b = sum((i,j)$sameAs(i,j),1);
```

Note that in the assignment statement we `sum` over both sets and we use the function `sameAs` to restrict the domain of the indexed operation to those label combinations `(i,j)` where the function `sameAs` evaluates as TRUE. Thus only identical elements are counted.

Note that in this example the function `diag` could have been used with the same result.

The functions `ord` and `card` are frequently used to single out the first or last element of an ordered set. For example, we may want to fix a variable for the first and last elements of a set:

```gams
x.fx(i) $(ord(i) = 1) = 3;
x.fx(i) $(ord(i) = card(i)) = 7;
```

In the first assignment the variable `x` is fixed for the first element of the set `i` and in the second assignment `x` is fixed for the final element of `i`.

Note

As an alternative to the formulation above, one could also use the set attributes `first` and `last` to get the same result:

\[
x.fx(i) \ (i.first) = 3;
\]

\[
x.fx(i) \ (i.last) = 7;
\]

### 4.31.3.5 Numerical Values of Logical Conditions

We have seen that logical conditions may take the form of numerical expressions, expressions with relational operators, complex expressions using logical operators, set membership and set functions. However, GAMS does not have a Boolean data type.

Attention

GAMS follows the convention that the result of a relational operation is zero if the assertion is `FALSE`, and 1 if it is `TRUE`.

Consider the following example as illustration.

\[
x = (1 < 2) + (2 < 3);
\]

The expression to the right of the assignment evaluates to 2 since both logical conditions within parentheses are `TRUE` and therefore assume a value of 1. Note that this is different from the assignment below:

\[
x = (1 < 2) \ or \ (2 < 3)
\]

This assignment evaluates to 1, since both statements to the left and right of `or` are `TRUE` and therefore the whole expression is `TRUE`.

### 4.31.3.6 Mixed Logical Conditions

The building blocks introduced in the subsections above may be combined to generate more complex logical conditions. These may contain standard arithmetic operations, numerical relational operations and logical operations. All operations, their symbols and their order of precedence are given in Table 5. Note that 1 denotes the highest order of precedence and 7 denotes the lowest order of precedence. As usual, the default order of precedence holds only in the absence of parentheses and operators (symbols) on the same level are evaluated from left to right.

<table>
<thead>
<tr>
<th>Type of Operation</th>
<th>Operation</th>
<th>Operator</th>
<th>Order of precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard arithmetic operation</td>
<td>Exponentiation</td>

<td><code>or</code>, <code>xor</code>, <code>imp</code>, <code>eqv</code></td>
<td>7</td>
</tr>
</tbody>
</table>
Table 5: Complete Hierarchy for Operator Precedence in GAMS

Note

We recommend to use parentheses rather than relying on the order of precedence of operators. Parentheses prevent errors and make the intention clear.

Consider the following example:

\[x - 5*y \text{ and } z - 5\]

\[(x - (5*y)) \text{ and } (z-5)\]

These two complex logical conditions are equivalent. However, the parentheses make the second expression easier to understand.

Some simple examples of complex logical conditions, their numerical values and their logical values are given in Table 6.

<table>
<thead>
<tr>
<th>Logical Condition</th>
<th>Numerical Value</th>
<th>Logical Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>((1 &lt; 2) + (3 &lt; 4))</td>
<td>2</td>
<td>TRUE</td>
</tr>
<tr>
<td>((2 &lt; 1) \text{ and } (3 &lt; 4))</td>
<td>0</td>
<td>FALSE</td>
</tr>
<tr>
<td>((4+5 - 3) + (10/8))</td>

<td>2</td>
<td>TRUE</td>
</tr>
<tr>
<td>((4 \text{ and } 0) + (2+3 &lt; 6))</td>
<td>0</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Table 6: Examples of Complex Logical Conditions

4.31.3.7 Nested Dollar Conditions

An alternative way to model complex logical conditions is by nesting them. The syntax is:

\[\text{term } \$(\text{logical\_condition1\$\text{(logical\_condition2\$\ldots)})}\]

Note that in nested dollar conditions all succeeding expressions after the dollar operator must be enclosed in parentheses. The nested expression is equivalent to the following conditional expression that uses the logical operator \textbf{and} instead of the nesting:

\[\text{term } \$(\text{logical\_condition1 \text{ and logical\_condition2 \text{ and } \ldots})}\]

Consider the following example. Note that \(i, j(i)\) and \(k(i)\) are sets, and \(u(i)\) and \(v(i)\) are parameters.

\[u(i) \$(j(i) k(i)) = v(i) \]

The assignment will be made only for those members of the set \(i\) that are members of both sets \(j\) and \(k\). Note the position of the parentheses in the dollar condition. The assignment statement above can be rewritten in the following way.

\[u(i) \$(j(i) \text{ and } k(i)) = v(i) \]

Note

We recommend to use the logical \textbf{and} operator instead of nesting dollar operators, because this formulation is easier to read.
4.31 Conditional Expressions, Assignments and Equations

4.31.4 Conditional Assignments

A conditional assignment is an assignment statement with a dollar condition on the left-hand side or on the right-hand side. Most examples until now were conditional assignments with the dollar operator on the left.

Attention

The effect of the dollar condition is significantly different depending on which side of the assignment it is located.

The next two subsections describe the use of the dollar condition on each side of the assignment. Note that in many cases it may be possible to use either of the two forms of the dollar condition to describe an assignment. We recommend to choose the clearer formulation.

Note that if the logical condition in an assignment statement refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section Filtering Sets in Assignments below.

4.31.4.1 Dollar on the Left

If the dollar condition is on the left-hand side of an assignment, an assignment is made only in case the logical condition is satisfied. If the logical condition is not satisfied then no assignment is made and the previous content of the parameter on the left will remain unchanged. In case the parameter on the left-hand side of the assignment has not previously been initialized or assigned any values, zeros will be used for any label for which the assignment was suppressed.

Consider the following example adapted from [CHENERY]. Note that the parameter $sig$ has been previously defined in the model.

\[
\text{rho}(i) \;\$\; (\text{sig}(i) \not= 0) = (1./\text{sig}(i)) - 1. ;
\]

In this assignment $\text{rho}(i)$ is calculated and the dollar condition on the left protects against dividing by zero. If any of the values associated with the parameter $\text{sig}$ turns out to be zero, no assignment is made and the previous values of $\text{rho}(i)$ remain. As it happens, $\text{rho}(i)$ was not previously initialized, and therefore all the labels for which $\text{sig}(i)$ is zero will result in a value of zero.

Now recall the convention that non-zero implies TRUE and zero implies FALSE. The assignment above could therefore be written as:

\[
\text{rho}(i) \;\$\; \text{sig}(i) = (1./\text{sig}(i)) - 1. ;
\]

In the following examples $i$ is a set and $s$ and $t$ are parameters.

\[
\text{s}(i) \;\$\; \text{t}(i) = \text{t}(i);
\]

\[
\text{s}(i) \;\$\; ((\text{t}(i)-1) > 0) = \text{t}(i)**0.5;
\]

Note that the first assignment is suppressed if the value of the parameter $t$ equals zero. The second assignment is suppressed for values of the parameter $t$ that are smaller or equal to 1.

Note

The first of the last two examples is special in the way that the logical condition used with the dollar on the left and the expression on the right hand side of the assignment are actually the same. This allows to use a shorter notation using the combined $\$=$ assignment. That assignment is equivalent to the following one (which called sparse assignment):

\[
\text{s}(i) \;\$\;= \text{t}(i);
\]
4.31.4.2 Sparse Assignments

Sparse assignments will assign a value to the left-hand side of the = sign only if the right-hand side is nonzero. This behavior is triggered using the $=$ notation as in the following example.

```
Set i /a,b,c/
Parameter d1(i) "Initial data" /a 1, b 1, c 1/
   d2(i) "Data to be used to overwrite d1" /a 0, b -2 /
   d3(i) "Empty data parameter";

* Initialize d3 to d1
   d3(i) = d1(i);
* Use dollar on the left to overwrite d3 with non-zero values from d2
   d3(i)$d2(i) = d2(i);
* Result: d3('a')=1; d3('b')=-2; d3('c')=1;

* Re-Initialize d3 to d1
   d3(i) = d1(i);
* Use sparse assignment to overwrite d3 with non-zero values from d2
   d3(i) $= d2(i);
* Result: d3('a')=1; d3('b')=-2; d3('c')=1;
```

Note that in the final assignments above, the values of the parameter d3(i) are replaced with values from parameter d2(i) only if the entry in d2(i) is non-zero, the other values are left untouched. Both assignments are equivalent.

4.31.4.3 Dollar on the Right

If the dollar condition is on the right-hand side of an assignment statement, an assignment will always be made. In case the logical condition is not satisfied the value of zero is assigned.

Above we had the following simple conditional assignment:

```
a $ (b > 1.5) = 2;
```

Now we move the dollar condition to the right-hand side:

```
a = 2 $ (b > 1.5) ;
```

This is equivalent to:

```
if (b > 1.5) then (a = 2), else (a = 0)
```

Note that an if-then-else type of construct is implied, but the else operation is predefined and never made explicit. The else could be made explicit with the following formulation:

```
a = 2 $ (b > 1.5) + 0 $ (b <= 1.5) ;
```
The use of this feature is more apparent in instances when an else condition needs to be made explicit. Consider the next example adapted from the fertilizer model [FERTD]. The set $i$ is the set of plants, and we are calculating $mur(i)$, the cost of transporting imported raw materials. In some cases a barge trip must be followed by a road trip because the plant is not alongside the river and we must combine the separate costs. The assignment is:

\[
mur(i) = (1.0 + 0.0030 \cdot ied(i,'barge')) \cdot ied(i,'barge') + (0.5 + 0.0144 \cdot ied(i,'road')) \cdot ied(i,'road');
\]

This means that if the entry in the distance table $ied$ is not zero, then the cost of shipping using that link is added to the total cost. If there is no distance entry, there is no contribution to the cost, presumably because that mode is not used.

Consider another example for a conditional assignment with the dollar operator on the right:

\[b = \text{sum}(i,t(i)) \cdot (a > 0) + 4;\]

Here $a$ and $b$ are scalars, $i$ is a set and $t$ is a parameter. If the scalar $a$ is positive, the scalar $b$ is assigned the sum of all values of the parameter $t$ plus 4. If $a$ is zero or negative, $b$ becomes just 4. Note that the sum is only computed if the condition holds, this potentially makes the program faster.

### 4.31.5 Conditional Indexed Operations

We have seen how exceptions in assignments are modeled with dollar conditions. Dollar conditions are also used in indexed operations, where they control the domain of operation. This is conceptually similar to the conditional assignment with the dollar on the left.

Consider the following example adapted from [GTM], a gas trade model for interrelated gas markets. Here the set $i$ contains supply regions and the parameter $supc$ models supply capacities. The scalar $tsupc$ is computed with the following statement:

\[tsupc = \text{sum}(i \cdot (supc(i) \neq \text{inf}), supc(i));\]

This assignment restricts the sum to the finite values of the parameter $supc$.

In indexed operations the logical condition is often a set. This set is called the conditional set and assignments are made only for labels that are elements of the conditional set. This concept plays an important role in dynamic sets.

Multi-dimensional sets are introduced in section Multi-Dimensional Sets. In the example used there a two-dimensional set is used to define the mapping between countries and ports. Another typical example for a multi-dimensional set is a set-to-set mapping that defines the relationship between states and regions. This is useful for aggregating data from the state to the regional level. Consider the following example:

Sets $r$ "regions" / north, south /
$s$ "states" / florida, texas, vermont, maine /
corr(r,s) / north.(vermont,maine) /
  south.(florida,texas) /;

Parameter $y(r)$ "income for each region"
income(s) "income of each state"
  / florida 4.5, vermont 4.2, texas 6.4, maine 4.1 /;
The set \texttt{corr} links the states to their respective regions, the parameter \texttt{income} is the income of each state. The parameter \texttt{y} is computed with the following assignment statement:

\[
y(r) = \text{sum}(s \in \texttt{corr}(r,s), \texttt{income}(s)) ;
\]

The conditional set \texttt{corr}(r,s) restricts the domain of the summation: for each region \texttt{r} the summation over the set \texttt{s} is restricted to the label combinations \((r,s)\) that are elements of the set \texttt{corr}(r,s). Conceptually, this is analogous to the Boolean value \texttt{TRUE} or the arithmetic value \texttt{non-zero}. The effect is that only the contributions of \texttt{vermont} and \texttt{maine} are included in the total for \texttt{north}, and \texttt{south} is the sum of the incomes from only \texttt{texas} and \texttt{florida}.

Note that the summation above can also be written as:

\[
y(r) = \text{sum}(s, \texttt{income}(s) \in \texttt{corr}(r,s));
\]

In this formulation the parameter \texttt{income} is controlled by the conditional set \texttt{corr} instead of the index \texttt{s}. Note that both formulations yield the same result, but the second alternative is more difficult to read.

In the next example the logical condition on the right-hand side appears in the context of an indexed operation, but it does not refer to the index. Thus it is treated similarly to a dollar on the right logical condition. Note that \texttt{a} and \texttt{b} are scalars, \texttt{i} is a set and \texttt{s} is a parameter.

\[
b = \text{sum}(i \in a, s(i));
\]

Here the scalar \texttt{b} is assigned the sum of the values of the parameter \texttt{s} only if \texttt{a} does not equal zero. Otherwise \texttt{b} will be assigned the value zero. Observe that the following alternative formulation will generally be faster than the assignment above:

\[
b = \text{sum}(i, s(i)) \in a;
\]

Note that if the logical condition in the context of indexed operations refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section \texttt{Filtering Controlling Indices in Indexed Operations} below.

\subsection*{4.31.6 Conditional Equations}

The dollar operator is also used for exception handling in equations. The next two subsections discuss the two main uses of dollar operators in the context of equations: in the body of an equation and over the domain of definition.
4.31.6.1 Dollar Operators within the Algebra of Equations

A dollar operator in the algebraic formulation of an equation is analogous to the dollar control on the right of assignments, as presented in section Dollar on the Right. Assuming that "the right" means the right of the '...' then the analogy is even closer. As in the context of assignments, an if-else operation is implied. It is used to exclude parts of the definition from some of the generated constraints.

Consider the following example adapted from the production model [CHENERY].

Set i "sectors" / light-ind, food+agr, heavy-ind, services /
    t(i) "tradables" / light-ind, food+agr, heavy-ind /;
Variables x(i) "quantity of output"
    y(i) "final consumption"
    e(i) "quantity of exports"
    m(i) "quantity of imports";
Equations mb(i) "material balance";

mb(i).. x(i) =g= y(i) + (e(i) - m(i)) $ t(i) ;

Note that in the equation definition in the last line, the term \((e(i) - m(i))\) on the right-hand side of the equation is added only for those elements of the set \(i\) that also belong to the subset \(t(i)\), so that the element services is excluded.

Further, conditional indexed operations may also feature in expressions in equation definitions. The supply balance equation from the gas trade model [GTM] is an example. Note that the set \(i\) contains the supply regions, the set \(j\) contains the demand regions, and the two-dimensional set \(ij\) is the set of feasible links; the variable \(x\) denotes the shipment of natural gas and the variable \(s\) denotes the regional supply.

\[
sb(i).. \sum(j \; ij(i,j), \; x(i,j)) =l= \; s(i) ;
\]

Similar to the assignment example seen before, the conditional set \(ij(i,j)\) restricts the domain of the summation: for each supply region \(i\) the summation over the demand regions \(j\) is restricted to the label combinations \((i,j)\) that are elements of the set of feasible links \(ij(i,j)\).

4.31.6.2 Dollar Control over the Domain of Definition

In case constraints should only be included in the model if particular conditions are met, a dollar condition in the domain of definition of an equation may be used to model this restriction. Such a dollar condition is analogous to the dollar control on the left of assignments. Assuming that "the left" means the left of the symbols '...' then the analogy is even closer.

Note

The dollar control over the domain of definition of equations restricts the number of constraints generated to less than the number implied by the domain of the defining sets.

Consider the following example adapted from the Andean fertilizer model [ANDEAN] :

\[
gple(w,wp,te) \; gple(w,wp).. \; yw(w,te) - yw(wp,te) =l= \; dpack;
\]
Here \( u, \wp \) and \( te \) are sets, \( \text{ple} \) is a two-dimensional parameter, \( \yw \) is a variable and \( \text{dpack} \) is a scalar. Note that the dollar condition restricts the first two indices of the domain of the equation to those label combinations that have non-zero entries in the two-dimensional parameter \( \text{ple} \).

Sometimes the desired restriction of an equation may be achieved either way: through a condition in the algebra or a condition in the domain of definition. Compare the following two lines, where \( \text{eq1} \) and \( \text{eq2} \) are equations, \( i \) and \( j \) are sets, \( b \) is a scalar, \( s \) is a parameter and \( x \) is a two-dimensional variable.

\[
\text{eq1}(i) \quad b.. \quad \sum(j, x(i,j)) =g= -s(i); \\
\text{eq2}(i) \quad \sum(j, x(i,j)) \quad b =g= -s(i) \quad b;
\]

In the first line the dollar condition is in the domain of definition, in the second line the dollar conditions are in the algebraic formulation of the equation. If \( b \) is non-zero, the generated equations \( \text{eq1} \) and \( \text{eq2} \) will be identical. However, if \( b \) is 0, no equation \( \text{eq1} \) will be generated, but for each \( i \) we will see a trivial equation \( \text{eq2} \) of the form \( 0 =g= 0; \).

Note that if the logical condition in the domain of definition of an equation refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section Filtering the Domain of Definition below.

### 4.31.7 Filtering Sets

If the logical condition refers to set membership, the restriction modeled with a dollar condition may sometimes be achieved without the dollar operator. Consider the following statement, where \( i \) and \( j(i) \) are sets, and \( u \) and \( s \) are parameters:

\[
u(i) \quad j(i) = s(i) ;
\]

Note that the assignment is made only for those elements of the set \( i \) that are also elements of the subset \( j \). This conditional assignment may be rewritten in a shorter way:

\[
u(j) = s(j) ;
\]

In this statement the assignment has been filtered through the condition without the dollar operator by using the subset \( j \) as the domain for the parameters \( u \) and \( s \). This formulation is cleaner and easier to understand. It is particularly useful in the context of multi-dimensional sets (tuples), and it may be used in assignments, indexed operations and the domain of definition of equations.

### 4.31.7.1 Filtering Sets in Assignments

Suppose we want to compute the transportation cost between local collection sites and regional transportation hubs for a fictional parcel delivery service. We define sets for the collection sites and transportation hubs and a two-dimensional set where the collection sites are matched with their respective hubs:
Set i "local collection sites" / miami, boston, chicago, houston, phoenix /
   j "regional transportation hubs" / newyork, detroit, losangeles, atlanta /;

Set r(i,j) "regional transportation hub for each local collection site" /
   boston .newyork
   miami .atlanta
   houston .atlanta
   chicago .detroit
   phoenix .losangeles /;

Table distance(i,j) "distance in miles"
   newyork detroit losangeles atlanta
   miami 1327 1387 2737 665
   boston 216 699 3052 1068
   chicago 843 275 2095 695
   houston 1636 1337 1553 814
   phoenix 2459 1977 398 1810;

Parameter factor "cost estimate per unit mile"
   shipcost(i,j) "cost of transporting parcels from a local collection site to a regional hub"

factor = 0.009 ;
shipcost(i,j) $ r(i,j) = factor*distance(i,j) ;

The distance between collection sites and transportation hubs is given in the table. The last line is a
conditional assignment for the parameter shipcost. This assignment is only made if the label combination
(i,j) is an element of the set r. Note that in each instance the indices i and j appear together. Thus
the assignment may be simply written as:

shipcost(r) = factor*distance(r) ;

Note that the assignment is explicitly restricted to the members of the set r; the dollar operator is not
necessary. Observe that if the indices i or j appear separately in any assignment, the above simplification
cannot be made. For example, consider the case where the shipping cost depends not only on the parameter
factor and the distance between collection sites and regional hubs, but also on the congestion at the
regional hub. We introduce a new parameter congestfac that models the congestion at each regional
hub and is indexed only over the set j:

Parameter congestfac(j) "congestion factor" /
   newyork 1.5
   detroit 0.7
   losangeles 1.2
   atlanta 0.9/ ;

The new cost of shipment is computed as follows:

shipcost(i,j) $ r(i,j) = factor*congestfac(j)*distance(i,j) ;

Note that this conditional assignment cannot be reformulated as:

shipcost(r) = factor*congestfac(j)*distance(r) ;

In the representation above the index j appears on the right-hand side, but not on the left-hand side.
GAMS will flag this assignment as an error. However, the following representation will work:

shipcost(r(i,j)) = factor*congestfac(j)*distance(r) ;

In this formulation the set r is explicitly denoted as a tuple of the sets i and j. The set j may then
appear on the right-hand side.
4.31.7.2 Filtering Controlling Indices in Indexed Operations

Similarly, the controlling indices in indexed operations may be filtered through the conditional set without the use of the dollar operator. We continue with the shipping cost example from the last subsection. The total cost of shipment is obtained through the equation that follows. We also include the variable definitions for clarity.

Variable shipped(i,j), totcost ;
Equation costequ ;

costequ.. totcost =e= sum((i,j) $ r(i,j), shipcost(i,j)*shipped(i,j));

Here the variable shipped is the number of parcels shipped from the local collection site i to the regional transportation hub j, and the variable totcost is the total cost of all shipments. Note that the summation in the equation is restricted to the label combinations that are elements of the set r. Alternatively, the equation above may be written as:

costequ.. totcost =e= sum(r, shipcost(r)*shipped(r));

In this formulation the summation is performed explicitly only over the elements of the set r, no dollar condition is necessary. However, if the expression in the equation included a term dependent only on index j, then we would have to reformulate differently. Suppose the equation included also the congestion factor congestfac that is indexed only over j:

cost.. totcost =e= sum((i,j) $ r(i,j), factor*congestfac(j)*distance(i,j)*shipped(i,j));

In this case the equation needs to be simplified in the following way:

cost.. totcost =e= sum(r(i,j), factor*congestfac(j)*distance(r)*shipped(r));

Like before, the domain of the indexed operation sum is the set r. But this time the domain of r has to be named explicitly, so that the parameter congestfac which is indexed only over the set j is permitted in the scope of the indexed operation. Note that this reasoning is analogous to the reasoning for filtering sets in assignments in the subsection above.

4.31.7.3 Filtering the Domain of Definition

The rules for filtering sets that we have introduced in subsections Filtering Sets in Assignments and Filtering Controlling Indices in Indexed Operations also apply in the context of equation domains. We continue with the parcel transport example introduced above and add a binary variable bin, the parameter bigM and the equation connect to the model. Recall that shipped(i,j) is a variable and r(i,j) is a set.

Parameter bigM(i,j) ;
Binary variable bin(i,j) ;
Equation connect(i,j) ;

connect(i,j) $ r(i,j).. shipped(i,j) =l= bigM(i,j)*bin(i,j) ;
The dollar condition restricts the domain of definition of the equation \texttt{connect} to those label combinations of the sets \texttt{i} and \texttt{j} that are elements of the set \texttt{r}. The equation relates the continuous variable \texttt{shipped}(i,j) to the binary variable \texttt{bin}(i,j). Note that each domain in the equation is the index pair \texttt{(i,j)}. So the equation may be simplified as follows:

\begin{verbatim}
connect(r).. shipped(r) =l= bigM(r)*bin(r) ;
\end{verbatim}

In this formulation the domain of the equation is explicitly restricted to the members of the set \texttt{r}, without the use of a dollar condition. Note that if the right-hand side of the equation contained any term that was indexed over \texttt{i} or \texttt{j} separately, then the domain of definition of the equation would have to be simplified as:

\begin{verbatim}
connect(r(i,j))
\end{verbatim}

The reasoning is the same as in the case of assignments and indexed operations.

### 4.32 The Display Statement

#### 4.32.1 Introduction

The \texttt{display} statement in GAMS is a quick way to write data into the listing file. It does not provide a publication quality reporting function, but is instead aimed at functionality that is easy to use and provides graceful defaults. These defaults may be modified by the user to control the layout and appearance of the output. Both defaults and customization options are presented in this chapter. For information on the listing file, see chapter \texttt{GAMS Output}. In addition to the \texttt{display} statement, GAMS offers the \texttt{put writing facility}, a more sophisticated way to generate reports, where the user has much more flexibility and control over the output of individual items.

#### 4.32.2 The Syntax

In general, the syntax for the \texttt{display} statement in GAMS is as follows:

\begin{verbatim}
display ident | quoted text {, ident | quoted text};
\end{verbatim}

The keyword \texttt{display} indicates that this is a \texttt{display} statement. It is followed by an \texttt{identifier}. If the identifier is a set or a parameter, only the name of the set or parameter itself is specified. If the identifier is a variable, an equation or a model, it must be followed by a suffix, i.e. a \texttt{variable attribute}, \texttt{equation attribute} or \texttt{model attribute} respectively. As usual, \texttt{quoted text} must be surrounded by single or double quotes. The identifiers and the text may be mixed and matched in any order, and the whole statement may be continued over several lines. For conditional \texttt{displays} a dollar condition may follow the keyword \texttt{display}.

The output produced by a display statement consists of labels and data. For multi-dimensional sets the keyword \texttt{yes} (indicating membership) is used instead of values.
Note

Only the non-default values are displayed for all data types.

The default value is generally zero. Exceptions are some upper and lower bounds of variables and
equations (the attributes .lo and .up). Their default values are listed in sections Variable Attributes and
Equation Attributes respectively.

The syntax of the display statement is illustrated by the following example:

```plaintext
Sets  s   / s1*s4 /  
t   / t5*t7 /  
    st(s,t) / s1.t5, s1.t7, s2.t6, s3.t7, s4.t5 / ;
Parameters p(s)  / s1 0.33, s3 0.67 /  
    q(t)  / t5 0.33, t7 0.67 / ;
Variable v(s,t) ;  
v.l(s,t) = p(s)*q(t);  
display 'first a simple set', s, 'then a two-dimensional set', st, 'then a parameter', p,  
'then the activity level of a variable', v.l;
```

The display statement will generate the following lines in the listing file:

```plaintext
----- 8 first a simple set
----- 8 SET s
     s1, s2, s3, s4

----- 8 then a two-dimensional set
----- 8 SET st
     t5    t6    t7
     s1 YES  YES
     s2 YES
     s3 YES
     s4 YES

----- 8 then a parameter
----- 8 PARAMETER p
     s1 0.330, s3 0.670

----- 8 then the activity level of a variable
----- 8 VARIABLE v.L
     t5     t7
     s1 0.109 0.221
     s3 0.221 0.449
```
In the case of multi-dimensional identifiers like the set \texttt{st} and the level values of the variable \texttt{v}, the data is by default reported in a tabular form that is easy to read. Note that only the non-default values are displayed. To display zero values, the special value \texttt{EPS} can be used. In the example above, all values of the parameter \texttt{p} can be displayed by adding the following lines.

```gams
display 'display all values';
p(s)$(not p(s)) = EPS;
display p;
```

The following lines will be displayed in the listing file.

```gams
11 display all values
13 PARAMETER p
s1 0.330, s2 EPS, s3 0.670, s4 EPS
```

An alternative to displaying \texttt{EPS} is to use \texttt{acronym} but computations cannot be done with the resulting parameters.

### 4.32.3 Displaying Multi-Dimensional Identifiers: Label Order

We have seen that two-dimensional identifiers are displayed in table format. The default layout for displaying multi-dimensional identifiers is summarized in Table 1. Note that the default format may be modified with the local display control. The figures in the table refer to the index position in the domain list of the identifier. For example, if we display \texttt{x}, where \texttt{x} has been declared as \texttt{x(i,j,k,l)}, then the \texttt{i} labels (the first index) will by default be associated with the individual subtables, the \texttt{j} and \texttt{k} with the row labels and the \texttt{l} (the fourth and last index) with the column headings.

<table>
<thead>
<tr>
<th>Number of Indices</th>
<th>Subtable</th>
<th>Index Position(s) on the Row</th>
<th>Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>list format</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>-</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>-</td>
<td>1,2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>2,3</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>1,2</td>
<td>3,4</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>1,2,3</td>
<td>4,5</td>
<td>6</td>
</tr>
</tbody>
</table>

**Table 1:** Default Layout for Displaying Multi-Dimensional Identifiers

For 7 to the maximum number of indices the natural progression is followed. For the current maximum number of indices, see Dimensions. The labels vary slowest for the first index position and quickest for the highest. Within each index position the order of the label is the GAMS entry order of the labels. Some users may need to manipulate the order of the labels.

Note

The only way to change the order in which the labels for each index position appear in the display output is to change the order of appearance of the labels in the GAMS program.
This is most easily done by declaring a set whose only purpose is to list all the labels in the order that is needed. Make this set the very first declaration in the GAMS program.

Note that the order of the indices in an identifier is always as the order in the declaration statement. One can declare them in the order that is found appealing, or make an assignment to a new identifier with a different order, as illustrated in the example below.

### 4.32.3.1 Example for Multi-Dimensional Displays

Consider the following example. The parameter \( x \) has four dimensions or index positions. It is initialized using parameter format and then displayed as shown below.

Set \( i \) first index / first, second /
   \( j \) second index / one, two, three /
   \( k \) third index / a, b /
   \( l \) fourth index / i, ii / ;

Parameter \( x(i,j,k,l) \) a four dimensional structure /
second.one.a.i 0.00013, first .three.b.i -6.3161
first .one.b.i 5.63559, second.two .b.i 20000.00
second.one.b.ii -17.29948, first .two .b.ii 10.3457
first .two.a.ii 0.02873, second.one .a.ii 1.0037
second.two.a.ii +inf, first .two .a.i -2.9393
first .one.a.ii 0.00000 /

\( y(k,l,i,j) \) a four dimensional structure with changed index order;
\( y(k,l,i,j) = x(i,j,k,l) \);
display \( x, y \);

For variable \( x \) the code fragment produces the following output:

```
---- 16 PARAMETER x a four dimensional structure

INDEX 1 = first

   i     ii

   one .b  5.636
   two .a -2.939  0.029
   two .b  10.346
   three.b -6.316

INDEX 1 = second

   i     ii

   one.a 1.300000E-4  1.004
   one.b  -17.299
   two.a  +INF
   two.b  20000.000
```
Notice that there are two subtables, one for each label in the first index position. Note further that the order of the labels is not the same as in the input data list of the parameter x, but is according to the label order in the driving sets. Observe that the numbers closer in magnitude to one are displayed in fixed format, rounded to three digits (the default). This default may be modified with display controls, the topic of the next section. In contrast, the especially small value appears in E-format: it would display as all zeros in fixed format. Note also that the zero in the list for \( x('first', 'one', 'a', 'ii') \) has vanished, since default values are not shown. Similarly, rows and columns containing only zero values are suppressed in each subtable separately.

Notice furthermore how parameter y can be used to display the same data with a different index order.

### 4.32.4 Display Controls

GAMS allows the user to modify the number of row and column labels in the display listing as well as the accuracy of the data being displayed. There are global and local display controls. Global display controls allow the user to affect more than one display statement. The local display control may be used to override the global controls if specific data need to be listed in a particular format. Both controls are expressed with option statements.

#### 4.32.4.1 Global Display Controls

The first option for global display controls specifies the number of digits shown after the decimal point. It affects the numbers appearing in all display output following the option statement, unless it is changed for a specific identifier as shown below. The general form of this option statement is:

\[
\text{option decimals = value;}
\]

The keyword `option` indicates that this is an option statement, `decimals` is the specific option and `value` is an integer between 0 and 8. The value 0 supresses decimals as well as the decimal point. Note that the default is `decimals=3`, and that setting this option does not change the field width, just the number of decimals. Increasing `decimals` results in more digits being displayed; this may in turn cause numbers to appear in E-format if the longer fixed-format result would exceed the field width.

A word about rounding for display purposes is in order. In the event of ties, the display routines use the round-to-even tie-breaking rule. So for example, with `decimals=0`, both 1.5 and 2.5 will display as 2. Similarly, with `decimals=1`, 2.25 displays as 2.2 while 2.75 displays as 2.8.

Consider the following extension to the example discussed in the previous section.

\[
\text{option decimals = 1; display x;}
\]

GAMS will display numbers using E-format where necessary to avoid exceeding the display width or showing all zeros. The output is as follows:

\[
---
14 \text{ PARAMETER} \ x \ \text{a four dimensional structure}
\]

\[
\text{INDEX} \ i = \text{first}
\]

\[
\begin{array}{ll}
    \text{one} & \text{.b} & 5.6
\end{array}
\]
Note that GAMS overrode the decimal choice for $x('first', 'two', 'a', 'ii$) to ensure that small numbers are not displayed as zeroes.

Another option for global display control modifies the width of the display. This is particularly important for longer label names. Label names that are headers of columns are cut off after 9 characters when data is displayed in table format. The following option may be used to display longer names in full:

```
option dispwidth = value;
```

The name of the option is `dispwidth` and `value` is a positive integer smaller or equal to 31. An illustrative example follows.

```
Set i 'South African cities' / Johannesburg, Cape_Town /
    j 'other African cities' / Maputo, Dar_es_Salaam /
    f(i,j) 'direct flight connections' / Johannesburg.Maputo, Johannesburg.Dar_es_Salaam, Cape_Town.Maputo;

display f;
```

The display statement generates the following output:

```
---- 4 SET f direct flight connections
       Maputo Dar_es_Salaam
Johannesburg         YES         YES
Cape_Town            YES
```

Note that only the label 'Dar_es_Salaam' is cut off since it is heading a column. The label 'Johannesburg' is not cut off as it is the label for a row. Now we add the following line to change the width of the display statement:

```
option dispwidth = 15; display f;
```

As expected, the output changes and the label 'Dar_es_Salaam' is no longer cut off:

```
---- 5 SET f direct flight connections
       Maputo     Dar_es_Salaam
Johannesburg         YES         YES
Cape_Town            YES
```
4.32.4.2 Local Display Control

It is often useful to control the number of decimals for specific identifiers separately. The following option statement accomplishes this:

option ident:d-value;

Ident denotes the name of the identifier and d-value is an integer in the range 0 to 8. The number of decimal places shown on all displays of ident that follow will be d-value.

This option statement can be extended to control the layout of the data in addition to the decimal places. The general form is as follows:

option ident:d-value:r-value:c-value ;

Here r-value denotes the number of index positions that are combined to form the row label and c-value means the number of indices on the column headers.

The example discussed in the previous section is further extended in order to illustrate the local display control.

option x:5:3:1; display x;

These two statements generate the following output:

```
---- 17 PARAMETER x a four dimensional structure
       i    ii
  first .one .b   5.63559
  first .two .a  -2.93930  0.02873
  first .two .b    10.34570
 first .three .b -6.31610
second .one .a   0.00013   1.00370
second .one .b    -17.29948
second .two .a     +INF
second .two .b 20000.00000
```

Note that five decimal places are shown, three labels are used to mark the rows and one label acts as head of the column. Since this is a four-dimensional structure, all indices are accounted for.

The next example places two indices on each of the row and column labels and retains five decimal places:

option x:5:2:2; display x;

The output is:
--- 18 PARAMETER x a four dimensional structure

  a.i  a.ii  b.i  b.ii

first .one      5.63559
first .two  -2.93930  0.02873  10.34570
first .three  -6.31610
second.one    0.00013  1.00370 -17.29948
second.two  +INF  20000.00000

If in the option statement less dimensions are specified than the number of indices in the domain, then subtables will be generated for the labels of the beginning indices. Observe how the display layout will change if we use the following statement:

option x:0:1:1; display x;

The output follows.

--- 19 PARAMETER x a four dimensional structure

INDEX 1 = first  INDEX 2 = one
   i

   b  6

INDEX 1 = first  INDEX 2 = two
   i  ii

   a  -3  2.873000E-2
   b  10

INDEX 1 = first  INDEX 2 = three
   i

   b  -6

INDEX 1 = second  INDEX 2 = one
   i  ii

   a  1.300000E-4  1
   b  -17

INDEX 1 = second  INDEX 2 = two
   i  ii

   a  +INF
   b  20000

The option statement is checked for consistency against the dimensionality of the identifier and error messages will be issued if the number of the dimensions specified in the option statement is larger than the number of indices in the domain of the identifier.
4.32 The Display Statement

4.32.4.3 Display Statement to Generate Data in List Format

The option statement for local display controls may be used to generate data in list format by setting the \texttt{r-value} to zero:

\begin{verbatim}
option ident:d-value:0:c-value;
\end{verbatim}

In this case the \texttt{c-value} specifies the maximum number of items displayed on a line. The actual number will depend on the page width and the number and length of the labels.

Using the same example as in the previous sections, we change the \texttt{r-value} to zero in the option statement:

\begin{verbatim}
option x:5:0:1; display x;
option x:5:0:2; display x;
\end{verbatim}

Note that we specified one and two columns to illustrate the impact of different \texttt{c-value} settings. These statements will generate the following output:

\begin{verbatim}
---- 20 PARAMETER x a four dimensional structure
first .one .b.i  5.63559
first .two .a.i  -2.93930
first .two .a.ii  0.02873
first .two .b.ii  10.34570
first .three .b.i  -6.31610
second .one .a.i  0.00013
second .one .a.ii  1.00370
second .one .b.ii  -17.29948
second .two .a.ii  +INF
second .two .b.i  20000.00000

---- 21 PARAMETER x a four dimensional structure
first .one .b.i  5.63559, first .two .a.i  -2.93930
first .two .a.ii  0.02873, first .two .b.ii  10.34570
first .three .b.i  -6.31610, second .one .a.i  0.00013
second .one .a.ii  1.00370, second .one .b.ii  -17.29948
second .two .a.ii  +INF, second .two .b.i  20000.00000
\end{verbatim}

This output nicely illustrates the label order used. The first index varies the slowest, the last the fastest, and each one runs from beginning to end before the next one to the left advances. This ordering scheme is also used in equation and column lists and in the solution report which are all generated by the solve statement.
### 4.32.5 Conditional Displays

This section assumes familiarity with the if statement and the dollar condition.

The display statement may be controlled by conditional expressions. Conditionals have the effect that the items are displayed only if a logical condition is satisfied. There are two ways to express conditional displays in GAMS: with dollar conditions and using if statements. The syntax using a dollar condition is as follows:

\[
\text{display$\text{logical\_condition} \text{ ident | quoted text } \{, \text{ ident | quoted text}\};}
\]

Note that the dollar condition is inserted after the keyword display. For details on the various forms of conditional expressions in GAMS, see sections Logical Conditions and Filtering Sets. Consider the following simple example:

```gams
Scalars x, y;
x = 7;
y = 3;
display$(x-y < 0) "display if x minus y is less than 0", x, y;
```

The logical condition \((x-y < 0)\) controls the display statement. In this case it is not satisfied, hence there will be no display output. If the value of \(y\) is changed to, say 10, then the logical condition will be satisfied and the display statement will generate the following output:

```
---- 4 display if x minus y is less than 0
       PARAMETER x = 7.000
       PARAMETER y = 10.000
```

The syntax for conditional displays using an if statement is as follows:

```gams
if( logical\_condition, display\_statement );
```

The simple example above may be reformulated as follows:

```gams
Scalars x, y;
x = 7;
y = 3;
if( x-y < 0,
   display "display if x minus y is less than 0", x, y;
);
```

### 4.33 Programming Flow Control Features

#### 4.33.1 Introduction

In this chapter we will describe the programming flow control features available in GAMS. The if statement facilitates expressing complex conditional statements (see also chapter Conditional Expressions, Assignments and Equations).

In addition, GAMS offers four loop constructs to handle looping requirements: the loop statement, the while statement, the for statement and the repeat statement. At the end of this chapter we will introduce the break, and continue statements, which give additional control over the execution of loop structures, and the abort statement, a statement that may be used to terminate the execution of a program.

Note that this chapter deals with programming flow control features at execution time. In addition, GAMS provides a dollar control option that allows for conditional processing of input files at compile time. For more information, see the detailed description of the option $if. For details on dollar control options in general, see chapter Dollar Control Options.
4.33.2 The If Statement

The *if* statement is useful to branch conditionally around a group of statements. In some cases this can also be written as a set of dollar conditions, but the *if* statement may make the GAMS code more readable. An optional *else* and/or *elseif* part allows the user to formulate traditional *if-then-else* constructs.

4.33.2.1 The If Statement: Syntax

The syntax for an *if* statement in GAMS is as follows:

```gams
if (logical_condition,
    statement; {statement;}
{ elseif logical_condition,
    statement; {statement;}} 
[ else
    statement; {statement;] }
);
```

The keyword *if* indicates that this is an *if* statement. The logical condition is followed by one or more *statements* that are executed if the logical condition is satisfied. For details on the various forms of logical conditions in GAMS, see sections *Logical Conditions* and *Filtering Sets*. The *if* statement may end at this point, without any specifications for cases when the logical condition is *FALSE* and no action is taken in these cases. However, GAMS also allows further specifications: optional alternative *if* tests and optional *statements* for cases when all previous *if* tests have failed. The keyword *elseif* introduces an alternative *if* test with a logical condition and one or more *statements*. Note that the *elseif* case is optional and may be repeated multiple times. Note further that the *elseif* case implies that the logical condition of the *if* case has not been satisfied. The keyword *else* introduces the final part of the construct. It is optional and allows specification for cases when the logical condition of the *if* case (and possibly the *elseif* case(s)) has not been satisfied.

**Attention**

Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside an *if* statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option `onEnd`.

4.33.2.2 The If Statement: Examples

Consider the following set of conditional assignment statements that use dollar conditions:

```gams
p(i)$(f <= 0) = -1 ;
p(i)$(f > 0) and (f < 1)) = p(i)**2 ;
p(i)$(f >= 1) = p(i)**3 ;
q(j)$(f <= 0) = -1 ;
q(j)$(f > 0) and (f < 1)) = q(j)**2 ;
q(j)$(f >= 1) = q(j)**3 ;
```
They may be expressed using an if-elseif-else statement:

```gams
if (f <= 0,
    p(i) = -1 ;
    q(j) = -1 ;
elseif ((f > 0) and (f < 1)),
    p(i) = p(i)**2 ;
    q(j) = q(j)**2 ;
else
    p(i) = p(i)**3 ;
    q(j) = q(j)**3 ;
)
```

Note that the body of the if statement may contain solve statements. For instance, consider the bit of GAMS code that follows. Note that ml is a GAMS model, z is a free variable, j is a set and x is a variable.

```gams
solve ml using lp minimizing z;
if (ml.modelstat = 4,
    display "model ml was infeasible, relax bounds on x and solve again";
    x.up(j) = 2*x.up(j) ;
    solve ml using lp minimizing z ;
else
    if (ml.modelstat <> 1,
        abort "error solving model ml" ;
    );
);
```

First the model ml is solved. For details on solve statements in GAMS, see section The Solve Statement. Then a post solution analysis is done with the if statement. If the model is infeasible, the upper bound on the variable x is relaxed and the model is solved again. If the original model is not infeasible and it is not optimal either, then the compilation is aborted and the error message above is reported. For more information on GAMS output, see chapter GAMS Output, particularly subsection Model Status for a list of all GAMS model statuses. The display statement is introduced in chapter The Display Statement. For details on the abort command, see abort.

The following GAMS code is illegal since it is not permitted to define equations inside an if statement.

```gams
if (s > 0,
    eq.. sum(i,x(i)) =g= 2 ;
);
```

The following GAMS code is also illegal since declarations inside an if statement are not allowed.

```gams
if (s > 0,
    scalar y ; y = 5 ;
);
```

### 4.33.3 The Loop Statement

The loop statement facilitates executing a group of statements for each member of a set. Loop statements are particularly useful for cases when parallel assignments are not sufficient. This is the case most often when there is no analytic relationship between the values to be assigned to a parameter. It is, of course, also useful to have a looping statement for general programming.
4.33.3.1 The Loop Statement: Syntax

The syntax for the loop statement in GAMS is as follows:

```
loop(index_list[$(logical_condition)],
    statement; {statement;}
) ;
```

The keyword loop indicates that this is a loop statement. The index_list is the controlling domain of the loop. Note that loops may be controlled by more than one set. In this case parentheses are required around the index list, which is also called the loop set(s). Observe that dynamic sets are allowed as loop sets. The loop set(s) may be restricted by a logical condition. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. For an introduction to dollar conditions in general, see chapter Conditional Expressions, Assignments and Equations. The index list is followed by one or more statements. Except for the final statement, each statement must end with a semicolon ';'. The loop statements are executed for each member of the controlling domain in turn. The order of evaluation is the entry order of the labels. A loop is thus another, more general, type of indexed operation.

Attention

- Only execution statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a loop statement.
- It is illegal to modify any controlling set inside the body of the loop.

Loop statements in GAMS are often used for iterative calculations, generating reports with put statements and doing scenario based studies with solve statements. Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.

4.33.3.2 The Loop Statement: Examples

Consider a hypothetical case when a growth rate is empirical:

- Set t / 1985*1990 /
- Parameter pop(t) / 1985 3456 / 

The loop statement is then used to calculate the cumulative sums iteratively:

```
loop(t, pop(t+1) = pop(t) + growth(t) ) ;
```

In this example the driving set is t and we have just one statement in the scope of the loop.

The following small artificial examples illustrate the effects of a dollar condition in a loop statement.
Sets
  i / i1*i3 /
  j / j1*j5 /
  k(i,j) / i1.j1, i1.j3, i3.j3, i3.j5 /
Parameter
  c(i) / i1 3, i2 1 /
  q(i,j) / i1.j1 1, i1.j2 3, i1.j4 2 /
Scalars
  x, y, z;
  x = 1; y = 3; z = 1;
loop ( (i,j) $ (q(i,j) > 0), x = x + q(i,j));
loop ( i $ (c(i) + c(i)**2), z = z + 1);
loop ( i $ sum(j, abs(q(i,j))), z = z + 1);
loop ( j $ (ord(j) > 1 and ord(j) < card(j)), z = z + 1);
loop ( (i,j) $ k(i,j), y = y + ord(i) + 2*ord(j));

In the first loop statement the controlling domain is the set pair (i,j). It is restricted to those label combinations whose values associated with the parameter q are greater than zero. The logical condition in the second loop statement is c(i) + c(i)**2. This is shorthand for c(i) + c(i)**2 != 0. The domain in the third loop statement is restricted to those elements of the set i where the sum over j of the absolute values of the parameter q does not equal zero. Note that this condition is satisfied only for the label "i1". Observe that i and j are both ordered sets. In the fourth loop statement the first and the last element of the set j are excluded. For more on the set operators ord and card, see sections The Ord Operator and The Card Operator respectively. The dollar control in the last loop statement excludes all label combinations that are not members of the set k. For further details on dollar conditions, see chapter Conditional Expressions, Assignments and Equations.

Note
The dollar condition may be replaced by an if statement; see the example below.

The next example shows how a model can be solved for each element of a set i with different data using a loop statement. Note that problemdata is a scalar, g(i) and d(i) are parameters, mymodel is a GAMS model and profit is a free variable.

loop (i,  
  problemdata = g(i);  
  solve mymodel using lp maximizing profit;  
  d(i) = profit.l;  
);

In the first statement some data in the model is updated in accordance with the ith element of the parameter g. In the second statement the model is solved. For details on the solve statement, see section The Solve Statement. The objective value for each iteration is saved in the parameter d in the third statement.

A loop is often used to perform iterative calculations. Consider the following example, which finds square roots by Newton’s method. This example is purely for illustration - in practice, the function sqrt should be used. Newton’s method is based on the assertion that if x is an approximation to the square root of v, then (x + v/x)/2 is a better approximation.

Set
  i "set to drive iterations" / i-1*i-100 /
Parameter
  value(i) "used to hold successive approximations";
Scalars
  target "number whose square root is needed" / 23.456 /
  sqrtval "final approximation to sqrt(target)"
  curacc "accuracy of current approximation"
  reltol "required relative accuracy" / 1.0e-06 /;
4.33 Programming Flow Control Features

abort\$(target <= 0) "argument to newton must be positive";
value("i-1") = target/2 ;
curacc = 1 ;
loop(i$(curacc > reltol),
  value(i+1) = 0.5*(value(i) + target/value(i));
  sqrtval = value(i+1);
  curacc = abs (value(i+1)-value(i))/(1+abs(value(i+1)))
  ) ;
abort\$(curacc > reltol) "square root not found"
option decimals=8;
display "square root found within tolerance", sqrtval, value;

Note that in this example the dollar condition in the loop does not restrict the driving set \( i \), but it is used to terminate the loop procedure. The scalar \( \text{curacc} \) is updated in every iteration. As soon as it becomes equal to or smaller than the required relative accuracy \( \text{reltol} \) the loop stops. As the output below shows, this is the case after seven iterations. The body of the loop statement consists of three statements. The first statement calculates the current approximation and assigns it to the parameter \( \text{value} \). The second statement updates the scalar \( \text{sqrtval} \), and the third statements computes the accuracy of the current approximation in each iteration. Note that before and after the loop statement we added lines to account for special cases. For details on the abort statement, see section The Abort Statement at the end of this chapter. The output generated by the display statement is given below.

---

19 square root found within tolerance

---

19 PARAMETER SQRTVAL = 4.84313948 final approximation to sqrt(target)

---

19 PARAMETER VALUE used to hold successive approximations

i-1 11.72800000, i-2 6.86400000, i-3 5.14062471, i-4 4.85174713
i-5 4.84314711, i-6 4.84313948, i-7 4.84313948

Note that a statement within the body of a loop may be an if statement (or any other programming flow control statement). Moreover, the logical condition in a loop statement may be expressed with an if statement instead of a dollar condition. The following example serves as illustration. Observe that \( k \) is a set and \( s, t, u \) and \( a \) are parameters.

loop \( (k, \)
  if((s(k) < 0 and t(k)),
    u(k) = a(k);
  );
); 

Note that if the logical condition is not satisfied the assignment is not made and the parameter \( u \) remains unchanged.

Recall that subsets are connected with their supersets by arcs thus building a domain tree where the root node is the universal set. The following example demonstrates how the domain tree may be used in a loop statement.
Set i / i1*i10 /  
  ii(i)  
  j(i) / i1*i9 /  
  jj(j) / i1*i8 /  
  jjj(jj) / i1*i7 /;

loop(i(jjj), ii(i) = yes;);
display ii;

Observe that the looping set is i(jjj). This means that we loop over those elements of i that are also elements of the set jjj. This construct is permitted since i is in the domain tree on the path from jjj to the universe or universal set. It is allowed to go up the domain tree on one path and go down on another path. Therefore all the elements of jjj are assigned to ii. The outcome of the display statement confirms this:

---- 8 SET ii
i1, i2, i3, i4, i5, i6, i7

4.33.4 The While Statement

The while statement facilitates the repeated execution of one or more statements as long as a logical condition is satisfied.

4.33.4.1 The While Statement: Syntax

The syntax for the while statement in GAMS is as follows:

while(logical_condition,
    statement; {statement;}
);

The keyword while indicates that this is a while statement. Inside the while statement a logical condition is followed by one or more statements. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. The statements are executed as long as the logical condition is TRUE.

Attention

Only execution statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a while statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.
4.33.4.2 The While Statement: Examples

Consider the following simple example:

Scalar x; x = 1;
while ( round(x,2) < 10,
    x = x + 0.01;
);
display x;

Note that the scalar x is increased in each iteration until it equals 10. Note further, that to ensure an exact result, in numerical comparisons we need a stable check like we have above (round(x,2) < 10), otherwise rounding errors may occur. As soon as x reaches 10, the logical condition is no longer satisfied and therefore there will be no further passes. Hence the final value of x equals 10.

Note that the number of passes in a while statement may be restricted using the command line parameter or option forlim. For details on command line parameters and options, see section Specifying Options Through the Command Line and chapter The Option Statement respectively.

While statements may be used to control the solve statement. For instance, consider the following implementation of a random multi-start method for non-convex optimization.

scalar count / 1 /;
scalar globmin / inf /;
option bratio = 1;
while(count <= 1000,
    x.l(j) = uniform(x.lo(j),x.up(j)) ;
solve ml using nlp minimizing obj ;
if (obj.l < globmin,
    globmin = obj.l ;
    besstop(j) = x.l(j) ;
) ;
count = count+1 ;
);

Note that we start from a random starting point by setting the initial level values randomly between the upper and lower bounds. This assumes that the bounds have been previously specified and are not infinity. When the method improves, that is, if the logical condition (obj.l < globmin) is satisfied, the best known solution is stored in the scalar globmin. The level values associated with the best known solution so far are then saved in the parameter besstop. This procedure is repeated 1000 times. The model [PRIME] is another example where the use of the while statement is illustrated. In this model the set of all prime numbers smaller than 200 is generated.

The following GAMS code is illegal since equation definitions inside a while statement are not permitted.

while(s > 0,
    eq.. sum(i,x(i)) =g= 2 ;
);

The following GAMS code is also illegal since declarations inside a while statement are not allowed.

while(s > 0,
    scalar y ; y = 5 ;
);
4.33.5 The For Statement

The for statement provides a compact way to iterate over a range of values and execute one or more statements each time.

4.33.5.1 The For Statement: Syntax

The syntax for the for statement in GAMS is as follows:

```gams
for (a = start_value to|downto end_value [by incr],
    statement; {statement;}
); 
```

The keyword for indicates that this is a for statement. The scalar a begins with the real number start_value and is changed after each pass of the loop by the increment incr until it reaches the real number end_value. Note that the specification of an increment is optional, the default is 1. If the increment is given, it has to be a positive real number. Note further that to indicates that the scalar a is increased and downto indicates that it is decreased. In each iteration one or more statements are executed.

Attention

Only execution statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a for statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.

4.33.5.2 The For Statement: Examples

Consider the following simple example:

```gams
Scalar s;
for (s = -3.8 to -0.1 by 1.4,
    display s ;
); 
```

Note that negative real numbers are possible for the start and end values. The resulting listing file will contain the following lines:

```
---- 3 PARAMETER s = -3.800
---- 3 PARAMETER s = -2.400
---- 3 PARAMETER s = -1.000
```

Observe that the value of s was increased by 1.4 with each pass of the loop as long as it did not exceed -0.1. In the next example the value of s is decreased:
Scalar s;
for (s = 3 downto -0.1 by 1.4,
     display s ;
);

Note that the number of passes in a for statement may be restricted using the command line parameter or option forlim. For details on command line parameters and options, see section Specifying Options Through the Command Line and chapter The Option Statement respectively.

Like while statements, for statements may be used to control the solve statement. The following example illustrates the use of the for statement by replicating the random search for a global optimum of a non-convex model that we discussed above.

scalar i ;
scalar globmin / inf / ;
option bratio = 1 ;
for (i = 1 to 1000,
     x.l(j) = uniform(x.lo(j),x.up(j)) ;
     solve ml using nlp minimizing obj ;
     if (obj.l < globmin,
         globmin = obj.l ;
         bestsol(j) = x.l(j) ;
     );
);

Note that the logical condition in the while loop (count <= 1000) is replaced by the specification of the range of values for the scalar i. The body of the for loop is identical to the body of the while loop, except for the statement to update the scalar count that we needed in the while loop. This demonstrates the similarities and differences between the two loops.

The following GAMS code is illegal since it is not allowed to define equations inside a for statement.

for (s = 1 to 5,
     eq.. sum(i,x(i)) =g= 2 ;
);

The following GAMS code is also illegal since declarations inside a for statement are not permitted.

for (s = 1 to 5,
     scalar y ; y = 5 ;
);

4.33.6 The Repeat Statement

The repeat statement facilitates the repeated execution of one or more statements. This is done unconditionally at least once and stopped when a logical condition is satisfied.
4.33.6.1 The Repeat Statement: Syntax

The syntax for the repeat statement in GAMS is as follows:

```gams
repeat (
    statement; {statement;}
until logical_condition );
```

The keyword repeat indicates that this is a repeat statement. One or more statements are executed in each iteration. The keyword until introduces the termination criterion: if the logical condition is satisfied, the repeat loop is terminated. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

Note that the repeat statement is similar to the while statement, but a repeat loop is guaranteed to be executed at least one time since the logical condition is stated after the statements.

Attention

Only execution statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a repeat statement.

Examples are given in the next subsection.

4.33.6.2 The Repeat Statement: Examples

Consider the following simple example:

```gams
Scalar a / 1 /;
repeat (
    a = a + 1;
    display a;
until a = 5 );
```

The scalar `a` is increased in each iteration by 1. If `a` equals 5, the termination criterion is satisfied and the loop stops. Note that this example works nicely since both, the scalar and the increment, are integer. In case the entity on the right-hand side of the termination condition is not an integer or the increment is not an integer, we recommend a formulation of the check that is more stable to avoid rounding errors. An example for a stable termination condition follows.

```gams
Scalar a / 1 /;
repeat (
    a = a + 0.1;
    display a;
until abs(a-5) < 1e-6 );
```

Observe that in the next example the termination condition is TRUE from the start. In this case the statement in the body of the repeat statement is executed once and then the loop is terminated. Hence the final value of `a` will be 5.
Scalar a / 4 /;
repeat (  
a = a + 1;
display a;
until a >= 3 );

Note that the number of passes in a while statement may be restricted using the command line parameter or option forlim. For details on command line parameters and options, see section Specifying Options Through the Command Line and chapter The Option Statement respectively.

Here is a little more complex example. A repeat statement is used to narrow the interval where a quadratic function passes through zero. Note that, as is often the case, one of the statements in the repeat loop is another programming flow control statement, in this case an if statement.

Scalar max "current upper boundary of interval" /10/  
min "current lower boundary of interval" /-10/  
root "value where function equals zero"  
function_value1 "function value at min"  
function_value2 "function value at max"  
tolerance "tolerance for root" /0.00000001/  
signswitch "indicates that sign switch was found" /0/  
inc "increment to try to find sign switch" ;

function_value1 = 6 - 5*min + sqr(min);
inc = (max - min)/37;
root = min;
repeat (  
    root = root + inc;
    function_value2 = 6 - 5*root + sqr(root);
    if(( sign(function_value1) <> sign(function_value2)  
        and abs(function_value1) > 0  
        and abs(function_value2) > tolerance ),
        max = root;
        signswitch = 1;
    else
        if(abs(function_value2) > tolerance,  
            function_value1 = function_value2;
            min = root;
        );
    );
until (signswitch > 0) or (root > max );
display min, max, function_value1, function_value2;

The result of the display statement shows that the value of min is 1.892 and the value of max is 2.432, the interval was narrowed to 0.54, which is just a little less than the value of inc. As expected, function_value1 and function_value2 differ in sign, confirming that the root of the quadratic function is indeed in the interval.

4.33.7 The Break Statement

The break statement gives additional control over the execution of loop structures, namely the loop statement, the while statement, the for statement and the repeat statement. It allows to break the execution of a loop structure prematurely.
4.33.7.1 The Break Statement: Syntax

The syntax for the break statement is as follows:

break[n];

The keyword break indicates that this is a break statement. It terminates the n inner most control structures. n is optional and if it is omitted, it is set to 1.

Most often break statements are used in the context of if statements or with dollar conditions. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

4.33.7.2 The Break Statement: Examples

This is a simple, artificial example using the break statement to exit a loop statement:

Set i / i1*i10 /;
Scalar cnt / 0 /;
loop(i,  
  break$sameas('i6',i);  
  cnt = cnt+1;  
);
display cnt;

The break statement in combination with the dollar condition terminates the execution of the loop body in the 6th iteration. This can be seen looking at the value of cnt after the loop, which will be 5.

Here is a little more complex example which uses the optional argument n to terminate more than one loop structure at once:

Set i / i1*i10 /;
Scalar x, y,  
cnt / 0 /;
for(x = 1 to 10,  
  y = 0;  
  while(y < 10,  
    y = y+1;  
    loop(i,  
      break$sameas('i6',i) 2;  
      cnt = cnt+1;  
    );  
  );  
);
display cnt;

In this example, cnt will be 50 at the end. As in the previous example, it is increased 5 times in the inner most loop, before the break statement is executed. This time break is called with the argument 2, which causes the two inner most control structures (namely the loop and the while) to be terminated. The outer most control structure (the for) is not influenced, so that its body gets executed 10 times, which results in a total of 50 increments for the scalar cnt.

Note, if break would be called with the argument 3 instead of 2, also the for loop would be terminated, so that cnt would be 5 at the end. If break would be called with 1 (or without additional argument) instead of 2, only the inner most loop would be terminated so that cnt would be 500 at the end.
4.33 Programming Flow Control Features

4.33.8 The Continue Statement

The continue statement gives additional control over the execution of loop structures, namely the loop statement, the while statement, the for statement and the repeat statement. It allows to jump to the end of the inner most loop structure without executing the remaining statements in the body.

4.33.8.1 The Continue Statement: Syntax

The syntax for the continue statement is as follows:

```
continue;
```

The keyword continue indicates that this is a continue statement. It jumps to the end of the inner most control structure.

Most often continue statements are used in the context of if statements or with dollar conditions. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

4.33.8.2 The Continue Statement: Examples

This is a simple, artificial example using the continue statement to skip parts of a loop body:

```
Set    i / i1*i10 /;
Scalar cnt / 0 /;
loop(i,
    continue$(mod(ord(i),2)=0);
    cnt=cnt+1
);
display cnt;
```

In that example, every 2nd iteration of the loop statement is skipped. Therefore, cnt will be 5 at the end of the loop.

4.33.9 The Abort Statement

The abort statement is used to terminate the execution of a program. Most often the abort statement is used in the context of conditionals. Examples are given below. Also it may be used to display a text or an identifier in the listing file similar to the display statement but mostly to present the reason for the termination of the execution.

Note that the abort statement is to be distinguished from the dollar control option $abort which may be used to terminate the compilation of a program.
4.33.9.1 The Abort Statement: Syntax

The syntax for the `abort` statement is as follows:

```plaintext
abort [ ident | quoted text {, ident | quoted text} ];
```

The keyword `abort` indicates that this is an abort statement, all other elements of the statement are optional. `Ident` denotes an identifier. If the identifier is a set or a parameter, only the name of the set or parameter itself is specified, without any domains. If the identifier is a variable, an equation or a model, it must be followed by a suffix, since only `attributes` of variables, equations and models can be displayed. For more on variable and equation attributes including full lists, see sections Variable Attributes and Equation Attributes respectively. For details on model attributes, see section Model Attributes. Recall that sets also have attributes, they may also be displayed using the suffix notation. For details on set attributes, see section Set Attributes. As usual, `quoted text` must be surrounded by single or double quotes. The identifiers and the text may be mixed and matched in any order, and the whole statement may be continued over several lines.

An abort statement causes the termination of the execution with an execution error and the information in the statement will be displayed.

There is also a variant with the extension `.noError` that terminates the execution and displays the information, but does not cause an execution error. The syntax is as follows:

```plaintext
abort.noError [ ident | quoted text {, ident | quoted text} ];
```

Most often `abort` statements are used in the context of `if` statements or with `dollar conditions`. The syntax is as follows:

```plaintext
if (logical_condition, abort [ ident | quoted text {, ident | quoted text} ]; );
```

or

```plaintext
abort$logical_condition [ ident | quoted text {, ident | quoted text} ];
```

For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

4.33.9.2 The Abort Statement: Examples

Consider the following artificial example:

```plaintext
Set i / i1*i5 /;
Parameter p(i) / i1 1, i2 2, i3 3, i4 5, i5 8 /;
loop(i,  
  if (p(i) > 3, abort "Parameter larger than 3", p);  
  p(i) = p(i) + 2;
);
```
Note that the abort statement is part of an if statement which is part of a loop statement. The execution of this program will be terminated with the following display and error message:

```
---- 4 Parameter larger than 3
---- 4 PARAMETER p
i1 3.000, i2 4.000, i3 5.000, i4 5.000, i5 8.000
**** Exec Error at line 4: Execution halted: abort 'Parameter larger than 3'
```

Observe that the values of $p('1')$, $p('2')$ and $p('3')$ were updated, but the values of $p('4')$ and $p('5')$ are equal to the initialization values since the program was terminated before they could be updated.

If the extension .noError is used in the example above, the following lines will appear in the listing file:

```
---- 4 Parameter larger than 3
---- 4 PARAMETER p
i1 3.000, i2 4.000, i3 5.000, i4 5.000, i5 8.000
****
**** Execution halted from line 4: abort.noError 'Parameter larger than 3'
****
```

Note that the execution of the program is aborted as before, but there is no execution error in this case.

Instead of an if statement we may use a dollar condition in the loop:

```gams
Set i / i1*i5 /;
Parameter p(i) / i1 1, i2 2, i3 3, i4 5, i5 8 /;
loop(i,
   abort$(p(i) > 3) "Parameter larger than 3", p;
   p(i) = p(i) + 2;
);
```

Observe that this alternative formulation has the same outcome as above.

### 4.34 The Option Statement

#### 4.34.1 Introduction

The option statement is used to set various global system parameters to control among other things output detail, the solution process and the layout of displays. GAMS provides default values for global system parameters that are adequate for the most purposes. However, there are always cases when the user would like to maintain control of some aspects of the run. In addition, the option statement provides an efficient and compact syntax to perform powerful operations on identifiers. Observe that option statements are processed at execution time unlike dollar control options that are processed at compile time.

This chapter is organized as follows. We will first introduce the general syntax of the option statement, then we will continue with a list of all available options that may be used with option statements and provide links to their detailed explanations in the GAMS Call chapter. Finally we turn to the special options that involve identifiers.
4.34.1.1 The Syntax of the Option Statement

The general form of an option statement is as follows:

```
option(s) key1 [= value1] { ,|EOL key2 [= value2] } ;
```

The keyword `option` or `options` indicates that this is an option statement. It is followed by `key1`, which is one of the options that are listed in this chapter. Consider the following simple example:

```
option reslim=800;
```

Here the keyword `option` is followed by the `key reslim`. The option `reslim` specifies the maximum time in seconds that a solver may run before it terminates. Thus, in this example we give the solver 800 seconds to come up with a solution.

Note

Option names are not reserved words and therefore they do not conflict with other uses of their names.

Observe that it depends on the respective option whether a value is expected and if so, what type of value. There are six different cases. An overview is given in Table 1.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Type of Value</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>yes</td>
<td>no</td>
<td>-</td>
<td>dmpOpt, eject, memoryStat</td>

<td>identifier</td>
<td>See identifier options.</td>
</tr>
<tr>
<td>no</td>
<td>no</td>
<td>-</td>
<td>See identifier operations.</td>
</tr>
</tbody>
</table>

**Table 1: Types of Options**

Note that the last type is special: it does not involve a named option or key, but the keyword `option` is followed by identifiers and identifier operators. These special option statements are discussed in detail in section Special Options: Identifier Operations.

Observe that the value of an option may be reset as often as necessary, the new value will replace the previous value each time. Further, more than one option may be specified with one option statement and commas or end-of-line characters are both legal separators between options.

We will demonstrate with the following example how several options may be used. The code snippet may be added to the model [DICE].

```
option measure, limcol = 100
    optcr = 0.00, mip = xpress 
solve xdice using mip max wnx;
option clear = comp;
```
Note that in the first option statement four options are specified: option measure has no associated value, option limcol expects an integer value, option optcr expects a real value and option MIP expects a text string as value. The second option statement specifies just one identifier option: clear, which has the variable comp as value.

Attention

Option statements are executed in sequence with other instructions. Therefore, if an option statement is located between two solve statements, the new values will be assigned between the solves and thus they will apply only to the second solve statement.

4.34.2 List of Options

The options available through the option statement are grouped into the following functional categories:

- Options that affect output details
- Solver specific parameters
- Options that control choice of solver
- Options that affect input program control
- Other options
- Special options that involve identifiers

In the following subsections we will offer brief descriptions of the options in the first five categories. Note that each entry is linked to a detailed description of the respective option. Observe that detailed descriptions of all GAMS command line parameters, options and model attributes are given in section Detailed Descriptions of All Options. The options that belong to the last category are special, they are introduced and discussed in section Special Options that Involve Identifiers below.

4.34.2.1 Options that Control Output Details

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asyncSolLst</td>
<td>Print solution listing when asynchronous solve (Grid or Threads) is used</td>
</tr>
<tr>
<td>decimals</td>
<td>Decimal places for display statements</td>
</tr>
<tr>
<td>dispWidth</td>
<td>Number of characters to be printed in the column labels of all subsequent display statements</td>
</tr>
<tr>
<td>eject</td>
<td>Inject a page break into the LST file</td>
</tr>
<tr>
<td>epsToZero</td>
<td>Treat eps as zero when unloading to GDX</td>
</tr>
<tr>
<td>limCol</td>
<td>Maximum number of columns listed in one variable block</td>
</tr>
<tr>
<td>limRow</td>
<td>Maximum number of rows listed in one equation block</td>
</tr>
<tr>
<td>maxGenericFiles</td>
<td>Maximum number of generic file names tried at execution time file creation</td>
</tr>
<tr>
<td>MCPRHoldFx</td>
<td>Print list of rows that are perpendicular to variables removed due to the holdfixed setting</td>
</tr>
<tr>
<td>profile</td>
<td>Execution profiling</td>
</tr>
<tr>
<td>profileTol</td>
<td>Minimum time a statement must use to appear in profile generated output</td>
</tr>
<tr>
<td>solPrint</td>
<td>Solution report print option</td>

</tr>
<tr>
<td>sys19</td>
<td>Disable permutation on Column Generation (aka execute this as pre-GAMS 36)</td>
</tr>
<tr>
<td>threadsAsync</td>
<td>Limit on number of threads to be used for asynchronous solves (solveLink=6)</td>
</tr>
</tbody>
</table>

### 4.34.2.6 Special Options that Involve Identifiers

Several options involve identifiers: they either take identifiers as values or have no key and value, but perform an operation on an identifier. In the following two subsections we will introduce and discuss these special options.

#### 4.34.2.6.1 Special Options: Identifier Options

The value of identifier options is not a string or a number, but an identifier. In this subsection we will describe these options in detail.

**clear**

This option resets an identifier to its default value to free memory. The syntax is as follows:

```
option clear = identifier;
```
The following identifier types may be reset: sets, parameters, equations and variables. The option will free up memory to the GAMS heap manager, thus the memory may be used by GAMS but not by the operating system. To force the memory to be freed up to the operating system, the GAMS process needs to be terminated. One way to do this is to restart the execution system by solving a dummy model with the option SolveLink set to zero.

**kill**

This option is a synonym to option clear. Observe that the dollar control option $kill is not a synonym to $clear.

**shuffle**

This option rearranges the values of a parameter in a random order. The syntax is as follows:

```plaintext
option shuffle = itemname;
```

Here `itemname` is a one-dimensional parameter. One-dimensional parameters may be declared (and defined) in four different ways, depending on the domain and the data. The following table gives an overview of the effect of the option `shuffle` in the four cases.

<table>
<thead>
<tr>
<th>Universal set as domain</th>
<th>Has Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use the universal set to initialize the data (case 1 in the example below).</td>
<td>Use the universal set to add zero values before shuffling the data (case 3 in the example below).</td>
</tr>
<tr>
<td>Specific set as domain</td>
<td>Use the domain to initialize the data (case 2 in the example below).</td>
</tr>
</tbody>
</table>

If the parameter was declared without data (the second column in the table above), the domain or the universal set will be used to assign the numbers 1 to \( N \), where \( N \) is the number of elements in the domain or the universal set. If the parameter was declared with data (the third column in the table above), the domain or the universal set will be used to add zeroes for possibly missing entries. These zero values will participate in the random shuffle, but they will not be stored in the parameter. The following example serves as illustration:

```plaintext
Set i / i1*i5 /  
j / j1*j5 /;
option decimals = 0;

*Case 1: universal set as domain and no data
Parameter A(*) "The universe is used to fill the parameter";
option shuffle = A;
display A;

*Case 2: set j as domain and no data
Parameter B(j) "The set j is used to fill the parameter";
option shuffle = B;
display B;

*Case 3: universal set as domain and has data
Parameter C(*) "The universe is used to add zeroes" / j2 2, j4 4 /;
option shuffle = C;
display C;
```
The code above will generate the output that follows. Observe that in this example, the universal set is the union of the sets $i$ and $j$, which means that all elements of the sets $i$ and $j$ are members of the universal set. Note that we use random numbers, therefore the outcomes from a different run may vary.

---- 9 PARAMETER A  The universe is used to fill the parameter
i1 4,  i2 1,  i3 7,  i4 9,  i5 6,  j1 10,  j2 3,  j3 5
j4 8,  j5 2

---- 14 PARAMETER B  The set $j$ is used to fill the parameter
j1 1,  j2 5,  j3 2,  j4 4,  j5 3

---- 19 PARAMETER C  The universe is used to add zeroes
j1 2,  j2 4

---- 24 PARAMETER D  The set $i$ is used to add zeroes
i2 30,  i4 50,  i5 10

In the next example we will demonstrate how to generate a random mapping of a set:

Set $i$  / i1*i6 /,
    rmi(i,i) "random mapping";
Parameter A(i);
option shuffle = A;

rmi(i, i + (- Ord(i) + A(i))) = yes;
display rmi;

A display of the set $rmi$ follows. Note that there is exactly one element in each row and each column:

---- 7 SET rmi  random mapping

i1  i2  i3  i4  i5  i6
i1  YES
i2  YES
i3  YES
i4  YES
i5  YES
i6  YES

Observe that each use of the option shuffle will generate a new random data rearrangement.
4.34.2.6.2 Special Options: Identifier Operations  In some cases the keyword option in an option statement is followed by an identifier and one or more operators to perform identifier operations like display control, index matching, projection and aggregation of sets and parameters and permutation of sets and parameters.

4.34.2.6.2.1 Display Control  The display statement is introduced and discussed in chapter The Display Statement. While GAMS provides defaults for the displayed identifiers that suffice in most cases, the print format may be customized with the following option statement:

```plaintext
option ident:d;
option ident:d:r:c;
```

The keyword option is followed by the name of an identifier ident, a colon and an integer value d. Note that d may be between 0 and 8 and specifies the number of decimal places that will be displayed for the respective identifier. The specifications r and c are optional. They denote the number of index positions printed as row labels and the number of index positions printed as column labels respectively. Note that if r is zero, a list format will be used. For more information and examples, see sections Local Display Control and Display Statement to Generate Data in List Format.

4.34.2.6.2.2 Index Matching  Index matching is a very compact way to define multi-dimensional sets. The general syntax is as follows:

```plaintext
option set_name(index1:index2[:index3:...]);
```

The keyword option is followed by the name of the set, set_name, and two (or more) indices in parentheses that are linked with the matching operator ':'. Note that the set must have been declared earlier in the program. If the set has also been defined earlier in the program, it will be cleared first and then the matching operation will be processed. Note furthermore that the list of identifiers may be expanded to more than two and that besides the matching operator ':' also ',' may be used and will be interpreted as product operator. Consider the following example which also makes use of display control:

```plaintext
Set i / i1,i2/  
  j / j1,j2,j3 /  
  k / k1*k5 /  
  ij(i,j), ijk(i,j,k), kij(k,i,j);
* index matching
Option ij(i:j), ijk(i,j:k), kij(k:i,j);
* display control
Option ij:0:0:1, ijk:0:0:1, kij:0:0:1;
Display ij, ijk, kij;
```

In its simplest form the matching operator is used to create the two dimensional set ij.

```plaintext
-----     9 SET ij
  i1.j1
  i2.j2
```

Note that each member of the index \( i \) has been matched with a member of the index \( j \) until one of the indices ran out of members.

The index matching operations to define the three-dimensional sets \( ijk \) and \( kij \) illustrate a more sophisticated usage of the index operator. The sets \( ijk \) and \( kij \) are built with the indices from left to right using the product operator when a ',' is encountered or the matching operator when a '::' is found.

For \( ijk \) the first operator is the ',' which is interpreted as product operator for the sets \( i \) and \( j \) and hence builds the Cartesian product of the two sets which has six 2-tuples as elements (\( i1.j1, i1.j2, i1.j3, i2.j1, i2.j2, i2.j3 \)). The matching operator '::' is then applied to match those 2-tuples with the five set elements in \( k \). The resulting sets are:

---- 9 SET ijk

\[
\begin{align*}
i1.j1.k1 \\
i1.j2.k2 \\
i1.j3.k3 \\
i2.j1.k4 \\
i2.j2.k5 
\end{align*}
\]

---- 9 SET kij

\[
\begin{align*}
k1.i1.j1 \\
k1.i1.j2 \\
k1.i1.j3 \\
k2.i2.j1 \\
k2.i2.j2 \\
k2.i2.j3 
\end{align*}
\]

The previous example can be extended to define sets of even higher dimension in the following way:

```plaintext
set h / h1*h4 / 
  hijk_1(h:ijk); 
  hijk_2(h:i,j:k); 
* display control 
  Option hijk_1:0:0:1, hijk_2:0:0:1; 
  Display hijk_1, hijk_2;
```

Note that sets \( hijk_1 \) and \( hijk_2 \) will be different even though \( hijk_1 \) uses set \( ijk \) and \( hijk_2 \) uses the same matching and product operation used at definition of \( ijk \) but spelled out. As already mentioned above, the matching operator builds up the sets with the indices from left to right. Hence, as set \( ijk \) is build first and then used on the right of the matching operator the two sets are built up differently.

---- 19 SET hijk_1

\[
\begin{align*}
h1.i1.j1.k1 \\
h2.i1.j2.k2 \\
h3.i1.j3.k3 \\
h4.i2.j1.k4 
\end{align*}
\]
4.34.2.6.2.3 Projection and Aggregation of Sets and Parameters  In GAMS, projection and aggregation operations on sets may be performed in two different ways: with an assignment and the `sum` operator, and with an option statement.

Using an assignment and the `sum` operator is the slower but more intuitive way. Assignments and the `sum` operator are introduced and discussed in detail in chapter Data Manipulations with Parameters and section Indexed Operations respectively. Here we only show how they may be used in the context of sets to perform projections and aggregations. The following example serves as illustration.

Sets i        / i1*i3 /  
  j        / j1*j2 /  
  k        / k1*k4 /  
  ijk(i,j,k) / #i.#j.#k /  
  ij1a(i,j)  
  ij1b(i,j);  

Scalars Count_1a, Count_1b, Count_2a, Count_2b;  

* Method 1: Using an assignment and the sum operator for a projection  
ij1a(i,j) = sum(k, ijk(i,j,k));  

* Method 1: Using an assignment and the sum operator for aggregations  
Count_2a = sum(ijk(i,j,k),1);  
Count_1a = sum(ij1a(i,j),1);  

Note that the set `ijk` is a three-dimensional set, its elements are 3-tuples and all permutations of the elements of the three sets `i`, `j` and `k` are in its domain. Thus the number of elements of the set `ijk` is 3 x 2 x 4 = 24. The sets `ij1a` and `ij1b` are two-dimensional sets that are declared in the set statement, but not defined. The first assignment statement defines the members of the set `ij1a`. This is a projection from the set `ijk` to the set `ij1a` where the three-tuples of the first set are mapped onto the pairs of the second set, such that the dimension `k` is eliminated. This means that the four elements "i1.j1.k1", "i1.j1.k2", "i1.j1.k3" and "i1.j1.k4" of the set `ijk` are all mapped to the element "i1.j1" of the set `ij1a`. Note that in this context, the result of the `sum` operation is not a number but a set. The second and third assignments are aggregations, where the number of elements of the two sets are computed. As already mentioned, the result of the first aggregation is 24 and the result of the second aggregation is 6 = 24 / 4.

The second way to perform projections and aggregations is faster and more compact, it uses an option statement. The general syntax of this option statement is as follows.

```gams
option ident1 < ident2 ;
option ident1 <= ident2 ;
```
The keyword *option* is followed by the identifiers *ident1* and *ident2* which are linked by the symbol `'<'` or `'<='`. Observe that in most cases the two symbols have the same effect. The exception is the special case when both identifiers are defined over domains that use at least one shared index set more than once, see the example below. Note that in general the dimension of the item on the left has to be equal or less than the dimension of the item on the right. Further, the index space of the two identifiers must be matchable. If the dimensions of the two identifiers are equal, then the same indices must appear in both, albeit the order may differ. If the dimension of the left item is less than the dimension of the right item, then the indices on the left must also appear on the right.

Observe that if both identifiers are sets, the operation will be a *projection*. However, if the identifier on the left-hand side is a *scalar* or a *parameter* and the identifier on the right-hand side is a set it will be an *aggregation*. The example that follows shows how the projection and the two aggregations above are accomplished with the option statement.

* Method 2: Option statement performs a projection
  Option ij1b < ijk;

* Method 2: Option statements performs aggregations (counting of elements)
  Option Count_2b < ijk;
  Option Count_1b < ij1b;

display ijk, ij1a, ij1b, Count_1a, Count_1b, Count_2a, Count_2b;

In the example above, the set on the left-hand side, *ij1b*, has fewer indices than the set on the right-hand side, *ijk*. Observe that if the two sets differ only in the order of the indices then a projection will have the effect of a *permutation* of the tuple.

Note

The option statement for projection and aggregation operations may also be applied to parameters.

Until now the indices in the domain of the sets were unique. A special case arises when sets are defined over a domain with the same indices, for example the set *s(i,i,i)*. In this case, a projection always has the effect of a permutation. Users may choose whether they wish to perform the permutation from left to right or from right to left. The option statement

Option item1 < item2;

means a right-to-left permutation, while the option statement

Option item1 <= item2;

entails a left-to-right permutation. The following example clarifies the difference:

Set i / i1*i3 /
s(i,i,i) "Set members" / i1.i2.i3, i3.i3.i1/
pR1(i,i) "projection right to left with assignment"
pR2(i,i) "projection right to left with option statement"
pL1(i,i) "projection left to right with assignment"
pL2(i,i) "projection left to right with option statement";
Alias (i,ii,iii);

* Right-to-left permutation, two ways
pR1(i,ii) = sum(s(iii,ii,i),1);
option pR2 < s;

* Left-to-right permutation, two ways
pL1(i,ii) = sum(s(i,ii,iii),1);
option pL2 <= s;

option s:0:0:1, pR1:0:0:1, pR2:0:0:1, pL1:0:0:1, pL2:0:0:1;
display s, pR1, pR2, pL1, pL2 ;

Note that in the right-to-left permutation, the element "i1.i2.i3" is projected to "i3.i2" and the element "i3.i3.i1" is projected to "i1.i3". In the left-to-right permutation however, the element "i1.i2.i3" is projected to "i1.i2" and the element "i3.i3.i1" is projected to "i3.i3". Hence, the left-to-right permutation (<=) might be more intuitive.

Our examples so far involved only sets. As mentioned above, projections and aggregations may also be performed with parameters. However, there are some subtle differences. The first difference refers to the terminology: we aggregate sets, but we count parameters. The second difference is the result of the operation if the domain of the left symbol is just a permuted version of the domain of the right symbol. Consider the following example:

Set i / i1*i3 /
   j / j1*j2 /;
Table p(i,j)
   j1 j2
  i1  1  2
  i2  3  4
  i3  5  6;
parameter pperm(j,i);
option pperm < p;
option decimals = 0;
display p, pperm;

The output generated by the display statement follows:

---- 13 PARAMETER p

   j1   j2
i1  1  2
i2  3  4
i3  5  6

---- 13 PARAMETER pperm

   i1   i2   i3
j1  1   3   5
j2  2   4   6
4.34 The Option Statement

4.34.2.6.2.4 Permutation of Sets and Parameters  In GAMS, the > sign can be used to create complete permutations of one- and multi-dimensional sets and parameters. Consider the following example based on the test library model [PERM1]:

First, a set \( i \) for which all permutations should be computed is declared and defined. A permutation of a one-dimensional set \( i \) can be represented by a two-dimensional set like \( \text{perm}(i,i) \) where the \( i \) index is duplicated. In the example, set \( \text{perm}(i,i) \) represents permutation \((1 2)(3)\) in cycle notation. For a set with three elements, there are \(3 \times 2 \times 1 = 6\) permutations. The statement \( \text{option pall} > i; \) results in all permutations of \( i \) being computed and stored in three-dimensional set \( \text{pall}(p,i,i) \) where the first index \( p \) serves as a counter to enumerate all permutations.

```gams
set i 'set to permute' / i1*i3 / 
perm(i,i) 'exemplary permutation' / i1.i2, i2.i1, i3.i3 / 
$eval pmax fact(card(i)) 
p 'permutation index' / p1*p%pmax% / 
pall(p,i,i) 'permutation set';
option pall > i;
option pall:0:0:1;
display pall;
```

Note that we use \( \text{display control} \) such that the display statement results in:

```
---- 8 SET pall permutation set

p1.i1.i1
p1.i2.i2
p1.i3.i3
p2.i1.i1
p2.i2.i3
p2.i3.i2
p3.i1.i2
p3.i2.i1
p3.i3.i3
p4.i1.i2
p4.i2.i3
p4.i3.i1
p5.i1.i3
p5.i2.i1
p5.i3.i2
p6.i1.i3
p6.i2.i2
p6.i3.i1
```

For multi-dimensional sets, the permutation operator follows the same logic. Consider the following example:

Sets \( j, k \) and a two-dimensional set \( \text{jk}(j,k) \) are defined. In order to find all permutations of \( \text{jk}(j,k) \), the indices are again duplicated and a permutation index is introduced:

```gams
set j / j1*j2 /, k / k1*k5 / 
jk(j,k) / j1.k3, j1.k5, j2.k1 / 
$eval pmax fact(card(jk)) 
p / p1*p%pmax% / 
pall(p,j,k,j,k); 
option pall > jk; 
option pall:0:0:1; 
display pall;
```

For multi-dimensional sets, the permutation operator follows the same logic. Consider the following example:
The display statement results in:

```plaintext
    8 SET pall
p1.j1.k3.j1.k3
p1.j1.k5.j1.k5
p1.j2.k1.j2.k1
p2.j1.k3.j1.k3
p2.j1.k5.j2.k1
p2.j2.k1.j1.k5
p3.j1.k3.j1.k5
p3.j1.k5.j1.k3
p3.j2.k1.j2.k1
p4.j1.k3.j1.k5
p4.j1.k5.j2.k1
p4.j2.k1.j1.k3
p5.j1.k3.j2.k1
p5.j1.k5.j1.k3
p5.j2.k1.j1.k3
p6.j1.k5.j1.k5
p6.j1.k3.j2.k1
p6.j2.k1.j1.k3
```

In addition to set elements, it is also possible to permute numerical data in a GAMS parameter. Consider the following example where all permutations of the numerical values stored in the one-dimensional parameter `a(i)` are computed:

```plaintext
set i / i1*i3 /
$eval pmax fact(card(i))
p / p1*p%pmax% /;
Parameter a(i) /i1 1, i2 2, i3 3/
    pall_a(p,i);
option pall_a > a;
option pall_a:0:1:1;
display pall_a;
```

The display statement results in:

```plaintext
    8 PARAMETER pall_a
      i1   i2   i3
   p1    1    2    3
   p2    1    3    2
   p3    2    1    3
   p4    2    3    1
   p5    3    1    2
   p6    3    2    1
```

The permutation can also be extended to multi-dimensional parameters. Consider the following example where all permutations of the numerical values stored in the two-dimensional parameter `b(j,k)` are computed:
4.35 System Attributes

4.35.1 Introduction

System attributes give access to string constants in the GAMS system environment. We will refer to these string constants as system suffixes. Moreover, there are attributes that can be used as data elements for user symbols. This way one can get access e.g. to the solvers (as set elements) in the system. We will refer to these data elements as system data. Two special system data attributes, namely powerSetLeft and powerSetRight, for a three dimensional set setName(n,s,b) create data which can be interpreted as a numbering system with base b and s digits. Finally, a system attribute can provide access to a system function that was hidden by the compiler because of a name conflict with a user symbol.

4.35.2 System Suffixes

System suffixes contain information about the GAMS system environment during a run. There are two ways to reference them: system.suffix and %system.suffix%. Here system is a keyword and .suffix is the name of the system suffix. A full list is given in section List of all System Suffixes below. Note that system.suffix references the execution-time version of the system suffix and %system.suffix% references the compile-time version resulting in a textual replacement. The execution-time system suffix can only be used in the context of put files. Consider the following example where both versions are used:

```
file fx;
put fx 'lp:' system(LP);
option lp=gurobi;
put / 'lp:' system(LP)
put / 'lp:%system(LP)%';
```

Observe that the compile-time string %system(LP)% is evaluated at compile time and does not change. However, the execution-time system suffix system(LP) is evaluated at execution time and it does change. It is first CPLEX, since CPLEX is the default LP solver. Then it changes to GUROBI as a result of the execution-time command option LP=gurobi;. The resulting put file fx.put follows:
4.35.2.1 Execution-Time System Suffixes

Execution-time system suffixes are only used in the context of the put writing facility with commands like `put`, `putclose` and `put utility`. Consider the following simple example. We have the files `x.gms` and `dummy.gms`, where `x.gms` contains just the following line:

```gams
file fx; put fx system.version;
```

The file `dummy.gms` contains the following:

```gams
$exit;
```

We run these files with the following calls:

```bash
> c:\gams\win64\24.7\gams x.gms action=c s=putVersion
```

Note that the value `c` for the command-line parameter `action` causes the first input file to be compiled only. The result is saved in the work file `putVersion`. Then we restart and execute `dummy.gms`. Now, depending on the GAMS release version, the `put` file `fx` will have a different content:

- `c:\gams\win64\24.7\gams dummy.gms r=putVersion` // this produces a put file with content "GAMS Rev 247"
- `c:\gams\win64\24.8\gams dummy.gms r=putVersion` // this produces a put file with content "GAMS Rev 248"

In contrast, the value of the compile-time system suffix `%system.version%` is determined at compile time. Suppose we change the file `x.gms` to contain the following line:

```gams
file fx; put fx "%system.version%";
```

The file `dummy.gms` is not changed and we use the same calls as above. Note that the `put` file will have the same content for both versions of GAMS:

- `c:\gams\win64\24.7\gams dummy.gms r=putVersion` // this produces a put file with content "GAMS Rev 247"
- `c:\gams\win64\24.8\gams dummy.gms r=putVersion` // this produces a put file with content "GAMS Rev 248"

4.35.2.2 Compile-Time System Suffixes

Compile-time system suffixes may be placed anywhere a compile-time variables makes sense, including code for conditional compilation. The quoting of these compile-time system suffixes depends on their use in the code. Consider the following example:

```gams
$set systemDATE %system.date%
display "system.date", "%system.date%";
$ifi %system.LP% == Xpress $log "LP solver is Xpress."
```

The resulting output generated by the display statement follows:

```
---- 3 system.DATE
11/07/16
```

4.35.2.3 List of all System Suffixes

In the following table all system suffixes are listed.
<table>
<thead>
<tr>
<th>System Suffix</th>
<th>Description</th>

A model that prints all system suffixes with its current values to a put file can be found in model [SSUFFIX].

#### 4.35.3 System Data

Some of the system relevant information does not fit into a single string. Such system data can be stored in GAMS symbols. The system data for this symbol can be accessed in the data statement of the symbol, e.g. `set allSolvers / system.solverNames /`. Now you can work with the solver names as you can work with any set. The system data can be viewed as an internal set, so it can be you can to create more complex GAMS symbols with this information. For example:

```gams
set seq / 1*1000 /;
set solvermap(seq,*) / set.seq:system.solverNames /;
parameter solverpar(*) / system.solverNames 1 /;
```

Here is the list and dimensionality of the system data:

### 4.35.3.1 Power Set

The very special system attribute `powerSetLeft` and `powerSetRight` do not provide access to static data relevant to the system but produce data based on existing sets `b` and `s`. This system data produced can be interpreted as a numbering system with base `b` and `s` digits. The total number of tuples created is `power(card(b), card(s))`. The first index of the resulting set has to have at least this size. The following small example demonstrates the functionality of `powerSetRight`:

```plaintext
$set digits 3
set s / s1*s%digits%/ , b / 0,1 /;
$eval nMax power(card(b),card(s))
set n / n1*n%nMax%/ ;
x(n,s,b) / system.powerSetRight /;
option x:0:0:%digits%; display x;
```

With 3 digits the display results in the following output:

```
---- 6 SET x
 n1.s1.0,  n1.s2.0,  n1.s3.0
 n2.s1.0,  n2.s2.0,  n2.s3.1
 n3.s1.0,  n3.s2.1,  n3.s3.0
 n4.s1.0,  n4.s2.1,  n4.s3.1
 n5.s1.1,  n5.s2.0,  n5.s3.0
 n6.s1.1,  n6.s2.0,  n6.s3.1
 n7.s1.1,  n7.s2.1,  n7.s3.0
 n8.s1.1,  n8.s2.1,  n8.s3.1
```

Changing `powerSetRight` to `powerSetLeft` reassigns the order of the digits. So the lowest digit is on the left:

```
---- 6 SET x
 n1.s1.0,  n1.s2.0,  n1.s3.0
 n2.s1.1,  n2.s2.0,  n2.s3.0
 n3.s1.0,  n3.s2.1,  n3.s3.0
 n4.s1.1,  n4.s2.1,  n4.s3.0
 n5.s1.0,  n5.s2.0,  n5.s3.1
 n6.s1.1,  n6.s2.0,  n6.s3.1
 n7.s1.0,  n7.s2.1,  n7.s3.1
 n8.s1.1,  n8.s2.1,  n8.s3.1
```
4.35.4 Access to Hidden Functions

Intrinsic functions are not keywords but they are stored in a list of predefined names. If a user program uses such a predefined name of a function for a user symbol, GAMS will hide the original function. For example,

```gams
set uniform 'School Uniform' / skirt, blouse, blazer, socks, shoes /;
scalar randomNumber;
randomNumber = uniform(0,1);
```

will result in a compilation error in the second line because GAMS expects `uniform` to be a set. The function `uniform` is hidden for this GAMS program. Renaming the user symbol that hides a function is often the best solution for this, but there are a few cases (including GAMS code already compiled and stored in a restart file) where renaming is not an option. A hidden function can be accessed via the system attribute `system.functionName`. So the following will successfully compile and execute:

```gams
set uniform 'School Uniform' / skirt, blouse, blazer, socks, shoes /;
scalar randomNumber;
randomNumber = system.uniform(0,1);
```

4.36 The Grid and Multi-Threading Solve Facility

4.36.1 Introduction

The GAMS Grid facility allows to take advantage of High Performance Computing Grids and systems with multiple CPUs. This language feature facilitates the management of asynchronous submission and collection of model solution tasks in a platform independent fashion. A simple architecture, relying on existing operating system functionality allows for rapid introduction of new environments and provides for an open research architecture.

A typical application uses a coarse grain approach involving hundreds or thousands of model solutions tasks which can be carried out in parallel. Examples include but are not limited to scenario analysis, Monte Carlo simulations, Lagrangian relaxation, decomposition algorithms and advanced solution approaches.

The grid features work on all GAMS platforms and have been tailored to many different environments, like the Condor Resource Manager, a system for high throughput computing from the University of Wisconsin-Madison. Researchers using Condor reported a delivery of 5000 CPU hours in 20 hours wall clock time.

Similarly, the GAMS Multi-Threading Solve Facility allows the asynchronous submission and collection of model solution tasks on a single, multi-threaded machine while using efficient in-memory communication between GAMS and the solver.

**Disclaimer:** The use of the term grid computing may be offensive to some purists in the computer science world. We use it very loosely to refer to a collection of computing components that allow us to provide high throughput to certain applications. One may also think of it as a resurrection of the commercial service bureau concept of some 30 years ago.

**Caution:** Although these features have been tested on all platforms and are part of our standard release we may change the approach and introduce alternative mechanisms in the future.

**Acknowledgments:** Prof. Monique Guignard-Spielberg and Antoine Sauré at that time at Wharton School at the University of Pennsylvania introduced us to parallel Lagrangian relaxation on the SUN Grid Environment. Prof. Michael Ferris from the University of Wisconsin-Madison adopted our original GAMS grid approach to the high throughput system Condor and helped to make this approach a practical proposition.
4.36.2 The Grid Facility: Basic Concepts

The Grid facility separates the solution process into several steps which then can be controlled separately. First we will review the steps taken during synchronous solution and then we will introduce the asynchronous or parallel solution steps.

When GAMS encounters a solve statement during execution it proceeds in three basic steps:

1. **Generation**: The symbolic equations of the model are used to instantiate the model using the current state of the GAMS data base. This instance contains all information and services needed by a solution method to attempt a solution. This representation is independent of the solver and computing platform.

2. **Solution**: The model instance is handed over to a solver and GAMS will wait until it terminates.

3. **Update**: The detailed solution and statistics are passed to GAMS from the solver to update the GAMS data base.

In most cases, the time taken to generate the model and update the data base with the solution will be much smaller than the actual time spent in a specific solver. The model generation will take a few seconds, whereas the time to obtain an optimal solution may take a few minutes to several hours or even longer. If sequential model solutions do not depend on each other, we can solve in parallel and update the data base in a random order. All we need is a facility to generate models, submit them for solution and continue. At a convenient point in our GAMS program we will then look for the completed solutions and update the data base accordingly. To summarize, solving in parallel entails two steps:

1. **Submission Loop**: In this phase we will generate and submit models for solutions that can be solved independently.

2. **Collection Loop**: The solutions of the previously submitted models are collected as soon as a solution is available. It may be necessary to wait for some solutions to complete by pausing the execution for some time.

Note that we have assumed that there will be no errors in any of these steps. Of course, this will not always be the case and elaborate mechanisms are in place to make the operation fail-safe.

**Note**

For scenario analysis the solver GUSS might be of particular interest. The model [GUSSGRID] demonstrates how GUSS is used together with the Grid facility.

4.36.3 The Grid Facility: A First Example

In this section we will illustrate the use of the basic grid facility with the model [QMEANVAR]. This model traces an efficiency frontier for restructuring an investment portfolio. Each point on the frontier requires the solution of independent quadratic mixed integer models. The original solution loop is shown below:

```gams
loop(p(pp),
   ret.fx = rmin + (rmax-rmin)/(card(pp)+1)*ord(pp) ;
   solve minvar min var using miqcp ;
   xres(i,p) = x.l(i);
   report(p,i,'inc') = xi.l(i);
   report(p,i,'dec') = xd.l(i);
);
```

This loop will save the solutions of the model minvar for different returns ret. As the solutions do not depend on the order in which they are carried out, we can rewrite this loop to operate in parallel.
4.36.3.1 The Submission Loop

The first step for solving in parallel using the Grid facility is to write the submission loop:

Parameter h(pp) 'model handles';
minvar.solveLink = 3;
loop(p(pp),
   ret.fx = rmin + (rmax-rmin)/(card(pp)+1)*ord(pp) ;
   solve minvar min var using miqcp;
   h(pp) = minvar.handle;
);

The model attribute solveLink controls the behavior of the solve statement. The value of 3 (which is equivalent to the compile-time constant %solveLink.Async Grid%) directs GAMS to generate the model and submit it for solution and then continue without waiting for the completion of the solution step. Thus with setting minvar.solveLink to 3 we activate grid computing.

A handle in the grid environment identifies the particular model and data instances available. The model attribute handle contains a unique identification of each submitted solution request and is typically stored in a parameter defined over a set that covers all model instances. The specific numerical values of handles are assigned by GAMS and may be used to recover solutions and manage models that are solved on the grid. In our example, the handle parameter is h and the set of all model instances is pp. The handle values that are stored in h are later used to collect the solutions once the solution processes are completed.

4.36.3.2 The Collection Loop

We collect the solutions with the following collection loop:

loop(pp$handleCollect(h(pp)),
   xres(i,pp) = x.l(i);
   report(pp,i,'inc') = xi.l(i);
   report(pp,i,'dec') = xd.l(i);
);

Note that the dollar condition restricts the looping set pp to those elements which return a nonzero value to the function handleCollect(h(pp)). The function handleCollect tests the solution status for each element of the set pp. And if the solution is available, it is read into the GAMS data base. In this case the function returns a value of 1. If the solution is not ready to be retrieved, the value zero will be returned.

Observe that the collection loop above has one big flaw. If a solution has not been ready (that is if handleCollect equaled zero), it will not be retrieved. We need to call this loop several times until all solutions have been retrieved or we get tired of it and quit. We will use a repeat until construct and the handle parameter h to control the loop to look only for the solutions that have not been loaded yet. The code follows:

repeat
   loop(pp$handleCollect(h(pp)),
      xres(i,pp) = x.l(i);
      report(pp,i,'inc') = xi.l(i);
      report(pp,i,'dec') = xd.l(i);
   );
   display$handleDelete(h(pp)) 'trouble deleting handles' ;
   h(pp) = 0;
until card(h) = 0 or timeelapsed > 100;
xres(i,pp)$h(pp) = na;
Once we have extracted a solution we will set the handle parameter \( h \) to zero. In addition, we want to remove the instance from the system by calling the function \( \text{handleDelete} \) which returns zero if successful. No harm is done if it fails but we want to be notified via the conditional display statement. Before running the collection loop again, we may want to wait a while to give the system time to complete more solution steps. This is done with the function \( \text{readyCollect} \) which waits until another model instance with a handle in \( h \) is ready to be collected (or the optionally defined number of seconds has passed). The final wrinkle is to terminate if all model instances have been deleted from the system since their solutions were retrieved or after 100 seconds have elapsed, even if we did not get all solutions. This is accomplished with the function \( \text{timeElapsed} \) and is important, because if one of the solution steps fails our program would never terminate. Recall that the handle parameter \( h \) equals zero for all elements of the set \( pp \) whose related models have been solved and their solutions have been extracted. The last statement in the code above sets the results of the missed solves to \( \text{na} \) to signal the failed solve. The parameter \( h \) will now contain the handles of the failed solves for later analysis.

Alternatively, we could use the function \( \text{handleStatus} \) and collect the solutions that are stored in a GDX file. For example, we could write:

```gams
loop(pp$(handleStatus(h(pp)) = 2),
   minvar.handle = h(pp);
   execute_loadhandle minvar;
   xres(i,pp) = x.l(i);
   report(pp,i,'inc') = xi.l(i);
   report(pp,i,'dec') = xd.l(i);
);
```

The function \( \text{handleStatus} \) tests the solution process and returns the value 2 if the solution process has been completed and the results can be retrieved. The solution is stored in a GDX file which can be loaded in a way similar to other GDX solution points. First, we need to specify which solution to retrieve by setting the the model attribute \( \text{minvar.handle} \) to the appropriate value. Then we can use the statement \( \text{execute_loadhandle} \) to load the solution for the model \( \text{minvar} \) back into the GAMS data base.

**Note**

Except for the requirement of a model with a previously specified handle, the command \( \text{execute_loadhandle} \) operates like the procedure \( \text{execute_loadpoint} \).

Using the function \( \text{handleStatus} \) and the command \( \text{execute_loadhandle} \) instead of the simpler \( \text{handleCollect} \), adds one more layer of control to the final collection loop. Now we need one additional \( \text{if} \) statement inside the collection loop above:

```gams
repeat
   loop(pp$h(pp),
      if(handleStatus(h(pp)) = 2,
         minvar.handle = h(pp);
         execute_loadhandle minvar;
         xres(i,pp) = x.l(i);
         report(pp,i,'inc') = xi.l(i);
         report(pp,i,'dec') = xd.l(i);
         display$h(pp)$handleDelete(h(pp)) 'trouble deleting handles' ;
         h(pp) = 0;
      );
   ) ;
   display$readyCollect(h, 100) 'Problem waiting for next instance to complete';
until card(h) = 0 or timeelapsed > 100;
```

Finally, we are ready to run the modified model.
4.36.3.3 The Execution Log

The execution log will contain some new information that may be useful for more advanced applications:

```plaintext
--- LOOPS pp = p1
--- 46 rows 37 columns 119 non-zeroes
--- 311 nl-code 7 nl-non-zeroes
--- 14 discrete-columns
--- Submitting model minvar with handle grid137000002
--- Executing after solve
... 
--- GDXin=C:\answerv5\gams_srcdev\225j\grid137000003\gmsgrid.gdx
--- Removing handle grid137000003
```

Note that the log contains some additional information about the submission, retrieval and removal of the solution instance. In the following sections we will make use of this additional information.

The execution log does not contain any solver log. Though, if a logOption value is set, that triggers writing to a file (i.e. 2 or 4), the solver log of each job will be written to the corresponding folder in the Grid Directory. So, if the solver log should be inspected when the job is done, one needs to make sure, that these folders do not get cleaned automatically, e.g. by setting the gridDir command line parameter.

For a complete example for grid computing, see the grid enabled transport model [TRNSGRID].

Observe that we have made no assumptions about what kind of solvers and what kind of computing environment we will operate. The example above is completely platform and solver independent and it runs on a Windows laptop or on a massive grid network like the Condor system without any changes in the GAMS source code.

4.36.4 Advanced Use of Grid Features

In this section we will describe a few special application requirements and show how this can be handled with the current system. Some of those applications may involve thousands of model instances with solution times of many hours each. Some may fail and require resubmission. More complex examples require communication and the use of GAMS facilities like the Branch-and-Cut-and-Heuristic Facility (BCH), which submit other models from within a running solver.

Imagine a situation with thousands of model instances each taking between minutes and many hours to solve. We will break the master program into a submitting program, an inquire program and a final collection program. We will again use the model [QMEANVAR] to demonstrate the principle. We will split the code of the modified [QMEANVAR] GAMS code into three components: qsubmit, qcheck and qreport.

4.36.4.1 Very Long Job Durations: The Submitting Program

The file qsubmit.gms will include everything up to and including the new submission loop. To save the instances we will need a unique grid directory gdir and to restart the problem we will have to create a save file. For details on the save and restart facility in GAMS, see chapter The Save and Restart Feature. When running the first job, we will use the command line parameter save or its synonym s to create the required save file:

```plaintext
> gams qsubmit s=submit gdir=c:\test\grid
```
4.36.4.2 Very Long Job Durations: The Inquire Program

The solution of all the model instances may take hours. From time to time we may run a quick inquiry job to learn about the status. The following program `qcheck.gms` will list the current status:

```gams
Parameter status(pp,*);
Scalar handle;
Acronym BadHandle, Waiting, Ready;
loop(pp,
  handle = handleStatus(h(pp));
  if(handle=0,
    handle = BadHandle;
  elseif handle=2,
    handle = Ready;
  minvar.handle = h(pp);
  execute_loadhandle minvar;
  status(pp,'solvestat') = minvar.solvestat;
  status(pp,'modelstat') = minvar.modelstat;
  status(pp,'seconds') = minvar.resusd;
  else
    handle = Waiting;
  );
  status(pp,'status') = handle;
); display status;
```

For details on the model attributes referenced in the code above, see `handle`, `solveStat`, `modelStat` and `resUsd`. To run the program above, we will restart from the previous save file by using the command line parameter `restart` or its synonym `r`.

```bash
> gams qcheck r=submit gdir=c:\test\grid
```

The output generated by the display statement may look like the following:

```
---- 173 PARAMETER status

<table>
<thead>
<tr>
<th>solvestat</th>
<th>modelstat</th>
<th>seconds</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>p1 1.000</td>
<td>1.000</td>
<td>0.328</td>
<td>Ready</td>
</tr>
<tr>
<td>p2 1.000</td>
<td>1.000</td>
<td>0.171</td>
<td>Ready</td>
</tr>
<tr>
<td>p3</td>
<td></td>
<td></td>
<td>Waiting</td>
</tr>
<tr>
<td>p4</td>
<td></td>
<td></td>
<td>Waiting</td>
</tr>
<tr>
<td>p5 1.000</td>
<td>1.000</td>
<td>0.046</td>
<td>Ready</td>
</tr>
</tbody>
</table>
```

We may want to do some more detailed analysis on one of the solved model instances. The respective program, called `qanalyze.gms`, may include the following lines of code:

```gams
$if not set instance $abort --instance is missing
if(not handleStatus(h('%instance%')),
  abort$yes 'model instance %instance% not ready');
minvar.handle = h('%instance%');
execute_loadhandle minvar;
display x.l,xi.l,xd.l;
...
```

For information on dollar control options, see chapter Dollar Control Options, especially the detailed descriptions of the options `$if` and `$abort`. Note that `instance` is a compile-time variable. The program may be called using a double dash parameter, which defines and sets a GAMS compile-time variable:

```bash
> gams qanalyze r=submit gdir=c:\test\grid --instance=p4
```
4.36.4.3 Very Long Job Durations: The Collection Program

Once all jobs are completed we are ready for the collection loop. For simplicity, we will not include the repeat loop, because we would not run the final collection program unless we were satisfied that we got most of the solutions that we wanted. The file `qreport.gms` could look like the following:

```plaintext
loop(pp$handleStatus(h(pp)),
  minvar.handle = h(pp);
  execute_loadhandle minvar;
  xres(i,pp) = x.l(i);  
  report(pp,i,'inc') = xi.l(i);
  report(pp,i,'dec') = xd.l(i);
  display$handleDelete(h(pp)) 'trouble deleting handles' ;
  h(pp) = 0;
);
  xres(i,pp)$h(pp) = na;
  ...
```

We will restart the program above from the `save file` that was created earlier:

```
> gams qreport r=submit gdir=c:\test\grid
```

Note that it is not necessary to run the job from the same directory that we have used for the initial submission; it is even possible to use a different operating system.

4.36.5 Summary of Grid Features

We introduced several GAMS features to facilitate the asynchronous or parallel execution of the solve statement. These GAMS features are summarized in the following subsections.

In addition to the features described below, the option or command line parameter `ThreadsAsync` was introduced. `ThreadsAsync` controls the number of threads or CPU cores that are used in multi-threading computing.

4.36.5.1 Grid Handle Functions

The grid handle functions are listed in Table 1. For details on functions in GAMS in general and complete lists of all GAMS functions, see section Functions. Note that the desired return values - the return values that indicate that no error has occurred - are marked with bold letters.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Return Values</th>
</tr>
</thead>
</table>
| handleCollect(HANDLE) | Tests if the solve of the model instance identified by HANDLE is done: if so, it loads the solution into the GAMS data base. If the option asyncSolLst is active the solution listing is printed to the listing file. **Note** that handleCollect ignores the setting of the option SolveOpt and always uses the default value *merge*. | 0: The model instance was not ready or could not be loaded.  
>0: **The model instance solution has been loaded.** (When using the Grid facility, this is always 1; when using the multi-threading option, this returns the thread ID used.) |
| handleStatus(HANDLE) | Tests if the solve of the model instance identified by HANDLE is done.  
**Note** that there are compile-time constants that are related to this function. | 0: The model instance is not known to the system.  
1: The model instance exists but the solution process is incomplete.  
2: **The solution process has terminated and the solution is ready for retrieval.**  
3: The solution process signaled completion but the solution cannot be retrieved. |
| handleDelete(HANDLE) | Deletes the model instance identified by HANDLE and returns a numerical indicator of the status of the deletion. If the HANDLE given is not valid, an execution error is triggered. | 0: **The model instance has been removed.**  
1: The argument HANDLE is not a legal handle.  
2: The model instance is not known to the system.  
3: The deletion of the model instance encountered errors. |
| handleSubmit(HANDLE) | Resubmits the model instance identified by HANDLE for solution. In case of a nonzero return an execution error is triggered. | 0: **The model instance has been resubmitted for solution.**  
1: The argument HANDLE is not a legal handle.  
2: The model instance is not known to the system.  
3: The completion signal could not be removed.  
4: The resubmit procedure could not be found.  
5: The resubmit process could not be started. |
### 4.36 The Grid and Multi-Threaded Solve Facility

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Return Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>readyCollect(HANDLES[,maxWait])</td>
<td>Waits until a model solution is ready to be collected. HANDLES must be either a scalar or parameter containing one or more model handles or a model with its handle attribute. MaxWait specifies the maximum time to wait in seconds, the default value is +inf.</td>
<td>0: One or more of the requested jobs is/are ready. 1: There is no active job to wait for. 2: The handle symbol is empty. 3: The argument is not a legal handle. 4: User specified time-out (using a solveLink = 6 handle). 5: User specified time-out (using a solveLink = 3 handle). 8: Unknown error (should not happen).</td>
</tr>
</tbody>
</table>

**Table 1: Grid Handle Functions**

Note that GAMS might issue execution errors which could give additional information that may help to identify the source of problems. The function execError may be used to get and set the number of execution errors.

#### 4.36.5.2 Grid Model Attributes

Model attributes are introduced in section Model Attributes. The following three model attributes are particularly relevant for grid computing:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>solveLink</td>
<td>Specifies the solver linking conventions. The following values direct the solve statement to use grid computing or multi-thread computing: 3, 4, 6 and 7. Note that the default for this model attribute can be set as command line parameter and option statement. For more information, see the detailed description.</td>
</tr>
<tr>
<td>handle</td>
<td>Specifies the current instance handle. This is used to identify a specific model instance and to provide additional information needed for the process signal management (compare subsections The Submission Loop and The Collection Loop above).</td>
</tr>
<tr>
<td>number</td>
<td>Specifies the current instance number. Any time a solve is attempted for a model, the instance number is incremented by one and the handle is update accordingly. The instance number can be reset by the user which then resynchronizes the handle.</td>
</tr>
</tbody>
</table>

**Table 2: Grid Handle Attributes**

#### 4.36.5.3 Grid Solution Retrieval

As an alternative to the function handleCollect a solution may be retrieved with the following statement:

```plaintext
eexecute_loadhandle mymodel;
```

This statement will update the GAMS data base with the status and solution for the current instance of `mymodel`. Note that the underlying mechanism is a GDX file. Except for the requirement of a model with a previously specified handle, this command operates like the procedure execute_loadpoint. If the option asyncSolLst is active the solution listing is printed to the listing file.
4.36.5.4 The Grid Directory

The instantiated (generated) models and their corresponding solutions are kept in unique directories that may be reached from the submitting system. Each GAMS job may have only one grid directory. By default, the grid directory is assumed to be the scratch directory. This may be overwritten by using the GAMS command line parameter GridDir, or short GDir. An example follows.

> gams myprogram ... GDir=gridpath

If gridpath is not a fully qualified name, the name will be completed using the current directory. If the grid path does not exist, an error will be issued and the GAMS job will be terminated. A related GAMS parameter is ScrDir or short SD.

Recall the following default mechanism: When a GAMS job is started a unique process directory is created in the current directory. These directories are named 225a to 225zz. When a GAMS job terminates, the system will remove the process directory at the completion of a GAMS job. Any file that has not been created by the GAMS core system will be flagged. If the call gamskeep instead of gams is used, another exit script will be activated that results in the process directory to be kept.

Note that if we do not specify a scratch directory, the scratch directory will be the same as the process directory. If we do not specify a grid directory, the grid directory will be the same as the scratch directory.

Observe that if we assume that some of the model instances may fail or we want to break the GAMS program into several pieces to run as separate jobs, we need to be careful not to remove the model instance we have not completely processed. In such cases we have to use the parameter GridDir, so that we may access previously created model instances.

4.36.6 The Grid Facility: Architecture and Customization

The current Grid facility relies on very basic operating system features and does not attempt to offer real and direct job or process control. The file system is used to signal the completion of a submitted task and GAMS has currently no other way to interact with the submitted process directly, like forcing termination or change the priority of a submitted task. This approach has its obvious advantages and disadvantages. There are a number of attempts to use grid computing to provide value added commercial remote computing services.

When GAMS executes a solve with the option solveLink set to 3 it will perform the following steps:

1. Create a subdirectory in the GridDir with the name gridnnn. Here nnn stands for the numeric value of the handle. The handle value is the internal symbol ID number x 1e6 + the model instance number. For example, in the [QMEANVAR] example the first grid subdirectory was grid137000002.

2. Remove the completion signal in case the file already exists. Currently the signal is a file called finished. For example, grid137000002/finished.

3. Create or replace a GDX file called gmsgrid.gdx which will contain a dummy solution with failed model and solver status. This file will be overwritten by the final step of the solution process and will be read when calling execute_loadhandle.

4. Place all standard GAMS solver interface files into the above instance directory.

5. Execute the submission wrapper called gmsgrid.cmd under Windows or gmsgrid.run under Unix. These submission scripts are usually located in the GAMS system directory, they may be located via the current path if they are not found in the GAMS system directory.
The grid submission script `gmsgrid.cmd` or `gmsgrid.run` is called with four arguments that are needed to make a standard GAMS solver call: the solver executable file name, the solver control file name, the solver scratch directory, and the solver name. The submission script then does the final submission to the operating system. This final script will perform the following steps:

1. call the solver,
2. call a utility that will create the final GDX file `gmsgrid.gdx`,
3. set the completion signal `finished`.

If we want to use the function `handleSubmit` we will also have to create the script `gmsrerun.cmd` or `gmsrerun.run`. This script could later be used to resubmit the job.

For example, the default submission script for Windows is shown below:

```
@echo off
: gams grid submission script
:
: arg1 solver executable
: 2 control file
: 3 scratch directory
: 4 solver name
:
: gmscr_nx.exe processes the solution and produces 'gmsgrid.gdx'
:
: note: %3 will be the short name, this is needed because
: the START command cannot handle spaces or "...
: before we use %"3 will strip surrounding "...
: makes the name short
:
: gmsrerun.cmd will resubmit runit.cmd

echo @echo off > %3runit.cmd
echo %1 %2 %4 >> %3runit.cmd
echo gmscr_nx.exe %2 >> %3runit.cmd
echo echo OK ^> %3finished ^& exit >> %3runit.cmd

echo @start /b /belownormal %3runit.cmd ~> nul > %3gmsrerun.cmd

start /b /belownormal %3runit.cmd > nul

exit
```

### 4.36.6.1 Grid Submission Testing

The grid submission process can be tested on any GAMS program without having to change the source text. The option `solveLink=4` instructs the solve statement to use the grid submission process and then wait until the results are available. Note that the option `solveLink` may be set via a GAMS command line parameter, a GAMS option statement or via assignment to the model attribute. Once the model instance has been submitted for solution, GAMS will check if the job has been completed. It will keep checking twice the `reslim` seconds allocated for this optimization job and report a failure if this limit has been exceeded. After successful or failed retrieval of the solution, GAMS will remove the grid directory, unless we have used the call `gamskeep` or have set the GAMS command line parameter `keep`.
4.36.7 Multi-Threading

As we have described in this chapter, each solve is handled in its own process space with the Grid facility. Recall that the Grid facility is activated by setting the option or model attribute `solveLink` to 3 or 4. If `solveLink` is set to 6 (or the compile-time constant `%solveLink.Async Threads%`) instead, a separate thread is used. This allows efficient in-memory communication between GAMS and the solver, like it is done if the option `solveLink` is set to 5 (or the compile-time constant `%solveLink.Load Library%`).

Apart from this, the multi-threading facility works in the same way as the Grid facility. The solve statement generates the model and passes it to the solver in a separate thread, then a handle of the model instance may be stored using the model attribute `handle` and the grid `handle` functions may be used to collect the solution and deal with the model instance, namely `handleCollect`, `handleDelete`, `handleStatus` and `readyCollect`.

Note that the option or command line parameter `ThreadsAsync` sets the maximum number of threads that should be used for the asynchronous solves.

The following matrix shows which solvers may be used with `solveLink = 6` on which platform:

<table>
<thead>
<tr>
<th>Solver</th>
<th>x86 64bit MS Windows</th>
<th>x86 64bit Linux</th>
<th>x86 64bit Mac OS X</th>
</tr>
</thead>
<tbody>

<td>×</td>
<td>×</td>
</tr>
</tbody>
</table>

If a solver is selected for which `solveLink = 6` is not supported on the corresponding platform, `solveLink = 3` will be used instead and it will be noted in the log.

4.36.7.1 Multi-threading Submission Testing

The multi-threading submission process may be tested on any GAMS program without having to change the source text. The option `solveLink = 7` (or, equivalently, the compile-time constant `%solveLink.Threads Simulate%`) instructs the solve statement to use the multi-threading submission process, wait until the results are available and then load the solution into the GAMS data base. Once the model instance has been submitted for solution, GAMS will check if the job has been completed. It will keep checking twice the `reslim` seconds allocated for this optimization job and report a failure if this limit has been exceed. After successful or failed retrieval of the solution GAMS will remove the thread handle.
4.37 Special Features for Mathematical Programs

4.37.1 Introduction

In this chapter we will introduce special GAMS features that are useful for specific model types. The features include model scaling, conic programming and features that facilitate mixed integer as well as indicator constraints, a feature that does not translate across solvers.

4.37.2 Special Mixed Integer Programming (MIP) Features

Some special features have been added to GAMS to help simplifying the modeling of Mixed Integer Programming (MIP) problems. In GAMS MIP is the model type for mixed integer linear programs, this section used MIP more generally, we consider model with discrete variables, including non-linear expressions and pure discrete problem. We will first present details on discrete variables in GAMS, then we will discuss how to customize priorities for the branching process. Next, we will cover the model attributes that are important for MIPs and we will conclude with some hints that will make mixed integer programming with GAMS easier.

4.37.2.1 Types of Discrete Variables

Variables and variable types are introduced in chapter Variables. GAMS provides six discrete variable types: binary, integer, sos1, sos2, semicont and semiint. In the following subsections we will present details and examples for each of these discrete variable types. Note that if any discrete variables feature in a model, it has to be a mixed integer model or one of the related model types, like MINLP or MIQCP. See section Classification of Models for a full listing of all GAMS model types.

4.37.2.1.1 Binary Variables

Binary variables can take values of 0 (zero) and 1 (one) only. They are declared as follows:

Binary Variable var_name [(index_list)] [text];

The keyword binary indicates that this is a binary variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as binary later. Consider the following code snippets from the orthogonal Latin Square model [LATIN]:

Sets k "rows" / row1*row4 /
    l "columns" / col1*col4 /
    v "values" / val1*val4 /;
alias (i,j,v);

Variables x(i,j,k,l) "pairs (i,j) allocated to cell(k,l)"
    z "some objective";
Binary Variable x;

Equations c1(i,j) "for each cell pick only one item pair"
    c1(i,j).. sum((k,l), x(i,j,k,l)) =e= 1;
Note that the binary variable $x$ is used in equation $c1$ to model the restriction that in each cell only one item pair is allowed. Binary variables are often used to model logical conditions such as imposing mutual exclusivity or complementarity.

Note that the default lower bound is 0 (zero) and the default upper bound is 1 (one). If the relaxed versions of the discrete models is solved, binary variables are treated like positive variables with the upper bound of 1. In addition, an infinite priority may be used to override binary specifications, see section Setting Priorities for Branching below for more information.

Even though the only possible values are 0 and 1, a solver might return a value for binary variable that is only close to 0 or 1. Every solver works with tolerances and also uses a tolerance to determine if a value is close enough to an integer values. So it is unwise to use code as $a(i)$(b.l(i)=1) = yes; because one will potentially miss some elements. A safe way to write such code is: $a(i)$(b.l(i)>0.5) = yes; Rounding the level of a binary variable after the solve is also possible, but it is not done by the solver or the solver link because even small rounding can lead to infeasibilities.

A binary variable can also have a truely fractional value after a solver if the model status does not indicate a feasible integer solution (model status 1 or 8).

### 4.37.2.1.2 Integer Variables

Integer variables are discrete variables that can take only values between their bounds. The user may change both bounds from the default value. The default lower bound is 0 (zero) and the default upper bound inside GAMS is $+\text{inf}$, and the same upper bound is passed on to the solver.

Note that in relaxed model types the integrality requirement is relaxed. In addition, an infinite priority may be used to override integer specifications, see section Setting Priorities for Branching below for more information. Integer variables are declared as follows:

```
Integer Variable var_name [(index_list)] [text];
```

The keyword `integer` indicates that this is an integer variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as `integer` later. Consider the following code snippets from the power scheduling model [MAGIC]:

```
Sets
t "demand blocks" / 12pm-6am, 6am-9am, 9am-3pm, 3pm-6pm, 6pm-12pm /
g "generators" / type-1, type-2, type-3 /;

Variables
x(g,t) "generator output (1000mw)"
n(g,t) "number of generators in use"
cost "total operating cost (1)"
;

Integer Variable n;
```

The integer variable $n$ models the number of generators of various types that are in use at any of the time blocks.
4.37.2.1.3 Special Order Sets of Type 1 (SOS1)  
SOS1 variables are a set of variables, such that at most one variable within the group may have a nonzero value. This variable may take any positive value. Special ordered sets of type 1 are defined as follows:

SOS1 Variable var_name (index_list) [text];

The keyword SOS1 indicates that this is a SOS1 variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as SOS1 later. Consider the following example:

SOS1 Variable s1(i), t1(k,j), w1(i,j,k) ;

Note that the members of the innermost (the right-most) index belong to the same SOS set. For example in the sets defined above, s1 represents one special ordered set of type 1 with i elements, t1 defines k sets with j elements each and w1 defines (i,j) sets with k elements each.

The default bounds for SOS1 variables are zero and +inf. As with any other variable, the user may change these bounds. Further, the user may explicitly provide whatever convexity row that the problem may need through an equation that requires the members of the SOS1 set to be less than a certain value. Any such convexity row will implicitly define bounds on each of the variables.

Consider the following example:

SOS1 Variable s1(i); Equation defsoss1;
defsoss1.. sum(i,s1(i)) =l= 3.5 ;

The equation defsoss1 implicitly defines the nonzero value that one of the elements of the SOS1 variable s1 may take as equal to or smaller than 3.5. Note that it is also possible that all variables s1 equal zero.

A special case arises when one of the elements of the set has to be nonzero and equal to a number, say 3.5. In this case equation defsoss1 will be:

defsoss1.. sum(i,s1(i)) =e= 3.5 ;

Frequently the nonzero value equals 1. As a result, the SOS1 variable is effectively a binary variable. It is only treated differently by the solver at the level of the branch and bound algorithm. For example, consider the following example where we want to model that one out of n options has to be selected. This is expressed as:

SOS1 Variable x(i); Equation defx;
defx.. sum(i, x(i)) =e= 1 ;

The variable x can be made binary without any change in meaning and the solution provided by the solver will be indistinguishable from the SOS1 case.

The use of special ordered sets may not always improve the performance of the branch and bound algorithm. If there is no natural order the use of binary variables may be a better choice. A good example of this is the classical assignment problem (see [H.P. Williams (2013) Model Building in Mathematical Programming], Wiley, Section 9.3.

Note that any model with SOS1 variables requires a MIP solver, because the solution process needs to impose the restrictions of at most one nonzero level values may be present.

For an example where SOS1 variables are used, see the production scheduling model  [PRODSCHX].
**4.37.2.1.4 Special Order Sets of Type 2 (SOS2)** SOS2 variables are a set of variables, such that at most two variables within the set may have nonzero values and these variables have to be adjacent. This requirement implies that the set is ordered, see chapter Sets as Sequences: Ordered Sets for details on ordered sets in GAMS. Note that the nonzero variables may take any positive value. Special ordered sets of type 2 are defined as follows:

```
SOS2 Variable var_name [(index_list)] [text];
```

The keyword **SOS2** indicates that this is a SOS2 variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as SOS2 later. Consider the following example:

```
Set i / i1*i5 /
SOS2 Variable s2(i), t2(k,j), w2(i,j,k);
```

The members of the innermost (the right-most) index belong to the same set. For example, in the sets defined above, s2 represents one special ordered set of type 2 with elements for each member of the set i. At most two variables s2 may be nonzero and they must reference adjacent elements of the set i. Note that the variables s2('i1') and s2('i2') are adjacent, but the variables s2('i1') and s2('i3') are not. Further, t2 defines k sets of SOS2 variables with j elements each and the adjacency requirement refers to the set j which must be ordered. Similarly, w2 defines (i,j) sets with k elements each and the adjacency requirement refers to the set k which must be ordered.

The default bounds for SOS2 variables are zero and +inf. As with any other variable, the user may change these bounds. SOS2 variables are most often used to model piece-wise linear approximations to nonlinear functions. The production scheduling model [PRODSCHX] shows SOS type formulations with binary, SOS1 and SOS2 sets.

Note that any model with SOS2 variables requires a MIP solver, because the solution process needs to impose the restrictions of adjacency and that no more than two nonzero level values may be present.

**4.37.2.1.5 Semi-Continuous Variables** Semi-continuous variables are either zero or above a given minimum level. This can be expressed algebraically as: either \( x = 0 \) or \( L \leq x \leq U \). By default, the lower bound \( L \) is 1 and the upper bound \( U \) is +inf. As usual, these bounds may be changed with the variable attributes .lo and .up. Semi-continuous variables are defined as follows:

```
SemiCont Variable var_name [(index_list)] [text];
```

The keyword **semicont** indicates that this is a semi-continuous variable and then the usual conventions for variable declarations” are followed. Alternatively, the variable may be declared first and specified as semicont later. Consider the following example:

```
SemiCont Variable x;
x.lo = 1.5; x.up = 23.1;
```

The slice of code above declares the variable x to be a semi-continuous variable that may either be zero or behave as a continuous variable between 1.5 and 23.1.

Note that any model with semi-continuous variables requires a MIP solver, because the solution process needs to impose the discontinuous jump between zero and the threshold value.
Note

- Not all MIP solvers allow semi-continuous variables. We recommend users to verify how the solver they are interested in handles semi-continuous variables by checking the relevant section of the respective solver manual.
- The lower bound has to be less than the upper bound, and both bounds have to be greater than zero, otherwise GAMS will report an error.
- The variable solution listing might show the level outside the lower and upper bound which for other variables indicates an infeasible variable, but not so for semi-continuous variables.
- Semi-continuous variables are especially helpful if the upper bound is $+\infty$ and no implicit bound can be easily derived. If a finite upper bound is available it can be computational more efficient to replace the semi-continuous variable $sc$ with lower bound $sc_{\text{Low}}$ by a continuous variable $x$ and binary variable $b$ and the following equations:

  Equation \texttt{xForceLowerBnd} "Force x to be greater than scLow if b is 1"
  \texttt{xForceZero} "Force x to be zero if b is zero"

  \begin{verbatim}
  xForceLowerBnd.. x =g= scLow*b;
  xForceZero.. x =l= x.up*b;
  \end{verbatim}

4.37.2.1.6 Semi-integer Variables

Semi-integer variables are either zero or integer and above a given minimum value. This can be expressed algebraically as: either $x = 0$ or $x \in \{L, \ldots, U\}$. By default, the lower bound $L$ is 1 and the upper bound $U$ inside GAMS is $+\infty$ and the same values are passed on to the solver. As usual, these default bounds may be changed with the variable attributes .lo and .up. Note that in relaxed model types the integrality requirement is relaxed. In addition, an infinite priority may be used to override integer specifications, see section Setting Priorities for Branching below for more information.

Semi-integer variables are defined as follows:

\texttt{SemiInt Variable var\_name [(index\_list)] [text];}

The keyword \texttt{semiint} indicates that this is a semi-integer variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as \texttt{semiint} later. Consider the following example:

\begin{verbatim}
SemiInt Variable x;
x.lo = 2; x.up = 25;
\end{verbatim}

The slice of code above declares the variable $x$ to be a semi-integer variable that may either be zero or take any integer value between 2 and 25. Note that the bounds for \texttt{semiint} variables have to take integer values, otherwise GAMS will flag an error during model generation. Note further, that any model with semi-integer variables requires a MIP solver.

Note

- Not all MIP solvers allow semi-integer variables. We recommend users to verify how the solver they are interested in handles semi-integer variables by checking the relevant section of the respective solver manual.
- The lower bound has to be less than the upper bound, and both bounds have to be greater than zero, otherwise GAMS will report an error.
- The variable solution listing might show the level outside the lower and upper bound which for other variables indicates an infeasible variable, but not so for semi-integer variables.
• Semi-integer variables are especially helpful if the upper bound is +\( \text{inf} \) and no implicit bound can be easily derived (together with the appropriate IntVarUp setting). If a finite upper bound is available, it can be computationally more efficient to replace the semi-integer variable \( s_i \), with lower bound \( s_{i\text{Low}} \), by an integer variable \( i \) and a binary variable \( b \) and the following equations:

\[
\text{Equation iForceLowerBnd } \quad "\text{Force } i \text{ to be greater than } s_{i\text{Low}} \text{ if } b \text{ is 1}" \\
iForceZero \quad "\text{Force } i \text{ to be zero if } b \text{ is zero}";
\]

\[
iForceLowerBnd. \quad i \geq s_{i\text{Low}} \cdot b;
\]

\[
iForceZero. \quad i \leq i.\text{up} \cdot b;
\]

### 4.37.2.2 Setting Priorities for Branching

By setting priorities users may specify an order for choosing variables to branch on during a branch and bound search for MIP models. Without priorities the MIP algorithm will internally determine which variable is the most suitable to branch on. Priorities for individual variables may be used only if the model attribute .prioropt is set to 1; the respective GAMS statement is:

\[
mymodel.prioropt = 1;
\]

Here \( \text{mymodel} \) is the name of the model specified in the model statement. The default value is NA.

If the model attribute .prioropt is set to 1, the variable attribute .prior may be used to set the priorities of individual discrete variables. Note that there is one .prior value for each individual component of a multidimensional variable. Priorities may be set to any real value; the default value is 1. As a general rule, the most important variables should be given the highest priority. The highest priority is denoted by the lowest nonzero value in the .prior attribute. Functionally, the attribute .prior establishes in what order variables are to be branched on in the branch-and-bound algorithm while searching for a solution. Variables with a specific .prior value will be branched on earlier until all fractional variables with higher .prior values have been branched on.

Note

The variable attribute .prior of a discrete variable may be used to relax the discrete restriction on that variable: setting the .prior value to +\( \text{inf} \) will relax a variable permanently (or until .prior gets a finite value assigned). This relaxation is done independently of the model attribute .prioropt.

Consider the following example:

\[
z.\text{prior}(i, \text{\textquoteleft}small\textquoteleft) = 3;
z.\text{prior}(i, \text{\textquoteleft}medium\textquoteleft) = 2;
z.\text{prior}(i, \text{\textquoteleft}large\textquoteleft) = 1;
\]

In this example the variables \( z(i, \text{\textquoteleft}large\textquoteleft) \) are branched on before the variables \( z(i, \text{\textquoteleft}medium\textquoteleft) \), which in turn are branched on before the variables \( z(i, \text{\textquoteleft}small\textquoteleft) \).

Note that knowledge about the problem may help to determine which variables should be considered first. For example, consider a problem with a binary variable \( u \) representing a yes/no decision whether to build a factory and other binary variables representing equipment selections within that factory. We would naturally want to explore whether or not the factory should be built before considering what specific equipment to be purchased within the factory. Therefore we would set the priority values lower for \( u \). By assigning a higher priority - a lower value of the attribute .prior - to the build/nobuild decision variable \( u \), we can force this logic into the tree search and thus speed up computation time since uninteresting portions of the tree are left unexplored.
Note

- The lower the value given to the .prior suffix, the higher the priority for branching.
- All members of any SOS1 or SOS2 set should be given the same priority value since it is the set itself which is branched upon rather than the individual members of the set.
- While any value is accepted for .prior, many solvers scale all giving priorities in the integer range of 0,...,1000.
- Branching priorities were a very important feature in the early days of mixed integer programming. Nowadays, it is not easy to find branching priorities that improve on the solvers default selection.
- Global non-linear optimization solvers branch on continuous variables too (see, for example BARON). In GAMS one cannot set the branching priority of a continuous variable. Such branching priorities need to be communicated via a solver option file.

4.37.2.3 Miscellaneous Hints

We will conclude the discussion of mixed integer models in GAMS with this section where we offer a variety of hints that are meant to make special facilities of mixed integer programming solvers more accessible.

4.37.2.3.1 Model Attributes for Mixed Integer Programming in GAMS GAMS offers several model attributes that may be used to influence MIP solver performance or report on results of MIPs. These model attributes include Cheat, CutOff, NodLim, ObjEst, OptCA, OptCR, PriorOpt and TryInt.

4.37.2.3.2 The Branch and Cut and Heuristic Facility Hard MIP problems can be solved faster with the help of user supplied routines that generate cutting planes and good integer feasible solutions. The GAMS Branch-and-Cut-and-Heuristic (BCH) automates all major steps necessary to define, execute and control the use of user defined routines within the framework of general purpose branch-and-cut codes. It is documented in Branch-and-Cut-and-Heuristic Facility (BCH).

4.37.2.3.3 Branch and Bound Output While the log output for each solver differs, some key figures are usually displayed for branch-and-bound based solvers. For example, solving a linear mixed integer model with CPLEX will yield output like the following:

<table>
<thead>
<tr>
<th>Nodes</th>
<th>Cuts/</th>
<th>Gap</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node Left</td>
<td>Objective</td>
<td>IInf</td>
</tr>
<tr>
<td>* 0+ 0</td>
<td>0.0000</td>
<td>5.05646e+08</td>
</tr>
<tr>
<td>Found incumbent of value 0.000000 after 0.01 sec. (0.73 ticks)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0 0</td>
<td>2.23031e+07</td>
<td>12</td>
</tr>
<tr>
<td>0 0</td>
<td>2.23031e+07</td>
<td>7</td>
</tr>
<tr>
<td>* 0+ 0</td>
<td>2.23031e+07</td>
<td>2.23031e+07</td>
</tr>
<tr>
<td>Found incumbent of value 2.2303094e+07 after 0.02 sec. (1.08 ticks)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>

<td></td>
<td></td>
</tr>
<tr>
<td>Solution satisfies tolerances.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MIP Solution: 22303093.628684 (23 iterations, 0 nodes)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Final Solve: 22303093.628684 (0 iterations)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Best possible: 22303113.950091</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Absolute gap: 20.321407</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Relative gap: 0.000001</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
A brief explanation of the columns follows:

- **Node** is the number of branch and bound nodes so far.
- **Nodes Left** is the number of problems created during the branching process that are yet to be examined.
- **Objective** gives the current objective function value of the relaxes node problem.
- **IInf** gives the number of discrete variables with fractional solution levels.
- **Best Integer** gives the incumbent solution. Note the last solution in that column is not necessarily the global best solution.
- **Cuts/Best Bound** gives the current lower bound on the solution.
- **Cnt** gives the accumulated LP iteration count
- **Gap** gives the maximum percentage difference from the theoretical optimum.

Note that it is common that solves of mixed integer models end with a gap between the solution found and the best possible solution. This may be controlled by limits (e.g. time), solver options and model attributes like .OptCR and .OptCA.

### 4.37.2.3.4 Nonlinear MIPs

Modelers may wish to impose integer restrictions on nonlinear formulations combining two hard model types: MIP and NLP. Such MINLP models can be solved with a selection of solvers. Many solvers, e.g. DICOPT and SBB, provide a local optimum where others, e.g. ANTIGONE and BARON provide a global optimum. In most cases both types of MINLP solver make use of MIP and NLP solvers to calculate a solution. Such subsolvers need to be licensed for the solver to succeed.

### 4.37.2.3.5 Model Termination Conditions and Recommended Actions

Recall that the termination condition of the model after the solution process has been completed is stored in the model attribute .modelStat. A list of all possible model statuses is given in section Model Status. We can easily check for the existence of a feasible solution (status 1 and 8). Linear models and MINLP problems solved with global solvers can achieve the "OPTIMAL" status, given sufficient resources (time) and a setting of OptCR and OptCA to 0. All other cases do not yield a feasible integer solution. If a problem is reported as infeasible (status 4,5,10, and 19), it might be a good idea to see if the relaxed version of the model is already infeasible. Debugging models that are relaxed feasible but integer infeasible is very difficult.

### 4.37.2.3.6 Frequent Problems

There are some problems users frequently encounter either due to GAMS settings or problem characteristics:

#### Default bounds

One needs to be aware that while the GAMS upper bound for integer and semi-integer variables is +inf, the bound that is passed to the solver can be different, namely 100 (see the discussion about integer variables). This can lead to unexpected results (e.g. infeasibilities or suboptimal solutions declared as optimal).

#### Ending with a gap – large default for optCR (10%)

MIP solves often end with a gap between the solution found and the best possible solution. This is controlled by OptCR or OptCA or by non-convergence. Note that the default value of 0.1 for optCR is relatively large. Users may want to reduce this to a smaller value. We will discuss the other cause of a gap next.

#### The nonending quest

Integer programming is a quite desirable formulation technique. However, integer problems are theoretically hard and the solution process (in the worst case) of exponential complexity. There are many ways that focus on improving the solution time of the solver. As with all models scaling is important (especially when using bigM formulations). For particular problems many different formulations exist and the literature about a particular problem together with the ability of GAMS to rapidly prototype and experiment is the best constellation to get the best results for the problem at hand. For fine tuning, some MIP solvers provide automated tuning tools (see e.g. Cplex tuning) that tweak the solver options to get the best performance.
4.37.3 Model Scaling - The Scale Option

The rules for good scaling are exclusively based on algorithmic needs. GAMS has been developed to increase the efficiency of modelers, and one of the best ways seems to be to encourage modelers to write their models using a notation that is as natural as possible. The units of measurement are one part of this natural notation. However, there is a potential conflict between what the modeler thinks is a good unit and what constitutes a well-scaled model.

4.37.3.1 The Scale Option

To facilitate the translation between a natural model and a well scaled model, GAMS has introduced the concept of a scale factor, both for variables and equations. The notations and definitions are quite simple. Scaling is turned off by default. Setting the model attribute .scaleopt to 1 turns on the scaling feature. For example,

```gams
model mymodel /all/ ;
mymodel.scaleopt = 1 ;
solve mymodel using nlp maximizing dollars ;
```

The statement should be inserted somewhere after the model statement and before the solve statement. To turn scaling off again, mymodel.scaleopt has to be set to zero before the next solve.

In most respects GAMS scaling is hidden from the user. The solution values reported back from a solution algorithm are always reported in the notation of the user. The algorithm's internal representation of the equations and variables are only reflected in the derivatives in the equation and column listings in the GAMS output if the values of the options limrow and limcol are positive. In addition, the internal representations will appear in the debugging output from the solution algorithm if the option sysout is set to on.

4.37.3.2 Scaling Variables

The scale factor of a variable is defined using the variable attribute .scale in the following way:

```gams
myvar.scale(i,j) = c;
```

The scale factor c is a number or a numerical expression that evaluates to a number. Note that the default scale factor is 1.

Note that there is one scale value for each individual component of a multidimensional variable.

Assume that c is the scale factor of a variable V_u. Assume further, that the variable seen by the algorithm is V_a. Then we have: V_a = V_u/c. This means that each variable as seen by the user is divided by the scale factor.

For example, consider the following code snippet:

```gams
Positive Variables x1, x2;
Equation eq;
eq.. 200*x1 + 0.5*x2 =l= 5;
x1.up = 0.01;
x2.up = 10;
x1.scale = 0.01;
x2.scale = 10;
```
By setting \texttt{x1.scale} to 0.01 and \texttt{x2.scale} to 10, the model seen by the solver is:

\begin{verbatim}
Positive Variables xPrime1, xPrime2;
Equation eq;
eq.. 2*xPrime1 + 5*xPrime2 =l= 5;
xPrime1.up = 1;
xPrime2.up = 1;
\end{verbatim}

Note that the solver does not see the variables \texttt{x1} or \texttt{x2}, but rather the scaled (and better-behaved) variables \texttt{xPrime1} and \texttt{xPrime2}. Note further, that upper and lower bounds on variables are automatically scaled in the same way as the variable itself.

**Attention**

- **Discrete variables** cannot be scaled.
- **Expert Note.** Internally, GAMS stores with each variable and equation one additional attribute or field (besides fields for level, marginal and lower and upper bound). Depending on the type of variable and sometimes even model type or solver, this field has different names in the GAMS language. For continuous variables, the field is called \texttt{scale}, while for discrete variable it is called \texttt{prior}. For stochastic 2-stage linear program models solved with DECIS, this field is called \texttt{stage}. The field \texttt{.stage} can lead to confusing results. Consider the following example:

\begin{verbatim}
Variable x;
x.scale = 0.1;
display x.stage;
\end{verbatim}

The output is:

\begin{verbatim}
---- 3 VARIABLE x.scale = 0.100
\end{verbatim}

The field \texttt{.scale} has to be in a certain range ( >1e-20 and no special value), but this is only checked at model generation time. The field \texttt{.prior} can be any number and even \texttt{+inf} (but no other special values). For further information on \texttt{.prior}, see section Setting Priorities for Branching. For an introduction to variable and equation fields, see sections Variable Attributes and Equation Attributes respectively.

### 4.37.3.3 Scaling Equations

The scale factor of an equation is defined using the equation attribute \texttt{.scale} in the following way:

\begin{verbatim}
mzeqn.scale(i,j) = d;
\end{verbatim}

The scale factor \(d\) is a number or a numerical expression that evaluates to a number. Note that the default scale factor is 1.

Assume that \(d\) is the scale factor of an equation \(G_u\). Assume further, that the equation seen by the algorithm is \(G_a\). Then we have: \(G_a = G_u/d\). This means that each equation as seen by the user is divided by the scale factor.

For example, consider the following equations:

\begin{verbatim}
Positive Variables y1, y2;
Equations eq1, eq2;
eq1.. 200*y1 + 100*y2 =l= 500;
eq2.. 3*y1 - 4*y2 =g= 6;
\end{verbatim}
By setting `eq1.scale` to 100, the model seen by the solver is:

```
Positive Variables y1, y2;
Equations eqPrime1, eq2;
  eqPrime1.. 2*y1 + 1*y2 =l= 5;
  eq2.. 3*y1 - 4*y2 =g= 6;
```

Note

The user may have to perform a combination of equation and variable scaling to obtain a well-scaled model.

Consider the following example:

```
Positive variables x1, x2;
Equations eq1, eq2;
  eq1.. 100*x1 + 5*x2 =g= 20;
  eq2.. 50*x1 - 10*x2 =l= 5;
x1.up = 0.2;
x2.up = 1.5;
```

Setting the following scale values:

```
x1.scale = 0.1;
eq1.scale = 5;
eq2.scale = 5;
```

will result in the solver seeing the following well-scaled model:

```
Positive Variables xPrime1, x2;
Equations eqPrime1, eqPrime2;
  eqPrime1.. 2*xPrime1 + x2 =g= 4;
  eqPrime2.. xPrime1 - 2*x2 =l= 1;
xPrime1.up = 2;
x2.up = 1.5;
```

### 4.37.3.4 Scaling Derivatives

In nonlinear models the derivatives also need to be well-scaled. Assume that the derivatives in the model of the user are denoted by $d(G_u)/d(V_u)$. Assume further, that the derivatives in the scaled model seen by the algorithm are denoted by $d(G_a)/d(V_a)$. Then we have: $d(G_a)/d(V_a) = d(G_u)/d(V_u) \cdot c/d$, where $c$ is the scale factor for the variable and $d$ is the scale factor for the equation.

The user may affect the scaling of derivatives by scaling both the equation and variable involved.
4.37.3.5 Scaling Data

Scaling input data is independent of the model attribute .scaleopt and may contribute considerably towards achieving a well-scaled model. We recommend users to try to define the units of the input data such that the largest values expected for decision variables and their marginals is under a million, if possible.

For example, in US agriculture about 325 million acres are cropped and the corn crop is 9-10 billion bushels per year. When defining production data, we could enter land in 1000’s of acres and all other resources in 1000’s of units. We could also define the corn crop in millions of bushels. The data will be simultaneously scaled, hence if resource endowments are quoted in 1000’s, corn yields are divided by 1000. This scaling results in a corn production variable in the units of millions. Consumption statistics would need to be scaled accordingly. Money units could also be in millions or billions of dollars. Such data scaling generally greatly reduces the disparity of coefficients in the model.

4.37.4 Conic Programming in GAMS

Conic programming models minimize a linear function over the intersection of an affine set and the product of nonlinear cones. The problem class involving second order (quadratic) cones is known as Second Order Cone Programs (SOCP). These are nonlinear convex problems that include linear and (convex) quadratic programs as special cases.

Conic programs allow the formulation of a wide variety of application models, including problems in engineering and financial management. Examples are portfolio optimization, Truss topology design in structural engineering, Finite Impulse Response (FIR) filter design and signal processing, antenna array weight design, grasping force optimization, quadratic programming, robust linear programming and norm minimization problems.

For more information, see References and Links at the end of this section.

4.37.4.1 Introduction to Conic Programming

Conic programs can be thought of as generalized linear programs with the additional nonlinear constraint \( x \in C \), where \( C \) is required to be a convex cone. The resulting class of problems is known as conic optimization and has the following form:

\[
\begin{align*}
\text{minimize} & \quad c^T x \\
\text{subject to} & \quad A x \leq r^c, \\
& \quad x \in [l^x, u^x] \\
& \quad x \in C
\end{align*}
\]

where \( A \in \mathbb{R}^{m \times n} \) is the constraint matrix, \( x \in \mathbb{R}^n \) the decision variable and \( c \in \mathbb{R}^n \) the objective function cost coefficients. The vector \( r^c \in \mathbb{R}^m \) represents the right-hand side and the vectors \( l^x, u^x \in \mathbb{R}^n \) are lower and upper bounds on the decision variable \( x \).

Now partition the set of decision variables \( x \) into sets \( S^t, t = 1, \ldots, k \), such that each decision variables \( x \) is a member of at most one set \( S^t \). For example, we could have

\[
S^1 = (x_1, x_4, x_7) \quad \text{and} \quad S^2 = (x_6, x_5, x_3, x_2).
\]

Let \( x_{S^t} \) denote the variables \( x \) belonging to set \( S^t \). Then define

\[
C := \{ x \in \mathbb{R}^n : x_{S^t} \in C_t, t = 1, \ldots, k \},
\]

where \( C_t \) must have one of the following forms:
4.37 Special Features for Mathematical Programs

- **Quadratic cone** (also referred to as Lorentz or ice cream cone):

\[
C_t = \left\{ x \in \mathbb{R}^n : x_1 \geq \sqrt{\sum_{j=2}^{n} x_j^2} \right\}.
\]

- **Rotated quadratic cone** (also referred to as hyperbolic constraints):

\[
C_t = \left\{ x \in \mathbb{R}^n : 2x_1 x_2 \geq \sum_{j=3}^{n} x_j^2, x_1, x_2 \geq 0 \right\}.
\]

These two types of cones allow the formulation of quadratic, quadratically constrained and many other classes of nonlinear convex optimization problems.

4.37.4.2 Implementation of Conic Constraints in GAMS

The recommended way to write conic constraints is by using a quadratic formulation. Many solvers have the capability to identify the conic constraints in a QCP model even if it is not in perfect form but can be easily reformulated to fit in the described form. However, some solvers (namely MOSEK) expect the conic constraints to be precisely in the form given above. In earlier versions this form was enforced by a special type of equation, the $\equiv=$ equation type. Moreover, such solvers have other requirements (e.g. disjunctive cones) that can be easily fulfilled by simple reformulation steps. Much progress is expected on the solver side in the coming years, so we don't go into much detail here.

Observe that we could formulate conic problems as regular NLPs using the following constraints:

- **Quadratic cone:**

\[
x('1') \equiv \sqrt{\text{sum}(i[\text{not sameas}(i, '1')], \text{sqr}[x(i)])};
\]

- **Rotated quadratic cone:**

\[
2x('1')x('2') \equiv \text{sum}(i[\text{not sameas}(i, '1') \text{ and not sameas}(i, '2')], \text{sqr}[x(i)]);
\]

Here \(x('1')\) and \(x('2')\) are positive variables.

The following example illustrates the different formulations for conic programming problems. Note that a conic optimizer usually outperforms a general NLP method for the reformulated (NLP) cone problems.

4.37.4.3 Example

Consider the following example, which illustrates the use of rotated conic constraints. We will give reformulations of the original problem in regular NLP form and in conic form (with conic constraints).

The original problem is:

\[
\begin{align*}
\text{minimize} & \quad \sum_{i=1}^{n} d_i / x_i \quad (4.2) \\
\text{subject to} & \quad a x \leq b \quad (4.3) \\
& \quad x_i \in [l_i, u_i], \quad i = 1, \ldots, n \quad (4.4)
\end{align*}
\]

where \(x \in \mathbb{R}^n\) is the decision variable, \(d, a, l, u \in \mathbb{R}^n\) are parameters with \(l_i > 0\) and \(d_i \geq 0\) and \(b \in \mathbb{R}\) is a scalar parameter. The original model may be written in GAMS using the equations:
We can write an equivalent QCP formulation by using the substitution \( t_i = 1/x_i \) in the objective function and adding a constraint. As we are dealing with a minimization problem, \( d_i \geq 0 \) and \( x_i \geq l_i > 0 \), we can relax the equality \( t_i x_i = 1 \) into an inequality \( t_i x_i \geq 1 \), which results in an equivalent problem with a convex feasible set:

\[
\text{minimize} \sum_{i=1}^{n} d_i t_i \quad (4.5)
\]

subject to

\[
a x \leq b \quad (4.6)
\]

\[
t_i x_i \geq 1, \quad i = 1, \ldots, n \quad (4.7)
\]

\[
x \in [l, u], \quad (4.8)
\]

\[
t \geq 0, \quad (4.9)
\]

where \( t \in \mathbb{R}^n \) is a new decision variable. The GAMS formulation of this QCP is:

\[
\text{defobjc..} \quad \text{sum}(n, d(n)*t(n)) =e= \text{obj} ;
\]

\[
\text{e1..} \quad \text{sum}(n, a(n)*x(n)) =l= b ;
\]

\[
\text{coneqc}(n) \quad t(n)*x(n) =g= 1 ;
\]

Model cqcp /defobjc, e1, coneqc/ ;

t.lo(n) = 0 ;
\]

\[
x.lo(n) = l(n) ;
\]

\[
x.up(n) = u(n) ;
\]

Note that the constraints \( t_i x_i \geq 1 \) are almost in rotated conic form. If we introduce a variable \( z \in \mathbb{R}^n \) with \( z_i = \sqrt{2} \), then we can reformulate the problem using conic constraints as:

\[
\text{minimize} \sum_{i=1}^{n} d_i t_i \quad (4.11)
\]

subject to

\[
a x \leq b \quad (4.12)
\]

\[
z_i = \sqrt{2}, \quad i = 1, \ldots, n \quad (4.13)
\]

\[
2t_i x_i \geq z_i^2, \quad i = 1, \ldots, n \quad (4.14)
\]

\[
x \in [l, u], \quad (4.15)
\]

\[
t \geq 0, \quad (4.16)
\]

The GAMS formulation using conic equations is:

\[
\text{defobjc..} \quad \text{sum}(n, d(n)*t(n)) =e= \text{obj} ;
\]

\[
\text{e1..} \quad \text{sum}(n, a(n)*x(n)) =l= b ;
\]

\[
\text{e2(n)} \quad z(n) =e= \text{sqr}(2) ;
\]

\[
\text{coneperfect(n)} \quad 2*x(n)*t(n) =g= \text{sqr}(z(n)) ;
\]

Model cperfect /defobjc, e1, e2, coneperfect/ ;

t.lo(n) = 0 ;
\]

\[
x.lo(n) = l(n) ;
\]

\[
x.up(n) = u(n) ;
\]
4.37 Special Features for Mathematical Programs

The complete model is listed below:

Set n / n1*n10 /;
Parameter d(n), a(n), l(n), u(n);
Scalar b;

d(n) = uniform(1,2);
a(n) = uniform(10,50);
l(n) = uniform(0.1,10);
u(n) = l(n) + uniform(0,12-l(n));

Variables x(n);
x.l(n) = uniform(l(n), u(n));
b = sum(n, x.l(n)*a(n));

Variables t(n), z(n), obj;
Equations defobjc, defobj, e1, e2(n), coneqcp(n), coneperfect(n), conenlp(n);

defobjc.. sum(n, d(n)*t(n)) =e= obj;
defobj.. sum(n, d(n)/x(n)) =e= obj;
e1.. sum(n, a(n)*x(n)) =l= b;
coneqcpcp(n).. t(n)*x(n) =g= 1;
e2(n).. z(n) =e= sqrt(2);
coneperfect(n).. 2*x(n)*t(n) =g= sqr(z(n));

- Seventh Dimacs Implementation Challenge on Semidefinite and Related Optimization Problems.

4.37.5 Indicator Constraints

An indicator constraint is a way of expressing relationships between variables by specifying a binary variable to control whether or not a constraint takes effect. For example, indicator constraints are useful in problems where there are fixed charges to express only if a given variable comes into play.

So-called Big M formulations require to estimate an upper bound of an expression in a model. In most cases the model data can be used to determine relatively small number for such coefficients. In some cases it is not possible to find small Big M values and a resulting solution may exhibit trickle flow and have other unwanted side-effects. The main purpose of indicator constraints is to overcome these limitations of Big M formulations. Generally, the use of indicator constraints is not warranted when the unwanted side-effects of Big M formulations are not present.

Consider the following example:

```
constr01.. x1 + x2 + x3 =l= 1e+9*y; // may cause problems
```

Here we use a Big M formulation, that relies on the x values to sum to less than one billion. Note that this formulation may cause numeric instability or undesirable solutions in some situations. Alternatively, we could use an indicator constraint:

```
constr01$(y=0).. x1 + x2 + x3 =l= 0; // alternative
```

Note that y is a binary variable; the logical condition makes sure that the constraint is only active if y = 0. Unfortunately, the $() expressions do not allow endogenous variables and we need a different way to specify such implications. Indicators are supported by CPLEX, GUROBI, SCIP, and XPRESS.

We should mention a formulation of indicators without the explicit indicator constraints. We can use a SOS1 constraint to express that a constraint holds or not based on a binary variable by having a SOS1 set of a slack variable and the binary variable SOS1(slack,1-y):

```
Positive variable slack;
constr01.. x1 + x2 + x3 =l= slack; // alternative
```

Recall that only one of the variables in a SOS1 constraint can be non-zero, so if 1-y is non-zero (i.e. y=0) then slack must be zero, i.e. the constraint holds. If 1-y=0 is non-zero, i.e. y=1 then slack can be used to make the constraint feasible for any setting of x1, x2, and x3. Here two unrelated variable, slack and y are part of an SOS1 constraint and some tricks are required to formulate this properly in GAMS:

```
Set oo / slack, yExpr /;
SOS1 variable indic(oo);
Equation iOn, iOff;
Positive variable slack;
constr01.. x1 + x2 + x3 =l= slack; // alternative
```

We should mention a formulation of indicators without the explicit indicator constraints. We can use a SOS1 constraint to express that a constraint holds or not based on a binary variable by having a SOS1 set of a slack variable and the binary variable SOS1(slack,1-y):

```
Positive variable slack;
constr01.. x1 + x2 + x3 =l= slack; // alternative
```
4.37.5.1 Indicator Constraints with GAMS

In the remainder of this section we will describe how to specify indicator constraints when using GAMS. Please consult the corresponding solver manual for information on whether indicator constraints are supported and possible differences in their specification.

The example from above will be implemented with a constraint in combination with additional information in a solver option file, e.g. CPLEX: cplex.opt:

```plaintext
constr01.. x1 + x2 + x3 =l= 0;
```

and the following entry in the option file:

```plaintext
indic constr01$y 0
```

This has the following effect: equation constr01 will become an indicator constraint and becomes active in a solution where the binary variable takes the value 0. If the value of $y$ in a solution is 1, the constraint is not active.

Note that this way of entering an indicator constraint is dangerous since the option files changes the model (usually an option file has some effect on the performance of the algorithm). Therefore, the solver will abort if there is a problem processing the indicator options in the solver option file.

Attention

If the model is given to a solver without the option file containing the indicator mapping (or to a solver that does not understand the `indic` keyword, a very different model will be solved. The current implementation of indicator constraints requires a significant amount of caution from the user.

There are two ways of entering the equation/binary variable mapping in a solver option file: with an indexed format and using labels.

The indexed format is a convenient shorthand notation which borrows its syntax from the GAMS syntax. It requires that the indices for the binary variable are already present in the index set of the equation.

Consider the following example of an invalid GAMS syntax with an endogenous variable in the dollar condition:

```plaintext
equ1(i,j,k)$(ord(i) < ord(j) and bin1(i,k)=1).. lhs =l= rhs;
```

This may be specified with the following equation in the GAMS file:

```plaintext
equ1(i,j,k)$(ord(i) < ord(j)).. lhs =l= rhs;
```

plus a solver option file with the following entry:

```plaintext
indic equ1(i,j,k)$bin1(i,k) 1
```
The *label format* is used in cases where the binary variable indices are not present in the equation indices or the binary variable is adjusted with lags or leads. In these cases the mapping of all individual equations and variables of the indicator constraints need to be specified. An example follows.

Set  
    i /i1*i3/, j /j1*j2/;
Binary variable bin1(j);
Equation  
    equ1(i,j);

\[
equ1(i,j)\$(bin1(j++1)=0).. lhs =e= 0;
\]

Note that the example above is not valid GAMS code. Instead, we will combine a valid GAMS equation and a solver option file using the label format as follows:

\[
equ1(i,j).. lhs =e= 0;
\]

and the solver option file

\[
indic equ1('i1','j1')$bin1('j2') 0
indic equ1('i1','j2')$bin1('j1') 0
indic equ1('i2','j1')$bin1('j2') 0
indic equ1('i2','j2')$bin1('j1') 0
indic equ1('i3','j1')$bin1('j2') 0
indic equ1('i3','j2')$bin1('j1') 0
\]

Note that the lines in such option files need not be entered manually. They may be easily generated using the GAMS The Put Writing Facility. For example, the lines above may be generated as follows:

```
file fcpx / cplex.opt /;
fcpx.pc=8;
loop((i,j), put fcpx 'indic' equ1(i,j) '$' bin1(j++1) '0'/);
putclose fcpx;
```

There are situations where the indicator binary variable exist in the indicator constraint only and hence will not be generated by GAMS to be passed on to the solver. In such cases the solver will issue the following error message:

**Error: Column is not of type Variable**

There is an easy way to fix this problem: adding the binary indicator variable artificially to the model. For example, it may be added with the coefficient \(\varepsilon\) to the objective:

```
defobj.. z =e= ... + \varepsilon*sum(j, bin1(j));
```
4.37.5.2 An Example for Indicator Constraints with GAMS

In this subsection we will comment on parts of the model [TRNSINDIC]. This model uses big M formulations and indicator constraints to solve the same problem. In addition, a formulation that makes it easy to switch between these two is presented. It is a fixed-charge network example based on the well-known model [TRNSPORT].

Recall that $i$ is the set of canning plants and $j$ is the set of markets where cases of some product are to be shipped. First, the basic model is reformulated to a MIP by introducing the binary variable $\text{use}(i,j)$ and two new equations:

Binary Variable $\text{use}(i,j)$ is 1 if arc is used in solution;

Equations

- $\text{minship}(i,j)$ ensure minimum shipping
- $\text{maxship}(i,j)$ ensure zero shipping if use variable is 0;

\[
\begin{align*}
\text{minship}(i,j) & : \quad x(i,j) \geq \text{minshipping} \times \text{use}(i,j); \\
\text{maxship}(i,j) & : \quad x(i,j) \leq \text{bigM} \times \text{use}(i,j);
\end{align*}
\]

Note that $\text{minshipping}$ is a scalar denoting the minimum amount of cases that may be shipped and $\text{bigM}$ is a sufficiently large number, as usual.

Next, the same problem is solved with indicator constraints: the two new equations are reformulated and a CPLEX option file with information on indicator constraints is added:

Equations

- $\text{iminship}(i,j)$ ensure minimum shipping using indicator constraints
- $\text{imaxship}(i,j)$ ensure zero shipping if use variable is 0 using indicator constraints;

\[
\begin{align*}
\text{iminship}(i,j) & : \quad x(i,j) \geq \text{minshipping}; \\
\text{imaxship}(i,j) & : \quad x(i,j) = 0;
\end{align*}
\]

Model $\text{indicatorModel} /\text{cost}, \text{supply}, \text{demand}, \text{iminship}, \text{imaxship}/$;

file fcpx Cplex Option file / cplex.opt /;
putclose fcpx 'indic iminship(i,j)$use(i,j) 1' / 'indic imaxship(i,j)$use(i,j) 0';
indicatorModel.optfile = 1;
Solve indicatorModel using mip minimizing $z$;

Note that the option file contains an entry for each of the two equations. Note further, that the binary variable $\text{use}$ moved from the equations to the option file. However, it also features in the objective equation of the model, therefore this is not problematic. Observe that the indexed format for the equation/binary variable mapping was used in the option file. Alternatively, the label format may be used:

\[
\begin{align*}
\text{loop}((i,j), \\
\quad \text{put fcpx 'indic ' iminship.tn(i,j)$use.tn(i,j) yes} \\
\qquad / 'indic ' imaxship.tn(i,j)$use.tn(i,j) no / );
\end{align*}
\]

In a final step the model is reformulated again such that the same problem may be solved with and without indicator constraints. This can be especially useful for debugging a model with indicator constraints. For details, see [TRNSINDIC].

Another example of a model with indicator constraints is the model [BILINEAR] where various formulations to represent bilinear product terms are demonstrated.
4.38 GAMS Output

4.38.1 Introduction

The output from GAMS contains many components in support for checking and comprehending a model. This chapter discusses the components of the GAMS output file generated from a GAMS run as well as ways to control the amount of diagnostic output produced. A GAMS run also generates a log which serves as a useful first step in analysing a GAMS run. The details regarding the log can be found in the GAMS log chapter.

The output file generated from a GAMS run is called *listing file*. The listing file has the file extension `.lst` and can be read using any text editor. By default the listing file has the same file name as the input file, but this can be changed using the command line parameter `Output`. See chapter The GAMS Call and Command Line Parameters for more information. The main components in the listing file are:

1. **Compilation.** The compilation output contains an echo print of the input file, possibly error messages, along with lists of GAMS objects and cross reference maps.
2. **Execution.** The execution output contains the results of display statements and possibly execution error messages.
3. **Model Generation.** The output generated during model generation contains listings of equations and variable listings as well as model statistics and possibly generation execution error messages.
4. **Solution.** The output generated when an external solver program processes the model is the solution report including the solve summary, the solver report, the solution listing and the report summary.
5. **Post-Solution.** The final components added to the listing file are the final execution summary and the file summary.

A small nonlinear program [ALAN] will be used to illustrate every component of the listing file. The possibilities for extension to large models with voluminous output (which is when the diagnostics are really useful) should be apparent. After covering all the components of the listing file we will discuss error reporting and conclude the chapter with a compiled list of how to customize the output file.

This chapter does not cover the output that can be generated by the user through display statements and put statements. This output is covered in the chapters The Display Statement and The Put Writing Facility respectively.

4.38.2 An Illustrative Model

[ALAN] is a portfolio selection model whose objective is to choose a portfolio of investments whose expected return meets a target while minimizing the variance. We will discuss a simplified version of this model. The input file is listed for reference.

$Title A Quadratic Programming Model for Portfolio Analysis (ALAN,SEQ=124a)

Model portfolio / fsum, dmean, dvar / ;
Solve portfolio using nlp minimizing variance;
display x.l, variance.l;

4.38.3 Compilation Output

The compilation output is the output produced during the initial check of the program, often referred to as compilation. It contains the following parts: the echo print of the input file, the symbol reference map, the symbol listing map, the unique element listing map, and the include file summary.

By default only the echo print and the include file summary is shown, the other parts are suppressed and may be turned on with dollar control options. See also section Customizing the Output File on how to control the appearance and amount of detail in the output file produced by the GAMS compiler.
4.38.3.1 The Echo Print of the Input File

The *echo print* of the program is always the first part of the output file. It is a listing of the input with added line numbers. It is possible to control the listing output using `$offlisting` to suppress the echo print and `$onlisting` to turn the echo print on again. The first few lines of the echo print of the Illustrative Model follow:

A Quadratic Programming Model for Portfolio Analysis (ALAN,SEQ=124a)

Compilation

2

This is a mini mean-variance portfolio selection problem described in 'GAMS/MINOS: Three examples' by Alan S. Manne, Department of Operations Research, Stanford University, May 1986.

10

* This model has been modified for use in the documentation

The default header of the GAMS listing file is General Algebraic Modeling System. This may be replaced using the $title at the start of a line. The text on that line will be the new header, as demonstrated above. After the header the compilation output is announced with the title Compilation.

The first three line numbers refer to empty lines in the input and line 11 is a comment line. If the lines on the input file are counted, it can be seen that this comment line appears after ten lines of dollar directives, comments and empty lines.

The dollar control options that follow in the model are used to display more information in the output file than the default and will be discussed in the subsections below.

Note

By default, dollar control option lines are not listed in the echo print. The $onDollar and $offDollar controls the echoing of Dollar Control Options lines in the listing file. Dollar control option lines are also listed if they contain errors.

The block comment enclosed by $ontext and $offtext is listed without line numbers, while single line comments starting with asterisks (*) are listed with the respective line numbers. Observe that line numbers always refer to the physical line number in the input file. The remainder of the echo print follows:

12
13 Set i securities /hardware, software, show-biz, t-bills/;
14 alias (i,j);
15
16 Scalar target target mean annual return on portfolio % /10/,
17 lowyield yield of lowest yielding security,    
18 highrisk variance of highest security risk ;
19
20 Parameters mean(i) mean annual returns on individual securities (%)
21 / hardware 8
22 software 9
23 show-biz 12
24 t-bills 7 / ;
25
26 Table v(i,j) variance-covariance array (%-squared annual return)
### Symbol Listing

<table>
<thead>
<tr>
<th>SYMBOL</th>
<th>TYPE</th>
<th>REFERENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>dmean</td>
<td>EQU</td>
<td>declared</td>
</tr>
<tr>
<td>dvar</td>
<td>EQU</td>
<td>declared</td>

<td>PARAM</td>
<td>declared</td>
</tr>
<tr>
<td>i</td>
<td>SET</td>
<td>declared</td>
</tr>
<tr>
<td>j</td>
<td>SET</td>
<td>declared</td>
</tr>
</tbody>
</table>

Lines in the echo print can be set to double space using `$double` and then reset to single space with `$single`. If errors were detected, the explanatory messages would be found at the end of the echo print. All discussions of error messages have been grouped together in the section **Error Reporting** below.

#### 4.38.3.2 The Symbol Reference Map

The other parts of the compilation outputs are maps. They are extremely useful for users looking at a model written by someone else or trying to make changes in their own model after spending some time away from it. By default all maps are suppressed and can be turned on with dollar control options that are specified below.

The first map is the **symbol cross reference**. It can be turned on with the dollar control option `$onSymXRef` at the beginning of the program. The symbol cross reference map lists all identifiers (symbols) from the model in alphabetical order, identifies them as to data type, shows the line numbers where the symbols appear and classifies each appearance. The map that was generated as part of the output of our *Illustrative Model* is shown below:
In the first two columns the name and type of each identifier are given. For example, the last symbol listed is x which is defined to be of type VAR, a shorthand symbol for variable. The complete list of data types and their shorthand symbols is given below:

<table>
<thead>
<tr>
<th>Shorthand Symbol</th>
<th>GAMS Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACRNM</td>
<td>acronym</td>
</tr>
<tr>
<td>EQU</td>
<td>equation</td>
</tr>
<tr>
<td>FILE</td>
<td>put file</td>
</tr>
<tr>
<td>MODEL</td>
<td>model</td>
</tr>
<tr>
<td>PARAM</td>
<td>parameter</td>
</tr>
<tr>
<td>SET</td>
<td>set</td>
</tr>
<tr>
<td>VAR</td>
<td>variable</td>
</tr>
</tbody>
</table>

For further details on data types in GAMS, see section Data Types and Definitions.

The symbol highrisk was declared as a scalar, but is listed as a parameter in the map above. Recall that parameters, scalars, and tables are three input formats for the data type parameter. For more information, see the overview Parameters, Scalars and Tables.

After the name and type of the identifier, a list of references to the symbol is given. References are grouped by reference type and identified by the line number in the output file. The actual reference can be found by referring to the echo print of the program, which has line numbers on it. In the case of the symbol x in the example above, the list of references as shown in the symbol reference map are as follows:

declared 37
impl-asn 50
ref 39 45 46 2*47 51

This means that x is declared on line 37, implicitly assigned through a solve statement on line 50 and referenced on lines 39, 45, 46, 47, and 51. The entry 2*47 means that there are two references to x on line 47 of the input file.

The complete list of reference types and their shorthand symbols in GAMS Output is given below:

<table>
<thead>
<tr>
<th>Shorthand Symbol</th>
<th>Reference Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>declared</td>
<td>Declaration</td>
<td>The identifier is declared as to type. This must be the first appearance of the identifier.</td>
</tr>
<tr>
<td>defined</td>
<td>Definition</td>
<td>An initialization (for a table or a data list between slashes) or symbolic definition (for an equation) starts for the identifier.</td>
</tr>
<tr>
<td>assigned</td>
<td>Assignment</td>
<td>Values are replaced because the identifier appears on the left-hand side of an assignment statement.</td>
</tr>
<tr>
<td>impl-asn</td>
<td>Implicit Assignment</td>
<td>An equation or variable will be updated as a result of being referred to implicitly in a solve statement.</td>
</tr>
<tr>
<td>Shorthand Symbol</td>
<td>Reference Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>control</td>
<td>Control</td>
<td>A set is used as (part of) the driving index in an assignment, equation, loop or indexed operation.</td>
</tr>
<tr>
<td>ref</td>
<td>Reference</td>
<td>The symbol has been referenced on the right-hand side of an assignment or in a display, equation, model, solve statement or put statement.</td>
</tr>
<tr>
<td>index</td>
<td>Index</td>
<td>Like control, but used only for set labels. Appears only in the cross reference map of unique elements. See section The Unique Element Listing Map for details.</td>
</tr>
</tbody>
</table>

Note that the symbol reference map may be useful in model development, documentation preparation, and to make sure that all declared items are actually used in the model (by checking that they all have reference symbols in addition to declared and defined).

### 4.38.3.3 The Symbol Listing Map

The second optional map is the symbol listing. In the symbol listing map all identifiers are grouped alphabetically by data type and listed with their explanatory texts. This is another very useful aid for trying to understand a large model prepared by someone else. Note that expressive explanatory text is particularly helpful here. The symbol listing map can be turned on by entering a line containing the dollar control option $onSymList at the beginning of the program. The symbol listing map generated from our Illustrative Model follows:

**SETS**

- i securities
- j Aliased with i

**PARAMETERS**

- highrisk variance of highest security risk
- lowyield yield of lowest yielding security
- mean mean annual returns on individual securities (%)
- target target mean annual return on portfolio %
- v variance-covariance array (%-squared annual return)

**VARIABLES**

- variance variance of portfolio
- x fraction of portfolio invested in asset i

**EQUATIONS**

- dmean definition of mean return on portfolio
- dvar definition of variance
- fsum fractions must add to 1.0

**MODELS**

portfolio
4.38.3.4 The Unique Element Listing Map

The last optional map is the Unique Element Listing (UEL). The unique element listing map can be turned on by entering a line containing the dollar control option $onUELList at the beginning of the program. All unique elements are first grouped in entry order and then in sorted order with their explanatory texts:

Unique Element Listing

Unique Elements in Entry Order
1 hardware software show-biz t-bills

Unique Elements in Sorted Order
1 hardware show-biz software t-bills

In addition, a map with references for every label is given if the dollar control option $onUELEXRef appears at the beginning of the program.

ELEMENT REFERENCES

<table>
<thead>
<tr>
<th>ELEMENT</th>
<th>REFERENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>hardware</td>
<td>declared</td>
</tr>
<tr>
<td>show-biz</td>
<td>declared</td>
</tr>
<tr>
<td>software</td>
<td>declared</td>
</tr>
<tr>
<td>t-bills</td>
<td>declared</td>
</tr>
</tbody>
</table>

The unique element list is important in the context of ordered sets. For details see section Ordered and Unordered Sets.

4.38.3.5 The Include File Summary

Often the GAMS program includes a text file specified by the dollar control option $include. Consider the following example:

$include 'file1.inc'
Set i / i1*i10 /
Scalar a; a = 7;
$include 'file2.inc'

The file file1.inc contains the following two lines:

Set j / j1*j5 /
Parameter k(j);

The file file2.inc contains the following line:

a = a+3;
The echo print follows:

```
\texttt{\include C:\models\file1.inc}
2 \texttt{Set j / j1\*j5 /;}
3 \texttt{Parameter k(j);}   
4 \texttt{Set i / i1\*i10 /;}
5 \texttt{Scalar a; a = 7;}
\texttt{\include C:\models\file2.inc}
7 \texttt{a = a+3;}
```

Note that the contents of the two include files are expanded in the echo print and the include file names and their path is echoed in the lines with the dollar control option $\texttt{include}$. If we insert the dollar control option $\texttt{offInclude}$ in the first line of the code, the echo print will not include the lines with the names of the include files any more, but the contents will still be echoed:

```
3 \texttt{Set j / j1\*j5 /;}
4 \texttt{Parameter k(j);}   
5 \texttt{Set i / i1\*i10 /;}
6 \texttt{Scalar a; a = 7;}
8 \texttt{a = a+3;}
```

If the program contains include files, there will be an Include File Summary at the end of the compilation output. The include file summary of the simple example above (without the line $\texttt{offInclude}$) follows. If $\texttt{offInclude}$ is active, it will be suppressed.

<table>
<thead>
<tr>
<th>SEQ</th>
<th>GLOBAL</th>
<th>TYPE</th>
<th>PARENT</th>
<th>LOCAL</th>
<th>FILENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>INPUT</td>
<td>0</td>
<td>0</td>
<td>C:\models\test.gms</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>INCLUDE</td>
<td>1</td>
<td>1</td>
<td>.C:\models\file1.inc</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>INCLUDE</td>
<td>1</td>
<td>4</td>
<td>.C:\models\file2.inc</td>
</tr>
</tbody>
</table>

In the first column the sequence number of the input files is given. Note that the parent file called by the GAMS call is always listed first. The second column gives the global (expanded) line number which contains the respective option include or one of its variants. The third column indicates the type of the respective file. An overview of the file types is given below:

<table>
<thead>
<tr>
<th>File Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INPUT</td>
<td>The GAMS input file that was called with the GAMS call.</td>
</tr>
<tr>
<td>INCLUDE</td>
<td>A file that was inserted with the dollar command option $\texttt{include}$.</td>
</tr>
<tr>
<td>BATINCLUDE</td>
<td>A file that was inserted with the dollar command option $\texttt{batinclude}$.</td>
</tr>
<tr>
<td>LIBINCLUDE</td>
<td>A file that was inserted with the dollar command option $\texttt{libinclude}$.</td>
</tr>
<tr>
<td>SYSINCLUDE</td>
<td>A file that was inserted with the dollar command option $\texttt{sysinclude}$.</td>
</tr>
</tbody>
</table>

The next column, named PARENT, provides the sequence number of the respective parent file. The column with the header LOCAL gives the local line number in the parent file where the file was included. The last column shows the path and the name of the respective file.

Note that compilation error messages in include files have additional information about the name of the include file and the local line number. For information on compilation errors, see section Compilation Errors below.
4.38.4 Execution Output

The execution output follows the compilation output in the GAMS listing file. It is introduced with the title **Execution**. The execution output is the output generated while GAMS is performing data manipulations and results from display statements. The output from the display statement on line 33 of our **Illustrative Model** is shown below.

```
---  33 PARAMETER lowyield = 7.000 yield of lowest yielding security
      PARAMETER highrisk = 10.000 variance of highest security risk
```

If errors are detected because of illegal data operations, a brief message indicating the cause and the line number of the offending statement will appear. For further information on execution errors, see section **Execution Errors** below.

**Note**

In case there is no display statement before The Solve Statement in the model and there are no execution errors, there will be no execution output in the GAMS listing file.

4.38.5 Model Generation Output

The model generation output, the solution report, and the post-solution Output are produced when a solve statement is executed. The actions that are initiated by a solve statement are presented in section **Actions Triggered by the Solve Statement**. All output generated as a result of a solve is labeled with a subtitle identifying the model, its type and the line number of the solve statement.

The output generated during model generation includes equations listing, variable listing, and model statistics.

4.38.5.1 The Equation Listing

The **equation listing** is the first part of the output generated by a solve statement. It is marked with the subtitle **Equation Listing**. By default, the first three equations in every block are listed. This can be modified with the option limrow. If there are three or fewer single equations in any equation block, then all the single equations are listed.

Note that by studying the equation listing the user may determine whether the model generated by GAMS is the model that the user has intended - an extremely important question. This component of the output shows the specific equations generated within the model when the current values of the sets and parameters are plugged into the general algebraic form of the model.

The equation listing from our **Illustrative Model** is given below. In our case we have three equation blocks, each producing one single equation.
A Quadratic Programming Model for Portfolio Analysis (ALAN, SEQ=124a)
Equation Listing  SOLVE portfolio Using NLP From line 50

---- fsum  =E=  fractions must add to 1.0
fsum..  x(hardware) + x(software) + x(show-biz) + x(t-bills) =E= 1 ; (LHS = 0, INFES = 1 ****)

---- dmean  =E=  definition of mean return on portfolio
dmean..  8*x(hardware) + 9*x(software) + 12*x(show-biz) + 7*x(t-bills) =E= 10 ; (LHS = 0, INFES = 10 ****)

---- dvar  =E=  definition of variance
dvar..  (0)*x(hardware) + (0)*x(software) + (0)*x(show-biz) - variance =E= 0 ; (LHS = 0)

Note
The equation listing is an extremely useful debugging aid. It shows the variables that appear in each constraint. In addition, it shows what the individual coefficients and right-hand side values evaluate to after the data manipulations have been done.

Each equation block is marked with four dashes which are useful for mechanical searching. The name, type of equation and explanatory text is shown, followed by the individual equations.

Note
All the terms that depend on variables are collected on the left-hand side and all the constant terms are combined into one number on the right-hand side, any necessary sign changes being made.

Four places of decimals are shown if necessary, but trailing zeroes following the decimal point are suppressed. E-format is used to prevent small numbers to be displayed as zeros.

Note
Nonlinear equations are treated differently. If the coefficient of a variable in the equation listing is enclosed in parentheses, then the corresponding constraint is nonlinear, and the value of the coefficient depends on the activity levels of one or more of the variables. The listing is not algebraic, but shows the partial derivative of each variable evaluated at their current level values.

Note that in the equation listing from our example the equation dvar is nonlinear. A simpler example will help to clarify the point. Consider the following equation and associated level values.

eq1..  2*sqr(x)*power(y,3) + 5*x - 1.5/y =e= 2; x.l = 2; y.l = 3 ;

This equation will appear in the equation listing as:

eq1.. (221)*x + (216.1667)*y =E= 2 ; (LHS = 225.5 ***)
The coefficient of $x$ is determined by first differentiating the equation above with respect to $x$. This results in $2 \times (2 \times x.l) \times (y.l)^3 + 5$, which evaluates to 221, given that $x.l$ equals 2 and $y.l$ equals 3. Similarly, the coefficient of $y$ is obtained by differentiating the equation above with respect to $y$, which results in $2 \times (x.l)^2 \times 3 \times (y.l)^2 + \frac{1.5}{(y.l)^2}$, giving 216.1667. Observe that the coefficient of $y$ could not have been determined if its level had been left at zero. The attempted division by zero would have produced an error and premature termination. For further information on modeling NLP problems with GAMS, see the tutorial Good NLP Formulations.

The result of evaluating the left-hand side of the equation at the initial point is shown at the end of each individual equation listing. In the example above it is 225.5, and the three asterisks(*** are a warning that the constraint is infeasible at the starting point.

Note

The order in which the equations are listed depends on how the model was defined. If it was defined with a list of equation names, then the listing will be in the order of that list. If it was defined as /all/, then the list will be in the order of declaration of the equations. The order of the entries for the individual constraints is determined by the label entry order.

### 4.38.5.2 The Column Listing

The column listing or variable listing is the next part of the output. It is marked with the title Column Listing and contains a list of the individual coefficients sorted by column rather than by row (like in the equation listing). By default the first three entries for each variable are shown, along with their lower bound .lo, upper bound .up and current level values .l. Note that the default number of entries shown may be modified with the option limcol.

The format for the coefficients is exactly as in the equation listing, with the nonlinear coefficients enclosed in parentheses and the trailing zeroes dropped. The column listing from our Illustrative Model follows.

A Quadratic Programming Model for Portfolio Analysis (ALAN,SEQ=124a)

Column Listing SOLVE portfolio Using NLP From line 50

---- variance  variance of portfolio

variance

(.LO, .L, .UP, .M = -INF, 0, +INF, 0)

-1  dvar

Note
The order in which the variables appear is the order in which they were declared.

4.38.5.3 The Range Statistics

This block shows a statistic about the range of values seen in the model. Namely, it prints the range of absolute non-zero values for the bounds, right hand sides and matrix coefficients. Zero values are marked explicitly. This is the example output when running the model [TRNSPORT]:

Range Statistics  SOLVE transport Using LP From line 71

RANGE STATISTICS (ABSOlUTE NON-ZERO FINITE VALUES)

RHS  [min, max] : [ 2.750E+02, 6.000E+02] - Zero values observed as well
Bound  [min, max] : [ NA, NA] - Zero values observed as well
Matrix  [min, max] : [ 1.260E-01, 1.000E+00]

Note the NA range for the bounds: For this model, the bounds are either 0 or +INF. Both values are excluded in this range calculation. Therefore we see the NA here.

4.38.5.4 The Model Statistics

The final information generated while a model is being prepared for solution is the statistics block. It is marked with the title Model Statistics. Its most obvious use is to provide details on the size and nonlinearity of the model. The model statistics of our Illustrative Model follow:

A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Model Statistics  SOLVE portfolio Using NLP From line 50

MODEL STATISTICS

| BLOCKS OF EQUATIONS | 3 | SINGLE EQUATIONS | 3 |
| BLOCKS OF VARIABLES | 2 | SINGLE VARIABLES | 5 |
| NON ZERO ELEMENTS   | 12 | NON LINEAR N-Z   | 3 |
| CODE LENGTH         | 25 | CONSTANT POOL    | 17 |

GENERATION TIME  = 0.004 SECONDS  4 MB

EXECUTION TIME  = 0.005 SECONDS  4 MB
The **BLOCK** counts indicate the number of GAMS symbols (**equations** and **variables**, respectively) appearing in the problem generated. The **SINGLE** counts indicate the number of individual rows and columns in the problem generated. The **NON ZERO ELEMENTS** entry refers to the number of nonzero coefficients in the problem matrix. To understand the remaining elements, some background will be useful.

For linear models, the model can be completely specified by the problem matrix and vectors for the RHS, etc. More is needed for nonlinear models. GAMS passes the nonlinear expressions defining the model algebra to the solvers in the form of **NL code** - opcode/address pairs in a simple stack-based language. For example, the expression \( \exp(x \cdot y - 1.675) \) results in code similar to this:

```
PUSHV column-index-of-x
MULV column-index-of-y
SUBC index-of-1.675
FUNC1 index-of-exp-function
STOR index-of-row
```

In addition to containing indices referring to the rows and columns of the model, the NL code contains indices of constants used to define the model algebra. These constants are not contained in the NL code directly but rather in a separate pool or list of constants used for the model.

There are three entries that provide additional information about nonlinear models. The **NON LINEAR N-Z** entry refers to the number of nonlinear matrix entries in the model. Nonlinear models may differ in the complexity or size of the nonlinear expressions defining them. For example, \( xy \) is a simpler form of nonlinearity than \( \exp(x \cdot y) \) and will require a shorter list of instructions to define, even though both of these terms result in two nonlinear entries in the matrix (one for \( x \) and one for \( y \)). The **CODE LENGTH** entry indicates the length of the NL code (i.e. number of instructions) required to define the model algebra, while the **CONSTANT POOL** indicates the length of the constant pool that is used by the NL code. In general, the more nonlinear a problem is, the more difficult it tends to be to solve.

The times that follow statistics are also useful. The **GENERATION TIME** is the time used since compilation (syntax check) is finished. This includes the time spent in generating the model. The measurement units are given and represent ordinary clock time on personal computers or central processor usage (CPU) time on other machines. Memory use is given in megabytes.

### 4.38.6 The Solution Report

The **solution report** is the next part of the output. It is marked with the title **Solution Report** and includes the **solve summary**, the **solver report**, the **solution listing**, and the **report summary**.

#### 4.38.6.1 The Solve Summary

The **solve summary** contains details about the solution process and is marked with the title **SOLVE SUMMARY**. The first part of the solve summary is common to all solvers and is discussed in this subsection. The second part of the solve summary is solver specific, it is covered in the subsection **Solver Report** below. The first part of the solve summary for our **Illustrative Model** follows.

---

```
A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Solution Report SOLVE portfolio Using NLP From line 50

SOLVE SUMMARY

MODEL portfolio OBJECTIVE variance
```
The entry **MODEL** contains the name of the model being solved, **TYPE** provides the model type of the model, **SOLVER** shows the name of the solver used to solve the model, **OBJECTIVE** gives the name of the objective variable being optimized, **DIRECTION** shows the direction of optimization being performed and the entry **FROM LINE** provides the line number of the solve statement the solve summary refers to.

Note that the four asterisks make it easy to find the solve summary if it is searched for mechanically.

The entries **SOLVER STATUS** and **MODEL STATUS** contain the solver and model status for the problem respectively. Their possible values are given in Model Status table and Solver Status tables below. The entry **OBJECTIVE VALUE** provides the value of the objective function at the termination of the solve. This value is the optimum value for the problem provided the solver and model have the right status.

The entry **RESOURCE USAGE, LIMIT** reports the amount of wall clock time (in seconds) taken by the solver and the upper limit allowed for the solver. Note that the solver will stop as soon as the limit on time usage has been reached. The default limit may be changed with the option reslim. Observe that the option statement `option reslim = x;` - where `x` is the desired limit in wall clock seconds - must be entered in the model before the solve statement.

The entry **ITERATION COUNT, LIMIT** provides the number of iterations used by the solver and the upper limit allowed for the solver. The solver will stop as soon as this limit is reached. The default limit on iterations used is practically infinity. This limit may be changed with the option iterlim. Observe that the option statement `option iterlim = n;` - where `n` is the desired limit of the iterations used - must be entered in the model before the solve statement.

Finally, the entry **EVALUATION ERRORS** reports the number of numerical errors encountered by the solver and the upper limit allowed for the solver. These errors result from numerical problems like division by zero. Note that this is suppressed for LP, RMIP and MIP models since evaluation errors are not applicable for these model types. The default limit on evaluation errors used is zero. This limit may be changed with the option domlim. Observe that the option statement `option domlim = n;` - where `n` is the desired limit of the evaluation errors allowed - must be entered in the model before the solve statement.

### 4.38.6.1.2 Solver Status

Note that the solver status is stored in the model attribute solveStat. For details on model attributes, see section **Model Attributes**. Observe that there are compile-time constants that are related to this model attribute.

### 4.38.6.2 Solver Report

The next section in the listing file is the part of the solve summary that is particular to the solver program that has been used. This section normally begins with a message identifying the solver and its authors: **MINOS and QUADMINOS** was used in the example here. There will also be diagnostic messages in plain language if anything unusual was detected and specific performance details, some of them probably
technical. The solver manual of the respective solver will help explain these. In case of serious trouble, the GAMS listing file will contain additional messages printed by the solver. This may help identify the cause of the difficulty. If the solver messages do not help, a perusal of the solver documentation or help from a more experienced user is recommended. The solver report from our Illustrative Model follows.

GAMS/MINOS
MINOS 5.6  (Nov 2014)

GAMS/Minos 5.6, Large Scale Nonlinear Solver
B. A. Murtagh, University of New South Wales
P. E. Gill, University of California at San Diego,
W. Murray, M. A. Saunders, and M. H. Wright,
Systems Optimization Laboratory, Stanford University

Work space allocated -- 0.77 Mb

EXIT - Optimal Solution found, objective: 2.899038

Note that the line Work space allocated -- 0.77 MB provides the amount of memory used by the solver for the problem. The solver estimates the amount of memory it will need to solve the problem. If this amount is not available on the machine used, GAMS will return a message saying that not enough memory was allocated. In addition, GAMS will return the maximum amount of memory available on the machine. The user may direct the solver to use less memory with the model attribute .workspace:

mymodel.workspace = x;

Here mymodel is the name of the model being solved as specified by the model statement and x is the amount of memory in Megabytes. Note that the solver will attempt to solve the problem with x MB of memory. However, it is not guaranteed to succeed since the problem may require more memory.

Note that more information for a successful run may be obtained using the option sysout. As usual, the respective option statement should be placed before the solve statement.

4.38.6.3 The Solution Listing

The solution listing is a row-by-row then column-by-column listing of the solutions returned to GAMS by the solver program. Each individual equation and variable is listed with four pieces of information. The solution listing may be suppressed with the option solprint:

option solprint = off;

This option statement should be placed before the solve statement. The solution listing generated from our Illustrative Model is shown below.

</tr>
</tbody>
</table>

variance variance of portfolio

The order of the equations and variables is the same as in the symbol listing map.

The four columns associated with each entry correspond to the equation and variable attributes and have the following meaning:

- **LOWER** lower bound (.lo)
- **LEVEL** level value (.l)
- **UPPER** upper bound (.up)
- **MARGINAL** marginal (.m)

For variables, the values in the **LOWER** and **UPPER** columns refer to the lower and upper bounds. For equations, they are obtained from the (constant) right-hand side value and from the relational type of the equation. For details see section Variable Attributes and Equation Attributes. Note that instead of level values, slack values may be shown in equations. For more information, see section Customizing the Output File below.

Note

The **LEVEL** and **MARGINAL** values have been determined by the solver and the values shown are used to update the GAMS values. In the list they are shown with fixed precision, but the values are returned to GAMS with full machine accuracy. The single dots '.' on the list represent zeros.

**EPS** is the GAMS extended value used for a stored zero. It is common to see a marginal value given as EPS, since GAMS uses the convention that marginals are necessarily zero for basic variables and typically non-zero for other variables.

Note

**EPS** is used to indicate non-basic variables whose marginal values are at or close to zero, and for nonlinear problems to indicate superbasic variables whose marginals are at or close to zero. A superbasic variable is one between its bounds at the final point but not in the basis.

Note that in the Glossary there are brief explanations of technical terms that were used in this section.

For models that are not solved to optimality or for models types without an objective, some constraints may additionally be marked with certain flags. The list of these flags and their description is given in the following table.
<table>
<thead>
<tr>
<th>Shorthand Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INFES</td>
<td>The row or column is infeasible. This mark is made for any entry where the level value is not between the upper and lower bounds.</td>
</tr>
<tr>
<td>NOPT</td>
<td>The row or column is non-optimal. This mark is made for any non-basic entries for which the marginal sign is incorrect, or superbasic ones for which the marginal value is too large.</td>
</tr>
<tr>
<td>UNBND</td>
<td>The row or column can increase without limit (e.g. in an unbounded ray) or has an excessively large magnitude.</td>
</tr>
<tr>
<td>REDEF</td>
<td>The equation type has been ignored or redefined for this solution point, e.g. because this is an MCP</td>
</tr>
<tr>
<td>REDIR</td>
<td>The equation has been flipped (i.e. negated or reoriented) in the model statement: useful for MCP and EMP</td>
</tr>
<tr>
<td>DEPND</td>
<td>The row or column is dependent on other rows or columns in the system: see CNS</td>
</tr>
</tbody>
</table>

### 4.38.6.4 Report Summary

The final section of the solution report is the report summary, marked with four asterisks (as are all important components of the output) followed by the title REPORT SUMMARY. It shows the count of rows or columns that have been marked INFES, NOPT or UNBND in the solution listing. For model types like MCP where REDEFs and REDIRs are possible, the counts for these markers may also be shown. The sum of infeasibilities will be shown if the reported solution is infeasible. The domain error count is only shown if the problem is nonlinear. If there are variables or equations where the levels were projected to one of the bounds, the count of those is also shown here.

```

### 4.38.7 Post-Solution Output

The final part of the listing file is the post-solution output. It contains Final Execution Summary and the File Summary.

#### 4.38.7.1 Final Execution Summary

The final execution summary is marked with the title Execution and contains the output from display statements that were placed after the solve statement in the model, allowing simple reporting. In addition, it shows the final execution time and memory use. The respective output from our Illustrive Model follows.
A Quadratic Programming Model for Portfolio Analysis ALAN, SEQ=124a)

**Execution**

---- 51 VARIABLE x.L fraction of portfolio invested in asset i

hardware 0.303, software 0.087, show-biz 0.505, t-bills 0.106

---- 51 VARIABLE variance.L = 2.899 variance of portfolio

EXECUTION TIME = 0.001 SECONDS 3 MB

For further information on this output and ways to customize it, see chapter The Display Statement.

### 4.38.7.2 File Summary

The file summary is the very last part of the output file. If output has been written to put files, there will be a REPORT FILE SUMMARY that is marked with four asterisks. The report will list the put files with their internal names and the full paths of their external names.

All listing files have a FILE SUMMARY that is marked with four asterisks and that reports the names of the input and output (listing) files.

**** FILE SUMMARY

<table>

</tr>
</thead>
<tbody>
<tr>
<td>Output</td>
<td>C:\PROGRAM FILES\gamsIDE\ALAN.LST</td>
</tr>
</tbody>
</table>

If work files (save or restart) have been used, they will be listed in the file summary as well.

### 4.38.8 Error Reporting

All comments and descriptions about errors have been collected in this section for easy reference when disaster strikes.

Effective error detection and recovery are important parts of any modeling system. GAMS is designed around the assumption that the error state is the normal state of modeling. Experience shows that most compilations during the early stages of development will produce errors. Not to worry! The computer is much better at checking details than the human mind and should be able to provide positive feedback and suggestions about how to correct errors or avoid ambiguities. Developing a model is like writing a paper or an essay; many drafts and rewrites are required until the arguments are presented in the most effective way and meet all the requirements of proper English. GAMS acts like a personal assistant with knowledge of mathematical modeling and of the syntactic and semantic details of the language.

Errors are detected at various stages in the modeling process. Most of them are caught at the compilation stage, which behaves like the proofreading stage of the modeling process. Once a problem has passed through the rigorous test of this stage, the error rate drops to almost zero. Most of the execution runs, which are much more expensive than compilation, proceed without difficulties because GAMS knows about modeling and has anticipated problems. Many of the typical errors made with conventional programming languages are associated with concepts that do not exist in GAMS. Those error sources – like address calculations, storage assignment, subroutine linkages, input-output and flow control – create problems at execution time, are difficult to locate, often lead to long and frustrating searches, and leave the computer user intimidated. GAMS takes a radically different approach. Errors are spotted as early as possible, they are reported in a way that is comprehensible to the user, including clear suggestions for how to correct the problem and a presentation of the source of the error in terms of the problem of the user.
Note

All errors are marked with four asterisks '****' at the beginning of a line in the output listing.

As soon as an error is detected, processing will be stopped at the next convenient opportunity. A model will never be solved after an error has been detected. The only remedy is to fix the error and repeat the run.

Errors are grouped into the three phases of GAMS modeling: compilation, execution and model generation (which includes the solution that follows). In the following subsections we will discuss the errors that may occur in each of these phases.

4.38.8.1 Compilation Errors

Compilation errors are discussed in some detail in the tutorial A GAMS Tutorial by Richard E. Rosenthal and the tutorial Fixing Compilation Errors. Note that there is some overlap between the material in the tutorials and this section. Several hundred different types of errors can be detected during compilation and can often be traced back to just one specific symbol in the GAMS input. Most of the errors are caused by simple mistakes: forgetting to declare an identifier, putting indices in the wrong order, leaving out a necessary semicolon or misspelling a label. For errors that are not caused by such simple mistakes, the explanatory error message text will help diagnose the problem and correct it.

Note

When a compilation error is discovered, a dollar symbol and error number are printed below the offending symbol (usually to the right) on a separate line that begins with four asterisks.

If more than one error is encountered on a line (possibly because the first error caused a series of other spurious errors) the dollar signs may be suppressed and error number squeezed. GAMS will not list more than 10 errors on any one line.

Note

A list of all error numbers encountered and a description of the probable cause of each error is printed at the end of the echo print of the program. The error messages are self-explanatory. For further information on compilation errors and advice on how to resolve them, see the tutorial Fixing Compilation Errors.

It is worth noting that it is easy to produce a model that does not do what you want it to do, but does not contain errors in the sense that the term is being used in this section. The best precaution is to check your work carefully and build in as many automatic consistency checks as possible.

Note that if a GAMS reserved word is accidentally used for the name of a label or an identifier it is impossible to provide helpful error messages for technical reasons. This may cause confusion. We recommend users to familiarize themselves with the reserved words.
Attention

In some cases an error may not be detected until the statement following its occurrence, where it may produce a number of error conditions whose explanations seem quite silly. We recommend to always check carefully for the cause of the first error in such a group. If nothing obvious is wrong, look at the previous statement and particularly watch out for missing semicolons.

The following example illustrates the general reporting format for compilation errors.

1 Set c crops / wheat, corn, wheat, longaname /  
  **** $172
2 Parameter price(c) / wheat 200, cotton 700 /  
  **** $170
3
Error Messages

170 Domain violation for element  
172 Element is redefined  

**** 2 ERROR(S) 0 WARNING(S)  

**** USER ERROR(S) ENCOUNTERED

4.38.8.2 Compilation Time Errors

The reporting format for errors found while analyzing solve statements is more complicated than for normal compilation errors, mainly because many things must be checked. All identifiers referenced must be defined or assigned, the mathematics in the equations must match the model class, and so on. More elaborate reporting is required to accurately describe any problems found. The solve statement is only checked if the model has been found to be error free up to this point. This is not only because the check is comparatively expensive, but also because many erroneous and confusing messages can be produced while checking a solve in a program containing other errors.

Attention

Compiler error messages related to a solve statement are reported in two places and in two formats:

1. They are shown immediately after the solve statement with a short text including the name of any offending identifier and the type of model involved. This will be sufficient in most cases.
2. A longer message with some hints appears with the other error messages at the end of the compilation.

The example below illustrates the general reporting format for compiler errors associated with a solve statement.

1 Variables x, y, z ;  
2 Equations eq1, eq2 ;  
3  
4 eq1.. x**2 - y =e= z ;  
5 eq2.. min(x,y) =l= 20 ;  
6  
7 Model silly / all / ;  
8 solve silly using lp maximizing z ;  
  **** $54,51,256
THE FOLLOWING LP ERRORS WERE DETECTED IN MODEL SILLY:

54 IN EQUATION EQ1 .. ENDOG OPERANDS FOR **
51 IN EQUATION EQ2 .. ENDOG ARGUMENT(S) IN FUNCTION

Error Messages

51 Endogenous function argument(s) not allowed in linear models
54 Endogenous operands for ** not allowed in linear models
256 Error(s) in analyzing solve statement. More detail appears
   Below the solve statement above

3 ERROR(S) 0 WARNING(S)
USER ERROR(S) ENCOUNTERED

4.38.8.3 Execution Errors

Execution time errors are usually caused by illegal arithmetic operations such as division by zero
or taking the log of a negative number. GAMS prints a message on the output file with the line
number of the offending statement and continues execution. A GAMS program should never abort
with an unintelligible message from the computer's operating system if an invalid operation is
attempted. GAMS has rigorously defined an extended algebra that contains all operations including illegal
ones. Note that the model [CRAZY] contains all non-standard operations and should be executed
to study for its exceptions. For advice on detecting and resolving execution errors, see the tutorial
Finding and Fixing Execution Errors and Performance Problems.

Recall that the GAMS arithmetic is defined over the closed interval [−INF, +INF] and contains the
extended range arithmetic values EPS (small but not zero), NA (not available) and UNDF (the result of
an illegal operation). The results of illegal operations are propagated through the entire system and can
be displayed with standard display statements. However, observe that, if errors have been previously
detected, a model cannot be solved and a work file cannot be saved.

4.38.8.4 Solve Errors

The execution of a solve statement can trigger additional errors called matrix errors. They report on
problems encountered during transformation of the model into a format required by the solver. Problems
are most often caused by illegal or inconsistent bounds, or by an extended range value that is used as a
matrix coefficient. The example below shows the general format of these errors:

```
1 Variable x;
2 Equation eq1;
3
4 eq1.. x =l= 10 ;
5 x.lo = 10 ;
6 x.up = 5 ;
7 Model wrong /eq1/;
8 solve wrong using lp maximizing x ;
9
**** Matrix error - lower bound > upper bound
x (.LO, .L, .UP = 10, 0, 5)
...
**** SOLVE from line 8 ABORTED, EXECERROR = 1
...
**** USER ERROR(S) ENCOUNTERED
```
Some solve statements require the evaluation of nonlinear functions and the computation of derivatives. Since these calculations are not carried out by GAMS but by other subsystems not under the direct control of GAMS, errors associated with these calculations are reported in the solution report. Note that by default the subsystems will interrupt the solution process if arithmetic exceptions are encountered. This may be changed with the option domlim. They are then reported on the listing as shown in the following example:

```
Variable x, y;
Equation one;

one.. y =e= sqrt(10/x);
x.l = 10;
x.lo = 0;

Model divide / all /;
solve divide maximizing y using nlp;
```

**** SOLVER STATUS 5 Evaluation Interrupt
**** MODEL STATUS 7 Feasible Solution
**** OBJECTIVE VALUE 3.1622776602E+0149

RESOURCE USAGE, LIMIT 0.182 1000.000
ITERATION COUNT, LIMIT 0 2000000000
EVALUATION ERRORS 2 0

EXIT - Function evaluation error limit exceeded.

**** ERRORS/WARNINGS IN EQUATION one
2 error(s): div: FUNC SINGULAR: x/y, |y| <= 1e-150 (RETURNED 1E299)

**** REPORT SUMMARY : 1 NONOPT ( NOPT)
0 INFEASIBLE
0 UNBOUNDED
1 ERRORS ( ****)

Note that the solver status returned with a value of 5, meaning that the solver has been interrupted because more than domlim evaluation errors have been encountered. The type of evaluation error and the equation causing the error are also reported.

In case the solver returns an intermediate feasible solution because of evaluation errors, the following solve will still be attempted. The only fatal GAMS error that can be caused by a solver program, is the failure to return any solution at all. If this happens all possible information is listed on the GAMS output file and any solves that follow will not be attempted.

### 4.38.9 Customizing the Output File

This section reviews the most commonly used dollar control options, options, and command line parameters to customize output in the listing file. Table 1 lists dollar control options, options, and command line parameters that are used in the input file to control the amount of detail in the output...
file produced by the GAMS compiler. Table 2 lists dollar control options and command line parameters that can change the layout and appearance of the output. The first column of the two tables shows the purpose of customizing the output that differs from the GAMS default behavior.

The output generated by display statements can also be customized. This topic is covered in section Display Controls from chapter The Display Statement. See also the complete list of dollar control options that affect the output format in section Dollar Control Options Affecting the Output Format.

**Table 1: Customization of output to be included in the listing file**

<table>
<thead>

4.39 GAMS Log

4.39.1 Introduction

The GAMS log provides the log of a GAMS run including the GAMS job description, defined command
line parameters, license information, solver log, and GAMS compilation and execution output. Looking at
the log gives a brief idea about the success of a GAMS run and is usually a useful first step in debugging
a GAMS model. The detailed output from GAMS is displayed in the output file. Log output can be
obtained in the form of a text file (typically with .log extension) that is generated with each GAMS run
based on the command line parameters logOption and logFile. The GAMS log consists of three major
sections: header, compilation log, and execution log.

4.39.2 Header

The header of the GAMS log consists of information that is independent of the content of the executed
GAMS file. It contains the job description, parameter log, and license log.

4.39.2.1 Job Description

In this line, the name of the GAMS file being run along with a timestamp, the GAMS version and
operating system information is provided.

--- Job trnsport.gms Start 08/30/21 17:29:15 36.1.0 r2c0a44a WEX-WEI x86 64bit/MS Windows

4.39.2.2 Parameter Log

The default parameters for the operating system and configuration are obtained via parameter file
(gmsprmNT.txt on Windows, gmsprmun.txt on Linux, gmsprmun.txt on MacOS) and gamsconfig.yaml
files. The parameter log explicitly lists all additional parameters in the following lines. For example, input
displays the full path of the GAMS input file. In the example log provided below, the output file option
PageSize is set to 0. ScrDir is the full path to the scratch directory; SysDir is the full path to the systems
directory, logOption is defined that controls the location of the output log.

--- Applying:
C:\GAMS\36\gmsprmNT.txt

--- GAMS Parameters defined
Input C:\test\trnsport.gms
PageSize 0
ScrDir C:\test\225a\nSysDir C:\GAMS\36\nLogOption 3
ErrMsg 1
ErrorLog 99
IDE 1
LstTitleLeftAligned 1
4.39.2.3 License Log

This section provides information about the license such as licensee, the organization, and the license number is provided on the second line. The full path to the license file that is being read is provided on the third line. The last line in the image shows the GAMS license type being used.

Licensee: John Smith
The ACME Corporation, USA
C:\Users\jsmith\Documents\GAMS\gamslice.txt
Other time limited license

4.39.2.4 Processor Information and GAMS version

This section provides information about the processor and GAMS version being used.

Processor information: 1 socket(s), 8 core(s), and 16 thread(s) available
GAMS 36.1.0 Copyright (C) 1987-2021 GAMS Development. All rights reserved

4.39.3 Compilation Log

A GAMS run consists of two phases: compilation and execution. The following lines provide details about the compilation, memory usage, the time elapsed in compilation. The number in parentheses refers to the line number in the echo print of the input file. In addition to the above-mentioned output, this part of the log also contains information about the output such as GDX files, the files included using $include, and outputs of commands such as $call as shown in the following lines.

--- Starting compilation
--- clad.gms(27) 2 Mb
--- $echo File C:\test\includefilename.gms
--- clad.gms(30) 2 Mb
--- . \includefilename.gms(1) 2 Mb
--- clad.gms(32) 2 Mb
--- call echo "hello!"
"hello!"
--- clad.gms(45) 3 Mb
--- GDIn=C:\test\claddat.gdx
--- GDX File ($gdIn) C:\test\claddat.gdx
--- clad.gms(164) 3 Mb

4.39.4 Execution Output

The beginning of the execution phase of the GAMS run is clearly indicated in the GAMS log:

--- Starting execution: elapsed 0:00:00.010

In general, the execution log output indicates the progress of the GAMS job, including line numbers, memory usage, elapsed time for the run, and time required for long-running statements. Several statements also result in specific log output.

Output of GDX files generated using execute_unload is shown in the log as follows.
--- GDX File (execute_unload) path\to\outputfile.gdx

The output for reference files generated is shown in the log as follows.

--- RefFile path\to\trnsport.ref

Similarly, the information about a file written using the Put writing facility is mentioned in the log as follows.

--- Putfile results path\to\results.txt

The output of the program flow control features such as abort is shown as follows.

*** Error at line 61: Execution halted: abort$1 'model not solved as expected'

If there are loops in the program, the log shows information about the current iteration as follows.

--- LOOPS scen = s1

Similar to the output of call command shown during compilation phase, the output for execute command is shown in the execution phase. The following line of GAMS code

```gams
eexecute "echo output of execute command";
```

will result in the following output in the log.

--- trnsport.gms(67) 4 Mb
output of execute command

For each solve statement, there will also be a solver log embedded in the execution output (see below for details regarding the solver log). After a solver log, the execution output continues. It ends with the status of the GAMS Job (here *** Status: Normal completion), a timestamp and the total run time of the GAMS job.

--- Executing after solve: elapsed 0:00:02.892
--- trnsport.gms(66) 4 Mb
*** Status: Normal completion
--- Job trnsport.gms Stop 08/30/21 17:29:18 elapsed 0:00:02.892
4.39.4.1 Solver Log

One of the most important GAMS statements is the solve statement: a solve results in a substantial amount of log output.

The first line in the execution output is about model generation. Model generation can take a long time in which case the log also shows progress and equations that take long to generate.

--- Generating LP model transport
--- transport.gms(64) 4 Mb
--- 6 rows 7 columns 19 non-zeroes

This is followed by some statistics about the range of values seen in the model:

--- Range statistics (absolute non-zero finite values)
--- RHS [min, max] : [ 2.750E+02, 6.000E+02] - Zero values observed as well
--- Bound [min, max] : [ NA, NA] - Zero values observed as well
--- Matrix [min, max] : [ 1.260E-01, 1.000E+00]

After model generation, the solver name and solveLink are displayed.

--- Executing CPLEX (Solvelink=2): elapsed 0:00:02.066

The log output following this line is specific to the solver and will usually display the objective function value.

Optimal solution found
Objective: 153.675000

4.40 The GAMS Call and Command Line Parameters

There are multiple ways to trigger the run of a GAMS model: Running a model via F9 from GAMS Studio, executing GAMSJob.Run method in the object oriented APIs or calling the gams executable from a command line. In all cases the same GAMS engine runs the user’s model. Several options are available to customize the GAMS run. Depending on the particular way GAMS is triggered these options are supplied in different ways. For example, in Studio via the parameter editor in the toolbar, in the object oriented API through the GAMSOptions class, and from the command line via command line arguments. In order to avoid confusion with the often used word option we refer to theses entities as command line parameters and demonstrate its with the gams executable from the command line. Although details will vary with the type of computer and operating system used, the general operating principles are the same on all machines.

In this chapter we will introduce how GAMS is called from the command line and how parameters may be specified on the command line or in other ways. In addition, we will discuss user-defined command line parameters, compile-time variables and compile-time constants, which are GAMS specialties, and environment variables in GAMS. Moreover, most of the chapter is dedicated to the detailed description of all GAMS options (i.e. options available via command line parameters, option statement, and model attribute.

In almost all cases such a run continues from start to end without any user interaction. A GAMS run usually consists of two phases: the compilation and execution phase.
4.40.1 The Generic GAMS Call

The simplest way to start GAMS from a command shell is to enter the following command from the system prompt:

> gams myfile

GAMS will compile and execute the GAMS statements in the file myfile. If a file with this name cannot be found, GAMS will look for a file with the extended name myfile.gms. During the run GAMS will print a log to the console and create a listing file that is written by default to the file myfile.lst. For example, the following statements retrieves and runs the model [TRNSPORT] from the GAMS model library with the responds from the GAMS system:

> gamslib trnsport
Copy ASCII : trnsport.gms
> gams trnsport
--- Job trnsport Start 06/21/17 06:23:45 24.8.4 r60966 WEX-WEI x86 64bit/MS Windows

Note
GAMS can also run source files that have been compressed with Posix utility gzip or have been encrypted with tool ENDECRYPT, for example

> gamslib trnsport
> gzip trnsport.gms
> gams trnsport.gms.gz
results in

- retrieval of the [TRNSPORT] model from the GAMS Model Library
- compression the source file transport.gms
- GAMS running the compressed file transport.gms.gz.

Observe that some GAMS options may be specified on the command line as part of the GAMS call. In addition, command line parameters may be set by specifying a secondary customization parameter file and by modifying the GAMS system parameter file. As command line parameters may be specified in several different ways, there are rules of precedence in case of conflicting instructions. We will discuss these topics in the next four subsections.

### 4.40.1.1 Specifying Options Through the Command Line

GAMS permits certain options to be passed through the command line. The syntax of the simple GAMS call is extended as follows:

\[
> \text{gams myfile key1=value1 key2=value2 ...}
\]

Here `key1` is the name of the option that is being set on the command line and `value1` is the value to which the option is set. Depending on the option, `value1` could be a character string, an integer number or a real number. Note that the options that may be set on the command line are called *GAMS command line parameters*.

For example, consider the following commands to run the transportation model [TRNSPORT]:

\[
> \text{gams transport o myrun.lst logOption 2}
> \text{gams transport -o myrun.lst -logOption 2}
> \text{gams transport /o myrun.lst /logOption 2}
> \text{gams transport o=myrun.lst logOption=2}
> \text{gams transport -o=myrun.lst -logOption=2}
> \text{gams transport /o=myrun.lst /logOption=2}
\]

All six commands above are equivalent: each directs the output listing to the file `myrun.lst`. Note that `o` is the synonym of the command line parameter `output` and it is set to the value `myrun.lst`. In addition, the parameter `LogOption` is set to 2, which has the effect that the log output is redirected to the file `transport.log`. Please also note that the option name can be specified without consideration of the casing of the option. Hence `logoption` works as well as `LogOption` or any other casing. The way options are specified can vary with each option. So a mixed alternative, e.g. `gams transport -o=myrun.lst /logoption=3` is valid too.

In addition to predefined command line parameters, GAMS also allows user-defined command line parameters which work in tandem with compile-time variables. User-defined parameters, also called *double dash parameters*, and compile-time variables are introduced in section Double Dash Parameters, Compile-Time Variables and Environment Variables below.
4.40.1.1 Option Values with Spaces  

One may want to set string valued options including double dash parameters to an empty string or a string containing spaces, even trailing or leading spaces. All this requires the use of quotes. Quotes may be handled differently, depending on the operating system. Users should be attentive when using such string values. This is also important if GAMS is called from within a GAMS program with $call [=]gams ... and execute [=]gams ... because platform independence might be violated.

A platform independent way to set a string value with spaces is to use the variant that separates the option name and option value by a space, e.g. opt "". The variant without space, e.g. opt="" might cause issues on some Unix shells. Consider the following example where spacy.gms contains only the following line to write the content of the double dash parameter dd to the log:

$log value of dd: >%dd%<

Here is a sequence of GAMS runs with a variety of string values

> gams spacy --dd normal
> gams spacy --dd "normal"
> gams spacy --dd ""
> gams spacy --dd " leading"
> gams spacy --dd "trailing "
> gams spacy --dd " leading and trailing "
> gams spacy --dd " "

that result on all platforms in the following log output (only relevant part):

value of dd: >normal<
value of dd: >normal<
value of dd: ><
value of dd: > leading<
value of dd: >trailing <
value of dd: > leading and trailing <
value of dd: > <

An even better way to pass arguments to a GAMS run without the system shell interfering with interpretation of some characters is described in the next section.

Attention

GAMS options specifying file names may also contain leading and trailing blanks. Please be aware that while leading blanks in a file name are significant on all platforms, trailing blanks are only significant on some platforms (e.g. Linux). Hence output "mymodel.lst " and output "mymodel.lst" refer to the same file on Windows and to different files on Linux.

4.40.1.2 Specifying Options Through a Secondary Parameter File

Command line parameters may also be set by specifying a secondary customization parameter file. For example, we will create a file with the following two lines, call it moreOptions.txt and save it in the current working directory.

limCol=0
limRow=0
Note that setting \texttt{limcol} and \texttt{limrow} to zero will suppress the column listing and equation listing respectively. Moreover, note that we can specify the option in different way in this secondary parameter file, even have multiple options on one line. In the next step we will use the following command to run the transportation model [\texttt{TRNSPORT}]:

\begin{verbatim}
> gams trnsport parmFile=moreOptions.txt
\end{verbatim}

Note that this call has the same effect as the following specification:

\begin{verbatim}
> gams trnsport limCol=0 limRow=0
\end{verbatim}

Observe that command line parameter include files are particularly useful if modelers wish to use the same set of command line parameters repeatedly.

If options are listed multiple times on the command line, the last specification sets the option. This is important in particular in combination with a secondary parameter file. In the following example, GAMS will operate with \texttt{limRow=0}:

\begin{verbatim}
> gams trnsport limRow=10 parmFile=moreOptions.txt
\end{verbatim}

while with the order reversed, GAMS operates with \texttt{limrow=10}:

\begin{verbatim}
> gams trnsport parmFile=moreOptions.txt limRow=10
\end{verbatim}

\subsection*{4.40.1.3 Specifying Options Through the GAMS System Parameter File}

A third way to specify command line parameters is by modifying the GAMS system parameter file, which is part of the GAMS system. It has different names depending on the operating system: \texttt{gmsprmnt.txt} for Windows and \texttt{gmsprmun.txt} for UNIX/Linux and Mac OS X. The parameter file may be modified in the following way:

\begin{verbatim}
P*******************************
* GAMS 2.50 default Unix parameter file  *
* Gams Development Corp.            *
* Date : 4 May, 1998               *
*******************************
entries required by CMEX, put in by the gams script
SYSDIR
SCRDIR
SCRIPTNEXT
INPUT
PageWidth 95
ParmFile "c:\some\central\location\moreOptions.txt"
\end{verbatim}

Note that the last two lines were added to the standard GAMS system parameter file. As a consequence, each GAMS run will have a print width of 95 columns on the pages of the listing file. In addition, the command line parameters specified in the file \texttt{moreOptions.txt} will now apply to each GAMS run.
4.40.1.4 The GAMS Configuration in YAML Format

The GAMS configuration file `gamsconfig.yaml` written in the YAML format is easy to process by humans and computers. The GAMS Configuration Editor can be used to view and edit the GAMS configuration file but any other text editor can be used as well. This file has three configuration sections: command line parameters (`commandLineParameters`), operating system environment variables (`environmentVariables`), and external solver configuration (`solverConfig`). The latter is only relevant if you need to make a solver available to GAMS that is not shipped with the GAMS distribution. The COIN-OR GAMSlinks project has solver (links), e.g. Couenne, that could be added this way.

The first two sections are most easily described by an example:

```
commandLineParameters:
  - intVarUp:
    value: 1
  - eolCom:
    value: '//'
    maxVersion: 31
  - eolCom:
    value: '#'
    minVersion: 32
environmentVariables:
  - GDXCOMPRESS:
    value: 1
    maxVersion: 31
  - GDXCOMPRESS:
    value: 0
    minVersion: 31.1.0
    maxVersion: 31.1.0
    pathVariable: True
  - PATH:
    value: /my/path/to/R/bin:/my/path/to/R/site-bin
    minVersion: 31.1.0
    maxVersion: 31.1.0
```

In this example, the `gamsconfig.yaml` initializes some command line parameters and some environment variables. It initializes `intVarUp` unconditionally to 1. It also sets `eolCom` to the character sequence `//` for GAMS version 31 and earlier, while it uses the character `#` for GAMS version 32 and later. The keywords `minVersion` and `maxVersion` allow to have different entries for the same command line parameter for different versions. Also the file `gamsconfig.yaml` allows the repetition of entries. Hence, when GAMS runs it will filter all entries with appropriate `minVersion` and `maxVersion` and applies the setting of entries in sequence, so the last entry wins. Similarly, GAMS sets the environment variables `GDXCOMPRESS` to 0 or 1 depending on the actual version of GAMS. The last entry to set the `PATH` environment variable will be only applied for the GAMS version 31.1.0. Moreover, the indicator `pathVariable` set to `True` will result in prefixing the environment variable `PATH` with `/my/path/to/R/bin:/my/path/to/R/site-bin`.

The YAML syntax for the `gamsconfig.yaml` file is straightforward. Each section starts with a fixed name (`commandLineParameters` or `environmentVariables`) and is followed by a list of entries. Each entry starts with `-` and the name of the command line parameter or the name of the environment variable followed by a colon `:`. The next lines start with a keyword (`value`, `minVersion`, `maxVersion` and for environment variables also `pathVariable`) followed by a colon `:` and a value. The syntax of YAML files is very simple but it is crucial to use a consistent alignment. So all entries of a section must be perfectly aligned. Please be careful when mixing spaces and the tab character. If GAMS complains during the processing of a `gamsconfig.yaml` file with e.g. `System problems in yaml_parser_parse: mapping values are not allowed in this context` most likely your alignment is off as in the following erroneous example:
commandLineParameters:
  - eolCom:
    value: '//'
    maxVersion: 31

The lines with `value` and `maxVersion` need to start in the same column. There are plenty of online syntax checkers for YAML files. Use your favorite search engine and search for `yaml validator` (check the popular YAML validator) and copy and paste your problematic `gamsconfig.yaml` to get more insight into the YAML syntax problem. Moreover, the `gamsconfig.yaml` file has some required fields and some requirements for the value of some keys. In fact there is a schema file that validates that a syntactically correct `gamsconfig.yaml` fulfills the GAMS schema for configuration files. The schema file is part of the distribution and can be found in the system directory (`gamsconfig_schema.json`). One can validate a `gamsconfig.yaml` against this schema via a Python program (you might need to install additional Python packages `jsonschema` and `ruamel.yaml`):

```python
import jsonschema
from ruamel.yaml import YAML
import json

with open('gamsconfig_schema.json') as f:
    schema = json.load(f)

yaml = YAML(typ="safe")
with open('gamsconfig.yaml') as f:
    config = yaml.load(f)

print(jsonschema.validate(instance=config, schema=schema))
```

Besides the required fields like `value` the schema also imposes restrictions on some value types (e.g. `True` and `False` for `pathVariable` and a proper release number for `minVersion` and `maxVersion`). The form of the release number can be just the major release (e.g. 31), the major and minor release number (e.g. 31.1) or the full detailed release number, e.g. 31.1.0. So if `maxVersion` is set to e.g. 31 then all releases of 31 fulfill this version requirement.

Some parts of the GAMS system react on environment variables, e.g. the environment variable `GMSPYTHONLIB` decides about the Python library and installation used for embedded Python code. At the start of a GAMS run environment variables are set to the values given in the `gamsconfig.yaml` file. This is a convenient way to manage GAMS-related environment variables without utilizing OS-specific ways to set environment variables.

GAMS will process a sequence of `gamsconfig.yaml` files. It starts with the file in the GAMS system directory and then searches through some system-wide and user-specific standard locations.

Note

With GAMS 32 new defaults for several options were introduced. We have collected these options and their old or legacy default values in the file `gamsLegacyConfig.yaml` located in the GAMS system directory. Copy this file as `gamsconfig.yaml` to a location searched by GAMS to continue to work with the legacy defaults. The `minVersion` keyword in this file indicates when the new default became active.
4.40.1.4.1 Adding Solvers via gamsconfig.yaml

The third section in the GAMS configuration file gamsconfig.yaml allows to make a solver not shipped with GAMS available to the GAMS system. For that, an interface between an instantiation of a GAMS model and a solver needs to be implemented by use of libraries GMO and GEV. The COIN-OR GAMSlinks project provides examples of such solver interfaces. For the remainder of this section assume that we want to introduce a new version of the MINLP/MIQCP solver SHOT. GAMS knows about available solvers from the sub-system configuration file gmscmpNT.txt (gmscmpun.txt for non-Windows platforms). Here is a section from this file for the MINLP/MIQCP solver SHOT on Windows:

```
SHOT 1001 5 000102030405 1 0 2 MINLP MIQCP

```

The gamsconfig.yaml file provides the same information in a more descriptive way:

```
solverConfig:
  - SHOT2:
      minVersion: 33
      fileType: 1001
      dictType: 5
      licCodes: 000102030405
      defName: optshot.def
      scriptName: gmsgennt.cmd
      executableName: gmsgennx.exe
      library:
        libName: D:\Users\janeDoe\Downloads\gamslink\GamsShot-20.dll
        auditCode: sht
        solverInterfaceType: 1
        threadSafeIndic: True
      modelTypes:
        - MINLP
        - MIQCP

```

The new solver will be called SHOT2 and has almost the identical information as the solver SHOT that comes with GAMS. We could also use the name SHOT again. This would hide the original solver SHOT and use the one described by gamsconfig.yaml. In addition to the solver information, this section allows the keywords min/maxVersion that instructs whether to include the solver depending on the GAMS version.

The `fileType` (line 1 second item in the section of gmscmpNT.txt) determines the type of the scratch files that contain the model instance. The one-digit determines binary (1) or text (0) format of the scratch files. The ten-digit determines whether GAMS puts the initial marginal information into the scratch files (1 for writing, 0 for not writing). The scratch file with the constraint matrix is stored column wise, the hundred-digit instructs GAMS to write (if at 1) the row count per column, so the solver can layout memory in advance for storing the constraint matrix. With GAMS’ current libraries gmo and gev this information is not used and hence the hundred-digit should be at 0. The thousand-digit is about scaling. A non-zero value instructs GAMS to write the information stored in the .scale/.prior/.stage variable and equation attributes into the scratch files. With a value of 1 this is only done if scaleOpt/priorOpt are on. With a value of 2 this information is written independently of scaleOpt/priorOpt. With a value of 3 for models with variable and matching information (e.g. MCP) the reported marginals will be scaled by GAMS. The ten thousand-digit is always 0 and the hundred thousand-digit (if set to 1) instructs GAMS to write the variable/equation matching information to the scratch files for models that need this information (e.g. MCP). The leading zeros of the value for key `fileType` should be omitted.

The `dictType` (line 1 third item in the section of gmscmpNT.txt) decides about the type of the dictionary scratch file that contains the mapping information between the GAMS names and the variable and equation indexes seen by the solver. For example, this helps the solver to form good variable and equation names for error messages. Four values are allowed:
4.40 The GAMS Call and Command Line Parameters

- 0: no dictionary information
- 5: dictionary with all labels that are used in the model instance
- 15: dictionary with all labels that are used in GAMS program
- 25: dictionary with all labels that are used in GAMS model plus an extra GDX file with the entire GAMS database (similar to `execute unload "everything";` prior to the solve statement)

The **licCode** (line 1 fourth item in the section of `gmscmpNT.txt`) gives a guess about what license codes are required to run the solver. This is not the actual license information but allows other programs like e.g. "GAMS Studio" to list the solvers available with a particular license. In most cases solvers that are added this way should list the GAMS BASE license codes "000102030405".

The **defName** (line 2 second item in the section of `gmscmpNT.txt`) points to a file that contains all the solver options for the solver. This key does not need to be provided (same in `gmscmpNT.txt`) if the **defName** is `opt + solvername + .def` and the file resides in the GAMS system directory. Since we use the name SHOT2 GAMS would expect the solver options to be in `optshot2.def`. If there were an `optshot.def` in the GAMS system directory for the original SHOT, we could reuse that file and list `optshot.def` for the **defName** key. The **defName** provided here is used by other programs like "GAMS Studio" that can assist with building solver options files.

The next three items on line 1 in the section of `gmscmpNT.txt` are for internal purposes and not discussed here in detail. They can be set via `gamsconfig.yaml` via the keys `defaultOkFlag` and `hiddenFlag` with values True or False.

GAMS has different ways of calling a solver controlled by the **solveLink** option. The **scriptName** (line 2 in the section of `gmscmpNT.txt`) contains the name of the script that calls the solver (in case of `solveLink=0` (chainScript) or 1 (callScript)). For solvers that are capable of `solveLink=5` (loadLibrary) a generic script `gmsgennt.cmd` (or `gmsgenus.run`) can be used. The **executableName** (line 3 in the section of `gmscmpNT.txt`) provides the name of the solver executable. Again for solvers capable of `solveLink=5` (loadLibrary) a generic executable `gmsgennx.exe` (or `gmsgenux.out`) can be used.

The section library is necessary only for solvers capable of `solveLink=5` (loadLibrary). The **libName** (line 3 first item in the section of `gmscmpNT.txt`) contains the name of the solver library file (line 3 first item in the section of `gmscmpNT.txt`). The **auditCode** (line 3 second item in the section of `gmscmpNT.txt`) is the prefix of the functions in the solver library (e.g. `shtCallSolver`). The **solverInterfaceType** (line 3 third item in the section of `gmscmpNT.txt`) defines the API implemented by the solver library and loaded by GAMS. Currently, there are only two types: 1 (xyzReadyApi and xyzCallSolver) and 2 (xyzCallSolver only). The **threadSafeIndic** (line 3 third item in the section of `gmscmpNT.txt`) indicates whether the solver library is thread-safe and can be used in combination with `solveLink=6` (aSyncThreads).

The final section **modelTypes** is about the model types the solver can handle. This information can be found in line 1 after item 7 in `gmscmpNT.txt`.

### 4.40.1.5 Order of Precedence for Options

The order of precedence for command line parameters including customization specifications in the GAMS IDE is as follows:

1. Command line parameters that are specified on the command line or in the Studio/IDE command line field.
2. Command line specifications in the IDE options window **Execute** (this is reached through File|Options|Execute).
3. Command line specifications in the specific IDE dialogs, e.g. Output (this is reached through File|Options|...).

4. Entries in the GAMS configuration files gamsconfig.yaml.

5. Entries in the GAMS system parameter file.

Many command line parameters initialize the default for a GAMS Option also accessible inside the GAMS program. For example, the system default for option MIQCP is SBB. If the command line parameter MIQCP has been set, e.g. to DICOPT, DICOPT will be new default MIQCP solver. Inside the GAMS program, one can reset the MIQCP via option MIQCP=SHOT; but setting it back to the default will result in DICOPT (not SBB) being the default solver: option MIQCP=default;.

### 4.40.2 Double Dash Parameters, Compile-Time Variables and Environment Variables

In this section we will cover double-dash parameters that enable users to set values for specific variables on the command line. These variables are substituted with their respective specified values at compile time. We will also discuss how operating system specific environment variables may be accessed and modified from a GAMS program.

#### 4.40.2.1 Double Dash Parameters and Compile-Time Variables: A Simple Example

We will introduce double dash parameters and compile-time variables using as an example the well-known transportation model [TRNSPORT]. Assume we wish to explore how the solution changes if the demand assumes various values. To model this, we will introduce the compile-time variable DMULT, a multiplier for the demand b:

```gams
$set DMULT 1
...
demand(j) .. sum(i, x(i,j)) =g= %DMULT% * b(j) ;
```

Note that DMULT is defined with the dollar control option $set and its value is set to 1, which corresponds to the base line. Observe that the compile-time variable is referenced in the equation with the %...% notation. %DMULT% will be replaced at compile time by its value, in this case 1. We are now in the position to run the program multiple times by just changing the value of DMULT in the first line, which will automatically change the multiplier in the equation to the respective value.

GAMS offers a more convenient way for setting a compile-time variable like DMULT to a variety of values:

```gams
$if not set DMULT $set DMULT 1
...
demand(j) .. sum(i, x(i,j)) =g= %DMULT% * b(j) ;
```

Note that we set a default value for DMULT using conditional compilation. We may change this default on the command line when calling GAMS by specifying DMULT as a double dash parameter as follows:

```bash
> gams trnsport.gms --DMULT=0.9
```

Observe that with the specification --DMULT=0.9 the compile-time variable DMULT is set and therefore the default does not apply. Thus the double dash parameter facilitates changing the value of a compile-time variable directly on the command line as part of the GAMS call while the respective GAMS file remains unchanged.

Assume that the model contains a second compile-time variable called METHOD that acts as a switch for various methods of solving the model and it may take the values 1, 2 and 3. In this case both compile-time variables may be set on the command line as follows:

```bash
> gams trnsport.gms --DMULT=1.12 --METHOD=3
```

In the next two subsections we will discuss double dash parameters and compile-time variables in more detail.
Double dash parameters are user-defined command line parameters that are used to define scoped compile-time variables or to assign values to scoped compile-time variables. The general syntax is:

> gams myfile --NAME=value

Here \textit{NAME} is the name of the double dash parameter and \textit{value} is its assigned value that may be any string. If the string contains spaces or other token terminating characters, the string value should be quoted. Consider the following simple example:

> gams myfile --keycity=Boston --myvalue=7.6 --dothis="display x;"

Suppose that \textit{myfile.gms} contains the following lines with the scoped compile-time variables \textit{keycity}, \textit{myvalue} and \textit{dothis}:

\begin{verbatim}
x("%keycity%")=%myvalue%;
%dothis%
\end{verbatim}

Note that the compile-time variables are referenced using the notation \%...\%. The GAMS call above has the effect that at compile time the compile-time variables are substituted with the values specified through the double dash parameters resulting in the following:

\begin{verbatim}
x("Boston")=7.6;
display x;
\end{verbatim}

GAMS offers three alternative syntax variants for defining double dash parameters:

> gams myfile //NAME=value
> gams myfile /-NAME=value
> gams myfile -/NAME=value

Note that the four syntax variants may be used interchangeably and have the same effect.

Double dash parameters are particularly useful for specifying granularity when modeling a discretization of time and or space. For example, in the model \textit{[CHAIN]} the problem is to find the chain with minimal potential energy, assuming the chain has uniform density, is suspended between two points and has a given length \(L\). Consider the following code snippet:

\begin{verbatim}
$if not set nh $set nh 50
Set nh / i0*i%nh% /;
\end{verbatim}

The first two lines use \textit{conditional compilation} to set a default value for the compile-time variable \textit{nh}. Note that the value of \textit{nh} determines the cardinality of the set \textit{nh}, which is used for the discretization. The value of \textit{nh} may be easily set on the command line to any desired value using \textit{nh} as a double dash parameter:

> gams chain --nh=100
Note that the double dash functionality supersedes the command line parameters user1, ..., user5 which are accessible in the source file via %gams.user1%, ..., %gams.user5%. The example above would work with user1 in the following way:

\[
\begin{align*}
\$set\ nh\ 50 \\
\$if\ not\ "%gams.user1"==""\$set\ nh\ %gams.user1\% \\
Set\ nh\ /\ i0*i%nh%/ ;
\end{align*}
\]

The modified code could be called with:

> gams chain user1=100

Note that the double dash parameters facilitate using meaningful names instead of the generic names user1, ..., user5. This is especially useful if there are multiple parameters to pass on to the GAMS program.

Observe that the dollar control option $setDDList may be used to ensure that a model can only be run with the listed double dash parameters:

\[
\begin{align*}
\$setDDList\ nh \\
\$if\ not\ errorFree\$log ***\ Only\ allowed\ double\ dash\ options\ is:\ --nh=value
\end{align*}
\]

### 4.40.2.3 Compile-Time Variables

Compile-time variables are special variables that are substituted with their values at compile-time. They are not declared and defined with regular declaration statements like standard symbols (sets, parameters, ...), but they are defined with the dollar control option $set and its variants. There are three kinds of compile-time variables that differ in their scope level: local, scoped and global. An overview is given in Table 1.

<table>
<thead>
<tr>
<th>Scope</th>
<th>Availability</th>
<th>Defined with</th>
<th>Removed from the system with</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local</td>
<td>Available only in the input file where they are defined</td>
<td>$setLocal.</td>
<td>$dropLocal</td>
</tr>
<tr>
<td>Scoped</td>
<td>Available in the input file where they are defined and in all include files of the input file.</td>
<td>$set</td>
<td>$drop</td>
</tr>
<tr>
<td>Global</td>
<td>Available in the input file where they are defined, in all parent files and in all include files.</td>
<td>$setGlobal</td>
<td>$dropGlobal</td>
</tr>
</tbody>
</table>

**Table 1**: Scope Levels for Compile-Time Variables in GAMS

Note that scoped compile-time variables may also be defined on the command line with double dash parameters. For example, in the example above the compile-time variable DMULT may be referenced in the equation demand without being defined with the dollar control option $set as long as it is defined and set on the command line. Note further, that global compile-time variables are saved in work files.

While the scope of a compile-time variable cannot be directly changed, but dropping and adding variables in different scopes accomplishes the same. Consider the following example:
Note that the compile-time variable MYVAR is first defined as a scoped variable with the value xxx. The dollar control option ifThen tests whether MYVAR was defined with $set and since this is TRUE the next four dollar control statements are processed: a new global compile-time variable called MYVAR is defined and is set to the value of the scoped compile-time variable MYVAR, the resulting compile-time variables are shown, the scoped compile-time variable is removed from the system with the option $drop and the resulting compile-time variables are shown again. A similar procedure is followed to change the global compile-time variable MYVAR to a local compile-time variable with the same name and value.

The output generated by the four dollar control options $show follows:

<table>
<thead>
<tr>
<th>Level</th>
<th>SetVal</th>
<th>Type</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>MYVAR</td>
<td>SCOPED</td>
<td>xxx</td>
</tr>
<tr>
<td>0</td>
<td>MYVAR</td>
<td>GLOBAL</td>
<td>xxx</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Level</th>
<th>SetVal</th>
<th>Type</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>MYVAR</td>
<td>GLOBAL</td>
<td>xxx</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Level</th>
<th>SetVal</th>
<th>Type</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>MYVAR</td>
<td>LOCAL</td>
<td>xxx</td>
</tr>
<tr>
<td>0</td>
<td>MYVAR</td>
<td>GLOBAL</td>
<td>xxx</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Level</th>
<th>SetVal</th>
<th>Type</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>MYVAR</td>
<td>LOCAL</td>
<td>xxx</td>
</tr>
</tbody>
</table>

Observe that this report is called Environment Report. This name is unfortunate, since the variables reported are in fact compile-time variables. Environment variables in GAMS are discussed in section Environment Variables in GAMS below.

Note that if a compile-time variable is referenced with %MYVAR%, it could reference a global, scoped or local compile-time variable called MYVAR. GAMS will always access the compile-time variable MYVAR with the most local scope. Thus if all three scopes are defined, the local compile-time variable is accessed first, then the scoped and then the global, as demonstrated in the following example:
The resulting log output will be:

```
local
scoped
global
%XXX%
```

Note that how `%XXX%` will be handled if no compile-time variable `XXX` is defined, is determined by the command line parameter `stringChk`.

For a full list of dollar control options that affect compile-time variables, see section Dollar Control Options for Compile-Time Variables and Environment Variables.

### 4.40.2.4 Environment Variables in GAMS

GAMS programs have access to operating systems via `%sysEnv.NAME%`. Operating system environment variables may be modified or new environment variables may be defined with the dollar control option `$setEnv`. Consider the following artificial example:

```
$log %sysEnv.GEORGE%
$setEnv GEORGE Dantzig
$log %sysEnv.GEORGE%
$dropEnv GEORGE
$log %sysEnv.GEORGE%
```

Note that the dollar control option `$dropEnv` removes an environment variable. The log output follows:

```
%sysEnv.GEORGE%
Dantzig
%sysEnv.GEORGE%
```

There are two environment variables in GAMS that are specific to the GDX facility: `GDXCONVERT` and `GDXCOMPRESS`. Since GDX is used by utilities and other programs some general customization can be achieved via these environment variables. Their values determine the type of GDX files that are written. These environment variables may be overwritten through the command line parameters `gdxConvert` and `gdxCompress` or inside the GAMS file with the dollar control option `$setEnv`. Consider the following example that uses the latter functionality:
Scalar x /1/;
$log %sysEnv.GDXCONVERT%
$log %sysEnv.GDXCOMPRESS%
$gdxOut x.gdx
$unLoad x
$gdxOut
$call gdxdump x.gdx -v | grep "File format\|Compression"

$setEnv GDXCONVERT v6
$setEnv GDXCOMPRESS 1
$gdxOut x.gdx
$unLoad x
$gdxOut
$call gdxdump x.gdx -v | grep "File format\|Compression"

$setEnv GDXCONVERT v7
$setEnv GDXCOMPRESS 0
$gdxOut x.gdx
$unLoad x
$gdxOut
$call gdxdump x.gdx -v | grep "File format\|Compression"

Note that gdxdump is a **GDX utility** that writes the contents of a GDX file as a GAMS formatted text file. The switch -v lets gdxdump print the file version information. With the grep utility we filter the lines that contain either File format or Compression. This code is run with the following call that initializes GDXCOMPRESS and GDXCONVERT:

> gams gdxenv.gms gdxCompress=0 gdxConvert=v6 lo=3

The output follows:

--- Starting compilation
v6
0
--- gdxenv.gms(7) 2 Mb
--- call gdxdump x.gdx -v | grep "File format\|Compression"
* File format : 6
* Compression : 0
--- gdxenv.gms(14) 2 Mb
--- call gdxdump x.gdx -v | grep "File format\|Compression"
* File format : 6
* Compression : 1
--- gdxenv.gms(21) 2 Mb
--- call gdxdump x.gdx -v | grep "File format\|Compression"
* File format : 7
* Compression : 0
--- gdxenv.gms(22) 2 Mb
--- Starting execution - empty program

### 4.40.3 Compile-Time Constants

Compile-time constants are constants that are related to some **functions, model attributes or options**. They have a fixed value and are referenced as %prefix.constant%. Here prefix is the name of the respective function, model attribute or option and constant is the name of the constant.

For example, the function handleStatus is used in the context of grid computing. Typically, a **collection loop** may take the following form:
loop(pp$(handleStatus(h(pp)) = 2), ... );

Alternatively, the following formulation may be used:

\[
\text{loop}(pp$(\text{handleStatus}(h(pp)=%\text{handleStatus.ready}%), ... );
\]

Observe that the compile-time constant \%\text{handleStatus.ready}\% equals the value of 2. See the table below for other compile-time constants that are related to the function \text{handleStatus}.

Note

Compile-time constants are replaced at compile time and cannot be manipulated or reassigned.

Though compile-time constants are most often used in the context of the function, model attribute or option indicated with the prefix, they are in fact context free and may be used anywhere where an integer is expected. Consider the following example:

Scalar \( x / %\text{solPrint.on}% /; \) display \( x; \)

A complete list of the compile-time constants is given in Table 2.

\textit{Table 2: Compile-Time Constants}

### 4.40.4 GAMS Compile Time and Execution Time Phase

The GAMS log indicates different phases of a job run in the log file:

```plaintext
...  
--- Starting compilation  
...  
--- Starting execution: elapsed 0:00:00.056  
...  
```

During compilation GAMS converts the GAMS user program into lower-level instructions that are executed during execution time. Before the user program is converted into lower-level instructions the compiler
processes the input: the compile time variables and macros are substituted and comments are removed. Moreover, during compilation any dollar control option present in the user code is executed. Many of these dollar control options impact the behavior of the compilation phase (e.g. $include instructs the compiler to process a file before continuing processing the remaining part of the current file). The code the compiler actually converts into lower-level instructions is echoed (by default) to the listing file. The compiler also assembles the list of user symbols (sets, parameters, variables, ...) and the list of labels. These lists become immutable after the compiler finishes. So during execution time, for example, no new labels can be added. The only exception from this is during a continued compilation/execution using the save and restart facility. The separation between compile time and execution time is confusing especially for novice users and mistakes as the following are frequent:

```gams
file fInput / data.txt /;
scalar iCnt; for (iCnt=1 to 100, put fInput iCnt:0:0 /); putClose fInput;
set i /
$include data.txt
/;
```

The intention of the code, that does not work, is clear: The put facility is used to create the input file data.txt that is included via the $include instruction. The problem with this code is that the $include instruction is executed at compile time while the code using the put statement is executed at execution time, i.e. after the compilation phase is over. Hence, the compiler tries to include this file before the put instructions are executed. If the file data.txt is not present, the compiler will terminate with a compilation error, but if a file with name data.txt is present this one will be processed by the $include and a mistake like this might remain undiscovered for a long time.

Most of the time GAMS performs compilation and execution in one GAMS job which makes it even harder to grasp the concept of compile and execution time. The command line parameter action can be used to separate the compilation and execution phase into multiple jobs.

### 4.40.5 List of Command Line Parameters

In the following two subsections we will present an overview of the command line parameters with brief descriptions. Detailed descriptions of all command line parameters follow in section Detailed Descriptions of All Options below.

#### 4.40.5.1 General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>GAMS processing request</td>
</tr>
<tr>
<td>appendExpand</td>
<td>Expand file append option</td>
</tr>
<tr>
<td>appendLog</td>
<td>Log file append option</td>
</tr>
<tr>
<td>appendOut</td>
<td>Output file append option</td>
</tr>
<tr>
<td>asyncSolLst</td>
<td>Print solution listing when asynchronous solve (Grid or Threads) is used</td>
</tr>
<tr>
<td>captureModelInstance</td>
<td>Switch to capture all model instances within a run</td>
</tr>
<tr>
<td>case</td>
<td>Output case option for LST file</td>
</tr>
<tr>
<td>cErr</td>
<td>Compile time error limit</td>
</tr>
<tr>
<td>charSet</td>
<td>Character set flag</td>
</tr>
<tr>
<td>checkErrorLevel</td>
<td>Check errorLevel automatically after executing external program</td>
</tr>
<tr>
<td>connectIn</td>
<td>Specify YAML Connect script file processed at start of GAMS</td>
</tr>
<tr>
<td>connectOut</td>
<td>Specify YAML Connect script file processed at end of GAMS</td>
</tr>
<tr>
<td>curDir</td>
<td>Current directory</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>decryptKey</td>
<td>Key to decrypt a text file that was encrypted via <code>$encrypt</code></td>
</tr>
<tr>
<td>dFormat</td>
<td>Date format</td>
</tr>
<tr>
<td>digit</td>
<td>Switch default for &quot;$on/offDigit&quot;</td>
</tr>
<tr>
<td>docFile</td>
<td>Filename stem for documentation files</td>
</tr>
<tr>
<td>dumpOpt</td>
<td>Writes preprocessed input to the file input.dmp</td>
</tr>
<tr>
<td>dumpOptGDX</td>
<td>Defines a GDX file name stem created when using DumpOpt</td>
</tr>
<tr>
<td>dumpParms</td>
<td>GAMS parameter logging</td>
</tr>
<tr>
<td>dumpParmsLogPrefix</td>
<td>Prefix of lines triggered by DumpParms&gt;1</td>
</tr>
<tr>
<td>ECImplicitLoad</td>
<td>Allow implicit loading of symbols from embedded code or not</td>
</tr>
<tr>
<td>empty</td>
<td>Switch default for &quot;$on/offEmpty&quot;</td>
</tr>
<tr>
<td>encryptKey</td>
<td>Key to encrypt a text file using <code>$encrypt</code></td>
</tr>
<tr>
<td>eolCom</td>
<td>Switch default for &quot;$on/offEolCom&quot; and &quot;$eolCom&quot;</td>
</tr>
<tr>
<td>eolOnly</td>
<td>Single key-value pairs (immediate switch)</td>
</tr>
<tr>
<td>epsToZero</td>
<td>Treat eps as zero when unloading to GDX</td>
</tr>
<tr>
<td>errMsg</td>
<td>Placing of compilation error messages</td>
</tr>
<tr>
<td>errNam</td>
<td>Name of error message file</td>
</tr>
<tr>
<td>error</td>
<td>Force a compilation error with message</td>
</tr>
<tr>
<td>errorLog</td>
<td>Max error message lines written to the log for each error</td>
</tr>
<tr>
<td>ctLim</td>
<td>Elapsed time limit in seconds</td>
</tr>
<tr>
<td>execMode</td>
<td>Limits on external programs that are allowed to be executed</td>
</tr>
<tr>
<td>expand</td>
<td>Expanded (include) input file name</td>
</tr>
<tr>
<td>fdDelta</td>
<td>Step size for finite differences</td>
</tr>
<tr>
<td>fdOpt</td>
<td>Options for finite differences</td>
</tr>
<tr>
<td>fErr</td>
<td>Alternative error message file</td>
</tr>
<tr>
<td>fileCase</td>
<td>Casing of file names and paths (put, gdx, ref, $include, etc.)</td>
</tr>
<tr>
<td>fileStem</td>
<td>Sets the file stem for output files which use the input file name as stem by default</td>
</tr>
<tr>
<td>fileStemApFromEnv</td>
<td>Append a string read from an environment variable to the &quot;FileStem&quot;</td>
</tr>
<tr>
<td>filtered</td>
<td>Switch default for &quot;$on/offFiltered&quot;</td>
</tr>
<tr>
<td>forceWork</td>
<td>Force GAMS to process a save file created with a newer GAMS version or with execution errors</td>
</tr>
<tr>
<td>forLim</td>
<td>GAMS looping limit</td>
</tr>
<tr>
<td>G205</td>
<td>Use GAMS version 2.05 syntax</td>
</tr>
<tr>
<td>GDX</td>
<td>GAMS data exchange file name</td>
</tr>
<tr>
<td>gdxCompress</td>
<td>Compression of generated GDX file</td>
</tr>
<tr>
<td>gdxConvert</td>
<td>Version of GDX files generated (for backward compatibility)</td>
</tr>
<tr>
<td>gdxUels</td>
<td>Unload labels or UELs to GDX either squeezed or full</td>
</tr>
<tr>
<td>gridDir</td>
<td>Grid file directory</td>
</tr>
<tr>
<td>gridScript</td>
<td>Grid submission script</td>
</tr>
<tr>
<td>heapLimit</td>
<td>Maximum Heap size allowed in MB</td>
</tr>
<tr>
<td>IDCGenerateGDXInput</td>
<td>GDX file name with data for implicit input</td>
</tr>
<tr>
<td>IDCGenerateGDXOutput</td>
<td>GDX file name for data for implicit output</td>
</tr>
<tr>
<td>IDCGenerateGDX</td>
<td>Specify GDX file name of input and output side of data contract</td>
</tr>
<tr>
<td>IDCGenerateGDXInput</td>
<td>Specify GDX file name of input side of data contract</td>
</tr>
<tr>
<td>IDCGenerateGDXOutput</td>
<td>Specify GDX file name of output side of data contract</td>
</tr>
<tr>
<td>IDCGenerateJSON</td>
<td>Specify JSON file name of data contract</td>
</tr>
<tr>
<td>IDCJSON</td>
<td>Specify JSON file name to verify data contract</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IDCProtect</td>
<td>Flag to control assignment protection of external input symbols</td>
</tr>
<tr>
<td>IDE</td>
<td>Integrated Development Environment flag</td>
</tr>
<tr>
<td>inlineCom</td>
<td>Switch default for &quot;$on/offInline&quot; and &quot;$inlineCom&quot;</td>
</tr>
<tr>
<td>input</td>
<td>Input file</td>
</tr>
<tr>
<td>inputDir, inputDir1..40</td>
<td>Input file directories</td>
</tr>
<tr>
<td>interactiveSolver</td>
<td>Allow solver to interact via command line input</td>
</tr>
<tr>
<td>jobTrace</td>
<td>Job trace string to be written to the trace file at the end of a GAMS job</td>
</tr>
<tr>
<td>keep</td>
<td>Controls keeping or deletion of process directory and scratch files</td>
</tr>
<tr>
<td>libIncDir</td>
<td>LibInclude directory</td>
</tr>
<tr>
<td>license</td>
<td>Use alternative license file</td>
</tr>
<tr>
<td>listing</td>
<td>Switch default for &quot;$on/offListing&quot;</td>
</tr>
<tr>
<td>logFile</td>
<td>Log file name</td>
</tr>
<tr>
<td>logLine</td>
<td>Amount of line tracing to the log file</td>
</tr>
<tr>
<td>logOption</td>
<td>Log option</td>
</tr>
<tr>
<td>lstTitleLeftAligned</td>
<td>Write title of LST file all left aligned</td>
</tr>
<tr>
<td>maxExecError</td>
<td>Execution time error limit</td>
</tr>
<tr>
<td>maxGenericFiles</td>
<td>Maximum number of generic file names tried at execution time file creation</td>
</tr>
<tr>
<td>maxProcDir</td>
<td>Maximum number of 225+ process directories</td>
</tr>
<tr>
<td>MCPRHoldFx</td>
<td>Print list of rows that are perpendicular to variables removed due to the holdfixed setting</td>
</tr>
<tr>
<td>multi</td>
<td>Switch default for &quot;$on/offMulti[R]&quot;</td>
</tr>
<tr>
<td>multiPass</td>
<td>Multipass facility</td>
</tr>
<tr>
<td>noNewVarEqu</td>
<td>Triggers a compilation error when new equations or variable symbols are introduced</td>
</tr>
<tr>
<td>on115</td>
<td>Generate errors for unknown unique element in an equation</td>
</tr>
<tr>
<td>output</td>
<td>Listing file name</td>
</tr>
<tr>
<td>pageContr</td>
<td>Output file page control option</td>
</tr>
<tr>
<td>pageSize</td>
<td>Output file page size (=0 no paging)</td>
</tr>
<tr>
<td>pageWidth</td>
<td>Output file page width</td>
</tr>
<tr>
<td>parmFile</td>
<td>Command Line Parameter include file</td>
</tr>
<tr>
<td>pLicense</td>
<td>Privacy license file name</td>
</tr>
<tr>
<td>prefixLoadPath</td>
<td>Prepend GAMS system directory to library load path</td>
</tr>
<tr>
<td>previousWork</td>
<td>Indicator for writing workfile with previous workfile version</td>
</tr>
<tr>
<td>procDir</td>
<td>Process Directory</td>
</tr>
<tr>
<td>procDirPath</td>
<td>Directory to create process directory in</td>
</tr>
<tr>
<td>procTreeMemMonitor</td>
<td>Monitor the memory used by the GAMS process tree</td>
</tr>
<tr>
<td>procTreeMemTicks</td>
<td>Set wait interval between memory monitor checks: ticks = milliseconds</td>
</tr>
<tr>
<td>profile</td>
<td>Execution profiling</td>
</tr>
<tr>
<td>profileFile</td>
<td>Write profile information to this file</td>
</tr>
<tr>
<td>profileTol</td>
<td>Minimum time a statement must use to appear in profile generated output</td>
</tr>
<tr>
<td>putDir</td>
<td>Put file directory</td>
</tr>
<tr>
<td>putND</td>
<td>Number of decimals for put files</td>
</tr>
<tr>
<td>putNR</td>
<td>Numeric round format for put files</td>
</tr>
<tr>
<td>putPS</td>
<td>Page size for put files</td>
</tr>
<tr>
<td>putPW</td>
<td>Page width for put files</td>
</tr>
<tr>
<td>pyMultInst</td>
<td>GAMS/Python Multiple Instance Interpreter</td>
</tr>
<tr>
<td>reference</td>
<td>Symbol reference file</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>referenceLineNo</td>
<td>Controls the line numbers written to a reference file</td>
</tr>
<tr>
<td>scrDir</td>
<td>Scratch directory</td>
</tr>
<tr>
<td>scrExt</td>
<td>Scratch file extension to be used with temporary files</td>
</tr>
<tr>
<td>scrNam</td>
<td>Work file names stem</td>
</tr>
<tr>
<td>seed</td>
<td>Random number seed</td>
</tr>
<tr>
<td>showOSMemory</td>
<td>Show the memory usage reported by the Operating System instead of the</td>
</tr>
<tr>
<td></td>
<td>internal counting</td>
</tr>
<tr>
<td>stepSum</td>
<td>Summary of computing resources used by job steps</td>
</tr>
<tr>
<td>strictSingleton</td>
<td>Error if assignment to singleton set has multiple elements</td>
</tr>
<tr>
<td>stringChk</td>
<td>String substitution options</td>
</tr>
<tr>
<td>suffixDLVars</td>
<td>Switch default for &quot;$on/offSuffixDLVars&quot;</td>
</tr>
<tr>
<td>suppress</td>
<td>Compiler listing option</td>
</tr>
<tr>
<td>symbol</td>
<td>Symbol table file</td>
</tr>
<tr>
<td>sys10</td>
<td>Changes rpower to ipower when the exponent is constant and within 1e-12</td>
</tr>
<tr>
<td></td>
<td>of an integer</td>
</tr>
<tr>
<td>sys11</td>
<td>Dynamic resorting if indices in assignment/data statements are not in</td>
</tr>
<tr>
<td></td>
<td>natural order</td>
</tr>
<tr>
<td>sys12</td>
<td>Pass model with generation errors to solver</td>
</tr>
<tr>
<td>sys15</td>
<td>Automatic switching of data structures used in search records</td>
</tr>
<tr>
<td>sys16</td>
<td>Disable search record memory (aka execute this as pre-GAMS 24.5)</td>
</tr>
<tr>
<td>sys17</td>
<td>Disable sparsity trees growing with permutation (aka execute this as</td>
</tr>
<tr>
<td></td>
<td>pre-GAMS 24.5)</td>
</tr>
<tr>
<td>sys18</td>
<td>Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-</td>
</tr>
<tr>
<td></td>
<td>point numbers</td>
</tr>
<tr>
<td>sys19</td>
<td>Disable permutation on Column Generation (aka execute this as pre-GAMS</td>
</tr>
<tr>
<td></td>
<td>36)</td>
</tr>
<tr>
<td>sysDir</td>
<td>GAMS system directory where GAMS executables reside</td>
</tr>
<tr>
<td>sysIncDir</td>
<td>SysInclude directory</td>
</tr>
<tr>
<td>tabIn</td>
<td>Tab spacing</td>
</tr>
<tr>
<td>tFormat</td>
<td>Time format</td>
</tr>
<tr>
<td>threadsAsync</td>
<td>Limit on number of threads to be used for asynchronous solves (solveLink=6)</td>
</tr>
<tr>
<td>timer</td>
<td>Instruction timer threshold in milli seconds</td>
</tr>
<tr>
<td>trace</td>
<td>Trace file name</td>
</tr>
<tr>
<td>traceLevel</td>
<td>Modelstat/Solvestat threshold used in conjunction with action=GT</td>
</tr>
<tr>
<td>traceOpt</td>
<td>Trace file format option</td>
</tr>
<tr>
<td>user1..5</td>
<td>User strings</td>
</tr>
<tr>
<td>warnings</td>
<td>Number of warnings permitted before a run terminates</td>
</tr>
<tr>
<td>workDir</td>
<td>Working directory</td>
</tr>
<tr>
<td>zeroRes</td>
<td>The results of certain operations will be set to zero if abs(result) LE</td>
</tr>
<tr>
<td></td>
<td>ZeroRes</td>
</tr>
<tr>
<td>zeroResRep</td>
<td>Report underflow as a warning when abs(results) LE ZeroRes and result set</td>
</tr>
<tr>
<td></td>
<td>to zero</td>
</tr>
</tbody>
</table>

### 4.40.5.2 Solver-Related Options

<table>
<thead>

<tr>
<td>solverSolu</td>
<td>Solver solution file name</td>
</tr>
<tr>
<td>solverStat</td>
<td>Solver status file name</td>
</tr>
<tr>
<td>subSys</td>
<td>Name of subsystem configuration file</td>
</tr>
<tr>
<td>sysOut</td>
<td>Solver Status file reporting option</td>
</tr>
<tr>
<td>threads</td>
<td>Number of threads to be used by a solver</td>
</tr>
<tr>
<td>workFactor</td>
<td>Memory Estimate multiplier for some solvers</td>
</tr>
<tr>
<td>workSpace</td>
<td>Work space for some solvers in MB</td>
</tr>
</tbody>
</table>
### 4.40.5.3 Save and Restart Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fSave</td>
<td>Creates a forced work file, i.e., the file is saved even if execution errors or other errors occurred</td>
</tr>
<tr>
<td>restart</td>
<td>Name of a restart file, see The Save and Restart Feature</td>
</tr>
<tr>
<td>restartNamed</td>
<td>Name of another matching restart file, see Obfuscated Work Files</td>
</tr>
<tr>
<td>save</td>
<td>Creates a work file, see The Save and Restart Feature</td>
</tr>
<tr>
<td>saveObfuscate</td>
<td>Creates an obfuscated work file, see Obfuscated Work Files</td>
</tr>
<tr>
<td>symPrefix</td>
<td>Prefix all symbols encountered during compilation by the specified string in work file</td>
</tr>
<tr>
<td>xSave</td>
<td>Creates a compressed work file</td>
</tr>
<tr>
<td>xSaveObfuscate</td>
<td>Creates a compressed obfuscated work file</td>
</tr>
</tbody>
</table>

### 4.40.6 Detailed Descriptions of All Options

In this section we will give detailed descriptions of all options that may be used as command line parameters, in option statements or as model attributes. Note that we indicate for each entry the context in which the option is available. Observe that the options are listed in alphabetical order for easy reference.

**action (string):** GAMS processing request

- **Synonym:** A
- **Available:** Command line

This option controls the way GAMS processes the input file. In particular GAMS currently processes the input file in multiple phases and this allows one to restrict the phases used. The two phases in order are:

- **Compilation** During this pass, the file is compiled, and syntax errors are checked for. Data initialization statements like scalar, parameter, and table statements are also processed during this stage.
- **Execution** During this stage, all execution time statements including assignments, loops, and solves are executed.

The special action GT is related to the creation of trace reports. See also option traceLevel for details.

- **Default:** CE

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Restart After Solve</td>
</tr>
<tr>
<td>C</td>
<td>CompileOnly</td>
</tr>
<tr>
<td>E</td>
<td>ExecuteOnly</td>
</tr>
<tr>
<td>CE</td>
<td>Compile and Execute</td>
</tr>
<tr>
<td>GT</td>
<td>Trace Report</td>
</tr>
</tbody>
</table>

**appendExpand (boolean):** Expand file append option

- **Synonym:** AE
Available: Command line

This option controls the manner of file opening of the option expand.

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reset expand file</td>
</tr>
<tr>
<td>1</td>
<td>Append to expand file</td>
</tr>
</tbody>
</table>

**appendLog (boolean):** Log file append option

Synonym: AL

Available: Command line

This option is used in conjunction with the setting of logOption to 2 and 4, where the log from the GAMS run is redirected to a file. Setting this option to 1 will ensure that the log file is appended to and not overwritten (replaced).

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reset log file</td>
</tr>
<tr>
<td>1</td>
<td>Append to logfile</td>
</tr>
</tbody>
</table>

**appendOut (boolean):** Output file append option

Synonym: AO

Available: Command line

Setting this option to 1 will ensure that the listing file is appended to and not overwritten (replaced).

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reset listing file</td>
</tr>
<tr>
<td>1</td>
<td>Append to listing file</td>
</tr>
</tbody>
</table>

**asyncSolLst (boolean):** Print solution listing when asynchronous solve (Grid or Threads) is used

Available: Command line, Option statement

This option determines whether the solution listing is printed in the listing file when an asynchronous (grid or threads) solve is used and the function handleCollect or command execute_loadHandle successfully collect the results.

Default: 0
### The GAMS Call and Command Line Parameters

#### 4.40 Value | Meaning
--- | ---
0 | Do not print solution listing into lst file for asynchronous solves
1 | Print solution listing into lst file for asynchronous solves

**bRatio (real):** Basis detection threshold

Available: Command line, Option statement, Attribute statement (use before solve)

The `bRatio` value is used to detect whether the initial point (levels and marginals) passed to the solver represents a basis suitable for use by the solver.

Certain (pivotal) solution procedures can restart from an advanced basis that is constructed automatically using existing basis information, i.e. they do a *warm start*. This option is used to influence whether a warm start is done or not. GAMS provides a hint to the solver to suggest whether a basis can or might be extracted from the initial point. The hint is based on the number of rows with nonzero marginals and is computed internally as:

\[
\text{hint} := (0 == \text{bRatio}) \text{ or } (\text{rowsWithNonzeroMarg} > \text{nRows} \times \text{bratio})
\]

Note that setting `bRatio` to 1 causes the hint to be false, while setting `bRatio` to 0 causes the hint to be true. Note also that this is only a hint to the solver: some solvers (e.g. barrier methods) do not use this hint value.

Default: 0.25

**captureModelInstance (boolean):** Switch to capture all model instances within a run

Available: Command line

This option is a debugging option that helps to capture, if set to 1, the model instances that are generated and solved during the execution of the `solve` commands in a GAMS run. This is particularly important if one needs to make a model instance available to GAMS technical support to investigate a solver failure or analyze poor solver performance. The model instances are stored in separate files with names `gamsNNN.gms` where `NNN` is an increasing number. So sorting the files by time or name will correspond to the order in which these instances have been generated and solved. The format of the model instance is the GAMS scalar format and the instance is captured before the instance is solved by the selected solver, hence it contains the starting point but not the solution point.

Another way of capturing model instances becomes useful (and is triggered independent of this option) in case the user model does modularization by calling other GAMS programs that execute a solve statement via the GAMS executable. Since options are not automatically passed on to the GAMS subprocesses one might miss capturing some model instances. Moreover, due to constant folding and rounding in the scalar model format, the run of a scalar model instance might not reproduce a particular problematic issue of the original solve. Hence GAMS can capture the binary scratch files produced by the solve statement when executed under `solveLink=0` in a ZIP file. This is activated by setting a system environment variable named `ZIPSCRDIR_PGAMS` (e.g. `set ZIPSCRDIR_PGAMS=mymodel`). The content of this environment variable is used as a prefix for the ZIP file names, e.g. `mymodelNNN.zip` where `NNN` is an increasing number. Such ZIP files can help GAMS support staff to execute the model and have an increased chance to reproduce a problematic issue.

Note

- `CaptureModelInstance` cannot be used with `solveLink=6/7`. If this was set, GAMS will reset `solveLink` to 3/4 automatically.

Default: 0
### Value | Meaning
--- | ---
0 | Do not capture model instances
1 | Capture model instances

**case** (*boolean*): Output case option for LST file

Available: Command line

This option controls the case of the text in the listing file.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Write listing file in mixed case</td>
</tr>
<tr>
<td>1</td>
<td>Write listing file in upper case only</td>
</tr>
</tbody>
</table>

### cErr (*integer*): Compile time error limit

Available: Command line

The compilation will be aborted after n errors have occurred. By default, there is no error limit and GAMS compiles the entire input file and collects all the compilation errors that occur. If the file is too long and the compilation process is time consuming, **cerr** could be used to set to a low value while debugging the input file.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error limit (default)</td>
</tr>
<tr>
<td>n</td>
<td>Stop after n errors</td>
</tr>
</tbody>
</table>

### charSet (*boolean*): Character set flag

Available: Command line

This option specifies whether foreign language characters are permitted in comments and text items. For a list of standard GAMS characters, see table Legal Characters.

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use limited GAMS characters set</td>
</tr>
<tr>
<td>1</td>
<td>Accept any character in comments and text items (foreign language characters)</td>
</tr>
</tbody>
</table>

### cheat (*real*): Cheat value, i.e. minimum solution improvement threshold

Available: Attribute statement (use before solve)

For a branch-and-bound based solver, each new feasible solution must be at least the value of **cheat** better than the current best feasible solution. Note that this may speed up the search,
but may cause some solutions, including optimal ones, to be missed. If a model has been solved with a nonzero cheat value, then the optimal solution will be within the cheat value or less of the found solution. Observe that the option cheat is specified in absolute terms (like the option optCA), therefore non-negative values are appropriate for both minimization and maximization models. Note that using this option will invalidate any reporting of the dual bound or optimality gaps. Further, certain solver options can override the cheat setting, e.g., the Cplex option objDif, and some solvers may ignore the cheat option.

Default: 0

checkErrorLevel (boolean): Check errorLevel automatically after executing external program

Available: Command line, Option statement

If this option is set to 1, the errorLevel is checked implicitly after executing an external program via execute, put_utility exec and put_utility shell. An execution error is triggered and the execution is aborted, if it is not 0. So, with checkErrorLevel = 1 the before mentioned statements behave like execute.checkErrorLevel, put_utility exec.checkErrorLevel and put_utility shell.checkErrorLevel respectively.

Also, if this option is set as a command line parameter it initializes the state of the dollar control option $onerrorLevel. So, with checkErrorLevel = 1, the errorLevel is checked implicitly after $call and $hiddenCall. A compilation error is triggered and the compilation is aborted if that is not 0. So, $call behaves like $call.checkErrorLevel and $hiddenCall behaves like $hiddenCall.checkErrorLevel in this case.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not check errorLevel automatically after execution of external program</td>
</tr>
<tr>
<td>1</td>
<td>Check errorLevel automatically after execution of external program</td>
</tr>
</tbody>
</table>

CNS (string): Constrained Nonlinear Systems - default solver

Available: Command line, Option statement

The default solver for models of the type Constrained Nonlinear Systems is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

connectIn (string): Specify YAML Connect script file processed at start of GAMS

Available: Command line

The YAML file provided by this command line parameter is passed to and processed by Connect. This allows Connect to prepare data for import at the beginning of a GAMS job. The GAMS program itself does not need to know where the various data files (CSV, Excel, etc) are located. The supply side of the data contract is encapsulated in the YAML script.

Here is an example. The content of the file p.yaml that is supplied via the option connectIn could look like this:
PandasExcelReader:
   file: myworkbook.xlsx
   symbols:
      - name: p
        range: Sheet1!A1
        rowDimension: 1
        columnDimension: 1

GDXWriter:
   file: input.gdx
   symbols:
      - name: p

The GDX file input.gdx can be loaded at the beginning of a GAMS job using gdxLoad:

Set i, j;
Parameter p(i<,j<);
$gdxLoad input.gdx p
display p;

Alternatively, this can be nicely combined with the IDCGDXInput to load external input symbols. The GDX file input.gdx can be specified as value for IDCGDXInput (gams mymodel
   connectIn=p.yaml IDCGDXInput=input.gdx):

Set i, j;
$onExternalInput
Parameter p(i<,j<) / i1.j1 1 /;
$offExternalInput
display p;

The YAML code in the connectIn file can also utilize the GAMSReader agent. Normally, there
are no symbols to read at the job's start, but in case the job restarts from an existing work file
(see command line option restart) the symbols available from the work file can be read into
the Connect database with the GAMSReader agent. The YAML code in the connectIn file can
utilize the GAMSWriter agent. It will update the symbols and data read from the restart file
at the beginning of the GAMS compilation phase.

connectOut (string): Specify YAML Connect script file processed at end of GAMS

Available: Command line

The YAML file provided by this command line parameter is passed to and processed by
Connect. This allows Connect to take the GAMS data at the end of the GAMS job and export
it to various formats (CSV, Excel, etc) according to the instructions in the YAML file.

Here is an example. The content of the file p.yaml that is supplied via the option connectOut
could look like this:

- GDXReader:
   file: output.gdx
   symbols:
      - name: p

- PandasExcelWriter:
   file: myworkbook.xlsx
   symbols:
      - name: p
        range: Sheet1!A1
        rowDimension: 1

The GDX file output.gdx can be written at the end of a GAMS job using execute_unload:
Set i /i1*i10/, j /j1*j10/;
Parameter p(i,j); p(i,j) = uniform(0,1);
execute_unload 'output.gdx', p;

Alternatively, this can be nicely combined with the IDCGDXOutput to process external output symbols. The GDX file output.gdx can be specified as value for IDCGDXOutput (gams mymodel connectOut=p.yaml IDCGDXOutput=output.gdx):

Set i /i1*i10/, j /j1*j10/;
$onExternalOutput
Parameter p(i,j); p(i,j) = uniform(0,1);
$offExternalOutput

The YAML code in the connectOut file can also utilize the GAMSReader agent. This reads directly from GAMS memory (without the detour via GDX) and processes any symbol available at the end of the GAMS run. The YAML code in the connectOut file cannot utilize the GAMSWriter agent.

curDir (string): Current directory

Synonym: CDir
Available: Command line

This option sets the current working directory. It is useful when GAMS is called from an external system like Visual Basic. If it is not specified, it will be set to the directory the GAMS module is called from.

cutOff (real): Cutoff value for branch and bound

Available: Attribute statement (use before solve, reset by solve statement)

Within a branch-and-bound based solver, the parts of the tree with an objective value worse than the cutoff value are ignored. Note that this may speed up the initial phase of the branch and bound algorithm (before the first integer solution is found). However, the true optimum may be beyond the cutoff value. In this case the true optimum will be missed and moreover, no solution will be found.

Observe that this option is specified in absolute terms (like the option optCA).

Default: 0

decimals (integer): Decimal places for display statements

Available: Option statement

This option specifies the number of decimals that will be printed for numeric values that do not have a specific print format attached. The range is $[0, 8]$.

Default: 3

decryptKey (string): Key to decrypt a text file that was encrypted via $encrypt$

Available: Command line

This option provides a key to decrypt a GAMS input file that has been encrypted with a key provided by encryptKey and $encrypt$. For more information, see Encrypting Files.

defPoint (integer): Indicator for passing on default point

Available: Attribute statement (use before solve, reset by solve statement)

This option determines the point that is passed to the solver as a basis. By default, the levels and marginals from the current basis are passed to the solver. In some circumstances (mostly during debugging), it can be useful to pass a standard default input point, i.e. with all levels set to 0 or lower bound.
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Pass user defined levels and marginals to solver</td>
</tr>
<tr>
<td>1</td>
<td>Pass default levels and marginals to solver</td>
</tr>
<tr>
<td>2</td>
<td>Pass default marginals to solver</td>
</tr>
</tbody>
</table>

**dFormat** *(integer)*: Date format

Synonym: DF

Available: Command line

This option controls the date format in the listing file. The three date formats correspond to various conventions used around the world. For example, the date December 2, 1996 will be written as 12/02/96 with the default df value of 0, as 02.12.96 with df=1, and as 96-12-02 with df=2.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Date as mm/dd/yy</td>
</tr>
<tr>
<td>1</td>
<td>Date as dd.mm.yy</td>
</tr>
<tr>
<td>2</td>
<td>Date as yy-mm-dy</td>
</tr>
</tbody>
</table>

**dictFile** *(real)*: Force writing of a dictionary file if dictfile > 0

Available: Attribute statement (use before solve, reset by solve statement)

If this option is set to a value that is larger than zero, it will instruct GAMS to make the GAMS names of variables and equations that have been generated by the solve statement available to the solver. In many solver links these names are registered with the solver and hence messages from the solver that involve variables and equations (e.g. an infeasible row or duplicate columns) can be easily interpreted by the user. Consider the following example:

Row 'demand(new-york)' infeasible, all entries at implied bounds.

Duplicate columns x(san-diego.new-york) and x(san-diego.chicago) make problem unbounded.

If we have modelname.dictfile=0 the same messages will read as follows:

Row 'c4' infeasible, all entries at implied bounds.

Duplicate columns x4 and x5 make problem unbounded.

Sometimes a dictionary is required for a successful run. Some solver option use the original GAMS names and need to be matched with the variables 1..n and equations 1..m in the solver. The dictionary file with its API allows to calculate such a mapping. Note that this is done automatically inside the solver links, so users do not need to be concerned with it.

For example, in the indicator constraints implementation a binary indicator variable is matched to a constraint. In the model [INDIC01] from the GAMS test library, this matching is done in the following GAMS/Cplex option file cplex.opt:

```plaintext
indic eq3(dice,f,fp)$comp(dice,f,fp) 1
```
Observe that if no dictionary is available, we will get an error:

**** Unable to read dictionary file required for indicator constraints

However, the dictionary comes at a price. Generating the names and calculating and storing the map takes time and space. In addition, GAMS names take up space in the solver. Thus, if the user needs very fast generation and does not need names, setting dictFile to zero is a good option.

Further, note that some solvers allow to suppress the loading of names (using the solver option names=no). Suppressing the loading of names facilitates to use the name mapping features required for models like INDIC01 above, but does not load the names into the solver name space for better reporting (and hence saves some space).

digit (string): Switch default for "$on/offDigit"

Available: Command line

For more info see $on/offDigit.

Default: off

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Activate $offDigit</td>
</tr>
<tr>
<td>on</td>
<td>Activate $onDigit</td>
</tr>
</tbody>
</table>

dispWidth (integer): Number of characters to be printed in the column labels of all subsequent display statements

Available: Option statement

This option controls the number of characters that are shown for a label in a column in the context of the display statement. Consider the following example:

```gams
Set i / thislabelhas24characters /
Parameter p(i,i) / thislabelhas24characters.thislabelhas24characters 2/
display p;

option dispWidth=24;
display p;
```

The two display statements in this code will generate the following output:

```plaintext
---- 3 PARAMETER p
        thislabel~
thislabelhas24characters 2.000
---- 6 PARAMETER p
        thislabelhas24characters
thislabelhas24characters 2.000
```
Observe that in the first display, the label in the column is cut off after 10 characters, while in the second display it is shown in full.

Note that the default value is 10 and the range is $[10,31]$.

Default: 10

**dmpOpt (no value):** Debugging option: causes GAMS to echo the runtime option settings

Available: Option statement

This debugging option has the effect that all available option statements and their current values are listed in the listing file.

**dmpSym (no value):** Debugging option: causes GAMS to echo the symbol table to the listing file

Available: Option statement

This debugging option is especially useful for diagnosing memory problems. It has the effect that GAMS will report the number of elements that are stored for each identifier at the point in the program where this option is inserted together with a memory estimate. The report that is generated in this way is called a memory dump. This is similar to the option dmpUserSym, but prints GAMS internal symbols and information as well. For details, see section Finding the Causes for Excessive Memory Use.

**dmpUserSym (no value):** Debugging option: causes GAMS to echo the symbol table to the listing file for user defined symbols only

Available: Option statement

This debugging option is especially useful for diagnosing memory problems. It has the effect that GAMS will report the number of elements that are stored for each identifier at the point in the program where this option is inserted together with a memory estimate. The report that is generated in this way is called a memory dump. This is similar to the option dmpSym, but prints user defined symbols only and also leaves out some very technical information which are mostly for internal use. For details, see section Finding the Causes for Excessive Memory Use.

**DNLP (string):** Non-Linear Programming with Discontinuous Derivatives - default solver

Available: Command line, Option statement

The default solver for models of the type Nonlinear Programs with Discontinuous Derivatives is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

**docFile (string):** Filename stem for documentation files

Available: Command line

**domLim (integer):** Domain violation limit solver default
Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the maximum number of domain errors (undefined operations like division by zero) a nonlinear solver will perform, while calculating function and derivative values, before it terminates the run and returns solver status 5 EVALUATION ERROR LIMIT. Nonlinear solvers have difficulties recovering after attempting an undefined operation. Note that some solvers operate in a mode where trial function evaluations are performed. These solvers will not move to points at which evaluation errors occur, thus the evaluation errors at trial points are not counted against the limit.

Default: ∞

**domUsd (integer):** Number of domain violations

Available: Attribute statement (use after solve)

This model attribute returns the number of domain violations after a solve.

**dualCheck (integer):** Output on the reduced cost condition

Available: Option statement

If this option is set to 1, the reduced cost condition for each variable in the column listing will be evaluated using the equation marginals. The default value is zero, which means that the calculation will be omitted.

Default: 0

**dumpOpt (integer):** Writes preprocessed input to the file input.dmp

Available: Command line

This option with value larger than 9 creates a GAMS input file of that will reproduce results encapsulating all include files into one GAMS file. If activated, a file will be written containing GAMS source code for the entire problem. The file name is the input file name with the extension dmp. For values smaller than 10, this option tries to encapsulate all the items from a restart file that are needed to execute a solve.

For the values smaller than 10, consider the following example. We will split the transportation model [TRNSPORT] into two files and run them with the save and restart feature. Then we will illustrate the option dumpOpt. The first file called trans1.gms contains the first part of the model up to and including the model statement:

Sets

\[
\text{i canning plants / seattle, san-diego /} \\
\text{j markets / new-york, chicago, topeka / ;}
\]

Parameters

\[
\text{a(i) capacity of plant i in cases} \\
\text{\quad / seattle 350, san-diego 600 /} \\
\text{b(j) demand at market j in cases} \\
\text{\quad / new-york 325, chicago 300, topeka 275 / ;}
\]

Table d(i,j) distance in thousands of miles

\[
\begin{array}{ccc}
\text{new-york} & \text{chicago} & \text{topeka} \\
\end{array}
\]
Scalar \( f \) freight in dollars per case per thousand miles /90/ ;

Parameter \( c(i,j) \) transport cost in thousands of dollars per case;
\[ c(i,j) = f \times d(i,j) / 1000 \]

Variables
- \( x(i,j) \) shipment quantities in cases
- \( z \) total transportation costs in thousands of dollars;

Positive Variable \( x \);

Equations
- \( \text{cost} \) define objective function
- \( \text{supply}(i) \) observe supply limit at plant \( i \)
- \( \text{demand}(j) \) satisfy demand at market \( j \);

\[
\begin{align*}
\text{cost} & \quad \text{define objective function} \\
\text{supply}(i) & \quad \text{observe supply limit at plant } i \\
\text{demand}(j) & \quad \text{satisfy demand at market } j \\
\end{align*}
\]

\[
\begin{align*}
\text{cost} & \quad z = \text{sum}((i,j), c(i,j) \times x(i,j)) \\
\text{supply}(i) & \quad \text{sum}(j, x(i,j)) = \text{a}(i) \\
\text{demand}(j) & \quad \text{sum}(i, x(i,j)) = \text{g} = b(j) \\
\end{align*}
\]

model transport /all/ ;

Note that we removed all comments for brevity. The second file called trans2.gms contains the solve statement and the display statement:

\[
\begin{align*}
\text{solve transport using lp minimizing } z \\
\text{display } x.l, x.m \\
\end{align*}
\]

We run the first file with the command line parameter save and thus generate a work file. For details on work files, see chapter The Save and Restart Feature. Then we run trans2.gms restarting from the saved work file. The result will be equivalent to running the original model [TRNSPORT].

Note
- The option dumpOpt can only be used effectively, if the first line in the second file, trans2.gms, is the solve statement.

Now, we will illustrate the use of the option dumpopt, by running the second file with the following command:

\[
> \text{gams} \text{ trans2 r=trans dumpopt=1}
\]

Here trans is the name of the saved files generated from the file trans1.gms. As a result of this call, a new file will be created. It is called trans2.dmp and has the following content:

* This file was written with DUMPOPT=1 at 11/25/21 15:15:17
* INPUT = C:\tmp\trans2.gms
* DUMP = C:\tmp\trans2.dmp
* RESTART = C:\tmp\0.g0?
* with time stamp of 11/16/21 17:18:53
* You may have to edit this file and the input file.
* There are 5 labels
Set WorkFileLabelOrder dummy set to establish the proper order /
   seattle,san-diego,new-york,chicago,topeka /;

Model transport;

Variable z 'total transportation costs in thousands of dollars';

Set i(*) 'canning plants' /
   seattle,san-diego /;

Set j(*) 'markets' /
   new-york,chicago,topeka /;

Parameter c(i,j) 'transport cost in thousands of dollars per case' /
   seattle.new-york 0.225,seattle.chicago 0.153,seattle.topeka 0.162,san-diego.new-york 0.225,san-diego.chicago 0.162,san-diego.topeka 0.126 /;

Positive Variable x(i,j) 'shipment quantities in cases';

Parameter a(i) 'capacity of plant i in cases' /
   seattle 350,san-diego 600 /;

Parameter b(j) 'demand at market j in cases' /
   new-york 325,chicago 300,topeka 275 /;

Equation demand(j) 'satisfy demand at market j';

Equation supply(i) 'observe supply limit at plant i';

Equation cost 'define objective function';

*     *** EDITS FOR INPUT FILE ***

*** END OF DUMP ***

Note that all the data that enters the model in the solve statement has been regenerated. Observe that the parameter d has not been regenerated since it does not appear in the model. Changing the value of the parameter dumpopt will have the effect that other names are used for the identifiers in the regenerated file, see table below.

Note

If $onVerbatim is active, DumpOpt = 11 behaves like DumpOpt = 21 (comments are kept)

See also dumpOptGDX.

Default: 0

<table>
<thead>

</tbody>
</table>
dumpOptGDX (string): Defines a GDX file name stem created when using DumpOpt

Available: Command line

This parameter works together with the dumpOpt parameter. If that is set to 1, 11 or 21 while dumpOptGDX is set, GAMS will create a GDX file with the data used in the dump file instead of data statements, and the dump file will load the data from that GDX file. So, with the parameter dumpOptGDX=trns2 the example above would generate the following dump file:

* This file was written with DUMPOPT=1 at 11/25/21 15:14:11
* INPUT = C:\tmp\trans2.gms
* DUMP = C:\tmp\trans2.dmp
* RESTART = C:\tmp\0.g0?
* DUMPOPTGDX = trans2
* with time stamp of 11/16/21 17:18:53

$gdxIn trans2.gdx

* You may have to edit this file and the input file.

* There are 5 labels

Set WorkFileLabelOrder dummy set to establish the proper order;
$loadDCR WorkFileLabelOrder=* Model transport;

Variable z 'total transportation costs in thousands of dollars';

Set i(*) 'canning plants';
$loadDCR i

Set j(*) 'markets';
$loadDCR j

Parameter c(i,j) 'transport cost in thousands of dollars per case';
$loadDCR c

Positive Variable x(i,j) 'shipment quantities in cases';

Parameter a(i) 'capacity of plant i in cases';
$loadDCR a

Parameter b(j) 'demand at market j in cases';
$loadDCR b

Equation demand(j) 'satisfy demand at market j';

Equation supply(i) 'observe supply limit at plant i';

Equation cost 'define objective function';

$gdxIn

* *** EDITS FOR INPUT FILE ***

*** END OF DUMP ***
Note that more than one GDX file could be created with a common file stem defined by this parameter. This will be necessary if the source model has multiple data definitions for the same symbol like in this simple example:

Set  i / i1*i3/;
Parameter a(i) / i1 1, i2 2/;
$onMulti
Parameter a(i) / i1 0, i3 3/;
Scalar  b / 7/;
Scalar  b / 77/;

Running this as

> gams dummy dumpOpt=11 dumpOptGDX=dummyIn

will generate this dump file:

* This file was written with DUMPOPT=11 at 11/25/21 15:26:02
* * DUMP = C:\tmp\dummy.dmp
* * INPUT = C:\tmp\dummy.gms
* * RESTART =
* * DUMPOPTGDX = dummyIn
* *

$gdxIn dummyIn.gdx

Set  i  
$loadDCR i
  ;
Parameter a(i)  
$loadDCR a  
  ;
$onMulti
Parameter a(i)  
$gdxIn dummyIn_m1.gdx
$loadDCR a  
  ;
Scalar  b  
$loadDCR b  
  ;
Scalar  b  
$gdxIn dummyIn_m2.gdx
$loadDCR b  
  ;
* *** EXIT  C:\Data\gspTest\dummy.gms

$gdxIn
*** END OF DUMP ***

And this is the data found in the GDX files:

dummyIn.gdx:
Set  i(*) /  
 'i1',  
 'i2',  
 'i3' /;
Parameter a(*) /  
 'i1' 1,  
 'i2' 2 /;
dummyIn_m1.gdx:

Parameter a(*) /
  'i2' 2,
  'i3' 3 /;

Scalar b / 7 /;

dummyIn_m2.gdx:

Scalar b / 77 /;

dumpParms \text{(integer)}: GAMS parameter logging

Synonym: DP

Available: Command line

This option lists the settings of all command line parameters that were changed or set by the user, GAMS or an IDE during the current run. Note that with \text{dp=2} all file operations are listed, including the full path of each file on which any operation is performed.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No logging</td>
</tr>
<tr>
<td>1</td>
<td>Lists accepted/set parameters</td>
</tr>
<tr>
<td>2</td>
<td>Log of file operations plus list of accepted/set parameters</td>
</tr>
</tbody>
</table>

dumpParmsLogPrefix \text{(string)}: Prefix of lines triggered by DumpParms>1

Synonym: DPLP

Available: Command line

This option prefixes in the log file the list of all command line parameters that were changed or set by the user, GAMS or an IDE during the current run. Note that the option dumpParms must be greater than 1 for dumpParmsLogPrefix to have an effect.

Default: ***

ECImplicitLoad \text{(string)}: Allow implicit loading of symbols from embedded code or not

Available: Command line, Option statement

The command line parameter ECImplicitLoad initializes both, the option ECImplicitLoad and the dollar control option \$on/offECImplicitLoad for the compile-time equivalent behavior.

Default: on

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Do not allow implicit loading from embedded code</td>
</tr>
<tr>
<td>on</td>
<td>Allow implicit loading from embedded code</td>
</tr>
</tbody>
</table>
eject (no value): Inject a page break into the LST file

   Available: Option statement

   This option has the effect that a page break is inserted in the listing file.

EMP (string): Extended Mathematical Programs - default solver

   Available: Command line, Option statement

   The default solver for models of the type Extended Mathematical Programs is set during
   installation. The user may change this default by setting this option to the desired solver.

   Observe that if the solver was changed using an option statement, the default solver may be
   reset later in the program with another option statement, where the value of the option is set
   to default.

empty (string): Switch default for "$on/offEmpty"

   Available: Command line

   For more info see $on/offEmpty.

   Default: on

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Activate $offEmpty</td>
</tr>
<tr>
<td>on</td>
<td>Activate $onEmpty</td>
</tr>
</tbody>
</table>

encryptKey (string): Key to encrypt a text file using $encrypt

   Available: Command line

   This option provides a key to encrypt a text file via $encrypt. For more information, see
   Encrypting Files.

eolCom (string): Switch default for "$on/offEolCom" and "$eolCom"

   Available: Command line

   If this is set to on or off it sets the state of $on/offEOLCom. Other strings (with not
   more than two characters) will set $EOLCom.

   Default: off

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Activate $offEolCom</td>
</tr>
<tr>
<td>on</td>
<td>Activate $onEolCom using default EOL comment character</td>
</tr>
<tr>
<td>other</td>
<td>Activate $onEolCom setting specific EOL comment character(s)</td>
</tr>
</tbody>
</table>

eolOnly (integer): Single key-value pairs (immediate switch)

   Synonym: EY
Available: Command line

This option controls formatting of parameters on the command line and is useful in conjunction with the option `parmFile`.

This option acts as an immediate switch that forces only one option-value pair to be read on a line. Note that by default, any number of option-value pairs may be present on the same line and termination characters and quoting is necessary to determine the end of key/value pair. With this option active the remainder after the key is used as the value independent of quoting or termination characters.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Any number of keys or values</td>
</tr>
<tr>
<td>1</td>
<td>Only one key-value pair on a line</td>
</tr>
</tbody>
</table>

**epsToZero (string):** Treat eps as zero when unloading to GDX

Available: Command line, Option statement

When this is set to `on`, EPS values are written as zero when unloading parameters or variable and equation levels to GDX at execution time. The command line parameter `EpsToZero` initializes both, the option `EpsToZero` and the dollar control option `$on/offEpsToZero` for the compile-time equivalent behavior.

Default: `off`

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Treat Eps as Eps</td>
</tr>
<tr>
<td>on</td>
<td>Treat Eps as Zero</td>
</tr>
</tbody>
</table>

**errMsg (integer):** Placing of compilation error messages

Available: Command line

This option controls the position of the compilation error messages in the listing file. To illustrate the option, consider the following slice of GAMS code:

```gams
Set i / 1*10 /;
Set j(i) / 10*11 /;
Parameter a(jj) / 12 25.0 /;
```

After running this code, the listing file will contain the following lines:

```
1 Set i / 1*10 /;
2 Set j(i) / 10*11 /;
**** $170
3 Parameter a(jj) / 12 25.0 /;
**** $120
4
120 Unknown identifier entered as set
170 Domain violation for element
```

** **** 2 ERROR(S) 0 WARNING(S)**
Note that numbers $170$ and $120$ flag the two errors as they occur, but the errors are explained only at the end of the compilation output. However, if the code is run using the option `errmsg=1`, the resulting listing file will contain the following:

```plaintext
1 Set i / 1*10 / ;
2 Set j(i) / 10*11 / ;
**** $170
**** 170 Domain violation for element
3 Parameter a(jj) / 12 25.0 / ;
**** $120
**** 120 Unknown identifier entered as set
4
**** 2 ERROR(S) 0 WARNING(S)
```

Observe that the explanation for each error is provided immediately following the error marker.

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Place error messages at the end of compiler listing</td>
</tr>
<tr>
<td>1</td>
<td>Place error messages immediately following the line with the error</td>
</tr>
<tr>
<td>2</td>
<td>Suppress error messages</td>
</tr>
</tbody>
</table>

**errNam** *(string)*: Name of error message file

Available: Command line

This option specifies the name of a file defining the internally used compiler error messages. It is used to change the name from the default name `gamserrs.txt`.

**error** *(string)*: Force a compilation error with message

Available: Command line

This option forces a parameter error with a specified message. It is useful in the context of incorporating a GAMS file within another batch file where the user needs to have control over the conditions when GAMS is called. See also section Conditional Compilation.

To illustrate, the default GAMS log file from running a model with the option `error=Hallo` will look as follows:

```plaintext
gams: **** Error: Parameter error(s)
      : Reading parameter(s) from "command line"
      : *** Error Hallo
      : Finished reading from "command line"
```

**errorLog** *(integer)*: Max error message lines written to the log for each error

Synonym: ER

Available: Command line

This option controls the number of error message lines that are written to the log file.

Under GAMS Studio, the default is reset to 99.

Default: 2147483647
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error messages to LOG file</td>
</tr>
<tr>
<td>n</td>
<td>Number of lines for each error that will be written to LOG file</td>
</tr>
</tbody>
</table>

**etAlg** *(real)*: Solver dependent timing information

Available: Attribute statement (use after solve)

Unlike **etSolve** and **etSolver**, this attribute is set by the individual solver links. If not set, it defaults to **NA**. This attribute was intended to allow solvers to return the elapsed time used by the solve algorithm without including any model generation, communication, or setup time. However, solvers are free to adapt this convention and return time-related information (but not necessarily elapsed time) for executing the solve algorithm. Please inspect your solver manual for the actual meaning of the value returned in this attribute.

**etLim** *(real)*: Elapsed time limit in seconds

Synonym: ETL

Available: Command line

This option controls the time limit for a GAMS job. The system will terminate with a compilation or execution error if the limit is reached. A GAMS job will terminate if the elapsed time in seconds exceeds the value of **etLim**. If a solve statement gets executed, and the **resLim** for the model to be solved is greater than **etLim - timeElapsed**, **resLim** will be reduced automatically.

Default: $\infty$

**etSolve** *(real)*: Elapsed time it took to execute a solve statement in total

Available: Attribute statement (use after solve)

This model attribute returns the elapsed time it took to execute a solve statement in total. This time includes the model generation time, the time to read and write files, the time to create the solution report and the time taken by the actual solve. The time is expressed in seconds of wall-clock time.

**etSolver** *(real)*: Elapsed time taken by the solver only

Available: Attribute statement (use after solve)

This model attribute returns the elapsed time taken by the solver only. This does not include the GAMS model generation time and the time taken to report and load the solution back into the GAMS database. The time is expressed in seconds of wall-clock time.

**execMode** *(integer)*: Limits on external programs that are allowed to be executed

Available: Command line

A higher value denotes a more restrictive alternative. If the restriction level **n** is chosen, then the restriction levels less than **n** will also be active. For example, if restriction level 3 is chosen, then restrictions 2 and 1 will apply too.

Default: 0
### 4.40 The GAMS Call and Command Line Parameters

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Everything allowed</td>
</tr>
<tr>
<td>1</td>
<td>Interactive shells in $call and execute commands are prohibited</td>
</tr>
<tr>
<td>2</td>
<td>Embedded Code and all $call and execute commands are prohibited</td>
</tr>
<tr>
<td>3</td>
<td>$echo or put commands can only write to directories in or below the working or scratchdir</td>
</tr>
<tr>
<td>4</td>
<td>$echo and put commands are not allowed</td>
</tr>
</tbody>
</table>

**expand** *(string)*: Expanded (include) input file name

Synonym: EF

Available: Command line

This option generates a file that contains information about all the input files processed during a particular compilation. By default, the names of the input files are composed by completing the name with the current directory.

Consider the following example:

```
$call rm expfile.txt
$onecho > file1.inc
a = a*2; display a;
$include file2.inc
$offecho
$onecho > file2.inc
a = a+1; display a;
$include file3.inc
$offecho
$onecho > file3.inc
a = a**2; display a;
$offecho
parameter a / 1 /;
$include file3.inc
$include file2.inc
$include file1.inc
```

If the model is run with the command line parameter **ef=expfile.txt**, a file called `expfile.txt` will be generated. This file will contain the following lines:

```
1 INPUT 0 0 0 1 29 C:\GAMS\Examples\expand.gms
2 CALL 0 1 1 1 1 1 rm expfile.txt
3 INCLUDE 1 1 14 14 15 C:\GAMS\Examples\file3.inc
4 INCLUDE 1 1 15 16 19 C:\GAMS\Examples\file2.inc
5 INCLUDE 2 4 2 18 19 C:\GAMS\Examples\file3.inc
6 INCLUDE 1 1 16 20 25 C:\GAMS\Examples\file1.inc
7 INCLUDE 2 6 2 22 25 C:\GAMS\Examples\file2.inc
8 INCLUDE 3 7 2 24 25 C:\GAMS\Examples\file3.inc
9 EXIT 0 1 20 29 29 C:\GAMS\Examples\expand.gms
```

Note that the first row always refers to the parent file, in this case the file `expand.gms`. The first column gives the sequence number of the input files that were encountered. The second column refers to the type of file that is referenced. The following file types are possible:
Observe that $\textit{call}$ is also listed. The third column describes the depth for nested include files. The fourth column provides the sequence number of the parent file for the file being referenced. The fifth column gives the local line number in the parent file where the dollar control option $\textit{include}$ appeared. The sixth column gives the global (expanded) line number which contained $\textit{include}$. The seventh column provides the total number of lines in the file after it is processed. The last column provides the name of the file.

Note that the listing in the expand file is similar to the include file summary in the listing file of the model. And like the include file summary, this file will not be written, if $\textit{offInclude}$ is set in the model.

\textbf{fdDelta (real): Step size for finite differences}

Available: Command line, Option statement, Attribute statement (use before solve)

This option allows users to control the step size while the numerical Hessian and numerical derivatives are computed in the context of the \texttt{function} suffixes \texttt{.hessn} and \texttt{.gradn}. For functions with one argument, GAMS evaluates the function at $f(x-d)$ and $f(x+d)$ for the numerical gradient. If function values are used for the numerical Hessian, GAMS will evaluate at $f(x-2d)$, $f(x)$ and $f(x+2d)$. For functions with multiple arguments, the same calculations are performed for the components of the input argument vector.

Default: $1.0\times10^{-5}$

\textbf{fdOpt (integer): Options for finite differences}

Available: Command line, Option statement, Attribute statement (use before solve)

This option allows users to control how numerical derivatives are computed. The values provide choice regarding the scaling of steps, Hessian calculation method and the use of numerical first derivatives.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>All derivatives analytically, for numerical Hessian use gradient values, scale delta</td>
</tr>
<tr>
<td>1</td>

<td>Same as 3, but no scale of delta</td>
</tr>
<tr>
<td>14</td>
<td>Same as 4, but no scale of delta</td>
</tr>
</tbody>
</table>

\textbf{fErr (string): Alternative error message file}
Available: Command line

This option redirects the compilation error messages to a file and names the file. By default, the file name is composed by completing the name with the scratch directory and the scratch extension. Note that under default settings such a file with compilation error messages is not generated. This option can be used when GAMS is being integrated into other environments like Visual Basic. The error messages that are reported in the listing file may be extracted with this option and their display may be controlled from the environment that is calling GAMS.

To illustrate, consider the slice of GAMS code that we used to explain the option errMsg. If we call this code with the command line parameter `ferr=myfile.err`, a file called `myfile.err` will be created in the scratch directory. This file will contain the following lines:

```
0 0 0 0 D:\GAMS\NEW.LST
1 1 170 31 D:\GAMS\NEW.GMS
2 2 120 14 D:\GAMS\NEW.GMS
```

Note that the first column refers to the global row number of the error in the listing file. The second column refers to the row number of the error in the individual file where the problem occurred. This will be different from the first column only if the error occurred in an include file. In this case, the second column will contain the line number in the include file where the error occurred, while the first number will contain the global line number (as reported in the listing file) where the error occurred. The number in the third column refers to the error number of the compilation error. The fourth number refers to the column number of the error in the source file. The last column contains the individual file in which the error occurred.

**fileCase (integer):** Casing of file names and paths (put, gdx, ref, $include, etc.)

Available: Command line

This option facilitates modifying the case of file names and paths. It applies to files created by a GAMS Job such as for example put files, GDX files and reference files. Under Windows, the casing of a created file will only be affected if the file does not yet exist, i.e. `fileCase=2` won’t create `transport.ref` if there is already a file `TRANSPORT.ref`. It should be noted that `fileCase` also applies to existing files that are used but not created by a GAMS job such as for example `$include files` or `$batInclude files`.

Note that many other file names and paths are affected by this option (e.g. the scratch directory (`scrDir`) or the GAMS system directory (`sysDir`)) and that it is recommended to use this option with caution.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Causes GAMS to use default casing</td>
</tr>
<tr>

<td>3</td>
<td>Causes GAMS to upper case file names only (leave the path alone)</td>
</tr>
<tr>
<td>4</td>
<td>Causes GAMS to lower case file names only (leave the path alone)</td>
</tr>
</tbody>
</table>

**fileStem (string):** Sets the file stem for output files which use the input file name as stem by default

Available: Command line

By default, some output files use the input file name as base. If the names of these output files were not set explicitly, then this option may be used to set another name than the input
file name as base for these output files. In particular, the names for the following files may be set with fileStem: dump files (see option dumpOpt), GDX files (if the option GDX was set to default), log files (see option logFile), lst files (see option output), reference files (if the option reference was set to default) and trace summary files (see also option trace).

fileStemApFromEnv (string): Append a string read from an environment variable to the "FileStem"

Available: Command line

This option for users that submit GAMS job via mpirun/mpiexec. Such commands will spawn multiple instances of GAMS (the precise number is an argument to mpirun/mpiexec). Each invocation of GAMS will run the identical job and only the contents of an environment variable (PMI_RANK) will differentiate the run. Since GAMS will normally write to modelname.log/lst if we run the GAMS file modelname.gms we will have many jobs writing to the same file. Therefore we use this option to append the content of a particular environment variable (name given by this option) to the default file names (see fileStem). Hence GAMS will create modelname0.log/lst, modelname1.log/lst, and so forth when started with mpirun/mpiexec and fileStemApFromEnv is set to the environment variable that provides the MPI rank of the invocation. We allow to specify the name of the environment variable because different MPI implementations use different variable names (e.g. PMI_RANK or OMPI_COMM_WORLD_RANK).

filtered (string): Switch default for "$on/offFiltered"

Available: Command line

For more info see $on/offFiltered.

Default: on

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Activate $offFiltered</td>
</tr>
<tr>
<td>on</td>
<td>Activate $onFiltered</td>
</tr>
</tbody>
</table>

forceOptFile (integer): Overwrites other option file section mechanism

Available: Command line

Default: 0

forceWork (boolean): Force GAMS to process a save file created with a newer GAMS version or with execution errors

Synonym: FW

Available: Command line

Work files generated by GAMS using the command line parameter save are saved in binary format. The information inside these files will change from one GAMS version to another GAMS version. GAMS makes every attempt to be backward compatible and ensure that all new GAMS systems are able to read save files generated by older GAMS systems. However, this cannot be guaranteed the other way around. Thus, GAMS does not allow to process a save file, that was generated by a newer version of GAMS in general. This can be changed by setting forceWork to 1. Also, GAMS does not continue after processing a save while with an execution error by default. This behavior can be changed as well by setting forceWork=1.
Attention

Forcing GAMS to continue after reading a save file from a newer GAMS version or a save file with execution errors may lead to unexpected behavior. If it is about the GAMS version and you can recreate the save file you may write it using GAMS command line parameter `previousWork=1`.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No translation</td>
</tr>
<tr>
<td>1</td>
<td>Try translation</td>
</tr>
</tbody>
</table>

**forLim** (*integer*): GAMS looping limit

Available: Command line, Option statement

This option specifies the maximum number of permitted executions of control structures with a `for` statement, a `while` statement or a `repeat` statement before GAMS signals an execution error and terminates the control structure.

Default: \(\infty\)

**fSave** (*boolean*): Creates a forced work file, i.e., the file is saved even if execution errors or other errors occurred

Available: Command line

This option allows to save a file even in the face of execution or other errors. How it works depends on the command line parameter `save`.

Note that the option value of 1 is mainly used by solvers that can be interrupted from the terminal.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Workfile only written to file specified by SAVE if no errors occur</td>
</tr>
<tr>
<td>1</td>
<td>Workfile always written to file specified by SAVE or if SAVE is not present to a name made up by GAMS</td>
</tr>
</tbody>
</table>

**G205** (*integer*): Use GAMS version 2.05 syntax

Available: Command line

This option sets the level of the GAMS syntax and is mainly used to ensure backward compatibility. New keywords have been introduced in the GAMS language since Release 2.05. Models developed earlier that use identifiers that have since become keywords will cause errors when they are run with the latest version of GAMS. This option enables users to run such old models.

For example, the word "if" is a keyword in GAMS that was introduced with the first version of Release 2.25. Setting the option `g205=1` allows the word "if" to be used as an identifier since it was not a keyword in Release 2.05. As another example, the word "for" is a keyword in GAMS that was introduced with the later versions of Release 2.25. Setting the option `g205=2` allows "for" to be used as an identifier since it was not a keyword in the first version of Release 2.25.
Note

If the values 1 or 2 are specified for option g205, then it will not be permitted to use enhancements of the GAMS language that were introduced in later versions.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use only latest syntax</td>
</tr>
<tr>
<td>1</td>
<td>Allow version 2.05 syntax only</td>
</tr>
<tr>
<td>2</td>
<td>Allow version 2.25 syntax only</td>
</tr>
</tbody>
</table>

**GDX** *(string)*: GAMS data exchange file name

Available: Command line

This option specifies the name of the GAMS data exchange file and causes a GDX file to be written that contains all data in the model at the end of the job. Setting `gdx` to the string 'default' causes GAMS to create a GDX file with the gms file root name and a gdx extension. Thus, e.g., the call

```
> gams trnsport gdx=default
```

will cause GAMS to write the GDX file `trnsport.gdx`.

**gdxCompress** *(boolean)*: Compression of generated GDX file

Available: Command line

This option specifies whether the GDX files are compressed or not.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not compress GDX files</td>
</tr>
<tr>
<td>1</td>
<td>Compress GDX files</td>
</tr>
</tbody>
</table>

**gdxConvert** *(string)*: Version of GDX files generated (for backward compatibility)

Available: Command line

This option specifies in which format the GDX files will be written.

Default: v7

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>v5</td>
<td>Version 5 GDX file, does not support compression</td>
</tr>
<tr>
<td>v6</td>
<td>Version 6 GDX file</td>
</tr>
<tr>
<td>v7</td>
<td>Version 7 GDX file</td>
</tr>
</tbody>
</table>

**gdxUels** *(string)*: Unload labels or UELs to GDX either squeezed or full

Available: Command line, Option statement
This option specifies the UEL export mode. The UEL table may be written to a GDX file in two different modes. In **squeezed** mode, only the UELs that are required by the exported symbols are exported. In **full** mode, all UELs are exported. The following code snippet illustrates the difference:

```gams
Set i / i1*i5 /;
Parameter p(i) / i3 3 /;
option gdxuels = squeezed;
execute_unload 'squeezed' p;
execute 'gdxdump squeezed UelTable=i';

option gdxuels = full;
execute_unload 'full' p;
execute 'gdxdump full UelTable=i';
```

The file `squeezed.gdx` will contain the following lines:

```plaintext
Set i /
   'i3' /;

Parameter p(*) /
   'i3' 3 /;
```

The file `full.gdx` on the other hand, will contain the following lines:

```plaintext
Set i /
   'i1' ,
   'i2' ,
   'i3' ,
   'i4' ,
   'i5' /;

Parameter p(*) /
   'i3' 3 /;
```

Default: **squeezed**

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Squeezed</td>
<td>Write only the UELs to Universe, that are used by the exported symbols</td>
</tr>
<tr>
<td>Full</td>
<td>Write all UELs to Universe</td>
</tr>
</tbody>
</table>

**gridDir** *(string)*: Grid file directory

Synonym: GDir

Available: Command line

This option sets the grid file directory. Note that each GAMS job has only one grid file directory.

**gridScript** *(string)*: Grid submission script

Synonym: GScript

Available: Command line
This option provides the name of a script file that is used to submit grid computing jobs. If only the file name is given the file is assumed to be located in the system directory. A fully qualified name can be given as well. The script needs to be similar to the file \texttt{gmsgrid.cmd} on Windows machines with arguments that give name and location of the solver executable, the solver control file name and the name of the scratch directory. For an example of such a script, see section \textit{The Grid Facility: Architecture and Customization}. However, note that advanced knowledge of how GAMS sets up and calls solvers is needed for successful use.

Default: \texttt{gmsgrid}

\textbf{handle (real):} Unique handle number of SOLVE statement

Available: Attribute statement (use after solve)

The model attribute \texttt{handle} contains a unique identification of each submitted solution request and is typically stored in a parameter defined over a set that covers all model instances. The handle number may be used by the functions \texttt{handleCollect}, \texttt{handleStatus}, \texttt{handleDelete}, \texttt{handleSubmit} and \texttt{readyCollect}. For details see chapter \textit{The Grid and Multi-Threading Solve Facility}.

\textbf{heapLimit (real):} Maximum Heap size allowed in MB

Synonym: \texttt{HL}

Available: Command line

This option allows to limit the amount of memory a GAMS job may use during compilation and execution. If the needed data storage exceeds this limit, the job will be terminated.

Default: $\infty$

\textbf{holdFixed (boolean):} Treat fixed variables as constants

Available: Command line, Attribute statement (use before solve)

This option facilitates treating fixed variables as constants. Thus the problems size may be reduced.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Fixed variables are not treated as constants</td>
</tr>
<tr>
<td>1</td>
<td>Fixed variables are treated as constants</td>
</tr>
</tbody>
</table>

\textbf{holdFixedAsync (boolean):} Allow HoldFixed for models solved asynchronously as well

Available: Command line, Option statement

By default, \texttt{holdFixed} is automatically deactivated if a model is solved asynchronously, since this could lead to inconsistent solutions otherwise. To allow this anyway, this parameter can be set to 1.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Ignore HoldFixed setting for async solves</td>
</tr>
<tr>
<td>1</td>
<td>Allow HoldFixed for async solves</td>
</tr>
</tbody>
</table>
**IDCGDXInput** *(string)*: GDX file name with data for implicit input  
Available: Command line  
Specify the name of a GDX file that is used for implicit loading of input data. Details about this are described with `$onExternalInput`.  

**IDCGDXOutput** *(string)*: GDX file name for data for implicit output  
Available: Command line  
Specify the name of a GDX file that is used for implicit writing of output data. Details about this are described with `$onExternalOutput`.  

**IDCGenerateGDX** *(string)*: Specify GDX file name of input and output side of data contract  
Available: Command line  
Specify the name of a GDX file that is used to store all symbols that are declared as external input or external output at the end of a GAMS run.  

**IDCGenerateGDXInput** *(string)*: Specify GDX file name of input side of data contract  
Available: Command line  
Specify the name of a GDX file that is used to store all symbols that are declared as external input at the end of a GAMS run.  

**IDCGenerateGDXOutput** *(string)*: Specify GDX file name of output side of data contract  
Available: Command line  
Specify the name of a GDX file that is used to store all symbols that are declared as external output at the end of a GAMS run.  

**IDCGenerateJSON** *(string)*: Specify JSON file name of data contract  
Available: Command line  
Specify the name of a JSON file that is used to store the information (but not the data) about all symbols that are declared as external input or external output at the end of a GAMS run.  

**IDCJSON** *(string)*: Specify JSON file name to verify data contract  
Available: Command line  
Specify the name of a JSON file that is read and used to verify that the implicit data contract given by the GAMS model by declaring symbols as external input or external output matches the expected symbol information given by this specified file. This is the expected schema of that file:  
```json  
{

4.40 The GAMS Call and Command Line Parameters

IDCProtect (boolean): Flag to control assignment protection of external input symbols

Available: Command line, Option statement

By default, it is not allowed to change symbols which are declared as external input at execution time. This parameter allows to ignore this restriction. It sets the initial state for the dollar control options $on/offIDCProtect.

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Allow to change external input symbols at execution time</td>
</tr>
<tr>
<td>1</td>
<td>Protect external input symbols from being changed at execution time</td>
</tr>
</tbody>
</table>

IDE (boolean): Integrated Development Environment flag

Available: Command line

This option instructs GAMS to write special instructions to the log file that are in turn read by an IDE.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Unknown environment</td>
</tr>
<tr>
<td>1</td>
<td>Runs under GAMS IDE</td>
</tr>
</tbody>
</table>
**inlineCom (string):** Switch default for "$on/offInline" and "$inlineCom"

Available: Command line

If this is set to on or off it sets the state of $on/offInline. Other strings (a pair with not more than two characters each) will set $inlineCom.

Default: off

<table>
<thead>
<tr>
<th>Value</th>

</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Activate $offInline</td>
</tr>
<tr>
<td>on</td>
<td>Activate $onInline using default inline comment characters</td>
</tr>
<tr>
<td>other</td>
<td>Activate $onInline setting specific inline comment characters</td>
</tr>
</tbody>
</table>

**input (string):** Input file

Synonym: I

Available: Command line

Completing the input file name with the current directory composes the final name. If such a file does not exist and the extension was not specified, the standard input extension will be attached and a second attempt will be made to open an input file.

**inputDir, inputDir1..40 (string):** Input file directories (searched at compile time)

Synonym: IDIR

Available: Command line

In general, GAMS searches for input and include files in the current working directory only. This option allows the user to specify additional directories for GAMS to search for include and batinclude files as well as GDX file via $gdxIn. A maximum of 40 separate directories may be included. The directories are separated by Operating System specific symbols. For example, on a PC the separator is a semicolon (;) character and under Unix it is the colon (:) character. Note that libinclude and sysinclude files are handled differently. Their paths are specified with the command line parameters libIncDir and sysIncDir respectively.

Consider the following illustration:

> gams myfile idir \mydir;\mydir2

Note that the search order for the file myfile.gms and all included files in PC systems will be as follows: (1) the current directory, (2) the directories specified by inputdir in their respective order (here the directories: \mydir and \mydir2). Under Unix, the corresponding GAMS call will be:

> gams myfile idir \mydir:\mydir2

Note that the information in the option inputDir may be also transferred to GAMS by entering the individual directories separately. A maximum of 40 directories may be passed on in this manner. The number appended to InputDir is important since the earlier InputDir directories will be searched first.

The example above may alternatively be formulated in the following way:

> gams myfile idir1 mydir1 idir2 mydir2
Note that in this case the search order will be as follows:

1. current directory
2. mydir1
3. mydir2

Observe that we could modify the command in the following way:

> gams myfile idir3 \mydir1 idir2 \mydir2

Note that in this case the search order will be as follows:

1. current directory
2. mydir2
3. mydir3

Thus it is not the order in which the directories are specified that matters, but the number of the option `inputDir` that they have been assigned to.

**integer1..5 (integer)**: Integer communication cell N

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies an integer communication cell that may contain any integer number.

**interactiveSolver (boolean)**: Allow solver to interact via command line input

Available: Command line

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interaction with solvelink 0 is not supported</td>
</tr>
<tr>
<td>1</td>
<td>Interaction with solvelink 0 is supported</td>
</tr>
</tbody>
</table>

**intVarUp (integer)**: Set mode for default upper bounds on integer variables

Available: Command line, Option statement

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Set default upper bound for integer variables to +INF</td>
</tr>
<tr>
<td>1</td>
<td>Pass a value of 100 instead of +INF to the solver as upper bound for integer variables</td>
</tr>
<tr>
<td>2</td>
<td>Same as 0 but writes a message to the log if the level of an integer variable is greater than 100</td>
</tr>
<tr>
<td>3</td>
<td>Same as 2 but issues an execution error if the level of an integer variable is greater than 100</td>
</tr>
</tbody>
</table>

**iterLim (integer)**: Iteration limit of solver
Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies the maximum number of permitted solver iterations, before the solver terminates the run. If this limit is reached, the solver will terminate and will return solver status 2 ITERATION INTERRUPT. Note that the definition of what constitutes an iteration depends on the solver. For LP solvers, \textit{iterlim} often refers to the number of simplex iterations (i.e., pivots). For MIP solvers, \textit{iterlim} often refers to the cumulative number of simplex iterations over all solves of LP relaxations. Observe that \textit{iterlim} does not apply to all iterations. For example, it might not apply to barrier iterations and major iterations in nonlinear solvers. For these iterations solver-specific options need to be set. Moreover, some solver links might \textit{reinterpret} the value of this option. For example, if left at default, the solver link might use the default iteration limit of the solver.

Default: 2147483647

\textbf{iterUsd (integer): Number of iterations used}

Available: Attribute statement (use after solve)

This model attribute returns the number of iterations used after a solve.

\textbf{jobTrace (string): Job trace string to be written to the trace file at the end of a GAMS job}

Synonym: JT

Available: Command line

This option specifies a string that is written to the trace file at the end of a GAMS job.

\textbf{keep (boolean): Controls keeping or deletion of process directory and scratch files}

Available: Command line

This option controls whether to keep the process directory. In the process directory the temporary/scratch files are located, unless the options \textit{scrDir} or \textit{procDir} were used.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Delete process directory</td>
</tr>
<tr>
<td>1</td>
<td>Keep process directory</td>
</tr>
</tbody>
</table>

\textbf{libIncDir (string): LibInclude directory}

Synonym: LDIR

Available: Command line

This option specifies the name of the directory to be used by GAMS for $\textit{libInclude}$ files that do not have a full path specification. An absolute or relative path may be specified. If the option \textit{libIncDir} is not set, it will be set to the subdirectory \textit{inclib} in the GAMS standard locations. A relative path is relative to the GAMS system directory.

Note that if the option \textit{libIncDir} parameter is set, the default library include directories will only be searched, if the libInclude file cannot be found in the specified folder.
4.40 The GAMS Call and Command Line Parameters

Attention

Only one directory may be set with the option libIncDir. Thus the string specified will be treated as one directory. If additional directories are added, errors will be reported.

Consider the following example:

> gams myfile libIncDir mydir

Note that GAMS will search for any referenced libInclude file in the directory `<GAMS System Directory>/mydir` first.

license (string): Use alternative license file

Available: Command line

This option specifies the name the file that contains the GAMS license. It may be used to point to an explicit license file rather letting GAMS search for the default `gamslice.txt` in various locations including the GAMS system directory. The locations ("Data directories") can be printed by running `gamsinst -listdirs`, see installation notes for details. The license option should only be used by advanced users attempting to override internal license information.

limCol (integer): Maximum number of columns listed in one variable block

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of columns that are listed for each variable in the column listing in the listing file. Note that the value of zero will suppress the column listing.

Default: 3

limRow (integer): Maximum number of rows listed in one equation block

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of rows that are listed for each equation in the equation listing in the listing file. Note that the value of zero will suppress the equation listing.

Default: 3

line (integer): Line number of last solve of the corresponding model

Available: Attribute statement (use after solve)

This model attribute returns the line number of the last solve of the respective model.

linkUsed (integer): Integer number that indicates the value of SolveLink used for the last solve

Available: Attribute statement (use after solve)

This model attribute returns an integer number that indicates the value of the option solveLink that was used for the last solve.

listing (string): Switch default for "$on/offListing"

Available: Command line

For more info see $on/offListing.

Default: on
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Activate $offListing</td>
</tr>
<tr>
<td>on</td>
<td>Activate $onListing</td>
</tr>
</tbody>
</table>

**logFile (string):** Log file name

Synonym: LF

Available: Command line

This option is used in conjunction with the option logOption or short LO. If lo is set to 2 or 4, this option will specify the name of the log file name. The name provided by the option is completed using the current directory. If no log file is given, but the value of lo is 2 or 4, then the file name will be the input file name with the extension .log.

Consider the following GAMS call:

```plaintext
> gams trnsport lo=2 lf=myfile.log
```

Note that the resulting log file will redirected to the file myfile.log. It will contain the following lines:

--- Starting compilation

**logLine** (integer): Amount of line tracing to the log file

Synonym: LL

Available: Command line

This option may be used to limit the number of line tracing sent out to the log file during the compilation phase of a GAMS run. Note that setting this option to zero will cause the line tracing to be suppressed for all phases of the GAMS processing.

The log file that results from running the model [TRNSPORT] with the option ll=0 is shown below.

--- Starting compilation

If we compare this output to the output shown in the example of option logFile, we will observe that the line numbers are missing from this log file.

Default: 2
logOption (integer): Log option

Synonym: LO

Available: Command line

This option controls the location of the output log of a GAMS run. By default, GAMS directs the log of the run to the screen/console. If logOption is set to 2, the log will be redirected to a file. With logOption=3 all the output goes to the standard output. Note that if no file name is provided for the log through the option logFile, the file name will be the input file name with the extension .log. Observe that the settings zero and 2 may be used to permit jobs to run in the background.

To illustrate, consider the following call:

```plaintext
> gams trnsport lo=2
```

Note that the resulting log file, trnsport.log, will be identical to the file myfile.log that is shown as part of the description of the option logFile.

Default: 3

LP (string): Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Linear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

lstTitleLeftAligned (boolean): Write title of LST file all left aligned

Available: Command line

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Split LST title into left and right aligned part</td>
</tr>
<tr>
<td>1</td>
<td>Write LST title completely left aligned</td>
</tr>
</tbody>
</table>
marginals (*integer*): Indicator for marginals present

Available: Attribute statement (use after solve)

**maxExecError** (*integer*): Execution time error limit

Synonym: ExecErr

Available: Command line

This option puts an upper limit on the number of errors that may be found during execution or preprocessing associated with a solve statement. If more than maxExecError errors have been found GAMS will abort. This value can be overwritten with the function maxExecError.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No errors allowed limit</td>
</tr>
<tr>
<td>n</td>
<td>Max number allowed</td>
</tr>
</tbody>
</table>

**maxGenericFiles** (*integer*): Maximum number of generic file names tried at execution time file creation

Available: Command line, Option statement

In case of a failed writing of put files and GDX files via execute_unload (e.g. because the given path is invalid or the file is open by another program), GAMS tries to write to a generic file name instead. The number of file names tried can be specified with this option. To avoid this completely and throw an error right away, if the given name is invalid, set this to 0.

Default: 20

**maxInfes** (*real*): Maximum of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the maximum number of infeasibilities after a solve.

**maxProcDir** (*integer*): Maximum number of 225* process directories

Available: Command line

This option controls the maximum number of work file directories that may be generated by GAMS. By default they are called 225a, 225b, ... 225aa, 225ab ... Note that the label 225 may be changed with the option procDir.

Default: 700

**MCP** (*string*): Mixed Complementarity Problems - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Complementarity Problems is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.
**MCPRHoldFx (boolean):** Print list of rows that are perpendicular to variables removed due to the holdfixed setting

Available: Command line, Option statement, Attribute statement (use before solve)

If option holdfixed is true, fixed columns in row.column matches are removed from MCP models but the matching rows remain. These rows are ignored by the solver. This option causes a list of such rows to be included in the listing file prior to the solve summary.

Default: 0

**meanInfes (real):** Mean of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the mean of the infeasibilities after a solve.

**measure (no value):** Output of time and memory use since the last measure statement or the program beginning

Available: Option statement

This option has the effect that three measurements will be displayed: the memory and time usage since the last option statement measure and the total time used. See also the related option profile.

**memoryStat (no value):** Show memory statistics in the LST file

Available: Option statement

This option has the effect that memory statistics will be shown in the listing file.

**MINLP (string):** Mixed-Integer Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Integer Nonlinear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

**MIP (string):** Mixed-Integer Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Integer Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

**MIQCP (string):** Mixed Integer Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Integer Quadratically Constrained Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

**modelStat (integer):** Integer number that indicates the model status

Available: Attribute statement (use after solve)

This model attribute returns the model status after a solve. Observe that there are compile-time constants that are related to modelStat. Note that additional information to the values given in the table below is provided in section Model Status.
The default solver for models of the type Mathematical Program with Equilibrium Constraints is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

multi (string): Switch default for "$on/offMulti[R]"

Available: Command line

If this is set to on or off it sets the state of $on/offMulti. The value onR activates $onMultiR.

Default: off

multiPass (boolean): Multipass facility

Synonym: MP

Available: Command line
This option may be used to instruct GAMS to use a quick syntax checking compilation facility which does not require all items to be declared. This alternative is useful when a large model is assembled from smaller pieces. It allows slices of GAMS code to be independently checked for syntax errors.

Consider the following example:

\[
\begin{align*}
   a(i) &= b(i)*5 ;
   b(i) &= c(j) ;
\end{align*}
\]

By default, running a file containing just these two statements will generate the following listing file:

\[
\begin{align*}
   1 & a(i) = b(i)*5 ; \\
   **** & $140,120,140 \\
   2 & b(i) = c(j) ; \\
   **** & $140,120,149 \\
   120 & \text{Unknown identifier entered as set} \\
   140 & \text{Unknown symbol} \\
   149 & \text{Uncontrolled set entered as constant} \\
   **** & 6 \text{ ERROR(S) 0 WARNING(S)}
\end{align*}
\]

Note that both sets i and j have not been defined or initialized. In addition, the identifiers a, b and c have not been defined either. Further, an assignment cannot be made without the right-hand side of the assignment being known. However, in both assignments there is no data available for the right-hand side. If we run the same two lines with the option \texttt{mp=1}, we will get the following listing file:

\[
\begin{align*}
   1 & a(i) = b(i)*5 ; \\
   2 & b(i) = c(j) ; \\
   **** & $149 \\
   149 & \text{Uncontrolled set entered as constant} \\
   **** & 1 \text{ ERROR(S) 0 WARNING(S)}
\end{align*}
\]

Observe that the statements have now been processed independently of their context. They are now checked only for consistency. GAMS now assumes that the sets i and j, as well as the identifiers a, b, and c have been defined and, if necessary, initialized elsewhere. The only error that is reported is the inconsistency of indices in the second statement.

Default: 0

\textbf{NLP (string)}: Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type \texttt{Nonlinear Programs} is set during installation. The user may change this default by setting this option to the desired solver.
Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

**nodLim (integer):** Node limit in branch and bound tree

Available: Command line, Attribute statement (use before solve)

This option specifies the maximum number of nodes that are to be processed in the branch and bound tree search for a MIP problem. Note that setting `nodLim` can stop solutions that are exhibiting “excessive” iterations: if the limit is reached the algorithm will terminate, without obtaining optimality. In this case the solver status will be 4 TERMINATED BY SOLVER. Observe that a value of zero is interpreted as 'not set'.

Default: 0

**nodUsd (integer):** Number of nodes used by the MIP solver

Available: Attribute statement (use after solve)

This model attribute returns the number of nodes used by the MIP solver after a solve.

**noNewVarEqu (integer):** Triggers a compilation error when new equations or variable symbols are introduced

Available: Command line

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>AllowNewVarEqu</td>
</tr>
<tr>
<td>1</td>
<td>DoNotAllowNewVarEqu</td>
</tr>
</tbody>
</table>

**number (real):** Model instance serial number

Available: Attribute statement (use after solve)

This model attribute returns the model instance serial number. Note that the first model solved is assigned number 1, the second number 2 etc. The user may also set a value n and the next model solved will be assigned the number n+1.

**numDepnd (integer):** Number of dependencies in a CNS model

Available: Attribute statement (use after solve)

This model attribute returns the number of dependencies identified in a CNS model after a solve.

**numDVar (integer):** Number of discrete variables

Available: Attribute statement (use after solve)

This model attribute returns the number of discrete variables after a solve.

**numEqu (integer):** Number of equations
Available: Attribute statement (use after solve)
This model attribute returns the number of equations after a solve.

\texttt{numInfes} (integer): Number of infeasibilities
Available: Attribute statement (use after solve)
This model attribute returns the number of infeasibilities after a solve.

\texttt{numNLIns} (integer): Number of nonlinear instructions
Available: Attribute statement (use after solve)
This model attribute returns the number of nonlinear instructions after a solve.

\texttt{numNLNZ} (integer): Number of nonlinear nonzeros
Available: Attribute statement (use after solve)
This model attribute returns the number of nonlinear nonzeros after a solve.

\texttt{numNOpt} (integer): Number of nonoptimalities
Available: Attribute statement (use after solve)
This model attribute returns the number of nonoptimalities after a solve.

\texttt{numNZ} (integer): Number of nonzero entries in the model coefficient matrix
Available: Attribute statement (use after solve)
This model attribute returns the number of nonzero entries in the model coefficient matrix after a solve.

\texttt{numRedef} (integer): Number of MCP redefinitions
Available: Attribute statement (use after solve)
This model attribute returns the number of MCP equation-type redefinitions after a solve.

\texttt{numVar} (integer): Number of variables
Available: Attribute statement (use after solve)
This model attribute returns the number of variables after a solve.

\texttt{numVarProj} (integer): Number of bound projections during model generation
Available: Attribute statement (use after solve)
This model attribute returns the number of bound projections during model generation.

\texttt{objEst} (real): Estimate of the best possible solution for a mixed-integer model
Available: Attribute statement (use after solve)
This model attribute returns the estimate of the best possible solution for a MIP or other models with discrete variables. The model attribute is mainly used after solve.

Some GAMS solvers implement algorithms (e.g. branch-and-bound) that generate a bound on the objective function value for the best possible solution. Users may access this bound by using the model attribute \texttt{objEst}. Note that this is mainly used for models with discrete variables (e.g. MIP and MINLP), but some global solvers implement spatial branch-and-bound algorithms that also provide such a bound for purely continuous problems. In case the solver does not set the attribute, its value is \texttt{na}.

\texttt{objVal} (real): Objective function value
Available: Attribute statement (use after solve)
This model attribute returns the objective function value after a solve.

\texttt{on115} (boolean): Generate errors for unknown unique element in an equation
Available: Command line
This option generates errors for unknown unique elements in an equation.
Default: 0

</tr>
</tbody>
</table>

**optCA (real):** Absolute Optimality criterion solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies an *absolute termination tolerance* for a global solver. General problems are often extremely difficult to solve and proving that a solution that was found for a nonconvex problem is indeed the best possible solution can use enormous amounts of resources. The absolute gap is defined to be |PB-DB|. Here the primal bound PB is the objective function value of the best feasible solution found thus far and the dual bound DB is the current bound on the optimal value of the problem (i.e., lower bound in case of minimization and upper bound in case of maximization).

If the absolute gap is not greater than optCA, the solver will terminate and return solver status 1 NORMAL COMPLETION and model status 8 INTEGER SOLUTION (for a problem with discrete variables) or 2 LOCAL OPTIMAL or 7 FEASIBLE SOLUTION (for a problem without discrete variables). Note that this is a termination test only; setting this option should not change the global search.

**Note**

As this is an *absolute* criterion, setting the value to 100 means that the objective value will be within the 100 units of the true objective value.

Observe that a nonzero value for optCA will reduce solution time. However, it may cause the true integer optimum to be missed. This will be the case if at the time the solution algorithm stops, the value of the true integer optimum is within the tolerance specified by optCA of the best current solution. Therefore the reported solution could be the best, but it is guaranteed only to be within the tolerance of the true optimal solution.

Default: 0

**optCR (real):** Relative Optimality criterion solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies a *relative termination tolerance* for a global solver. General problems are often extremely difficult to solve and proving that a solution that was found for a nonconvex problem is indeed the best possible solution can use enormous amounts of resources. The precise definition of optCR depends on the solver. GAMS and some solvers use the following formula to compute the *optimality gap*:

$$\frac{|PB-DB|}{\max(|PB|,|DB|)}$$

Here the primal bound PB is the objective function value of the best feasible solution found thus far and the dual bound DB is the current bound on the optimal value of the problem (i.e., lower bound in case of minimization and upper bound in case of maximization). However, two other formulas are also widely used, namely

$$\frac{|PB-DB|}{|PB|}$$

and

$$\frac{|PB-DB|}{|DB|}$$

Different adjustments when the denominator approaches zero or bounds are of different signs will be applied. The solver will stop as soon as it has found a feasible solution proven to be within optCR of optimal, that is, the optimality gap falls below optCR.
Note

As optCR is specified in proportional terms relative to the objective value, a value of 0.1 means that the objective value will be within 10% of the true objective value.

Observe that the solver will stop after finding a solution proven to be optimal within the tolerance specified with optCR and thus the solution time may be reduced. However, setting this option may cause the true integer optimum to be missed. This will be the case if at the time the solution algorithm stops, the value of the true integer optimum is within the tolerance specified by optCR of the best current solution. Therefore the reported solution could be the best, but it is guaranteed only to be within the tolerance of the true optimal solution.

Default: 1.0E-04

optDir (string): Option file directory

Available: Command line

This option may be used to specify the name of the directory for solver option files. By default, the directory will be set to the current working directory.

optFile (integer): Default option file

Available: Command line, Attribute statement (use before solve)

This option instructs the solver to read an option file. The value of optFile determines which option file is used (see table below). Solver options allow users to manipulate the way solvers work. This may affect various solver functions including the choice of the branch and bound tree handling strategies. Please consult the solver manuals for options for each solver.

Note that this option is available as model attribute and command line parameter. Consider the following GAMS call:

> gams myfile optfile=1

Observe that the value of 1 for optFile means that the option file with the name solverName.opt will be used. Here solverName is the name of the respective solver. For example, if the solver CONOPT is used, the name of the respective option file is conopt.opt.

Note

If optFile is set with the model attribute in the GAMS input file, the value of the model attribute will override any optFile specifications on the command line.

Different values for optFile allow access to different option files for the same solver. Note that the following rule is used: if we specify optfile = n, then solvername.opt will be used for n=1, otherwise solvername.opX, solvername.oXX or solvername.XXX will be used, where X's are the characters representing the value of n, for n > 1. Observe that no option file will be used if the value of optFile is zero.

Default: 0

<table>

</tbody>
</table>
output \textit{(string):} Listing file name

Synonym: OO

Available: Command line

By default, the name of the output file (or listing file) is automatically created by combining
the name of the input file with the current directory and applying the standard output file
extension \textit{.lst}. This option may be used to specify an alternative name for the output file. If
the value is a file name without an absolute path, the current directory will compose the final
name. If the absolute path is included in the file name, then the name is used as specified.

Consider the following examples:

\begin{verbatim}
gams trnsport
\end{verbatim}
\begin{verbatim}
gams trnsport o=trnsport.out
\end{verbatim}
\begin{verbatim}
gams trnsport o=c:\test\trnsport.out
\end{verbatim}

Note that the first call will create an output file called \textit{trnsport.lst} (for PC and Unix platforms) in the current directory. The second call will create a file called \textit{trnsport.out} in the current directory. The last call will create the file as listed. If the directory \texttt{c:\test} does not exist, GAMS will exit with a parameter error.

Creation of the lst file can be suppressed by setting \texttt{output} to \texttt{NUL} under Windows or to
\texttt{/dev/null} on most Unix machines.

\textbf{pageContr (integer):} Output file page control option

Synonym: PC

Available: Command line

This option affects the page control in the listing file.

Default: 2

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No page control, with padding</td>
</tr>
<tr>
<td>1</td>
<td>FORTRAN style line printer format</td>
</tr>
<tr>
<td>2</td>
<td>No page control, no padding</td>
</tr>
<tr>
<td>3</td>
<td>Formfeed character for new page</td>
</tr>
</tbody>
</table>

\textbf{pageSize (integer):} Output file page size (=0 no paging)

Synonym: PS

Available: Command line

This option specifies the number of lines that are used on a page for printing the listing file.
The lower bound is zero, which is interpreted as +inf. That means that everything is printed
to one page.

Default: 0

\textbf{pageWidth (integer):} Output file page width
Synonym: PW

Available: Command line

This option sets the print width on a page in the listing file with a possible range from 72 to 32767. If the value is outside the allowed range, the default value will be used.

Note that .pw is also a put file attribute. In the context of the put writing facility, it may be used to set the page width of a put file. See page width for further details.

Default: 32767

**parmFile** *(string): Command Line Parameter include file*

Synonym: PF

Available: Command line

This option specifies the name of a secondary customization parameter file to use. It is used to augment the command line adding more command line parameters from a file. It is read from the current directory unless a path is specified. For an example, see section Specifying Options Through a Secondary Parameter File.

**pLicense** *(string): Privacy license file name*

Available: Command line

This option gives the name of a privacy license file that contains file encryption codes. A full path should be used. For more information, see Encrypting Files.

**prefixLoadPath** *(boolean): Prepend GAMS system directory to library load path*

Available: Command line

The OS environment variable to locate shared libraries used to be prefixed with the GAMS system directory. The option controls if this done or not. For the platforms Windows and AIX setting of this option has no impact.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not set GAMS system directory at beginning of library load path</td>
</tr>
<tr>
<td>1</td>
<td>Set GAMS system directory at beginning of library load path</td>
</tr>
</tbody>
</table>

**previousWork** *(boolean): Indicator for writing workfile with previous workfile version*

Available: Command line

When GAMS creates a workfile (e.g. using command line parameter restart) by default it uses the most recent version of the workfile format. GAMS is backward compatible with respect to workfile formats, i.e. newer GAMS versions can process workfiles generated by older GAMS version. As long as the workfile format has not changed older GAMS versions can even process workfiles generated by newer GAMS versions (using the forceWork=1 command line parameter). This particular command line parameter allows to create a workfile using the previous workfile format with the current GAMS version, so the previous GAMS version...
(and probably a few more versions back) will properly restart from this workfile even without issuing a warning.

This option is mostly used in combination with submissions to the NEOS server. Setting this option to 1 allows to submit NEOS jobs with a restart file even if the NEOS version is somewhat older than the local GAMS version.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Write workfile using the current version</td>
</tr>
<tr>
<td>1</td>
<td>Write workfile using the previous workfile version</td>
</tr>
</tbody>
</table>

priorOpt *(real)*: Priority option for variable attribute .prior

Available: Attribute statement (use before solve)

Instructs the solver to use the priority branching information passed by GAMS through variable suffix values variable.prior. If and how priorities are used is solver-dependent.

Default: 0

procDir *(string)*: Process Directory

Available: Command line

This option specifies the name of the process directory. If specified, the directory must already exist and it will not be deleted when GAMS cleans up. By default, the process directory name is chosen automatically from the list 225a, 225b, ..., 225aa, 225ab ..., by skipping over existing entries, and the directory will be deleted during cleanup if the option keep is not used. Very little is written to the process directory, but the scratch directory is used more, and the option scrDir takes its default from the process directory.

This option specifies the directory where the process directory should be created. If specified, the directory must already exist. While the process directory does not get cleaned automatically if the option procDir is set, this is not the case if the option procDirPath is used instead. Thus it allows to conveniently change the location of the process directory without changing the GAMS cleanup behavior. Note that if the location of the process directory is changed, the location of the default scratch directory will be changed accordingly (see option scrDir).

procTreeMemMonitor *(boolean)*: Monitor the memory used by the GAMS process tree

Available: Command line

Setting this option to 1 will cause GAMS to record the high-memory mark for the GAMS process tree (i.e. the gams or gams.exe process and all its children) and note this information in the log just prior to finishing. This is done via a separate thread that runs periodically (use option procTreeMemTicks to control how often) to construct the GAMS process tree and compute the memory usage for each process in it. There is some overhead with this so it is suggested to use this option only when needed and with a procTreeMemTicks value not smaller than the default.

In addition to the memory high-water marks (measured using both the size of the resident set and the virtual set used by each process in the tree) the report indicates the number of times this measurement was taken and any failures during this computation.

Default: 0
**Value** | **Meaning**
---|---
0 | Do not monitor memory usage for the GAMS process tree
1 | Start a thread to monitor memory usage for the GAMS process tree

**procTreeMemTicks** *(integer)*: Set wait interval between memory monitor checks: ticks = milliseconds

Available: Command line

Sets the wait interval in milliseconds between checks of the GAMS process tree memory usage: see `procTreeMemMonitor` for details.

Default: 2000

**procUsed** *(integer)*: Integer number that indicates the used model type

Available: Attribute statement (use after solve)

</tbody>
</table>

**profile** *(integer)*: Execution profiling

Available: Command line, Option statement

The *execution profile* of a GAMS run contains the individual and cumulative time required to execute the sections of the GAMS model, as well as information on memory use. The option `profile` controls whether an execution profile will be generated in the listing file. Observe that `profile` is available as command line parameter and option statement.

Note

The value for `profile` that is specified with an option statement in the GAMS input file overrides the value of `profile` that is passed through the command line.

Observe that an execution profile will be generated if the option `profile` is assigned a value larger than zero (zero is the default). Setting `profile` to 1 has the effect that execution times for each statement and the number of set elements over which the particular statement is executed will be reported. However, statements in programming flow control structures like loops will be omitted. Information on the execution of these statements will be included in
the profile if the value is \( n \), with \( n > 1 \). Note that an overview of the values for profile is given in the table at the end of this description.

Consider the following GAMS call:

\[
> \text{gams transport profile=1}
\]

This call causes the following additional lines to appear in the listing file:

\[
\begin{align*}
- & - 1 \text{ InitE} & 0.000 & 0.000 \text{ SECS} & 3 \text{ MB} \\
- & - 1 \text{ ExecInit} & 0.000 & 0.000 \text{ SECS} & 3 \text{ MB} \\
- & - 44 \text{ Assignment c} & 0.011 & 0.011 \text{ SECS} & 4 \text{ MB} & 6 \\
- & - 63 \text{ Assignment transport} & 0.000 & 0.011 \text{ SECS} & 4 \text{ MB} & 3 \\
- & - 65 \text{ Solve Init transport} & 0.000 & 0.012 \text{ SECS} & 4 \text{ MB} \\
- & - 57 \text{ Equation cost} & 0.001 & 0.013 \text{ SECS} & 4 \text{ MB} & 1 \\
- & - 58 \text{ Equation supply} & 0.000 & 0.013 \text{ SECS} & 4 \text{ MB} & 2 \\
- & - 59 \text{ Equation demand} & 0.000 & 0.013 \text{ SECS} & 4 \text{ MB} & 3 \\
- & - 65 \text{ Solve Fini transport} & 0.009 & 0.022 \text{ SECS} & 4 \text{ MB} & 19 \\
- & - 65 \text{ GAMS Fini} & 0.001 & 0.001 \text{ SECS} & 4 \text{ MB} \\
- & - 1 \text{ InitE} & 0.000 & 0.000 \text{ SECS} & 2 \text{ MB} \\
- & - 1 \text{ ExecInit} & 0.000 & 0.000 \text{ SECS} & 2 \text{ MB} \\
- & - 65 \text{ Solve Alg transport} & 0.000 & 0.000 \text{ SECS} & 2 \text{ MB} \\
- & - 65 \text{ Solve Read transport} & 0.002 & 0.002 \text{ SECS} & 2 \text{ MB} \\
- & - 67 \text{ Display} & 0.000 & 0.002 \text{ SECS} & 3 \text{ MB} \\
- & - 69 \text{ Display} & 0.000 & 0.002 \text{ SECS} & 3 \text{ MB} \\
- & - 69 \text{ GAMS Fini} & 0.001 & 0.001 \text{ SECS} & 3 \text{ MB}
\end{align*}
\]

Observe that the first column provides the line number in the input file of the statement that is executed.

The second column reports the type of the respective statement. For an overview of all GAMS statements, see section Classification of GAMS Statements. In addition, ExecInit denotes the beginning of the execution phase of the GAMS input file and GAMS Fini denotes the end of this phase. Note that as soon as a solve statement is processed, GAMS will pass control to the solver system. Once the solver has completed its task, GAMS will restart. Thus we have two ExecInit/GAMS Fini pairs in our example. Note that only equations are listed, and not variables. This reflects the fact that GAMS uses an equation based scheme to generate a model.

The third and fourth columns show the individual time needed to execute the statement and the cumulative time taken by the GAMS system so far.

The last column gives the number of assignments that were generated in the specified line.

In addition to the lines above, a profile summary is created at the end of the listing file. This summary contains (up to) ten of the slowest execution steps. The profile summary from transport.lst follows:

\[
\begin{align*}
\text{----- Profile Summary (17 records processed)} \\
& 0.011 & 0.004\text{GB} & 44 \text{ Assignment c (6)} \\
& 0.009 & 0.004\text{GB} & 65 \text{ Solve Fini transport (19)} \\
& 0.002 & 0.002\text{GB} & 65 \text{ Solve Read transport} \\
& 0.001 & 0.004\text{GB} & 65 \text{ GAMS Fini} \\
& 0.001 & 0.004\text{GB} & 57 \text{ Equation cost (1)} \\
& 0.001 & 0.003\text{GB} & 69 \text{ GAMS Fini}
\end{align*}
\]

Note that execution profiles and profile summaries are particularly useful for detecting the sources of performance problems. For further details, see section Finding the Causes for Slow Program Execution.

</table>

**profileFile** *(string)*: Write profile information to this file

Synonym: PFILE

Available: Command line

This option causes profiling information to be written to a file. Note that profiling information is only created with the setting `profile=1` or `profile=2`. For example such a file may have the following content:

```
1   -1   0.000   0.003 ExecInit
45   6   0.000   0.004 Assignment c
66   -1   0.000   0.004 Solve Init transport
58    1   0.000   0.004 Equation cost
60    2   0.000   0.004 Equation supply
62    3   0.000   0.004 Equation demand
66    19   0.015   0.004 Solve Fini transport
66    -1   0.000   0.004 GAMS Fini
  1   -1   0.000   0.002 ExecInit
  66   -1   0.000   0.002 Solve Read transport
  68   -1   0.000   0.003 Display
  68    -1   0.000   0.003 GAMS Fini
```

**profileTol** *(real)*: Minimum time a statement must use to appear in profile generated output

Synonym: PTOL

Available: Command line, Option statement

This option sets the profile tolerance in seconds. All statements that take less time to execute than this tolerance are not reported in the listing file. Note that this option is only effective if the value of the option `profile` is larger than zero.

Default: 0

**putDir** *(string)*: Put file directory

Synonym: PDir

Available: Command line

By default, put files are generated and saved in the current working directory. This option may be used to specify an alternative directory. Note that this option does not work if an absolute file name is provided through the `file` statement.

**putND** *(integer)*: Number of decimals for put files

Available: Command line

This sets the default for the put file attribute `.nd`.

Default: 2

**putNR** *(integer)*: Numeric round format for put files

Available: Command line

This sets the default for the put file attribute `.nr`.

Default: 1
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Item is displayed in F or E format</td>
</tr>
<tr>
<td>1</td>
<td>Item is rounded to fit given width and decimals</td>
</tr>
<tr>
<td>2</td>
<td>Item is displayed in scientific notation</td>

<tr>
<td>3</td>
<td>Item is rounded to fit given width</td>
</tr>
<tr>
<td>4</td>
<td>Item is displayed in F or E format ignoring given decimals</td>
</tr>
</tbody>
</table>

**putPS** (*integer*): Page size for put files

Available: Command line

This sets the default for the put file attribute `.ps`.

Default: 58

**putPW** (*integer*): Page width for put files

Available: Command line

This sets the default for the put file attribute `.pw`.

Default: 32767

**pyMultInst** (*integer*): GAMS/Python Multiple Instance Interpreter

Available: Command line

This option controls the setup of the Python interpreter for use in embedded Python code sections. If this option is set to 1 the embedded Python code can work with multiple independent Python sessions. If `pyMultInst` is set to 0 there is a single interpreter even with multiple parallel embedded Python sessions that all share the same data space. With `pyMultInst` set to 0 or 1, the environment variable `GMSPYTHONMULTINST` is set by GAMS to this value. If the option is not set the value will be taken from the user environment variable `GMSPYTHONMULTINST`. Note that setting this to 1 might cause problems when using third party modules and packages (e.g. `numpy` or modules that make use of it) and might also impact the performance.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use a single-session Python interpreter</td>
</tr>
<tr>
<td>1</td>
<td>Use a multi-session Python interpreter</td>
</tr>
</tbody>
</table>

**QCP** (*string*): Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Quadratically Constrained Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`. 
real1..5 (real): Real communication cell N

Available: Option statement, Attribute statement (use before solve)

This option specifies a real communication cell that may contain any real number.

reference (string): Symbol reference file

Synonym: RF

Available: Command line

If this option is specified, all symbol references will be written to the specified file. Setting rf or Reference to the string 'default' will cause GAMS to create a reference file with the file root name of the GAMS input file and the extension ref. Thus the call

`> gams trnsport rf=default`

will generate the reference file `trnsport.ref`.

referenceLineNo (string): Controls the line numbers written to a reference file

Synonym: RFLN

Available: Command line

Default: actual

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>actual</td>
<td>Actual line number of symbol reference</td>
</tr>
<tr>
<td>start</td>
<td>Line number where the statement with the reference starts</td>
</tr>
</tbody>
</table>

reform (integer): Reformulation level

Available: Option statement, Attribute statement (use before solve)

This option triggers an objective function reformulation. The interpretation depends on the solver. The solvers MINOS and SNOPT support this option. Note that the default value is zero and the range is [-2147483647,2147483647].

resCalc (real): Time spent in function and derivative calculations (deprecated)

Available: Attribute statement (use after solve)

resDeriv (real): Time spent in derivative calculations (deprecated)

Available: Attribute statement (use after solve)

resGen (real): Time GAMS took to generate the model in CPU seconds (deprecated)

Available: Attribute statement (use after solve)

This model attribute returns the time GAMS took to generate the model in CPU seconds.

resIn (real): Time to import model (deprecated)
4.40 The GAMS Call and Command Line Parameters

Available: Attribute statement (use after solve)

**resLim** *(real):* Wall-clock time limit for solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies the time in seconds that the solver can run before it can terminate and return the solver status 3 **RESOURCE INTERRUPT**. The solver should start the clock soon after it starts, so the time required to read in the problem and do any reformulations, preprocessing or presolving is included in the time limit. Where possible, the time limit applies to the wall-clock time: this behavior translates well to multi-threaded solves. Moreover, some solver links might *reinterpret* the value of this option. For example, if left at default (1e+10), the solver link might use the default time limit of the solver.

Note

This value could be automatically reduced, if required because of **etLim**.

Default: 10000000000

**resOut** *(real):* Time to export solution (deprecated)

Available: Attribute statement (use after solve)

**restart** *(string):* Name of a restart file, see **The Save and Restart Feature**

Synonym: R

Available: Command line

This option specifies the name of a work file that was written with the option **save** that will be used to restart the GAMS program. The work file is also called **restart file**. For more information including examples, see chapter **The Save and Restart Feature**.

**restartNamed** *(string):* Name of another matching restart file, see **Obfuscated Work Files**

Synonym: RN

Available: Command line

**resUsd** *(real):* Time the solver used to solve the model in seconds

Available: Attribute statement (use after solve)

This model attribute returns the time in seconds used by the solver. Wherever possible, the units used (wall-clock time vs. CPU time) will be the same as used by the **reslim** option.

**RMINLP** *(string):* Relaxed Mixed-Integer Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type **Relaxed Mixed Integer Nonlinear Programs** is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.
RMIP (string): Relaxed Mixed-Integer Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mixed Integer Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

RMIQCP (string): Relaxed Mixed Integer Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mixed Integer Quadratically Constrained Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

RMPEC (string): Relaxed Mathematical Programs with Equilibrium Constraints - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mathematical Program with Equilibrium Constraints is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to default.

rngBndMax (real): Maximum absolute non-zero value of bounds passed to the solver (excluding infinity)

Available: Attribute statement (use after solve)

rngBndMin (real): Minimum absolute non-zero value of bounds passed to the solver

Available: Attribute statement (use after solve)

rngMatMax (real): Maximum absolute non-zero value of coefficients in the model matrix passed to the solver (excluding infinity)

Available: Attribute statement (use after solve)

Note
For non-linear models, the value of the coefficients looked at depends on the activity levels of one or more of the variables. More details are described here.

rngMatMin (real): Minimum absolute non-zero value of coefficients in the model matrix passed to the solver

Available: Attribute statement (use after solve)
Note
For non-linear models, the value of the coefficients looked at depends on the activity levels of one or more of the variables. More details are described here.

rngRhsMax (real): Maximum absolute non-zero value of right hand sides passed to the solver (excluding infinity)

Available: Attribute statement (use after solve)

rngRhsMin (real): Minimum absolute non-zero value of right hand sides passed to the solver

Available: Attribute statement (use after solve)

rObj (real): Objective function value from the relaxed solve of a mixed-integer model when the integer solver did not finish

Available: Attribute statement (use after solve)

This model attribute returns the objective function value from the relaxed solve of a MIP when the integer solver did not finish.

save (string): Creates a work file, see The Save and Restart Feature

Synonym: S

Available: Command line

This option specifies the name of a work file to be written. The work file is intended to be used later to restart the GAMS program and it is also frequently referred to as save file or restart file. If no explicit file extension is provided, the default file extension .g00 is used. If no specific file path is provided the work file is created in the current directory.

Note
- The character "?" is not allowed in save file names - that use was intended for old (pre-GAMS 21.7) save files only.
- Save files are platform-independent.

For further information including examples, see chapter The Save and Restart Feature.

saveObfuscate (string): Creates an obfuscated work file, see Obfuscated Work Files

Synonym: SO

Available: Command line

savePoint (integer): Save solver point in GDX file

Synonym: SP

Available: Command line, Option statement, Attribute statement (use before solve)

This option instructs GAMS to save a point format GDX file that contains the information on the current solution point.

Default: 0
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No point GDX file is to be saved</td>
</tr>
<tr>
<td>1</td>
<td>A point GDX file from the last solve is to be saved</td>
</tr>
<tr>
<td>2</td>
<td>A point GDX file from every solve is to be saved</td>
</tr>
<tr>
<td>3</td>
<td>A point GDX file from the last solve is to be saved in the scratch directory</td>
</tr>
<tr>
<td>4</td>
<td>A point GDX file from every solve is to be saved in the scratch directory</td>
</tr>
</tbody>
</table>

**scaleOpt (boolean):** Employ user specified variable and equation scaling factors

Available: Attribute statement (use before solve)

This option determines whether GAMS will employ user-specified variable and equation scaling factors. It must be set to a nonzero value if scaling factors are to be used. For more details on scaling, see section Model Scaling - The Scale Option.

Default: 0

**scrDir (string):** Scratch directory

Synonym: SD

Available: Command line

This option specifies the name of the scratch directory. The scratch directory is used by GAMS for intermediate files that are generated during execution. The scratch directory and all its contents are usually deleted at the end of the GAMS run. By default, the scratch directory takes its value from the process directory that is specified with the option procDir. If neither the scratch directory nor the process directory are specified, the scratch directory will be set to a subdirectory of the current working directory with an internally generated name. If the scratch directory is specified, the respective directory must already exist and neither the content nor the directory itself will be deleted by GAMS at the end of the run.

Note that the option solveLink may be used to reduce or eliminate the need for intermediate files.

**scrExt (string):** Scratch file extension to be used with temporary files

Synonym: SE

Available: Command line

This option specifies the name of the extension for the temporary files that GAMS is generating during execution.

Default: dat

**scriptExit (string):** Program or script to be executed at the end of a GAMS run

Available: Command line

By default, GAMS does not call an exit script anymore. If this is required, the option scriptExit has to be set explicitly to the script that should be called after GAMS terminates. Note that an empty template of an exit script is in the GAMS system directory: it is called gmsxitnt.cmd for Windows and gmsxitus.run for Unix.

**scriptFirst (string):** First line to be written to GAMSNEXT file.
Synonym: SF

Available: Command line

This option specifies the first line written to `gamsnext`. The default is an empty string and the first line is not written.

`scrNam (string):` Work file names stem

Synonym: SN

Available: Command line

This option specifies the name stem that is used to complete the names of intermediate work files. Note that the name stem must have at least one ‘?’. The name will be completed with the scratch directory and the standard scratch name extension.

`seed (integer):` Random number seed

Available: Command line, Option statement

This option specifies the seed that is used for the pseudo random number generator.

Default: `3141`

`showOSMemory (integer):` Show the memory usage reported by the Operating System instead of the internal counting

Available: Command line

Default: `0`

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Show memory by internal accounting</td>
</tr>
<tr>
<td>1</td>
<td>Show resident set size reported by operating system</td>
</tr>
<tr>
<td>2</td>
<td>Show virtual set size reported by operating system</td>
</tr>
</tbody>
</table>

`solPrint (integer or string):` Solution report print option

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the printing of the solution listing to the listing file.

N.B: the command line accepts the string and numeric value, the option statement only the string value, and the attribute statement accepts the numeric value and compile-time constant. The table below offers an overview of the different types of values and a description of the associated meaning.

<table>
<thead>
<tr>
<th>String Value</th>
<th>Numeric Value</th>
<th>Compile-Time Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>0</td>
<td><code>solprint.Off</code></td>
<td>Remove solution listings following solves</td>
</tr>
<tr>
<td>on</td>
<td>1</td>
<td><code>solprint.On</code></td>
<td>Include solution listings following solves</td>
</tr>
<tr>
<td>silent</td>
<td>2</td>
<td><code>solprint.Silent</code></td>
<td>Suppress all solution information</td>
</tr>
</tbody>
</table>
solSlack (boolean): Causes the equation output in the listing file to contain slack variable values instead of level values

Available: Option statement

If the value of this option is set to 1, the equation output in the listing file will contain slack variable values instead of level values.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>includes equation levels in the solution part of the LST file following solves</td>
</tr>
<tr>
<td>1</td>
<td>includes equation slacks in the solution part of the LST file following solves</td>
</tr>
</tbody>
</table>

solveLink (integer): Solver link option

Synonym: SL

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies what solver linking conventions are used when GAMS executes a solve statement. Note that values 3 and 6 are relevant for grid computing. Observe that there are compile-time constants that are associated with this option. When the model instance is saved to the scratch directory (values 0, 1, 2, and 3), the solution produced by the solve is also written to the scratch directory and read in by GAMS when the execution resumes.

Default: 2

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Model instance and entire GAMS state saved to scratch directory, GAMS exits (and vacates memory), and the solver script is called. After the solver terminates, GAMS restarts from the saved state and continues to executing</td>
</tr>
<tr>
<td>1</td>
<td>Model instance saved to scratch directory, the solver is called from a shell while GAMS remains open</td>
</tr>
<tr>
<td>2</td>
<td>Model instance saved to scratch directory, the solver is called with a spawn (if possible) or a shell (if spawn is not possible) while GAMS remains open - If this is not supported by the selected solver, it gets reset to 1 automatically</td>
</tr>
<tr>
<td>3</td>
<td>Model instance saved to scratch directory, the solver starts the solution and GAMS continues in a grid computing environment</td>
</tr>
<tr>
<td>4</td>
<td>Model instance saved to scratch directory, the solver starts the solution and GAMS waits for the solver to come back but uses same submission process as 3 (test mode)</td>
</tr>
<tr>
<td>5</td>
<td>The model instance is passed to the solver in-memory - If this is not supported by the selected solver, it gets reset to 2 automatically</td>
</tr>
<tr>
<td>6</td>
<td>The model instance is passed to the solver in-memory, the solver starts the solution and GAMS continues in a grid computing environment</td>
</tr>
<tr>
<td>7</td>
<td>The model instance is passed to the solver in-memory, the solver starts the solution and GAMS waits for the solver to come back but uses same submission process as 6 (test mode)</td>
</tr>
</tbody>
</table>

solveOpt (integer or string): Multiple solve management
Available: Option statement, Attribute statement (use before solve)

This option will instruct GAMS how to manage the model solution if only part of the variables and equations in the particular problem are solved.

Observe that this option is available as model attribute and option statement. The values for model attributes are numeric, while the values for option statements are text strings. In addition, there are compile-time constants that are associated with this option. The first of the two tables below offers an overview of how the different types of values are related and the second table gives the values in numerical terms and a description of the associated meaning.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Compile-Time Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>replace</td>
<td>solveOpt.Replace</td>
</tr>
<tr>
<td>1</td>
<td>merge</td>
<td>solveOpt.Merge</td>
</tr>
<tr>
<td>2</td>
<td>clear</td>
<td>solveOpt.Clear</td>
</tr>
</tbody>
</table>

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The solution information for all equations appearing in the model is completely replaced by the new model results; variables are only replaced if they appear in the final model</td>
</tr>
<tr>
<td>1</td>
<td>The solution information for all equations and variables is merged into the existing solution information</td>
</tr>
<tr>
<td>2</td>
<td>The solution information for all equations appearing in the model is completely replaced; in addition, variables appearing in the symbolic equations but removed by conditionals will be removed</td>
</tr>
</tbody>
</table>

**solver (string):** Default solver for all model types that the solver is capable to process

Available: Command line, Option statement

The command line parameter `solver=abc` initializes the default solver for the model types the solver "abc" is capable of to abc. This initialization is done before the default solvers of individual model types are set via command line parameters. Consider the following example:

```
> gams transp lp=conopt solver=soplex
```

Note that this GAMS call will first set the solver Soplex as the solver for the model types LP and RMIP, since these are the model types that Soplex can handle. Then Conopt will be reset as the default solver for LPs. Observe that the order of these parameters on the command line is irrelevant. If multiple occurrences of the option `solver` appear, the last entry will set the value of the option.

In addition, the solver for multiple model types may be set in the GAMS model source code via the following statement:

```
option solver = abc;
```

This statement sets the solver for the model types the solver abc can handle to abc. Note that in such an option statement the order of other solver setting options is significant. Consider the following example:

```
option lp=conopt, solver=soplex;
```
This statement will first set the solver for LPs to Conopt and in the next step to SOPLEX because SOPLEX is capable of handling the model type LP. In some cases it makes sense to set a solver twice. Consider the following example:

```
option solver=conopt, solver=cbc;
```

This option statement has the effect that models of the types CNS, DNLP, NLP, QCP, RMIQCP or RMINLP will be solved with Conopt and models of the types LP, RMIP or MIP will be solved with CBC.

Note that as usual, a specification of a solver through an option statement in the GAMS source takes precedence over a specification on the command line.

`solverCntr (string):` Solver control file name

- Synonym: SCNTR
- Available: Command line
- This option specifies the solver control file name. Note that the name is completed with the scratch directory and the scratch extension.

`solverDict (string):` Solver dictionary file name

- Synonym: SDICT
- Available: Command line
- This option specifies the solver dictionary file name. Note that the name completed with the scratch directory and the scratch extension.

`solverInst (string):` Solver instruction file name

- Synonym: SINST
- Available: Command line
- This option specifies the solver instruction file name. Note that the name is completed with the scratch directory and the scratch extension.

`solverMatr (string):` Solver matrix file name

- Synonym: SMATR
- Available: Command line
- This option specifies the solver matrix file name. Note that the name is completed with the scratch directory and the scratch extension.

`solverSolu (string):` Solver solution file name

- Synonym: SSOLU
- Available: Command line
- This option specifies the solver solution file name. Note that the name is completed with the scratch directory and the scratch extension.

`solverStat (string):` Solver status file name

- Synonym: SSTAT
- Available: Command line
- This option specifies the solver status file name. Note that the name is completed with the scratch directory and the scratch extension.

The model attribute indicates the solver termination condition. Observe that there are compile-time constants that are related to `solveStat`. Note that additional information to the values given in the table below is provided in section Solver Status.
4.40 The GAMS Call and Command Line Parameters

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>

<td>Solve Processing Skipped</td>
</tr>
<tr>
<td>13</td>
<td>System Failure</td>
</tr>
</tbody>
</table>

**stepSum** *(boolean)*: Summary of computing resources used by job steps

Available: Command line

This option controls the generation of a step summary of the processing times taken by GAMS during a given run.

For example, the call

```
> gams trnsport stepsum=1
```

will generate the following *step summaries* in the listing file:

```
STEP SUMMARY: 0.016 0.016 STARTUP
               0.005 0.005 COMPIILATION
               0.065 0.065 EXECUTION
               0.001 0.001 CLOSEDOWN
               0.087 0.087 TOTAL SECONDS
               0.089 0.089 ELAPSED SECONDS
               3.942 3.942 MAX HEAP SIZE (MB)
```

Note that this step summary will be printed before the model is sent to the solver, thus it may be found before the solve summary. The second step summary will be printed after solution, it will appear at the very end of the listing file:

```
STEP SUMMARY: 0.004 0.020 STARTUP
               0.000 0.005 COMPIILATION
               0.003 0.068 EXECUTION
               0.000 0.001 CLOSEDOWN
               0.007 0.094 TOTAL SECONDS
               0.239 0.328 ELAPSED SECONDS
               2.899 3.942 MAX HEAP SIZE (MB)
```

Observe that the first column reports the time for the individual section of the run, while the second column reports accumulated times including previous sections.

Default: 0
**strictSingleton** *(boolean):* Error if assignment to singleton set has multiple elements

Available: Command line, Option statement

This option affects the behavior of a membership assignment to a singleton set. If the value is set to zero, GAMS will not complain about a singleton set with more than one element, but will take only the first element. However, if the value is set to 1, a singleton set definition with more than one element will cause an error. Also, if this option is set as a command line parameter it initializes the state of the dollar control option `$on/offStrictSingleton`. So, it influences the singleton set checking at both compile- and execution time.

Default: 1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No step summary</td>
</tr>
<tr>
<td>1</td>
<td>Step summary printed</td>
</tr>
</tbody>
</table>

**stringChk** *(integer):* String substitution options

Available: Command line

This option affects the result of the check for `%xxx%` symbols. Note that `%xxx%` symbols may be environment variables (also at execution time) or compile-time variables.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No substitution if symbol undefined and no error</td>
</tr>
<tr>
<td>1</td>
<td>Error if symbol undefined</td>
</tr>
<tr>
<td>2</td>
<td>Remove entire symbol reference if undefined and no error</td>
</tr>
</tbody>
</table>

**subSys** *(string):* Name of subsystem configuration file

Available: Command line

This option specifies the name of the configuration file that contains solver defaults and other information. This option should be used only by advanced users who attempt to override internal subsystem information. In case you want to add a solver to your GAMS system, please inspect the section Adding Solvers via gamsconfig.yaml.

**subSystems** *(no value):* Lists all solvers available as well as the current default and active solvers in the LST file

Available: Option statement

This option has the effect that all available subsystems will be displayed in the listing file. Note that a solver is considered a subsystem.

**suffixDLVars** *(string):* Switch default for "$on/offSuffixDLVars"
Available: Command line

For more info see $on/offSuffixDLVars.

Default: off
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Activate $offSuffixDLVars</td>
</tr>
<tr>
<td>on</td>
<td>Activate $onSuffixDLVars</td>
</tr>
</tbody>
</table>

**sumInfs** *(real)*: Sum of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the sum of infeasibilities after a solve.

**suppress** *(boolean)*: Compiler listing option

Available: Command line

If set to 1, this option will suppress the echoing of the contents of the input file(s) to the listing file. Note that this option is similar in functionality to the dollar control option $offlisting.

Note

The dollar control options $on/offlisting will affect the echo print in the listing file only if suppress is set to zero. If suppress is set to 1, the input file(s) will not be echoed to the listing file and the dollar control options will not have any effect on the listing file.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Standard compiler listing</td>
</tr>
<tr>
<td>1</td>
<td>Suppress compiler listing</td>
</tr>
</tbody>
</table>

**symbol** *(string)*: Symbol table file

Available: Command line

This option specifies the name of a partial symbol table that may be written in conjunction with reference files.

**symPrefix** *(string)*: Prefix all symbols encountered during compilation by the specified string in work file

Available: Command line

**sys10** *(boolean)*: Changes rpower to ipower when the exponent is constant and within 1e-12 of an integer

Available: Command line, Option statement

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disable conversion</td>
</tr>
<tr>
<td>1</td>
<td>Enable conversion</td>
</tr>
</tbody>
</table>

**sys11** *(integer)*: Dynamic resorting if indices in assignment/data statements are not in natural order

Available: Command line, Option statement
Speed-up for expressions containing constant indices or indices that are not in the natural order at the cost of increased memory use.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic optimization/restructuring of data</td>
</tr>
<tr>
<td>1</td>
<td>No optimization</td>
</tr>
<tr>
<td>2</td>
<td>Always optimize/restructure</td>
</tr>
</tbody>
</table>

**sys12 (integer):** Pass model with generation errors to solver

Synonym: noSolveSkip

Available: Command line, Option statement

Default: 0

**sys15 (integer):** Automatic switching of data structures used in search records

Available: Command line, Option statement

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic switching to dense data structures</td>
</tr>
<tr>
<td>1</td>
<td>No switching</td>
</tr>
<tr>
<td>2</td>
<td>Always switch</td>
</tr>
<tr>
<td>1x</td>
<td>Print additional information in lst file</td>
</tr>
</tbody>
</table>

**sys16 (integer):** Disable search record memory (aka execute this as pre-GAMS 24.5)

Available: Command line, Option statement

Default: 0

**sys17 (integer):** Disable sparsity trees growing with permutation (aka execute this as pre-GAMS 24.5)

Available: Command line, Option statement

Default: 0

**sys18 (integer):** Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers

Available: Command line, Option statement

By default GAMS accepts floating-point numbers with arbitrarily many digits and converts them to correctly-rounded double-precision values. This option selects a backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers (see also the offDigit dollar control option).

Default: 0
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use modern scheme for reading floating-point numbers</td>
</tr>
<tr>
<td>1</td>
<td>Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers</td>
</tr>
</tbody>
</table>

**sys19** *(integer)*: Disable permutation on Column Generation (aka execute this as pre-GAMS 36)

Available: Command line, Option statement
Default: 0

**sysDir** *(string)*: GAMS system directory where GAMS executables reside

Available: Command line

This option sets the GAMS system directory. It is useful if there are multiple systems installed on the machine or when GAMS is called from an external system like Visual Basic.

**sysIdent** *(real)*: Solver identification number

Available: Attribute statement (use after solve)

**sysIncDir** *(string)*: SysInclude directory

Synonym: SDIR

Available: Command line

This option specifies the name of the directory to be used by GAMS for sysinclude files that do not have a full path specification. An absolute or relative path may be specified. If this option is not set, it will be set to the GAMS system directory.

Note that if this option is set, the default system include directory will not be searched.

Attention

Only one directory may be set with the option sDir. Thus the string specified will be treated as one directory. If additional directories are added, errors will be reported.

Consider the following example:

> gams myfile sdir mydir

Note that GAMS will search for any referenced sysinclude file in the directory mydir.

**sysOut** *(boolean or string)*: Solver Status file reporting option

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls whether additional solver generated output (the solver status file) is included in the listing file. Note that the contents of the solver status file are useful for debugging or to get additional information about a solver run. Normally, only those messages flagged by the solver as destined for the listing file will be listed. If the solver crashes or encounters any unexpected difficulties, the contents of the solver status file will be automatically sent to the listing file.

Note that the boolean values *(off: 0 and off: 1)* are deprecated, they are only relevant for backward compatibility. The table below gives the boolean values and the associated meaning.
### 4.40 The GAMS Call and Command Line Parameters

#### String Value | Meaning
--- | ---
off | Suppress additional solver generated output
on | Include additional solver generated output

Default: **off**

**sysVer** (*real*): Solver version

Available: Attribute statement (use after solve)

**tabIn** (*integer*): Tab spacing

Available: Command line

This option sets the tab spacing. By default, tabs are not allowed in GAMS. However, the most common setting is 8. As a result, the tabs are at columns 1, 9, 17, ... and the intermediate columns are replaced by blanks.

Default: **8**

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Tabs are not allowed</td>
</tr>
<tr>
<td>1</td>
<td>Tabs are replaced by blanks</td>
</tr>
<tr>
<td>n</td>
<td>Tabs are 1, n+1, 2n+1,... (default: n=8)</td>
</tr>
</tbody>
</table>

**tFormat** (*boolean*): Time format

**Synonym**: **TF**

Available: Command line

This option controls the time format in the listing file. The three date formats correspond to the various conventions used around the world. For example, the time 7:45 PM will be written as 19:45:00 with the default **tf** value of zero and as 19.45.00 with **tf=1**.

Default: **0**

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Time as hh:mm:ss</td>
</tr>
<tr>
<td>1</td>
<td>Time as hh.mm.ss</td>
</tr>
</tbody>
</table>

**threads** (*integer*): Number of threads to be used by a solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of threads (and thereby the number of processors) to be used by a solver. If the number is greater than the number of available processors, it will be reduced to the number of processors available. Note that a value of zero implies the number of threads used will be equal to the number of processors available.

Default: **1**
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use number of available processors</td>
</tr>
<tr>
<td>n</td>
<td>Use n threads</td>
</tr>
<tr>
<td>minus_n</td>
<td>Number of processors to leave free for other tasks</td>
</tr>
</tbody>
</table>

**threadsAsync** (*integer*): Limit on number of threads to be used for asynchronous solves (solveLink=6)

Available: Command line, Option statement

Default: -1

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use number of available processors</td>
</tr>
<tr>
<td>n</td>
<td>Use n threads</td>
</tr>
<tr>
<td>minus_n</td>
<td>Number of processors to leave free for other tasks</td>
</tr>
</tbody>
</table>

**timer** (*integer*): Instruction timer threshold in milli seconds

Available: Command line

This option specifies an instruction timer threshold in milli seconds. That means that only details about internal GAMS instructions that took more than n milli seconds are echoed to the log.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interpreted as +inf, no details echoed</td>
</tr>
<tr>
<td>n</td>
<td>Echo all details about internal GAMS instructions that took more than n milli seconds to the log</td>
</tr>
</tbody>
</table>

**tolInfeas** (*real*): Infeasibility tolerance for an empty row of the form a.. 0*x =e= 0.0001;

Available: Attribute statement (use before solve)

This option specifies the infeasibility tolerance for an empty row of the following form:

a.. 0*x =e= 0.0001;

If the option is not set, a tolerance of 10 times the machine precision will be used. Empty rows that fail this infeasibility check will be flagged with the listing file message Equation infeasible due to rhs value.

**tolInfRep** (*real*): This attribute sets the tolerance for marking infeasible in the equation listing

Available: Attribute statement (use before solve)

This option sets the tolerance for marking an equation infeasible in the equation listing. Note that the default value is 1.0e-13.

Default: 1.0E-13
**tolProj** (real): Tolerance for setting solution values to a nearby bound when reading a solution

Available: Attribute statement (use before solve)

When a solution is returned from a solver, equation and variable level values that are very close to their lower or upper bounds are projected or moved to that bound, and a count of the projections/moves made is included in the solution report’s REPORT SUMMARY. This option controls the relative tolerance used in testing for closeness: project if \( \text{abs(level-bound)} < \text{tolproj} \times (1+\text{abs(level)}) \). For MCP models, this projection is also applied to the variable marginal values. In this case the projection count is not incremented and the test is an absolute and not a relative test: project if \( \text{abs(marginal)} < \text{tolproj} \).

Default: 0

**trace** (string): Trace file name

Available: Command line

This option specifies the trace file name and causes a trace file to be written. Note that if a previous trace file of the same name already exists, then all new data output will be appended. Therefore, users should be careful to delete all old versions of the trace file if the a file name is reused and they do wish the new data to be appended.

**traceLevel** (integer): Modelstat/Solvestat threshold used in conjunction with action=GT

Synonym: TL

Available: Command line

Default: 0

**traceOpt** (integer): Trace file format option

Available: Command line

This option specifies the format of the trace file. Note that several different types of trace files may be created, depending on what output information is desired.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Solver and GAMS step trace</td>
</tr>
<tr>
<td>1</td>
<td>Solver and GAMS exit trace</td>
</tr>
<tr>
<td>2</td>
<td>Solver trace only</td>
</tr>
<tr>
<td>3</td>
<td>Solver trace only in format used for GAMS performance world</td>
</tr>
<tr>
<td>5</td>
<td>Gams exit trace with all available trace fields</td>
</tr>
</tbody>
</table>

**tryInt** (real): Whether solver should make use of a partial integer-feasible solution

Available: Attribute statement (use before solve, reset by solve statement)

Signals the solver to make use of a partial or near-integer-feasible solution stored in current variable values to get a quick integer-feasible point. The exact form of implementation depends on the solver and may be partly controlled by solver settings or options. See the solver manuals for details.
tryLinear (real): Examine empirical NLP model to see if there are any NLP terms active. If there are none the default LP solver will be used

Available: Attribute statement (use before solve)

If this option is set to 1, empirical NLP models will be examined to determine if there are any active NLP terms. If there are none, the default LP solver will be used. The procedure also checks to see if QCP and DNLP models can be reduced to an LP; MIQCP and MINLP can be solved as a MIP; RMIQCP and RMINLP can be solved as an RMIP. Note that the default value is zero.

user1..5 (string): User string N

Synonym: U1

Available: Command line

This option permits users to enter a text for up to 5 user-defined options. The double dash parameters supersede these parameters.

warnings (integer): Number of warnings permitted before a run terminates

Available: Command line

This option specifies the maximum number of allowable warnings, before the run terminates.

Default: ∞

workDir (string): Working directory

Synonym: WDir

Available: Command line

This option sets the working directory. This option is useful when GAMS is called from an external system like Visual Basic. If it is not specified, the working directory will be set to the directory curDir.

workFactor (real): Memory Estimate multiplier for some solvers

Available: Command line, Attribute statement (use before solve)

This option instructs the solver how much workspace to allocate for problem solution relative to the solver-computed estimate. For example, setting the value to 2 will double the memory estimate. In cases where a solver allocates memory dynamically as it is needed, this option will have no effect. Note that in cases where both options workfactor and workSpace are specified, the value for workSpace will take precedence.

Default: 1

workSpace (real): Work space for some solvers in MB

Available: Command line, Attribute statement (use before solve)

This option instructs the solver how much workspace in Megabytes to allocate. If it is not specified by the user, the solver will estimate the size. In cases where a solver allocates memory dynamically as it is needed, this option will have no effect, or it may be used as a memory limit.
4.40 The GAMS Call and Command Line Parameters

xSave (string): Creates a compressed work file

Synonym: XS
Available: Command line

This option specifies the name of a save file written in ASCII format in older GAMS systems (versions older than 21.7), in order for the save file to be platform dependent and may be moved to machines with different operating systems.

In GAMS systems from release 22.3 and newer this option has the effect that compressed save files are written.

xSaveObfuscate (string): Creates a compressed obfuscated work file

Synonym: XSO
Available: Command line

zeroRes (real): The results of certain operations will be set to zero if abs(result) LE ZeroRes

Available: Command line

This option specifies the threshold value for internal rounding to zero in certain operations.

Default: 0

zeroResRep (boolean): Report underflow as a warning when abs(results) LE ZeroRes and result set to zero

Available: Command line

This option causes GAMS to issue warnings whenever a rounding occurs because of the setting of the option zeroRes.

Default: 0

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No warning when a rounding occurs because of ZeroRes</td>
</tr>
<tr>
<td>1</td>
<td>Issue warnings whenever a rounding occurs because of ZeroRes</td>
</tr>
</tbody>
</table>

zeroToEps (string): Treat zero as eps

Available: Option statement

When this is set to on, zero values are interpreted as EPS when loading non-scalar parameters from GDX or embedded code at execution time. Also, when deriving a set from a parameter in a GDX file at execution time, set records will be created for parameter records with value 0, if zeroToEps is set to on, but not, if it is off.

See dollar control option $onEps for the compile-time equivalent.

Default: off

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Treat Zero as Zero</td>
</tr>
<tr>
<td>on</td>
<td>Treat Zero as Eps</td>
</tr>
</tbody>
</table>
4.40.7 Executing an External Program

External programs may be run during a GAMS job either using the $call, Execute or Put_utility syntax. The $call procedure is executed at the moment that is encountered during compilation. The Execute and Put_utility commands causes the external program to be run during GAMS program execution. The contrast between these statements is important in two ways.

- Influence on results that can be included in a GAMS program – Anything run with $Call can generate files that can be included in the subsequent compilation. On the other hand files generated with Execute and Put_utility cannot be included because $Include operates only at compile time (unless you use Save and Restart).

- Influence on results that can be fed into the external program – Obviously when one is running an external program there is the desire to pass it data depicting results of the GAMS execution. $Call cannot do this as the data passed have to exist at compile time and cannot use the result of any GAMS calculations and solves in the current program. Execute commands on the other hand can use any data generated during a run which arise before the Execute and Put_utility command's position in the file through passage via put files or other mechanisms.

The big difference between the $call and execute is

- $call
  - can generate results to be immediately incorporated back into GAMS
  - cannot use GAMS results generated within this run because the $Call is executed at compile time.

- execute and put_utility
  - can cause a program to be started using results generated by the GAMS program (note such results do have to have been saved in an external file using a command like put)
  - cannot generate results which can be immediately reincluded into the GAMS program because new material can only be added compile time.

4.40.7.1 Execute

This command uses the syntax

`execute[.async[NC] | .checkErrorLevel] "[=]command_to_execute"`

to execute a program specified by command_to_execute. The execution occurs during the GAMS execution phase.

- The = will call the program directly, while without the = GAMS calls a shell that executes the program. When a program is executed in a shell, mechanisms like redirection (>) and pipe (|) will work.
- The .async suffix makes GAMS go ahead without waiting.
- The .asyncNC option tells the operating system to start the run a new console rather than sharing the console of the parent process allowing use of multiple processors. This is available under Windows only.
- The .checkErrorLevel suffix checks the errorLevel implicitly, raises an execution error and aborts the execution, if that is not 0.
- Since this occurs during execution one cannot use the compile time $Include to incorporate the results of that external run into the GAMS code except through a GAMS from GAMS approach as discussed below or through save and restart use (see the Save Restart chapter).
4.40.7.2 Asynchronous Execution

The `.async` variant of `$\texttt{call}$` and `$\texttt{execute}$` start a job without waiting for the result. One can continue in the GAMS program and collect the return code of the job later. There are three ways to start a job asynchronously:

- `$\texttt{call\.async \ldots}$` (compile phase)
- `$\texttt{execute\.async }'\ldots''` (execution phase)
- `'put_utility fx 'exec.async' / '\ldots'; / put_utility fx 'shell.async' / '\ldots';` (execution phase)

After each of those the function `JobHandle` can be used to get the Process ID (pid) of the last job started. With `jobStatus(pid)` one could check for the status of a job. Possible return values are:

- 0: error (input is not a valid PID or access is denied)
- 1: process is still running
- 2: process is finished with return code which could be accessed by `errorLevel`
- 3: process not running anymore or was never running, no return code available

With `jobTerminate(pid)` a interrupt signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.

With `jobKill(pid)` a kill signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.

The model `[ASYNCEXEC]` from the GAMS Test Library demonstrates the use of this feature.

4.41 Dollar Control Options

4.41.1 Introduction

Dollar control options are used to indicate compiler directives and options. Dollar control options are not part of the GAMS language and must be entered on separate lines marked with the symbol `$` in the first column. A dollar control option line may be placed anywhere within a GAMS program and it is processed during the compilation of the program. The symbol `$` is followed by one or more options separated by spaces. Since the dollar control options are not part of the GAMS language, they do not appear on the compilation output in the listing file unless an error has been detected or the user has requested them to be shown (with the option `$\texttt{onDollar}$`). Note that dollar control option lines are not case sensitive and a continued compilation uses the previous settings.

This chapter is organized as follows. First an overview of the dollar control options will be given in section List of Dollar Control Options, where the options will be presented in groups reflecting their major functional categories. Section Detailed Description of Dollar Control Options will contain a reference list of all dollar control options in alphabetical order with detailed description for each.

We will conclude this chapter with separate sections for two important topics: Conditional Compilation, Macros in GAMS, Compressing and Decompressing Files, and Encrypting Files.
4.41.1 Syntax

In general, the syntax in GAMS for dollar control statements is as follows:

\$option_name argument_list {option_name argument_list}

The symbol \$ in the first column indicates that this is a dollar control statement. It is followed by the name of the dollar control option \option_name and the list of arguments \argument_list of the option. Depending on the particular option, the number of arguments required can vary from 0 to many. More than one dollar control option may be activated in one statement. Note that in this case the symbol \$ is not repeated. Observe that some dollar control options require that they be the first option on a line.

Note

- No blank space is permitted between the character \$ and the first option that follows.
- The effect of the dollar control option is felt immediately after the option is processed.
- Dollar control options are not part of the GAMS language they instruct the compiler to perform some task. Therefore, dollar control options are not terminated with a semicolon as real GAMS language statements.

A simple example of a list of dollar control options is shown below:

\$title Example to illustrate dollar control options
\$onsymxref onsymlist

Note that there is no blank space between the character \$ and the option that follows. The first dollar control option \$title sets the title of the pages in the listing file to the text that follows the option name. In the second line of the example above, two options are set: \$onSymXRef and \$onSymList. These options turn on the echoing of the symbol cross reference table and symbol listing in the compilation output in the listing file.

Observe that it is also permitted to place a dollar control statement in a column other than column 1. However, in this case the statement must begin with the symbols $$, like in this example

$$title Example showing that dollar control option can start in any column with an extra $ added

4.41.2 List of Dollar Control Options

The dollar control options are grouped into nine major functional categories affecting

- the input comment format
- the input data format
- the output format
- reference maps
- program control
- GDX operations
- compile-time variables and environment variables
- macro definitions
- compressing and encrypting source files

The following subsections briefly describe the options in each of the categories.

4.41.2.1 Dollar Control Options Affecting the Input Comment Format
Note that comments in GAMS are introduced in section Comments.

### 4.41 Dollar Control Options Affecting the Input Data Format

<table>
<thead>

</table>

### 4.41.3 Detailed Description of Dollar Control Options

In this section we will describe each dollar control option in detail. Note that the dollar control options are listed in alphabetical order for easy reference. Note further, that in each entry the default value, if applicable, is given in parentheses.

#### $\text{abort}[, \text{noError}]$

**Syntax:**

\[
\text{\$abort[, noError]} [\text{text}]
\]

If used as `$\text{abort}$`, this option will issue a compilation error and abort the compilation. It may be followed by a text.

**Example:**

\[
\text{\$if not \%system.fileSys\% == UNIX } \\
\text{\$abort We only do UNIX}
\]

This stops compilation if the operating system is not Unix. Running the example above on Windows will result in the compilation being aborted and the following lines in the listing file:
2. \$abort We only do UNIX

Error Messages
343 Abort triggered by above statement

This option has a variant: \$abort.noError. If the extension .noError is used in the compilation, the compilation will be aborted as well, but there will be no error. If a save file is written, all remaining unexecuted code will be flushed. This allows effective reuse of the save file.

Note that there is also an abort statement in GAMS, it is used to terminate the execution of a program.

See also \$exit, \$error, \$stop, and \$terminate.

\$batInclude

Syntax:

\$batInclude external_file {arg}

The \$batInclude facility performs the same task as the \$include facility: it inserts the contents of the specified file external_file at the location of the call. However, in addition, the option \$batInclude also passes on arguments arg which may be used inside the include file. External_file is the name of the batch include file, it may be quoted or unquoted. The arguments arg are passed on to the batch include file. These arguments are treated as character strings that are substituted by numbers inside the included file. The arguments may be single unbroken strings (quoted or unquoted) or quoted multi-part strings.

Note that the syntax has been modeled after the DOS batch facility. Inside the batch file, a parameter substitution is indicated by using the character % followed immediately by an integer value corresponding to the order of parameters on the list where %1 refers to the first argument, %2 to the second argument, and so on. If an integer value is specified that does not correspond to a passed parameter, then the parameter flag is substituted with a null string. The parameter flag %0 is a special case that will substitute a fully expanded file name specification of the current batch included file. The flag %$ is the current $ symbol (see \$dollar). Observe that parameters are substituted independent of context and the entire line is processed before it is passed to the compiler. There is one exception: parameter flags that appear in comments are not substituted.

Attention

- GAMS requires that processing the substitutions must result in a line of less than or equal to the maximum input line length.
- The case of the passed parameters is preserved, thus it may be used in string comparisons.

Example:

\$batInclude "file1.inc" abcd "bbbb" "cccc dddd"

Note that file1.inc is included with abcd as the first parameter, bbbb as the second parameter and cccc dddd as the third parameter.

Parameter a,b,c ;
a = 1 ; b = 0 ; c = 2 ;
\$batInclude inc2.inc b a
display b ;
\$batInclude inc2.inc b c
display b ;
\$batInclude inc2.inc b "a+5"
display b ;
The external file inc2.inc contains the following line:

%1 = sqr(%2) - %2 ;

The echo print in the corresponding listing file follows:

1 Parameter a,b,c ;
2 a = 1 ; b = 0 ; c = 2 ;
BATINCLUDE C:\tmp\inc2.inc
4 b = sqr(a) - a ;
5 display b ;
BATINCLUDE C:\tmp\inc2.inc
7 b = sqr(c) - c ;
8 display b ;
BATINCLUDE C:\tmp\inc2.inc
10 b = sqr(a+5) - a+5 ;
11 display b ;

Note that the option $batInclude appears three times with different arguments. GAMS interprets the contents of the batch include file in turn as:

\[
\begin{align*}
    b &= \text{sqr}(a) - a \\
    b &= \text{sqr}(c) - c \\
    b &= \text{sqr}(a+5) - (a+5) \\
\end{align*}
\]

Note that the third call is not interpreted as \( \text{sqr}(a+5)-(a+5) \), but instead as \( \text{sqr}(a+5)-a+5 \).

The results of the display statement are shown at the end of the listing file are given below:

<table>
<thead>
<tr>
<th></th>
<th>5 Parameter b</th>
<th>=</th>
<th>0.000</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>8 Parameter b</td>
<td>=</td>
<td>2.000</td>
</tr>
<tr>
<td></td>
<td>11 Parameter b</td>
<td>=</td>
<td>40.000</td>
</tr>
</tbody>
</table>

Observe that the third call leads to \( b = \text{sqr}(6)-1+5 \), thus the final value of \( b \) is 40. Suppose the statement in the batch include file is modified to read as follows:

%1 = sqr(%2) - (%2) ;

With this modification the output generated by the display statement will be as follows:

<table>
<thead>
<tr>
<th></th>
<th>5 Parameter b</th>
<th>=</th>
<th>0.000</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>8 Parameter b</td>
<td>=</td>
<td>2.000</td>
</tr>
<tr>
<td></td>
<td>11 Parameter b</td>
<td>=</td>
<td>30.000</td>
</tr>
</tbody>
</table>

Note that the third call leads to \( b = \text{sqr}(6)-6 \) which results in \( b \) taking a value of 30.

Note

The option $batInclude without any arguments is equivalent to the option $include.

See also $include, $include, $sysInclude.

$call

Syntax:

$call [=]command
This option passes a command to the current operating system command processor and interrupts compilation until the command has been completed. If the command string is empty or omitted, a new interactive command processor will be loaded.

Example:

$call dir

This command creates a directory listing on a PC.

Note that the command string may be passed to the system and executed directly without using a command processor by prefixing the command with an '=' sign. Compilation errors will be issued if the command or the command processor cannot be loaded and executed properly.

$call gams trnsport
$call =gams trnsport

The first call will run the model [TRNSPORT] in a new command shell. The DOS command shell does not send any return codes from the run back to GAMS. Therefore any errors in the run are not reported back. The second call, however, will send the command directly to the system. The return codes from the system will be intercepted correctly and they will be available to the GAMS system through the errorLevel function.

Attention

• Some commands (like copy on a PC and cd in Unix) are shell commands and cannot be spawned off to the system. Using these in a system call will create a compilation error.

  $call 'copy myfile.txt mycopy.txt'
  $call '=copy myfile.txt mycopy.txt'

  The first call will work on a PC, but the second will not. The copy command may be used only from a command line shell. The system is not aware of this command (Try this command after clicking Run under the Start menu in Windows. You will find that it does not work).

• One has to take special care when the first argument of the command contains spaces (for example an executable with absolute path), e.g.:

  $call C:\path with spaces\gams.exe trnsport.gms

  This would fail, since the command processor would try to call C:\path as the executable. So, one might think that protecting the spaces using quotes will resolve this problem:

  $call "C:\path with spaces\gams.exe" trnsport.gms

  However, the quotes delimit the entire $call command, so that trnsport.gms gets interpreted as new dollar control option instead of an argument for the executable. The solution is to use nested quotes: One pair to delimit the $call command and another one to protect the spaces of the executable like this:

  $call ""C:\path with spaces\gams.exe" trnsport.gms"

  It gets even more complicated if the argument contains spaces as well, e.g. if we have my model.gms instead of trnsport.gms. Another pair of quotes solves this:

  $call """C:\path with spaces\gams.exe" my model.gms"

See also $call.Async, $call.checkErrorLevel, $hiddenCall.

$call.Async[NC]

Syntax:

$call.Async[NC] command
$\text{call.Async}$ works like $\text{call}$ but allows asynchronous job handling. This means users may start a job command without having to wait for the result, they may continue in their model and collect the return code of the job later. The function jobHandle may be used to get the process ID (pid) of the last job started. The status of the job may be checked using the function jobStatus(pid). An interrupt signal to a running job may be sent with the function jobTerminate(pid). With the function jobKill(pid) a kill signal may be sent to a running job.

The difference between $\text{call.Async}$ and $\text{call.AsyncNC}$ is, that the latter starts processes in a new console, rather than sharing the console of the parent process.

Note

On non-Windows platforms $\text{call.AsyncNC}$ and $\text{call.Async}$ are synonyms.

$\text{call.checkErrorLevel}$

Syntax:

$\text{call.checkErrorLevel [=}command$\n
$\text{call.checkErrorLevel}$ works like $\text{call}$ but checks the errorLevel implicitly, raises a compilation error and aborts compilation, if that is not 0.

Example:

$\text{call.checkErrorLevel gams trnsport}$

This is doing the same as:

$\text{call gams trnsport}$

$\text{ifE errorLevel<>0 abort 'Problem calling gams trnsport'}$

$\text{clear}$

Syntax:

$\text{clear ident {ident}}$

This option resets all data for the identifiers ident to their default values. Note that only the following data types may be reset: sets, parameters, variables and equations. Note further, that the clearing is carried out during compile time and not when the GAMS program executes.

Example:

Set i / 1*20 /;
Scalar a / 2 /;
$\text{clear i a}$
display i, a;

The option $\text{clear}$ resets i and a to their default values: an empty set for i and zero for a. The output generated by the display statement follows:

---- 4 SET i         ( EMPTY )

---- 4 PARAMETER a = 0.000
Attention

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Both the dollar control options and the data initialization is done in the first pass, and assignments in the second, irrespective of their relative locations. This is an issue particularly with `$clear` since data can be both initialized and assigned.

Scalar a / 12 /;
a = 5;
$c\text{lear} a
display a;

Note that the scalar data initialization statement is processed during compilation and the assignment statement $a = 5;$ during execution. In the order that it is processed, the example above is read by GAMS as:

* compilation step
Scalar a /12/ ;
$c\text{lear} a
* execution step
a = 5;
display a ;

Therefore the result is that $a$ takes the value of 5. The output from the display statement is as follows:

    4 PARAMETER a = 5.000

Compare also `$kill` and the execution time option `clear`.

$\text{clearError}[s]$

Syntax:

$\text{clearError}[s]$

This option ($\text{clearError}$ and $\text{clearErrors}$ are synonyms) clears GAMS awareness of compiler errors and turn them into warning messages instead.

Example:

Scalar z / 11 /;
$\text{eval} x \sqrt{(-1)}$
$c\text{learError}$
$log \%x\%$
Display z;

Note that without the use of $\text{clearError}$ the program above would not continue with the execution after line 2.

$\text{comment } (^*)$

Syntax:

$\text{comment } \text{char}$

This option changes the symbol indicating a single line comment from the default $*$ to the single character $\text{char}$. Note that after this option is used, the new comment character $\text{char}$ cannot be used in column 1 as before, since it got a special meaning. Note further, that the case of the character does not matter if it is used as a comment character. This option should be used with great care and we recommend to reset the symbol quickly to the default.
Attention

The case of the start-of-line comment character does not matter when being used.

Example:

```gams
$comment c
  c now we use a FORTRAN style comment symbol
$comment *
  * now we are back to the default
```

See also section Comments.

$compress

Syntax:

```
$compress source target
```

This option causes the file `source` to be compressed into the packed file `target`.

Example: Consider the following example where the well-known model [TRNSPORT] is used:

```
$call gamslib trnsport
$compress trnsport.gms t2.gms
$include t2.gms
```

The first command retrieves the file `trnsport.gms` and the second command compresses it. Note that a compressed GAMS file is treated like any other GAMS file, therefore it may be included and executed as usual. Large data files that do not change often can be compressed this way to save disk space.

The following example serves as a little utility to compress and decompress files:

```
$ifthen set decompress
  "$ if not set input $set input file_c.gms
  "$ if not exist %input% $abort No file input file %input% exist
  "$ if not set output $set output file.gms
  "$ log Decompressing %input% into %output%
  "$ decompress %input% %output%
$else
  "$ if not set input $set input file.gms
  "$ if not exist %input% $abort No file input file %input% exist
  "$ if not set output $set output file_c.gms
  "$ log Compressing %input% into %output%
  "$ compress %input% %output%
$endif
```

The program (saved to a file called `compress.gms`) can be used as follows:

```
> gams compress.gms --input myfile.gms --output myfile_c.gms
> gams compress.gms --decompress=1 --input myfile_c.gms --output myfile.gms
```

See also `$decompress`. Further details are given in chapter Compressing and Decompressing Files.

$decompress
4.41 Dollar Control Options

Syntax:

$decompress source target

This option causes the compressed file source to be decompressed into the unpacked file target.

Example: Consider the following example where the well-known model [TRNSPORT] is used:

$call gamslib trnsport
$compress trnsport.gms t2.gms
$decompress t2.gms t3.gms
$call diff t3.gms trnsport.gms
$if errorlevel 1 $abort t3.gms and trnsport.gms are not identical!

The first command retrieves the file trnsport.gms, the second command compresses it and the third command decompresses the compressed file. Note that the resulting file, t3.gms, is identical to the original file trnsport.gms which is tested via the diff program.

See also $compress. Further details are given in chapter Compressing and Decompressing Files.

$dollar ($)

Syntax:

$dollar char

This option changes the current 'dollar' symbol to the single character char.

Note

The special %$ substitution symbol can be used to get the current 'dollar' symbol.

Example:

$dollar #
#log now we can use '%$' as the '$' symbol

$double

Syntax:

$double

The lines following this option will be echoed double spaced to the echo print in the listing file.

Example:

Set  i / 1*2 / ;
Scalar a / 1 / ;
$double
Set  j / 10*15 / ;
Scalar b / 2 / ;

The resulting echo print in the listing file looks as follows:
1 Set i /1*2/ ;
2 Scalar a /1/ ;
4 Set j /10*15/ ;
5 Scalar b /2/ ;

Note that lines before the option $double are listed single spaced, while the lines after the option are listed with double space.

See also $single.

$drop

Syntax:

$drop VARNAME

This option destroys (removes from the program) the scoped compile-time variable VARNAME that was defined with the dollar control option $set.

Example:

$set NAME my name
$if set NAME $log Scoped compile-time variable NAME is set to "%NAME%"
$drop NAME
$if not set NAME $log Scoped compile-time variable NAME is not available anymore

See also $set, $dropGlobal, and $dropLocal.

$dropEnv

Syntax:

$dropEnv VARNAME

This dollar control option destroys (removes from the program) the operating system environment variable VARNAME. For detailed information, see the dollar control option.

Example:

$if setEnv GDXCOMPRESS $dropEnv GDXCOMPRESS

See also $setEnv, and $if setEnv.

$dropGlobal

Syntax:

$dropGlobal VARNAME

This option destroys (removes from the program) the global compile-time variable VARNAME that was defined with the dollar control option $setGlobal.

Example:
4.41 Dollar Control Options

=setGlobal NAME my name
$if setGlobal NAME $log Global compile-time variable NAME is set to "%NAME%"
=dropGlobal NAME
$if not setGlobal NAME $log Global compile-time variable NAME is not available anymore

See also $setGlobal, and $drop.

$dropLocal

Syntax:
$dropLocal VARNAME

This option destroys (removes from the program) the local compile-time variable VARNAME that was defined with the dollar control option $setLocal.

=setLocal NAME my name
$if setLocal NAME $log Local compile-time variable NAME is set to "%NAME%"
=dropLocal NAME
$if not setLocal NAME $log Local compile-time variable NAME is not available anymore

See also $setLocal, and $drop.

$echo

Syntax:
$echo text >[>] external_file

This option allows to write the text text to a file external_file. The text and the file name may both be quoted or unquoted. The file name is expanded using the working directory. The option $echo tries to minimize file operations by keeping the file open in anticipation of another $echo to be appended to the same file. The file will be closed at the end of the compilation or when an option $call or any variant of the option $include is encountered. The redirection symbols > and >> have the usual meaning of starting at the beginning or appending to an existing file respectively.

Example:

$echo > echo.txt
$echo 'The message written goes from the first non blank' >> echo.txt
$echo 'to the first > or >> symbol unless the text is' >> echo.txt
$echo "is quoted. The input File is %gams.input%. The" >> echo.txt
$echo 'file name "echo.txt" will be completed with' >> echo.txt
$echo %gams.workdir%. >> echo.txt
$echo >> echo.txt

The content of the resulting file echo.txt is the following:

The message written goes from the first non blank to the first > or >> symbol unless the text is is quoted. The input File is C:\tmp\echoTest.gms. The file name "echo.txt" will be completed with C:\tmp\. 

See also $on/offEcho, and $echoN.

$echoN
Syntax:

$echoN text >[>] external_file

This option sends a text message text to an file external_file like $echo but writes no end of line marker so the line is repeatedly appended to by subsequent commands. The redirection symbols > and >> have the usual meaning of starting at the beginning or appending to an existing file respectively. Note that the text and the file name may be quoted or unquoted. By default the file will be saved in the working directory.

Example:

$echoN 'Text to be sent' > 'aaa.txt'
$echoN 'More text' >> aaa.txt
$echoN And more and more and more >> aaa.txt
$echo This was entered with $echo >> 'aaa.txt'
$echo This too >> aaa.txt

The created file aaa.txt contains the following text:

Text to be sent
More text
And more and more and more
This was entered with $echo
This too

See also $on/offEcho, and $echo.

$eject

Syntax:

$eject

This option advances the echo print to the next page.

Example:

$eject
Set i,j ;
Parameter Data(i,j) ;
$eject
Scalar a;
a = 7;

The statements following the first $eject will be listed on one page in the echo print of the listing file and the statements following the second $eject will be listed on the next page.

$else

Syntax:

$ifThen[ElI] cond
...
{ $elseif[ElI] cond
  ...
} [$else
  ...
]$endif
This option always appears together with the option $IfThen[E/I]$. It is followed by an instruction which is executed if the conditional expression of the matching option $IfThen[E/I]$ is not true. For an example, see section Conditional Compilation with $IfThen and $else.

See also $IfThen, $elseIf and section Conditional Compilation.

$elseIf

Syntax:

$ifThen[E|I] cond
...
{$elseIf[E|I] cond
...
[ $else
...
$]}
$endIf

This option always appears together with the option $IfThen[E/I]. It is followed by another condition and instruction. For an example, see section Conditional Compilation with $IfThen and $else.

See also $IfThen, $else, $elseIfE, $elseIfI and section Conditional Compilation.

$elseIfE

Syntax:

$ifThen[E|I] cond
...
{$elseIf[E|I] cond
...
[ $else
...
$]}
$endIf

This option does the same as $elseIf but evaluates numerical values of the control variables.

See also $elseIf and section Conditional Compilation.

$elseIfI

Syntax:

$ifThen[E|I] cond
...
{$elseIf[E|I] cond
...
[ $else
...
$]}
$endIf

This option does the same as $elseIf but it is case insensitive.

See also $elseIf and section Conditional Compilation.

$encrypt

Syntax:
$encrypt source target

This option causes a file to be converted into an encrypted file. Here source is the name of the source file to be encrypted and target is the name for the resulting encrypted file. Note that encryption requires the secure option to be licensed and is available for commercial licenses only. The command line parameter pLicense specifies the target license to be used for encryption. The encrypted file can only run on a system licensed with the license file used for encryption. No special action is required on the executing system since GAMS recognizes whether a file is encrypted and will process it accordingly. There is no option to decrypt an encrypted file, so better keep the original unencrypted file.

Further details and examples are given in chapter Encrypting Files.

$endif

Syntax:

$ifThen[E|I] cond
...
{ $elseif[E|I] cond
  ...
}
[ $else
  ...
]$endif
